INTRODUCTION

1. Overview

The *Review of Particle Physics* and the abbreviated version, the *Particle Physics Booklet,* are reviews of the field of Particle Physics. This complete *Review* includes a compilation/evaluation of data on particle properties, called the "Particle Listings." These Listings include 2000 new measurements from 610 papers, in addition to the 16,800 measurements from 4850 papers that first appeared in previous editions.

Both books include Summary Tables with our best values and limits for particle properties such as masses, widths or lifetimes, and branching fractions, as well as an extensive summary of searches for hypothetical particles. In addition, we give a long section of "Reviews, Tables, and Plots" on a wide variety of theoretical and experimental topics, a quick reference for the practicing particle physicist.

The *Review* and the *Booklet* are published in even-numbered years. This edition is an updating through December 1999 (and, in some areas, well into 2000). As described in the section "Using Particle Physics Databases" following this introduction, the content of this *Review* is available on the World-Wide Web, and is updated between printed editions (`http://pdg.lbl.gov/`).

The Summary Tables give our best values of the properties of the particles we consider to be well established, a summary of search limits for hypothetical particles, and a summary of experimental tests of conservation laws.

The Particle Listings contain all the data used to get the values given in the Summary Tables. Other measurements considered recent enough or important enough to mention, but which for one reason or another are not used to get the best values, appear separately just beneath the data we do use for the Summary Tables. The Particle Listings also give information on unconfirmed particles and on particle searches, as well as short "reviews" on subjects of particular interest or controversy.

The Particle Listings were once an archive of all published data on particle properties. This is no longer possible because of the large quantity of data. We refer interested readers to earlier editions for data now considered to be obsolete.

We organize the particles into six categories:

- Gauge and Higgs bosons
- Leptons
- Quarks
- Mesons
- Baryons
- Searches for monopoles, supersymmetry, compositeness, *etc.*

The last category only includes searches for particles that do not belong to the previous groups; searches for heavy charged leptons and massive neutrinos, by contrast, are with the leptons.

In Sec. 2 of this Introduction, we list the main areas of responsibility of the authors, and also list our large number of consultants, without whom we would not have been able to produce this *Review.* In Sec. 3, we mention briefly the naming scheme for hadrons. In Sec. 4, we discuss our procedures for choosing among measurements of particle properties and for obtaining best values of the properties from the measurements.

The accuracy and usefulness of this *Review* depend in large part on interaction between its users and the authors. We appreciate comments, criticisms, and suggestions for improvements of any kind. Please send them to the appropriate author, according to the list of responsibilities in Sec. 2 below, or to the LBNL addresses below.

To order a copy of the *Review* or the *Particle Physics Booklet* from North and South America, Australia, and the Far East, write to

Particle Data Group, MS 50-308
Lawrence Berkeley National Laboratory
Berkeley, CA 94720, USA
or send e-mail to `PDG@LBL.GOV`.

To order more than one copy of the *Review* or booklet, write to

c/o Anne Fleming
Technical Information Division, MS 50B-4206
Lawrence Berkeley National Laboratory
Berkeley, CA 94720, USA
or send e-mail to `ASFLEMING@LBL.GOV`.

From all other areas, write to

CERN Scientific Information Service
CH-1211 Geneva 23
Switzerland
or send e-mail to `LIBDESK@CERN.CH`.
or via the WWW from CERN

2. Authors and consultants

The authors' main areas of responsibility are shown below:

* Asterisk indicates the person to contact with questions or comments

Gauge and Higgs bosons

γ	D.E. Groom*
Gluons	R.M. Barnett,* A.V. Manohar
Graviton	D.E. Groom*
W, Z	C. Caso,* A. Gurtu*
Higgs bosons	K. Hikasa, M.L. Mangano*
Heavy bosons	C. Kolda,* M. Tanabashi, T.G. Trippe*
Axions	M.L. Mangano,* H. Murayama, K.A. Olive

Leptons

Neutrinos	M. Goodman, D.E. Groom,* K. Nakamura, K.A. Olive, A. Piepke, P. Vogel
e, μ	C. Grab, D.E. Groom*
ν_τ, τ	D.E. Groom, K.G. Hayes, K. Mönig*

Quarks

Quarks	R.M. Barnett,* A.V. Manohar
Top quark	J.L. Feng, K. Hagiwara, T.G. Trippe*
b'	J.L. Feng, K. Hagiwara, T.G. Trippe*
Free quark	D.E. Groom*

Mesons

π, η	C. Grab, D.E. Groom,* C.G. Wohl
Unstable mesons	M. Aguilar-Benitez, C. Amsler, M. Doser,* S. Eidelman, J.J. Hernández, A. Masoni, S. Navas, M. Roos, N.A. Törnqvist
K (stable)	G. Conforto, T.G. Trippe*
D (stable)	P.R. Burchat, C.G. Wohl*
B (stable)	L. Gibbons, K. Honscheid, W.-M. Yao*

Baryons

Stable baryons	C. Grab, C.G. Wohl*
Unstable baryons	C.G. Wohl,* R.L. Workman
Charmed baryons	P.R. Burchat, C.G. Wohl*
Bottom baryons	L. Gibbons, K. Honscheid, W.-M. Yao*

Miscellaneous searches

Monopole	D.E. Groom*
Supersymmetry	M.L. Mangano,* H. Murayama, K.A. Olive, L. Pape
Technicolor	C. Kolda,* T.G. Trippe*
Compositeness	C.D. Carone, M. Tanabashi, T.G. Trippe*
WIMPs and Other	J.L. Feng, K. Hikasa, K.A. Olive, T.G. Trippe*

Reviews, tables, figures, and formulae

R.M. Barnett, D.E. Groom,* T.G. Trippe, C.G. Wohl, W.-M. Yao

Technical support

B. Armstrong,* J.L. Casas Serradilla, B.B. Filimonov, P.S. Gee, S.B. Lugovsky, S. Mankov

The Particle Data Group benefits greatly from the assistance of some 700 physicists who are asked to verify every piece of data entered into this *Review.* Of special value is the advice of the PDG Advisory Committee which meets annually and thoroughly reviews all aspects of our operation. The members of the 1999 committee were:

P. Bloch (CERN), Chair
A. Ali (DESY)
T. Kondo (KEK)
P. Kreitz (SLAC)
Z. Kunszt (ETH Zurich)
J. LoSecco (Notre Dame)

We have especially relied on the expertise of the following people for advice on particular topics:

- L. Addis (SLAC)
- S.I. Alekhin (COMPAS Group, IHEP, Serpukhov)
- A. Ali (DESY)
- J. Annala (Fermilab)
- T. Appelquist (Yale University)
- M. Artuso (Syracuse University)
- R. Bailey (CERN)
- A.R. Barker (University of Colorado)
- T. Barnes (University of Tennessee)
- J.-L. Basdevant (University of Paris)
- M. Battaylia (University of Helsinki)
- M. Berg (University of Texas)
- E. Berger (ANL)
- S. Bethke (CERN)
- I.I. Bigi (Notre Dame University)
- S. Bilenky (Joint Inst. for Nuclear Research, Dubna)
- M. Billing (Cornell University)
- E. Blucher (University of Chicago)
- R.A. Briere (Harvard University)
- D. Bryman (TRIUMF)
- A. Buras (Tech. University of Munich)
- S.V. Burdin (Budker Inst. of Nuclear Physics)
- M. Carena (Fermilab)
- S. Catani (CERN)
- D. Chakraborty (SUNY, Stony Brook)
- M. Chanowitz (LBNL)
- M. Chertok (Texas A&M University)
- R. Clare (MIT)
- E.D. Commins (University of California, Berkeley)
- J. Conway (Rutgers University)
- G. Cowan (University of Siegen)
- P. Coyle (CPP, Marseille)
- R.L. Crawford (Glasgow)
- R.H. Dalitz (Oxford University)
- S.E. Deustua (LBNL)
- L. Di Ciaccio (Rome University)
- S. Dittmaier (CERN)
- J. Donoghue (University of Massachusetts, Amherst)
- R.K. Ellis (Fermilab)
- J. Ellison (University of California, Riverside)
- A. Falk (Johns Hopkins University)
- A. Favara (California Institute of Technology)
- T. Feldmann (RWTH Aachen)
- T. Ferbel (Rochester University)
- R. Fleischer (DESY)
- G. Fogli (University of Bari)
- S.J. Freedman (LBNL)
- H. Fritzsch (University of Munich)
- F. Gabbiani (Duke University)
- J.-F. Genat (LPHNE, Paris)
- A. Goldhaber (Stony Brook)
- A. Goussiou (SUNY, Stony Brook)
- H. Greenlee (Fermilab)
- J.-F. Grivax (INPNP, Univeristy of Paris, Sud)
- E.M. Gullikson (LBNL)
- R. Hagstrom (ANL)
- L. Hall (LBNL)
- F. Halzen (University of Wisconsin)
- D.L. Hartill (Cornell University)
- R. Harris (Fermilab)
- W.C. Haxton (University of Washington)
- J. Hewett (SLAC)
- J. Huston (Michigan State University)
- J. Imazato (KEK)
- G. Isidori (INFN, Frascati)
- P.M. Ivanov (Budker Inst. of Nuclear Physics)
- Yu.M. Ivanov (Petersburg Nuclear Physics Inst.)
- F. James (CERN)
- P. Janot (CERN)
- T. Junk (Carleton University)
- J.A. Kadyk (LBNL)
- R.W. Kenney (LBNL)
- B. Klima (Fermilab)
- I. Koop (Budker Inst. of Nuclear Physics)

- P.P. Krokovny (Budker Inst. of Nuclear Physics)
- S. Kurokawa (KEK)
- M. Lancaster (Bristol University)
- G. Landsberg (Brown University)
- K. Lane (Boston University)
- P. Lefevre (CERN)

- M.P. Worah (LBNL)
- M. Zeller (Yale University)
- P. Zerwas (DESY)
- C. Zhang (IHEP, Beijing)

3. Naming scheme for hadrons

We introduced in the 1986 edition [2] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of u, d, and s quarks. Otherwise, the only important change to known hadrons was that the $F^{\pm}$ became the $D_s^{\pm}$. None of the lightest pseudoscalar or vector mesons changed names, nor did the $c\bar{c}$ or $b\bar{b}$ mesons (we do, however, now use χ_c for the $c\bar{c}$ χ states), nor did any of the established baryons. The Summary Tables give both the new and old names whenever a change has occurred.

The scheme is described in "Naming Scheme for Hadrons" (p. 84) of this *Review*.

We give here our conventions on type-setting style. Particle symbols are italic (or slanted) characters: e^-, p, Λ, π^0, K_L, D_s^+, b. Charge is indicated by a superscript: B^-, Δ^{++}. Charge is not normally indicated for p, n, or the quarks, and is optional for neutral isosinglets: η or η^0. Antiparticles and particles are distinguished by charge for charged leptons and mesons: τ^+, K^-. Otherwise, distinct antiparticles are indicated by a bar (overline): $\overline{\nu}_\mu$, $\overline{t}$, $\overline{p}$, $\overline{K}^0$, and $\overline{\Sigma}^+$ (the antiparticle of the Σ^-).

4. Procedures

4.1. ***Selection and treatment of data***: The Particle Listings contain all relevant data known to us that are published in journals. With very few exceptions, we do not include results from preprints or conference reports. Nor do we include data that are of historical importance only (the Listings are not an archival record). We search every volume of 20 journals through our cutoff date for relevant data. We also include later published papers that are sent to us by the authors (or others).

In the Particle Listings, we clearly separate measurements that are used to calculate or estimate values given in the Summary Tables from measurements that are not used. We give explanatory comments in many such cases. Among the reasons a measurement might be excluded are the following:

- It is superseded by or included in later results.
- No error is given.
- It involves assumptions we question.
- It has a poor signal-to-noise ratio, low statistical significance, or is otherwise of poorer quality than other data available.
- It is clearly inconsistent with other results that appear to be more reliable. Usually we then state the criterion,

which sometimes is quite subjective, for selecting "more reliable" data for averaging. See Sec. 4.
- It is not independent of other results.
- It is not the best limit (see below).
- It is quoted from a preprint or a conference report.

In some cases, *none* of the measurements is entirely reliable and no average is calculated. For example, the masses of many of the baryon resonances, obtained from partial-wave analyses, are quoted as estimated ranges thought to probably include the true values, rather than as averages with errors. This is discussed in the Baryon Particle Listings.

For upper limits, we normally quote in the Summary Tables the strongest limit. We do not average or combine upper limits except in a very few cases where they may be re-expressed as measured numbers with Gaussian errors.

As is customary, we assume that particle and antiparticle share the same spin, mass, and mean life. The Tests of Conservation Laws table, following the Summary Tables, lists tests of CPT as well as other conservation laws.

We use the following indicators in the Particle Listings to tell how we get values from the tabulated measurements:

- OUR AVERAGE—From a weighted average of selected data.
- OUR FIT—From a constrained or overdetermined multiparameter fit of selected data.
- OUR EVALUATION—Not from a direct measurement, but evaluated from measurements of related quantities.
- OUR ESTIMATE—Based on the observed range of the data. Not from a formal statistical procedure.
- OUR LIMIT—For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

An experimentalist who sees indications of a particle will of course want to know what has been seen in that region in the past. Hence we include in the Particle Listings all reported states that, in our opinion, have sufficient statistical merit and that have not been disproved by more reliable data. However, we promote to the Summary Tables only those states that we feel are well established. This judgment is, of course, somewhat subjective and no precise criteria can be given. For more detailed discussions, see the minireviews in the Particle Listings.

4.2. ***Averages and fits***: We divide this discussion on obtaining averages and errors into three sections: (1) treatment of errors; (2) unconstrained averaging; (3) constrained fits.

4.2.1. *Treatment of errors:* In what follows, the "error" δx means that the range $x \pm \delta x$ is intended to be a 68.3% confidence interval about the central value x. We treat this error as if it were Gaussian. Thus when the error *is* Gaussian, δx is the usual one standard deviation (1σ). Many experimenters now give statistical and systematic errors separately, in which case we usually quote both errors, with the statistical error first. For averages and fits, we then add the the two errors in quadrature and use this combined error for δx.

When experimenters quote asymmetric errors $(\delta x)^+$ and $(\delta x)^-$ for a measurement x, the error that we use for that measurement in making an average or a fit with other measurements is a continuous function of these three quantities. When the resultant average or fit $\overline{x}$ is less than $x-(\delta x)^-$, we use $(\delta x)^-$; when it is greater than $x+(\delta x)^+$, we use $(\delta x)^+$. In between, the error we use is a linear function of x. Since the errors we use are functions of the result, we iterate to get the final result. Asymmetric output errors are determined from the input errors assuming a linear relation between the input and output quantities.

In fitting or averaging, we usually do not include correlations between different measurements, but we try to select data in such a way as to reduce correlations. Correlated errors are, however, treated explicitly when there are a number of results of the form $A_i \pm \sigma_i \pm \Delta$ that have identical systematic errors Δ. In this case, one can first average the $A_i \pm \sigma_i$ and then combine the resulting statistical error with Δ. One obtains, however, the same result by averaging $A_i \pm (\sigma_i^2 + \Delta_i^2)^{1/2}$, where $\Delta_i = \sigma_i \Delta [\sum(1/\sigma_j^2)]^{1/2}$. This procedure has the advantage that, with the modified systematic errors Δ_i, each measurement may be treated as independent and averaged in the usual way with other data. Therefore, when appropriate, we adopt this procedure. We tabulate Δ and invoke an automated procedure that computes Δ_i before averaging and we include a note saying that there are common systematic errors.

Another common case of correlated errors occurs when experimenters measure two quantities and then quote the two and their difference, *e.g.*, m_1, m_2, and $\Delta = m_2 - m_1$. We cannot enter all of m_1, m_2 and Δ into a constrained fit because they are not independent. In some cases, it is a good approximation to ignore the quantity with the largest error and put the other two into the fit. However, in some cases correlations are such that the errors on m_1, m_2 and Δ are comparable and none of the three values can be ignored. In this case, we put all three values into the fit and invoke an automated procedure to increase the errors prior to fitting such that the three quantities can be treated as independent measurements in the constrained fit. We include a note saying that this has been done.

4.2.2. *Unconstrained averaging:* To average data, we use a standard weighted least-squares procedure and in some cases, discussed below, increase the errors with a "scale factor." We begin by assuming that measurements of a given quantity are uncorrelated, and calculate a weighted average and error as

$$\overline{x} \pm \delta\overline{x} = \frac{\sum_i w_i\, x_i}{\sum_i w_i} \pm \left(\textstyle\sum_i w_i\right)^{-1/2} , \qquad (1)$$

where

$$w_i = 1/(\delta x_i)^2 .$$

Here x_i and δx_i are the value and error reported by the ith experiment, and the sums run over the N experiments. We then calculate $\chi^2 = \sum w_i(\overline{x} - x_i)^2$ and compare it with $N-1$, which is the expectation value of χ^2 if the measurements are from a Gaussian distribution.

If $\chi^2/(N-1)$ is less than or equal to 1, and there are no known problems with the data, we accept the results.

If $\chi^2/(N-1)$ is very large, we may choose not to use the average at all. Alternatively, we may quote the calculated average, but then make an educated guess of the error, a conservative estimate designed to take into account known problems with the data.

Finally, if $\chi^2/(N-1)$ is greater than 1, but not greatly so, we still average the data, but then also do the following:

(a) We increase our quoted error, $\delta\overline{x}$ in Eq. (1), by a scale factor S defined as

$$S = \left[\chi^2/(N-1)\right]^{1/2} . \tag{2}$$

Our reasoning is as follows. The large value of the χ^2 is likely to be due to underestimation of errors in at least one of the experiments. Not knowing which of the errors are underestimated, we assume they are all underestimated by the same factor S. If we scale up all the input errors by this factor, the χ^2 becomes $N-1$, and of course the output error $\delta\overline{x}$ scales up by the same factor. See Ref. 3.

When combining data with widely varying errors, we modify this procedure slightly. We evaluate S using only the experiments with smaller errors. Our cutoff or ceiling on δx_i is arbitrarily chosen to be

$$\delta_0 = 3N^{1/2}\,\delta\overline{x} ,$$

where $\delta\overline{x}$ is the unscaled error of the mean of all the experiments. Our reasoning is that although the low-precision experiments have little influence on the values $\overline{x}$ and $\delta\overline{x}$, they can make significant contributions to the χ^2, and the contribution of the high-precision experiments thus tends to be obscured. Note that if each experiment has the same error δx_i, then $\delta\overline{x}$ is $\delta x_i/N^{1/2}$, so each δx_i is well below the cutoff. (More often, however, we simply exclude measurements with relatively large errors from averages and fits: new, precise data chase out old, imprecise data.)

Our scaling procedure has the property that if there are two values with comparable errors separated by much more than their stated errors (with or without a number of other values of lower accuracy), the scaled-up error $\delta\overline{x}$ is approximately half the interval between the two discrepant values.

We emphasize that our scaling procedure for *errors* in no way affects central values. And if you wish to recover the unscaled error $\delta\overline{x}$, simply divide the quoted error by S.

(b) If the number M of experiments with an error smaller than δ_0 is at least three, and if $\chi^2/(M-1)$ is greater than 1.25, we show in the Particle Listings an ideogram of the data. Figure 1 is an example. Sometimes one or two data points lie apart from the main body; other times the data split into two or more groups. We extract no numbers from these ideograms; they are simply visual aids, which the reader may use as he or she sees fit.

Each measurement in an ideogram is represented by a Gaussian with a central value x_i, error δx_i, and area proportional to $1/\delta x_i$. The choice of $1/\delta x_i$ for the area is somewhat arbitrary. With this choice, the center of gravity of the ideogram corresponds to an average that uses weights $1/\delta x_i$ rather than the $(1/\delta x_i)^2$ actually used in the averages. This may be appropriate when some of the experiments have seriously underestimated systematic errors. However, since for this choice of area the height of the Gaussian for each measurement is proportional to $(1/\delta x_i)^2$, the peak position of the ideogram will often favor the high-precision measurements at least as much as does the least-squares average. See our 1986 edition [2] for a detailed discussion of the use of ideograms.

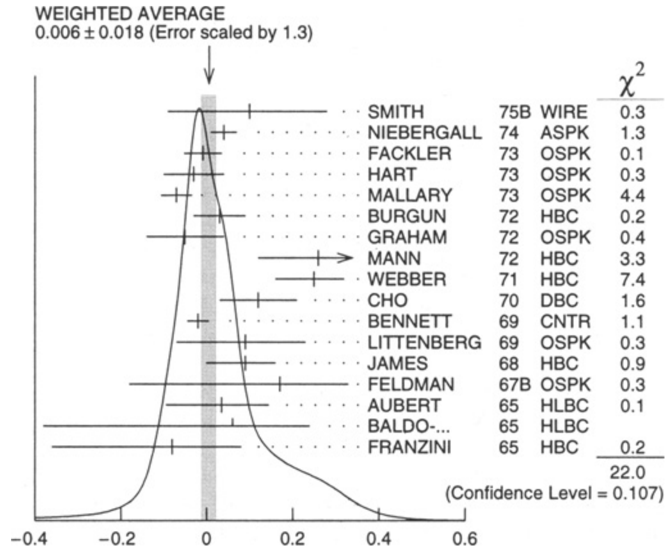

Figure 1: A typical ideogram. The arrow at the top shows the position of the weighted average, while the width of the shaded pattern shows the error in the average after scaling by the factor S. The column on the right gives the χ^2 contribution of each of the experiments. Note that the next-to-last experiment, denoted by the incomplete error flag ($\perp$), is not used in the calculation of S (see the text).

4.2.3. *Constrained fits:* Except for trivial cases, all branching ratios and rate measurements are analyzed by making a simultaneous least-squares fit to all the data and extracting the partial decay fractions P_i, the partial widths Γ_i, the full width Γ (or mean life), and the associated error matrix.

Assume, for example, that a state has m partial decay fractions P_i, where $\sum P_i = 1$. These have been measured in N_r different ratios R_r, where, e.g., $R_1 = P_1/P_2$, $R_2 = P_1/P_3$, *etc.* [We can handle any ratio R of the form $\sum \alpha_i P_i / \sum \beta_i P_i$, where α_i and β_i are constants, usually 1 or 0. The forms $R = P_i P_j$ and $R = (P_i P_j)^{1/2}$ are also allowed.] Further assume that *each* ratio R has been measured by N_k experiments (we designate each experiment with a subscript k, e.g., R_{1k}). We then find the best values of the fractions P_i by minimizing the χ^2 as a function of the $m-1$ independent parameters:

$$\chi^2 = \sum_{r=1}^{N_r} \sum_{k=1}^{N_k} \left(\frac{R_{rk} - R_r}{\delta R_{rk}} \right)^2 , \tag{3}$$

where the R_{rk} are the measured values and R_r are the fitted values of the branching ratios.

In addition to the fitted values $\overline{P}_i$, we calculate an error matrix $\langle \delta\overline{P}_i\ \delta\overline{P}_j \rangle$. We tabulate the diagonal elements of $\delta\,\overline{P}_i = \langle \delta\,\overline{P}_i\ \delta\,\overline{P}_i \rangle^{1/2}$ (except that some errors are scaled as discussed below). In the Particle Listings, we give the complete correlation matrix; we also calculate the fitted value of each ratio, for comparison with the input data, and list it above the relevant input, along with a simple unconstrained average of the same input.

Three comments on the example above:

(1) There was no connection assumed between measurements of the full width and the branching ratios. But

often we also have information on partial widths Γ_i as well as the total width Γ. In this case we must introduce Γ as a parameter in the fit, along with the P_i, and we give correlation matrices for the widths in the Particle Listings.

(2) We do *not* allow for correlations between input data. We *do* try to pick those ratios and widths that are as independent and as close to the original data as possible. When one experiment measures all the branching fractions and constrains their sum to be one, we leave one of them (usually the least well-determined one) out of the fit to make the set of input data more nearly independent.

(3) We calculate scale factors for both the R_r and P_i when the measurements for any R give a larger-than-expected contribution to the χ^2. According to Eq. (3), the double sum for χ^2 is first summed over experiments $k = 1$ to N_k, leaving a single sum over ratios $\chi^2 = \sum \chi_r^2$. One is tempted to define a scale factor for the ratio r as $S_r^2 = \chi_r^2/\langle\chi_r^2\rangle$. However, since $\langle\chi_r^2\rangle$ is not a fixed quantity (it is somewhere between N_k and N_{k-1}), we do not know how to evaluate this expression. Instead we define

$$S_r^2 = \frac{1}{N_k}\sum_{k=1}^{N_k}\frac{\left(R_{rk}-\overline{R}_r\right)^2}{(\delta R_{rk})^2-(\delta\overline{R}_r)^2}\ , \qquad (4)$$

where $\delta\overline{R}_r$ is the fitted error for ratio r. With this definition the expected value of S_r^2 is one.

The fit is redone using errors for the branching ratios that are scaled by the larger of S_r and unity, from which new and often larger errors $\delta\overline{P}_i^{\prime}$ are obtained. The scale factors we finally list in such cases are defined by $S_i = \delta\overline{P}_i^{\prime}/\delta\overline{P}_i$. However, in line with our policy of not letting S affect the central values, we give the values of $\overline{P}_i$ obtained from the original (unscaled) fit.

There is one special case in which the errors that are obtained by the preceding procedure may be changed. When a fitted branching ratio (or rate) $\overline{P}_i$ turns out to be less than three standard deviations $(\delta\overline{P}_i^{\prime})$ from zero, a new smaller error $(\delta\overline{P}_i^{\prime\prime})^-$ is calculated on the low side by requiring the area under the Gaussian between $\overline{P}_i - (\delta\,\overline{P}_i^{\prime\prime})^-$ and $\overline{P}_i$ to be 68.3% of the area between zero and $\overline{P}_i$. A similar correction is made for branching fractions that are within three standard deviations of one. This keeps the quoted errors from overlapping the boundary of the physical region.

4.3. ***Discussion***: The problem of averaging data containing discrepant values is nicely discussed by Taylor in Ref. 4. He considers a number of algorithms that attempt to incorporate inconsistent data into a meaningful average. However, it is difficult to develop a procedure that handles simultaneously in a reasonable way two basic types of situations: (a) data that lie apart from the main body of the data are incorrect (contain unreported errors); and (b) the opposite—it is the main body of data that is incorrect. Unfortunately, as Taylor shows, case (b) is not infrequent. He concludes that the choice of procedure is less significant than the initial choice of data to include or exclude.

We place much emphasis on this choice of data. Often we solicit the help of outside experts (consultants). Sometimes, however, it is simply impossible to determine which of a set of discrepant measurements are correct. Our scale-factor technique is an attempt to address this ignorance by increasing the error. In effect, we are saying that present experiments do not allow a precise determination of this quantity because of unresolvable discrepancies, and one must await further measurements. The reader is warned of this situation by the size of the scale factor, and if he or she desires can go back to the literature (via the Particle Listings) and redo the average with a different choice of data.

Our situation is less severe than most of the cases Taylor considers, such as estimates of the fundamental constants like $\hbar$, *etc.* Most of the errors in his case are dominated by systematic effects. For our data, statistical errors are often at least as large as systematic errors, and statistical errors are usually easier to estimate. A notable exception occurs in partial-wave analyses, where different techniques applied to the same data yield different results. In this case, as stated earlier, we often do not make an average but just quote a range of values.

A brief history of early Particle Data Group averages is given in Ref. 3. Figure 2 shows some histories of our values of a few particle properties. Sometimes large changes occur. These usually reflect the introduction of significant new data or the discarding of older data. Older data are discarded in favor of newer data when it is felt that the newer data have smaller systematic errors, or have more checks on systematic errors, or have made corrections unknown at the time of the older experiments, or simply have much smaller errors. Sometimes, the scale factor becomes large near the time at which a large jump takes place, reflecting the uncertainty introduced by the new and inconsistent data. By and large, however, a full scan of our history plots shows a dull progression toward greater precision at central values quite consistent with the first data points shown.

We conclude that the reliability of the combination of experimental data and our averaging procedures is usually good, but it is important to be aware that fluctuations outside of the quoted errors can and do occur.

ACKNOWLEDGMENTS

The publication of the *Review of Particle Physics* is supported by the Director, Office of Science, Office of High Energy and Nuclear Physics, the Division of High Energy Physics of the U.S. Department of Energy under Contract No. DE-AC03-76SF00098; by the U.S. National Science Foundation under Agreement No. PHY-9703140; by the European Laboratory for Particle Physics (CERN); by an implementing arrangement between the governments of Japan (Monbusho) and the United States (DOE) on cooperative research and development; and by the Italian National Institute of Nuclear Physics (INFN).

We thank all those who have assisted in the many phases of preparing this *Review*. We particularly thank the many who have responded to our requests for verification of data entered in the Listings, and those who have made suggestions or pointed out errors.

ONLINE PARTICLE PHYSICS INFORMATION

Revised April 2000 by P. Kreitz (SLAC).

The purpose of this list is to organize a broad set of online catalogs, databases, directories, World-Wide Web (WWW) pages, *etc.*, that are of value to the particle physics community. This compilation is prescreened and highly selective. It attempts to describe the scope, size, and organization of the resources so that efficient choices can be made amongst many sites which may appear similar. Because this list must be fixed in print, it is important to consult the updated version of this compilation which includes newly added resources and hypertext links to more complete information at:

`http://www.slac.stanford.edu/library/pdg/`

In this edition, a resource is excluded if it provides information primarily of interest to one institution. In the case where there are multiple resources covering similar material, an attempt has been made in the annotation to identify the particular strength of each source. Databases and resources focusing primarily on accelerator physics have been excluded in deference to the excellent compilation at the World Wide Web Virtual Library of Beam Physics and Accelerator Technology:

`http://www.slac.stanford.edu/grp/arb/dhw/dpb/w3vl/w3.html`

My thanks to Betty Armstrong, Particle Data Group, Molly Moss, SLAC Library, Rich Dominiak, SLAC Library, and the many particle physics Web site and database maintainers who have all given me their generous assistance. Please send suggestions, additions, changes, ideas for category groupings, exclusions, *etc.*, by e-mail to `pkreitz@slac.stanford.edu`.

1. Particles & Properties Data:

- REVIEW OF PARTICLE PHYSICS (RPP): A biennial comprehensive review summarizing much of the known data about the field of Particle Physics produced by the international Particle Data Group (PDG). Includes a compilation/evaluation of data on particle properties, summary tables with best values and limits for particle properties, extensive summaries of searches for hypothetical particles, and a long section of reviews, tables, and plots on a wide variety of theoretical and experimental topics of interest to particle and astrophysicists. The linked table of contents provides access to particle listings, reviews, summary tables, errata, indices, *etc.* The current printed version is Eur. Phys. J. **C15**, 1 (2000). Maintained at:

  `http://pdg.lbl.gov/`

- PARTICLE PHYSICS BOOKLET: A pocket-sized booklet containing the Summary Tables and abbreviated versions of some of the other sections of the full *Review of Particle Physics*. This is extracted from the most recent edition of the full RPP. Contains images in an easy-to-read print useful for classroom studies. The last edition was July 1998 and the next edition will be August 2000. Until the new edition is published and available via the Web, students, teachers, and researchers should use the full RPP:

  `http://pdg.lbl.gov/`

- COMPUTER-READABLE FILES: Currently available from the PDG: Tables of masses, widths, and PDG Monte Carlo particle numbers and cross-section data, including hadronic total and elastic cross sections vs laboratory momenta, and total center-of-mass energy. Check out the Palm Pilot version of the table of masses, widths, and PDG Monte Carlo particle numbers. This version will be updated in the Summer of even-numbered years coinciding with the production of the *Review of Particle Properties*:

  `http://pdg.lbl.gov/computer_read.html`

- PARTICLE PHYSICS DATA SYSTEM: Contains an indexed bibliography of experimental particle physics (1895 - 1995) and computerized numerical data extracted from publications. The Web interfaces permitting simple searching for numerical data on observables in reactions and for compilations of integrated cross-section data are still under construction. Maintained by the COMPAS group at IHEP:

  `http://pdg.lbl.gov/ppds`

- HEPDATA: Reaction Data Database: A part of the HEPDATA databases at University of Durham/RAL, this database is compiled by the Durham Database Group (UK) with help from the COMPAS Group (Russia) for the PDG. Contains numerical values of HEP reaction data such as total and differential cross sections, fragmentation functions, structure functions, and polarization measurements from a wide range of experiments. Updated at regular intervals and contains links to precompiled reviewed data such as 'Structure Functions in DIS', 'Single Photon Production in Hadronic Interactions', and 'Drell-Yan Cross-Sections':

  `http://durpdg.dur.ac.uk/HEPDATA/REAC`

- NIST Physics Laboratory: This unit of the National Institute of Standards and Technology provides measurement services and research for electronic, optical, and radiation technologies. Two sub-pages, one on Physical Reference Data and another on Constants, Units & Uncertainty are extremely useful. Additional links to other physical properties and data of tangential interest to particle physics are also available from this page:

  `http://physics.nist.gov/`

2. Collaborations & Experiments:

- EXPERIMENTS Database: Contains more than 2,000 experiments in elementary particle physics covering past, current, and proposed experiments in both accelerator and non-accelerator physics. Simple searches by: participant; title; experiment number; institution; date approved; accelerator; or detector; return a result that fully describes the experiment, including a complete list of authors, title, description of the experiment's goals and methods, a list of resulting journal articles, and a link to the experiment's Web page if available:

  `http://www.slac.stanford.edu/spires/experiments/`

- EXPERIMENTS ONLINE: Current Experiments in Particle Physics: A list of almost 500 current experiments with active home pages. This list is abstracted from the EXPERIMENTS Database and links back to it for more complete information. Accelerator experiments are organized by institution, machine, and experiment name. Non-accelerator experiments are alphabetical by name:

  `http://www.slac.stanford.edu/spires/experiments/`
  `online_exp.html`

- HIGH ENERGY PHYSICS EXPERIMENTS: A HEPiC page providing links to collaboration Web pages. Collaborations are arranged alphabetically by name or number under 15 major laboratories or in a catch-all group labeled 'Other':

  `http://www.hep.net/experiments/all_sites.html`

3. Conferences:

- CONFERENCES: Contains conferences, schools, and meetings of interest to high-energy physics and related fields. Searchable SPIRES database produced by the SLAC, DESY, CERN, and KEK libraries with 9,000 listings covering 1973 to 2002+. Search or browse by title, acronym, date, location. Includes information about published proceedings, links to submitted papers from the SPIRES-HEP database, and links to the conference website when available. New feature permits searches by day, month, quarter, or year:

  `http://www.slac.stanford.edu/spires/conferences.html`

- CONFERENCES AND CONFERENCES: (Subtitled: There Are Too Many Conferences!): Lists over a hundred current and future meetings in many fields of physics. This Web page provides a complete list of all conferences in ASCII or specialized lists arranged by topic: particle, quantum, condensed matter, classical, mathematical or interdisciplinary physics are provided. Includes links to the conference Web page and the contact:

  `http://www.physics.umd.edu/robot/confer/confmenu.html`

- CONFERENCES, WORKSHOPS AND SCHOOLS: Maintained by the PhysicsWeb, this site contains several hundred entries for current national and regional physics meetings worldwide. Searchable by sub-discipline or by free text words. Provides a Web form and email address for adding a conference. Automatically uploads new entries to the EPS EurophysNet meeting list:

  `http://physicsweb.org/TIPTOP/FORUM/CONF/`

- EUROPHYSICS MEETINGS LIST: Maintained by the European Physical Society, this international list of links to other conference lists is organized alphabetically by name of the organization, institution or other group providing a particular list of conferences. Useful for searching by organization and for providing access to meetings and conferences that are of peripheral interest:

  `http://epswww.epfl.ch/conf/urls.html`

- HEP Events: A list maintained by CERN of approximately 100 upcoming conferences, schools, workshops, seminars, and symposia of interest to high-energy physics. Usefully organized by type of meeting, *e.g.*: school, workshop:

  `http://www.cern.ch/Physics/Events`

4. Current Notices & Announcement Services:

- SUBMIT EVENTS: PhysicsWeb Calendar: Maintained by The Internet Pilot to Physics. Provides a Web form for adding a conference and automatically uploads new entries to the EPS EurophysNet meeting list. Directions on the top-level page enable you to sign up to receive weekly email notification of new conferences and deadlines:

  `http://physicsweb.org/events/newconfentry.phtml`

- CONFNEWS & WEBNEWS: Provides a system for broadcasting a conference or job opening to "a large number of physicists worldwide." For further information, e-mail: `yskim@physics.umd.edu`

- E-PRINT ARCHIVES LISTSERV NOTICES: The LANL-based E-Print Archives provides daily notices of preprints in the fields of physics, mathematics, nonlinear sciences, and computer sciences which have been submitted to the archives as full text electronic documents. Use the Web-accessible listings:

  `http://xxx.lanl.gov/`

  or subscribe:

  `http://xxx.lanl.gov/help/subscribe`

- NEW EXPERIMENTS Announcement: Submit information about a new particle physics experiment to the SPIRES EXPERIMENTS Database or modify an older entry using the form at:

  `http://www.slac.stanford.edu/spires/experiments/submit.html`

- SPIRES NEW CONFERENCES IN PARTICLE PHYSICS: Use this form, or send email or a fax to submit information about a conference of value to the field of particle physics:

  `http://www.slac.stanford.edu/spires/conferences/add_conference.html`

Note: Use the library pages in Section 5.3 below to find additional announcement lists for recently received preprints, books, and proceedings. Use the online journal links in Section 7 below for journal table of contents.

5. Directories:

5.1. *Directories—Research Institutions:*

- CERN RESEARCH INSTITUTES: Contains HEP Institutes used in the CERN Library catalog. Provides almost a thousand addresses, and, where available, the following: phone and fax numbers; e-mail addresses; active Web links; and information about the institution's physics program. Provides free text searching and result sorting by organization, country, or town:

  `http://weblib.cern.ch/Home/HEPInstitutes/`

- HEP INSTITUTIONS ONLINE: Active links to the home pages of more than 800 HEP-related institutions with Web servers. Maintained by SLAC. Listed by country, and then alphabetically by institution:

  `http://www.slac.stanford.edu/spires/institutions/online_institutions.html`

- INSTITUTIONS: Database of over 6,000 high-energy physics institutes, laboratories, and university departments in which some research on particle physics is performed. Covers six continents and almost one hundred countries. Searchable by name, acronym, location, *etc.* Provides address, phone and fax numbers, e-mail address, and Web links where available. Has pointers to the recent HEP papers from that institution. Maintained by SLAC and DESY libraries:

  `http://www.slac.stanford.edu/spires/institutions/`

- PHYSICSWEB LINKS: SEARCH DEPARTMENTS: A useful database of web links to the home pages of physics departments worldwide. Searchable by field of research, country, or by a combination of both. Results vary since information is dependent upon submission by the institutions or by individual departments from a university:

  `http://physicsweb.org/resources/dsearch.phtml`

- WWW VIRTUAL LIBRARY—HIGH ENERGY PHYSICS WEB SITES: An alphabetical listing of particle physics web sites maintained at CERN. Provides links to the institution's Web pages. Somewhat difficult to use because entries are listed by institutional acronym or by short name:

  `http://www.cern.ch/Physics/HEP.html`

5.2. *Directories—People:*

- HEPNAMES: Searchable worldwide database of 37,000 e-mail addresses of people associated with particle physics, synchrotron radiation, and related fields:

  `http://www.slac.stanford.edu/spires/hepnames/`

- HEP VIRTUAL PHONEBOOK: A list of links to phonebooks and directories of high-energy physics sites and collaborations around the world. Very useful if you know the place or group and are trying to find a particular individual. Maintained by HEPiC:

  `http://www.hep.net/sites/directories.html`

- US-HEPFOLK: A searchable database of almost 3,500 physicists from 155 U.S. institutions based on a survey conducted in 1997. Searchable by first or last name, by affiliation, and/or by email address. Also provides some interesting demographic plots of the survey data:

  `http://pdg.lbl.gov/us-hepfolk/index.html`

5.3. *Directories—Libraries:*

- Argonne National Lab Library:
  `http://www.library.anl.gov/library/services.html`
- Berkeley Lab (LBNL) Library:
  `http://www-library.lbl.gov/`
- Brookhaven National Lab Library:
  `http://inform.bnl.gov/RESLIB/reslib.html`
- (CERN) European Organization for Nuclear Research Library:
  `http://library.cern.ch/`
- Deutsches Elektronen-Synchrotron (DESY) Library:
  `http://www-library.desy.de/`
- Fermilab Library:
  `http://fnalpubs.fnal.gov/`
- Jefferson Lab Library:
  `http://www.jlab.org/div_dept/admin/library/`
- (KEK) National Laboratory for High Energy Physics Library:
  `http://www-lib.kek.jp/publib.html`
- Lawrence Livermore National Laboratory Library:
  `http://www.llnl.gov/tid/Library.html`
- Los Alamos National Laboratory Library:
  `http://lib-www.lanl.gov/`
- Oak Ridge National Laboratory Library:
  `http://www.ornl.gov/Library/library-home.html`
- Sandia National Laboratory Library:
  `http://www.sandia.gov/library.htm`
- Stanford Linear Accelerator Center Library:
  `http://www.slac.stanford.edu/library`

5.4. *Directories—Publishers:*

- COMPANIES/PUBLISHERS: Contains 50 links to institutions, societies, or companies involved in supplying physics-related information:
  `http://physicsweb.org/TIPTOP/paw/paw.phtml`
  `?k=Companies/Publishers&t=k&f=1`
- DIRECTORY OF PUBLISHERS AND VENDORS: Outstanding and comprehensive directory of web links to publishers. Additional lists include publishers' email addresses and a directory of science book reviews on the web. Publisher and vendor lists are searchable alphabetically or by subject areas: Science, Mathematics, and Technology Publishers; Biomedical Publishers; Computer Publishers; Engineering Publishers; General Publishers; Natural History Publishers, and University Presses:
  `http://www.library.vanderbilt.edu/law/acqs/pubr.html`

5.5. *Directories—Scholarly Societies:*

- American Association for the Advancement of Science:
  `http://www.aaas.org/`
- American Association of Physics Teachers:
  `http://www.aapt.org/`
- American Astronomical Society:
  `http://www.aas.org`
- American Institute of Physics:
  `http://www.aip.org/`
- American Mathematical Society:
  `http://www.ams.org/`
- American Physical Society:
  `http://www.aps.org`
- European Physical Society:
  `http://epswww.epfl.ch/`
- IEEE Nuclear and Plasma Sciences Society:
  `http://hibp7.ecse.rpi.edu/~connor/ieee/npss.html`
- Institute of Physics:
  `http://www.iop.org/`
- PHYSICSWEB LINKS: SOCIETIES/PHYSICAL: Contains 141 links to societies involved in the physical sciences. Organized by country with some entries containing a small annotation describing the society's focus:
  `http://physicsweb.org/resources/paw.phtml?k=`
  `Societies/Physical&o=country&t=k&f=1`
- RESOURCES OF SCHOLARLY SOCIETIES—PHYSICS: Alphabetical list of several hundred scholarly societies with links to their websites. Includes acronyms and indicates when a website contains both its native language and an English-language version. Maintained by the University of Waterloo:
  `http://www.lib.uwaterloo.ca/society/physics_soc.html`

6. E-Prints/Pre-Prints, Papers, & Reports:

- CERN ARTICLES & PREPRINTS: The CERN Library's database which contains records of more than 200,000 (CERN and non-CERN) articles, preprints, theses, CERN Yellow reports, technical notes, Grey Books, and official committee documents held by the Library or the Archives. Provides access to full text of the document and to the references when available:
  `http://weblib.cern.ch/Home/Library_Catalogue/`
  `Articles_and_Preprints/`
- HEP DATABASE (SPIRES): Contains over 415,000 bibliographic summaries for particle physics e-prints, journal articles, preprints, reports, conferences papers, and theses, *etc.* Covers 1974 to the present with substantial older materials added. Updated daily with links to electronic texts (*e.g.* from LANL, CERN, KEK, and other HEP servers). Searchable by all authors and authors' affiliations, title, topic, report number, citation (footnotes), e-print archive number, date, journal, *etc.* A joint project of the SLAC and DESY libraries with the collaboration of Fermilab, Durham (UK), KEK, Kyoto, and many other research institutions and scholarly societies such as the APS:
  `http://www.slac.stanford.edu/spires/hep/`

- KISS (KEK Information Service System) for Preprints: KEK Library preprint and technical report database. Contains bibliographic records of preprints and technical reports held in the KEK library with links to the full text images of more than 100,000 papers scanned from their worldwide collection of preprints:

  `http://www-lib.kek.jp/KISS/kiss_prepri.html`

- arXive.org E-PRINT ARCHIVE: An automated electronic repository of physics, mathematics, computer, and nonlinear science preprints. Used heavily by the sub-disciplines of high-energy physics. Began with a core set of archives in 1991. Provides access to the full text of the electronic versions of these preprints. Permits searching by author, title, and keyword in abstract. Allows limiting by subfield archive or by date. Has over 15 mirror sites around the world. Papers are sent electronically to the archives by authors:

  `http://xxx.lanl.gov`

- PARTICLE PHYSICS DATA SYSTEM—PPDS: A search interface to the bibliography of the print publication *A Guide to Experimental Elementary Particle Physics Literature* (LBL-90). This bibliography covers the published literature of theoretical and experimental particle physics from 1895 to 1995:

  `http://pdg.lbl.gov/ppds`

- PPF: PREPRINTS IN PARTICLES AND FIELDS: A weekly listing averaging 250 new preprints in particle physics and related fields. Contains bibliographic listings for and, in the Web version, full text links to, the new preprints received by and cataloged into the SPIRES High-Energy Physics (HEP) database. Includes that week's titles from the LANL e-print archives as well as preprints and articles received from other sources. Directions for subscribing to an email version can be found on the page listing the most recent week's preprints:

`http://www.slac.stanford.edu/library/documents/newppf.html`

7. Particle Physics Journals & Reviews:

7.1. *Online Journals and Tables of Contents:*

Please note, some of these journals, publishers, and reviews may limit access to subscribers. If you encounter access problems, check with your institution's library.

- Advances in Theoretical and Mathematical Physics: Bimonthly electronic and hard copy publication. Table of contents has links to LANL E-Print Archives where papers for this journal are submitted:

  `http://www.intlpress.com/journals/ATMP/`

- American Journal of Physics: A monthly publication of the American Association of Physics Teachers on instructional and cultural aspects of physical science:

  `http://ojps.aip.org/ajp`

- Applied Physics Letters: Weekly publication of short (3 pages maximum) articles:

  `http://ojps.aip.org/aplo/`

- Astrophysical Journal: Published three times a month by the American Astronomical Society. See also AAS entry under Journal Publishers (below):

  `http://www.journals.uchicago.edu/ApJ/`

- Classical and Quantum Gravity: Published 24 times a year by IOP:

  `http://www.iop.org/Journals/cq`

- European Physical Journal A: Hadrons and Nuclei: This monthly journal merges Il Nuovo Cimento A and Zeitschrift fur Physik A:

  `http://link.springer.de/link/service/journals/10050/index.htm`

- European Physical Journal C: Particles and Fields: This twice monthly journal is the successor to Zeitschrift fur Physik C:

  `http://link.springer.de/link/service/journals/10052/index.htm`

- Journal of High Energy Physics: Electronic and print available. Like *ATMP*, this is an electronically-run journal. It accepts email submission notices and 'fetches' the submitted paper from the LANL E-print archives:

  `http://jhep.sissa.it/`

- Journal of Physics G: Nuclear and Particle Physics: Monthly, published by IOP:

  `http://www.iop.org/Journals/jg`

- Journal of the Physical Society of Japan: JPSJ Online: Monthly, online since 1993:

  `http://wwwsoc.nacsis.ac.jp/jps/jpsj/index.html`

- Modern Physics Letters A: Published 40 times a year, this contains research papers in gravitation, cosmology, nuclear physics, and particles and fields. *Brief Review* section for short reports on new findings and developments:

  `http://www.wspc.com.sg/journals/mpla/mpla.html`

- Modern Physics Letters B: Published 40 times a year, this contains research papers in condensed matter physics, statistical physics, applied physics and High Tc Superconductivity. *Brief Review* section for short reports on new findings and developments:

  `http://www.wspc.com.sg/journals/mplb/mplb.html`

- New Journal of Physics: Funded by article charges from authors of published papers, *NJP* is available in a free, electronic form:

  `http://www.njp.org/`

- Nuclear Instruments and Methods in Physics Research A: Accelerators, Spectrometers, Detectors, and Associated Equipment: Published approximately 36 times per year, this journal focuses on instrumentation and large scale facilities:

  `http://www.elsevier.nl/locate/nima`

- Nuclear Physics A: Nuclear and Hadronic Physics:

  `http://www.elsevier.nl/inca/publications/store/5/0/5/7/1/5/`

- Nuclear Physics B: Particle Physics, Field Theory, Statistical Systems, and Mathematical Physics:

  `http://www.elsevier.nl/inca/publications/store/5/0/5/7/1/6/`

- Nuclear Physics B: Proceedings Supplement: Publishes proceedings of international conferences and topical meetings in high-energy physics and related areas:

  `http://www.elsevier.nl/inca/publications/store/5/0/5/7/1/7/`

- Physical Review D: Particles, Fields, Gravitation, and Cosmology: Published 24 times a year:

  `http://prd.aps.org/`

- Physical Review Special Topics - Accelerators and Beams: A peer-reviewed electronic journal freely available from the APS:

  `http://prst-ab.aps.org/`

- Physics Letters B: Nuclear and Particle Physics: Published weekly:

  `http://www.elsevier.nl/locate/plb`

- Physics—Uspekhi: English edition of Uspekhi Fizicheskikh Nauk:

  `http://ufn.ioc.ac.ru/`

- Progress in Particle and Nuclear Physics: Published four times a year. Many, but not all, articles are at a level suitable for the general nuclear and particle physicist:

  `http://www.elsevier.nl/locate/ppartnuclphys`

7.2. *Journals – Directories:*

- DESY Library Electronic Journals: Use this Web page for up-to-date links to electronic journals of interest to particle physics. Contains a broader list than is included in this compilation:

  `http://www-library.desy.de/eljnl.html`

- Electronic Journals: A directory of over 900 science, technology, and engineering journals online compiled by the University of Buffalo's Science and Engineering Library:

  `http://ublib.buffalo.edu/libraries/units/sel/collections/ejournal2.html`

7.3. *Journals – Publishers & Repositories:*

- AAS: NASA Astrophysics Data System: Provides free electronic access to back issues of the *Astrophysical Journal*, *Astrophysical Journal Letters*, and the *Astrophysical Journal Supplement Series* through the end of 1996. The NASA ADS is in the process of scanning more back issues and will eventually make the complete *ApJ* available:

  `http://adswww.harvard.edu/`

- AIP JOURNAL CENTER: The American Institute of Physics' top-level page for their electronic journals may be found at:

  `http://www.aip.org/ojs/service.html`

- AMERICAN PHYSICAL SOCIETY: The top-level page for the APS research journals is:

  `http://publish.aps.org/`

- ELSEVIER SCIENCE: This website enables browsing Elsevier-published journals by subject field. Selecting 'physics' and publication type 'journals' returns an intermediate page with links organized by the first letter of the name of the journal. Thus one must select "A" to retrieve a list of all of Elsevier's physics-related journals beginning with that letter. A somewhat inefficient way to search what Elsevier offers:

  `http://www.elsevier.nl/homepage/`

- EUROPEAN PHYSICAL SOCIETY: Their journals are handled by various publishers but may be reached from this top-level page:

  `http://epswww.epfl.ch/pub/index.html`

- INSTITUTE OF PHYSICS: Journals: Information: A list of the IOP journals organized by subject. A page organized by title is also available linked to this page:

  `http://www.iop.org/Journals/jnlsubj`

- SPRINGER PUBLISHING: Physics: This link provides a list of Springer journals covering topics of interest to physicists. Small bullets containing the letter 'E' beside each title indicate which journals are electronic:

  `http://link.springer.de/ol/pol/all.htm`

7.4. *Review Publications:*

- Net Advance of Physics: A free electronic service providing review articles and tutorials in an encyclopedic format. Covers all areas of physics. Includes e-prints, book announcements, full text of electronic books, and other resources with hypertext links when available. Welcomes contributions of original review articles:

  `http://web.mit.edu/afs/athena.mit.edu/user/r/e/redingtn/www/netadv/welcome.html`

- Physics Reports: A review section for *Physics Letters A* and *Physics Letters B*. Each report deals with one subject. The reviews are specialized in nature, more extensive than a literature survey but normally less than book length:

  `http://www.elsevier.nl/locate/physrep`

- Reviews of Modern Physics: Published quarterly. Includes traditional scholarly reviews and shorter colloquium papers intended to describe recent research of interest to a broad audience of physicists:

  `http://www.phys.washington.edu/~rmp/Welcome.html`

8. Particle Physics Education Sites:

8.1. *Particle Physics Education: General Sites:*

- Argonne National Laboratory Gee Whiz!: Includes links to other interesting and publically-accessible information such as the Rube Goldberg Machine Contest; Arts in Science; and the parts of the movie 'Chain Reaction' that were filmed at Argonne:

  `http://www.anl.gov/OPA/geewhiz.htm`

- Brookhaven National Laboratory: Science Museum Programs:

  `http://www.pubaf.bnl.gov/bnl_museum.htm`

- Contemporary Physics Education Project (CPEP): Provides charts, brochures, Web links, and classroom activities. Online interactive courses include: Particle Adventure; Fusion – Physics of a Fundamental Energy Source; and Nuclear Science ABC's:

  `http://www.cpepweb.org/`

- Center for Particle Astrophysics in Berkeley: Excellent source for online demos aimed at middle school students (modifiable for other levels). Online demonstrations include: Air-Powered Rockets; Desktop Stars; Lunar Topography, Ping Pong Ball Launcher; Potato Power; Solar System; and more to come. Each includes an introduction, teacher and student worksheets, and a list of materials needed:

  `http://cfpa.berkeley.edu/Education/DEMOS/DEMOS.html`

- Fermilab: Education and Outreach Resources for Particle Physicists: Outstanding collection of resources from the 'grandmother' of all physics lab educational programs. Sections are organized for students and educators by grade level and for general visitors:

  `http://www-ed.fnal.gov/trc/phys_resc.html_resc.html`

- Stanford Linear Accelerator Center: This Virtual Visitor's Center website explains basic particle physics, linear and synchrotron accelerators, and the experiments conducted at SLAC. Aimed at the general public, as well as at students and teachers: `http://www2.slac.stanford.edu/vvc/home.html`

8.2. *Particle Physics Education: Meta-Sites:*

- ESTEEM: The Department of Energy's exciting and visually appealing meta-site for Education in Science, Technology, Energy, Engineering, and Math. Organized both textually and graphically as a 'city'. Users can explore resources by source (energy and science museums), by subject (windmills, 'playground', virtual experiments, computers), or by targeted audience (university, middle, or elementary students). Provides excellent links to many other sites:

  `http://www.sandia.gov/ESTEEM/home.html`

- Physical Science: Educational Hotlists: Created by the outstanding Franklin Institute Science Museum, these hotlists contain a prescreened list of resources for science educators, students, and enthusiasts. The criteria for inclusion is that a site stimulates creative thinking and learning bout science. The excellent Physical Science list contains useful links for physics, physicists, optics, material science, applied design and engineering, sites for museums, 'doing science,' and inventors and engineers:

  `http://sln.fi.edu/tfi/hotlists/hotlists.html`

- PhysicsEd: Physics Education Resources: From a group renowned for doing research on physics education. Provides links to courses and topics; curriculum development; resources for demonstrations; software; research and projects in physics education; textbooks; journals and newsletters; email discussion groups; reference resources; organizations and companies; FAQ's; and links to much more:

  `http://www-hpcc.astro.washington.edu/scied/physics.html`

8.3. *Particle Physics Education: Ask-a-Scientist Sites:*

- Ask A Scientist: Questions are answered by volunteer scientists throughout the world. Service provided by the Newton BBS through Argonne National Lab. Submission form permits very specific age information to be included with the question so that the answer can be targeted to the questioner's level of knowledge:

  `http://newton.dep.anl.gov/aasquest.htm`

- How Things Work: The author of the popular *How Things Work: the Physics of Everyday Life* has created a site that functions as a virtual 'radio call-in program'. Submit questions about how something works or consult the 60 pages of most recent questions which are searchable by date, topic, or keyword:

  `http://howthingswork.virginia.edu`

- Mad Scientist's Network: Ask A Question: Responds to hundreds of questions a week. Be sure to check out their extensive archive of answered questions:

  `http://www.madsci.org/submit.html`

- The Science Club: An excellent compilation of places to ask science questions. Organized by 'general' sites and then by sites that specialize in specific subjects or professions:

  `http://www.halcyon.com/sciclub/kidquest.html`

8.4. *Particle Physics Education: Experiments, Demos, & Fun*

- Albert Einstein Online: A meta-Einstein site with links to dozens of resources by and about this scientist. Organized into Overviews; Moments (recollections of Einstein by others); Physics; Writings; Quotes; Pictures; and Miscellaneous:

  `http://www.westegg.com/einstein/`

- Deep Space: Remote Access Astronomy Project: This project (RAAP) was developed as a supplement for high school, college or advanced placement physics courses to enable students to combine theory with observation by working with satellite imaging data and a Remotely Operated Telescope. The labs are available as PostScript and .doc files. Classes should also obtain the 180 page curriculum and image processing manual available for $15.00 plus shipping:

  `http://www.deepspace.ucsb.edu/rot.htm`

- The Edible/Inedible Experiments Archive of the Mad Scientist Network: Astronomy, Mathematics, and Physics are included in the scientific fields covered. Each experiment uses common materials and identifies whether the experiment is edible, inedible, or 'partially drinkable', or 'not all that edible' (!?) categories:

  `http://www.madsci.org/experiments/`

- Pages of Light: From Fermi National Accelerator Laboratory, a delightful collection of pages explaining light at the advanced placement high school level or above:

  `http://www.fnal.gov/pub/light/`

- The Particle Adventure: An interactive tour of particle physics and the inner workings of the atom for the general public, students and teachers. Available in five languages:

  `http://ParticleAdventure.org/`

- Physics Around the World's Educational Section: Contains several useful links to collections of resources particularly the sections covering: Hands-On Experiments; Exercises and Problems; and Demonstrations. Targeted to the university level:

  `http://physicsweb.org/TIPTOP/paw/`

- Science for the Millennium: Expo Web: Aimed at diverse audiences, this site focuses chiefly on astronomy, astrophysics, advanced computation, and virtual environments to showcase recent advances in these fields. The content is deep and the site is well-designed, permitting hierarchical and serendipitous use. Maintained by NCSA with significant help from the Electronic Visualization Laboratory:

  `http://www.ncsa.uiuc.edu/Cyberia/Expo/information-pavilion.html`

- The Virtual Laboratory: Physics Applets: Maintained by the University of Oregon's Physics Department. A series of experiments using Java applets that are targeted to non-majors physics classes which have no physical lab sections. The experiments provide conceptual interfaces to the equations of physics and represent interaction with data that simulates a real physics experiment. Includes: Astrophysics applets; Energy and Environment applets; Mechanics applets; Thermodynamics applets; and the beginnings of some general tools such as a whiteboard to create a gif image of a particular applet's output for submitting as a homework assignment:

  `http://jersey.uoregon.edu/vlab/index.html`

9. Software Directories:

- CERNLIB: CERN PROGRAM LIBRARY: A large collection of general purpose libraries and modules offered in both source code and object code forms from the CERN central computing division. Provides programs applicable to a wide range of physics research problems such as general mathematics, data analysis, detectors simulation, data-handling, *etc.* Also includes links to commercial, free, and other software:

  `http://wwwinfo.cern.ch/asd/index.html`

- FREEHEP: A collection of software and information about software useful in high-energy physics. Searching can be done by title, subject, date acquired, date updated, or by browsing an alphabetical list of all packages:

  `http://www.slac.stanford.edu/find/fhmain.html`

- FERMILAB Software Tools Program: Software repository of Fermilab-developed software packages of value to the HEP community. Permits searching for packages by title or subject, by browsing FTP site, and by recent acquisitions:

  `http://www.fnal.gov/fermitools/`

- HEPIC: Software & Tools Used in HEP Research: A meta-level site with links to other sites of HEP-related software and computing tools:

  `http://www.hep.net/resources/software.html`

- INTERNET PILOT TO PHYSICS: COMPUTING: The section on computing contains links to separate Web listings of: software archives; hands-on experiments; graphics & visualization; parallel computing; Java applets; and computing centers:

  `http://physicsweb.org/TIPTOP/paw/`

- LIFECYCLE GLOBAL HYPERTEXT: Originally developed for managing ALEPH's massive programming code, this is a Web-based template system that publishes all documents from the software lifecycle including diagrams and code and automatically cross references the information. It can be configured to present Web output and to integrate both internal and external links. Excellent system for accessing massive amounts of complex code:

  `http://light.cern.ch/`

10. Specialized Subject Pages:

10.1. *Subject Pages–Applied*

- Nanotechnology: A selective set of links providing recent news, introductory-level explanations, web videos, bibliographies of books and articles, conferences, events, and an excellent list of links to other sites:

  `http://www.zyvex.com/nano/`

- Sean Morgan's Nanotechnology Pages: A large compilation that must be browsed to discover all it's gems. Includes News; Molecular Nanotechnology, Scanning Probe Microscopy; Molecular Modeling; Nanoelectronics and Micromachining; Nanotechnology Mailing Lists; Electronic Magazines and Journals on MNT; and a Nanotechnology Timeline. Each list includes articles, books, conferences, and more:

  `http://www.lucifer.com/~sean/Nano.html`

10.2. *Subject Pages–Concepts & Theories*

- The Official String Theory Web Site: Outstanding compilation of information about string theory includes: an introductory section on theory; cosmology; links to other sites; experiments testing string theory; black holes; a directory of people working on string theory; and a discussion forum. Many of the explanations are very accessible to an advanced high school level:

  `http://superstringtheory.com/`

- Relativity: Bookmarks: Presents an almost overwhelming number of worldwide links. Topical divisions include: university sites; experimental gravitation projects; relativity-related journals and databases; historical relativity; popular relativity; visualization; relativistic raytracing; elementary, intermediate, and advanced relativity; workshops; courses and seminars; astrophysical and black hole relativity; computational; symbolic; quantum; applied; and philosophical:

  `http://physics.syr.edu/research/relativity/RELATIVITY.html`

- Relativity on the World Wide Web: An excellent set of pages offering links and written information about relativity. Organized into: popular science sites; visualization sites; web tutorials; observational and experimental evidence and rebuttals; course work (divided into undergraduate and graduate levels); software; research frontiers; and further reading:

  `http://www.math.washington.edu/~hillman/relativity.html`

10.3. *Subject Pages–Particles*

- Neutrino Website: John Bahcall has compiled links to: technical and popular articles books; Hubble Space Telescope and other images; models; viewgraphs; cross-section data; software; and more. The place to begin researching neutrinos at a graduate student level and beyond:

  `http://www.sns.ias.edu/~jnb/`

SUMMARY TABLES OF PARTICLE PROPERTIES

Extracted from the Particle Listings of the
Review of Particle Physics
D.E. Groom *et al.*, Eur. Phys. Jour. **C15**, **1** (2000)
Available at http://pdg.lbl.gov

Particle Data Group Authors:

D.E. Groom, M. Aguilar-Benitez, C. Amsler, R.M. Barnett, P.R. Burchat, C.D. Carone, C. Caso, G. Conforto, O. Dahl, M. Doser, S. Eidelman, J.L. Feng, L. Gibbons, M. Goodman, C. Grab, A. Gurtu, K. Hagiwara, K.G. Hayes, J.J. Hernández, K. Hikasa, K. Honscheid, C. Kolda, M.L. Mangano, A.V. Manohar, A. Masoni, K. Mönig, H. Murayama, K. Nakamura, S. Navas, K.A. Olive, L. Pape, A. Piepke, M. Roos, M. Tanabashi, N.A. Törnqvist, T.G. Trippe, P. Vogel, C.G. Wohl, R.L. Workman, W.-M. Yao

Technical Associates: B. Armstrong, J.L. Casas Serradilla, B.B. Filimonov, P.S. Gee, S.B. Lugovsky, F. Nicholson

Other Authors who have made substantial contributions to reviews since the 1996 edition:

K.S. Babu, D. Besson, O. Biebel, P. Bloch, R.N. Cahn, A. Cattai, R.S. Chivukula, R.D. Cousins, T. Damour, K. Desler, R.J. Donahue, D.A. Edwards, J. Erler, V.V. Ezhela, A. Fassò, W. Fetscher, D. Froidevaux, M. Fukugita, T.K. Gaisser, L. Garren, S. Geer, H.-J. Gerber, F.J. Gilman, H.E. Haber, C. Hagmann, I. Hinchliffe, C.J. Hogan, G. Höhler, P. Igo-Kemenes, J.D. Jackson, K.F. Johnson, D. (Approximate closing date for data: January 1, 2000)

GAUGE AND HIGGS BOSONS

γ

$I(J^{PC}) = 0,1(1^{--})$

Mass $m < 2 \times 10^{-16}$ eV
Charge $q < 5 \times 10^{-30}$ e
Mean life τ = Stable

g or gluon

$I(J^P) = 0(1^-)$

Mass $m = 0$ [a]
SU(3) color octet

W

$J = 1$

Charge = ± 1 e
Mass $m = 80.419 \pm 0.056$ GeV
$m_Z - m_W = 10.76 \pm 0.05$ GeV
$m_{W^+} - m_{W^-} = -0.2 \pm 0.6$ GeV
Full width $\Gamma = 2.12 \pm 0.05$ GeV
$\langle N_{charged} \rangle = 19.3 \pm 0.4$

W^- modes are charge conjugates of the modes below.

W^+ DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
$\ell^+\nu$	[b]	(10.56 ± 0.14) %		–
$e^+\nu$		(10.66 ± 0.20) %		40205
$\mu^+\nu$		(10.49 ± 0.29) %		40205
$\tau^+\nu$		(10.4 ± 0.4) %		40185
hadrons		(68.5 ± 0.6) %		–
$\pi^+\gamma$		$< 7 \times 10^{-5}$	95%	40205
$D_s^+\gamma$		$< 1.3 \times 10^{-3}$	95%	–
cX		(35 ± 4) %		–
$c\bar{s}$		$(32 \ {}^{+13}_{-11})$ %		–
invisible	[c]	(1.4 ± 2.8) %		–

Z

$J = 1$

Charge = 0
Mass $m = 91.1882 \pm 0.0022$ GeV [d]
Full width $\Gamma = 2.4952 \pm 0.0026$ GeV
$\Gamma(\ell^+\ell^-) = 84.057 \pm 0.099$ MeV [b]
$\Gamma(\text{invisible}) = 499.4 \pm 1.7$ MeV [e]
$\Gamma(\text{hadrons}) = 1743.8 \pm 2.2$ MeV
$\Gamma(\mu^+\mu^-)/\Gamma(e^+e^-) = 0.9999 \pm 0.0032$
$\Gamma(\tau^+\tau^-)/\Gamma(e^+e^-) = 1.0012 \pm 0.0036$ [f]

Average charged multiplicity

$\langle N_{charged} \rangle = 21.07 \pm 0.11$

Couplings to leptons

$g_V^\ell = -0.03795 \pm 0.00071$
$g_A^\ell = -0.50145 \pm 0.00030$
$g^{\nu_e} = 0.53 \pm 0.09$
$g^{\nu_\mu} = 0.502 \pm 0.017$

Asymmetry parameters [g]

$A_e = 0.152 \pm 0.004$ (S = 1.2)
$A_\mu = 0.102 \pm 0.034$
$A_\tau = 0.141 \pm 0.006$
$A_c = 0.66 \pm 0.11$
$A_b = 0.91 \pm 0.05$

Charge asymmetry (%) at Z pole

$A_{FB}^{(0\ell)} = 1.82 \pm 0.11$
$A_{FB}^{(0u)} = 4 \pm 7$
$A_{FB}^{(0s)} = 9.8 \pm 1.1$
$A_{FB}^{(0c)} = 7.01 \pm 0.45$
$A_{FB}^{(0b)} = 10.03 \pm 0.22$

Z DECAY MODES		Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)

Higgs Bosons — H^0 and $H^{\pm}$, Searches for

H^0 Mass $m >$ 95.3 GeV, CL = 95%

H_1^0 in Supersymmetric Models ($m_{H_1^0} < m_{H_2^0}$)

Mass $m >$ 82.6 GeV, CL = 95%

A^0 Pseudoscalar Higgs Boson in Supersymmetric Models [k]

Mass $m >$ 84.1 GeV, CL = 95% $\tan\beta > 1$

$H^{\pm}$ Mass $m >$ 69.0 GeV, CL = 95%

See the Particle Listings for a Note giving details of Higgs Bosons.

Heavy Bosons Other Than Higgs Bosons, Searches for

Additional W Bosons

W_R — right-handed W
Mass $m >$ 715 GeV, CL = 90% (electroweak fit)

W' with standard couplings decaying to $e\nu$, $\mu\nu$
Mass $m >$ 720 GeV, CL = 95%

Additional Z Bosons

Z'_{SM} with standard couplings
Mass $m >$ 690 GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m >$ 898 GeV, CL = 95% (electroweak fit)

Z_{LR} of $SU(2)_L \times SU(2)_R \times U(1)$ (with $g_L = g_R$)
Mass $m >$ 630 GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m >$ 564 GeV, CL = 95% (electroweak fit)

Z_χ of $SO(10) \to SU(5) \times U(1)_\chi$ (with $g_\chi = e/\cos\theta_W$)
Mass $m >$ 595 GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m >$ 545 GeV, CL = 95% (electroweak fit)

Z_ψ of $E_6 \to SO(10) \times U(1)_\psi$ (with $g_\psi = e/\cos\theta_W$)
Mass $m >$ 590 GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m >$ 294 GeV, CL = 95% (electroweak fit)

Z_η of $E_6 \to SU(3) \times SU(2) \times U(1) \times U(1)_\eta$ (with $g_\eta = e/\cos\theta_W$)
Mass $m >$ 620 GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m >$ 365 GeV, CL = 95% (electroweak fit)

Scalar Leptoquarks

Mass $m >$ 225 GeV, CL = 95% (1st generation, pair prod.)
Mass $m >$ 200 GeV, CL = 95% (1st gener., single prod.)
Mass $m >$ 202 GeV, CL = 95% (2nd gener., pair prod.)
Mass $m >$ 73 GeV, CL = 95% (2nd gener., single prod.)
Mass $m >$ 99 GeV, CL = 95% (3rd gener., pair prod.)
(See the Particle Listings for assumptions on leptoquark quantum numbers and branching fractions.)

Axions (A^0) and Other Very Light Bosons, Searches for

The standard Peccei-Quinn axion is ruled out. Variants with reduced couplings or much smaller masses are constrained by various data. The Particle Listings in the full *Review* contain a Note discussing axion searches.

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is > 7.2×10^{24} years (CL = 90%).

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] Theoretical value. A mass as large as a few MeV may not be precluded.

[b] ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

[c] This represents the width for the decay of the W boson into a charged particle with momentum below detectability, p< 200 MeV.

[d] The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator.

[e] This partial width takes into account Z decays into $\nu\overline{\nu}$ and any other possible undetected modes.

[f] This ratio has not been corrected for the τ mass.

[g] Here $A \equiv 2g_V g_A/(g_V^2+g_A^2)$.

[h] The value is for the sum of the charge states or particle/antiparticle states indicated.

[i] See the Z Particle Listings for the γ energy range used in this measurement.

[j] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.

[k] The limits assume no invisible decays.

LEPTONS

e

$J = \frac{1}{2}$

Mass $m = 0.510998902 \pm 0.000000021$ MeV
$= (5.485799110 \pm 0.000000012) \times 10^{-4}$ u

Electric dipole moment $d = (3.7 \pm 3.4) \times 10^{-19}$ $e$cm

Decay parameters [b]

$\rho = 0.7518 \pm 0.0026$
$\eta = -0.007 \pm 0.013$
$\delta = 0.749 \pm 0.004$
$\xi P_\mu = 1.003 \pm 0.008$ [c]
$\xi P_\mu \delta/\rho > 0.99682$, CL = 90% [c]
$\xi' = 1.00 \pm 0.04$
$\xi'' = 0.7 \pm 0.4$
$\alpha/A = (0 \pm 4) \times 10^{-3}$
$\alpha'/A = (0 \pm 4) \times 10^{-3}$
$\beta/A = (4 \pm 6) \times 10^{-3}$
$\beta'/A = (2 \pm 6) \times 10^{-3}$
$\overline{\eta} = 0.02 \pm 0.08$

μ^+ modes are charge conjugates of the modes below.

μ^- DECAY MODES			Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
$e^- \overline{\nu}_e \nu_\mu$			≈ 100%		53
$e^- \overline{\nu}_e \nu_\mu \gamma$		[d]	(1.4±0.4) %		53
$e^- \overline{\nu}_e \nu_\mu e^+ e^-$		[e]	(3.4±0.4) × 10^{-5}		53
Lepton Family number (*LF*) violating modes					
$e^- \nu_e \overline{\nu}_\mu$	*LF*	[f]	< 1.2 %	90%	53
$e^- \gamma$	*LF*		< 1.2 × 10^{-11}	90%	53
$e^- e^+ e^-$	*LF*		< 1.0 × 10^{-12}	90%	53
$e^- 2\gamma$	*LF*		< 7.2 × 10^{-11}	90%	53

τ

$J = \frac{1}{2}$

Mass $m = 1777.03^{+0.30}_{-0.26}$ MeV
Mean life $\tau = (290.6 \pm 1.1) \times 10^{-15}$ s
$c\tau = 87.11$ μm
Magnetic moment anomaly > −0.052 and < 0.058, CL = 95%
Electric dipole moment $d > -3.1$ and $< 3.1 \times 10^{-16}$ $e$cm, CL = 95%

Weak dipole moment

$\mathrm{Re}(d^w_\tau) < 0.56 \times 10^{-17}$ $e$cm, CL = 95%
$\mathrm{Im}(d^w_\tau) < 1.5 \times 10^{-17}$ $e$cm, CL = 95%

Weak anomalous magnetic dipole moment

$\mathrm{Re}(\alpha^w_\tau) < 4.5 \times 10^{-3}$, CL = 90%
$\mathrm{Im}(\alpha^w_\tau) < 9.9 \times 10^{-3}$, CL = 90%

Decay parameters

See the τ Particle Listings for a note concerning τ-decay parameters.

$\rho^\tau(e \text{ or } \mu) = 0.747 \pm 0.009$
$\rho^\tau(e) = 0.749 \pm 0.011$
$\rho^\tau(\mu) = 0.752 \pm 0.021$
$\xi^\tau(e \text{ or } \mu) = 0.997 \pm 0.032$
$\xi^\tau(e) = 0.996 \pm 0.044$
$\xi^\tau(\mu) = 1.046 \pm 0.065$
$\eta^\tau(e \text{ or } \mu) = 0.011 \pm 0.031$
$\eta^\tau(\mu) = -0.013 \pm 0.097$
$(\delta\xi)^\tau(e \text{ or } \mu) = 0.746 \pm 0.023$
$(\delta\xi)^\tau(e) = 0.735 \pm 0.030$
$(\delta\xi)^\tau(\mu) = 0.774 \pm 0.043$
$\xi^\tau(\pi) = 0.992 \pm 0.046$
$\xi^\tau(\rho) = 0.998 \pm 0.010$
$\xi^\tau(a_1) = 0.998 \pm 0.077$
$\xi^\tau(\text{all hadronic modes}) = 1.000 \pm 0.008$

τ^+ modes are charge conjugates of the modes below. "$h^\pm$" stands for $\pi^\pm$ or $K^\pm$. "ℓ" stands for e or μ. "Neutral" means neutral hadron whose decay products include γ's and/or π^0's.

τ^- DECAY MODES		Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)
Modes with one charged particle				
particle$^-$ ≥ 0 neutrals ≥ $0K^0_L \nu_\tau$ ("1-prong")		(84.71±0.13) %	S=1.2	–

Lepton Family number (*LF*), Lepton number (*L*), or Baryon number (*B*) violating modes

(In the modes below, ℓ means a sum over e and μ modes)

L means lepton number violation (*e.g.* $\tau^- \to e^+\pi^-\pi^-$). Following common usage, *LF* means lepton family violation *and not* lepton number violation (*e.g.* $\tau^- \to e^-\pi^+\pi^-$). *B* means baryon number violation.

$e^-\gamma$	*LF*	$< 2.7 \times10^{-6}$	CL=90%	888
$\mu^-\gamma$	*LF*	$< 1.1 \times10^{-6}$	CL=90%	885
$e^-\pi^0$	*LF*	$< 3.7 \times10^{-6}$	CL=90%	883
$\mu^-\pi^0$	*LF*	$< 4.0 \times10^{-6}$	CL=90%	880
e^-K^0	*LF*	$< 1.3 \times10^{-3}$	CL=90%	819
μ^-K^0	*LF*	$< 1.0 \times10^{-3}$	CL=90%	815
$e^-\eta$	*LF*	$< 8.2 \times10^{-6}$	CL=90%	804
$\mu^-\eta$	*LF*	$< 9.6 \times10^{-6}$	CL=90%	800
$e^-\rho^0$	*LF*	$< 2.0 \times10^{-6}$	CL=90%	722
$\mu^-\rho^0$	*LF*	$< 6.3 \times10^{-6}$	CL=90%	718

Heavy Charged Lepton Searches

$L^\pm$ – charged lepton

Mass $m >$ 92.4 GeV, CL = 95% [h] $m_\nu \approx 0$

$L^\pm$ – stable charged heavy lepton

Mass $m >$ 93.5 GeV, CL = 95%

Neutrinos

See the Particle Listings for a Note "Neutrino Mass" giving details of neutrinos, masses, mixing, and the status of experimental searches.

ν_e

$J = \frac{1}{2}$

Mass $m <$ 3 eV Interpretation of tritium beta decay experiments is complicated by anomalies near the endpoint, and the limits are not without ambiguity.

Mean life/mass, $\tau/m_{\nu_e} > 7 \times 10^9$ s/eV (solar)

Mean life/mass, $\tau/m_{\nu_e} >$ 300 s/eV, CL = 90% (reactor)

Magnetic moment $\mu < 1.5 \times 10^{-10}$ μ_B, CL = 90%

ν_μ

$J = \frac{1}{2}$

Mass $m <$ 0.19 MeV, CL = 90% [i]

Mean life/mass, $\tau/m_{\nu_\mu} >$ 15.4 s/eV, CL = 90%

Magnetic moment $\mu < 7.4 \times 10^{-10}$ μ_B, CL = 90%

ν_τ

$J = \frac{1}{2}$

Mass $m <$ 18.2 MeV, CL = 95% [j]

Magnetic moment $\mu < 5.4 \times 10^{-7}$ μ_B, CL = 90%

Electric dipole moment $d < 5.2 \times 10^{-17}$ $e$cm, CL = 95%

Number of Light Neutrino Types

(including ν_e, ν_μ, and ν_τ)

Number $N = 2.994 \pm 0.012$ (Standard Model fits to LEP data)

Number $N = 3.00 \pm 0.06$ (Direct measurement of invisible Z width)

Massive Neutrinos and Lepton Mixing, Searches for

For excited leptons, see Compositeness Limits below.

See the Particle Listings for a Note "Neutrino Mass" giving details of neutrinos, masses, mixing, and the status of experimental searches.

There is now rather convincing evidence that neutrinos have nonzero mass from the apparent observation of neutrino oscillations, where the neutrinos come from π (or K) $\rightarrow$ μ $\rightarrow$ e decays in the atmosphere; the mesons are produced in cosmic-ray cascades.

Stable Neutral Heavy Lepton Mass Limits

Mass $m >$ 45.0 GeV, CL = 95% (Dirac)

Mass $m >$ 39.5 GeV, CL = 95% (Majorana)

Neutral Heavy Lepton Mass Limits

Mass $m >$ 83.3 GeV, CL = 95%

(Dirac ν_L coupling to e, μ, τ; conservative case(τ))

Mass $m >$ 73.5 GeV, CL = 95%

(Majorana ν_L coupling to e, μ, τ; conservative case(τ))

Solar Neutrinos

Detectors using gallium ($E_\nu \gtrsim 0.2$ MeV), chlorine ($E_\nu \gtrsim 0.8$ MeV), and Čerenkov effect in water ($E_\nu \gtrsim 7$ MeV) measure significantly lower neutrino rates than are predicted from solar models. The deficit in the solar neutrino flux compared with solar model calculations could be explained by oscillations with $\Delta m^2 \leq 10^{-5}$ eV^2 causing the disappearance of ν_e.

Atmospheric Neutrinos

Underground detectors observing neutrinos produced by cosmic rays in the atmosphere have measured a ν_μ/ν_e ratio much less than expected and also a deficiency of upward going ν_μ compared to downward. This could be explained by oscillations leading to the disappearance of ν_μ with $\Delta m^2 \approx 10^{-3}$ to 0.1 eV^2. This is presently the best evidence for neutrino mass.

ν oscillation: $\overline{\nu}_e \not\rightarrow \overline{\nu}_e$ (θ = mixing angle)

$\Delta m^2 < 7 \times 10^{-4}$ eV^2, CL = 90% (if $\sin^2 2\theta = 1$)

$\sin^2 2\theta < 0.02$, CL = 90% (if $\Delta(m^2)$ is large)

ν oscillation: ν_μ ($\overline{\nu}_\mu$) $\rightarrow$ ν_e ($\overline{\nu}_e$) (any combination)

$\Delta m^2 < 0.075$ eV^2, CL = 90% (if $\sin^2 2\theta = 1$)

$\sin^2 2\theta < 1.8 \times 10^{-3}$, CL = 90% (if $\Delta(m^2)$ is large)

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] This is the best "electron disappearance" limit. The best limit for the mode $e^- \rightarrow \nu\gamma$ is $> 2.35 \times 10^{25}$ yr (CL=68%).

[b] See the "Note on Muon Decay Parameters" in the μ Particle Listings for definitions and details.

[c] P_μ is the longitudinal polarization of the muon from pion decay. In standard $V-A$ theory, $P_\mu = 1$ and $\rho = \delta = 3/4$.

[d] This only includes events with the γ energy > 10 MeV. Since the $e^- \overline{\nu}_e \nu_\mu$ and $e^- \overline{\nu}_e \nu_\mu \gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.

[e] See the relevant Particle Listings for the energy limits used in this measurement.

[f] A test of additive vs. multiplicative lepton family number conservation.

[g] Basis mode for the τ.

[h] $L^\pm$ mass limit depends on decay assumptions; see the Full Listings.

[i] Assumes ν_2 is the dominant mass eigenstate.

[j] Assumes ν_3 is the dominant mass eigenstate.

Quark Summary Table

QUARKS

The u-, d-, and s-quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as $\overline{\text{MS}}$ at a scale $\mu \approx 2$ GeV. The c- and b-quark masses are estimated from charmonium, bottomonium, D, and B masses. They are the "running" masses in the $\overline{\text{MS}}$ scheme. These can be different from the heavy quark masses obtained in potential models.

u

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m = 1$ to 5 MeV [a] Charge $= \frac{2}{3}\,e$ $I_z = +\frac{1}{2}$
$m_u/m_d = 0.2$ to 0.8

d

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m = 3$ to 9 MeV [a] Charge $= -\frac{1}{3}\,e$ $I_z = -\frac{1}{2}$
$m_s/m_d = 17$ to 25
$\overline{m} = (m_u+m_d)/2 = 2.5$ to 6 MeV

s

$I(J^P) = 0(\frac{1}{2}^+)$

Mass $m = 75$ to 170 MeV [a] Charge $= -\frac{1}{3}\,e$ Strangeness $= -1$
$(m_s - (m_u + m_d)/2)/(m_d - m_u) = 34$ to 51

c

$I(J^P) = 0(\frac{1}{2}^+)$

Mass $m = 1.15$ to 1.35 GeV Charge $= \frac{2}{3}\,e$ Charm $= +1$

b

$I(J^P) = 0(\frac{1}{2}^+)$

Mass $m = 4.0$ to 4.4 GeV Charge $= -\frac{1}{3}\,e$ Bottom $= -1$

t

$I(J^P) = 0(\frac{1}{2}^+)$

Charge $= \frac{2}{3}\,e$ Top $= +1$

Mass $m = 174.3 \pm 5.1$ GeV (direct observation of top events)
Mass $m = = 168.2^{+9.6}_{-7.4}$ GeV (Standard Model electroweak fit)

t DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
$W b$				–
$\ell \nu_\ell$ anything		[b,c] (9.4±2.4) %		–
$\tau \nu_\tau b$				–
$\gamma q(q=u,c)$		[d] < 3.2 %	95%	–
$\Delta T = 1$ weak neutral current ($T1$) modes				
$Z q(q=u,c)$	$T1$	[e] < 33 %	95%	–

b' (4th Generation) Quark, Searches for

Mass $m >$ 199 GeV, CL = 95% ($p\overline{p}$, neutral-current decays)
Mass $m >$ 128 GeV, CL = 95% ($p\overline{p}$, charged-current decays)
Mass $m >$ 46.0 GeV, CL = 95% (e^+e^-, all decays)

Free Quark Searches

All searches since 1977 have had negative results.

NOTES

[a] The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of u and d masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the u quark could be essentially massless. The s-quark mass is estimated from SU(3) splittings in hadron masses.

[b] ℓ means e or μ decay mode, not the sum over them.

[c] Assumes lepton universality and W-decay acceptance.

[d] This limit is for $\Gamma(t \to \gamma q)/\Gamma(t \to Wb)$.

[e] This limit is for $\Gamma(t \to Zq)/\Gamma(t \to Wb)$.

LIGHT UNFLAVORED MESONS
($S = C = B = 0$)

For $I = 1$ (π, b, ρ, a): $u\overline{d}$, $(u\overline{u}-d\overline{d})/\sqrt{2}$, $d\overline{u}$;
for $I = 0$ (η, η', h, h', ω, ϕ, f, f'): $c_1(u\overline{u} + d\overline{d}) + c_2(s\overline{s})$

$\pi^{\pm}$

$I^G(J^P) = 1^-(0^-)$

Mass $m = 139.57018 \pm 0.00035$ MeV (S = 1.2)
Mean life $\tau = (2.6033 \pm 0.0005) \times 10^{-8}$ s (S = 1.2)
$c\tau = 7.8045$ m

$\pi^{\pm} \rightarrow \ell^{\pm}\nu\gamma$ form factors [a]

$F_V = 0.017 \pm 0.008$
$F_A = 0.0116 \pm 0.0016$ (S = 1.3)
$R = 0.059^{+0.009}_{-0.008}$

π^- modes are charge conjugates of the modes below.

BOTTOM MESONS
$(B = \pm1)$

$B^+ = u\bar{b}$, $B^0 = d\bar{b}$, $\bar{B}^0 = \bar{d}b$, $B^- = \bar{u}b$, similarly for B^*'s

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the $B^\pm$ section, but because of their importance we have created two new sections: "$B^\pm/B^0$ Admixture" for $\Upsilon(4S)$ results and "$B^\pm/B^0/B_s^0/b$-baryon Admixture" for results at higher energies. Most inclusive decay branching fractions are found in the Admixture sections. B^0-$\bar{B}^0$ mixing data are found in the B^0 section, while B_s^0-$\bar{B}_s^0$ mixing data and B-$\bar{B}$ mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. CP-violation data are found in the B^0 section. b-baryons are found near the end of the Baryon section.

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

- $B^\pm$
  - mass, mean life
  - branching fractions
- B^0
  - mass, mean life
  - branching fractions
  - polarization in B^0 decay
  - B^0-$\bar{B}^0$ mixing
  - CP violation
- $B^\pm$ B^0 Admixtures
  - branching fractions
- $B^\pm/B^0/B_s^0/b$-baryon Admixtures
  - mean life
  - production fractions
  - branching fractions
- B^*
  - mass
- B_s^0
  - mass, mean life
  - branching fractions
  - polarization in B_s^0 decay
  - B_s^0-$\bar{B}_s^0$ mixing
  - B-$\bar{B}$ mixing (admixture of B^0, B_s^0)
- $B_c^\pm$
  - mass, mean life
  - branching fractions

At end of Baryon Listings:

- Λ_b
  - mass, mean life
  - branching fractions
- b-baryon Admixture
  - mean life
  - branching fractions

Meson Summary Table

$B^{\pm}$

$I(J^P) = \frac{1}{2}(0^-)$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

Mass $m_{B^{\pm}} = 5279.0 \pm 0.5$ MeV
Mean life $\tau_{B^{\pm}} = (1.653 \pm 0.028) \times 10^{-12}$ s
$c\tau = 496\ \mu$m

B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the $B^{\pm}/B^0$ ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

B^0

$I(J^P) = \frac{1}{2}(0^-)$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

Mass $m_{B^0} = 5279.4 \pm 0.5$ MeV
$m_{B^0} - m_{B^\pm} = 0.33 \pm 0.28$ MeV (S = 1.1)
Mean life $\tau_{B^0} = (1.548 \pm 0.032) \times 10^{-12}$ s
$c\tau = 464\ \mu$m
$\tau_{B^+}/\tau_{B^0} = 1.060 \pm 0.029$ (average of direct and inferred)
$\tau_{B^+}/\tau_{B^0} = 1.062 \pm 0.029$ (direct measurements)
$\tau_{B^+}/\tau_{B^0} = 0.95^{+0.15}_{-0.12}$ (inferred from branching fractions)

B^0-$\overline{B}^0$ mixing parameters

$\chi_d = 0.174 \pm 0.009$
$\Delta m_{B^0} = m_{B^0_H} - m_{B^0_L} = (0.472 \pm 0.017) \times 10^{12}\ \hbar\ s^{-1}$
$x_d = \Delta m_{B^0}/\Gamma_{B^0} = 0.730 \pm 0.029$

CP violation parameters

$\mathrm{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2) = 0.002 \pm 0.007$
$\sin(2\beta) = 0.9 \pm 0.4$

$\overline{B}^0$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the $B^\pm/B^0$ ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

B^0 DECAY MODES		Fraction (Γ_i/Γ)		Scale factor/ Confidence level	p (MeV/c)

$B^{\pm}/B^0$ ADMIXTURE

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \to B\overline{B}) = 100\%$.

For inclusive branching fractions, *e.g.*, $B \to D^{\pm}$ anything, the treatment of multiple D's in the final state must be defined. One possiblity would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

$\overline{B}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

$B^{\pm}/B^0/B^0_s/b$-baryon ADMIXTURE

These measurements are for an admixture of bottom particles at high energy (LEP, Tevatron, $Sp\overline{p}S$).

Mean life $\tau = (1.564 \pm 0.014) \times 10^{-12}$ s

Mean life $\tau = (1.72 \pm 0.10) \times 10^{-12}$ s Charged b-hadron admixture

Mean life $\tau = (1.58 \pm 0.14) \times 10^{-12}$ s Neutral b-hadron admixture

$\tau_{\text{charged } b\text{-hadron}}/\tau_{\text{neutral } b\text{-hadron}} = 1.09 \pm 0.13$

$|\Delta\tau_b|/\tau_{b,\overline{b}} = -0.001 \pm 0.014$

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, $Sp\overline{p}S$) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LEP and at the Tevatron.

For inclusive branching fractions, *e.g.*, $B \to D^{\pm}$anything, the treatment of multiple D's in the final state must be defined. One possiblity would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

The modes below are listed for a $\overline{b}$ initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

$\overline{b}$ DECAY MODES		Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the LEP B Oscillation Working Group as described in the note "Production and Decay of b-Flavored Hadrons" in the $B^{\pm}$ Particle Listings. Values assume

$B(\overline{b} \to B^+) = B(\overline{b} \to B^0)$

$B(\overline{b} \to B^+) + B(\overline{b} \to B^0) + B(\overline{b} \to B^0_s) + B(b \to b\text{-baryon}) = 100\ \%$.

The notation for production fractions varies in the literature (f_d, d_{B^0}, $f(b \to \overline{B}^0)$, $\text{Br}(b \to \overline{B}^0)$). We use our own branching fraction notation here, $B(\overline{b} \to B^0)$.

$\mu^+\mu^-$ anything	$B1$	< 3.2 $\times 10^{-4}$	CL=90%	–

B^*

$I(J^P) = \frac{1}{2}(1^-)$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

Mass $m_{B^*} = 5325.0 \pm 0.6$ MeV

$m_{B^*} - m_B = 45.78 \pm 0.35$ MeV

B^* DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$B\gamma$	dominant	46

BOTTOM, STRANGE MESONS ($B = \pm1, S = \mp1$)

$B_s^0 = s\overline{b}$, $\overline{B}_s^0 = \overline{s}b$, similarly for B_s^*'s

B_s^0

$I(J^P) = 0(0^-)$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

Mass $m_{B_s^0} = 5369.6 \pm 2.4$ MeV

Mean life $\tau = (1.493 \pm 0.062) \times 10^{-12}$ s

$c\tau = 448$ μm

B_s^0-$\overline{B}_s^0$ mixing parameters

χ_B at high energy $= f_d\chi_d + f_s\chi_s = 0.118 \pm 0.005$

$\Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0} > 10.6 \times 10^{12}\ \hbar\ s^{-1}$, CL = 95%

$x_s = \Delta m_{B_s^0}/\Gamma_{B_s^0} > 15.7$, CL = 95%

$\chi_s > 0.4980$, CL = 95%

These branching fractions all scale with $B(\overline{b} \to B_s^0)$, the LEP B_s^0 production fraction. The first four were evaluated using $B(\overline{b} \to B_s^0) = (10.7 \pm 1.4)\%$ and the rest assume $B(\overline{b} \to B_s^0) = 12\%$.

The branching fraction $B(B_s^0 \to D_s^- \ell^+ \nu_\ell \text{anything})$ is not a pure measurement since the measured product branching fraction $B(\overline{b} \to B_s^0) \times B(B_s^0 \to D_s^- \ell^+ \nu_\ell \text{anything})$ was used to determine $B(\overline{b} \to B_s^0)$, as described in the note on "Production and Decay of b-Flavored Hadrons."

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] See the "Note on $\pi^\pm \to \ell^\pm\nu\gamma$ and $K^\pm \to \ell^\pm\nu\gamma$ Form Factors" in the $\pi^\pm$ Particle Listings for definitions and details.

[b] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ's, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy γ's. Therefore, since no clean separation is possible, we consider the modes with γ's to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{total} = 100\%$.

[c] See the $\pi^\pm$ Particle Listings for the energy limits used in this measurement; low-energy γ's are not included.

[*d*] Derived from an analysis of neutrino-oscillation experiments.

[*e*] Astrophysical and cosmological arguments give limits of order 10^{-13}; see the π^0 Particle Listings.

[*f*] See the "Note on the Decay Width $\Gamma(\eta \rightarrow \gamma\gamma)$" in our 1994 edition, Phys. Rev. **D50**, 1 August 1994, Part I, p. 1451.

[*g*] C parity forbids this to occur as a single-photon process.

[*h*] See the "Note on scalar mesons" in the $f_0(1370)$ Particle Listings . The interpretation of this entry as a particle is controversial.

[*i*] See the "Note on $\rho(770)$" in the $\rho(770)$ Particle Listings .

[*j*] The e^+e^- branching fraction is from $e^+e^- \rightarrow \pi^+\pi^-$ experiments only. The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \rightarrow \mu^+\mu^-) = \Gamma(\rho^0 \rightarrow e^+e^-) \times 0.99785$.

[*k*] See the "Note on scalar mesons" in the $f_0(1370)$ Particle Listings .

[*l*] See the "Note on $a_1(1260)$" in the $a_1(1260)$ Particle Listings .

[*m*] This is only an educated guess; the error given is larger than the error on the average of the published values. See the Particle Listings for details.

[*n*] See the "Note on the $f_1(1420)$" in the $\eta(1440)$ Particle Listings.

[*o*] See also the $\omega(1650)$ Particle Listings.

[*p*] See the "Note on the $\eta(1440)$" in the $\eta(1440)$ Particle Listings.

[*q*] See the "Note on the $\rho(1450)$ and the $\rho(1700)$" in the $\rho(1700)$ Particle Listings.

[*r*] See the "Note on non-$q\overline{q}$ mesons" in the Particle Listings (see the index for the page number).

[*s*] See also the $\omega(1420)$ Particle Listings.

[*t*] See the "Note on $f_0(1710)$" in the $f_0(1710)$ Particle Listings .

[*u*] See the note in the $K^\pm$ Particle Listings.

[*v*] The definition of the slope parameter g of the $K \rightarrow 3\pi$ Dalitz plot is as follows (see also "Note on Dalitz Plot Parameters for $K \rightarrow 3\pi$ Decays" in the $K^\pm$ Particle Listings):

$$|M|^2 = 1 + g(s_3 - s_0)/m_{\pi^+}^2 + \cdots .$$

[*w*] For more details and definitions of parameters see the Particle Listings.

[*x*] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[*y*] See the $K^\pm$ Particle Listings for the energy limits used in this measurement.

[*z*] Direct-emission branching fraction.

[*aa*] Structure-dependent part.

[*bb*] Derived from measured values of ϕ_{+-}, ϕ_{00}, $|\eta|$, $|m_{K_L^0} - m_{K_S^0}|$, and $\tau_{K_S^0}$, as described in the introduction to "Tests of Conservation Laws."

[*cc*] The CP-violation parameters are defined as follows (see also "Note on CP Violation in $K_S \rightarrow 3\pi$" and "Note on CP Violation in K_L^0 Decay" in the Particle Listings):

$$\eta_{+-} = |\eta_{+-}|e^{i\phi_{+-}} = \frac{A(K_L^0 \rightarrow \pi^+\pi^-)}{A(K_S^0 \rightarrow \pi^+\pi^-)} = \epsilon + \epsilon'$$

$$\eta_{00} = |\eta_{00}|e^{i\phi_{00}} = \frac{A(K_L^0 \rightarrow \pi^0\pi^0)}{A(K_S^0 \rightarrow \pi^0\pi^0)} = \epsilon - 2\epsilon'$$

$$\delta = \frac{\Gamma(K_L^0 \rightarrow \pi^-\ell^+\nu) - \Gamma(K_L^0 \rightarrow \pi^+\ell^-\nu)}{\Gamma(K_L^0 \rightarrow \pi^-\ell^+\nu) + \Gamma(K_L^0 \rightarrow \pi^+\ell^-\nu)},$$

$$\mathrm{Im}(\eta_{+-0})^2 = \frac{\Gamma(K_S^0 \rightarrow \pi^+\pi^-\pi^0)^{CP\ \text{viol.}}}{\Gamma(K_L^0 \rightarrow \pi^+\pi^-\pi^0)},$$

$$\mathrm{Im}(\eta_{000})^2 = \frac{\Gamma(K_S^0 \rightarrow \pi^0\pi^0\pi^0)}{\Gamma(K_L^0 \rightarrow \pi^0\pi^0\pi^0)}.$$

where for the last two relations CPT is assumed valid, *i.e.*, $\mathrm{Re}(\eta_{+-0}) \simeq 0$ and $\mathrm{Re}(\eta_{000}) \simeq 0$.

[*dd*] See the K_S^0 Particle Listings for the energy limits used in this measurement.

[*ee*] The value is for the sum of the charge states or particle/antiparticle states indicated.

[*ff*] ϵ'/ϵ is derived from $|\eta_{00}/\eta_{+-}|$ measurements using theoretical input on phases.

[*gg*] See the K_L^0 Particle Listings for the energy limits used in this measurement.

[*hh*] Allowed by higher-order electroweak interactions.

[*ii*] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

[*jj*] See the "Note on $f_0(1370)$" in the $f_0(1370)$ Particle Listings and in the 1994 edition.

[*kk*] See the note in the $L(1770)$ Particle Listings in Reviews of Modern Physics **56** No. 2 Pt. II (1984), p. S200. See also the "Note on $K_2(1770)$ and the $K_2(1820)$" in the $K_2(1770)$ Particle Listings .

[*ll*] See the "Note on $K_2(1770)$ and the $K_2(1820)$" in the $K_2(1770)$ Particle Listings .

[*mm*] This result applies to $Z^0 \rightarrow c\overline{c}$ decays only. Here ℓ^+ is an average (not a sum) of e^+ and μ^+ decays.

[*nn*] This is a weighted average of $D^\pm$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0 \rightarrow$ (η anything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in the Particle Listings.

[*oo*] This value averages the e^+ and μ^+ branching fractions, after making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence our ℓ^+ here is really an e^+.

[*pp*] An ℓ indicates an e or a μ mode, not a sum over these modes.

[*qq*] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Particle Listings.

[*rr*] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[*ss*] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.

[*tt*] This D_1^0-D_2^0 limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0$)) / $\Gamma(K^-\pi^+)$ near the end of the D^0 Listings.

[*uu*] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.

[*vv*] However, these upper limits are in serious disagreement with values obtained in another experiment.

[*ww*] For now, we average together measurements of the $X e^+\nu_e$ and $X\mu^+\nu_\mu$ branching fractions. This is the *average*, not the *sum*.

[*xx*] This branching fraction includes all the decay modes of the final-state resonance.

[*yy*] This value includes only K^+K^- decays of the $f_0(1710)$, because branching fractions of this resonance are not known.

[*zz*] This value includes only $\pi^+\pi^-$ decays of the $f_0(1500)$, because branching fractions of this resonance are not known.

[*aaa*] B^0 and B_s^0 contributions not separated. Limit is on weighted average of the two decay rates.

[*bbb*] These values are model dependent. See 'Note on Semileptonic Decays' in the B^+ Particle Listings.

[*ccc*] D^{**} stands for the sum of the $D(1\,^1P_1)$, $D(1\,^3P_0)$, $D(1\,^3P_1)$, $D(1\,^3P_2)$, $D(2\,^1S_0)$, and $D(2\,^1S_1)$ resonances.

[*ddd*] $D^{(*)}\overline{D}^{(*)}$ stands for the sum of $D^*\overline{D}^*$, $D^*\overline{D}$, $D\overline{D}^*$, and $D\overline{D}$.

[*eee*] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

[*fff*] D_j represents an unresolved mixture of pseudoscalar and tensor D^{**} (P-wave) states.

[*ggg*] Not a pure measurement. See note at head of B_s^0 Decay Modes.

[*hhh*] Not a pure branching ratio, it is the fraction $(\Gamma_i/\Gamma)\times\mathrm{B}(\overline{B} \rightarrow B_c)$.

[*iii*] Includes $p\overline{p}\pi^+\pi^-\gamma$ and excludes $p\overline{p}\eta$, $p\overline{p}\omega$, $p\overline{p}\eta'$.

[*jjj*] J^{PC} known by production in e^+e^- via single photon annihilation. I^G is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.

[*kkk*] Spectroscopic labeling for these states is theoretical, pending experimental information.

See also the table of suggested $q\overline{q}$ quark-model assignments in the Quark Model section.

- • Indicates particles that appear in the preceding Meson Summary Table. We do not regard the other entries as being established.
- † Indicates that the value of J given is preferred, but needs confirmation.

Baryon Summary Table

This short table gives the name, the quantum numbers (where known), and the status of baryons in the Review. Only the baryons with 3- or 4-star status are included in the main Baryon Summary Table. Due to insufficient data or uncertain interpretation, the other entries in the short table are not established as baryons. The names with masses are of baryons that decay strongly. See our 1986 edition (Physics Letters **170B**) for listings of evidence for Z baryons (KN resonances).

p

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m = 938.27200 \pm 0.00004$ MeV [a]
$= 1.00727646688 \pm 0.00000000013$ u
$|m_p - m_{\overline{p}}|/m_p < 5 \times 10^{-7}$ [b]
$|\frac{q_{\overline{p}}}{m_{\overline{p}}}|/(\frac{q_p}{m_p}) = 0.99999999991 \pm 0.00000000009$
$|q_p + q_{\overline{p}}|/e < 5 \times 10^{-7}$ [b]
$|q_p + q_e|/e < 1.0 \times 10^{-21}$ [c]
Magnetic moment $\mu = 2.792847337 \pm 0.000000029\ \mu_N$
$(\mu_p + \mu_{\overline{p}}) / \mu_p = (-2.6 \pm 2.9) \times 10^{-3}$
Electric dipole moment $d = (-4 \pm 6) \times 10^{-23}$ $e$cm
Electric polarizability $\overline{\alpha} = (12.1 \pm 0.9) \times 10^{-4}$ fm^3
Magnetic polarizability $\overline{\beta} = (2.1 \pm 0.9) \times 10^{-4}$ fm^3
Mean life $\tau > 1.6 \times 10^{25}$ years (independent of mode)
$> 10^{31}$ to 10^{33} years [d] (mode dependent)

Below, for N decays, p and n distinguish proton and neutron partial lifetimes. See also the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1673) for a short review.

The "partial mean life" limits tabulated here are the limits on τ/B_i, where τ is the total mean life and B_i is the branching fraction for the mode in question.

p DECAY MODES	Partial mean life (10^{30} years)	Confidence level	p (MeV/c)

$\Sigma^+\pi^0$ $\alpha = -0.45 \pm 0.32$
$\Lambda\ell^+\nu_\ell$ $\alpha = -0.82^{+0.11}_{-0.07}$

Nearly all branching fractions of the Λ_c^+ are measured relative to the $pK^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of $B(\Lambda_c^+ \to pK^-\pi^+)$ in a Note at the beginning of the branching-ratio measurements in the Listings. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

Λ_c^+ DECAY MODES		Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)
Hadronic modes with a p and one $\overline{K}$				
$p\overline{K}^0$		(2.3 ± 0.6) %		872
$pK^-\pi^+$	[l]	(5.0 ± 1.3) %		822
$p\overline{K}^*(892)^0$	[m]	(1.6 ± 0.5) %		681
$\Delta(1232)^{++}K^-$		$(8.6 \pm 3.0) \times 10^{-3}$		709

$\Lambda_c(2593)^+$

$I(J^P) = 0(\frac{1}{2}^-)$

The spin-parity follows from the fact that $\Sigma_c(2455)\pi$ decays, with little available phase space, are dominant.

Mass $m = 2593.9 \pm 0.8$ MeV
$m - m_{\Lambda_c^+} = 308.9 \pm 0.6$ MeV (S = 1.1)
Full width $\Gamma = 3.6^{+2.0}_{-1.3}$ MeV

$\Lambda_c^+\pi\pi$ and its submode $\Sigma_c(2455)\pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_c^+ having this mass; and the submode seems to dominate.

$\Lambda_c(2593)^+$ DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$\Lambda_c^+\pi^+\pi^-$	[p] ≈ 67 %	124
$\Sigma_c(2455)^{++}\pi^-$	24 ± 7 %	17
$\Sigma_c(2455)^0\pi^+$	24 ± 7 %	23
$\Lambda_c^+\pi^+\pi^-$ 3-body	18 ± 10 %	124
$\Lambda_c^+\pi^0$	not seen	261
$\Lambda_c^+\gamma$	not seen	290

$\Lambda_c(2625)^+$

$I(J^P) = 0(\frac{3}{2}^-)$

J^P has not been measured; $\frac{3}{2}^-$ is the quark-model prediction.

Mass $m = 2626.6 \pm 0.8$ MeV (S = 1.2)
$m - m_{\Lambda_c^+} = 341.7 \pm 0.6$ MeV (S = 1.6)
Full width $\Gamma < 1.9$ MeV, CL = 90%

$\Lambda_c^+\pi\pi$ and its submode $\Sigma(2455)\pi$ are the only strong decays allowed to an excited Λ_c^+ having this mass.

$\Lambda_c(2625)^+$ DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
$\Lambda_c^+\pi^+\pi^-$	[p]	≈ 67%		184
$\Sigma_c(2455)^{++}\pi^-$		<5	90%	100
$\Sigma_c(2455)^0\pi^+$		<5	90%	101
$\Lambda_c^+\pi^+\pi^-$ 3-body		large		184
$\Lambda_c^+\pi^0$		not seen		293
$\Lambda_c^+\gamma$		not seen		319

$\Sigma_c(2455)$

$I(J^P) = 1(\frac{1}{2}^+)$

J^P has not been measured; $\frac{1}{2}^+$ is the quark-model prediction.

$\Sigma_c(2455)^{++}$ mass $m = 2452.8 \pm 0.6$ MeV
$\Sigma_c(2455)^+$ mass $m = 2453.6 \pm 0.9$ MeV
$\Sigma_c(2455)^0$ mass $m = 2452.2 \pm 0.6$ MeV
$m_{\Sigma_c^{++}} - m_{\Lambda_c^+} = 167.87 \pm 0.19$ MeV
$m_{\Sigma_c^+} - m_{\Lambda_c^+} = 168.7 \pm 0.6$ MeV
$m_{\Sigma_c^0} - m_{\Lambda_c^+} = 167.30 \pm 0.20$ MeV
$m_{\Sigma_c^{++}} - m_{\Sigma_c^0} = 0.57 \pm 0.23$ MeV
$m_{\Sigma_c^+} - m_{\Sigma_c^0} = 1.4 \pm 0.6$ MeV

$\Lambda_c^+\pi$ is the only strong decay allowed to a Σ_c having this mass.

$\Sigma_c(2455)$ DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$\Lambda_c^+\pi$	≈ 100 %	90

$\Sigma_c(2520)$

$I(J^P) = 1(\frac{3}{2}^+)$

J^P has not been measured; $\frac{3}{2}^+$ is the quark-model prediction.

$\Sigma_c(2520)^{++}$ mass $m = 2519.4 \pm 1.5$ MeV
$\Sigma_c(2520)^0$ mass $m = 2517.5 \pm 1.4$ MeV
$m_{\Sigma_c(2520)^{++}} - m_{\Lambda_c^+} = 234.5 \pm 1.4$ MeV
$m_{\Sigma_c(2520)^0} - m_{\Lambda_c^+} = 232.6 \pm 1.3$ MeV
$m_{\Sigma_c(2520)^{++}} - m_{\Sigma_c(2520)^0} = 1.9 \pm 1.7$ MeV
$\Sigma_c(2520)^{++}$ full width $\Gamma = 18 \pm 5$ MeV
$\Sigma_c(2520)^0$ full width $\Gamma = 13 \pm 5$ MeV

$\Lambda_c^+\pi$ is the only strong decay allowed to a Σ_c having this mass.

$\Sigma_c(2520)$ DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$\Lambda_c^+\pi$	≈ 100 %	180

Ξ_c^+

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

J^P has not been measured; $\frac{1}{2}^+$ is the quark-model prediction.

Mass $m = 2466.3 \pm 1.4$ MeV
Mean life $\tau = (0.33^{+0.06}_{-0.04}) \times 10^{-12}$ s
$c\tau = 98$ μm

No absolute branching fractions have been measured. The following are branching *ratios* relative to $\Xi^- \pi^+ \pi^+$.

Ξ_c^+ DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
$\Lambda K^- \pi^+ \pi^+$	[q]	0.58 ± 0.18		785
$\Lambda \overline{K}^*(892)^0 \pi^+$	[m,q]	<0.29	90%	603
$\Sigma(1385)^+ K^- \pi^+$	[m,q]	<0.41	90%	677

$\Xi_c'^+$

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

J^P has not been measured; $\frac{1}{2}^+$ is the quark-model prediction.

Mass $m = 2574.1 \pm 3.3$ MeV
$m_{\Xi_c'^+} - m_{\Xi_c^+} = 107.8 \pm 3.0$ MeV

The $\Xi_c'^+$-Ξ_c^+ mass difference is too small for any strong decay to occur.

$\Xi_c'^+$ DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$\Xi_c^+ \gamma$	seen	106

$\Xi_c'^0$

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

J^P has not been measured; $\frac{1}{2}^+$ is the quark-model prediction.

Mass $m = 2578.8 \pm 3.2$ MeV
$m_{\Xi_c'^0} - m_{\Xi_c^0} = 107.0 \pm 2.9$ MeV

The $\Xi_c'^0 - \Xi_c^0$ mass difference is too small for any strong decay to occur.

$\Xi_c'^0$ DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$\Xi_c^0 \gamma$	seen	105

$\Xi_c(2645)$

$I(J^P) = \frac{1}{2}(\frac{3}{2}^+)$

J^P has not been measured; $\frac{3}{2}^+$ is the quark-model prediction.

$\Xi_c(2645)^+$ mass $m = 2647.4 \pm 2.0$ MeV (S = 1.2)
$\Xi_c(2645)^0$ mass $m = 2644.5 \pm 1.8$ MeV
$m_{\Xi_c(2645)^+} - m_{\Xi_c^0} = 175.6 \pm 1.4$ MeV (S = 1.7)
$m_{\Xi_c(2645)^0} - m_{\Xi_c^+} = 178.2 \pm 1.1$ MeV
$\Xi_c(2645)^+$ full width $\Gamma < 3.1$ MeV, CL = 90%
$\Xi_c(2645)^0$ full width $\Gamma < 5.5$ MeV, CL = 90%

$\Xi_c \pi$ is the only strong decay allowed to a Ξ_c resonance having this mass.

$\Xi_c(2645)$ DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$\Xi_c^0 \pi^+$	seen	103
$\Xi_c^+ \pi^-$	seen	107

$\Xi_c(2815)$

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$

J^P has not been measured; $\frac{3}{2}^-$ is the quark-model prediction.

$\Xi_c(2815)^+$ mass $m = 2814.9 \pm 1.8$ MeV
$\Xi_c(2815)^0$ mass $m = 2819.0 \pm 2.5$ MeV
$m_{\Xi_c(2815)^+} - m_{\Xi_c^+} = 348.6 \pm 1.2$ MeV
$m_{\Xi_c(2815)^0} - m_{\Xi_c^0} = 347.2 \pm 2.1$ MeV
$\Xi_c(2815)^+$ full width $\Gamma < 3.5$ MeV, CL = 90%
$\Xi_c(2815)^0$ full width $\Gamma < 6.5$ MeV, CL = 90%

The $\Xi_c \pi\pi$ modes are consistent with being entirely via $\Xi_c(2645)\pi$.

$\Xi_c(2815)$ DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$\Xi_c^+ \pi^+ \pi^-$	seen	196
$\Xi_c^0 \pi^+ \pi^-$	seen	193

Ω_c^0

$I(J^P) = 0(\frac{1}{2}^+)$

J^P has not been measured; $\frac{1}{2}^+$ is the quark-model prediction.

Mass $m = 2704 \pm 4$ MeV (S = 1.8)
Mean life $\tau = (0.064 \pm 0.020) \times 10^{-12}$ s
$c\tau = 19$ μm

BOTTOM BARYONS
$(B = -1)$

$\Lambda_b^0 = udb$, $\Xi_b^0 = usb$, $\Xi_b^- = dsb$

Λ_b^0

$I(J^P) = 0(\frac{1}{2}^+)$

$I(J^P)$ not yet measured; $0(\frac{1}{2}^+)$ is the quark model prediction.

Mass $m = 5624 \pm 9$ MeV (S = 1.8)
Mean life $\tau = (1.229 \pm 0.080) \times 10^{-12}$ s
$c\tau = 368\ \mu$m

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates in Z decay (or high-energy $p\overline{p}$), branching ratios, and detection efficiencies. They scale with the LEP b-baryon production fraction B($b \to b$-baryon) and are evaluated for our value B($b \to b$-baryon) = (11.6 ± 2.0)%.

The branching fractions B(b-baryon $\to \Lambda \ell^- \overline{\nu}_\ell$anything) and B($\Lambda_b^0 \to \Lambda_c^+ \ell^- \overline{\nu}_\ell$anything) are not pure measurements because the underlying measured products of these with B($b \to b$-baryon) were used to determine B($b \to b$-baryon), as described in the note "Production and Decay of b-Flavored Hadrons."

NOTES

This Summary Table only includes established baryons. The Particle Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit-Wigner parameters, but pole positions are also given for most of the N and Δ resonances.

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together. Furthermore, the systematic errors on the results are not well understood. Thus, we usually only give ranges for the parameters. We then also give a best guess for the mass (as part of the name of the resonance) and for the width. The *Note on N and Δ Resonances* and the *Note on Λ and Σ Resonances* in the Particle Listings review the partial-wave analyses.

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame. For any resonance, the *nominal* mass is used in calculating p. A dagger ("†") in this column indicates that the mode is forbidden when the nominal masses of resonances are used, but is in fact allowed due to the nonzero widths of the resonances.

[a] The masses of the p and n are most precisely known in u (unified atomic mass units). The conversion factor to MeV, 1 u = 931.494013 ± 0.000037 MeV, is less well known than are the masses in u.

[b] These two results are not independent, and both use the more precise measurement of $|q_{\overline{p}}/m_{\overline{p}}|/(q_p/m_p)$.

[c] The limit is from neutrality-of-matter experiments; it assumes $q_n = q_p + q_e$. See also the charge of the neutron.

[d] The first limit is geochemical and independent of decay mode. The second entry, a rough range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray $\overline{p}$'s is $\tau_{\overline{p}} > 10^7$ yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\overline{p}}/B(\overline{p} \to e^-\gamma) > 7 \times 10^5$ yr.

[e] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.

[f] The parameters g_A, g_V, and g_{WM} for semileptonic modes are defined by $\overline{B}_f[\gamma_\lambda(g_V + g_A\gamma_5) + i(g_{WM}/m_{B_i})\,\sigma_{\lambda\nu}\,q^\nu]B_i$, and ϕ_{AV} is defined by $g_A/g_V = |g_A/g_V|e^{i\phi_{AV}}$. See the "Note on Baryon Decay Parameters" in the neutron Particle Listings.

[g] Time-reversal invariance requires this to be 0° or 180°.

[h] The decay parameters γ and Δ are calculated from α and ϕ using

$$\gamma = \sqrt{1-\alpha^2}\cos\phi\,, \qquad \tan\Delta = -\frac{1}{\alpha}\sqrt{1-\alpha^2}\sin\phi\,.$$

See the "Note on Baryon Decay Parameters" in the neutron Particle Listings.

[i] See the Listings for the pion momentum range used in this measurement.

[j] The error given here is only an educated guess. It is larger than the error on the weighted average of the published values.

[k] A theoretical value using QED.

[l] See the "Note on Λ_c^+ Branching Fractions" in the Branching Fractions of the Λ_c^+ Particle Listings.

[m] This branching fraction includes all the decay modes of the final-state resonance.

[n] An ℓ indicates an e or a μ mode, not a sum over these modes.

[o] The value is for the sum of the charge states or particle/antiparticle states indicated.

[p] Assuming isospin conservation, so that the other third is $\Lambda_c^+\pi^0\pi^0$.

[q] No absolute branching fractions have been measured. The following are branching *ratios* relative to $\Xi^-\pi^+\pi^+$.

[r] Not a pure measurement. See note at head of Λ_b^0 Decay Modes.

SEARCHES FOR MONOPOLES, SUPERSYMMETRY, TECHNICOLOR, COMPOSITENESS, etc.

Magnetic Monopole Searches

Isolated supermassive monopole candidate events have not been confirmed. The most sensitive experiments obtain negative results.

Best cosmic-ray supermassive monopole flux limit:

$< 1.0 \times 10^{-15}$ cm^{-2}sr^{-1}s^{-1} for $1.1 \times 10^{-4} < \beta < 0.1$

Supersymmetric Particle Searches

Limits are based on the Minimal Supersymmetric Standard Model.

Assumptions include: 1) $\widetilde{\chi}_1^0$ (or $\widetilde{\gamma}$) is lightest supersymmetric particle; 2) R-parity is conserved; 3) With the excepton of $\widetilde{t}$ and $\widetilde{b}$, all scalar quarks are assumed to be degenerate in mass and $m_{\widetilde{q}_R} = m_{\widetilde{q}_L}$. 4) Limits for sleptons refer to the $\widetilde{\ell}_R$ states.

See the Particle Listings for a Note giving details of supersymmetry.

$\widetilde{\chi}_i^0$ — neutralinos (mixtures of $\widetilde{\gamma}$, $\widetilde{Z}^0$, and $\widetilde{H}_i^0$)

Mass $m_{\widetilde{\chi}_1^0} > 32.5$ GeV, CL = 95%
[$\tan\beta > 0.7$, $m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0} > 5$ GeV]

Mass $m_{\widetilde{\chi}_2^0} > 55.9$ GeV, CL = 95%
[$\tan\beta > 1.5$, $m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0} > 10$ GeV]

Mass $m_{\widetilde{\chi}_3^0} > 106.6$ GeV, CL = 95%
[$\tan\beta > 1.5$, $m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0} > 10$ GeV]

$\widetilde{\chi}_i^\pm$ — charginos (mixtures of $\widetilde{W}^\pm$ and $\widetilde{H}_i^\pm$)

Mass $m_{\widetilde{\chi}_1^\pm} > 67.7$ GeV, CL = 95%
[$\tan\beta > 0.7$, $m_{\widetilde{\chi}_1^\pm} - m_{\widetilde{\chi}_1^0} > 3$ GeV]

$\widetilde{e}$ — scalar electron (selectron)

Mass $m > 87.1$ GeV, CL = 95% [$m_{\widetilde{e}_R} - m_{\widetilde{\chi}_1^0} > 5$ GeV]

$\widetilde{\mu}$ — scalar muon (smuon)

Mass $m > 82.3$ GeV, CL = 95% [$m_{\widetilde{\mu}_R} - m_{\widetilde{\chi}_1^0} > 3$ GeV]

$\widetilde{\tau}$ — scalar tau (stau)

Mass $m > 81.0$ GeV, CL = 95% [$m_{\widetilde{\tau}_R} - m_{\widetilde{\chi}_1^0} > 8$ GeV]

$\widetilde{q}$ — scalar quark (squark)

These limits include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling.

Mass $m > 250$ GeV, CL = 95% [$\tan\beta = 2$, $\mu < 0$, $A = 0$]

$\widetilde{b}$ — scalar bottom (sbottom)

Mass m none 40–75 GeV, CL = 95%
[$\widetilde{b} \to b\widetilde{\chi}_1^0$, all θ_b, $m_{\widetilde{b}} - m_{\widetilde{\chi}_1^0} > 10$ GeV]

$\widetilde{t}$ — scalar top (stop)

Mass $m > 86.4$ GeV, CL = 95%
[$\widetilde{t} \to t\widetilde{\chi}_1^0$, all θ_t, $m_{\widetilde{t}} - m_{\widetilde{\chi}_1^0} > 5$ GeV]

$\widetilde{g}$ — gluino

There is some controversy on whether gluinos in a low-mass window ($1 \lesssim m_{\widetilde{g}} \lesssim 5$ GeV) are excluded or not. See the Supersymmetry Listings for details.

The limits summarised here refere to the high-mass region ($m_{\widetilde{g}} \gtrsim 5$ GeV), and include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling,

Mass $m > 190$ GeV, CL = 95% [$\tan\beta = 2$, $\mu < 0$, $A = 0$]
Mass $m > 260$ GeV, CL = 95% [$m_{\widetilde{q}} = m_{\widetilde{g}}$, $\tan\beta = 2$, $\mu < 0$, $A = 0$]

Technicolor

Searches for a color-octet techni-ρ constrain its mass to be greater than 260 to 480 GeV, depending on allowed decay channels. Similar bounds exist on the color-octet techni-ω.

Quark and Lepton Compositeness, Searches for

Scale Limits Λ for Contact Interactions (the lowest dimensional interactions with four fermions)

If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \overline{\psi}_L \gamma_\mu \psi_L \overline{\psi}_L \gamma^\mu \psi_L$$

(with $g^2/4\pi$ set equal to 1), then we define $\Lambda \equiv \Lambda_{LL}^\pm$. For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

$\Lambda_{LL}^+(eeee)$	> 3.5 TeV, CL = 95%
$\Lambda_{LL}^-(eeee)$	> 3.8 TeV, CL = 95%

$\Lambda_{LL}^-(qqqq)$	> 2.4 TeV, CL = 95%
$\Lambda_{LL}^+(\nu\nu qq)$	> 5.0 TeV, CL = 95%
$\Lambda_{LL}^-(\nu\nu qq)$	> 5.4 TeV, CL = 95%

Excited Leptons

The limits from $\ell^{*+}\ell^{*-}$ do not depend on λ (where λ is the $\ell\ell^*$ transition coupling). The λ-dependent limits assume chiral coupling, except for the third limit for e^* which is for nonchiral coupling. For chiral coupling, this limit corresponds to $\lambda_\gamma = \sqrt{2}$.

$e^{*\pm}$ — excited electron

Mass $m >$ 90.7 GeV, CL = 95% (from $e^{*+}e^{*-}$)
Mass m = none 30–200 GeV, CL = 95% (from $ep \rightarrow e^* X$)
Mass $m >$ 91 GeV, CL = 95% (if $\lambda_Z > 1$)
Mass $m >$ 306 GeV, CL = 95% (if $\lambda_\gamma = 1$)

$\mu^{*\pm}$ — excited muon

Mass $m >$ 90.7 GeV, CL = 95% (from $\mu^{*+}\mu^{*-}$)
Mass $m >$ 91 GeV, CL = 95% (if $\lambda_Z > 1$)

$\tau^{*\pm}$ — excited tau

Mass $m >$ 89.7 GeV, CL = 95% (from $\tau^{*+}\tau^{*-}$)
Mass $m >$ 90 GeV, CL = 95% (if $\lambda_Z > 0.18$)

ν^* — excited neutrino

Mass $m >$ 90.0 GeV, CL = 95% (from $\nu^*\overline{\nu}^*$)
Mass $m >$ 91 GeV, CL = 95% (if $\lambda_Z > 1$)
Mass m = none 40–96 GeV, CL = 95% (from $ep \rightarrow \nu^* X$)

q^* — excited quark

Mass $m >$ 45.6 GeV, CL = 95% (from $q^*\overline{q}^*$)
Mass $m >$ 88 GeV, CL = 95% (if $\lambda_Z > 1$)
Mass $m >$ 570 GeV, CL = 95% ($p\overline{p} \rightarrow q^* X$)

Color Sextet and Octet Particles

Color Sextet Quarks (q_6)

Mass $m >$ 84 GeV, CL = 95% (Stable q_6)

Color Octet Charged Leptons (ℓ_8)

Mass $m >$ 86 GeV, CL = 95% (Stable ℓ_8)

Color Octet Neutrinos (ν_8)

Mass $m >$ 110 GeV, CL = 90% ($\nu_8 \rightarrow \nu g$)

TESTS OF CONSERVATION LAWS

Revised by L. Wolfenstein and T.G. Trippe, May 2000.

In keeping with the current interest in tests of conservation laws, we collect together a Table of experimental limits on all weak and electromagnetic decays, mass differences, and moments, and on a few reactions, whose observation would violate conservation laws. The Table is given only in the full *Review of Particle Physics*, not in the Particle Physics Booklet. For the benefit of Booklet readers, we include the best limits from the Table in the following text. Limits in this text are for CL=90% unless otherwise specified. The Table is in two parts: "Discrete Space-Time Symmetries," *i.e.*, C, P, T, CP, and CPT; and "Number Conservation Laws," *i.e.*, lepton, baryon, hadronic flavor, and charge conservation. The references for these data can be found in the the Particle Listings in the *Review*. A discussion of these tests follows.

CPT INVARIANCE

General principles of relativistic field theory require invariance under the combined transformation CPT. The simplest tests of CPT invariance are the equality of the masses and lifetimes of a particle and its antiparticle. The best test comes from the limit on the mass difference between K^0 and $\overline{K}^0$. Any such difference contributes to the CP-violating parameter ϵ. Assuming CPT invariance, ϕ_ϵ, the phase of ϵ should be very close to 44°. (See the review "CP Violation" in this edition.) In contrast, if the entire source of CP violation in K^0 decays were a $K^0-\overline{K}^0$ mass difference, ϕ_ϵ would be 44° + 90°.

Assuming that there is no other source of CPT violation than this mass difference, it is possible to deduce that [1]

$$m_{\overline{K}^0} - m_{K^0} \approx \frac{2(m_{K_L^0} - m_{K_S^0})\,|\eta|\,(\frac{2}{3}\phi_{+-} + \frac{1}{3}\phi_{00} - \phi_0)}{\sin\phi_0} ,$$

where $\phi_0 = 43.5°$ with an uncertainty of less than 0.1°. Using our best values of the CP-violation parameters, we get $|(m_{\overline{K}^0} - m_{K^0})/m_{K^0}| \le 10^{-18}$ at CL=95%. Limits can also be placed on specific CPT-violating decay amplitudes. Given the small value of $(1-|\eta_{00}/\eta_{+-}|)$, the value of $\phi_{00} - \phi_{+-}$ provides a measure of CPT violation in $K_L^0 \to 2\pi$ decay. Results from CERN [1] and Fermilab [2] indicate no CPT-violating effect.

CP AND T INVARIANCE

Given CPT invariance, CP violation and T violation are equivalent. So far most of the evidence for CP or T violation comes from the measurements of η_{+-}, η_{00}, $\eta_{+-\gamma}$, the semileptonic decay charge asymmetry for K_L, and the decay plane asymmetry in $K_L \to \pi^+\pi^-e^+e^-$, *e.g.*, $|\eta_{+-}| = |A(K_L^0 \to \pi^+\pi^-)/A(K_S^0 \to \pi^+\pi^-)| = (2.285 \pm 0.019) \times 10^{-3}$ and $[\Gamma(K_L^0 \to \pi^-e^+\nu) - \Gamma(K_L^0 \to \pi^+e^-\overline{\nu})]/[\text{sum}] = (0.333 \pm 0.014)\%$. There is also a measurement from CPLEAR of the difference between the oscillation probabilities of $K^0 \to \overline{K}^0$ and $\overline{K}^0 \to K^0$ [3]. In the Standard Model, much larger effects are expected in B decays and the first measurement of the CP-violating parameter $\sin 2\beta$ at Fermilab gives a value of 0.9 ± 0.4. Other searches for CP or T violation involve effects that are expected to be unobservable in the Standard Model. The most sensitive are probably the searches for an electric dipole moment of the neutron, measured to be $< 6 \times 10^{-26}$ e cm, and the electron $(0.18 \pm 0.16) \times 10^{-26}$ e cm. A nonzero value requires both P and T violation.

CONSERVATION OF LEPTON NUMBERS

Present experimental evidence and the standard electroweak theory are consistent with the absolute conservation of three separate lepton numbers: electron number L_e, muon number L_μ, and tau number L_τ. Searches for violations are of the following types:

a) $\Delta L = 2$ for one type of charged lepton. The best limit comes from the search for neutrinoless double beta decay $(Z, A) \to (Z+2, A) + e^- + e^-$. The best laboratory limit is $t_{1/2} > 1.6 \times 10^{25}$ yr (CL=90%) for ^{76}Ge.

b) Conversion of one charged-lepton type to another. For purely leptonic processes, the best limits are on $\mu \to e\gamma$ and $\mu \to 3e$, measured as $\Gamma(\mu \to e\gamma)/\Gamma(\mu \to \text{all}) < 1.2 \times 10^{-11}$ and $\Gamma(\mu \to 3e)/\Gamma(\mu \to \text{all}) < 1.0 \times 10^{-12}$. For semileptonic processes, the best limit comes from the coherent conversion process in a muonic atom, $\mu^- + (Z, A) \to e^- + (Z, A)$, measured as $\Gamma(\mu^-\text{Ti} \to e^-\text{Ti})/\Gamma(\mu^-\text{Ti} \to \text{all}) < 4 \times 10^{-12}$. Of special interest is the case in which the hadronic flavor also changes, as in $K_L \to e\mu$ and $K^+ \to \pi^+e^-\mu^+$, measured as $\Gamma(K_L \to e\mu)/\Gamma(K_L \to \text{all}) < 4.7 \times 10^{-12}$ and $\Gamma(K^+ \to \pi^+e^-\mu^+)/\Gamma(K^+ \to \text{all}) < 2.1 \times 10^{-10}$. Limits on the conversion of τ into e or μ are found in τ decay and are much less stringent than those for $\mu \to e$ conversion, *e.g.*, $\Gamma(\tau \to \mu\gamma)/\Gamma(\tau \to \text{all}) < 1.1 \times 10^{-6}$ and $\Gamma(\tau \to e\gamma)/\Gamma(\tau \to \text{all}) < 2.7 \times 10^{-6}$.

c) Conversion of one type of charged lepton into another type of charged antilepton. The case most studied is $\mu^- + (Z, A) \to e^+ + (Z-2, A)$, the strongest limit being $\Gamma(\mu^-\text{Ti} \to e^+\text{Ca})/\Gamma(\mu^-\text{Ti} \to \text{all}) < 3.6 \times 10^{-11}$.

d) Neutrino oscillations. If neutrinos have mass, then it is expected even in the standard electroweak theory that the lepton numbers are not separately conserved, as a consequence of lepton mixing analogous to Cabibbo quark mixing. However, in this case lepton-number-violating processes such as $\mu \to e\gamma$ are expected to have extremely small probability. For small neutrino masses, the lepton-number violation would be observed first in neutrino oscillations, which have been the subject of extensive experimental searches. For example, searches for $\overline{\nu}_e$ disappearance, which we label as $\overline{\nu}_e \not\to \overline{\nu}_e$, give measured limits $\Delta(m^2) < 7 \times 10^{-4}$ eV^2 for $\sin^2(2\theta) = 1$, and $\sin^2(2\theta) < 0.02$ for large $\Delta(m^2)$, where θ is the neutrino mixing angle. Possible evidence for mixing has come from two sources. The deficit in the solar neutrino flux compared with solar model calculations could be explained by oscillations with $\Delta(m^2) \le 10^{-4}$ eV^2 causing the disappearance of ν_e. In addition, underground detectors observing neutrinos produced by cosmic rays in the atmosphere have measured a ν_μ/ν_e ratio much less than expected and have also found a factor of 2 deficiency of upward going ν_μ compared to downward. This provides compelling evidence for ν_μ disappearance, for which the most probable explanation is $\nu_\mu \to \nu_\tau$ oscillations with nearly maximal mixing and $\Delta(m^2)$ of the order 0.001–0.01 eV^2.

CONSERVATION OF HADRONIC FLAVORS

In strong and electromagnetic interactions, hadronic flavor is conserved, *i.e.* the conversion of a quark of one flavor (d, u, s, c, b, t) into a quark of another flavor is forbidden. In the Standard Model, the weak interactions violate these conservation laws in a manner described by the Cabibbo-Kobayashi-Maskawa mixing (see the section "Cabibbo-Kobayashi-Maskawa Mixing Matrix"). The way in which these conservation laws are violated is tested as follows:

Tests of Conservation Laws

a) $\Delta S = \Delta Q$ rule. In the strangeness-changing semileptonic decay of strange particles, the strangeness change equals the change in charge of the hadrons. Tests come from limits on decay rates such as $\Gamma(\Sigma^+ \to n e^+ \nu)/\Gamma(\Sigma^+ \to \text{all}) < 5 \times 10^{-6}$, and from a detailed analysis of $K_L \to \pi e \nu$, which yields the parameter x, measured to be $(\text{Re}\, x, \text{Im}\, x) = (-0.002 \pm 0.006, -0.0012 \pm 0.0019)$. Corresponding rules are $\Delta C = \Delta Q$ and $\Delta B = \Delta Q$.

b) Change of flavor by two units. In the Standard Model this occurs only in second-order weak interactions. The classic example is $\Delta S = 2$ via $K^0 - \overline{K}^0$ mixing, which is directly measured by $m(K_S) - m(K_L) = (3.489 \pm 0.008) \times 10^{-12}$ MeV. There is now evidence for $B^0 - \overline{B}^0$ mixing ($\Delta B = 2$), with the corresponding mass difference between the eigenstates $(m_{B^0_H} - m_{B^0_L}) = (0.730 \pm 0.029)\Gamma_{B^0} = (3.11 \pm 0.11) \times 10^{-10}$ MeV, and for B^0_s-$\overline{B}^0_s$ mixing, with $(m_{B^0_{sH}} - m_{B^0_{sL}}) > 16\Gamma_{B^0_s}$ or $> 7 \times 10^{-9}$ MeV (CL=95%). For $D^0 - \overline{D}^0$ mixing $m_{D^0_H} - m_{D^0_L} < 5 \times 10^{-11}$ MeV; the value in the Standard Model is expected to be much small than this.

c) Flavor-changing neutral currents. In the Standard Model the neutral-current interactions do not change flavor. The low rate $\Gamma(K_L \to \mu^+\mu^-)/\Gamma(K_L \to \text{all}) = (7.2 \pm 0.5) \times 10^{-9}$ puts limits on such interactions; the nonzero value for this rate is attributed to a combination of the weak and electromagnetic interactions. The best test should come from $K^+ \to \pi^+ \nu \overline{\nu}$, which occurs in the Standard Model only as a second-order weak process with a branching fraction of (0.4 to 1.2)$\times 10^{-10}$. Recent results, including observation of one event, yields $\Gamma(K^+ \to \pi^+ \nu \overline{\nu})/\Gamma(K^+ \to \text{all}) = (1.5^{+3.4}_{-1.2}) \times 10^{-10}$ [5]. Limits for charm-changing or bottom-changing neutral currents are much less stringent: $\Gamma(D^0 \to \mu^+\mu^-)/\Gamma(D^0 \to \text{all}) < 4 \times 10^{-6}$ and $\Gamma(B^0 \to \mu^+\mu^-)/\Gamma(B^0 \to \text{all}) < 7 \times 10^{-7}$. One cannot isolate flavor-changing neutral current (FCNC) effects in non leptonic decays. For example, the FCNC transition $s \to d + (\overline{u} + u)$ is equivalent to the charged-current transition $s \to u + (\overline{u} + d)$. Tests for FCNC are therefore limited to hadron decays into lepton pairs. Such decays are expected only in second-order in the electroweak coupling in the Standard Model.

Unless otherwise stated, limits are given at the 90% confidence level, while errors are given as ± 1 standard deviation.

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

[a] C parity forbids this to occur as a single-photon process.

[b] Time-reversal invariance requires this to be 0° or 180°.

[c] Allowed by higher-order electroweak interactions.

[d] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

[e] ϵ'/ϵ is derived from $|\eta_{00}/\eta_{+-}|$ measurements using theoretical input on phases.

[f] Neglecting photon channels. See, *e.g.*, A. Pais and S.B. Treiman, Phys. Rev. **D12**, 2744 (1975).

[g] Derived from measured values of ϕ_{+-}, ϕ_{00}, $|\eta|$, $|m_{K_L^0} - m_{K_S^0}|$, and $\tau_{K_S^0}$, as described in the introduction to "Tests of Conservation Laws."

[h] These two results are not independent, and both use the more precise measurement of $|q_{\overline{p}}/m_{\overline{p}}|/(q_p/m_p)$.

[i] The value is for the sum of the charge states or particle/antiparticle states indicated.

[j] A test of additive vs. multiplicative lepton family number conservation.

[k] $\Delta(m^2) = 100$ eV^2.

[l] 190 eV^2 $< \Delta(m^2) <$ 320 eV^2.

[m] Derived from an analysis of neutrino-oscillation experiments.

[n] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.

[o] This is the best "electron disappearance" limit. The best limit for the mode $e^- \to \nu\gamma$ is $> 2.35 \times 10^{25}$ yr (CL=68%).

[p] This D_1^0-D_2^0 limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0$)) / $\Gamma(K^-\pi^+)$ near the end of the D^0 Listings.

[q] See the K_L^0 Particle Listings for the energy limits used in this measurement.

[r] This limit is for $\Gamma(t \to Zq)/\Gamma(t \to Wb)$.

1. PHYSICAL CONSTANTS

Table 1.1. Reviewed 2000 by P.J. Mohr and B.N. Taylor (NIST). Based mainly on the "CODATA Recommended Values of the Fundamental Physical Constants: 1998" by P.J. Mohr and B.N. Taylor, J. Phys. Chem. Ref. Data **28**, 1713 (1999) and Rev. Mod. Phys. **72**, 351 (2000). The last group of constants (beginning with the Fermi coupling constant) comes from the Particle Data Group. The figures in parentheses after the values give the 1-standard-deviation uncertainties in the last digits; the corresponding uncertainties in parts per billion (ppb) are given in the last column. This set of constants (aside from the last group) is recommended for international use by CODATA (the Committee on Data for Science and Technology). The full 1998 CODATA set of constants may be found at `http://physics.nist.gov/constants`

Quantity	Symbol, equation	Value	Uncertainty (ppb)
speed of light in vacuum	c	$299\ 792\ 458$ m s^{-1}	exact*

* The meter is the length of the path traveled by light in vacuum during a time interval of 1/299 792 458 of a second.

† At $Q^2 = 0$. At $Q^2 \approx m_W^2$ the value is approximately 1/128.

‡ Absolute lab measurements of G_N have been made only on scales of 1 mm to 1 m.

** See the discussion in Sec. 10, "Electroweak model and constraints on new physics."

†† The corresponding $\sin^2\theta$ for the effective angle is 0.23147(16).

2. ASTROPHYSICAL CONSTANTS

Table 2.1. Revised 2000 by D.E. Groom (LBNL). The figures in parentheses after some values give the one-standard deviation uncertainties in the last digit(s). Physical constants are from Ref. 1. While every effort has been made to obtain the most accurate current values of the listed quantities, the table does not represent a critical review or adjustment of the constants, and is not intended as a primary reference.

Quantity	Symbol, equation	Value	Reference, footnote
speed of light	c	$299\,792\,458$ m s^{-1}	defined2
Newtonian gravitational constant	G_N	$6.673(10) \times 10^{-11}$ m^3 kg^{-1} s^{-2}	3

3. The value of G_N [1] is the same as in Ref. 26, but the quoted error is 12 times larger. See Measurement, Science, and Technology **10**, No. 6 (June 1999), special section: "The gravitational constant: Theory and experiment 200 years after Cavendish."
   In the context of the scale dependence of field theoretic quantities, it should be remarked that absolute lab measurements of G_N have been performed on scales of 0.01–1.0 m.

5. JPL Planetary Ephemerides, E. Myles Standish, Jr., private communication (1989).
6. 1 AU divided by $\pi/648\,000$; quoted error is from the JPL Planetary Ephemerides value of the AU [5].
7. Product of $2/c^2$ and the heliocentric gravitational constant [4]. The given 9-place accuracy seems consistent with uncertainties in defining the earth's orbital parameters.
8. Obtained from the heliocentric gravitational constant [4] and G_N [3]. The error is the 1500 ppm standard deviation of G_N.
9. 1996 mean total solar irradiance (TSI) = 1367.5 ± 2.7 [27]; the solar luminosity is $4\pi \times (1\ \text{AU})^2$ times this quantity. This value increased by 0.036% between the minima of solar cycles 21 and 22. It was modulated with an amplitude of 0.039% during solar cycle 21 [28].
   Sackmann *et al.* [29] use TSI = 1370 ± 2 W m^{-2}, but conclude that the solar luminosity ($L_\odot = 3.853 \times 10^{26}$ J s^{-1}) has an uncertainty of 1.5%. Their value comes from three 1977–83 papers, and they comment that the error is based on scatter among the reported values, which is substantially in excess of that expected from the individual quoted errors.
   The conclusion of the 1971 review by Thekaekara and Drummond [30] ($1353 \pm 1\%$ W m^{-2}) is often quoted [31]. The conversion to luminosity is not given in the Thekaekara and Drummond paper, and we cannot exactly reproduce the solar luminosity given in Ref. 31.
   Finally, a value based on the 1954 spectral curve due to Johnson [32] ($1395 \pm 1\%$ W m^{-2}, or $L_\odot = 3.92 \times 10^{26}$ J s^{-1}) has been used widely, and may be the basis for the higher value of the solar luminosity and the corresponding lower value of the solar absolute bolometric magnitude (4.72) still common in the literature [12].
10. Product of $2/c^2$, the heliocentric gravitational constant from Ref. 4, and the earth/sun mass ratio, also from Ref. 4. The given 9-place accuracy appears to be consistent with uncertainties in actually defining the earth's orbital parameters.
11. Obtained from the geocentric gravitational constant [4] and G_N [3]. The error is the 1500 ppm standard deviation of G_N.
12. E.W. Kolb and M.S. Turner, *The Early Universe*, Addison-Wesley (1990).
13. F.J. Kerr and D. Lynden-Bell, Mon. Not. R. Astr. Soc. **221**, 1023–1038 (1985). "On the basis of this review these [$R_\circ = 8.5 \pm 1.1$ kpc and $\Theta_\circ = 220 \pm 20$ km s^{-1}] were adopted by resolution of IAU Commission 33 on 1985 November 21 at Delhi".
14. M.J. Reid, Annu. Rev. Astron. Astrophys. **31**, 345–372 (1993). Note that $\Theta_\circ$ from the 1985 IAU Commission 33 recommendations is adopted in this review, although the new value for $R_\circ$ is smaller.

17. The final uncertainty arises from dichotomous estimates of the distance to the Large Magellanic Cloud.
18. G. Gilmore, R.F.G. Wyse, and K. Kuijken, Annu. Rev. Astron. Astrophys. **27**, 555 (1989).
19. E.I. Gates, G. Gyuk, and M.S. Turner (Astrophys. J. **449**, L133 (1995)) find the local halo density to be $9.2^{+3.8}_{-3.1} \times 10^{-25}$ g cm^{-3}, but also comment that previously published estimates are in the range $1\text{–}10 \times 10^{-25}$ g cm^{-3}.
   The value 0.3 GeV/c^2 has been taken as "standard" in several papers setting limits on WIMP mass limits, *e.g.* in M. Mori *et al.*, Phys. Lett. **B289**, 463 (1992).
20. Fukugita & Hogan find a more restrictive limit, $0.2 \lesssim \Omega_M \lesssim 0.4$, if the Universe is flat.
21. In addition to the pressureless mass density Ω_M and the scaled cosmological constant Ω_Λ, Ω_{tot} contains very small contributions from the cosmic background radiation, the primordial neutrino energy density, and perhaps other sources. $1 - \Omega_{\text{tot}}$ is the three-dimensional scalar curvature scaled by the squared inverse Hubble length, variously written as $kc^2/(H_0R(t_0))^2$ [12], Kc^2/H_0^2 [36], and Ω_k[37]. Thus $\Omega_{\text{tot}} = 1$ indicates a flat universe.
22. First results from both BOOMERANG [33] and MAXIMA-1 [34] indicate $\Omega_M + \Omega_\Lambda \approx 1$ with $\approx 10\%$ uncertainties, providing the strongest evidence to date for a flat universe. See discussions elsewhere in this *Review* concerning the remarkable consistency of Ω_M and Ω_Λ measurements by different methods [16,24,35].

4. PERIODIC TABLE OF THE ELEMENTS

Table 4.1. Revised 1997 by C.G. Wohl (LBNL). Heavy element updates in May 2000 by D.E. Groom. The atomic number (top left) is the number of protons in the nucleus. The atomic mass (bottom) is weighted by isotopic abundances in the Earth's surface. Atomic masses are relative to the mass of the carbon-12 isotope, defined to be exactly 12 unified atomic mass units (u). Errors range from 1 to 9 in the last digit quoted. Relative isotopic abundances often vary considerably, both in natural and commercial samples. A number in parentheses is the mass of the longest-lived isotope of that element—no stable isotope exists. However, although Th, Pa, and U have no stable isotopes, they do have characteristic terrestrial compositions, and meaningful weighted masses can be given. For elements 110–112, the atomic numbers of known isotopes are given. Adapted from the Commission of Atomic Weights and Isotopic Abundances, "Atomic Weights of the Elements 1995," Pure and Applied Chemistry **68**, 2339 (1996), and G. Audi and A.H. Wapstra, "The 1993 Mass Evaluation," Nucl. Phys. **A565**, 1 (1993).

5. ELECTRONIC STRUCTURE OF THE ELEMENTS

Table 5.1. Reviewed 1999 by W.C. Martin (NIST). The electronic configurations and the ionization energies (except for a few newer values, marked with an *) are taken from "Atomic Spectroscopy," W.C. Martin and W.L. Wiese, in *Atomic, Molecular, and Optical Physics Reference Book*, G.W.F. Drake, ed., Amer. Inst. Phys., 1995. The electron configuration for, say, iron indicates an argon electronic core (see argon) plus six $3d$ electrons and two $4s$ electrons. The ionization energy is the least energy necessary to remove to infinity one electron from an atom of the element.

	Element		Electron configuration ($3d^5$ = five $3d$ electrons, *etc.*)		Ground state $^{2S+1}L_J$	Ionization energy (eV)
1	H	Hydrogen	$1s$		$^2S_{1/2}$	13.5984
2	He	Helium	$1s^2$		$^1S_0$	24.5874
3	Li	Lithium	(He) $2s$		$^2S_{1/2}$	5.3917
4	Be	Beryllium	(He) $2s^2$		$^1S_0$	9.3227
5	B	Boron	(He) $2s^2\ 2p$		$^2P_{1/2}$	8.2980
6	C	Carbon	(He) $2s^2\ 2p^2$		$^3P_0$	11.2603
7	N	Nitrogen	(He) $2s^2\ 2p^3$		$^4S_{3/2}$	14.5341
8	O	Oxygen	(He) $2s^2\ 2p^4$		$^3P_2$	13.6181
9	F	Fluorine	(He) $2s^2\ 2p^5$		$^2P_{3/2}$	17.4228
10	Ne	Neon	(He) $2s^2\ 2p^6$		$^1S_0$	21.5646
11	Na	Sodium	(Ne) $3s$		$^2S_{1/2}$	5.1391
12	Mg	Magnesium	(Ne) $3s^2$		$^1S_0$	7.6462
13	Al	Aluminum	(Ne) $3s^2\ 3p$		$^2P_{1/2}$	5.9858
14	Si	Silicon	(Ne) $3s^2\ 3p^2$		$^3P_0$	8.1517
15	P	Phosphorus	(Ne) $3s^2\ 3p^3$		$^4S_{3/2}$	10.4867
16	S	Sulfur	(Ne) $3s^2\ 3p^4$		$^3P_2$	10.3600
17	Cl	Chlorine	(Ne) $3s^2\ 3p^5$		$^2P_{3/2}$	12.9676
18	Ar	Argon	(Ne) $3s^2\ 3p^6$		$^1S_0$	15.7596
19	K	Potassium	(Ar) $4s$		$^2S_{1/2}$	4.3407

6. ATOMIC AND NUCLEAR PROPERTIES OF MATERIALS

Table 6.1. Revised May 2000 by D.E. Groom (LBNL). Gases are evaluated at 20°C and 1 atm (in parentheses) or at STP [square brackets]. Densities and refractive indices without parentheses or brackets are for solids or liquids, or are for cryogenic liquids at the indicated boiling point (BP) at 1 atm. Refractive indices are evaluated at the sodium D line. Data for compounds and mixtures are from Refs. 1 and 2. Futher materials and properties are given in Ref. 3.

Material	Z	A	$\langle Z/A \rangle$	Nuclear [a] collision length λ_T {g/cm^2}	Nuclear [a] interaction length λ_I {g/cm^2}	$dE/dx\|_{\min}$ [b] $\left\{\frac{\text{MeV}}{\text{g/cm}^2}\right\}$	Radiation length [c] X_0 {g/cm^2}	Radiation length [c] X_0 {cm}	Density {g/cm^3} ({g/ℓ} for gas)	Liquid boiling point at 1 atm(K)	Refractive index n ($(n-1)\times10^6$ for gas)

a. σ_T, λ_T and λ_I are energy dependent. Values quoted apply to high energy range, where energy dependence is weak. Mean free path between collisions (λ_T) or inelastic interactions (λ_I), calculated from $\lambda^{-1} = N_A \sum w_j \sigma_j / A_j$, where N is Avogadro's number and w_j is the weight fraction of the jth element in the element, compound, or mixture. σ_{total} at 80–240 GeV for neutrons ($\approx \sigma$ for protons) from Murthy *et al.*, Nucl. Phys. **B92**, 269 (1975). This scales approximately as $A^{0.77}$. $\sigma_{\text{inelastic}} = \sigma_{\text{total}} - \sigma_{\text{elastic}} - \sigma_{\text{quasielastic}}$; for neutrons at 60–375 GeV from Roberts *et al.*, Nucl. Phys. **B159**, 56 (1979). For protons and other particles, see Carroll *et al.*, Phys. Lett. **80B**, 319 (1979); note that $\sigma_I(p) \approx \sigma_I(n)$. σ_I scales approximately as $A^{0.71}$.

b. For minimum-ionizing muons (results are very slightly different for other particles). Minimum dE/dx from Ref. 3, using density effect correction coefficients from Ref. 1. For electrons and positrons see Ref. 4. Ionization energy loss is discussed in Sec. 23.

c. From Y.S. Tsai, Rev. Mod. Phys. **46**, 815 (1974); X_0 data for all elements up to uranium are given. Corrections for molecular binding applied for H_2 and D_2. For atomic H, X_0 = 63.05 g/cm^2.

d. For molecular hydrogen (deuterium). For atomic H, X_0 = 63.047 g cm^{-2}.

e. For pure graphite; industrial graphite density may vary 2.1–2.3 g/cm^3.

f. Standard shielding blocks, typical composition O_2 52%, Si 32.5%, Ca 6%, Na 1.5%, Fe 2%, Al 4%, plus reinforcing iron bars. The attenuation length, $\ell = 115 \pm 5$ g/cm^2, is also valid for earth (typical ρ = 2.15), from CERN-LRL-RHEL Shielding exp., UCRL-17841 (1968).

g. For typical fused quartz. The specific gravity of crystalline quartz is 2.64.

h. Solid ethane density at −60°C; gaseous refractive index at 0°C, 546 mm pressure.

i. Nylon, Type 6, $(NH(CH_2)_5CO)_n$

j. Polycarbonate (Lexan), $(C_{16}H_{14}O_3)_n$

k. Polyethylene terephthlate, monomer, $C_5H_4O_2$

l. Polyethylene, monomer $CH_2=CH_2$

m. Polymide film (Kapton), $(C_{22}H_{10}N_2O_5)_n$

n. Polymethylmethacralate, monomer $CH_2=C(CH_3)CO_2CH_3$

o. Polystyrene, monomer $C_6H_5CH{=}CH_2$

p. Teflon, monomer $CF_2=CF_2$

q. Polyvinyltolulene, monomer 2-$CH_3C_6H_4CH{=}CH_2$

r. Bismuth germanate (BGO), $(Bi_2O_3)_2(GeO_2)_3$

s. $n(SiO_2) + 2n(H_2O)$ used in Čerenkov counters, ρ = density in g/cm^3. From M. Cantin *et al.*, Nucl. Instrum. Methods **118**, 177 (1974).

t. G10-plate, typically 60% SiO_2 and 40% epoxy.

7. ELECTROMAGNETIC RELATIONS

Quantity	Gaussian CGS	SI

7.1. Impedances (SI units)

ρ = resistivity at room temperature in $10^{-8}\,\Omega$ m:

$\sim$ 1.7 for Cu	$\sim$ 5.5 for W
$\sim$ 2.4 for Au	$\sim$ 73 for SS 304
$\sim$ 2.8 for Al	$\sim$ 100 for Nichrome

(Al alloys may have double the Al value.)

For alternating currents, instantaneous current I, voltage V, angular frequency ω:

$$V = V_0\, e^{j\omega t} = ZI\ . \tag{7.1}$$

Impedance of self-inductance L: $Z = j\omega L$.

Impedance of capacitance C: $Z = 1/j\omega C$.

Impedance of free space: $Z = \sqrt{\mu_0/\epsilon_0} = 376.7\ \Omega$.

High-frequency surface impedance of a good conductor:

$$Z = \frac{(1+j)\,\rho}{\delta}\ , \quad \text{where } \delta = \text{skin depth}\ ; \tag{7.2}$$

$$\delta = \sqrt{\frac{\rho}{\pi\nu\mu}} \approx \frac{6.6\ \text{cm}}{\sqrt{\nu\,(\text{Hz})}} \quad \text{for Cu}\ . \tag{7.3}$$

7.2. Capacitance $\widehat{C}$ and inductance $\widehat{L}$ per unit length (SI units) [negligible skin depth]

Flat rectangular plates of width w, separated by $d \ll w$ with linear medium (ϵ, μ) between:

$$\widehat{C} = \epsilon\,\frac{w}{d}\ ; \qquad \widehat{L} = \mu\,\frac{d}{w}\ ; \tag{7.4}$$

$$\epsilon/\epsilon_0 = 2 \text{ to } 6 \text{ for plastics; } 4 \text{ to } 8 \text{ for porcelain, glasses;} \tag{7.5}$$

$$\mu/\mu_0 \simeq 1\ . \tag{7.6}$$

Coaxial cable of inner radius r_1, outer radius r_2:

$$\widehat{C} = \frac{2\pi\,\epsilon}{\ln\,(r_2/r_1)}\ ; \qquad \widehat{L} = \frac{\mu}{2\pi}\,\ln\,(r_2/r_1)\ . \tag{7.7}$$

Transmission lines (no loss):

$$\text{Impedance: } Z = \sqrt{\widehat{L}/\widehat{C}}\ . \tag{7.8}$$

$$\text{Velocity: } v = 1/\sqrt{\widehat{L}\,\widehat{C}} = 1/\sqrt{\mu\,\epsilon}\ . \tag{7.9}$$

7.3. Synchrotron radiation (CGS units)

For a particle of charge e, velocity $v = \beta c$, and energy $E = \gamma mc^2$, traveling in a circular orbit of radius R, the classical energy loss per revolution δE is

$$\delta E = \frac{4\pi}{3}\,\frac{e^2}{R}\,\beta^3\,\gamma^4\ . \tag{7.10}$$

For high-energy electrons or positrons ($\beta \approx 1$), this becomes

$$\delta E\ (\text{in MeV}) \approx 0.0885\ [E(\text{in GeV})]^4/R(\text{in m})\ . \tag{7.11}$$

For $\gamma \gg 1$, the energy radiated per revolution into the photon energy interval $d(\hbar\omega)$ is

$$dI = \frac{8\pi}{9}\alpha\,\gamma\,F(\omega/\omega_c)\,d(\hbar\omega)\ , \tag{7.12}$$

where $\alpha = e^2/\hbar c$ is the fine-structure constant and

$$\omega_c = \frac{3\gamma^3 c}{2R} \tag{7.13}$$

is the critical frequency. The normalized function $F(y)$ is

$$F(y) = \frac{9}{8\pi}\sqrt{3}\,y\int_y^\infty K_{5/3}(x)\ dx\ , \tag{7.14}$$

where $K_{5/3}(x)$ is a modified Bessel function of the third kind. For electrons or positrons,

$$\hbar\omega_c\,(\text{in keV}) \approx 2.22\ [E(\text{in GeV})]^3/R(\text{in m})\ . \tag{7.15}$$

Fig. 7.1 shows $F(y)$ over the important range of y.

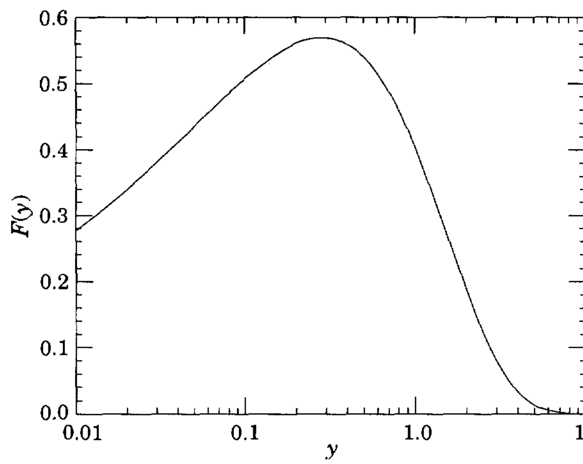

Figure 7.1: The normalized synchrotron radiation spectrum $F(y)$.

For $\gamma \gg 1$ and $\omega \ll \omega_c$,

$$\frac{dI}{d(\hbar\omega)} \approx 3.3\alpha\,(\omega R/c)^{1/3}\ , \tag{7.16}$$

whereas for

$$\gamma \gg 1 \text{ and } \omega \gtrsim 3\omega_c\ ,$$

$$\frac{dI}{d(\hbar\omega)} \approx \sqrt{\frac{3\pi}{2}}\,\alpha\,\gamma\left(\frac{\omega}{\omega_c}\right)^{1/2} e^{-\omega/\omega_c}\left[1 + \frac{55}{72}\frac{\omega_c}{\omega} + \ldots\right]\ . \tag{7.17}$$

The radiation is confined to angles $\lesssim 1/\gamma$ relative to the instantaneous direction of motion. The mean number of photons emitted per revolution is

$$N_\gamma = \frac{5\pi}{\sqrt{3}}\alpha\gamma\ , \tag{7.18}$$

and the mean energy per photon is

$$\langle\hbar\omega\rangle = \frac{8}{15\sqrt{3}}\hbar\omega_c\ . \tag{7.19}$$

When $\langle\hbar\omega\rangle \gtrsim O(E)$, quantum corrections are important.

See J.D. Jackson, *Classical Electrodynamics*, 2nd edition (John Wiley & Sons, New York, 1975) for more formulae and details. In his book, Jackson uses a definition of ω_c that is twice as large as the customary one given above.

8. NAMING SCHEME FOR HADRONS

Maintained 2000 by M. Roos (University of Finland) and C.G. Wohl (LBNL).

8.1. Introduction

We introduced in the 1986 edition [1] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of the light (u, d, and s) quarks. Old and new names were listed alongside until 1994. Names also change from edition to edition because some characteristic like mass or spin changes. The Summary Tables give both the new and old names whenever a change occurred.

8.2. "Neutral-flavor" mesons ($S=C=B=T=0$)

Table 8.1 shows the names for mesons having the strangeness and all heavy-flavor quantum numbers equal to zero. The scheme is designed for all ordinary non-exotic mesons, but it will work for many exotic types too, if needed.

Table 8.1: Symbols for mesons with the strangeness and all heavy-flavor quantum numbers equal to zero.

	$J^{PC}=$	0^{-+}, 2^{-+}, ⋮	1^{+-}, 3^{+-}, ⋮	1^{--}, 2^{--}, ⋮	0^{++}, 1^{++}, ⋮
$q\overline{q}$ content	$^{2S+1}L_J=$	$^1(L\,\text{even})_J$	$^1(L\,\text{odd})_J$	$^3(L\,\text{even})_J$	$^3(L\,\text{odd})_J$
$u\overline{d}, u\overline{u}-d\overline{d}, d\overline{u}$	$(I=1)$	π	b	ρ	a
$d\overline{d}+u\overline{u}$ and/or $s\overline{s}$	$(I=0)$	η, η'	h, h'	ω, ϕ	f, f'
$c\overline{c}$		η_c	h_c	ψ†	χ_c
$b\overline{b}$		η_b	h_b	Υ	χ_b
$t\overline{t}$		η_t	h_t	θ	χ_t

†The J/ψ remains the J/ψ.

First, we assign names to those states with quantum numbers compatible with being $q\overline{q}$ states. The rows of the Table give the possible $q\overline{q}$ content. The columns give the possible parity/charge-conjugation states,

$$PC = -+,\ +-,\ --,\ \text{and}\ ++\ ;$$

these combinations correspond one-to-one with the angular-momentum state $^{2S+1}L_J$ of the $q\overline{q}$ system being

$$^1(L\ \text{even})_J,\ ^1(L\ \text{odd})_J,\ ^3(L\ \text{even})_J,\ \text{or}\ ^3(L\ \text{odd})_J\ .$$

Here S, L, and J are the spin, orbital, and total angular momenta of the $q\overline{q}$ system. The quantum numbers are related by

$$P=(-1)^{L+1},\ C=(-1)^{L+S},\ \text{and}\ G\ \text{parity}\ =(-1)^{L+S+I},$$

where of course the C quantum number is only relevant to neutral mesons.

The entries in the Table give the meson names. The spin J is added as a subscript except for pseudoscalar and vector mesons, and the mass is added in parentheses for mesons that decay strongly. However, for the lightest meson resonances, we omit the mass.

Measurements of the mass, quark content (where relevant), and quantum numbers I, J, P, and C (or G) of a meson thus fix its symbol. Conversely, these properties may be inferred unambiguously from the symbol.

If the main symbol cannot be assigned because the quantum numbers are unknown, X is used. Sometimes it is not known whether a meson is mainly the isospin-0 mix of $u\overline{u}$ and $d\overline{d}$ or is mainly $s\overline{s}$. A prime (or pair ω, ϕ) may be used to distinguish two such mixing states.

We follow custom and use spectroscopic names such as $\Upsilon(1S)$ as the primary name for most of those ψ, Υ, and χ states whose spectroscopic identity is known. We use the form $\Upsilon(9460)$ as an alternative, and as the primary name when the spectroscopic identity is not known.

Names are assigned for $t\overline{t}$ mesons, although the top quark is evidently so heavy that it is expected to decay too rapidly for bound states to form.

Gluonium states or other mesons that are not $q\overline{q}$ states are, if the quantum numbers are *not* exotic, to be named just as are the $q\overline{q}$ mesons. Such states will probably be difficult to distinguish from $q\overline{q}$ states and will likely mix with them, and we make no attempt to distinguish those "mostly gluonium" from those "mostly $q\overline{q}$."

An "exotic" meson with J^{PC} quantum numbers that a $q\overline{q}$ system cannot have, namely $J^{PC}=0^{--}, 0^{+-}, 1^{-+}, 2^{+-}, 3^{-+}, \cdots$, would use the same symbol as does an ordinary meson with all the same quantum numbers as the exotic meson except for the C parity. But then the J subscript may still distinguish it; for example, an isospin-0 1^{-+} meson could be denoted ω_1.

8.3. Mesons with nonzero S, C, B, and/or T

Since the strangeness or a heavy flavor of these mesons is nonzero, none of them are eigenstates of charge conjugation, and in each of them one of the quarks is heavier than the other. The rules are:

1. The main symbol is an upper-case italic letter indicating the heavier quark as follows:

$$s\to\overline{K}\qquad c\to D\qquad b\to\overline{B}\qquad t\to T\ .$$

We use the convention that *the flavor and the charge of a quark have the same sign.* Thus the strangeness of the s quark is negative, the charm of the c quark is positive, and the bottom of the b quark is negative. In addition, I_3 of the u and d quarks are positive and negative, respectively. The effect of this convention is as follows: *Any flavor carried by a charged meson has the same sign as its charge.* Thus the K^+, D^+, and B^+ have positive strangeness, charm, and bottom, respectively, and all have positive I_3. The D_s^+ has positive charm *and* strangeness. Furthermore, the Δ(flavor) $=\Delta Q$ rule, best known for the kaons, applies to every flavor.

2. If the lighter quark is not a u or a d quark, its identity is given by a subscript. The D_s^+ is an example.
3. If the spin-parity is in the "normal" series, $J^P=0^+, 1^-, 2^+, \cdots$, a superscript "*" is added.
4. The spin is added as a subscript except for pseudoscalar or vector mesons.

8.4. Baryons

The symbols N, Δ, Λ, Σ, Ξ, and Ω used for more than 30 years for the baryons made of light quarks (u, d, and s quarks) tell the isospin and quark content, and the same information is conveyed by the symbols used for the baryons containing one or more heavy quarks (c and b quarks). The rules are:

1. Baryons with *three* u and/or d quarks are N's (isospin 1/2) or Δ's (isospin 3/2).
2. Baryons with *two* u and/or d quarks are Λ's (isospin 0) or Σ's (isospin 1). If the third quark is a c, b, or t quark, its identity is given by a subscript.
3. Baryons with *one* u or d quark are Ξ's (isospin 1/2). One or two subscripts are used if one or both of the remaining quarks are heavy: thus Ξ_c, Ξ_{cc}, Ξ_b, *etc.**
4. Baryons with *no* u or d quarks are Ω's (isospin 0), and subscripts indicate any heavy-quark content.
5. A baryon that decays strongly has its mass as part of its name. Thus p, Σ^-, Ω^-, Λ_c^+, *etc.*, but $\Delta(1232)^0$, $\Sigma(1385)^-$, $\Xi_c(2645)^+$, *etc.*

In short, the number of u plus d quarks together with the isospin determine the main symbol, and subscripts indicate any content of heavy quarks. A Σ always has isospin 1, an Ω always has isospin 0, *etc.*

Footnote and Reference:

* Sometimes a prime is necessary to distinguish two Ξ_c's in the same SU(n) multiplet. See the "Note on Charmed Baryons" in the Charmed Baryon Listings.

9. QUANTUM CHROMODYNAMICS

9.1. The QCD Lagrangian

Revised September 1999 by I. Hinchliffe (LBNL).

Quantum Chromodynamics (QCD), the gauge field theory which describes the strong interactions of colored quarks and gluons, is one of the components of the SU(3)×SU(2)×U(1) Standard Model. A quark of specific flavor (such as a charm quark) comes in 3 colors; gluons come in eight colors; hadrons are color-singlet combinations of quarks, anti-quarks, and gluons. The Lagrangian describing the interactions of quarks and gluons is (up to gauge-fixing terms)

$$L_{\rm QCD} = -\frac{1}{4}F^{(a)}_{\mu\nu}\, F^{(a)\mu\nu} + i\sum_q \overline{\psi}^i_q\, \gamma^\mu\, (D_\mu)_{ij}\, \psi^j_q - \sum_q m_q\, \overline{\psi}^i_q\, \psi_{qi}\ , \tag{9.1}$$

$$F^{(a)}_{\mu\nu} = \partial_\mu\, A^a_\nu - \partial_\nu\, A^a_\mu + g_s\, f_{abc}\, A^b_\mu\, A^c_\nu\ , \tag{9.2}$$

$$(D_\mu)_{ij} = \delta_{ij}\, \partial_\mu - i g_s \sum_a \frac{\lambda^a_{i,j}}{2} A^a_\mu\ , \tag{9.3}$$

where g_s is the QCD coupling constant, and the f_{abc} are the structure constants of the SU(3) algebra (the λ matrices and values for f_{abc} can be found in "SU(3) Isoscalar Factors and Representation Matrices," Sec. 32 of this *Review*). The $\psi^i_q(x)$ are the 4-component Dirac spinors associated with each quark field of (3) color i and flavor q, and the $A^a_\mu(x)$ are the (8) Yang-Mills (gluon) fields. A complete list of the Feynman rules which derive from this Lagrangian, together with some useful color-algebra identities, can be found in Ref. 1.

The principle of "asymptotic freedom" (see below) determines that the renormalized QCD coupling is small only at high energies, and it is only in this domain that high-precision tests—similar to those in QED—can be performed using perturbation theory. Nonetheless, there has been in recent years much progress in understanding and quantifying the predictions of QCD in the nonperturbative domain, for example, in soft hadronic processes and on the lattice [2]. This short review will concentrate on QCD at short distances (large momentum transfers), where perturbation theory is the standard tool. It will discuss the processes that are used to determine the coupling constant of QCD. Other recent reviews of the coupling constant measurements may be consulted for a different perspective [3,4].

9.2. The QCD coupling and renormalization scheme

The renormalization scale dependence of the effective QCD coupling $\alpha_s = g_s^2/4\pi$ is controlled by the β-function:

$$\mu\frac{\partial\alpha_s}{\partial\mu} = -\frac{\beta_0}{2\pi}\alpha_s^2 - \frac{\beta_1}{4\pi^2}\alpha_s^3 - \frac{\beta_2}{64\pi^3}\alpha_s^4 - \cdots\ , \tag{9.4a}$$

$$\beta_0 = 11 - \frac{2}{3}n_f\ , \tag{9.4b}$$

$$\beta_1 = 51 - \frac{19}{3}n_f\ , \tag{9.4c}$$

$$\beta_2 = 2857 - \frac{5033}{9}n_f + \frac{325}{27}n_f^2\ ; \tag{9.4d}$$

where n_f is the number of quarks with mass less than the energy scale μ. The expression for the next term in this series (β_3) can be found in Ref. 5. In solving this differential equation for α_s, a constant of integration is introduced. This constant is the one fundamental constant of QCD that must be determined from experiment. The most sensible choice for this constant is the value of α_s at a fixed-reference scale μ_0. It has become standard to choose $\mu_0 = M_Z$. It is also convenient to introduce the dimensional parameter Λ, since this provides a parameterization of the μ dependence of α_s. The definition of Λ is arbitrary. One way to define it (adopted here) is to write a solution of Eq. (9.4) as an expansion in inverse powers of $\ln(\mu^2)$:

$$\alpha_s(\mu) = \frac{4\pi}{\beta_0\, \ln(\mu^2/\Lambda^2)}\left[1 - \frac{2\beta_1}{\beta_0^2}\, \frac{\ln\left[\ln(\mu^2/\Lambda^2)\right]}{\ln(\mu^2/\Lambda^2)} + \frac{4\beta_1^2}{\beta_0^4\ln^2(\mu^2/\Lambda^2)} \times\left(\left(\ln\left[\ln(\mu^2/\Lambda^2)\right] - \frac{1}{2}\right)^2 + \frac{\beta_2\beta_0}{8\beta_1^2} - \frac{5}{4}\right)\right]\ . \tag{9.5a}$$

The last term in this expansion is

$$\mathcal{O}\left(\frac{\ln^2\left[\ln(\mu^2/\Lambda^2)\right]}{\ln^3(\mu^2/\Lambda^2)}\right)\ , \tag{9.5b}$$

and is usually neglected in the definition of Λ. We choose to include it. For a fixed value of $\alpha_s(M_Z)$, the inclusion of this term shifts the value of Λ by $\sim$ 15 MeV. This solution illustrates the *asymptotic freedom* property: $\alpha_s \to 0$ as $\mu \to \infty$.

Consider a "typical" QCD cross section which, when calculated perturbatively, starts at $\mathcal{O}(\alpha_s)$:

$$\sigma = A_1\, \alpha_s + A_2\, \alpha_s^2 + \cdots\ . \tag{9.6}$$

The coefficients A_1, A_2 come from calculating the appropriate Feynman diagrams. In performing such calculations, various divergences arise, and these must be regulated in a consistent way. This requires a particular renormalization scheme (RS). The most commonly used one is the modified minimal subtraction ($\overline{\rm MS}$) scheme [6]. This involves continuing momentum integrals from 4 to 4-2ϵ dimensions, and then subtracting off the resulting $1/\epsilon$ poles and also ($\ln 4\pi - \gamma_E$), which is another artifact of continuing the dimension. (Here γ_E is the Euler-Mascheroni constant.) To preserve the dimensionless nature of the coupling, a mass scale μ must also be introduced: $g \to \mu^\epsilon g$. The finite coefficients A_i ($i \geq 2$) thus obtained depend implicitly on the renormalization convention used and explicitly on the scale μ.

The first two coefficients (β_0, β_1) in Eq. (9.4) are independent of the choice of RS's. In contrast, the coefficients of terms proportional to α_s^n for $n > 3$ *are* RS-dependent. The form given above for β_2 is in the $\overline{\rm MS}$ scheme.

The fundamental theorem of RS dependence is straightforward. Physical quantities, in particular the cross section, calculated to all orders in perturbation theory, do not depend on the RS. It follows that a truncated series *does* exhibit RS dependence. In practice, QCD cross sections are known to leading order (LO), or to next-to-leading order (NLO), or in a few cases, to next-to-next-to-leading order (NNLO); and it is only the latter two cases, which have reduced RS dependence, that are useful for precision tests. At NLO the RS dependence is completely given by one condition which can be taken to be the value of the renormalization scale μ. At NNLO this is not sufficient, and μ is no longer equivalent to a choice of scheme; both must now be specified. One, therefore, has to address the question of what is the "best" choice for μ within a given scheme, usually $\overline{\rm MS}$. There is no definite answer to this question—higher-order corrections do not "fix" the scale, rather they render the theoretical predictions less sensitive to its variation.

One should expect that choosing a scale μ characteristic of the typical energy scale (E) in the process would be most appropriate. In general, a poor choice of scale generates terms of order $\ln(E/\mu)$ in the A_i's. Various methods have been proposed including choosing the scale for which the next-to-leading-order correction vanishes ("Fastest Apparent Convergence [7]"); the scale for which the next-to-leading-order prediction is stationary [8], (*i.e.*, the value of μ where $d\sigma/d\mu = 0$); or the scale dictated by the effective charge scheme [9] or by the BLM scheme [10]. By comparing the values of α_s that different reasonable schemes give, an estimate of theoretical errors can be obtained. It has also been suggested to replace the perturbation series by its Pade approximant [11]. Results obtained using this method have, in certain cases, a reduced scale dependence [12,13]. One can also attempt to determine the scale from data by allowing it to vary and using a fit to determine it. This method can allow a determination of the error due to the scale choice and can give more confidence in the end result [14]. In many of the cases discussed below this scale uncertainty is the dominant error.

An important corollary is that if the higher-order corrections are naturally small, then the additional uncertainties introduced by the μ dependence are likely to be small. There are some processes, however, for which the choice of scheme *can* influence the extracted value of $\alpha_s(M_Z)$. There is no resolution to this problem other than to try to calculate even more terms in the perturbation series. It is important to note that, since the perturbation series is an asymptotic expansion, there is a limit to the precision with which any theoretical quantity can be calculated. In some processes, the highest-order perturbative terms may be comparable in size to nonperturbative corrections (sometimes called higher-twist or renormalon effects, for a discussion see [15]); an estimate of these terms and their uncertainties is required if a value of α_s is to be extracted.

Cases occur where there is more than one large scale, say μ_1 and μ_2. In these cases, terms appear of the form $\log(\mu_1/\mu_2)$. If the ratio μ_1/μ_2 is large, these logarithms can render naive perturbation theory unreliable and a modified perturbation expansion that takes these terms into account must be used. A few examples are discussed below.

In the cases where the higher-order corrections to a process are known and are large, some caution should be exercised when quoting the value of α_s. In what follows, we will attempt to indicate the size of the theoretical uncertainties on the extracted value of α_s. There are two simple ways to determine this error. First, we can estimate it by comparing the value of $\alpha_s(\mu)$ obtained by fitting data using the QCD formula to highest known order in α_s, and then comparing it with the value obtained using the next-to-highest-order formula (μ is chosen as the typical energy scale in the process). The corresponding Λ's are then obtained by evolving $\alpha_s(\mu)$ to $\mu = M_Z$ using Eq. (9.4) to the same order in α_s as the fit. Alternatively, we can vary the value of μ over a reasonable range, extracting a value of Λ for each choice of μ. This method is by its nature imprecise, since "reasonable" involves a subjective judgment. In either case, if the perturbation series is well behaved, the resulting error on $\alpha_s(M_Z)$ will be small.

In the above discussion we have ignored quark-mass effects, *i.e.*, we have assumed an idealized situation where quarks of mass greater than μ are neglected completely. In this picture, the β-function coefficients change by discrete amounts as flavor thresholds (a quark of mass M) are crossed when integrating the differential equation for α_s. Now imagine an experiment at energy scale μ; for example, this could be $e^+e^- \to$ hadrons at center-of-mass energy μ. If $\mu \gg M$, the mass M is negligible and the process is well described by QCD with n_f massless flavors and its parameter $\alpha_{(n_f)}$ up to terms of order M^2/μ^2. Conversely if $\mu \ll M$, the heavy quark plays no role and the process is well described by QCD with $n_f - 1$ massless flavors and its parameter $\alpha_{(n_f-1)}$ up to terms of order μ^2/M^2. If $\mu \sim M$, the effects of the quark mass are process-dependent and cannot be absorbed into the running coupling. The values of $\alpha^{(n_f)}$ and $\alpha^{(n_f-1)}$ are related so that a physical quantity calculated in both "theories" gives the same result [16]. This implies

$$\alpha_{(n_f)}(M) = \alpha_{(n_f-1)}(M) - \frac{7}{72\pi^2}\alpha^2_{(n_f-1)}(M) \tag{9.7}$$

which is almost identical to the naive result $\alpha_{(n_f)}(M) = \alpha_{(n_f-1)}(M)$. Here M is the mass of the value of the running quark mass defined in the $\overline{\rm MS}$ scheme (see the note on "Quark Masses" in the Particle Listings for more details), *i.e.*, where $M_{\overline{\rm MS}}(M) = M$.

It also follows that, for a relationship such as Eq. (9.5) to remain valid for all values of μ, Λ must also change as flavor thresholds are crossed, the value corresponds to an effective number of massless quarks: $\Lambda \to \Lambda^{(n_f)}$ [16,17]. The formulae are given in the previous edition of this review.

An alternative matching procedure can be used [18]. This procedure requires the equality $\alpha_s(\mu)^{(n_f)} = \alpha_s(\mu)^{(n_f-1)}$ for $\mu = M$. This matching is somewhat arbitrary; a different relation between $\Lambda^{(n_f)}$ and $\Lambda^{(n_f-1)}$ would result if $\mu = M/2$ were used. In practice, the differences between these procedures are very small. $\Lambda^{(5)} = 200$ MeV corresponds to $\Lambda^{(4)} = 289$ MeV in the scheme of Ref. 18 and $\Lambda^{(4)} = 280$ MeV in the scheme we adopt. Note that the differences between $\Lambda^{(5)}$ and $\Lambda^{(4)}$ are numerically very significant.

Data from deep-inelastic scattering are in a range of energy where the bottom quark is not readily excited, and hence, these experiments quote $\Lambda^{(4)}_{\overline{\rm MS}}$. Most data from PEP, PETRA, TRISTAN, LEP, and SLC quote a value of $\Lambda^{(5)}_{\overline{\rm MS}}$ since these data are in an energy range where the bottom quark is light compared to the available energy. We have converted it to $\Lambda^{(4)}_{\overline{\rm MS}}$ as required. A few measurements, including the lattice gauge theory values from the J/ψ system, and from τ decay are at sufficiently low energy that $\Lambda^{(3)}_{\overline{\rm MS}}$ is appropriate.

In order to compare the values of α_s from various experiments, they must be evolved using the renormalization group to a common scale. For convenience, this is taken to be the mass of the Z boson. This evolution uses third-order perturbation theory and can introduce additional errors particularly if extrapolation from very small scales is used. The variation in the charm and bottom quark masses ($m_b = 4.3 \pm 0.2$ GeV and $m_c = 1.3 \pm 0.3$ GeV are used) can also introduce errors. These result in a fixed value of $\alpha_s(2$ GeV) giving an uncertainty in $\alpha_s(M_Z) = \pm 0.001$ if only perturbative evolution is used. There could be additional errors from nonperturbative effects that enter at low energy.

9.3. QCD in deep-inelastic scattering

The original and still one of the most powerful quantitative tests of perturbative QCD is the breaking of Bjorken scaling in deep-inelastic lepton-hadron scattering. In the leading-logarithm approximation, the measured structure functions $F_i(x, Q^2)$ are related to the quark distribution functions $q_i(x, Q^2)$ according to the naive parton model, by the formulae in "Cross-section Formulae for Specific Processes," Sec. 35 of this *Review*. (In that section, q_i is denoted by the notation f_q). In describing the way in which scaling is broken in QCD, it is convenient to define nonsinglet and singlet quark distributions:

$$F^{NS} = q_i - q_j \qquad F^S = \sum_i (q_i + \overline{q}_i) \; . \tag{9.8}$$

The nonsinglet structure functions have nonzero values of flavor quantum numbers such as isospin or baryon number. The variation with Q^2 of these is described by the so-called DGLAP equations [19,20]:

$$Q^2 \frac{\partial F^{NS}}{\partial Q^2} = \frac{\alpha_s(|Q|)}{2\pi} P^{qq} * F^{NS} \tag{9.9a}$$

$$Q^2 \frac{\partial}{\partial Q^2}\begin{pmatrix} F^S \\ G \end{pmatrix} = \frac{\alpha_s(|Q|)}{2\pi}\begin{pmatrix} P^{qq} & 2n_f P^{qg} \\ P^{gq} & P^{gg} \end{pmatrix} * \begin{pmatrix} F^S \\ G \end{pmatrix} \tag{9.9b}$$

where $*$ denotes a convolution integral:

$$f * g = \int_x^1 \frac{dy}{y} f(y)\, g\left(\frac{x}{y}\right) \; . \tag{9.10}$$

The leading-order Altarelli-Parisi [20] splitting functions are

$$P^{qq} = \frac{4}{3}\left[\frac{1+x^2}{(1-x)_+}\right] + 2\delta(1-x) \; , \tag{9.11a}$$

$$P^{qg} = \frac{1}{2}\left[x^2 + (1-x)^2\right] \; , \tag{9.11b}$$

$$P^{gq} = \frac{4}{3}\left[\frac{1+(1-x)^2}{x}\right] \; , \tag{9.11c}$$

$$P^{gg} = 6\left[\frac{1-x}{x} + x(1-x) + \frac{x}{(1-x)_+} + \frac{11}{12}\delta(1-x)\right] - \frac{n_f}{3}\delta(1-x) \; . \tag{9.11d}$$

Here the gluon distribution $G(x, Q^2)$ has been introduced and $1/(1-x)_+$ means

$$\int_0^1 dx \frac{f(x)}{(1-x)_+} = \int_0^1 dx\, \frac{f(x) - f(1)}{(1-x)} \; . \tag{9.12}$$

The precision of contemporary experimental data demands that higher-order corrections also be included [21]. The above results are for massless quarks. At low Q^2 values, there are also important "higher-twist" (HT) contributions of the form:

$$F_i(x, Q^2) = F_i^{(LT)}(x, Q^2) + \frac{F_i^{(HT)}(x, Q^2)}{Q^2} + \cdots \; . \tag{9.13}$$

Leading twist (LT) indicates a term whose behavior is predicted by perturbative QCD. These corrections are numerically important only for $Q^2 < \mathcal{O}(\text{few GeV}^2)$ except for x very close to 1. At very large values of x perturbative corrections proportional to $\log(1-x)$ can become important [22].

A detailed review of the current status of the experimental data can be found, for example, in Refs. [23–26], and only a brief summary will be presented here. We shall only include determinations of Λ from the recently published results; the earlier editions of this *Review* should be consulted for the earlier data. Data now exist from HERA at much smaller values of x than the fixed-target data. They provide valuable information about the shape of the antiquark and gluon distribution functions at $x \sim 10^{-4}$ [27].

From Eq. (9.9), it is clear that a nonsinglet structure function offers in principle the most precise test of the theory, since the Q^2 evolution is independent of the unmeasured gluon distribution. The CCFR collaboration fit to the Gross-Llewellyn Smith sum rule [28] which is known to order α_s^3 [29,30](Estimates of the order α_s^4 term are available [31])

$$\int_0^1 dx\left(F_3^{\overline{\nu}p}(x,Q^2)+F_3^{\nu p}(x,Q^2)\right)= 3\left[1-\frac{\alpha_s}{\pi}(1+3.58\frac{\alpha_s}{\pi}+19.0\left(\frac{\alpha_s}{\pi}\right)^2)-\Delta HT\right] \quad , \qquad (9.14)$$

where the higher-twist contribution ΔHT is estimated to be $(0.09 \pm 0.045)/Q^2$ in Refs. [29,32] and to be somewhat smaller by Ref. 33. The CCFR collaboration [35], combines their data with that from other experiments [36] and gives α_s ($\sqrt{3}$ GeV) = 0.28 ± 0.035 (expt.) $\pm$ 0.05 (sys)$^{+0.035}_{-0.03}$ (theory). The error from higher-twist terms (assumed to be $\Delta HT = 0.05 \pm 0.05$) dominates the theoretical error. If the higher twist result of Ref. 33 is used, the central value increases to 0.31 in agreement with the fit of [37]. This value corresponds to $\alpha_s(M_Z) = 0.118 \pm 0.011$.

Measurements involving singlet-dominated structure functions, such as F_2, result in measurements of α_s and the gluon structure function. A full next-to-leading-order fit combining date from SLAC [38], BCDMS [39], E665 [40] and HERA [27] has been performed by Ref. 41. These authors extend the analysis to next-to-next-to-leading order (NNLO). In this case the full theoretical calculation is not available as not all the three loop anomalous dimensions are known; their analysis uses moments of structure functions and is restricted to those moments where the full calculation is available [21,42,37]. The NNLO result is $\alpha_s(M_Z) = 0.1172 \pm 0.0017$ (expt.) ± 0.0017 (sys). Here the first error is a combination of statistical and systematic experimental errors, and the second error is due to the uncertainties in the quark masses, higher twist and target mass corrections, and errors from the gluon distribution. If only a next-to-leading-order fit is performed then the value decreases to $\alpha_s(M_Z) = 0.116$ indicating that the theoretical results are stable. Scale uncertainties are not included. This result is consistent with earlier determinations [43,44,45]. The second of these authors estimated the scale uncertainty at ± 0.004 when a NLO fit was used. The error of Ref. 41 should be increased to take account of the possible scale error. We will therefore use $\alpha_s(M_Z) = 0.1172 \pm 0.0045$ in the final average.

The spin-dependent structure functions, measured in polarized lepton-nucleon scattering, can also be used to test QCD and to determine α_s. Here the values of $Q^2 \sim 2.5$ GeV^2 are small, particularly for the E143 data [49], and higher-twist corrections are important. A fit [46] using the measured spin dependent structure functions for several experiments themselves from Refs. [48,49] gives $\alpha_s(M_Z) = 0.121 \pm 0.002$(expt.) $\pm$ 0.006(theory and syst.). Data from HERMES [50] are not included in this fit; they are consistent with the older data. α_s can also be determined from the Bjorken sum rule [51]; a fit gives [47] $\alpha_s(M_Z) = 0.118^{+0.010}_{-0.024}$; consistent with an earlier determination [52], the larger error being due to the extrapolation into the (unmeasured) small x region. Theoretically, the sum rule is preferable as the perturbative QCD result is known to higher order and these terms are important at the low Q^2 involved. It has been shown that the theoretical errors associated with the choice of scale are considerably reduced by the use of Pade approximants [12] which results in $\alpha_s(1.7 \text{ GeV}) = 0.328 \pm 0.03$(expt.) $\pm$ 0.025(theory) corresponding to $\alpha_s(M_Z) = 0.116^{+0.003}_{-0.005}$(expt.) $\pm$ 0.003(theory). No error is included from the extrapolation into the region of x that is unmeasured. Should data become available at smaller values of x so that this extrapolation could be more tightly constrained, the sum rule method could provide the best determination of α_s; the result from the structure functions themselves is used in the average.

At very small values of x and Q^2, the x and Q^2 dependence of the structure functions is predicted by perturbative QCD [53]. Here terms to all orders in $\alpha_s \ln(1/x)$ are summed. The data from HERA [27] on $F_2^{ep}(x,Q^2)$ can be fitted to this form [54], including the NLO terms which are required to fix the Q^2 scale. The data are dominated by 4 GeV$^2 < Q^2 <$ 100 GeV^2. The fit [55] using H1 data [56] gives $\alpha_s(M_Z) = 0.122 \pm 0.004$ (expt.) ± 0.009 (theory). (The theoretical error is taken from Ref. 54.) The dominant part of the theoretical error is from the scale dependence; errors from terms that are suppressed by $1/\log(1/x)$ in the quark sector are included [57] while those from the gluon sector are not.

Typically, Λ is extracted from the deep inelastic scattering data by parameterizing the parton densities in a simple analytic way at some Q_0^2, evolving to higher Q^2 using the next-to-leading-order evolution equations, and fitting globally to the measured structure functions to obtain $\Lambda^{(4)}_{\overline{\rm MS}}$. Thus, an important by-product of such studies is the extraction of parton densities at a fixed-reference value of Q_0^2. These can then be evolved in Q^2 and used as input for phenomenological studies in hadron-hadron collisions (see below). To avoid having to evolve from the starting Q_0^2 value each time, a parton density is required; it is useful to have available a simple analytic approximation to the densities valid over a range of x and Q^2 values. A package is available from the CERN computer library that includes an exhaustive set of fits [58]. Most of these fits are obsolete. In using a parameterization to predict event rates, a next-to-leading order fit must be used if the process being calculated is known to next-to-leading order in QCD perturbation theory. In such a case, there is an additional scheme dependence; this scheme dependence is reflected in the $\mathcal{O}(\alpha_s)$ corrections that appear in the relations between the structure functions and the quark distribution functions. There are two common schemes: a deep-inelastic scheme where there are no order α_s corrections in the formula for $F_2(x,Q^2)$ and the minimal subtraction scheme. It is important when these next-to-leading order fits are used in other processes (see below), that the same scheme is used in the calculation of the partonic rates. Most current sets of parton distributions are obtained using fits to all relevant event data [59]. In particular, data from purely hadronic initial states are used as they can provide important constraints on the gluon distributions.

9.4. QCD in decays of the τ lepton

The semi-leptonic branching ratio of the tau ($\tau \to \nu_\tau$ + hadrons, R_τ) is an inclusive quantity. It is related to the contribution of hadrons to the imaginary part of the W self energy ($\Pi(s)$). It is sensitive to a range of energies since it involves an integral

$$R_\tau \sim \int_0^{m_\tau^2} \frac{ds}{m_\tau^2}(1-\frac{s}{m_\tau^2})^2 \, \text{Im}(\Pi(s)) \ .$$

Since the scale involved is low, one must take into account nonperturbative (higher-twist) contributions which are suppressed by powers of the τ mass.

$$R_\tau = 3.058\left[1+\frac{\alpha_s(m_\tau)}{\pi}+5.2\left(\frac{\alpha_s(m_\tau)}{\pi}\right)^2+26.4\left(\frac{\alpha_s(m_\tau)}{\pi}\right)^3 + a\frac{m^2}{m_\tau^2}+b\frac{m\psi\overline{\psi}}{m_\tau^4}+c\frac{\psi\overline{\psi}\psi\overline{\psi}}{m_\tau^6}+\cdots\right] \ . \qquad (9.15)$$

Here a, b, and c are dimensionless constants and m is a light quark mass. The term of order $1/m_\tau^2$ is a kinematical effect due to the light quark masses and is consequently very small. The nonperturbative terms are estimated using sum rules [60]. In total, they are estimated to be -0.014 ± 0.005 [61,62]. This estimate relies on there being no

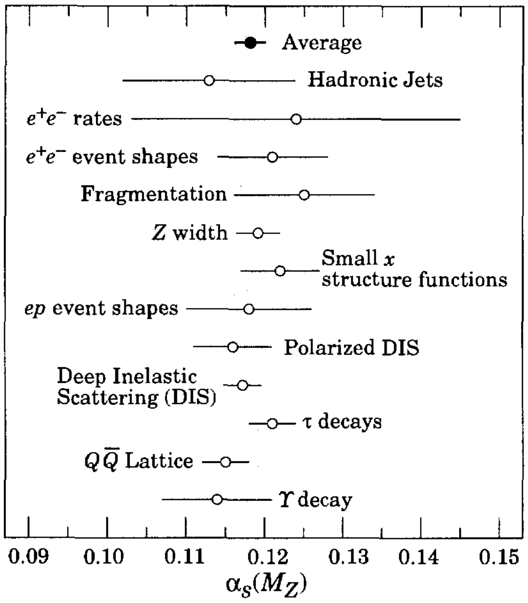

Figure 9.1: Summary of the values of $\alpha_s(M_Z)$ and $\Lambda^{(5)}$ from various processes. The values shown indicate the process and the measured value of α_s extrapolated up to $\mu = M_Z$. The error shown is the *total* error including theoretical uncertainties.

term of order Λ^2/m_τ^2 $\left(\text{note that } \frac{\alpha_s(m_\tau)}{\pi} \sim (\frac{0.5 \text{ GeV}}{m_\tau})^2\right)$. The a, b, and c can be determined from the data [63] by fitting to moments of the $\Pi(s)$ and separately to the final states accessed by the vector and axial parts of the W coupling. The values so extracted [64,65] are consistent with the theoretical estimates. If the nonperturbative terms are omitted from the fit, the extracted value of $\alpha_s(m_\tau)$ decreases by ~ 0.02.

For $\alpha_s(m_\tau) = 0.35$ the perturbative series for R_τ is $R_\tau \sim 3.058(1 + 0.112 + 0.064 + 0.036)$. The size (estimated error) of the nonperturbative term is 20% (7%) of the size of the order α_s^3 term. The perturbation series is not very well convergent; if the order α_s^3 term is omitted, the extracted value of $\alpha_s(m_\tau)$ increases by 0.05. The order α_s^4 term has been estimated [111] and attempts made to resum the entire series [67,68]. These estimates can be used to obtain an estimate of the errors due to these unknown terms [69,70]. We assign an uncertainty of ± 0.02 to $\alpha_s(m_\tau)$ from these sources.

R_τ can be extracted from the semi-leptonic branching ratio from the relation $R_\tau = 1/(B(\tau \to e\nu\overline{\nu}) - 1.97256$; where $B(\tau \to e\nu\overline{\nu})$ is measured directly or extracted from the lifetime, the muon mass, and the muon lifetime assuming universality of lepton couplings. Using the average lifetime of 290.0 ± 1.2 fs and a τ mass of 1777.05 ± 0.29 MeV from the PDG fit gives $R_\tau = 3.655 \pm 0.023$. The direct measurement of $B(\tau \to e\nu\overline{\nu})$ can be combined with $B(\tau \to \mu\nu\overline{\nu})$ to give $B(\tau \to e\nu\overline{\nu}) = 0.1783 \pm 0.0007$ which gives $R_\tau = 3.636 \pm 0.021$. Averaging these yields $\alpha_s(m_\tau) = 0.351 \pm 0.008$ using the experimental error alone. We assign a theoretical error equal to 40% of the contribution from the order α^3 term and all of the nonperturbative contributions. This then gives $\alpha_s(m_\tau) = 0.35 \pm 0.03$ for the final result. This corresponds to $\alpha_s(M_Z) = 0.121 \pm 0.003$.

9.5. QCD in high-energy hadron collisions

There are many ways in which perturbative QCD can be tested in high-energy hadron colliders. The quantitative tests are only useful if the process in question has been calculated beyond leading order in QCD perturbation theory. The production of hadrons with large transverse momentum in hadron-hadron collisions provides a direct probe of the scattering of quarks and gluons: $qq \to qq$, $qg \to qg$, $gg \to gg$, *etc.* Higher-order QCD calculations of the jet rates [71] and shapes are in impressive agreement with data [72]. This agreement has led to the proposal that these data could be used to provide a determination of α_s [73]. A set of structure functions is assumed and Tevatron collider data are fitted over a very large range of transverse momenta, to the QCD prediction for the underlying scattering process that depends on α_s. The evolution of the coupling over this energy range (40 to 250 GeV) is therefore tested in the analysis. CDF obtains $\alpha_s(M_Z) = 0.1129 \pm 0.0001$ (stat.) $\pm$ 0.0085 (syst.) [74]. Estimation of the theoretical errors is not straightforward. The structure functions used depend implicitly on α_s and an iteration procedure must be used to obtain a consistent result; different sets of structure functions yield different correlations between the two values of α_s. I estimate an uncertainty of ± 0.005 from examining the fits. Ref. 73 estimates the error from unknown higher order QCD corrections to be ± 0.005. Combining these then gives. $\alpha_s(M_Z) = 0.113 \pm 0.011$. Data are also available on the angular distribution of jets; these are also in agreement with QCD expectations [75,76].

QCD corrections to Drell-Yan type cross sections (*i.e.*, the production in hadron collisions by quark-antiquark annihilation of lepton pairs of invariant mass Q from virtual photons, or of real W or Z bosons), are known [77]. These $\mathcal{O}(\alpha_s)$ QCD corrections are sizable at small values of Q. The correction to W and Z production, as measured in $p\overline{p}$ collisions at $\sqrt{s} = 0.63$ TeV and $\sqrt{s} = 1.8$ TeV, is of order 30%. The NNLO corrections to this process are known [78].

The production of W and Z bosons and photons at large transverse momentum can also be used to test QCD. The leading-order QCD subprocesses are $q\overline{q} \to \gamma g$ and $qg \to \gamma q$. If the parton distributions are taken from other processes and a value of α_s assumed, then an absolute prediction is obtained. Conversely, the data can be used to extract information on quark and gluon distributions and on the value of α_s. The next-to-leading-order QCD corrections are known [79,80] (for photons), and for W/Z production [81], and so a precision test is possible. Data exist on photon production from the CDF and DØ collaborations [82,83] and from fixed target experiments [84]. Detailed comparisons with QCD predictions [85] may indicate an excess of the data over the theoretical prediction at low value of transverse momenta. although other authors [86] find smaller excesses.

The UA2 collaboration [87] extracted a value of $\alpha_s(M_W) = 0.123 \pm 0.018(\text{stat.}) \pm 0.017(\text{syst.})$ from the measured ratio $R_W = \frac{\sigma(W + 1\text{jet})}{\sigma(W + 0\text{jet})}$. The result depends on the algorithm used to define a jet, and the dominant systematic errors due to fragmentation and corrections for underlying events (the former causes jet energy to be lost, the latter causes it to be increased) are connected to the algorithm. There is also dependence on the parton distribution functions, and hence, α_s appears explicitly in the formula for R_W, and implicitly in the distribution functions. This result is not used in the final average. Data from CDF and D0 on the W p_t distribution [89] are in agreement with QCD but are not able to determine α_s with sufficient precision to have any weight in a global average.

In the region of low p_t, fixed order perturbation theory is not applicable; one must sum terms of order $\alpha_s^n \ln^n(p_t/M_W)$ [88]. Data from D0 [90] on the p_t distribution of Z bosons agree well with these predictions.

The production rates of b quarks in $p\overline{p}$ have been used to determine α_s [91]. The next-to-leading-order QCD production processes [92] have been used. By selecting events where the b quarks are back-to-back in azimuth, the next-to-leading-order calculation can be used to compare rates to the measured value and a value of α_s extracted. The errors are dominated by the measurement errors, the choice of μ and M, and uncertainties in the choice of structure functions. The last were estimated by varying the structure functions used. The result is $\alpha_s(M_Z) = 0.113^{+0.009}_{-0.013}$.

9.6. QCD in heavy-quarkonium decay

Under the assumption that the hadronic and leptonic decay widths of heavy $Q\overline{Q}$ resonances can be factorized into a nonperturbative part—dependent on the confining potential—and a calculable perturbative part, the ratios of partial decay widths allow measurements of α_s at the heavy-quark mass scale. The most precise data come from the decay widths of the 1^{--} $J/\psi(1S)$ and Υ resonances. The total decay width of the Υ is predicted by perturbative QCD [93]

$$R_\mu(\Upsilon) = \frac{\Gamma(\Upsilon \to \text{hadrons})}{\Gamma(\Upsilon \to \mu^+\mu^-)} = \frac{10(\pi^2-9)\alpha_s^3(M)}{9\pi\alpha_{\rm em}^2} \times \left[1 + \frac{\alpha_s}{\pi}\left(-19.4 + \frac{3\beta_0}{2}\left(1.162 + \ln\left(\frac{2M}{M_\Upsilon}\right)\right)\right)\right] \quad (9.16)$$

Data are available for the Υ, Υ', Υ'', and J/ψ. The result is very sensitive to α_s and the data are sufficiently precise ($R_\mu(\Upsilon) = 32.5 \pm 0.9$) [94] that the theoretical errors will dominate. There are theoretical corrections to this simple formula due to the relativistic nature of the $Q\overline{Q}$ system; $v^2/c^2 \sim 0.1$ for the Υ. They are more severe for the J/ψ. There are also nonperturbative corrections of the form Λ^2/M_Υ^2; again these are more severe for the J/ψ. A fit to Υ, Υ', and Υ'' [95] gives $\alpha_s(M_Z) = 0.113 \pm 0.001$ (expt.). The results from each state separately and also from the J/ψ are consistent with each other. There is an uncertainty of order ± 0.005 from the choice of scale; the error from v^2/c^2 corrections is a little larger. The ratio of widths $\frac{\Upsilon \to \gamma gg}{\Upsilon \to ggg}$ has been measured by the CLEO collaboration who use it to determine $\alpha_s(9.45\text{ GeV}) = 0.163 \pm 0.002 \pm 0.014$ [97] which corresponds to $\alpha_s(M_Z) = 0.110 \pm 0.001 \pm 0.007$. The error is dominated by theoretical uncertainties associated with the scale choice. The theoretical uncertainties due to the production of photons in fragmentation [96] are small [97]. Higher order QCD calculations of the photon energy distribution are available [98]; this distribution could now be used to further test the theory. The width $\Gamma(\Upsilon \to e^+e^-)$ can also be used to determine α_s by using moments of the quantity $R_b(s) = \frac{\sigma(e^+e^- \to b\bar{b})}{\sigma(e^+e^- \to \mu^+\mu^-)}$ defined by $M_n = \int_0^\infty \frac{R_b(s)}{s^{n+1}}$ [99]. At large values of n, M_n is dominated by $\Gamma(\Upsilon \to e^+e^-)$. Higher order corrections are available and the method gives [100] $\alpha_s(m_b) = 0.220 \pm 0.027$. The dominant error is theoretical and is dominated by the choice of scale and by uncertainties in Coulomb corrections. It corresponds to $\alpha_s(M_Z) = 0.119 \pm 0.008$. These various Υ measurements can be combined and give $\alpha_s(M_Z) = 0.114 \pm 0.008$.

9.7. Perturbative QCD in e^+e^- collisions

The total cross section for $e^+e^- \to$ hadrons is obtained (at low values of $\sqrt{s}$) by multiplying the muon-pair cross section by the factor $R = 3\Sigma_q e_q^2$. The higher-order QCD corrections to this quantity have been calculated, and the results can be expressed in terms of the factor:

$$R = R^{(0)}\left[1 + \frac{\alpha_s}{\pi} + C_2\left(\frac{\alpha_s}{\pi}\right)^2 + C_3\left(\frac{\alpha_s}{\pi}\right)^3 + \cdots\right], \quad (9.17)$$

where $C_2 = 1.411$ and $C_3 = -12.8$ [101].

$R^{(0)}$ can be obtained from the formula for $d\sigma/d\Omega$ for $e^+e^- \to f\bar{f}$ by integrating over Ω. The formula is given in Sec. 35.2 of this *Review*. This result is only correct in the zero-quark-mass limit. The $\mathcal{O}(\alpha_s)$ corrections are also known for massive quarks [102]. The principal advantage of determining α_s from R in e^+e^- annihilation is that there is no dependence on fragmentation models, jet algorithms, *etc.*

A measurement by CLEO [103] at $\sqrt{s} = 10.52$ GeV yields $\alpha_s(10.52\text{ GeV}) = 0.20 \pm 0.01 \pm 0.06$, which corresponds to $\alpha_s(M_Z) = 0.13 \pm 0.005 \pm 0.03$. A comparison of the theoretical prediction of Eq. (9.17) (corrected for the b-quark mass), with all the available data at values of $\sqrt{s}$ between 20 and 65 GeV, gives [104] $\alpha_s(35\text{ GeV}) = 0.146 \pm 0.030$. The size of the order α_s^3 term is of order 40% of that of the order α_s^2 and 3% of the order α_s. If the order α_s^3 term is not included, a fit to the data yields α_s (34 GeV) $= 0.142 \pm 0.03$, indicating that the theoretical uncertainty is smaller than the experimental error.

Measurements of the ratio of hadronic to leptonic width of the Z at LEP and SLC, Γ_h/Γ_μ probe, the same quantity as R. Using the average of $\Gamma_h/\Gamma_\mu = 20.783 \pm 0.029$ gives $\alpha_s(M_Z) = 0.123 \pm 0.004$ [105]. There are theoretical errors arising from the values of top-quark and Higgs masses which enter due to electroweak corrections to the Z width and from the choice of scale.

While this method has small theoretical uncertainties from QCD itself, it relies sensitively on the electroweak couplings of the Z to quarks [106]. The presence of new physics which changes these couplings via electroweak radiative corrections would invalidate the value of $\alpha_s(M_Z)$. However, given the excellent agreement [107] of the many measurements at the Z, there is no reason not to use the value of $\alpha_s(M_Z) = 0.1192 \pm 0.0028 \pm 0.002(scale)$ from the global fits of the various precision measurements at LEP/SLC and the W and top masses in the world average (see the section on "Electroweak model and constraints on new physics," Sec. 10 of this *Review*).

An alternative method of determining α_s in e^+e^- annihilation is from measuring quantities that are sensitive to the relative rates of two-, three-, and four-jet events. A review should be consulted for more details [108] of the issues mentioned briefly here. In addition to simply counting jets, there are many possible choices of such "shape variables": thrust [109], energy-energy correlations [110], average jet mass, *etc.* All of these are infrared safe, which means they can be reliably calculated in perturbation theory. The starting point for all these quantities is the multijet cross section. For example, at order α_s, for the process $e^+e^- \to qqg$: [111]

$$\frac{1}{\sigma}\frac{d^2\sigma}{dx_1 dx_2} = \frac{2\alpha_s}{3\pi}\frac{x_1^2 + x_2^2}{(1-x_1)(1-x_2)}, \quad (9.18)$$

$$x_i = \frac{2E_i}{\sqrt{s}} \quad (9.19)$$

where x_i are the center-of-mass energy fractions of the final-state (massless) quarks. A distribution in a "three-jet" variable, such as those listed above, is obtained by integrating this differential cross section over an appropriate phase space region for a fixed value of the variable. The order α_s^2 corrections to this process have been computed, as well as the 4-jet final states such as $e^+e^- \to qqgg$ [112].

There are many methods used by the e^+e^- experimental groups to determine α_s from the event topology. The jet-counting algorithm, originally introduced by the JADE collaboration [113], has been used by many other groups. Here, particles of momenta p_i and p_j are combined into a pseudo-particle of momentum $p_i + p_j$ if the invariant mass of the pair is less than $y_0\sqrt{s}$. The process is then iterated until no more pairs of particles or pseudo-particles remain. The remaining number is then defined to be the number of jets in the event, and can be compared to the QCD prediction. The Durham algorithm is slightly different: in computing the mass of a pair of partons, it uses $M^2 = 2\min(E_1^2, E_2^2)(1 - \cos\theta_{ij})$ for partons of energies E_i and E_j separated by angle θ_{ij} [114].

There are theoretical ambiguities in the way this process is carried out. Quarks and gluons are massless, whereas the observed hadrons are not, so that the massive jets that result from this scheme cannot be compared directly to the massless jets of perturbative QCD. Different recombination schemes have been tried, for example combining 3-momenta and then rescaling the energy of the cluster so that it remains massless. These schemes result in the same data giving a slightly different values [115,116] of α_s. These differences can be used to determine a systematic error. In addition, since what is observed are hadrons rather than quarks and gluons, a model is needed to describe the evolution of a partonic final state into one involving hadrons, so that detector corrections can be applied. The QCD matrix elements are combined with a parton-fragmentation model. This model can then be used to correct the data for a direct comparison with the parton calculation. The different hadronization models that are used [117–120] model the dynamics that are controlled by nonperturbative QCD effects which we cannot yet calculate. The fragmentation parameters of these Monte Carlos are tuned to get agreement with the observed data. The differences between these models contribute to the systematic errors. The systematic errors from recombination schemes and fragmentation effects dominate over the statistical and other errors of the LEP/SLD experiments.

The scale M at which $\alpha_s(M)$ is to be evaluated is not clear. The invariant mass of a typical jet (or $\sqrt{sy_0}$) is probably a more appropriate choice than the e^+e^- center-of-mass energy. While there is no justification for doing so, if the value is allowed to float in the fit to the data, the fit improves and the data tend to prefer values of order $\sqrt{s}/10$ GeV for some variables [116,121]; the exact value depends on the variable that is fitted.

The perturbative QCD formulae can break down in special kinematical configurations. For example, the thrust (T) distribution contains terms of the type $\alpha_s \ln^2(1-T)$. The higher orders in the perturbation expansion contain terms of order $\alpha_s^n \ln^m(1-T)$. For $T \sim 1$ (the region populated by 2-jet events), the perturbation expansion is unreliable. The terms with $n \leq m$ can be summed to all orders in α_s [122]. If the jet recombination methods are used higher-order terms involve $\alpha_s^n \ln^m(y_0)$, these too can be resummed [123]. The resummed results give better agreement with the data at large values of T. Some caution should be exercised in using these resummed results because of the possibility of overcounting; the showering Monte Carlos that are used for the fragmentation corrections also generate some of these leading-log corrections. Different schemes for combining the order α_s^2 and the resummations are available [124]. These different schemes result in shifts in α_s of order ± 0.002. The use of the resummed results improves the agreement between the data and the theory. An average of the recent results at the Z resonance from SLD [116], OPAL [125], L3 [126], ALEPH [127], and DELPHI [128], using the combined α_s^2 and resummation fitting to a large set of shape variables, gives $\alpha_s(M_Z) = 0.122 \pm 0.007$. The errors in the values of $\alpha_s(M_Z)$ from these shape variables are totally dominated by the theoretical uncertainties associated with the choice of scale, and the effects of hadronization Monte Carlos on the different quantities fitted.

Similar studies on event shapes have been undertaken at lower energies at TRISTAN, PEP/PETRA, and CLEO. A combined result from various shape parameters by the TOPAZ collaboration gives $\alpha_s(58 \text{ GeV}) = 0.125 \pm 0.009$, using the fixed order QCD result, and $\alpha_s(58 \text{ GeV}) = 0.132 \pm 0.008$ (corresponding to $\alpha_s(M_Z) = 0.123 \pm 0.007$), using the same method as in the SLD and LEP average [129]. The measurements of event shapes at PEP/PETRA are summarized in earlier editions of this note. A recent reevaluation of the JADE data [130] obtained using resummed QCD results and by averaging over several shape variables gives $\alpha_s(35 \text{ GeV}) = 0.145^{+0.012}_{-0.007}$. An analysis by the TPC group [131] gives $\alpha_s(29 \text{ GeV}) = 0.160 \pm 0.012$, using the same method as TOPAZ. This value corresponds to $\alpha_s(M_Z) = 0.131 \pm 0.010$

The CLEO collaboration fits to the order α_s^2 results for the two jet fraction at $\sqrt{s} = 10.53$ GeV, and obtains $\alpha_s(10.93 \text{ GeV}) = 0.164 \pm 0.004$ (expt.) ± 0.014 (theory) [132]. The dominant systematic error arises from the choice of scale (μ), and is determined from the range of α_s that results from fit with $\mu = 10.53$ GeV, and a fit where μ is allowed to vary to get the lowest χ^2. The latter results in $\mu = 1.2$ GeV. Since the quoted result corresponds to $\alpha_s(1.2 \text{ GeV}) = 0.35$, it is by no means clear that the perturbative QCD expression is reliable and the resulting error should, therefore, be treated with caution. A fit to many different variables as is done in the LEP/SLC analyses would give added confidence to the quoted error.

Recently studies have been carried out at energies between ~130 GeV [133] and ~189 GeV [134]. These can be combined to give $\alpha_s(130 \text{ GeV}) = 0.114 \pm 0.008$ and $\alpha_s(189 \text{ GeV}) = 0.1104 \pm 0.005$. The dominant errors are theoretical and systematic and, as most of these are in common at the two energies. These data and those at the Z resonance provide clear confirmation of the expected decrease in α_s as the energy is increased.

Since the errors in the event shape measurements are dominantly systematic, and are common to the experiments, the results from PEP/PETRA, TRISTAN, LEP, SLC, and CLEO are combined to give $\alpha_s(M_Z) = 0.121 \pm 0.007$. All of the experiments are consistent with this average and, taken together, provide verification of the running of the coupling constant with energy.

Estimates are available for the nonperturbative corrections to the mean value of $1-T$ [136]. These are of order $1/E$ and involve a single parameter to be determined from experiment. These corrections can then be used as an alternative to those modeled by the fragmentation Monte-Carlos. The DELPHI collaboration [135] uses data up to the Z mass from many experiments and determines $\alpha_s(M_Z) = 0.119 \pm 0.006$, the error being dominated by the choice of scale. The value is also determined by a fit to a second variable (the mean jet mass); while the extracted values of $\alpha_s(M_Z)$ are consistent with each other, the values of the non perturbative parameter are not. The analysis is useful as one can directly determine the size of the $1/E$ corrections; they are approximately 20% (50%) of the perturbative result at $\sqrt{s} = 91(11)$ GeV.

9.8. Scaling violations in fragmentation functions

Measurements of the fragmentation function $d_i(z, E)$, (the probability that a hadron of type i be produced with energy zE in e^+e^- collisions at $\sqrt{s} = 2E$) can be used to determine α_s. As in the case of scaling violations in structure functions, QCD predicts only the E dependence. Hence, measurements at different energies are needed to extract a value of α_s. Because the QCD evolution mixes the fragmentation functions for each quark flavor with the gluon fragmentation function, it is necessary to determine each of these before α_s can be extracted. The ALEPH collaboration has used data from energies ranging from $\sqrt{s} = 22$ GeV to $\sqrt{s} = 91$ GeV. A flavor tag is used to discriminate between different quark species, and the longitudinal and transverse cross sections are used to extract the gluon fragmentation function [137]. The result obtained is $\alpha_s(M_Z) = 0.126 \pm 0.007$ (expt.) ± 0.006 (theory) [138]. The theory error is due mainly to the choice of scale. The OPAL collaboration [139] has also extracted the separate fragmentation functions. DELPHI [140] has also performed a similar analysis using data from other experiments at lower energy with the result $\alpha_s(M_Z) = 0.124 \pm 0.007 \pm 0.009$ (theory). The larger theoretical error is due to the larger range of scales that were used in the fit. These results can be combined to give $\alpha_s(M_Z) = 0.125 \pm 0.005 \pm 0.008$ (theory).

9.9. Photon structure functions

e^+e^- can also be used to study photon-photon interactions, which can be used to measure the structure function of a photon [141], by selecting events of the type $e^+e^- \to e^+e^- + \textit{hadrons}$ which proceeds via two photon scattering. If events are selected where one of the photons is almost on mass shell and the other has a large invariant mass Q, then the latter probes the photon structure function at scale Q; the process is analogous to deep inelastic scattering where a highly virtual photon is used to probe the proton structure. This process was included in earlier versions of this *Review* which can be consulted or details on older measurements [142–145]. A recent review of the data can be found in Ref. 146. Data have become available from LEP [147–150] and from TRISTAN [151,152] which extend the range of Q^2 to of order 300 GeV^2 and x as low as $2 \times 10^{-3}$and show Q^2 dependence of the structure function that is consistent with QCD expectations. Experiments at HERA can also probe the photon structure function by looking at jet production in γp collisions; this is analogous to the jet production in hadron-hadron collisions which is sensitive to hadron structure functions. The data [153] are consistent with theoretical models [154].

9.10. Jet rates in ep collisions

At lowest order in α_s, the ep scattering process produces a final state of (1+1) jets, one from the proton fragment and the other from the quark knocked out by the process $e + quark \rightarrow e + quark$. At next order in α_s, a gluon can be radiated, and hence a (2+1) jet final state produced. By comparing the rates for these (1+1) and (2+1) jet processes, a value of α_s can be obtained. A NLO QCD calculation is available [155]. The basic methodology is similar to that used in the jet counting experiments in e^+e^- annihilation discussed above. Unlike those measurements, the ones in ep scattering are not at a fixed value of Q^2. In addition to the systematic errors associated with the jet definitions, there are additional ones since the structure functions enter into the rate calculations. Results from H1 [156] and ZEUS [157] can be combined to give $\alpha_s(M_Z) = 0.118 \pm 0.0015$ (stat.) $\pm$ 0.009 (syst.). The contributions to the systematic errors from experimental effects (mainly the hadronic energy scale) are comparable to the theoretical ones arising from scale choice, structure functions, and jet definitions. The theoretical errors are common to the two measurements; therefore, we have not reduced the systematic error after forming the average.

9.11. QCD in diffractive events

In approximately 10% of the deep-inelastic scattering events at HERA a rapidity gap is observed [158]; that is events are seen where there are almost no hadrons produced in the direction of the incident proton. This was unexpected; QCD based models of the final state predicted that the rapidity interval between the quark that is hit by the electron and the proton remnant should be populated approximately evenly by the hadrons. Similar phenomena have been observed at the Tevatron in W and jet production. For a review see Ref. 159.

9.12. Lattice QCD

Lattice gauge theory calculations can be used to calculate, using non-perturbative methods, a physical quantity that can be measured experimentally. The value of this quantity can then be used to determine the QCD coupling that enters in the calculation. For a review of the methodology see Ref. 160. For example, the energy levels of a $Q\overline{Q}$ system can be determined and then used to extract α_s. The masses of the $Q\overline{Q}$ states depend only on the quark mass and on α_s. A limitation is that calculations cannot be performed for three light quark flavors. Results are available for zero ($n_f = 0$, quenched approximation) and two light flavors, which allow extrapolation to three. The coupling constant so extracted is in a lattice renormalization scheme, and must be converted to the $\overline{\text{MS}}$ scheme for comparison with other results. Using the mass differences of Υ and Υ' and Υ'' and χ_b, Davies *et al.* [161] extract a value of $\alpha_s(M_Z) = 0.1174 \pm 0.0024$. A similar result with larger errors is reported by [162], where results are consistent with $\alpha_s(M_Z) = 0.111 \pm 0.006$. The SESAM collaboration [163] uses the Υ and Υ' and χ_b masses to obtain $\alpha_s(M_Z) = 0.1118 \pm 0.0017$ using Wilson fermions. These authors point out that their result is more than 3σ from that of Davies *et al.* which uses Kogut-Susskind fermions. A combination of the results from quenched [164] and ($n_f = 2$) [165] gives $\alpha_s(M_Z) = 0.116 \pm 0.003$ [166]. Calculations [167] using the strength of the force between two heavy quarks computed in the quenched approximation obtains a value of α_s(5 GeV) that is consistent with these results. There have also been investigations of the running of α_s [168]. These show remarkable agreement with the two loop perturbative result of Eq. (9.5).

There are several sources of error in these estimates of $\alpha_s(M_Z)$. The experimental error associated with the measurements of the particle masses is negligible. The conversion from the lattice coupling constant to the $\overline{\text{MS}}$ constant is obtained using a perturbative expansion where one coupling expanded as a power series in the other. This series is only known to second order. A third order calculation exists only from the $n_f = 0$ case [169]. Its inclusion leads to a shift in the extracted value of $\alpha_s(M_Z)$ of +0.002. Other theoretical errors arising from the limited statistics of the Monte-Carlo calculation, extrapolation in n_f, and corrections for light quark masses are smaller than this.

The result of averaging [163,161,164] gives with a more conservative error $\alpha_s(M_Z) = 0.115 \pm 0.003$. This will be used in the average.

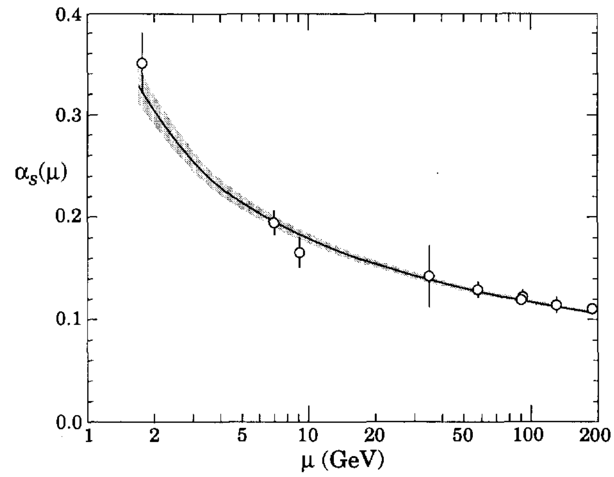

Figure 9.2: Summary of the values of $\alpha_s(\mu)$ at the values of μ where they are measured. The lines show the central values and the $\pm 1\sigma$ limits of our average. The figure clearly shows the decrease in $\alpha_s(\mu)$ with increasing μ. The data are, in increasing order of μ, τ width, deep inelastic scattering, Υ decays, e^+e^- event rate at 25 GeV, event shapes at TRISTAN, Z width, e^+e^- event shapes of M_Z, 135, and 189 GeV.

9.13. Conclusions

The need for brevity has meant that many other important topics in QCD phenomenology have had to be omitted from this review. One should mention in particular the study of exclusive processes (form factors, elastic scattering, ...), the behavior of quarks and gluons in nuclei, the spin properties of the theory, and QCD effects in hadron spectroscopy.

We have focused on those high-energy processes which currently offer the most quantitative tests of perturbative QCD. Figure 9.1 shows the values of $\alpha_s(M_Z)$ deduced from the various experiments. Figure 9.2 shows the values and the values of Q where they are measured. This figure clearly shows the experimental evidence for the variation of $\alpha_s(Q)$ with Q.

An average of the values in Fig. 9.1 gives $\alpha_s(M_z) = 0.1181$, with a total χ^2 of 3.8 for twelve fitted points, showing good consistency among the data. The error on the average, assuming that all of the errors in the contributing results are uncorrelated, is ± 0.0014, and may be an underestimate. Almost all of the values used in the average are dominated by systematic, usually theoretical, errors. Only some of these, notably from the choice of scale, are correlated. The average is not dominated by a single measurement; there are several results with comparable small errors: these are the ones from τ decay, lattice gauge theory, deep inelastic scattering, and the Z^0 width. We quote our average value as $\alpha_s(M_Z) = 0.1181 \pm 0.002$, which corresponds to $\Lambda^{(5)} = 208^{+25}_{-23}$ MeV using Eq. (9.5*a*). Future experiments can be expected to improve the measurements of α_s somewhat. Precision at the 1% level may be achievable if the systematic and theoretical errors can be reduced [170].

The value of α_s at any scale corresponding to our average can be obtained from `http://www-theory.lbl.gov/~ianh/alpha/alpha.html`

10. ELECTROWEAK MODEL AND CONSTRAINTS ON NEW PHYSICS

Revised August 1999 by J. Erler and P. Langacker (Univ. of Pennsylvania).

10.1. Introduction

The standard electroweak model is based on the gauge group [1] SU(2) × U(1), with gauge bosons W^i_μ, $i = 1, 2, 3$, and B_μ for the SU(2) and U(1) factors, respectively, and the corresponding gauge coupling constants g and g'. The left-handed fermion fields $\psi_i = \begin{pmatrix} \nu_i \\ \ell^-_i \end{pmatrix}$ and $\begin{pmatrix} u_i \\ d'_i \end{pmatrix}$ of the i^{th} fermion family transform as doublets under SU(2), where $d'_i \equiv \sum_j V_{ij}\, d_j$, and V is the Cabibbo-Kobayashi-Maskawa mixing matrix. (Constraints on V are discussed in the section on the Cabibbo-Kobayashi-Maskawa mixing matrix.) The right-handed fields are SU(2) singlets. In the minimal model there are three fermion families and a single complex Higgs doublet $\phi \equiv \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}$.

After spontaneous symmetry breaking the Lagrangian for the fermion fields is

$$\begin{aligned} \mathscr{L}_F = & \sum_i \overline{\psi}_i \left(i \not\partial - m_i - \frac{g m_i H}{2M_W} \right) \psi_i \\ & - \frac{g}{2\sqrt{2}} \sum_i \overline{\psi}_i\, \gamma^\mu\, (1-\gamma^5)(T^+\, W^+_\mu + T^-\, W^-_\mu)\, \psi_i \\ & - e \sum_i q_i\, \overline{\psi}_i\, \gamma^\mu\, \psi_i\, A_\mu \\ & - \frac{g}{2\cos\theta_W} \sum_i \overline{\psi}_i\, \gamma^\mu (g^i_V - g^i_A \gamma^5)\, \psi_i\, Z_\mu \,. \end{aligned} \tag{10.1}$$

$\theta_W \equiv \tan^{-1}(g'/g)$ is the weak angle; $e = g\sin\theta_W$ is the positron electric charge; and $A \equiv B\cos\theta_W + W^3 \sin\theta_W$ is the (massless) photon field. $W^\pm \equiv (W^1 \mp iW^2)/\sqrt{2}$ and $Z \equiv -B\sin\theta_W + W^3\cos\theta_W$ are the massive charged and neutral weak boson fields, respectively. T^+ and T^- are the weak isospin raising and lowering operators. The vector and axial vector couplings are

$$g^i_V \equiv t_{3L}(i) - 2q_i \sin^2\theta_W \,, \tag{10.2a}$$

$$g^i_A \equiv t_{3L}(i) \,, \tag{10.2b}$$

where $t_{3L}(i)$ is the weak isospin of fermion i (+1/2 for u_i and ν_i; −1/2 for d_i and e_i) and q_i is the charge of ψ_i in units of e.

The second term in $\mathscr{L}_F$ represents the charged-current weak interaction [2]. For example, the coupling of a W to an electron and a neutrino is

$$-\frac{e}{2\sqrt{2}\sin\theta_W}\left[W^-_\mu\; \overline{e}\, \gamma^\mu (1-\gamma^5)\nu + W^+_\mu\; \overline{\nu}\, \gamma^\mu\, (1-\gamma^5) e\right] \,. \tag{10.3}$$

For momenta small compared to M_W, this term gives rise to the effective four-fermion interaction with the Fermi constant given (at tree level, *i.e.*, lowest order in perturbation theory) by $G_F/\sqrt{2} = g^2/8M_W^2$. *CP* violation is incorporated in the Standard Model by a single observable phase in V_{ij}. The third term in $\mathscr{L}_F$ describes electromagnetic interactions (QED), and the last is the weak neutral-current interaction.

In Eq. (10.1), m_i is the mass of the i^{th} fermion ψ_i. For the quarks these are the current masses. For the light quarks, as described in the Particle Listings, $\widehat{m}_u \approx$ 1–5 MeV, $\widehat{m}_d \approx$ 3–9 MeV, and $\widehat{m}_s \approx$ 75–170 MeV. These are running $\overline{\rm MS}$ masses evaluated at the scale $\mu = 2$ GeV. (In this section we denote quantities defined in the $\overline{\rm MS}$ scheme by a caret; the exception is the strong coupling constant, α_s, which will always correspond to the $\overline{\rm MS}$ definition and where the caret will be dropped.) For the heavier quarks, $\widehat{m}_c(\mu = \widehat{m}_c) \approx$ 1.15–1.35 GeV and $\widehat{m}_b(\mu = \widehat{m}_b) \approx$ 4.0–4.4 GeV. The average of the recent CDF [4] and DØ [5] values for the top quark "pole" mass is $m_t = 174.3 \pm 5.1$ GeV. We will use this value for m_t (together with $M_H = 100$ GeV) for the numerical values quoted in Sec. 10.2–Sec. 10.4. See "The Note on Quark Masses" in the Particle Listings for more information.

H is the physical neutral Higgs scalar which is the only remaining part of ϕ after spontaneous symmetry breaking. The Yukawa coupling of H to ψ_i, which is flavor diagonal in the minimal model is $g m_i/2M_W$. In nonminimal models there are additional charged and neutral scalar Higgs particles [6].

10.2. Renormalization and radiative corrections

The Standard Model has three parameters (not counting the Higgs boson mass, M_H, and the fermion masses and mixings). A particularly useful set is:

(*a*) The fine structure constant $\alpha = 1/137.0359895(61)$, determined from the quantum Hall effect. In most electroweak-renormalization schemes, it is convenient to define a running α dependent on the energy scale of the process, with $\alpha^{-1} \sim 137$ appropriate at very low energy. (The running has also been observed directly. [7]) For scales above a few hundred MeV this introduces an uncertainty due to the low-energy hadronic contribution to vacuum polarization. In the modified minimal subtraction ($\overline{\rm MS}$) scheme [8] (used for this *Review*), and with $\alpha_s(M_Z) = 0.120$ for the QCD coupling at M_Z, one has $\widehat{\alpha}(m_\tau)^{-1} = 133.513 \pm 0.026$ and $\widehat{\alpha}(M_Z)^{-1} = 127.934 \pm 0.027$ [9]. The non-linear α_s dependence of $\widehat{\alpha}(M_Z)$ and the resulting correlation with the input variable α_s, is fully taken into account in the fits. The uncertainty is from e^+e^- annihilation data below 1.8 GeV [10], from uncalculated higher order perturbative and non-perturbative QCD corrections, and from the $\overline{\rm MS}$ quark masses, $\widehat{m}_c(\widehat{m}_c) = 1.31 \pm 0.07$ and $\widehat{m}_b(\widehat{m}_b) = 4.24 \pm 0.11$ [9]. Such a short distance mass definition (unlike the pole mass) is free from non-perturbative and renormalon uncertainties. Various recent evaluations of the contributions of the five light quark flavors, $\Delta\alpha^{(5)}_{\rm had}$, to the conventional (on-shell) QED coupling, $\alpha(M_Z) = \dfrac{\alpha}{1-\Delta\alpha}$, are summarized in Table 10.1. Most of the older results relied on $e^+e^- \to$ hadrons cross-section measurements up to energies of 40 GeV which were somewhat higher than the QCD prediction, suggested stronger running, and were less precise. The most recent results assume the validity of perturbative QCD (PQCD) at scales of 1.8 GeV and above (outside of resonance regions), and are in very good agreement with each other. They imply higher central values for the extracted M_H by $\mathcal{O}$(20 GeV). On the other hand, the upper limits for M_H are all similar due to a compensation of the latter effect and the higher precision. Further improvement of this dominant theoretical uncertainty in the interpretation of precision data will require better measurements of the cross-section for $e^+e^- \to$ hadrons at low energy.

(*b*) The Fermi constant, $G_F = 1.16637(1) \times 10^{-5}$ GeV^{-2}, determined from the muon lifetime formula [22,23],

$$\begin{aligned} \tau_\mu^{-1} = & \frac{G_F^2 m_\mu^5}{192\pi^3}\, F\left(\frac{m_e^2}{m_\mu^2}\right)\left(1 + \frac{3}{5}\frac{m_\mu^2}{M_W^2}\right) \\ & \times \left[1 + \left(\frac{25}{8} - \frac{\pi^2}{2}\right)\frac{\alpha(m_\mu)}{\pi} + C_2 \frac{\alpha^2(m_\mu)}{\pi^2}\right] \,, \end{aligned} \tag{10.4a}$$

where

$$F(x) = 1 - 8x + 8x^3 - x^4 - 12x^2 \ln x \,, \tag{10.4b}$$

$$C_2 = \frac{156815}{5184} - \frac{518}{81}\pi^2 - \frac{895}{36}\zeta(3) + \frac{67}{720}\pi^4 + \frac{53}{6}\pi^2 \ln(2) \,, \tag{10.4c}$$

and

$$\alpha(m_\mu)^{-1} = \alpha^{-1} - \frac{2}{3\pi}\ln\left(\frac{m_\mu}{m_e}\right) + \frac{1}{6\pi} \approx 136 \,. \tag{10.4d}$$

Table 10.1: Recent evaluations of the on-shell $\Delta\alpha^{(5)}_{\rm had}(M_Z)$. For better comparison we adjusted central values and errors to correspond to a common and fixed value of $\alpha_s(M_Z) = 0.120$. References quoting results without the top quark decoupled are converted to the five flavor definition. Ref. [20] uses $\Lambda_{\rm QCD} = 380 \pm 60$ MeV; for the conversion we assumed $\alpha_s(M_Z) = 0.118 \pm 0.003$.

The $\mathcal{O}(\alpha^2)$ corrections to μ decay have been completed recently [23]. The remaining uncertainty in G_F is from the experimental input.

(*c*) The Z boson mass, $M_Z = 91.1872 \pm 0.0021$ GeV, determined from the Z lineshape scan at LEP 1 [24].

With these inputs, $\sin^2\theta_W$ can be calculated when values for m_t and M_H are given; conversely (as is done at present), M_H can be constrained by $\sin^2\theta_W$. The value of $\sin^2\theta_W$ is extracted from Z pole observables, the W mass, and neutral-current processes [25], and depends on the renormalization prescription. There are a number of popular schemes [27–32] leading to values which differ by small factors depending on m_t and M_H. The notation for these schemes is shown in Table 10.2. Discussion of the schemes follows the table.

Table 10.2: Notations used to indicate the various schemes discussed in the text. Each definition of $\sin\theta_W$ leads to values that differ by small factors depending on m_t and M_H.

Scheme	Notation
On-shell	$s_W = \sin\theta_W$
NOV	$s_{M_Z} = \sin\theta_W$
$\overline{\rm MS}$	$\widehat{s}_Z = \sin\theta_W$
$\overline{\rm MS}$ *ND*	$\widehat{s}_{ND} = \sin\theta_W$
Effective angle	$\overline{s}_f = \sin\theta_W$

(*i*) The on-shell scheme [27] promotes the tree-level formula $\sin^2\theta_W = 1 - M_W^2/M_Z^2$ to a definition of the renormalized $\sin^2\theta_W$ to all orders in perturbation theory, *i.e.*, $\sin^2\theta_W \to s_W^2 \equiv 1 - M_W^2/M_Z^2$. This scheme is simple conceptually. However, M_W is known much less precisely than M_Z and in practice one extracts s_W^2 from M_Z alone using

$$M_W = \frac{A_0}{s_W(1-\Delta r)^{1/2}} , \qquad (10.5a)$$

$$M_Z = \frac{M_W}{c_W} , \qquad (10.5b)$$

where $c_W \equiv \cos\theta_W$, $A_0 = (\pi\alpha/\sqrt{2}G_F)^{1/2} = 37.2805(2)$ GeV, and Δr includes the radiative corrections relating α, $\alpha(M_Z)$, G_F, M_W, and M_Z. One finds $\Delta r \sim \Delta r_0 - \rho_t/\tan^2\theta_W$, where $\Delta r_0 = 1 - \alpha/\widehat{\alpha}(M_Z) = 0.0664(2)$ is due to the running of α and $\rho_t = 3G_F m_t^2/8\sqrt{2}\pi^2 = 0.00952(m_t/174.3\ \text{GeV})^2$ represents the dominant (quadratic) m_t dependence. There are additional contributions to Δr from bosonic loops, including those which depend logarithmically on M_H. One has $\Delta r = 0.0350 \mp 0.0019 \pm 0.0002$, where the second uncertainty is from $\alpha(M_Z)$. Thus the value of s_W^2 extracted from M_Z includes an uncertainty (∓ 0.0006) from the currently allowed range of m_t.

(*ii*) A more precisely determined quantity $s_{M_Z}^2$ can be obtained from M_Z by removing the (m_t, M_H) dependent term from Δr [28], *i.e.*,

$$s_{M_Z}^2 c_{M_Z}^2 \equiv \frac{\pi\alpha(M_Z)}{\sqrt{2}G_F M_Z^2} . \qquad (10.6)$$

Using $\alpha(M_Z)^{-1} = 128.92 \pm 0.03$ yields $s_{M_Z}^2 = 0.23105 \mp 0.00008$. The small uncertainty in $s_{M_Z}^2$ compared to other schemes is because most of the m_t dependence has been removed by definition. However, the m_t uncertainty reemerges when other quantities (*e.g.*, M_W or other Z pole observables) are predicted in terms of M_Z.

Both s_W^2 and $s_{M_Z}^2$ depend not only on the gauge couplings but also on the spontaneous-symmetry breaking, and both definitions are awkward in the presence of any extension of the Standard Model which perturbs the value of M_Z (or M_W). Other definitions are motivated by the tree-level coupling constant definition $\theta_W = \tan^{-1}(g'/g)$.

(*iii*) In particular, the modified minimal subtraction ($\overline{\rm MS}$) scheme introduces the quantity $\sin^2\widehat{\theta}_W(\mu) \equiv \widehat{g}'^2(\mu)/[\widehat{g}^2(\mu) + \widehat{g}'^2(\mu)]$, where the couplings $\widehat{g}$ and $\widehat{g}'$ are defined by modified minimal subtraction and the scale μ is conveniently chosen to be M_Z for electroweak processes. The value of $\widehat{s}_Z^2 = \sin^2\widehat{\theta}_W(M_Z)$ extracted from M_Z is less sensitive than s_W^2 to m_t (by a factor of $\tan^2\theta_W$), and is less sensitive to most types of new physics than s_W^2 or $s_{M_Z}^2$. It is also very useful for comparing with the predictions of grand unification. There are actually several variant definitions of $\sin^2\widehat{\theta}_W(M_Z)$, differing according to whether or how finite $\alpha\ln(m_t/M_Z)$ terms are decoupled (subtracted from the couplings). One cannot entirely decouple the $\alpha\ln(m_t/M_Z)$ terms from all electroweak quantities because $m_t \gg m_b$ breaks SU(2) symmetry. The scheme that will be adopted here decouples the $\alpha\ln(m_t/M_Z)$ terms from the $\gamma - Z$ mixing [8,29], essentially eliminating any $\ln(m_t/M_Z)$ dependence in the formulae for asymmetries at the Z pole when written in terms of $\widehat{s}_Z^2$. (A similar definition is used for $\widehat{\alpha}$.) The various definitions are related by

$$\widehat{s}_Z^2 = c\,(m_t, M_H) s_W^2 = \bar{c}\,(m_t, M_H)\, s_{M_Z}^2 , \qquad (10.7)$$

where $c = 1.0371 \pm 0.0021$ and $\bar{c} = 1.0004 \mp 0.0007$. The quadratic m_t dependence is given by $c \sim 1 + \rho_t/\tan^2\theta_W$ and $\bar{c} \sim 1 - \rho_t/(1 - \tan^2\theta_W)$, respectively. The expressions for M_W and M_Z in the $\overline{\rm MS}$ scheme are

$$M_W = \frac{A_0}{\widehat{s}_Z(1-\Delta\widehat{r}_W)^{1/2}} , \qquad (10.8a)$$

$$M_Z = \frac{M_W}{\widehat{\rho}^{1/2}\widehat{c}_Z} , \qquad (10.8b)$$

and one predicts $\Delta\widehat{r}_W = 0.0695 \pm 0.0001 \pm 0.0002$. $\Delta\widehat{r}_W$ has no quadratic m_t dependence, because shifts in M_W are absorbed into the observed G_F, so that the error in $\Delta\widehat{r}_W$ is dominated by $\Delta r_0 = 1 - \alpha/\widehat{\alpha}(M_Z)$, which induces the second quoted uncertainty. The quadratic m_t dependence has been shifted into $\widehat{\rho} \sim 1 + \rho_t$, where including bosonic loops, $\widehat{\rho} = 1.0107 \pm 0.0006$.

(*iv*) A variant $\overline{\rm MS}$ quantity $\widehat{s}_{\rm ND}^2$ (used in the 1992 edition of this *Review*) does not decouple the $\alpha\ln(m_t/M_Z)$ terms [30]. It is related to $\widehat{s}^2_Z$ by

$$\widehat{s}^2_Z = \widehat{s}^2_{\rm ND}/\left(1 + \frac{\widehat{\alpha}}{\pi} d\right) , \qquad (10.9a)$$

$$d = \frac{1}{3}\left(\frac{1}{\widehat{s}^2} - \frac{8}{3}\right)\left[(1 + \frac{\alpha_s}{\pi}) \ln \frac{m_t}{M_Z} - \frac{15\alpha_s}{8\pi}\right] , \qquad (10.9b)$$

Thus, $\widehat{s}^2_Z - \widehat{s}^2_{\rm ND} \sim -0.0002$ for $m_t = 174.3$ GeV.

(v) Yet another definition, the effective angle [31,32] $\bar{s}^2_f$ for Z coupling to fermion f, is described in Sec. 10.3.

Experiments are now at such a level of precision that complete $\mathcal{O}(\alpha)$ radiative corrections must be applied. For neutral-current and Z pole processes, these corrections are conveniently divided into two classes:

1. QED diagrams involving the emission of real photons or the exchange of virtual photons in loops, but not including vacuum polarization diagrams. These graphs often yield finite and gauge-invariant contributions to observable processes. However, they are dependent on energies, experimental cuts, *etc.*, and must be calculated individually for each experiment.
2. Electroweak corrections, including $\gamma\gamma$, γZ, ZZ, and WW vacuum polarization diagrams, as well as vertex corrections, box graphs, *etc.*, involving virtual W's and Z's. Many of these corrections are absorbed into the renormalized Fermi constant defined in Eq. (10.4). Others modify the tree-level expressions for Z pole observables and neutral-current amplitudes in several ways [25]. One-loop corrections are included for all processes. In addition, certain two-loop corrections are also important. In particular, two-loop corrections involving the top-quark modify ρ_t in $\widehat{\rho}$, Δr, and elsewhere by

$$\rho_t \to \rho_t[1 + R(M_H, m_t)\rho_t/3] . \qquad (10.10)$$

$R(M_H, m_t)$ is best described as an expansion in M^2_Z/m^2_t. The unsuppressed terms were first obtained in Ref. 33, and are known analytically [34]. Contributions suppressed by M^2_Z/m^2_t were studied in Ref. 35 with the help of small and large Higgs mass expansions, which can be interpolated. These contributions are about as large as the leading ones in Refs. 33 and 34. A subset of the relevant two-loop diagrams has also been calculated numerically without any heavy mass expansion [36]. This serves as a valuable check on the M_H dependence of the leading terms obtained in Refs. 33–35. The difference turned out to be small. For M_H above its lower direct limit, $-17 < R < -12$. Mixed QCD-electroweak loops of order $\alpha\alpha_s m^2_t$ [37] and $\alpha\alpha^2_s m^2_t$ [38] increase the predicted value of m_t by 6%. This is, however, almost entirely an artifact of using the pole mass definition for m_t. The equivalent corrections when using the $\overline{\rm MS}$ definition $\widehat{m}_t(\widehat{m}_t)$ increase m_t by less than 0.5%. The leading electroweak [33,34] and mixed [39] two-loop terms are also known for the $Z \to b\bar{b}$ vertex, but not the respective subleading ones. $\mathcal{O}(\alpha\alpha_s)$-vertex corrections involving massless quarks have been obtained in Ref. [40]. Since they add coherently, the resulting effect is sizable, and shifts the extracted $\alpha_s(M_Z)$ by $\approx +0.0007$. Corrections of the same order to $Z \to b\bar{b}$ decays have also been completed [41].

Throughout this Review we utilize electroweak radiative corrections from the program GAPP, which works entirely in the $\overline{\rm MS}$ scheme, and which is independent of the package ZFITTER.

10.3. Cross-section and asymmetry formulas

It is convenient to write the four-fermion interactions relevant to ν-hadron, ν-e, and parity violating e-hadron neutral-current processes in a form that is valid in an arbitrary gauge theory (assuming massless left-handed neutrinos). One has

$$-\mathcal{L}^{\nu{\rm Hadron}} = \frac{G_F}{\sqrt{2}}\, \bar{\nu}\, \gamma^\mu\, (1 - \gamma^5)\nu$$
$$\times \sum_i \left[\epsilon_L(i)\, \bar{q}_i\, \gamma_\mu(1 - \gamma^5)q_i + \epsilon_R(i)\, \bar{q}_i\, \gamma_\mu(1 + \gamma^5)q_i\right] , \qquad (10.11)$$

$$-\mathcal{L}^{\nu e} = \frac{G_F}{\sqrt{2}}\, \bar{\nu}_\mu\, \gamma^\mu(1 - \gamma^5)\nu_\mu\, \bar{e}\, \gamma_\mu(g^{\nu e}_V - g^{\nu e}_A\gamma^5)e \qquad (10.12)$$

(for ν_e-e or $\bar{\nu}_e$-e, the charged-current contribution must be included), and

$$-\mathcal{L}^{e{\rm Hadron}} = -\frac{G_F}{\sqrt{2}}$$
$$\times \sum_i \left[C_{1i}\, \bar{e}\, \gamma_\mu\, \gamma^5\, e\, \bar{q}_i\, \gamma^\mu\, q_i + C_{2i}\, \bar{e}\, \gamma_\mu\, e\, \bar{q}_i\, \gamma^\mu\, \gamma^5\, q_i\right] . \qquad (10.13)$$

(One must add the parity-conserving QED contribution.)

The Standard Model expressions for $\epsilon_{L,R}(i)$, $g^{\nu e}_{V,A}$, and C_{ij} are given in Table 10.3. Note, that $g^{\nu e}_{V,A}$ and the other quantities are coefficients of effective four-fermi operators, which differ from the quantities defined in Eq. (10.2) in the radiative corrections and in the presence of possible physics beyond the Standard Model.

A precise determination of the on-shell s^2_W, which depends only very weakly on m_t and M_H, is obtained from deep inelastic neutrino scattering from (approximately) isoscalar targets [42]. The ratio $R_\nu \equiv \sigma^{NC}_{\nu N}/\sigma^{CC}_{\nu N}$ of neutral- to charged-current cross-sections has been measured to 1% accuracy by the CDHS [43] and CHARM [44] collaborations at CERN, and the CCFR [45] collaboration at Fermilab has obtained an even more precise result, so it is important to obtain theoretical expressions for R_ν and $R_{\bar{\nu}} \equiv \sigma^{NC}_{\bar{\nu}N}/\sigma^{CC}_{\bar{\nu}N}$ to comparable accuracy. Fortunately, most of the uncertainties from the strong interactions and neutrino spectra cancel in the ratio. The largest theoretical uncertainty is associated with the c-threshold, which mainly affects σ^{CC}. Using the slow rescaling prescription [46] the central value of $\sin^2\theta_W$ from CCFR varies as $0.0111(m_c\,[{\rm GeV}] - 1.31)$, where m_c is the effective mass which is numerically close to the $\overline{\rm MS}$ mass $\widehat{m}_c(\widehat{m}_c)$, but their exact relation is unknown at higher orders. For $m_c = 1.31 \pm 0.24$ GeV (determined from ν-induced dimuon production [47]) this contributes ± 0.003 to the total uncertainty $\Delta\sin^2\theta_W \sim \pm 0.004$. (The experimental uncertainty is also ± 0.003.) This uncertainty largely cancels, however, in the Paschos-Wolfenstein ratio [48],

$$R^- = \frac{\sigma^{NC}_{\nu N} - \sigma^{NC}_{\bar{\nu}N}}{\sigma^{CC}_{\nu N} - \sigma^{CC}_{\bar{\nu}N}} . \qquad (10.14)$$

It was measured recently by the NuTeV collaboration [49] for the first time, and required a high-intensity and high-energy anti-neutrino beam.

A simple zeroth-order approximation is

$$R_\nu = g^2_L + g^2_R r , \qquad (10.15a)$$

$$R_{\bar{\nu}} = g^2_L + \frac{g^2_R}{r} , \qquad (10.15b)$$

$$R^- = g^2_L - g^2_R , \qquad (10.15c)$$

where

$$g^2_L \equiv \epsilon_L(u)^2 + \epsilon_L(d)^2 \approx \frac{1}{2} - \sin^2\theta_W + \frac{5}{9}\sin^4\theta_W , \qquad (10.16a)$$

$$g^2_R \equiv \epsilon_R(u)^2 + \epsilon_R(d)^2 \approx \frac{5}{9}\sin^4\theta_W , \qquad (10.16b)$$

and $r \equiv \sigma^{CC}_{\bar{\nu}N}/\sigma^{CC}_{\nu N}$ is the ratio of $\bar{\nu}$ and ν charged-current cross-sections, which can be measured directly. (In the simple parton model, ignoring hadron energy cuts, $r \approx (\frac{1}{3} + \epsilon)/(1 + \frac{1}{3}\epsilon)$, where $\epsilon \sim 0.125$ is the ratio of the fraction of the nucleon's momentum carried by antiquarks to that carried by quarks.) In practice, Eq. (10.15) must be corrected for quark mixing, quark sea effects, c-quark threshold effects, nonisoscalarity, $W - Z$ propagator differences, the finite muon mass, QED and electroweak radiative corrections. Details of the neutrino spectra, experimental cuts, x and Q^2 dependence of structure functions, and longitudinal structure functions enter only at the level of these corrections and therefore lead to very small uncertainties. The CCFR group quotes $s^2_W = 0.2236 \pm 0.0041$ for $(m_t, M_H) = (175, 150)$ GeV with very little sensitivity to (m_t, M_H). The NuTeV collaboration finds $s^2_W = 0.2253 \pm 0.0022$ using the

Table 10.3: Standard Model expressions for the neutral-current parameters for ν-hadron, ν-e, and e-hadron processes. At tree level, $\rho = \kappa = 1$, $\lambda = 0$. If radiative corrections are included, $\rho^{NC}_{\nu N} = 1.0083$, $\widehat{\kappa}_{\nu N}(\langle Q^2\rangle = -10\ \text{GeV}^2) = 0.9980$, $\widehat{\kappa}_{\nu N}(\langle Q^2\rangle = -35\ \text{GeV}^2) = 0.9965$, $\lambda_{uL} = -0.0031$, $\lambda_{dL} = -0.0025$, and $\lambda_{dR} = 2\,\lambda_{uR} = 7.5\times10^{-5}$. For ν-e scattering, $\rho_{\nu e} = 1.0129$ and $\widehat{\kappa}_{\nu e} = 0.9967$ (at $\langle Q^2\rangle = 0.$). For atomic parity violation and the SLAC polarized electron experiment, $\rho'_{eq} = 0.9878$, $\rho_{eq} = 1.0008$, $\widehat{\kappa}'_{eq} = 1.0026$, $\widehat{\kappa}_{eq} = 1.0300$, $\lambda_{1d} = -2\,\lambda_{1u} = 3.7\times10^{-5}$, $\lambda_{2u} = -0.0121$ and $\lambda_{2d} = 0.0026$. The dominant m_t dependence is given by $\rho \sim 1+\rho_t$, while $\widehat{\kappa} \sim 1$ ($\overline{\text{MS}}$) or $\kappa \sim 1 + \rho_t/\tan^2\theta_W$ (on-shell).

Quantity	Standard Model Expression
$\epsilon_L(u)$	$\rho^{NC}_{\nu N}\left(\frac{1}{2}-\frac{2}{3}\widehat{\kappa}_{\nu N}\,\widehat{s}^2_Z\right)+\lambda_{uL}$
$\epsilon_L(d)$	$\rho^{NC}_{\nu N}\left(-\frac{1}{2}+\frac{1}{3}\widehat{\kappa}_{\nu N}\,\widehat{s}^2_Z\right)+\lambda_{dL}$
$\epsilon_R(u)$	$\rho^{NC}_{\nu N}\left(-\frac{2}{3}\widehat{\kappa}_{\nu N}\,\widehat{s}^2_Z\right)+\lambda_{uR}$
$\epsilon_R(d)$	$\rho^{NC}_{\nu N}\left(\frac{1}{3}\widehat{\kappa}_{\nu N}\,\widehat{s}^2_Z\right)+\lambda_{dR}$
$g^{\nu e}_V$	$\rho_{\nu e}\left(-\frac{1}{2}+2\widehat{\kappa}_{\nu e}\,\widehat{s}^2_Z\right)$
$g^{\nu e}_A$	$\rho_{\nu e}\left(-\frac{1}{2}\right)$
C_{1u}	$\rho'_{eq}\left(-\frac{1}{2}+\frac{4}{3}\widehat{\kappa}'_{eq}\,\widehat{s}^2_Z\right)+\lambda_{1u}$
C_{1d}	$\rho'_{eq}\left(\frac{1}{2}-\frac{2}{3}\widehat{\kappa}'_{eq}\,\widehat{s}^2_Z\right)+\lambda_{1d}$
C_{2u}	$\rho_{eq}\left(-\frac{1}{2}+2\widehat{\kappa}_{eq}\,\widehat{s}^2_Z\right)+\lambda_{2u}$
C_{2d}	$\rho_{eq}\left(\frac{1}{2}-2\widehat{\kappa}_{eq}\,\widehat{s}^2_Z\right)+\lambda_{2d}$

same reference values. Combining all of the precise deep-inelastic measurements, one obtains $s^2_W = 0.2253 \pm 0.0021$.

The laboratory cross-section for $\nu_\mu e \to \nu_\mu e$ or $\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ elastic scattering is

$$\frac{d\sigma_{\nu_\mu,\overline{\nu}_\mu}}{dy} = \frac{G_F^2 m_e E_\nu}{2\pi} \times\left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + (g_V^{\nu e} \mp g_A^{\nu e})^2(1-y)^2 - (g_V^{\nu e2} - g_A^{\nu e2})\frac{y\, m_e}{E_\nu}\right] , \tag{10.17}$$

where the upper (lower) sign refers to $\nu_\mu(\overline{\nu}_\mu)$, and $y \equiv E_e/E_\nu$ (which runs from 0 to $(1 + m_e/2E_\nu)^{-1}$) is the ratio of the kinetic energy of the recoil electron to the incident ν or $\overline{\nu}$ energy. For $E_\nu \gg m_e$ this yields a total cross-section

$$\sigma = \frac{G_F^2\, m_e\, E_\nu}{2\pi}\left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + \frac{1}{3}(g_V^{\nu e} \mp g_A^{\nu e})^2\right] . \tag{10.18}$$

The most accurate leptonic measurements [50–52] of $\sin^2\theta_W$ are from the ratio $R \equiv \sigma_{\nu_\mu e}/\sigma_{\overline{\nu}_\mu e}$ in which many of the systematic uncertainties cancel. Radiative corrections (other than m_t effects) are small compared to the precision of present experiments and have negligible effect on the extracted $\sin^2\theta_W$. The most precise experiment (CHARM II) [52] determined not only $\sin^2\theta_W$ but $g^{\nu e}_{V,A}$ as well. The cross-sections for ν_e-e and $\overline{\nu}_e$-e may be obtained from Eq. (10.17) by replacing $g^{\nu e}_{V,A}$ by $g^{\nu e}_{V,A} + 1$, where the 1 is due to the charged-current contribution.

The SLAC polarized-electron experiment [53] measured the parity-violating asymmetry

$$A = \frac{\sigma_R - \sigma_L}{\sigma_R + \sigma_L} , \tag{10.19}$$

where $\sigma_{R,L}$ is the cross-section for the deep-inelastic scattering of a right- or left-handed electron: $e_{R,L}N \to e$X. In the quark parton model

$$\frac{A}{Q^2} = a_1 + a_2\,\frac{1-(1-y)^2}{1+(1-y)^2} , \tag{10.20}$$

where $Q^2 > 0$ is the momentum transfer and y is the fractional energy transfer from the electron to the hadrons. For the deuteron or other isoscalar targets, one has, neglecting the s-quark and antiquarks,

$$a_1 = \frac{3G_F}{5\sqrt{2}\pi\alpha}\left(C_{1u} - \frac{1}{2}C_{1d}\right) \approx \frac{3G_F}{5\sqrt{2}\pi\alpha}\left(-\frac{3}{4}+\frac{5}{3}\sin^2\theta_W\right) , \tag{10.21a}$$

$$a_2 = \frac{3G_F}{5\sqrt{2}\pi\alpha}\left(C_{2u} - \frac{1}{2}C_{2d}\right) \approx \frac{9G_F}{5\sqrt{2}\pi\alpha}\left(\sin^2\theta_W - \frac{1}{4}\right) . \tag{10.21b}$$

There are now precise experiments measuring atomic parity violation [54] in cesium (at the 0.4% level) [55], thallium [56], lead [57], and bismuth [58]. The uncertainties associated with atomic wave functions are quite small for cesium [59], and have been reduced recently to about 0.4% [60]. In the past, the semi-empirical value of the tensor polarizability added another source of theoretical uncertainty [61]. The ratio of the off-diagonal hyperfine amplitude to the polarizability has now been measured directly by the Boulder group [60]. Combined with the precisely known hyperfine amplitude [62] one finds excellent agreement with the earlier results, reducing the overall theory uncertainty to only 0.5% (while slightly increasing the experimental error). The theoretical uncertainties are 3% for thallium [63] but larger for the other atoms. For heavy atoms one determines the "weak charge"

$$Q_W = -2\left[C_{1u}\,(2Z+N) + C_{1d}(Z+2N)\right] \approx Z(1-4\sin^2\theta_W) - N . \tag{10.22}$$

The recent Boulder experiment in cesium also observed the parity-violating weak corrections to the nuclear electromagnetic vertex (the anapole moment [64]).

In the future it should be possible to reduce the theoretical wave function uncertainties by taking the ratios of parity violation in different isotopes [54,65]. There would still be some residual uncertainties from differences in the neutron charge radii, however [66].

The forward-backward asymmetry for $e^+e^- \to \ell^+\ell^-$, $\ell = \mu$ or τ, is defined as

$$A_{FB} \equiv \frac{\sigma_F - \sigma_B}{\sigma_F + \sigma_B} , \tag{10.23}$$

where $\sigma_F(\sigma_B)$ is the cross-section for ℓ^- to travel forward (backward) with respect to the e^- direction. A_{FB} and R, the total cross-section relative to pure QED, are given by

$$R = F_1 , \tag{10.24}$$

$$A_{FB} = 3F_2/4F_1 , \tag{10.25}$$

where

$$F_1 = 1 - 2\chi_0\, g_V^e\, g_V^\ell\, \cos\delta_R + \chi_0^2\left(g_V^{e2} + g_A^{e2}\right)\left(g_V^{\ell 2} + g_A^{\ell 2}\right), \tag{10.26a}$$

$$F_2 = -2\chi_0\, g_A^e\, g_A^\ell\, \cos\delta_R + 4\chi_0^2\, g_A^e\, g_A^\ell\, g_V^e\, g_V^\ell , \tag{10.26b}$$

$$\tan\delta_R = \frac{M_Z\Gamma_Z}{M_Z^2 - s} , \tag{10.27}$$

$$\chi_0 = \frac{G_F}{2\sqrt{2}\pi\alpha}\,\frac{sM_Z^2}{\left[(M_Z^2-s)^2 + M_Z^2\Gamma_Z^2\right]^{1/2}} , \tag{10.28}$$

and $\sqrt{s}$ is the CM energy. Eq. (10.26) is valid at tree level. If the data is radiatively corrected for QED effects (as described above), then the remaining electroweak corrections can be incorporated [67,68] (in an approximation adequate for existing PEP, PETRA, and TRISTAN data, which are well below the Z pole) by replacing χ_0 by $\chi(s) \equiv (1+\rho_t)\chi_0(s)\alpha/\alpha(s)$, where $\alpha(s)$ is the running QED coupling, and evaluating g_V in the $\overline{\text{MS}}$ scheme. Formulas for $e^+e^- \to$ hadrons may be found in Ref. 69.

At LEP and SLC, there are high-precision measurements of various Z pole observables [70–78]. These include the Z mass and total width, Γ_Z, and partial widths $\Gamma(f\bar{f})$ for $Z \to f\bar{f}$ where fermion $f = e$, μ, τ, hadrons, b, or c. It is convenient to use the variables M_Z, Γ_Z, $R_\ell \equiv \Gamma(\text{had})/\Gamma(\ell^+\ell^-)$, $\sigma_{\text{had}} \equiv 12\pi\Gamma(e^+e^-)\Gamma(\text{had})/M_Z^2\Gamma_Z^2$, $R_b \equiv \Gamma(b\bar{b})/\Gamma(\text{had})$, and $R_c \equiv \Gamma(c\bar{c})/\Gamma(\text{had})$, most of which are weakly correlated experimentally. ($\Gamma(\text{had})$ is the partial width into hadrons.) $\mathcal{O}(\alpha^3)$ QED corrections introduce a large anticorrelation (-28%) between Γ_Z and σ_{had}, while the anticorrelation between R_b and R_c (-14%) is smaller than previously. R_ℓ is insensitive to m_t except for the $Z \to b\bar{b}$ vertex and final state corrections and the implicit dependence through $\sin^2\theta_W$. Thus it is especially useful for constraining α_s. The width for invisible decays [24], $\Gamma(\text{inv}) = \Gamma_Z - 3\Gamma(\ell^+\ell^-) - \Gamma(\text{had}) = 498.8 \pm 1.5$ MeV, can be used to determine the number of neutrino flavors much lighter than $M_Z/2$, $N_\nu = \Gamma(\text{inv})/\Gamma^{\text{theory}}(\nu\bar{\nu}) = 2.983 \pm 0.009$ for $(m_t, M_H) = (174.3, 100)$ GeV.

There are also measurements of various Z pole asymmetries. These include the polarization or left-right asymmetry

$$A_{LR} \equiv \frac{\sigma_L - \sigma_R}{\sigma_L + \sigma_R} , \tag{10.29}$$

where $\sigma_L(\sigma_R)$ is the cross-section for a left-(right)-handed incident electron. A_{LR} has been measured precisely by the SLD collaboration at the SLC [71,72], and has the advantages of being extremely sensitive to $\sin^2\theta_W$ and that systematic uncertainties largely cancel. In addition, the SLD collaboration has extracted the final-state couplings A_b, A_c [24,73], A_s [74], A_τ, and A_μ [72,75] from left-right forward-backward asymmetries, using

$$A_{LR}^{FB}(f) = \frac{\sigma_{LF}^f - \sigma_{LB}^f - \sigma_{RF}^f + \sigma_{RB}^f}{\sigma_{LF}^f + \sigma_{LB}^f + \sigma_{RF}^f + \sigma_{RB}^f} = \frac{3}{4}A_f , \tag{10.30}$$

where, for example, σ_{LF} is the cross-section for a left-handed incident electron to produce a fermion f traveling in the forward hemisphere. Similarly, A_τ is measured at LEP [24,76] through the negative total τ polarization, $\mathcal{P}_\tau$, and A_e is extracted from the angular distribution of $\mathcal{P}_\tau$. An equation such as (10.30) assumes that initial state QED corrections, photon exchange, $\gamma - Z$ interference, the tiny electroweak boxes, and corrections for $\sqrt{s} \neq M_Z$ are removed from the data, leaving the pure electroweak asymmetries. This allows the use of effective tree-level expressions,

$$A_{LR} = A_e P_e , \tag{10.31}$$

$$A_{FB} = \frac{3}{4}A_f \frac{A_e + P_e}{1 + P_e A_e} , \tag{10.32}$$

where

$$A_f \equiv \frac{2\bar{g}_V^f \bar{g}_A^f}{\bar{g}_V^{f2} + \bar{g}_A^{f2}} , \tag{10.33}$$

and

$$\bar{g}_V^f = \sqrt{\rho_f}\,(t_{3L}^{(f)} - 2q_f\kappa_f \sin^2\theta_W) , \tag{10.33b}$$

$$\bar{g}_A^f = \sqrt{\rho_f}\, t_{3L}^{(f)} . \tag{10.33c}$$

P_e is the initial e^- polarization, so that the second equality in Eq. (10.30) is reproduced for $P_e = 1$, and the Z pole forward-backward asymmetries at LEP ($P_e = 0$) are given by $A_{FB}^{(0,f)} = \frac{3}{4}A_e A_f$ where $f = e$, μ, τ, b, c, s [77], and q, and where $A_{FB}^{(0,q)}$ refers to the hadronic charge asymmetry. Corrections for t-channel exchange and s/t-channel interference cause $A_{FB}^{(0,e)}$ to be strongly anticorrelated with R_e (-36%). The initial state coupling, A_e, is also determined through the left-right charge asymmetry [78] and in polarized Bhabba scattering at the SLC [72,75].

The electroweak-radiative corrections have been absorbed into corrections $\rho_f - 1$ and $\kappa_f - 1$, which depend on the fermion f and on the renormalization scheme. In the on-shell scheme, the quadratic m_t dependence is given by $\rho_f \sim 1 + \rho_t$, $\kappa_f \sim 1 + \rho_t/\tan^2\theta_W$, while in $\overline{\text{MS}}$, $\widehat{\rho}_f \sim \widehat{\kappa}_f \sim 1$, for $f \neq b$ ($\widehat{\rho}_b \sim 1 - \frac{4}{3}\rho_t$, $\widehat{\kappa}_b \sim 1 + \frac{2}{3}\rho_t$). In the $\overline{\text{MS}}$ scheme the normalization is changed according to $G_F M_Z^2/2\sqrt{2}\pi \to \widehat{\alpha}/4\widehat{s}_Z^2\widehat{c}_Z^2$. (If one continues to normalize amplitudes by $G_F M_Z^2/2\sqrt{2}\pi$, as in the 1996 edition of this *Review*, then $\widehat{\rho}_f$ contains an additional factor of $\widehat{\rho}$.) In practice, additional bosonic and fermionic loops, vertex corrections, leading higher order contributions, *etc.*, must be included. For example, in the $\overline{\text{MS}}$ scheme one has $\widehat{\rho}_\ell = 0.9979$, $\widehat{\kappa}_\ell = 1.0013$, $\widehat{\rho}_b = 0.9866$ and $\widehat{\kappa}_b = 1.0068$. It is convenient to define an effective angle $\bar{s}_f^2 \equiv \sin^2\bar{\theta}_{Wf} \equiv \widehat{\kappa}_f \widehat{s}_Z^2 = \kappa_f s_W^2$, in terms of which $\bar{g}_V^f$ and $\bar{g}_A^f$ are given by $\sqrt{\rho_f}$ times their tree-level formulae. Because $\bar{g}_V^\ell$ is very small, not only $A_{LR}^0 = A_e$, $A_{FB}^{(0,\ell)}$, and $\mathcal{P}_\tau$, but also $A_{FB}^{(0,b)}$, $A_{FB}^{(0,c)}$, $A_{FB}^{(0,s)}$, and the hadronic asymmetries are mainly sensitive to $\bar{s}_\ell^2$. One finds that $\widehat{\kappa}_f$ ($f \neq b$) is almost independent of (m_t, M_H), so that one can write

$$\bar{s}_\ell^2 \sim \widehat{s}_Z^2 + 0.00029 . \tag{10.34}$$

Thus, the asymmetries determine values of $\bar{s}_\ell^2$ and $\widehat{s}_Z^2$ almost independent of m_t, while the κ's for the other schemes are m_t dependent.

The Z boson properties are extracted assuming the Standard Model expressions for the $\gamma - Z$ interference terms. These have also been tested experimentally by performing more general fits [79] to the LEP data obtained at CM energies of about 91, 130, and 172 GeV. Assuming family universality this approach introduces three additional parameters relative to the standard fit [76],

$$j_{\text{had}}^{\text{tot}} \sim g_V^\ell g_V^{\text{had}} = 0.14 \pm 0.14 , \tag{10.35a}$$

$$j_\ell^{\text{tot}} \sim g_V^\ell g_V^\ell = 0.004 \pm 0.012 , \tag{10.35b}$$

$$j_\ell^{\text{fb}} \sim g_A^\ell g_A^\ell = 0.780 \pm 0.013 , \tag{10.35c}$$

where the first two parameters describe the $\gamma - Z$ interference contribution to the total hadronic and leptonic cross-sections, and the third to the leptonic forward-backward asymmetries. The results in Eq. (10.35) are in good agreement with the Standard Model expectations [76], 0.22, 0.004, and 0.799, respectively. This is a valuable test of the Standard Model; but it should be cautioned that new physics is not expected to be described by this set of parameters, since (i) they do not account for extra interactions beyond the standard weak neutral current, and (ii) the photonic amplitude remains fixed to its Standard Model value.

As another test, strong constraints on anomalous triple gauge couplings were obtained at LEP 2 above the W^+W^- threshold and by DØ at the Tevatron. While there are a total of 14 independent couplings, one can use SU(2) × U(1) gauge invariance, discrete symmetries, and LEP 1 constraints to reduce the number of triple gauge couplings to three. Each coupling is extracted from the data by setting the other two to zero (the SM value). Including the run at CM energy of 189 GeV, LEP 2 quotes the results [24],

$$\Delta\kappa_\gamma = 0.038^{+0.079}_{-0.075} , \tag{10.36a}$$

$$\Delta g_1^Z = -0.010 \pm 0.033 , \tag{10.36b}$$

$$\lambda_\gamma = -0.037^{+0.035}_{-0.036} , \tag{10.36c}$$

in excellent agreement with Standard Model expectations. Eq. (10.36*a*) can be used to rule out Kaluza-Klein theories which predict $\Delta\kappa_\gamma = -3$ [80]. In addition, the first direct limits on anomalous quartic gauge couplings were obtained by OPAL [81] through measurements of the $W^+W^-\gamma$ cross-section and of acoplanar photon pair events.

The CLEO collaboration [82] reported a precise measurement of the flavor changing transition $b \to s\gamma$. The result for the branching fraction is

$$\mathcal{B}(b \to s\gamma) = (3.37 \pm 0.37 \pm 0.34 \pm 0.24^{+0.35}_{-0.16} \pm 0.38) \times 10^{-4} , \tag{10.37}$$

where the first three errors are the quoted statistical, systematical, and model uncertainties, respectively. The fourth uncertainty accounts for the extrapolation from the finite photon energy cutoff (2.1 GeV) to the full theoretical branching ratio [83], and the last one is our estimate of the theory uncertainty (excluding parametric errors such as from α_s). It is advantageous to normalize the result with respect to the semi-leptonic branching fraction [84,85], $\mathcal{B}(b \to ce\nu) = 0.1034 \pm 0.0046$, yielding

$$R = \frac{\mathcal{B}(b \to s\gamma)}{\mathcal{B}(b \to ce\nu)} = (3.26^{+0.75}_{-0.68}) \times 10^{-3} \ , \qquad (10.38)$$

and to use the variable $\ln R = -5.73 \pm 0.22$ in electroweak fits to assure an approximately Gaussian error [86]. This measurement is to be compared to the next-to-leading order calculations of Refs. 85,87.

The present world average of the muon anomalous magnetic moment is

$$a_\mu^{\text{exp}} = \frac{g_\mu - 2}{2} = (116592300 \pm 840) \times 10^{-11} \ , \qquad (10.39)$$

while the estimated SM electroweak contribution [88], $a_\mu^{\text{EW}} = (151 \pm 4) \times 10^{-11}$, is much smaller than the uncertainty. However, a new experiment at BNL is expected to reduce the experimental error to $\pm 40 \times 10^{-11}$ or better. The limiting factor will then be the uncertainty from the hadronic contribution [19], $a_\mu^{\text{had}} = (6924 \pm 62) \times 10^{-11}$, which has recently been estimated with the help of τ decay data and finite-energy QCD sum rule techniques. This result constitutes a major improvement over previous ones which had more than twice the uncertainty [12]. It would be important to verify it, and reduce the error even further to meet the experimental precision. Additional hadronic uncertainties are induced by the light-by-light scattering contribution [89], $a_\mu^{\text{LBLS}} = (-92 \pm 32) \times 10^{-11}$, and other subleading hadronic contributions [90], $a_\mu^{\text{had}}\left[\left(\frac{\alpha}{\pi}\right)^3\right] = (-100 \pm 6) \times 10^{-11}$. The SM prediction is

$$a_\mu^{\text{theory}} = (116591596 \pm 67) \times 10^{-11} \ . \qquad (10.40)$$

With the anticipated accuracy at BNL it will be possible to explore new physics (specifically supersymmetry in the large $\tan\beta$ region [91]) up to energies of 5 TeV and more. If greater precision is achieved, it will be important to properly correlate the theoretical error on a_μ^{had} with the one in $\Delta\alpha^{(5)}_{\text{had}}$.

10.4. *W* and *Z* decays

The partial decay width for gauge bosons to decay into massless fermions $f_1 \overline{f}_2$ is

$$\Gamma(W^+ \to e^+\nu_e) = \frac{G_F M_W^3}{6\sqrt{2}\pi} \approx 226.5 \pm 0.3 \text{ MeV} \ , \qquad (10.41a)$$

$$\Gamma(W^+ \to u_i\overline{d}_j) = \frac{C G_F M_W^3}{6\sqrt{2}\pi} |V_{ij}|^2 \approx (707 \pm 1) |V_{ij}|^2 \text{ MeV} \ , \quad (10.41b)$$

$$\Gamma(Z \to \psi_i\overline{\psi}_i) = \frac{C G_F M_Z^3}{6\sqrt{2}\pi} \left[g_V^{i2} + g_A^{i2}\right] \qquad (10.41c)$$

$$\approx \begin{cases} 300.3 \pm 0.2 \text{ MeV } (u\overline{u}), & 167.24 \pm 0.08 \text{ MeV } (\nu\overline{\nu}), \\ 383.1 \pm 0.2 \text{ MeV } (d\overline{d}), & 84.01 \pm 0.05 \text{ MeV } (e^+e^-), \\ 375.9 \mp 0.1 \text{ MeV } (b\overline{b}). & \end{cases}$$

For leptons $C = 1$, while for quarks $C = 3\left(1 + \alpha_s(M_V)/\pi + 1.409\alpha_s^2/\pi^2 - 12.77\alpha_s^3/\pi^3\right)$, where the 3 is due to color and the factor in parentheses represents the universal part of the QCD corrections [92] for massless quarks [93]. The $Z \to f\overline{f}$ widths contain a number of additional corrections: universal (non-singlet) top-mass contributions [94]; fermion mass effects and further QCD corrections proportional to $\widehat{m}_q^2(M_Z^2)$ [95] which are different for vector and axial-vector partial widths; and singlet contributions starting from two-loop order which are large, strongly top-mass dependent, family universal, and flavor non-universal [96]. All QCD effects are known and included up to three loop order. The QED factor $1 + 3\alpha q_f^2/4\pi$, as well as two-loop $\alpha\alpha_s$ and α^2 self-energy corrections [97] are also included. Working in the on-shell scheme, *i.e.*, expressing the widths in terms of $G_F M_{W,Z}^3$, incorporates the largest radiative corrections from the running QED coupling [27,98]. Electroweak corrections to the Z widths are then incorporated by replacing $g_{V,A}^{i2}$ by $\overline{g}_{V,A}^{i2}$. Hence, in the on-shell scheme the Z widths are proportional to $\rho_i \sim 1 + \rho_t$. The $\overline{\text{MS}}$ normalization accounts also for the leading electroweak corrections [31]. There is additional (negative) quadratic m_t dependence in the $Z \to b\overline{b}$ vertex corrections [99] which causes $\Gamma(b\overline{b})$ to decrease with m_t. The dominant effect is to multiply $\Gamma(b\overline{b})$ by the vertex correction $1 + \delta\rho_{b\overline{b}}$, where $\delta\rho_{b\overline{b}} \sim 10^{-2}(-\frac{1}{2}\frac{m_t^2}{M_Z^2} + \frac{1}{5})$. In practice, the corrections are included in ρ_b and κ_b, as discussed before.

For 3 fermion families the total widths are predicted to be

$$\Gamma_Z \approx 2.4963 \pm 0.0012 \text{ GeV} \ , \qquad (10.42)$$

$$\Gamma_W \approx 2.0927 \pm 0.0025 \text{ GeV} \ . \qquad (10.43)$$

We have assumed $\alpha_s(M_Z) = 0.1200$. An uncertainty in α_s of ± 0.0028 introduces an additional uncertainty of 0.1% in the hadronic widths, corresponding to ± 1.4 MeV in Γ_Z. These predictions are to be compared with the experimental results $\Gamma_Z = 2.4944 \pm 0.0024$ GeV [24] and $\Gamma_W = 2.06 \pm 0.05$ GeV [100].

10.5. Experimental results

The values of the principal Z pole observables are listed in Table 10.4, along with the Standard Model predictions for $M_Z = 91.1870 \pm 0.0021$ GeV, $M_H = 98^{+57}_{-38}$ GeV, $m_t = 172.9 \pm 4.6$ GeV, $\alpha_s(M_Z) = 0.1192 \pm 0.0028$, and $\widehat{\alpha}(M_Z)^{-1} = 127.938 \pm 0.027$ ($\Delta\alpha^{(5)}_{\text{had}} \approx 0.02776 \pm 0.00020$). Note, that the values of the Z pole observables (as well as M_W) differ from those in the Particle Listings because they include recent preliminary results [24,72]. The values and predictions of M_W [24,101]; the Q_W for cesium [55,60] and thallium [56]; deep inelastic [43–45,49] and ν_μ-e scattering [50–52]; and the $b \to s\gamma$ observable [82] are also listed. The agreement is very good. Even the largest discrepancies, $A_{FB}^{(0,b)}$ and Q_W(Cs), deviate by only 2.3 σ. The hadronic peak cross-section, σ_{had}, the A_{LR}^0 from hadronic final states, and the R^ν result by the CHARM collaboration deviate by 1.7 σ; all the other observables agree with the Standard Model prediction at the 1.5 σ level or better. Other observables like $R_b = \Gamma(b\overline{b})/\Gamma(\text{had})$ and $R_c = \Gamma(c\overline{c})/\Gamma(\text{had})$ which showed significant deviations in the past, are now in reasonable agreement. In particular, R_b whose measured value deviated as much as 3.7 σ from the Standard Model prediction is now only 0.9 σ (0.3%) high.

A_b can be extracted from $A_{FB}^{(0,b)}$ when $A_e = 0.1497 \pm 0.0016$ is taken from a fit to leptonic asymmetries (using lepton universality), and combined with the measurement at the SLC. The result, $A_b = 0.892 \pm 0.016$, is 2.7 σ below the Standard Model prediction.† However, it would be extremely difficult to account for this nearly 5% deviation by new physics radiative corrections since a 25% correction to $\widehat{\kappa}_b$ would be necessary to account for the central value of A_b. If this deviation is due to new physics, it is most likely of tree-level type affecting preferentially the third generation. It seems difficult, however, to simultaneously account for R_b, which has been measured on the Z peak, off-peak [103], and recently at LEP 2 [24]). $A_{FB}^{(b)} = 0.44 \pm 0.12$ has also been measured at LEP 2 [24], and found to be 1.2 σ below the Standard Model prediction (0.58).

The left-right asymmetry, $A_{LR}^0 = 0.15108 \pm 0.00218$ [72], based on all hadronic data from 1992–1998 has moved closer to the Standard Model expectation of 0.1475 ± 0.0013 than previous values. The combined value of $A_\ell = 0.1512 \pm 0.0020$ from SLD (using lepton-family universality) is still 1.8 σ above the Standard Model prediction; but there is now only a minor experimental difference of ~ 1.2 σ between this SLD value and the LEP value, $A_\ell = 0.1471 \pm 0.0026$, obtained from a fit to $A_{FB}^{(0,\ell)}$, $A_e(\mathcal{P}_\tau)$, and $A_\tau(\mathcal{P}_\tau)$, again assuming universality.

† Alternatively, one can use $A_\ell = 0.1471 \pm 0.0026$, which is from LEP alone and in excellent agreement with the Standard Model, and obtain $A_b = 0.904 \pm 0.018$ which is 1.7 σ low. This illustrates that some of the discrepancy is related to the one in A_{LR}.

Table 10.4: Principal Z-pole and other recent observables, compared with the Standard Model predictions for the global best fit values $M_Z = 91.1870 \pm 0.0021$ GeV, $M_H = 98^{+57}_{-38}$ GeV, $m_t = 172.9 \pm 4.6$ GeV, $\alpha_s(M_Z) = 0.1192 \pm 0.0028$, and $\widehat{\alpha}(M_Z)^{-1} = 127.938 \pm 0.027$. The LEP averages of the ALEPH, DELPHI, L3, and OPAL results include common systematic errors and correlations [24,76]. The heavy flavour results of LEP and SLD are based on common inputs and correlated, as well [73]. $\bar{s}^2_\ell(A^{(0,q)}_{FB})$ is the effective angle extracted from the hadronic charge asymmetry. The values of $\Gamma(\ell^+\ell^-)$, Γ(had), and Γ(inv) are not independent of Γ_Z, the R_ℓ, and $\sigma_{\rm had}$. The first M_W value is from CDF, UA2, and DØ [101] while the second one is from LEP 2 [24]. The first M_W and M_Z are correlated, but the effect is negligible due to the tiny M_Z error. The three values of A_e are (i) from A_{LR} for hadronic final states [71]; (ii) from A_{LR} for leptonic final states and from polarized Bhabba scattering [75]; and (iii) from the angular distribution of the τ polarization. The two A_τ values are from SLD and the total τ polarization, respectively. The two values of R^ν from deep-inelastic scattering (DIS) are from CDHS [43] and CHARM [44], respectively; similarly, κ^ν (proportional to R^ν) is from CCFR [45]. The two values for $g^{\nu e}_{V,A}$ are from CHARM II [52] and the world average. The second errors in Q_W and DIS are theoretical. In the Standard Model predictions, the uncertainty is from M_Z, M_H, m_t, $\widehat{\alpha}(M_Z)^{-1}$, and α_s, and their correlations have been accounted for. The errors in Γ_Z, Γ(had), R_ℓ, and $\sigma_{\rm had}$ are largely dominated by the uncertainty in α_s.

Quantity	Value	Standard Model	Pull
m_t [GeV]	174.3 ± 5.1	172.9 ± 4.6	0.3
M_W [GeV]	80.448 ± 0.062	80.378 ± 0.020	1.1
	80.350 ± 0.056		−0.5
M_Z [GeV]	91.1872 ± 0.0021	91.1870 ± 0.0021	0.1

Γ(had) [GeV]	1.7439 ± 0.0020	1.7422 ± 0.0015	—
Γ(inv) [MeV]	498.8 ± 1.5	501.65 ± 0.15	—
$\Gamma(\ell^+\ell^-)$ [MeV]	83.96 ± 0.09	84.00 ± 0.03	—
$\sigma_{\rm had}$ [nb]	41.544 ± 0.037	41.480 ± 0.014	1.7
R_e	20.803 ± 0.049	20.740 ± 0.018	1.3
R_μ	20.786 ± 0.033	20.741 ± 0.018	1.4
R_τ	20.764 ± 0.045	20.786 ± 0.018	−0.5
R_b	0.21642 ± 0.00073	0.2158 ± 0.0002	0.9
R_c	0.1674 ± 0.0038	0.1723 ± 0.0001	−1.3
$A^{(0,e)}_{FB}$	0.0145 ± 0.0024	0.0163 ± 0.0003	−0.8
$A^{(0,\mu)}_{FB}$	0.0167 ± 0.0013		0.3
$A^{(0,\tau)}_{FB}$	0.0188 ± 0.0017		1.5
$A^{(0,b)}_{FB}$	0.0988 ± 0.0020	0.1034 ± 0.0009	−2.3
$A^{(0,c)}_{FB}$	0.0692 ± 0.0037	0.0739 ± 0.0007	−1.3
$A^{(0,s)}_{FB}$	0.0976 ± 0.0114	0.1035 ± 0.0009	−0.5
$\bar{s}^2_\ell(A^{(0,q)}_{FB})$	0.2321 ± 0.0010	0.2315 ± 0.0002	0.6

Despite these discrepancies the goodness of the fit to all data is reasonable with a χ^2/d.o.f. $= 42/37$. The probability of a larger χ^2 is 27%. The observables in Table 10.4, as well as some other less precise observables, are used in the global fits described below. The correlations on the LEP lineshape, the LEP/SLD heavy flavor, and the deep inelastic scattering observables, are included. There are also small correlations between some of the SLD measurements, and between the two observables from the τ polarization at LEP, which have not been fully investigated, yet.

The data allow a simultaneous determination of M_H, m_t, $\sin^2\theta_W$, and the strong coupling $\alpha_s(M_Z)$. ($\Delta\alpha^{(5)}_{\rm had}$ is also allowed to float in the fits, subject to the theoretical constraints [9] described in

Table 10.4: (continued)

Quantity	Value	Standard Model	Pull

elastic $\nu_\mu(\overline{\nu_\mu})p$	0.211(32)	0.203(32)	0.1200 (†)	100 (†)

Sec. 10.2.) α_s is determined mainly from R_ℓ, Γ_Z, and $\sigma_{\rm had}$, and is only weakly correlated with the other variables. The global fit to all data, including the CDF/DØ value, $m_t = 174.3 \pm 5.1$ GeV, yields

$$\begin{aligned} M_H &= 98^{+57}_{-38}\ \text{GeV}\ , \\ m_t &= 172.9 \pm 4.6\ \text{GeV}\ , \\ \widehat{s}^2_Z &= 0.23117 \pm 0.00016\ , \\ \alpha_s(M_Z) &= 0.1192 \pm 0.0028\ . \end{aligned} \tag{10.44}$$

In the on-shell scheme one has $s^2_W = 0.22302 \pm 0.00040$, the larger error due to the stronger sensitivity to m_t, while the corresponding effective angle is related by Eq. (10.34), *i.e.*, $\bar{s}^2_\ell = 0.23147 \pm 0.00016$. In all fits, the errors include full statistical, systematic, and theoretical uncertainties. The $\hat{s}^2_Z$ ($\bar{s}^2_\ell$) error reflects the error on $\bar{s}^2_f = 0.23151 \pm 0.00017$ from a fit to the Z pole asymmetries.

The weak mixing angle can be determined from Z pole observables, M_W, and from a variety of neutral-current processes spanning a very wide Q^2 range. The results (for the older low-energy neutral-current data see [25,26]) shown in Table 10.5, are in reasonable agreement with each other, indicating the quantitative success of the Standard Model. The largest discrepancy is the value $\hat{s}^2_Z = 0.23204 \pm 0.00034$ from the forward-backward asymmetries into bottom and charm quarks combined with M_Z, which is 2.6 σ above the value 0.23117 ± 0.00016 from the global fit to all data. Similarly, the SLD asymmetries, when combined with M_Z, yield $\hat{s}^2_Z = 0.23070 \pm 0.00028$, which is 1.7 σ low. The new value of Q_W from atomic parity violation corresponds (for $M_H = 100$ GeV) to $\hat{s}^2_Z = 0.2269 \pm 0.0018$, which is 2.4 σ low.

The extracted value of $\alpha_s(M_Z)$ is based on a formula with negligible theoretical uncertainty (± 0.0005 in $\alpha_s(M_Z)$) if one assumes the exact validity of the Standard Model. It is in excellent agreement with other precise values, such as 0.1202 ± 0.0027 (ALEPH) and 0.1219 ± 0.0020 (OPAL) from τ decays [104], 0.120 ± 0.005 from jet-event shapes in e^+e^- annihilation, 0.119 ± 0.002 (exp) ± 0.004 (scale) from deep-inelastic scattering [105], and 0.1174 ± 0.0024 ($b\bar{b}$) [106] and 0.116 ± 0.003 ($c\bar{c}$) [107] from lattice calculations of quarkonium spectra. The results from the τ lifetime have been converted from the 3-flavor definition, $\alpha_s^{(3)}(m_\tau) = 0.334 \pm 0.022$ (ALEPH) and $\alpha_s^{(3)}(m_\tau) = 0.348 \pm 0.021$ (OPAL), to the 5-flavor definition at the Z scale using the four-loop QCD β-function [108] with three-loop matching [109]. We note, that this introduces an asymmetric error (the lower error bar being larger), and that the quoted OPAL error for $\alpha_s^{(5)}(M_Z)$ is slightly underestimated given their result for $\alpha_s^{(3)}(m_\tau)$. For more details, see our Section 9 on "Quantum Chromodynamics" in this *Review*. The average $\alpha_s(M_Z)$ obtained from Section 9 when ignoring the precision measurements discussed in this Section is 0.1182 ± 0.0013. We use this value as an external constraint for the second fit in Table 10.5. The resulting value, $\alpha_s(M_Z) = 0.1184 \pm 0.0012$, can be regarded as the present world average. One should keep in mind, however, that the Z lineshape value of α_s is very sensitive to many types of new physics.

The data indicate a preference for a small Higgs mass. There is a strong correlation between the quadratic m_t and logarithmic M_H terms in $\hat{\rho}$ in all of the indirect data except for the $Z \to b\bar{b}$ vertex. Therefore, observables (other than R_b) which favor m_t values higher than the Tevatron range favor lower values of M_H. This effect is enhanced by R_b, which has little direct M_H dependence but favors the lower end of the Tevatron m_t range. M_W has additional M_H dependence through $\Delta\hat{r}_W$ which is not coupled to m_t^2 effects. The strongest individual pulls towards smaller M_H are from M_W and A^0_{LR}. The difference in χ^2 for the global fit is $\Delta\chi^2 = \chi^2(M_H = 1000 \text{ GeV}) - \chi^2_{\min} = 30.4$. Hence, the data favor a small value of M_H, as in supersymmetric extensions of the Standard Model, and m_t on the lower side of the Tevatron range. The central value of the global fit result, $M_H = 98^{+57}_{-38}$ GeV, is close to the present kinematic reach at LEP 2, and slightly above the direct lower bound, $M_H \geq 95.2$ GeV (95% CL) [110].

The 90% central confidence range from all precision data is

$$42 \text{ GeV} \leq M_H \leq 201 \text{ GeV} .$$

Including the results of the direct searches as an extra contribution to the likelihood function drives the 95% upper limit to $M_H \leq 231$ GeV. As two further refinements, we account for (i) theoretical uncertainties from uncalculated higher order contributions by allowing the T parameter (see next subsection) subject to the constraint $T = 0 \pm 0.02$, (ii) the M_H dependence of the correlation matrix which gives slightly more weight to lower Higgs masses [112]. The resulting limits at 95 (90, 99)% CL are

$$M_H \leq 235 \; (205, 306) \text{ GeV} ,$$

respectively. The extraction of M_H from the precision data depends strongly on the value used for $\alpha(M_Z)$. Upper limits, however, are more robust due to two compensating effects: the older results indicated more QED running and were less precise, yielding M_H distributions which were broader with centers shifted to smaller values.

One can also carry out a fit to the indirect data alone, *i.e.*, without including the value, $m_t = 174.3 \pm 5.1$ GeV, observed directly by CDF and DØ. (The indirect prediction is for the $\overline{\text{MS}}$ mass, $\hat{m}_t(\hat{m}_t) = 158.7^{+9.1}_{-7.0}$ GeV, which is in the end converted to the pole mass using a BLM optimized [113] version of the two-loop perturbative QCD formula [114]; this should correspond approximately to the kinematic mass extracted from the collider events.) One obtains $m_t = 168.2^{+9.6}_{-7.4}$ GeV, with little change in the $\sin^2\theta_W$ and α_s values, in remarkable agreement with the direct CDF/DØ value. The central M_H value of this fit (see the third line of Table 10.5) is below the direct lower bound; keeping $M_H = 100$ GeV fixed results in $m_t = 172.2 \pm 4.0$ GeV in even better agreement. The relations between M_H and m_t for various observables are shown in Fig. 10.1.

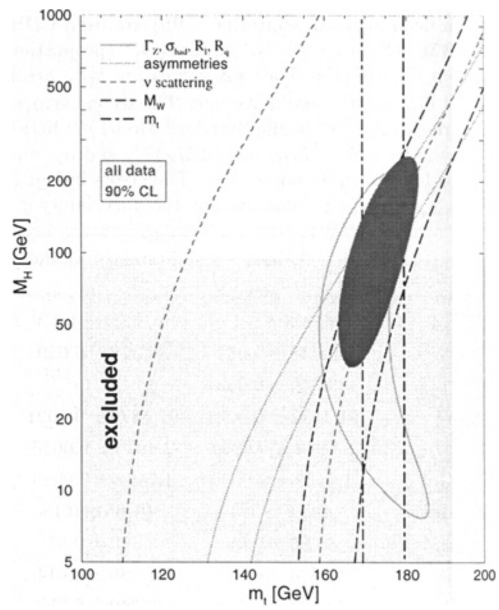

Figure 10.1: One-standard-deviation (39.35%) uncertainties in M_H as a function of m_t for various inputs, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data. $\alpha_s(M_Z) = 0.120$ is assumed except for the fit to all data. The 95% direct lower limit from LEP 2 is also shown.

Using $\alpha(M_Z)$ and $\hat{s}^2_Z$ as inputs, one can predict $\alpha_s(M_Z)$ assuming grand unification. One predicts [115] $\alpha_s(M_Z) = 0.130 \pm 0.001 \pm 0.01$ for the simplest theories based on the minimal supersymmetric extension of the Standard Model, where the first (second) uncertainty is from the inputs (thresholds). This is slightly larger, but consistent with the experimental $\alpha_s(M_Z) = 0.1192 \pm 0.0028$ from the Z lineshape, and with the world average 0.1184 ± 0.0012. Nonsupersymmetric unified theories predict the low value $\alpha_s(M_Z) = 0.073 \pm 0.001 \pm 0.001$. See also the note on "Low-Energy Supersymmetry" in the Particle Listings.

One can also determine the radiative correction parameters Δr: from the global fit one obtains $\Delta r = 0.0354 \pm 0.0012$ and $\Delta\hat{r}_W = 0.0694 \pm 0.0004$. M_W measurements [24,101] (when combined with M_Z) are equivalent to measurements of $\Delta r = 0.0345 \pm 0.0025$, in excellent agreement with the result from all indirect data, $\Delta r = 0.0357 \pm 0.0014$. Fig. 10.2 shows the 1 σ contours in the $M_W - m_t$ plane from the direct and indirect determinations, as well as the combined 90% CL region. The indirect determination uses M_Z from LEP 1 as input, which is defined assuming an s-dependent decay width. M_W then corresponds to the s-dependent width definition, as well, and can be directly compared with the results from the Tevatron and LEP 2 which have been obtained using the same definition. The difference to a constant width definition is formally only of $\mathcal{O}(\alpha^2)$, but is strongly enhanced since the decay channels add up coherently. It is about 34 MeV for M_Z and 27 MeV for M_W. The residual difference between working consistently with one or the other definition is about 3 MeV, *i.e.*, of typical size for non-enhanced (and generally uncalculated) $\mathcal{O}(\alpha^2)$ corrections.

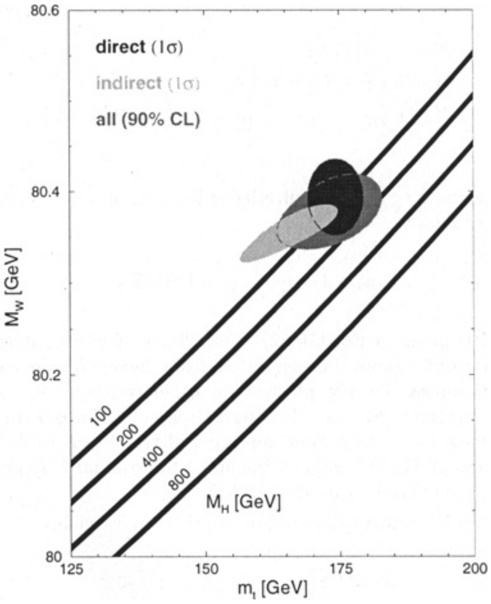

Figure 10.2: One-standard-deviation (39.35%) region in M_W as a function of m_t for the direct and indirect data, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data. The Standard Model prediction as a function of M_H is also indicated. The widths of the M_H bands reflect the theoretical uncertainty from $\alpha(M_Z)$ for $\alpha_s(M_Z) = 0.120$.

Most of the parameters relevant to ν-hadron, ν-e, e-hadron, and e^+e^- processes are determined uniquely and precisely from the data in "model independent" fits (*i.e.*, fits which allow for an arbitrary electroweak gauge theory). The values for the parameters defined in Eqs. (10.11)–(10.13) are given in Table 10.6 along with the predictions of the Standard Model. The agreement is reasonable. The low-energy e^+e^- results are difficult to present in a model-independent way because Z propagator effects are non-negligible at TRISTAN, PETRA, and PEP energies. However, assuming e-μ-τ universality, the lepton asymmetries imply [69] $4(g_A^e)^2 = 0.99 \pm 0.05$, in good agreement with the Standard Model prediction $\simeq 1$.

The results presented here are generally in reasonable agreement with the ones obtained by the LEP Electroweak Working Group [24,76]. We obtain slightly higher best fit values for α_s and M_H. We could trace most of the differences to be due to (i) the inclusion of recent higher order radiative corrections, in particular, the leading $\mathcal{O}(\alpha_s^4)$ contribution to hadronic Z decays [111]; (ii) a different evaluation of $\alpha(M_Z)$ [9]; (iii) slightly different data sets; and (iv) scheme dependences. Taking into account these differences, the agreement is excellent.

10.6. Constraints on new physics

The Z pole, W mass, and neutral-current data can be used to search for and set limits on deviations from the Standard Model. In particular, the combination of these indirect data with the direct CDF and DØ value for m_t allows to set stringent limits on new physics. We will mainly discuss the effects of exotic particles (with heavy masses $M_{\rm new} \gg M_Z$ in an expansion in $M_Z/M_{\rm new}$) on the gauge boson self-energies. (Brief remarks are made on new physics which is not of this type.) Most of the effects on precision measurements can be described by three gauge self-energy parameters S, T, and U. We will define these, as well as related parameters, such as ρ_0, ϵ_i, and $\widehat{\epsilon}_i$, to arise from new physics only. *I.e.*, they are equal to zero ($\rho_0 = 1$) exactly in the Standard Model, and do not include any contributions from m_t or M_H, which are treated separately. Our treatment differs from most of the original papers.

Many extensions of the Standard Model are described by the ρ_0 parameter,

$$\rho_0 \equiv M_W^2/(M_Z^2\,\widehat{c}_Z^{\,2}\,\widehat{\rho}) \ , \qquad (10.45)$$

which describes new sources of SU(2) breaking that cannot be accounted for by the Standard Model Higgs doublet or m_t effects. In the presence of $\rho_0 \neq 1$, Eq. (10.45) generalizes Eq. (10.8*b*), while Eq. (10.8*a*) remains unchanged. Provided that the new physics which yields $\rho_0 \neq 1$ is a small perturbation which does not significantly affect the radiative corrections, ρ_0 can be regarded as a phenomenological parameter which multiplies G_F in Eqs. (10.11)–(10.13), (10.28), and Γ_Z in Eq. (10.41). There is enough data to determine ρ_0, M_H, m_t, and α_s, simultaneously. From the global fit,

$$\rho_0 = 0.9998^{+0.0011}_{-0.0006} \ , \qquad (10.46)$$

$$95 \text{ GeV} < M_H < 211 \text{ GeV} \ , \qquad (10.47)$$

$$m_t = 173.6 \pm 4.9 \text{ GeV} \ , \qquad (10.48)$$

$$\alpha_s(M_Z) = 0.1194 \pm 0.0028 \ , \qquad (10.49)$$

where the lower limit on M_H is the direct search bound. (If the direct limit is ignored one obtains $M_H = 72^{+125}_{-36}$ and $\rho_0 = 0.9995^{+0.0013}_{-0.0009}$). The error bar in Eq. (10.46) is highly asymmetric: at the 2 σ level one has $\rho_0 = 0.9998^{+0.0034}_{-0.0012}$ and $M_H < 1002$ GeV. Clearly, in the presence of ρ_0 upper limits on M_H become very weak.

The result in Eq. (10.46) is in remarkable agreement with the Standard Model expectation, $\rho_0 = 1$. It can be used to constrain higher-dimensional Higgs representations to have vacuum expectation values of less than a few percent of those of the doublets. Indeed, the relation between M_W and M_Z is modified if there are Higgs multiplets with weak isospin > 1/2 with significant vacuum expectation values. In order to calculate to higher orders in such theories one must define a set of four fundamental renormalized parameters which one may

Table 10.6: Values of the model-independent neutral-current parameters, compared with the Standard Model predictions for the global best fit values $M_Z = 91.1870 \pm 0.0021$ GeV, $M_H = 98^{+57}_{-38}$ GeV, $m_t = 172.9 \pm 4.6$ GeV, $\alpha_s(M_Z) = 0.1192 \pm 0.0028$, and $\widehat{\alpha}(M_Z)^{-1} = 127.938 \pm 0.027$. There is a second $g_{V,A}^{\nu e}$ solution, given approximately by $g_V^{\nu e} \leftrightarrow g_A^{\nu e}$, which is eliminated by e^+e^- data under the assumption that the neutral current is dominated by the exchange of a single Z. The ϵ_L, as well as the ϵ_R, are strongly correlated and non-Gaussian, so that for implementations we recommend the parametrization using g_i and $\theta_i = \tan^{-1}[\epsilon_i(u)/\epsilon_i(d)]$, $i = L$ or R. θ_R is only weakly correlated with the g_i, while the correlation coefficient between θ_R and θ_L is 0.27.

Quantity	Experimental Value	Standard Model Prediction	Correlation	
$\epsilon_L(u)$	0.330 ± 0.016	0.3459 ± 0.0002		
$\epsilon_L(d)$	-0.439 ± 0.011	-0.4291 ± 0.0002		non-
$\epsilon_R(u)$	$-0.176\ ^{+0.014}_{-0.006}$	-0.1550 ± 0.0001		Gaussian
$\epsilon_R(d)$	$-0.023\ ^{+0.070}_{-0.047}$	0.0776		
g_L^2	0.3020 ± 0.0019	0.3038 ± 0.0003	0.32	−0.39
g_R^2	0.0315 ± 0.0016	0.0301		−0.10
θ_L	2.50 ± 0.034	2.4631 ± 0.0001		
θ_R	$4.58\ ^{+0.40}_{-0.27}$	5.1765		
$g_V^{\nu e}$	-0.041 ± 0.015	-0.0397 ± 0.0003		−0.04
$g_A^{\nu e}$	-0.507 ± 0.014	-0.5064 ± 0.0001		
C_{1u}	-0.211 ± 0.041	-0.1886 ± 0.0002	−0.9996	−0.78
C_{1d}	0.359 ± 0.037	0.3413 ± 0.0002		0.78
$C_{2u} - \frac{1}{2}C_{2d}$	-0.04 ± 0.12	-0.0491 ± 0.0005		

conveniently choose to be α, G_F, M_Z, and M_W, since M_W and M_Z are directly measurable. Then $\widehat{s}^2_Z$ and ρ_0 can be considered dependent parameters.

Eq. (10.46) can also be used to constrain other types of new physics. For example, nondegenerate multiplets of heavy fermions or scalars break the vector part of weak SU(2) and lead to a decrease in the value of M_Z/M_W. A nondegenerate SU(2) doublet $\binom{f_1}{f_2}$ yields a positive contribution to ρ_0 [116] of

$$\frac{CG_F}{8\sqrt{2}\pi^2}\Delta m^2 \;, \tag{10.50}$$

where

$$\Delta m^2 \equiv m_1^2 + m_2^2 - \frac{4m_1^2 m_2^2}{m_1^2 - m_2^2}\ln\frac{m_1}{m_2} \geq (m_1 - m_2)^2 \;, \tag{10.51}$$

and $C = 1$ (3) for color singlets (triplets). Thus, in the presence of such multiplets, one has

$$\frac{3G_F}{8\sqrt{2}\pi^2}\sum_i \frac{C_i}{3}\,\Delta m_i^2 = \rho_0 - 1 \;, \tag{10.52}$$

where the sum includes fourth-family quark or lepton doublets, $\binom{t'}{b'}$ or $\binom{E^0}{E^-}$, and scalar doublets such as $\binom{\tilde{t}}{\tilde{b}}$ in supersymmetry (in the absence of $L - R$ mixing). This implies

$$\sum_i \frac{C_i}{3}\,\Delta m_i^2 \leq (100\ \text{GeV})^2 \tag{10.53}$$

at 95% CL. The corresponding constraints on nondegenerate squark and slepton doublets are even stronger, $\Delta m_i^2 \leq (69\ \text{GeV})^2$. This is due to the MSSM Higgs mass bound, $m_{h^0} < 150$ GeV, and the strong correlation between m_{h^0} and ρ_0 (81%).

Nondegenerate multiplets usually imply $\rho_0 > 1$. Similarly, heavy Z' bosons decrease the prediction for M_Z due to mixing and generally lead to $\rho_0 > 1$ [117]. On the other hand, additional Higgs doublets which participate in spontaneous symmetry breaking [118], heavy lepton doublets involving Majorana neutrinos [119], and the vacuum expectation values of Higgs triplets or higher-dimensional representations can contribute to ρ_0 with either sign. Allowing for the presence of heavy degenerate chiral multiplets (the S parameter, to be discussed below) affects the determination of ρ_0 from the data, at present leading to a smaller value (for fixed M_H).

A number of authors [120–125] have considered the general effects on neutral current and Z and W boson observables of various types of heavy (*i.e.*, $M_{\text{new}} \gg M_Z$) physics which contribute to the W and Z self-energies but which do not have any direct coupling to the ordinary fermions. In addition to nondegenerate multiplets, which break the vector part of weak SU(2), these include heavy degenerate multiplets of chiral fermions which break the axial generators. The effects of one degenerate chiral doublet are small, but in technicolor theories there may be many chiral doublets and therefore significant effects [120].

Such effects can be described by just three parameters, S, T, and U at the (electroweak) one loop level. (Three additional parameters are needed if the new physics scale is comparable to M_Z [126].) T is proportional to the difference between the W and Z self-energies at $Q^2 = 0$ (*i.e.*, vector SU(2)-breaking), while S ($S + U$) is associated with the difference between the Z (W) self-energy at $Q^2 = M^2_{Z,W}$ and $Q^2 = 0$ (axial SU(2)-breaking). Denoting the contributions of new physics to the various self-energies by Π^{new}_{ij}, we have

$$\widehat{\alpha}(M_Z)T \equiv \frac{\Pi^{\text{new}}_{WW}(0)}{M_W^2} - \frac{\Pi^{\text{new}}_{ZZ}(0)}{M_Z^2} \;, \tag{10.54a}$$

$$\frac{\widehat{\alpha}(M_Z)}{4\widehat{s}^2_Z\widehat{c}^2_Z}S \equiv \frac{\Pi^{\text{new}}_{ZZ}(M_Z^2) - \Pi^{\text{new}}_{ZZ}(0)}{M_Z^2} - \frac{\widehat{c}^2_Z - \widehat{s}^2_Z}{\widehat{c}_Z\widehat{s}_Z}\frac{\Pi^{\text{new}}_{Z\gamma}(M_Z^2)}{M_Z^2} - \frac{\Pi^{\text{new}}_{\gamma\gamma}(M_Z^2)}{M_Z^2} \;, \tag{10.54b}$$

$$\frac{\widehat{\alpha}(M_Z)}{4\widehat{s}^2_Z}(S + U) \equiv \frac{\Pi^{\text{new}}_{WW}(M_W^2) - \Pi^{\text{new}}_{WW}(0)}{M_W^2} - \frac{\widehat{c}_Z}{\widehat{s}_Z}\frac{\Pi^{\text{new}}_{Z\gamma}(M_Z^2)}{M_Z^2} - \frac{\Pi^{\text{new}}_{\gamma\gamma}(M_Z^2)}{M_Z^2} \;. \tag{10.54c}$$

S, T, and U are defined with a factor proportional to $\widehat{\alpha}$ removed, so that they are expected to be of order unity in the presence of new physics. In the $\overline{\text{MS}}$ scheme as defined in Ref. [29], the last two terms in Eq. (10.54*b*) and Eq. (10.54*c*) can be omitted (as was done in earlier editions of this *Review*). They are related to other parameters (S_i, h_i, $\widehat{\epsilon}_i$) defined in [29,121,122] by

$$\begin{aligned} T &= h_V = \widehat{\epsilon}_1/\alpha \;, \\ S &= h_{AZ} = S_Z = 4\widehat{s}^2_Z\widehat{\epsilon}_3/\alpha \;, \\ U &= h_{AW} - h_{AZ} = S_W - S_Z = -4\widehat{s}^2_Z\widehat{\epsilon}_2/\alpha \;. \end{aligned} \tag{10.55}$$

A heavy nondegenerate multiplet of fermions or scalars contributes positively to T as

$$\rho_0 - 1 = \frac{1}{1 - \alpha T} - 1 \simeq \alpha T \;, \tag{10.56}$$

where ρ_0 is given in Eq. (10.52). The effects of nonstandard Higgs representations cannot be separated from heavy nondegenerate multiplets unless the new physics has other consequences, such as vertex corrections. Most of the original papers defined T to include the effects of loops only. However, we will redefine T to include all new sources of SU(2) breaking, including nonstandard Higgs, so that T and ρ_0 are equivalent by Eq. (10.56).

A multiplet of heavy degenerate chiral fermions yields

$$S = C\sum_i\Big(t_{3L}(i) - t_{3R}(i)\Big)^2/3\pi \;, \tag{10.57}$$

where $t_{3L,R}(i)$ is the third component of weak isospin of the left- (right-) handed component of fermion i and C is the number of colors. For example, a heavy degenerate ordinary or mirror family would contribute $2/3\pi$ to S. In technicolor models with QCD-like dynamics, one expects [120] $S \sim 0.45$ for an isodoublet of technifermions, assuming $N_{TC} = 4$ technicolors, while $S \sim 1.62$ for a full technigeneration with $N_{TC} = 4$; T is harder to estimate because it is model dependent. In these examples one has $S \geq 0$. However, the QCD-like models are excluded on other grounds (flavor-changing neutral currents, and too-light quarks and pseudo-Goldstone bosons [127]). In particular, these estimates do not apply to models of walking technicolor [127], for which S can be smaller or even negative [128]. Other situations in which $S < 0$, such as loops involving scalars or Majorana particles, are also possible [129]. Supersymmetric extensions of the Standard Model generally give very small effects [130]. Most simple types of new physics yield $U = 0$, although there are counter-examples, such as the effects of anomalous triple-gauge vertices [122].

The Standard Model expressions for observables are replaced by

$$\begin{aligned} M_Z^2 &= M_{Z0}^2\,\frac{1 - \alpha T}{1 - G_F M_{Z0}^2 S/2\sqrt{2}\pi} \;, \\ M_W^2 &= M_{W0}^2\,\frac{1}{1 - G_F M_{W0}^2(S + U)/2\sqrt{2}\pi} \;, \end{aligned} \tag{10.58}$$

where M_{Z0} and M_{W0} are the Standard Model expressions (as functions of m_t and M_H) in the $\overline{\text{MS}}$ scheme. Furthermore,

$$\begin{aligned} \Gamma_Z &= \frac{1}{1 - \alpha T}M_Z^3\beta_Z \;, \\ \Gamma_W &= M_W^3\beta_W \;, \\ A_i &= \frac{1}{1 - \alpha T}A_{i0} \;, \end{aligned} \tag{10.59}$$

where β_Z and β_W are the Standard Model expressions for the reduced widths Γ_{Z0}/M_{Z0}^3 and Γ_{W0}/M_{W0}^3, M_Z and M_W are the physical masses, and A_i (A_{i0}) is a neutral current amplitude (in the Standard Model).

The data allow a simultaneous determination of $\widehat{s}^2_Z$ (from the Z pole asymmetries), S (from M_Z), U (from M_W), T (mainly from

Γ_Z), α_s (from R_ℓ and σ_{had}), and m_t (from CDF and DØ), with little correlation among the Standard Model parameters:

$$\begin{aligned} S &= -0.07 \pm 0.11\,(-0.09)\,, \\ T &= -0.10 \pm 0.14\,(+0.09)\,, \\ U &= 0.11 \pm 0.15\,(+0.01)\,, \end{aligned} \tag{10.60}$$

and $\hat{s}^2_Z = 0.23117 \pm 0.00017$, $\alpha_s(M_Z) = 0.1203 \pm 0.0031$, $m_t = 173.4 \pm 4.9$ GeV, where the uncertainties are from the inputs. The central values assume $M_H = 100$ GeV, and in parentheses we show the change for $M_H = 300$ GeV. As can be seen, the Standard Model parameters (U) can be determined with no (little) M_H dependence. On the other hand, S, T, and M_H cannot be obtained simultaneously, because the Higgs boson loops themselves are resembled approximately by oblique effects. The first Eq. (10.60) shows that negative contributions to the S parameter can weaken or entirely remove the strong constraints on M_H from the Standard Model fits. The parameters in Eqs. (10.60) which by definition are due to new physics only, are all consistent with the Standard Model values of zero. Using Eq. (10.56) the value of ρ_0 corresponding to T is $0.9992 \pm 0.0011\,(+0.0007)$. The values of the $\hat{\epsilon}$ parameters defined in Eq. (10.55) are

$$\begin{aligned} \hat{\epsilon}_3 &= -0.0006 \pm 0.0009\,(-0.0008)\,, \\ \hat{\epsilon}_1 &= -0.0008 \pm 0.0011\,(+0.0007)\,, \\ \hat{\epsilon}_2 &= -0.0009 \pm 0.0013\,(-0.0001)\,. \end{aligned} \tag{10.61}$$

Unlike the original definition, we defined the quantities in Eqs. (10.61) to vanish identically in the absence of new physics and to correspond directly to the parameters S, T, and U in Eqs. (10.60). There is a strong correlation (81%) between the S and T parameters. The allowed region in $S - T$ is shown in Fig. 10.3. From Eqs. (10.60) one obtains $S \leq 0.11\,(0.01)$ and $T \leq 0.13\,(0.22)$ at 95% CL for $M_H = 100$ GeV (300 GeV). If one fixes $M_H = 600$ GeV and requires the constraint $S \geq 0$ (as is appropriate in QCD-like technicolor models) then $S \leq 0.09$. This rules out simple technicolor models with many techni-doublets and QCD-like dynamics.

An extra generation of ordinary fermions is excluded at the 99.6% CL on the basis of the S parameter alone. This result assumes that there are no new contributions to T or U. Allowing a contribution of 0.18 ± 0.08 to T reduces the CL to 97%. This is in agreement with a fit to the number of light neutrinos, $N_\nu = 2.985 \pm 0.008$ (which favors a larger value for $\alpha_s(M_Z) = 0.1229 \pm 0.0034$ mainly from R_ℓ). However, the S parameter fit is valid even for a very heavy fourth family neutrino.

Although S is consistent with zero, the electroweak asymmetries, especially the SLD left-right asymmetry and Q_W, favor $S < 0$. The simplest origin of $S < 0$ would probably be an additional heavy Z' boson [117], which could mimic $S < 0$. Similarly, there is a slight indication of negative T, while, as discussed above, nondegenerate scalar or fermion multiplets generally predict $T > 0$.

There is no simple parametrization that is powerful enough to describe the effects of every type of new physics on every possible observable. The S, T, and U formalism describes many types of heavy physics which affect only the gauge self-energies, and it can be applied to all precision observables. However, new physics which couples directly to ordinary fermions, such as heavy Z' bosons [117] or mixing with exotic fermions [131] cannot be fully parametrized in the S, T, and U framework. It is convenient to treat these types of new physics by parametrizations that are specialized to that particular class of theories (*e.g.*, extra Z' bosons), or to consider specific models (which might contain, *e.g.*, Z' bosons and exotic fermions with correlated parameters). Constraints on various types of new physics are reviewed in [26,132,133]. Fits to models with technicolor, extended technicolor, and supersymmetry are described, respectively, in [134], [135], and [86,136]. In a new development, the effects of compactified extra spatial dimensions at the TeV scale have been considered in Ref. 137.

An alternate formalism [138] defines parameters, ϵ_1, ϵ_2, ϵ_3, ϵ_b in terms of the specific observables M_W/M_Z, $\Gamma_{\ell\ell}$, $A^{(0,\ell)}_{FB}$, and R_b.

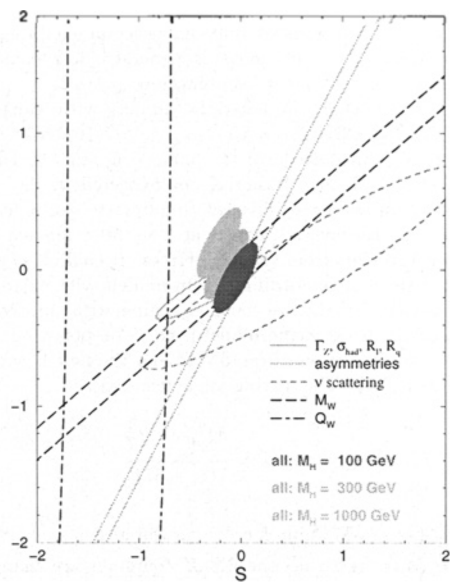

Figure 10.3: 1 σ constraints (39.35%) on S and T from various inputs. S and T represent the contributions of new physics only. (Uncertainties from m_t are included in the errors.) The contours assume $M_H = 100$ GeV except for the central and upper 90% CL contours allowed by all data, which are for $M_H = 300$ GeV and 1000 GeV, respectively. Data sets not involving M_W are insensitive to U. Due to higher order effects, however, $U = 0$ has to be assumed in all fits. $\alpha_s(M_Z) = 0.120$ is assumed for the 1 σ constraints, while in the fits to all data α_s is allowed to float.

The definitions coincide with those for $\hat{\epsilon}_i$ in Eqs. (10.54) and (10.55) for physics which affects gauge self-energies only, but the ϵ's now parametrize arbitrary types of new physics. However, the ϵ's are not related to other observables unless additional model-dependent assumptions are made. Another approach [139–141] parametrizes new physics in terms of gauge-invariant sets of operators. It is especially powerful in studying the effects of new physics on non-Abelian gauge vertices. The most general approach introduces deviation vectors [132]. Each type of new physics defines a deviation vector, the components of which are the deviations of each observable from its Standard Model prediction, normalized to the experimental uncertainty. The length (direction) of the vector represents the strength (type) of new physics.

Table 10.7: 95% CL lower mass limits (in GeV) on various extra Z' bosons, appearing in models of unification and string theory. ρ_0 free indicates a completely arbitrary Higgs sector, while $\rho_0 = 1$ restricts to Higgs doublets and singlets with still unspecified charges.

Z'	ρ_0 free	$\rho_0 = 1$
Z_χ	551	545
Z_ψ	151	146
Z_η	379	365
Z_{LR}	570	564
Z_{SM}	822	809
Z_{string}	582	578

One of the best motivated kinds of physics beyond the Standard Model besides supersymmetry are extra Z' bosons. They do not spoil the observed approximate gauge coupling unification, and appear copiously in many Grand Unified Theories (GUTs) and most superstring models. For example, the $SO(10)$ GUT contains an extra $U(1)$ as can be seen from its maximal subgroup,

$SU(5) \times U(1)_\chi$. Similarly, the E_6 GUT contains the subgroup $SO(10) \times U(1)_\psi$. It possesses only axial-vector couplings to the ordinary fermions, and its mass is generally less constrained. The Z_η boson is the linear combination $\sqrt{3/8}\,Z_\chi - \sqrt{5/8}\,Z_\psi$. The Z_{LR} boson occurs in left-right models with gauge group $SU(3)_C \times SU(2)_L \times SU(2)_R \times U(1)_{B-L} \subset SO(10)$. The sequential Z_{SM} boson is defined to have the same couplings to fermions as the SM Z boson. Such a boson is not expected in the context of gauge theories unless it has different couplings to exotic fermions than the ordinary Z. However, it serves as a useful reference case when comparing constraints from various sources. It could also play the role of an excited state of the ordinary Z in models with extra dimensions at the weak scale. Finally, we consider a superstring motivated Z_{string} boson appearing in a specific model [142]. The potential Z' boson is in general a superposition of the SM Z and the new boson associated with the extra $U(1)$. The mixing angle θ satisfies,

$$\tan^2\theta = \frac{M_{Z_1^0}^2 - M_Z^2}{M_{Z'}^2 - M_{Z_1^0}^2},$$

where $M_{Z_1^0}$ is the SM value for M_Z in the absence of mixing. Note, that $M_Z < M_{Z_1^0}$, and that the SM Z couplings are changed by the mixing. If the Higgs $U(1)'$ quantum numbers are known, there will be an extra constraint,

$$\theta = C\frac{g_2}{g_1}\frac{M_Z^2}{M_{Z'}^2}, \tag{10.62}$$

where $g_{1,2}$ are the $U(1)$ and $U(1)'$ gauge couplings with $g_2 = \sqrt{\frac{5}{3}}\sin\theta_W\sqrt{\lambda}\,g_1$. $\lambda = 1$ (which we assume) if the GUT group breaks directly to $SU(3) \times SU(2) \times U(1) \times U(1)'$. C is a function of vacuum expectation values. For minimal Higgs sectors it can be found in reference [117]. Table 10.7 shows the 95% CL lower mass limits obtained from a somewhat earlier data set [143] for ρ_0 free and $\rho_0 = 1$, respectively. In cases of specific minimal Higgs sectors where C is known, the Z' mass limits are generally pushed into the TeV region. For more details see Ref. 143 and the Section on "The Z' Searches" in this *Review*. The more recent values for Q_W(Cs) and $\sigma_{\rm had}$ used in this Review modify the results and even suggest the possible existence of Z' [144].

11. THE CABIBBO-KOBAYASHI-MASKAWA QUARK-MIXING MATRIX

Revised 2000 by F.J. Gilman (Carnegie-Mellon University), K. Kleinknecht and B. Renk (Johannes-Gutenberg Universität Mainz).

In the Standard Model with SU(2) × U(1) as the gauge group of electroweak interactions, both the quarks and leptons are assigned to be left-handed doublets and right-handed singlets. The quark mass eigenstates are not the same as the weak eigenstates, and the matrix relating these bases was defined for six quarks and given an explicit parametrization by Kobayashi and Maskawa [1] in 1973. It generalizes the four-quark case, where the matrix is parametrized by a single angle, the Cabibbo angle [2].

By convention, the mixing is often expressed in terms of a 3 × 3 unitary matrix V operating on the charge $-e/3$ quark mass eigenstates (d, s, and b):

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix} . \qquad (11.1)$$

The values of individual matrix elements can in principle all be determined from weak decays of the relevant quarks, or, in some cases, from deep inelastic neutrino scattering. Using the constraints discussed below together with unitarity, and assuming only three generations, the 90% confidence limits on the magnitude of the elements of the complete matrix are

$$\begin{pmatrix} 0.9742 \text{ to } 0.9757 & 0.219 \text{ to } 0.226 & 0.002 \text{ to } 0.005 \\ 0.219 \text{ to } 0.225 & 0.9734 \text{ to } 0.9749 & 0.037 \text{ to } 0.043 \\ 0.004 \text{ to } 0.014 & 0.035 \text{ to } 0.043 & 0.9990 \text{ to } 0.9993 \end{pmatrix} . \qquad (11.2)$$

The ranges shown are for the individual matrix elements. The constraints of unitarity connect different elements, so choosing a specific value for one element restricts the range of others.

There are several parametrizations of the Cabibbo-Kobayashi-Maskawa (CKM) matrix. We advocate a "standard" parametrization [3] of V that utilizes angles θ_{12}, θ_{23}, θ_{13}, and a phase, δ_{13}

$$V = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta_{13}} \\ -s_{12}c_{23}-c_{12}s_{23}s_{13}e^{i\delta_{13}} & c_{12}c_{23}-s_{12}s_{23}s_{13}e^{i\delta_{13}} & s_{23}c_{13} \\ s_{12}s_{23}-c_{12}c_{23}s_{13}e^{i\delta_{13}} & -c_{12}s_{23}-s_{12}c_{23}s_{13}e^{i\delta_{13}} & c_{23}c_{13} \end{pmatrix} , \qquad (11.3)$$

with $c_{ij} = \cos\theta_{ij}$ and $s_{ij} = \sin\theta_{ij}$ for the "generation" labels $i, j = 1, 2, 3$. This has distinct advantages of interpretation, for the rotation angles are defined and labelled in a way that relates to the mixing of two specific generations and if one of these angles vanishes, so does the mixing between those two generations; in the limit $\theta_{23} = \theta_{13} = 0$ the third generation decouples, and the situation reduces to the usual Cabibbo mixing of the first two generations with θ_{12} identified with the Cabibbo angle [2]. The real angles θ_{12}, θ_{23}, θ_{13} can all be made to lie in the first quadrant by an appropriate redefinition of quark field phases.

The matrix elements in the first row and third column, which can be directly measured in decay processes, are all of a simple form, and, as c_{13} is known to deviate from unity only in the sixth decimal place, $V_{ud} = c_{12}$, $V_{us} = s_{12}$, $V_{ub} = s_{13}\, e^{-i\delta_{13}}$, $V_{cb} = s_{23}$, and $V_{tb} = c_{23}$ to an excellent approximation. The phase δ_{13} lies in the range $0 \le \delta_{13} < 2\pi$, with nonzero values generally breaking CP invariance for the weak interactions. The generalization to the n generation case contains $n(n-1)/2$ angles and $(n-1)(n-2)/2$ phases. The range of matrix elements in Eq. (11.2) corresponds to 90% CL limits on the sines of the angles of $s_{12} = 0.219$ to $0.226, s_{23} = 0.037$ to 0.043, and $s_{13} = 0.002$ to 0.005.

Kobayashi and Maskawa [1] originally chose a parametrization involving the four angles θ_1, θ_2, θ_3, and δ:

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} c_1 & -s_1c_3 & -s_1s_3 \\ s_1c_2 & c_1c_2c_3-s_2s_3e^{i\delta} & c_1c_2s_3+s_2c_3e^{i\delta} \\ s_1s_2 & c_1s_2c_3+c_2s_3e^{i\delta} & c_1s_2s_3-c_2c_3e^{i\delta} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix} , \qquad (11.4)$$

where $c_i = \cos\theta_i$ and $s_i = \sin\theta_i$ for $i = 1, 2, 3$. In the limit $\theta_2 = \theta_3 = 0$, this reduces to the usual Cabibbo mixing with θ_1 identified (up to a sign) with the Cabibbo angle [2]. Several different forms of the Kobayashi-Maskawa parametrization are found in the literature. Since all these parametrizations are referred to as "the" Kobayashi-Maskawa form, some care about which one is being used is needed when the quadrant in which δ lies is under discussion.

A popular approximation that emphasizes the hierarchy in the size of the angles, $s_{12} \gg s_{23} \gg s_{13}$, is due to Wolfenstein [4], where one sets $\lambda \equiv s_{12}$, the sine of the Cabibbo angle, and then writes the other elements in terms of powers of λ:

$$V \approx \begin{pmatrix} 1-\lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1-\lambda^2/2 & A\lambda^2 \\ A\lambda^3(1-\rho-i\eta) & -A\lambda^2 & 1 \end{pmatrix} . \qquad (11.5)$$

with A, ρ, and η real numbers that were intended to be of order unity.

More recently, another parametrization has been advocated [5]. It arises in many theories of quark masses and is particularly useful where one builds models in which initially $m_u = m_d = 0$ and there is no nontrivial phase in the CKM matrix. In this parametrization [5] no phases occur in the third row or third column of the CKM matrix, so that the CP-violating phase only occurs in the CKM matrix elements connecting first and second generation quarks. Consequently, the connection between measurements of CP-violating effects for B mesons and single CKM parameters is less obvious than in the standard parametrization.

No physics can depend on which of the above parametrizations (or any other) is used, as long as a single one is used consistently and care is taken to be sure that no other choice of phases is in conflict.

Our present knowledge of the matrix elements comes from the following sources:

(1)$|V_{ud}|$: Analyses have been performed comparing nuclear beta decays that proceed through a vector current to muon decay. Radiative corrections are essential to extracting the value of the matrix element. They already include [6] effects of order $Z\alpha^2$, and most of the theoretical argument centers on the nuclear mismatch and structure-dependent radiative corrections [7,8]. New data have been obtained on superallowed $0^+ \to 0^+$ beta decays [9].

Taking the complete data set, a value of $|V_{ud}| = 0.9740 \pm 0.0005$ has been obtained [10]. It has been argued [11] that the change in charge-symmetry-violation for quarks inside nucleons that are in nuclear matter results in an additional change in the predicted decay rate by 0.075 to 0.2%, leading to a systematic underestimate of $|V_{ud}|$. This reasoning has been used [12] to explain quantitatively the binding energy differences of the valence protons and neutrons of mirror nuclei. While it can be argued [10] that there may be double-counting of corrections, until this is settled, we take this correction as an additional uncertainty to obtain a value of $|V_{ud}| = 0.9740 \pm 0.0010$.

The theoretical uncertainties in extracting a value of $|V_{ud}|$ from neutron decays are significantly smaller than for decays of mirror nuclei, but the value depends on both the value of g_A/g_V and the neutron lifetime. Experimental progress has been made on the former quantity using very highly polarized cold neutrons together with improved detectors. Averaging over recent experiments [13] gives $g_A/g_V = -1.2715 \pm 0.0021$ and results in $|V_{ud}| = 0.9728 \pm 0.0012$ from neutron decay. Since most of the contributions to the errors in these two determinations of $|V_{ud}|$ are independent, we average them to obtain

$$|V_{ud}| = 0.9735 \pm 0.0008 \ . \qquad (11.6)$$

(2)$|V_{us}|$: Analysis of K_{e3} decays yields [14]

$$|V_{us}| = 0.2196 \pm 0.0023 \ . \qquad (11.7)$$

With isospin violation taken into account in K^+ and K^0 decays, the extracted values of $|V_{us}|$ are in agreement at the 1% level.

A reanalysis [8] obtains essentially the same value, but quotes a somewhat smaller error, which is only statistical. The analysis [15] of hyperon decay data has larger theoretical uncertainties because of first order SU(3) symmetry breaking effects in the axial-vector couplings. This has been redone incorporating second order SU(3) symmetry breaking corrections in models [16] applied to the WA2 data [17] to give a value of $|V_{us}| = 0.2176 \pm 0.0026$, which is consistent with Eq. (11.7) using the "best-fit" model. Since the values obtained in the models differ outside the errors and generally do not give good fits, we retain the value in Eq. (11.7) for $|V_{us}|$.

(3)$|V_{cd}|$: The magnitude of $|V_{cd}|$ may be deduced from neutrino and antineutrino production of charm off valence d quarks. The dimuon production cross sections of the CDHS group [18] yield $\overline{B}_c\,|V_{cd}|^2 = 0.41 \pm 0.07 \times 10^{-2}$, where $\overline{B}_c$ is the semileptonic branching fraction of the charmed hadrons produced. The corresponding value from the more recent CCFR Tevatron experiment [19], where a next-to-leading-order QCD analysis has been carried out, is $0.534 \pm 0.021^{+0.025}_{-0.051} \times 10^{-2}$, where the last error is from the scale uncertainty. Assuming a similar scale error for the CDHS result and averaging these two results gives $0.49 \pm 0.05 \times 10^{-2}$. Supplementing this with data [20] on the mix of charmed particle species produced by neutrinos and PDG values for their semileptonic branching fractions (to give [19] $\overline{B}_c = 0.099 \pm 0.012$) then yields

$$|V_{cd}| = 0.224 \pm 0.016 \ . \qquad (11.8)$$

(4)$|V_{cs}|$: Values of $|V_{cs}|$ from neutrino production of charm are dependent on assumptions about the strange-quark density in the parton sea. The most conservative assumption, that the strange-quark sea does not exceed the value corresponding to an SU(3)-symmetric sea, leads to a lower bound [18], $|V_{cs}| > 0.59$. It is more advantageous to proceed analogously to the method used for extracting $|V_{us}|$ from K_{e3} decay; namely, we compare the experimental value for the width of D_{e3} decay with the expression [21] that follows from the standard weak interaction amplitude:

$$\Gamma(D \to \overline{K}e^+\nu_e) = |f_+^D(0)|^2\,|V_{cs}|^2\,(1.54 \times 10^{11}\ \mathrm{s}^{-1}) \ . \qquad (11.9)$$

Here $f_+^D(q^2)$, with $q = p_D - p_K$, is the form factor relevant to D_{e3} decay; its variation has been taken into account with the parametrization $f_+^D(t)/f_+^D(0) = M^2/(M^2 - t)$ and $M = 2.1\ \mathrm{GeV}/c^2$, a form and mass consistent with direct measurements [22]. Combining data on branching fractions for D_{e3} decays with accurate values for the D lifetimes [22] yields a value of $(0.818 \pm 0.041) \times 10^{11}\ \mathrm{s}^{-1}$ for $\Gamma(D \to \overline{K}e^+\nu_e)$. Therefore

$$|f_+^D(0)|^2\,|V_{cs}|^2 = 0.531 \pm 0.027 \ . \qquad (11.10)$$

A very conservative assumption is that $|f_+^D(0)| < 1$, from which it follows that $|V_{cs}| > 0.62$. Calculations of the form factor either performed [23,24] directly at $q^2 = 0$, or done [25] at the maximum value of $q^2 = (m_D - m_K)^2$ and interpreted at $q^2 = 0$ using the measured q^2 dependence, give the value $f_+^D(0) = 0.7 \pm 0.1$. It follows that

$$|V_{cs}| = 1.04 \pm 0.16 \ . \qquad (11.11)$$

Recent measurements [26] of $|V_{cs}|$ in charmed-tagged W decays give a consistent result of $|V_{cs}| = 0.97 \pm 0.09$ (stat.) $\pm$ 0.07 (syst.). The constraint of unitarity when there are only three generations gives a much tighter bound (see below).

(5)$|V_{cb}|$: The heavy quark effective theory [27] (HQET) provides a nearly model-independent treatment of B semileptonic decays to charmed mesons, assuming that both the b and c quarks are heavy enough for the theory to apply. Measurements of the exclusive decay $B \to \overline{D}^*\ell^+\nu_\ell$ have been used primarily to extract a value of $|V_{cb}|$ using corrections based on the HQET. Exclusive $B \to \overline{D}\ell^+\nu_\ell$ decays give a consistent but less precise result. Analysis of inclusive decays, where the measured semileptonic bottom hadron partial width is assumed to be that of a b quark decaying through the usual V–A interaction, depends on going from the quark to the hadron level. This is also understood within the context of the HQET [28], and the results for $|V_{cb}|$ are again consistent with those from exclusive decays. Combining all the LEP data on both exclusive and inclusive decays gives [29]

$$|V_{cb}| = 0.0402 \pm 0.0019 \ , \qquad (11.12)$$

which is consistent with the latest CLEO result [29] from exclusive and inclusive decays, $|V_{cb}| = 0.0404 \pm 0.0034$. The combination of large data samples and the HQET make this the third most accurately measured CKM matrix element, after $|V_{ud}|$ and $|V_{us}|$.

(6)$|V_{ub}|$: The decay $b \to u\ell\overline{\nu}$ and its charge conjugate can be observed from the semileptonic decay of B mesons produced on the $\Upsilon(4S)$ ($b\overline{b}$) resonance by measuring the lepton energy spectrum above the endpoint of the $b \to c\ell\overline{\nu}_\ell$ spectrum. There the $b \to u\ell\overline{\nu}_\ell$ decay rate can be obtained by subtracting the background from nonresonant e^+e^- reactions. This continuum background is determined from auxiliary measurements off the $\Upsilon(4S)$. The interpretation of the result in terms of $|V_{ub}/V_{cb}|$ depends fairly strongly on the theoretical model used to generate the lepton energy spectrum, especially for $b \to u$ transitions [24,25,30].

The LEP experiments ALEPH [31], L3 [32], and DELPHI [33] have presented new analyses that measure the $b \to u\ell\nu_\ell$ component in b decays at the Z^0. Discrimination between u-like and c-like decays is based on up to 20 different event parameters which are sensitive to the mass of the quark of the final state. Using an extended range of the spectrum compared to the end-point analysis, this extraction of $|V_{ub}|$ is less sensitive to theoretical assumptions, but requires a detailed understanding of the decay $b \to c\ell\nu_\ell$.

The value of $|V_{ub}|$ can also be extracted from exclusive decays, such as $B \to \pi\ell\nu_\ell$ and $B \to \rho\ell\nu_\ell$, but there is an associated theoretical model dependence in the values of the matrix elements of the weak current between exclusive states. There has been a substantial increase in the data from CLEO for these exclusive decays [29], and the error on $|V_{ub}|$, arising primarily from the theoretical model dependence, is comparable to that obtained from inclusive decays. Enhanced awareness of the theoretical uncertainties and the difference between the results obtained from inclusive and exclusive analyses leads us to be even more conservative in setting the error bar than in previous reviews and we quote [34]

$$|V_{ub}/V_{cb}| = 0.090 \pm 0.025 \ . \qquad (11.13)$$

(7)V_{tb}: The discovery of the top quark by the CDF and DØ collaborations utilized in part the semileptonic decays of t to b. One can set a (still rather crude) limit on the fraction of decays of the form $t \to b\ \ell^+\ \nu_\ell$, as opposed to semileptonic t decays that involve s or d quarks, of [35]

$$\frac{|V_{tb}|^2}{|V_{td}|^2 + |V_{ts}|^2 + |V_{tb}|^2} = 0.99 \pm 0.29 \ . \qquad (11.14)$$

(8)*Hadronic W decays*: The ratio of hadronic W decays to leptonic decays has been measured at LEP, with the result [36] that $\Sigma_{i,j}|V_{ij}|^2 = 2.032 \pm 0.032$, where the sum extends over $i = u, c$ and $j = d, s, b$. With a three-generation CKM matrix, from unitarity this sum would be expected to have the value 2. Since five of the CKM matrix elements are well measured or contribute negligibly to the sum of the squares, this measurement can also be used as a precision measurement of $|V_{cs}| = 0.9891 \pm 0.016$.

For most of these CKM matrix elements the principal error is no longer experimental, but rather theoretical. This arises from explicit model dependence in interpreting data or in the use of specific hadronic matrix elements to relate experimental measurements to weak transitions of quarks. This type of uncertainty arises even more strongly in extracting CKM matrix elements from loop diagrams, as discussed below. Such errors are not distributed in a Gaussian manner. We have taken the interpretation that a "1 σ" range in a theoretical error corresponds to a 68% likelihood that the true value lies within "$\pm 1\ \sigma$" of the central value. While we do use the central values with the quoted errors to make a best overall fit to the CKM matrix, the result should be taken with appropriate care, and we regard extending this to multi-standard-deviation determinations of allowed regions for CKM matrix elements as unfounded.

The results for three generations of quarks, from Eqs. (11.6)–(11.8) and Eqs. (11.11)–(11.14), plus unitarity, are summarized in the matrix in Eq. (11.2). The ranges given there are different from those given in Eqs. (11.6)–(11.14) because of the inclusion of unitarity, but are consistent with the one-standard-deviation errors on the input matrix elements. Note in particular that the unitarity constraint has pushed $|V_{ud}|$ about one standard deviation higher than given in Eq. (11.6). If we had kept the error on $|V_{ud}|$ quoted by Hardy and Towner [10], we would have a violation of unitarity in the first row of the CKM matrix by about two standard deviations. While this bears watching and encourages another more accurate measurement of $|V_{us}|$, we do not see this presently as a major challenge to the validity of the three-generation Standard Model.

The data do not preclude there being more than three generations. Moreover, the entries deduced from unitarity might be altered when the CKM matrix is expanded to accommodate more generations. Conversely, the known entries restrict the possible values of additional elements if the matrix is expanded to account for additional generations. For example, unitarity and the known elements of the first row require that any additional element in the first row have a magnitude $|V_{ub'}| < 0.10$. When there are more than three generations, the allowed ranges (at 90% CL) of the matrix elements connecting the first three generations are

$$\begin{pmatrix} 0.9722 \text{ to } 0.9748 & 0.216 \text{ to } 0.223 & 0.002 \text{ to } 0.005 & \ldots \\ 0.209 \text{ to } 0.228 & 0.959 \text{ to } 0.976 & 0.037 \text{ to } 0.043 & \ldots \\ 0 \text{ to } 0.09 & 0 \text{ to } 0.16 & 0.07 \text{ to } 0.993 & \ldots \\ \vdots & \vdots & \vdots & \end{pmatrix}, \tag{11.15}$$

where we have used unitarity (or the expanded matrix) and the measurements of the magnitudes of the CKM matrix elements (including the constraint from hadronic W decays), resulting in the weak bound $|V_{tb}| > 0.07$.

Further information, particularly on CKM matrix elements involving the top quark, can be obtained from flavor-changing processes that occur at the one-loop level. We have not used this information in the discussion above since the derivation of values for V_{td} and V_{ts} in this manner from, for example, B mixing or $b \to s\gamma$, require an additional assumption that the top-quark loop, rather than new physics, gives the dominant contribution to the process in question. Conversely, the agreement of CKM matrix elements extracted from loop diagrams with the values based on direct measurements and three generations can be used to place restrictions on new physics.

The measured value [37] of $\Delta M_{B_d} = 0.473 \pm 0.016$ ps^{-1} from $B_d^0 - \overline{B}_d^0$ mixing can be turned in this way into information on $|V_{tb}{}^* V_{td}|$, assuming that the dominant contribution to the mass difference arises from the matrix element between a B_d and a $\overline{B}_d$ of an operator that corresponds to a box diagram with W bosons and top quarks as sides. Using the characteristic hadronic matrix element that then occurs, $\widehat{B}_{B_d} f_{B_d}{}^2 = (210 \pm 40 \text{ MeV})^2$ from lattice QCD calculations [38], which we regard as having become the most reliable source of such matrix elements, next-to-leading-order QCD corrections ($\eta_{\rm QCD} = 0.55$) [39], and the running top-quark mass, $\overline{m}_t(m_t) = 166 \pm 5$ GeV, as input,

$$|V_{tb}{}^* \cdot V_{td}| = 0.0083 \pm 0.0016 \;, \tag{11.16}$$

where the uncertainty comes primarily from that in the hadronic matrix elements, whose estimated errors are combined linearly.

In the ratio of B_s to B_d mass differences, many common factors (such as the QCD correction and dependence on the top-quark mass) cancel, and we have

$$\frac{\Delta M_{B_s}}{\Delta M_{B_d}} = \frac{M_{B_s}}{M_{B_d}} \frac{\widehat{B}_{B_s} f_{B_s}^2}{\widehat{B}_{B_d} f_{B_d}^2} \frac{|V_{tb}^* \cdot V_{ts}|^2}{|V_{tb}^* \cdot V_{td}|^2} \,. \tag{11.17}$$

With the experimentally measured masses [22], $\widehat{B}_{B_s}/\widehat{B}_{B_d} = (1.14 \pm 0.13)^2$ with quite conservative error bars from lattice QCD [38], and the improved experimental lower limit [37] at 95% CL of $\Delta M_{B_s} > 14.3$ ps^{-1},

$$|V_{td}|/|V_{ts}| < 0.24 \tag{11.18}$$

Since with three generations, $|V_{ts}| \approx |V_{cb}|$, this result converts to $|V_{td}| < 0.010$, which is a significant constraint by itself (see Fig. 11.2).

The CLEO observation [40] of $b \to s\gamma$ can be translated [41] similarly into $|V_{ts}|/|V_{cb}| = 1.1 \pm 0.43$, where the large uncertainty is again dominantly theoretical. In $K^+ \to \pi^+ \nu\overline{\nu}$ there are significant contributions from loop diagrams involving both charm and top quarks. Experiment is just beginning to probe the level predicted in the Standard Model [42].

All these additional indirect constraints are consistent with the matrix elements obtained from the direct measurements plus unitarity, assuming three generations; with the recent results on B mixing and theoretical improvements in lattice calculations, adding the indirect constraints to the fit reduces the range allowed for $|V_{td}|$.

Direct and indirect information on the CKM matrix is neatly summarized in terms of "the unitarity triangle," one of six such triangles that correspond to the unitarity condition applied to two different rows or columns of the CKM matrix. Unitarity of the 3×3 CKM matrix applied to the first and third columns yields

$$V_{ud} V_{ub}^* + V_{cd} V_{cb}^* + V_{td} V_{tb}^* = 0 \,. \tag{11.19}$$

The unitarity triangle is just a geometrical presentation of this equation in the complex plane [43]. We can always choose to orient the triangle so that $V_{cd}\ V_{cb}{}^*$ lies along the horizontal; in the parametrization we have chosen, V_{cb} is real, and V_{cd} is real to a very good approximation in any case. Setting cosines of small angles to unity, Eq. (11.19) becomes

$$V_{ub}{}^* + V_{td} = s_{12}\ V_{cb}{}^* \;, \tag{11.20}$$

which is shown as the unitarity triangle in Fig. 11.1(a). Rescaling the triangle by a factor $[1/|s_{12}\ V_{cb}|]$ so that the base is of unit length, the coordinates of the vertices become

$$A(\mathrm{Re}(V_{ub})/|s_{12}\ V_{cb}| \;,\; -\mathrm{Im}(V_{ub})/|s_{12} V_{cb}|) \;,\; B(1,0) \;,\; C(0,0) \;. \tag{11.21}$$

In the Wolfenstein parametrization [4], the coordinates of the vertex A of the unitarity triangle are simply (ρ, η), as shown in Fig. 11.1(b). The angle $\gamma = \delta_{13}$.

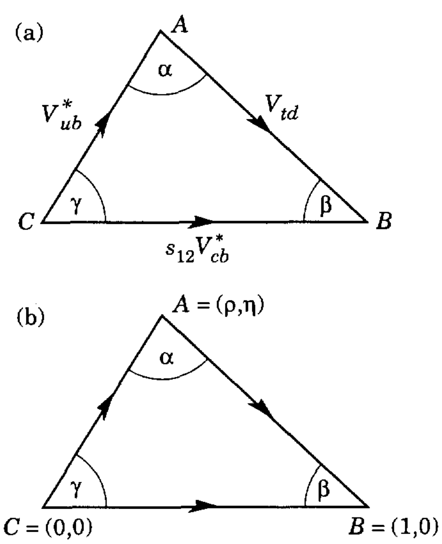

Figure 11.1: (a) Representation in the complex plane of the triangle formed by the CKM matrix elements $V_{ub}{}^*$, V_{td}, and $s_{12}\ V_{cb}{}^*$. (b) Rescaled triangle with vertices $A(\rho,\eta)$, $B(1,0)$, and $C(0,0)$.

CP-violating processes will involve the phase in the CKM matrix, assuming that the observed CP violation is solely related to a nonzero value of this phase. This allows additional constraints to be brought to bear. More specifically, a necessary and sufficient condition for CP violation with three generations can be formulated in a parametrization-independent manner in terms of the nonvanishing of the determinant of the commutator of the mass matrices for the charge $2e/3$ and charge $-e/3$ quarks [44]. CP-violating amplitudes or differences of rates are all proportional to the CKM factor in this quantity. This is the product of factors $s_{12}s_{13}s_{23}c_{12}c_{13}^2c_{23}s_{\delta_{13}}$ in the parametrization adopted above, and is $s_1^2s_2s_3c_1c_2c_3s_\delta$ in that of Ref. 1. With the approximation of setting cosines to unity, this is just twice the area of the unitarity triangle.

While hadronic matrix elements whose values are imprecisely known generally enter the calculations, the constraints from CP violation in the neutral kaon system, taken together with the restrictions on the magnitudes of the CKM matrix elements shown above, are tight enough to restrict considerably the range of angles and the phase of the CKM matrix. For example, the constraint obtained from the CP-violating parameter ϵ in the neutral K system corresponds to the vertex A of the unitarity triangle lying on a hyperbola for fixed values of the hadronic matrix elements [45,46]. In addition, following the initial evidence [47], it is now established that direct CP violation in the weak transition from a neutral K to two pions exists, *i.e.*, that the parameter ϵ' is nonzero [48]. However, theoretical uncertainties in hadronic matrix elements of cancelling amplitudes presently preclude this measurement from giving a significant constraint on the unitarity triangle.

The constraints on the vertex of the unitarity triangle that follow from $|V_{ub}|$, B mixing, and ϵ are shown in Fig. 11.2. The improved limit in Eq. (11.18) that arises from the ratio of B_s to B_d mixing eliminates a significant region for the vertex A of the unitarity triangle, a region otherwise allowed by direct measurements of the CKM matrix elements, essentially limiting the vertex A to be in the first quadrant (ρ positive). The limit is not far from the value we would expect from the other information on the unitarity triangle. Thus a significant increase in experimental sensitivity to B_s mixing will lead either to an observation of mixing or an indication of physics beyond the Standard Model. This limit is more robust theoretically since it depends on ratios (rather than absolute values) of hadronic matrix elements and is independent of the top mass or QCD corrections (which cancel in the ratio).

Ultimately in the Standard Model, the CP-violating process $K_L \to \pi^0\nu\overline{\nu}$ offers high precision in measuring the imaginary part of $V_{td} \cdot V_{ts}{}^*$, which, given V_{ts}, will yield the altitude of the unitarity triangle. However, the experimental upper limit is presently many orders of magnitude away from the requisite sensitivity.

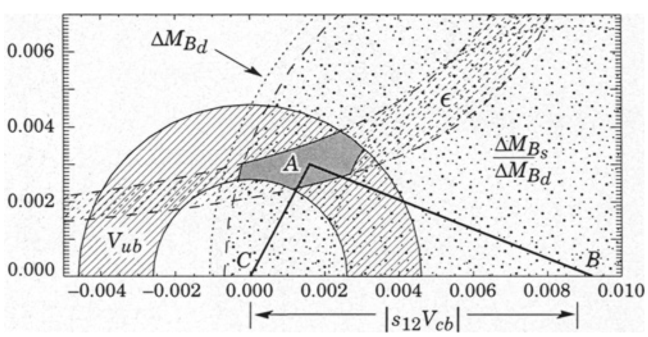

Figure 11.2: Constraints on the position of the vertex, A, of the unitarity triangle following from $|V_{ub}|$, B mixing, and ϵ. A possible unitarity triangle is shown with A in the preferred region.

For CP-violating asymmetries of neutral B mesons decaying to CP eigenstates, for certain final states arising from a single weak decay amplitude there is a direct relationship between the magnitude of the asymmetry in a given decay and $\sin 2\phi$, where $\phi = \alpha$, β, γ is an appropriate angle of the unitarity triangle [43]. The CDF Collaboration has used the decay $B_d(\overline{B}_d) \to \psi K_S$ to obtain a first indication [49] of a nonvanishing asymmetry, corresponding to a value of $\sin 2\beta$:

$$\sin 2\beta = 0.79^{+0.41}_{-0.44} \ . \qquad (11.22)$$

This is consistent with the other information in Fig. 11.2 including having the correct sign, which is positive at the 93% CL. It presages the data that will be obtained in the next several years on both the magnitudes and relative phases of the CKM matrix elements, permitting incisive tests of this part of the Standard Model. (See Sec. 12 on CP Violation and the review on "CP Violation in B decay—Standard Model Predictions" in the B Listings.)

12. *CP* VIOLATION

Revised April 2000 by L. Wolfenstein (Carnegie-Mellon Univ.).

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. In 1964 CP violation was observed in K^0 decays at a level given by the parameter $\epsilon \approx 2.3 \times 10^{-3}$. Larger CP-violation effects are anticipated in B^0 decays.

12.1. *CP* violation in Kaon decay

CP violation has been observed in the semi-leptonic decays $K_L^0 \to \pi^\mp \ell^\pm \nu$ and in the nonleptonic decay $K_L^0 \to 2\pi$. The experimental numbers that have been measured are

$$\delta = \frac{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) - \Gamma(K_L^0 \to \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) + \Gamma(K_L^0 \to \pi^+ \ell^- \nu)} \tag{12.1a}$$

$$\begin{aligned} \eta_{+-} &= A(K_L^0 \to \pi^+\pi^-)/A(K_S^0 \to \pi^+\pi^-) \\ &= |\eta_{+-}|\, e^{i\phi_{+-}} \qquad (12.1b) \\ \eta_{00} &= A(K_L^0 \to \pi^0\pi^0)/A(K_S^0 \to \pi^0\pi^0) \\ &= |\eta_{00}|\, e^{i\phi_{00}} \ . \qquad (12.1c) \end{aligned}$$

CP violation can occur either in the K^0–$\overline{K}^0$ mixing or in the decay amplitudes. Assuming CPT invariance, the mass eigenstates of the K^0–$\overline{K}^0$ system can be written

$$|K_S\rangle = p|K^0\rangle + q|\overline{K}^0\rangle \ , \qquad |K_L\rangle = p|K^0\rangle - q|\overline{K}^0\rangle \ . \tag{12.2}$$

If CP invariance held, we would have $q = p$ so that K_S would be CP even and K_L CP odd. (We define $|\overline{K}^0\rangle$ as $CP\,|K^0\rangle$). CP violation in K^0–$\overline{K}^0$ mixing is then given by the parameter $\widetilde{\epsilon}$ where

$$\frac{p}{q} = \frac{(1+\widetilde{\epsilon})}{(1-\widetilde{\epsilon})} \ . \tag{12.3}$$

CP violation can also occur in the decay amplitudes

$$A(K^0 \to \pi\pi(I)) = A_I e^{i\delta_I} \ , \qquad A(\overline{K}^0 \to \pi\pi(I)) = A_I^* e^{i\delta_I} \ , \tag{12.4}$$

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The CP-violating observables are usually expressed in terms of ϵ and ϵ' defined by

$$\eta_{+-} = \epsilon + \epsilon' \ , \qquad \eta_{00} = \epsilon - 2\epsilon' \ , \tag{12.5a}$$

One can then show [1]

$$\epsilon = \widetilde{\epsilon} + i\ (\text{Im}\ A_0/\text{Re}\ A_0) \ , \tag{12.5b}$$

$$\sqrt{2}\epsilon' = ie^{i(\delta_2-\delta_0)}(\text{Re}\ A_2/\text{Re}\ A_0)\ (\text{Im}\ A_2/\text{Re}\ A_2 - \text{Im}\ A_0/\text{Re}\ A_0) \ , \tag{12.5c}$$

$$\delta = 2\text{Re}\ \epsilon/(1+|\epsilon|^2) \approx 2\text{Re}\ \epsilon \ . \tag{12.5d}$$

In Eq. (12.5c) small corrections of order $\epsilon' \times \text{Re}\ (A_2/A_0)$ are neglected and Eq. (12.5d) assumes the $\Delta S = \Delta Q$ rule.

The quantities Im A_0, Im A_2, and Im ϵ depend on the choice of phase convention since one can change the phases of K^0 and $\overline{K}^0$ by a transformation of the strange quark state $|s\rangle \to |s\rangle\ e^{i\alpha}$; of course, observables are unchanged. It is possible by a choice of phase convention to set Im A_0 or Im A_2 or Im $\widetilde{\epsilon}$ to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice Im $A_0 = 0$ is called the Wu-Yang phase convention [2] in which case $\epsilon = \widetilde{\epsilon}$. The value of ϵ' is independent of phase convention and a nonzero value demonstrates CP violation in the decay amplitudes, referred to as direct CP violation. The possibility that direct CP violation is essentially zero and that CP violation occurs only in the mixing matrix was referred to as the superweak theory [3].

By applying CPT invariance and unitarity the phase of ϵ is given approximately by

$$\phi(\epsilon) \approx \tan^{-1}\frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} = 43.49 \pm 0.08^\circ \tag{12.6a}$$

while Eq. (12.5c) gives

$$\phi(\epsilon') = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 48 \pm 4^\circ \ , \tag{12.6b}$$

where the numerical value is based on an analysis of π–π scattering [4]. The approximation in Eq. (12.6a) depends on the assumption that direct CP violation is very small in all K^0 decays. This is expected to be good to a few tenths of a degree as indicated by the small value of ϵ' and of η_{+-0}, the CP violation parameter in the decay $K_S \to \pi^+\pi^-\pi^0$ [5], although limits on η_{000} are still poor. The relation in Eq. (12.6a) is exact in the superweak theory so this is sometimes called the superweak phase. An important point for the analysis is that $\cos[\phi(\epsilon') - \phi(\epsilon)] \simeq 1$. The consequence is that only two real quantities need be measured, the magnitude of ϵ and the value of (ϵ'/ϵ) including its sign. The measured quantity $|\eta_{00}/\eta_{+-}|^2$, which is very close to unity, is given to a good approximation by

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re}\ (\epsilon'/\epsilon) \approx 1 - 6\epsilon'/\epsilon \ . \tag{12.7}$$

From the experimental measurements, one finds

$$\epsilon = (2.271 \pm 0.017) \times 10^{-3} \ , \tag{12.8a}$$

$$\text{Re}(\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (2.1 \pm 0.5) \times 10^{-3} \ , \tag{12.8b}$$

$$\phi_{+-} = 43.5 \pm 0.5^\circ \ , \tag{12.8c}$$

$$\phi_{00} - \phi_{+-} = -0.1 \pm 0.8 \ , \tag{12.8d}$$

$$\delta = (3.33 \pm 0.14) \times 10^{-3} \ . \tag{12.8e}$$

Direct CP violation, as indicated by ϵ'/ϵ, is expected in the Standard Model; most calcuations [6] give a somewhat smaller value, but they have a large uncertainty. The value of δ agrees with Eq. (12.5d). The values of ϕ_{+-} and $\phi_{00} - \phi_{+-}$ are used to set limits on CPT violation. [See Tests of Conservation Laws.]

In the Standard Model, CP violation arises as a result of a single phase entering the CKM matrix (Sec. 11). As a result in what is now the standard phase convention, two elements have large phases, $V_{ub} \sim e^{-i\gamma}$, $V_{td} \sim e^{-i\beta}$. Because these elements have small magnitudes and involve the third generation, CP violation in the K^0 system is small. On the other hand, large effects are expected in the B^0 system, which is a major motivation for B factories.

12.2. *CP* violation in *B* decay

CP violation in the B^0 system can be observed by comparing B^0 and $\overline{B}^0$ decays [7]. For a final CP eigenstate a, the decay rate has a time dependence given by

$$\Gamma_a \sim e^{-\Gamma t}\Big([1+|\lambda_a|^2] \pm [1-|\lambda_a|^2]\ \cos(\Delta M t) \mp \text{Im}\ \lambda_a\ \sin(\Delta M t)\Big) \tag{12.9}$$

where the top sign is for B^0 and the bottom for $\overline{B}^0$ and

$$\lambda_a = (q_B/p_B)\ \overline{A}_a/A_a \ . \tag{12.10}$$

The quantities p_B and q_B come from the analogue for B^0 of Eq. (12.2), and $A_a(\overline{A}_a)$ is the decay amplitude to state a for $B^0(\overline{B}^0)$. However, for B^0 the eigenstates are expected to have a negligible lifetime difference and are only distinguished by the mass difference ΔM; also as a consequence $|q_B/p_B| \approx 1$ so that $\widetilde{\epsilon}_B$ is purely imaginary.

If only one quark weak transition contributes to the decay, $|\overline{A}_a/A_a| = 1$ so that $|\lambda_a| = 1$ and the $\cos(\Delta Mt)$ term vanishes. In this case, the difference between B^0 and $\overline{B}^0$ decays is given by the $\sin(\Delta Mt)$ term with the asymmetry coefficient

$$a_a = \frac{\Gamma_a(t) - \overline{\Gamma}_a(t)}{(\Gamma_a(t) + \overline{\Gamma}_a(t))\sin(\Delta Mt)} = \eta_a \sin\Big(2(\phi_M + \phi_D)\Big) , \quad (12.11)$$

where $2\phi_M$ is the phase of the B^0–$\overline{B}^0$ mixing, ϕ_D is the weak phase of the decay transition, and η_a is the CP eigenvalue of a.

For $B^0(\overline{B}^0) \to \psi K_S$ from the transition $b \to c\overline{c}s$, one finds in the Standard Model that the asymmetry is given directly in terms of a CKM phase with no hadronic uncertainty:

$$a_{\psi K_S} = -\sin 2\beta \ . \quad (12.12)$$

From the constraints on the CKM matrix (Sec. 11) $\sin 2\beta$ is predicted to be between 0.3 and 0.9. A significantly different value could be a sign of new physics.

A second decay of interest is B^0 $(\overline{B}^0) \to \pi^+\pi^-$ from the transition $b \to u\overline{u}d$ with

$$a_{\pi\pi} = \sin 2(\beta + \gamma) \ . \quad (12.13)$$

While either of these asymmetries could be ascribed to B^0–$\overline{B}^0$ mixing (q_B/p_B or $\overline{\epsilon}_B$), the difference between the two asymmetries is evidence for direct CP violation. From Eq. (12.10) it is seen that this corresponds to a phase difference between $A_{\psi K_S}$ and $A_{\pi^+\pi^-}$. Thus this is analogous to ϵ'. In the standard phase convention, 2β in Eqs. (12.12) and (12.13) arises from B^0–$\overline{B}^0$ mixing whereas the γ in Eq. (12.13) comes from V_{ub} in the transition $b \to u\overline{u}d$. The result in Eq. (12.13) may have a sizeable correction due to what is called a penguin diagram. This is a one-loop graph producing $b \to d +$ gluon with a W and a quark, predominantly the t quark, in the loop. This leads to an amplitude proportional to $V_{tb}^* V_{td}$, which has a weak phase different from that of the original tree amplitude proportional to $V_{ub}V_{ud}^*$. There are several methods to approximately determine this correction using additional measurements [8].

CP violation in the decay amplitude is also revealed by the $\cos(\Delta Mt)$ term in Eq. (12.9) or by a difference in rates of B^+ and B^- to charge-conjugate states. These effects, however, require two contributing amplitudes to the decay (such as a tree amplitude plus a penguin) and also require final-state interaction phases. Predicted effects are very uncertain and are generally small [9].

In the case of the B_s system, the mass difference ΔM is much larger than for B^0 and has not yet been measured. As a result, it will be difficult to isolate the $\sin(\Delta Mt)$ term to measure asymmetries. Furthermore, in the Standard Model with the standard phase convention, ϕ_M is very small so that decays due to $b \to c\overline{c}s$, yielding $B_s \to \psi\eta'$, would have zero asymmetry. Decays due to $b \to u\overline{u}d$, yielding $B_s \to \rho^0 K_S$, would have an asymmetry $\sin 2\gamma$ in the tree approximation. The width difference $\Delta\Gamma$ is also expected to be much larger for B_s so that $\Delta\Gamma/\Gamma$ might be as large as 0.15. In this case, there might be a possibility of detecting CP violation as in the case of K^0 by observing the B_s states with different lifetimes decaying into the same CP eigenstate [10].

For further details, see the notes on CP violation in the K_L^0, K_S^0, and B^0 Particle Listings of this *Review*.

13. QUARK MODEL

Revised April 2000 by C. Amsler (Univ. of Zürich) and C.G. Wohl (LBNL).

13.1. Quantum numbers of the quarks

Each quark has spin 1/2 and baryon number 1/3. Table 13.1 gives the additive quantum numbers (other than baryon number) of the three generations of quarks. Our convention is that the *flavor* of a quark (I_z, S, C, B, or T) has the same sign as its *charge*. With this convention, any flavor carried by a *charged* meson has the same sign as its charge; *e.g.*, the strangeness of the K^+ is +1, the bottomness of the B^+ is +1, and the charm *and* strangeness of the D_s^- are each −1.

By convention, each quark is assigned positive parity. Then each antiquark has negative parity.

Table 13.1: Additive quantum numbers of the quarks.

Property \ Quark	d	u	s	c	b	t
Q – electric charge	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$
I_z – isospin z-component	$-\frac{1}{2}$	$+\frac{1}{2}$	0	0	0	0
S – strangeness	0	0	−1	0	0	0
C – charm	0	0	0	+1	0	0
B – bottomness	0	0	0	0	−1	0
T – topness	0	0	0	0	0	+1

13.2. Mesons: $q\overline{q}$ states

Nearly all known mesons are bound states of a quark q and an antiquark $\overline{q}'$ (the flavors of q and q' may be different). If the orbital angular momentum of the $q\overline{q}'$ state is L, then the parity P is $(-1)^{L+1}$. A state $q\overline{q}$ of a quark and its own antiquark is also an eigenstate of charge conjugation, with $C = (-1)^{L+S}$, where the spin S is 0 or 1. The $L = 0$ states are the pseudoscalars, $J^P = 0^-$, and the vectors, $J^P = 1^-$. Assignments for many of the known mesons are given in Table 13.2. States in the "normal" spin-parity series, $P = (-1)^J$, must, according to the above, have $S = 1$ and hence $CP = +1$. Thus mesons with normal spin-parity and $CP = -1$ are forbidden in the $q\overline{q}'$ model. The $J^{PC} = 0^{--}$ state is forbidden as well. Mesons with such J^{PC} may exist, but would lie outside the $q\overline{q}'$ model.

The nine possible $q\overline{q}'$ combinations containing u, d, and s quarks group themselves into an octet and a singlet:

$$\mathbf{3} \otimes \mathbf{\overline{3}} = \mathbf{8} \oplus \mathbf{1} \tag{13.1}$$

States with the same IJ^P and additive quantum numbers can mix. (If they are eigenstates of charge conjugation, they must also have the same value of C.) Thus the $I = 0$ member of the ground-state pseudoscalar octet mixes with the corresponding pseudoscalar singlet to produce the η and η'. These appear as members of a nonet, which is shown as the middle plane in Fig. 13.1(a). Similarly, the ground-state vector nonet appears as the middle plane in Fig. 13.1(b).

A fourth quark such as charm can be included in this scheme by extending the symmetry to SU(4), as shown in Fig. 13.1. Bottom extends the symmetry to SU(5); to draw the multiplets would require four dimensions.

For the pseudoscalar mesons, the Gell-Mann-Okubo formula is

$$m_\eta^2 = \frac{1}{3}(4m_K^2 - m_\pi^2) , \tag{13.2}$$

assuming no octet-singlet mixing. However, the octet η_8 and singlet η_1 mix because of SU(3) breaking. In general, the mixing angle is mass dependent and becomes complex for resonances of finite width. Neglecting this, the physical states η and η' are given in terms of a mixing angle θ_P by

$$\eta = \eta_8 \cos\theta_P - \eta_1 \sin\theta_P \tag{13.3a}$$

$$\eta' = \eta_8 \sin\theta_P + \eta_1 \cos\theta_P . \tag{13.3b}$$

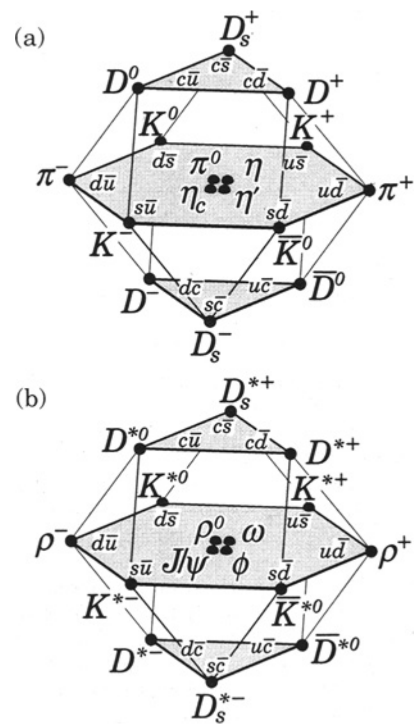

Figure 13.1: SU(4) 16-plets for the (a) pseudoscalar and (b) vector mesons made of u, d, s, and c quarks. The nonets of light mesons occupy the central planes, to which the $c\overline{c}$ states have been added. The neutral mesons at the centers of these planes are mixtures of $u\overline{u}$, $d\overline{d}$, $s\overline{s}$, and $c\overline{c}$ states.

These combinations diagonalize the mass-squared matrix

$$M^2 = \begin{pmatrix} M_{11}^2 & M_{18}^2 \\ M_{18}^2 & M_{88}^2 \end{pmatrix} , \tag{13.4}$$

where $M_{88}^2 = \frac{1}{3}(4m_K^2 - m_\pi^2)$. It follows that

$$\tan^2\theta_P = \frac{M_{88}^2 - m_\eta^2}{m_{\eta'}^2 - M_{88}^2} . \tag{13.5}$$

The sign of θ_P is meaningful in the quark model. If

$$\eta_1 = (u\overline{u} + d\overline{d} + s\overline{s})/\sqrt{3} \tag{13.6a}$$

$$\eta_8 = (u\overline{u} + d\overline{d} - 2s\overline{s})/\sqrt{6} , \tag{13.6b}$$

then the matrix element M_{18}^2, which is due mostly to the strange quark mass, is negative. From the relation

$$\tan\theta_P = \frac{M_{88}^2 - m_\eta^2}{M_{18}^2} , \tag{13.7}$$

we find that $\theta_P < 0$. However, caution is suggested in the use of the η-η' mixing-angle formulas, as they are extremely sensitive to SU(3)

Table 13.2: Suggested $q\bar{q}$ quark-model assignments for most of the known mesons. Some assignments, especially for the 0^{++} multiplet and for some of the higher multiplets, are controversial. Mesons in bold face are included in the Meson Summary Table. Of the light mesons in the Summary Table, the $f_0(1500)$, $f_1(1510)$, $f_2(1950)$, $f_2(2300)$, $f_2(2340)$, and one of the two peaks in the $\eta(1440)$ entry are not in this table. Within the $q\bar{q}$ model, it is especially hard to find a place for the first two of these f mesons and for one of the $\eta(1440)$ peaks. See the "Note on Non-$q\bar{q}$ Mesons" at the end of the Meson Listings.

* See our scalar minireview in the Particle Listings. The candidates for the $I=1$ states are $a_0(980)$ and $a_0(1450)$, while for $I=0$ they are: $f_0(400\text{–}1200)$, $f_0(980)$, $f_0(1370)$, and $f_0(1710)$. The light scalars are problematic, since there may be two poles for one $q\bar{q}$ state and $a_0(980)$, $f_0(980)$ may be $K\overline{K}$ bound states.

† The K_{1A} and K_{1B} are nearly equal (45°) mixes of the $K_1(1270)$ and $K_1(1400)$.

‡The $K^*(1410)$ could be replaced by the $K^*(1680)$ as the $2\,^3S_1$ state.

If we allow $M_{88}^2 = \frac{1}{3}(4m_K^2 - m_\pi^2)\,(1+\Delta)$, the mixing angle is determined by

$$\tan^2\theta_P = 0.0319(1+17\Delta) \tag{13.8}$$

$$\theta_P = -10.1°(1+8.5\Delta) \tag{13.9}$$

to first order in Δ. A small breaking of the Gell-Mann-Okubo relation can produce a major modification of θ_P.

For the vector mesons, $\pi \to \rho$, $K \to K^*$, $\eta \to \phi$, and $\eta' \to \omega$, so that

$$\phi = \omega_8 \cos\theta_V - \omega_1 \sin\theta_V \tag{13.10}$$

$$\omega = \omega_8 \sin\theta_V + \omega_1 \cos\theta_V \ . \tag{13.11}$$

For "ideal" mixing, $\phi = s\bar{s}$, so $\tan\theta_V = 1/\sqrt{2}$ and $\theta_V = 35.3°$. Experimentally, θ_V is near 35°, the sign being determined by a formula like that for $\tan\theta_P$. Following this procedure we find the mixing angles given in Table 13.3.

Table 13.3: Singlet-octet mixing angles for several nonets, neglecting possible mass dependence and imaginary parts. The sign conventions are given in the text. The values of θ_{quad} are obtained from the equations in the text, while those for θ_{lin} are obtained by replacing m^2 by m throughout. Of the two isosinglets in a nonet, the mostly octet one is listed first.

J^{PC}	Nonet members	θ_{quad}	θ_{lin}
0^{-+}	π, K, η, η'	−10°	−23°
1^{--}	ρ, $K^*(892)$, ϕ, ω	39°	36°
2^{++}	$a_2(1320)$, $K_2^*(1430)$, $f_2'(1525)$, $f_2(1270)$	28°	26°
3^{--}	$\rho_3(1690)$, $K_3^*(1780)$, $\phi_3(1850)$, $\omega_3(1670)$	29°	28°

In the quark model, the coupling of neutral mesons to two photons is proportional to $\sum_i Q_i^2$, where Q_i is the charge of the i-th quark. This provides an alternative characterization of mixing. For example, defining

$$\mathrm{Amp}\,[P \to \gamma(k_1)\,\gamma(k_2)] = M\epsilon^{\mu\nu\alpha\beta}\,\epsilon^*_{1\mu}\,k_{1\nu}\,\epsilon^*_{2\alpha}\,k_{2\beta}\;, \qquad (13.12)$$

where $\epsilon_{i\lambda}$ is the λ component of the polarization vector of the i^{th} photon, one finds

$$\frac{M(\eta \to \gamma\gamma)}{M(\pi^0 \to \gamma\gamma)} = \frac{1}{\sqrt{3}}(\cos\theta_P - 2\sqrt{2}\sin\theta_P) = \frac{1.73 \pm 0.18}{\sqrt{3}} \qquad (13.13a)$$

$$\frac{M(\eta' \to \gamma\gamma)}{M(\pi^0 \to \gamma\gamma)} = 2\sqrt{2/3}\left(\cos\theta_P + \frac{\sin\theta_P}{2\sqrt{2}}\right) = 2\sqrt{2/3}\,(0.78 \pm 0.04)\;, \qquad (13.13b)$$

where the numbers with errors are experimental. These data favor $\theta_P \approx -20°$, which is compatible with the quadratic mass mixing formula with about 12% SU(3) breaking in M^2_{88}.

13.3. Baryons: qqq states

All the established baryons are apparently 3-quark (qqq) states, and each such state is an SU(3) color singlet, a completely antisymmetric state of the three possible colors. Since the quarks are fermions, the state function for any baryon must be antisymmetric under interchange of any two equal-mass quarks (up and down quarks in the limit of isospin symmetry). Thus the state function may be written as

$$|\,qqq\,\rangle_A = |\,\mathrm{color}\,\rangle_A \times |\,\mathrm{space,\ spin,\ flavor}\,\rangle_S\;, \qquad (13.14)$$

where the subscripts S and A indicate symmetry or antisymmetry under interchange of any two of the equal-mass quarks. Note the contrast with the state function for the three nucleons in ^{3}H or ^{3}He:

$$|\,NNN\,\rangle_A = |\,\mathrm{space,\ spin,\ isospin}\,\rangle_A\;. \qquad (13.15)$$

This difference has major implications for internal structure, magnetic moments, *etc.* (For a nice discussion, see Ref. 1.)

The "ordinary" baryons are made up of u, d, and s quarks. The three flavors imply an approximate flavor SU(3), which requires that baryons made of these quarks belong to the multiplets on the right side of

$$\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{10}_S \oplus \mathbf{8}_M \oplus \mathbf{8}_M \oplus \mathbf{1}_A \qquad (13.16)$$

(see Sec. 33, on "SU(n) Multiplets and Young Diagrams"). Here the subscripts indicate symmetric, mixed-symmetry, or antisymmetric states under interchange of any two quarks. The **1** is a uds state (Λ_1) and the octet contains a similar state (Λ_8). If these have the same spin and parity they can mix. An example is the mainly octet D_{03} $\Lambda(1690)$ and mainly singlet D_{03} $\Lambda(1520)$. In the ground state multiplet, the SU(3) flavor singlet Λ is forbidden by Fermi statistics. The mixing formalism is the same as for η-η' or ϕ-ω (see above), except that for baryons the mass M instead of M^2 is used. Section 32, on "SU(3) Isoscalar Factors and Representation Matrices", shows how relative decay rates in, say, $\mathbf{10} \to \mathbf{8} \otimes \mathbf{8}$ decays may be calculated. A summary of results of fits to the observed baryon masses and decay rates for the best-known SU(3) multiplets is given in Appendix II of our 1982 edition [2].

The addition of the c quark to the light quarks extends the flavor symmetry to SU(4). Figures 13.2(a) and 13.2(b) show the (badly broken) SU(4) baryon multiplets that have as their bottom levels an SU(3) octet, such as the octet that includes the nucleon, or an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$. All the particles in a given SU(4) multiplet have the same spin and parity. The charmed baryons are discussed in more detail in the "Note on Charmed Baryons" in the Particle Listings. The addition of a b quark extends the flavor symmetry to SU(5); it would require four dimensions to draw the multiplets.

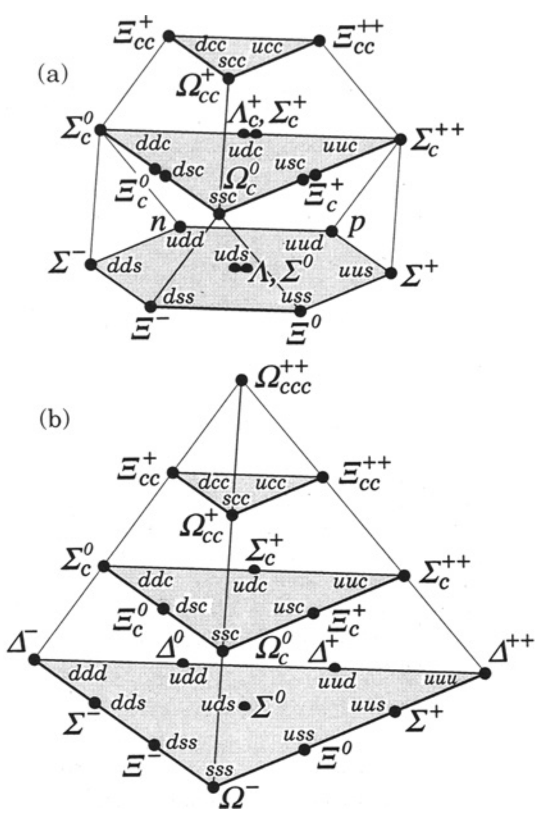

Figure 13.2: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet. (b) The 20-plet with an SU(3) decuplet.

For the "ordinary" baryons (no c or b quark), flavor and spin may be combined in an approximate flavor-spin SU(6) in which the six basic states are $d\uparrow$, $d\downarrow$, $\cdots$, $s\downarrow$ ($\uparrow$, $\downarrow$ = spin up, down). Then the baryons belong to the multiplets on the right side of

$$\mathbf{6} \otimes \mathbf{6} \otimes \mathbf{6} = \mathbf{56}_S \oplus \mathbf{70}_M \oplus \mathbf{70}_M \oplus \mathbf{20}_A\;. \qquad (13.17)$$

These SU(6) multiplets decompose into flavor SU(3) multiplets as follows:

$$\mathbf{56} = {}^4\mathbf{10} \oplus {}^2\mathbf{8} \qquad (13.18a)$$

$$\mathbf{70} = {}^2\mathbf{10} \oplus {}^4\mathbf{8} \oplus {}^2\mathbf{8} \oplus {}^2\mathbf{1} \qquad (13.18b)$$

$$\mathbf{20} = {}^2\mathbf{8} \oplus {}^4\mathbf{1}\;, \qquad (13.18c)$$

where the superscript $(2S+1)$ gives the net spin S of the quarks for each particle in the SU(3) multiplet. The $J^P = 1/2^+$ octet containing the nucleon and the $J^P = 3/2^+$ decuplet containing the $\Delta(1232)$ together make up the "ground-state" 56-plet in which the orbital angular momenta between the quark pairs are zero (so that the spatial part of the state function is trivially symmetric). The **70** and **20** require some excitation of the spatial part of the state function in order to make the overall state function symmetric. States with nonzero orbital angular momenta are classified in SU(6)$\otimes$O(3) supermultiplets. Physical baryons with the same quantum numbers do not belong to a single supermultiplet, since SU(6) is broken by spin-dependent interactions, differences in quark masses, *etc.* Nevertheless, the SU(6)$\otimes$O(3) basis provides a suitable framework for describing baryon state functions.

It is useful to classify the baryons into bands that have the same number N of quanta of excitation. Each band consists of a number of supermultiplets, specified by (D, L^P_N), where D is the dimensionality of the SU(6) representation, L is the total quark orbital angular momentum, and P is the total parity. Supermultiplets contained in bands up to $N = 12$ are given in Ref. 3. The $N = 0$ band, which contains the nucleon and $\Delta(1232)$, consists only of the $(56,0_0^+)$ supermultiplet. The $N = 1$ band consists only of the $(70,1_1^-)$ multiplet and contains the negative-parity baryons with masses below about 1.9 GeV. The $N = 2$ band contains five supermultiplets: $(56,0_2^+)$, $(70,0_2^+)$, $(56,2_2^+)$, $(70,2_2^+)$, and $(20,1_2^+)$. Baryons belonging to the $(20,1_2^+)$ supermultiplet are not ever likely to be observed, since a coupling from the ground-state baryons requires a two-quark excitation. Selection rules are similarly responsible for the fact that many other baryon resonances have not been observed [4].

In Table 13.4, quark-model assignments are given for many of the established baryons whose SU(6)⊗O(3) compositions are relatively unmixed. We note that the unestablished resonances $\Sigma(1480)$, $\Sigma(1560)$, $\Sigma(1580)$, $\Sigma(1770)$, and $\Xi(1620)$ in our Baryon Particle Listings are too low in mass to be accommodated in most quark models [4,5].

Table 13.4: Quark-model assignments for many of the known baryons in terms of a flavor-spin SU(6) basis. Only the dominant representation is listed. Assignments for some states, especially for the $\Lambda(1810)$, $\Lambda(2350)$, $\Xi(1820)$, and $\Xi(2030)$, are merely educated guesses. For assignments of the charmed baryons, see the "Note on Charmed Baryons" in the Particle Listings.

The quark model for baryons is extensively reviewed in Ref. 6 and 7.

13.4. Dynamics

Many specific quark models exist, but most contain the same basic set of dynamical ingredients. These include:

i) A confining interaction, which is generally spin-independent.

ii) A spin-dependent interaction, modeled after the effects of gluon exchange in QCD. For example, in the S-wave states, there is a spin-spin hyperfine interaction of the form

$$H_{HF} = -\alpha_S M \sum_{i>j} (\vec{\sigma}\lambda_a)_i (\vec{\sigma}\lambda_a)_j \ , \tag{13.19}$$

where M is a constant with units of energy, λ_a $(a = 1, \cdots, 8,)$ is the set of SU(3) unitary spin matrices, defined in Sec. 32, on "SU(3) Isoscalar Factors and Representation Matrices," and the sum runs over constituent quarks or antiquarks. Spin-orbit interactions, although allowed, seem to be small.

iii) A strange quark mass somewhat larger than the up and down quark masses, in order to split the SU(3) multiplets.

iv) In the case of isoscalar mesons, an interaction for mixing $q\overline{q}$ configurations of different flavors (*e.g.*, $u\overline{u} \leftrightarrow d\overline{d} \leftrightarrow s\overline{s}$), in a manner which is generally chosen to be flavor independent.

These four ingredients provide the basic mechanisms that determine the hadron spectrum.

14. EXPERIMENTAL TESTS OF GRAVITATIONAL THEORY

Revised October 1999 by T. Damour (IHES, Bures-sur-Yvette, France).

Einstein's General Relativity, the current "standard" theory of gravitation, describes gravity as a universal deformation of the Minkowski metric:

$$g_{\mu\nu}(x^\lambda) = \eta_{\mu\nu} + h_{\mu\nu}(x^\lambda)\ , \text{ where } \eta_{\mu\nu} = \text{diag}(-1,+1,+1,+1)\ . \quad (14.1)$$

Alternatively, it can be defined as the unique, consistent, local theory of a massless spin-2 field $h_{\mu\nu}$, whose source must then be the total, conserved energy-momentum tensor [1]. General Relativity is classically defined by two postulates. One postulate states that the Lagrangian density describing the propagation and self-interaction of the gravitational field is

$$\mathcal{L}_{\rm Ein}[g_{\mu\nu}] = \frac{c^4}{16\pi G_N}\sqrt{g}\,g^{\mu\nu}R_{\mu\nu}(g)\ , \quad (14.2)$$

$$R_{\mu\nu}(g) = \partial_\alpha\Gamma^\alpha_{\mu\nu} - \partial_\nu\Gamma^\alpha_{\mu\alpha} + \Gamma^\beta_{\alpha\beta}\Gamma^\alpha_{\mu\nu} - \Gamma^\beta_{\nu\alpha}\Gamma^\alpha_{\mu\beta}\ , \quad (14.3)$$

$$\Gamma^\lambda_{\mu\nu} = \tfrac{1}{2}g^{\lambda\sigma}(\partial_\mu g_{\nu\sigma} + \partial_\nu g_{\mu\sigma} - \partial_\sigma g_{\mu\nu})\ , \quad (14.4)$$

where G_N is Newton's constant, $g = -\det(g_{\mu\nu})$, and $g^{\mu\nu}$ is the matrix inverse of $g_{\mu\nu}$. A second postulate states that $g_{\mu\nu}$ couples universally, and minimally, to all the fields of the Standard Model by replacing everywhere the Minkowski metric $\eta_{\mu\nu}$. Schematically (suppressing matrix indices and labels for the various gauge fields and fermions and for the Higgs doublet),

$$\begin{aligned}\mathcal{L}_{\rm SM}[\psi, A_\mu, H, g_{\mu\nu}] = &-\tfrac{1}{4}\sum\sqrt{g}\,g^{\mu\alpha}g^{\nu\beta}F^a_{\mu\nu}F^a_{\alpha\beta}\\ &-\sum\sqrt{g}\,\overline{\psi}\,\gamma^\mu D_\mu\psi\\ &-\tfrac{1}{2}\sqrt{g}\,g^{\mu\nu}\overline{D_\mu H}D_\nu H - \sqrt{g}\,V(H)\\ &-\sum\lambda\sqrt{g}\,\overline{\psi}\,H\psi\ , \end{aligned}\quad (14.5)$$

where $\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2g^{\mu\nu}$, and where the covariant derivative D_μ contains, besides the usual gauge field terms, a (spin dependent) gravitational contribution $\Gamma_\mu(x)$ [2]. From the total action $S_{\rm tot}[g_{\mu\nu},\psi,A_\mu,H] = c^{-1}\int d^4x(\mathcal{L}_{\rm Ein} + \mathcal{L}_{\rm SM})$ follow Einstein's field equations,

$$R_{\mu\nu} - \tfrac{1}{2}Rg_{\mu\nu} = \frac{8\pi G_N}{c^4}T_{\mu\nu}\ . \quad (14.6)$$

Here $R = g^{\mu\nu}R_{\mu\nu}$, $T_{\mu\nu} = g_{\mu\alpha}g_{\nu\beta}T^{\alpha\beta}$, and $T^{\mu\nu} = (2/\sqrt{g})\delta\mathcal{L}_{\rm SM}/\delta g_{\mu\nu}$ is the (symmetric) energy-momentum tensor of the Standard Model matter. The theory is invariant under arbitrary coordinate transformations: $x'^\mu = f^\mu(x^\nu)$. To solve the field equations Eq. (14.6) one needs to fix this coordinate gauge freedom. E.g. the "harmonic gauge" (which is the analogue of the Lorentz gauge, $\partial_\mu A^\mu = 0$, in electromagnetism) corresponds to imposing the condition $\partial_\nu(\sqrt{g}g^{\mu\nu}) = 0$.

In this *Review*, we only consider the classical limit of gravitation (*i.e.* classical matter and classical gravity). Considering quantum matter in a classical gravitational background already poses interesting challenges, notably the possibility that the zero-point fluctuations of the matter fields generate a nonvanishing vacuum energy density $\rho_{\rm vac}$, corresponding to a term $-\sqrt{g}\ \rho_{\rm vac}$ in $\mathcal{L}_{\rm SM}$ [3]. This is equivalent to adding a "cosmological constant" term $+\Lambda\, g_{\mu\nu}$ on the left-hand side of Einstein's equations Eq. (14.6), with $\Lambda = 8\pi G_N\,\rho_{\rm vac}/c^4$. Cosmological observations set upper bounds (as well as, possibly, lower bounds) on Λ (see "Astrophysical Constants," Sec. 2 of this *Review*) which, when translated in particle physics units, appear suspiciously small: $\rho_{\rm vac} \lesssim 10^{-46}$ GeV^4. This bound shows that $\rho_{\rm vac}$, even if it is not strictly zero, has a negligible effect on the tests discussed below. Quantizing the gravitational field itself poses a very difficult challenge because of the perturbative non-renormalizability of Einstein's Lagrangian. Supergravity and superstring theory offer promising avenues toward solving this challenge.

14.1. Experimental tests of the coupling between matter and gravity

The universality of the coupling between $g_{\mu\nu}$ and the Standard Model matter postulated in Eq. (14.5) ("Equivalence Principle") has many observable consequences. First, it predicts that the outcome of a local non-gravitational experiment, referred to local standards, does not depend on where, when, and in which locally inertial frame, the experiment is performed. This means, for instance, that local experiments should neither feel the cosmological evolution of the universe (constancy of the "constants"), nor exhibit preferred directions in spacetime (isotropy of space, local Lorentz invariance). These predictions are consistent with many experiments and observations. The best limit on a possible time variation of the basic coupling constants concerns the fine-structure constant $\alpha_{\rm em}$ and has been obtained by analyzing a natural fission reactor phenomenon which took place at Oklo, Gabon, two billion years ago [4]

$$-6.7\times10^{-17}{\rm yr}^{-1} < \frac{\dot\alpha_{\rm em}}{\alpha_{\rm em}} < 5.0\times10^{-17}{\rm yr}^{-1}\ . \quad (14.7)$$

The highest precision tests of the isotropy of space have been performed by looking to possible quadrupolar shifts of nuclear energy levels [5]. The (null) results can be interpreted as testing the fact that the various pieces in the matter Lagrangian Eq. (14.5) are indeed coupled to one and the same external metric $g_{\mu\nu}$ to the 10^{-27} level.

The universal coupling to $g_{\mu\nu}$ postulated in Eq. (14.5) implies that two (electrically neutral) test bodies dropped at the same location and with the same velocity in an external gravitational field fall in the same way, independently of their masses and compositions. The universality of the acceleration of free fall has been verified at the 10^{-12} level both for laboratory bodies [6],

$$\left(\frac{\Delta a}{a}\right)_{\rm BeCu} = (-1.9\pm2.5)\times10^{-12}\ , \quad (14.8)$$

and for the gravitational accelerations of the Moon and the Earth toward the Sun [7],

$$\left(\frac{\Delta a}{a}\right)_{\rm MoonEarth} = (-3.2\pm4.6)\times10^{-13}\ . \quad (14.9)$$

Finally, Eq. (14.5) also implies that two identically constructed clocks located at two different positions in a static external Newtonian potential $U(\boldsymbol{x}) = \sum G_N m/r$ exhibit, when intercompared by means of electromagnetic signals, the (apparent) difference in clock rate,

$$\frac{\tau_1}{\tau_2} = \frac{\nu_2}{\nu_1} = 1 + \frac{1}{c^2}[U(\boldsymbol{x}_1) - U(\boldsymbol{x}_2)] + O\left(\frac{1}{c^4}\right)\ , \quad (14.10)$$

independently of their nature and constitution. This universal gravitational redshift of clock rates has been verified at the 10^{-4} level by comparing a hydrogen-maser clock flying on a rocket up to an altitude $\sim 10{,}000$ km to a similar clock on the ground [8]. For more details and references on experimental gravity see, *e.g.*, Refs. 9 and 10.

14.2. Tests of the dynamics of the gravitational field in the weak field regime

The effect on matter of one-graviton exchange, *i.e.* the interaction Lagrangian obtained when solving Einstein's field equations Eq. (14.6) written in, say, the harmonic gauge at first order in $h_{\mu\nu}$,

$$\Box h_{\mu\nu} = -\frac{16\pi G_N}{c^4}(T_{\mu\nu} - \tfrac{1}{2}T\eta_{\mu\nu}) + O(h^2) + O(hT) , \qquad (14.11)$$

reads $-(8\pi G_N/c^4)T^{\mu\nu}\Box^{-1}(T_{\mu\nu} - \frac{1}{2}T\eta_{\mu\nu})$. For a system of N moving point masses, with free Lagrangian $L^{(1)} = \sum_{A=1}^{N} - m_A c^2\sqrt{1 - v_A^2/c^2}$, this interaction, expanded to order v^2/c^2, reads (with $r_{AB} \equiv |\boldsymbol{x}_A - \boldsymbol{x}_B|$, $\boldsymbol{n}_{AB} \equiv (\boldsymbol{x}_A - \boldsymbol{x}_B)/r_{AB}$)

$$\begin{aligned} L^{(2)} =& \frac{1}{2}\sum_{A\neq B}\frac{G_N m_A m_B}{r_{AB}}\left[1 + \frac{3}{2c^2}(\boldsymbol{v}_A^2 + \boldsymbol{v}_B^2) - \frac{7}{2c^2}(\boldsymbol{v}_A\cdot\boldsymbol{v}_B)\right. \\ &\left. - \frac{1}{2c^2}(\boldsymbol{n}_{AB}\cdot\boldsymbol{v}_A)(\boldsymbol{n}_{AB}\cdot\boldsymbol{v}_B) + O\left(\frac{1}{c^4}\right)\right] . \end{aligned} \qquad (14.12)$$

The two-body interactions Eq. (14.12) exhibit v^2/c^2 corrections to Newton's $1/r$ potential induced by spin-2 exchange. Consistency at the "post-Newtonian" level $v^2/c^2 \sim G_N m/rc^2$ requires that one also considers the three-body interactions induced by some of the three-graviton vertices and other nonlinearities (terms $O(h^2)$ and $O(hT)$ in Eq. (14.11)),

$$L^{(3)} = -\frac{1}{2}\sum_{B\neq A\neq C}\frac{G_N^2 m_A m_B m_C}{r_{AB}r_{AC}c^2} + O\left(\frac{1}{c^4}\right) . \qquad (14.13)$$

All currently performed gravitational experiments in the solar system, including perihelion advances of planetary orbits, the bending and delay of electromagnetic signals passing near the Sun, and very accurate ranging data to the Moon obtained by laser echoes, are compatible with the post-Newtonian results Eqs. (14.11)–(14.13).

Similarly to what is done in discussions of precision electroweak experiments (see Section 10 in this *Review*), it is useful to quantify the significance of precision gravitational experiments by parameterizing plausible deviations from General Relativity. Endowing the spin-2 excitations with a (Pauli-Fierz) mass term is excluded both for phenomenological (discontinuities in observable predictions [11]) and theoretical (no energy lower bound [12]) reasons. Therefore, deviations from Einstein's pure spin-2 theory are defined by adding new, bosonic, ultra light or massless, macroscopically coupled fields. The addition of a vector (spin 1) field necessarily leads to violations of the universality of free fall and is constrained by "fifth force" experiments. See Refs. [6,13] for compilations of constraints. The addition of a scalar (spin 0) field is the most studied type of deviation from General Relativity, being motivated by many attempts to unify gravity with the Standard Model (Kaluza-Klein program, supergravity, string theory). The technically simplest class of tensor-scalar (spin 2 $\oplus$ spin 0) theories consists in adding a massless scalar field φ coupled to the trace of the energy-momentum tensor $T = g_{\mu\nu}T^{\mu\nu}$ [14]. The most general such theory contains an arbitrary function $a(\varphi)$ of the scalar field, and can be defined by the Lagrangian

$$\begin{aligned} \mathcal{L}_{\rm tot}[g_{\mu\nu}, \varphi, \psi, A_\mu, H] =& \frac{c^4}{16\pi G}\sqrt{g}(R(g) - 2g^{\mu\nu}\partial_\mu\varphi\partial_\nu\varphi) \\ &+ \mathcal{L}_{\rm SM}[\psi, A_\mu, H, \widetilde{g}_{\mu\nu}] , \end{aligned} \qquad (14.14)$$

where G is a "bare" Newton constant, and where the Standard Model matter is coupled not to the "Einstein" (pure spin-2) metric $g_{\mu\nu}$, but to the conformally related ("Jordan-Fierz") metric $\widetilde{g}_{\mu\nu} = \exp(2a(\varphi))g_{\mu\nu}$. The scalar field equation $\Box_g\varphi = -(4\pi G/c^4)\alpha(\varphi)T$ displays $\alpha(\varphi) \equiv \partial a(\varphi)/\partial\varphi$ as the basic (field-dependent) coupling between φ and matter [15]. The one-parameter Jordan-Fierz-Brans-Dicke theory [14] is the special case $a(\varphi) = \alpha_0\varphi$ leading to a field-independent coupling $\alpha(\varphi) = \alpha_0$.

In the weak field, slow motion, limit appropriate to describing gravitational experiments in the solar system, the addition of φ modifies Einstein's predictions only through the appearance of two "post-Einstein" dimensionless parameters: $\overline{\gamma} = -2\alpha_0^2/(1+\alpha_0^2)$ and $\overline{\beta} = +\frac{1}{2}\beta_0\alpha_0^2/(1+\alpha_0^2)^2$, where $\alpha_0 \equiv \alpha(\varphi_0)$, $\beta_0 \equiv \partial\alpha(\varphi_0)/\partial\varphi_0$, φ_0 denoting the vacuum expectation value of φ. These parameters show up also naturally (in the form $\gamma_{\rm PPN} = 1 + \overline{\gamma}$, $\beta_{\rm PPN} = 1 + \overline{\beta}$) in phenomenological discussions of possible deviations from General Relativity [16,9]. The parameter $\overline{\gamma}$ measures the admixture of spin 0 to Einstein's graviton, and contributes an extra term $+\overline{\gamma}(\boldsymbol{v}_A - \boldsymbol{v}_B)^2/c^2$ in the square brackets of the two-body Lagrangian Eq. (14.12). The parameter $\overline{\beta}$ modifies the three-body interaction Eq. (14.13) by a factor $1 + 2\overline{\beta}$. Moreover, the combination $\eta \equiv 4\overline{\beta} - \overline{\gamma}$ parameterizes the lowest order effect of the self-gravity of orbiting masses by modifying the Newtonian interaction energy terms in Eq. (14.12) into $G_{AB}m_A m_B/r_{AB}$, with a body-dependent gravitational "constant" $G_{AB} = G_N[1 + \eta(E_A^{\rm grav}/m_A c^2 + E_B^{\rm grav}/m_B c^2) + O(1/c^4)]$, where $G_N = G\exp[2a(\varphi_0)](1+\alpha_0^2)$ and where $E_A^{\rm grav}$ denotes the gravitational binding energy of body A.

The best current limits on the post-Einstein parameters $\overline{\gamma}$ and $\overline{\beta}$ are (at the 68% confidence level): (i) $-3.8\times10^{-4} < \overline{\gamma} < 2.6\times10^{-4}$ deduced from Very Long Baseline Interferometry (VLBI) measurements of the deflection of radio waves by the Sun [17], and (ii) $4\overline{\beta} - \overline{\gamma} = -0.0007 \pm 0.0010$ [7] from Lunar Laser Ranging measurements of a possible polarization of the Moon toward the Sun [18]. More stringent limits on $\overline{\gamma}$ are obtained in models (*e.g.*, string-inspired ones [19]) where scalar couplings violate the Equivalence Principle.

14.3. Tests of the dynamics of the gravitational field in the radiative and/or strong field regimes

The discovery of pulsars (*i.e.* rotating neutron stars emitting a beam of radio noise) in gravitationally bound orbits [20,21] has opened up an entirely new testing ground for relativistic gravity, giving us an experimental handle on the regime of radiative and/or strong gravitational fields. In these systems, the finite velocity of propagation of the gravitational interaction between the pulsar and its companion generates damping-like terms at order $(v/c)^5$ in the equations of motion [22]. These damping forces are the local counterparts of the gravitational radiation emitted at infinity by the system ("gravitational radiation reaction"). They cause the binary orbit to shrink and its orbital period P_b to decrease. The remarkable stability of the pulsar clock has allowed Taylor and collaborators to measure the corresponding very small orbital period decay $\dot{P}_b \equiv dP_b/dt \sim (v/c)^5 \sim 10^{-12}$ [21,23], thereby giving us a direct experimental confirmation of the propagation properties of the gravitational field. In addition, the surface gravitational potential of a neutron star $h_{00}(R) \simeq 2Gm/c^2R \simeq 0.4$ being a factor $\sim 10^8$ higher than the surface potential of the Earth, and a mere factor 2.5 below the black hole limit ($h_{00} = 1$), pulsar data are sensitive probes of the strong-gravitational-field regime.

Binary pulsar timing data record the times of arrival of successive electromagnetic pulses emitted by a pulsar orbiting around the center of mass of a binary system. After correcting for the Earth motion around the Sun and for the dispersion due to propagation in the interstellar plasma, the time of arrival of the Nth pulse t_N can be described by a generic, parameterized "timing formula [24]" whose functional form is common to the whole class of tensor-scalar gravitation theories:

$$t_N - t_0 = F[T_N(\nu_p, \dot{\nu}_p, \ddot{\nu}_p); \{p^K\}; \{p^{PK}\}] . \qquad (14.15)$$

Here, T_N is the pulsar proper time corresponding to the Nth turn given by $N/2\pi = \nu_p T_N + \frac{1}{2}\dot{\nu}_p T_N^2 + \frac{1}{6}\ddot{\nu}_p T_N^3$ (with $\nu_p \equiv 1/P_p$ the spin frequency of the pulsar, etc.), $\{p^K\} = \{P_b, T_0, e, \omega_0, x\}$ is the set of "Keplerian" parameters (notably, orbital period P_b, eccentricity e and projected semi-major axis $x = a\sin i/c$), and $\{p^{PK}\} = \{k, \gamma_{\rm timing}, \dot{P}_b, r, s, \delta_\theta, \dot{e}, \dot{x}\}$ denotes the set of (separately measurable) "post-Keplerian" parameters. Most important among these are: the fractional periastron advance per orbit $k \equiv \dot{\omega}P_b/2\pi$, a dimensionful time-dilation parameter $\gamma_{\rm timing}$, the orbital period derivative $\dot{P}_b$, and the "range" and "shape" parameters of the gravitational time delay caused by the companion, r and s.

Without assuming any specific theory of gravity, one can phenomenologically analyze the data from any binary pulsar by least-squares fitting the observed sequence of pulse arrival times to the timing formula Eq. (14.15). This fit yields the "measured" values of the parameters $\{\nu_p, \dot{\nu}_p, \ddot{\nu}_p\}$, $\{p^K\}$, $\{p^{PK}\}$. Now, each specific relativistic theory of gravity predicts that, for instance, k, $\gamma_{\rm timing}$, $\dot{P}_b$, r and s (to quote parameters that have been successfully measured from some binary pulsar data) are some theory-dependent functions of the Keplerian parameters and of the (unknown) masses m_1, m_2 of the pulsar and its companion. For instance, in General Relativity, one finds (with $M \equiv m_1 + m_2$, $n \equiv 2\pi/P_b$)

$$\begin{aligned} k^{\rm GR}(m_1,m_2) =& 3(1-e^2)^{-1}(G_N M n/c^3)^{2/3} , \\ \gamma^{\rm GR}_{\rm timing}(m_1,m_2) =& e n^{-1}(G_N M n/c^3)^{2/3} m_2(m_1+2m_2)/M^2 , \\ \dot{P}^{\rm GR}_b(m_1,m_2) =& -(192\pi/5)(1-e^2)^{-7/2}\left(1+\tfrac{73}{24}e^2+\tfrac{37}{96}e^4\right) \\ & \times (G_N M n/c^3)^{5/3} m_1 m_2/M^2 , \\ r(m_1,m_2) =& G_N m_2/c^3 , \\ s(m_1,m_2) =& n x (G_N M n/c^3)^{-1/3} M/m_2 . \end{aligned} \qquad (14.16)$$

In tensor-scalar theories, each of the functions $k^{\rm theory}(m_1,m_2)$, $\gamma^{\rm theory}_{\rm timing}(m_1,m_2)$, $\dot{P}^{\rm theory}_b(m_1,m_2)$, etc is modified by quasi-static strong field effects (associated with the self-gravities of the pulsar and its companion), while the particular function $\dot{P}^{\rm theory}_b(m_1,m_2)$ is further modified by radiative effects (associated with the spin 0 propagator) [15,25].

Let us summarize the current experimental situation. In the first discovered binary pulsar PSR1913 + 16 [20,21], it has been possible to measure with accuracy the three post-Keplerian parameters k, $\gamma_{\rm timing}$ and $\dot{P}_b$. The three equations $k^{\rm measured} = k^{\rm theory}(m_1,m_2)$, $\gamma^{\rm measured}_{\rm timing} = \gamma^{\rm theory}_{\rm timing}(m_1,m_2)$, $\dot{P}^{\rm measured}_b = \dot{P}^{\rm theory}_b(m_1,m_2)$ determine, for each given theory, three curves in the two-dimensional mass plane. This yields one (combined radiative/strong-field) test of the specified theory, according to whether the three curves meet at one point, as they should. After subtracting a small ($\sim 10^{-14}$ level in $\dot{P}^{\rm obs}_b = (-2.422 \pm 0.006) \times 10^{-12}$), but significant, Newtonian perturbing effect caused by the Galaxy [26], one finds that General Relativity passes this $(k - \gamma_{\rm timing} - \dot{P}_b)_{1913+16}$ test with complete success at the 10^{-3} level [21,23]

$$\begin{aligned} \left[\frac{\dot{P}^{\rm obs}_b - \dot{P}^{\rm galactic}_b}{\dot{P}^{\rm GR}_b[k^{\rm obs},\gamma^{\rm obs}_{\rm timing}]}\right]_{1913+16} =& 1.0032 \pm 0.0023({\rm obs}) \pm 0.0026({\rm galactic}) \\ =& 1.0032 \pm 0.0035 . \end{aligned} \qquad (14.17)$$

Here $\dot{P}^{\rm GR}_b[k^{\rm obs},\gamma^{\rm obs}_{\rm timing}]$ is the result of inserting in $\dot{P}^{\rm GR}_b(m_1,m_2)$ the values of the masses predicted by the two equations $k^{\rm obs} = k^{\rm GR}(m_1,m_2)$, $\gamma^{\rm obs}_{\rm timing} = \gamma^{\rm GR}_{\rm timing}(m_1,m_2)$. This experimental evidence for the reality of gravitational radiation damping forces at the 0.3% level is illustrated in Fig. 14.1, which shows actual orbital phase data (after subtraction of a linear drift).

The discovery of the binary pulsar PSR1534 + 12 [27] has allowed one to measure the four post-Keplerian parameters k, $\gamma_{\rm timing}$, r and s, and thereby to obtain two (four observables minus two masses) tests of strong field gravity, without mixing of radiative effects [28]. General Relativity passes these tests within the measurement accuracy [28,21]. The most precise of these new, pure, strong-field tests is the one obtained by combining the measurements of k, γ, and s. Using the most recent data [29], one finds agreement at the 1% level:

$$\left[\frac{s^{\rm obs}}{s^{\rm GR}[k^{\rm obs},\gamma^{\rm obs}_{\rm timing}]}\right]_{1534+12} = 1.007 \pm 0.008 . \qquad (14.18)$$

It has also been possible to measure the orbital period change of PSR1534 + 12. General Relativity passes the corresponding $(k - \gamma_{\rm timing} - \dot{P}_b)_{1534+12}$ test with success at the 15% level [29].

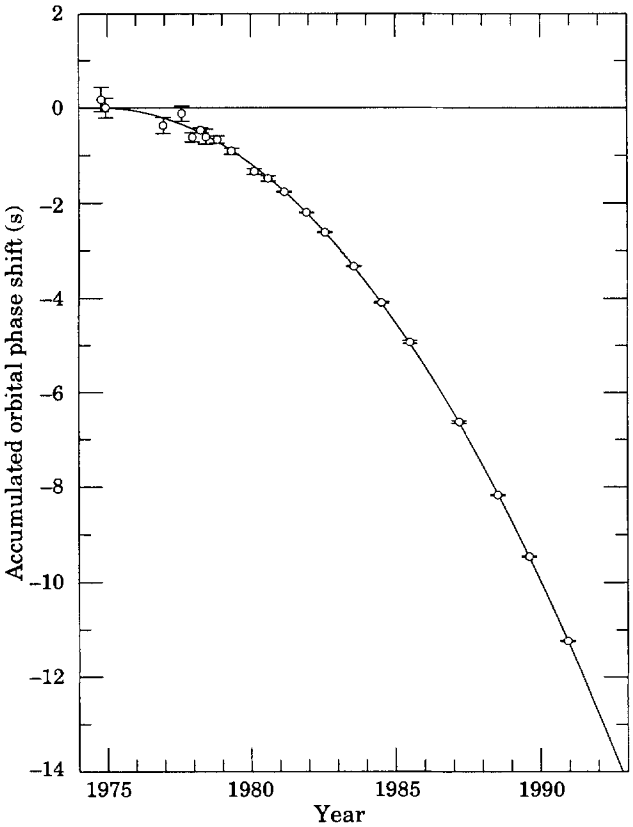

Figure 14.1: Accumulated shift of the times of periastron passage in the PSR 1913+16 system, relative to an assumed orbit with a constant period. The parabolic curve represents the general relativistic prediction, modified by Galactic effects, for orbital period decay from gravitational radiation damping forces. (Figure obtained with permission from Ref. 21.)

Several other binary pulsar systems, of a nonsymmetric type (nearly circular systems made of a neutron star and a white dwarf), can also be used to test relativistic gravity [30,31]. The constraints on tensor-scalar theories provided by three binary-pulsar "experiments" have been analyzed in [25] and shown to exclude a large portion of the parameter space allowed by solar-system tests. Recently, measurements of the pulse shape of PSR1913 + 16 [32] have detected a time variation of the pulse shape compatible with the prediction [33] that the general relativistic spin-orbit coupling should cause a secular change in the orientation of the pulsar beam with respect to the line of sight ("geodetic precession").

The tests considered above have examined the gravitational interaction on scales between a few centimeters and a few astronomical units. Millimeter scale tests of Newtonian gravity have been reported in Ref. 34. On the other hand, the general relativistic action on light and matter of an external gravitational field on a length scale $\sim$ 100 kpc has been verified to $\sim$ 30% in some gravitational lensing systems (see, *e.g.*, Ref. 35). Some tests on cosmological scales are also available. In particular, Big Bang Nucleosynthesis (see Section 15 of this *Review*) has been used to set significant constraints on the variability of the gravitational "constant" [36].

14.4. Conclusions

All present experimental tests are compatible with the predictions of the current "standard" theory of gravitation: Einstein's General Relativity. The universality of the coupling between matter and gravity (Equivalence Principle) has been verified at the 10^{-12} level. Solar system experiments have tested the weak-field predictions of Einstein's theory at the 10^{-3} level. The propagation properties of relativistic gravity, as well as several of its strong-field aspects, have been verified at the 10^{-3} level in binary pulsar experiments. Several important new developments in experimental gravitation are expected in the near future. The approved NASA Gravity Probe B mission (a space gyroscope experiment; due for launch within the next two years) will directly measure the gravitational spin-orbit and spin-spin couplings, thereby measuring the weak-field post-Einstein parameter $\overline{\gamma}$ to the 10^{-5} level. The planned NASA-ESA MiniSTEP mission (a satellite test of the Equivalence Principle) should test the universality of acceleration of free fall down to the 10^{-18} level (an improvement by six orders of magnitude). Laboratory experiments (motivated by recent theoretical ideas [37]) plan to test possible deviations from standard Newtonian gravity on sub-millimeter distance scales. Finally, the various kilometer-size laser interferometers under construction (notably LIGO in the USA and VIRGO in Europe) should, soon after 2002, directly detect gravitational waves arriving on Earth. As the sources of these waves are expected to be extremely relativistic objects with strong internal gravitational fields (*e.g.*, coalescing binary black holes), their detection will allow one to experimentally probe gravity in highly dynamical circumstances.

15. THE POCKET COSMOLOGY

Written April 2000 by E.W. Kolb and M.S. Turner (The University of Chicago and Fermilab).

15.1. The Universe Observed

15.1.1. *The Hubble expansion:*

The most fundamental discovery of modern observational cosmology is the expansion of the Universe. The expansion is just a rescaling of the Universe: the proper distance between points at rest in the cosmic rest frame scales as the cosmic scale factor $R(t)$ [sometimes denoted as $a(t)$]. The expansion rate is given by

$$H(t) \equiv \dot{R}(t)/R(t) \; . \tag{15.1}$$

In general, H is a function of time. The present value of the expansion rate, the Hubble constant H_0, can be measured in a number of ways, all of which fundamentally involve dividing the recessional velocity of a distant galaxy by its distance. It is conventional to express H_0 in terms of a dimensionless constant h: $H_0 = 100\; h\,\mathrm{km\,s^{-1}\,Mpc^{-1}}$. While the linear nature of the distance–redshift relation for nearby objects (Hubble's Law) is clear (see Fig. 15.1), until recently there was a systematic uncertainty of almost a factor of two in the value of h. Today, virtually all methods are now consistent with $h = 0.65 \pm 0.05$ ($H_0 = 65 \pm 5\,\mathrm{km\,s^{-1}\,Mpc^{-1}}$), with a possible systematic error of about 10% [1].

The Hubble constant sets the scale of the Universe in both time and space: the time since the scale factor $R(t)$ was zero is measured in units of the Hubble time $H_0^{-1} = 9.778\; h^{-1}\,\mathrm{Gyr}$, and the size of the observable Universe is set by the Hubble distance $cH_0^{-1} = 2998\; h^{-1}\,\mathrm{Mpc} = 9.251\; h^{-1} \times 10^{27}\,\mathrm{cm}$. The precise relationships between H_0 and the size and age depend upon the expansion history of the Universe and are discussed in Sec. 15.2.

Another fundamental parameter is the deceleration parameter, q_0, which measures the rate of change of the expansion:

$$H_0^2 q_0 \equiv -\ddot{R}(t_0)/R(t_0) \; . \tag{15.2}$$

In a universe comprised only of matter, q_0 equals $\Omega_M/2$, where Ω_M is the fraction of critical density contributed by matter. The critical density is determined by H_0 and the gravitational constant G:

$$\begin{aligned}\rho_{\rm crit} &\equiv \frac{3H_0^2}{8\pi G} = 1.879\; h^2 \times 10^{-29}\,\mathrm{g\,cm^{-3}} \\ &= 1.054\; h^2 \times 10^4\,\mathrm{eV\,cm^{-3}} \; .\end{aligned} \tag{15.3}$$

For a matter-dominated or radiation-dominated universe the density determines the fate of the universe: a sub-critical-density universe expands forever and a super-critical-density universe recollapses. A cosmological constant (or similar form of energy density) complicates the connection between destiny and energy density.

Measurements of the distances to very distant supernovae indicate that q_0 is actually negative, *i.e.*, the Universe is accelerating (see below). If correct, this illustrates dramatically that the energy density of the Universe is dominated by something other than matter or relativistic particles, since their gravity would slow (decelerate) the expansion.

15.1.2. *The redshift:*

As the Universe expands, all distances are stretched with the cosmic scale factor, including the wavelengths of photons. (The exception to this universal stretching is the size of a bound system, *e.g.*, a galaxy, a Hydrogen atom, or a proton.) Because the Universe is expanding, photons emitted long ago are redshifted:

$$1 + z \equiv \frac{\lambda_{\rm today}}{\lambda_{\rm emission}} = \frac{R(t_0)}{R(t_{\rm emission})} \; . \tag{15.4}$$

Redshift (z) directly indicates the relative linear size of the Universe when that photon was emitted. For example, the most distant quasar has $z = 5.82$; when the light from that quasar was emitted, the Universe was a factor of $1 + z \simeq 6.82$ times smaller. The relative size of the Universe is simply $(1+z)^{-1}$, while its age at a given redshift depends upon the expansion history.

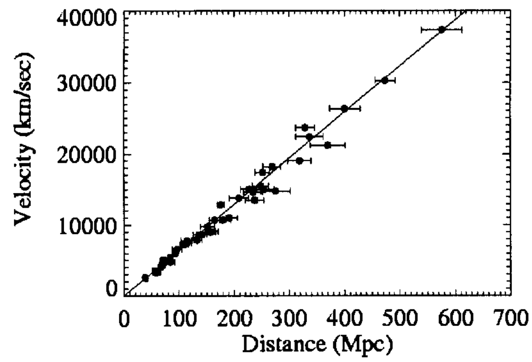

Figure 15.1: The distance–redshift diagram illustrates the expansion of the Universe. This "Hubble diagram" with linear axes is derived from a sample of type Ia supernovae and $H_0 = 65 \pm 2\;\mathrm{km\,s^{-1}\,Mpc^{-1}}$ (error purely statistical; figure courtesy of Adam Riess).

15.1.3. *The age of the Universe:*

The relationship between the expansion age (time since zero scale factor) and the Hubble age H_0^{-1} depends upon the slowing or speeding of the expansion rate. For plausible values of the Hubble constant and expansion histories, the expansion age is between 10 and 17 Gyr. The supernova measurements that indicate the Universe is accelerating also constrain the expansion history, and imply an expansion age of $15^{+1.4}_{-1.1}\,\mathrm{Gyr}$ [2].

An important cosmological consistency test is the comparison of the expansion age with independent age measurements of objects within the Universe: consistency requires the Universe to be older than any object within it. Independent age measurements include the ages of the oldest globular clusters dated by their stars, of the heavy elements as dated by radioactive decays, and of the oldest white-dwarf stars in the disk of our galaxy as measured by their cooling. The last two clocks are less easily compared to the expansion age because of the uncertainty of when the disk formed relative to the galaxy and the time history of heavy-element formation.

The reliability of the globular-cluster technique has improved in the last five years due to better stellar models, better atomic-physics data, and more accurate globular-cluster distance measurements. Current estimates for the age of the Universe based upon globular clusters are $t_0 = 14 \pm 2$ Gyr, with a possible systematic error of similar size [3]. Ages for the Universe based upon white-dwarf cooling and nuclecosmochronology are consistent with this number. While the error bars are still significant, the expansion age is comfortably consistent with the independent estimates of the age of the Universe.

15.1.4. *The composition of the Universe:*

We have taken the first steps toward a full accounting of the composition of the Universe. In units of the critical density, our assessment is

$$\begin{aligned}\text{total} : \Omega_0 &= 1 \pm 0.1 \; , \\ \text{matter} : \Omega_M &= 0.35 \pm 0.1 \; , \\ \text{energy} : \Omega_E &= 0.8 \pm 0.2 \; ,\end{aligned} \tag{15.5}$$

where the errors quoted are meant to be 1σ. By matter we mean material that is nonrelativistic (*i.e.*, pressure p much smaller than its energy density). As discussed below, energy refers to components that are intrinsically relativistic; *e.g.*, photons (γ), massless neutrinos (ν), and vacuum energy (Λ).

The total of matter plus energy density has been determined by measurements of the dependence of the anisotropy of the cosmic microwave background (CMB) upon angular scale (see the review on "Cosmic background radiation" (Sec. 19) in the full *Review* and Figure 15.2).

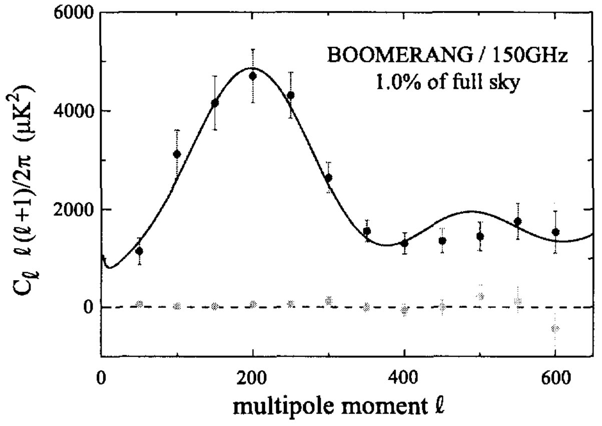

Figure 15.2: CMB angular power spectrum as determined by the Long Duration Balloon Flight of Boomerang, based on one frequency channel and 1% of the sky [4]. The curve is a flat CDM model with $\Omega_\Lambda = 0.65$. The Boomerang data by themselves imply $\Omega_0 = 1 \pm 0.06$. (The broken line and associated points show the difference of the two halves of the time stream of data; the absence of a difference indicates internal consistency.)

The matter density consists of several components: optically bright baryons in stars, optically dark baryons (in hot, cold, and warm gas, neutral atomic gas, molecular clouds, and stellar remnants), neutrinos, and nonbaryonic dark matter of an unknown form, here referred to as cold dark matter (CDM). The matter density breaks down as follows

$$\begin{aligned} \text{CDM} &: \Omega_{\text{CDM}} = 0.30 \pm 0.1 \\ \text{Baryons} &: \Omega_B = (0.019 \pm 0.001)h^{-2} \simeq 0.045 \pm 0.01 \\ &\quad \text{optically bright baryons } \Omega_* \sim 0.005 \\ &\quad \text{dark baryons } \Omega_B \sim 0.04 \\ \text{Neutrinos} &: 0.10 \gtrsim \Omega_\nu \gtrsim 0.003\ . \end{aligned} \tag{15.6}$$

The baryon density is most precisely probed by comparing the big-bang production of deuterium and the measurements of the primeval deuterium abundances in high-redshift clouds of hydrogen (see the review on "Big-bang nucleosynthesis (BBN)" (Sec. 16) in the full *Review* and Ref. 5). The total matter density is determined many ways, all of which are consistent with $\Omega_M = 0.35 \pm 0.07$. We believe that it is most cleanly determined from the baryon density and the ratio of baryonic mass to total mass in clusters of galaxies ($\equiv f_B$): $\Omega_M = \Omega_B / f_B$ [6].

The lower bound to the contribution of light neutrinos is from the SuperKamionkande evidence for neutrino oscillations involving muon neutrinos and a mass difference squared of $\mathcal{O}(10^{-2}\,\text{eV}^2)$ [7]. The upper bound to Ω_ν is from the requirement that neutrinos not interfere with the formation of structure in the Universe [8]. While the neutrino contribution is small, it is comparable to that of bright stars. Finally, the CDM mass density is derived from the difference of Ω_M and Ω_B, assuming that neutrinos do not contribute significantly and that the nonbaryonic dark matter is slowly moving cold particles (the "C" in CDM).

Almost seventy years ago Zwicky pointed out that the gravity of stars in clusters of galaxies is not great enough to hold together clusters. More precise measurements today show that the total matter density is almost 100 times that of stars and that the dark matter problem is manifold. The factor of seven discrepancy between Ω_M and Ω_B is strong evidence that most of the matter is nonbaryonic. Further, the study of the formation of structure in the Universe indicates that the nonbaryonic dark matter must be slowly moving particles (cold dark matter), with the leading candidates being elementary particles left over from the earliest moments (see the review on "Dark matter" (Sec. 18) in the full *Review*). Finally, (optically) dark baryons outweigh those in stars by about a factor of ten.

Relativistic energy denoted by Ω_E appears in several forms today:

$$\begin{aligned} \text{photons} &: \Omega_\gamma h^2 = 2.471 \times 10^{-5} \\ \text{massless neutrinos} &: \Omega_\nu h^2 = 1.122 \times 10^{-5} \\ \text{dark energy} &: \Omega_X = 0.8 \pm 0.2\ . \end{aligned} \tag{15.7}$$

The contribution of the photons in the cosmic microwave background and the (undetected) relativistic neutrino seas (two relativistic species assumed) are simple to calculate. Today, this relativistic contribution is negligible, but during the earliest moments it was the dominant component.

The mysterious entry, dark energy, is suggested by the type Ia supernovae measurements (SNeIa) that indicate the Universe is accelerating [2,9]. The supernovae data were analyzed assuming that the dark energy is a cosmological constant, and the results can be summarized by

$$\Omega_\Lambda = \frac{4}{3}\Omega_M + \frac{1}{3} \pm \frac{1}{6}\ . \tag{15.8}$$

All data are consistent with a cosmological constant of this size; however, theoretical estimates for the contribution to the cosmological constant coming from vacuum energy (zero-point energies) are at least 55 orders of magnitude larger than the critical density. This is the long-standing cosmological-constant problem.

It might well be that the resolution of the cosmological-constant puzzle is that vacuum energy does not contribute anything to the energy budget of the Universe today. If this is so, any acceleration of the expansion must be due to something else! The requirement for acceleration is an inequality involving the energy density and the pressure: $\rho + 3p < 0$. Since this component is clearly dark and relativistic ($|p| \sim \rho$ if $\rho > 0$), we have called it dark energy. Theorists have been busy, and there are already a number of interesting suggestions for the dark energy; they include a very light, slowly evolving scalar field (sometimes referred to as quintessence), vacuum energy, and a network of light, tangled topological defects. The supernova measurements, combined with other data, indicate that $-1 \le p/\rho \le -\frac{1}{2}$ [10].

As shown in Fig. 15.3 there is consistency between the independent determinations of the matter/energy content of the Universe. The emerging picture for the matter-energy of the Universe challenges the Standard Model of particle physics since nonbaryonic dark matter, massive neutrinos, and dark energy are not part of the Standard Model.

15.1.5. *The cosmic microwave background*:

The cosmic microwave background contributes only a tiny fraction of critical density today; however, its presence means that during early history ($t < 40{,}000\,\text{yrs}$) radiation dominated the energy density of the Universe. See the review on "Cosmic background radiation" (Sec. 19) in the full *Review* for a summary of the CMB with references; here we touch upon the most salient features.

The CMB is to an extraordinary precision black-body radiation (any deviation from the Planck spectrum is less than 50 parts per million and statistically insignificant). The temperature has been measured to four significant figures: $T_0 = 2.725 \pm 0.001\,\text{K}$. This corresponds to a photon number density of $n_\gamma = 410.5\,\text{cm}^{-3}$ and fraction of critical density $\Omega_\gamma = 2.471\ h^{-2} \times 10^{-5}$.

The CMB has a dipole anisotropy on the sky of amplitude $3.372 \pm 0.004\,\text{mK}$, which arises from the velocity of the solar system with respect to the cosmic rest frame (defined as the CMB rest frame). This implies a solar-system velocity of $371 \pm 0.5\,\text{km}\,\text{s}^{-1}$, and a velocity of the local group of $622 \pm 22\,\text{km}\,\text{s}^{-1}$.

CMB anisotropy has now been detected on angular scales from 90° (multipole $l = 2$) to a fraction of a degree ($l \sim 500$), with amplitudes of tens of μK (see Figure 15.2). This anisotropy is due to

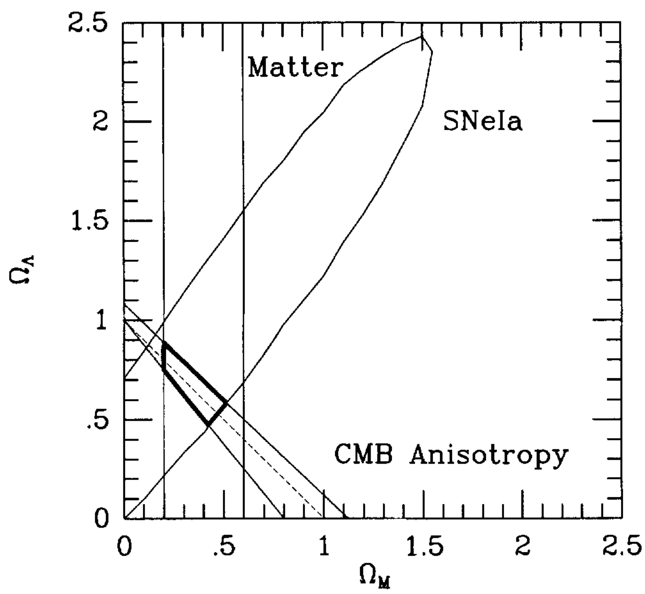

Figure 15.3: Summary of independent determinations of Ω_0, Ω_X and Ω_M, assuming the dark energy is vacuum energy (cosmological constant). Note the consistency of the three 95% confidence contours. Data are consistent with $\Omega_o = \Omega_\Lambda + \Omega_M = 1$ (dashed line).

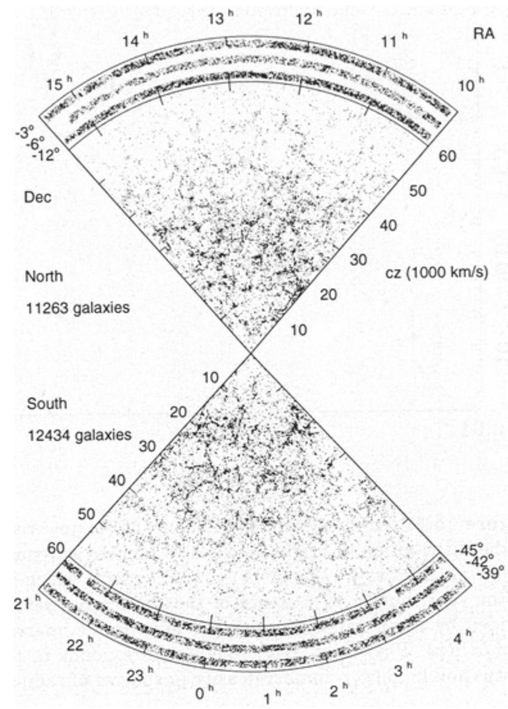

Figure 15.4: A slice from the Las Campanas Redshift Survey [11]. Each point represents a galaxy in the survey. Recessional velocity cz may be translated into distance d from us by Hubble's Law, $d = 10\ h^{-1}$ Mpc $(cz/1000$ km/s).

inhomogeneity in the distribution of matter of the same amplitude, $\delta\rho/\rho \sim \delta T/T \sim 10^{-5}$. Since the surface of last scattering for the CMB is the Universe at about 500,000 years after the bang, this CMB anisotropy implies that the Universe at that time was very smooth, but not perfectly smooth. The level of matter inhomogeneity indicated is what is needed to explain the structure that exists today, after taking into account the growth of inhomogeneity due to the attractive force of gravity over the past 14 Gyr.

15.1.6. *Large-scale structure of the Universe*:

Einstein and others assumed isotropy and homogeneity to simplify the field equations of general relativity. While the Universe on small scales (much less than 100 Mpc) is neither isotropic or homogeneous, at early times, and on large scales today, there is ample evidence for isotropy and homogeneity. The evidence at early times is provided by the uniformity of the CMB ($\delta T/T \sim \delta\rho/\rho \sim 10^{-5}$). Redshift surveys, three-dimensional maps of the distribution of galaxies, now probe the Universe on scales as large as 300 h^{-1} Mpc. They indicate that the distribution of galaxies becomes homogeneous and isotropic on scales much greater than 100 Mpc (see Fig. 15.4). Even larger surveys to be completed over the next five years [*e.g.*, the Sloan Digital Sky Survey (SDSS) and the 2° Field project (2dF)] will probe the distribution of matter on even larger scales.

On smaller scales the Universe is highly structured: there are galaxies, small groups of galaxies, great clusters containing thousands of galaxies, superclusters, and giant sheet-like structures extending across 100 h^{-1} Mpc. This structure can be explained by the level of inhomogeneity revealed by the CMB anisotropy and the subsequent growth due to gravitational amplification, provided there is nonbaryonic dark matter.

Redshift surveys reveal the distribution of light, rather than matter itself. In principle, the two could be very different. After all, the bulk of the matter is not even baryons. This problem is called biasing: light is likely to be a biased tracer of mass. The ratio of the inhomogeneity in the distribution of galaxies to that of matter is called the bias factor b. (The bias is likely to depend on scale and the type of galaxy.) A variety of studies show that biasing is important, but not overwhelming: b differs from unity by of order 50% or less. For example, the *rms* fluctuation in the number of galaxies within a sphere of radius 8 h^{-1} Mpc is unity; on the same scale the *rms* mass fluctuation has been inferred to be about 0.8, from the abundance of rich clusters and numerical simulations of structure formation.

Figure 15.5 summarizes the power spectrum $P(k) \equiv |\delta_k|^2$ of the distribution of galaxies today, where δ_k is the Fourier transform of the galaxy number density. On the very largest scales, $\lambda \gtrsim 10\ h^{-1}$ Mpc, the inhomogeneity of matter is probed by the CMB anisotropy; on small scales it is probed by the present distribution of galaxies. When the MAP and Planck CMB anisotropy maps and the 2dF and SDSS redshift surveys are complete, there will be a range of scales, from about 10 h^{-1} Mpc up to about 500 h^{-1} Mpc, where both the matter and galaxy inhomogeneity will be probed. On these scales biasing will be directly examined.

15.2. The Standard Cosmology

15.2.1. *Robertson–Walker line element*:

The distribution of matter in the observable Universe today is isotropic and homogeneous on the largest scales ($\gg 10\ h^{-1}$ Mpc). The smoothness of the CMB, $\delta_T/T < 10^{-4}$ on all angular scales measured, indicates that at early times the distribution of matter and radiation were isotropic and homogeneous. Thus, for purposes of describing the present observable Universe on sufficiently large scales, as well as the Universe at early times, we may assume that the Universe is isotropic and homogeneous.

The metric for a space with homogeneous and isotropic spatial sections is the maximally symmetric Robertson-Walker (RW) metric, which can be written in the form

$$ds^2 = dt^2 - R^2(t)\left\{\frac{dr^2}{1-kr^2} + r^2 d\theta^2 + r^2 \sin^2\theta\, d\phi^2\right\}, \qquad (15.9)$$

where $(t,\ r,\ \theta,\ \phi)$ are coordinates (referred to as comoving coordinates), and $R(t)$ is the cosmic scale factor. With an appropriate rescaling of the coordinates, k can be chosen to be $+1$, -1, or 0 for spaces of constant positive, negative, or zero spatial curvature, respectively. Nonetheless, there are an infinity of RW models, distinguished

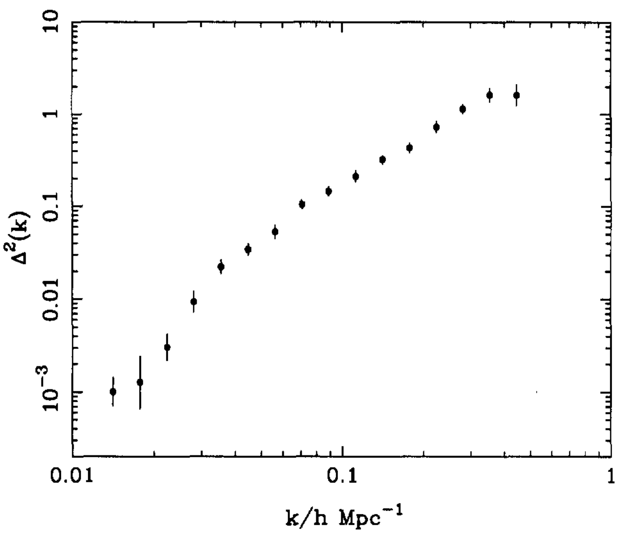

Figure 15.5: Summary of measurements of the power spectrum of the distribution of bright galaxies vs Fourier wavenumber k, shown as $\Delta(k)$ vs k [12]. $\Delta^2(k) = k^3 P(k)/2\pi^2$, which is equal to the contribution to variance of the galaxy number density divided by mean galaxy density per logarithmic interval in k ($d\sigma^2/d\ln k$). Physically, $\Delta(k)$ roughly corresponds to the rms fluctuation in galaxy-number density in spheres of radius $\approx \pi/k$.

by their radii of spatial curvature, $R_{\rm curv} = R(t)/\sqrt{|k|}$. A convenient and widely used convention is to set the cosmic scale factor to unity today; then, the coordinate r and $1/\sqrt{|k|}$ have dimensions of length. We shall usually use this convention.

The time coordinate is just the proper (or clock) time measured by an observer at rest in the comoving frame, *i.e.*, (r, θ, ϕ)=const. The term *comoving* is well chosen: Observers at rest in the comoving frame remain at rest, *i.e.*, (r, θ, ϕ) remain unchanged, and observers initially moving with respect to this frame will eventually come to rest in it.

15.2.2. *Particle kinematics and conservation of energy*:

If the stress-energy tensor has the form of a perfect fluid, the conservation of stress energy ($T^{\mu\nu}{}_{;\nu} = 0$) gives the first law of thermodynamics in the form

$$d(\rho R^3) = -pd(R^3) \ , \tag{15.10}$$

or equivalently,

$$\begin{aligned} d\ln\rho &= -\,3(1+w)d\ln R \\ \Rightarrow \ \rho &\propto \exp\left[-3\int(1+w)d\ln R\right] \ , \end{aligned} \tag{15.11}$$

where $w \equiv p/\rho$ characterizes the equation of state of the fluid. The physical significance of the above equation is clear: The change in energy in a comoving volume element, $d(\rho R^3)$, is equal to minus the pressure times the change in volume, $-pd(R^3)$. If w is independent of time, the energy density evolves as $\rho \propto R^{-3(1+w)}$. Examples of interest include

$$\begin{aligned} \text{radiation}: \quad & p = \frac{1}{3}\rho \Longrightarrow \rho \propto R^{-4} \\ \text{matter}: \quad & p = 0 \Longrightarrow \rho \propto R^{-3} \\ \text{vacuum energy}: \quad & p = -\rho \Longrightarrow \rho \propto \text{const} \ . \end{aligned} \tag{15.12}$$

The "early" Universe was radiation dominated, and the "adolescent" Universe was matter dominated. The Universe today appears to be dominated by a form of energy similar to vacuum energy ($w \approx -1$). If the Universe underwent inflation, there was a "very early" period when the stress-energy was dominated by vacuum energy.

The equation of motion for a freely falling particle in RW space-time is very simple: the three-momentum decreases as the inverse of the cosmic scale factor:

$$|\mathbf{p}| \propto 1/R \tag{15.13}$$

For a massless particle, this is the cosmological redshift of wavelength. For a massive, nonrelativistic particle, this implies that any velocity with respect to the cosmic rest frame decreases as the inverse of the scale factor, with the particle eventually coming to rest in comoving RW coordinates.

15.2.3. *Friedmann equations*:

The dynamics of the expansion are determined from the Einstein equations. For the Robertson–Walker metric they are known as the Friedmann equations:

$$\begin{aligned} H^2 &= \frac{\dot{R}^2}{R^2} = \frac{8\pi G}{3}\rho - \frac{k}{R^2} \\ \frac{\ddot{R}}{R} &= -\,\frac{4\pi G}{3}(\rho + 3p) \ . \end{aligned} \tag{15.14}$$

Note that the equation for the expansion rate is the first integral of the second Friedmann equation.

These equations can be used to write the deceleration parameter as

$$q_0 = \frac{1}{2}\Omega_0 + \frac{3}{2}\sum_i w_i\Omega_i \ . \tag{15.15}$$

This formula applies to any epoch, provided the values of Ω_i corresponding to that epoch are used. For example, assuming a flat Universe and matter and cosmological-constant components,

$$q_z = \frac{1}{2} - \frac{3}{2}\left[\frac{\Omega_\Lambda}{\Omega_\Lambda + (1+z)^3(1-\Omega_\Lambda)}\right] \tag{15.16}$$

where the factor following 3/2 is $\Omega_\Lambda(z)$. It follows that the epoch of accelerated expansion ($q_z < 0$) began at redshift $z = (2\Omega_\Lambda/\Omega_M)^{1/3} - 1 \approx 0.6$ (taking $\Omega_M = 0.35$ and $\Omega_\Lambda = 0.65$).

In the simple case in which the right side of the Friedmann equation is dominated by a fluid whose pressure is given by $p = w\rho$, it follows that

$$\rho \propto R^{-3(1+w)} \qquad R \propto t^{2/3(1+w)} \ , \tag{15.17}$$

This leads to the results: $R \propto t^{1/2}$ for $w = 1/3$ (radiation-dominated universe); $R \propto t^{2/3}$ for $w = 0$ (matter dominated); $R \propto \exp(H_0 t)$ for $w = -1$ (vacuum dominated); and $R \propto t$ for a curvature-dominated universe (*i.e.*, $H^2 = |k|/R^2$). Dark energy with $-1/3 > w \geq -1$ leads to the scale factor growing more rapidly than t and perhaps as rapidly as $\exp(H_0 t)$. Note that in terms of the dynamics of the expansion, curvature-domination and dark energy with $w = -1/3$ both lead to $R \propto t$.

15.2.4. *The three ages of the Universe*:

Because the energy density in relativistic particles (photons and neutrinos) evolves as R^{-4}, while that in matter evolves as R^{-3}, when $R(t) \leq R_{EQ} = 2.663 \times 10^{-4}/(\Omega_M h^2/0.156)$ the Universe was "radiation dominated." This corresponds to temperatures $T \geq T_{EQ} = 0.8819\,\text{eV}(\Omega_M h^2/0.156)$. (In computing R_{EQ} we have assumed that all three neutrino species were relativistic at early times.) During the radiation era, the scale factor $R(t) \propto t^{1/2}$. Note that the 1σ uncertainty in $\Omega_M h^2$ is nearly 30%; the fiducial value $\Omega_M h^2 = 0.156$ derives from the somewhat arbitrarily selected central values, $\Omega_M = 0.35$ and $h = 2/3$;

After matter-radiation equality, the Universe begins a matter-dominated phase with scale factor $R(t) \propto t^{2/3}$. During the matter-dominated era,

$$t(z) = 16.5\,\text{Gyr}/(1+z)^{3/2}(\Omega_M h^2/0.156)^{1/2} \ . \tag{15.18}$$

When the contributions to the energy density from both matter and radiation are comparable, the scale factor and age are related by

$$\frac{t}{t_{EQ}} = \frac{(R/R_{EQ} - 2)(R/R_{EQ} + 1)^{1/2} + 2}{2 - \sqrt{2}} \ , \tag{15.19}$$

This exact expression reduces to $R \propto t^{1/2}$ for $t \ll t_{EQ}$ and $R \propto t^{2/3}$ for $t \gg t_{EQ}$. The age of the Universe at matter-radiation equality is

$$\begin{aligned} t_{EQ} =& 4(\sqrt{2}-1)H_{EQ}^{-1}/3 \\ =& 4.25 \times 10^4\,\text{yrs}/(\Omega_M h^2/0.156)^2 \,. \end{aligned} \tag{15.20}$$

Last scattering of the CMB photons occurs shortly after matter-radiation equality, at a redshift $z_{LS} \simeq 1100$, when the age of the Universe was

$$t_{LS} \simeq 4.5 \times 10^5\,\text{yrs}/(\Omega_M h^2/0.156)^{1/2} \,. \tag{15.21}$$

Acceleration implies that dark energy has recently began to control the behavior of the expansion. Assuming that the dark energy exists in the form of a cosmological constant, the transition to a vacuum-energy dominated age occurred at

$$R_\Lambda = (\Omega_M/\Omega_\Lambda)^{1/3} = 0.814 \tag{15.22}$$

for $\Omega_M = 0.35$ and $\Omega_\Lambda = 0.65$, which corresponds to a redshift $z_\Lambda = 0.23$. Well into the Λ-dominated era, the scale factor evolves as

$$R(t) \propto \exp\left[\sqrt{\Omega_\Lambda} H_0 t\right] \,. \tag{15.23}$$

15.2.5. *Destiny*:

In a universe where all forms of energy density decrease more rapidly than R^{-2} ($w_i > -1/3$ for all i), there is a connection between geometry and destiny: open universes ($k \le 0$) expand forever and closed universes ($k > 0$) recollapse. We thought until recently that we lived in this kind of universe *i.e.*, matter plus radiation. With the advent of a sizable dark energy component, all that goes out the window! For example, a closed universe with a positive cosmological constant ($w = -1$) can expand forever and an open universe with a negative cosmological constant must recollapse.

15.2.6. *Age and deceleration parameter*:

The equality $dt = RdR/H$ can be integrated to give the age of the Universe as a function of redshift:

$$t(z) = \int_z^\infty \frac{dz}{(1+z)H(z)} \,. \tag{15.24}$$

where the present age $t_0 = t(z=0)$ (see Fig. 15.6). An interesting example is a flat vacuum energy + matter universe:

$$t(z) = \frac{2}{3} H(z)^{-1} \Omega_\Lambda(z)^{-1/2} \ln\left[\frac{1+\Omega_\Lambda(z)^{1/2}}{\sqrt{\Omega_M(z)}}\right] \,. \tag{15.25}$$

where

$$\begin{aligned} \Omega_M(z) =& \frac{\Omega_M}{\Omega_M + \Omega_\Lambda/(1+z)^3} \\ \Omega_\Lambda(z) =& 1 - \Omega_M(z) \\ H^2(z) =& H_0^2\left[\Omega_M(1+z)^3 + \Omega_\Lambda\right] \,. \end{aligned} \tag{15.26}$$

15.2.7. *The classic tests*:

The behavior of the expansion, and thereby the underlying mean properties of the mass and energy in the Universe, as well as the curvature of the Universe are probed by the classical kinematic cosmological tests: the magnitude vs redshift (Hubble) diagram, the angular diameter vs redshift diagram, and the number count vs redshift test. At the heart of all three tests is the comoving distance to an object with redshift z:

$$\begin{aligned} r(z) =& \kappa^{-1/2} \sinh\left[\kappa^{-1/2} \int_0^z \frac{dx}{H(x)}\right] \\ \kappa =& (1-\Omega_0)H_0^2 \\ H^2(z) =& H_0^2\left[\Omega_M(1+z)^3 + \Omega_X \exp\left(3\int(1+w)d\ln z\right)\right. \\ & \left. + (1-\Omega_0)(1+z)^2\right] \,. \end{aligned} \tag{15.27}$$

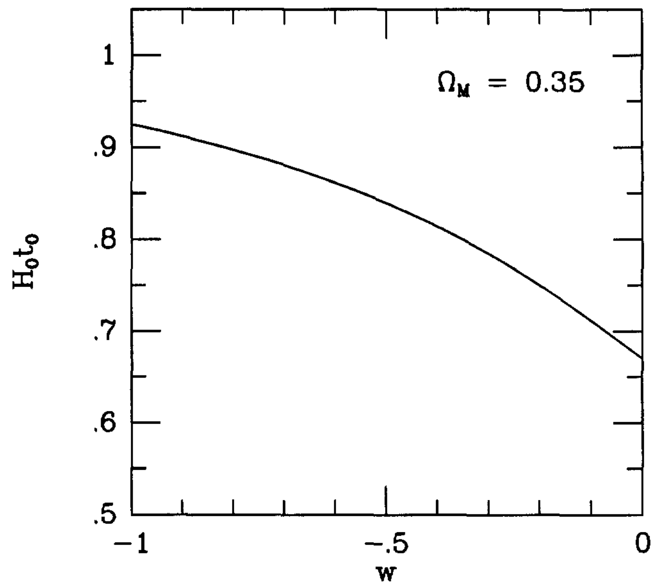

Figure 15.6: $H_0 t_0$ as a function of w, assuming a two-component universe with $\Omega_M = 0.35$ and $\Omega_X = 0.65$. $w = -1$ corresponds to a cosmological constant and $w = -1/3$ corresponds to an open universe with $\Omega_0 = \Omega_M = 0.35$. Accelerated expansion (or less decelerated expansion) leads to an older universe for a given present expansion rate; thus, $H_0 t_0$ increases with decreasing w.

For definiteness, $k < 0$ was assumed. For $k > 0$, sinh $\to$ sin and $\kappa \to k$.

Luminosity distance as a function of redshift

$$d_L(z) = (1+z)r(z) \tag{15.28}$$

can be inferred from flux measurements of standard (or standardizable) candles such as supernovae of type Ia:

$$d_L = \sqrt{\mathcal{L}/4\pi\mathcal{F}} \tag{15.29}$$

where $\mathcal{L}$ is the luminosity of the standard candle and $\mathcal{F}$ is the measured flux. It is this technique, used with type Ia supernovae, that has revealed the acceleration of the expansion.

The angular-diameter distance

$$d_A(z) = r(z)/(1+z) \tag{15.30}$$

can be inferred through measurements of the angular size of standard rules,

$$d_A = D/\theta \tag{15.31}$$

where D is the size of the standard ruler and θ is the subtended angle. This method is central to the determination of Ω_0 from CMB anisotropy. The standard ruler is the sound horizon distance at last scattering, $D \propto v_s t_{LS}$.

The comoving volume element is given by

$$\frac{dV}{d\Omega dr} = \frac{r^2}{\sqrt{1+\kappa r^2}} \quad \Rightarrow \quad \frac{dV}{d\Omega dz} = \frac{r^2(z)}{H(z)} \,. \tag{15.32}$$

It can be related to counts of objects of a constant (or known) comoving number density (*e.g.*, clusters or galaxies of a certain mass) vs a function of redshift,

$$\frac{dN}{dz d\Omega} = \frac{n(z)r^2(z)}{H(z)} \,. \tag{15.33}$$

Using this technique and theoretical expectations for the comoving number density of clusters in the CDM scenario, a matter density of about 0.3 has been inferred.

15.2.8. *Thermal history*:

During much of the history of the Universe, particularly the earliest history, conditions of thermal equilibrium existed. The total energy density and pressure of all species in equilibrium can be expressed in terms of the photon temperature T

$$\rho_R = T^4 \sum_{i=\text{species}} \left(\frac{T_i}{T}\right)^4 \frac{g_i}{2\pi^2} \int_{x_i}^{\infty} \frac{(u^2 - x_i^2)^{1/2} u^2 du}{\exp(u - y_i) \pm 1}$$
$$p_R = T^4 \sum_{i=\text{species}} \left(\frac{T_i}{T}\right)^4 \frac{g_i}{6\pi^2} \int_{x_i}^{\infty} \frac{(u^2 - x_i^2)^{3/2} du}{\exp(u - y_i) \pm 1} , \qquad (15.34)$$

where $x_i \equiv m_i/T$, $y_i \equiv \mu_i/T$, the + sign applies to fermions, the − sign to bosons, and we have taken into account the possibility that the species i may have a thermal distribution, but with a different temperature than that of the photons. We have used natural units, where $\hbar = c = k_B = 1$.

Since the energy density and pressure of a nonrelativistic species (*i.e.*, one with mass $m \gg T$) is exponentially smaller than that of a relativistic species (*i.e.*, one with mass $m \ll T$), it is a very convenient and a good approximation to include only the relativistic species in the sums for ρ_R and p_R, in which case the above expressions greatly simplify:

$$\rho_R = \frac{\pi^2}{30} g_* T^4 ,$$
$$p_R = \frac{\rho_R}{3} = \frac{\pi^2}{90} g_* T^4 , \qquad (15.35)$$

where g_* counts the total number of effectively massless degrees of freedom (those species with mass $m_i \ll T$),

$$g_* = \sum_{i=\text{bosons}} g_i \left(\frac{T_i}{T}\right)^4 + \frac{7}{8} \sum_{i=\text{fermions}} g_i \left(\frac{T_i}{T}\right)^4 . \qquad (15.36)$$

Fig. 15.7 shows $g_*(T)$ for the degrees of freedom in the Standard Model of particle physics.

During the early radiation-dominated epoch ($t \lesssim 40{,}000$ yrs) $\rho \simeq \rho_R$; and further, when $g_* \simeq$ const, $p_R = \rho_R/3$ (*i.e.*, $w = 1/3$) and $R(t) \propto t^{1/2}$. From this it follows

$$H = 1.660\ g_*^{1/2} \frac{T^2}{m_{\rm Pl}}$$
$$t = 0.3012\ g_*^{-1/2} \frac{m_{\rm Pl}}{T^2} \sim \frac{\rm MeV}{T^2}\ {\rm s} , \qquad (15.37)$$

where $m_{\rm Pl}$ is the Planck mass 1.221×10^{19} GeV.

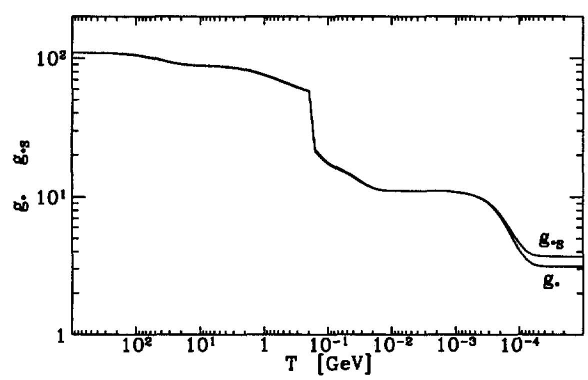

Figure 15.7: Number of relativistic degrees of freedom g_* and g_{*S} vs temperature according to the Standard Model of particle physics.

In the expanding Universe the entropy density s is given by

$$s \equiv \frac{\rho + p}{T} . \qquad (15.38)$$

It is dominated by the contribution of relativistic particles, so that to a good approximation,

$$s = \frac{2\pi^2}{45} g_{*S} T^3 , \qquad (15.39)$$

where

$$g_{*S} = \sum_{i=\text{bosons}} g_i \left(\frac{T_i}{T}\right)^3 + \frac{7}{8} \sum_{i=\text{fermions}} g_i \left(\frac{T_i}{T}\right)^3 . \qquad (15.40)$$

For most of the history of the Universe all particle species had a common temperature, and g_{*S} can be replaced by g_*. The annihilation of electron-positron pairs after neutrinos ceased interacting with the electromagnetic plasma ("decoupled") about 1 s after the bang leads to the slight heating of photons and $T_\gamma = (11/4)^{1/3} T_\nu$. Since then

$$g_* = 2.0 + N_\nu \frac{7}{8} (4/11)^{4/3} = 3.363$$
$$g_{*S} = 2.0 + N_\nu \frac{7}{8} \frac{4}{11} = 43/11 = 3.91 \qquad (15.41)$$

where $N_\nu = 3$ has been used to obtain numerical values since much of the time since BBN all three neutrino species have been relativistic.

In the absence of an entropy producing event (*e.g.*, phase transition or particle decay), the entropy per comoving volume $S \propto R^3 s$ is conserved. The constancy of S implies that the temperature of the Universe evolves as

$$T \propto g_{*S}^{-1/3} R^{-1}$$
$$\Longrightarrow R = 3.699 \times 10^{-10}\, g_{*S}(T)^{-1/3} \frac{\rm MeV}{T} . \qquad (15.42)$$

Whenever g_{*S} is constant, the familiar result, $T \propto R^{-1}$, obtains. The factor of $g_{*S}^{-1/3}$ enters because whenever a particle species becomes nonrelativistic and disappears, its entropy is transferred to the other relativistic particle species still present in the thermal plasma, causing T to *decrease slightly less slowly*.

Constancy of S also implies that $s \propto R^{-3}$. This means the physical size of a comoving volume element is proportional to $R^3 \propto s^{-1}$. Thus the number of some species per unit comoving volume, $N \equiv R^3 n$, is equal to the number density of that species divided by s: $N \equiv n/s$. Particle-number conservation in the expanding Universe is thus simply expressed as the constancy of n/s.

The entropy density s is proportional to the number density of relativistic particles, and therefore, to the photon number density, $s = 1.80 g_{*S} n_\gamma$. Today $s = 7.04 n_\gamma$; g_{*S} is a function of temperature, and the factor relating s and n_γ has decreased with time. However, since about 1 s that factor has been constant.

As an example of the utility of the ratio n/s, consider the baryon number. The baryon number in a comoving volume is

$$\frac{n_B}{s} \equiv \frac{n_b - n_{\bar b}}{s} . \qquad (15.43)$$

So long as baryon number nonconserving interactions are occurring very slowly, the baryon number in a comoving volume, n_B/s, is conserved. Today, there are only baryons and $s = 7.04\ n_\gamma$; thus, the baryon number of the Universe $n_B/s \simeq \eta/7$, where η is the present baryon-to-photon ratio. From BBN we know $\eta = (5.1 \pm 0.3) \times 10^{-10}$, and so we can infer that the baryon number of the Universe $n_B/s = (7.2 \pm 0.4) \times 10^{-11}$. It is believed that this tiny asymmetry between matter and antimatter arises due to B, C, and CP violating interactions that occurred out of equilibrium in the early Universe (baryogenesis).

Finally, thermal equilibrium in the expanding Universe corresponds to the limit of particle interactions occurring much more rapidly than the rate at which the temperature is dropping (set by expansion rate H). The opposite limit, a particle species that interacts slowly compared to the expansion rate (said to be decoupled), can be easily discussed. This limit applies to CMB photons after last scattering (redshift $z_{LS} \simeq 1100$) and neutrinos when the temperature of the Universe falls below about 1 MeV. The evolution of the phase-space distribution of a decoupled species is simple: particle momenta decrease as $1/R(t)$ and particle number density decrease as $1/R^3$. For a relativistic particle species that was in thermal equilibrium at decoupling (neutrinos and CMB photons), the phase-space distributions remain of the Fermi-Dirac or Bose-Einstein form, with a temperature that decreases precisely as $1/R(t)$. (Should the species eventually become nonrelativistic—for example a light neutrino species—the momentum phase-space distribution retains the FD or BE form, with $T \propto 1/R$.)

This fact explains why the CMB remains a perfect black body, and with some simple algebra and the constancy of S, how the factor of $(4/11)^{1/3}$ relating the neutrino and photon temperatures arises.

15.3. Beyond the Standard Cosmology: Inflation

Inflation is the most predictive and best developed idea about the earliest moments of the Universe. Further, its basic predictions—a flat Universe, a nearly scale-invariant spectrum of Gaussian, adiabatic density perturbations, and a nearly scale invariant spectrum of gravitational waves—are now being tested. The early results are consistent with the first two of these predictions; the third prediction will be much harder to test.

Inflation can provide insight about very fundamental issues not addressed by the standard cosmology: the origin of the large-scale isotropy and homogeneity; the origin of the small-scale inhomogeneity; the explanation for the oldness/flatness of the Universe; and in the context of simple grand unified theories, the monopole problem.

The key features of inflation are a period of accelerated expansion (typically exponential expansion), followed by an enormous release of entropy. During the period of exponential expansion a small, sub-horizon sized portion of the Universe is blown up to enormous size and made spatially flat. Quantum fluctuations in the field responsible for inflation, and in the metric of space time itself, are likewise stretched in size and eventually become density perturbations and gravitational waves. The entropy release that follows provides the heat that becomes the bath of radiation and other particles, thereby smoothly handing over the Universe to the standard hot big-bang phase. Provided that all of this occurs well before the epoch of big bang nucleosynthesis (*i.e.*, $T \gtrsim 1\,\text{MeV}$ and $t \lesssim 1\,\text{s}$), inflation can successfully address the fundamental questions without upsetting the success of the standard hot big-bang cosmology.

15.3.1. *Scalar-field dynamics*:

While there is no standard model of inflation, essentially all models can be described by the evolution of a scalar field ϕ initially displaced from the minimum of its potential energy curve $V(\phi)$. The evolution of the field can be described by two phases: (1) the slow roll during which nearly exponential expansion is driven by the nearly constant potential energy; (2) the coherent oscillation/reheat phase, during which the field oscillates rapidly about the minimum of its potential and eventually decays into lighter fields reheating the Universe and producing the heat of the big bang.

During the first phase, the equation of motion for the homogeneous mode scalar field in the expanding Universe is

$$\ddot{\phi} + 3H\dot{\phi} + V'(\phi) = 0 , \tag{15.44}$$

which is supplemented by the Friedmann equation

$$H^2 = \frac{8\pi}{3{m_{\rm Pl}}^2}\left[\frac{1}{2}\dot{\phi}^2 + V(\phi)\right] . \tag{15.45}$$

Over a small patch of the Universe, the scalar field should be smooth enough to justify the homogeneity assumption, and as inflation proceeds, the inhomogeneities in the scalar field decay away rapidly. Likewise, the energy density associated with the scalar field quickly come to dominate all other forms of energy in the Universe (*e.g.*, matter and radiation).

During the slow-roll phase the equations can be further simplified, as the $\ddot{\phi}$ term in the equation of motion and the $\dot{\phi}^2$ term in the expression for H^2 can be neglected:

$$\begin{aligned} \dot{\phi} &\simeq \frac{-V'}{3H} \\ dN &\equiv d\ln R = H dt = -\frac{8\pi}{{m_{\rm Pl}}^2}\frac{d\phi}{V'/V} , \end{aligned} \tag{15.46}$$

where prime denotes $d/d\phi$. These equations hold until the potential steepens and the slow-roll conditions, $m_{\rm Pl}V'/V \lesssim \sqrt{48\pi}$ and ${m_{\rm Pl}}^2V''/V \lesssim 24\pi$, are no longer valid.

During the slow-roll phase the Universe grows in size by a factor $\exp(N)$, where N is given by the integral of dN. To solve the flatness and horizon problems, N must be greater than about 60 (the precise number depends upon when inflation takes place and the temperature to which the Universe reheats after inflation). Quantum fluctuations in ϕ, which correspond to energy density fluctuations, $\Delta\rho \sim \Delta\phi V'$, are stretched exponentially from microscopic size to astrophysical size. Likewise, quantum fluctuations in the metric undergo similar exponential stretching.

When the slow-roll phase ends, accelerated expansion ends and the scale factor grows as a power law that depends upon the shape of the potential. Ultimately, the energy in the ϕ field is transferred to other, lighter fields. These fields interact and create the thermal bath of particles that we are confident existed during the earliest moments of the Universe.

Though there are many interesting intermediate details, the reheating of the Universe involves the transition from a cold Universe dominated by the zero-momentum mode of the scalar field to a hot Universe dominated by many degrees of freedom.

While there is no standard model for inflation, typically the energy scale of inflation is $V^{1/4} \sim 10^{14}\,\text{GeV}$, though models exists with energy scales as small as 1 TeV. The potential V must be very flat, typically with a dimensionless coupling of the order of 10^{-14} (which is driven to be this small by the requirement of the density perturbation amplitude of 10^{-5}). The simplest model of inflation is a potential of the form $V(\phi) = \lambda\phi^4$; in this case, $\lambda \simeq 10^{-14}$ and the 60 or so e-folds of inflation needed to produce a large enough patch to contain our present Hubble volume occurs as ϕ rolls from $4.5m_{\rm Pl}$ to $m_{\rm Pl}/\sqrt{2\pi}$.

15.3.2. *Predictions for observables*:

The spectrum of gravity waves (tensor perturbations) and density (or scalar) perturbations are the basis of the observables associated with inflation. They can be directly calculated from the properties of the scalar-field potential. This fact is the basis for the belief that observations may someday pin down the underlying model of inflation.

In most models both scalar and tensor perturbations have an approximately scale-invariant spectrum. In physical terms, that means that the dimensionless strain amplitude of gravity waves when they re-enter the horizon after inflation is independent of scale; in terms of the inflationary potential, that amplitude is $h_{\rm HOR} \sim H/m_{\rm Pl} \sim V^{1/2}/{m_{\rm Pl}}^2$. For density perturbations, it is the amplitude of the density perturbation at horizon crossing that is independent of scale: $(\delta\rho/\rho)_{\rm HOR} \sim H^2/\dot{\phi} \sim V^{3/2}/{m_{\rm Pl}}^3V'$. Further, both spectra are expected to deviate from exact scale invariance by a small amount that depends upon the potential. Finally, the Fourier components of both scalar and tensor perturbations are approximately power-law in wavenumber k.

Primordial perturbations and gravity waves lead to CMB fluctuations, so measurable quantities may be expressed in terms of the inflationary potential. For instance, the scalar contribution (S) and the tensor contribution (T) to the CMB quadrupole anisotropy are

$$\begin{aligned} S &\equiv \frac{5C_2^S}{4\pi} \simeq 2.9\,\frac{V/{m_{\rm Pl}}^4}{(m_{\rm Pl}V'/V)^2} \\ T &\equiv \frac{5C_2^T}{4\pi} \simeq 0.56(V/{m_{\rm Pl}}^4) , \end{aligned} \tag{15.47}$$

where C_2^S and C_2^T are the contribution of scalar and tensor perturbations to the variance of the $l = 2$ multipole amplitude ($\langle |a_{2m}|^2 \rangle = C_2^S + C_2^T$) and V is the value of the inflationary potential when the scale $k = H_0$ (present horizon scale) crossed the Hubble radius during inflation. Note, that the numerical coefficients in these expressions depend upon the composition of the Universe; the numbers shown are for $\Omega_M = 0.35$ and $\Omega_\Lambda = 0.65$.

The power-law indices that characterize the scalar and gravity-wave spectra may also be expressed in terms of the inflationary potential and its derivatives:

$$n - 1 = -\frac{1}{8\pi}\left(\frac{m_{\rm Pl}V'}{V}\right)^2 + \frac{m_{\rm Pl}}{4\pi}\left(\frac{m_{\rm Pl}V'}{V}\right)'$$
$$n_T = -\frac{1}{8\pi}\left(\frac{m_{\rm Pl}V'}{V}\right)^2 . \qquad (15.48)$$

Variations in the power-law indices with k may be expressed in terms of higher derivatives of V. For example,

$$\frac{dn}{d\ln k} = -\frac{m_{\rm Pl}}{8\pi}\left(\frac{m_{\rm Pl}V'}{V}\right)\frac{dn}{d\phi} . \qquad (15.49)$$

Finally, one can in principle use these observables to solve for the inflationary potential and its first two derivatives at the value of ϕ when the scale that fixes the CMB quadrupole crossed the Hubble radius during inflation:

$$V = 1.8T\, m_{\rm Pl}{}^4,$$
$$V' = \pm\sqrt{\frac{8\pi}{7}\frac{T}{S}}\, V/m_{\rm Pl},$$
$$V'' = 4\pi\left[(n-1) + \frac{3}{7}\frac{T}{S}\right] V/m_{\rm Pl}{}^2, \qquad (15.50)$$

where the factor 1.8 depends upon the composition of the Universe and is given for $\Omega_M = 0.35$ and $\Omega_\Lambda = 0.65$. The key to learning about the inflationary potential is measuring the ratio of the gravity-wave to density-perturbation contributions to the CMB quadrupole anisotropy. From that ratio, T/S, and the quadrupole anisotropy ($= T + S$), which has been measured by COBE, one can infer T. Further, if the spectrum of the inflation-produced gravity waves (n_T) can be measured, there is an important consistency test: inflation predicts $T/S = -4.9\ n_T$ (for $\Omega_M = 0.35$ and $\Omega_\Lambda = 0.65$).

15.3.3. *The new standard model*:

Motivated by the predictions of inflation and the best fit for the matter/energy content of the Universe, a standard model is emerging: ΛCDM. The model is characterized by its energy/matter content; in terms of the critical density, 65% vacuum energy, 30% cold dark matter particles, and 5% baryons with a tiny bit of hot dark matter. It is a flat ($k = 0$) model with a Hubble constant of about 65 km s^{-1} Mpc^{-1} and inflation-produced density perturbations that are close to being scale invariant. This model embodies all the successes of the hot big-bang cosmology, as well as the aspirations of inner space/outer space connection. Just as importantly, it is consistent with a very large (and rapidly growing) body of cosmological observations, including, the age of the Universe, the power spectrum of inhomogeneity, the CMB anisotropy measurements from 0.1° to 100°, the studies of the abundance and evolution of galaxies and clusters, the mapping of dark matter in clusters and galaxies, further supernovae observations, and more.

But important questions remain: If there is dark energy, is it just a cosmological constant, and if so why is it so small? What is the nonbaryonic dark matter? What is the primeval spectrum of inhomogeneity and is it consistent with the simplest models of inflation? What are the underlying model parameters of inflation? How does baryogenesis work and can the baryon asymmetry be related to laboratory measurements of CP violation, neutrino masses or proton decay? Is there a fundamental explanation for the odd matter/energy recipe for our Universe? Will one of the seemingly minor puzzles that exist today (the sheet like structures separated by 125 h^{-1} Mpc or the disagreement between theory and observation about the structure of CDM halos) unravel the whole picture? With the flood of observations and data that are coming, we can hope to answer these questions and more in the next decade or so.

16. BIG-BANG NUCLEOSYNTHESIS

Revised September 1999 by K.A. Olive (Univ. of Minnesota).

Among the successes of the standard big-bang model is the agreement between the predictions of big-bang nucleosynthesis (BBN) for the abundances of the light elements, D, ^{3}He, ^{4}He, and ^{7}Li, and the primordial abundances inferred from observational data (see [1–4] for a more complete discussion). These abundances span some nine orders of magnitude: ^{4}He has an abundance by number relative to hydrogen of about 0.08 (accounting for about 25% of the baryonic mass), while ^{7}Li, the least abundant of the elements with a big-bang origin, has an abundance by number relative to hydrogen of about $\sim 10^{-10}$.

16.1. Big-bang nucleosynthesis theory

The BBN theory matches the observationally determined abundances with a single well-defined parameter, the baryon-to-photon ratio, η. All the light-element abundances can be explained with η in the range $(1.2\text{–}5.7) \times 10^{-10}$, or $\eta_{10} \equiv \eta \times 10^{10} = 1.2\text{–}5.7$. Equivalently, this range can be expressed as the allowed range for the baryon mass density, $\rho_B = 0.8\text{–}3.9 \times 10^{-31}$ g cm^{-3}, and can be converted to the fraction, Ω, of the critical density, ρ_c.

The synthesis of the light elements was affected by conditions in the early Universe at temperatures $T \lesssim 1$ MeV, corresponding to an age as early as 1 s. At somewhat higher temperatures, weak-interaction rates were in equilibrium, thus fixing the ratio of the neutron and proton number densities. At $T \gg 1$ MeV, $n/p \approx 1$, since the ratio was given approximately by the Saha relation, $n/p \approx e^{-Q/T}$, where Q is the neutron-proton mass difference. As the temperature fell, the Universe approached the point ("freeze-out") where the weak-interaction rates were no longer fast enough to maintain equilibrium. The final abundance of ^{4}He is very sensitive to the n/p ratio at freeze-out.

The nucleosynthesis chain begins with the formation of deuterium in the process $pn \to D\gamma$. However, photo-dissociation by the high number density of photons ($n_\gamma/n_B = \eta^{-1} \sim 10^{10}$) delays production of deuterium (and other complex nuclei) well past the point where T reaches the binding energy of deuterium, $E_B = 2.2$ MeV. (The average photon energy in a blackbody is $\overline{E}_\gamma \approx 2.7\ T$.) When the quantity $\eta^{-1}\exp(-E_B/T)$ reaches about 1 (at $T \approx 0.1$ MeV), the photo-dissociation rate finally falls below the nuclear production rate.

The 25% fraction of mass in ^{4}He due to BBN is easily estimated by counting the number of neutrons present when nucleosynthesis begins. When the weak-interaction rates freeze-out at about $T \approx 0.8$ MeV, the n-to-p ratio is about 1/6. When free-neutron decays prior to deuterium formation are taken into account, the ratio drops to $n/p \lesssim 1/7$. Then simple counting yields a primordial ^{4}He mass fraction

$$Y_p = \frac{2(n/p)}{1 + n/p} \lesssim 0.25 \ . \qquad (16.1)$$

In the Standard Model, the ^{4}He mass fraction depends primarily on the baryon-to-photon ratio η, as it is this quantity that determines when nucleosynthesis via deuterium production may begin. But because the n/p ratio depends only weakly on η, the ^{4}He mass fraction is relatively flat as a function of η. The effect of the uncertainty in the neutron half-life, $\tau_n = 886.7 \pm 1.9$ s, is now small. Lesser amounts of the other light elements are produced: D and ^{3}He at the level of a few times 10^{-5} by number relative to H, and ^{7}Li/H at the level of about 10^{-10}, when η is in the range 1 - 10 $\times 10^{-10}$.

When we go beyond the Standard Model, the ^{4}He abundance is very sensitive to changes in the expansion rate, which can be related to the effective number of neutrino flavors. This will be discussed below.

The calculated abundances of the light elements are shown in Fig. 16.1 as a function of η_{10}. The curves for the ^{4}He mass fraction, Y_p, bracket the range based primarily on the uncertainty of the neutron mean-life. The spread in the ^{7}Li curves is due to the 1σ uncertainties in nuclear cross sections leading to ^{7}Li and ^{7}Be which subsequently decays to ^{7}Li [5–7]. Similarly, the spread in the curves for D and ^{3}He are 1σ uncertainties in the D and ^{3}He predictions. The boxes show the observed abundances with their range of uncertainty, discussed below. Since the observational boxes line up on top of each other, there is an overall agreement between theory and observations for η_{10} in the range 1.2–5.7.

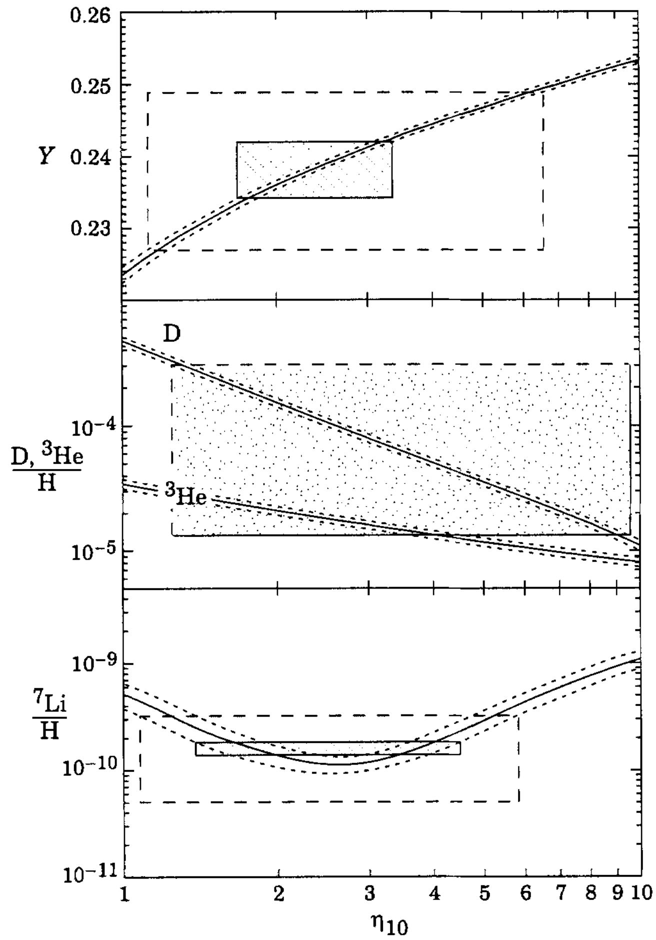

Figure 16.1: The abundances of D, ^{3}He, ^{4}He and ^{7}Li as predicted by the standard model of big-bang nucleosynthesis. Also shown by a series of boxes is the comparison between these predictions and the observational determination of the light element abundances. See text for details.

16.2. Observations

Because stars produce helium as well as heavier elements, one must search for primordial helium in regions where stellar processing has been minimal, *i.e.*, in regions where abundances of elements such as carbon, nitrogen and oxygen are very low. There are extensive compilations of observed abundances of ^{4}He, N, and O in many different extra-galactic regions of ionized H [8,9]. Extrapolating the ^{4}He abundances from the data leads to an observational estimate for Y_p of [10–13]

$$Y_p = 0.238 \pm 0.002 \pm 0.005 \ . \qquad (16.2)$$

(Here and elsewhere, the first error is the statistical standard deviation, and the second systematic.) The box in Fig. 16.1 bracketing the ^{4}He curves covers the range 0.234–0.242, where the half height is given as twice the statistical error. Of course the real uncertainty is dominated by systematic effects and the the dashed box is obtained using a larger error (twice the statistical and systematic error when added in quadrature) allowing Y_p to take values in an extended range 0.227–0.249.

Observations for deuterium and ^{3}He abundances currently present certain difficulties. All deuterium is primordial [14], but some of the primordial deuterium has been destroyed. Thus, as can be seen in the figure, the present deuterium abundance gives us an absolute upper limit to η. However, to get more information requires either an understanding of galactic chemical evolution of deuterium or a direct measurement of primordial deuterium. Even more problematical is ^{3}He: Not only is primordial ^{3}He destroyed in stars but it is very likely that at least some low-mass stars are net producers of ^{3}He. Neither the galactic chemical evolution of ^{3}He nor the production of ^{3}He in stars is well understood with standard models and observations presenting an inconsistent picture.

It appears that D/H has decreased over the age of the galaxy. Samples obtained deep inside meteorites provide measurements of the true (pre)-solar system abundance of ^{3}He, while measurements on meteoritic near-surface samples, the solar wind, and lunar soil samples also contain ^{3}He converted from deuterium in the early pre-main-sequence stage of the sun. The best current values are [15]

$$\left(\frac{\mathrm{D}+{}^3\mathrm{He}}{\mathrm{H}}\right)_\odot = (4.1 \pm 1.0) \times 10^{-5} ,$$
$$\left(\frac{{}^3\mathrm{He}}{\mathrm{H}}\right)_\odot = (1.5 \pm 0.3) \times 10^{-5} . \qquad (16.3)$$

The difference between these, is the pre-solar D abundance. There has also been a recent measurement of HD in the atmosphere of Jupiter [16] yielding a value $\mathrm{D/H} = (2.7 \pm 0.7) \times 10^{-5}$ which is consistent with the above presolar value of D/H.

The present interstellar-medium abundance of D/H is [17]

$$\mathrm{D/H} = 1.60 \pm 0.09^{+0.05}_{-0.10} \times 10^{-5} . \qquad (16.4)$$

It is this lowest value of D/H that provides the most robust upper bound on η, since D is only destroyed. It is shown (decreased by twice the errors added in quadrature) as the lower right corner of the D and ^{3}He box in Fig. 16.1. Thus, with confidence we can be sure that $\eta_{10} < 9.5$ And correspondingly $\Omega_B h^2 < 0.035$.

Deuterium has also been detected in high-redshift, low-metallicity quasar absorption systems [18–20]. These measured abundances should represent the primordial value, but, they are at present not consistent: Two [18,19] give a relatively high value for $\mathrm{D/H} \approx 2 \times 10^{-4}$ while another two [20] give $\mathrm{D/H} \approx 3.4 \pm 0.3 \times 10^{-5}$. Although it appears that the quality of the low D/H data is better than those showing high D/H, the latter can be used at the very least as an upper limit to primordial D/H and this is shown by the dashed box in Fig. 16.1, taking a 2σ upper limit of $\mathrm{D/H} < 3 \times 10^{-4}$. As one can see, the corresponding value of Y_p (at the same value of η as inferred by the observation of a high D/H) is in good agreement with the data. ^{7}Li is also in agreement at this value as well. However, due to the still somewhat preliminary status of this observation, it is premature to use it to fix the primordial abundance. A high value for the D abundance would require an even greater degree of D destruction over the age of the galaxy. The lower measurement for D/H requires that systematics work coherently for both ^{4}He and ^{7}Li to give an overlap with this data. Systematic effects [21] may, however, imply a higher D/H abundance (in the low D/H objects) which is in the range $3.5\text{-}5 \times 10^{-5}$. At the upper end of this range, all of the light element abundances are also in concordance. Eventually, the primordial D/H issue will hopefully be resolved and give a correspondingly narrow allowed range in η and perhaps change the nature of the ^{3}He and ^{7}Li (see below) arguments which are currently dominated by galactic and/or stellar evolution issuses.

Finally, we turn to ^{7}Li. In old, hot, population-II stars, ^{7}Li is found to have a very nearly uniform abundance. For stars with a surface temperature $T > 5500$ K and a metallicity less than about 1/20th solar (so that effects such as stellar convection may not be important), the abundances show little or no dispersion beyond that consistent with the errors of individual measurements. Much data has been obtained recently from a variety of sources, and the best estimate for the mean ^{7}Li abundance and its statistical uncertainty in halo stars is [22] (the estimate of the systematic uncertainty discussed below is our own)

$$\mathrm{Li/H} = (1.6 \pm 0.1^{+0.4}_{-0.3}{}^{+0.9}_{-0.6}) \times 10^{-10} . \qquad (16.5)$$

The first error is statistical. The box in Fig. 16.1 corresponds to a $2\sigma_{\mathrm{stat}}$ spread. The second set of errors is a systematic uncertainty that covers the range of abundances derived by various methods. The third set of errors in Eq. (16.5) accounts for the possibility that some of the primordial ^{7}Li has been destroyed in stars, and that as much as 40% of the observed ^{7}Li was produced in cosmic ray collisions rather than in the Big Bang. This uncertainty has been constrained by recent observations showing some evidence for evolution in ^{7}Li [23]. These uncertainties (depicted with a half height of $2\sigma_{\mathrm{stat}} + \sigma_{\mathrm{syst}}$) are shown by the dashed box in Fig. 16.1. Observations of ^{6}Li, Be, and B help constrain the degree to which these effects play a role [24–26].

16.3. A consistent value for η

For the Standard Model of BBN to be deemed successful, theory and observation of the light element abundances must agree using a single value of η. We summarize the constraints on η from each of the light elements. From the ^{4}He mass fraction, $Y_p < (0.242\text{–}0.249)$, we have $\eta_{10} < (3.4\text{–}6.6)$ as a 2σ upper limit (the highest values use possible systematic errors as shown by the shaded box in the figure). Because of the sensitivity to the assumed upper limit on Y_p and Li/H, the upper limit on η from D/H, is still of value. From D/H $> 1.3 \times 10^{-5}$, we have $\eta_{10} \lesssim 9.5$.

The lower limit on η_{10} can be obtained from either D/H or ^{7}Li. From the high D/H measurement in quasar absorption systems, we obtain $\eta_{10} > 1.2$. ^{7}Li allows a broad range for η_{10} consistent with the other elements. When uncertainties in the reaction rates and systematic uncertainties in the observed abundances are both taken into account, ^{7}Li allows values of η_{10} between (1.1–5.7).

The determination of η depends on our certainty that the observations of the light elements abundances can be translated into primordial abundnaces. This is perhaps more straightforward for ^{4}He and ^{7}Li, where the element abundances are determined in primitive low metallicity environments. If it turns out that a consistent value for D/H can be obtained from quasar absorption systems, then because of the slope of D/H with respect to η, D/H will be the best isotope for the determination of η. Until then, the use of the D and ^{3}He abundance determinations is necessarily complicated by th evolution of the abundances of these elements over the star forming history of the galaxy. Uncertainties in the ^{3}He evolution are compounded by uncertainties of stellar production/destruction mechanisms. The resulting overall consistent range for η_{10} is extended to (1.2–5.7) when systematic errors are pushed to their limits. These bounds on η_{10} constrain the fraction of critical density in baryons, Ω_B, to be

$$0.004 < \Omega_B h_0^2 < 0.021 . \qquad (16.6)$$

For a Hubble parameter, h_0, between 0.4 and 1.0, the corresponding range for Ω_B is 0.004–0.13.

Perhaps the best test of BBN will come when anisotropies in the microwave background check the determination of Ω_B. At present, other measurements (such as of hot X-ray gas in clusters of galaxies, Lyman-α clouds, or microwave anisotropies) of Ω_B give considerably larger uncertainties than those from BBN, but they are consistent with the BBN range.

16.4. Beyond the Standard Model

Limits on particle physics beyond the Standard Model come mainly from the observational bounds on the ^{4}He abundance. As discussed earlier, the neutron-to-proton ratio is fixed by its equilibrium value at the freeze-out of the weak-interaction rates at a temperature $T_f \sim 1$ MeV, with corrections for free neutron decay. Furthermore, freeze-out is determined by the competition between the weak-interaction rates and the expansion rate of the Universe,

$$G_F{}^2 T_f{}^5 \sim \Gamma_{\mathrm{wk}}(T_f) = H(T_f) \sim \sqrt{G_N N}\, T_f{}^2 , \qquad (16.7)$$

where N counts the total (equivalent) number of relativistic particle species. The presence of additional neutrino flavors (or of any other relativistic species) at the time of nucleosynthesis increases the energy density of the Universe and hence the expansion rate, leading to a larger value of T_f, n/p, and ultimately Y_p. It is clear that just as one can place limits [27] on N, any changes in the weak or gravitational coupling constants can be similarly constrained.

In the Standard Model, the number of particle species can be written as $N = 5.5 + \frac{7}{4}N_\nu$; 5.5 accounts for photons and $e^\pm$, and N_ν is the number of (massless) neutrino flavors. The helium curves in Fig. 16.1 were computed assuming $N_\nu = 3$, and the computed ^{4}He abundance scales roughly as $\Delta Y_{\rm BBN} \approx 0.012$–$0.014\ \Delta N_\nu$. Clearly the central value for N_ν from BBN will depend on η. If the best value for the observed primordial ^{4}He abundance is 0.238, then, for $\eta_{10} \sim 1.8$, the central value for N_ν is very close to 3. By means of a likelihood analysis on η and N_ν based on ^{4}He and ^{7}Li [28,29](see also [30]) it was found that the 95% CL ranges are $1.7 \leq N_\nu \leq 4.3$, and $1.4 \leq \eta \leq 4.9$.

The limits on N_ν can be translated into limits on other types of particles or particle masses that would affect the expansion rate of the Universe just prior to nucleosynthesis. In some cases, it is the interaction strengths of new particles which are constrained. Particles with less than full weak strength interactions contribute less to the energy density than particles that remain in equilibrium up to the time of nucleosynthesis [31].

We close with a simple example. Suppose there exist three right-handed neutrinos with only right-handed interactions of strength $G_R < G_F$. The standard left-handed neutrinos are no longer in equilibrium at temperatures below ~ 1 MeV. Particles with weaker interactions decouple at higher temperatures, and their number density ($\propto T^3$) relative to neutrinos is reduced by the annihilations of particles more massive than 1 MeV. If we use the upper bound $N_\nu < 4.0$, then the three right-handed neutrinos must have a temperature $3(T_{\nu_R}/T_{\nu_L})^4 < 1$. Since the temperature of the decoupled ν_R's is determined by entropy conservation, $T_{\nu_R}/T_{\nu_L} = [(43/4)/N(T_f)]^{1/3} < 0.76$, where T_f is the freeze-out temperature of the ν_R's. Thus $N(T_f) > 24$ and decoupling must have occurred at $T_f > 140$ MeV. Finally, the decoupling temperature is related to G_R by $(G_R/G_F)^2 \sim (T_f/3\text{ MeV})^{-3}$, where 3 MeV corresponds to the decoupling temperature for ν_L. This yields a limit $G_R \lesssim 10^{-2}\ G_F$. These limits are strongly dependent on the assumed upper limit to N_ν; for $N_\nu < 3.5$, the limit on G_R stegnthened to $G_R < 0.002\ G_F$, since T_f is constrained to be larger than the temperature corresponding to the QCD transition in the early Universe.

17. GLOBAL COSMOLOGICAL PARAMETERS: H_0, Ω_M, and Λ

Written April 2000 by M. Fukugita (University of Tokyo, Institute for Cosmic Ray Research) and C.J. Hogan (University of Washington).

This review surveys the current status of the determination of the three cosmological parameters, the Hubble constant H_0, the mass density parameter Ω_M and the cosmological constant Λ. These quantities set the scale and characterize the mean mass-energy content and curvature in cosmological solutions of Einstein's equations which describe the geometry and evolution of the universe as a whole. For technical details, see Ref. 1.

We adopt the normalization $\Omega_M + \Omega_\Lambda = 1$ for zero curvature (flat universe), where $\Omega_\Lambda = \Lambda/3H_0^2$ with Λ being the cosmological constant entering in the Einstein equation. The case with $\Omega_M = 1$ and $\Omega_\Lambda = 0$ is referred to as the Einstein-de Sitter (EdS) universe. We often use distance modulus $m - M = 5\log(d_L/10\text{ pc})$ instead of the luminosity distance d_L, where m is the apparent magnitude of an object whose magnitude at 10 pc would be M. We omit the unit km s^{-1}Mpc^{-1} for the Hubble constant and adopt the abbreviation $h = H_0/100$.

17.1. The Hubble Constant

17.1.1. ***Overview***: The Hubble constant, which has dimension of inverse time, sets the scale of the size and age of the Universe. Recent efforts to measure it have almost solved the long-standing discrepancy concerning the extragalactic distance scale; at the same time, new uncertainties have been revealed in the Milky Way distance scale.

The global value of H_0 was uncertain by a factor of two for several decades. Before 1980 the dispute was between two schools: Sandage and collaborators insisted on $H_0 = 50$; de Vaucouleurs and collaborators preferred a high value, $H_0 = 90$–100. The dichotomy persisted even after the discovery of an empirical but tight relationship between a galaxy's luminosity and rotation velocity, known as the Tully-Fisher relation, which allowed relative distances between whole galaxies to be estimated far out into the smooth Hubble flow. A straightforward reading of the Tully-Fisher relation gave values $H_0 = 80$–90, but this result was challenged over the issue of the Malmquist bias—whether the sample selects preferentially bright galaxies, biasing towards a shorter distance. A related dispute concerned the distance to the Virgo cluster, 16 Mpc or 22 Mpc, depending on the sample used.

The next major advance came in 1989–1990 when new, more precise relative distance indicators were discovered: the apparently universal shape of the the planetary nebula luminosity function (PNLF), and the surface brightness fluctuations (SBF) in galaxy images, utilizing the fact that a more distant galaxy shows a smoother light distribution. The two completely independent methods predicted relative distances to individual galaxies in excellent agreement with each other, and also with the Tully-Fisher relation (albeit with a somewhat larger scatter) [2]. These new techniques, when calibrated with the distance to M31, yielded a value around $H_0 = 80$ and a Virgo distance of 15 Mpc.

Around the same time Type Ia supernovae (SNeIa) were widely adopted as standard candles. This led to $H_0 = 50$–55, when calibrated with a Cepheid distance to the nearest SNIa host galaxy using the pre-refurbished *Hubble Space Telescope* (HST). Thus in the early nineties estimates were still dichotomous between $H_0 = 50$ and 80.

The refurbishment of HST allowed accurate measurements of Cepheids in galaxies as distant as 20 Mpc. This secured the distance to the Virgo cluster and tightened the calibrations of the extragalactic distance indicators, and resulted in $H_0 = (70\text{–}75) \pm 10$, 10% lower than the 'high value'. Another important contribution was the discovery that the maximum brightness of SNeIa varies from supernova to supernova, and that it correlates tightly with the decline rate of brightness. Direct calibration of the maximum brightness of several SNeIa with HST Cepheid observations yielded $H_0 = 65^{+5}_{-10}$, and nearly resolved the long-standing controversy.

All the methods mentioned above use distance ladders and take the distance to the Large Magellanic Cloud (LMC) to be 50 kpc ($m - M = 18.5$) as the zero point. Before 1997 few doubts were cast on the distance to LMC. With the exception of determinations using RR Lyr stars, the distance modulus converged to $m - M = 18.5 \pm 0.1$, *i.e.*, with a 5% error, and the RR Lyr discrepancy was blamed on its larger calibration error. It had been believed that the Hipparcos astrometric satellite would secure the distance within the Milky Way and tighten the distance to LMC. To everyone's surprise, Hipparcos instead revealed the contrary: the distance to LMC was more uncertain than we had thought, introducing new uncertainties into the determination of H_0. Connected to this, the age of the Universe turned out to be more uncertain than had been believed.

17.1.2. ***Extragalactic distance scale***: The measurement of cosmological distances traditionally employs distance ladders, as shown in Table 17.1. The listings written in italics indicate new methods which circumvent intermediate rungs. The most important milestone of the ladder is the LMC distance, 50 kpc ($m - M = 18.5$). The century-old Cepheid period-luminosity (PL) relation is still given great weight, but requires a few lower rungs to calibrate its zero point.

The refurbishment of HST achieved sufficient resolution to resolve Cepheids in the Virgo cluster [3]. Now 28 nearby spiral galaxies within 25 Mpc are given distances measured using the Cepheid PL relation [4]. A typical random error is 4–5% (0.08–0.10 mag), and the systematic error (from photometry) is 5% (0.1 mag) excluding the uncertainty of the LMC distance, to which the HST-KP ("Key Project") group assigns 6.5% error (0.13 mag). The prime use of these galaxies is to calibrate secondary distance indicators, which penetrate to sufficient depth that perturbations in the Hubble flow are a minor component of the error budget. The results are summarized in Table 17.2. We include a few earlier SNIa results which employed a partial list of Cepheid calibrators.

Table 17.1: Traditional distance ladders.

Method	Distance range	typical targets
Population I stars		
trigonometric or kinematic methods (ground)	< 50 pc	Hyades, nearby dwarfs
main sequence fitting (FG stars) Pop. I	< 200 pc	Pleiades
trigonometric method (Hipparcos)	< 500 pc	nearby open clusters
main sequence fitting (B stars)	40 pc–10 kpc	open clusters
Cepheids [Population I] (ground)	1 kpc–3 Mpc	LMC, M31, M81
Cepheids [Population I] (HST)	< 30 Mpc	Virgo included
secondary (extragalactic) indicators	700 kpc–100 Mpc	
Population II stars		
trigonometric method (Hipparcos)	< 500 pc	nearby subdwarfs
subdwarf main sequence fitting	100 pc–10 kpc	global clusters
cluster RR Lyr	5 kpc–100 kpc	LMC, age determinations

Table 17.2: Hubble constant (uncertainties in the LMC distance are not included).

Secondary indicators	References	Hubble constant
Tully-Fisher	HST-KP (Sakai *et al.*, [8])	$71 \pm 4 \pm 7$
Fundamental plane	HST-KP (Kelson *et al.*, [9])	$78 \pm 8 \pm 10$
SBF	HST-KP (Ferrarese *et al.*, [10])	$69 \pm 4 \pm 6$
SBF	Tonry *et al.*, [7]	$77 \pm 4 \pm 7$
SBF (galaxy z survey)	Blakeslee *et al.*, [11]	$74 \pm 4 \pm 7$
SNeIa	Riess *et al.*, [12]	67 ± 7
SNeIa	Hamuy *et al.*, [13]	$63 \pm 3 \pm 3$
SNeIa	Jha *et al.*, [14]	$64.4^{+5.6}_{-5.1}$
SNeIa	Suntzeff *et al.*, [15]	65.6 ± 1.8
SNeIa	HST-KP (Gibson *et al.*, [16])	$68 \pm 2 \pm 5$
SNeIa	Saha *et al.*, ([17])	60 ± 2

We emphasize H_0 determinations by two methods, SBF and SNeIa, in particular those underlined in the table. A cross correlation analysis showed that the relative distances agree well between SBF and others, including the Cepheids [5,6], and that it is probably the best secondary indicator presently available together with SNeIa. It is also important that there are now 300 galaxies measured with SBF, which are essential to make corrections for peculiar velocity flows for the ≤ 4000 km s^{-1} sample. The final value of Tonry *et al.* [7] is $H_0 = 77 \pm 8$, in which ± 4 is allotted to uncertainties in the flow model and another ± 4 to SBF calibration procedure in addition to the error of the Cepheid distance ± 6 (a quadrature sum is taken). When supplemented with peculiar velocity information from redshift surveys of galaxies, the value is further constrained to be 74 ± 4 up to the Cepheid distance error [11].

It is impressive that analyses of SNeIa Hubble diagram give virtually the same answer despite differences and corrections. The smaller H_0 of Saha *et al.* [17] arises from omission of the luminosity-decline rate correction; including this would push H_0 up by 10%. The other notable difference is a slightly higher value of HST-KP. Gibson *et al.* [16] made a reanalysis for all Cepheid observations performed by other groups and showed that the distances are all farther than would be derived from the HST-KP procedure. Taking the luminosity-decline rate correlation to be real and adopting Cepheid distances from the HST-KP data reduction, we adopt $H_0 = 68$ from SNeIa.

Leaving out the uncertainty of the Cepheid distance, H_0 from Tonry *et al.*'s [7] SBF determination is 77 ± 6, and that from SNeIa (HST-KP) is 68 ± 4. The difference is 13%, and the two values overlap at $H_0 = 71$. Allowing for individual 2σ errors, the overlap is in a range of $H_0 = 65$–76. An additional uncertainty is the 6% error ($\delta H_0 = \pm 4.5$) from the Cepheid distance which is common to both, still excluding the uncertainty of the LMC distance. We may summarize $H_0 = 71 \pm 7$ or 64–78 as our current standard, provided that the LMC distance is 50 kpc.

The convergence is a great achievement, in spite of the fact that the SNeIa results are still lower than those from other secondary indicators by 10%. All analyses are based on the LMC distance modulus $m - M = 18.50$ [18,19]. Doubts about this distance are discussed next.

17.1.3. ***The Local Distance Scale: Distance to LMC***: Most traditional paths to the LMC distance follow the ladder shown in the upper half of Table 17.1. The Hipparcos satellite can measure a parallax as small as 2 milliarcsec (mas), corresponding to a distance of 500 pc. It was a reasonable expectation that the geometric distance to the Pleiades cluster could be determined, circumventing the main sequence fitting from nearby parallax stars to the Pleiades and thus securing the Galactic distance scale. Hipparcos results have also opened new methods to estimate the distance to the LMC. However, the new detailed information has actually brought confusion.

The "Pleiades problem": The Pleiades cluster at 130 pc has long been taken to be the first milestone of the distance work, since it has nearly solar abundance of heavy elements. Hipparcos results have led to a revision of the previous distance modulus, based on main sequence fitting of FGK dwarfs, shorter by 0.25 mag (12%) [20,21]. This is a serious problem, since the disagreement means that either our understanding of FGK dwarfs, for which we have the best knowledge about stellar evolution, is incomplete, or that the Hipparcos parallax measurements contain systematic errors [22,23].

Metallicity effects in the LMC Cepheid calibration: The Cepheid distance to LMC is based on calibration using open cluster Cepheids, the distances to which are estimated by B star main sequence fitting that ties to the Pleiades (see Ref. 18 and references therein). It is shown that the residual of the PL fit shows a strong metallicity (Z) dependence. This means *either* the Cepheid PL relation suffers from a large Z effect, or the distances to open clusters contain significant Z-dependent errors [24]. A correction for this effect changes the distance to LMC either way, depending upon which interpretation is correct. So far direct Hipparcos Cepheid distances are too noisy to resolve this issue directly [25–27].

Red clump: Hipparcos has recalibrated the "red clump," the He burning stage of Population I stars, giving the distance modulus to LMC as 18.1 ± 0.1. Although much shorter than distances from other methods, this value is substantially in agreement with earlier red clump results [28,29].

Eclipsing binaries: Double-spectroscopic eclipsing binaries in principle yield the distance in a semi-geometric way out to LMC or even farther. The LMC distance modulus is estimated to be $m - M = 18.30 \pm 0.07$ [30]. There is a claim that the extinction used is too small by an amount of $\Delta E(B - V) = 0.037$ mag, leading to $m - M = 18.19$ [31].

RR Lyr calibration: The absolute luminosity of RR Lyr depends on metallicity, usually expressed as

$$\langle M_V(\mathrm{RR\ Lyr}) \rangle = a[\mathrm{Fe/H}] + b \ . \tag{17.1}$$

(V means values obtained using a "visual" wideband filter.) Considerable effort has been invested in determining the coefficients (a, b). The problem is again how to estimate the distance to RR Lyr stars. The calibration from the ground, $(a, b) = (0.2, 1.04)$, leads to an LMC distance of $m - M \approx 18.3$. Using Hipparcos field subdwarfs with parallax to calibrate RR Lyr in globular clusters gives $(a, b) = (0.22 \pm 0.09, 0.76)$, which brings the LMC distance to $m - M = 18.5$–18.6 [32]; see also Ref. 33. Statistical parallax for field RR Lyr in the Hipparcos catalogue [34,35], however, agrees better with the ground-based estimate. The uncertainties of 0.3 mag in the RR Lyr calibration translate to the LMC distance modulus 18.25–18.55.

Summary of the LMC distance problem: The distance modulus of the LMC is now uncertain by as much as 0.4 mag (20% in distance), ranging from 18.20 to 18.60. Recent observations with new techniques argue for the lower value. There is clearly a systematic effect, so that we cannot simply take an 'average of all observations'. Rather, we should leave both possibilities open.

17.1.4. ***Direct and Physical Methods***: Techniques called 'physical methods,' allow distance estimates without resorting to astronomical ladders. The advantage of the ladder is that the error of each ladder can be well documented, while the disadvantage is accumulation of errors. Physical methods are free from 'accumulation of errors,' but in this case the central problem is to minimize the model dependence and document realistic systematic errors. (The use of SNeIa maximum brightness was once taken to be a physical method; when it was 'downgraded' to an empirically-calibrated ladder, the accuracy and reliability were significantly enhanced.) A few direct results are reliable enough to be compared with the distances from ladders.

Geometrical calibration of the Cepheids: NGC4258 (M106) shows H_2O maser emission from clouds orbiting around a black hole of mass $4 \times 10^7 M_\odot$ located at the center. Precise VLBA measurements of Doppler velocities show that the motion of the clouds is very close to Keplerian and is perturbed very little. A complete determination is made for the orbital parameters, including centripetal acceleration and a bulk proper motion of the emission system. This yields a geometric distance to NGC4258 to be 7.2 ± 0.3 Mpc [36]. The distance is also measured using the conventional Cepheid PL relation to give 8.1 ± 0.4 Mpc with $(m-M)_{\rm LMC} = 18.5$, 13% longer than that from the maser measurement [37]. The short LMC distance would bring the Cepheid distance in a perfect agreement with the geometric distance. However, this is only one example, and the difference could be merely a statistical effect: the deviation is only twice the error.

Expansion photosphere model (EPM) for Type II supernovae (SNeII): If a supernova is a black body emitter one can calculate source brightness from temperature. The distance can then be estimated by comparing source brightness with the observed flux. In SNeII atmospheres the flux is diluted due to electron scattering opacity, requiring more sophisticated model atmospheres. Schmidt *et al.* [38,39] developed this approach and obtained absolute distances of SNeII in agreement with those from the ladder. The Hubble constant they obtained is 73 ± 9.

Gravitational lensing time delay: When a quasar image is split into two or more by gravitational lensing, a time delay arises among images from different path lengths and potentials at the image postition of the galaxy. The time delay is written as a product of a cosmological factor and a deflector model. It is observable if the source is variable, and can be used to infer H_0 [40]. The cosmological factor depends on Ω_M only weakly; its Ω_Λ dependence is even weaker. However, a crucial ingredient in this argument is a well-constrained model of the mass distribution of the deflector.

The first estimates of H_0 used the 0957+561 lens system. The deflector is not simple but includes a giant elliptical galaxy embedded in a cluster. There is an ambiguity associated with a galaxy mass/cluster mass separation, which does not change any observed lens properties but affects the derived Hubble constant. One way to resolve this degeneracy is to use the velocity dispersion of the central galaxy [41]. While the long-standing issue as to the value of the time delay was settled and $H_0 = 64 \pm 13$ was reported [42], the inclusion of a wider class of models [43] produces a significantly wider range, $H_0 = 77^{+29}_{-24}$, representing uncertainties associated with the choice of models. The second example, PG1115+080, is again not a simple deflector but includes an elliptical galaxy embedded in a compact group of galaxies. Various models for this system yield $H_0 = 36$–70 [44–47], but, as is discussed in the papers, the derived H_0 depends on the assumption for the dark matter distribution, with H_0 varying from 44 ± 4 to 65 ± 5.

Recently time delays have been measured for three simpler lenses, B0218+357, B1608+656 and PKS1830-211. Among them B0218+357 is a rather clean, isolated spiral galaxy lens, giving $H_0 = 69^{+13}_{-19}$ (the central value will be 74 if $\Omega_M = 0.3$) with a simple galaxy model of a singular isothermal ellipsoid [48]. For B1608+656 one obtained 64 ± 7 for $\Omega_M = 0.3$ (59 ± 7 for an EdS universe) and for PKS1830-211 75^{+18}_{-10} for EdS and 85^{+20}_{-11} for $\Omega_M = 0.3$ from the time delay measured by Koopmans and Fassnacht [49]. These authors concluded 74 ± 8 for low density cosmologies (69 ± 7 for EdS) from four (excluding the second) lensing systems with the simplest model of deflectors. It is encouraging to find such good agreement with the values from ladders from completely independent arguments.

Zeldovich-Sunyaev effect: The observation of the Zeldovich-Sunyaev (ZS) effect (the statistical heating of background photons by Compton scattering off hot electrons) for clusters tells us about the cluster depth (times electron density), which, when combined with angular diameter (times electron density squared) from x-ray observations, gives us the distance to the cluster provided that the cluster is spherical [50–52]. Although new and promising samples of ZS data are being assembled [52], we give little weight to this method for the time being since it is still subject to large systematic errors ($\pm30\%$). Even with a large sample, selection effects would bias towards clusters elongated along the line of sight because of higher surface brightness.

17.1.5. ***Age of globular clusters***: The most restrictive estimate for cosmic age is obtained from the evolution of globular clusters. Here, the RR Lyr calibration is also crucial, since the stellar age is proportional to the inverse of luminosity, *i.e.*, inverse square of the distance. Modern calculated evolutionary tracks of the main sequence by different authors agree reasonably well. There are occasional disagreements of colors at around the turn-off point, largely depending on the treatment of convection, but the turnoff luminosity is little affected (see *e.g.*, Renzini [53] and VandenBerg *et al.* [54]). The absolute magnitude at the turn-off point M_V^{TO} of the main sequence is hence a good indicator of the age [53]:

$$\log t_9 = -0.41 + 0.37 M_V^{TO} - 0.43\,Y - 0.13[\mathrm{Fe/H}]\,, \tag{17.2}$$

in units of Gyr, or

$$\log t_9 = -0.41 + (0.37a - 0.13)[\mathrm{Fe/H}] + 0.37[(M_V^{TO} - M_V^{\rm RR}) + b]] - 0.43\,Y \tag{17.3}$$

if Eq. (17.1) is inserted. (Y is the helium mass fraction.) The difference of the magnitudes between the turn-off point and RR Lyr ($M_V^{TO} - M_V^{\rm RR}$) depends little on clusters and is measured to be 3.5 ± 0.1 mag [55]. The a dependence appears in such a way that the metallicity dependence of the cluster age disappears if $a = 0.35$, *i.e.*, globular cluster formation appears coeval [56]. Current estimates (see above) give $a \approx 0.2$, which indicates that metal-poor clusters appear older.

The dichotomous calibrations of RR Lyr stars obviously affect the age of globular clusters. The result also depends on whether one takes the age-metallicity correlation to be real, as indicating metal-poor clusters being formed earlier, or merely due to a systematic error, the formation of globular clusters being coeval. The possibilities are four-fold:

b	$(m-M)_{\rm LMC}$	t_0 (noncoeval)	t_0 (coeval)
1.05	18.25	18 Gyr	15 Gyr
0.75	18.55	14 Gyr	12 Gyr

In addition there are $\pm10\%$ errors of various origin. The recent claims of Gratton *et al.* [32], Reid [33], and Chaboyer *et al.* [57] for young universe (11–12 Gyr) assume a coeval-formation interpretation together with the long RR Lyr calibration and the mean of globular cluster ages. The three other possibilities, however, are not excluded.

17.1.6. ***Conclusions on*** $\boldsymbol{H_0}$: Progress in the extragalactic distance scale has been substantial. The ladders yield values convergent within 10%, compared to a factor of 1.6 disagreement in early nineties. A new uncertainty, however, becomes manifest in the Galactic distance scale: there is a 15–20% uncertainty in the distance to LMC. Therefore, we may summarize

$$H_0 = (71 \pm 7) \times^{1.15}_{0.95} \tag{17.4}$$

as a currently acceptable value of the Hubble constant. This agrees with a HST-KP summary of Mould *et al.* [58] up to the uncertainty from the LMC distance, though we followed a different argument. This still allows $H_0 = 90$ at the high end (if Tonry *et al.*'s SBF [7,11] is given a higher weight) and 60 at the low end (if the SNeIa results are weighted). Note that H_0 from both EPM and gravitational lensing are consistent with the ladder value for $(m-M)_{\rm LMC} = 18.5$. With the shorter LMC distance the overlap is marginal.

The short LMC distance also causes trouble for H_0-age consistency. The LMC distance modulus of $m - M = 18.25$ would raise the lower limit of H_0 to 72, and increase the lower limit of age from $\approx$11.5 Gyr to $\approx$14.5 Gyr at the same time. There is then no solution for a $\Lambda = 0$ universe. Even with a non-zero Ω_Λ the solution is marginal (see Fig. 17.1 below).

17.2. The Density Parameter

The dimensionless cosmological density parameter directly controls the gravitational formation of cosmic structure. As our understanding of the cosmic structure formation is tightened, we should have a convergence of the Ω_M parameter. An important test is to examine whether estimates of Ω_M parameter extracted from cosmic structure formation agree with each other and with the values estimated in more direct ways.

17.2.1. *Model-independent determinations*:

***Luminosity density* $\times$ $\langle M/L \rangle$:** The mass density can be obtained by multiplying the luminosity density ($\mathcal{L}_B = (2.0 \pm 0.4) \times 10^8 h L_\odot$ Mpc^{-3}) with the average mass-to-light ratio $\langle M/L \rangle$. The M/L_B of galaxies is about 1–2 in galaxy disks and generally increases with the scale due to the increasing dominance of dark matter. If the dark matter distribution is isothermal within the virial radius ($r = 0.13$ Mpc $\Omega_M^{-0.15}[M/10^{12}M_\odot]^{1/2}_{<100\text{ kpc}}$ in a spherical collapse model), the value of M/L_B inside the virial radius is (150–400) h for L^* galaxies. This is about the value of M/L_B estimated for groups and clusters, (150–500)h, both from dynamics [59] and from lensing, (see *e.g.*, Kaiser *et al.* [60]). Multiplying the two values we get [61] $\Omega_M = 0.20 \times 2^{\pm 1}$. The CNOC group [62] made a self-contained estimate using their cluster sample and built-in field galaxy sample. They estimated $M/L_r \approx (210 \pm 60)\,h$ (n.b.: $M/L_B \approx 1.4 \times M/L_r$) for field galaxies from the cluster value $(289 \pm 50)h$. Their luminosity density of field galaxies is $\mathcal{L}_r = (1.7 \pm 0.2) \times 10^8 h L_\odot$ Mpc^{-3}, and therefore $\Omega_M = 0.19 \pm 0.06$.

H_0 versus cosmic age: For $H_0 \geq 60$, the age is 10.9 Gyr for the EdS universe. Since this is too short, Ω_M must be smaller than unity. The limits on H_0 and Ω_M are best compared graphically (see Fig. 17.1 below).

Type Ia supernova Hubble diagram: The type Ia supernova Hubble diagram now reaches $z \approx 0.4$–0.8. It can be used to infer the mass density parameter and the cosmological constant. As we discuss later, the observations favor a low Ω_M and a positive Λ. If we accept the published formal errors, $\Omega_M > 0.1$ is allowed only at three sigma for a zero Λ universe [63,64]. With some allowance for systematic effects, a zero Λ open universe may not be excluded yet, but an EdS geometry is far away from the observations. The favored value for Ω_M is approximately 0.8 $\Omega_\Lambda - 0.4$.

Baryon fractions in Galaxy Clusters: If the gas in a galaxy cluster is in approximate hydrostatic equilibrium (at the virial temperature $T \approx 7 \times 10^7(\sigma/1000$ km s$^{-1})^2$ K), its mass can be estimated by the luminosity and temperature of x-ray emission. In typical clusters baryon mass in the gas exceeds that in stars by an order of magnitude, so the gas gives the total baryon mass [65,66]. From 19 clusters White and Fabian [67] obtained $M_{\rm gas}/M_{\rm grav} = 0.056\ h^{-2/3}$, where $M_{\rm grav}$ is the dynamical mass. By requiring that the cluster baryon fraction agrees with Ω_B/Ω_M in the field, we have $\Omega_M = 0.066\ h^{-1/2}\eta_{10} = 0.39\ (\eta_{10}/5)$, where η_{10} is the global baryon to photon ratio in units of 10^{-10} and the last number assumes $h = 0.7$. An independent estimate from the Zeldovich-Sunyaev effect observed in clusters [51,68] yields $M_{\rm gas}/M_{\rm grav} = 0.082\ h^{-1}$, or $\Omega_M = 0.044\ h^{-1}\eta_{10} = 0.31\ (\eta_{10}/5)$. With $\eta_{10} = 3$–5 from primordial nucleosynthesis (see Sec. 16 on "Big-bang nucleosynthesis" in this *Review*) we have $\Omega_M = 0.2$–0.4.

Nonlinear Statistical Dynamics on Small Scales: For small scales ($r < 1$ Mpc) perturbations are non-linear, and a statistical equilibrium argument is invoked for ensemble averages: the peculiar acceleration induced by a pair of galaxies is balanced by relative motions (the cosmic virial theorem). Current estimates [69] give $\Omega_M(10\text{ kpc} \lesssim r \lesssim 1\text{ Mpc}) = 0.15 \pm 0.10$ from the pairwise velocity dispersion (with samples excluding clusters) and the three point correlation function of galaxies via a statistical stability argument. Least action principle reconstruction of galaxy orbits in the Local Group gives $\Omega_M = 0.15 \pm 0.15$. All arguments involving velocity are uncertain regarding the extent to which galaxies trace the mass distribution (biasing), or how much mass is present far away from galaxies.

Simple quasi-linear infall models: For larger scales ($r > 10$ Mpc), where perturbations are still in a linear regime, the velocity field is described by

$$\nabla \cdot \vec{v} + H_0\,\Omega_M^{0.6}\,\delta = 0\ , \qquad (17.5)$$

where δ is the enclosed mass overdensity. An integral form of Eq. (17.5) for a spherically symmetric case, $v/H_0 r = \Omega_M^{0.6}\langle\delta\rangle/3$, when applied to the Virgocentric flow, gives $\Omega_M \approx 0.2$ for $v \approx 200$–400 km s^{-1} and $\langle\delta\rangle \sim 2$, assuming no biasing, *i.e.*, galaxies mass [70]. Recently, Tonry *et al.* [7] argued that the peculiar velocity ascribed to the Virgo cluster is only $\lesssim 140$ km s^{-1}, while the rest of the peculiar velocity flow is attributed to the Hydra-Centarus supercluster and the quadrupole field.

Large-scale velocity flows: There are several methods to statistically compare large-scale velocity flows and density perturbations [71,72]. If δ is measured from galaxy clustering, Ω_M always appears in the measured combination $\beta = \Omega_M^{0.6}/b$ where b is a linear biasing factor of galaxies against the mass distribution. The value of $\Omega_M^{0.6}/b$ varies from 0.3 to 1.1, and tends to favor a high value. The most recent POTENT analysis using the Mark III compilation of velocities indicates a high-density universe, $\Omega_M = 0.5$–0.7 with $\Omega_M < 0.3$ excluded at a 99% CL [73]. Blakeslee *et al.* [11] derived $\Omega_M \approx 0.25 \pm 0.05$, if b is close to unity, using better-determined distances from SBF. In spite of substantial effort the results are controversial. The difficulty is that one needs accurate information for velocity fields, for which an accurate estimate of distances *and their errors* is crucial. Random errors of the distance indicators introduce large noise in the velocity field. This seems particularly serious in the POTENT algorithm, in which the derivative $\nabla \cdot \vec{v}/\Omega_M^{0.6}$ and its square are numerically computed. This procedure enhances noise, especially for a small Ω_M.

17.2.2. *Model-dependent determinations*:

The following derivations of the mass density parameter are based on the hierarchical clustering model of cosmic structure formation assuming the cold dark matter (CDM) model. The extraction of Ω_M is therefore indirect. On the other hand it is reasonable to appeal to such models, since Ω_M is the parameter that predominantly controls gravitational structure formation.

Shape parameter of the transfer function: Perturbations of density are described by the Fourier power spectrum $P(k)$, where k is the spatial wavenumber. CDM models predict a shape for the linear power spectrum $P(k) \propto k^{n-4}$ on small scales and $P(k) \propto k^n$ on large scales, where $n \approx 1$ is the primordial power law index. The transition scale is determined by $k_{eq} \approx 2\pi/c\,t_{eq}$, where the characteristic length $c\,t_{eq} = 6.5(\Omega_M h)^{-1}h^{-1}$ Mpc is the horizon size at the time of matter-radiation equality (in comoving units, appropriately stretched to the present epoch). The "shape parameter" $\Gamma \equiv \Omega_M h$ can be estimated from galaxy clustering, and to yield sufficient clustering power on scales of tens of Mpc must be small, about 0.2 [74–76].

Power spectrum in nonlinear galaxy clustering: It is argued that the power spectrum in a small scale region ($k^{-1} < 3h^{-1}$ Mpc), where nonlinear effects are dominant, shows more power than is expected in $\Omega_M = 1$ cosmological models. The excess power is understood if $\Omega_M \approx 0.3$ [77].

Evolution of the rich cluster abundance: The cluster abundance at $z \approx 0$ requires the rms mass fluctuation $\sigma_8 = \langle(\delta M/M)\rangle^{1/2}|_{r=8h^{-1}\text{ Mpc}}$ to satisfy $\sigma_8 \approx 0.6\ \Omega_M^{-0.5}$ [78,79]. The evolution of the cluster abundance is sensitive to σ_8 in early epochs of growth, corresponding to $z \gtrsim 0.3$ for rich clusters. The rich cluster abundance at $z \sim 0.3$–1, when compared with that at a low z, thus determines both σ_8 and Ω_M [80]. Carlberg [81] derived $\Omega_M = 0.4 \pm 0.2$, and Bahcall and Fan [82] obtained $\Omega_M = 0.2^{+0.3}_{-0.1}$, while Eke *et al.* [76] reported $\Omega_M = 0.43 \pm 0.25$ for an open universe, and $\Omega_M = 0.36 \pm 0.25$ for a flat universe, corresponding to a slow growth of the abundance. On the other hand, Blanchard and Bartlett [83] and Reichart *et al.* [84]

obtained $\Omega_M \approx 1$ from a more rapid growth. The controversy among authors arises from different estimates of the cluster mass at high z.

Cluster abundance versus the COBE normalization: The cluster abundance gives an accurate estimate of σ_8 for a low-z universe. Another place we can extract an accurate σ_8 is from the fluctuation power imprinted on cosmic microwave background radiation (CBR) anisotropies. Assuming the model CDM transfer function $\sigma_8 = \sigma_8(H_0, \Omega_M, \Omega_\Lambda, \Omega_B, n \ldots)$, matching of the COBE [85] with the cluster abundance gives a significant constraint on cosmological parameters $\Omega_M = \Omega_M(H_0, \Omega_\Lambda)$ [79,86], which improves by adding small-angle CBR data [87–90]. The presence of the tensor mode makes the range of n more uncertain, but notwithstanding these uncertainties, $\Omega_M > 0.5$ is difficult to reconcile with the matching condition whereas too-small Ω_M ($\lesssim 0.15$) is not consistent with the cluster abundance. These constraints will rapidly improve with new CBR data.

17.3. The Cosmological Constant

17.3.1. ***Type Ia supernova Hubble diagram***: The luminosity distance receives a cosmology-dependent correction as z increases: Ω_M pulls down d_L and Ω_Λ pushes it up. In first order of z the correction enters in the combination of $q_0 = \Omega_M/2 - \Omega_\Lambda$, so this is historically referred to as a q_0 test, a measure of cosmic deceleration, although this single-parameter description is not adequate at the redshifts of the current samples. The discovery by two groups that distant supernovae are fainter than expected from the local sample, even fainter than expected for $q_0 = 0$, points to the reality of $\Lambda > 0$ [63,64]. The best fits are currently for $\Omega_\Lambda \approx 0.7, \Omega_M \approx 0.3$—a flat, Λ-dominated universe.

The challenge of this analysis is to differentiate among interesting cosmologies with small differences of brightness. The samples are on average about 0.25 mag fainter than in the $\Omega_M = 0.2$, $\Omega_\Lambda = 0$ model, a difference most economically explained by adopting a cosmology with $\Lambda > 0$. On the other hand, at $z = 0.4$ where many supernovae are observed, the difference is $\Delta m = 0.12$ mag between $(\Omega_M, \Omega_\Lambda) = (0.3, 0.7)$ and $(0, 0)$, and $\Delta m = 0.22$ from $(0, 0)$ to $(1.0, 0)$. Therefore, an accuracy of $\lesssim 0.05$ mag ($\lesssim 5\%$) must be attained including systematics to prove the presence of Λ without appeal to other constraints (on Ω_M, $\Omega_M + \Omega_\Lambda$, *etc.*). Each SN data point contains at best ± 0.2 mag (20%) statistical error; the question is whether the total error is mostly random and systematics are controlled to a level of $\lesssim 0.05$ mag. A particular difficulty arises from a procedure to match high z SNe with the template at $z \approx 0$, which involves an integration over SN spectra dominated by strong features as well as a careful calibration of the flux zero points at different color bands. Even for spectrophotometric standard stars, the synthetic magnitude usually contains errors of 0.02–0.05 mag, especially when the color band involves the Balmer or Paschen regions. Dust obscuration may also be amplified into an important potential source of error, since, for example, a 0.02 mag error in color results in a 0.06 mag error in A_V. Perlmutter *et al.* [64] estimate 0.02 mag and Riess *et al.* [63] (see also Ref. 91) estimate 0.03 mag for K correction plus zero point errors, and 0.025 and 0.06 for dust extinction errors, respectively.

17.3.2. ***Gravitational lensing frequencies for quasars***: The cosmological factor in the gravitational lensing optical depth is very sensitive to the cosmological constant, if $\Omega_\Lambda \gg \Omega_M$ [92,93]. On the other hand, it is nearly insensitive to the change of Λ when it is small ($\Omega_\Lambda \lesssim 0.6$, say); in that case the uncertainties in the normalization factor (galaxy number density and the mass distribution of galaxies) dominate. It is likely that $\Omega_\Lambda > 0.8$ is excluded. On the other hand, a more stringent limit or solid detection is liable to be elusive for a smaller Ω_Λ. Nearly a decade of continuous efforts have brought substantial improvement in reducing uncertainties in the normalization factor [94–96]. Nevertheless, the luminosity density of early type galaxies which dominate lensing is uncertain by about a factor of two. We should adopt a conservative limit at present $\Omega_\Lambda < 0.8$ which is insensitive to this concern.

17.3.3. ***Harmonics of CBR anisotropies***: The angular scale of the first acoustic peak is particularly sensitive to a combination of Ω_M and Ω_Λ. The position of the first acoustic peak as estimated numerically using CMBFAST [97] is

$$\ell_1 \approx 220 \left(\frac{1 - \Omega_\Lambda}{\Omega_M}\right)^{1/2} , \tag{17.6}$$

valid to about 10% accuracy for the parameter range that concerns us. This means that the position of the acoustic peak is about $\ell \approx 220$ if $\Omega_M + \Omega_\Lambda = 1$, but it shifts to a high ℓ as $\Omega_M^{-1/2}$ if $\Omega_\Lambda = 0$. On the other hand, there is little power to determine Ω_M separately from Ω_Λ. The harmonics C_ℓ measured at small angles now reveal the acoustic peak [98], and its position favors a universe close to flat [87–89]. The most rescent result [99] indicates $0.88 \le \Omega_M + \Omega_\Lambda \le 1.12$, which means that a zero Λ universe is not tenable when combined with Ω_M from other arguments.

Table 17.3: Summary of Ω and Ω_Λ.

Method	Ω_M	Ω_Λ
H_0 vs t_0	< 0.7	
luminosity density +M/L	0.1–0.4	
cluster baryon fraction	0.15–0.35	
SNeIa Hubble diagram	≤ 0.3	≈ 0.7
small-scale velocity field		
(summary)	0.2 ± 0.15	
(pairwise velocity)	0.15 ± 0.1	
(Local Group kinematics)	0.15 ± 0.15	
(Virgocentric flow)	0.2 ± 0.2	
large-scale velocity field	0.2–1	
cluster evolution		
(low Ω_M sol'n)	$0.2^{+0.3}_{-0.1}$*	
(high Ω_M sol'n)	~1*	
COBE-cluster matching	0.35–0.45 (if $\Omega_\Lambda = 0$)*	
	0.20–0.40 (if $\Omega_\Lambda \neq 0$) *	
shape parameter Γ	0.2–0.4*	
CBR acoustic peak	$\approx (1 \pm 0.12) - \Omega_\Lambda$*	$\approx (1 \pm 0.12) - \Omega_M$
gravitational lensing		< 0.8
Summary	0.15–0.45 (if open)	
	0.2–0.4 (if flat)	
		0.6–0.8

*CDM model used.

17.4. Conclusions

The status of Ω_M and Ω_Λ is summarized in Table 17.3. We have a reasonable convergence of the Ω_M parameter towards a low value $\Omega_M = 0.15$–0.4. The convergence of Ω_M is significantly better with the presence of a cosmological constant that makes the universe flat. Particularly encouraging is the agreement of Ω_M derived with the most reliable arguments. Even so, the current 'low Ω_M concordance' means values that still vary by more than a factor of two. The indication of $\Omega_\Lambda \neq 0$ from the SNeIa Hubble diagram is very interesting and important, but on its own the conclusion is susceptible to small systematic effects. On the other hand small-scale CBR anisotropy observations confirming a nearly flat universe, in combination with the sum of the other evidence considered here, strongly suggest the presence of Λ or other exotic (highly negative pressure) form of dark mass-energy.

In conclusion we present in Fig. 17.1 allowed ranges of H_0 and Ω_M (and Ω_Λ) for the case of (a) flat and (b) open universes. With the flat case we cut the lower limit of Ω_M at 0.2 due to a strong constraint from lensing. An ample amount of parameter space is allowed for a

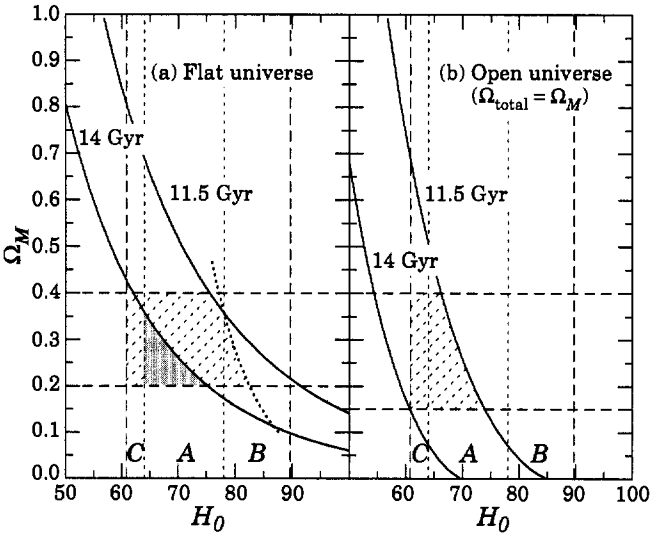

Figure 17.1: Consistent parameter ranges in the H_0–Ω_M plane for (a) a flat universe and (b) an open universe. A is the range of the Hubble constant when $(m - M)_{\rm LMC} = 18.5$. B is also allowed when the LMC distance is shorter by 0.3 mag, and C when longer by 0.1 mag. Note in panel (a) that most of the range of B is forbidden by the compatibility of age and H_0 that are simultaneously driven by the RR Lyr calibration (short dotted curve, see Sec. 17.1.6). Also note that the age range between ≈11.5 Gyr and ≈14 Gyr (light cross-hatched) is possible only with the interpretation that globular cluster formation is coeval (Sec. 17.1.5). The 'most natural' parameter region is dark gray.

flat universe. A high value of $H_0 > 82$, which would be driven only by a short LMC distance, is excluded by self-consistency with the age of globular clusters, as noted earlier. Therefore, we are led to the range $H_0 \approx 60$–82 from consistency. For an open universe the coeval-formation interpretation is compelling for globular clusters, or else no region is allowed; the allowed H_0 is limited to 60–70. No solution is available if LMC is at the shorter distance.

18. DARK MATTER

Revised Sep. 1999 by M. Srednicki (University of California, Santa Barbara).

The total mass-energy of the Universe is composed of several constituents, each of which may be characterized by its energy density $\rho_i \equiv \Omega_i \rho_c$ and its pressure $p_i \equiv w_i \rho_i$. Here $\rho_c \equiv 3H_0^2/8\pi G_N$ is the critical density, and H_0 is the present value of the Hubble parameter. We will take $H_0 = 70\,\mathrm{km\,s^{-1}\,Mpc^{-1}}$ when a numerical value is needed; then $\rho_c = 5.2 \times 10^{-6}\,\mathrm{GeV/cm^3}$. We can express the total density as $\rho_0 = \Omega_0 \rho_c$, where $\Omega_0 = \sum_i \Omega_i$. The deceleration parameter $q_0 \equiv (\ddot{R}/R)_0/H_0^2$, where $R(t)$ is the scale factor and the subscript 0 denotes the present value, is then given by $q_0 = \frac{1}{2}\Omega_0 + \frac{3}{2}\sum_i \Omega_i w_i$.

In general, relativistic particles have an equation of state specified by $w = +\frac{1}{3}$, nonrelativistic particles have $w = 0$, and the cosmological constant (here treated as another form of matter) has $w = -1$. Spatially uniform scalar fields which are oscillating rapidly in time (that is, with a frequency much greater than the Hubble parameter H_0) also have $w = 0$. Spatially uniform scalar fields which are changing slowly in time have $-1 < w < 0$.

Certain contributions to the mass density are well determined. The photons of the cosmic microwave background radiation (CMB) have $\rho_\gamma = \frac{\pi^2}{15}T_0^4$, where $T_0 = 2.73\,\mathrm{K} = 2.35 \times 10^{-4}\,\mathrm{eV}$ is the present temperature of the CMB; this yields $\Omega_\gamma = 5.1 \times 10^{-5}$. Results from Big-Bang nucleosynthesis indicate that the total baryon density is in the range $0.008 < \Omega_b < 0.043$; of this, roughly 0.004 is accounted for by stars. A single species of neutrino with a Majorana mass m_ν would have $\Omega_\nu = 0.56\, G_N T_0^3 H_0^{-2} m_\nu = m_\nu/(45\,\mathrm{eV})$ and $w_\nu = 0$ if $m_\nu \gg T_0$, and $\Omega_\nu = 0.23\,\Omega_\gamma$ and $w_\nu = \frac{1}{3}$ if $m_\nu \ll T_0$.

There is strong evidence from a variety of different observations for a large amount of dark matter in the Universe [1,2,3,4]. The phrase "dark matter" signifies matter whose existence has been inferred only through its gravitational effects. Two categories should be distinguished: baryonic dark matter, composed of baryons which are not seen (including black holes formed by stellar collapse), and nonbaryonic dark matter, composed either of massive neutrinos, or of elementary particles or fields which are as yet undiscovered (including primordial black holes). The particles or fields which comprise nonbaryonic dark matter must have survived from the Big Bang, and therefore must either be stable or have lifetimes in excess of the current age of the Universe.

There are a number of different observations which indicate the presence of dark matter (baryonic or nonbaryonic). These observations include rotation curves of spiral galaxies [5], which indicate that individual galaxies have halos of dark matter whose density falls off as $1/r^2$ at large distances r from the galaxy's center. In our own Galaxy, estimates of the local density of dark matter typically give $\rho_{\mathrm{dm}} \simeq 0.3\,\mathrm{GeV/cm^3}$, but this result depends sensitively on how the dark-matter halo is modeled.

An estimate of the total pressureless matter density Ω_m (that is, of all components, baryonic and nonbaryonic, with $w_i = 0$) can be made from studies of rich clusters of galaxies. The baryonic mass of a cluster can be inferred from X-ray emissions, and the total mass from galactic velocities (via the virial theorem) or gas dynamics [6]. Assuming that the ratio of these masses is typical of the Universe as a whole, we obtain the value of Ω_m/Ω_b. Using the nucleosynthesis value of Ω_b then yields $\Omega_m = 0.4 \pm 0.1$. This is at least roughly consistent with a number of other estimates of Ω_m, such as from mass-to-light ratios for clusters [7] and from large-scale velocity fields [8]. This value of Ω_m would imply that 90% of the pressureless matter in the Universe is nonbaryonic.

An estimate of the total density Ω_0 can be made from fluctuations in the CMB (see Section 15 on "Big-Bang Cosmology" in this *Review*). The first acoustic peak in the power spectrum of these fluctuations is predicted to occur at a multipole $\ell \sim 220\,\Omega_0^{-1/2}$; current data yields $\Omega_0 \sim 0.8 \pm 0.2$ [9]. This is consistent with the generic prediction $\Omega_0 = 1$ of inflationary models.

Type Ia supernovae can be used as standard candles to get information on the relationship between redshift and distance [10]. If we assume that the dominant contributions to Ω_0 are from pressureless matter and an unknown component X, then the results require $w_X < -0.6$ (at the 95% CL, ignoring any systematic errors). Assuming $w_X = -1$ (a cosmological constant), the results constrain the combination $0.8\,\Omega_m - 0.6\,\Omega_X$ to be -0.2 ± 0.1.

None of these observations give us any direct indication of the nature of the dark matter. The halos of galaxies could have significant fractions of baryonic dark matter in the form of remnants (white dwarfs, neutron stars, black holes) of an early generation of massive stars, or smaller objects which never initiated nuclear burning (and would therefore have masses less than about $0.1\,M_\odot$). These massive compact halo objects are collectively called MACHOs. Results from searches via gravitational lensing effects [11] show that MACHOs with masses from $10^{-6}\,M_\odot$ to $0.1\,M_\odot$ each are not a significant component of our Galaxy's halo. However, the results also indicate that MACHOs with masses of approximately $0.5\,M_\odot$ each comprise roughly half the total mass of the halo. This situation is difficult to reconcile with models of star formation.

For purposes of galaxy formation models [12], nonbaryonic dark matter is classified as "hot" or "cold," depending on whether the dark matter particles were relativistic or nonrelativistic at the time when the horizon of the Universe enclosed enough matter to form a galaxy. If the dark matter particles are in thermal equilibrium with the baryons and radiation, then only the mass of a dark matter particle is relevant to knowing whether the dark matter is hot or cold, with the dividing line being $m_{\mathrm{dm}} \sim 1\,\mathrm{keV}$. In addition, specifying a model requires giving the power spectrum of initial density fluctuations. Inflationary models generically predict a power spectrum which is nearly scale invariant. With these inputs, galaxy formation models require primarily cold dark matter, with significantly less hot dark matter. However, either a negative-pressure component or some hot dark matter is needed in addition to cold dark matter. For example, a model with $\Omega_{\mathrm{cdm}} = 0.3$, $\Omega_{\mathrm{hdm}} = 0$, $\Omega_X = 0.7$ and $w_X = -0.6$ gives a good fit to all current data [13].

There is a constraint on neutrinos (or any light fermions) if they are to comprise the halos of dwarf galaxies: the Fermi–Dirac distribution in phase space restricts the number of neutrinos that can be put into a halo [14], and this implies a lower limit on the neutrino mass of roughly $m_\nu > 80\,\mathrm{eV}$.

There are no presently known particles which could be cold dark matter. However, many proposed extensions of the Standard Model predict a stable (or sufficiently long lived) particle. The key question then becomes the predicted value of Ω_{cdm}.

If the particle is its own antiparticle (or there are particles and antiparticles present in equal numbers), and these particles were in thermal equilibrium with radiation at least until they became nonrelativistic, then their relic abundance is determined by their annihilation cross section σ_{ann}: $\Omega_{\mathrm{cdm}} \sim G_N^{3/2} T_0^3 H_0^{-2} \langle \sigma_{\mathrm{ann}} v_{\mathrm{rel}} \rangle^{-1}$. Here v_{rel} is the relative velocity of the two incoming dark matter particles, and the angle brackets denote an averaging over a thermal distribution of velocities for each at the freeze-out temperature T_{fr} when the dark matter particles go out of thermal equilibrium with radiation; typically $T_{\mathrm{fr}} \simeq \frac{1}{20} m_{\mathrm{dm}}$. One then finds (putting in appropriate numerical factors) that $\Omega_{\mathrm{cdm}} \simeq 7 \times 10^{-27}\,\mathrm{cm^3\,s^{-1}}/\langle \sigma_{\mathrm{ann}} v_{\mathrm{rel}} \rangle$. The value of $\langle \sigma_{\mathrm{ann}} v_{\mathrm{rel}} \rangle$ needed for $\Omega_{\mathrm{cdm}} \simeq 1$ is remarkably close to what one would expect for a weakly interacting massive particle (WIMP) with a mass of $m_{\mathrm{dm}} = 100\,\mathrm{GeV}$: $\langle \sigma_{\mathrm{ann}} v_{\mathrm{rel}} \rangle \sim \alpha^2/8\pi m_{\mathrm{dm}}^2 \sim 3 \times 10^{-27}\,\mathrm{cm^3\,s^{-1}}$.

If the dark matter particle is not its own antiparticle, and the number of particles minus antiparticles is conserved, then an initial asymmetry in the abundances of particles and antiparticles will be preserved, and can give relic abundances much larger than those predicted above.

If the dark matter particles were never in thermal equilibrium with radiation, then their abundance today must be calculated in some other way, and will in general depend on the precise initial conditions which are assumed.

The two best known and most studied cold dark matter candidates are the neutralino and the axion. The neutralino is predicted by the Minimal Supersymmetric extension of the Standard Model (MSSM) [15,16]. It qualifies as a WIMP, with a theoretically expected mass in the range of tens to hundreds of GeV. The axion is predicted by extensions of the Standard Model which resolve the strong CP problem [17]. Axions can occur in the early universe in the form of a Bose condensate which never comes into thermal equilibrium. The axions in this condensate are always nonrelativistic, and can be a significant component of the dark matter if the axion mass is approximately 10^{-5} eV. Axions can also arise from the decay of a network of axion strings and domain walls.

There are prospects for direct experimental detection of both these candidates (and other WIMP candidates as well). WIMPs will scatter off nuclei at a calculable rate, and produce observable nuclear recoils [2,16,19]; current data excludes certain regions of parameter space of the MSSM. Axions can be detected by axion to photon conversion in a microwave cavity in a strong magnetic field, and limits on the allowed axion-photon coupling have been set [18].

WIMP candidates can have indirect signatures as well, via present day annihilations into particles which can be detected as cosmic rays. The most promising possibility arises from the fact that WIMPs collect at the centers of the sun and the earth, thus greatly increasing their annihilation rate, and producing high energy neutrinos which can escape and arrive at the earth's surface in potentially observable numbers [16,20].

19. COSMIC BACKGROUND RADIATION

Revised February 2000 by G.F. Smoot (LBNL) and D. Scott (University of British Columbia).

19.1. Introduction

The observed cosmic microwave background (CMB) radiation provides strong evidence for the hot big bang. The success of primordial nucleosynthesis calculations (see Sec. 16, "Big-bang nucleosynthesis") requires a cosmic background radiation (CBR) characterized by a temperature $kT \sim 1\,\mathrm{MeV}$ at a redshift of $z \simeq 10^9$. In their pioneering work, Gamow, Alpher, and Herman [1] realized this and predicted the existence of a faint residual relic, primordial radiation, with a present temperature of a few degrees. The observed CMB is interpreted as the current manifestation of the required CBR.

The CMB was serendipitously discovered by Penzias and Wilson [2] in 1965. Its spectrum is well characterized by a 2.73 K black-body (Planckian) spectrum over more than three decades in frequency (see Fig. 19.1). A non-interacting Planckian distribution of temperature T_i at redshift z_i transforms with the universal expansion to another Planckian distribution at redshift z_f with temperature $T_f/(1+z_f) = T_i/(1+z_i)$. Hence thermal equilibrium, once established (*e.g.* at the nucleosynthesis epoch), is preserved by the expansion, in spite of the fact that photons decoupled from matter at early times. Because there are about 10^9 photons per nucleon, the transition from the ionized primordial plasma to neutral atoms at $z \sim 1000$ does not significantly alter the CBR spectrum [3].

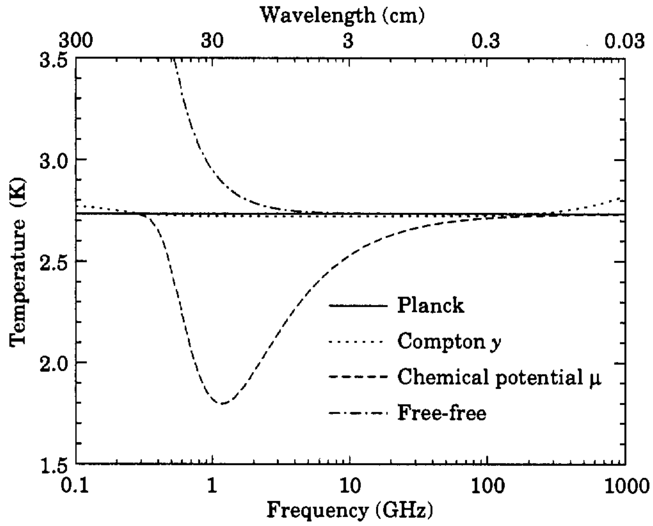

Figure 19.2: The shapes of expected, but so far unobserved, CMB distortions, resulting from energy-releasing processes at different epochs.

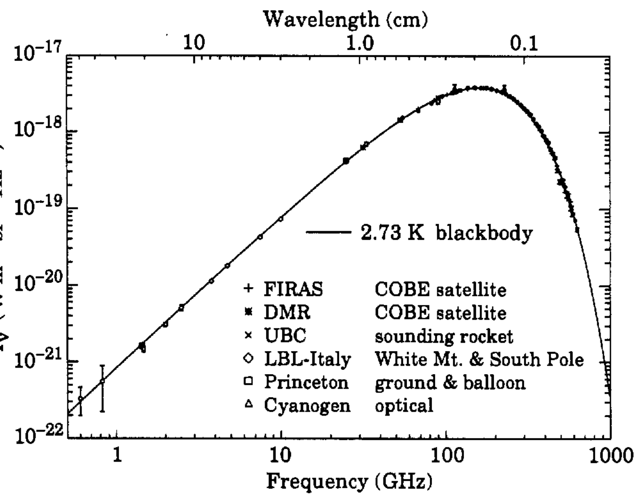

Figure 19.1: Precise measurements of the CMB spectrum. The line represents a 2.73 K blackbody, which describes the spectrum very well, especially around the peak of intensity. The spectrum is less well constrained at 10 cm and longer wavelengths. (References for this figure are at the end of this section under "CMB Spectrum References.")

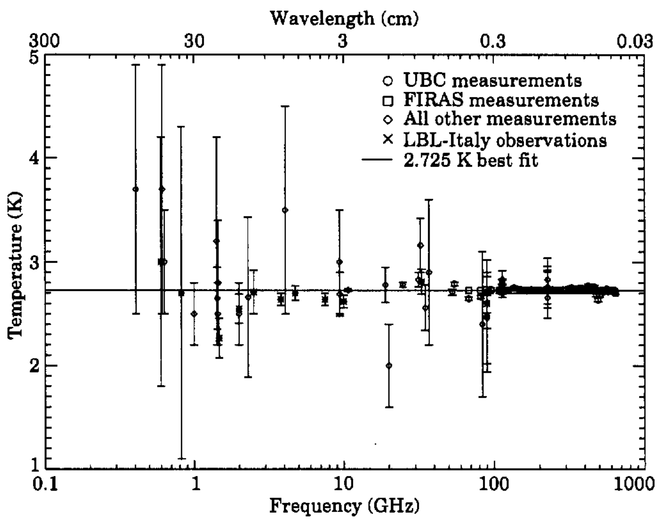

Figure 19.3: Observed thermodynamic temperature as a function frequency.

19.2. The CMB frequency spectrum

The remarkable precision with which the CMB spectrum is fitted by a Planckian distribution provides limits on possible energy releases in the early Universe, at roughly the fractional level of 10^{-4} of the CBR energy, for redshifts $\lesssim 10^7$ (corresponding to epochs $\gtrsim 1$ year). The following three important classes of theoretical spectral distortions (see Fig. 19.2) generally correspond to energy releases at different epochs. The distortion results from the CBR photon interactions with a hot electron gas at temperature T_e.

19.2.1. ***Compton distortion***: Late energy release ($z \lesssim 10^5$). Compton scattering ($\gamma e \to \gamma' e'$) of the CBR photons by a hot electron gas creates spectral distortions by transferring energy from the electrons to the photons. Compton scattering cannot achieve thermal equilibrium for $y \lesssim 1$, where

$$y = \int_0^z \frac{kT_e(z') - kT_\gamma(z')}{m_e c^2}\, \sigma_T\, n_e(z')\, c\, \frac{dt}{dz'}\, dz' \,, \tag{19.1}$$

is the integral of the number of interactions, $\sigma_T\, n_e(z)\, c\, dt$, times the mean-fractional photon-energy change per collision [4]. For $T_e \gg T_\gamma$ y is also proportional to the integral of the electron pressure $n_e k T_e$ along the line of sight. For standard thermal histories $y < 1$ for epochs later than $z \simeq 10^5$.

The resulting CMB distortion is a temperature decrement

$$\Delta T_{\rm RJ} = -2y\, T_\gamma \tag{19.2}$$

in the Rayleigh-Jeans ($h\nu/kT \ll 1$) portion of the spectrum, and a rise in temperature in the Wien ($h\nu/kT \gg 1$) region, *i.e.* photons are shifted from low to high frequencies. The magnitude of the distortion is related to the total energy transfer [4] ΔE by

$$\Delta E/E_{\rm CBR} = e^{4y} - 1 \simeq 4y \, . \qquad (19.3)$$

A prime candidate for producing a Comptonized spectrum is a hot intergalactic medium. A hot ($T_e > 10^5$ K) medium in clusters of galaxies can and does produce a partially Comptonized spectrum as seen through the cluster, known as the Sunyaev-Zel'dovich effect [5]. Based upon X-ray data, the predicted large angular scale total combined effect of the hot intracluster medium should produce $y \sim 10^{-6}$ [6].

19.2.2. ***Bose-Einstein or chemical potential distortion***: Early energy release ($z \sim 10^5$–10^7). After many Compton scatterings ($y \gg 1$), the photons and electrons will reach statistical (not thermodynamic) equilibrium, because Compton scattering conserves photon number. This equilibrium is described by the Bose-Einstein distribution with non-zero chemical potential:

$$n = \frac{1}{e^{x+\mu_0} - 1} \, , \qquad (19.4)$$

where $x \equiv h\nu/kT$ and $\mu_0 \simeq 1.4 \; \Delta E/E_{\rm CBR}$, with μ_0 being the dimensionless chemical potential that is required to conserve photon number.

The collisions of electrons with nuclei in the plasma produce free-free (thermal bremsstrahlung) radiation: $eZ \to e'Z'\gamma$. Free-free emission thermalizes the spectrum to the plasma temperature at long wavelengths and Compton scattering begins to shift these photons upward. Including this effect, the chemical potential becomes frequency-dependent,

$$\mu(x) = \mu_0 e^{-2x_{\rm b}/x} \, , \qquad (19.5)$$

where $x_{\rm b}$ is the transition frequency at which Compton scattering of photons to higher frequencies is balanced by free-free creation of new photons. The resulting spectrum has a sharp drop in brightness temperature at centimeter wavelengths [7]. The minimum wavelength is determined by Ω_B.

The equilibrium Bose-Einstein distribution results from the oldest non-equilibrium processes ($10^5 < z < 10^7$), such as the decay of relic particles or primordial inhomogeneities. Note that free-free emission (thermal bremsstrahlung) and radiative-Compton scattering effectively erase any distortions [8] to a Planckian spectrum for epochs earlier than $z \sim 10^7$.

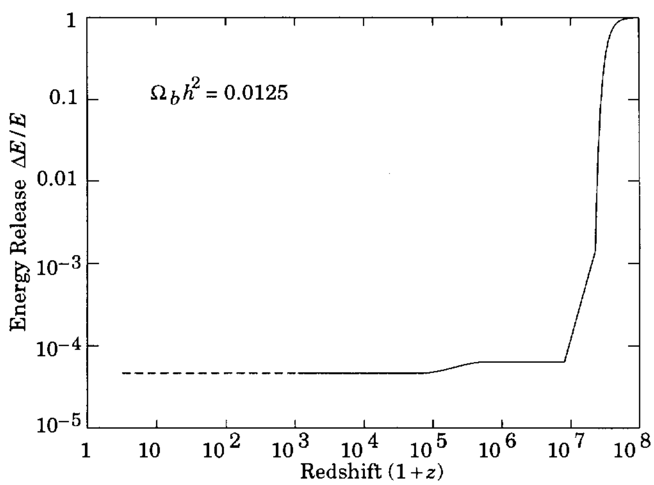

Figure 19.4: Upper Limits (95% CL) on fractional energy ($\Delta E/E_{\rm CBR}$) releases from processes at different epochs as set by resulting lack of CMB spectral distortions. These can be translated into constraints on the mass, lifetime and photon branching ratio of unstable relic particles, with some additional dependence on cosmological parameters such as Ω_B [11,12].

19.2.3. ***Free-free distortion***: Very late energy release ($z \ll 10^3$). Free-free emission can create rather than erase spectral distortion in the late Universe, for recent reionization ($z < 10^3$) and from a warm intergalactic medium. The distortion arises because of the lack of Comptonization at recent epochs. The effect on the present-day CMB spectrum is described by

$$\Delta T_{\rm ff} = T_\gamma \, Y_{\rm ff}/x^2, \qquad (19.6)$$

where T_γ is the undistorted photon temperature, x is the dimensionless frequency, and $Y_{\rm ff}/x^2$ is the optical depth to free-free emission:

$$Y_{\rm ff} = \int_0^z \frac{T_e(z') - T_\gamma(z')}{T_e(z')} \frac{8\pi e^6 h^2 n_e^2 \, g}{3m_e(kT_\gamma)^3 \sqrt{6\pi \, m_e \, kT_e}} \frac{dt}{dz'} dz' \, . \qquad (19.7)$$

Here h is Planck's constant, n_e is the electron density and g is the Gaunt factor [9].

19.2.4. ***Spectrum summary***: The CMB spectrum is consistent with a blackbody distribution over more than three decades of frequency around the peak. The best-fit to the COBE FIRAS data yields $T_\gamma = 2.725 \pm 0.002$ K (95% CL) [10]. The following table is a summary of all CMB spectrum measurements:

$$\begin{aligned}
&T_\gamma = 2.725 \pm 0.002 \text{ K} \quad (95\% \text{ CL}) \, ; \\
&n_\gamma = (2\zeta(3)/\pi^2) \, T_\gamma^3 \simeq 411 \, \text{cm}^{-3} \, ; \\
&\rho_\gamma = (\pi^2/15) \, T_\gamma^4 \simeq 4.64 \times 10^{-34} \, \text{g cm}^{-3} \simeq 0.260 \, \text{eV cm}^{-3} \, ; \\
&|y| < 1.2 \times 10^{-5} \quad (95\% \text{ CL}) \, ; \\
&|\mu_0| < 9 \times 10^{-5} \quad (95\% \text{ CL}) \, ; \\
&|Y_{\rm ff}| < 1.9 \times 10^{-5} \quad (95\% \text{ CL}) \, .
\end{aligned}$$

These limits [13] correspond to constraints [13–15] on energetic processes $\Delta E/E_{\rm CBR} < \; 2 \times 10^{-4}$ occurring between redshifts 10^3 and 5×10^6 (see Fig. 19.4).

19.3. Deviations from isotropy

Penzias and Wilson reported that the CMB was isotropic and unpolarized at the 10% level. Current observations show that the CMB is unpolarized at the 10^{-5} level but has a dipole anisotropy at the 10^{-3} level, with smaller-scale anisotropies at the 10^{-5} level. Standard theories predict temperature anisotropies of roughly the amplitude now being detected, and anisotropies in linear polarization at a level which should soon be reached.

It is customary to express the CMB temperature anisotropies on the sky in a spherical harmonic expansion,

$$\frac{\Delta T}{T}(\theta, \phi) = \sum_{\ell m} a_{\ell m} Y_{\ell m}(\theta, \phi) \, , \qquad (19.8)$$

and to discuss the various multipole amplitudes. The power at a given angular scale is roughly $\ell \sum_m |a_{\ell m}|^2 / 4\pi$, with $\ell \sim 1/\theta$.

19.3.1. ***The dipole***: The largest anisotropy is in the $\ell = 1$ (dipole) first spherical harmonic, with amplitude at the level of $\Delta T/T = 1.23 \times 10^{-3}$. The dipole is interpreted as the result of the Doppler shift caused by the solar system motion relative to the nearly isotropic blackbody field, as confirmed by measurements of the velocity field of local galaxies [16]. The motion of the observer (receiver) with velocity $\beta = v/c$ relative to an isotropic Planckian radiation field of temperature T_0 produces a Doppler-shifted temperature

$$\begin{aligned}
T(\theta) &= T_0(1 - \beta^2)^{1/2}/(1 - \beta\cos\theta) \\
&= T_0 \left(1 + \beta\cos\theta + (\beta^2/2)\cos 2\theta + O(\beta^3)\right) \, . \qquad (19.9)
\end{aligned}$$

The implied velocity [13,17] for the solar-system barycenter is $\beta = 0.001237 \pm 0.000002$ (68% CL) or $v = 371 \pm 0.5 \, \text{km s}^{-1}$, assuming a value $T_0 = T_\gamma$, towards $(\alpha, \delta) = (11.20^{\rm h} \pm 0.01^{\rm h}, -7.22^\circ \pm 0.08^\circ)$, or $(\ell, b) = (264.31^\circ \pm 0.17^\circ, 48.05^\circ \pm 0.10^\circ)$. Such a solar-system velocity implies a velocity for the Galaxy and the Local Group of galaxies relative to the CMB. The derived velocity is $v_{LG} = 627 \pm 22\,\mathrm{km\,s^{-1}}$ toward $(\ell, b) = (276° \pm 3°, 30° \pm 3°)$, where most of the error comes from uncertainty in the velocity of the solar system relative to the Local Group.

The Doppler effect of this velocity and of the velocity of the Earth around the Sun, as well as any velocity of the receiver relative to the Earth, is normally removed for the purposes of CMB anisotropy study. The resulting high degree of CMB isotropy is the strongest evidence for the validity of the Robertson-Walker metric.

19.3.2. ***The quadrupole***: The rms quadrupole anisotropy amplitude is defined through $Q^2_{\rm rms}/T^2_\gamma = \sum_m |a_{2m}|^2/4\pi$. The current estimate of its value is $4\,\mu\mathrm{K} \le Q_{\rm rms} \le 28\,\mu\mathrm{K}$ for a 95% confidence interval [18]. The uncertainty here includes both statistical errors and systematic errors, which are dominated by the effects of galactic emission modelling. This level of quadrupole anisotropy allows one to set general limits on anisotropic expansion, shear, and vorticity; all such dimensionless quantities are constrained to be less than about 10^{-5}.

For specific homogeneous cosmologies, fits to the whole anisotropy pattern allow stringent limits to be placed on, for example, the global rotation at the level of about 10^{-7} of the expansion rate [19].

19.3.3. ***Smaller angular scales***: The COBE-discovered [20] higher-order ($\ell > 2$) anisotropy is interpreted as being the result of perturbations in the energy density of the early Universe, manifesting themselves at the epoch of the CMB's last scattering. The detection of these anisotropies at just the right level for gravity to have grown all of the structure observed in today's Universe demonstrates that gravitational instability acting on primordial density perturbations was the main mechanism for structure formation.

Theoretical models generally predict a power spectrum in spherical harmonic amplitudes, since the models lead to primordial fluctuations and thus $a_{\ell m}$ that are Gaussian random fields, and hence the power spectrum in ℓ is sufficient to characterize the results. The power at each ℓ is $(2\ell+1)C_\ell/(4\pi)$, where $C_\ell \equiv \langle |a_{\ell m}|^2 \rangle$ and a statistically isotropic sky means that all m's are equivalent. For an idealized full-sky observation, the variance of each measured C_ℓ is $[2/(2\ell+1)]C_\ell^2$. This sampling variance (known as cosmic variance) comes about because each C_ℓ is chi-squared distributed with $(2\ell+1)$ degrees of freedom for our observable volume of the Universe [21].

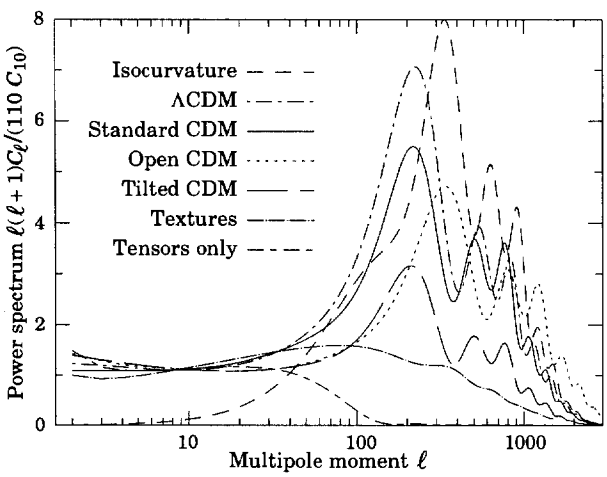

Figure 19.5: Theoretically predicted $\ell(\ell+1)C_\ell$ or CMB anisotropy power spectra [24] for a range of models. The top curve is an isocurvature CDM model which has a characteristically different shape than the adiabatic models. The next four are variants of adiabatic Cold Dark Matter models. The textures model [25] is an example with perturbations seeded by topological defects. We also show the power spectrum from gravity waves (tensors), which could contribute at large angles. All the models have been normalized at $\ell = 10$ except for the isocurvature case, which was arbitrarily normalized to the height of the box. Such curves depend in detail on the precise values of the cosmological parameters, and those shown here are examples only.

Figure 19.5 shows the theoretically predicted anisotropy power spectrum for a sample of models, plotted as $\ell(\ell+1)C_\ell$ versus ℓ which is the power per logarithmic interval in ℓ or, equivalently, the two-dimensional power spectrum. If the initial power spectrum of perturbations is the result of quantum mechanical fluctuations produced and amplified during inflation, then for simple models the shape of the anisotropy spectrum is coupled to the ratio of contributions from density (scalar) and gravitational wave (tensor) perturbations [22]. In such models the large angle contribution from tensors is constrained to be $\lesssim 0.5$ [23]. However, there are other inflationary models which allow higher tensor contribution. In particular if the energy scale of inflation at the appropriate epoch is $\simeq 10^{16}$GeV, then detection of the effect of gravitons is more likely and partial reconstruction of the inflaton potential may be feasible. However, if the energy scale is $\lesssim 10^{14}$GeV, then typically density fluctuations dominate and less constraint is possible.

On angular scales corresponding to $\ell \gtrsim 50$ scalar modes certainly dominate. In the standard scenario the last scattering epoch happens at a redshift of approximately 1100, by which time the large number of photons was no longer able to keep the hydrogen ionized. The optical thickness of the cosmic photosphere is roughly $\Delta z \sim 100$ corresponding to about 5 arcminutes on the sky, so that features smaller than this size are damped.

Anisotropies have now been observed on angular scales above this damping scale by a large number of experiments (see Fig. 19.6), and are consistent with those expected from an initially scale-invariant (also referred to as 'flat') power spectrum of potential and thus metric fluctuations. The initial spectrum of density perturbations is reflected in the large angle (small ℓ) power spectrum, but perturbations can evolve significantly in the epoch $z \gtrsim 1100$ for causally connected regions (angles $\lesssim 1°\,\Omega_{\rm tot}^{1/2}$). The primary mode of evolution is through acoustic oscillations, leading to a series of peaks at small angular scales, which encode information about the primordial perturbations, geometry, matter and radiation content, and ionization history of the Universe [26]. Thus, precise measurement of the shape of the anisotropy power spectrum will provide information on the amplitude and slope of the initial conditions, as well as Ω_0, Ω_B, Ω_Λ (cosmological constant), H_0 and other cosmological parameters.

Fits to experimental data are often quoted as the expected value of the quadrupole $\langle Q \rangle$ for some specific theory over some range of ℓ (*e.g.* a model with power-law initial conditions, having primordial density perturbation power spectrum $|\delta_k|^2 \propto k^n$). The full 4-year COBE DMR data give $\langle Q \rangle = 15.3^{+3.7}_{-2.8}\,\mu$K, after projecting out the slope dependence, while the best-fit slope is $n = 1.2 \pm 0.3$, and for a pure $n = 1$ (scale-invariant potential perturbation) spectrum $\langle Q \rangle (n = 1) = 18 \pm 1.6\,\mu$K [18,27]. The conventional notation is such that $\langle Q \rangle^2/T^2_\gamma = 5C_2/4\pi$. An alternative convention is to quote the 'band-power' $\sqrt{\ell(2\ell+1)C_\ell/4\pi}$. Many recent experiments give results for a number of band-powers covering different ranges of ℓ. $\langle Q \rangle^2/T^2_\gamma = 5C_2/4\pi$. fluctuations measured by other experiments can also be quoted in terms $(n = 1)$

The initial density perturbations can either be 'adiabatic' (meaning that there is no change to the entropy per particle for each species) or 'isocurvature' (meaning that, for example, matter perturbations compensate radiation perturbations so that the total energy density remains unchanged). Within the family of adiabatic models, the location of the first acoustic peak is predicted to be at $\ell \sim 220\,\Omega_{\rm tot}^{-1/2}$ or $\theta \sim 0.3°\,\Omega_{\rm tot}^{1/2}$ and its amplitude is a calculable function of the parameters (see Fig. 19.5).

It has been clear for several years that there is more power at sub-degree scales than at COBE scales [26]. More recently results have indicated that there is a localized peak, and the general shape of the power spectrum favors adiabatic-type perturbations (compare Fig. 19.5 and Fig. 19.6). Within the adiabatic scenario, the currently available data imply that the Universe is close to flat [28], with $0.62 < \Omega_{\rm tot} < 1.24$ (95% CL) [29]. Together with a number of observations indicating that the matter density $\Omega_{\rm M} \simeq 0.3$ (*e.g.* see Ref. 37), this implies that there is some unknown contribution to the energy, 'dark energy,' which is independently indicated through distant supernova studies [30]. The height of the peak can also be used to constrain models, but currently the results depend sensitively on what range of models are considered and what other cosmological

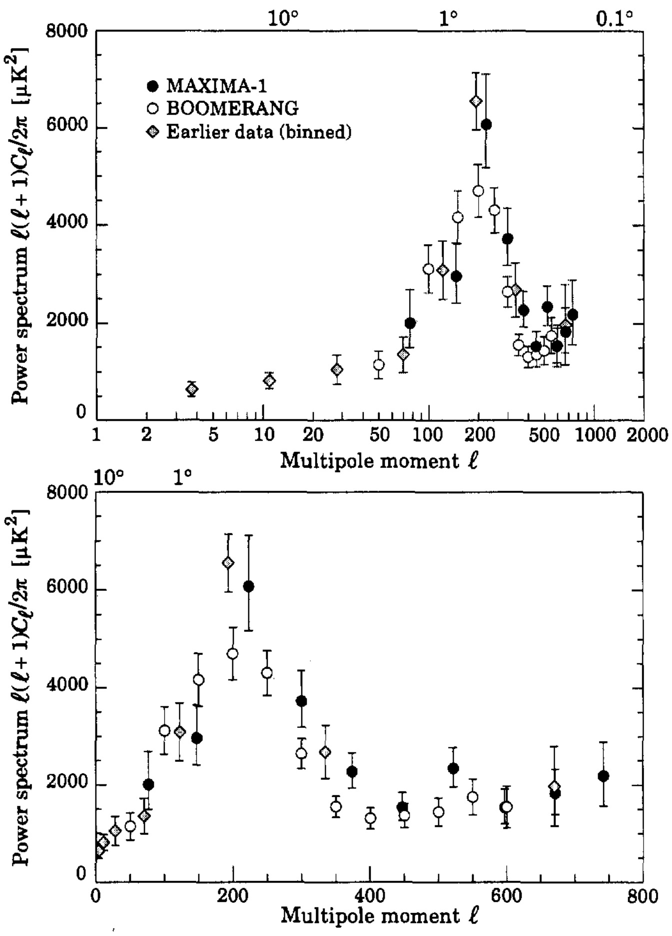

Figure 19.6: There is now so much CMB data that it is difficult and confusing to show all the individual results. Instead the figure shows the new BOOMERANG [32] (open circles) and MAXIMA [33] data (filled circles), together with binned results of all previous experiments, based on data with references given at the end of this section under "CMB Anisotropy References." The previous data are shown as grey diamonds, which were obtained [38] by maximizing the likelihood for a power spectrum assumed to be piece-wise constant between $\ell = 2$ and 1000, permitting experimental errors to be asymmetric, and allowing for correlated calibration uncertainties for each experiment [39]. These binned values are somewhat correlated, partly explaining the apparent discrepancy, which is consistent with calibration uncertainties between experiments. The sub-set of data from the first Antarctic flight of BOOMERANG and the data from the MAXIMA-1 flight are independent, with essentially no correlations between bins. The figure clearly shows a localized peak at $\ell \simeq 200$ and some structure at higher ℓ. Upper limits at smaller angular scales, indicating further evidence for a falloff at high ℓ, have not been shown.

constraints are used [28,29,31]. Detailed measurements of parameters are expected to follow soon, but certainly some more general questions are already being answered.

Recent experimental results from the Boomerang 98 [32] and MAXIMA-1 [33] balloon flights have dramatically improved the power spectrum measurements. These new data indicate a very well-defined first acoustic peak, at close to the position expected in flat models with adiabatic fluctuations. It is difficult generate this feature by an incoherent causal mechanism, such as with topological defects. The position of the first peak constrains the total density parameter to be $\Omega_{\rm tot} \simeq 1.0 \pm 0.1$ [34,35]. Intriguingly, the second peak does not appear as pronounced as had been expected in the previously favored models. There are several ways to explain this [36], including a combination of tilt, higher baryon density and some other mild parameter variations, as well as more exotic explanations such as delayed recombination, partial loss of coherence of the oscillations, or features in the underlying power spectrum. Detailed measurement of the second and third peaks ought to distinguish among these possibilities.

Causal mechanisms, such as arise in topological defect models, cannot naturally account for the observed power spectrum (see Fig. 19.5), and isocurvature models also generically give the wrong shape. Thus the present data appear to point to models with adiabatic and apparently acausal fluctuations. Since inflation is the only mechanism we have to provide the large-scale homogeneity and anisotropy observed in the universe and to produce these apparently acausal fluctuations, one might consider the current CMB data as supporting the inflationary paradigm. A more stringent test of inflation will be provided with the arrival of data that have the fidelity to resolve the sub-degree region into the oscillating peaks and troughs which must be present in inflationary models.

New data are being acquired at an increasing rate, with a large number of improved ground- and balloon-based experiments being developed. The current suite of experiments promises to map out the CMB anisotropy power spectrum to about 10% accuracy, and determine several parameters at the 10 to 20% level in the very near future. A vigorous sub-orbital and interferometric program should push those numbers further in the next few years.

There are also now two approved satellite experiments: the NASA Microwave Anisotropy Probe (MAP), scheduled for launch in late 2000; and the ESA Planck mission, expected to launch in 2007. The improved sensitivity, freedom from earth-based systematics, and all-sky coverage allow a simultaneous determination of many of the cosmological parameters to unprecedented precision: for example, Ω_0 and n to about 1%, Ω_B and H_0 at the level of a few percent [40]. Just as with the frequency spectrum, precise measurement of the anisotropies should also lead to constraints on a particle physics effects at $z \sim 1000$ [41].

Since Thomson scattering of the anisotropic radiation field also generates linear polarization at the roughly 5% level [42], there is additional cosmological information to be gleaned from polarization measurements. Although difficult to detect, the polarization signal should act as a strong confirmation of the general paradigm. Furthermore, detailed measurement of the polarization signal provides more precise information on the physical parameters. In particular it allows a clear distinction of any gravity wave contribution, which is crucial to probing the $\sim 10^{16}$ GeV energy range. The fulfillment of this promise may await an even more sensitive generation of satellites.

20. COSMIC RAYS

Revised February 2000 by T.K. Gaisser and T. Stanev (Bartol Research Inst., Univ. of Delaware).

20.1. Primary spectra

The cosmic radiation incident at the top of the terrestrial atmosphere includes all stable charged particles and nuclei with lifetimes of order 10^6 years or longer. Technically, "primary" cosmic rays are those particles accelerated at astrophysical sources and "secondaries" are those particles produced in interaction of the primaries with interstellar gas. Thus electrons, protons and helium, as well as carbon, oxygen, iron, and other nuclei synthesized in stars, are primaries. Nuclei such as lithium, beryllium, and boron (which are not abundant end-products of stellar nucleosynthesis) are secondaries. Antiprotons and positrons are partly, if not entirely, secondaries, but the fraction of these particles that may be primary is a question of current interest.

Apart from particles associated with solar flares, the cosmic radiation comes from outside the solar system. The incoming charged particles are "modulated" by the solar wind, the expanding magnetized plasma generated by the Sun, which decelerates and partially excludes the lower energy galactic cosmic rays from the inner solar system. There is a significant anticorrelation between solar activity (which has an eleven-year cycle) and the intensity of the cosmic rays with energies below about 10 GeV. In addition, the lower-energy cosmic rays are affected by the geomagnetic field, which they must penetrate to reach the top of the atmosphere. Thus the intensity of any component of the cosmic radiation in the GeV range depends both on the location and time.

There are four different ways to describe the spectra of the components of the cosmic radiation: (1) By particles per unit rigidity. Propagation (and probably also acceleration) through cosmic magnetic fields depends on gyroradius or *magnetic rigidity*, R, which is gyroradius multiplied by the magnetic field strength:

$$R = \frac{pc}{Ze} = r_L B \; . \tag{20.1}$$

(2) By particles per energy-per-nucleon. Fragmentation of nuclei propagating through the interstellar gas depends on energy per nucleon, since that quantity is approximately conserved when a nucleus breaks up on interaction with the gas. (3) By nucleons per energy-per-nucleon. Production of secondary cosmic rays in the atmosphere depends on the intensity of nucleons per energy-per-nucleon, approximately independently of whether the incident nucleons are free protons or bound in nuclei. (4) By particles per energy-per-nucleus. Air shower experiments that use the atmosphere as a calorimeter generally measure a quantity that is related to total energy per particle.

The units of differential intensity I are $[\mathrm{cm}^{-2}\mathrm{s}^{-1}\mathrm{sr}^{-1}\mathcal{E}^{-1}]$, where $\mathcal{E}$ represents the units of one of the four variables listed above.

The intensity of primary nucleons in the energy range from several GeV to somewhat beyond 100 TeV is given approximately by

$$I_N(E) \approx 1.8\, E^{-\alpha}\, \frac{\text{nucleons}}{\mathrm{cm^2\ s\ sr\ GeV}} \; , \tag{20.2}$$

where E is the energy-per-nucleon (including rest mass energy) and $\alpha\ (\equiv \gamma + 1) = 2.7$ is the differential spectral index of the cosmic ray flux and γ is the integral spectral index. About 79% of the primary nucleons are free protons and about 70% of the rest are nucleons bound in helium nuclei. The fractions of the primary nuclei are nearly constant over this energy range (possibly with small but interesting variations). Fractions of both primary and secondary incident nuclei are listed in Table 20.1. Figure 20.1 [1] shows the major components as a function of energy at a particular epoch of the solar cycle. There has been a series of more precise measurements of the primary spectrum of protons and helium in the past decade [2,3,4,5].

The spectrum of electrons and positrons incident at the top of the atmosphere is steeper than the spectra of protons and nuclei, as shown in Fig. 20.2. The positron fraction is about 10% in the region in which it is measured (< 20 GeV), but it is not yet fully understood [8].

Above 10 GeV the fraction of antiprotons to protons is about 10^{-4}, and there is evidence for the kinematic suppression at lower energy expected for secondary antiprotons [9,10,11,12]. There is at this time no evidence for a significant primary component of antiprotons.

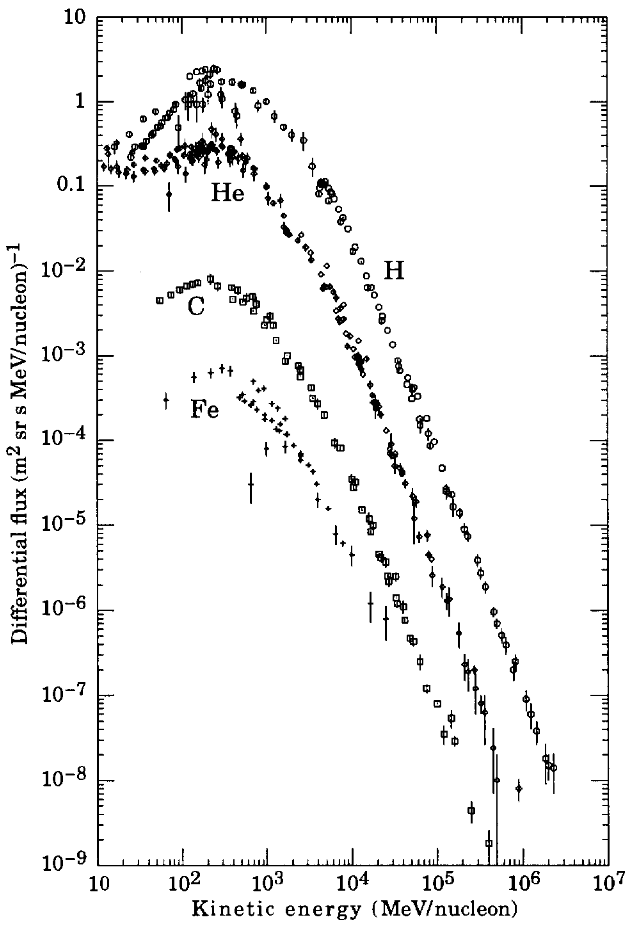

Figure 20.1: Major components of the primary cosmic radiation (from Ref. 1).

Table 20.1: Relative abundances F of cosmic-ray nuclei at 10.6 GeV/nucleon normalized to oxygen ($\equiv 1$) [6]. The oxygen flux at kinetic energy of 10.6 GeV/nucleon is 3.26×10^{-6} cm^{-2} s^{-1} sr^{-1} (GeV/nucleon)$^{-1}$. Abundances of hydrogen and helium are from Ref. 2.

20.2. Cosmic rays in the atmosphere

Figure 20.3 shows the vertical fluxes of the major cosmic ray components in the atmosphere in the energy region where the particles are most numerous (except for electrons, which are most numerous near their critical energy, which is about 81 MeV in air). Except for protons and electrons near the top of the atmosphere, all particles are produced in interactions of the primary cosmic rays in the air. Muons and neutrinos are products of the decay of charged mesons, while electrons and photons originate in decays of neutral mesons.

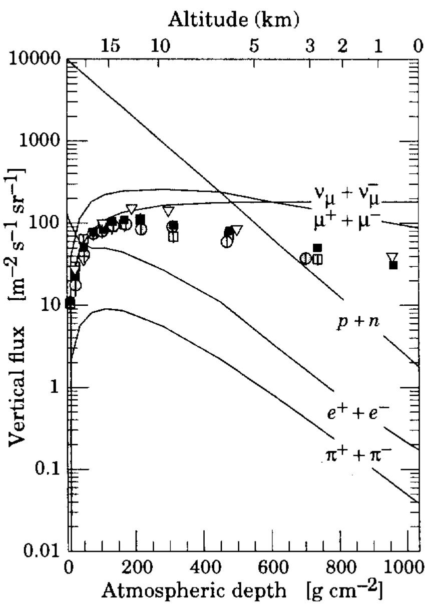

Figure 20.3: Vertical fluxes of cosmic rays in the atmosphere with $E > 1$ GeV estimated from the nucleon flux of Eq. (20.2). The points show measurements of negative muons with $E_\mu > 1$ GeV [3,13,14,15].

Most measurements are made at ground level or near the top of the atmosphere, but there are also measurements of muons and electrons from airplanes and balloons. Fig. 20.3 includes recent measurements of negative muons [3,13,14,15]. Since $\mu^+(\mu^-)$ are produced in association with $\nu_\mu(\overline{\nu}_\mu)$, the measurement of muons near the maximum of the intensity curve for the parent pions serves to calibrate the atmospheric ν_μ beam [16]. Because muons typically lose almost two GeV in passing through the atmosphere, the comparison near the production altitude is important for the sub-GeV range of $\nu_\mu(\overline{\nu}_\mu)$ energies.

The flux of cosmic rays through the atmosphere is described by a set of coupled cascade equations with boundary conditions at the top of the atmosphere to match the primary spectrum. Numerical or Monte Carlo calculations are needed to account accurately for decay and energy-loss processes, and for the energy-dependences of the cross sections and of the primary spectral index γ. Approximate analytic solutions are, however, useful in limited regions of energy [17]. For example, the vertical intensity of nucleons at depth X (g cm^{-2}) in the atmosphere is given by

$$I_N(E, X) \approx I_N(E, 0)\, e^{-X/\Lambda} , \tag{20.3}$$

where Λ is the attenuation length of nucleons in air.

The corresponding expression for the vertical intensity of charged pions with energy $E_\pi \ll \epsilon_\pi = 115$ GeV is

$$I_\pi(E_\pi, X) \approx \frac{Z_{N\pi}}{\lambda_N} I_N(E_\pi, 0)\, e^{-X/\Lambda} \frac{X\, E_\pi}{\epsilon_\pi} . \tag{20.4}$$

This expression has a maximum at $t = \Lambda \approx 120$ g cm^{-2}, which corresponds to an altitude of 15 kilometers. The quantity $Z_{N\pi}$ is the spectrum-weighted moment of the inclusive distribution of charged pions in interactions of nucleons with nuclei of the atmosphere. The intensity of low-energy pions is much less than that of nucleons because $Z_{N\pi} \approx 0.079$ is small and because most pions with energy much less than the critical energy ϵ_π decay rather than interact.

20.3. Cosmic rays at the surface

20.3.1. ***Muons***: Muons are the most numerous charged particles at sea level (see Fig. 20.3). Most muons are produced high in the atmosphere (typically 15 km) and lose about 2 GeV to ionization before reaching the ground. Their energy and angular distribution reflect a convolution of production spectrum, energy loss in the atmosphere, and decay. For example, 2.4 GeV muons have a decay length of 15 km, which is reduced to 8.7 km by energy loss. The mean energy of muons at the ground is ≈ 4 GeV. The energy spectrum is almost flat below 1 GeV, steepens gradually to reflect the primary spectrum in the 10–100 GeV range, and steepens further at higher energies because pions with $E_\pi > \epsilon_\pi \approx 115$ GeV tend to interact in the atmosphere before they decay. Asymptotically ($E_\mu \gg 1$ TeV), the energy spectrum of atmospheric muons is one power steeper than the primary spectrum. The integral intensity of vertical muons above 1 GeV/c at sea level is ≈ 70 m^{-2}s^{-1}sr^{-1} [18,19]. Experimentalists are familiar with this number in the form $I \approx 1$ cm^{-2} min^{-1} for horizontal detectors.

The overall angular distribution of muons at the ground is $\propto \cos^2\theta$, which is characteristic of muons with $E_\mu \sim 3$ GeV. At lower energy the angular distribution becomes increasingly steeper, while at higher energy it flattens and approaches a $\sec\theta$ distribution for $E_\mu \gg \epsilon_\pi$ and $\theta < 70°$.

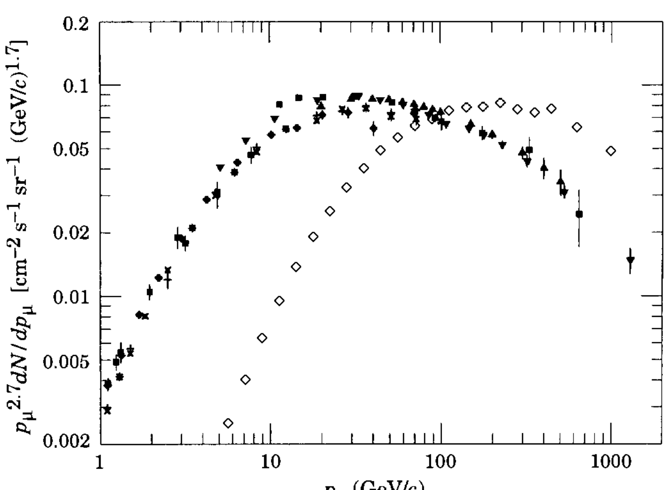

Figure 20.4: Spectrum of muons at $\theta = 0°$ (♦ [18], ■ [20], ▼ [21], ▲ [22], X,+ [23]), and $\theta = 75°$ ◊ [24]).

Figure 20.4 shows the muon energy spectrum at sea level for two angles. At large angles low energy muons decay before reaching the surface and high energy pions decay before they interact, thus the average muon energy increases. An approximate extrapolation formula valid when muon decay is negligible ($E_\mu > 100/\cos\theta$ GeV) and the curvature of the Earth can be neglected ($\theta < 70°$) is

$$\frac{dN_\mu}{dE_\mu} \approx \frac{0.14\, E_\mu^{-2.7}}{\text{cm}^2 \text{ s sr GeV}} \times \left\{ \frac{1}{1 + \frac{1.1 E_\mu \cos\theta}{115\,\text{GeV}}} + \frac{0.054}{1 + \frac{1.1 E_\mu \cos\theta}{850\,\text{GeV}}} \right\}, \tag{20.5}$$

where the two terms give the contribution of pions and charged kaons. Eq. (20.5) neglects a small contribution from charm and heavier flavors which is negligible except at very high energy [27].

The muon charge ratio reflects the excess of π^+ over π^- in the forward fragmentation region of proton initiated interactions together with the fact that there are more protons than neutrons in the primary spectrum. The charge ratio is between 1.1 and 1.4 from 1 GeV to 100 GeV [18,23]. Below 1 GeV there is a systematic dependence on location due to geomagnetic effects. [23]

20.3.2. ***Electromagnetic component***: At the ground, this component consists of electrons, positrons, and photons primarily from electromagnetic cascades initiated by decay of neutral and charged mesons. Muon decay is the dominant source of low-energy electrons at sea level. Decay of neutral pions is more important at high altitude or when the energy threshold is high. Knock-on electrons also make a small contribution at low energy [25]. The integral vertical intensity of electrons plus positrons is very approximately 30, 6, and 0.2 $\text{m}^{-2}\text{s}^{-1}\text{sr}^{-1}$ above 10, 100, and 1000 MeV respectively [19,26], but the exact numbers depend sensitively on altitude, and the angular dependence is complex because of the different altitude dependence of the different sources of electrons [25,26,28]. The ratio of photons to electrons plus positrons is approximately 1.3 above a GeV and 1.7 below the critical energy [28].

20.3.3. ***Protons***: Nucleons above 1 GeV/c at ground level are degraded remnants of the primary cosmic radiation. The intensity is approximately represented by Eq. (20.3) with the replacement $t \to t/\cos\theta$ for $\theta < 70°$ and an attenuation length $\Lambda = 123$ g cm^{-2}. At sea level, about 1/3 of the nucleons in the vertical direction are neutrons (up from $\approx 10\%$ at the top of the atmosphere as the n/p ratio approaches equilibrium). The integral intensity of vertical protons above 1 GeV/c at sea level is $\approx 0.9\ \text{m}^{-2}\text{s}^{-1}\text{sr}^{-1}$ [19,29].

20.4. Cosmic rays underground

Only muons and neutrinos penetrate to significant depths underground. The muons produce tertiary fluxes of photons, electrons, and hadrons.

20.4.1. ***Muons***: As discussed in Section 23.6 of this *Review*, muons lose energy by ionization and by radiative processes: bremsstrahlung, direct production of e^+e^- pairs, and photonuclear interactions. The total muon energy loss may be expressed as a function of the amount of matter traversed as

$$-\frac{dE_\mu}{dX} = a + b\,E_\mu\,, \tag{20.6}$$

where a is the ionization loss and b is the fractional energy loss by the three radiation processes. Both are slowly varying functions of energy. The quantity $\epsilon \equiv a/b$ (≈ 500 GeV in standard rock) defines a critical energy below which continuous ionization loss is more important than radiative losses. Table 20.2 shows a and b values for standard rock as a function of muon energy. The second column of Table 20.2 shows the muon range in standard rock ($A = 22$, $Z = 11$, $\rho = 2.65$ g cm^{-3}). These parameters are quite sensitive to the chemical composition of the rock, which must be evaluated for each experimental location.

The intensity of muons underground can be estimated from the muon intensity in the atmosphere and their rate of energy loss. To the extent that the mild energy dependence of a and b can be neglected, Eq. (20.6) can be integrated to provide the following relation between

Table 20.2: Average muon range R and energy loss parameters calculated for standard rock[30]. Range is given in km-water-equivalent, or 10^5 g cm^{-2}.

E_μ	R	a	b_{brems}	b_{pair}	b_{nucl}	$\sum b_i$
GeV	km.w.e.	MeV g^{-1} cm^2	——	10^{-6} g^{-1} cm^2		——
10	0.05	2.17	0.70	0.70	0.50	1.90
100	0.41	2.44	1.10	1.53	0.41	3.04
1000	2.45	2.68	1.44	2.07	0.41	3.92
10000	6.09	2.93	1.62	2.27	0.46	4.35

the energy $E_{\mu,0}$ of a muon at production in the atmosphere and its average energy E_μ after traversing a thickness X of rock (or ice or water):

$$E_\mu = (E_{\mu,0} + \epsilon)\, e^{-bX} - \epsilon\,. \tag{20.7}$$

Especially at high energy, however, fluctuations are important and an accurate calculation requires a simulation that accounts for stochastic energy-loss processes [31].

There are two depth regimes for Eq. (20.7). For $X \ll b^{-1} \approx$ 2.5 km water equivalent, $E_{\mu,0} \approx E_\mu(X) + aX$, while for $X \gg b^{-1}$ $E_{\mu,0} \approx (\epsilon + E_\mu(X))\exp(bX)$. Thus at shallow depths the differential muon energy spectrum is approximately constant for $E_\mu < aX$ and steepens to reflect the surface muon spectrum for $E_\mu > aX$, whereas for $X > 2.5$ km.w.e. the differential spectrum underground is again constant for small muon energies but steepens to reflect the surface muon spectrum for $E_\mu > \epsilon \approx 0.5$ TeV. In the deep regime the shape is independent of depth although the intensity decreases exponentially with depth. In general the muon spectrum at slant depth X is

$$\frac{dN_\mu(X)}{dE_\mu} = \frac{dN_\mu}{dE_{\mu,0}} \frac{dE_{\mu,0}}{dE_\mu} = \frac{dN_\mu}{dE_{\mu,0}} e^{bX}\,, \tag{20.8}$$

where $E_{\mu,0}$ is the solution of Eq. (20.7) in the approximation neglecting fluctuations.

Fig. 20.5 shows the vertical muon intensity versus depth. In constructing this "depth-intensity curve," each group has taken account of the angular distribution of the muons in the atmosphere, the map of the overburden at each detector, and the properties of the local medium in connecting measurements at various slant depths and zenith angles to the vertical intensity. Use of data from a range of angles allows a fixed detector to cover a wide range of depths. The flat portion of the curve is due to muons produced locally by charged-current interactions of ν_μ.

20.4.2. ***Neutrinos***: Because neutrinos have small interaction cross sections, measurements of atmospheric neutrinos require a deep detector to avoid backgrounds. There are two types of measurements: contained (or semi-contained) events, in which the vertex is determined to originate inside the detector, and neutrino-induced muons. The latter are muons that enter the detector from zenith angles so large (*e.g.*, nearly horizontal or upward) that they cannot be muons produced in the atmosphere. In neither case is the neutrino flux measured directly. What is measured is a convolution of the neutrino flux and cross section with the properties of the detector (which includes the surrounding medium in the case of entering muons).

Contained and semi-contained events reflect neutrinos in the sub-GeV to multi-GeV region where the product of increasing cross section and decreasing flux is maximum. In the GeV region the neutrino flux and its angular distribution depend on the geomagnetic location of the detector and, to a lesser extent, on the phase of the solar cycle. Naively, we expect $\nu_\mu/\nu_e = 2$ from counting neutrinos of the two flavors coming from the chain of pion and muon decay. This ratio is only slightly modified by the details of the decay kinematics, but the fraction of electron neutrinos gradually decreases above a GeV as parent muons begin to reach the ground before decaying. Experimental measurements have to account for the ratio of $\bar{\nu}/\nu$, which have cross sections different by a factor of 3 in this energy range. In addition, detectors generally have different efficiencies for

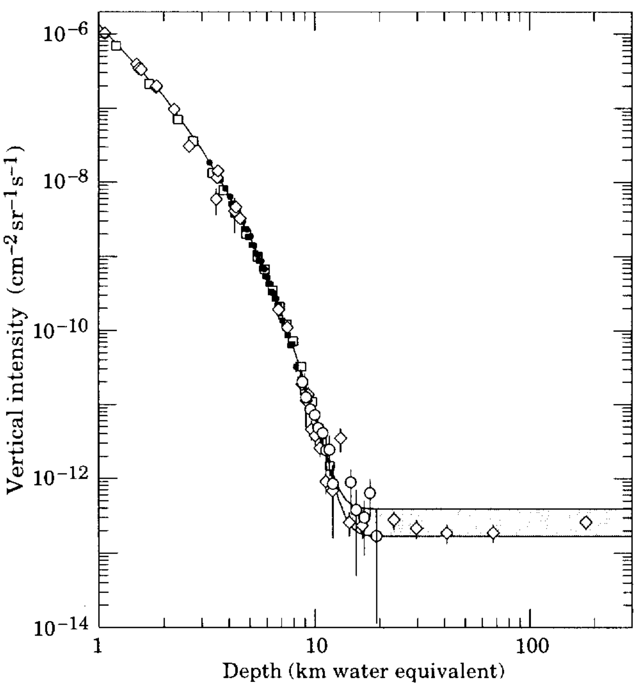

Figure 20.5: Vertical muon intensity vs depth (1 km.w.e. = 10^5 g cm^{-2} of standard rock). The experimental data are from: ◊: the compilations of Crouch [32], □: Baksan [33], ○ : LVD [34], ● : MACRO [35], ■: Frejus [36]. The shaded area at large depths represents neutrino induced muons of energy above 2 GeV. The upper line is for horizontal neutrino-induced muons, the lower one for vertically upward muons.

detecting muon neutrinos and electron neutrinos which need to be accounted for in comparing measurements with expectation. Fig. 20.6 shows the distributions of the visible energy in the Super-Kamiokande detector [39] for electron-like and muon-like charged current neutrino interactions. Contrary to expectation, the numbers of the two classes of events are similar rather than different by a factor of two. The exposure for the data sample shown here is 50 kiloton-years. The falloff of the muon-like events at high energy is a consequence of the poor containment for high energy muons. Corrections for detection efficiencies and backgrounds are, however, insufficient to account for the large difference from the expectation.

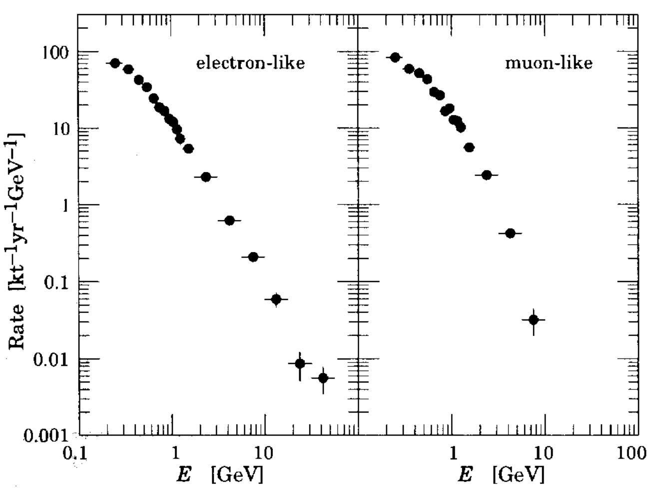

Figure 20.6: Sub-GeV and multi-GeV neutrino interactions from SuperKamiokande [39]. The plot shows the spectra of visible energy in the detector.

Two well-understood properties of atmospheric cosmic rays provide a standard for comparison of the measurements of atmospheric neutrinos. These are the "sec θ effect" and the "east-west effect". The former refers originally to the enhancement of the flux of > 10 GeV muons (and neutrinos) at large zenith angles because the parent pions propagate more in the low density upper atmosphere where decay is enhanced relative to interaction. For neutrinos from muon decay, the enhancement near the horizontal becomes important for $E_\nu > 1$ GeV and arises mainly from the increased pathlength through the atmosphere for muon decay in flight. Fig. 20.7 from Ref. 40 shows a comparison between measurement and expectation for the zenith angle dependence of multi-GeV electron-like (mostly ν_e) and muon-like (mostly ν_μ) events separately. The ν_e show an enhancement near the horizontal and approximate equality for nearly upward ($\cos\theta \approx -1$) and nearly downward ($\cos\theta \approx 1$) events. There is, however, a very significant deficit of upward ($\cos\theta < 0$) ν_μ events, which have long pathlengths comparable to the radius of the Earth. This pattern has been interpreted as evidence for oscillations involving muon neutrinos [39]. (See the article on neutrino properties in this *Review*.) Including three dimensional effects in the calculation of atmospheric neutrinos may change somewhat the expected angular distributions of neutrinos at low energy [41], but it does not change the fundamental expectation of up-down symmetry, which is the basis of the evidence for oscillations.

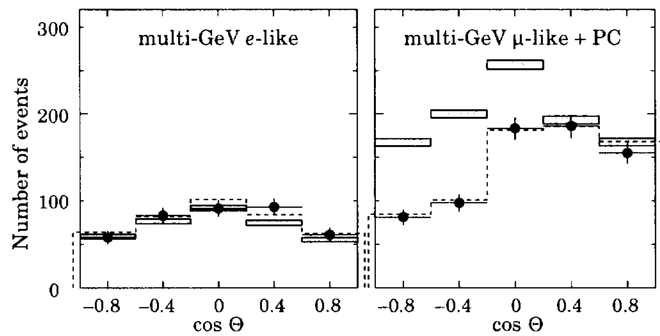

Figure 20.7: Zenith-angle dependence of multi-GeV neutrino interactions from SuperKamiokande [40]. The shaded boxes show the expectation in the absence of any oscillations. The lines show fits with some assumed oscillation parameters, as described in Ref. 40.

The east-west effect [42,43] is the enhancement, especially at low geomagnetic latitudes, of cosmic rays incident on the atmosphere from the west as compared to those from the east. This is a consequence of the fact that the cosmic rays are postively charged nuclei which are bent systematically in one sense in the geomagnetic field. Not all trajectories can reach the atmosphere from outside the geomagnetic field. The standard procedure to see which trajectories are allowed is to inject antiprotons outward from near the top of the atmosphere in various directions and see if they escape from the geomagnetic field without becoming trapped indefinitely or intersecting the surface of the Earth. Any direction in which an antiproton of a given momentum can escape is an allowed direction from which a proton of the opposite momentum can arrive. Since the geomagnetic field is oriented from south to north in the equatorial region, antiprotons injected toward the east are bent back towards the Earth. Thus there is a range of momenta and zenith angles for which positive particles cannot arrive from the east but can arrive from the west. This east-west asymmetry of the incident cosmic rays induces a similar asymmetry on the secondaries, including neutrinos. Since this is an azimuthal effect, the resulting asymmetry is independent of possible oscillations, which depend on pathlength (equivalently zenith angle), but not on azimuth. Fig. 20.8 (from Ref. 44) is a comparison of data and expectation for this effect, which serves as a consistency check of the measurement and analysis.

Muons that enter the detector from outside after production in charged-current interactions of neutrinos naturally reflect a higher energy portion of the neutrino spectrum than contained events because the muon range increases with energy as well as the cross section. The relevant energy range is $\sim 10 < E_\nu < 1000$ GeV, depending somewhat on angle. Neutrinos in this energy range show a sec θ effect similar

Table 20.3: Measured fluxes (10^{-13} cm^{-2} s^{-1} sr^{-1}) of neutrino-induced muons as a function of the effective minimum muon energy E_μ.

$E_\mu >$	1 GeV	1 GeV	1 GeV	2 GeV	3 GeV	3 GeV
Ref.	CWI [45]	Baksan [46]	MACRO [47]	IMB [48]	Kam [49]	SuperK [50]
F_μ	2.17±0.21	2.77±0.17	2.29 ± 0.15	2.26±0.11	1.94±0.12	1.74±0.07

to muons (see Eq. (20.5)). This causes the flux of horizontal neutrino induced muons to be approximately a factor two higher than the vertically upward flux. The upper and lower edges of the horizontal shaded region in Fig. 20.5 correspond to horizontal and vertical intensities of neutrino-induced muons. Table 20.3 gives the measured fluxes of upward-moving neutrino-induced muons averaged over the lower hemisphere. Generally the definition of minimum muon energy depends on where it passes through the detector. The tabulated effective minimum energy estimates the average over various accepted trajectories.

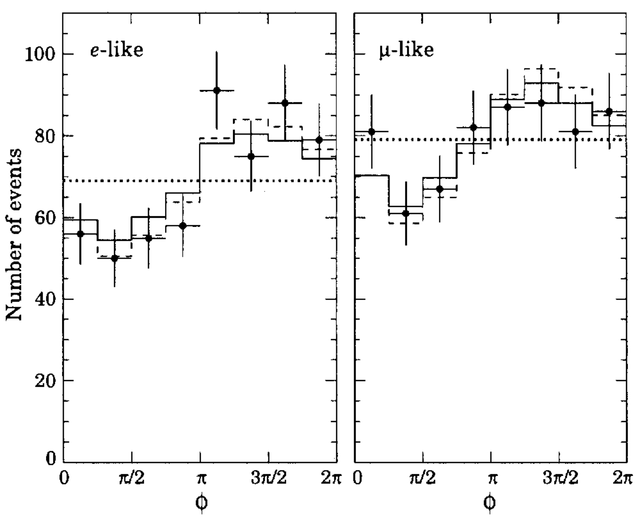

Figure 20.8: Azimuthal dependence of ~GeV neutrino interactions from SuperKamiokande [44]. The cardinal points of the compass are S, E, N, W starting at 0. These are the direction from which the particles arrive. The lines show the expectation based on two different calculations, as described in Ref. 44.

20.5. Air showers

So far we have discussed inclusive or uncorrelated fluxes of various components of the cosmic radiation. An air shower is caused by a single cosmic ray with energy high enough for its cascade to be detectable at the ground. The shower has a hadronic core, which acts as a collimated source of electromagnetic subshowers, generated mostly from $\pi^0 \to \gamma\gamma$. The resulting electrons and positrons are the most numerous particles in the shower. The number of muons, produced by decays of charged mesons, is an order of magnitude lower.

Air showers spread over a large area on the ground, and arrays of detectors operated for long times are useful for studying cosmic rays with primary energy $E_0 > 100$ TeV, where the low flux makes measurements with small detectors in balloons and satellites difficult.

Greisen [51] gives the following approximate expressions for the numbers and lateral distributions of particles in showers at ground level. The total number of muons N_μ with energies above 1 GeV is

$$N_\mu(>1\ \mathrm{GeV}) \approx 0.95 \times 10^5 \left(N_e/10^6\right)^{3/4} , \qquad (20.9)$$

where N_e is the total number of charged particles in the shower (not just $e^\pm$). The number of muons per square meter, ρ_μ, as a function of the lateral distance r (in meters) from the center of the shower is

$$\rho_\mu = \frac{1.25\, N_\mu}{2\pi\, \Gamma(1.25)} \left(\frac{1}{320}\right)^{1.25} r^{-0.75} \left(1 + \frac{r}{320}\right)^{-2.5} , \qquad (20.10)$$

where Γ is the gamma function. The number density of charged particles is

$$\rho_e = C_1(s,d,C_2)\, x^{(s-2)}(1+x)^{(s-4.5)}(1 + C_2 x^d) . \qquad (20.11)$$

Here s, d, and C_2 are parameters in terms of which the overall normalization constant $C_1(s,d,C_2)$ is given by

$$C_1(s,d,C_2) = \frac{N_e}{2\pi r_1^2}\, [B(s, 4.5 - 2s) + C_2\, B(s+d, 4.5-d-2s)]^{-1} , \qquad (20.12)$$

where $B(m,n)$ is the beta function. The values of the parameters depend on shower size (N_e), depth in the atmosphere, identity of the primary nucleus, etc. For showers with $N_e \approx 10^6$ at sea level, Greisen uses $s = 1.25$, $d = 1$, and $C_2 = 0.088$. Finally, x is r/r_1, where r_1 is the Molière radius, which depends on the density of the atmosphere and hence on the altitude at which showers are detected. At sea level $r_1 \approx 78$ m. It increases with altitude.

The lateral spread of a shower is determined largely by Coulomb scattering of the many low-energy electrons and is characterized by the Molière radius. The lateral spread of the muons (ρ_μ) is larger and depends on the transverse momenta of the muons at production as well as multiple scattering.

There are large fluctuations in development from shower to shower, even for showers of the same energy and primary mass—especially for small showers, which are usually well past maximum development when observed at the ground. Thus the shower size N_e and primary energy E_0 are only related in an average sense, and even this relation depends on depth in the atmosphere. One estimate of the relation is [52]

$$E_0 \sim 3.9 \times 10^6\ \mathrm{GeV}\ (N_e/10^6)^{0.9} \qquad (20.13)$$

for vertical showers with $10^{14} < E < 10^{17}$ eV at 920 g cm^{-2} (965 m above sea level). Because of fluctuations, N_e as a function of E_0 is not the inverse of Eq. (20.13). As E_0 increases the shower maximum (on average) moves down into the atmosphere and the relation between N_e and E_0 changes. At the maximum of shower development, there are approximately 2/3 particles per GeV of primary energy.

Detailed simulations and cross-calibrations between different types of detectors are necessary to establish the primary energy spectrum from air-shower experiments [52,53]. Figure 20.9 shows the "all-particle" spectrum. In establishing this spectrum, efforts have been made to minimize the dependence of the analysis on the primary composition. In the energy range above 10^{17} eV, the Fly's Eye technique [71] is particularly useful because it can establish the primary energy in a model-independent way by observing most of the longitudinal development of each shower, from which E_0 is obtained by integrating the energy deposition in the atmosphere.

In Fig. 20.9 the differential energy spectrum has been multiplied by $E^{2.7}$ in order to display the features of the steep spectrum that are otherwise difficult to discern. The steepening that occurs between 10^{15} and 10^{16} eV is known as the *knee* of the spectrum. The feature between 10^{18} and 10^{19} eV is called the *ankle* of the spectrum.

If the cosmic ray spectrum below 10^{18} eV is of galactic origin, the *knee* could reflect the fact that some (but not all) cosmic accelerators have reached their maximum energy. Some types of expanding supernova remnants, for example, are estimated not to be able to accelerate particles above energies in the range of 10^{15} eV total energy per particle. Effects of propagation and confinement in the galaxy [61] also need to be considered.

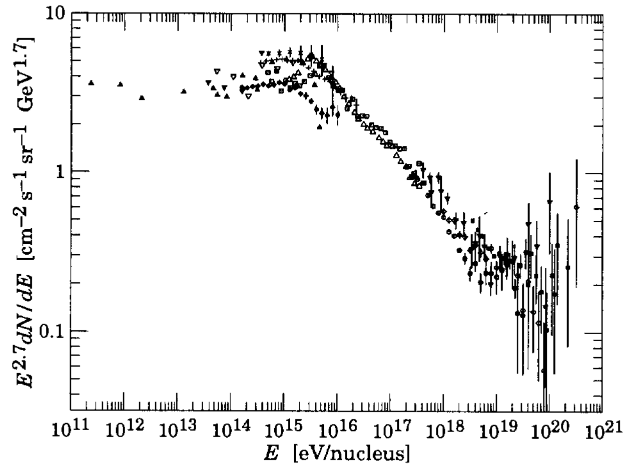

Figure 20.9: The all-particle spectrum: □ [52], ▲ [54], ▼ [55], ▽ [56], △ [57], + [58], X [59], ♦ [60]. References for the high energy portion of the spectrum are given in Fig. 20.10.

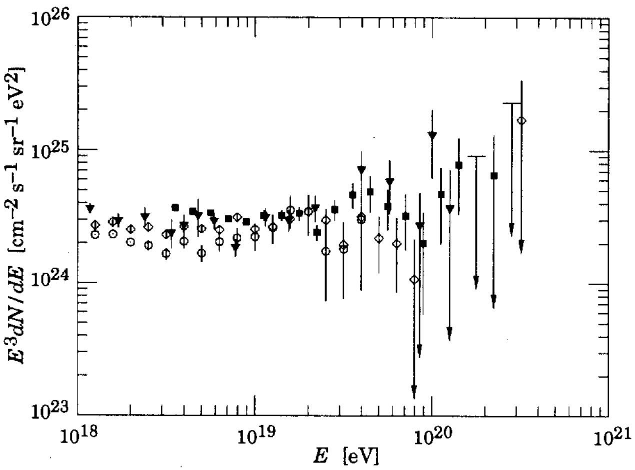

Figure 20.10: Expanded view of the highest energy portion of the cosmic-ray spectrum: o [71] (stereo), ◊ [71] (monocular) ■ [72], ▼ [73].

The *ankle* has the classical characteristic shape [62] of a higher energy population of particles overtaking a lower energy population. A possible interpretation is that the higher energy population represents cosmic rays of extragalactic origin. If this is the case and if the cosmic rays are cosmological in origin, then there should be a cutoff around 5×10^{19} eV, resulting from interactions with the microwave background [63,64]. It is therefore of special interest that several events have been assigned energies above 10^{20} eV [65,66,67,68].

Figure 20.10 gives an expanded view of the high energy end of the spectrum. Not included in the figure are the preliminary results of the Hi-Res Fly's Eye group [69]. Their spectrum is consistent with the others and includes several events above 10^{20} eV. To expand the scale in Fig. 20.10, the differential flux is multiplied by E^3, a process which amplifies small systematic differences in energy assignments into sizeable differences in rate. The different measurements agree with each other within 20% systematic shifts in energy scale and consistently show that the spectrum continues well past the expected cutoff for a cosmological distribution of sources. The implication is that some sources of the highest energy particles must be relatively nearby. For example, the attenuation length for protons at 2×10^{20} eV is 30 Mpc [70].

21. ACCELERATOR PHYSICS OF COLLIDERS

Revised October 1999 by K. Desler and D.A. Edwards (DESY).

21.1. Introduction

This article is intended to be a mini-introduction to accelerator physics, with emphasis on colliders. Essential data are summarized in the "Tables of Collider Parameters" (Sec. 22). Luminosity is the quantity of most immediate interest for HEP, and so we begin with its definition and a discussion of the various factors involved. Then we talk about some of the underlying beam dynamics. Finally, we comment on present limitations and possible future directions.

The focus is on colliders because they provide the highest c.m. energy, and so the longest potential discovery reach. All present-day colliders are synchrotrons with the exception of the SLAC Linear Collider. In the pursuit of higher c.m. energy with electrons, synchrotron radiation presents a formidable barrier to energy beyond LEP. The LHC will be the first proton collider in which synchrotron radiation has significant design impact.

21.2. Luminosity

The event rate R in a collider is proportional to the interaction cross section $\sigma_{\rm int}$ and the factor of proportionality is called the *luminosity*:

$$R = \mathscr{L}\sigma_{\rm int} \ . \qquad (21.1)$$

If two bunches containing n_1 and n_2 particles collide with frequency f, then the luminosity is

$$\mathscr{L} = f\frac{n_1 n_2}{4\pi\sigma_x\sigma_y} \qquad (21.2)$$

where σ_x and σ_y characterize the Gaussian transverse beam profiles in the horizontal (bend) and vertical directions. Though the initial distribution at the source may be far from Gaussian, by the time the beam reaches high energy the normal form is a very good approximation thanks to the central limit theorem of probability and diminished importance of space charge effects.

Luminosity is normally expressed in units of cm^{-2}s^{-1}, and tends to be a large number. For example, as we write this update in late 1999, PEP II has just reached 1.3×10^{33} cm^{-2}s^{-1}. The highest luminosity for protons so far is 2.3×10^{32} cm^{-2}s^{-1} at the now decommissioned ISR. The critical quantity for HEP is the integrated luminosity, often stated in pb^{-1}; the two-year Tevatron run that concluded in February 1996 yielded 148 pb^{-1}, for instance.

The beam size can be expressed in terms of two quantities, one termed the *transverse emittance*, ϵ and the other, the *amplitude function*, β. The transverse emittance is a beam quality concept reflecting the process of bunch preparation, extending all the way back to the source for hadrons and, in the case of electrons, mostly dependent on synchrotron radiation. The amplitude function is a beam optics quantity and is determined by the accelerator magnet configuration.

The transverse emittance is a measure of the phase space area associated with either of the two transverse degrees of freedom, x and y. These coordinates represent the position of a particle with reference to some ideal design trajectory. Think of x as the "horizontal" displacement (in the bend plane for the case of a synchrotron), and y as the "vertical" displacement. The conjugate coordinates are the transverse momenta, which at constant energy are proportional to the angles of particle motion with respect to the design trajectory, x' and y'. Various conventions are in use to characterize the boundary of phase space. Beam sizes are usually given as the standard deviations characterizing Gaussian beam profiles in the two transverse degrees of freedom. In each degree of freedom, the one-σ contour in displacement and angle is frequently used and we will follow this choice.

Suppose that at some location in the collider, the phase space boundary appears as an upright ellipse where the coordinates are the displacement x (using the horizontal plane for instance) and the angle x' with respect to the beam axis. The choice of an elliptical contour will be justified under Beam Dynamics below. If σ and σ' are the ellipse semi-axes in the x and x' directions respectively, then the emittance may be defined by $\epsilon \equiv \pi\sigma\sigma'$. Transverse emittance is often stated in units of mm-mrad.

The aspect ratio, σ/σ', is the so-called *amplitude function*, β, and its value depends on position within the focussing structure. When expressed in terms of σ and β the transverse emittance becomes

$$\epsilon = \pi\sigma^2/\beta \ . \qquad (21.3)$$

Of particular significance is the value of the amplitude function at the interaction point, β^*. To achieve high luminosity, one wants β^* to be as small as possible; how small depends on the capability of the hardware to make a near-focus at the interaction point. For example, in the HERA proton ring, β^* at one of the major detectors is 1 m while elsewhere in the synchrotron typical values of the amplitude function lie in the range 30–100 m.

Eq. (21.2) can now be recast in terms of emittances and amplitude functions as

$$\mathscr{L} = f\frac{n_1 n_2}{4\sqrt{\epsilon_x\beta_x^*\,\epsilon_y\beta_y^*}} \ . \qquad (21.4)$$

Thus, to achieve high luminosity, all one has to do is make high population bunches of low emittance to collide at high frequency at locations where the beam optics provides as low values of the amplitude functions as possible.

Depending on the particular facility, there are other ways of stating the expression for the luminosity. In a multibunch collider, the various bunch populations will differ, in a facility such as HERA, the electron and proton bunches may differ in emittance, the variation of the beam size in the neighborhood of the interaction point may be significant, and so on.

21.3. Beam dynamics

A major concern of beam dynamics is stability: conservation of adequate beam properties over a sufficiently long time scale. Several time scales are involved, and the approximations used in writing the equations of motion reflect the time scale under consideration. For example, when, in Sec. 21.3.1 below, we write the equations for transverse stability no terms associated with phase stability or synchrotron radiation appear; the time scale associated with the last two processes is much longer than that demanded by the need for transverse stability.

21.3.1. *Betatron oscillations*:

Present-day high-energy accelerators employ alternating gradient focussing provided by quadrupole magnetic fields [1]. The equations of motion of a particle undergoing oscillations with respect to the design trajectory are

$$x'' + K_x(s)\,x = 0 \ , \quad y'' + K_y(s)\,y = 0 \ , \qquad (21.5)$$

with

$$x' \equiv dx/ds \ , \quad y' \equiv dy/ds \qquad (21.6)$$

$$K_x \equiv B'/(B\rho) + \rho^{-2} \ , \quad K_y \equiv -B'/(B\rho) \qquad (21.7)$$

$$B' \equiv \partial B_y/\partial x \ . \qquad (21.8)$$

The independent variable s is path length along the design trajectory. This motion is called a *betatron* oscillation because it was initially studied in the context of that type of accelerator. The functions K_x and K_y reflect the transverse focussing—primarily due to quadrupole fields except for the radius of curvature, ρ, term in K_x for a synchrotron—so each equation of motion resembles that for a harmonic oscillator but with spring constants that are a function of position. No terms relating to synchrotron oscillations appear, because their time scale is much longer and in this approximation play no role.

These equations have the form of Hill's equation and so the solution in one plane may be written as

$$x(s) = A\sqrt{\beta(s)}\,\cos(\psi(s) + \delta), \qquad (21.9)$$

where A and δ are constants of integration and the phase advances according to $d\psi/ds = 1/\beta$. The dimension of A is the square root of length, reflecting the fact that the oscillation amplitude is modulated by the square root of the amplitude function. In addition to describing the envelope of the oscillation, β also plays the role of an 'instantaneous' $\lambda\!\!\!^{-}$. The wavelength of a betatron oscillation may be some tens of meters, and so typically values of the amplitude function are of the order of meters rather than on the order of the beam size. The beam optics arrangement generally has some periodicity and the amplitude function is chosen to reflect that periodicity. As noted above, at the interaction point a small value of the amplitude function is desired, and so the focussing optics is tailored in the neighborhood to provide a suitable β^*.

The number of betatron oscillations per turn in a synchrotron is called the *tune* and is given by

$$\nu = \frac{1}{2\pi}\oint\frac{ds}{\beta} \ . \tag{21.10}$$

Expressing the integration constant A in the solution above in terms of x, x' yields the *Courant-Snyder invariant*

$$A^2 = \gamma(s)\,x(s)^2 + 2\alpha(s)\,x(s)\,x'(s) + \beta(s)\,x'(s)^2$$

where

$$\alpha \equiv -\beta'/2, \ \ \gamma \equiv \frac{1+\alpha^2}{\beta} \ . \tag{21.11}$$

(The Courant-Snyder parameters α, β and γ employ three Greek letters which have other meanings and the significance at hand must often be recognized from context.) Because β is a function of position in the focussing structure, this ellipse changes orientation and aspect ratio from location to location but the area πA^2 remains the same.

As noted above the transverse emittance is a measure of the area in x, x' (or y, y') phase space occupied by an ensemble of particles. The definition used in Eq. (21.3) is the area that encloses 39% of a Gaussian beam.

For electron synchrotrons the equilibrium emittance results from the balance between synchrotron radiation damping and excitation from quantum fluctuations in the radiation rate. The equilibrium is reached in a time small compared with the storage time.

For present-day hadron synchrotrons, synchrotron radiation does not play a similar role in determining the transverse emittance. Rather the emittance during storage reflects the source properties and the abuse suffered by the particles throughout acceleration and storage. Nevertheless it is useful to argue as follows: Though x' and x can serve as canonically conjugate variables at constant energy this definition of the emittance would not be an adiabatic invariant when the energy changes during the acceleration cycle. However, $\gamma(v/c)x'$, where here γ is the Lorentz factor, is proportional to the transverse momentum and so qualifies as a variable conjugate to x. So often one sees a normalized emittance defined according to

$$\epsilon_N = \gamma\frac{v}{c}\epsilon. \tag{21.12}$$

21.3.2. *Phase stability*: The particles in a circular collider also undergo synchrotron oscillations. This is usually referred to as motion in the *longitudinal* degree-of-freedom because particles arrive at a particular position along the accelerator earlier or later than an ideal reference particle. This circumstance results in a finite bunch length, which is related to an energy spread.

For dynamical variables in longitudinal phase space, let us take ΔE and Δt, where these are the energy and time differences from that of the ideal particle. A positive Δt means a particle is behind the ideal particle. The equation of motion is the same as that for a physical pendulum and therefore is nonlinear. But for small oscillations, it reduces to a simple harmonic oscillator:

$$\frac{d^2\Delta t}{dn^2} = -(2\pi\nu_s)^2\Delta t \tag{21.13}$$

where the independent variable n is the turn number and ν_s is the number of synchrotron oscillations per turn, analogous to the betatron oscillation tune defined earlier.

In the high-energy limit, where $v/c \approx 1$,

$$\nu_s = \left[\frac{h\eta eV\cos\phi_s}{2\pi E}\right]^{1/2} \ . \tag{21.14}$$

There are four as yet undefined quantities in this expression: the harmonic number h, the slip factor η, the maximum energy eV gain per turn from the acceleration system, and the synchronous phase ϕ_s. The frequency of the RF system is normally a relatively high multiple, h, of the orbit frequency. The slip factor relates the fractional change in the orbit period τ to changes in energy according to

$$\frac{\Delta\tau}{\tau} = \eta\frac{\Delta E}{E} \ . \tag{21.15}$$

At sufficiently high energy, the slip factor just reflects the relationship between path length and energy, since the speed is a constant; η is positive for all the synchrotrons in the tables.

The synchronous phase is a measure of how far up on the RF wave the average particle must ride in order to maintain constant energy in the face of synchrotron radiation. That is, $\sin\phi_s$ is the ratio of the energy loss per turn to the maximum energy per turn that can be provided by the acceleration system. For hadron colliders built to date, $\sin\phi_s$ is effectively zero. This is not the case for electron storage rings; for example, the electron ring of HERA runs at a synchronous phase of 45°.

Now if one has a synchrotron oscillation with amplitudes $\widehat{\Delta t}$ and $\widehat{\Delta E}$,

$$\Delta t = \widehat{\Delta t}\,\sin(2\pi\nu_s n) \ , \qquad \Delta E = \widehat{\Delta E}\,\cos(2\pi\nu_s n) \tag{21.16}$$

then the amplitudes are related according to

$$\widehat{\Delta E} = \frac{2\pi\nu_s E}{\eta\tau}\widehat{\Delta t} \ . \tag{21.17}$$

The longitudinal emittance ϵ_ℓ may be defined as the phase space area bounded by particles with amplitudes $\widehat{\Delta t}$ and $\widehat{\Delta E}$. In general, the longitudinal emittance for a given amplitude is found by numerical integrations. For $\sin\phi_s = 0$, an analytical expression is as follows:

$$\epsilon_\ell = \left[\frac{2\pi^3 EeVh}{\tau^2\eta}\right]^{1/2}(\widehat{\Delta t})^2 \tag{21.18}$$

Again, a Gaussian is a reasonable representation of the longitudinal profile of a well-behaved beam bunch; if $\sigma_{\Delta t}$ is the standard deviation of the time distribution, then the bunch length can be characterized by

$$\ell = c\sigma_{\Delta t} \ . \tag{21.19}$$

In the electron case the longitudinal emittance is determined by the synchrotron radiation process just as in the transverse degrees of freedom. For the hadron case the history of acceleration plays a role and because energy and time are conjugate coordinates, the longitudinal emittance is a quasi-invariant.

For HEP bunch length is a significant quantity because if the bunch length becomes larger than β^* the luminosity is adversely affected. This is because β grows parabolically as one proceeds from the IP and so the beam size increases thus lowering the contribution to the luminosity from such locations.

21.3.3. *Synchrotron radiation* [2]: A relativistic particle undergoing centripetal acceleration radiates at a rate given by the Larmor formula multiplied by the 4th power of the Lorentz factor:

$$P = \frac{1}{6\pi\epsilon_0}\frac{e^2a^2}{c^3}\gamma^4. \tag{21.20}$$

Here, $a = v^2/\rho$ is the centripetal acceleration of a particle with speed v undergoing deflection with radius of curvature ρ. In a synchrotron that has a constant radius of curvature within bending magnets, the energy lost due to synchrotron radiation per turn is the above multiplied by the time spent in bending magnets, $2\pi\rho/v$. Expressed in familiar units, this result may be written

$$W = 8.85 \times 10^{-5} E^4/\rho \text{ MeV per turn} \tag{21.21}$$

for electrons at sufficiently high energy that $v \approx c$. The energy E is in GeV and ρ is in kilometers. The radiation has a broad energy spectrum which falls off rapidly above the *critical energy*, $E_c = (3c/2\rho)\hbar\gamma^3$. Typically, E_c is in the hard x-ray region.

The characteristic time for synchrotron radiation processes is the time during which the energy must be replenished by the acceleration system. If f_0 is the orbit frequency, then the characteristic time is given by

$$\tau_0 = \frac{E}{f_0 W} . \tag{21.22}$$

Oscillations in each of the three degrees of freedom either damp or antidamp depending on the design of the accelerator. For a simple separated function alternating gradient synchrotron, all three modes damp. The damping time constants are related by Robinson's Theorem [3], which, expressed in terms of τ_0, is

$$\frac{1}{\tau_x} + \frac{1}{\tau_y} + \frac{1}{\tau_s} = 2\frac{1}{\tau_0} . \tag{21.23}$$

Even though all three modes may damp, the emittances do not tend toward zero. Statistical fluctuations in the radiation rate excite synchrotron oscillations and radial betatron oscillations. Thus there is an equilibrium emittance at which the damping and excitation are in balance. The vertical emittance is non-zero due to horizontal-vertical coupling.

Polarization can develop from an initially unpolarized beam as a result of synchrotron radiation. A small fraction $\approx E_c/E$ of the radiated power flips the electron spin. Because the lower energy state is that in which the particle magnetic moment points in the same direction as the magnetic bend field, the transition rate toward this alignment is larger than the rate toward the reverse orientation. An equilibrium polarization of 92% is predicted, and despite a variety of depolarizing processes, polarization above 80% has been observed at a number of facilities.

The radiation rate for protons is of course down by a factor of the fourth power of the mass ratio, and is given by

$$W = 7.8 \times 10^{-3} E^4/\rho \text{ keV per turn} \tag{21.24}$$

where E is now in TeV and ρ in km. For the LHC, synchrotron radiation presents a significant load to the cryogenic system, and impacts magnet design due to gas desorption and secondary electron emission from the wall of the cold beam tube.

21.3.4. ***Beam-beam tune shift***: In a bunch-bunch collision the particles of one bunch see the other bunch as a nonlinear lens. Therefore the focussing properties of the ring are changed in a way that depends on the transverse oscillation amplitude. And so there is a spread in the frequency of betatron oscillations.

There is an extensive literature on the subject of how large this tune spread can be. In practice, the limiting value is hard to predict. It is consistently larger for electrons because of the beneficial effects of damping from synchrotron radiation.

In order that contributions to the total tune spread arise only at the detector locations, the beams in a multibunch collider are kept apart elsewhere by a variety of techniques. For equal energy particles of opposite charge circulating in the same vacuum chamber, electrostatic separators may be used assisted by a crossing angle if appropriate. For particles of equal energy and of the same charge, a crossing angle is needed not only for tune spread reasons but to steer the particles into two separate beam pipes. In HERA, because of the large ratio of proton to electron energy, separation can be achieved by bending magnets.

21.3.5. ***Luminosity lifetime***: In electron synchrotrons the luminosity degrades during the store primarily due to particles leaving the phase stable region in longitudinal phase space as a result of quantum fluctuations in the radiation rate and bremsstrahlung. For hadron colliders the luminosity deteriorates due to emittance dilution resulting from a variety of processes. In practice, stores are intentionally terminated when the luminosity drops to the point where a refill will improve the integrated luminosity.

21.4. Status and prospects

Present facilities represent a balance among current technology, the desires of High Energy Physics, and public support. For forty-five years, beam optics has exploited the invention of alternating gradient focussing. This principle is employed in all colliders both linear and circular. Superconducting technology has grown dramatically in importance during the last two decades. Superconducting magnets are vital to the Tevatron, HERA, and to the future LHC. Superconducting accelerating structures are necessary to CESR, LEP, HERA, Jefferson Laboratory and other facilities requiring high-gradient long pulse length RF systems. Present room temperature accelerating structures produce very short pulses, but with gradients well in excess of the superconducting variety [7].

At present, the next potential facilities are perceived to include the LHC and an electron linear collider. The LHC is an approved project that will represent a major step forward in superconducting magnet technology. No linear collider project has been approved as yet, and the conventional and superconducting approaches compete for prominence. Of perhaps more immediate impact are the B and τ "factories" that are designed to go beyond the 10^{33} cm^{-2}s^{-1} level in luminosity.

In addition to the possibilities of the preceding paragraph, there are other synchrotron-based collider studies underway. Despite formidable R&D challenges a muon-muon collider may become feasible. Proponents of a very large hadron collider at higher energy than the cancelled SSC project are exploring low-cost magnets and tunnels for a facility on the 100 TeV c.m. energy scale.

Ideas abound in accelerator R&D for the long term. Approaches such as wakefield accelerators, plasma-laser combinations, and related investigations may if successful deliver gradients far higher than anything realized today. These studies could potentially lead to a new vision for HEP facilities.

HIGH-ENERGY COLLIDER PARAMETERS: e^+e^- Colliders (I)

The numbers here were received from representatives of the colliders in late 1999 (contact C.G. Wohl, LBNL). Many of the numbers of course change with time, and only the latest values (or estimates) are given here; those in brackets are for coming upgrades. Quantities are, where appropriate, r.m.s. H and V indicate horizontal and vertical directions. Parameters for the defunct SPEAR, DORIS, PETRA, PEP, and TRISTAN colliders may be found in our 1996 edition (Phys. Rev. **D54**, 1 July 1996, Part I).

23. PASSAGE OF PARTICLES THROUGH MATTER

Revised October 1999 by D.E. Groom and S.R. Klein (LBNL).

23.1. Notation

Table 23.1: Summary of variables used in this section. The kinematic variables β and γ have their usual meanings.

Symbol	Definition	Units or Value
α	Fine structure constant ($e^2/4\pi\epsilon_0\hbar c$)	1/137.035 999 76(50)
M	Incident particle mass	MeV/c^2
E	Incident particle energy γMc^2	MeV
T	Kinetic energy	MeV
m_ec^2	Electron mass $\times$ c^2	0.510 998 902(21) MeV
r_e	Classical electron radius $e^2/4\pi\epsilon_0 m_ec^2$	2.817 940 285(31) fm
N_A	Avogadro's number	6.022 141 99(47) $\times$ 10^{23} mol^{-1}
ze	Charge of incident particle	
Z	Atomic number of medium	
A	Atomic mass of medium	g mol^{-1}
K/A	$4\pi N_A r_e^2 m_e c^2/A$	0.307 075 MeV g^{-1} cm^2 for $A = 1$ g mol^{-1}
I	Mean excitation energy	eV (*Note bene!*)
δ	Density effect correction to ionization energy loss	
$\hbar\omega_p$	Plasma energy ($\sqrt{4\pi N_e r_e^3}\ m_ec^2/\alpha$)	$28.816\sqrt{\rho\langle Z/A\rangle}$ eV[(a)]
N_c	Electron density	(units of r_e)$^{-3}$
w_j	Weight fraction of the jth element in a compound or mixture	
n_j	$\propto$ number of jth kind of atoms in a compound or mixture	
X_0	Radiation length	g cm^{-2}
—	$4\alpha r_e^2 N_A/A$	(716.408 g cm^{-2})$^{-1}$ for $A = 1$ g mol^{-1}
E_c	Critical energy	MeV
E_s	Scale energy $\sqrt{4\pi/\alpha}\ m_ec^2$	21.2052 MeV
R_M	Molière radius	g cm^{-2}

[(a)] For ρ in g cm^{-3}.

23.2. Ionization energy loss by heavy particles [4–1]

Moderately relativistic charged particles other than electrons lose energy in matter primarily by ionization. The mean rate of energy loss (or stopping power) is given by the Bethe-Bloch equation,

$$-\frac{dE}{dx} = Kz^2\frac{Z}{A}\frac{1}{\beta^2}\left[\frac{1}{2}\ln\frac{2m_ec^2\beta^2\gamma^2T_{\rm max}}{I^2} - \beta^2 - \frac{\delta}{2}\right] . \qquad (23.1)$$

Here $T_{\rm max}$ is the maximum kinetic energy which can be imparted to a free electron in a single collision, and the other variables are defined in Table 23.1. The units are chosen so that dx is measured in mass per unit area, *e.g.*, in g cm^{-2}.

In this form, the Bethe-Bloch equation describes the energy loss of pions in a material such as copper to about 1% accuracy for energies between about 6 MeV and 6 GeV (momenta between about 40 MeV/c and 6 GeV/c). At lower energies "C/Z" corrections for tightly-bound atomic electrons and other effects must be made, and at higher energies radiative effects begin to be important. These limits of validity depend on both the effective atomic number of the absorber and the mass of the slowing particle. Low-energy effects will be discussed in Sec. 23.2.2.

The function as computed for muons on copper is shown by the solid curve in Fig. 23.1, and for pions on other materials in Fig. 23.3. A minor dependence on M at the highest energies is introduced through $T_{\rm max}$, but for all practical purposes in high-energy physics dE/dx in a given material is a function only of β. Except in hydrogen, particles of the same velocity have very similar rates of energy loss in different materials; there is a slow decrease in the rate of energy loss with increasing Z. The qualitative difference in stopping power behavior at high energies between a gas (He) and the other materials shown in Fig. 23.3 is due to the density-effect correction, δ, discussed below. The stopping power functions are characterized by broad minima whose position drops from $\beta\gamma = 3.5$ to 3.0 as Z goes from 7 to 100. The values of minimum ionization as a function of atomic number are shown in Fig. 23.2.

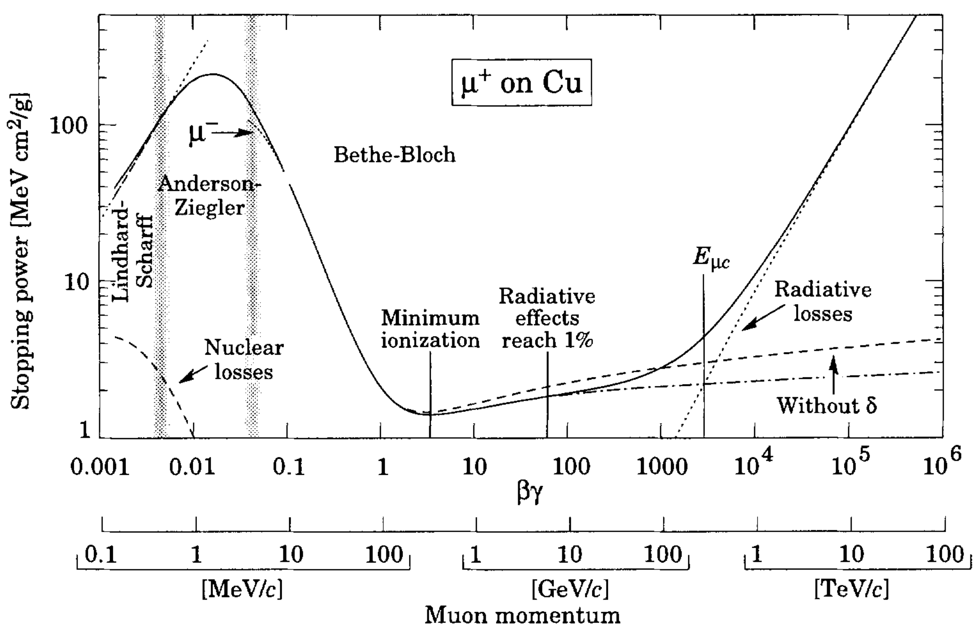

Fig. 23.1: Stopping power (= $\langle -dE/dx\rangle$) for positive muons in copper as a function of $\beta\gamma = p/Mc$ over nine orders of magnitude in momentum (12 orders of magnitude in kinetic energy) [1]. Solid curves indicate the total stopping power. Data below the break at $\beta\gamma \approx 0.1$ are taken from ICRU 49 [2], and data at higher energies are from Ref. 1. Vertical bands indicate boundaries between different approximations discussed in the text. The short dotted lines labeled "μ^-" illustrate the "Barkas effect," the dependence of stopping power on projectile charge at very low energies [3].

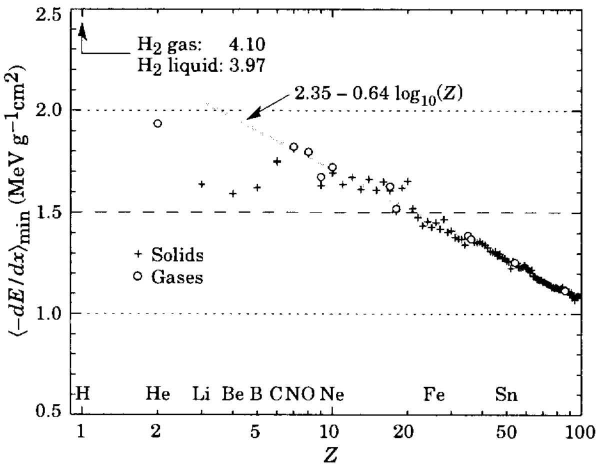

Figure 23.2: Stopping power at minimum ionization for the chemical elements. The straight line is fitted for $Z > 6$. A simple functional dependence is not to be expected, since $\langle -dE/dx \rangle$ depends on other properties than atomic number.

In practical cases, most relativistic particles (*e.g.*, cosmic-ray muons) have energy loss rates close to the minimum, and are said to be minimum ionizing particles, or mip's.

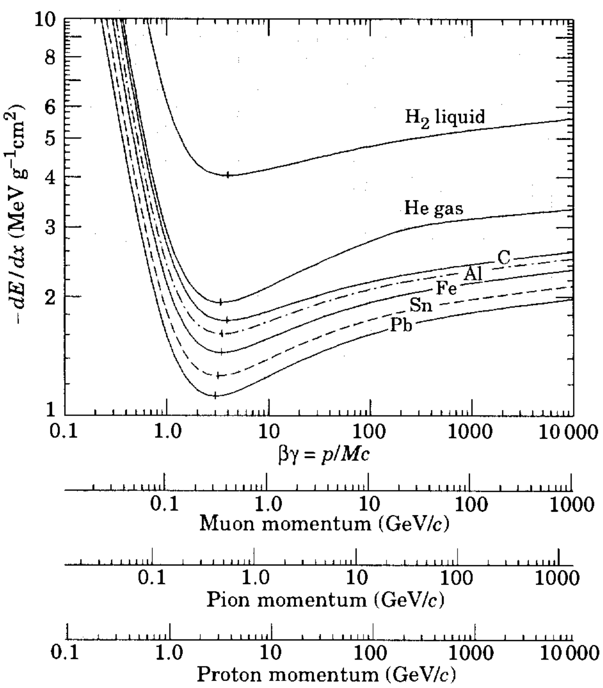

Figure 23.3: Energy loss rate in liquid (bubble chamber) hydrogen, gaseous helium, carbon, aluminum, tin, and lead.

Eq. (23.1) may be integrated to find the total range R for a particle which loses energy only through ionization. Since dE/dx depends only on β, R/M is a function of E/M or pc/M. In practice, range is a useful concept only for low-energy hadrons ($R \lesssim \lambda_I$, where λ_I is the nuclear interaction length), and for muons below a few hundred GeV (above which radiative effects dominate). R/M as a function of $\beta\gamma = p/Mc$ is shown for a variety of materials in Fig. 23.4.

For a particle with mass M and momentum $M\beta\gamma c$, T_{max} is given by

$$T_{max} = \frac{2m_e c^2\, \beta^2\gamma^2}{1 + 2\gamma m_e/M + (m_e/M)^2} \ . \qquad (23.2)$$

It is usual [4,5] to make the "low-energy" approximation $T_{max} = 2m_e c^2\, \beta^2\gamma^2$, valid for $2\gamma m_e/M \ll 1$; this, in fact, is done

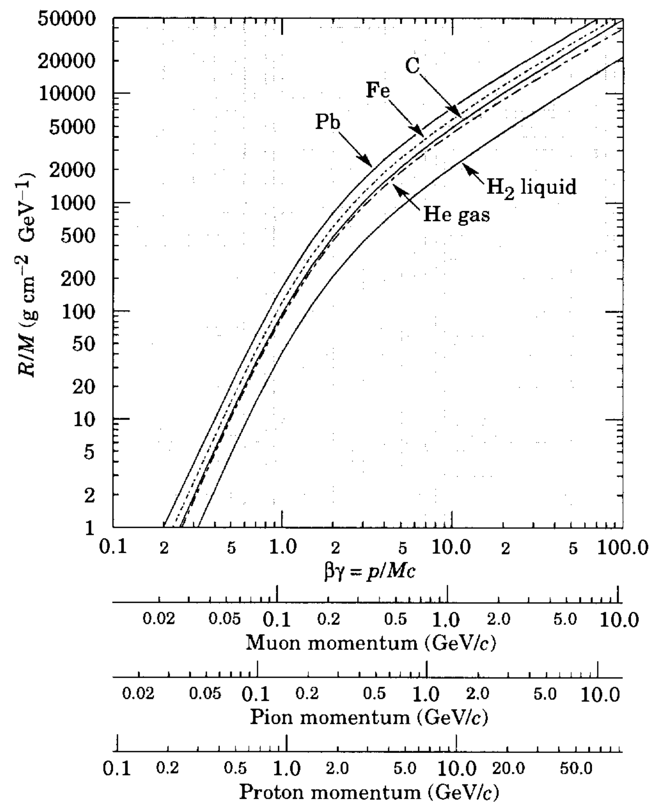

Figure 23.4: Range of heavy charged particles in liquid (bubble chamber) hydrogen, helium gas, carbon, iron, and lead. For example: For a K^+ whose momentum is 700 MeV/c, $\beta\gamma = 1.42$. For lead we read $R/M \approx 396$, and so the range is 195 g cm^{-2}.

implicitly in many standard references. For a pion in copper, the error thus introduced into dE/dx is greater than 6% at 100 GeV. The correct expression should be used.

At energies of order 100 GeV, the maximum 4-momentum transfer to the electron can exceed 1 GeV/c, where structure effects significantly modify the cross sections. This problem has been investigated by J.D. Jackson [6], who concluded that for hadrons (but not for large nuclei) corrections to dE/dx are negligible below energies where radiative effects dominate. While the cross section for rare hard collisions is modified, the average stopping power, dominated by many softer collisions, is almost unchanged.

"The determination of the mean excitation energy is the principal non-trivial task in the evaluation of the Bethe stopping-power formula" [7]. Recommended values have varied substantially with time. Estimates based on experimental stopping-power measurements for protons, deuterons, and alpha particles and on oscillator-strength distributions and dielectric-response functions were given in ICRU 37 [8]. These values, shown in Fig. 23.5, have since been widely used. Machine-readable versions can also be found [9].

23.2.1. ***The density effect***: As the particle energy increases, its electric field flattens and extends, so that the distant-collision contribution to Eq. (23.1) increases as $\ln\beta\gamma$. However, real media become polarized, limiting the field extension and effectively truncating this part of the logarithmic rise [10,11–14]. At very high energies,

$$\delta/2 \rightarrow \ln(\hbar\omega_p/I) + \ln\beta\gamma - 1/2 \ , \qquad (23.3)$$

where $\delta/2$ is the density effect correction introduced in Eq. (23.1) and $\hbar\omega_p$ is the plasma energy defined in Table 23.1. A comparison with Eq. (23.1) shows that $|dE/dx|$ then grows as $\ln\beta\gamma$ rather than $\ln\beta^2\gamma^2$, and that the mean excitation energy I is replaced by the plasma energy $\hbar\omega_p$. The ionization stopping power as calculated with and without the density effect correction is shown in Fig. 23.1. Since the plasma frequency scales as the square root of the electron density, the correction is much larger for a liquid or solid than for a gas, as is illustrated by the examples in Fig. 23.3.

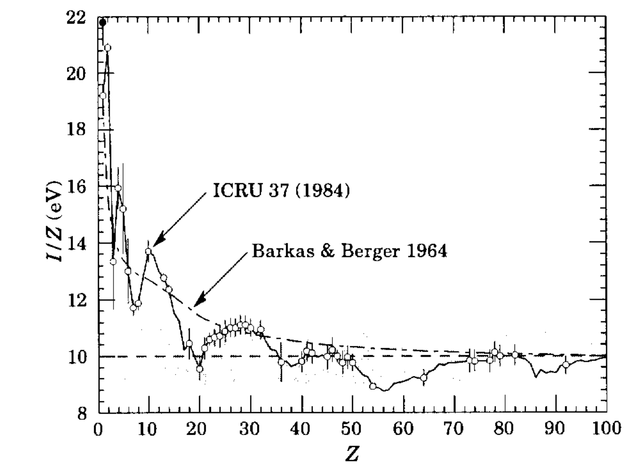

Figure 23.5: Excitation energies (divided by Z) as adopted by the ICRU [8]. Those based on measurement are shown by points with error flags; the interpolated values are simply joined. The solid point is for liquid H_2; the open point at 19.2 is for H_2 gas. Also shown are the $I/Z = 10 \pm 1$ eV band and an early approximation.

The density effect correction is usually computed using Sternheimer's parameterization [11]:

$$\delta = \begin{cases} 2(\ln 10)x - \overline{C} & \text{if } x \geq x_1; \\ 2(\ln 10)x - \overline{C} + a(x_1 - x)^k & \text{if } x_0 \leq x < x_1; \\ 0 & \text{if } x < x_0 \text{ (nonconductors)}; \\ \delta_0 10^{2(x-x_0)} & \text{if } x < x_0 \text{ (conductors)} \end{cases} \tag{23.4}$$

Here $x = \log_{10}\eta = \log_{10}(p/Mc)$. $\overline{C}$ (the negative of the C used in Ref. 11) is obtained by equating the high-energy case of Eq. (23.4) with the limit given in Eq. (23.3). The other parameters are adjusted to give a best fit to the results of detailed calculations for momenta below $Mc\exp(x_1)$. Parameters for elements and nearly 200 compounds and mixtures of interest are published in a variety of places, notably in Ref. 14. A recipe for finding the coefficients for nontabulated materials is given by Sternheimer and Peierls [13], and is summarized in Ref. 1.

The remaining relativistic rise can be attributed to large energy transfers to a few electrons. If these escape or are otherwise accounted for separately, the energy deposited in an absorbing layer (in contrast to the energy lost by the particle) approaches a constant value, the Fermi plateau (see Sec. 23.2.5 below). At extreme energies (*e.g.*, > 332 GeV for muons in iron), radiative effects are more important than ionization losses. These are especially relevant for high-energy muons, as discussed in Sec. 23.6.

23.2.2. ***Energy loss at low energies***: A shell correction C/Z is often included in the square brackets of Eq. (23.1) [2,8,15] to correct for atomic binding having been neglected in calculating some of the contributions to Eq. (23.1). We show the Barkas form [15] in Fig. 23.1. For copper it contributes about 1% at $\beta\gamma = 0.3$ (kinetic energy 6 MeV for a pion), and the correction decreases very rapidly with energy.

Eq. (23.1) is based on a first-order Born approximation. Higher-order corrections, again important only at lower energy, are normally included by adding a term $z^2 L_2(\beta)$ inside the square brackets.

An additional "Barkas correction" $zL_1(\beta)$ makes the stopping power for a negative particle somewhat larger than for a positive particle with the same mass and velocity. In a 1956 paper, Barkas *et al.* noted that negative pions had a longer range than positive pions [3]. The effect has been measured for a number of negative/positive particle pairs, most recently for antiprotons at the CERN LEAR facility [16].

A detailed discussion of low-energy corrections to the Bethe formula is given in ICRU Report 49 [2]. When the corrections are properly included, the accuracy of the Bethe-Bloch treatment is accurate to about 1% down to $\beta \approx 0.05$, or about 1 MeV for protons.

For $0.01 < \beta < 0.05$, there is no satisfactory theory. For protons, one usually relies on the empirical fitting formulae developed by Andersen and Ziegler [2,17]. For particles moving more slowly than $\approx 0.01c$ (more or less the velocity of the outer atomic electrons), Lindhard has been quite successful in describing electronic stopping power, which is proportional to β [18,19]. Finally, we note that at low energies, *e.g.*, for protons of less than several hundred eV, non-ionizing nuclear recoil energy loss dominates the total energy loss [2,19,20].

As shown in ICRU49 [2] (using data taken from Ref. 17), the nuclear plus electronic proton stopping power in copper is 113 MeV cm^2 g^{-1} at $T = 10$ keV, rises to a maximum of 210 MeV cm^2 g^{-1} at 100–150 keV, then falls to 120 MeV cm^2 g^{-1} at 1 MeV. Above 0.5–1.0 MeV the corrected Bethe-Block theory is adequate.

23.2.3. ***Fluctuations in energy loss***: The quantity $(dE/dx)\delta x$ is the mean energy loss via interaction with electrons in a layer of the medium with thickness δx. For finite δx, there are fluctuations in the actual energy loss. The distribution is skewed toward high values (the Landau tail) [4,21]. Only for a thick layer $[(dE/dx)\delta x \gg T_{\rm max}]$ is the distribution nearly Gaussian. The large fluctuations in the energy loss are due to the small number of collisions involving large energy transfers. The fluctuations are smaller for the so-called restricted energy loss rate, as discussed in Sec. 23.2.5 below.

23.2.4. ***Energy loss in mixtures and compounds***: A mixture or compound can be thought of as made up of thin layers of pure elements in the right proportion (Bragg additivity). In this case,

$$\frac{dE}{dx} = \sum w_j \left.\frac{dE}{dx}\right|_j , \tag{23.5}$$

where $dE/dx|_j$ is the mean rate of energy loss (in MeV g cm^{-2}) in the jth element. Eq. (23.1) can be inserted into Eq. (23.5) to find expressions for $\langle Z/A \rangle$, $\langle I \rangle$, and $\langle \delta \rangle$; for example, $\langle Z/A \rangle = \sum w_j Z_j / A_j = \sum n_j Z_j / \sum n_j A_j$. However, $\langle I \rangle$ as defined this way is an underestimate, because in a compound electrons are more tightly bound than in the free elements, and $\langle \delta \rangle$ as calculated this way has little relevance, because it is the electron density which matters. If possible, one uses the tables given in Refs. 14 and 22, which include effective excitation energies and interpolation coefficients for calculating the density effect correction for the chemical elements and nearly 200 mixtures and compounds. If a compound or mixture is not found, then one uses the recipe for δ given in Ref. 13 (or Ref. 23), and calculates $\langle I \rangle$ according to the discussion in Ref. 7. (Note the "13%" rule!)

23.2.5. ***Restricted energy loss rates for relativistic ionizing particles***: Fluctuations in energy loss are due mainly to the production of a few high-energy knock-on electrons. Practical detectors often measure the energy *deposited*, not the energy *lost*. When energy is carried off by energetic knock-on electrons, it is more appropriate to consider the mean energy loss excluding energy transfers greater than some cutoff $T_{\rm cut}$. The restricted energy loss rate is

$$-\left.\frac{dE}{dx}\right|_{T<T_{\rm cut}} = Kz^2 \frac{Z}{A}\frac{1}{\beta^2}\left[\frac{1}{2}\ln\frac{2m_ec^2\beta^2\gamma^2 T_{\rm upper}}{I^2} - \frac{\beta^2}{2}\left(1 + \frac{T_{\rm upper}}{T_{\rm max}}\right) - \frac{\delta}{2}\right] \tag{23.6}$$

where $T_{\rm upper} = {\rm MIN}(T_{\rm cut}, T_{\rm max})$. This form agrees with the equation given in previous editions of this *Review* [24] for $T_{\rm cut} \ll T_{\rm max}$ but smoothly joins the normal Bethe-Bloch function (Eq. (23.1)) for $T_{\rm cut} > T_{\rm max}$.

23.2.6. ***Energetic knock-on electrons (δ rays)***: The distribution of secondary electrons with kinetic energies $T \gg I$ is given by [4]

$$\frac{d^2N}{dTdx} = \frac{1}{2}Kz^2\frac{Z}{A}\frac{1}{\beta^2}\frac{F(T)}{T^2} \tag{23.7}$$

for $I \ll T \leq T_{\rm max}$, where $T_{\rm max}$ is given by Eq. (23.2). The factor F is spin-dependent, but is about unity for $T \ll T_{\rm max}$. For spin-0 particles $F(T) = (1 - \beta^2 T/T_{\rm max})$; forms for spins 1/2 and 1 are also given by Rossi [4]. When Eq. (23.7) is integrated from $T_{\rm cut}$ to $T_{\rm max}$,one obtains the difference between Eq. (23.1) and Eq. (23.6). For incident electrons, the indistinguishability of projectile and target means that the range of T extends only to half the kinetic energy of the incident particle. Additional formulae are given in Ref. 25. Equation (23.7) is inaccurate for T close to I: for $2I \lesssim T \lesssim 10I$, the $1/T^2$ dependence above becomes approximately $T^{-\eta}$, with $3 \lesssim \eta \lesssim 5$ [26].

23.2.7. ***Ionization yields***: Physicists frequently relate total energy loss to the number of ion pairs produced near the particle's track. This relation becomes complicated for relativistic particles due to the wandering of energetic knock-on electrons whose ranges exceed the dimensions of the fiducial volume. For a qualitative appraisal of the nonlocality of energy deposition in various media by such modestly energetic knock-on electrons, see Ref. 27. The mean local energy dissipation per local ion pair produced, W, while essentially constant for relativistic particles, increases at slow particle speeds [28]. For gases, W can be surprisingly sensitive to trace amounts of various contaminants [28]. Furthermore, ionization yields in practical cases may be greatly influenced by such factors as subsequent recombination [29].

23.3. Multiple scattering through small angles

A charged particle traversing a medium is deflected by many small-angle scatters. Most of this deflection is due to Coulomb scattering from nuclei, and hence the effect is called multiple Coulomb scattering. (However, for hadronic projectiles, the strong interactions also contribute to multiple scattering.) The Coulomb scattering distribution is well represented by the theory of Molière [30]. It is roughly Gaussian for small deflection angles, but at larger angles (greater than a few θ_0, defined below) it behaves like Rutherford scattering, having larger tails than does a Gaussian distribution.

If we define

$$\theta_0 = \theta^{\,\rm rms}_{\rm plane} = \frac{1}{\sqrt{2}}\,\theta^{\rm rms}_{\rm space}\ . \tag{23.8}$$

then it is sufficient for many applications to use a Gaussian approximation for the central 98% of the projected angular distribution, with a width given by [31,32]

$$\theta_0 = \frac{13.6\ {\rm MeV}}{\beta c p}\, z\, \sqrt{x/X_0}\Big[1 + 0.038\ln(x/X_0)\Big]\ . \tag{23.9}$$

Here p, βc, and z are the momentum, velocity, and charge number of the incident particle, and x/X_0 is the thickness of the scattering medium in radiation lengths (defined below). This value of θ_0 is from a fit to Molière distribution [30] for singly charged particles with $\beta = 1$ for all Z, and is accurate to 11% or better for $10^{-3} < x/X_0 < 100$.

Eq. (23.9) describes scattering from a single material, while the usual problem involves the multiple scattering of a particle traversing many different layers and mixtures. Since it is from a fit to a Molière distribution, it is incorrect to add the individual θ_0 contributions in quadrature; the result is systematically too small. It is much more accurate to apply Eq. (23.9) once, after finding x and X_0 for the combined scatterer.

Lynch and Dahl have extended this phenomenological approach, fitting Gaussian distributions to a variable fraction of the Molière distribution for arbitrary scatterers [32], and achieve accuracies of 2% or better.

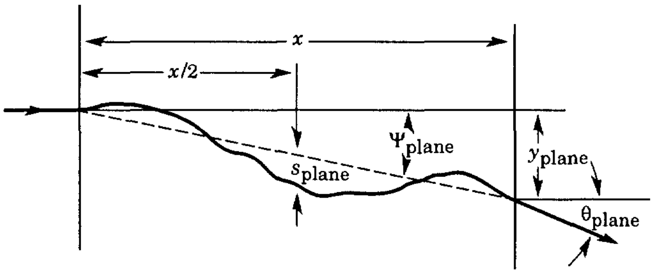

Figure 23.6: Quantities used to describe multiple Coulomb scattering. The particle is incident in the plane of the figure.

The nonprojected (space) and projected (plane) angular distributions are given approximately by [30]

$$\frac{1}{2\pi\,\theta_0^2}\exp\left(-\frac{\theta^2_{\rm space}}{2\theta_0^2}\right)d\Omega\ , \tag{23.10}$$

$$\frac{1}{\sqrt{2\pi}\,\theta_0}\exp\left(-\frac{\theta^2_{\rm plane}}{2\theta_0^2}\right)d\theta_{\rm plane}\ , \tag{23.11}$$

where θ is the deflection angle. In this approximation, $\theta^2_{\rm space} \approx (\theta^2_{{\rm plane},x} + \theta^2_{{\rm plane},y})$, where the x and y axes are orthogonal to the direction of motion, and $d\Omega \approx d\theta_{{\rm plane},x}\, d\theta_{{\rm plane},y}$. Deflections into $\theta_{{\rm plane},x}$ and $\theta_{{\rm plane},y}$ are independent and identically distributed.

Figure 23.6 shows these and other quantities sometimes used to describe multiple Coulomb scattering. They are

$$\psi^{\,\rm rms}_{\rm plane} = \frac{1}{\sqrt{3}}\,\theta^{\,\rm rms}_{\rm plane} \quad = \frac{1}{\sqrt{3}}\,\theta_0\ , \tag{23.12}$$

$$y^{\,\rm rms}_{\rm plane} = \frac{1}{\sqrt{3}}\,x\,\theta^{\,\rm rms}_{\rm plane} \quad = \frac{1}{\sqrt{3}}\,x\,\theta_0\ , \tag{23.13}$$

$$s^{\,\rm rms}_{\rm plane} = \frac{1}{4\sqrt{3}}\,x\,\theta^{\,\rm rms}_{\rm plane} = \frac{1}{4\sqrt{3}}\,x\,\theta_0\ . \tag{23.14}$$

All the quantitative estimates in this section apply only in the limit of small $\theta^{\,\rm rms}_{\rm plane}$ and in the absence of large-angle scatters. The random variables s, ψ, y, and θ in a given plane are distributed in a correlated fashion (see Sec. 27.1 of this *Review* for the definition of the correlation coefficient). Obviously, $y \approx x\psi$. In addition, y and θ have the correlation coefficient $\rho_{y\theta} = \sqrt{3}/2 \approx 0.87$. For Monte Carlo generation of a joint $(y_{\,\rm plane}, \theta_{\rm plane})$ distribution, or for other calculations, it may be most convenient to work with independent Gaussian random variables (z_1, z_2) with mean zero and variance one, and then set

$$\begin{aligned} y_{\rm plane} =& z_1\, x\,\theta_0(1-\rho^2_{y\theta})^{1/2}/\sqrt{3} + z_2\,\rho_{y\theta} x\,\theta_0/\sqrt{3} \\ =& z_1\, x\,\theta_0/\sqrt{12} + z_2\, x\,\theta_0/2\ ; \end{aligned} \tag{23.15}$$

$$\theta_{\rm plane} = z_2\,\theta_0\ . \tag{23.16}$$

Note that the second term for $y_{\,\rm plane}$ equals $x\,\theta_{\rm plane}/2$ and represents the displacement that would have occurred had the deflection $\theta_{\rm plane}$ all occurred at the single point $x/2$.

For heavy ions the multiple Coulomb scattering has been measured and compared with various theoretical distributions [33].

23.4. Photon and electron interactions in matter

23.4.1. ***Radiation length***: High-energy electrons predominantly lose energy in matter by bremsstrahlung, and high-energy photons by e^+e^- pair production. The characteristic amount of matter traversed for these related interactions is called the radiation length X_0, usually measured in g cm^{-2}. It is the mean distance over which a high-energy electron loses all but $1/e$ of its energy by bremsstrahlung, and the e-folding distance for pair production by a high-energy photon is $\frac{7}{9}X_0$. It is also the appropriate scale length for describing high-energy electromagnetic cascades. X_0 has been calculated and tabulated by Y.S. Tsai [34]:

$$\frac{1}{X_0} = 4\alpha r_e^2 \frac{N_A}{A}\Big\{Z^2\big[L_{\rm rad} - f(Z)\big] + Z\,L'_{\rm rad}\Big\}\ . \tag{23.17}$$

For $A = 1$ g mol^{-1}, $4\alpha r_e^2 N_A/A = (716.408$ g cm$^{-2})^{-1}$. $L_{\rm rad}$ and $L'_{\rm rad}$ are given in Table 23.2. The function $f(Z)$ is an infinite sum, but for elements up to uranium can be represented to 4-place accuracy by

$$\begin{aligned} f(Z) =& a^2\big[(1+a^2)^{-1} + 0.20206 \\ & -0.0369\,a^2 + 0.0083\,a^4 - 0.002\,a^6\big]\ , \end{aligned} \tag{23.18}$$

where $a = \alpha Z$ [35].

Table 23.2: Tsai's $L_{\rm rad}$ and $L'_{\rm rad}$, for use in calculating the radiation length in an element using Eq. (23.17).

Element	Z	$L_{\rm rad}$	$L'_{\rm rad}$
H	1	5.31	6.144
He	2	4.79	5.621
Li	3	4.74	5.805
Be	4	4.71	5.924
Others	>4	$\ln(184.15\,Z^{-1/3})$	$\ln(1194\,Z^{-2/3})$

Although it is easy to use Eq. (23.17) to calculate X_0, the functional dependence on Z is somewhat hidden. Dahl provides a compact fit to the data [36]:

$$X_0 = \frac{716.4\ \mathrm{g\ cm^{-2}}\ A}{Z(Z+1)\ln(287/\sqrt{Z})} \qquad (23.19)$$

Results obtained with this formula agree with Tsai's values to better than 2.5% for all elements except helium, where the result is about 5% low.

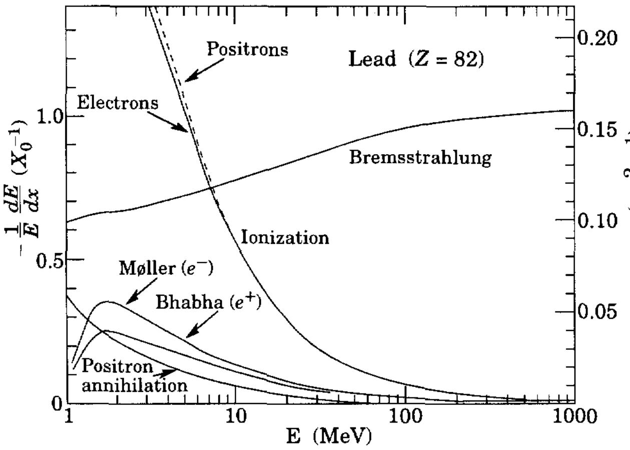

Figure 23.7: Fractional energy loss per radiation length in lead as a function of electron or positron energy. Electron (positron) scattering is considered as ionization when the energy loss per collision is below 0.255 MeV, and as Moller (Bhabha) scattering when it is above. Adapted from Fig. 3.2 from Messel and Crawford, *Electron-Photon Shower Distribution Function Tables for Lead, Copper, and Air Absorbers*, Pergamon Press, 1970. Messel and Crawford use X_0(Pb) = 5.82 g/cm^2, but we have modified the figures to reflect the value given in the Table of Atomic and Nuclear Properties of Materials (X_0(Pb) = 6.37 g/cm^2).

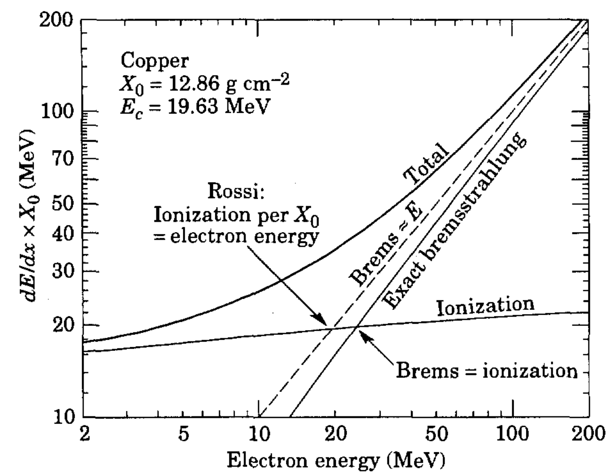

Figure 23.8: Two definitions of the critical energy E_c.

The radiation length in a mixture or compound may be approximated by

$$1/X_0 = \sum w_j/X_j\ , \qquad (23.20)$$

where w_j and X_j are the fraction by weight and the radiation length for the jth element.

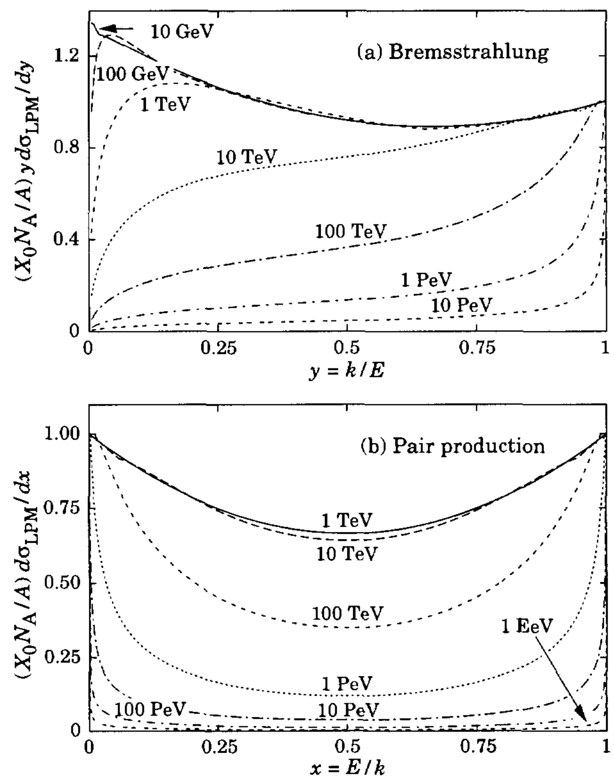

Figure 23.9: (a) The normalized bremsstrahlung cross section $k\, d\sigma_{LPM}/dk$ in lead versus the fractional photon energy $y = k/E$. The vertical axis has units of photons per radiation length. (b) The normalized pair production cross section $d\sigma_{LPM}/dy$, versus fractional electron energy $x = E/k$.

23.4.2. ***Energy loss by electrons***: At low energies electrons and positrons primarily lose energy by ionization, although other processes (Møller scattering, Bhabha scattering, e^+ annihilation) contribute, as shown in Fig. 23.7. While ionization loss rates rise logarithmically with energy, bremsstrahlung losses rise nearly linearly (fractional loss is nearly independent of energy), and dominates above a few tens of MeV in most materials (see Fig. 23.8).

Ionization loss by electrons and positrons differs from loss by heavy particles because of the kinematics, spin, and the identity of the incident electron with the electrons which it ionizes. Complete discussions and tables can be found in Refs. 7, 8, and 22.

At very high energies and except at the high-energy tip of the bremsstrahlung spectrum, the cross section can be approximated in the "complete screening case" as [34]

$$d\sigma/dk = (1/k)4\alpha r_e^2\{(\tfrac{4}{3} - \tfrac{4}{3}y + y^2)[Z^2(L_{\rm rad} - f(Z)) + Z\,L'_{\rm rad}] + \tfrac{1}{9}(1-y)(Z^2+Z)\}\ , \qquad (23.21)$$

where $y = k/E$ is the fraction of the electron's energy transfered to the radiated photon. At small y (the "infrared limit") the term on the second line can reach 2.5%. If it is ignored and the first line simplified with the definition of X_0 given in Eq. (23.17), we have

$$\frac{d\sigma}{dk} = \frac{A}{X_0 N_A k}\left(\tfrac{4}{3} - \tfrac{4}{3}y + y^2\right)\ . \qquad (23.22)$$

This cross section (times k) is shown by the top curve in Fig. 23.9(a).

This formula is accurate except in near $y = 1$, where screening may become incomplete, and near $y = 0$, where the infrared divergence is removed by the interference of bremsstrahlung amplitudes from nearby scattering centers (the LPM effect) [37,38] and dielectric supression [39,40]. These and other supression effects in bulk media are discussed in Sec. 23.4.5.

With decreasing energy ($E \lesssim 10$ GeV) the high-y cross section drops and the curves become rounded as $y \to 1$. Curves of this familar

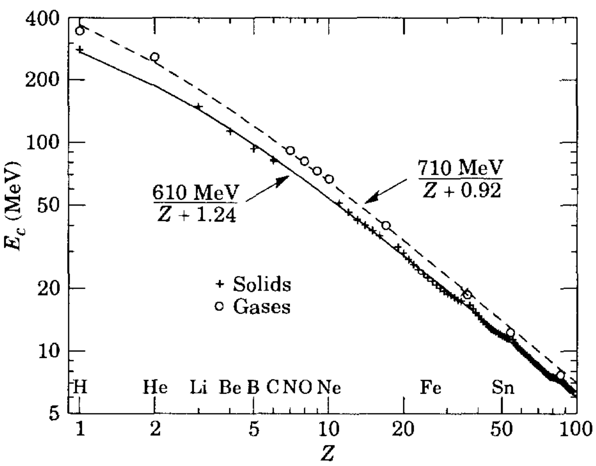

Figure 23.10: Electron critical energy for the chemical elements, using Rossi's definition [4]. The fits shown are for solids and liquids (solid line) and gases (dashed line). The rms deviation is 2.2% for the solids and 4.0% for the gases. (Computed with code supplied by A. Fassó.)

shape can be seen in Rossi [4] (Figs. 2.11.2,3); see also the review by Koch & Motz [41].

Except at these extremes, and still in the complete-screening approximation, the the number of photons with energies between $k_{\rm min}$ and $k_{\rm max}$ emitted by an electron travelling a distance $d \ll X_0$ is

$$N_\gamma = \frac{d}{X_0}\left[\frac{4}{3}\ln\left(\frac{k_{\rm max}}{k_{\rm min}}\right) - \frac{4(k_{\rm max}-k_{\rm min})}{3E} + \frac{(k_{\rm max}-k_{\rm min})^2}{2E^2}\right] . \tag{23.23}$$

23.4.3. ***Critical energy***: An electron loses energy by bremsstrahlung at a rate nearly proportional to its energy, while the ionization loss rate varies only logarithmically with the electron energy. The *critical energy* E_c is sometimes defined as the energy at which the two loss rates are equal [42]. Berger and Seltzer [42] also give the approximation $E_c = (800~{\rm MeV})/(Z + 1.2)$. This formula has been widely quoted, and has been given in previous editions of this *Review* [24]. Among alternate definitions is that of Rossi [4], who defines the critical energy as the energy at which the ionization loss per radiation length is equal to the electron energy. Equivalently, it is the same as the first definition with the approximation $|dE/dx|_{\rm brems} \approx E/X_0$. This form has been found to describe more accurately transverse electromagnetic shower development (see below). These definitions are illustrated in the case of copper in Fig. 23.8.

The accuracy of approximate forms for E_c has been limited by the failure to distinguish between gases and solid or liquids, where there is a substantial difference in ionization at the relevant energy because of the density effect. We distinguish these two cases in Fig. 23.10. Fits were also made with functions of the form $a/(Z + b)^\alpha$, but α was essentially unity. Since E_c also depends on A, I, and other factors, such forms are at best approximate.

23.4.4. ***Energy loss by photons***: Contributions to the photon cross section in a light element (carbon) and a heavy element (lead) are shown in Fig. 23.11. At low energies it is seen that the photoelectric effect dominates, although Compton scattering, Rayleigh scattering, and photonuclear absorption also contribute. The photoelectric cross section is characterized by discontinuities (absorption edges) as thresholds for photoionization of various atomic levels are reached. Photon attenuation lengths for a variety of elements are shown in Fig. 23.12, and data for 30 eV< k <100 GeV for all elements is available from the web pages given in the caption. Here k is the photon energy.

The increasing domination of pair production as the energy increases is shown in Fig. 23.13. Using approximations similar to those used to obtain Eq. (23.22), Tsai's formula for the differential cross section [34] reduces to

$$\frac{d\sigma}{dE} = \frac{A}{X_0 N_A}\left[1 - \tfrac{4}{3}x(1-x)\right] \tag{23.24}$$

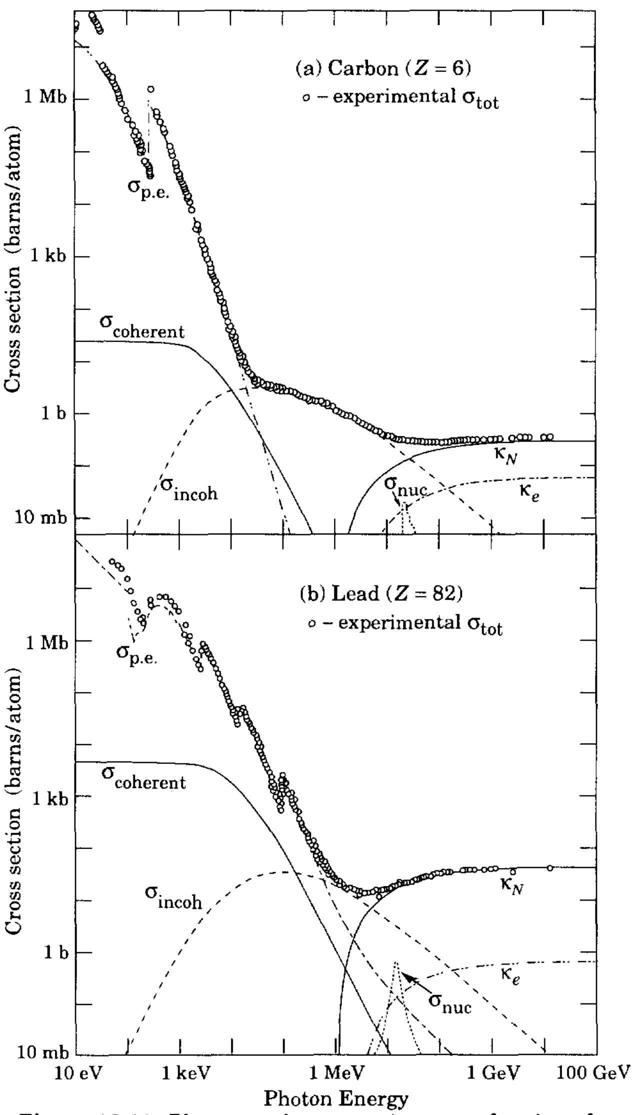

Figure 23.11: Photon total cross sections as a function of energy in carbon and lead, showing the contributions of different processes:

$\sigma_{\rm p.e.}$ = Atomic photoeffect (electron ejection, photon absorption)

$\sigma_{\rm coherent}$ = Coherent scattering (Rayleigh scattering—atom neither ionized nor excited)

$\sigma_{\rm incoherent}$ = Incoherent scattering (Compton scattering off an electron)

κ_n = Pair production, nuclear field

κ_e = Pair production, electron field

$\sigma_{\rm nuc}$ = Photonuclear absorption (nuclear absorption, usually followed by emission of a neutron or other particle)

From Hubbell, Gimm, and Øverbø, J. Phys. Chem. Ref. Data **9**, 1023 (1980). Data for these and other elements, compounds, and mixtures may be obtained from `http://physics.nist.gov/PhysRefData`. The photon total cross section is assumed approximately flat for at least two decades beyond the energy range shown. Figures courtesy J.H. Hubbell (NIST).

in the complete-screening limit valid at high energies. Here $x = E/k$ is the fractional energy transfer to the pair-produced electron (or positron), and k is the incident photon energy. The cross section is very closely related to that for bremsstrahlung, since the Feynman

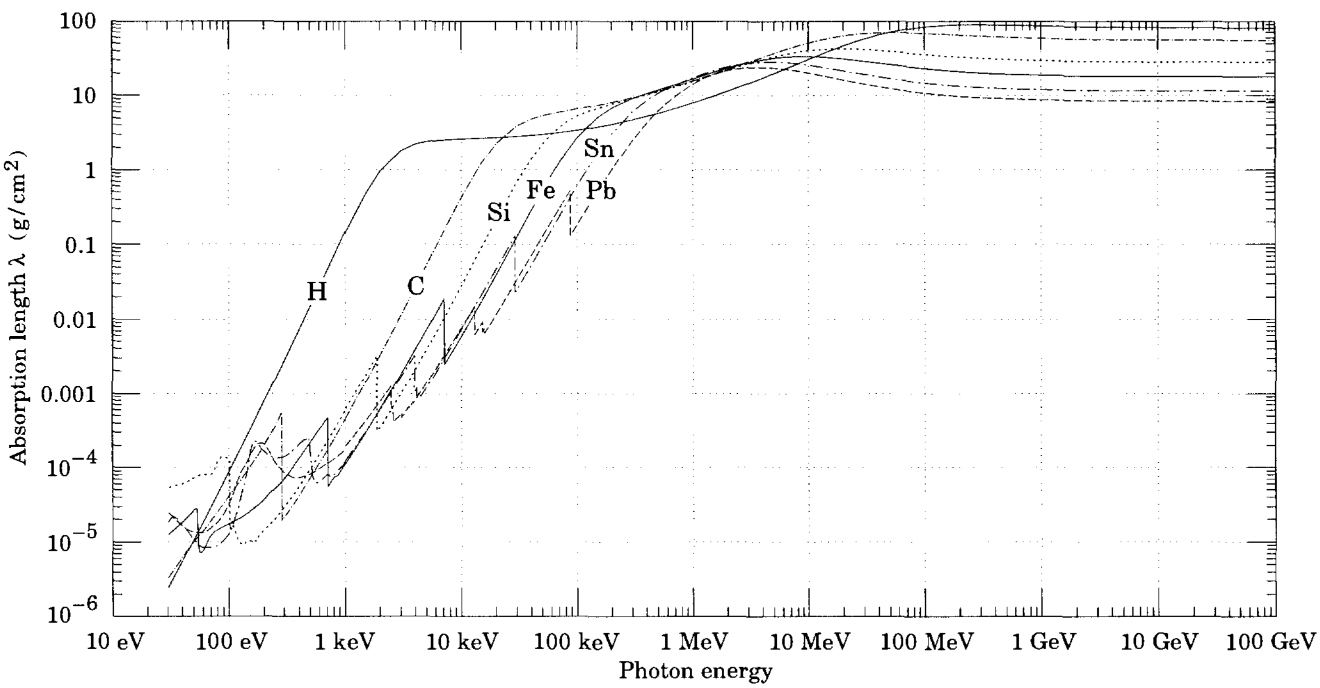

Fig. 23.12: The photon mass attenuation length (or mean free path) $\lambda = 1/(\mu/\rho)$ for various elemental absorbers as a function of photon energy. The mass attenuation coefficient is μ/ρ, where ρ is the density. The intensity I remaining after traversal of thickness t (in mass/unit area) is given by $I = I_0\,\exp(-t/\lambda)$. The accuracy is a few percent. For a chemical compound or mixture, $1/\lambda_{\rm eff} \approx \sum_{\rm elements} w_Z/\lambda_Z$, where w_Z is the proportion by weight of the element with atomic number Z. The processes responsible for attenuation are given in not Fig. 23.7. Since coherent processes are included, not all these processes result in energy deposition. The data for 30 eV $< E <$ 1 keV are obtained from `http://www-cxro.lbl.gov/optical_constants` (courtesy of Eric M. Gullikson, LBNL). The data for 1 keV $< E <$ 100 GeV are from `http://physics.nist.gov/PhysRefData`, through the courtesy of John H. Hubbell (NIST).

diagrams are variants of one another. The cross section is of necessity symmetric between x and $1-x$, as can be seen by the solid curve in Fig. 23.9(b). See the review by Motz, Olsen, & Koch for a more detailed treatment [43].

Eq. (23.24) may be integrated to find the high-energy limit for the total e^+e^- pair-production cross section:

$$\sigma = \tfrac{7}{9}(A/X_0N_A)\ . \tag{23.25}$$

Equation Eq. (23.25) is accurate to within a few percent down to energies as low as 1 GeV, particularly for high-Z materials.

23.4.5. ***Bremsstrahlung and pair production at very high energies***: At ultrahigh energies, Eqns. 23.21–23.25 will fail because of quantum mechanical interference between amplitudes from different scattering centers. Since the longitudinal momentum transfer to a given center is small ($\propto k/E^2$, in the case of bremsstrahlung), the interaction is spread over a comparatively long distance called the formation length ($\propto E^2/k$) via the uncertainty principle. In alternate language, the formation length is the distance over which the highly relatistic electron and the photon "split apart." The interference is usually destructive. Calculations of the "Landau-Pomeranchuk-Migdal" effect may be made semi-classically based on the average multiple scattering, or more rigorously using a quantum transport approach [37,38].

In amorphous media, bremsstrahlung is suppressed if the photon energy is above $k > E^2/E_{LPM}$ [38], where*

$$E_{LPM} = \frac{(m_ec^2)^2\alpha\rho X_0}{4\pi\hbar c} = (7.7\ \text{TeV/cm}) \times \rho X_0\ . \tag{23.26}$$

* This definition differs from that of Ref. 44 by a factor of two. It is also pointed out that E_{LPM} scales as the 4th power of the mass of the incident particle, so that $E_{LPM} = (1.4\times10^{10}\ \text{TeV/cm})\times\rho X_0$ for a muon.

Since physical distances are involved, ρX_0, in cm, appears. The energy-weighted bremsstrahlung spectrum for lead, $k\,d\sigma_{LPM}/dk$, is shown in Fig. 23.9(a). With appropriate scaling by ρX_0, other materials behave similarly.

For photons, pair production is reduced for $E(k-E) > k\,E_{LPM}$. The pair-production cross sections for different photon energies are shown in Fig. 23.9(b).

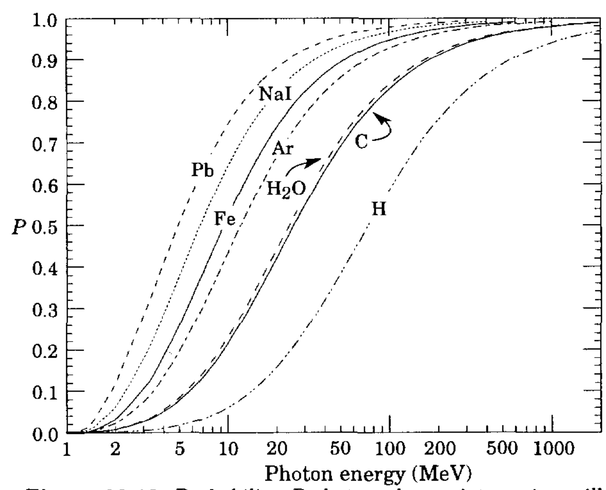

Figure 23.13: Probability P that a photon interaction will result in conversion to an e^+e^- pair. Except for a few-percent contribution from photonuclear absorption around 10 or 20 MeV, essentially all other interactions in this energy range result in Compton scattering off an atomic electron. For a photon attenuation length λ (Fig. 23.12), the probability that a given photon will produce an electron pair (without first Compton scattering) in thickness t of absorber is $P[1-\exp(-t/\lambda)]$.

If $k \ll E$, several additional mechanisms can also produce suppression. When the formation length is long, even weak factors can perturb the interaction. For example, the emitted photon can coherently forward scatter off of the electrons in the media. Because of this, for $k < \omega_p E/m_e \sim 10^{-4}$, bremsstrahlung is suppressed by a factor $(km_e/\omega_p E)^2$ [40]. Magnetic fields can also suppress bremsstrahlung.

In crystalline media, the situation is more complicated, with coherent enhancement or suppression possible. The cross section depends on the electron and photon energies and the angles between the particle direction and the crystalline axes [38].

23.5. Electromagnetic cascades

When a high-energy electron or photon is incident on a thick absorber, it initiates an electromagnetic cascade as pair production and bremsstrahlung generate more electrons and photons with lower energy. The longitudinal development is governed by the high-energy part of the cascade, and therefore scales as the radiation length in the material. Electron energies eventually fall below the critical energy, and then dissipate their energy by ionization and excitation rather than by the generation of more shower particles. In describing shower behavior, it is therefore convenient to introduce the scale variables

$$t = x/X_0 \qquad y = E/E_c\ , \tag{23.27}$$

so that distance is measured in units of radiation length and energy in units of critical energy.

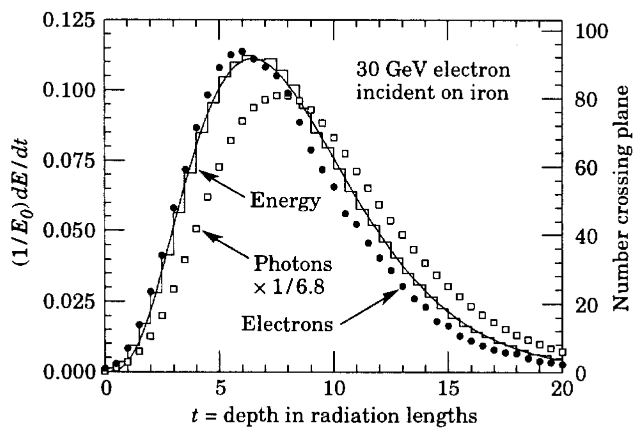

Figure 23.14: An EGS4 simulation of a 30 GeV electron-induced cascade in iron. The histogram shows fractional energy deposition per radiation length, and the curve is a gamma-function fit to the distribution. Circles indicate the number of electrons with total energy greater than 1.5 MeV crossing planes at $X_0/2$ intervals (scale on right) and the squares the number of photons with $E \geq 1.5$ MeV crossing the planes (scaled down to have same area as the electron distribution).

Longitudinal profiles for an EGS4 [23] simulation of a 30 GeV electron-induced cascade in iron are shown in Fig. 23.14. The number of particles crossing a plane (very close to Rossi's Π function [4]) is sensitive to the cutoff energy, here chosen as a total energy of 1.5 MeV for both electrons and photons. The electron number falls off more quickly than energy deposition. This is because, with increasing depth, a larger fraction of the cascade energy is carried by photons. Exactly what a calorimeter measures depends on the device, but it is not likely to be exactly any of the profiles shown. In gas counters it may be very close to the electron number, but in glass Čerenkov detectors and other devices with "thick" sensitive regions it is closer to the energy deposition (total track length). In such detectors the signal is proportional to the "detectable" track length T_d, which is in general less than the total track length T. Practical devices are sensitive to electrons with energy above some detection threshold E_d, and $T_d = T\,F(E_d/E_c)$. An analytic form for $F(E_d/E_c)$ obtained by Rossi [4] is given by Fabjan [45]; see also Amaldi [46].

The mean longitudinal profile of the energy deposition in an electromagnetic cascade is reasonably well described by a gamma distribution [47]:

$$\frac{dE}{dt} = E_0\, b\, \frac{(bt)^{a-1} e^{-bt}}{\Gamma(a)} \tag{23.28}$$

The maximum $t_{\max}$ occurs at $(a-1)/b$. We have made fits to shower profiles in elements ranging from carbon to uranium, at energies from 1 GeV to 100 GeV. The energy deposition profiles are well described by Eq. (23.28) with

$$t_{\max} = (a-1)/b = 1.0 \times (\ln y + C_j)\ , \qquad j = e, \gamma\ , \tag{23.29}$$

where $C_e = -0.5$ for electron-induced cascades and $C_\gamma = +0.5$ for photon-induced cascades. To use Eq. (23.28), one finds $(a-1)/b$ from Eq. (23.29) and Eq. (23.27), then finds a either by assuming $b \approx 0.5$ or by finding a more accurate value from Fig. 23.15. The results are very similar for the electron number profiles, but there is some dependence on the atomic number of the medium. A similar form for the electron number maximum was obtained by Rossi in the context of his "Approximation B," [4] (see Fabjan's review in Ref. 45), but with $C_e = -1.0$ and $C_\gamma = -0.5$; we regard this as superseded by the EGS4 result.

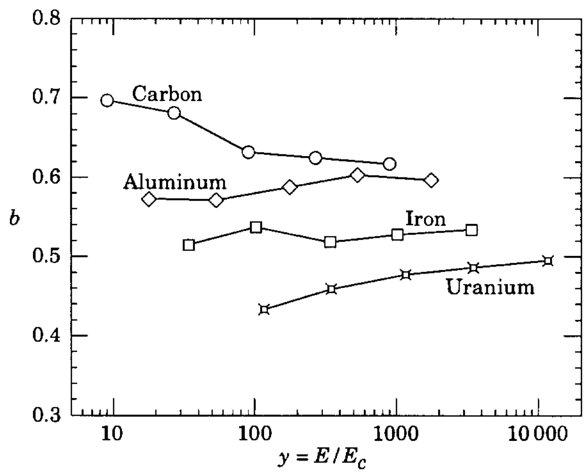

Figure 23.15: Fitted values of the scale factor b for energy deposition profiles obtained with EGS4 for a variety of elements for incident electrons with $1 \leq E_0 \leq 100$ GeV. Values obtained for incident photons are essentially the same.

The "shower length" $X_s = X_0/b$ is less conveniently parameterized, since b depends upon both Z and incident energy, as shown in Fig. 23.15. As a corollary of this Z dependence, the number of electrons crossing a plane near shower maximum is underestimated using Rossi's approximation for carbon and seriously overestimated for uranium. Essentially the same b values are obtained for incident electrons and photons. For many purposes it is sufficient to take $b \approx 0.5$.

The gamma distribution is very flat near the origin, while the EGS4 cascade (or a real cascade) increases more rapidly. As a result Eq. (23.28) fails badly for about the first two radiation lengths; it was necessary to exclude this region in making fits.

Because fluctuations are important, Eq. (23.28) should be used only in applications where average behavior is adequate. Grindhammer *et al.* have developed fast simulation algorithms in which the variance and correlation of a and b are obtained by fitting Eq. (23.28) to individually simulated cascades, then generating profiles for cascades using a and b chosen from the correlated distributions [48].

The transverse development of electromagnetic showers in different materials scales fairly accurately with the *Molière radius* R_M, given by [49,50]

$$R_M = X_0\, E_s/E_c\ , \tag{23.30}$$

where $E_s \approx 21$ MeV (see Table 23.1), and the Rossi definition of E_c is used.

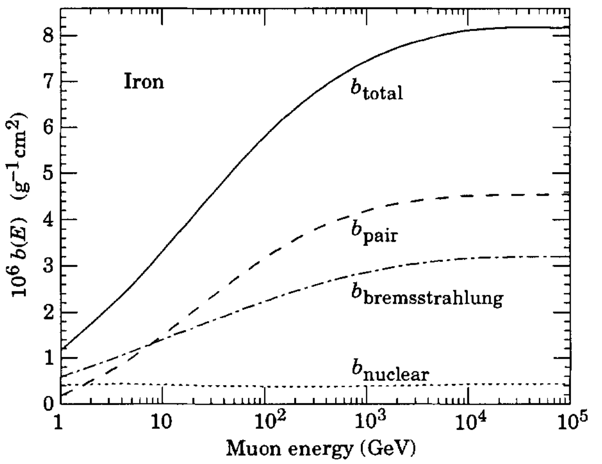

Figure 23.16: Contributions to the fractional energy loss by muons in iron due to e^+e^- pair production, bremsstrahlung, and photonuclear interactions, as obtained from Lohmann *et al.* [61].

In a material containing a weight fraction w_j of the element with critical energy E_{cj} and radiation length X_j, the Molière radius is given by

$$\frac{1}{R_M} = \frac{1}{E_s} \sum \frac{w_j\, E_{cj}}{X_j} \, . \tag{23.31}$$

Measurements of the lateral distribution in electromagnetic cascades are shown in Refs. 49 and 50. On the average, only 10% of the energy lies outside the cylinder with radius R_M. About 99% is contained inside of $3.5 R_M$, but at this radius and beyond composition effects become important and the scaling with R_M fails. The distributions are characterized by a narrow core, and broaden as the shower develops. They are often represented as the sum of two Gaussians, and Grindhammer [48] describes them with the function

$$f(r) = \frac{2r\,R^2}{(r^2+R^2)^2} \, , \tag{23.32}$$

where R is a phenomenological function of x/X_0 and $\ln E$.

At high enough energies, the LPM effect (Sec. 23.4.5) reduces the cross sections for bremsstrahlung and pair production, and hence can cause significant enlongation of electromagnetic cascades [38].

23.6. Muon energy loss at high energy

At sufficiently high energies, radiative processes become more important than ionization for all charged particles. For muons and pions in materials such as iron, this "critical energy" occurs at several hundred GeV. Radiative effects dominate the energy loss of energetic muons found in cosmic rays or produced at the newest accelerators. These processes are characterized by small cross sections, hard spectra, large energy fluctuations, and the associated generation of electromagnetic and (in the case of photonuclear interactions) hadronic showers [51–59]. As a consequence, at these energies the treatment of energy loss as a uniform and continuous process is for many purposes inadequate.

It is convenient to write the average rate of muon energy loss as [60]

$$-dE/dx = a(E) + b(E)\,E \, . \tag{23.33}$$

Here $a(E)$ is the ionization energy loss given by Eq. (23.1), and $b(E)$ is the sum of e^+e^- pair production, bremsstrahlung, and photonuclear contributions. To the approximation that these slowly-varying functions are constant, the mean range x_0 of a muon with initial energy E_0 is given by

$$x_0 \approx (1/b)\ln(1 + E_0/E_{\mu c}) \, , \tag{23.34}$$

where $E_{\mu c} = a/b$. Figure 23.16 shows contributions to $b(E)$ for iron. Since $a(E) \approx 0.002$ GeV g^{-1} cm^2, $b(E)E$ dominates the energy loss above several hundred GeV, where $b(E)$ is nearly constant. The rate of energy loss for muons in hydrogen, uranium, and iron is shown in Fig. 23.17 [61].

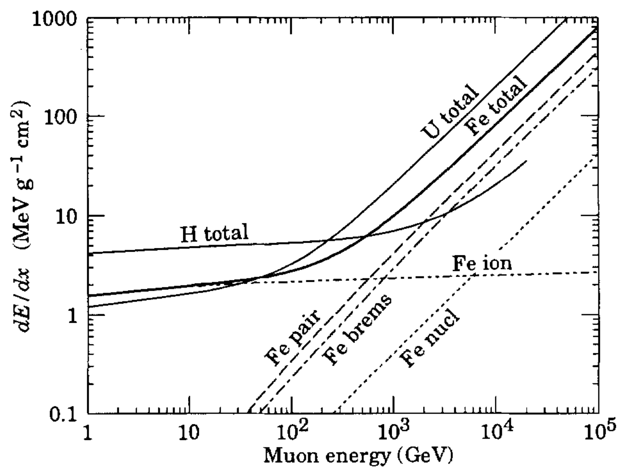

Figure 23.17: The average energy loss of a muon in hydrogen, iron, and uranium as a function of muon energy. Contributions to dE/dx in iron from ionization and the processes shown in Fig. 23.16 are also shown.

The "muon critical energy" $E_{\mu c}$ can be defined more exactly as the energy at which radiative and ionization losses are equal, and can be found by solving $E_{\mu c} = a(E_{\mu c})/b(E_{\mu c})$. This definition corresponds to the solid-line intersection in Fig. 23.8, and is different from the Rossi definition we used for electrons. It serves the same function: below $E_{\mu c}$ ionization losses dominate, and above $E_{\mu c}$ dominate. The dependence of $E_{\mu c}$ on atomic number Z is shown in Fig. 23.18.

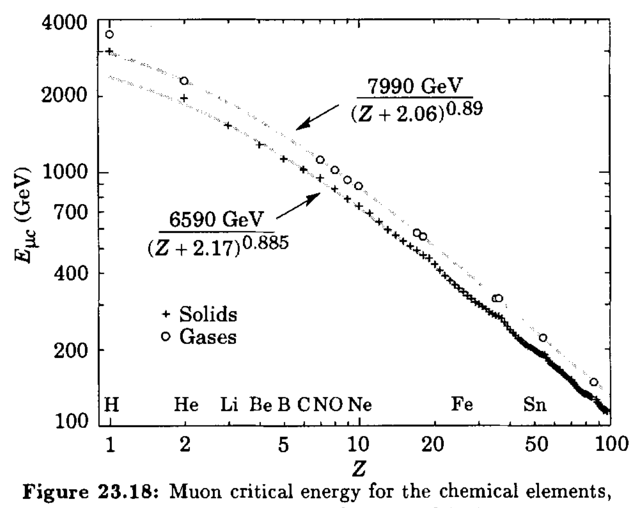

Figure 23.18: Muon critical energy for the chemical elements, defined as the energy at which radiative and ionization energy loss rates are equal. The equality comes at a higher energy for gases than for solids or liquids with the same atomic number because of a smaller density effect reduction of the ionization losses. The fits shown in the figure exclude hydrogen. Alkali metals fall 3–4% above the fitted function, while most other solids are within 2% of the function. Among the gases the worst fit is for neon (1.4% high). (Courtesy of N.V. Mokhov and S.I. Striganov.)

The radiative cross sections are expressed as functions of the fractional energy loss ν. The bremsstrahlung cross section goes roughly as $1/\nu$ over most of the range, while for the pair production case the distribution goes as ν^{-3} to ν^{-2} (see Ref. 62). "Hard" losses are therefore more probable in bremsstrahlung, and in fact energy losses due to pair production may very nearly be treated as continuous. The calculated momentum distribution of an incident 1 TeV/c muon beam after it crosses 3 m of iron is shown in Fig. 23.19. The most probable loss is 9 GeV, or 3.8 MeV g^{-1}cm^2. The full width at half maximum is 7 GeV/c, or 0.7%. The radiative tail is almost entirely due to bremsstrahlung; this includes most of the 10% that lost more than 2.8% of their energy. Most of the 3.3% that lost more than 10% of their incident energy experienced photonuclear interactions, which are concentrated in rare, relatively hard collisions. The latter can exceed nominal detector resolution [63], necessitating the reconstruction of lost energy. Electromagnetic and hadronic cascades in detector materials can obscure muon tracks in detector planes and reduce tracking efficiency [64].

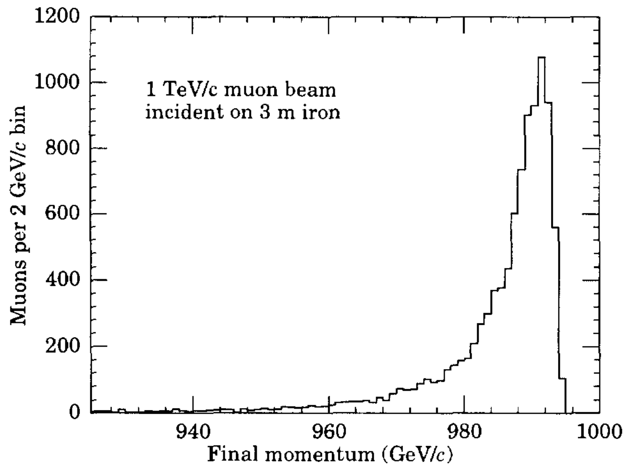

Figure 23.19: The momentum distribution of 1 TeV/c muons after traversing 3 m of iron, as obtained with Van Ginniken's TRAMU muon transport code [62].

23.7. Čerenkov and transition radiation [10,65,66]

A charged particle radiates if its velocity is greater than the local phase velocity of light (Čerenkov radiation) or if it crosses suddenly from one medium to another with different optical properties (transition radiation). Neither process is important for energy loss, but both are used in high-energy physics detectors.

Čerenkov Radiation. The half-angle θ_c of the Čerenkov cone for a particle with velocity βc in a medium with index of refraction n is

$$\begin{aligned}\theta_c &= \arccos(1/n\beta)\\ &\approx \sqrt{2(1-1/n\beta)} \quad \text{for small } \theta_c, \textit{e.g.} \text{ in gases.}\end{aligned} \tag{23.35}$$

The threshold velocity β_t is $1/n$, and $\gamma_t = 1/(1-\beta_t^2)^{1/2}$. Therefore, $\beta_t\gamma_t = 1/(2\delta+\delta^2)^{1/2}$, where $\delta = n-1$. Values of δ for various commonly used gases are given as a function of pressure and wavelength in Ref. 67. For values at atmospheric pressure, see Table 6.1. Data for other commonly used materials are given in Ref. 68.

The number of photons produced per unit path length of a particle with charge ze and per unit energy interval of the photons is

$$\begin{aligned}\frac{d^2N}{dEdx} &= \frac{\alpha z^2}{\hbar c}\sin^2\theta_c = \frac{\alpha^2 z^2}{r_e m_e c^2}\left(1-\frac{1}{\beta^2 n^2(E)}\right)\\ &\approx 370\sin^2\theta_c(E)\ \mathrm{eV^{-1}cm^{-1}} \qquad (z=1)\ ,\end{aligned} \tag{23.36}$$

or, equivalently,

$$\frac{d^2N}{dxd\lambda} = \frac{2\pi\alpha z^2}{\lambda^2}\left(1-\frac{1}{\beta^2 n^2(\lambda)}\right) . \tag{23.37}$$

The index of refraction is a function of photon energy E, as is the sensitivity of the transducer used to detect the light. For practical use, Eq. (23.36) must be multiplied by the the transducer response function and integrated over the region for which $\beta\, n(E) > 1$. Further details are given in the discussion of Čerenkov detectors in the Detectors section (Sec. 24 of this *Review*).

Transition radiation. The energy radiated when a particle with charge ze crosses the boundary between vacuum and a medium with plasma frequency ω_p is

$$I = \alpha z^2\gamma\hbar\omega_p/3\ , \tag{23.38}$$

where

$$\begin{aligned}\hbar\omega_p &= \sqrt{4\pi N_e r_e^3}\ m_e c^2/\alpha\\ &= \sqrt{4\pi N_e a_\infty^3}\ 2\times 13.6\ \mathrm{eV}\ .\end{aligned} \tag{23.39}$$

Here N_e is the electron density in the medium, r_e is the classical electron radius, and a_∞ is the Bohr radius. For styrene and similar materials, $\sqrt{4\pi N_e a_\infty^3} \approx 0.8$, so that $\hbar\omega_p \approx 20$ eV. The typical emission angle is $1/\gamma$.

The radiation spectrum is logarithmically divergent at low energies and decreases rapidly for $\hbar\omega/\gamma\hbar\omega_p > 1$. About half the energy is emitted in the range $0.1 \le \hbar\omega/\gamma\hbar\omega_p \le 1$. For a particle with $\gamma = 10^3$, the radiated photons are in the soft x-ray range 2 to 20 keV. The γ dependence of the emitted energy thus comes from the hardening of the spectrum rather than from an increased quantum yield. For a typical radiated photon energy of $\gamma\hbar\omega_p/4$, the quantum yield is

$$\begin{aligned}N_\gamma &\approx \frac{1}{2}\,\frac{\alpha z^2\gamma\hbar\omega_p}{3}\Big/\frac{\gamma\hbar\omega_p}{4}\\ &\approx \tfrac{2}{3}\alpha z^2 \approx 0.5\%\times z^2\ .\end{aligned} \tag{23.40}$$

More precisely, the number of photons with energy $\hbar\omega > \hbar\omega_0$ is given by [10]

$$N_\gamma(\hbar\omega > \hbar\omega_0) = \frac{\alpha z^2}{\pi}\left[\left(\ln\frac{\gamma\hbar\omega_p}{\hbar\omega_0}-1\right)^2+\frac{\pi^2}{12}\right]\ , \tag{23.41}$$

within corrections of order $(\hbar\omega_0/\gamma\hbar\omega_p)^2$. The number of photons above a fixed energy $\hbar\omega_0 \ll \gamma\hbar\omega_p$ thus grows as $(\ln\gamma)^2$, but the number above a fixed fraction of $\gamma\hbar\omega_p$ (as in the example above) is constant. For example, for $\hbar\omega > \gamma\hbar\omega_p/10$, $N_\gamma = 2.519\,\alpha z^2/\pi = 0.59\%\times z^2$.

The yield can be increased by using a stack of plastic foils with gaps between. However, interference can be important, and the soft x rays are readily absorbed in the foils. The first problem can be overcome by choosing thicknesses and spacings large compared to the "formation length" $D = \gamma c/\omega_p$, which in practical situations is tens of μm. Other practical problems are discussed in Sec. 24.

24. PARTICLE DETECTORS

Revised 1999 (see the various sections for authors).

In this section we give various parameters for common detector components. The quoted numbers are usually based on typical devices, and should be regarded only as rough approximations for new designs. A more detailed discussion of detectors can be found in Ref. 1. In Table 24.1 are given typical spatial and temporal resolutions of common detectors.

Table 24.1: Typical detector characteristics.

Detector Type	Accuracy (rms)	Resolution Time	Dead Time
Bubble chamber	10 to 150 μm	1 ms	50 ms[a]
Streamer chamber	300 μm	2 μs	100 ms
Proportional chamber	$\geq$ 300 μm[b,c]	50 ns	200 ns
Drift chamber	50 to 300 μm	2 ns[d]	100 ns
Scintillator	—	150 ps	10 ns
Emulsion	1 μm	—	—
Silicon strip	pitch[e] / 3 to 7	f	f
Silicon pixel	2 μm[g]	f	f

[a] Multiple pulsing time.

[b] 300 μm is for 1 mm pitch.

[c] Delay line cathode readout can give $\pm$150 μm parallel to anode wire.

[d] For two chambers.

[e] The highest resolution ("7") is obtained for small-pitch detectors ($\lesssim$25 μm) with pulse-height-weighted center finding.

[f] Limited at present by properties of the readout electronics. (Time resolution of $\leq$ 25 ns is planned for the ATLAS SCT.)

[g] Analog readout of 34 μm pitch, monolithic pixel detectors.

24.1. Organic scintillators

Written October 1995 by K.F. Johnson (FSU).

Organic scintillators are broadly classed into three types, crystalline, liquid, and plastic, all of which utilize the ionization produced by charged particles (see the section on "Passage of particles through matter" (Sec. 23.2) of this *Review*) to generate optical photons, usually in the blue to green wavelength regions [2]. Plastic scintillators are by far the most widely used and we address them primarily; however, most of the discussion will also have validity for liquid scintillators with obvious caveats. Crystal organic scintillators are practically unused in high-energy physics.

Densities range from 1.03 to 1.20 g cm^{-3}. Typical photon yields are about 1 photon per 100 eV of energy deposit [3]. A one-cm-thick scintillator traversed by a minimum-ionizing particle will therefore yield $\approx 2 \times 10^4$ photons. The resulting photoelectron signal will depend on the collection and transport efficiency of the optical package and the quantum efficiency of the photodetector.

Plastic scintillators do not respond linearly to the ionization density. Very dense ionization columns emit less light than expected on the basis of dE/dx for minimum-ionizing particles. A widely used semi-empirical model by Birks' posits that recombination and quenching effects between the excited molecules reduce the light yield [4]. These effects are more pronounced the greater the density of the excited molecules. Birks' formula is

$$\frac{d\mathscr{L}}{dx} = \mathscr{L}_0 \frac{dE/dx}{1 + k_B\, dE/dx}\,, \tag{24.1}$$

where $\mathscr{L}$ is the luminescence, $\mathscr{L}_0$ is the luminescence at low specific ionization density, and k_B is Birks' constant, which must be determined for each scintillator by measurement.

Decay times are in the ns range; rise times are much faster. The combination of high light yield and fast response time allows the possibility of sub-ns timing resolution [5]. The fraction of light emitted during the decay "tail" can depend on the exciting particle. This allows pulse shape discrimination as a technique to carry out particle identification. Because of the hydrogen content (carbon to hydrogen ratio $\approx$ 1) plastic scintillator is sensitive to proton recoils from neutrons. Ease of fabrication into desired shapes and low cost has made plastic scintillators a common detector component. Recently, plastic scintillators in the form of scintillating fibers have found widespread use in tracking and calorimetry [6].

24.1.1. *Scintillation mechanism* :

Scintillation: A charged particle traversing matter leaves behind it a wake of excited molecules. Certain types of molecules, however, will release a small fraction ($\approx$ 3%) of this energy as optical photons. This process, scintillation, is especially marked in those organic substances which contain aromatic rings, such as polystyrene, polyvinyltoluene, and napthalene. Liquids which scintillate include toluene and xylene.

Fluorescence: In fluorescence, the initial excitation takes place via the absorption of a photon, and de-excitation by emission of a longer wavelength photon. Fluors are used as "waveshifters" to shift scintillation light to a more convenient wavelength. Occurring in complex molecules, the absorption and emission are spread out over a wide band of photon energies, and have some overlap, that is, there is some fraction of the emitted light which can be re-absorbed [7]. This "self-absorption" is undesirable for detector applications because it causes a shortened attenuation length. The wavelength difference between the major absorption and emission peaks is called the Stokes' shift. It is usually the case that the greater the Stokes' shift, the smaller the self absorption—thus, a large Stokes' shift is a desirable property for a fluor.

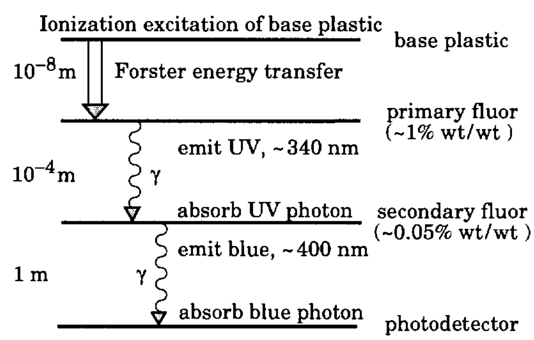

Figure 24.1: Cartoon of scintillation "ladder" depicting the operating mechanism of plastic scintillator. Approximate fluor concentrations and energy transfer distances for the separate sub-processes are shown.

Scintillators: The plastic scintillators used in high-energy physics are binary or ternary solutions of selected fluors in a plastic base containing aromatic rings. (See the appendix in Ref. 8 for a comprehensive list of plastic scintillator components.) Virtually all plastic scintillators contain as a base either polyvinyltoluene, polystyrene, or acrylic, whereby polyvinyltoluene-based scintillator can be up to 50% brighter than the others. Acrylic is non-aromatic and has therefore a very low scintillation efficiency. It becomes an acceptable scintillator when napthalene, a highly aromatic compound, is dissolved into the acrylic at 5% to 20% weight fraction. Thus, in "acrylic" scintillator the active component is napthalene. The fluors must satisfy additional conditions besides being fluorescent. They must be sufficiently stable, soluble, chemically inert, fast, radiation tolerant, and efficient.

The plastic base is the ionization-sensitive (*i.e.*, the scintillator) portion of the plastic scintillator (see Fig. 24.1). In the absence of fluors the base would emit UV photons with short attenuation length (several mm). Longer attenuation lengths are obtained by dissolving a "primary" fluor in high concentration (1% by weight) into the

25. RADIOACTIVITY AND RADIATION PROTECTION

Revised March 1998 by R.J. Donahue (LBNL) and A. Fassò (SLAC).

25.1. Definitions

The International Commission on Radiation Units and Measurements (ICRU) recommends the use of SI units. Therefore we list SI units first, followed by cgs (or other common) units in parentheses, where they differ.

- **Unit of activity** = becquerel (curie):

  1 Bq = 1 disintegration s^{-1} [= $1/(3.7 \times 10^{10})$ Ci]

- **Unit of absorbed dose** = gray (rad):

  1 Gy = 1 joule kg^{-1} (= 10^4 erg g^{-1} = 100 rad)

  = 6.24×10^{12} MeV kg^{-1} deposited energy

- **Unit of exposure**, the quantity of x- or γ- radiation at a point in space integrated over time, in terms of charge of either sign produced by showering electrons in a small volume of air about the point:

  = 1 coul kg^{-1} of air (roentgen; 1 $R = 2.58 \times 10^{-4}$ coul kg^{-1})

  = 1 esu cm^{-3}(= 87.8 erg released energy per g of air)

Implicit in the definition is the assumption that the small test volume is embedded in a sufficiently large uniformly irradiated volume that the number of secondary electrons entering the volume equals the number leaving. This unit is somewhat historical, but appears on many measuring instruments.

- **Unit of equivalent dose** (for biological damage) = sievert [= 100 rem (roentgen equivalent for man)]: Equivalent dose in Sv = absorbed dose in grays × w_R, where w_R (radiation weighting factor, formerly the quality factor Q) expresses long-term risk (primarily cancer and leukemia) from low-level chronic exposure. It depends upon the type of radiation and other factors, as follows [2]:

Table 25.1: Radiation weighting factors.

Radiation	w_R
X- and γ-rays, all energies	1
Electrons and muons, all energies	1
Neutrons < 10 keV	5
10–100 keV	10
> 100 keV to 2 MeV	20
2–20 MeV	10
> 20 MeV	5
Protons (other than recoils) > 2 MeV	5
Alphas, fission fragments, & heavy nuclei	20

25.2. Radiation levels [3]

- **Natural annual background**, all sources: Most world areas, whole-body equivalent dose rate ≈ (0.4–4) mSv (40–400 millirems). Can range up to 50 mSv (5 rems) in certain areas. U.S. average ≈ 3.6 mSv, including ≈ 2 mSv (≈ 200 mrem) from inhaled natural radioactivity, mostly radon and radon daughters (0.1–0.2 mSv in open areas. Average is for a typical house and varies by more than an order of magnitude. It can be more than two orders of magnitude higher in poorly ventilated mines).
- **Cosmic ray background** in counters (Earth's surface): ~ 1 min^{-1} cm^{-2} sr^{-1}. For more accurate estimates and details, see the Cosmic Rays section (Sec. 20 of this *Review*).
- **Fluxes** (per cm^2) to deposit one Gy, assuming uniform irradiation:

  ≈ (**charged particles**) $6.24 \times 10^9/(dE/dx)$, where dE/dx (MeV g^{-1} cm^2), the energy loss per unit length, may be obtained from the Mean Range and Energy Loss figures.

  ≈ 3.5×10^9 cm^{-2} minimum-ionizing singly-charged particles in carbon.

  ≈ (**photons**) $6.24 \times 10^9/[Ef/\lambda]$, for photons of energy E (MeV), attenuation length λ (g cm^{-2}) (see Photon Attenuation Length figure), and fraction $f \lesssim 1$ expressing the fraction of the photon's energy deposited in a small volume of thickness $\ll \lambda$ but large enough to contain the secondary electrons.

  ≈ 2×10^{11} photons cm^{-2} for 1 MeV photons on carbon ($f \approx 1/2$).

  (Quoted fluxes are good to about a factor of 2 for all materials.)

- **Recommended limits to exposure of radiation workers (whole-body dose):***

  CERN: 15 mSv yr^{-1}

  U.K.: 15 mSv yr^{-1}

  U.S.: 50 mSv yr^{-1} (5 rem yr^{-1})†

- **Lethal dose**: Whole-body dose from penetrating ionizing radiation resulting in 50% mortality in 30 days (assuming no medical treatment) 2.5–3.0 Gy (250–300 rads), as measured internally on body longitudinal center line. Surface dose varies due to variable body attenuation and may be a strong function of energy.

25.3. Prompt neutrons at accelerators

25.3.1. ***Electron beams***: At electron accelerators neutrons are generated via photonuclear reactions from bremsstrahlung photons. Neutron yields from semi-infinite targets per unit electron beam power are plotted in Fig. 25.1 as a function of electron beam energy [4]. In the photon energy range 10–30 MeV neutron production results from the giant photonuclear resonance mechanism. Neutrons are produced roughly isotropically (within a factor of 2) and with a Maxwellian energy distribution described as:

$$\frac{dN}{dE_n} = \frac{E_n}{T^2} e^{-E_n/T} , \tag{25.1}$$

where T is the nuclear temperature characteristic of the target nucleus, generally in the range of T = 0.5–1.0 MeV. For higher energy photons the quasi-deuteron and photopion production mechanisms become important.

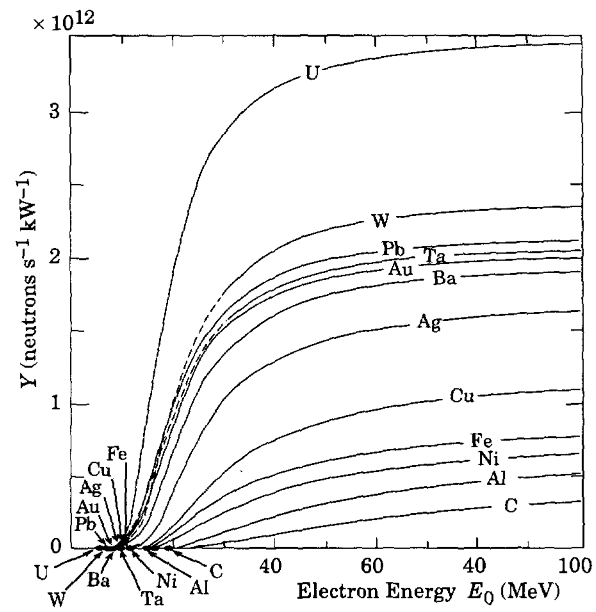

Figure 25.1: Neutron yields from semi-infinite targets, per kW of electron beam power, as a function of electron beam energy, disregarding target self-shielding.

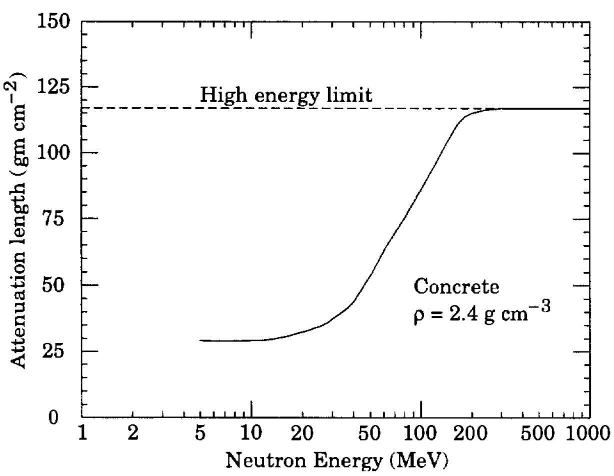

Figure 25.3: The variation of the attenuation length for monoenergetic neutrons in concrete as a function of neutron energy [5].

25.3.2. ***Proton beams***: At proton accelerators neutron yields emitted per incident proton by different target materials are roughly independent [5] of proton energy between 20 MeV and 1 GeV and are given by the ratio C:Al:Cu-Fe:Sn:Ta-Pb = 0.3 : 0.6 : 1.0 : 1.5 : 1.7. Above 1 GeV neutron yield [6] is proportional to E^m, where $0.80 \leq m \leq 0.85$.

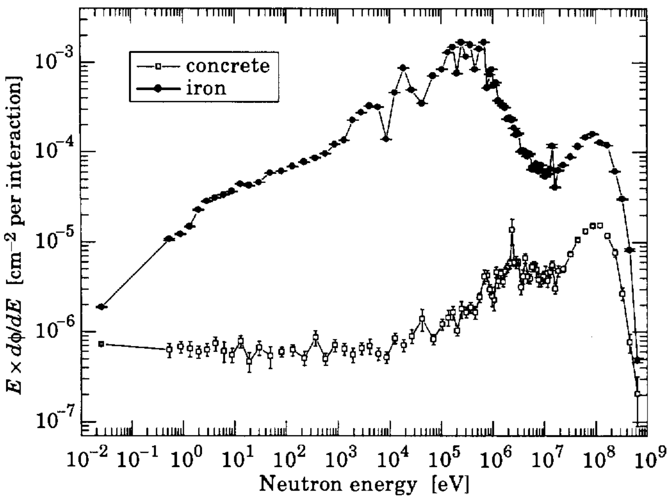

Figure 25.2: Calculated neutron spectrum from 205 GeV/c hadrons (2/3 protons and 1/3 π^+) on a thick copper target. Spectra are evaluated at 90° to beam and through 80 cm of normal density concrete or 40 cm of iron.

A typical neutron spectrum [7] outside a proton accelerator concrete shield is shown in Fig. 25.2. The shape of these spectra are generally characterized as having a thermal-energy peak which is very dependent on geometry and the presence of hydrogenic material, a low-energy evaporation peak around 2 MeV, and a high-energy spallation shoulder.

Letaw's [8] formula for the energy dependence of the inelastic proton cross-section (asymptotic values given in Table 6.1) for $E < 2$ GeV is:

$$\sigma(E) = \sigma_{\text{asympt}} \left[1 - 0.62 e^{-E/200} \sin(10.9 E^{-0.28})\right] , \qquad (25.2)$$

and for $E > 2$ GeV:

$$\sigma_{\text{asympt}} = 45 A^{0.7} \left[1 + 0.016 \sin(5.3 - 2.63 \ln A)\right] , \qquad (25.3)$$

where σ is in mb, E is the proton energy in MeV and A is the mass number.

The neutron-attenuation length, λ, is shown in Fig. 25.3 for monoenergetic broad-beam conditions. These values give a satisfactory representation at depths greater than 1 m in concrete.

25.4. Dose conversion factors

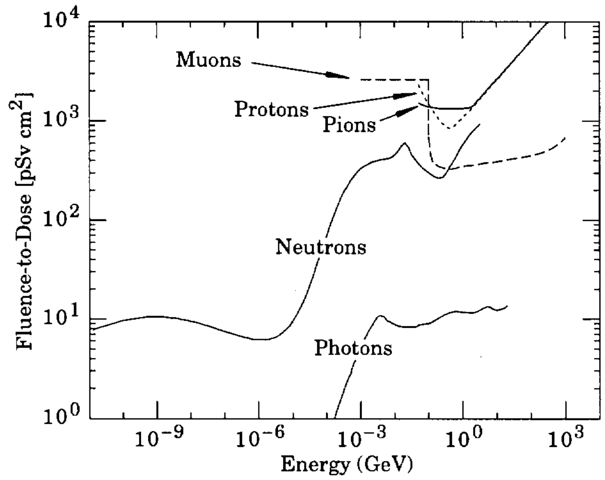

Figure 25.4: Fluence to dose equivalent conversion factors for various particles.

Fluence to dose equivalent factors are given in Fig. 25.4 for photons [9], neutrons [10], muons [11], protons and pions [12]. These factors can be used for converting particle fluence to dose for personnel protection purposes.

25.5. Accelerator-induced activity

The dose rate at 1 m due to spallation-induced activity by high energy hadrons in a 1 g medium atomic weight target can be estimated [13] from the following expression:

$$D = D_0 \ \Phi \ \ln[(T + t)/t] , \qquad (25.4)$$

where T is the irradiation time, t is the decay time since irradiation, Φ is the flux of irradiating hadrons (hadrons cm^{-2} s^{-1}) and D_0 has a value of 5.2×10^{-17} [(Sv hr^{-1})/(hadron cm^{-2} s^{-1})]. This relation is essentially independent of hadron energy above 200 MeV.

Dose due to accelerator-produced induced activity can also be estimated with the use of "ω factors" [5]. These factors give the dose rate per unit star density (inelastic reaction for $E > 50$ MeV) after a 30-day irradiation and 1-day decay. The ω factor for steel or iron is $\simeq 3 \times 10^{-12}$ (Sv cm^3/star). This does not include possible contributions from thermal-neutron activation. Induced activity in concrete can vary widely depending on concrete composition, particularly with the concentration of trace quantities such as sodium. Additional information can be found in Barbier [14].

25.6. Photon sources

The dose rate from a gamma point source of C Curies emitting one photon of energy $0.07 < E < 4$ MeV per disintegration at a distance of 30 cm is 6CE (rem/hr), or 60CE (mSv/hr), ±20%.

The dose rate from a semi-infinite uniform photon source of specific activity C (μCi/g) and gamma energy E (MeV) is $1.07CE$ (rem/hr), or $10.7CE$ (mSv/hr).

25.7. Radiation levels in detectors at hadron colliders

An SSC Central Design Group task force studied the radiation levels to be expected in SSC detectors [15]. The study focused on scaling with energy, distance, and angle. As such, it is applicable to future detectors such as those at the LHC. Although superior detector-specific calculations have since been made, the scaling is in most cases not evident, and so the SSC results have some relevance. The SSC/CDG model assumed

- The machine luminosity at $\sqrt{s} = 40$ TeV is $\mathscr{L} = 10^{33}$ cm^{-2}s^{-1}, and the pp inelastic cross section is $\sigma_{\rm inel} = 100$ mb. This luminosity is effectively achieved for 10^7 s yr^{-1}. The interaction rate is thus 10^8 s^{-1}, or 10^{15} yr^{-1};
- All radiation comes from pp collisions at the interaction point;
- The charged particle distribution is (a) flat in pseudorapidity for $|\eta| < 6$ and (b) has a momentum distribution whose perpendicular component is independent of rapidity, which is taken as independent of pseudorapidity:

$$\frac{d^2N_{\rm ch}}{d\eta dp_\perp} = H\, f(p_\perp) \tag{25.5}$$

  (where $p_\perp = p\sin\theta$). Integrals involving $f(p_\perp)$ are simplified by replacing $f(p_\perp)$ by $\delta(p_\perp - \langle p_\perp\rangle)$; in the worst case this approximation introduces an error of less than 10%;
- Gamma rays from π^0 decay are as abundant as charged particles. They have approximately the same η distribution, but half the mean momentum;
- At the SSC ($\sqrt{s} = 40$ TeV), $H \approx 7.5$ and $\langle p_\perp\rangle \approx 0.6$ GeV/c; assumed values at other energies are given in Table 25.3. Together with the model discussed above, these values are thought to describe particle production to within a factor of two or better.

It then follows that the flux of charged particles from the interaction point passing through a normal area da located a distance $r_\perp$ from the beam line is given by

$$\frac{dN_{\rm ch}}{da} = \frac{1.2\times 10^8\,{\rm s}^{-1}}{r_\perp^2}\ . \tag{25.6}$$

In a typical organic material, a relativistic charged particle flux of 3×10^9 cm^{-2} produces an ionizing radiation dose of 1 Gy, where 1 Gy $\equiv$ 1 joule kg^{-1} (= 100 rads). The above result may thus be rewritten as dose rate,

$$\dot{D} = \frac{0.4\ {\rm MGy\ yr^{-1}}}{(r_\perp/1\ {\rm cm})^2}\ . \tag{25.7}$$

If a magnetic field is present, "loopers" may increase this dose rate by a factor of two ore more.

In a medium in which cascades can develop, the ionizing dose or neutron fluence is proportional to $dN_{\rm ch}/da$ multiplied by $\langle E\rangle^\alpha$, where $\langle E\rangle$ is the mean energy of the particles going through da and the power α is slightly less than unity. Since $E \approx p = p_\perp/\sin\theta$ and $r_\perp = r\sin\theta$, the above expression for $dN_{\rm ch}/da$ becomes

$$\text{Dose or fluence}^\ddagger = \frac{A}{r^2}\cosh^{2+\alpha}\eta = \frac{A}{r^2\sin^{2+\alpha}\theta}\ . \tag{25.8}$$

The constant A contains the total number of interactions $\sigma_{\rm inel}\int\mathscr{L}dt$, so the ionizing dose or neutron fluence at another accelerator scales as $\sigma_{\rm inel}\int\mathscr{L}dt\, H\,\langle p_\perp\rangle^\alpha$.

The dose or fluence in a calorimeter scales as $1/r^2$, as does the neutron fluence inside a central cavity with characteristic dimension r.

Under all conditions so far studied, the neutron spectrum shows a broad log-normal distribution peaking at just under 1 MeV. In a 2 m radius central cavity of a detector with coverage down to $|\eta| = 3$, the average neutron flux is 2×10^{12} cm^{-2}yr^{-1}, including secondary scattering contributions.

Values of A and α are given in Table 25.2 for several relevant situations. Examples of scaling to other accelerators are given in Table 25.3. It should be noted that the assumption that all radiation comes from the interaction point does not apply to the present generation of accelerators.

The constant A includes factors evaluated with cascade simulation programs as well as constants describing particle production at the interaction point. It is felt that each could introduce an error as large as a factor of two in the results.

Table 25.2: Coefficients $A/(100\ {\rm cm})^2$ and α for the evaluation of calorimeter radiation levels at cascade maxima under SSC nominal operating conditions. At a distance r and angle θ from the interaction point the annual fluence or dose is $A/(r^2\sin^{2+\alpha}\theta)$.

Quantity	$A/(100\ {\rm cm})^2$	Units	$\langle p_\perp\rangle$	α
Neutron flux	1.5×10^{12}	cm^{-2}yr^{-1}	0.6 GeV/c	0.67
Dose rate from photons	124	Gy yr^{-1}	0.3 GeV/c	0.93
Dose rate from hadrons	29	Gy yr^{-1}	0.6 GeV/c	0.89

Table 25.3: A rough comparison of beam-collision induced radiation levels at the Tevatron, high-luminosity LHC, SSC, and a possible 100 TeV machine [16].

	Tevatron	LHC	SSC	100 TeV
$\sqrt{s}$ (TeV)	1.8	15.4	40	100
$\mathscr{L}_{\rm nom}$ (cm^{-2}s^{-1})	2×10^{30}	1.7×10^{34} [a]	1×10^{33}	1×10^{34}
$\sigma_{\rm inel}$	56 mb	84 mb	100 mb	134 mb
H	3.9	6.2	7.5	10.6
$\langle p_\perp\rangle$ (GeV/c)	0.46	0.55	0.60	0.70
Relative dose rate [b]	5×10^{-4}	11	1	20

[a] High-luminosity option.
[b] Proportional to $\mathscr{L}_{\rm nom}\,\sigma_{\rm inel}\,H\,\langle p_\perp\rangle^{0.7}$

Footnotes:

* The ICRP recomendation [2] is 20 mSv yr^{-1} averaged over 5 years, with the dose in any one year $\leq$ 50 mSv.

† Many laboratories in the U.S. and elsewhere set lower limits.

‡ *Dose* is the time integral of *dose rate*, and *fluence* is the time integral of *flux*.

		$\approx$ 20 γ's/fission; 80% $<$ 1 MeV $\approx$ 4 neutrons/fission; $\langle E_n \rangle = 2.14$ MeV				

"Emission probability" is the probability per decay of a given emission; because of cascades these may total more than 100%. Only principal emissions are listed. EC means electron capture, and e^- means monoenergetic internal conversion (Auger) electron. The intensity of 0.511 MeV e^+e^- annihilation photons depends upon the number of stopped positrons. Endpoint $\beta^{\pm}$ energies are listed. In some cases when energies are closely spaced, the γ-ray values are approximate weighted averages. Radiation from short-lived daughter isotopes is included where relevant.

Half-lives, energies, and intensities are from E. Browne and R.B. Firestone, *Table of Radioactive Isotopes* (John Wiley & Sons, New York, 1986), recent *Nuclear Data Sheets*, and *X-ray and Gamma-ray Standards for Detector Calibration*, IAEA-TECDOC-619 (1991).

Neutron data are from *Neutron Sources for Basic Physics and Applications* (Pergamon Press, 1983).

27. PROBABILITY

Revised May 1996 by D.E. Groom (LBNL) and F. James (CERN). Updated September 1999 by R. Cousins (UCLA).

27.1. General [1–6]

Let x be a possible outcome of an observation. The probability of x is the relative frequency with which that outcome occurs out of a (possibly hypothetical) large set of similar observations. If x can take any value from a *continuous* range, we write $f(x;\theta)\,dx$ as the probability of observing x between x and $x + dx$. The function $f(x;\theta)$ is the *probability density function* (p.d.f.) for the *random variable* x, which may depend upon one or more parameters θ. If x can take on only *discrete* values (*e.g.*, the non-negative integers), then $f(x;\theta)$ is itself a probability, but we shall still call it a p.d.f. The p.d.f. is always normalized to unit area (unit sum, if discrete). Both x and θ may have multiple components and are then often written as column vectors. If θ is unknown and we wish to estimate its value from a given set of data measuring x, we may use statistics (see Sec. 28).

The *cumulative distribution function* $F(a)$ is the probability that $x \le a$:

$$F(a) = \int_{-\infty}^{a} f(x)\,dx \; . \tag{27.1}$$

Here and below, if x is discrete-valued, the integral is replaced by a sum. The endpoint a is expressly included in the integral or sum. Then $0 \le F(x) \le 1$, $F(x)$ is nondecreasing, and $\text{Prob}(a < x \le b) = F(b) - F(a)$. If x is discrete, $F(x)$ is flat except at allowed values of x, where it has discontinuous jumps equal to $f(x)$.

Any function of random variables is itself a random variable, with (in general) a different p.d.f. The *expectation value* of any function $u(x)$ is

$$E\left[u(x)\right] = \int_{-\infty}^{\infty} u(x)\; f(x)\; dx \; , \tag{27.2}$$

assuming the integral is finite. For $u(x)$ and $v(x)$ any two functions of x, $E(u + v) = E(u) + E(v)$. For c and k constants, $E(cu + k) = cE(u) + k$.

The nth moment of a distribution is

$$\alpha_n \equiv E(x^n) = \int_{-\infty}^{\infty} x^n f(x)dx \; , \tag{27.3a}$$

and the nth moment about the mean of x, α_1, is

$$m_n \equiv E[(x-\alpha_1)^n] = \int_{-\infty}^{\infty} (x-\alpha_1)^n f(x)dx \; . \tag{27.3b}$$

The most commonly used moments are the mean μ and variance σ^2:

$$\mu \equiv \alpha_1 \tag{27.4a}$$
$$\sigma^2 \equiv \text{Var}(x) \equiv m_2 = \alpha_2 - \mu^2 \; . \tag{27.4b}$$

The mean is the location of the "center of mass" of the probability density function, and the variance is a measure of the square of its width. Note that $\text{Var}(cx + k) = c^2\text{Var}(x)$.

Any odd moment about the mean is a measure of the skewness of the p.d.f. The simplest of these is the dimensionless coefficient of skewness $\gamma_1 \equiv m_3/\sigma^3$.

Besides the mean, another useful indicator of the "middle" of the probability distribution is the *median* x_{med}, defined by $F(x_{\text{med}}) = 1/2$; *i.e.*, half the probability lies above and half lies below x_{med}. For a given *sample* of events, x_{med} is the value such that half the events have larger x and half have smaller x (not counting any that have the same x as the median). If the sample median lies between two observed x values, it is set by convention halfway between them. If the p.d.f. for x has the form $f(x-\mu)$ and μ is both mean and median, then for a large number of events N, the variance of the median approaches $1/[4Nf^2(0)]$, provided $f(0) > 0$.

Let x and y be two random variables with a joint p.d.f. $f(x,y)$. The *marginal* p.d.f. of x (the distribution of x with y unobserved) is

$$f_1(x) = \int_{-\infty}^{\infty} f(x,y)\,dy \; , \tag{27.5}$$

and similarly for the marginal p.d.f. $f_2(y)$. We define $f_3(y|x)$, the *conditional* p.d.f. of y given fixed x, by

$$f_3(y|x)\,f_1(x) = f(x,y) \; . \tag{27.6a}$$

Similarly, $f_4(x|y)$, the conditional p.d.f. of x given fixed y, is

$$f_4(x|y)\,f_2(y) = f(x,y) \; . \tag{27.6b}$$

From these definitions we immediately obtain Bayes' theorem [2]:

$$f_4(x|y) = \frac{f_3(y|x)\,f_1(x)}{f_2(y)} = \frac{f_3(y|x)\,f_1(x)}{\int f_3(y|x)\,f_1(x)\,dx} \; . \tag{27.7}$$

The mean of x is

$$\mu_x = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} x\; f(x,y)\; dx\; dy = \int_{-\infty}^{\infty} x\; f_1(x)\; dx \; , \tag{27.8}$$

and similarly for y. The *correlation* between x and y is

$$\rho_{xy} = E\left[(x-\mu_x)(y-\mu_y)\right]/\sigma_x\,\sigma_y = \text{Cov}(x,y)/\sigma_x\,\sigma_y \; , \tag{27.9}$$

where σ_x and σ_y are defined in analogy with Eq. (27.4*b*). It can be shown that $-1 \le \rho_{xy} \le 1$. Here "Cov" is the covariance of x and y, a 2-dimensional generalization of the variance.

Two random variables are *independent* if and only if

$$f(x,y) = f_1(x)\; f_2(y) \; . \tag{27.10}$$

If x and y are independent then $\rho_{xy} = 0$; the converse is not necessarily true except for Gaussian-distributed x and y. If x and y are independent, $E[u(x)\;v(y)] = E[u(x)]\;E[v(y)]$, and $\text{Var}(x + y) = \text{Var}(x)+\text{Var}(y)$; otherwise, $\text{Var}(x + y) = \text{Var}(x)+\text{Var}(y)+ 2\text{Cov}(x,y)$, and $E(u\;v)$ does not factor.

In a *change of continuous random variables* from $\boldsymbol{x} \equiv (x_1,\ldots,x_n)$, with p.d.f. $f(\boldsymbol{x}) = f(x_1,\ldots,x_n)$, to $\boldsymbol{y} \equiv (y_1,\ldots,y_n)$, a one-to-one function of the x_i's, the p.d.f. $g(\boldsymbol{y}) = g(y_1,\ldots,y_n)$ is found by substitution for $(x_1,\ldots,x_n)$ in f followed by multiplication by the absolute value of the Jacobian of the transformation; that is,

$$g(\boldsymbol{y}) = f\left[w_1(\boldsymbol{y}),\ldots,w_n(\boldsymbol{y})\right]|J| \; . \tag{27.11}$$

The functions w_i express the *inverse* transformation, $x_i = w_i(\boldsymbol{y})$ for $i = 1,\ldots,n$, and $|J|$ is the absolute value of the determinant of the square matrix $J_{ij} = \partial x_i/\partial y_j$. If the transformation from $\boldsymbol{x}$ to $\boldsymbol{y}$ is not one-to-one, the situation is more complex and a unique solution may not exist. For example, if the change is to $m < n$ variables, then a given y may correspond to more than one x, leading to multiple integrals over the contributions [1].

To change variables for discrete random variables simply substitute; no Jacobian is necessary because now f is a probability rather than a probability density.

If f depends upon a parameter set $\boldsymbol{\alpha}$, a change to a different parameter set $\phi_i = \phi_i(\boldsymbol{\alpha})$ is made by simple substitution; no Jacobian is used.

27.2. Characteristic functions

The characteristic function $\phi(u)$ associated with the p.d.f. $f(x)$ is essentially its (inverse) Fourier transform, or the expectation value of $\exp(iux)$:

$$\phi(u) = E(e^{iux}) = \int_{-\infty}^{\infty} e^{iux} f(x)dx \; . \tag{27.12}$$

It is often useful, and several of its properties follow [1].

It follows from Eqs. (27.3*a*) and (27.12) that the nth moment of the distribution $f(x)$ is given by

$$i^{-n}\frac{d^n\phi}{du^n}\bigg|_{u=0} = \int_{-\infty}^{\infty} x^n f(x)dx = \alpha_n \; . \tag{27.13}$$

Thus it is often easy to calculate all the moments of a distribution defined by $\phi(u)$, even when $f(x)$ is difficult to obtain.

If $f_1(x)$ and $f_2(y)$ have characteristic functions $\phi_1(u)$ and $\phi_2(u)$, then the characteristic function of the weighted sum $ax + by$ is $\phi_1(au)\phi_2(bu)$. The addition rules for common distributions (*e.g.*, that the sum of two numbers from Gaussian distributions also has a Gaussian distribution) easily follow from this observation.

Let the (partial) characteristic function corresponding to the conditional p.d.f. $f_2(x|z)$ be $\phi_2(u|z)$, and the p.d.f. of z be $f_1(z)$. The characteristic function after integration over the conditional value is

$$\phi(u) = \int \phi_2(u|z)\, f_1(z) dz \ . \qquad (27.14)$$

Suppose we can write ϕ_2 in the form

$$\phi_2(u|z) = A(u) e^{ig(u)z} \ . \qquad (27.15)$$

Then

$$\phi(u) = A(u)\phi_1(g(u)) \ . \qquad (27.16)$$

The semi-invariants κ_n are defined by

$$\phi(u) = \exp\left(\sum_1^\infty \frac{\kappa_n}{n!}(iu)^n\right) = \exp\left(i\kappa_1 u - \tfrac{1}{2}\kappa_2 u^2 + \ldots\right) \ . \qquad (27.17)$$

The κ_n's are related to the moments α_n and m_n. The first few relations are

$$\begin{aligned} \kappa_1 &= \alpha_1 \ (= \mu, \text{ the mean}) \\ \kappa_2 &= m_2 \ = \alpha_2 - \alpha_1^2 \ (= \sigma^2, \text{ the variance}) \\ \kappa_3 &= m_3 = \alpha_3 - 3\alpha_1\alpha_2 + 2\alpha_1^2 \ . \end{aligned} \qquad (27.18)$$

27.3. Some probability distributions

Table 27.1 gives a number of common probability density functions and corresponding characteristic functions, means, and variances. Further information may be found in Refs. 1–7; Ref. 7 has particularly detailed tables. Monte Carlo techniques for generating each of them may be found in our Sec. 29.4. We comment below on all except the trivial uniform distribution.

27.3.1. ***Binomial distribution***: A random process with exactly two possible outcomes is called a *Bernoulli* process. If the probability of obtaining a certain outcome (a "success") in each trial is p, then the probability of obtaining exactly r successes ($r = 0, 1, 2, \ldots, n$) in n trials, without regard to the order of the successes and failures, is given by the binomial distribution $f(r; n, p)$ in Table 27.1. If r successes are observed in n_r trials with probability p of a success, and if s successes are observed in n_s similar trials, then $t = r + s$ is also binomial with $n_t = n_r + n_s$.

27.3.2. ***Poisson distribution***: The Poisson distribution $f(r; \mu)$ gives the probability of finding exactly r events in a given interval of x (*e.g.*, space and time) when the events occur independently of one another and of x at an average rate of μ per the given interval. The variance σ^2 equals μ. It is the limiting case $p \to 0$, $n \to \infty$, $np = \mu$ of the binomial distribution. The Poisson distribution approaches the Gaussian distribution for large μ.

Two or more Poisson processes (*e.g.*, *signal* + *background*, with parameters μ_s and μ_b) that independently contribute amounts n_s and n_b to a given measurement will produce an observed number $n = n_s + n_b$, which is distributed according to a new Poisson distribution with parameter $\mu = \mu_s + \mu_b$.

27.3.3. ***Normal or Gaussian distribution***: The normal (or Gaussian) probability density function $f(x; \mu, \sigma^2)$ given in Table 27.1 has mean $\overline{x} = \mu$ and variance σ^2. Comparison of the characteristic function $\phi(u)$ given in Table 27.1 with Eq. (27.17) shows that all semi-invariants κ_n beyond κ_2 vanish; this is a unique property of the Gaussian distribution. Some properties of the distribution are:

rms deviation $= \sigma$

probability x in the range $\mu \pm \sigma = 0.6827$

probability x in the range $\mu \pm 0.6745\sigma = 0.5$

expection value of $|x - \mu|$, $E(|x - \mu|) = (2/\pi)^{1/2}\sigma = 0.7979\sigma$

half-width at half maximum $= (2 \ln 2)^{1/2}\sigma = 1.177\sigma$

The cumulative distribution, Eq. (27.1), for a Gaussian with $\mu = 0$ and $\sigma^2 = 1$ is related to the error function erf(y) by

$$F(x; 0, 1) = \tfrac{1}{2}\left[1 + \text{erf}(x/\sqrt{2})\right] \ . \qquad (27.19)$$

The error function is tabulated in Ref. 7 and is available in computer math libraries and personel computer spreadsheets. For a mean μ and variance σ^2, replace x by $(x - \mu)/\sigma$. The probability of x in a given range can be calculated with Eq. (28.36).

For x and y independent and normally distributed, $z = ax + by$ obeys $f(z;\ a\mu_x + b\mu_y,\ a^2\sigma_x^2 + b^2\sigma_y^2)$; that is, the weighted means and variances add.

The Gaussian gets its importance in large part from the *central limit theorem*: If a continuous random variable x is distributed according to *any* p.d.f. with finite mean and variance, then the sample mean, $\overline{x}_n$, of n observations of x will have a p.d.f. that approaches a Gaussian as n increases. Therefore the end result $\sum^n x_i \equiv n\overline{x}_n$ of a large number of small fluctuations x_i will be distributed as a Gaussian, even if the x_i themselves are not.

(Note that the *product* of a large number of random variables is not Gaussian, but its logarithm is. The p.d.f. of the product is *lognormal*. See Ref. 6 for details.)

For a set of n Gaussian random variables $\boldsymbol{x}$ with means $\boldsymbol{\mu}$ and corresponding Fourier variables $\boldsymbol{u}$, the characteristic function for a one-dimensional Gaussian is generalized to

$$\phi(\boldsymbol{x}; \boldsymbol{\mu}, S) = \exp\left[i\boldsymbol{\mu}\cdot\boldsymbol{u} - \tfrac{1}{2}\boldsymbol{u}^T S \boldsymbol{u}\right] \ . \qquad (27.20)$$

From Eq. (27.13), the covariance about the mean is

$$E\left[(x_j - \mu_j)(x_k - \mu_k)\right] = S_{jk} \ . \qquad (27.21)$$

If the $\boldsymbol{x}$ are independent, then $S_{jk} = \delta_{jk}\sigma_j^2$, and Eq. (27.20) is the product of the c.f.'s of n Gaussians.

The covariance matrix S can be related to the correlation matrix defined by Eq. (27.9) (a sort of normalized covariance matrix). With the definition $\sigma_k^2 \equiv S_{kk}$, we have $\rho_{jk} = S_{jk}/\sigma_j\sigma_k$.

The characteristic function may be inverted to find the corresponding p.d.f.

$$f(\boldsymbol{x}; \boldsymbol{\mu}, S) = \frac{1}{(2\pi)^{n/2}\sqrt{|S|}} \exp\left[-\tfrac{1}{2}(\boldsymbol{x} - \boldsymbol{\mu})^T S^{-1} (\boldsymbol{x} - \boldsymbol{\mu})\right] \qquad (27.22)$$

where the determinant $|S|$ must be greater than 0. For diagonal S (independent variables), $f(\boldsymbol{x}; \boldsymbol{\mu}, S)$ is the product of the p.d.f.'s of n Gaussian distributions.

Table 27.1. Some common probability density functions, with corresponding characteristic functions and means and variances. In the Table, $\Gamma(k)$ is the gamma function, equal to $(k-1)!$ when k is an integer.

Distribution	Probability density function f (variable; parameters)	Characteristic function $\phi(u)$	Mean	Variance σ^2
Uniform	$f(x;a,b) = \begin{cases} 1/(b-a) & a \le x \le b \\ 0 & \text{otherwise} \end{cases}$	$\dfrac{e^{ibu}-e^{iau}}{(b-a)iu}$	$\overline{x} = \dfrac{a+b}{2}$	$\dfrac{(b-a)^2}{12}$
Binomial	$f(r;n,p) = \dfrac{n!}{r!(n-r)!}\, p^r q^{n-r}$ $r = 0,1,2,\ldots,n\,;\quad 0 \le p \le 1\,;\quad q = 1-p$	$(q+pe^{iu})^n$	$\overline{r} = np$	npq
Poisson	$f(r;\mu) = \dfrac{\mu^r e^{-\mu}}{r!}\,;\quad r = 0,1,2,\ldots\,;\quad \mu > 0$	$\exp[\mu(e^{iu}-1)]$	$\overline{r} = \mu$	μ
Normal (Gaussian)	$f(x;\mu,\sigma^2) = \dfrac{1}{\sigma\sqrt{2\pi}}\exp(-(x-\mu)^2/2\sigma^2)$ $-\infty < x < \infty\,;\quad -\infty < \mu < \infty\,;\quad \sigma > 0$	$\exp(i\mu u - \frac{1}{2}\sigma^2 u^2)$	$\overline{x} = \mu$	σ^2
Multivariate Gaussian	$f(\boldsymbol{x};\boldsymbol{\mu},S) = \dfrac{1}{(2\pi)^{n/2}\sqrt{\lvert S\rvert}}$ $\times \exp\left[-\frac{1}{2}(\boldsymbol{x}-\boldsymbol{\mu})^T S^{-1}(\boldsymbol{x}-\boldsymbol{\mu})\right]$ $-\infty < x_j < \infty;\quad -\infty < \mu_j < \infty;\quad \det S > 0$	$\exp\left[i\boldsymbol{\mu}\cdot\boldsymbol{u} - \frac{1}{2}\boldsymbol{u}^T S\boldsymbol{u}\right]$	$\boldsymbol{\mu}$	S_{jk}
χ^2	$f(z;n) = \dfrac{z^{n/2-1}e^{-z/2}}{2^{n/2}\Gamma(n/2)}\,;\quad z \ge 0$	$(1-2iu)^{-n/2}$	$\overline{z} = n$	$2n$
Student's t	$f(t;n) = \dfrac{1}{\sqrt{n\pi}}\dfrac{\Gamma[(n+1)/2]}{\Gamma(n/2)}\left(1+\dfrac{t^2}{n}\right)^{-(n+1)/2}$ $-\infty < t < \infty\,;\quad n$ not required to be integer	—	$\overline{t} = 0$ for $n \ge 2$	$n/(n-2)$ for $n \ge 3$
Gamma	$f(x;\lambda,k) = \dfrac{x^{k-1}\lambda^k e^{-\lambda x}}{\Gamma(k)}\,;\quad 0 < x < \infty\,;$ k not required to be integer	$(1-iu/\lambda)^{-k}$	$\overline{x} = k/\lambda$	k/λ^2

For $n = 2$, $f(\boldsymbol{x};\boldsymbol{\mu},S)$ is

$$f(x_1,x_2;\ \mu_1,\mu_2,\sigma_1,\sigma_2,\rho) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}}$$
$$\times\ \exp\left\{\frac{-1}{2(1-\rho^2)}\left[\frac{(x_1-\mu_1)^2}{\sigma_1^2} - \frac{2\rho(x_1-\mu_1)(x_2-\mu_2)}{\sigma_1\sigma_2} + \frac{(x_2-\mu_2)^2}{\sigma_2^2}\right]\right\}. \qquad (27.23)$$

The marginal distribution of any x_i is a Gaussian with mean μ_i and variance S_{ii}. S is $n \times n$, symmetric, and positive definite. Therefore for any vector $\boldsymbol{X}$, the quadratic form $\boldsymbol{X}^T S^{-1}\boldsymbol{X} = C$, where C is any positive number, traces an n-dimensional ellipsoid as $\boldsymbol{X}$ varies. If $X_i = (x_i - \mu_i)/\sigma_i$, then C is a random variable obeying the $\chi^2(n)$ distribution, discussed in the following section. The probability that $\boldsymbol{X}$ corresponding to a set of Gaussian random variables x_i lies *outside* the ellipsoid characterized by a given value of $C\,(=\chi^2)$ is given by Eq. (27.24) and may be read from Fig. 27.1. For example, the "s-standard-deviation ellipsoid" occurs at $C = s^2$. For the two-variable case ($n = 2$), the point $\boldsymbol{X}$ lies outside the one-standard-deviation ellipsoid with 61% probability. (This assumes that μ_i and σ_i are correct.) For $X_i = x_i/\sigma_i$, the ellipsoids of constant χ^2 have the same size and orientation but are centered at $\boldsymbol{\mu}$. The use of these ellipsoids as indicators of probable error is described in Sec. 28.6.2.

27.3.4. χ^2 *distribution*: If $x_1,\ldots,x_n$ are independent Gaussian distributed random variables, the sum $z = \sum^n (x_i-\mu_i)^2/\sigma_i^2$ is distributed as a χ^2 with n *degrees of freedom*, $\chi^2(n)$. Under a linear transformation to n dependent Gaussian variables x_i', the χ^2 at each transformed point retains its value; then $z = \boldsymbol{X}'^T V^{-1}\boldsymbol{X}'$ as in the previous section. For a set of z_i, each of which is $\chi^2(n_i)$, $\sum z_i$ is a new random variable which is $\chi^2\left(\sum n_i\right)$.

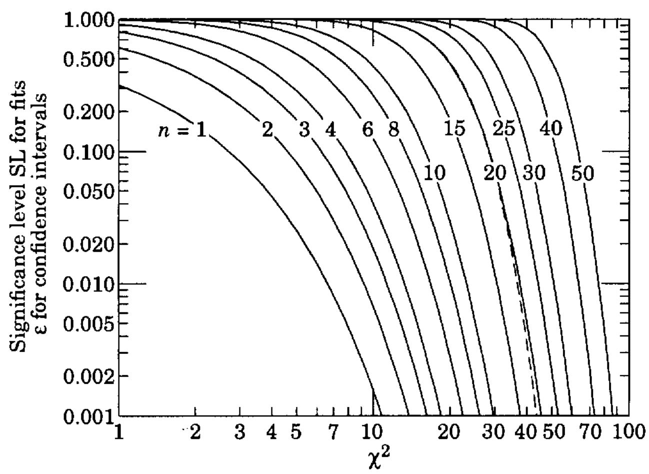

Figure 27.1: The significance level versus χ^2 for n degrees of freedom, as defined in Eq. (27.24). The curve for a given n gives the probability that a value at least as large as χ^2 will be obtained in an experiment; *e.g.*, for $n = 10$, a value $\chi^2 \gtrsim 18$ will occur in 5% of a large number of experiments. For a fit, the SL is a measure of goodness-of-fit, in that a good fit to a correct model is expected to yield a low χ^2 (see Sec. 28.5.0). For a confidence interval, ε measures the probability that the interval *does not* cover the true value of the quantity being estimated (see Sec. 28.6). The dashed curve for $n = 20$ is calculated using the approximation of Eq. (27.25).

Fig. 27.1 shows the signficance level (SL) obtained by integrating the tail of $f(z;n)$:

$$\mathrm{SL}(\chi^2) = \int_{\chi^2}^{\infty} f(z;\, n)\, dz \,. \qquad (27.24)$$

This is shown for a special case in Fig. 27.2, and is equal to 1.0 minus the cumulative distribution function $F(z = \chi^2;\, n)$. It is useful in evaluating the consistency of data with a model (see Sec. 28): The SL is the probability that a random repeat of the given experiment would observe a greater χ^2, assuming the model is correct. It is also useful for confidence intervals for statistical estimators (see Sec. 28.6), in which case one is interested in the unshaded area of Fig. 27.2.

Since the mean of the χ^2 distribution is equal to n, one expects in a "reasonable" experiment to obtain $\chi^2 \approx n$. Hence the "reduced χ^2" $\equiv \chi^2/n$ is sometimes reported. Since the p.d.f. of χ^2/n depends on n, one must report n as well in order to make a meaningful statement. Figure 27.3 shows χ^2/n for useful SL's as a function of n.

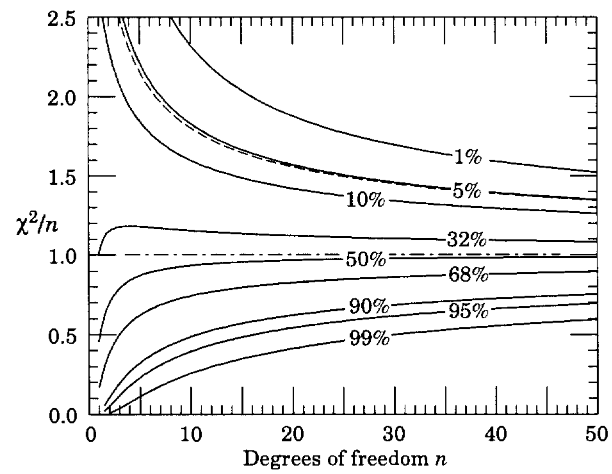

Figure 27.3: Significance levels as a function of the "reduced χ^2" $\equiv \chi^2/n$ and the number of degrees of freedom n. Curves are labeled by the probability that a measurement will give a value of χ^2/n greater than that given on the y axis; *e.g.*, for $n = 10$, a value $\chi^2/n \gtrsim 1.8$ can be expected 5% of the time.

For large n, the SL is approximately given by [1,8]

$$\mathrm{SL}(\chi^2) \approx \frac{1}{\sqrt{2\pi}} \int_y^{\infty} e^{-x^2/2}\, dx \,, \qquad (27.25)$$

where $y = \sqrt{2\chi^2} - \sqrt{2n-1}$. This approximation was used to draw the dashed curves in Fig. 27.1 (for $n = 20$) and Fig. 27.3 (for SL = 5%). Since all the functions and their inverses are now readily available in standard mathematical libraries (such as IMSL, used to generate these figures, and personal computer spreadsheets, such as Microsoft® Excel [9]), the approximation (and even figures and tables) are seldom needed.

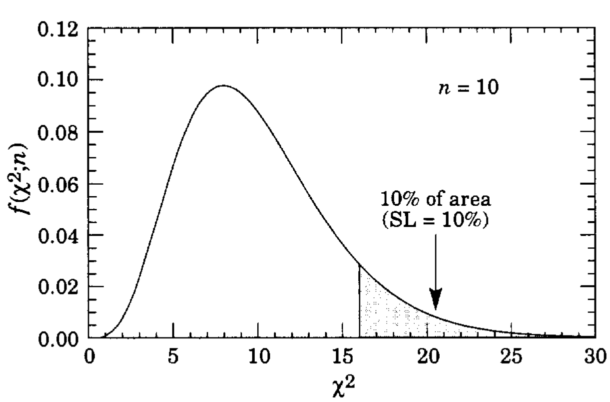

Figure 27.2: Illustration of the significance level integral given in Eq. (27.24). This particlar example is for $n = 10$, where the area above 15.99 is 0.1.

27.3.5. ***Student's t distribution:*** Suppose that x and $x_1, \ldots, x_n$ are independent and Gaussian distributed with mean 0 and variance 1. We then define

$$z = \sum_1^n x_i^2 \,, \quad \text{and} \quad t = \frac{x}{\sqrt{z/n}} \,. \qquad (27.26)$$

The variable z thus belongs to a $\chi^2(n)$ distribution. Then t is distributed according to a Student's t distribution with n degrees of freedom, $f(t;n)$, given in Table 27.1.

The Student's t distribution resembles a Gaussian distribution with wide tails. As $n \to \infty$, the distribution approaches a Gaussian. If $n = 1$, the distribution is a *Cauchy* or *Breit-Wigner* distribution. The mean is finite only for $n > 1$ and the variance is finite only for $n > 2$, so for $n = 1$ or $n = 2$, the central limit theorem is not applicable to t.

As an example, consider the *sample mean* $\overline{x} = \sum x_i/n$ and the *sample variance* $s^2 = \sum(x_i - \overline{x})^2/(n-1)$ for normally distributed random variables x_i with unknown mean μ and variance σ^2. The sample mean has a Gaussian distribution with a variance σ^2/n, so the variable $(\overline{x} - \mu)/\sqrt{\sigma^2/n}$ is normal with mean 0 and variance 1. Similarly, $(n-1)\,s^2/\sigma^2$ is independent of this and is χ^2 distributed with $n-1$ degrees of freedom. The ratio

$$t = \frac{(\overline{x} - \mu)/\sqrt{\sigma^2/n}}{\sqrt{(n-1)\, s^2/\sigma^2\, (n-1)}} = \frac{\overline{x} - \mu}{\sqrt{s^2/n}} \qquad (27.27)$$

is distributed as $f(t;\, n-1)$. The unknown true variance σ^2 cancels, and t can be used to test the probability that the true mean is some particular value μ.

In Table 27.1, n in $f(t;n)$ is not required to be an integer. A Student's t distribution with nonintegral $n > 0$ is useful in certain applications.

27.3.6. ***Gamma distribution:*** For a process that generates events as a function of x (*e.g.*, space or time) according to a Poisson distribution, the distance in x from an arbitrary starting point (which may be some particular event) to the k^{th} event belongs to a *gamma* distribution, $f(x;\, \lambda,\, k)$. The Poisson parameter μ is λ per unit x. The special case $k = 1$ (*i.e.*, $f(x; \lambda, 1) = \lambda e^{-\lambda x}$) is called the *exponential* distribution. A sum of k' exponential random variables x_i is distributed as $f(\sum x_i;\, \lambda, k')$.

The parameter k is not required to be an integer. For $\lambda = 1/2$ and $k = n/2$, the gamma distribution reduces to the $\chi^2(n)$ distribution.

27. PROBABILITY

Revised May 1996 by D.E. Groom (LBNL) and F. James (CERN). Updated September 1999 by R. Cousins (UCLA).

27.1. General [1–6]

Let x be a possible outcome of an observation. The probability of x is the relative frequency with which that outcome occurs out of a (possibly hypothetical) large set of similar observations. If x can take any value from a *continuous* range, we write $f(x;\theta)\,dx$ as the probability of observing x between x and $x+dx$. The function $f(x;\theta)$ is the *probability density function* (p.d.f.) for the *random variable* x, which may depend upon one or more parameters θ. If x can take on only *discrete* values (*e.g.*, the non-negative integers), then $f(x;\theta)$ is itself a probability, but we shall still call it a p.d.f. The p.d.f. is always normalized to unit area (unit sum, if discrete). Both x and θ may have multiple components and are then often written as column vectors. If θ is unknown and we wish to estimate its value from a given set of data measuring x, we may use statistics (see Sec. 28).

The *cumulative distribution function* $F(a)$ is the probability that $x \le a$:

$$F(a) = \int_{-\infty}^{a} f(x)\,dx \ . \tag{27.1}$$

Here and below, if x is discrete-valued, the integral is replaced by a sum. The endpoint a is expressly included in the integral or sum. Then $0 \le F(x) \le 1$, $F(x)$ is nondecreasing, and $\text{Prob}(a < x \le b) = F(b) - F(a)$. If x is discrete, $F(x)$ is flat except at allowed values of x, where it has discontinuous jumps equal to $f(x)$.

Any function of random variables is itself a random variable, with (in general) a different p.d.f. The *expectation value* of any function $u(x)$ is

$$E[u(x)] = \int_{-\infty}^{\infty} u(x)\, f(x)\,dx \ , \tag{27.2}$$

assuming the integral is finite. For $u(x)$ and $v(x)$ any two functions of x, $E(u+v) = E(u) + E(v)$. For c and k constants, $E(cu+k) = cE(u) + k$.

The nth moment of a distribution is

$$\alpha_n \equiv E(x^n) = \int_{-\infty}^{\infty} x^n f(x) dx \ , \tag{27.3a}$$

and the nth moment about the mean of x, α_1, is

$$m_n \equiv E[(x-\alpha_1)^n] = \int_{-\infty}^{\infty} (x-\alpha_1)^n f(x) dx \ . \tag{27.3b}$$

The most commonly used moments are the mean μ and variance σ^2:

$$\mu \equiv \alpha_1 \tag{27.4a}$$
$$\sigma^2 \equiv \text{Var}(x) \equiv m_2 = \alpha_2 - \mu^2 \ . \tag{27.4b}$$

The mean is the location of the "center of mass" of the probability density function, and the variance is a measure of the square of its width. Note that $\text{Var}(cx+k) = c^2\text{Var}(x)$.

Any odd moment about the mean is a measure of the skewness of the p.d.f. The simplest of these is the dimensionless coefficient of skewness $\gamma_1 \equiv m_3/\sigma^3$.

Besides the mean, another useful indicator of the "middle" of the probability distribution is the *median* x_{med}, defined by $F(x_{\text{med}}) = 1/2$; *i.e.*, half the probability lies above and half lies below x_{med}. For a given *sample* of events, x_{med} is the value such that half the events have larger x and half have smaller x (not counting any that have the same x as the median). If the sample median lies between two observed x values, it is set by convention halfway between them. If the p.d.f. for x has the form $f(x-\mu)$ and μ is both mean and median, then for a large number of events N, the variance of the median approaches $1/[4Nf^2(0)]$, provided $f(0) > 0$.

Let x and y be two random variables with a joint p.d.f. $f(x,y)$. The *marginal* p.d.f. of x (the distribution of x with y unobserved) is

$$f_1(x) = \int_{-\infty}^{\infty} f(x,y)\,dy \ , \tag{27.5}$$

and similarly for the marginal p.d.f. $f_2(y)$. We define $f_3(y|x)$, the *conditional* p.d.f. of y given fixed x, by

$$f_3(y|x)\,f_1(x) = f(x,y) \ . \tag{27.6a}$$

Similarly, $f_4(x|y)$, the conditional p.d.f. of x given fixed y, is

$$f_4(x|y)\,f_2(y) = f(x,y) \ . \tag{27.6b}$$

From these definitions we immediately obtain Bayes' theorem [2]:

$$f_4(x|y) = \frac{f_3(y|x)\,f_1(x)}{f_2(y)} = \frac{f_3(y|x)\,f_1(x)}{\int f_3(y|x)\,f_1(x)\,dx} \ . \tag{27.7}$$

The mean of x is

$$\mu_x = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} x\, f(x,y)\,dx\,dy = \int_{-\infty}^{\infty} x\, f_1(x)\,dx \ , \tag{27.8}$$

and similarly for y. The *correlation* between x and y is

$$\rho_{xy} = E\left[(x-\mu_x)(y-\mu_y)\right]/\sigma_x\,\sigma_y = \text{Cov}(x,y)/\sigma_x\,\sigma_y \ , \tag{27.9}$$

where σ_x and σ_y are defined in analogy with Eq. (27.4b). It can be shown that $-1 \le \rho_{xy} \le 1$. Here "Cov" is the covariance of x and y, a 2-dimensional generalization of the variance.

Two random variables are *independent* if and only if

$$f(x,y) = f_1(x)\,f_2(y) \ . \tag{27.10}$$

If x and y are independent then $\rho_{xy} = 0$; the converse is not necessarily true except for Gaussian-distributed x and y. If x and y are independent, $E[u(x)\,v(y)] = E[u(x)]\,E[v(y)]$, and $\text{Var}(x+y) = \text{Var}(x)+\text{Var}(y)$; otherwise, $\text{Var}(x+y) = \text{Var}(x)+\text{Var}(y)+ 2\text{Cov}(x,y)$, and $E(u\,v)$ does not factor.

In a *change of continuous random variables* from $\boldsymbol{x} \equiv (x_1,\ldots,x_n)$, with p.d.f. $f(\boldsymbol{x}) = f(x_1,\ldots,x_n)$, to $\boldsymbol{y} \equiv (y_1,\ldots,y_n)$, a one-to-one function of the x_i's, the p.d.f. $g(\boldsymbol{y}) = g(y_1,\ldots,y_n)$ is found by substitution for $(x_1,\ldots,x_n)$ in f followed by multiplication by the absolute value of the Jacobian of the transformation; that is,

$$g(\boldsymbol{y}) = f\left[w_1(\boldsymbol{y}),\ldots,w_n(\boldsymbol{y})\right]|J| \ . \tag{27.11}$$

The functions w_i express the *inverse* transformation, $x_i = w_i(\boldsymbol{y})$ for $i = 1,\ldots,n$, and $|J|$ is the absolute value of the determinant of the square matrix $J_{ij} = \partial x_i/\partial y_j$. If the transformation from $\boldsymbol{x}$ to $\boldsymbol{y}$ is not one-to-one, the situation is more complex and a unique solution may not exist. For example, if the change is to $m < n$ variables, then a given y may correspond to more than one x, leading to multiple integrals over the contributions [1].

To change variables for discrete random variables simply substitute; no Jacobian is necessary because now f is a probability rather than a probability density.

If f depends upon a parameter set $\boldsymbol{\alpha}$, a change to a different parameter set $\phi_i = \phi_i(\boldsymbol{\alpha})$ is made by simple substitution; no Jacobian is used.

27.2. Characteristic functions

The characteristic function $\phi(u)$ associated with the p.d.f. $f(x)$ is essentially its (inverse) Fourier transform, or the expectation value of $\exp(iux)$:

$$\phi(u) = E(e^{iux}) = \int_{-\infty}^{\infty} e^{iux} f(x) dx \ . \tag{27.12}$$

It is often useful, and several of its properties follow [1].

It follows from Eqs. (27.3a) and (27.12) that the nth moment of the distribution $f(x)$ is given by

$$i^{-n}\frac{d^n\phi}{du^n}\bigg|_{u=0} = \int_{-\infty}^{\infty} x^n f(x) dx = \alpha_n \ . \tag{27.13}$$

28. STATISTICS

Revised April 1998 by F. James (CERN). Updated February 2000 by R. Cousins (UCLA).

A probability density function $f(x;\alpha)$ (p.d.f.) with known parameters α enables us to predict the frequency with which random data x will take on a particular value (if discrete) or lie in a given range (if continuous). Here we are concerned with the inverse problem, that of making inferences about α from a set of actual observations. Such inferences are part of a larger subject variously known as statistics, statistical inference, or inverse probability.

There are two different approaches to statistical inference, which we may call Frequentist and Bayesian. In the former, the frequency definition of probability (Sec. 27.1) is used, and it is usually meaningless to define a p.d.f. in α (for example, a parameter which is a constant of nature has a value which is fixed). In Frequentist statistics, one can compute confidence intervals as a function of the observed data, and they will contain ("cover") the unknown true value of α a specified fraction of the time in the long run, as defined in Sec. 28.6.

In Bayesian statistics, the concept of probability is not based on limiting frequencies, but is more general and includes *degree of belief.* With this definition, one may define p.d.f.'s in α, and then inverse probability simply obeys the general rules of probability. Bayesian methods allow for a natural way to input additional information such as physical boundaries and subjective information; in fact they *require* as input the *prior* p.d.f. for any parameter to be estimated. Using Bayes' Theorem (Eq. (27.7)), the prior degree of belief is updated by incoming data.

For many inference problems, the Frequentist and Bayesian approaches give the same numerical answers, even though they are based on fundamentally different assumptions. However, for exact results for small samples and for measurements near a physical boundary, the different approaches may yield very different confidence limits, so we are forced to make a choice. There is an enormous amount of literature devoted to the question of Bayesian vs non-Bayesian methods, much of it written by people who are fervent advocates of one or the other methodology, which often leads to exaggerated conclusions. For a reasonably balanced discussion, we recommend the following articles: by a statistician [1], and by a physicist [2]. A more advanced comparison is offered in Ref. 3.

In high energy physics, where experiments are repeatable (at least in principle) the frequentist definition of probability is normally used. However, Bayesian equations are often used to treat uncertainties on luminosity, background, *etc.* If the result has poor properties from a Frequentist point of view, one should note that the result is not a classical confidence interval.

Frequentist methods cannot provide the probability that a theory is true, or that a parameter has a particular value. (Such probabilities require input of prior belief.) Rather, Frequentist methods calculate probabilities that various data sets are obtained given specified theories or parameters; these frequencies are often calculated by Monte Carlo methods. As described below, confidence intervals are constructed from such frequencies, and therefore do not represent degree of belief.

The Bayesian methodology is particularly well-adapted to *decision-making*, which requires subjective input not only for prior belief, but also for risk tolerance, etc. Even primarily Frequentist texts such as Ref. 4 outline Bayesian decision theory. However, the usefulness of Bayesian methods as a means for the communication of experimental measurements is controversial.

Recently, the first Workshop on Confidence Limits [5] was held at CERN, where proponents of various statistical methods presented and discussed the issues. One sees that there was not a consensus on the best way to report confidence limits. We recommend the web site and eventual proceedings as a starting point for discussion of these issues. The methods described below use the Frequentist definition of probability, except where noted.

28.1. Parameter estimation [3, 4, 6–9]

Here we review *parametric* statistics in which one desires estimates of the parameters α from a set of actual observations.

A *statistic* is any function of the data, plus known constants, which does not depend upon any of the unknown parameters. A statistic is a random variable if the data have random errors. An *estimator* is any statistic whose value (the *estimate* $\widehat{\alpha}$) is intended as a meaningful guess for the value of the parameter α, or the vector $\boldsymbol{\alpha}$ if there is more than one parameter.

Since we are free to choose any function of the data as an estimator of the parameter α, we will try to choose that estimator which has the best properties. The most important properties are (a) *consistency*, (b) *bias*, (c) *efficiency*, and (d) *robustness.*

(a) An estimator is said to be *consistent* if the estimate $\widehat{\alpha}$ converges to the true value α as the amount of data increases. This property is so important that it is possessed by all commonly used estimators.

(b) The *bias*, $b = E(\widehat{\alpha}) - \alpha$, is the difference between the true value and the expectation of the estimates, where the expectation value is taken over a hypothetical set of similar experiments in which $\widehat{\alpha}$ is constructed the same way. When $b = 0$ the estimator is said to be unbiased. The bias depends on the chosen metric, i.e., if $\widehat{\alpha}$ is an unbiased estimator of α, then $(\widehat{\alpha})^2$ is generally not an unbiased estimator of α^2. The bias may be due to statistical properties of the estimator or to *systematic* errors in the experiment. If we can estimate the b we can subtract it from $\widehat{\alpha}$ to obtain a new $\widehat{\alpha}' \equiv \widehat{\alpha} - b$. However, b may depend upon α or other unknowns, in which case we usually try to choose an estimator which minimizes its average size.

(c) *Efficiency* is the inverse of the ratio between the *variance of the estimates* $\mathrm{Var}(\widehat{\alpha})$ and the minimum possible value of the variance. Under rather general conditions, the minimum variance is given by the Rao-Cramér-Frechet bound:

$$\mathrm{Var}_{\min} = \left[1 + \partial b/\partial\alpha\right]^2 / I(\alpha) \; ; \tag{28.1}$$

$$I(\alpha) = E\left\{ \left[\frac{\partial}{\partial\alpha} \sum_i \ln f(x_i;\,\alpha) \right]^2 \right\} .$$

(Compare with Eq. (28.6) below.) The sum is over all data and b is the bias, if any; the x_i are assumed independent and distributed as $f(x_i;\alpha)$, and the allowed range of x must not depend upon α. *Mean-squared error*, mse $= E[(\widehat{\alpha} - \alpha)^2] = V(\widehat{\alpha}) + b^2$ is a convenient quantity which combines in the appropriate way the errors due to bias and efficiency.

(d) *Robustness*; is the property of being insensitive to departures from assumptions in the p.d.f. due to such factors as noise.

For some common estimators the above properties are known exactly. More generally, it is always possible to evaluate them by Monte Carlo simulation. Note that they will often depend on the unknown α.

28.2. Data with a common mean

Suppose we have a set of N independent measurements y_i assumed to be unbiased measurements of the same unknown quantity μ with a common, but unknown, variance σ^2 resulting from measurement error. Then

$$\widehat{\mu} = \frac{1}{N} \sum_{i=1}^{N} y_i \tag{28.2}$$

$$\widehat{\sigma}^2 = \frac{1}{N-1} \sum_{i=1}^{N} (y_i - \widehat{\mu})^2 \tag{28.3}$$

are unbiased estimators of μ and σ^2. The variance of $\widehat{\mu}$ is σ^2/N. If the common p.d.f. of the y_i is Gaussian, these estimates are uncorrelated. Then, for large N, the standard deviation of $\widehat{\sigma}$ (the "error of the error") is $\sigma/\sqrt{2N}$. Again if the y_i are Gaussian, $\widehat{\mu}$ is an efficient estimator for μ. Otherwise the mean is in general not the most efficient estimator. For example, if the y follow a double-exponential distribution $[\sim \exp(-\sqrt{2}|y-\mu|/\sigma)]$, the most efficient estimator of the mean is the sample median (the value for which half the y_i lie above and half below). This is discussed in more detail in Ref. 4, Sec. 8.7.

If σ^2 is known, it does not improve the estimate $\widehat{\mu}$, as can be seen from Eq. (28.2); however, if μ is known, substitute it for $\widehat{\mu}$ in Eq. (28.3) and replace $N-1$ by N, to obtain a somewhat better estimator of σ^2.

If the y_i have different, known, variances σ_i^2, then the weighted average

$$\widehat{\mu} = \frac{1}{w}\sum_{i=1}^{N} w_i\, y_i\ , \tag{28.4}$$

is an unbiased estimator for μ with smaller variance than an unweighted average; here $w_i = 1/\sigma_i^2$ and $w = \sum w_i$. The standard deviation of $\widehat{\mu}$ is $1/\sqrt{w}$.

28.3. The method of maximum likelihood

28.3.1. ***Parameter estimation by maximum likelihood:***

"From a theoretical point of view, the most important general method of estimation so far known is the *method of maximum likelihood*" [6]. We suppose that a set of independently measured quantities x_i came from a p.d.f. $f(x;\boldsymbol{\alpha})$, where $\boldsymbol{\alpha}$ is an unknown set of parameters. The method of maximum likelihood consists of finding the set of values, $\widehat{\boldsymbol{\alpha}}$, which maximizes the joint probability density for all the data, given by

$$\mathscr{L}(\boldsymbol{\alpha}) = \prod_i f(x_i;\boldsymbol{\alpha})\ , \tag{28.5}$$

where $\mathscr{L}$ is called the likelihood. It is usually easier to work with $\ln\mathscr{L}$, and since both are maximized for the same set of $\boldsymbol{\alpha}$, it is sufficient to solve the *likelihood equation*

$$\frac{\partial \ln\mathscr{L}}{\partial\alpha_n} = 0\ . \tag{28.6}$$

When the solution to Eq. (28.6) is a maximum, it is called the *maximum likelihood estimate* of $\boldsymbol{\alpha}$. The importance of the approach is shown by the following proposition, proved in Ref. 3:

If an efficient estimate $\widehat{\boldsymbol{\alpha}}$ of $\boldsymbol{\alpha}$ exists, the likelihood equation will have a unique solution equal to $\widehat{\boldsymbol{\alpha}}$.

In evaluating $\mathscr{L}$, it is important that any normalization factors in the f's which involve $\boldsymbol{\alpha}$ be included. However, we will only be interested in the maximum of $\mathscr{L}$ and in ratios of $\mathscr{L}$ at different $\boldsymbol{\alpha}$'s; hence any multiplicative factors which do not involve the parameters we want to estimate may be dropped; this includes factors which depend on the data but not on $\boldsymbol{\alpha}$. The results of two or more independent experiments may be combined by forming the product of the $\mathscr{L}$'s, or the sum of the $\ln\mathscr{L}$'s.

Most commonly the solution to Eq. (28.6) will be found using a general numerical minimization program such as the CERN program MINUIT [10], which contains considerable code to take account of the many special cases and problems which can arise.

Under a one-to-one change of parameters from $\boldsymbol{\alpha}$ to $\boldsymbol{\beta} = \boldsymbol{\beta}(\boldsymbol{\alpha})$, the maximum likelihood estimate $\widehat{\boldsymbol{\alpha}}$ transforms to $\boldsymbol{\beta}(\widehat{\boldsymbol{\alpha}})$. That is, the maximum likelihood solution is invariant under change of parameter. However, many properties of $\widehat{\boldsymbol{\alpha}}$, in particular the bias, are not invariant under change of parameter.

28.3.2. ***Uses of $\mathscr{L}$: $\mathscr{L}(\alpha)$ is not a p.d.f. for α:***

Recall the definition of a probability *density* function: a function $p(\alpha)$ is a p.d.f. for α if $p(\alpha)d\alpha$ is the *probability* for α to be within α and $\alpha + d\alpha$. The likelihood function $\mathscr{L}(\alpha)$ is *not* a p.d.f. for α, so in general it is nonsensical to integrate the likelihood function with respect to its parameter(s).

Consider, for example, the Poisson probability for obtaining n when sampling from a distribution with mean α: $f(n;\alpha) = \alpha^n \exp(-\alpha)/n!$. If one obtains $n=3$ in a particular experiment, then $\mathscr{L}(\alpha) = \alpha^3\exp(-\alpha)/6$. Nothing in the construction of $\mathscr{L}$ makes it a probability *density*, *i.e.*, a function which one can multiply by $d\alpha$ in order to obtain a probability.

In Bayesian theory, one applies Bayes' Theorem to construct the posterior p.d.f. for α by multiplying the prior p.d.f. for α by $\mathscr{L}$:

$$p_{\text{posterior}}(\alpha) \propto \mathscr{L}(\alpha) \times p_{\text{prior}}(\alpha).$$

If the prior p.d.f. is uniform, integrating the posterior p.d.f. may give the appearance of integrating $\mathscr{L}$. But note that the prior p.d.f. crucially provides the *density* which makes it sensible to multiply by $d\alpha$ to obtain a probability. In non-Bayesian applications, such as those considered in the following subsections, only likelihood *ratios* are used (or equivalently, differences in $\ln\mathscr{L}$).

Because $\mathscr{L}$ is so useful, we strongly encourage publishing it (or enough information to allow the reader to reconstruct it), when practical.

28.3.3. ***Confidence intervals from the likelihood function:***

The covariance matrix V may be estimated from

$$V_{nm} = \left(E\left[-\frac{\partial^2\ln\mathscr{L}}{\partial\alpha_n\,\partial\alpha_m}\bigg|_{\widehat{\alpha}}\right]\right)^{-1}\ . \tag{28.7}$$

(Here and below, the superscript -1 indicates matrix inversion, followed by application of the subscripts.)

In the large sample case (or a linear model with Gaussian errors), $\mathscr{L}$ is Gaussian, $\ln\mathscr{L}$ is a (multidimensional) parabola, and the second derivative in Eq. (28.7) is constant, so the "expectation" operation has no effect. This leads to the usual approximation of calculating the error matrix of the parameters by inverting the second derivative matrix of $\ln\mathscr{L}$. In this asymptotic case, it can be seen that a numerically equivalent way of determining s-standard-deviation errors is from the contour given by the $\boldsymbol{\alpha}'$ such that

$$\ln\mathscr{L}(\boldsymbol{\alpha}') = \ln\mathscr{L}_{\max} - s^2/2\ , \tag{28.8}$$

where $\ln\mathscr{L}_{\max}$ is the value of $\ln\mathscr{L}$ at the solution point (compare with Eq. (28.32), below). The extreme limits of this contour parallel to the α_n axis give an approximate s-standard-deviation confidence interval in α_n. These intervals may not be symmetric and in pathological cases they may even consist of two or more disjoint intervals.

Although asymptotically Eq. (28.7) is equivalent to Eq. (28.8) with $s=1$, the latter is a better approximation when the model deviates from linearity. This is because Eq. (28.8) is invariant with respect to even a non-linear transformation of parameters $\boldsymbol{\alpha}$, whereas Eq. (28.7) is not. Still, when the model is non-linear or errors are not Gaussian, confidence intervals obtained with both these formulas are only approximate. The true coverage of these confidence intervals can always be determined by a Monte Carlo simulation, or exact confidence intervals can be determined as in Sec. 28.6.1.

28.3.4. ***Application to Poisson-distributed data:***

In the case of Poisson-distributed data in a counting experiment, the unbinned maximum likelihood method (where the index i in Eq. (28.5) labels events) is preferred if the total number of events is very small. (Sometimes it is "extended" to include the total number of events as a Poisson-distributed observable.) If there are enough events to justify binning them in a histogram, then one may alternatively maximize the likelihood function for the contents of the bins (so i labels bins). This is equivalent to minimizing [11]

$$\chi^2 = \sum_i \left[2(N_i^{\text{th}} - N_i^{\text{obs}}) + 2N_i^{\text{obs}}\ln(N_i^{\text{obs}}/N_i^{\text{th}})\right]. \tag{28.9}$$

where N_i^{obs} and N_i^{th} are the observed and theoretical (from f) contents of the ith bin. In bins where $N_i^{\text{obs}} = 0$, the second term is zero. This function asymptotically behaves like a classical χ^2 for purposes of point estimation, interval estimation, *and goodness-of-fit*. It also guarantees that the area under the fitted function f is equal to the sum of the histogram contents (as long as the overall normalization of f is effectively left unconstrained during the fit), which is not the case for χ^2 statistics based on a least-squares procedure with traditional weights.

28.4. Propagation of errors

Suppose that $F(x;\alpha)$ is some function of variable(s) x and the fitted parameters α, with a value $\widehat{F}$ at $\widehat{\alpha}$. The variance matrix of the parameters is V_{mn}. To first order in $\alpha_m - \widehat{\alpha}_m$, F is given by

$$F = \widehat{F} + \sum_m \frac{\partial F}{\partial \alpha_m}(\alpha_m - \widehat{\alpha}_m) , \tag{28.10}$$

and the variance of F about its estimator is given by

$$(\Delta F)^2 = E[(F - \widehat{F})^2] = \sum_{mn} \frac{\partial F}{\partial \alpha_m}\frac{\partial F}{\partial \alpha_n} V_{mn} , \tag{28.11}$$

evaluated at the x of interest. For different functions F_j and F_k, the covariance is

$$E[(F_j - \widehat{F}_j)(F_k - \widehat{F}_k)] = \sum_{mn} \frac{\partial F_j}{\partial \alpha_m}\frac{\partial F_k}{\partial \alpha_n} V_{mn} . \tag{28.12}$$

If the first-order approximation is in serious error, the above results may be very approximate. $\widehat{F}$ may be a biased estimator of F even if the $\widehat{\alpha}$ are unbiased estimators of α. Inclusion of higher-order terms or direct evaluation of F in the vicinity of $\widehat{\alpha}$ will help to reduce the bias.

28.5. Method of least squares

The *method of least squares* can be derived from the maximum likelihood theorem. We suppose a set of N measurements at points x_i. The ith measurement y_i is assumed to be chosen from a Gaussian distribution with mean $F(x_i;\alpha)$ and variance σ_i^2. Then

$$\chi^2 = -2\ln\mathscr{L} + \text{constant} = \sum_i \frac{[y_i - F(x_i;\alpha)]^2}{\sigma_i^2} . \tag{28.13}$$

Finding the set of parameters α which maximizes $\mathscr{L}$ is the same as finding the set which minimizes χ^2.

In many practical cases one further restricts the problem to the situation in which $F(x_i;\alpha)$ is a linear function of the α_m's,

$$F(x_i;\alpha) = \sum_n \alpha_n f_n(x_i) , \tag{28.14}$$

where the f_n are k linearly independent functions (*e.g.*, 1, x, x^2, ..., or Legendre polynomials) which are single-valued over the allowed range of x. We require $k \le N$, and at least k of the x_i must be distinct. We wish to estimate the linear coefficients α_n. Later we will discuss the nonlinear case.

If the point errors $\epsilon_i = y_i - F(x_i;\alpha)$ are Gaussian, then the minimum χ^2 will be distributed as a χ^2 random variable with $n = N - k$ degrees of freedom. We can then evaluate the goodness-of-fit (significance level) from Figs. 27.1 or 27.3, as per the earlier discussion. The significance level expresses the probability that a *worse* fit would be obtained in a large number of similar experiments under the assumptions that: (a) the model $y = \sum \alpha_n f_n$ is correct and (b) the errors ϵ_i are Gaussian and unbiased with variance σ_i^2. If this probability is larger than an agreed-upon value (0.001, 0.01, or 0.05 are common choices), the data are *consistent* with the assumptions; otherwise we may want to find improved assumptions. As for the converse, most people do not regard a model as being truly *inconsistent* unless the probability is as low as that corresponding to four or five standard deviations for a Gaussian (6×10^{-3} or 6×10^{-5}; see Sec. 28.6.2). If the ϵ_i are not Gaussian, the method of least squares still gives an answer, but the goodness-of-fit test would have to be done using the correct distribution of the random variable which is still called "χ^2."

Minimizing χ^2 in the linear case is straightforward:

$$-\frac{1}{2}\frac{\partial \chi^2}{\partial \alpha_m} = \sum_i f_m(x_i)\left(\frac{y_i - \sum_n \alpha_n f_n(x_i)}{\sigma_i^2}\right)$$

$$= \sum_i \frac{y_i\, f_m(x_i)}{\sigma_i^2} - \sum_n \alpha_n \sum_i \frac{f_n(x_i)\, f_m(x_i)}{\sigma_i^2} . \tag{28.15}$$

With the definitions

$$g_m = \sum_i y_i\, f_m(x_i)/\sigma_i^2 \tag{28.16}$$

and

$$V_{mn}^{-1} = \sum_i f_n(x_i)\, f_m(x_i)/\sigma_i^2 , \tag{28.17}$$

the k-element column vector of solutions $\widehat{\alpha}$, for which $\partial\chi^2/\partial\alpha_m = 0$ for all m, is given by

$$\widehat{\alpha} = V\, g . \tag{28.18}$$

With this notation, χ^2 for the special case of a linear fitting function (Eq. (28.14)) can be rewritten in the compact form

$$\chi^2 = \chi^2_{\rm min} + (\alpha - \widehat{\alpha})^T V^{-1}(\alpha - \widehat{\alpha}) . \tag{28.19}$$

Nonindependent y_i's

Eq. (28.13) is based on the assumption that the likelihood function is the product of independent Gaussian distributions. More generally, the measured y_i's are not independent, and we must consider them as coming from a multivariate distribution with nondiagonal covariance matrix S, as described in Sec. 27.3.3. The generalization of Eq. (28.13) is

$$\chi^2 = \sum_{jk} [y_j - F(x_j;\alpha)] S_{jk}^{-1} [y_k - F(x_k;\alpha)] . \tag{28.20}$$

In the case of a fitting function that is linear in the parameters, one may differentiate χ^2 to find the generalization of Eq. (28.15), and with the extended definitions

$$g_m = \sum_{jk} y_j\, f_m(x_k) S_{jk}^{-1}$$
$$V_{mn}^{-1} = \sum_{jk} f_n(x_j)\, f_m(x_k) S_{jk}^{-1} \tag{28.21}$$

solve Eq. (28.18) for the estimators $\widehat{\alpha}$.

The problem of constructing the covariance matrix S is simplified by the fact that contributions to S (not to its inverse) are additive. For example, suppose that we have three variables, all of which have independent statistical errors. The first two also have a common error resulting in a positive correlation, perhaps because a common baseline with its own statistical error (variance s^2) was subtracted from each. In addition, the second two have a common error (variance a^2), but this time the values are anticorrelated. This might happen, for example, if the sum of the two variables is a constant. Then

$$S = \begin{pmatrix} \sigma_1^2 & 0 & 0 \\ 0 & \sigma_2^2 & 0 \\ 0 & 0 & \sigma_3^2 \end{pmatrix} + \begin{pmatrix} s^2 & s^2 & 0 \\ s^2 & s^2 & 0 \\ 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & a^2 & -a^2 \\ 0 & -a^2 & a^2 \end{pmatrix} . \tag{28.22}$$

If unequal amounts of the common baseline were subtracted from variables 1, 2, and 3—*e.g.*, fractions f_1, f_2, and f_3, then we would have

$$S = \begin{pmatrix} \sigma_1^2 & 0 & 0 \\ 0 & \sigma_2^2 & 0 \\ 0 & 0 & \sigma_3^2 \end{pmatrix} + \begin{pmatrix} f_1^2 s^2 & f_1 f_2 s^2 & f_1 f_3 s^2 \\ f_1 f_2 s^2 & f_2^2 s^2 & f_2 f_3 s^2 \\ f_1 f_3 s^2 & f_2 f_3 s^2 & f_3^2 s^2 \end{pmatrix} . \tag{28.23}$$

While in general this "two-vector" representation is not possible, it underscores the procedure: Add zero-determinant correlation matrices to the matrix expressing the independent variation.

Care must be taken when fitting to correlated data, since off-diagonal contributions to χ^2 are not necessarily positive. It is even possible for all of the residuals to have the same sign.

Example: straight-line fit

For the case of a straight-line fit, $y(x) = \alpha_1 + \alpha_2 x$, one obtains, for independent measurements y_i, the following estimates of α_1 and α_2,

$$\widehat{\alpha}_1 = (g_1 \Lambda_{22} - g_2 \Lambda_{12})/D \ , \tag{28.24}$$

$$\widehat{\alpha}_2 = (g_2 \Lambda_{11} - g_1 \Lambda_{12})/D \ , \tag{28.25}$$

where

$$(\Lambda_{11}, \Lambda_{12}, \Lambda_{22}) = \sum(1,\, x_i,\, x_i^2)/\sigma_i^2 \ , \tag{28.26a}$$

$$(g_1, g_2) = \sum(1,\, x_i) y_i/\sigma_i^2 \ . \tag{28.26b}$$

respectively, and

$$D = \Lambda_{11}\Lambda_{22} - (\Lambda_{12})^2 \ . \tag{28.27}$$

The covariance matrix of the fitted parameters is:

$$\begin{pmatrix} V_{11} & V_{12} \\ V_{12} & V_{22} \end{pmatrix} = \frac{1}{D}\begin{pmatrix} \Lambda_{22} & -\Lambda_{12} \\ -\Lambda_{12} & \Lambda_{11} \end{pmatrix} \ . \tag{28.28}$$

The estimated variance of an interpolated or extrapolated value of y at point x is:

$$(\widehat{y} - y_{\text{true}})^2\Big|_{\text{est}} = \frac{1}{\Lambda_{11}} + \frac{\Lambda_{11}}{D}\left(x - \frac{\Lambda_{12}}{\Lambda_{11}}\right)^2 \ . \tag{28.29}$$

28.5.1. ***Confidence intervals from the chisquare function:***

If y is not linear in the fitting parameters $\boldsymbol{\alpha}$, the solution vector may have to be found by iteration. If we have a first guess $\boldsymbol{\alpha}_0$, then we may expand to obtain

$$\left.\frac{\partial\chi^2}{\partial\boldsymbol{\alpha}}\right|_{\boldsymbol{\alpha}} = \left.\frac{\partial\chi^2}{\partial\boldsymbol{\alpha}}\right|_{\boldsymbol{\alpha}_0} + V_{\boldsymbol{\alpha}_0}^{-1}\cdot(\boldsymbol{\alpha} - \boldsymbol{\alpha}_0) + \dots \ , \tag{28.30}$$

where $\partial\chi^2/\partial\boldsymbol{\alpha}$ is a vector whose mth component is $\partial\chi^2/\partial\alpha_m$, and $(V_{mn}^{-1}) = \frac{1}{2}\partial^2\chi^2/\partial\alpha_m\partial\alpha_n$. (See Eqns. 28.7 and 28.17. When evaluated at $\widehat{\boldsymbol{\alpha}}$, V^{-1} is the inverse of the covariance matrix.) The next iteration toward $\widehat{\boldsymbol{\alpha}}$ can be obtained by setting $\partial\chi^2/\partial\alpha_m|_{\boldsymbol{\alpha}} = 0$ and neglecting higher-order terms:

$$\boldsymbol{\alpha} = \boldsymbol{\alpha}_0 - V_{\boldsymbol{\alpha}_0}\cdot\partial\chi^2/\partial\boldsymbol{\alpha}|_{\boldsymbol{\alpha}_0} \ . \tag{28.31}$$

If V is constant in the vicinity of the minimum, as it is when the model function is linear in the parameters, then χ^2 is parabolic as a function of $\boldsymbol{\alpha}$ and Eq. (28.31) gives the solution immediately. Otherwise, further iteration is necessary. If the problem is highly nonlinear, considerable difficulty may be encountered. There may be secondary minima, and χ^2 may be decreasing at physical boundaries. Numerical methods have been devised to find such solutions without divergence [9,10]. In particular, the CERN program MINUIT [10] offers several iteration schemes for solving such problems.

Note that minimizing any function proportional to χ^2 (or maximizing any function proportional to $\ln\mathscr{L}$) will result in the same parameter set $\widehat{\boldsymbol{\alpha}}$. Hence, for example, if the variances σ_j^2 are known only up to a common constant, one can still solve for $\widehat{\boldsymbol{\alpha}}$. One cannot, however, evaluate goodness-of-fit, and the covariance matrix is known only to within the constant multiplier. The scale can be estimated at least roughly from the value of χ^2 compared to its expected value.

Additional information can be extracted from the behavior of the normalized residuals (known as "pulls"), $r_j = (y_j - F(x_j;\boldsymbol{\alpha})/\sigma_j$, which should themselves distribute normally with mean 0 and rms deviation 1.

If the data covariance matrix S has been correctly evaluated (or, equivalently, the σ_j's, if the data are independent), then the s-standard deviation limits on each of the parameters are given by a set $\boldsymbol{\alpha}'$ such that

$$\chi^2(\boldsymbol{\alpha}') = \chi^2_{\min} + s^2 \ . \tag{28.32}$$

This equation gives confidence intervals in the same sense as 28.8, and all the discussion of Sec. 28.3.3 applies as well here, substituting $-\chi^2/2$ for $\ln\mathscr{L}$.

28.6. Exact confidence intervals

The unqualified phrase "confidence intervals" refers to frequentist (also called classical) intervals obtained with a construction due to Neyman [12], described below. Approximate confidence intervals are obtained in classical statistics from likelihood *ratios* as described in the preceeding subsections. The validity of the approximation (in terms of coverage; see below) should be checked (typically by the Monte Carlo method) when in doubt, as is usually the case with small numbers of events.

Intervals in Bayesian statistics, usually called credible intervals or Bayesian confidence intervals, are obtained by integrating the posterior p.d.f. (based on a non-frequency definition of probability), and in many cases do not obey the defining properties of confidence intervals. Correspondingly, confidence intervals do not in general behave like credible intervals.

In the Bayesian framework, all uncertainty including systematic and theoretical uncertainties can be treated in a straightforward manner: one includes in the p.d.f. one's degree of belief about background estimates, luminosity, etc. Then one integrates out such "nuisance parameters." In the Frequentist approach, one should have exact coverage no matter what the value of the nuisance parameters, and this is not in general possible. If one performs a Bayesian-style integration over nuisance parameters while constructing nominally Frequentist intervals, then coverage must be checked.

28.6.1. ***Neyman's Construction of Confidence intervals:***

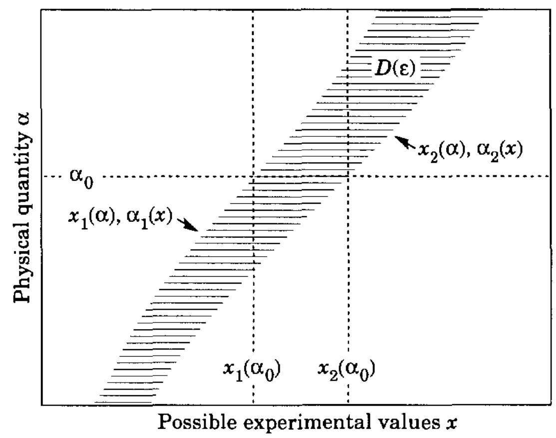

Figure 28.1: Confidence intervals for a single unknown parameter α. One might think of the p.d.f. $f(x;\alpha)$ as being plotted out of the paper as a function of x along each horizontal line of constant α. The domain $D(\varepsilon)$ contains a fraction $1-\varepsilon$ of the area under each of these functions.

We consider the parameter α whose true value is fixed but unknown. The properties of our experimental apparatus are expressed in the function $f(x;\alpha)$ which gives the probability of observing data x if the true value of the parameter is α. This function must be known in order to interpret the results of an experiment. For a large complex experiment, f is usually determined numerically using Monte Carlo simulation.

Given $f(x;\alpha)$, we can find for every value of α, two values $x_1(\alpha,\varepsilon)$ and $x_2(\alpha,\varepsilon)$ such that

$$P(x_1 < x < x_2;\alpha) \;=\; 1-\varepsilon \;=\; \int_{x_1}^{x_2} f(x;\alpha)\,dx \ . \tag{28.33}$$

This is shown graphically in Fig. 28.1: a horizontal line segment $[x_1(\alpha,\varepsilon), x_2(\alpha,\varepsilon)]$ is drawn for representative values of α. The union of all intervals $[x_1(\alpha,\varepsilon), x_2(\alpha,\varepsilon)]$, designated in the figure as the domain $D(\varepsilon)$, is known as the *confidence belt.* Typically the curves $x_1(\alpha,\varepsilon)$ and $x_2(\alpha,\varepsilon)$ are monotonic functions of α, which we assume for this discussion.

Upon performing an experiment to measure x and obtaining the value x_0, one draws a vertical line through x_0 on the horizontal axis.

The confidence interval for α is the union of all values of α for which the corresponding line segment $[x_1(\alpha,\varepsilon), x_2(\alpha,\varepsilon)]$ is intercepted by this vertical line. The confidence interval is an interval $[\alpha_1(x_0), \alpha_2(x_0)]$, where $\alpha_1(x_0)$ and $\alpha_2(x_0)$ are on the boundary of $D(\varepsilon)$. Thus, the boundaries of $D(\varepsilon)$ can be considered to be functions $x(\alpha)$ when constructing D, and then to be functions $\alpha(x)$ when reading off confidence intervals.

Such confidence intervals are said to have Confidence Level (CL) equal to $1-\varepsilon$.

Now suppose that some unknown particular value of α, say α_0 (indicated in the figure), is the true value of α. We see from the figure that α_0 lies between $\alpha_1(x)$ and $\alpha_2(x)$ if and only if x lies between $x_1(\alpha_0)$ and $x_2(\alpha_0)$. Thus we can write:

$$P[x_1(\alpha_0) < x < x_2(\alpha_0)] = 1 - \varepsilon = P[\alpha_2(x) < \alpha_0 < \alpha_1(x)] \ . \tag{28.34}$$

And since, by construction, this is true for any value α_0, we can drop the subscript 0 and obtain the relationship we wanted to establish for the probability that the confidence limits will contain the true value of α:

$$P[\alpha_2(x) < \alpha < \alpha_1(x)] = 1 - \varepsilon \ . \tag{28.35}$$

In this probability statement, α_1 and α_2 are the random variables (not α), and we can verify that the statement is true, as a limiting ratio of frequencies in random experiments, for any assumed value of α. In a particular real experiment, the numerical values α_1 and α_2 are determined by applying the algorithm to the real data, and the probability statement is (all too frequently) misinterpreted to be a statement about the true value α since this is the only unknown remaining in the equation. It should however be interpreted as the probability of obtaining values α_1 and α_2 which include the true value of α, in an ensemble of identical experiments. Any method which gives confidence intervals that contain the true value with probability $1-\varepsilon$ (no matter what the true value of α is) is said to have the correct *coverage*. The frequentist intervals as constructed above have the correct *coverage* by construction. Coverage is a critical property of confidence intervals [2]. (Power to exclude false values of α, related to the length of the intervals in a relevant measure, is also important.)

The condition of coverage Eq. (28.33) does not determine x_1 and x_2 uniquely, since any range which gives the desired value of the integral would give the same coverage. Additional criteria are thus needed. The most common criterion is to choose *central intervals* such that the area of the excluded tail on either side is $\varepsilon/2$. This criterion is sufficient in most cases, but there is a more general *ordering principle* which reduces to centrality in the usual cases and produces confidence intervals with better properties when in the neighborhood of a physical limit. This ordering, which consists of taking the interval which includes the largest values of a likelihood ratio, is briefly outlined in Ref. 3 and has been applied to prototypical problems by Feldman and Cousins [13].

For the problem of a counting rate experiment in the presence of background, Roe and Woodroofe [14] have proposed a modification to Ref. 13 incorporating *conditioning*, i.e., conditional probabilities computed using constraints on the number of background events actually observed. This and other prescriptions giving frequentist intervals have not yet been fully explored [5].

28.6.2. *Gaussian errors*:

If the data are such that the distribution of the estimator(s) satisfies the central limit theorem discussed in Sec. 27.3.3, the function $f(x;\alpha)$ is the Gaussian distribution. If there is more than one parameter being estimated, the multivariate Gaussian is used. For the univariate case with known σ,

$$1 - \varepsilon = \int_{\mu-\delta}^{\mu+\delta} e^{\frac{-(x-\mu)^2}{2\sigma^2}} \, dx = \mathrm{erf}\left(\frac{\delta}{\sqrt{2}\,\sigma}\right) \tag{28.36}$$

is the probability that the measured value x will fall within $\pm\delta$ of the true value μ. From the symmetry of the Gaussian with respect to x and μ, this is also the probability that the true value will be within $\pm\delta$ of the measured value. Fig. 28.2 shows a $\delta = 1.64\sigma$ confidence interval unshaded. The choice $\delta = \sqrt{\mathrm{Var}(\mu)} \equiv \sigma$ gives an interval called the ***standard error*** which has $1-\varepsilon = 68.27\%$ if σ is known. Confidence coefficients ε for other frequently used choices of δ are given in Table 28.1.

Table 28.1: Area of the tails ε outside $\pm\delta$ from the mean of a Gaussian distribution.

ε (%)	δ	ε (%)	δ
31.73	1σ	20	1.28σ
4.55	2σ	10	1.64σ
0.27	3σ	5	1.96σ
6.3×10^{-3}	4σ	1	2.58σ
5.7×10^{-5}	5σ	0.1	3.29σ
2.0×10^{-7}	6σ	0.01	3.89σ

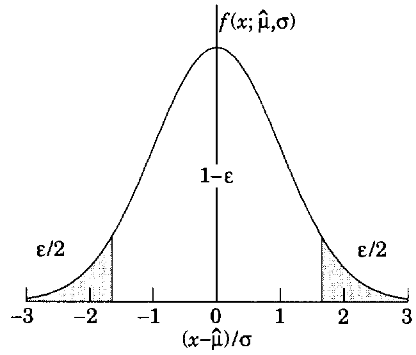

Figure 28.2: Illustration of a symmetric 90% confidence interval (unshaded) for a measurement of a single quantity with Gaussian errors. Integrated probabilities, defined by ε, are as shown.

For other δ, find ε as the ordinate of Fig. 27.1 on the $n=1$ curve at $\chi^2 = (\delta/\sigma)^2$. We can set a one-sided (upper or lower) limit by excluding above $\mu+\delta$ (or below $\mu-\delta$); ε's for such limits are 1/2 the values in Table 28.1.

For multivariate $\boldsymbol{\alpha}$ the scalar $\mathrm{Var}(\mu)$ becomes a full variance-covariance matrix. Assuming a multivariate Gaussian, Eq. (27.22), and subsequent discussion the standard error ellipse for the pair $(\widehat{\alpha}_m, \widehat{\alpha}_n)$ may be drawn as in Fig. 28.3.

The minimum χ^2 or maximum likelihood solution is at $(\widehat{\alpha}_m, \widehat{\alpha}_n)$. The standard errors σ_m and σ_n are defined as shown, where the ellipse is at a constant value of $\chi^2 = \chi^2_{\mathrm{min}} + 1$ or $\ln\mathscr{L} = \ln\mathscr{L}_{\mathrm{max}} - 1/2$. The angle of the major axis of the ellipse is given by

$$\tan 2\phi = \frac{2\rho_{mn}\,\sigma_m\,\sigma_n}{\sigma_m^2 - \sigma_n^2} \ . \tag{28.37}$$

For non-Gaussian or nonlinear cases, one may construct an analogous contour from the same χ^2 or $\ln\mathscr{L}$ relations. Any other parameters $\widehat{\alpha}_\ell, \ell \neq m,n$ must be allowed freely to find their optimum values for every trial point.

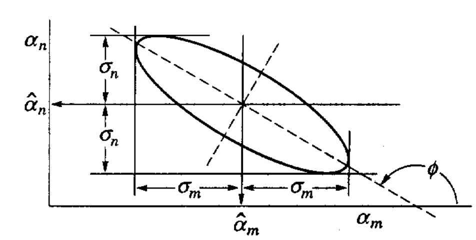

Figure 28.3: Standard error ellipse for the estimators $\widehat{\alpha}_m$ and $\widehat{\alpha}_n$. In this case the correlation is negative.

Table 28.2: $\Delta\chi^2$ corresponding to $(1-\varepsilon)$, for joint estimation of k parameters.

$(1-\varepsilon)$ (%)	$k=1$	$k=2$	$k=3$
68.27	1.00	2.30	3.53
90.	2.71	4.61	6.25
95.45	4.00	6.18	8.03
99.	6.63	9.21	11.34
99.73	9.00	11.83	14.16

For any unbiased procedure (*e.g.*, least squares or maximum likelihood) used to estimate k parameters α_i, $i = 1,\ldots,k$, the probability $1-\varepsilon$ that the true values of all k parameters lie within an ellipsoid bounded by a fixed value of $\Delta\chi^2 = \chi^2 - \chi^2_{\rm min}$ may be found from Fig. 27.1. This is because the *difference*, $\Delta\chi^2 = \chi^2 - \chi^2_{\rm min}$, obeys the "$\chi^2$" p.d.f. given in Table 27.1, if the parameter n in the formula is taken to be k (rather than degrees-of-freedom in the fit). In Fig. 27.1, read the ordinate as ε and the abscissa as $\Delta\chi^2$. The correct values of ε are on the $n = k$ curve. For $k > 1$, the values of ε for given $\Delta\chi^2$ are much greater than for $k = 1$. Hence, using $\Delta\chi^2 = s^2$, which gives s-standard-deviation errors on a single parameter (*irrespective of the other parameters*), is not appropriate for a multi-dimensional ellipsoid. For example, for $k = 2$, the probability $(1-\varepsilon)$ that the true values of α_1 and α_2 simultaneously lie within the one-standard-deviation error ellipse ($s = 1$), centered on $\widehat{\alpha}_1$ and $\widehat{\alpha}_2$, is only 39%.

Values of $\Delta\chi^2$ corresponding to commonly used values of ε and k are given in Table 28.2. These probabilities assume Gaussian errors, unbiased estimators, and that the model describing the data in terms of the α_i is correct. When these assumptions are not satisfied, a Monte Carlo simulation is typically performed to determine the relation between $\Delta\chi^2$ and ε.

28.6.3. *Upper limits and two-sided intervals*:

When a measured value is close to a physical boundary, it is natural to report a one-sided confidence interval (often an upper limit). It is straightforward to force the procedure of Sec. 28.6.1 to produce only an upper limit, by setting $x_2 = \infty$ in Eq. (28.33). Then x_1 is uniquely determined. Clearly this procedure will have the desired coverage, but *only if we always choose to set an upper limit.* In practice one might decide after seeing the data whether to set an upper limit or a two-sided limit. In this case the upper limits calculated by Eq. (28.33) will not give exact coverage, as has been noted in Ref. 13.

In order to correct this problem and assure coverage in all circumstances, it is necessary to adopt a *unified procedure*, that is, a single ordering principle which will provide coverage globally. Then it is the *ordering principle* which decides whether a one-sided or two-sided interval will be reported for any given set of data. The unified procedure and ordering principle which follows from the theory of likelihood-ratio tests [3] is described in Ref. 13. We reproduce below the main results.

28.6.4. *Gaussian data close to a boundary*:

One of the most controversial statistical questions in physics is how to report a measurement which is close to the edge or even outside of the allowed physical region. This is because there are several admissible possibilities depending on how the result is to be used or interpreted. Normally one or more of the following should be reported:

(a) The actual measurement should be reported, even if it is outside the physical region. As with any other measurement, it is best to report the value of a quantity which is nearly Gaussian distributed if possible. Thus one may choose to report mass squared rather than mass, or $\cos\theta$ rather than θ. For a complex quantity z close to zero, report Re(z) and Im(z) rather than amplitude and phase of z. Data carefully reported in this way can be unbiased, objective, easily interpreted and combined (averaged) with other data in a straightforward way, even if they lie partly or wholly outside the physical region. The reported error is a direct measure of the intrinsic accuracy of the result, which cannot always be inferred from the upper limits proposed below.

(b) If the data are to be used to make a decision, for example to determine the dimensions of a new experimental apparatus for an improved measurement, it may be appropriate to report a Bayesian upper limit, which must necessarily contain subjective belief about the possible values of the parameter, as well as containing information about the physical boundary. Its interpretation requires knowledge of the prior distribution which was necessarily used to obtain it.

(c) If it is desired to report an upper limit that has a well-defined meaning in terms of a limiting frequency, then report the Frequentist confidence bound(s) as given by the unified approach [3], [13]. This algorithm always gives a non-null interval (that is, the confidence limits are always inside the physical region, even for a measurement well outside the physical region), and still has correct global coverage. These confidence limits for a Gaussian measurement close to a non-physical boundary are summarized in Fig. 28.4. Additional tables are given in Ref. 13.

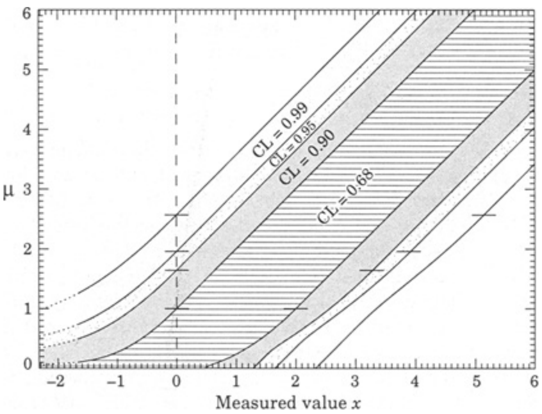

Figure 28.4: Plot of 99%, 95%, 90%, and 68.27% ("one σ") confidence intervals (using the unified approach as in Ref. 13) for a physical quantity μ based on a Gaussian measurement x (in units of standard deviations), for the case where the true value of μ cannot be negative. The curves become straight lines above the horizontal tick marks. The probability of obtaining an experimental value at least as negative as the left edge of the graph ($x = -2.33$) is less than 1%. Values of x more negative than -1.64 (dotted segments) are less than 5% probable, no matter what the true value of μ.

28.6.5. *Poisson data for small samples*:

When the observable is restricted to integer values (as in the case of Poisson and binomial distributions), it is not generally possible to construct confidence intervals with exact coverage for all values of α. In these cases the integral in Eq. (28.33) becomes a sum of finite contributions and it is no longer possible (in general) to find consecutive terms which add up exactly to the required confidence level $1-\varepsilon$ for all values of α. Thus one constructs intervals which happen to have exact coverage for a few values of α, and unavoidable over-coverage for all other values.

In addition to the problem posed by the discreteness of the data, we usually have to contend with possible background whose expectation must be evaluated separately and may not be known precisely. For these reasons, the reporting of this kind of data is even more controversial than the Gaussian data near a boundary as discussed above. This is especially true when the number of observed counts is greater than the expected background. As for the Gaussian case, there are at least three possibilities for reporting such results depending on how the result is to be used:

(a) The actual measurements should be reported, which means (1) the number of recorded counts, (2) the expected background, possibly with its error, and (3) normalization factor which turns the number of counts into a cross section, decay rate, *etc.* As with Gaussian data, these data can be combined with that of other experiments, to make improved upper limits for example.

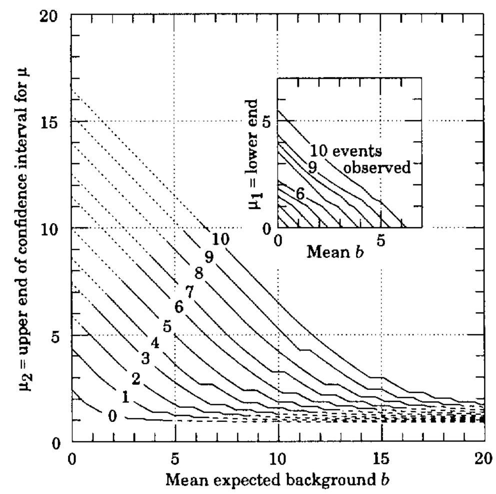

Figure 28.5: 90% confidence intervals $[\mu_1, \mu_2]$on the number of signal events as a function of the expected number of background events b. For example, if the expected background is 8 events and 5 events are observed, then the signal is 2.60 or less with 90% confidence. Dotted portions of the μ_2 curves on the upper left indicate regions where μ_1 is non-zero (as shown by the inset). Dashed portions in the lower right indicate regions where the probability of obtaining the number of events observed or fewer is less than 1%, even if $\mu = 0$. Horizontal curve sections occur because of discrete number statistics. Tables showing these data as well as the CL = 68.27%, 95%, and 99% results are given in Ref. 13. There is considerable discussion about the behavior of the intervals when the number of observed events is less than the expected background; see Ref. 5

(b) A Bayesian upper limit may be reported. This has the advantages and disadvantages of any Bayesian result as discussed above. The noninformative priors (based on invariance principles rather than subjective degree of belief) recommended in the statistics literature for Poisson mean are rarely, if at all, used in high energy physics; they diverge for the case of zero events observed, and they give upper limits which undercover when evaluated by the Frequentist criterion of coverage. Rather, priors uniform in the counting rate have been used by convention; care must be used in interpreting such results either as "degree of belief" or as a limiting frequency.

(c) An upper limit (or confidence region) with optimal coverage can be reported using the unified approach of Ref. 13. At the moment these confidence limits have been calculated only for the case of exactly known background expectation. The main results can be read from Fig. 28.5 or from Table 28.3; more extensive tables can be found in Ref. 13.

Table 28.3: Poisson limits $[\mu_1, \mu_2]$ for n_0 observed events in the absence of background.

	CI = 90%		CI = 95%	
n_0	μ_1	μ_2	μ_1	μ_2
0	0.00	2.44	0.00	3.09
1	0.11	4.36	0.05	5.14
2	0.53	5.91	0.36	6.72
3	1.10	7.42	0.82	8.25
4	1.47	8.60	1.37	9.76
5	1.84	9.99	1.84	11.26
6	2.21	11.47	2.21	12.75
7	3.56	12.53	2.58	13.81
8	3.96	13.99	2.94	15.29
9	4.36	15.30	4.36	16.77
10	5.50	16.50	4.75	17.82

None of the above gives a single number which quantifies the quality or sensitivity of the experiment. This is a serious shortcoming of most upper limits including those of method (c), since it is impossible to distinguish, from the upper limit alone, between a clean experiment with no background and a lucky experiment with fewer observed counts than expected background. For this reason, we suggest that in addition to (a) and (c) above, a measure of the sensitivity should be reported whenever expected background is larger or comparable to the number of observed counts. The best such measure we know of is that proposed and tabulated in Ref. 13, defined as the average upper limit that would be attained by an ensemble of experiments with the expected background and no true signal.

29. MONTE CARLO TECHNIQUES

Revised July 1995 by S. Youssef (SCRI, Florida State University). Updated February 2000 by R. Cousins (UCLA) in consultation with F. James (CERN).

Monte Carlo techniques are often the only practical way to evaluate difficult integrals or to sample random variables governed by complicated probability density functions. Here we describe an assortment of methods for sampling some commonly occurring probability density functions.

29.1. Sampling the uniform distribution

Most Monte Carlo sampling or integration techniques assume a "random number generator" which generates uniform statistically independent values on the half open interval $[0, 1)$. There is a long history of problems with various generators on a finite digital computer, but recently, the RANLUX generator [1] has emerged with a solid theoretical basis in chaos theory. Based on the method of Lüscher, it allows the user to select different quality levels, trading off quality with speed.

Other generators are also available which pass extensive batteries of tests for statistical independence and which have periods which are so long that, for practical purposes, values from these generators can be considered to be uniform and statistically independent. In particular, the lagged-Fibonacci based generator introduced by Marsaglia, Zaman, and Tsang [2] is efficient, has a period of approximately 10^{43}, produces identical sequences on a wide variety of computers and, passes the extensive "DIEHARD" battery of tests [3]. Many commonly available congruential generators fail these tests and often have sequences (typically with periods less than 2^{32}) which can be easily exhausted on modern computers and should therefore be avoided [4].

29.2. Inverse transform method

If the desired probability density function is $f(x)$ on the range $-\infty < x < \infty$, its cumulative distribution function (expressing the probability that $x \leq a$) is given by Eq. (27.1). If a is chosen with probability density $f(a)$, then the integrated probability up to point a, $F(a)$, is itself a random variable which will occur with uniform probability density on $[0, 1]$. If x can take on any value, and ignoring the endpoints, we can then find a unique x chosen from the p.d.f. $f(s)$ for a given u if we set

$$u = F(x) \ , \tag{29.1}$$

provided we can find an inverse of F, defined by

$$x = F^{-1}(u) \ . \tag{29.2}$$

This method is shown in Fig. 29.1a. It is most convenient when one can calculate by hand the inverse function of the indefinite integral of f. This is the case for some common functions $f(x)$ such as $\exp(x)$, $(1-x)^n$, and $1/(1+x^2)$ (Cauchy or Breit-Wigner), although it does not necessarily produce the fastest generator. CERNLIB contains routines to implement this method numerically, working from functions or histograms.

For a discrete distribution, $F(x)$ will have a discontinuous jump of size $f(x_k)$ at each allowed $x_k, k = 1, 2, \cdots$. Choose u from a uniform distribution on (0,1) as before. Find x_k such that

$$F(x_{k-1}) < u \leq F(x_k) \equiv \text{Prob}\,(x \leq x_k) = \sum_{i=1}^{k} f(x_i) \ ; \tag{29.3}$$

then x_k is the value we seek (note: $F(x_0) \equiv 0$). This algorithm is illustrated in Fig. 29.1b.

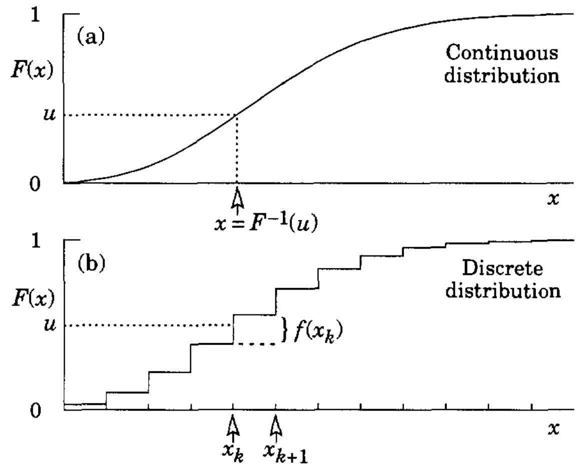

Figure 29.1: Use of a random number u chosen from a uniform distribution (0,1) to find a random number x from a distribution with cumulative distribution function $F(x)$.

29.3. Acceptance-rejection method (Von Neumann)

Very commonly an analytic form for $F(x)$ is unknown or too complex to work with, so that obtaining an inverse as in Eq. (29.2) is impractical. We suppose that for any given value of x the probability density function $f(x)$ can be computed and further that enough is known about $f(x)$ that we can enclose it entirely inside a shape which is C times an easily generated distribution $h(x)$ as illustrated in Fig. 29.2.

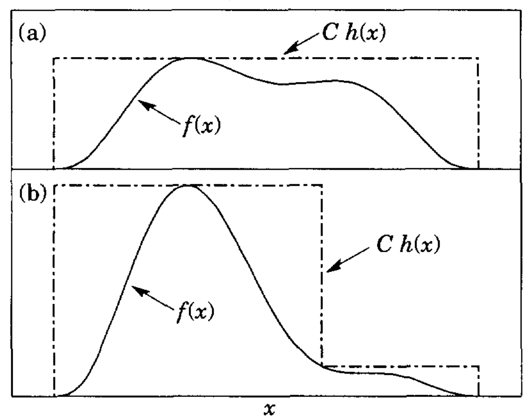

Figure 29.2: Illustration of the acceptance-rejection method. Random points are chosen inside the upper bounding figure, and rejected if the ordinate exceeds $f(x)$. Lower figure illustrates importance sampling.

Frequently $h(x)$ is uniform or is a normalized sum of uniform distributions. Note that both $f(x)$ and $h(x)$ must be normalized to unit area and therefore the proportionality constant $C > 1$. To generate $f(x)$, first generate a candidate x according to $h(x)$. Calculate $f(x)$ and the height of the envelope $C\,h(x)$; generate u and test if $uC\,h(x) \leq f(x)$. If so, accept x; if not reject x and try again. If we regard x and $uC\,h(x)$ as the abscissa and ordinate of a point in a two-dimensional plot, these points will populate the entire area $C\,h(x)$ in a smooth manner; then we accept those which fall under $f(x)$. The efficiency is the ratio of areas, which must equal $1/C$; therefore we must keep C as close as possible to 1.0. Therefore we try to choose $C\,h(x)$ to be as close to $f(x)$ as convenience dictates, as in the lower part of Fig. 29.2. This practice is called importance sampling, because we generate more trial values of x in the region where $f(x)$ is most important.

29.4. Algorithms

Algorithms for generating random numbers belonging to many different distributions are given by Press [5], Ahrens and Dieter [6], Rubinstein [7], Everett and Cashwell [8], Devroye [9], and Walck [10]. For many distributions alternative algorithms exist, varying in complexity, speed, and accuracy. For time-critical applications, these algorithms may be coded in-line to remove the significant overhead often encountered in making function calls. Variables named "u" are assumed to be independent and uniform on (0,1). (Hence, u must be verified to be non-zero where relevant.)

In the examples given below, we use the notation for the variables and parameters given in Table 27.1.

29.4.1. ***Exponential decay***:

This is a common application of the inverse transform method, also using the fact that $(1-u)$ is uniform if u is uniform. To generate decays between times t_1 and t_2 according to $f(t) = \exp(-t/\tau)$: let $r_2 = \exp(-t_2/\tau)$ and $r_1 = \exp(-t_1/\tau)$; generate u and let

$$t = -\tau \ln(r_2 + u(r_1 - r_2)). \tag{29.4}$$

For $(t_1, t_2) = (0, \infty)$, we have simply $t = -\tau \ln u$. (See also Sec. 29.4.6.)

29.4.2. ***Isotropic direction in 3D***:

Isotropy means the density is proportional to solid angle, the differential element of which is $d\Omega = d(\cos\theta)d\phi$. Hence $\cos\theta$ is uniform $(2u_1 - 1)$ and ϕ is uniform $(2\pi u_2)$. For alternative generation of $\sin\phi$ and $\cos\phi$, see the next subsection.

29.4.3. ***Sine and cosine of random angle in 2D***:

Generate u_1 and u_2. Then $v_1 = 2u_1 - 1$ is uniform on (−1,1), and $v_2 = u_2$ is uniform on (0,1). Calculate $r^2 = v_1^2 + v_2^2$. If $r^2 > 1$, start over. Otherwise, the sine (S) and cosine (C) of a random angle are given by

$$S = 2v_1v_2/r^2 \quad \text{and} \quad C = (v_1^2 - v_2^2)/r^2 \ . \tag{29.5}$$

29.4.4. ***Gaussian distribution***:

If u_1 and u_2 are uniform on (0,1), then

$$z_1 = \sin 2\pi u_1 \sqrt{-2\ln u_2} \quad \text{and} \quad z_2 = \cos 2\pi u_1 \sqrt{-2\ln u_2} \tag{29.6}$$

are independent and Gaussian distributed with mean 0 and $\sigma = 1$.

There are many faster variants of this basic algorithm. For example, construct $v_1 = 2u_1 - 1$ and $v_2 = 2u_2 - 1$, which are uniform on (−1,1). Calculate $r^2 = v_1^2 + v_2^2$, and if $r^2 > 1$ start over. If $r^2 < 1$, it is uniform on (0,1). Then

$$z_1 = v_1\sqrt{\frac{-2\ln r^2}{r^2}} \quad \text{and} \quad z_2 = v_2\sqrt{\frac{-2\ln r^2}{r^2}} \tag{29.7}$$

are independent numbers chosen from a normal distribution with mean 0 and variance 1. $z_i' = \mu + \sigma z_i$ distributes with mean μ and variance σ^2.

A recent implementation of the fast algorithm of Leva Ref. 11 is in CERNLIB.

For a multivariate Gaussian, see the algorithm in Ref. 12.

29.4.5. **$\chi^2(n)$ distribution**:

For n even, generate $n/2$ uniform numbers u_i; then

$$y = -2\ln\left(\prod_{i=1}^{n/2} u_i\right) \quad \text{is} \quad \chi^2(n) \ . \tag{29.8}$$

For n odd, generate $(n-1)/2$ uniform numbers u_i and one Gaussian z as in Sec. 29.4.4; then

$$y = -2\ln\left(\prod_{i=1}^{(n-1)/2} u_i\right) + z^2 \quad \text{is} \quad \chi^2(n) \ . \tag{29.9}$$

For $n \gtrsim 30$ the much faster Gaussian approximation for the χ^2 may be preferable: generate z as in Sec. 29.4.4 and use $y = \left[z + \sqrt{2n-1}\right]^2/2$; if $z < -\sqrt{2n-1}$ reject and start over.

29.4.6. ***Gamma distribution***:

All of the following algorithms are given for $\lambda = 1$. For $\lambda \neq 1$, divide the resulting random number x by λ.

- If $k = 1$ (the *exponential* distribution), accept $x = -(\ln u)$. (See also Sec. 29.4.1.)

- If $0 < k < 1$, initialize with $v_1 = (e + k)/e$ (with $e = 2.71828...$ being the natural log base). Generate u_1, u_2. Define $v_2 = v_1 u_1$.

  Case 1: $v_2 \le 1$. Define $x = v_2^{1/k}$. If $u_2 \le e^{-x}$, accept x and stop, else restart by generating new u_1, u_2.
  Case 2: $v_2 > 1$. Define $x = -\ln([v_1 - v_2]/k)$. If $u_2 \le x^{k-1}$, accept x and stop, else restart by generating new u_1, u_2. Note that, for $k < 1$, the probability density has a pole at $x = 0$, so that return values of zero due to underflow must be accepted or otherwise dealt with.

- Otherwise, if $k > 1$, initialize with $c = 3k - 0.75$. Generate u_1 and compute $v_1 = u_1(1 - u_1)$ and $v_2 = (u_1 - 0.5)\sqrt{c/v_1}$. If $x = k + v_2 - 1 \le 0$, go back and generate new u_1; otherwise generate u_2 and compute $v_3 = 64v_1^3u_2^2$. If $v_3 \le 1 - 2v_2^2/x$ **or** if $\ln v_3 \le 2\{[k-1]\ln[x/(k-1)] - v_2\}$, accept x and stop; otherwise go back and generate new u_1.

29.4.7. ***Binomial distribution***:

If $p \le 1/2$, iterate until a successful choice is made: begin with $k = 1$; compute $P_k = q^n$ [for $k \neq 1$ use $P_k \equiv f(r_k; n, p)$, and store P_k into B; generate u. If $u \le B$ accept $r_k = k - 1$ and stop; otherwise increment k by 1 and compute next P_k and add to B; generate a new u and repeat. If we arrive at $k = n + 1$, stop and accept $r_{n+1} = n$. If $p > 1/2$ it will be more efficient to generate r from $f(r; n, q)$, *i.e.*, with p and q interchanged, and then set $r_k = n - r$.

29.4.8. ***Poisson distribution***:

Iterate until a successful choice is made: Begin with $k = 1$ and set $A = 1$ to start. Generate u. Replace A with uA; if now $A < \exp(-\mu)$, where μ is the Poisson parameter, accept $n_k = k - 1$ and stop. Otherwise increment k by 1, generate a new u and repeat, always starting with the value of A left from the previous try. For large $\mu(\gtrsim 10)$ it may be satisfactory (and much faster) to approximate the Poisson distribution by a Gaussian distribution (see our Probability chapter, Sec. 27.3.3) and generate z from $f(z;0,1)$; then accept $x = \max(0, [\mu + z\sqrt{\mu} + 0.5])$ where [ ] signifies the greatest integer $\le$ the expression. [13]

29.4.9. ***Student's t* distribution**:

For $n > 0$ degrees of freedom (n not necessarily integer), generate x from a Gaussian with mean 0 and $\sigma^2 = 1$ according to the method of 29.4.4. Next generate y, an independent gamma random variate with $k = n/2$ degrees of freedom. Then $z = x\sqrt{2n}/\sqrt{y}$ is distributed as a t with n degrees of freedom.

For the special case $n = 1$, the Breit-Wigner distribution, generate u_1 and u_2; set $v_1 = 2u_1 - 1$ and $v_2 = 2u_2 - 1$. If $v_1^2 + v_2^2 \le 1$ accept $z = v_1/v_2$ as a Breit-Wigner distribution with unit area, center at 0.0, and FWHM 2.0. Otherwise start over. For center M_0 and FWHM Γ, use $W = z\Gamma/2 + M_0$.

30. MONTE CARLO PARTICLE NUMBERING SCHEME

Revised April 2000 by L. Garren (Fermilab), I.G. Knowles (Edinburgh U.), T. Sjöstrand (Lund U.), and T. Trippe (LBNL).

The Monte Carlo particle numbering scheme presented here is intended to facilitate interfacing between event generators, detector simulators, and analysis packages used in particle physics. The numbering scheme was introduced in 1988 [1] and a revised version [2,3] was adopted in 1998 in order to allow systematic inclusion of quark model states which are as yet undiscovered and hypothetical particles such as SUSY particles. The numbering scheme is used in several event generators, *e.g.* HERWIG and PYTHIA/JETSET, and in the /HEPEVT/ [4] standard interface.

The general form is a 7–digit number:

$$\pm n\, n_r\, n_L\, n_{q_1}\, n_{q_2}\, n_{q_3}\, n_J\ .$$

This encodes information about the particle's spin, flavor content, and internal quantum numbers. The details are as follows:

1. Particles are given positive numbers, antiparticles negative numbers. The PDG convention for mesons is used, so that K^+ and B^+ are particles.
2. Quarks and leptons are numbered consecutively starting from 1 and 11 respectively; to do this they are first ordered by family and within families by weak isospin.
3. In composite quark systems (diquarks, mesons, and baryons) $n_{q_{1-3}}$ are quark numbers used to specify the quark content, while the rightmost digit $n_J = 2J + 1$ gives the system's spin (except for the K^0_S and K^0_L). The scheme does not cover particles of spin $J > 4$.
4. Diquarks have 4-digit numbers with $n_{q_1} \geq n_{q_2}$ and $n_{q_3} = 0$.
5. The numbering of mesons is guided by the nonrelativistic (L–S decoupled) quark model, as listed in Table 13.2.
   a. The numbers specifying the meson's quark content conform to the convention $n_{q_1} = 0$ and $n_{q_2} \geq n_{q_3}$. The special case K^0_L is the sole exception to this rule.
   b. The quark numbers of flavorless, light (u, d, s) mesons are: 11 for the member of the isotriplet $(\pi^0, \rho^0, \ldots)$, 22 for the lighter isosinglet $(\eta, \omega, \ldots)$, and 33 for the heavier isosinglet $(\eta', \phi, \ldots)$. Since isosinglet mesons are often large mixtures of $u\overline{u} + d\overline{d}$ and $s\overline{s}$ states, 22 and 33 are assigned by mass and do not necessarily specify the dominant quark composition.
   c. The special numbers 310 and 130 are given to the K^0_S and K^0_L respectively.
   d. The fifth digit n_L is reserved to distinguish mesons of the same total (J) but different spin (S) and orbital (L) angular momentum quantum numbers. For $J > 0$ the numbers are: $(L, S) = (J-1, 1)$ $n_L = 0$, $(J, 0)$ $n_L = 1$, $(J, 1)$ $n_L = 2$ and $(J+1, 1)$ $n_L = 3$. For the exceptional case $J = 0$ the numbers are $(0, 0)$ $n_L = 0$ and $(1, 1)$ $n_L = 1$ (*i.e.* $n_L = L$). See Table 30.1.

Table 30.1: Meson numbering logic. Here qq stands for $n_{q2}\, n_{q3}$.

	$L = J-1,\ S = 1$			$L = J,\ S = 0$			$L = J,\ S = 1$			$L = J+1,\ S = 1$		
J	code	J^{PC}	L	code	J^{PC}	L	code	J^{PC}	L	code	J^{PC}	L
0	—	—	—	00qq1	0^{-+}	0	—	—	—	10qq1	0^{++}	1
1	00qq3	1^{--}	0	10qq3	1^{+-}	1	20qq3	1^{++}	1	30qq3	1^{--}	2
2	00qq5	2^{++}	1	10qq5	2^{-+}	2	20qq5	2^{--}	2	30qq5	2^{++}	3
3	00qq7	3^{--}	2	10qq7	3^{+-}	3	20qq7	3^{++}	3	30qq7	3^{--}	4
4	00qq9	4^{++}	3	10qq9	4^{-+}	4	20qq9	4^{--}	4	30qq9	4^{++}	5

   e. If a set of physical mesons correspond to a (non-negligible) mixture of basis states, differing in their internal quantum numbers, then the lightest physical state gets the smallest basis state number. For example the $K_1(1270)$ is numbered 10313 (1^1P_1 K_{1B}) and the $K_1(1400)$ is numbered 20313 (1^3P_1 K_{1A}).
   f. The sixth digit n_r is used to label mesons radially excited above the ground state.
   g. Numbers have been assigned for complete $n_r = 0$ S- and P-wave multiplets, even where states remain to be identified.
   h. In some instances assignments within the $q\overline{q}$ meson model are only tentative; here best guess assignments are made.
   i. Many states appearing in the Meson Listings are not yet assigned within the $q\overline{q}$ model. Here $n_{q_{2-3}}$ and n_J are assigned according to the state's likely flavors and spin; all such unassigned light isoscalar states are given the flavor code 22. Within these groups $n_L = 0, 1, 2, \ldots$ is used to distinguish states of increasing mass. These states are flagged using $n = 9$. It is to be expected that these numbers will evolve as the nature of the states are elucidated.
6. The numbering of baryons is again guided by the nonrelativistic quark model, see Table 13.4.
   a. The numbers specifying a baryon's quark content are such that in general $n_{q_1} \geq n_{q_2} \geq n_{q_3}$.
   b. Two states exist for $J = 1/2$ baryons containing 3 different types of quarks. In the lighter baryon $(\Lambda, \Xi, \Omega, \ldots)$ the light quarks are in an antisymmetric ($J = 0$) state while for the heavier baryon $(\Sigma^0, \Xi', \Omega', \ldots)$ they are in a symmetric ($J = 1$) state. In this situation n_{q_2} and n_{q_3} are reversed for the lighter state, so that the smaller number corresponds to the lighter baryon.
   c. At present most Monte Carlos do not include excited baryons and no systematic scheme has been developed to denote them, though one is foreseen. In the meantime, use of the PDG 96 [5] numbers for excited baryons is recommended.
7. The gluon, when considered as a gauge boson, has official number 21. In codes for glueballs, however, 9 is used to allow a notation in close analogy with that of hadrons.
8. The pomeron and odderon trajectories and a generic reggeon trajectory of states in QCD are assigned codes 990, 9990, and 110 respectively, where the final 0 indicates the indeterminate nature of the spin, and the other digits reflect the expected "valence" flavor content. We do not attempt a complete classification of all reggeon trajectories, since there is currently no need to distinguish a specific such trajectory from its lowest-lying member.
9. Two-digit numbers in the range 21–30 are provided for the Standard Model gauge bosons and Higgs.
10. Codes 81–100 are reserved for generator-specific pseudoparticles and concepts.
11. The search for physics beyond the Standard Model is an active area, so these codes are also standardized as far as possible.
    a. A standard fourth generation of fermions is included by analogy with the first three.
    b. The graviton and the boson content of a two-Higgs-doublet scenario and of additional SU(2)×U(1) groups are found in the range 31–40.
    c. "One-of-a-kind" exotic particles are assigned numbers in the range 41–80.
    d. Fundamental supersymmetric particles are identified by adding a nonzero n to the particle number. The superpartner of a boson or a left-handed fermion has $n = 1$ while the superpartner of a right-handed fermion has $n = 2$. When mixing occurs, such as between the winos and charged Higgsinos to give charginos, or between left and right sfermions, the lighter physical state is given the smaller basis state number.
    e. Technicolor states have $n = 3$. In the absence of a unique theory we only number generic states whose digits reflect the techniquark content.
    f. Excited (composite) quarks and leptons are identified by setting $n = 4$.
12. Occasionally program authors add their own states. To avoid confusion, these should be flagged by setting $nn_r = 99$.
13. Concerning the non-99 numbers, it may be noted that only quarks, excited quarks, squarks, and diquarks have $n_{q_3} = 0$;

only diquarks, baryons, and the odderon have $n_{q_1} \neq 0$; and only mesons, the reggeon, and the pomeron have $n_{q_1} = 0$ and $n_{q_2} \neq 0$. Concerning mesons (not antimesons), if n_{q_1} is odd then it labels a quark and an antiquark if even.

This text and lists of particle numbers can be found on the WWW [6]. The StdHep Monte Carlo standardization project [7] maintains the list of PDG particle numbers, as well as numbering schemes from most event generators and software to convert between the different schemes.

Figure 31.1: The sign convention is that of Wigner (*Group Theory*, Academic Press, New York, 1959), also used by Condon and Shortley (*The Theory of Atomic Spectra*, Cambridge Univ. Press, New York, 1953), Rose (*Elementary Theory of Angular Momentum*, Wiley, New York, 1957), and Cohen (*Tables of the Clebsch-Gordan Coefficients*, North American Rockwell Science Center, Thousand Oaks, Calif., 1974). The coefficients here have been calculated using computer programs written independently by Cohen and at LBNL.

32. SU(3) ISOSCALAR FACTORS AND REPRESENTATION MATRICES

Written by R.L. Kelly (LBNL).

The most commonly used SU(3) isoscalar factors, corresponding to the singlet, octet, and decuplet content of $8 \otimes 8$ and $10 \otimes 8$, are shown at the right. The notation uses particle names to identify the coefficients, so that the pattern of relative couplings may be seen at a glance. We illustrate the use of the coefficients below. See J.J de Swart, Rev. Mod. Phys. **35**, 916 (1963) for detailed explanations and phase conventions.

A $\sqrt{\ }$ is to be understood over every integer in the matrices; the exponent 1/2 on each matrix is a reminder of this. For example, the $\Xi \to \Omega K$ element of the $10 \to 10 \otimes 8$ matrix is $-\sqrt{6}/\sqrt{24} = -1/2$.

Intramultiplet relative decay strengths may be read directly from the matrices. For example, in decuplet → octet + octet decays, the ratio of $\Omega^* \to \Xi\overline{K}$ and $\Delta \to N\pi$ partial widths is, from the $10 \to 8 \times 8$ matrix,

$$\frac{\Gamma(\Omega^* \to \Xi\overline{K})}{\Gamma(\Delta \to N\pi)} = \frac{12}{6} \times \text{(phase space factors)} . \tag{32.1}$$

Including isospin Clebsch-Gordan coefficients, we obtain, *e.g.*,

$$\frac{\Gamma(\Omega^{*-} \to \Xi^0 K^-)}{\Gamma(\Delta^+ \to p\pi^0)} = \frac{1/2}{2/3} \times \frac{12}{6} \times p.s.f. = \frac{3}{2} \times p.s.f. \tag{32.2}$$

Partial widths for $8 \to 8 \otimes 8$ involve a linear superposition of 8_1 (symmetric) and 8_2 (antisymmetric) couplings. For example,

$$\Gamma(\Xi^* \to \Xi\pi) \sim \left(-\sqrt{\frac{9}{20}}\, g_1 + \sqrt{\frac{3}{12}}\, g_2\right)^2 . \tag{32.3}$$

The relations between g_1 and g_2 (with de Swart's normalization) and the standard D and F couplings that appear in the interaction Lagrangian,

$$\mathscr{L} = -\sqrt{2}\, D\, Tr\,(\{\overline{B}, B\}M) + \sqrt{2}\, F\, Tr\,([\overline{B}, B]\, M) , \tag{32.4}$$

where $[\overline{B}, B] \equiv \overline{B}B - B\overline{B}$ and $\{\overline{B}, B\} \equiv \overline{B}B + B\overline{B}$, are

$$D = \frac{\sqrt{30}}{40}\, g_1 , \qquad F = \frac{\sqrt{6}}{24}\, g_2 . \tag{32.5}$$

Thus, for example,

$$\Gamma(\Xi^* \to \Xi\pi) \sim (F - D)^2 \sim (1 - 2\alpha)^2 , \tag{32.6}$$

where $\alpha \equiv F/(D + F)$. (This definition of α is de Swart's. The alternative $D/(D + F)$, due to Gell-Mann, is also used.)

The generators of SU(3) transformations, λ_a $(a = 1, 8)$, are 3×3 matrices that obey the following commutation and anticommutation relationships:

$$[\lambda_a, \lambda_b] \equiv \lambda_a\lambda_b - \lambda_b\lambda_a = 2i f_{abc}\lambda_c \tag{32.7}$$

$$\{\lambda_a, \lambda_b\} \equiv \lambda_a\lambda_b + \lambda_b\lambda_a = \frac{4}{3}\delta_{ab} I + 2 d_{abc}\lambda_c \,, . \tag{32.8}$$

where I is the 3×3 identity matrix, and δ_{ab} is the Kronecker delta symbol. The f_{abc} are odd under the permutation of any pair of indices, while the d_{abc} are even. The nonzero values are

$1 \to 8 \otimes 8$

$$(\Lambda) \to (N\overline{K}\ \ \Sigma\pi\ \ \Lambda\eta\ \ \Xi K) = \frac{1}{\sqrt{8}}\,(2\ \ 3\ \ -1\ \ -2)^{1/2}$$

$8_1 \to 8 \otimes 8$

$$\begin{pmatrix} N \\ \Sigma \\ \Lambda \\ \Xi \end{pmatrix} \to \begin{pmatrix} N\pi\ \ N\eta\ \ \Sigma K\ \ \Lambda K \\ N\overline{K}\ \ \Sigma\pi\ \ \Lambda\pi\ \ \Sigma\eta\ \ \Xi K \\ N\overline{K}\ \ \Sigma\pi\ \ \Lambda\eta\ \ \Xi K \\ \Sigma\overline{K}\ \ \Lambda\overline{K}\ \ \Xi\pi\ \ \Xi\eta \end{pmatrix} = \frac{1}{\sqrt{20}} \begin{pmatrix} 9 & -1 & -9 & -1 & \\ -6 & 0 & 4 & 4 & -6 \\ 2 & -12 & -4 & -2 & \\ 9 & -1 & -9 & -1 & \end{pmatrix}^{1/2}$$

$8_2 \to 8 \otimes 8$

$$\begin{pmatrix} N \\ \Sigma \\ \Lambda \\ \Xi \end{pmatrix} \to \begin{pmatrix} N\pi\ \ N\eta\ \ \Sigma K\ \ \Lambda K \\ N\overline{K}\ \ \Sigma\pi\ \ \Lambda\pi\ \ \Sigma\eta\ \ \Xi K \\ N\overline{K}\ \ \Sigma\pi\ \ \Lambda\eta\ \ \Xi K \\ \Sigma\overline{K}\ \ \Lambda\overline{K}\ \ \Xi\pi\ \ \Xi\eta \end{pmatrix} = \frac{1}{\sqrt{12}} \begin{pmatrix} 3 & 3 & 3 & -3 & \\ 2 & 8 & 0 & 0 & -2 \\ 6 & 0 & 0 & 6 & \\ 3 & 3 & 3 & -3 & \end{pmatrix}^{1/2}$$

$10 \to 8 \otimes 8$

$$\begin{pmatrix} \Delta \\ \Sigma \\ \Xi \\ \Omega \end{pmatrix} \to \begin{pmatrix} N\pi\ \ \Sigma K \\ N\overline{K}\ \ \Sigma\pi\ \ \Lambda\pi\ \ \Sigma\eta\ \ \Xi K \\ \Sigma\overline{K}\ \ \Lambda\overline{K}\ \ \Xi\pi\ \ \Xi\eta \\ \Xi\overline{K} \end{pmatrix} = \frac{1}{\sqrt{12}} \begin{pmatrix} -6 & 6 & & & \\ -2 & 2 & -3 & 3 & 2 \\ 3 & -3 & 3 & 3 & \\ 12 & & & & \end{pmatrix}^{1/2}$$

$8 \to 10 \otimes 8$

$$\begin{pmatrix} N \\ \Sigma \\ \Lambda \\ \Xi \end{pmatrix} \to \begin{pmatrix} \Delta\pi\ \ \Sigma K \\ \Delta\overline{K}\ \ \Sigma\pi\ \ \Sigma\eta\ \ \Xi K \\ \Sigma\pi\ \ \Xi K \\ \Sigma\overline{K}\ \ \Xi\pi\ \ \Xi\eta\ \ \Omega K \end{pmatrix} = \frac{1}{\sqrt{15}} \begin{pmatrix} -12 & 3 & & \\ 8 & -2 & -3 & 2 \\ -9 & 6 & & \\ 3 & -3 & -3 & 6 \end{pmatrix}^{1/2}$$

$10 \to 10 \otimes 8$

$$\begin{pmatrix} \Delta \\ \Sigma \\ \Xi \\ \Omega \end{pmatrix} \to \begin{pmatrix} \Delta\pi\ \ \Delta\eta\ \ \Sigma K \\ \Delta\overline{K}\ \ \Sigma\pi\ \ \Sigma\eta\ \ \Xi K \\ \Sigma\overline{K}\ \ \Xi\pi\ \ \Xi\eta\ \ \Omega K \\ \Xi\overline{K}\ \ \Omega\eta \end{pmatrix} = \frac{1}{\sqrt{24}} \begin{pmatrix} 15 & 3 & -6 & \\ 8 & 8 & 0 & -8 \\ 12 & 3 & -3 & -6 \\ 12 & -12 & & \end{pmatrix}^{1/2}$$

abc	f_{abc}	abc	d_{abc}	abc	d_{abc}
123	1	118	$1/\sqrt{3}$	355	$1/2$
147	$1/2$	146	$1/2$	366	$-1/2$
156	$-1/2$	157	$1/2$	377	$-1/2$
246	$1/2$	228	$1/\sqrt{3}$	448	$-1/(2\sqrt{3})$
257	$1/2$	247	$-1/2$	558	$-1/(2\sqrt{3})$
345	$1/2$	256	$1/2$	668	$-1/(2\sqrt{3})$
367	$-1/2$	338	$1/\sqrt{3}$	778	$-1/(2\sqrt{3})$
458	$\sqrt{3}/2$	344	$1/2$	888	$-1/\sqrt{3}$
678	$\sqrt{3}/2$				

The λ_a's are

$$\lambda_1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda_2 = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$\lambda_4 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix} \quad \lambda_5 = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix} \quad \lambda_6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

$$\lambda_7 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix} \quad \lambda_8 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}$$

Equation (32.7) defines the Lie algebra of SU(3). A general d-dimensional representation is given by a set of $d \times d$ matrices satisfying Eq. (32.7) with the f_{abc} given above. Equation (32.8) is specific to the defining 3-dimensional representation.

33. SU(n) MULTIPLETS AND YOUNG DIAGRAMS

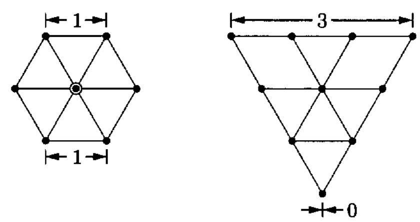
Written by C.G. Wohl (LBNL).

This note tells (1) how SU(n) particle multiplets are identified or labeled, (2) how to find the number of particles in a multiplet from its label, (3) how to draw the Young diagram for a multiplet, and (4) how to use Young diagrams to determine the overall multiplet structure of a composite system, such as a 3-quark or a meson-baryon system.

In much of the literature, the word "representation" is used where we use "multiplet," and "tableau" is used where we use "diagram."

33.1. Multiplet labels

An SU(n) multiplet is uniquely identified by a string of $(n-1)$ nonnegative integers: $(\alpha, \beta, \gamma, \ldots)$. Any such set of integers specifies a multiplet. For an SU(2) multiplet such as an isospin multiplet, the single integer α is the number of ***steps*** from one end of the multiplet to the other (*i.e.*, it is one fewer than the number of particles in the multiplet). In SU(3), the two integers α and β are the numbers of steps across the top and bottom levels of the multiplet diagram. Thus the labels for the SU(3) octet and decuplet



are (1,1) and (3,0). For larger n, the interpretation of the integers in terms of the geometry of the multiplets, which exist in an $(n-1)$-dimensional space, is not so readily apparent.

The label for the SU(n) singlet is $(0, 0, \ldots, 0)$. In a flavor SU(n), the n quarks together form a $(1, 0, \ldots, 0)$ multiplet, and the n antiquarks belong to a $(0, \ldots, 0, 1)$ multiplet. These two multiplets are *conjugate* to one another, which means their labels are related by $(\alpha, \beta, \ldots) \leftrightarrow (\ldots, \beta, \alpha)$.

33.2. Number of particles

The number of particles in a multiplet, $N = N(\alpha, \beta, \ldots)$, is given as follows (note the pattern of the equations).

In SU(2), $N = N(\alpha)$ is

$$N = \frac{(\alpha + 1)}{1} \,. \tag{33.1}$$

In SU(3), $N = N(\alpha, \beta)$ is

$$N = \frac{(\alpha + 1)}{1} \cdot \frac{(\beta + 1)}{1} \cdot \frac{(\alpha + \beta + 2)}{2} \,. \tag{33.2}$$

In SU(4), $N = N(\alpha, \beta, \gamma)$ is

$$N = \frac{(\alpha{+}1)}{1} \cdot \frac{(\beta{+}1)}{1} \cdot \frac{(\gamma{+}1)}{1} \cdot \frac{(\alpha{+}\beta{+}2)}{2} \cdot \frac{(\beta{+}\gamma{+}2)}{2} \cdot \frac{(\alpha{+}\beta{+}\gamma{+}3)}{3} \,. \tag{33.3}$$

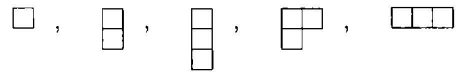
Note that in Eq. (33.3) there is no factor with $(\alpha + \gamma + 2)$: only a ***consecutive*** sequence of the label integers appears in any factor. One more example should make the pattern clear for any SU(n). In SU(5), $N = N(\alpha, \beta, \gamma, \delta)$ is

$$N = \frac{(\alpha{+}1)}{1} \cdot \frac{(\beta{+}1)}{1} \cdot \frac{(\gamma{+}1)}{1} \cdot \frac{(\delta{+}1)}{1} \cdot \frac{(\alpha{+}\beta{+}2)}{2} \cdot \frac{(\beta{+}\gamma{+}2)}{2} \times \frac{(\gamma{+}\delta{+}2)}{2} \cdot \frac{(\alpha{+}\beta{+}\gamma{+}3)}{3} \cdot \frac{(\beta{+}\gamma{+}\delta{+}3)}{3} \cdot \frac{(\alpha{+}\beta{+}\gamma{+}\delta{+}4)}{4} \tag{33.4}$$

From the symmetry of these equations, it is clear that multiplets that are conjugate to one another have the same number of particles, but so can other multiplets. For example, the SU(4) multiplets (3,0,0) and (1,1,0) each have 20 particles. Try the equations and see.

33.3. Young diagrams

A Young diagram consists of an array of boxes (or some other symbol) arranged in one or more *left-justified* rows, with each row being *at least as long* as the row beneath. The correspondence between a diagram and a multiplet label is: The top row juts out α boxes to the right past the end of the second row, the second row juts out β boxes to the right past the end of the third row, *etc.* A diagram in SU(n) has at most n rows. There can be any number of "completed" columns of n boxes buttressing the left of a diagram; these don't affect the label. Thus in SU(3) the diagrams



represent the multiplets (1,0), (0,1), (0,0), (1,1), and (3,0). In any SU(n), the quark multiplet is represented by a single box, the antiquark multiplet by a column of $(n-1)$ boxes, and a singlet by a completed column of n boxes.

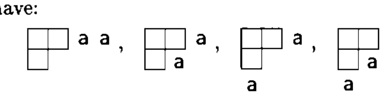
33.4. Coupling multiplets together

The following recipe tells how to find the multiplets that occur in coupling two multiplets together. To couple together more than two multiplets, first couple two, then couple a third with each of the multiplets obtained from the first two, *etc.*

First a definition: A sequence of the letters $a, b, c, \ldots$ is ***admissible*** if at any point in the sequence at least as many a's have occurred as b's, at least as many b's have occurred as c's, *etc.* Thus *abcd* and *aabcb* are admissible sequences and *abb* and *acb* are not. Now the recipe:

(a) Draw the Young diagrams for the two multiplets, but in one of the diagrams replace the boxes in the first row with a's, the boxes in the second row with b's, *etc.* Thus, to couple two SU(3) octets (such as the π-meson octet and the baryon octet), we start with  and a a / b. The *unlettered* diagram forms the *upper left-hand corner* of all the enlarged diagrams constructed below.

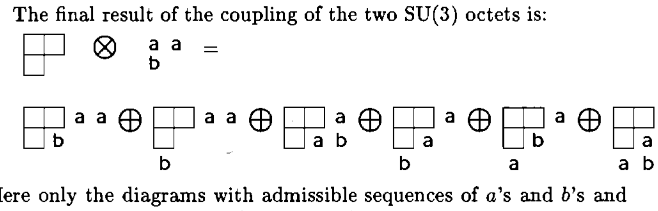
(b) Add the a's from the lettered diagram to the right-hand ends of the rows of the unlettered diagram to form all possible legitimate Young diagrams that have no more than one a per column. In general, there will be several distinct diagrams, and all the a's appear in each diagram. At this stage, for the coupling of the two SU(3) octets, we have:



(c) Use the b's to further enlarge the diagrams already obtained, subject to the same rules. Then throw away any diagram in which the full sequence of letters formed by reading *right to left* in the first row, then the second row, *etc.*, is not admissible.

(d) Proceed as in (c) with the c's (if any), *etc.*

The final result of the coupling of the two SU(3) octets is:



Here only the diagrams with admissible sequences of a's and b's and with fewer than four rows (since $n = 3$) have been kept. In terms of multiplet labels, the above may be written

$$(1,1) \otimes (1,1) = (2,2) \oplus (3,0) \oplus (0,3) \oplus (1,1) \oplus (1,1) \oplus (0,0) \,.$$

In terms of numbers of particles, it may be written

$$\mathbf{8} \otimes \mathbf{8} = \mathbf{27} \oplus \mathbf{10} \oplus \overline{\mathbf{10}} \oplus \mathbf{8} \oplus \mathbf{8} \oplus \mathbf{1} \,.$$

The product of the numbers on the left here is equal to the sum on the right, a useful check. (See also Sec. 13 on the Quark Model.)

34. KINEMATICS

Revised January 2000 by J.D. Jackson (LBNL).

Throughout this section units are used in which $\hbar = c = 1$. The following conversions are useful: $\hbar c = 197.3$ MeV fm, $(\hbar c)^2 = 0.3894$ (GeV)^2 mb.

34.1. Lorentz transformations

The energy E and 3-momentum $\boldsymbol{p}$ of a particle of mass m form a 4-vector $p = (E, \boldsymbol{p})$ whose square $p^2 \equiv E^2 - |\boldsymbol{p}|^2 = m^2$. The velocity of the particle is $\boldsymbol{\beta} = \boldsymbol{p}/E$. The energy and momentum $(E^*, \boldsymbol{p}^*)$ viewed from a frame moving with velocity $\boldsymbol{\beta}_f$ are given by

$$\begin{pmatrix} E^* \\ p_{\|}^* \end{pmatrix} = \begin{pmatrix} \gamma_f & -\gamma_f\beta_f \\ -\gamma_f\beta_f & \gamma_f \end{pmatrix} \begin{pmatrix} E \\ p_{\|} \end{pmatrix} , \quad p_T^* = p_T , \qquad (34.1)$$

where $\gamma_f = (1 - \beta_f^2)^{-1/2}$ and p_T $(p_{\|})$ are the components of $\boldsymbol{p}$ perpendicular (parallel) to $\boldsymbol{\beta}_f$. Other 4-vectors, such as the space-time coordinates of events, of course transform in the same way. The scalar product of two 4-momenta $p_1 \cdot p_2 = E_1 E_2 - \boldsymbol{p}_1 \cdot \boldsymbol{p}_2$ is invariant (frame independent).

34.2. Center-of-mass energy and momentum

In the collision of two particles of masses m_1 and m_2 the total center-of-mass energy can be expressed in the Lorentz-invariant form

$$\begin{aligned} E_{\rm cm} &= \left[(E_1 + E_2)^2 - (\boldsymbol{p}_1 + \boldsymbol{p}_2)^2\right]^{1/2} , \\ &= \left[m_1^2 + m_2^2 + 2E_1E_2(1 - \beta_1\beta_2\cos\theta)\right]^{1/2} , \end{aligned} \qquad (34.2)$$

where θ is the angle between the particles. In the frame where one particle (of mass m_2) is at rest (lab frame),

$$E_{\rm cm} = (m_1^2 + m_2^2 + 2E_{1\,\rm lab}\, m_2)^{1/2} . \qquad (34.3)$$

The velocity of the center-of-mass in the lab frame is

$$\boldsymbol{\beta}_{\rm cm} = \boldsymbol{p}_{\rm lab}/(E_{1\,\rm lab} + m_2) , \qquad (34.4)$$

where $\boldsymbol{p}_{\rm lab} \equiv \boldsymbol{p}_{1\,\rm lab}$ and

$$\gamma_{\rm cm} = (E_{1\,\rm lab} + m_2)/E_{\rm cm} . \qquad (34.5)$$

The c.m. momenta of particles 1 and 2 are of magnitude

$$p_{\rm cm} = p_{\rm lab}\frac{m_2}{E_{\rm cm}} . \qquad (34.6)$$

For example, if a 0.80 GeV/c kaon beam is incident on a proton target, the center of mass energy is 1.699 GeV and the center of mass momentum of either particle is 0.442 GeV/c. It is also useful to note that

$$E_{\rm cm}\, dE_{\rm cm} = m_2\, dE_{1\,\rm lab} = m_2\,\beta_{1\,\rm lab}\, dp_{\rm lab} . \qquad (34.7)$$

34.3. Lorentz-invariant amplitudes

The matrix elements for a scattering or decay process are written in terms of an invariant amplitude $-i\mathscr{M}$. As an example, the S-matrix for $2 \to 2$ scattering is related to $\mathscr{M}$ by

$$\begin{aligned} \langle p_1' p_2' \,|S|\, p_1 p_2\rangle &= I - i(2\pi)^4\, \delta^4(p_1 + p_2 - p_1' - p_2') \\ &\times \frac{\mathscr{M}(p_1, p_2; p_1', p_2')}{(2E_1)^{1/2}(2E_2)^{1/2}(2E_1')^{1/2}(2E_2')^{1/2}} . \end{aligned} \qquad (34.8)$$

The state normalization is such that

$$\langle p'|p\rangle = (2\pi)^3\delta^3(\boldsymbol{p} - \boldsymbol{p}') . \qquad (34.9)$$

34.4. Particle decays

The partial decay rate of a particle of mass M into n bodies in its rest frame is given in terms of the Lorentz-invariant matrix element $\mathscr{M}$ by

$$d\Gamma = \frac{(2\pi)^4}{2M}\,|\mathscr{M}|^2\, d\Phi_n\,(P;\, p_1, \ldots, p_n), \qquad (34.10)$$

where $d\Phi_n$ is an element of n-body phase space given by

$$d\Phi_n(P;\, p_1, \ldots, p_n) = \delta^4\,(P - \sum_{i=1}^{n} p_i)\,\prod_{i=1}^{n}\frac{d^3p_i}{(2\pi)^3 2E_i} . \qquad (34.11)$$

This phase space can be generated recursively, viz.

$$\begin{aligned} d\Phi_n(P;\, p_1, \ldots, p_n) &= d\Phi_j(q;\, p_1, \ldots, p_j) \\ &\times\, d\Phi_{n-j+1}\,(P;\, q, p_{i+1}, \ldots, p_n)(2\pi)^3 dq^2 , \end{aligned} \qquad (34.12)$$

where $q^2 = (\sum_{i=1}^{j} E_i)^2 - \left|\sum_{i=1}^{j} \boldsymbol{p}_i\right|^2$. This form is particularly useful in the case where a particle decays into another particle that subsequently decays.

34.4.1. ***Survival probability***: If a particle of mass M has mean proper lifetime τ $(= 1/\Gamma)$ and has momentum $(E, \boldsymbol{p})$, then the probability that it lives for a time t_0 or greater before decaying is given by

$$P(t_0) = e^{-t_0\,\Gamma/\gamma} = e^{-Mt_0\,\Gamma/E} , \qquad (34.13)$$

and the probability that it travels a distance x_0 or greater is

$$P(x_0) = e^{-Mx_0\,\Gamma/|\boldsymbol{p}|} . \qquad (34.14)$$

34.4.2. ***Two-body decays***:

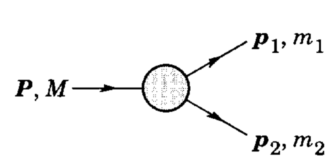


Figure 34.1: Definitions of variables for two-body decays.

In the rest frame of a particle of mass M, decaying into 2 particles labeled 1 and 2,

$$E_1 = \frac{M^2 - m_2^2 + m_1^2}{2M} , \qquad (34.15)$$

$$\begin{aligned} |\boldsymbol{p}_1| &= |\boldsymbol{p}_2| \\ &= \frac{\left[\left(M^2 - (m_1 + m_2)^2\right)\left(M^2 - (m_1 - m_2)^2\right)\right]^{1/2}}{2M} , \end{aligned} \qquad (34.16)$$

and

$$d\Gamma = \frac{1}{32\pi^2}\,|\mathscr{M}|^2\,\frac{|\boldsymbol{p}_1|}{M^2}\, d\Omega , \qquad (34.17)$$

where $d\Omega = d\phi_1 d(\cos\theta_1)$ is the solid angle of particle 1.

34.4.3. ***Three-body decays***:

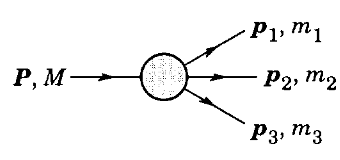

Figure 34.2: Definitions of variables for three-body decays.

Defining $p_{ij} = p_i + p_j$ and $m_{ij}^2 = p_{ij}^2$, then $m_{12}^2 + m_{23}^2 + m_{13}^2 = M^2 + m_1^2 + m_2^2 + m_3^2$ and $m_{12}^2 = (P - p_3)^2 = M^2 + m_3^2 - 2ME_3$, where E_3 is the energy of particle 3 in the rest frame of M. In that frame, the momenta of the three decay particles lie in a plane. The relative orientation of these three momenta is fixed if their energies are known. The momenta can therefore be specified in space by giving three Euler angles (α, β, γ) that specify the orientation of the final system relative to the initial particle [1]. Then

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M} |\mathscr{M}|^2 \, dE_1 \, dE_2 \, d\alpha \, d(\cos\beta) \, d\gamma \; . \tag{34.18}$$

Alternatively

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M^2} |\mathscr{M}|^2 \, |\mathbf{p}_1^*| \, |\mathbf{p}_3| \, dm_{12} \, d\Omega_1^* \, d\Omega_3 \; , \tag{34.19}$$

where $(|\mathbf{p}_1^*|, \Omega_1^*)$ is the momentum of particle 1 in the rest frame of 1 and 2, and Ω_3 is the angle of particle 3 in the rest frame of the decaying particle. $|\mathbf{p}_1^*|$ and $|\mathbf{p}_3|$ are given by

$$|\mathbf{p}_1^*| = \frac{\left[\left(m_{12}^2 - (m_1 + m_2)^2\right)\left(m_{12}^2 - (m_1 - m_2)^2\right)\right]^{1/2}}{2m_{12}} \; , \tag{34.20a}$$

and

$$|\mathbf{p}_3| = \frac{\left[\left(M^2 - (m_{12} + m_3)^2\right)\left(M^2 - (m_{12} - m_3)^2\right)\right]^{1/2}}{2M} \; . \tag{34.20b}$$

[Compare with Eq. (34.16).]

If the decaying particle is a scalar or we average over its spin states, then integration over the angles in Eq. (34.18) gives

$$d\Gamma = \frac{1}{(2\pi)^3} \frac{1}{8M} \overline{|\mathscr{M}|^2} \, dE_1 \, dE_2$$

$$= \frac{1}{(2\pi)^3} \frac{1}{32M^3} \overline{|\mathscr{M}|^2} \, dm_{12}^2 \, dm_{23}^2 \; . \tag{34.21}$$

This is the standard form for the Dalitz plot.

34.4.3.1. *Dalitz plot:* For a given value of m_{12}^2, the range of m_{23}^2 is determined by its values when $\mathbf{p}_2$ is parallel or antiparallel to $\mathbf{p}_3$:

$$(m_{23}^2)_{\max} =$$

$$(E_2^* + E_3^*)^2 - \left(\sqrt{E_2^{*2} - m_2^2} - \sqrt{E_3^{*2} - m_3^2}\right)^2 \; , \tag{34.22a}$$

$$(m_{23}^2)_{\min} =$$

$$(E_2^* + E_3^*)^2 - \left(\sqrt{E_2^{*2} - m_2^2} + \sqrt{E_3^{*2} - m_3^2}\right)^2 \; . \tag{34.22b}$$

Here $E_2^* = (m_{12}^2 - m_1^2 + m_2^2)/2m_{12}$ and $E_3^* = (M^2 - m_{12}^2 - m_3^2)/2m_{12}$ are the energies of particles 2 and 3 in the m_{12} rest frame. The scatter plot in m_{12}^2 and m_{23}^2 is called a Dalitz plot. If $\overline{|\mathscr{M}|^2}$ is constant, the allowed region of the plot will be uniformly populated with events [see Eq. (34.21)]. A nonuniformity in the plot gives immediate information on $|\mathscr{M}|^2$. For example, in the case of $D \to K\pi\pi$, bands appear when $m_{(K\pi)} = m_{K^*(892)}$, reflecting the appearance of the decay chain $D \to K^*(892)\pi \to K\pi\pi$.

34.4.4. ***Kinematic limits***: In a three-body decay the maximum of $|\mathbf{p}_3|$, [given by Eq. (34.20)], is achieved when $m_{12} = m_1 + m_2$, *i.e.*, particles 1 and 2 have the same vector velocity in the rest frame of the decaying particle. If, in addition, $m_3 > m_1, m_2$, then $|\mathbf{p}_3|_{\max} > |\mathbf{p}_1|_{\max}, |\mathbf{p}_2|_{\max}$.

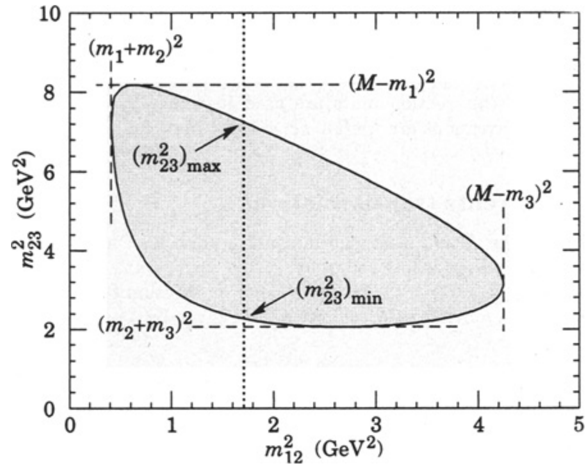

Figure 34.3: Dalitz plot for a three-body final state. In this example, the state is $\pi^+\overline{K}^0p$ at 3 GeV. Four-momentum conservation restricts events to the shaded region.

34.4.5. ***Multibody decays***: The above results may be generalized to final states containing any number of particles by combining some of the particles into "effective particles" and treating the final states as 2 or 3 "effective particle" states. Thus, if $p_{ijk\ldots} = p_i + p_j + p_k + \ldots$, then

$$m_{ijk\ldots} = \sqrt{p^2{}_{ijk\ldots}} \; , \tag{34.23}$$

and $m_{ijk\ldots}$ may be used in place of *e.g.*, m_{12} in the relations in Sec. 34.4.3 or 34.4.3.1 above.

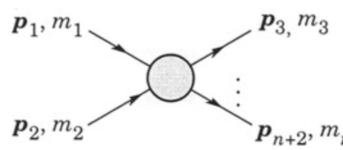

Figure 34.4: Definitions of variables for production of an n-body final state.

34.5. Cross sections

The differential cross section is given by

$$d\sigma = \frac{(2\pi)^4 |\mathscr{M}|^2}{4\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2}}$$

$$\times \; d\Phi_n(p_1 + p_2; \, p_3, \ldots, p_{n+2}) \; . \tag{34.24}$$

[See Eq. (34.11).] In the rest frame of m_2(lab),

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = m_2 p_{1\,\text{lab}} \; ; \tag{34.25a}$$

while in the center-of-mass frame

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = p_{1\text{cm}}\sqrt{s} \; . \tag{34.25b}$$

34.5.1. ***Two-body reactions***:

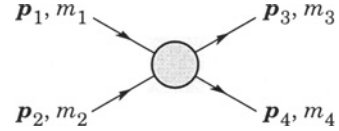

Figure 34.5: Definitions of variables for a two-body final state.

Two particles of momenta p_1 and p_2 and masses m_1 and m_2 scatter to particles of momenta p_3 and p_4 and masses m_3 and m_4; the Lorentz-invariant Mandelstam variables are defined by

$$\begin{aligned} s &= (p_1+p_2)^2 = (p_3+p_4)^2 \\ &= m_1^2 + 2E_1E_2 - 2\mathbf{p}_1\cdot\mathbf{p}_2 + m_2^2 \,, \end{aligned} \tag{34.26}$$

$$\begin{aligned} t &= (p_1-p_3)^2 = (p_2-p_4)^2 \\ &= m_1^2 - 2E_1E_3 + 2\mathbf{p}_1\cdot\mathbf{p}_3 + m_3^2 \,, \end{aligned} \tag{34.27}$$

$$\begin{aligned} u &= (p_1-p_4)^2 = (p_2-p_3)^2 \\ &= m_1^2 - 2E_1E_4 + 2\mathbf{p}_1\cdot\mathbf{p}_4 + m_4^2 \,, \end{aligned} \tag{34.28}$$

and they satisfy

$$s+t+u = m_1^2+m_2^2+m_3^2+m_4^2 \,. \tag{34.29}$$

The two-body cross section may be written as

$$\frac{d\sigma}{dt} = \frac{1}{64\pi s}\,\frac{1}{|\mathbf{p}_{1\text{cm}}|^2}\,|\mathscr{M}|^2 \,. \tag{34.30}$$

In the center-of-mass frame

$$\begin{aligned} t &= (E_{1\text{cm}} - E_{3\text{cm}})^2 - (p_{1\text{cm}} - p_{3\text{cm}})^2 \quad - 4p_{1\text{cm}}\,p_{3\text{cm}}\,\sin^2(\theta_{\text{cm}}/2) \\ &= t_0 - 4p_{1\text{cm}}\,p_{3\text{cm}}\,\sin^2(\theta_{\text{cm}}/2) \,, \end{aligned} \tag{34.31}$$

where θ_{cm} is the angle between particle 1 and 3. The limiting values t_0 ($\theta_{\text{cm}}=0$) and t_1 ($\theta_{\text{cm}}=\pi$) for $2\to2$ scattering are

$$t_0(t_1) = \left[\frac{m_1^2-m_3^2-m_2^2+m_4^2}{2\sqrt{s}}\right]^2 - (p_{1\,\text{cm}} \mp p_{3\,\text{cm}})^2 \,. \tag{34.32}$$

In the literature the notation t_{min} (t_{max}) for t_0 (t_1) is sometimes used, which should be discouraged since $t_0 > t_1$. The center-of-mass energies and momenta of the incoming particles are

$$E_{1\text{cm}} = \frac{s+m_1^2-m_2^2}{2\sqrt{s}} \,, \qquad E_{2\text{cm}} = \frac{s+m_2^2-m_1^2}{2\sqrt{s}} \,, \tag{34.33}$$

For $E_{3\text{cm}}$ and $E_{4\text{cm}}$, change m_1 to m_3 and m_2 to m_4. Then

$$p_{i\,\text{cm}} = \sqrt{E_{i\,\text{cm}}^2 - m_i^2} \text{ and } p_{1\text{cm}} = \frac{p_{1\,\text{lab}}\,m_2}{\sqrt{s}} \,. \tag{34.34}$$

Here the subscript lab refers to the frame where particle 2 is at rest. [For other relations see Eqs. (34.2)–(34.4).]

34.5.2. ***Inclusive reactions***: Choose some direction (usually the beam direction) for the z-axis; then the energy and momentum of a particle can be written as

$$E = m_T\cosh y \,,\ p_x \,,\ p_y \,,\ p_z = m_T\sinh y \,, \tag{34.35}$$

where m_T is the transverse mass

$$m_T^2 = m^2 + p_x^2 + p_y^2 \,, \tag{34.36}$$

and the rapidity y is defined by

$$\begin{aligned} y &= \frac{1}{2}\ln\left(\frac{E+p_z}{E-p_z}\right) \\ &= \ln\left(\frac{E+p_z}{m_T}\right) = \tanh^{-1}\left(\frac{p_z}{E}\right) \,. \end{aligned} \tag{34.37}$$

Under a boost in the z-direction to a frame with velocity β, $y \to y - \tanh^{-1}\beta$. Hence the shape of the rapidity distribution dN/dy is invariant. The invariant cross section may also be rewritten

$$E\frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi\,dy\,p_T\,dp_T} \Longrightarrow \frac{d^2\sigma}{\pi\,dy\,d(p_T^2)} \,. \tag{34.38}$$

The second form is obtained using the identity $dy/dp_z = 1/E$, and the third form represents the average over ϕ.

Feynman's x variable is given by

$$x = \frac{p_z}{p_{z\,\text{max}}} \approx \frac{E+p_z}{(E+p_z)_{\text{max}}} \quad (p_T \ll |p_z|) \,. \tag{34.39}$$

In the c.m. frame,

$$x \approx \frac{2p_{z\,\text{cm}}}{\sqrt{s}} = \frac{2m_T\sinh y_{\text{cm}}}{\sqrt{s}} \tag{34.40}$$

and

$$= (y_{\text{cm}})_{\text{max}} = \ln(\sqrt{s}/m) \,. \tag{34.41}$$

For $p \gg m$, the rapidity [Eq. (34.37)] may be expanded to obtain

$$\begin{aligned} y &= \frac{1}{2}\ln\frac{\cos^2(\theta/2) + m^2/4p^2 + \ldots}{\sin^2(\theta/2) + m^2/4p^2 + \ldots} \\ &\approx -\ln\tan(\theta/2) \equiv \eta \end{aligned} \tag{34.42}$$

where $\cos\theta = p_z/p$. The pseudorapidity η defined by the second line is approximately equal to the rapidity y for $p \gg m$ and $\theta \gg 1/\gamma$, and in any case can be measured when the mass and momentum of the particle is unknown. From the definition one can obtain the identities

$$\sinh\eta = \cot\theta \,,\quad \cosh\eta = 1/\sin\theta \,,\quad \tanh\eta = \cos\theta \,. \tag{34.43}$$

34.5.3. ***Partial waves***: The amplitude in the center of mass for elastic scattering of spinless particles may be expanded in Legendre polynomials

$$f(k,\theta) = \frac{1}{k}\sum_\ell (2\ell+1)a_\ell P_\ell(\cos\theta) \,, \tag{34.44}$$

where k is the c.m. momentum, θ is the c.m. scattering angle, $a_\ell = (\eta_\ell e^{2i\delta_\ell} - 1)/2i$, $0 \le \eta_\ell \le 1$, and δ_ℓ is the phase shift of the ℓ^{th} partial wave. For purely elastic scattering, $\eta_\ell = 1$. The differential cross section is

$$\frac{d\sigma}{d\Omega} = |f(k,\theta)|^2 \,. \tag{34.45}$$

The optical theorem states that

$$\sigma_{\text{tot}} = \frac{4\pi}{k}\text{Im}\,f(k,0) \,, \tag{34.46}$$

and the cross section in the ℓ^{th} partial wave is therefore bounded:

$$\sigma_\ell = \frac{4\pi}{k^2}(2\ell+1)|a_\ell|^2 \le \frac{4\pi(2\ell+1)}{k^2} \,. \tag{34.47}$$

The evolution with energy of a partial-wave amplitude a_ℓ can be displayed as a trajectory in an Argand plot, as shown in Fig. 34.6.

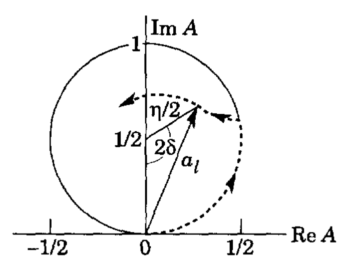

Figure 34.6: Argand plot showing a partial-wave amplitude a_ℓ as a function of energy. The amplitude leaves the unitary circle where inelasticity sets in ($\eta_\ell < 1$).

The usual Lorentz-invariant matrix element $\mathscr{M}$ (see Sec. 34.3 above) for the elastic process is related to $f(k,\theta)$ by

$$\mathscr{M} = -8\pi\sqrt{s}\,f(k,\theta) \,, \tag{34.48}$$

so

$$\sigma_{\text{tot}} = -\frac{1}{2p_{\text{lab}}\,m_2}\,\text{Im}\,\mathscr{M}(t=0) \,, \tag{34.49}$$

where s and t are the center-of-mass energy squared and momentum transfer squared, respectively (see Sec. 34.4.1).

34.5.3.1. *Resonances:* The Breit-Wigner (nonrelativistic) form for an elastic amplitude a_ℓ with a resonance at c.m. energy E_R, elastic width $\Gamma_{\rm el}$, and total width $\Gamma_{\rm tot}$ is

$$a_\ell = \frac{\Gamma_{\rm el}/2}{E_R - E - i\Gamma_{\rm tot}/2} , \tag{34.50}$$

where E is the c.m. energy. As shown in Fig. 34.7, in the absence of background the elastic amplitude traces a counterclockwise circle with center $ix_{\rm el}/2$ and radius $x_{\rm el}/2$, where the elasticity $x_{\rm el} = \Gamma_{\rm el}/\Gamma_{\rm tot}$. The amplitude has a pole at $E = E_R - i\Gamma_{\rm tot}/2$.

The spin-averaged Breit-Wigner cross section for a spin-J resonance produced in the collision of particles of spin S_1 and S_2 is

$$\sigma_{BW}(E) = \frac{(2J+1)}{(2S_1+1)(2S_2+1)} \frac{\pi}{k^2} \frac{B_{\rm in}B_{\rm out}\Gamma^2_{\rm tot}}{(E-E_R)^2 + \Gamma^2_{\rm tot}/4} , \tag{34.51}$$

where k is the c.m. momentum, E is the c.m. energy, and $B_{\rm in}$ and $B_{\rm out}$ are the branching fractions of the resonance into the entrance and exit channels. The $2S+1$ factors are the multiplicities of the incident spin states, and are replaced by 2 for photons. This expression is valid only for an isolated state. If the width is not small, $\Gamma_{\rm tot}$ cannot be treated as a constant independent of E. There are many other forms for σ_{BW}, all of which are equivalent to the one given here in the narrow-width case. Some of these forms may be more appropriate if the resonance is broad.

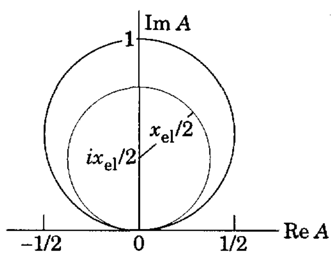

Figure 34.7: Argand plot for a resonance.

The relativistic Breit-Wigner form corresponding to Eq. (34.50) is:

$$a_\ell = \frac{-m\Gamma_{\rm el}}{s - m^2 + im\Gamma_{\rm tot}} . \tag{34.52}$$

A better form incorporates the known kinematic dependences, replacing $m\Gamma_{\rm tot}$ by $\sqrt{s}\,\Gamma_{\rm tot}(s)$, where $\Gamma_{\rm tot}(s)$ is the width the resonance particle would have if its mass were $\sqrt{s}$, and correspondingly $m\Gamma_{\rm el}$ by $\sqrt{s}\,\Gamma_{\rm el}(s)$ where $\Gamma_{\rm el}(s)$ is the partial width in the incident channel for a mass $\sqrt{s}$:

$$a_\ell = \frac{-\sqrt{s}\,\Gamma_{\rm el}(s)}{s - m^2 + i\sqrt{s}\,\Gamma_{\rm tot}(s)} . \tag{34.53}$$

For the Z boson, all the decays are to particles whose masses are small enough to be ignored, so on dimensional grounds $\Gamma_{\rm tot}(s) = \sqrt{s}\,\Gamma_0/m_Z$, where Γ_0 defines the width of the Z, and $\Gamma_{\rm el}(s)/\Gamma_{\rm tot}(s)$ is constant. A full treatment of the line shape requires consideration of dynamics, not just kinematics. For the Z this is done by calculating the radiative corrections in the Standard Model.

35. CROSS-SECTION FORMULAE FOR SPECIFIC PROCESSES

Revised April 1998 by R.N. Cahn (LBNL).

35.1. Leptoproduction

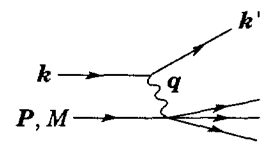

Figure 35.1: Kinematic quantities for description of lepton-nucleon scattering. k and k' are the four-momenta of incoming and outgoing leptons, P is the four-momentum of a nucleon with mass M. The exchanged particle is a γ, $W^\pm$, or Z^0; it transfers four-momentum $q = k - k'$ to the target.

Invariant quantities:

$\nu = \dfrac{q \cdot P}{M} = E - E'$ is the lepton's energy loss in the lab (in earlier literature sometimes $\nu = q \cdot P$). Here, E and E' are the initial and final lepton energies in the lab.

$Q^2 = -q^2 = 2(EE' - \vec{k} \cdot \vec{k}') - m_\ell^2 - m_{\ell'}^2$ where $m_\ell(m_{\ell'})$ is the initial (final) lepton mass. If $EE' \sin^2(\theta/2) \gg m_\ell^2, m_{\ell'}^2$, then

$\approx 4EE' \sin^2(\theta/2)$, where θ is the lepton's scattering angle in the lab.

$x = \dfrac{Q^2}{2M\nu}$ In the parton model, x is the fraction of the target nucleon's momentum carried by the struck quark. [See section on Quantum Chromodynamics (Sec. 9 of this *Review*.)]

$y = \dfrac{q \cdot P}{k \cdot P} = \dfrac{\nu}{E}$ is the fraction of the lepton's energy lost in the lab.

$W^2 = (P + q)^2 = M^2 + 2M\nu - Q^2$ is the mass squared of the system recoiling against the lepton.

$s = (k + P)^2 = \dfrac{Q^2}{xy} + M^2$

35.1.1. *Leptoproduction cross sections*:

$$\frac{d^2\sigma}{dx\, dy} = \nu(s - M^2)\, \frac{d^2\sigma}{d\nu\, dQ^2} = \frac{2\pi\, M\nu}{E'} \frac{d^2\sigma}{d\Omega_{\rm lab}\, dE'} = x(s - M^2)\, \frac{d^2\sigma}{dx\, dQ^2}\ . \qquad (35.1)$$

35.1.2. *Leptoproduction structure functions*:

The neutral-current process, $eN \to eX$, at low Q^2 is just electromagnetic and parity conserving. It can be written in terms of two structure functions $F_1^{\rm em}(x, Q^2)$ and $F_2^{\rm em}(x, Q^2)$:

$$\frac{d^2\sigma}{dx\, dy} = \frac{4\pi\, \alpha^2(s - M^2)}{Q^4} \times \left[(1 - y)\, F_2^{\rm em} + y^2\, xF_1^{\rm em} - \frac{M^2}{(s - M^2)}\, xy\, F_2^{\rm em}\right]\ . \qquad (35.2)$$

The charged-current processes, $e^-N \to \nu X$, $\nu N \to e^-X$, and $\overline{\nu}N \to e^+X$, are parity violating and can be written in terms of three structure functions $F_1^{\rm CC}(x, Q^2)$, $F_2^{\rm CC}(x, Q^2)$, and $F_3^{\rm CC}(x, Q^2)$:

$$\frac{d^2\sigma}{dx\, dy} = \frac{G_F^2\, (s - M^2)}{2\pi} \frac{M_W^4}{(Q^2 + M_W^2)^2} \qquad (35.3)$$

$$\times \left\{\left[1 - y - \frac{M^2xy}{(s - M^2)}\right] F_2^{\rm CC} + \frac{y^2}{2}\, 2x\, F_1^{\rm CC} \pm (y - \frac{y^2}{2})\, x\, F_3^{\rm CC}\right\}\ ,$$

where the last term is positive for the e^- and ν reactions and negative for $\overline{\nu}N \to e^+X$. As explained below there are different structure functions for charge-raising and charge-lowering currents.

35.1.3. *Structure functions in the QCD parton model*:

In the QCD parton model, the structure functions defined above can be expressed in terms of parton distribution functions. The quantity $f_i(x, Q^2)dx$ is the probability that a parton of type i (quark, antiquark, or gluon), carries a momentum fraction between x and $x + dx$ of the nucleon's momentum in a frame where the nucleon's momentum is large. For the cross section corresponding to the *neutral-current process* $ep \to eX$, we have for $s \gg M^2$ (in the case where the incoming electron is either left- (L) or right- (R) handed):

$$\frac{d^2\sigma}{dx\, dy} = \frac{\pi\alpha^2}{sx^2\, y^2} \left[\sum_q \left(x\, f_q\, (x, Q^2) + x\, f_{\overline{q}}\, (x, Q^2)\right)\right] \times \left[A_q + (1 - y)^2\, B_q\right]\ . \qquad (35.4)$$

Here the index q refers to a quark flavor (*i.e.*, u, d, s, c, b, or t), and

$$A_q = \left(-q_q + g_{Lq}\, g_{Le}\, \frac{Q^2}{Q^2 + M_Z^2}\right)^2 + \left(-q_q + g_{Rq}\, g_{Re}\, \frac{Q^2}{Q^2 + M_Z^2}\right)^2\ , \qquad (35.5)$$

$$B_q = \left(-q_q + g_{Rq}\, g_{Le}\, \frac{Q^2}{Q^2 + M_Z^2}\right)^2 + \left(-q_q + g_{Lq}\, g_{Re}\, \frac{Q^2}{Q^2 + M_Z^2}\right)^2\ . \qquad (35.6)$$

Here q_q is the charge of flavor q. For a left-handed electron, $g_{Re} = 0$ and $g_{Le} = (-1/2 + \sin^2\theta_W)/(\sin\theta_W \cos\theta_W)$, while for a right-handed electron, $g_{Le} = 0$ and $g_{Re} = (\sin^2\theta_W)/(\sin\theta_W \cos\theta_W)$. For the quarks, $g_{Lq} = (T_3 - q_q \sin^2\theta_W)/(\sin\theta_W \cos\theta_W)$, and $g_{Rq} = (-q_q \sin^2\theta_W)\ /\ (\sin\theta_W \cos\theta_W)$.

For neutral-current *neutrino* (*antineutrino*) *scattering*, the same formula applies with g_{Le} replaced by $g_{L\nu} = 1/(2\sin\theta_W \cos\theta_W)$ ($g_{L\overline{\nu}} = 0$) and g_{Re} replaced by $g_{R\nu} = 0$ [$g_{R\overline{\nu}} = -1/(2\sin\theta_W \cos\theta_W)$].

In the case of the *charged-current processes* $e_L^- p \to \nu X$ and $\overline{\nu}p \to e^+X$, Eq. (35.3) applies with

$$F_2 = 2xF_1 = 2x\Big[f_u(x, Q^2) + f_c(x, Q^2) + f_t(x, Q^2) + f_{\overline{d}}\,(x, Q^2) + f_{\overline{s}}\,(x, Q^2) + f_{\overline{b}}\,(x, Q^2)\Big]\ , \qquad (35.7)$$

$$F_3 = 2\Big[f_u(x, Q^2) + f_c(x, Q^2) + f_t(x, Q^2) - f_{\overline{d}}\,(x, Q^2) - f_{\overline{s}}\,(x, Q^2) - f_{\overline{b}}\,(x, Q^2)\Big]\ . \qquad (35.8)$$

For the process $\nu p \to e^-X$:

$$F_2 = 2xF_1 = 2x\Big[f_d(x, Q^2) + f_s(x, Q^2) + f_b(x, Q^2) + f_{\overline{u}}\,(x, Q^2) + f_{\overline{c}}\,(x, Q^2) + f_{\overline{t}}\,(x, Q^2)\Big]\ , \qquad (35.9)$$

$$F_3 = 2\Big[f_d(x, Q^2) + f_s(x, Q^2) + f_b(x, Q^2) - f_{\overline{u}}\,(x, Q^2) - f_{\overline{c}}\,(x, Q^2) - f_{\overline{t}}\,(x, Q^2)\Big]\ . \qquad (35.10)$$

35.2. e^+e^- annihilation

For pointlike, spin-1/2 fermions, the differential cross section in the c.m. for $e^+e^- \to f\overline{f}$ via single photon annihilation is (θ is the angle between the incident electron and the produced fermion; $N_c = 1$ if f is a lepton and $N_c = 3$ if f is a quark).

$$\frac{d\sigma}{d\Omega} = N_c \frac{\alpha^2}{4s} \beta\left[1 + \cos^2\theta + (1 - \beta^2)\sin^2\theta\right] Q_f^2\ , \qquad (35.11)$$

where β is the velocity of the final state fermion in the c.m. and Q_f is the charge of the fermion in units of the proton charge. For $\beta \to 1$,

$$\sigma = N_c \frac{4\pi\alpha^2}{3s} Q_f^2 = N_c \frac{86.8 Q_f^2\ nb}{s({\rm GeV}/c^2)^2}\ . \qquad (35.12)$$

At higher energies, the Z^0 (mass M_Z and width Γ_Z) must be included. If the mass of a fermion f is much less than the mass of the Z^0, then the differential cross section for $e^+e^- \to f\bar{f}$ is

$$\frac{d\sigma}{d\Omega} = N_c\frac{\alpha^2}{4s}\left\{(1+\cos^2\theta)\left[Q_f^2 - 2\chi_1 v_e v_f Q_f + \chi_2(a_e^2+v_e^2)(a_f^2+v_f^2)\right] + 2\cos\theta\left[-2\chi_1 a_e a_f Q_f + 4\chi_2 a_e a_f v_e v_f\right]\right\} \quad (35.13)$$

where

$$\begin{aligned} \chi_1 &= \frac{1}{16\sin^2\theta_W\cos^2\theta_W}\frac{s(s-M_Z^2)}{(s-M_Z^2)^2+M_Z^2\Gamma_Z^2}, \\ \chi_2 &= \frac{1}{256\sin^4\theta_W\cos^4\theta_W}\frac{s^2}{(s-M_Z^2)^2+M_Z^2\Gamma_Z^2}, \\ a_e &= -1, \\ v_e &= -1+4\sin^2\theta_W, \\ a_f &= 2T_{3f}, \\ v_f &= 2T_{3f} - 4Q_f\sin^2\theta_W, \end{aligned} \quad (35.14)$$

where $T_{3f} = 1/2$ for u, c and neutrinos, while $T_{3f} = -1/2$ for d, s, b, and negatively charged leptons.

At LEP II it may be possible to produce the orthodox Higgs boson, H, (see the mini-review on Higgs bosons) in the reaction $e^+e^- \to HZ^0$, which proceeds dominantly through a virtual Z^0. The Standard Model prediction for the cross section [3] is

$$\sigma(e^+e^- \to HZ^0) = \frac{\pi\alpha^2}{24}\cdot\frac{2K}{\sqrt{s}}\cdot\frac{K^2+3M_Z^2}{(s-M_Z^2)^2}\cdot\frac{1-4\sin^2\theta_W+8\sin^4\theta_W}{\sin^4\theta_W\cos^4\theta_W}. \quad (35.15)$$

where K is the c.m. momentum of the produced H or Z^0. Near the production threshold, this formula needs to be corrected for the finite width of the Z^0.

35.3. Two-photon process at e^+e^- colliders

When an e^+ and an e^- collide with energies E_1 and E_2, they emit dn_1 and dn_2 virtual photons with energies ω_1 and ω_2 and 4-momenta q_1 and q_2. In the equivalent photon approximation, the cross section for $e^+e^- \to e^+e^-X$ is related to the cross section for $\gamma\gamma \to X$ by (Ref. 1)

$$d\sigma_{e^+e^-\to e^+e^-X}(s) = dn_1\,dn_2\,d\sigma_{\gamma\gamma\to X}(W^2) \quad (35.16)$$

where $s = 4E_1E_2$, $W^2 = 4\omega_1\omega_2$ and

$$dn_i = \frac{\alpha}{\pi}\left[1 - \frac{\omega_i}{E_i} + \frac{\omega_i^2}{2E_i^2} - \frac{m_e^2\omega_i^2}{(-q_i^2)E_i^2}\right]\frac{d\omega_i}{\omega_i}\frac{d(-q_i^2)}{(-q_i^2)}. \quad (35.17)$$

After integration (including that over q_i^2 in the region $m_e^2\omega_i^2/E_i(E_i-\omega_i) \le -q_i^2 \le (-q^2)_{\max}$), the cross section is

$$\begin{aligned} \sigma_{e^+e^-\to e^+e^-X}(s) &= \frac{\alpha^2}{\pi^2}\int_{z_{th}}^1 \frac{dz}{z}\left[f(z)\left(\ln\frac{(-q^2)_{\max}}{m_e^2 z} - 1\right)^2 - \frac{1}{3}\left(\ln\frac{1}{z}\right)^3\right]\sigma_{\gamma\gamma\to X}(zs); \\ f(z) &= \left(1+\frac{1}{2}z\right)^2\ln\frac{1}{z} - \frac{1}{2}(1-z)(3+z); \\ z &= \frac{W^2}{s}. \end{aligned} \quad (35.18)$$

The quantity $(-q^2)_{\max}$ depends on properties of the produced system X, in particular, $(-q^2)_{\max} \sim m_\rho^2$ for hadron production ($X = h$) and $(-q^2)_{\max} \sim W^2$ for lepton pair production ($X = \ell^+\ell^-$, $\ell = e, \mu, \tau$).

For production of a resonance of mass m_R and spin $J \neq 1$

$$\sigma_{e^+e^-\to e^+e^-R}(s) = (2J+1)\frac{8\alpha^2\Gamma_{R\to\gamma\gamma}}{m_R^3} \times\left[f(m_R^2/s)\left(\ln\frac{sm_V^2}{m_e^2m_R^2} - 1\right)^2 - \frac{1}{3}\left(\ln\frac{s}{m_R^2}\right)^3\right] \quad (35.19)$$

where m_V is the mass that enters into the form factor of the $\gamma\gamma \to R$ transition: $m_V \sim m_\rho$ for $R = \pi^0$, η, $f_2(1270)$, …, $m_V \sim m_R$ for $R = c\bar{c}$ or $b\bar{b}$ resonances.

35.4. Inclusive hadronic reactions

One-particle inclusive cross sections $Ed^3\sigma/d^3p$ for the production of a particle of momentum p are conveniently expressed in terms of rapidity (see above) and the momentum p_T transverse to the beam direction (defined in the center-of-mass frame)

$$E\frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi\,dy\,p_T dp_T}. \quad (35.20)$$

In the case of processes where p_T is large or the mass of the produced particle is large (here large means greater than 10 GeV), the parton model can be used to calculate the rate. Symbolically

$$\sigma_{\text{hadronic}} = \sum_{ij}\int f_i(x_1, Q^2)\,f_j(x_2, Q^2)\,dx_1\,dx_2\,\hat{\sigma}_{\text{partonic}}, \quad (35.21)$$

where $f_i(x, Q^2)$ is the parton distribution introduced above and Q is a typical momentum transfer in the partonic process and $\hat{\sigma}$ is the partonic cross section. Some examples will help to clarify. The production of a W^+ in pp reactions at rapidity y in the center-of-mass frame is given by

$$\begin{aligned} \frac{d\sigma}{dy} = \frac{G_F\,\pi\sqrt{2}}{3} \times \tau\Big[&\cos^2\theta_c\Big(u(x_1, M_W^2)\,\bar{d}(x_2, M_W^2) + u(x_2, M_W^2)\,\bar{d}(x_1, M_W^2)\Big) \\ &+ \sin^2\theta_c\Big(u(x_1, M_W^2)\,\bar{s}(x_2, M_W^2) + s(x_2, M_W^2)\,\bar{u}(x_1, M_W^2)\Big)\Big], \end{aligned} \quad (35.22)$$

where $x_1 = \sqrt{\tau}\,e^y$, $x_2 = \sqrt{\tau}\,e^{-y}$, and $\tau = M_W^2/s$. Similarly the production of a jet in pp (or $p\bar{p}$) collisions is given by

$$\frac{d^3\sigma}{d^2p_T\,dy} = \sum_{ij}\int f_i(x_1, p_T^2)\,f_j(x_2, p_T^2) \times\left[\hat{s}\frac{d\hat{\sigma}}{d\hat{t}}\right]_{ij} dx_1\,dx_2\,\delta(\hat{s}+\hat{t}+\hat{u}), \quad (35.23)$$

where the summation is over quarks, gluons, and antiquarks. Here

$$s = (p_1+p_2)^2, \quad (35.24)$$

$$t = (p_1 - p_{\text{jet}})^2, \quad (35.25)$$

$$u = (p_2 - p_{\text{jet}})^2, \quad (35.26)$$

p_1 and p_2 are the momenta of the incoming p and p (or $\bar{p}$) and $\hat{s}$, $\hat{t}$, and $\hat{u}$ are s, t, and u with $p_1 \to x_1p_1$ and $p_2 \to x_2p_2$. The partonic cross section $\hat{s}[(d\hat{\sigma})/(d\hat{t})]$ can be found in Ref. 2. Example: for the process $gg \to q\bar{q}$,

$$\hat{s}\frac{d\sigma}{dt} = 3\alpha_s^2\frac{(\hat{t}^2+\hat{u}^2)}{8\hat{s}}\left[\frac{4}{9\hat{t}\hat{u}} - \frac{1}{\hat{s}^2}\right]. \quad (35.27)$$

The prediction of Eq. (35.23) is compared to data from the UA1 and UA2 collaborations in Fig. 37.8 in the Plots of Cross Sections and Related Quantities section of this *Review*.

The associated production of a Higgs boson and a gauge boson is analogous to the process $e^+e^- \to HZ^0$ in Sec. 35.2. The required parton-level cross sections [4], averaged over initial quark colors, are

$$\begin{aligned} \sigma(q_i\bar{q}_j \to W^\pm H) &= \frac{\pi\alpha^2|V_{ij}|^2}{36\sin^4\theta_W}\cdot\frac{2K}{\sqrt{s}}\cdot\frac{K^2+3M_W^2}{(s-M_W^2)^2} \\ \sigma(q\bar{q} \to Z^0H) &= \frac{\pi\alpha^2(a_q^2+v_q^2)}{144\sin^4\theta_W\cos^4\theta_W}\cdot\frac{2K}{\sqrt{s}}\cdot\frac{K^2+3M_Z^2}{(s-M_Z^2)^2}. \end{aligned}$$

Here V_{ij} is the appropriate element of the Kobayashi-Maskawa matrix and K is the c.m. momentum of the produced H. The axial and vector couplings are defined as in Sec. 35.2.

35.5. One-particle inclusive distributions

In order to describe one-particle inclusive production in e^+e^- annihilation or deep inelastic scattering, it is convenient to introduce a fragmentation function $D_i^h\,(z,Q^2)$ where $D_i^h\,(z,Q^2)$ is the number of hadrons of type h and momentum between zp and $(z+dz)p$ produced in the fragmentation of a parton of type i. The Q^2 evolution is predicted by QCD and is similar to that of the parton distribution functions [see section on Quantum Chromodynamics (Sec. 9 of this *Review*)]. The $D_i^h(z,Q^2)$ are normalized so that

$$\sum_h \int zD_i^h\,(z,Q^2)dz = 1\ . \qquad (35.28)$$

If the contributions of the Z boson and three-jet events are neglected, the cross section for producing a hadron h in e^+e^- annihilation is given by

$$\frac{1}{\sigma_{\rm had}}\frac{d\sigma}{dz} = \frac{\sum_i e_i^2\, D_i^h\,(z,Q^2)}{\sum_i e_i^2}\ , \qquad (35.29)$$

where e_i is the charge of quark-type i, $\sigma_{\rm had}$ is the total hadronic cross section, and the momentum of the hadron is $zE_{\rm cm}/2$.

In the case of deep inelastic muon scattering, the cross section for producing a hadron of energy E_h is given by

$$\frac{1}{\sigma_{\rm tot}}\frac{d\sigma}{dz} = \frac{\sum_i e_i^2\, q_i(x,Q^2)\, D_i^h(z,Q^2)}{\sum_i e_i^2\, q_i(x,Q^2)}\ , \qquad (35.30)$$

where $E_h = \nu z$. (For the kinematics of deep inelastic scattering, see Sec. 34.4.2 of the Kinematics section of this *Review*.) The fragmentation functions for light and heavy quarks have a different z dependence; the former peak near $z=0$. They are illustrated in Figs. 36.1 and 36.2 in the section on "Heavy Quark Fragmentation in e^+e^- Annihilation" (Sec. 36 of this *Review*).

36. HEAVY-QUARK FRAGMENTATION IN e^+e^- ANNIHILATION

Written January 1998 by D. Besson (University of Kansas).

Measurement of the fragmentation functions of heavy quarks provides information about non-perturbative particle production in a variety of experimental environments. The CDF observation of high p_T $J/\psi(1S)$ production rates far in excess of the extant theoretical predictions prompted the development of the color octet model (*e.g.*, $p\overline{p} \to gg \to \chi_c \to \psi + X$) and highlighted the role of gluon fragmentation in charmonium production. Recent results from both LEP and HERA have also helped elucidate the gluonic contribution to charmed meson production. Current estimates from LEP are that gluon fragmentation accounts for approximately half of the D^* production in the lowest momentum region (the lowest quarter of the allowed kinematic region).

Many functional forms have been suggested to describe these momentum spectra for heavy quarks produced in e^+e^- annihilations. The functional form given by Peterson *et al.* [1] in terms of just one free parameter ϵ_P has found widespread use; other parameterizations are also given in the literature [2]. The earliest Peterson form was a function of one variable z, defined for a heavy-quark Q, light-quark $\overline{q}$ system as the ratio of the energy plus the longitudinal momentum of the hadron $Q\overline{q}$ to the sum of the energy and momentum of the heavy quark after accounting for initial state radiation, gluon bremsstrahlung, and final state radiation: $z = (E + p_{\|})_{Q\overline{q}}/(E + p_Q)$. The main advantage of this variable is that it is relativistically invariant with respect to boosts in the direction of the primary quark. Unfortunately, as this quantity is not directly accessible, experiments typically use other scaling variables which are close approximations to z—either $x^+ = (p_{\|} + E)_{\text{hadron}}/(p_{\|} + E)_{\text{max}}$, $x_p = p/p_{\text{max}}$, or $x_E = E_{\text{hadron}}/E_{\text{beam}}$.

The Peterson functional form is:

$$\frac{dN}{dz} = \frac{1}{z[1 - (1/z) - \epsilon_P/(1 - z)]^2} \tag{36.1}$$

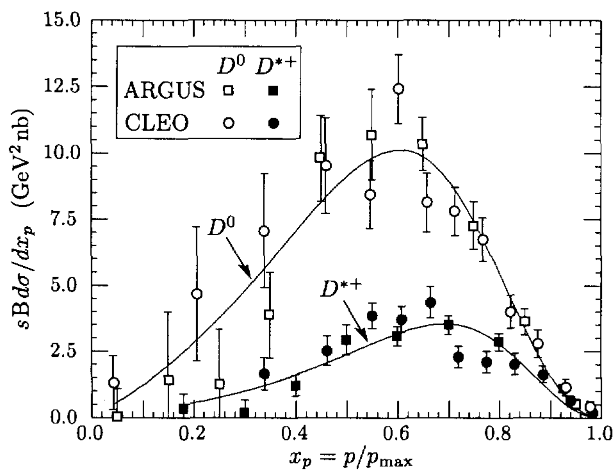

Figure 36.1: Efficiency-corrected inclusive cross section measurements for the production of D^0 and D^{*+} in e^+e^- measurements at $\sqrt{s} \approx 10$ GeV. The variable x_p is related to the Peterson variable z, but is not identical to it.

The bulk of the available fragmentation function data on charmed mesons (excluding $J/\psi(1S)$) is from measurements at $\sqrt{s} = 10$ GeV. Shown in Fig. 36.1 are the efficiency-corrected (but not branching ratio corrected) CLEO [3] and ARGUS [4] inclusive cross sections ($s \cdot \mathcal{B} d\sigma/dx_p$ in units of GeV^2-nb, with $x_p = p/p_{\text{max}}$) for the production of pseudoscalar D^0 and vector D^{*+} in e^+e^- annihilations at $\sqrt{s} \approx 10$ GeV. For the D^0, $\mathcal{B}$ represents the branching fraction for $D^0 \to K^-\pi^+$; for the D^{*+}, $\mathcal{B}$ represents the product branching fraction: $D^{*+} \to D^0\pi^+; D^0 \to K^-\pi^+$. These inclusive spectra have not been corrected for cascades from higher states, nor for radiative effects. Note that since the momentum spectra are sensitive to radiative corrections, comparison of charm spectra at $\sqrt{s} = 10$ GeV cannot be compared directly with spectra at higher center-of-mass energies, and must be appropriately evolved.

Fits to the combined CLEO and ARGUS D^0 and D^{*+} data give $\epsilon_P(D^0) = 0.135 \pm 0.01$ and $\epsilon_P(D^*) = 0.078 \pm 0.008$; these are indicated in the solid curves. Measurement of the fragmentation functions for a variety of particles has allowed comparisons between mesons and baryons, and particles of different spin structure, as shown in Table 36.1

Table 36.1: The Peterson momentum hardness parameter ϵ_P as obtained from $e^+e^- \to$ (particle) + X measurements.

Particle	L	$\sqrt{s}$	ϵ_P	Reference
D^0	0	10 GeV	0.135 ± 0.01	[3]
D^{*+}	0	10 GeV	0.078 ± 0.008	[3]
D_s^*	0	10 GeV	$0.04^{+0.03}_{-0.01}$	[5]
$D_1^0(2420)$	1	10 GeV	$0.034^{+0.018}_{-0.012}$	[6]
$D_2^0(2460)$	1	10 GeV	0.015 ± 0.004	[6]
$D_1^+(2420)$	1	10 GeV	$0.020^{+0.011}_{-0.006}$	[7]
$D_2^+(2460)$	1	10 GeV	0.013 ± 0.007	[7]
$D_{s1}(2536)$	1	10 GeV	$0.06^{+0.035}_{-0.03}$	[8]
$D_{s2}(2573)$	1	10 GeV	$0.027^{+0.043}_{-0.016}$	[9]
Λ_c	0	10 GeV	0.25 ± 0.03	[10,11]
Ξ_c	0	10 GeV	0.23 ± 0.05	[12,13]
Σ_c	0	10 GeV	0.29 ± 0.06	[14,15]
Σ_c^*	0	10 GeV	$0.30^{+0.10}_{-0.07}$	[16]
Ξ_c^{*+}	0	10 GeV	$0.24^{+0.22}_{-0.10}$	[17]
Ξ_c^{*0}	0	10 GeV	$0.22^{+0.15}_{-0.08}$	[18]
$\Lambda_{c,1}$	1	10 GeV	0.059 ± 0.028	[19,20]
$\Lambda_{c,2}$	1	10 GeV	0.053 ± 0.012	[19,21]
$\Xi_{c,2}$	1	10 GeV	$0.058^{+0.037}_{-0.021}$	[22]
b hadrons	—	90 GeV	$0.0047^{+0.0010}_{-0.0008}$	[23]

We note from Table 36.1 that the mass dependence of ϵ_P is less marked than the dependence on the orbital angular momentum structure of the charmed hadron being measured. Orbitally excited $L = 1$ charmed hadrons (D_J, $D_{s,J}$, and $\Lambda_{c,J}$) show consistently harder spectra (*i.e.*, smaller values of ϵ_P) than the $L = 0$ ground states, whereas the data for the ground state charmed baryons Λ_c and Ξ_c show agreement with the lighter (by $\approx$ 400–600 MeV) ground-state D and D_s charmed mesons. To some extent, the harder spectra of $L = 1$ hadrons can be attributed to the fact that all the $L = 1$ charmed hadrons will eventually decay into $L = 0$ hadrons.

Bottom-flavored hadrons at LEP have been measured to have n even harder momentum spectrum than charmed hadrons at ɔwer energies [23–25]. Qualitatively, whereas charm spectra peak at $x_p \approx 0.6$, the spectra of bottom hadrons peak at $x_p \approx 0.8$. This is as expected in the Peterson model, where the value ϵ_P is expected to vary as the ratio of the effective light quark mass to the heavy quark mass in a heavy quark + light (di)quark hadron. In the case of charm, the Peterson functional form provides an acceptable description of the shape of the x_p distribution, provided the appropriate ϵ_P value is independently determined for each separate species of charmed particle. However, unlike charm, the numbers of fully reconstructed b-flavored hadrons is too small to allow a statistically compelling measure of ϵ_P for each separate bottom hadron. Consequently, a b-enriched sample is isolated kinematically, using, *e.g.*, a high p_T lepton and/or a displaced vertex to tag a primary b quark. The x_p distribution therefore includes all b-flavored hadrons in the sample, and does not yet allow a straightforward species-by-species ϵ_P extraction. Additional uncertainties in the case of bottom arise from the sensitivity of ϵ_P to the fragmentation model used to non-perturbatively evolve the initial $q\bar{q}$ system into final state hadrons.

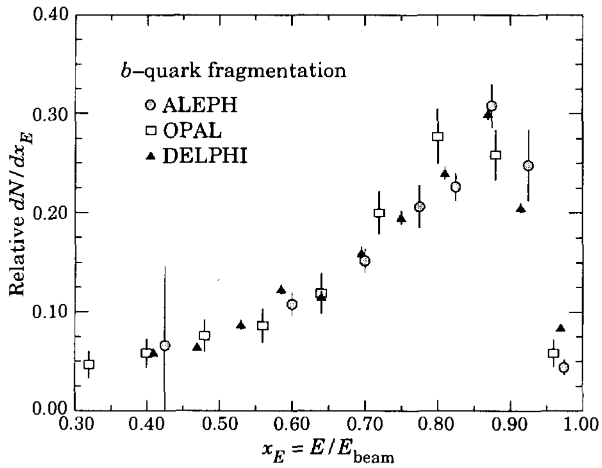

Figure 36.2: Fractional energy distribution for b-quark fragmentation for inclusive b production at LEP.

In general, the b-quark fragmentation function distribution is found to be somewhat narrower than the shape of the Peterson function; this may be due to a systematic underestimate of soft gluon emission in event generators, and/or uncertainties in the appropriate mix of b-flavored hadrons. The match of a single Peterson function to data is therefore much more difficult for bottom than charm at this time, although there is relatively good agreement from experiment to experiment, as seen in Fig. 36.2, which displays the fragmentation function data from OPAL [23], ALEPH [24], and DELPHI [25].

37. PLOTS OF CROSS SECTIONS AND RELATED QUANTITIES

NOTE: THE FIGURES IN THIS SECTION ARE INTENDED TO SHOW THE REPRESENTATIVE DATA. THEY ARE NOT MEANT TO BE COMPLETE COMPILATIONS OF ALL THE WORLD'S RELIABLE DATA.

Structure Functions

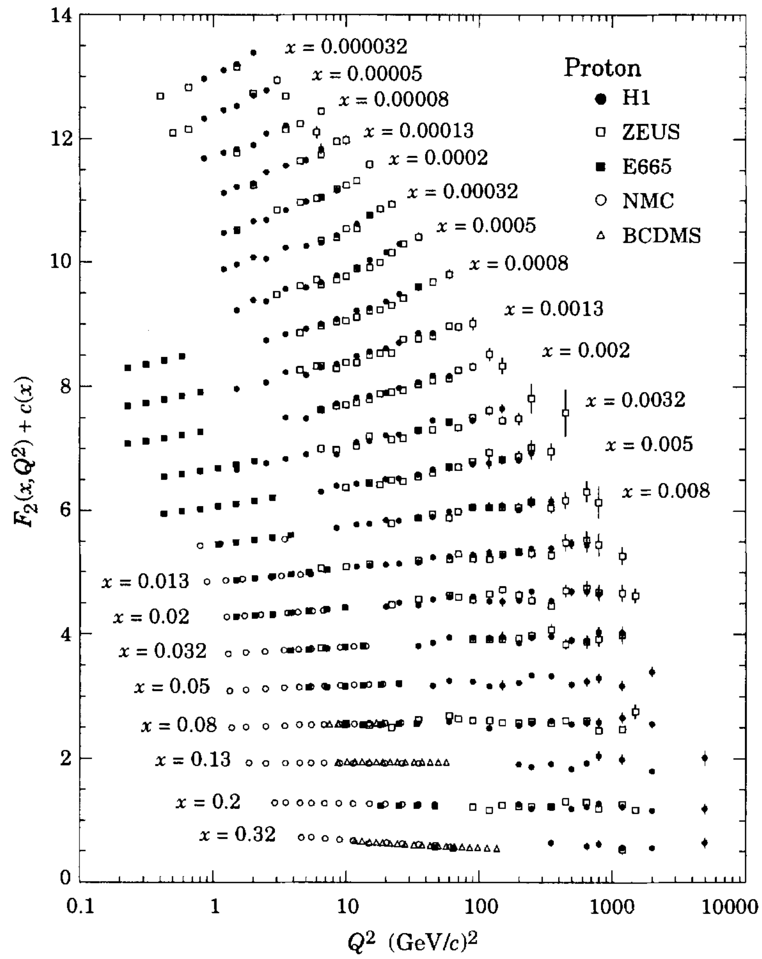

Figure 37.1: The proton structure function F_2^p measured in electromagnetic scattering of electrons (H1, ZEUS) and muons (BCDMS, E665, NMC), in the kinematic domain of the HERA data, for $x > 0.00003$; *cf.* Fig. 37.2 for data at smaller x. Only statistical errors are shown. The data are plotted as a function of Q^2 in bins of fixed x. The H1 binning in x is used in this plot; the ZEUS, BCDMS, E665 and NMC data are rebinned to the x values of the H1 data using a phenomenological parametrization. For the purpose of plotting, a constant $c(x) = 0.6(i_x - 0.4)$ is added to F_2^p, where i_x is the number of the x bin ranging from $i_x = 1$ ($x = 0.32$) to $i_x = 21$ ($x = 0.000032$). Arneodo *et al.*, Phys. Lett. **B364**, 107 (1995). (Courtesy of R. Voss, 1997.)

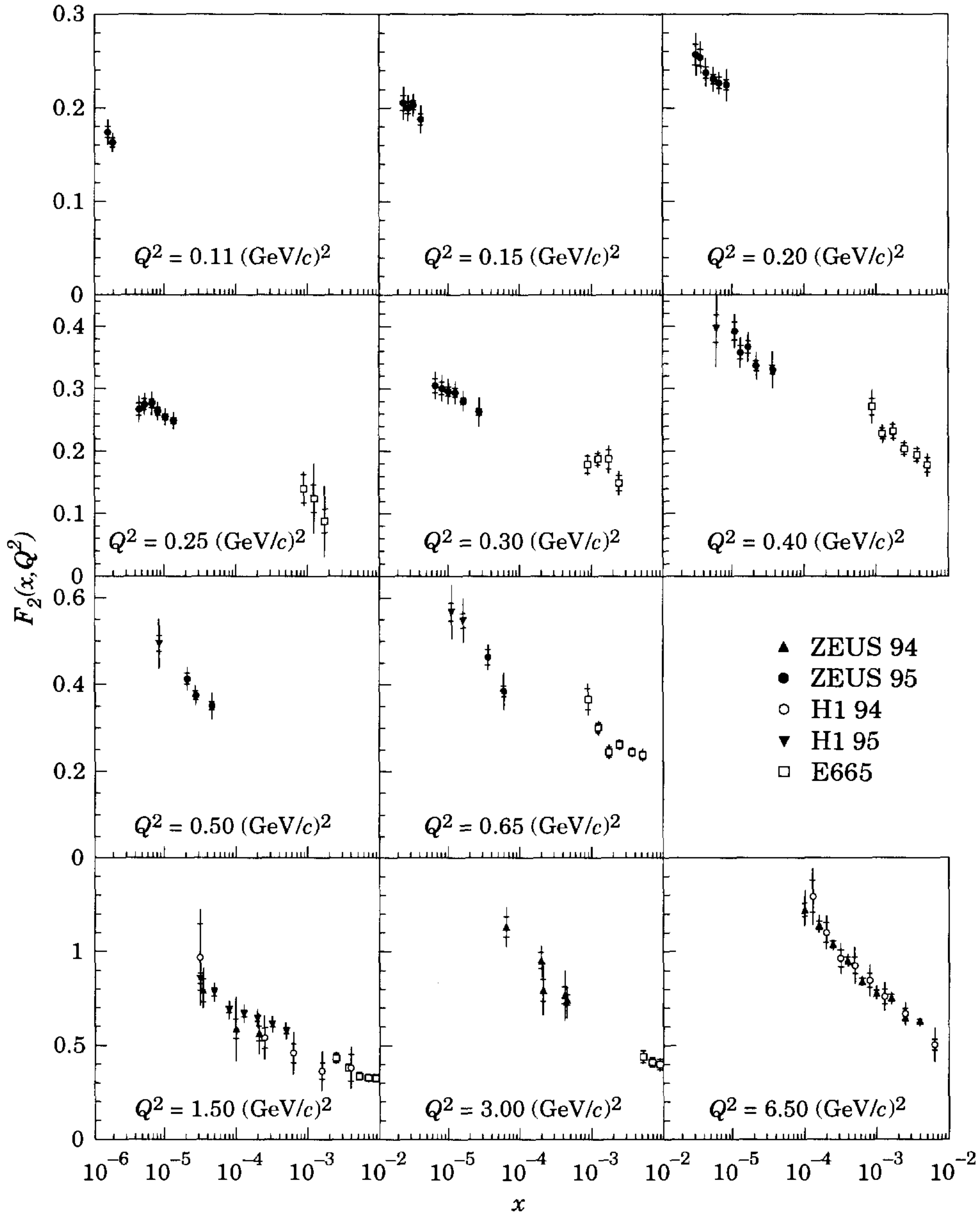

Figure 37.2: The proton structure function F_2^p at small x and Q^2, measured in electromagnetic scattering of electrons (H1, ZEUS) and muons (E665). The data are plotted as a function of x in bins of fixed Q^2. References: **ZEUS 94**—M. Derrick *et al.*, Z. Phys. **C72**, 399 (1996); **ZEUS 95**—J. Breitweg *et al.*, Phys. Lett. **B407**, 432 (1997); **H1 94**—S. Aid *et al.*, Nucl. Phys. **B470**, 3 (1996); **H1 95**—C. Adloff *et al.*, Nucl. Phys. **B497**, 3 (1997); **E665**—M.R. Adams *et al.*, Phys. Rev. **D54**, 3006 (1996). (Courtesy of R. Voss, 1997.)

Structure Functions

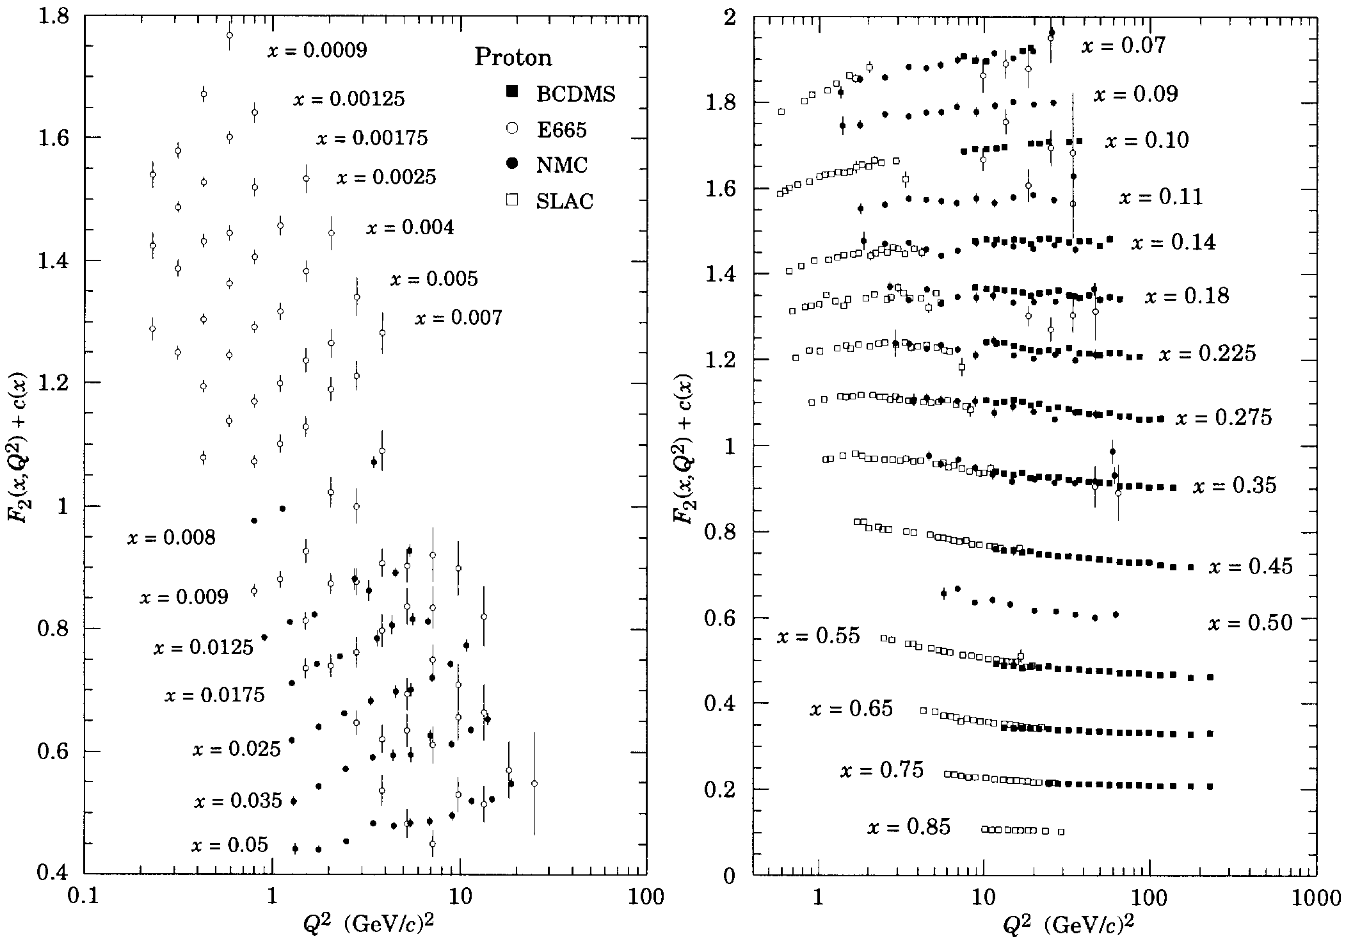

Figure 37.3: The proton structure function F_2^p measured in electromagnetic scattering of electrons (SLAC) and muons (BCDMS, E665, NMC), shown as a function of Q^2 for bins of fixed x. Only statistical errors are shown. For the purpose of plotting, a constant $c(x) = 0.1 i_x$ is added to F_2^p where i_x is the number of the x bin, ranging from 1 ($x = 0.05$) to 14 ($x = 0.0009$) on the left-hand figure, and from 1 ($x = 0.85$) to 15 ($x = 0.07$) on the right-hand figure. For HERA data in the kinematic range of this figure, see Fig. 37.1. References: **BCDMS**—A.C. Benvenuti *et al.*, Phys. Lett. **B223**, 485 (1989); **E665**—M.R. Adams *et al.*, Phys. Rev. **D54**, 3006 (1996); **NMC**—M. Arneodo *et al.*, Phys. Lett. **B364**, 107 (1995). **SLAC**—L.W. Whitlow *et al.*, Phys. Lett. **B282**, 475 (1992). (Courtesy of R. Voss, 1996.)

Structure Functions

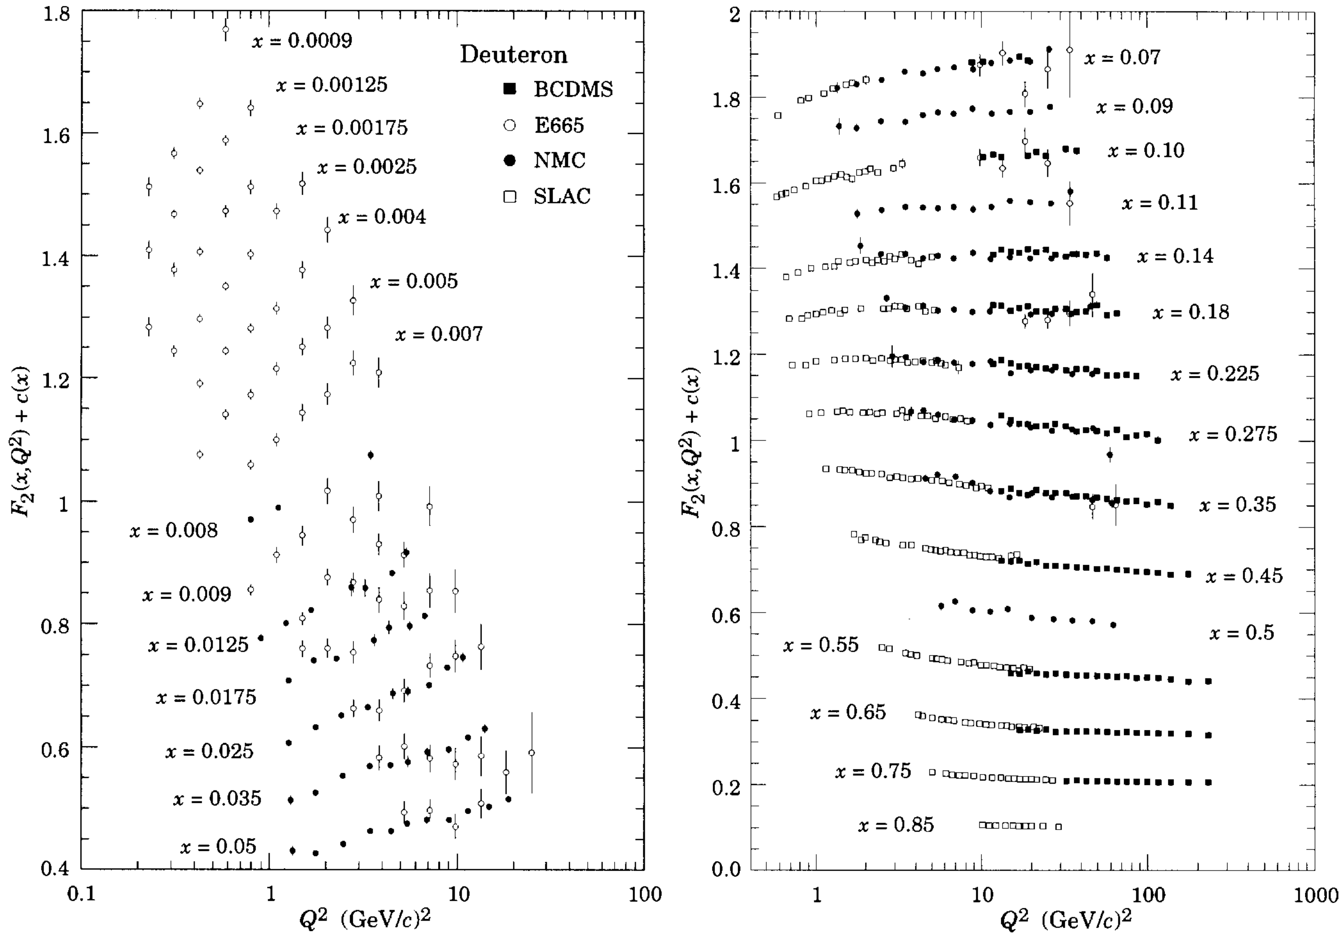

Figure 37.4: As Fig. 37.3, for the deuteron structure function F_2^d. References: **BCDMS**—A.C. Benvenuti *et al.*, Phys. Lett. **B237**, 592 (1990). **E665, NMC, SLAC**—same references as Fig. 37.3. (Courtesy of R. Voss, 1996.)

Structure Functions

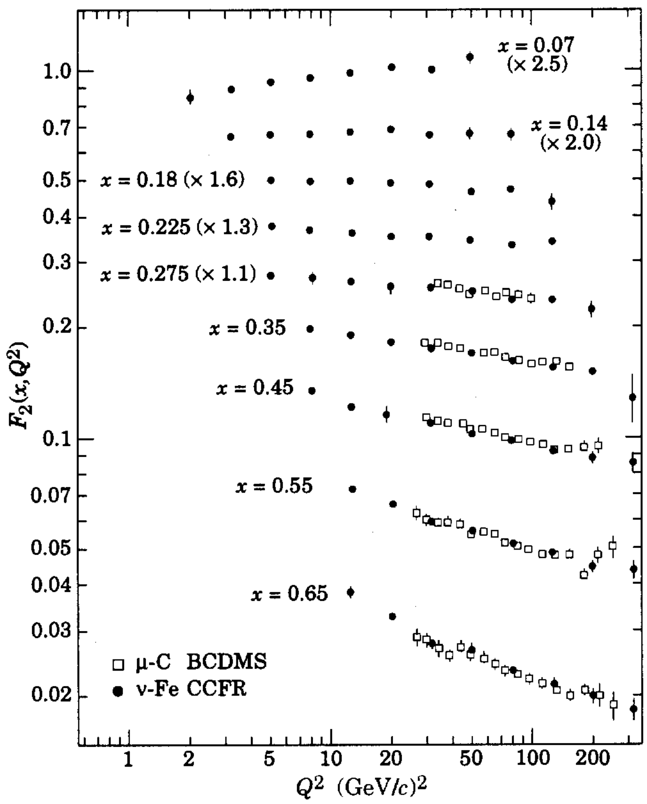

Figure 37.5: The nucleon structure function F_2 measured in deep inelastic scattering of muons on carbon (BCDMS) and neutrinos on iron (CCFR). The data are shown versus Q^2, for bins of fixed x, and have been scaled by the factors shown in parentheses. References: **BCDMS**—A.C. Benvenuti *et al.*, Phys. Lett. **B195**, 91 (1987); **CCFR**—S.R. Mishra *et al.*, NEVIS-1465 (1992). (Courtesy of R. Voss, 1996.)

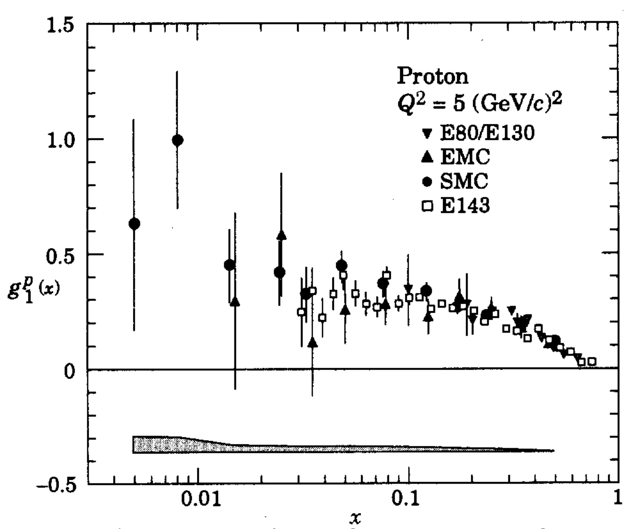

Figure 37.6: The spin-dependent structure function $g_1(x)$ of the proton measured in deep inelastic scattering of polarized electrons (E80, E130, E143) and muons (EMC, SMC), shown at $Q^2 = 5$ GeV^2. Only statistical errors are shown with the data points. As an example, the SMC systematic error is indicated by the shaded area. References: **E80**—M.J. Alguard *et al.*, Phys. Rev. Lett. **37**, 1261 (1976); ibid. **41**, 70 (1978); **E130**—G. Baum *et al.*, Phys. Rev. Lett. **51**, 1135 (1983); **E143**—K. Abe *et al.*, Phys. Rev. Lett. **74**, 346 (1995); **EMC**—J. Ashman *et al.*, Nucl. Phys. **B328**, 1 (1989); **SMC**—B. Adeva *et al.*, Phys. Lett. **B412**, 414 (1997). In this plot, the E80, E130 and EMC data have been reevaluated using up-to-date parametrizations of F_2^p and $R = \sigma_L/\sigma_T$. (Courtesy of R. Voss, 1997.)

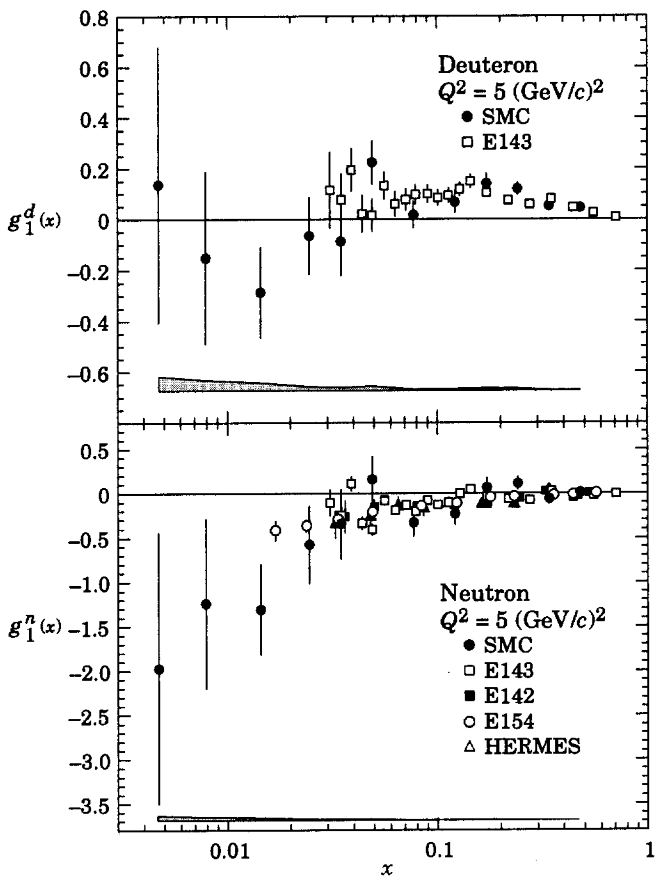

Figure 37.7: The spin-dependent structure function $g_1(x)$ of the deuteron (top) and the neutron (bottom) measured in deep inelastic scattering of polarized electrons (E142, E143, E154, HERMES) and muons (SMC). The SMC and E143 results for the neutron are evaluated from the difference of deuteron and proton data; the E142, E154, and HERMES results were obtained with polarized ^{3}He targets. Only statistical errors are shown with the data points. As an example, the SMC systematic error is indicated by the shaded area. All results except the HERMES data are shown at $Q^2 = 5$ GeV^2; the HERMES results are shown at the average Q^2 of the respective data point which varies from $Q^2 = 1.22$ GeV^2 at $x = 0.033$ to $Q^2 = 5.25$ GeV^2 at $x = 0.464$. Next-to-leading order QCD curves are shown for 630 GeV and 1800 GeV. (Courtesy of S. Geer, FNAL, 1995.)

Pseudorapidity Distributions in $\bar{p}p$ Interactions

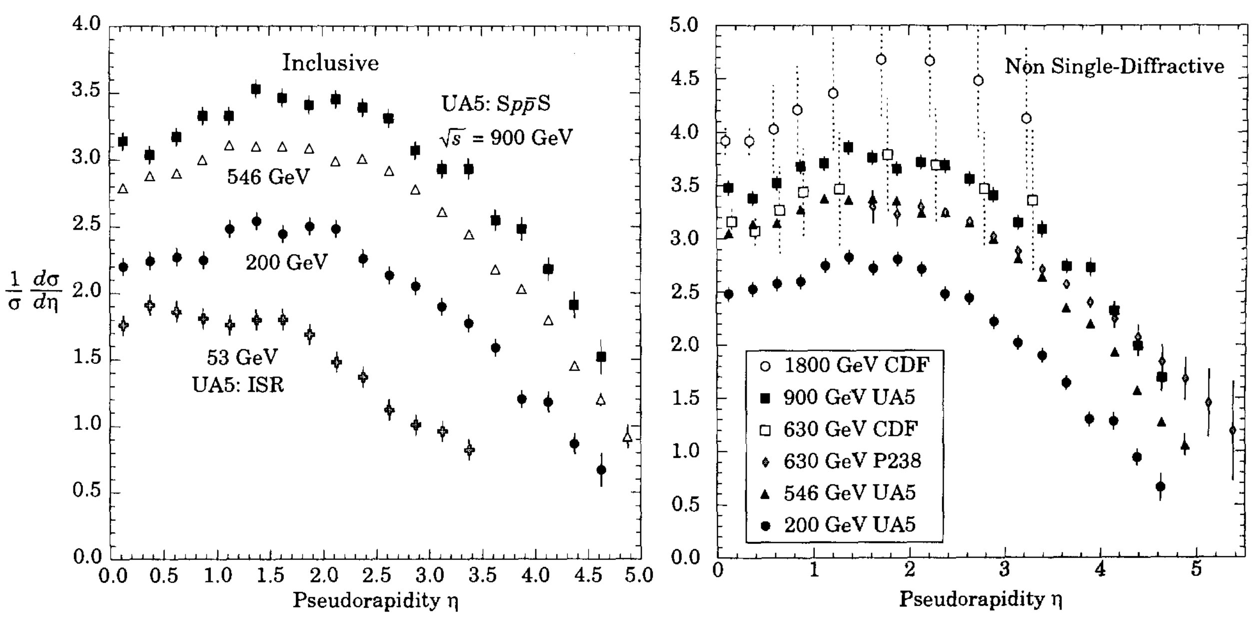

Figure 37.10: Charged particle pseudorapidity distributions in $p\bar{p}$ collisions for 53 GeV $\leq \sqrt{s} \leq$ 1800 GeV. UA5 data from the $Sp\bar{p}S$ are taken from G.J. Alner *et al.*, Z. Phys. **C33**, 1 (1986), and from the ISR from K. Alpgøard *et al.*, Phys. Lett. **112B**, 193 (1982). The UA5 data are shown for both the full inelastic cross-section and with singly diffractive events excluded. Additional non single-diffractive measurements are available from CDF at the Tevatron, F. Abe *et al.*, Phys. Rev. **D41**, 2330 (1990) and Experiment P238 at the $Sp\bar{p}S$, R. Harr *et al.*, Phys. Lett. **B401**, 176 (1997). (Courtesy of D.R. Ward, Cambridge Univ., 1999.)

Average Hadron Multiplicities in Hadronic e^+e^- Annihilation Events

Table 37.1: Average hadronic multiplicities per hadronic e^+e^- annihilation event at $\sqrt{s} \approx 10$, 29–35, and 91 GeV. The rates given include decay products from resonances with $c\tau < 10$ cm, and include charge conjugated states. Correlations of the systemaic uncertainties were considered for the calculation of the averages. (Updated July 1999 by O. Biebel.)

All average multiplicites are per hadronic e^+e^- annihilation event.

(a) $B(D_s \to \eta\pi,\ \eta'\pi)$ was used (RPP94).

(b) The Standard Model $B(Z \to b\bar{b}) = 0.217$ was used.

(c) $x_p = p/p_{\text{beam}} > 0.1$ only.

(d) Both charge states.

(e) Any charge state (*i.e.*, B_d^*, B_u^*, or B_s^*).

(f) $B(D_s^* \to D_S^+\gamma)$, $B(D_s^+ \to \phi\pi^+)$, $B(\phi \to K^+K^-)$ have been used (RPP98).

(g) $B(Z \to \text{hadrons}) = 0.699$ was used (RPP94).

(h) Any charge state (*i.e.*, B_d^{**}, B_u^{**}, or B_s^{**}).

(i) The value was derived from the cross section of $\Lambda_c^+ \to p\pi K$, assuming the branching fraction to be $(3.2 \pm 0.7)\%$ (RPP92).

Annihilation Cross Section Near M_Z

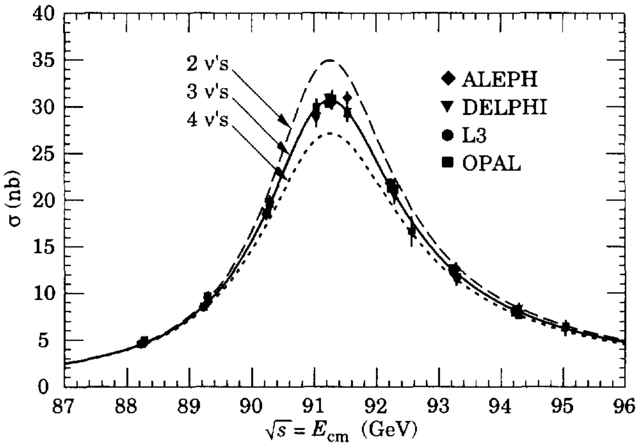

Figure 37.14: Data from the ALEPH, DELPHI, L3, and OPAL Collaborations for the cross section in e^+e^- annihilation into hadronic final states as a function of c.m. energy near the Z. LEP detectors obtained data at the same energies; some of the points are obscured by overlap. The curves show the predictions of the Standard Model with three species (solid curve) and four species (dashed curve) of light neutrinos. The asymmetry of the curves is produced by initial-state radiation. References:

R in e^+e^- Collisions

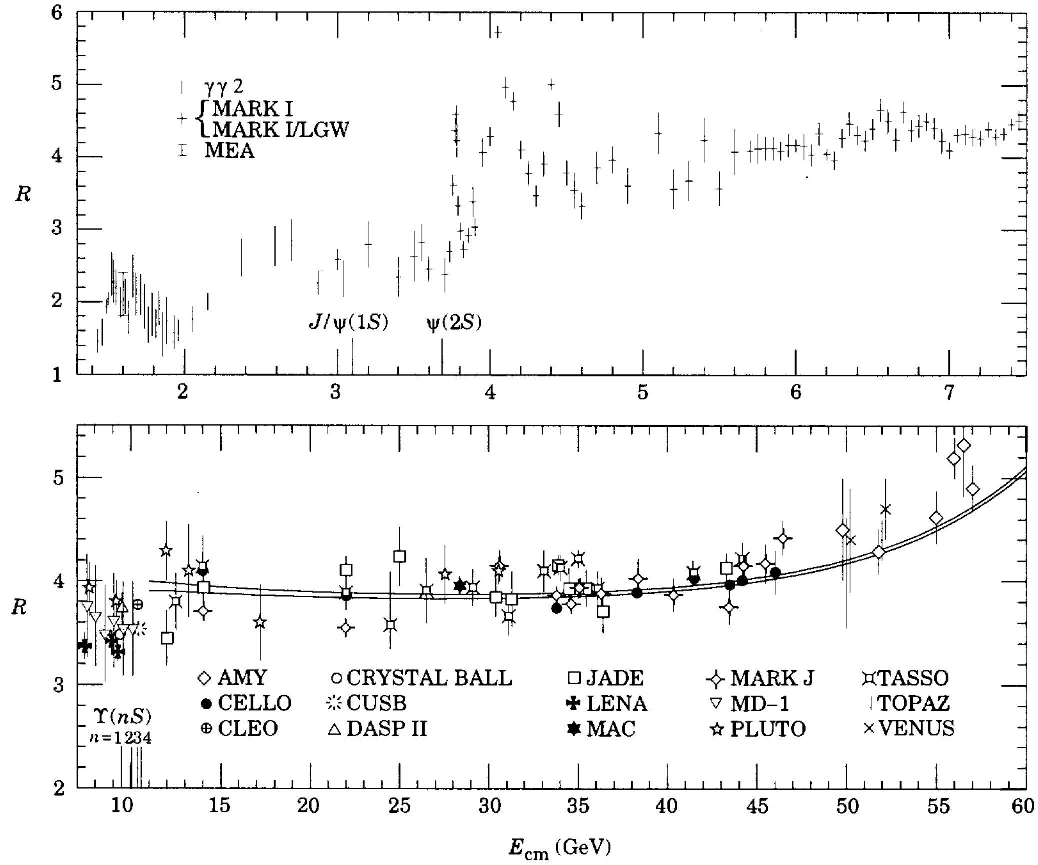

Figure 37.16: Selected measurements of $R \equiv \sigma(e^+e^- \to \text{hadrons})/\sigma(e^+e^- \to \mu^+\mu^-)$, where the annihilation in the numerator proceeds via one photon or via the Z. Measurements in the vicinity of the Z mass are shown in the following figure. The denominator is the calculated QED single-photon process; see the section on Cross-Section Formulae for Specific Processes. Radiative corrections and, where important, corrections for two-photon processes and τ production have been made. Note that the ADONE data ($\gamma\gamma 2$ and MEA) is for ≥ 3 hadrons. The points in the $\psi(3770)$ region are from the MARK I—Lead Glass Wall experiment. To preserve clarity only a representative subset of the available measurements is shown—references to additional data are included below. Also for clarity, some points have been combined or shifted slightly ($< 4\%$) in $E_{\rm cm}$, and some points with low statistical significance have been omitted. Systematic normalization errors are not included; they range from $\sim$5–20%, depending on experiment. We caution that especially the older experiments tend to have large normalization uncertainties. Note the suppressed zero. The horizontal extent of the plot symbols has no significance. The positions of the $J/\psi(1S)$, $\psi(2S)$, and the four lowest Υ vector-meson resonances are indicated. Two curves are overlaid for $E_{\rm cm} > 11$ GeV, showing the theoretical prediction for R, including higher order QCD [M. Dine and J. Sapirstein, Phys. Rev. Lett. **43**, 668 (1979)] and electroweak corrections. The Λ values are for 5 flavors in the $\overline{\rm MS}$ scheme and are $\Lambda^{(5)}_{\overline{\rm MS}} = 60$ MeV (lower curve) and $\Lambda^{(5)}_{\overline{\rm MS}} = 250$ MeV (upper curve). (Courtesy of F. Porter, 1992.) References (including several references to data not appearing in the figure and some references to preliminary data):

Muon Neutrino and Anti-Neutrino Charged-Current Total Cross Section

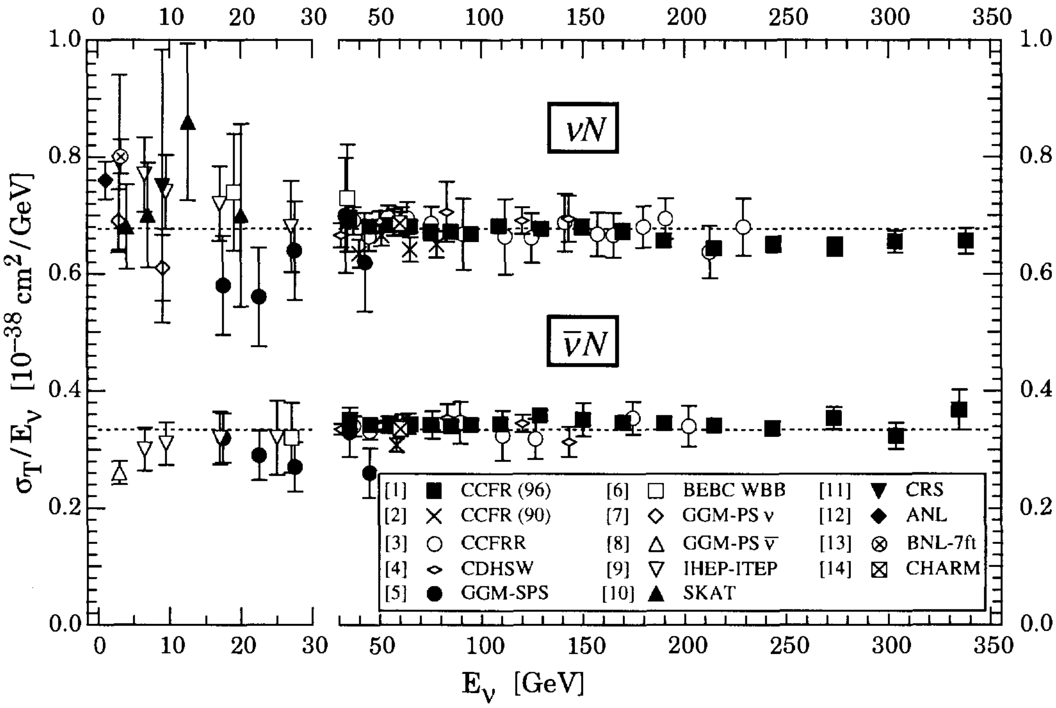

Figure 37.17: σ_T/E_ν, for the muon neutrino and anti-neutrino charged-current total cross section as a function of neutrino energy. The error bars include both statistical and systematic errors. The straight lines are the averaged values over all energies as measured by the experiments in Refs. [1–4]: $= 0.677 \pm 0.014$ $(0.334 \pm 0.008) \times 10^{-38}$ cm^2/GeV. Note the change in the energy scale at 30 GeV. (Courtesy W. Seligman and M.H. Shaevitz, Columbia University, 2000.)

Table 37.2: Total hadronic cross section. Regge theory suggests a parameterization of total cross sections as

$$\sigma_{AB} = X_{AB}s^{\epsilon} + Y_{1AB}s^{-\eta_1} - Y_{2AB}s^{-\eta_2}, \qquad \sigma_{\overline{A}B} = X_{AB}s^{\epsilon} + Y_{1AB}s^{-\eta_1} + Y_{2AB}s^{-\eta_2}$$

where X_{AB}, Y_{iAB} are in mb and s is in GeV^2. The exponents ϵ, η_1, and η_2 are independent of the particles $A, \overline{A}$, and B and represent the pomeron, and lower-lying C-even and C-odd exchanges, respectively. Requiring $\eta_1 = \eta_2$ results in much poorer fits. In addition to total cross section, the measured ratio of the real to the imaginary part of the forward scattering amplitudes were included in the fits by assuming that the C-even and C-odd amplitudes have the simple behavior $(-s)^{\alpha} \pm s^{\alpha}$, where $\alpha = 1+\epsilon, 1-\eta_1, 1-\eta_2$. Fits were made to the 1999-updated data for $p^{\pm}p, \pi^{\pm}p, K^{\pm}p, \gamma p$, and $\gamma\gamma$. The exponents $\epsilon = 0.093(2), \eta_1 = 0.358(15)$, and $\eta_2 = 0.560(17)$ thus obtained were then fixed and used as inputs to a fit to a larger data sample that included cross sections on deuterons and neutrons. In the initial fit only data above $\sqrt{s_{\rm min}} = 9$ GeV were used. In the subsequent fit, data above $p_{\rm lab} = 10$ GeV (hadronic collisions) and $\sqrt{s_{\rm min}} = 4$ GeV (γp and $\gamma\gamma$) collisions were used.

Fits to $\overline{p}(p)\,p$, $\pi^{\pm}p$, $K^{\pm}p$, γp, $\gamma\gamma$			Colliding particles	Fits to groups			χ^2/dof by groups
X	Y_1	Y_2		X	Y_1	Y_2	
18.751(27)	63.58(26)	35.46(34)	$\overline{p}(p)p$	18.760(22)	63.52(23)	35.43(34)	
			$\overline{p}(p)n$	18.760(22)	64.74(33)	31.42(63)	1.23
11.883(21)	28.59(14)	5.90(12)	$\pi^{\pm}p$	11.883(23)	28.59(15)	5.90(13)	1.50
10.546(27)	16.42(20)	13.84(18)	$K^{\pm}p$	10.587(22)	16.13(17)	13.82(18)	
			$K^{\pm}n$	10.587(22)	14.68(38)	7.78(38)	1.21
0.0593(4)	0.1202(26)		γp	0.0593(2)	0.1202(17)		
1.56(11)E-4	0.37(10)E-3		$\gamma\gamma$	1.56(7)E-4	0.37(7)E-3		0.7
$\chi^2/dof = 1.23$ with fixed $\epsilon = 0.093(2)$, $\eta_1 = 0.358(15)$, $\eta_2 = 0.560(17)$ at their central values			$\overline{p}(p)d$	33.290(47)	154.3(8)	91.6(1.1)	1.69
			$\pi^{\pm}d$	21.550(36)	68.87(53)	1.42(63)	1.74
			$K^{\pm}d$	19.327(38)	37.53(50)	30.49(61)	1.46

The fitted functions are shown in the following figures, along with one-standard-deviation error bands. When the reduced χ^2 is greater than one, a scale factor has been included. Where appropriate, statistical and systematic errors were combined quadratically in constructing weights for all fits. On the plots only statistical error bars are shown. Vertical arrows indicate lower limits on the $p_{\rm lab}$ or $E_{\rm cm}$ range used in the fits. The user may decide on the range of applicability of the extrapolated curves.

One can find the details of the fits and exact parameterizations of the ratio of the real to imaginary part of the forward scattering amplitude in J.R. Cudell *et al.*, Phys. Rev. **D61**, 034019 (2000), as well as comparisons of the simple pole pomeron parameterization with the "unitarized" pomeron parameterizations. It should be noted that parameterization with linear logarithmic pomeron

$$\sigma_{AB} = X_{AB}\ln(\frac{s}{s_0}) + Y_{1AB}(\frac{s}{s_0})^{-\eta_1} - Y_{2AB}(\frac{s}{s_0})^{-\eta_2}, \qquad \sigma_{\overline{A}B} = X_{AB}\ln(\frac{s}{s_0}) + Y_{1AB}(\frac{s}{s_0})^{-\eta_1} + Y_{2AB}(\frac{s}{s_0})^{-\eta_2}$$

gives much better data description picture under the same fits strategy. The data were extracted from the PPDS accessible at

[1] LAKES 98 report limits on torque on a toroid Cavendish balance, obtaining a limit on $\mu^2 A$ via the Maxwell-Proca equations, where μ is the photon mass and A is the ambient vector potential in the Lorentz gauge. This is the most conservative limit reported, in which $A \approx (1\,\mu\,\mathrm{G}) \times (600\,\mathrm{pc})$ is based on the Galactic field.

[2] FISCHBACH 94 report $< 8 \times 10^{-16}$ with unknown CL. We report Baysian CL used elsewhere in these Listings and described in the Statistics section.

[3] CHERNIKOV 92 measures the photon mass at 1.24 K, following a theoretical suggestion that electromagnetic gauge invariance might break down at some low critical temperature. See the erratum for a correction, included here, to the published result.

[4] RYAN 85 measures the photon mass at 1.36 K (see the footnote to CHERNIKOV 92).

[5] CHIBISOV 76 depends in critical way on assumptions such as applicabilty of virial theorem. Some of the arguments given only in unpublished references.

[6] See criticism questioning the validity of these results in KROLL 71 and GOLDHABER 71.

OMITTED FROM SUMMARY TABLE

graviton MASS

All of the following limits are obtained assuming Yukawa potential in weak field limit. VANDAM 70 argue that a massive field cannot approach general relativity in the zero-mass limit; however, see GOLDHABER 74 and references therein. h_0 is the Hubble constant in units of 100 km s^{-1} Mpc^{-1}.

$<7 \times 10^{-28}$	HARE	73	Galaxy
$<8 \times 10^{4}$	HARE	73	2γ decay

[1] DAMOUR 91 is an analysis of the orbital period change in binary pulsar PSR 1913+16, and confirms the general relativity prediction to 0.8%. "The theoretical importance of the [rate of orbital period decay] measurement has long been recognized as a direct confirmation that the gravitational interaction propagates with velocity c (which is the immediate cause of the appearance of a damping force in the binary pulsar system) and thereby as a test of the existence of gravitational radiation and of its quadrupolar nature." TAYLOR 93 adds that orbital parameter studies now agree with general relativity to 0.5%, and set limits on the level of scalar contribution in the context of a family of tensor [spin 2]-biscalar theories.

W

$J = 1$

THE MASS OF THE W BOSON

Revised March 2000 by C. Caso (Univ. of Genova) and A. Gurtu (Tata Inst.)

Till 1995 the production and study of the W boson was the exclusive domain of the $\overline{p}p$ colliders at CERN and FNAL. W production in these hadron colliders is tagged by a high p_T lepton from W decay. Owing to unknown parton–parton effective energy and missing energy in the longitudinal direction, the experiments reconstruct only the transverse mass of the W and derive the W mass from comparing the transverse mass distribution with Monte Carlo predictions as a function of M_W.

Beginning 1996 the energy of LEP increased to above 161 GeV, the threshold for W-pair production. A precise knowledge of the e^+e^- centre of mass energy enables one to reconstruct the W mass even if one of them decays leptonically. At LEP two methods have been used to obtain the W mass. In the first method the measured W-pair production cross sections, $\sigma(e^+e^- \to W^+W^-)$, have been used to determine the W mass using the predicted dependence of this cross section on M_W (see Fig. 1). At 161 GeV, which is just above the W-pair production threshold, this dependence is a much more sensitive function of the W mass than at the higher energies (172 to 202 GeV) at which LEP has run during 1996–99. In the second method, which is used at the higher energies, the

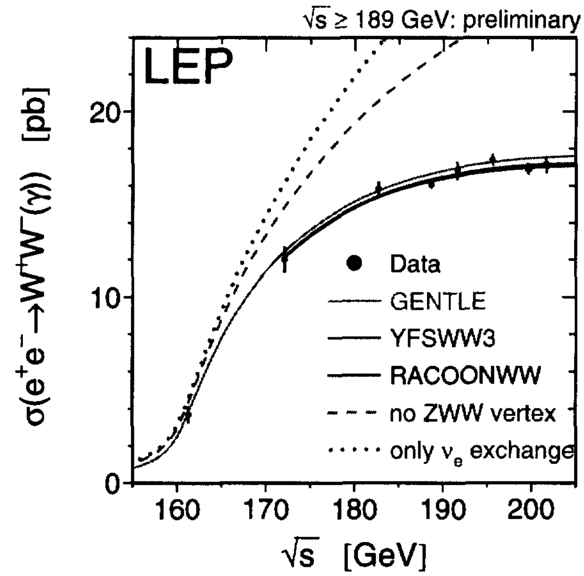

Figure 1: The W-pair cross section as a function of the center-of-mass energy. The data points are the LEP averages. The solid lines are predictions from different models of WW production. For comparison the figure contains also the cross section if the ZWW coupling did not exist (dashed line), or if only the t-channel ν_e exchange diagram existed (dotted line).

W mass has been determined by directly reconstructing the W from its decay products.

Each LEP experiment has combined their own mass values properly taking into account the common systematic errors. In order to compute the LEP average W mass each experiment has provided its measured W mass for the $qqqq$ and $qq\ell\nu$ channels at each center-of-mass energy along with a detailed break-up of errors (statistical and uncorrelated, partially correlated and fully correlated systematics [1]). These have been properly combined to obtain a *preliminary* [2] LEP W mass = 80.401±0.048 GeV. Errors due uncertainties in LEP energy (17 MeV) and possible effect of color reconnection (CR) and Bose-Einstein (BE) correlations between quarks from different W's (18 MeV) are included. The mass difference between $qqqq$ and $qq\ell\nu$ final states (due to possible CR and BE effects) is 35±55 MeV.

The two Tevatron experiments have also carried out the exercise of identifying common systematic errors and averaging with CERN UA2 data obtain an average W mass = 80.448±0.062 GeV.

Combining all the published and unpublished p-$\overline{p}$ Collider and LEP results (as of mid-March 2000) yields an average W-boson mass of 80.419±0.038 GeV assuming no common systematics between LEP and hadron collider measurements.

The Standard Model prediction from the electroweak fit, excluding the direct W mass measurements from LEP and Tevatron, gives a W-boson mass of 80.382 ± 0.026 GeV.

OUR EVALUATION in the listing below is obtained by combining only published LEP and p-$\overline{p}$ Collider results using the same procedure as above.

[1] ABBOTT 00 use $W \rightarrow e\nu_e$ events to measure the W mass with a fit to the transverse mass distribution. The result quoted here corresponds to electrons detected both in the forward and in the central calorimeters for the data recorded in 1992–1995. For the large rapidity electrons recorded in 1994–1995, the analysis combines results obtained from m_T, $p_T(e)$, and $p_T(\nu)$.

[2] ABBIENDI 99C obtain this value properly combining results from a direct W mass reconstruction at 172 and 183 GeV with that from the measurement of the total W-pair production cross section at 161 GeV. The systematic error includes an uncertainty of ±0.02 GeV due to the possible color-reconnection and Bose-Einstein effects in the purely hadronic final states and an uncertainty of ±0.02 GeV due to the beam energy.

[3] ABREU 99T obtain this value properly combining results obtained from a direct W mass reconstruction at 172 and 183 GeV with those from measurement of W-pair production cross sections at 161, 172, and 183 GeV. The systematic error includes ±0.021 GeV due to the beam energy uncertainty and ±0.030 GeV due to possible color reconnection and Bose-Einstein effects in the purely hadronic final state.

[4] ACCIARRI 99 obtain this value properly combining results obtained from a direct W mass reconstruction at 172 and 183 GeV with those from the measurements of the total W-pair production cross sections at 161 and 172 GeV. The value of the mass obtained from the direct reconstruction at 172 and 183 GeV is $M(W) = 80.58 \pm 0.14 \pm 0.08$ GeV.

[5] BARATE 99 obtain this value properly combining results from a direct W mass reconstruction at 172 and 183 GeV with those from the measurements of the total W-pair production cross sections at 161 and 172 GeV. The systematic error includes ± 0.023 GeV due to LEP energy uncertainty and ± 0.021 GeV due to theory uncertainty on account of possible color reconnection and Bose-Einstein correlations.

[6] ABE 95P use 3268 $W \rightarrow \mu\nu_\mu$ events to find $M = 80.310 \pm 0.205 \pm 0.130$ GeV and 5718 $W \rightarrow e\nu_e$ events to find $M = 80.490 \pm 0.145 \pm 0.175$ GeV. The result given here combines these while accounting for correlated uncertainties.

[7] ABE 90G result from $W \rightarrow e\nu$ is $79.91 \pm 0.35 \pm 0.24 \pm 0.19$(scale) GeV and from $W \rightarrow \mu\nu$ is $79.90 \pm 0.53 \pm 0.32 \pm 0.08$(scale) GeV.

[8] ABREU 99K derive this value using the Standard Model dependence on M_W of the W-W production cross sections measured at 161, 172, and 183 GeV. The systematics include an error of ± 0.03 GeV arising from the beam energy uncertainty.

[9] ABBOTT 98O fit the transverse mass distribution of 28323 $W \rightarrow e\nu_e$ events. The systematic error includes a detector related uncertainty of ± 60 MeV and a model uncertainty of ± 30 MeV. Combining with ABACHI 96E DØ obtain a W mass value of 80.43 ± 0.11 GeV.

[10] ABREU 98B obtain this value from a fit to the reconstructed W mass distribution. The W width was taken as its Standard Model value at the fitted W mass. The systematic error includes ± 0.03 GeV due to the beam energy uncertainty and ± 0.05 GeV due to the possible color reconnection and Bose-Einstein effects in the purely hadronic final state.

[11] ACKERSTAFF 98D obtain this value from a fit to the reconstructed W mass distribution. The W width was taken as its Standard Model value at the fitted W mass. When both W mass and width are varied they obtain $M(W) = 80.30 \pm 0.27 \pm 0.095$ GeV. The systematic error includes ± 0.03 GeV due to the beam energy uncertainty and ± 0.05 GeV due to the possible color reconnection and Bose-Einstein effects in the purely hadronic final state. Combining both values of ACKERSTAFF 98D with ACKERSTAFF 96B authors find: $M(W) = 80.35 \pm 0.24 \pm 0.07 \pm 0.03$ (LEP) GeV.

[12] ACKERSTAFF 98D derive this value from their measured $W\,W$ production cross section $\sigma_{WW} = 12.3 \pm 1.3 \pm 0.4$ pb using the Standard Model dependence of σ_{WW} on M_W at the given c.m. energy.

[13] BARATE 98B obtain this value from a fit to the reconstructed W mass distribution. The W width was taken as its Standard Model value at the fitted W mass. The systematic error includes ± 0.03 GeV due to the beam energy uncertainty and ± 0.032 GeV due to the possible color reconnection and Bose-Einstein effects in the purely hadronic final state. Combining with the M_W values from cross section measurements at 161 and 172 GeV (BARATE 97 and BARATE 97S) authors find: $M(W) = 80.51 \pm 0.23 \pm 0.08$ GeV.

[14] ACCIARRI 97 derive this value from their measured W-W production cross section $\sigma_{WW} = 2.89^{+0.81}_{-0.70} \pm 0.14$ pb using the Standard Model dependence of σ_{WW} on M_W at the given c.m. energy. Statistical and systematic errors are added in quadrature and the last error of ± 0.03 GeV arises from the beam energy uncertainty. The same result is given by a fit of the production cross sections to the data.

[15] ACCIARRI 97M derive this value from their measured $W\,W$ production cross section $\sigma_{WW} = 12.27^{+1.41}_{-1.32} \pm 0.23$ pb using the Standard Model dependence of σ_{WW} on M_W at the given c.m. energy. Combining with ACCIARRI 97 authors find $M(W) = 80.78^{+0.45}_{-0.41} \pm 0.03$ GeV where the last error is due to beam energy uncertainty.

[16] ACCIARRI 97S obtain this value from a fit to the reconstructed W mass distribution. The W width was taken as its Standard Model value at the fitted W mass. When both W mass and width are varied they obtain $M(W) = 80.72^{+0.31}_{-0.33} \pm 0.09$ GeV. The systematic error includes ± 0.03 GeV due to the beam energy uncertainty and ± 0.05 GeV due to the possible color reconnection and Bose-Einstein effects in the purely hadronic final state. Combining with ACCIARRI 97 and ACCIARRI 97M authors find: $M(W) = 80.75^{+0.26}_{-0.27} \pm 0.03$ (LEP) GeV.

[17] BARATE 97 derive this value from their measured W-W production cross section $\sigma_{WW} = 4.23 \pm 0.73 \pm 0.19$ pb using the Standard Model dependence of σ_{WW} on M_W at the given c.m. energy. The systematics include an error of ± 0.03 GeV arising from the beam energy uncertainty.

[18] BARATE 97S derive this value from their measured $W\,W$ production cross section $\sigma_{WW} = 11.71 \pm 1.23 \pm 0.28$ pb using the Standard Model dependence of σ_{WW} on M_W at the given c.m. energy. The errors quoted on the mass are statistical only. Combining with BARATE 97 authors find: $M(W) = 80.20 \pm 0.33 \pm 0.09 \pm 0.03$ (LEP) GeV.

[19] ABACHI 96E fit the transverse mass distribution of 5982 $W \rightarrow e\nu_e$ decays. An error of ± 160 MeV due to the uncertainty in the absolute energy scale of the EM calorimeter is included in the total systematics.

[20] ACKERSTAFF 96B derive this value from an analysis of the predicted M_W dependence of their accepted four-fermion cross section, explicitly taking into account interference effects. The systematics include an error of ± 0.03 GeV arising from the beam energy uncertainty.

[21] AID 96D derive this value as a propagator mass using the Q^2 shape and magnitude of the $e^\pm$ charged-current cross sections. $Q^2 > 5000\ \mathrm{GeV}^2$ events with p_T of the outgoing lepton > 25 GeV/c are used.

[22] ALITTI 92B result has two contributions to the systematic error (± 0.83); one (± 0.81) cancels in m_W/m_Z and one (± 0.17) is noncancelling. These were added in quadrature. We choose the ALITTI 92B value without using the LEP m_Z value, because we perform our own combined fit.

[23] There are two contributions to the systematic error (± 0.84): one (± 0.81) which cancels in m_W/m_Z and one (± 0.21) which is non-cancelling. These were added in quadrature.

[24] ABE 89I systematic error dominated by the uncertainty in the absolute energy scale.

[25] ALBAJAR 89 result is from a total sample of 299 $W \rightarrow e\nu$ events.

[26] ALBAJAR 89 result is from a total sample of 67 $W \rightarrow \mu\nu$ events.

[27] ALBAJAR 89 result is from $W \rightarrow \tau\nu$ events.

W/Z MASS RATIO

The fit uses the W and Z mass, mass difference, and mass ratio measurements.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.8820 ±0.0005 OUR FIT

W WIDTH

The CDF and DØ widths labelled "extracted value" are obtained by measuring $R = [\sigma(W)/\sigma(Z)]\,[\Gamma(W \rightarrow \ell\nu_\ell)]/(B(Z \rightarrow \ell\ell)\Gamma(W))$ where the bracketed quantities can be calculated with plausible reliability. $\Gamma(W)$ is then extracted by using a value of $B(Z \rightarrow \ell\ell)$ measured at LEP. The UA1 and UA2 widths used $R = [\sigma(W)/\sigma(Z)]\,[\Gamma(W \rightarrow \ell\nu_\ell)/\Gamma(Z \rightarrow \ell\ell)]\,\Gamma(Z)/\Gamma(W)$ and the measured value of $\Gamma(Z)$. The Standard Model prediction is 2.067 ± 0.021 (ROSNER 94).

[31] ABBOTT 00B measure $R = 10.43 \pm 0.27$ for the $W \rightarrow e\nu_e$ decay channel. They use the SM theoretical predictions for $\sigma(W)/\sigma(Z)$ and $\Gamma(W \rightarrow e\nu_e)$ and the world average for $B(Z \rightarrow ee)$. The value quoted here is obtained combining this result (2.169 ± 0.070 GeV) with that of ABBOTT 99H.

[32] ABBIENDI 99C obtain this value from a fit to the reconstructed W mass distribution using data at 172 and 183 GeV. The systematic error includes an uncertainty of ± 0.12 GeV due to the possible color-reconnection and Bose-Einstein effects in the purely hadronic final states and an uncertainty of ± 0.01 GeV due to the beam energy.

[33] ABREU 99T obtain this value using $WW \rightarrow \ell\bar{\nu}_\ell q\bar{q}$ and $WW \rightarrow q\bar{q}q\bar{q}$ events. The systematic error includes an uncertainty of ± 0.080 GeV due to possible color reconnection and Bose-Einstein effects in the purely hadronic final state.

[34] ACCIARRI 99 obtain this value from a fit to the reconstruced W mass distribution using data at 172 and 183 GeV.

[35] ABE 95C use the tail of the transverse mass distribution of $W \rightarrow e\nu_e$ decays.

[36] ABE 95W measured R = 10.90 ± 0.32 ± 0.29. They use m_W=80.23 ± 0.18 GeV, $\sigma(W)/\sigma(Z)$ = 3.35 ± 0.03, $\Gamma(W \to e\nu)$ = 225.9 ± 0.9 MeV, $\Gamma(Z \to e^+e^-)$ = 83.98 ± 0.18 MeV, and $\Gamma(Z)$ = 2.4969 ± 0.0038 GeV.

[37] ALITTI 92 measured $R = 10.4^{+0.7}_{-0.6} \pm 0.3$. The values of $\sigma(Z)$ and $\sigma(W)$ come from $O(\alpha_s^2)$ calculations using m_W = 80.14 ± 0.27 GeV, and m_Z = 91.175 ± 0.021 GeV along with the corresponding value of $\sin^2\theta_W$ = 0.2274. They use $\sigma(W)/\sigma(Z)$ = 3.26 ± 0.07 ± 0.05 and $\Gamma(Z)$ = 2.487 ± 0.010 GeV.

[38] ALBAJAR 91 measured $R = 9.5^{+1.1}_{-1.0}$ (stat. + syst.). $\sigma(W)/\sigma(Z)$ is calculated in QCD at the parton level using m_W = 80.18 ± 0.28 GeV and m_Z = 91.172 ± 0.031 GeV along with $\sin^2\theta_W$ = 0.2322 ± 0.0014. They use $\sigma(W)/\sigma(Z)$ = 3.23 ± 0.05 and $\Gamma(Z)$ = 2.498 ± 0.020 GeV. This measurement is obtained combining both the electron and muon channels.

[39] ABBOTT 99H measure R= 10.90 ± 0.52 combining electron and muon channels. They use M_W = 80.39 ± 0.06 GeV and the SM theoretical predictions for $\sigma(W)/\sigma(Z)$, $B(Z \to \ell\ell)$, and $\Gamma(W \to \ell\nu_\ell)$.

[40] BARATE 99I obtain this result with a fit to the WW measured cross sections at 161, 172, and 183 GeV. The theoretical prediction takes into account the sensitivity to the W total width.

[41] ACKERSTAFF 98D obtain this value from a fit to the reconstructed W mass distribution.

[42] ACCIARRI 97S obtain this value from a fit to the reconstructed W mass distribution.

[43] ALITTI 90C used the same technique as described for ABE 90. They measured $R = 9.38^{+0.82}_{-0.72} \pm 0.25$, obtained $\Gamma(W)/\Gamma(Z)$ = 0.902 ± 0.074 ± 0.024. Using $\Gamma(Z)$ = 2.546 ± 0.032 GeV, they obtained the $\Gamma(W)$ value quoted above and the limits $\Gamma(W)$ < 2.56 (2.64) GeV at the 90% (95%) CL. $E^{p\bar{p}}_{cm}$ = 546,630 GeV.

[44] ALBAJAR 89 result is from a total sample of 299 $W \to e\nu$ events.

[45] If systematic error is neglected, result is $2.7^{+1.4}_{-1.5}$ GeV. This is enhanced subsample of 172 total events.

W^+ DECAY MODES

W^- modes are charge conjugates of the modes below.

	Mode		Fraction (Γ_i/Γ)	Confidence level
Γ_1	$\ell^+\nu$	[a]	(10.56 ± 0.14) %	
Γ_2	$e^+\nu$		(10.66 ± 0.20) %

• • • We do not use the following data for averages, fits, limits, etc. • • •			
	[47] BARATE 99L	ALEP	E^{ee}_{cm}= 161+172+183 GeV

[46] BARATE 99I measure this quantity using the dependence of the total cross section σ_{WW} upon a change in the total width. The fit is performed to the WW measured cross sections at 161, 172, and 183 GeV. This partial width is < 139 MeV at 95%CL.

[47] BARATE 99L use W-pair production to search for effectively invisible W decays, tagging with the decay of the other W boson to Standard Model particles. The partial width for effectively invisible decay is < 27 MeV at 95%CL.

W BRANCHING RATIOS

Overall fits are performed to determine the branching ratios of the W. For each LEP experiment the correlation matrix of the leptonic branching ratios is used and the common systematic errors among LEP experiments are properly taken into account. A first fit determines three individual leptonic branching ratios, $B(W \to e\nu_e)$, $B(W \to \mu\nu_\mu)$, and $B(W \to \tau\nu_\tau)$. This fit has a χ^2 = 10.5 for 20 degrees of freedom. A second fit assumes lepton universality and determines the leptonic branching ratio $B(W \to \ell\nu_\ell)$. This fit has a χ^2=11.0 for 22 degrees of freedom. A separate fit is performed only to hadronic branching ratio data taking into account the common systematic errors. This fit has a χ^2=2.3 for 3 degrees of freedom.

$\Gamma(\ell^+\nu)/\Gamma_{total}$ Γ_1/Γ

ℓ indicates average over e, μ, and τ modes, not sum over modes.

Data marked "fit" are used for the fit. The other data is highly correlated with data appearing elsewhere in the Listings and are therefore not used in the fit.

[50] ABBOTT 00B measure $R \equiv [\sigma_W B(W \to e\nu_e)]/[\sigma_Z B(Z \to ee)]$ = 10.43 ± 0.27 for the $W \to e\nu_e$ decay channel. They use the SM theoretical prediction for $\sigma(W)/\sigma(Z)$ and the world average for $B(Z \to ee)$.

[51] ABE 95W result is from a measurement of $\sigma B(W \to e\nu)/\sigma B(Z \to e^+e^-)$ = 10.90 ± 0.32 ± 0.29, the theoretical prediction for the cross section ratio, the experimental knowledge of $\Gamma(Z \to e^+e^-)$ = 83.98 ± 0.18 MeV, and $\Gamma(Z)$ = 2.4969 ± 0.0038 GeV.

[52] The first error was obtained by adding the statistical and systematic experimental uncertainties in quadrature. The second error reflects the dependence on theoretical prediction of total W cross section: $\sigma(546\ \text{GeV}) = 4.7^{+1.4}_{-0.7}$ nb and $\sigma(630\ \text{GeV}) = 5.8^{+1.8}_{-1.0}$ nb. See ALTARELLI 85B.

[63] ABREU 98C combine results from both the fully hadronic as well semileptonic WW final states after demonstrating that the W decay charged multiplicity is independent of the topology within errors.

TRIPLE GAUGE COUPLINGS (TGC'S)

Revised March 2000 by C. Caso (Univ. of Genova) and A. Gurtu (Tata Inst.)

Fourteen independent couplings, 7 each for ZWW and γWW, completely describe the VWW vertices within the most general framework of the electroweak Standard Model (SM) consistent with Lorentz invariance and $U(1)$ gauge invariance. Of each of the 7 TGC's, 3 conserve C and P individually, 3 violate CP, and one TGC violates C and P individually while conserving CP. Assumption of C and P conservation and electromagnetic gauge invariance reduces the independent VWW couplings to five: one common set is $(\kappa_\gamma, \kappa_Z, \lambda_\gamma, \lambda_Z, g_1^Z)$, where $\kappa_\gamma = \kappa_Z = g_1^Z = 1$ and $\lambda_\gamma = \lambda_Z = 0$ in the Standard Model at the tree level. The W magnetic dipole moment, μ_W, and the W electric quadrupole moment, q_W, are expressed as $\mu_W = e\,(1 + \kappa_\gamma + \lambda_\gamma)/2M_W$ and $q_W = -e\,(\kappa_\gamma - \lambda_\gamma)/M_W^2$.

Precision measurements of suitable observables at LEP1 has already led to an exploration of much of the TGC parameter space. Three linear combinations of the TGC's, $\alpha_{W\phi}$, $\alpha_{B\phi}$ and α_W, have been proposed to investigate the leftover "blind" directions in the CP-conserving TGC parameter space, and two linear couplings, $\widetilde{\alpha}_{BW}$ and $\widetilde{\alpha}_W$ in the CP-violating TGC parameter space (see *e.g.*, papers by Hagiwara [1], Bilenky [2], and Gounaris [3,4]). The relations between these parameters and those contained in the above set, expressed as *deviations* from the SM, are $\Delta g_1^Z = \alpha_{W\phi}/c_w^2$, $\Delta\kappa_\gamma = \alpha_{W\phi} + \alpha_{B\phi}$, $\Delta\kappa_Z = \alpha_{W\phi} - t_w^2\alpha_{B\phi}$ and $\lambda_\gamma = \lambda_Z = \alpha_W$, where c_w and t_w are the cosine and tangent of the electroweak mixing angle. Similarly, $\widetilde{\kappa}_\gamma = \widetilde{\alpha}_{BW}, \widetilde{\kappa}_Z = t_w^2\widetilde{\alpha}_{BW}$ and $\widetilde{\lambda}_\gamma = \widetilde{\lambda}_Z = \widetilde{\alpha}_W$ within the CP-violating sector. The LEP Collaborations have recently agreed to express their results directly in terms of the parameters Δg_1^Z, $\Delta\kappa_\gamma$ and λ_γ.

At LEP2 the VWW coupling arises in W-pair production via s-channel exchange or in single W production via the radiation of a virtual photon off the incident e^+ or e^-. At the TEVATRON hard photon bremstrahlung off a produced W or Z signals the presence of a triple gauge vertex. In order to extract the value of one TGC the others are generally kept fixed to their SM values.

W ANOMALOUS MAGNETIC MOMENT ($\Delta\kappa$)

The full magnetic moment is given by $\mu_W = e(1+\kappa+\lambda)/2m_W$. In the Standard Model, at tree level, $\kappa = 1$ and $\lambda = 0$. Some papers have defined $\Delta\kappa = 1-\kappa$ and assume that $\lambda = 0$. Note that the electric quadrupole moment is given by $-e(\kappa-\lambda)/m^2_W$. A description of the parameterization of these moments and additional references can be found in HAGIWARA 87 and BAUR 88. The parameter Λ appearing in the theoretical limits below is a regularization cutoff which roughly corresponds to the energy scale where the structure of the W boson becomes manifest.

	[104] SUZUKI	85 THEO
	[105] HERZOG	84 THEO

[96] ABE 95G report $-1.3 < \kappa < 3.2$ for λ=0 and $-0.7 < \lambda < 0.7$ for κ=1 in $p\overline{p} \rightarrow e\nu_e\gamma X$ and $\mu\nu_\mu\gamma X$ at $\sqrt{s}$ = 1.8 TeV.

[97] ALITTI 92C measure $\kappa = 1^{+2.6}_{-2.2}$ and $\lambda = 0^{+1.7}_{-1.8}$ in $p\overline{p} \rightarrow e\nu\gamma + X$ at $\sqrt{s}$ = 630 GeV. At 95%CL they report $-3.5 < \kappa < 5.9$ and $-3.6 < \lambda < 3.5$.

[98] SAMUEL 92 use preliminary CDF and UA2 data and find $-2.4 < \kappa < 3.7$ at 96%CL and $-3.1 < \kappa < 4.2$ at 95%CL respectively. They use data for $W\gamma$ production and radiative W decay.

[99] SAMUEL 91 use preliminary CDF data for $p\overline{p} \rightarrow W\gamma X$ to obtain $-11.3 \leq \Delta\kappa \leq 10.9$. Note that their $\kappa = 1-\Delta\kappa$.

[100] GRIFOLS 88 uses deviation from ρ parameter to set limit $\Delta\kappa \lesssim 65\ (M^2_W/\Lambda^2)$.

[101] GROTCH 87 finds the limit $-37 < \Delta\kappa < 73.5$ (90% CL) from the experimental limits on $e^+e^- \rightarrow \nu\overline{\nu}\gamma$ assuming three neutrino generations and $-19.5 < \Delta\kappa < 56$ for four generations. Note their $\Delta\kappa$ has the opposite sign as our definition.

[102] VANDERBIJ 87 uses existing limits to the photon structure to obtain $|\Delta\kappa| < 33\ (m_W/\Lambda)$. In addition VANDERBIJ 87 discusses problems with using the ρ parameter of the Standard Model to determine $\Delta\kappa$.

[103] GRAU 85 uses the muon anomaly to derive a coupled limit on the anomalous magnetic dipole and electric quadrupole (λ) moments $1.05 > \Delta\kappa\ \ln(\Lambda/m_W) + \lambda/2 > -2.77$. In the Standard Model $\lambda = 0$.

[104] SUZUKI 85 uses partial-wave unitarity at high energies to obtain $|\Delta\kappa| \lesssim 190\ (m_W/\Lambda)^2$. From the anomalous magnetic moment of the muon, SUZUKI 85 obtains $|\Delta\kappa| \lesssim 2.2/\ln(\Lambda/m_W)$. Finally SUZUKI 85 uses deviations from the ρ parameter and obtains a very qualitative, order-of-magnitude limit $|\Delta\kappa| \lesssim 150\ (m_W/\Lambda)^4$ if $|\Delta\kappa| \ll 1$.

[105] HERZOG 84 consider the contribution of W-boson to muon magnetic moment including anomalous coupling of $WW\gamma$. Obtain a limit $-1 < \Delta\kappa < 3$ for $\Lambda \gtrsim 1$ TeV.

Z

$J = 1$

THE Z BOSON

Revised March 2000 by C. Caso (Univ. of Genova) and A. Gurtu (Tata Inst.)

Precision measurements at the Z-boson resonance using electron–positron colliding beams began in 1989 at the SLC and at LEP. During 1989–95, the four CERN experiments have made high-statistics studies of the Z. The availability of longitudinally polarized electron beams at the SLC since 1993 has enabled a precision determination of the effective electroweak mixing angle $\sin^2\overline{\theta}_W$ that is competitive with the CERN results on this parameter.

The Z-boson properties reported in this section may broadly be categorized as:

- The standard 'lineshape' parameters of the Z consisting of its mass, M_Z, its total width, Γ_Z, and its partial decay widths, Γ(hadrons), and $\Gamma(\ell\overline{\ell})$ where $\ell = e, \mu, \tau, \nu$;
- Z asymmetries in leptonic decays and extraction of Z couplings to charged and neutral leptons;
- The b- and c-quark-related partial widths and charge asymmetries which require special techniques;
- Determination of Z decay modes and the search for modes that violate known conservation laws;
- Average particle multiplicities in hadronic Z decay;
- Z anomalous couplings.

Details on Z-parameter determination and the study of $Z \to b\overline{b}, c\overline{c}$ at LEP and SLC are given in this note.

The standard 'lineshape' parameters of the Z are determined from an analysis of the production cross sections of these final states in e^+e^- collisions. The $Z \to \nu\overline{\nu}(\gamma)$ state is identified directly by detecting single photon production and indirectly by subtracting the visible partial widths from the total width. Inclusion in this analysis of the forward-backward asymmetry of charged leptons, $A_{FB}^{(0,\ell)}$, of the τ polarization, $P(\tau)$, and its forward-backward asymmetry, $P(\tau)^{fb}$, enables the separate determination of the effective vector ($\overline{g}_V$) and axial vector ($\overline{g}_A$) couplings of the Z to these leptons and the ratio ($\overline{g}_V/\overline{g}_A$) which is related to the effective electroweak mixing angle $\sin^2\overline{\theta}_W$ (see the "Electroweak Model and Constraints on New Physics" Review).

Determination of the b- and c-quark-related partial widths and charge asymmetries involves tagging the b and c quarks. Traditionally this was done by requiring the presence of a prompt lepton in the event with high momentum and high transverse momentum (with respect to the accompanying jet). Precision vertex measurement with high-resolution detectors enabled one to do impact parameter and lifetime tagging. Neural-network techniques have also been used to classify events as b or non-b on a statistical basis using event–shape variables. Finally, the presence of a charmed meson (D/D^*) has been used to tag heavy quarks.

Z-parameter determination

LEP was run at energy points on and around the Z mass (88–94 GeV) constituting an energy 'scan.' The shape of the cross-section variation around the Z peak can be described by a Breit-Wigner *ansatz* with an energy-dependent total width [1–3]. The **three** main properties of this distribution, viz., the **position** of the peak, the **width** of the distribution, and the **height** of the peak, determine respectively the values of M_Z, Γ_Z, and $\Gamma(e^+e^-) \times \Gamma(f\overline{f})$, where $\Gamma(e^+e^-)$ and $\Gamma(f\overline{f})$ are the electron and fermion partial widths of the Z. The quantitative determination of these parameters is done by writing analytic expressions for these cross sections in terms of the parameters and fitting the calculated cross sections to the measured ones by varying these parameters, taking properly into account all the errors. Single-photon exchange (σ^0_γ) and γ-Z interference ($\sigma^0_{\gamma Z}$) are included, and the large (~25 %) initial-state radiation (ISR) effects are taken into account by convoluting the analytic expressions over a 'Radiator Function' [1–6] $H(s, s')$. Thus for the process $e^+e^- \to f\overline{f}$:

$$\sigma_f(s) = \int H(s,s')\, \sigma^0_f(s')\, ds' \quad (1)$$

$$\sigma^0_f(s) = \sigma^0_Z + \sigma^0_\gamma + \sigma^0_{\gamma Z} \quad (2)$$

$$\sigma^0_Z = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\Gamma(f\overline{f})}{\Gamma_Z^2} \frac{s\,\Gamma_Z^2}{(s - M_Z^2)^2 + s^2\Gamma_Z^2/M_Z^2} \quad (3)$$

$$\sigma^0_\gamma = \frac{4\pi\alpha^2(s)}{3s}\, Q_f^2 N_c^f \quad (4)$$

$$\sigma^0_{\gamma Z} = -\frac{2\sqrt{2}\alpha(s)}{3} \left(Q_f G_F N_c^f \mathcal{G}_{Ve}\mathcal{G}_{Vf}\right) \times \frac{(s - M_Z^2)M_Z^2}{(s - M_Z^2)^2 + s^2\Gamma_Z^2/M_Z^2} \quad (5)$$

where Q_f is the charge of the fermion, $N_c^f = 3(1)$ for quark (lepton) and $\mathcal{G}_{Vf}$ is the neutral vector coupling of the Z to the fermion-antifermion pair $f\overline{f}$.

Since $\sigma^0_{\gamma Z}$ is expected to be much less than σ^0_Z, the LEP Collaborations have generally calculated the interference term in the framework of the Standard Model. This fixing of $\sigma^0_{\gamma Z}$ leads to a tighter constraint on M_Z and consequently a smaller error on its fitted value.

In the above framework, the QED radiative corrections have been explicitly taken into account by convoluting over the ISR and allowing the electromagnetic coupling constant to run [10]: $\alpha(s) = \alpha/(1 - \Delta\alpha)$. On the other hand, weak radiative corrections that depend upon the assumptions of the electroweak theory and on the values of the unknown $M_{\rm top}$ and $M_{\rm Higgs}$ are accounted for by **absorbing them into the couplings**, which are then called the *effective* couplings $\mathcal{G}_V$ and $\mathcal{G}_A$ (or alternatively the effective parameters of the $\star$ scheme of Kennedy and Lynn [11]).

$\mathcal{G}_{Vf}$ and $\mathcal{G}_{Af}$ are complex numbers with a small imaginary part. As experimental data does not allow simultaneous extraction of both real and imaginary parts of the effective couplings, the convention $g_{Af} = \mathrm{Re}(\mathcal{G}_{Af})$ and $g_{Vf} = \mathrm{Re}(\mathcal{G}_{Vf})$ is used and the imaginary parts are added in the fitting code [4].

Defining

$$A_f = 2\frac{g_{Vf} \cdot g_{Af}}{(g_{Vf}^2 + g_{Af}^2)} \tag{6}$$

the lowest-order expressions for the various lepton-related asymmetries on the Z pole are [7–9] $A_{FB}^{(0,\ell)} = (3/4)A_e A_f$, $P(\tau) = -A_\tau$, $P(\tau)^{fb} = -(3/4)A_e$, $A_{LR} = A_e$. The full analysis takes into account the energy dependence of the asymmetries. Experimentally A_{LR} is defined as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$ where $\sigma_{L(R)}$ are the $e^+e^- \to Z$ production cross sections with left-(right)-handed electrons.

The definition of the partial decay width of the Z to $f\overline{f}$ includes the effects of QED and QCD final state corrections as well as the contribution due to the imaginary parts of the couplings:

$$\Gamma(f\overline{f}) = \frac{G_F M_Z^3}{6\sqrt{2}\pi} N_c^f (|\mathcal{G}_{Vf}|^2 R_A^f + |\mathcal{G}_{VA}|^2 R_V^f) + \Delta_{ew/\mathrm{QCD}} \tag{7}$$

where R_V^f and R_A^f are radiator factors to account for final state QED and QCD corrections as well as effects due to nonzero fermion masses, and $\Delta_{ew/\mathrm{QCD}}$ represents the non-factorizable electroweak/QCD corrections.

S-matrix approach to the Z

While practically all experimental analyses of LEP/SLC data have followed the 'Breit-Wigner' approach described above, an alternative S-matrix-based analysis is also possible. The Z, like all unstable particles, is associated with a complex pole in the S matrix. The pole position is process independent and gauge invariant. The mass, $\overline{M}_Z$, and width, $\overline{\Gamma}_Z$, can be defined in terms of the pole in the energy plane via [12–15]

$$\overline{s} = \overline{M}_Z^2 - i\overline{M}_Z\overline{\Gamma}_Z \tag{8}$$

leading to the relations

$$\overline{M}_Z = M_Z/\sqrt{1+\Gamma_Z^2/M_Z^2}$$
$$\approx M_Z \ - 34.1 \text{ MeV} \tag{9}$$
$$\overline{\Gamma}_Z = \Gamma_Z/\sqrt{1+\Gamma_Z^2/M_Z^2}$$
$$\approx \Gamma_Z \ - 0.9 \text{ MeV} . \tag{10}$$

Some authors [16] choose to define the Z mass and width via

$$\overline{s} = (\overline{M}_Z - \frac{i}{2}\overline{\Gamma}_Z)^2 \tag{11}$$

which yields $\overline{M}_Z \approx M_Z - 26$ MeV, $\overline{\Gamma}_Z \approx \Gamma_Z - 1.2$ MeV.

The L3 and OPAL Collaborations at LEP (ACCIARRI 97K and ACKERSTAFF 97C) have analyzed their data using the S–matrix approach as defined in Eq. (8), in addition to the conventional one. They observe a downward shift in the Z mass as expected.

Handling the large-angle e^+e^- final state

Unlike other $f\overline{f}$ decay final states of the Z, the e^+e^- final state has a contribution not only from the s-channel but also from the t-channel and s-t interference. The full amplitude is not amenable to fast calculation, which is essential if one has to carry out minimization fits within reasonable computer time. The usual procedure is to calculate the non-s channel part of the cross section separately using the Standard Model programs ALIBABA [17] or TOPAZ0 [18] with the measured value of M_{top}, and $M_{\mathrm{Higgs}} = 150$ GeV and add it to the s-channel cross section calculated as for other channels. This leads to two additional sources of error in the analysis: firstly, the theoretical calculation in ALIBABA itself is known to be accurate to $\sim 0.5\%$, and secondly, there is uncertainty due to the error on M_{top} and the unknown value of M_{Higgs} (100–1000 GeV). These additional errors are propagated into the analysis by including them in the systematic error on the e^+e^- final state. As these errors are common to the four LEP experiments, this is taken into account when performing the LEP average.

Errors due to uncertainty in LEP energy determination [19–23]

The systematic errors related to the LEP energy measurement can be classified as:

- The absolute energy scale error;
- Energy-point-to-energy-point errors due to the non-linear response of the magnets to the exciting currents;
- Energy-point-to-energy-point errors due to possible higher-order effects in the relationship between the dipole field and beam energy;
- Energy reproducibility errors due to various unknown uncertainties in temperatures, tidal effects, corrector settings, RF status, *etc.*

Precise energy calibration was done outside normal data taking using the resonant depolarization technique. Run-time energies were determined every 10 minutes by measuring the relevant machine parameters and using a model which takes into account all the known effects, including leakage currents produced by trains in the Geneva area and the tidal effects due to gravitational forces of the Sun and the Moon. The LEP Energy Working Group has provided a covariance matrix from the determination of LEP energies for the different running periods during 1993–1995 [5].

Choice of fit parameters

The LEP Collaborations have chosen the following primary set of parameters for fitting: M_Z, Γ_Z, $\sigma^0_{\mathrm{hadron}}$, $R(\mathrm{lepton})$, $A_{FB}^{(0,\ell)}$, where $R(\mathrm{lepton}) = \Gamma(\mathrm{hadrons})/\Gamma(\mathrm{lepton})$, $\sigma^0_{\mathrm{hadron}} = 12\pi\Gamma(e^+e^-)\Gamma(\mathrm{hadrons})/M_Z^2\Gamma_Z^2$. With a knowledge of these fitted parameters and their covariance matrix, any other parameter can be derived. The main advantage of these parameters is that they form the **least correlated** set of parameters, so that it becomes easy to combine results from the different LEP experiments.

Thus, the most general fit carried out to cross section and asymmetry data determines the **nine parameters**: M_Z, Γ_Z, σ^0_{hadron}, $R(e)$, $R(\mu)$, $R(\tau)$, $A^{(0,e)}_{FB}$, $A^{(0,\mu)}_{FB}$, $A^{(0,\tau)}_{FB}$. Assumption of lepton universality leads to a **five-parameter fit** determining M_Z, Γ_Z, σ^0_{hadron}, $R(\text{lepton})$, $A^{(0,\ell)}_{FB}$. The use of **only** cross-section data leads to six- or four-parameter fits if lepton universality is or is not assumed, *i.e.*, $A^{(0,\ell)}_{FB}$ values are not determined.

In order to determine the best values of the effective vector and axial vector couplings of the charged leptons to the Z, the above mentioned nine- and five-parameter fits are carried out with added constraints from the measured values of A_τ and A_e obtained from τ polarization studies at LEP and the determination of A_{LR} at SLC.

Combining results from the LEP and SLC experiments [24]

Each LEP experiment provides the values of the parameters mentioned above together with the full covariance matrix. The statistical and experimental systematic errors are assumed to be uncorrelated among the four experiments. The sources of **common** systematic errors are i) the LEP energy uncertainties, ii) the effect of theoretical uncertainty in calculating the small-angle Bhabha cross section for luminosity determination and in estimating the non-s channel contribution to the large-angle Bhabha cross section, and iii) common theory errors. Using this information, a full covariance matrix, V, of all the input parameters is constructed and a combined parameter set is obtained by minimizing $\chi^2 = \Delta^T V^{-1} \Delta$, where Δ is the vector of residuals of the combined parameter set to the results of individual experiments.

Non-LEP measurement of a Z parameter, (*e.g.*, $\Gamma(e^+e^-)$ from SLD) is included in the overall fit by calculating its value using the fit parameters and constraining it to the measurement.

Study of $Z \to b\bar{b}$ and $Z \to c\bar{c}$

In the sector of c- and b-physics the LEP experiments have measured the ratios of partial widths $R_b = \Gamma(Z \to b\bar{b})/\Gamma(Z \to \text{hadrons})$ and $R_c = \Gamma(Z \to c\bar{c})/\Gamma(Z \to \text{hadrons})$ and the forward-backward (charge) asymmetries $A^{b\bar{b}}_{FB}$ and $A^{c\bar{c}}_{FB}$. Several of the analyses have also determined other quantities, in particular the semileptonic branching ratios, $\text{B}(b \to \ell)$, $\text{B}(b \to c \to \ell^+)$, and $\text{B}(c \to \ell)$, the average $B^0\overline{B}^0$ mixing parameter $\overline{\chi}$ and the probabilities for a c-quark to fragment into a D^+, a D_s, a D^{*+} , or a charmed baryon. The latter measurements do not concern properties of the Z boson and hence they do not appear in the listing below. However, for completeness, we will report at the end of this minireview their values as obtained fitting the data contained in the Z section. All these quantities are correlated with the electroweak parameters, and since the mixture of b hadrons is different from the one at the $\Upsilon(4S)$, their values might differ from those measured at the $\Upsilon(4S)$.

All the above quantities are correlated to each other since:

- Several analyses (for example the lepton fits) determine more than one parameter simultaneously;
- Some of the electroweak parameters depend explicitly on the values of other parameters (for example R_b depends on R_c);
- Common tagging and analysis techniques produce common systematic uncertainties.

The LEP Electroweak Heavy Flavour Working Group has developed [25] a procedure for combining the measurements taking into account known sources of correlation. The combining procedure determines twelve parameters: the four parameters of interest in the electroweak sector, R_b, R_c, $A^{b\bar{b}}_{FB}$, and $A^{c\bar{c}}_{FB}$ and, in addition, $\text{B}(b \to \ell)$, $\text{B}(b \to c \to \ell^+)$, $\text{B}(c \to \ell)$, $\overline{\chi}$, $f(D^+)$, $f(D_s)$, $f(c_{\text{baryon}})$ and $P(c \to D^{*+}) \times \text{B}(D^{*+} \to \pi^+ D^0)$, to take into account their correlations with the electroweak parameters. Before the fit both the peak and off-peak asymmetries are translated to the common energy $\sqrt{s} = 91.26$ GeV using the predicted dependence from ZFITTER [6].

Summary of the measurements and of the various kinds of analysis

The measurements of R_b and R_c fall into two classes. In the first, named single-tag measurement, a method for selecting b and c events is applied and the number of tagged events is counted. The second technique, named double-tag measurement, is based on the following principle: if the number of events with a single hemisphere tagged is N_t and with both hemispheres tagged is N_{tt}, then given a total number of N_{had} hadronic Z decays one has:

$$\frac{N_t}{2N_{\text{had}}} = \varepsilon_b R_b + \varepsilon_c R_c + \varepsilon_{uds}(1 - R_b - R_c) \quad (12)$$

$$\frac{N_{tt}}{N_{\text{had}}} = C_b \varepsilon_b^2 R_b + C_c \varepsilon_c^2 R_c + C_{uds} \varepsilon_{uds}^2 (1 - R_b - R_c) \quad (13)$$

where ε_b, ε_c, and ε_{uds} are the tagging efficiencies per hemisphere for b, c, and light quark events, and $C_q \neq 1$ accounts for the fact that the tagging efficiencies between the hemispheres may be correlated. In tagging the b one has $\varepsilon_b \gg \varepsilon_c \gg \varepsilon_{uds}$, $C_b \approx 1$. Neglecting the c and uds background and the hemisphere correlations, these equations give:

$$\varepsilon_b = 2N_{tt}/N_t \quad (14)$$

$$R_b = N_t^2/(4N_{tt}N_{\text{had}}) \; . \quad (15)$$

The double-tagging method has thus the great advantage that the tagging efficiency is directly derived from the data, reducing the systematic error of the measurement. The backgrounds, dominated by $c\bar{c}$ events, obviously complicate this simple picture, and their level must still be inferred by other means. The rate of charm background in these analyses depends explicitly on the value of R_c. The correlations in the tagging efficiencies between the hemispheres (due for instance to correlations in momentum between the b hadrons in the two hemispheres) are small but nevertheless lead to further systematic uncertainties.

The measurements in the b- and c-sector can be essentially grouped in the following categories:

- Lifetime (and lepton) double-tagging measurements of R_b. These are the most precise measurements of R_b and obviously dominate the combined result. The main sources of systematics come from the charm contamination and from estimating the hemisphere b-tagging efficiency correlation. The charm rejection has been improved (and hence the systematic errors reduced) by using either the information of the secondary vertex invariant mass or the information from the energy of all particles at the secondary vertex and their rapidity;
- Analyses with $D/D^{*\pm}$ to measure R_c. These measurements make use of several different tagging techniques (inclusive/exclusive double tag, exclusive double tag, reconstruction of all weakly decaying charmed states) and no assumptions are made on the energy dependence of charm fragmentation;
- Lepton fits which use hadronic events with one or more leptons in the final state to measure $A_{FB}^{b\bar{b}}$ and $A_{FB}^{c\bar{c}}$. Each analysis usually gives several other electroweak parameters. The dominant sources of systematics are due to lepton identification, to other semileptonic branching ratios and to the modeling of the semileptonic decay;
- Measurements of $A_{FB}^{b\bar{b}}$ using lifetime tagged events with a hemisphere charge measurement. Their contribution to the combined result has roughly the same weight as the lepton fits;
- Analyses with $D/D^{*\pm}$ to measure $A_{FB}^{c\bar{c}}$ or simultaneously $A_{FB}^{b\bar{b}}$ and $A_{FB}^{c\bar{c}}$;
- Measurements of A_b and A_c from SLD, using several tagging methods (lepton, kaon, D/D^*, and vertex mass). These quantities are directly extracted from a measurement of the left-right forward-backward asymmetry in $c\bar{c}$ and $b\bar{b}$ production using a polarized electron beam.

Averaging procedure

All the measurements are provided by the LEP Collaborations in the form of tables with a detailed breakdown of the systematic errors of each measurement and its dependence on other electroweak parameters.

The averaging proceeds via the following steps:

- Define and propagate a consistent set of external inputs such as branching ratios, hadron lifetimes, fragmentation models *etc.* All the measurements are also consistently checked to ensure that all use a common set of assumptions (for instance since the QCD corrections for the forward-backward asymmetries are strongly dependent on the experimental conditions, the data are corrected before combining);
- Form the full (statistical and systematic) covariance matrix of the measurements. The systematic correlations between different analyses are calculated from the detailed error breakdown in the measurement tables. The correlations relating several measurements made by the same analysis are also used;
- Take into account any explicit dependence of a measurement on the other electroweak parameters. As an example of this dependence we illustrate the case of the double-tag measurement of R_b, where c-quarks constitute the main background. The normalization of the charm contribution is not usually fixed by the data and the measurement of R_b depends on the assumed value of R_c, which can be written as:

$$R_b = R_b^{\text{meas}} + a(R_c)\frac{(R_c - R_c^{\text{used}})}{R_c} \,, \qquad (16)$$

  where R_b^{meas} is the result of the analysis which assumed a value of $R_c = R_c^{\text{used}}$ and $a(R_c)$ is the constant which gives the dependence on R_c;
- Perform a χ^2 minimization with respect to the combined electroweak parameters.

After the fit the average peak asymmetries $A_{FB}^{c\bar{c}}$ and $A_{FB}^{b\bar{b}}$ are corrected for the energy shift from 91.26 GeV to M_Z and for QED (initial state radiation), γ exchange, and γZ interference effects to obtain the corresponding pole asymmetries $A_{FB}^{0,c}$ and $A_{FB}^{0,b}$.

This averaging procedure, using the twelve parameters described above and applied to the data contained in the Z particle listing below, gives the following results:

$$R_b^0 = 0.21644 \pm 0.00075$$
$$R_c^0 = 0.1671 \pm 0.0048$$
$$A_{FB}^{0,b} = 0.1003 \pm 0.0022$$
$$A_{FB}^{0,c} = 0.0701 \pm 0.0045$$
$$B(b \to \ell) = 0.1056 \pm 0.0026$$
$$\mathrm{B}(b \to c \to \ell^+) = 0.0807 \pm 0.0034$$
$$B(c \to \ell) = 0.0990 \pm 0.0037$$
$$\overline{\chi} = 0.1177 \pm 0.0055$$
$$f(D^+) = 0.239 \pm 0.016$$
$$f(D_s) = 0.116 \pm 0.025$$
$$f(c_{\text{baryon}}) = 0.084 \pm 0.023$$
$$P(c \to D^{*+}) \times \mathrm{B}(D^{*+} \to \pi^+ D^0) = 0.1657 \pm 0.0057$$

Z MASS

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the "Note on the Z boson"). The fit is performed using the Z mass and width, the Z hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the Z pole forward-backward lepton asymmetries. This set is believed to be most free of correlations.

The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. The value is 34 MeV greater than the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator. Also the LEP experiments have generally assumed a fixed value of the $\gamma - Z$ interferences term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted Z mass. See ACCIARRI 97K and ACKERSTAFF 97C for a detailed investigation of both these issues.

93.1 ±1.0 ±3.0	24	[14] ALBAJAR 89	UA1	$E^{p\overline{p}}_{cm}$= 546,630 GeV

[1] The error includes 1.6 MeV due to LEP energy uncertainty.
[2] The error includes 1.8 MeV due to LEP energy uncertainty.
[3] BARATE 00C error includes approximately 2.4 MeV due to statistics, 0.2 MeV due to experimental systematics, and 1.7 MeV due to LEP energy uncertainty.
[4] ACCIARRI 97K interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism with a combined fit to their cross section and asymmetry data at the Z peak (ACCIARRI 94) and their data at 130, 136, 161, and 172 GeV. The authors have corrected the measurement for the 34.1 MeV shift with respect to the Breit-Wigner fits. The error contains a contribution of ±3 MeV due to the uncertainty on the γZ interference.
[5] ACKERSTAFF 97C obtain this using the S-matrix formalism for a combined fit to their cross-section and asymmetry data at the Z peak (AKERS 94) and their data at 130, 136, and 161 GeV. The authors have corrected the measurement for the 34 MeV shift with respect to the Breit-Wigner fits.
[6] ACCIARRI 96B interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix ansatz. The 130–136 GeV data constrains the γZ interference terms. As expected, this result is below the mass values obtained with a standard Breit-Wigner parametrization.
[7] ALEXANDER 96X obtain this using the S-matrix formalism for a combined fit to their cross-section and asymmetry data at the Z peak (AKERS 94) and their data at 130 and 136 GeV. The authors have corrected the measurement for the 34 MeV shift with respect to the Breit-Wigner fits.
[8] MIYABAYASHI 95 combine their low energy total hadronic cross-section measurement with the ACTON 93D data and perform a fit using an S-matrix formalism. As expected, this result is below the mass values obtained with the standard Breit-Wigner parametrization.
[9] The second error of 6.3 MeV is due to a common LEP energy uncertainty.
[10] Enters fit through W/Z mass ratio given in the W Particle Listings. The ALITTI 92B systematic error (±0.93) has two contributions: one (±0.92) cancels in m_W/m_Z and one (±0.12) is noncancelling. These were added in quadrature.
[11] ADACHI 90F use a Breit-Wigner resonance shape fit and combine their results with published data of PEP and PETRA.
[12] First error of ABE 89 is combination of statistical and systematic contributions; second is mass scale uncertainty.
[13] ABRAMS 89B uncertainty includes 35 MeV due to the absolute energy measurement.
[14] ALBAJAR 89 result is from a total sample of 33 $Z \rightarrow e^+e^-$ events.

Z WIDTH

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the "Note on the Z boson").

3.8	±0.8	±1.0	188	ABE	89C	CDF	$E^{p\overline{p}}_{cm}$= 1.8 TeV
2.42	$^{+0.45}_{-0.35}$		480	[22] ABRAMS	89B	MRK2	E^{ee}_{cm}= 89–93 GeV
2.7	$^{+1.2}_{-1.0}$	±1.3	24	[23] ALBAJAR	89	UA1	$E^{p\overline{p}}_{cm}$= 546,630 GeV
2.7	±2.0	±1.0	25	[24] ANSARI	87	UA2	$E^{p\overline{p}}_{cm}$= 546,630 GeV

[15] The error includes 1.2 MeV due to LEP energy uncertainty.

[16] The error includes 1.3 MeV due to LEP energy uncertainty.

[17] BARATE 00C error includes approximately 3.8 MeV due to statistics, 0.9 MeV due to experimental systematics, and 1.3 MeV due to LEP energy uncertainty.

[18] ACCIARRI 97K interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism with a combined fit to their cross section and asymmetry data at the Z peak (ACCIARRI 94) and their data at 130, 136, 161, and 172 GeV. The authors have corrected the measurement for the 0.9 MeV shift with respect to the Breit-Wigner fits.

[19] ABREU 96R obtain this value from a study of the interference between initial and final state radiation in the process $e^+e^- \rightarrow Z \rightarrow \mu^+\mu^-$.

[20] ACCIARRI 96B interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix ansatz. The 130–136 GeV data constrains the γZ interference terms. The fitted width is expected to be 0.9 MeV less than that obtained using the standard Breit-Wigner parametrization (see 'Note on the Z Boson').

[21] The second error of 4.5 MeV is due to a common LEP energy uncertainty.

[22] ABRAMS 89B uncertainty includes 50 MeV due to the miniSAM background subtraction error.

[23] ALBAJAR 89 result is from a total sample of 33 $Z \rightarrow e^+e^-$ events.

[24] Quoted values of ANSARI 87 are from direct fit. Ratio of Z and W production gives either $\Gamma(Z) < (1.09 \pm 0.07) \times \Gamma(W)$, CL = 90% or $\Gamma(Z) = (0.82^{+0.19}_{-0.14} \pm 0.06) \times \Gamma(W)$. Assuming Standard-Model value $\Gamma(W)$ = 2.65 GeV then gives $\Gamma(Z) <$ 2.89 ± 0.19 or = $2.17^{+0.50}_{-0.37}$ ± 0.16.

$\Gamma((u\overline{u}+c\overline{c})/2)/\Gamma(\text{hadrons})$ — Γ_7/Γ_6

This quantity is the branching ratio of $Z \to$ "up-type" quarks to $Z \to$ hadrons. Except ACKERSTAFF 97T the values of $Z \to$ "up-type" and $Z \to$ "down-type" branchings are extracted from measurements of Γ(hadrons), and $\Gamma(Z \to \gamma +$ jets) where γ is a high-energy (>5 GeV) isolated photon. As the experiments use different procedures and slightly different values of M_Z, Γ(hadrons) and α_s in their extraction procedures, our average has to be taken with caution.

VALUE	DOCUMENT ID		TECN	COMMENT
0.145±0.015 OUR AVERAGE				
0.160±0.019±0.019	[36] ACKERSTAFF	97T	OPAL	E^{ee}_{cm}= 88–94 GeV
$0.137^{+0.038}_{-0.054}$	[37] ABREU	95X	DLPH	E^{ee}_{cm}= 88–94 GeV
0.139±0.026	[38] ACTON	93F	OPAL	E^{ee}_{cm}= 88–94 GeV
0.137±0.033	[39] ADRIANI	93	L3	E^{ee}_{cm}= 91.2 GeV

[36] ACKERSTAFF 97T measure $\Gamma_{u\overline{u}}/(\Gamma_{d\overline{d}}+\Gamma_{u\overline{u}}+\Gamma_{s\overline{s}})$ = 0.258 ± 0.031 ± 0.032. To obtain this branching ratio authors use R_c+R_b = 0.380 ± 0.010. This measurement is fully negatively correlated with the measurement of $\Gamma_{d\overline{d},s\overline{s}}/(\Gamma_{d\overline{d}}+\Gamma_{u\overline{u}}+\Gamma_{s\overline{s}})$ given in the next data block.

[37] ABREU 95X use M_Z = 91.187 ± 0.009 GeV, Γ(hadrons) = 1725 ± 12 MeV and α_s = 0.123 ± 0.005. To obtain this branching ratio we divide their value of $C_{2/3} = 0.91^{+0.25}_{-0.36}$ by their value of $(3C_{1/3} + 2C_{2/3})$ = 6.66 ± 0.05.

[38] ACTON 93F use the LEP 92 value of Γ(hadrons) = 1740 ± 12 MeV and α_s = $0.122^{+0.006}_{-0.005}$.

[39] ADRIANI 93 use M_Z = 91.181 ± 0.022 GeV, Γ(hadrons) = 1742 ± 19 MeV and α_s = 0.125 ± 0.009. To obtain this branching ratio we divide their value of $C_{2/3}$ = 0.92 ± 0.22 by their value of $(3C_{1/3} + 2C_{2/3})$ = 6.720 ± 0.076.

$\Gamma((d\overline{d}+s\overline{s}+b\overline{b})/3)/\Gamma(\text{hadrons})$ — Γ_8/Γ_6

This quantity is the branching ratio of $Z \to$ "down-type" quarks to $Z \to$ hadrons. Except ACKERSTAFF 97T the values of $Z \to$ "up-type" and $Z \to$ "down-type" branchings are extracted from measurements of Γ(hadrons), and $\Gamma(Z \to \gamma +$ jets) where γ is a high-energy (>5 GeV) isolated photon. As the experiments use different procedures and slightly different values of M_Z, Γ(hadrons) and α_s in their extraction procedures, our average has to be taken with caution.

VALUE	DOCUMENT ID		TECN	COMMENT
0.237±0.009 OUR AVERAGE				
0.230±0.010±0.010	[40] ACKERSTAFF	97T	OPAL	E^{ee}_{cm}= 88–94 GeV
$0.243^{+0.036}_{-0.026}$	[41] ABREU	95X	DLPH	E^{ee}_{cm}= 88–94 GeV
0.241±0.017	[42] ACTON	93F	OPAL	E^{ee}_{cm}= 88–94 GeV
0.243±0.022	[43] ADRIANI	93	L3	E^{ee}_{cm}= 91.2 GeV

[40] ACKERSTAFF 97T measure $\Gamma_{d\overline{d},s\overline{s}}/(\Gamma_{d\overline{d}}+\Gamma_{u\overline{u}}+\Gamma_{s\overline{s}})$ = 0.371 ± 0.016 ± 0.016. To obtain this branching ratio authors use R_c+R_b = 0.380 ± 0.010. This measurement is fully negatively correlated with the measurement of $\Gamma_{u\overline{u}}/(\Gamma_{d\overline{d}}+\Gamma_{u\overline{u}}+\Gamma_{s\overline{s}})$ presented in the previous data block.

[41] ABREU 95X use M_Z = 91.187 ± 0.009 GeV, Γ(hadrons) = 1725 ± 12 MeV and α_s = 0.123 ± 0.005. To obtain this branching ratio we divide their value of $C_{1/3} = 1.62^{+0.24}_{-0.17}$ by their value of $(3C_{1/3} + 2C_{2/3})$ = 6.66 ± 0.05.

[42] ACTON 93F use the LEP 92 value of Γ(hadrons) = 1740 ± 12 MeV and α_s = $0.122^{+0.006}_{-0.005}$.

[43] ADRIANI 93 use M_Z = 91.181 ± 0.022 GeV, Γ(hadrons) = 1742 ± 19 MeV and α_s = 0.125 ± 0.009. To obtain this branching ratio we divide their value of $C_{1/3}$ = 1.63 ± 0.15 by their value of $(3C_{1/3} + 2C_{2/3})$ = 6.720 ± 0.076.

$R_c = \Gamma(c\overline{c})/\Gamma(\text{hadrons})$ — Γ_9/Γ_6

OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the "Note on the Z boson." As a cross check we have also performed a weighted average of the R_c measurements taking into account the various common systematic errors. Assuming that the smallest common systematic error is fully correlated, we obtain R_c = 0.1683 ± 0.0049.

Because of the high current interest, we mention the following preliminary results here, but do not average them or include them in the Listings or Tables. Combining published and unpublished preliminary LEP and SLD electroweak results (as of March 2000) yields R_c = 0.1674 ± 0.0038. The Standard Model predicts R_c = 0.1723 for m_t = 174.3 GeV and M_H = 150 GeV.

0.165 ±0.005 ±0.020	[52] BUSKULIC	94G	ALEP	Repl. by BARATE 00B

[44] ABREU 00 obtain this result properly combining the measurement from the D^{*+} production rate (R_c= 0.1610 ± 0.0104 ± 0.0077 ± 0.0043 (BR)) with that from the overall charm counting (R_c= 0.1692 ± 0.0047 ± 0.0063 ± 0.0074 (BR)) in $c\overline{c}$ events. The systematic error includes an uncertainty of ±0.0054 due to the uncertainty on the charmed hadron branching fractions.

[45] BARATE 00B use exclusive decay modes to independently determine the quantities R_c×f($c \to$ X), X=D^0, D^+, D^+_s, and Λ_c. Estimating R_c×f($c \to \Xi_c/\Omega_c$)= 0.0034, they simply sum over all the charm decays to obtain R_c= 0.1738 ± 0.0047 ± 0.0088 ± 0.0075(BR). This is combined with all previous ALEPH measurements (BARATE 98T and BUSKULIC 94G, R_c= 0.1681 ± 0.0054 ± 0.0062) to obtain the quoted value.

[46] ACKERSTAFF 98E use an inclusive/exclusive double tag. In one jet $D^{*\pm}$ mesons are exclusively reconstructed in several decay channels and in the opposite jet a slow pion (opposite charge inclusive $D^{*\pm}$) tag is used. The b content of this sample is measured by the simultaneous detection of a lepton in one jet and an inclusively reconstructed $D^{*\pm}$ meson in the opposite jet. The systematic error includes an uncertainty of ±0.006 due to the external branching ratios.

[47] ALEXANDER 96R obtain this value via direct charm counting, summing the partial contributions from D^0, D^+, D^+_s, and Λ^+_c, and assuming that strange-charmed baryons account for the 15% of the Λ^+_c production. An uncertainty of ±0.005 due to the uncertainties in the charm hadron branching ratios is included in the overall systematics.

[48] BARATE 98T perform a simultaneous fit to the p and p_T spectra of electrons from hadronic Z decays. The semileptonic branching ratio B($c \to e$) is taken as 0.098 ± 0.005 and the systematic error includes an uncertainty of ±0.0084 due to this.

[49] BARATE 98T obtain this result combining two double-tagging techniques. Searching for a D meson in each hemisphere by full reconstruction in an exclusive decay mode gives R_c= 0.173 ± 0.014 ± 0.0009. The same tag in combination with inclusive identification using the slow pion from the $D^{*+} \to D^0\pi^+$ decay in the opposite hemisphere yields R_c= 0.166 ± 0.012 ± 0.009. The R_b dependence is given by R_c= 0.1689–0.023×(R_b–0.2159). The three measurements of BARATE 98T are combined with BUSKULIC 94G to give the average R_c= 0.1681 ± 0.0054 ± 0.0062.

[50] ABREU 95D perform a maximum likelihood fit to the combined p and p_T distributions of single and dilepton samples. The second error includes an uncertainty of ±0.0124 due to models and branching ratios.

[51] AKERS 95O use the presence of a $D^{*\pm}$ to tag $Z \to c\overline{c}$ with $D^* \to D^0\pi$ and $D^0 \to K\pi$. They measure P_c∗Γ($c\overline{c}$)/Γ(hadrons) to be (1.006 ± 0.055 ± 0.061) × 10^{-3}, where P_c is the product branching ratio B($c \to D^*$)B($D^* \to D^0\pi$)B($D^0 \to K\pi$). Assuming that P_c remains unchanged with energy, they use its value (7.1 ± 0.5) × 10^{-3} determined at CESR/PETRA to obtain Γ($c\overline{c}$)/Γ(hadrons). The second error of AKERS 95O includes an uncertainty of ±0.011 from the uncertainty on P_c.

[52] BUSKULIC 94G perform a simultaneous fit to the p and p_T spectra of both single and dilepton events.

$R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$ — Γ_{10}/Γ_6

OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the "Note on the Z boson." As a cross check we have also performed a weighted average of the R_b measurements taking into account the various common systematic errors. We have assumed that the smallest common systematic error is fully correlated. For R_c = 0.1671 (as given by OUR FIT above), we obtain R_b = 0.21653 ± 0.00070. For an expected Standard Model value of R_c = 0.1723, our weighted average gives R_b = 0.21631 ± 0.00070.

Because of the high current interest, we mention the following preliminary results here, but do not average them or include them in the Listings or Tables. Combining published and unpublished preliminary LEP and SLD electroweak results (as of March 2000) yields R_b = 0.21642 ± 0.00073. The Standard Model predicts R_b = 0.21581 for m_t = 174.3 GeV and M_H = 150 GeV.

0.251 ±0.049 ±0.030	32	[64] JACOBSEN 91	MRK2	E^{ee}_{cm}= 91 GeV

[53] ACCIARRI 00 obtain this result using a double-tagging technique, with a high p_T lepton tag and an impact parameter tag in opposite hemispheres.

[54] ABBIENDI 99B tag $Z \to b\overline{b}$ decays using leptons and/or separated decay vertices. The b-tagging efficiency is measured directly from the data using a double-tagging technique.

[55] ABREU 99B obtain this result combining in a multivariate analysis several tagging methods (impact parameter and secondary vertex reconstruction, complemented by event shape variables). For R_c different from its Standard Model value of 0.172, R_b varies as $-0.024\times(R_c-0.172)$.

[56] ABE 98D use a double tag based on 3D impact parameter with reconstruction of secondary vertices. The charm background is reduced by requiring the invariant mass at the secondary vertex to be above 2 GeV. The systematic error includes an uncertainty of ±0.0002 due to the uncertainty on R_c.

[57] BARATE 97F combine the lifetime-mass hemisphere tag (BARATE 97E) with event shape information and lepton tag to identify $Z \to b\overline{b}$ candidates. They further use c- and uds-selection tags to identify the background. For R_c different from its Standard Model value of 0.172, R_b varies as $-0.019\times(R_c - 0.172)$.

[58] ACKERSTAFF 97K use lepton and/or separated decay vertex to tag independently each hemisphere. Comparing the numbers of single- and double-tagged events, they determine the b-tagging efficiency directly from the data.

[59] BARATE 97E combine a lifetime tag with a mass cut based on the mass difference between c hadrons and b hadrons. Included in BARATE 97F.

[60] ABE 96E obtain this value by combining results from three different b-tagging methods (2D impact parameter, 3D impact parameter, and 3D displaced vertex).

[61] ABREU 96 obtain this result combining several analyses (double lifetime tag, mixed tag and multivariate analysis). This value is obtained assuming R_c=Γ($c\overline{c}$)/Γ(hadrons) = 0.172. For a value of R_c different from this by an amount ΔR_c the change in the value is given by $-0.087 \cdot \Delta R_c$.

[62] ABREU 95D perform a maximum likelihood fit to the combined p and p_T distributions of single and dilepton samples. The second error includes an uncertainty of ±0.0023 due to models and branching ratios.

[63] BUSKULIC 94G perform a simultaneous fit to the p and p_T spectra of both single and dilepton events.

[64] JACOBSEN 91 tagged $b\overline{b}$ events by requiring coincidence of ≥ 3 tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties (±0.014).

0.174±0.016±0.018	539	[85] ABREU	93I	DLPH	E^{ee}_{cm}= 88–94 GeV

[85] The $D^{\pm}$ states in ABREU 93I are detected by the $K\pi\pi$ decay mode. This is a corrected result (see the erratum of ABREU 93I).

$\Gamma(D^*(2010)^{\pm}X)/\Gamma(\text{hadrons})$ — Γ_{31}/Γ_6

The value is for the sum of the charge states indicated.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.163±0.019 OUR AVERAGE	Error includes scale factor of 1.3.				
0.155±0.010±0.013	358	[86] ABREU	93I	DLPH	E^{ee}_{cm}= 88–94 GeV
0.21 ±0.04	362	[87] DECAMP	91J	ALEP	E^{ee}_{cm}= 88–94 GeV

[86] $D^*(2010)^{\pm}$ in ABREU 93I are reconstructed from $D^0\pi^{\pm}$, with $D^0 \rightarrow K^-\pi^+$. The new CLEO II measurement of B($D^{*\pm} \rightarrow D^0\pi^{\pm}$) = (68.1 ± 1.6) % is used. This is a corrected result (see the erratum of ABREU 93I).

[87] DECAMP 91J report B($D^*(2010)^+ \rightarrow D^0\pi^+$) B($D^0 \rightarrow K^-\pi^+$) $\Gamma(D^*(2010)^{\pm}X)$ / Γ(hadrons) = (5.11 ± 0.34) × 10^{-3}. They obtained the above number assuming B($D^0 \rightarrow K^-\pi^+$) = (3.62±0.34±0.44)% and B($D^*(2010)^+ \rightarrow D^0\pi^+$) = (55±4)%. We have rescaled their original result of 0.26 ± 0.05 taking into account the new CLEO II branching ratio B($D^*(2010)^+ \rightarrow D^0\pi^+$) = (68.1 ± 1.6)%.

$\Gamma(B^0_sX)/\Gamma(\text{hadrons})$ — Γ_{34}/Γ_6

VALUE	DOCUMENT ID		TECN	COMMENT
seen	[88] ABREU	92M	DLPH	E^{ee}_{cm}= 88–94 GeV
seen	[89] ACTON	92N	OPAL	E^{ee}_{cm}= 88–94 GeV
seen	[90] BUSKULIC	92E	ALEP	E^{ee}_{cm}= 88–94 GeV

[88] ABREU 92M reported value is $\Gamma(B^0_sX)$*B($B^0_s \rightarrow D_s\mu\nu_\mu X$) *B($D_s \rightarrow \phi\pi$)/Γ(hadrons) = (18 ± 8) × 10^{-5}.

[89] ACTON 92N find evidence for B^0_s production using D_s-ℓ correlations, with $D^+_s \rightarrow \phi\pi^+$ and $K^*(892)K^+$. Assuming R_b from the Standard Model and averaging over the e and μ channels, authors measure the product branching fraction to be f($\overline{b} \rightarrow B^0_s$)×B($B^0_s \rightarrow D^-_s\ell^+\nu_\ell X$)×B($D^-_s \rightarrow \phi\pi^-$) = (3.9 ± 1.1 ± 0.8) × 10^{-4}.

[90] BUSKULIC 92E find evidence for B^0_s production using D_s-ℓ correlations, with $D^+_s \rightarrow \phi\pi^+$ and $K^*(892)K^+$. Using B($D^+_s \rightarrow \phi\pi^+$) = (2.7 ± 0.7)% and summing up the e and μ channels, the weighted average product branching fraction is measured to be B($\overline{b} \rightarrow B^0_s$)×B($B^0_s \rightarrow D^-_s\ell^+\nu_\ell X$) = 0.040 ± 0.011$^{+0.010}_{-0.012}$.

$\Gamma(B^+_cX)/\Gamma(\text{hadrons})$ — Γ_{35}/Γ_6

searched for	[91] ACKERSTAFF	98O	OPAL	E^{ee}_{cm}= 88–94 GeV
searched for	[92] ABREU	97E	DLPH	E^{ee}_{cm}= 88–94 GeV
searched for	[93] BARATE	97H	ALEP	E^{ee}_{cm}= 88–94 GeV

[91] ACKERSTAFF 98O searched for the decay modes $B_c \rightarrow J/\psi\pi^+$, $J/\psi a^+_1$, and $J/\psi\ell^+\nu_\ell$, with $J/\psi \rightarrow \ell^+\ell^-$, $\ell = e,\mu$. The number of candidates (background) for the three decay modes is 2 (0.63 ± 0.2), 0 (1.10 ± 0.22), and 1 (0.82 ± 0.19) respectively. Interpreting the 2 $B_c \rightarrow J/\psi\pi^+$ candidates as signal, they report $\Gamma(B^+_cX)$×B($B_c \rightarrow J/\psi\pi^+$)/Γ(hadrons) =(3.8$^{+5.0}_{-2.4}$±0.5)×$10^{-5}$. Interpreted as background, the 90% CL bounds are $\Gamma(B^+_cX)$*B($B_c \rightarrow J/\psi\pi^+$)/Γ(hadrons) < 1.06 × 10^{-4}, $\Gamma(B^+_cX)$*B($B_c \rightarrow J/\psi a^+_1$)/Γ(hadrons) < 5.29 × 10^{-4}, $\Gamma(B^+_cX)$*B($B_c \rightarrow J/\psi\ell^+\nu_\ell$)/Γ(hadrons) < 6.96 × 10^{-5}.

[92] ABREU 97E searched for the decay modes $B_c \rightarrow J/\psi\pi^+$, $J/\psi\ell^+\nu_\ell$, and $J/\psi(3\pi)^+$, with $J/\psi \rightarrow \ell^+\ell^-$, $\ell = e,\mu$. The number of candidates (background) for the three decay modes is 1 (1.7), 0 (0.3), and 1 (2.3) respectively. They report the following 90% CL limits: $\Gamma(B^+_cX)$*B($B_c \rightarrow J/\psi\pi^+$)/Γ(hadrons) <(1.05–0.84) × 10^{-4}, $\Gamma(B^+_cX)$*B($B_c \rightarrow J/\psi\ell\nu_\ell$)/Γ(hadrons) <(5.8–5.0) × 10^{-5}, $\Gamma(B^+_cX)$*B($B_c \rightarrow J/\psi(3\pi)^+$)/Γ(hadrons) < 1.75 × 10^{-4}, where the ranges are due to the predicted B_c lifetime (0.4–1.4) ps.

[93] BARATE 97H searched for the decay modes $B_c \rightarrow J/\psi\pi^+$ and $J/\psi\ell^+\nu_\ell$ with $J/\psi \rightarrow \ell^+\ell^-$, $\ell = e,\mu$. The number of candidates (background) for the two decay modes is 0 (0.44) and 2 (0.81) respectively. They report the following 90% CL limits: $\Gamma(B^+_cX)$*B($B_c \rightarrow J/\psi\pi^+$)/Γ(hadrons) < 3.6 × 10^{-5} and $\Gamma(B^+_cX)$*B($B_c \rightarrow J/\psi\ell^+\nu_\ell$)/Γ(hadrons) < 5.2 × 10^{-5}.

$\Gamma(B^*X)/[\Gamma(BX)+\Gamma(B^*X)]$ — $\Gamma_{33}/(\Gamma_{32}+\Gamma_{33})$

As the experiments assume different values of the b-baryon contribution, our average should be taken with caution. If we assume a common baryon production fraction of (10.1$^{+3.9}_{-3.1}$)% as given in the 1998 edition of this *Review* OUR AVERAGE becomes 0.74 ± 0.04.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.75 ±0.04 OUR AVERAGE

Z HADRONIC POLE CROSS SECTION

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the "Note on the Z boson"). This quantity is defined as

$$\sigma^0_h = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\Gamma(\text{hadrons})}{\Gamma_Z^2}$$

It is one of the parameters used in the Z lineshape fit.

Z VECTOR COUPLINGS TO CHARGED LEPTONS

These quantities are the effective vector couplings of the Z to charged leptons. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e, A_μ, and A_τ. By convention the sign of g^e_A is fixed to be negative (and opposite to that of g^{ν_e} obtained using ν_e scattering measurements). The fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e, A_μ, and A_τ measurements. See "Note on the Z boson" for details.

Z COUPLINGS TO NEUTRAL LEPTONS

These quantities are the effective couplings of the Z to neutral leptons. $\nu_e e$ and $\nu_\mu e$ scattering results are combined with g_A^e and g_V^e measurements at the Z mass to obtain g^{ν_e} and g^{ν_μ} following NOVIKOV 93C.

g^{ν_e}

VALUE	DOCUMENT ID	TECN	COMMENT
0.528±0.085	[131] VILAIN 94	CHM2	From $\nu_\mu e$ and $\nu_e e$ scattering

[131] VILAIN 94 derive this value from their value of g^{ν_μ} and their ratio $g^{\nu_e}/g^{\nu_\mu} = 1.05^{+0.15}_{-0.18}$.

g^{ν_μ}

VALUE	DOCUMENT ID	TECN	COMMENT
0.502±0.017	[132] VILAIN 94	CHM2	From $\nu_\mu e$ scattering

[132] VILAIN 94 derive this value from their measurement of the couplings $g_A^{e\nu_\mu} = -0.503 \pm 0.017$ and $g_V^{e\nu_\mu} = -0.035 \pm 0.017$ obtained from $\nu_\mu e$ scattering. We have re-evaluated this value using the current PDG values for g_A^e and g_V^e.

Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are defined as

$$A_f = \frac{2 g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where g_V^f and g_A^f are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the 'Note on the Z Boson.'

A_e

Using polarized beams, this quantity can also be measured as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$, where σ_L and σ_R are the e^+e^- production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

[133] ABREU 00E obtain this result fitting the τ polarization as a function of the polar τ production angle. This measurement is a combination of different analyses (exclusive τ decay modes, inclusive hadronic 1-prong reconstruction, and a neural network analysis).

[134] Derived from the measurement of forward-backward τ polarization asymmetry.

[135] ABE 97 obtain this result from a measurement of the observed left-right charge asymmetry, $A_Q^{obs} = 0.225 \pm 0.056 \pm 0.019$, in hadronic Z decays. If they combine this value of A_Q^{obs} with their earlier measurement of A_{LR}^{obs} they determine A_e to be $0.1574 \pm 0.0197 \pm 0.0067$ independent of the beam polarization.

[136] ABE 97E measure the left-right asymmetry in hadronic Z production. This value (statistical and systematic errors added in quadrature) leads to $\sin^2\theta_W^{eff} = 0.23060 \pm 0.00050$.

[137] ABE 97N obtain this direct measurement using the lef-right cross section asymmetry and the left-right forward-backward asymmetry in leptonic decays of the Z boson obtained with a polarized electron beam.

[138] ALEXANDER 96U measure the τ-lepton polarization and the forward-backward polarization asymmetry.

[139] ABE 95J obtain this result from polarized Bhabha scattering.

[140] BUSKULIC 95Q obtain this result fitting the τ polarization as a function of the polar τ production angle.

[141] ABE 94C measured the left-right asymmetry in Z production. This value leads to $\sin^2\theta_W = 0.2292 \pm 0.0009 \pm 0.0004$.

A_μ

This quantity is directly extracted from a measurement of the left-right forward-backward asymmetry in $\mu^+\mu^-$ production at SLC using a polarized electron beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e.

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.102±0.034	3788	[142] ABE	97N SLD	E_{cm}^{ee}= 91.27 GeV

[142] ABE 97N obtain this direct measurement using the lef-right cross section asymmetry and the left-right forward-backward asymmetry in $\mu^+\mu^-$ decays of the Z boson obtained with a polarized electron beam.

A_τ

The LEP Collaborations derive this quantity from the measurement of the τ polarization in $Z \to \tau^+\tau^-$. The SLD Collaboration directly extracts this quantity from its measured left-right forward-backward asymmetry in $Z \to \tau^+\tau^-$ produced using a polarized e^- beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e.

[150] ABE 99O tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously A_b and A_c. The value of A_b so extracted, 0.910 ± 0.068 ± 0.037, is then combined with A_b from ABE 99L and ABE 99I to obtain the resulting SLD average value quoted here.

[151] ABE 99L obtain an enriched sample of $b\overline{b}$ events tagging with an inclusive vertex mass cut. For distinguishing b and $\overline{b}$ quarks they use the charge of identified $K^{\pm}$.

[152] ABE 98I obtain an enriched sample of $b\overline{b}$ events tagging with an inclusive vertex mass cut. A momentum-weighted track charge is used to identify the sign of the charge of the underlying b quark.

[153] ABE 95L tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract A_b and A_c.

TRANSVERSE SPIN CORRELATIONS IN $Z \to \tau^+\tau^-$

The correlations between the transverse spin components of $\tau^+\tau^-$ produced in Z decays may be expressed in terms of the vector and axial-vector couplings:

$$C_{TT} = \frac{|g_A^\tau|^2 - |g_V^\tau|^2}{|g_A^\tau|^2 + |g_V^\tau|^2}$$

$$C_{TN} = -2\frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2}\sin(\Phi_{g_V^\tau} - \Phi_{g_A^\tau})$$

C_{TT} refers to the transverse-transverse (within the collision plane) spin correlation and C_{TN} refers to the transverse-normal (to the collision plane) spin correlation.

The longitudinal τ polarization P_τ (= $-A_\tau$) is given by:

$$P_\tau = -2\frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2}\cos(\Phi_{g_V^\tau} - \Phi_{g_A^\tau})$$

Here Φ is the phase and the phase difference $\Phi_{g_V^\tau} - \Phi_{g_A^\tau}$ can be obtained using both the measurements of C_{TN} and P_τ.

C_{TT}

13.1 ±3.5 ±1.3		91.2	[168] ABREU 95G	DLPH

[166] ABREU 00B tag the presence of an s quark requiring a high-momentum-identified charged kaon. The s-quark pole asymmetry is extracted from the charged-kaon asymmetry taking the expected d- and u-quark asymmetries from the Standard Model and using the measured values for the c- and b-quark asymmetries.
[167] ACKERSTAFF 97T measure the forward-backward asymmetry of various fast hadrons made of light quarks. Then using SU(2) isospin symmetry and flavor independence for down and strange quarks authors solve for the different quark types. The value reported here corresponds then to the forward-backward asymmetry for "down-type" quarks.
[168] ABREU 95G require the presence of a high-momentum charged kaon or Λ^0 to tag the s quark. An unresolved s- and d-quark asymmetry of $(11.2 \pm 3.1 \pm 5.4)$% is obtained by tagging the presence of a high-energy neutron or neutral kaon in the hadron calorimeter. Superseded by ABREU 00B.

$A_{FB}^{(0,c)}$ CHARGE ASYMMETRY IN $e^+e^- \to c\overline{c}$

OUR FIT, which is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the "Note on the Z boson," refers to the Z pole asymmetry. As a cross check we have also performed a weighted average of the "near peak" measurements taking into account the various common systematic errors. We have assumed that the smallest common systematic error is fully correlated. Applying to this combined "peak" measurement QED and energy-dependence corrections, our weighted average gives a pole asymmetry of (7.18 ± 0.49)%.

[169] ABREU 99Y tag $Z \to b\overline{b}$ and $Z \to c\overline{c}$ events by an exclusive reconstruction of several D meson decay modes (D^{*+}, D^0, and D^+ with their charge-conjugate states).
[170] BARATE 98O tag $Z \to c\overline{c}$ events requiring the presence of high-momentum reconstructed D^{*+}, D^+, or D^0 mesons.
[171] ALEXANDER 97C identify the b and c events using a D/D^* tag.
[172] ALEXANDER 96 tag heavy flavors using one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average B^0-$\overline{B}^0$ mixing.
[173] ABREU 95K identify c and b quarks using both electron and muon semileptonic decays.
[174] BUSKULIC 94G perform a simultaneous fit to the p and p_T spectra of both single and dilepton events.
[175] ADRIANI 92D use both electron and muon semileptonic decays.
[176] ABREU 95E require the presence of a $D^{*\pm}$ to identify c and b quarks. Replaced by ABREU 99Y.
[177] BUSKULIC 95I require the presence of a high momentum $D^{*\pm}$ to have an enriched sample of $Z \to c\overline{c}$ events. Replaced by BARATE 98O.

$A_{FB}^{(0,b)}$ CHARGE ASYMMETRY IN $e^+e^- \to b\overline{b}$

OUR FIT, which is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the "Note on the Z boson," refers to the Z pole asymmetry. As a cross check we have also performed a weighted average of the "near peak" measurements taking into account the various common systematic errors. We have assumed that the smallest common systematic error is fully correlated. Applying to this combined "peak" measurement QED and energy-dependence corrections, our weighted average gives a pole asymmetry of (10.09 ± 0.22)%. For the jet-charge measurements (where the QCD effects are included since they represent an inherent part of the analysis), we use the corrections given by the authors.

[178] ABREU 99M tag $Z \rightarrow b\bar{b}$ events using lifetime and vertex charge. The original quark charge is obtained from the charge flow, the difference between the forward and backward hemisphere charges.

[179] ABREU 99Y tag $Z \rightarrow b\bar{b}$ and $Z \rightarrow c\bar{c}$ events by an exclusive reconstruction of several D meson decay modes (D^{*+}, D^0, and D^+ with their charge-conjugate states).

[180] ACCIARRI 99D tag $Z \rightarrow b\bar{b}$ events using high p and p_T leptons. The analysis determines simultaneously a mixing parameter $\chi_b = 0.1192 \pm 0.0068 \pm 0.0051$ which is used to correct the observed asymmetry.

[181] ACCIARRI 98U tag $Z \rightarrow b\bar{b}$ events using lifetime and measure the jet charge using the hemisphere charge.

[182] BARATE 98M tag $Z \rightarrow b\bar{b}$ events using lifetime and measure the jet charge using the hemisphere charge. The analysis is performed as a function of the b quark purity and b polar angle.

[183] ACKERSTAFF 97P tag b quarks using lifetime. The quark charge is measured using both jet charge and vertex charge, a weighted sum of the charges of tracks in a jet which contains a tagged secondary vertex.

[184] ALEXANDER 97C identify the b and c events using a D/D^* tag.

[185] ALEXANDER 96 tag heavy flavors using one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average B^0-$\bar{B}^0$ mixing.

[186] BUSKULIC 96Q tag b-quark flavor and charge using high transverse momentum leptons. The asymmetry value at the Z peak is obtained using a charm charge asymmetry of 6.17%.

[187] ABREU 95K identify c and b quarks using both electron and muon semileptonic decays. The systematic error includes an uncertainty of ±0.3 due to the mixing correction ($\chi = 0.115 \pm 0.011$).

[188] ABREU 95E require the presence of a $D^{*\pm}$ to identify c and b quarks. Replaced by ABREU 99Y.

[189] ABREU 95K tag b quarks using lifetime; the quark charge is identified using jet charge. The systematic error includes an uncertainty of ±0.3 due to the mixing correction ($\chi = 0.115 \pm 0.011$). Replaced by ABREU 99M.

[190] AKERS 95S tag b quarks using lifetime; the quark charge is measured using jet charge. These asymmetry values are obtained using $R_b = \Gamma(b\bar{b})/\Gamma(\text{hadrons}) = 0.216$. For a value of R_b different from this by an amount ΔR_b, the change in the asymmetry values is given by $-K\Delta R_b$, where $K = 0.082$, 0.471, and 0.855 for $\sqrt{s}$ values of 89.52, 91.25, and 92.94 GeV respectively. Replaced by ACKERSTAFF 97P.

[191] ACCIARRI 94D use both electron and muon semileptonic decays. Replaced by ACCIARRI 99D.

[192] BUSKULIC 94G perform a simultaneous fit to the p and p_T spectra of both single and dilepton events. Replaced by BUSKULIC 96Q.

[193] BUSKULIC 94I use the lifetime tag method to obtain a high purity sample of $Z \rightarrow b\bar{b}$ events and the hemisphere charge technique to obtain the jet charge. Replaced by BARATE 98M.

CHARGE ASYMMETRY IN $e^+e^- \rightarrow q\bar{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on B^0-$\bar{B}^0$ mixing and on other electroweak parameters.

ANOMALOUS $ZZ\gamma$, $Z\gamma\gamma$, AND ZZV COUPLINGS

Revised March 2000 by C. Caso (Univ. of Genova) and A. Gurtu (Tata Inst.)

In the reaction $e^+e^- \rightarrow Z\gamma$, deviations from the Standard Model for the $ZV\gamma$ couplings may be described in terms of 8 parameters, h_i^V $(i = 1,4;\ V = \gamma, Z)$ [1]. In this formalism h_1^V and h_2^V lead to CP-violating and h_3^V and h_4^V to CP-conserving effects. All these anomalous contributions to the cross section increase rapidly with center-of-mass energy. In order to ensure unitarity, these parameters are usually described by a form-factor representation, $h_i^V(s) = h_{io}^V/(1 + s/\Lambda^2)^n$, where Λ is the energy scale for the manifestation of a new phenomenon and n is a sufficiently large power. By convention one uses $n = 3$ for $h_{1,3}^V$ and $n = 4$ for $h_{2,4}^V$. Usually limits on h_i^V's are put assuming some value of Λ (sometimes ∞).

Above the $e^+e^- \rightarrow ZZ$ threshold, deviations from the Standard Model may be described by means of four anomalous couplings f_i^V $(i = 4,5; V = \gamma, Z)$ [2]. The anomalous couplings f_5^V lead to violation of C and P symmetries while f_4^V introduces CP violation. These couplings are zero at tree level in the Standard Model.

	[196] ABBOTT	98M D0
	[197] ABREU	98K DLPH
	[198] ACCIARRI	98L L3

[196] ABBOTT 98M study $p\bar{p} \rightarrow Z\gamma + X$, with $Z \rightarrow e^+e^-, \mu^+\mu^-, \bar{\nu}\nu$ at 1.8 TeV, to obtain 95% CL limits at Λ= 750 GeV: $|h_{30}^Z| < 0.36$, $|h_{40}^Z| < 0.05$ (keeping h_i^γ=0) and $|h_{30}^\gamma| < 0.37$, $|h_{40}^\gamma| < 0.05$ (keeping h_i^Z=0). Limits on the CP-violating couplings are $|h_{10}^Z| < 0.36$, $|h_{20}^Z| < 0.05$ (keeping h_i^γ=0), and $|h_{10}^\gamma| < 0.37$, $|h_{20}^\gamma| < 0.05$ (keeping h_i^Z=0).

[197] ABREU 98K determine a 95% CL upper limit on $\sigma(e^+e^- \rightarrow \gamma +$ invisible particles$)$ < 2.5 pb using 161 and 172 GeV data. This is used to set 95% CL limits on $|h_{30}^\gamma| < 0.8$ and $|h_{30}^Z| < 1.3$, derived at a scale Λ=1 TeV and with n=3 in the form factor representation.

[198] ACCIARRI 98L study 161, 172, and 183 GeV $e^+e^- \rightarrow q\bar{q}\gamma$ and $e^+e^- \rightarrow \nu\bar{\nu}\gamma$ events to derive 95% CL limits on h_i^V. For deriving each limit the others are fixed at zero. For $\Lambda = \infty$ they report: $-0.54 < h_1^Z < 0.17$, $-0.11 < h_2^Z < 0.37$, $-0.50 < h_3^Z < 0.36$, $-0.12 < h_4^Z < 0.39$, $-0.25 < h_1^\gamma < 0.23$, $-0.18 < h_2^\gamma < 0.18$, $-0.33 < h_3^\gamma < 0.01$, $-0.02 < h_4^\gamma < 0.24$.

Higgs Bosons — H^0 and $H^{\pm}$, Searches for

SEARCHES FOR HIGGS BOSONS

Written February 2000 by P. Igo-Kemenes (Physikalisches Institut, Heidelberg, Germany)

I. Introduction

One of the main challenges in high energy physics is the discovery of Higgs bosons. Their existence is related to the generation of elementary particle masses. In the Standard Model (SM) [1], the electroweak interaction is described by a gauge field theory based on the $SU(2)_L \times U(1)_Y$ symmetry group. Masses can be introduced by the Higgs mechanism [2], where fundamental scalar "Higgs" fields interact with each other such that they acquire a nonzero vacuum expectation value and the $SU(2)_L \times U(1)_Y$ symmetry is spontaneously broken down to the electromagnetic $U(1)_{EM}$ symmetry. Gauge bosons and fermions obtain their masses by interacting with the vacuum Higgs field. Associated with this mechanism is the existence of massive scalar particles called Higgs bosons, and the proof for the above mechanism would come from the direct observation of this novel particle species.

In its minimal version, the SM requires one Higgs field doublet and predicts a single neutral Higgs boson. Beyond the SM, supersymmetric (SUSY) models [3] are considered. They provide a consistent framework for the unification of the gauge interactions at a high energy scale $\Lambda_{GUT} \approx 10^{16}$ GeV and an explanation for the stability of the electroweak energy scale in the presence of quantum corrections (the "scale hierarchy problem"). Moreover, their predictions are compatible with existing high-precision data. The Minimal Supersymmetric Standard Model (MSSM) [4] is the SUSY extension of the SM with minimal new particle content. It needs two Higgs field doublets and predicts the existence of three neutral and a pair of charged Higgs bosons. While in the SM the mass of the Higgs boson is not predicted, in SUSY models the Higgs masses are related to the gauge couplings. As a consequence, one of the neutral Higgs bosons must have its mass close to the electroweak energy scale. In the MSSM this mass is predicted to be less than about 135 GeV [5].

Prior to 1989, when the e^+e^- collider LEP at CERN came into operation, Higgs boson searches were sensitive to masses below a few GeV only (see Ref. 6 for a review). The LEP collider, operating for five years at a center-of-mass energy $\sqrt{s} \approx M_{Z^0}$ (the LEP1 phase), definitively excluded a SM Higgs boson with a mass between zero and about 65 GeV [7]. Since 1995, the center-of-mass energy has increased each year (the LEP2 phase) and has reached $\sqrt{s} = 204$ GeV in 1999, within a few GeV of the highest energy expected. When the full data of the four LEP experiments are combined, the sensitivity for discovery will extend to SM Higgs boson masses of approximately 110 GeV. After the LEP experiments finish taking data, searches for Higgs bosons will be pursued primarily at the Tevatron $p\bar{p}$ collider. The sensitivity to Higgs bosons in the Run I data is rather limited, though the planned energy and luminosity upgrades (Run II [8]) would extend the sensitivity well beyond the LEP range. The searches will continue later at the LHC pp collider [9] covering the canonical mass range up to about 1 TeV. If Higgs bosons are discovered, the Higgs mechanism can be studied in great detail at future e^+e^- [10] and $\mu^+\mu^-$ colliders [11].

The sensitivity of current searches is continuously improving with increasing collider energies and sample sizes. There is also ongoing activity in refining the phenomenology relevant to Higgs boson searches. In order to provide an up to date description, recent documents are quoted even though in some cases they are not published. Such documents (indicated by **name** in the Reference list) can be accessed conveniently from the web page `http://home.cern.ch/p/pik/www/pdg2000/index.html`.

II. Higgs boson masses

In the Standard Model, the Higgs mass $m_{H^0} = \sqrt{2\lambda}\, v$ is proportional to the vacuum expectation value v of the Higgs field, which is fixed by the Fermi coupling. The quartic Higgs coupling λ, and thus m_{H^0}, is not determined, but arguments of self-consistency of the theory can be used to place upper and lower bounds on m_{H^0}.

Since the running coupling λ rises indefinitely with energy, the theory would eventually become non-perturbative. The requirement that in the SM this does not occur at a scale lower than Λ defines an upper bound for the Higgs mass [12]. On the other hand, a lower bound for m_{H^0} is obtained from top-loop induced quantum corrections to the Higgs interaction potential [13]. The requirement that the electroweak minimum is an absolute minimum up to the scale Λ yields a "vacuum stability" condition which limits m_{H^0} from below. These theoretical bounds are summarized in Fig. 1 [14] as a function of Λ. Self-consistency of the SM up to $\Lambda = \Lambda_{GUT}$ allows only the narrow band from about 130 to 190 GeV for the mass. This range is beyond the reach of LEP2, which implies that the discovery of a Higgs boson at LEP would indicate new physics beyond the SM at energies lower than Λ_{GUT}.

Indirect experimental bounds for the Higgs mass are obtained from fits to precision measurements of electroweak observables, primarily from Z^0 decay data, and to the measured top and $W^{\pm}$ masses [15]. These measurements are sensitive to $\log(m_{H^0})$ through radiative corrections. Currently the best fit value is $m_{H^0} = 77^{+69}_{-39}$ GeV, and $m_{H^0} < 215$ GeV is obtained at the 95% confidence level (CL) [16], still consistent with the SM being valid up to the GUT scale.

In the MSSM, one of the two Higgs field doublets, with vacuum expectation value v_1, couples to "down" quarks and charged leptons while the second, with v_2, couples to "up" quarks only. Assuming CP invariance, the spectrum of physical Higgs bosons [4] consists of two CP-even neutral scalars h^0 and H^0 (h^0 is the one with the smaller mass), one CP-odd neutral scalar A^0, and one pair of charged Higgs bosons $H^{\pm}$.

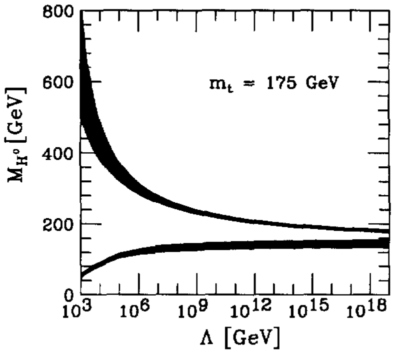

Figure 1: Bounds on the Higgs mass based on arguments of self-consistency of the SM [14]. Λ denotes the energy scale at which the SM would become non-perturbative or the electroweak potential unstable. The dark bands represent theoretical uncertainties.

At the tree level, only two parameters are required (beyond the Z^0 mass) to fix all Higgs masses and couplings. A convenient choice is the ratio $\tan\beta = v_2/v_1$ and the mass (m_{A^0}) of the CP-odd scalar A^0. The mixing angle α which diagonalizes the CP-even Higgs mass matrix can also be expressed in terms of $\tan\beta$ and m_{A^0}. The following ordering of masses is valid at the tree level: $m_{h^0} < M_Z$, $m_{A^0} < m_{H^0}$, and m_{A^0}, $M_W < m_{H^\pm}$. These relations are modified by radiative corrections; the largest contribution is a consequence of the incomplete cancelation between virtual-top and scalar-top (stop) loops. The corrections affect mainly the masses and decay branching ratios in the neutral Higgs sector. They depend strongly on the top quark mass ($\sim m_t^4$) and logarithmically on the stop masses, and involve a detailed parameterization of SUSY breaking and of the mixing between the SUSY partners of the left- and right-handed top quarks [17].

The Higgs masses, after radiative corrections, are displayed in Fig. 2 as a function of m_{A^0} for two representative values of $\tan\beta$ within the range from 1 to $\approx m_t/m_b$ which is preferred in grand unification schemes [18]. One observes that m_{h^0} may exceed M_Z.

III. Higgs boson production and decay

A comprehensive discussion of the Higgs boson phenomenology is given in Ref. 19. In this section the focus is on Higgs production in e^+e^- collisions at energies below 210 GeV (LEP2) [20] by which most of the recent search results have been obtained. Extensions to higher e^+e^- energies [10] and to production in hadron collisions [8,9] are discussed briefly in Sections V and VI.

Higgs boson production in e^+e^- collisions:

The principal mechanism for producing the ***SM Higgs particle*** in e^+e^- collisions at current energies is Higgs-strahlung in the s-channel [21], $e^+e^- \to H^0Z^0$, where a Higgs boson is radiated off an intermediate Z^0 boson. The Z^0 boson in the final state is either virtual (LEP1) or on the mass shell (LEP2).

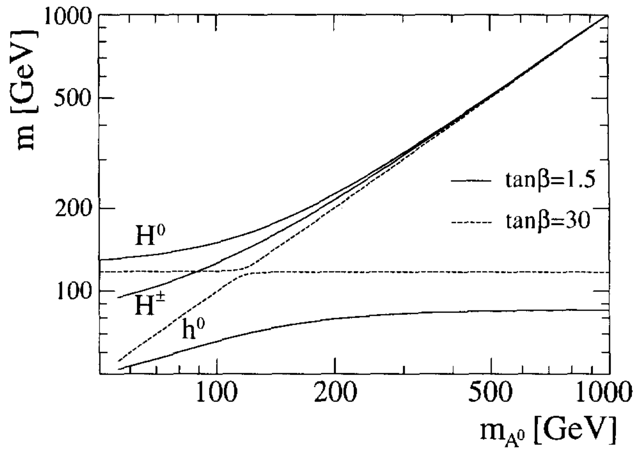

Figure 2: Higgs masses in the MSSM after radiative corrections, as a function of m_{A^0} for two representative values of $\tan\beta$; 1.5 and 30 (in the case of $H^\pm$ the variation with $\tan\beta$ is invisible on the scale of the figure).

In the latter case (at energies far from the Z^0 resonance) the cross section is given by

$$\sigma(e^+e^- \to Z^0H^0) = \frac{G_F^2 M_Z^4}{96\pi\, s}(v_e^2 + a_e^2)\lambda^{1/2}\frac{\lambda + 12M_Z^2/s}{(1 - M_Z^2/s)^2} \equiv \sigma_{\rm SM} \quad (1)$$

where s denotes the center-of-mass energy squared, $a_e = -1$, $v_e = -1 + 4s_W^2$ ($s_W = \sin\theta_W$ is the *sine* of the weak-mixing angle), and $\lambda = [1 - (m_{H^0} + M_Z)^2/s][1 - (m_{H^0} - M_Z)^2/s]$ is the two-particle phase-space function. The cross section [21,22] is shown in Fig. 3 as a function of $\sqrt{s}$, together with that of other SM processes.

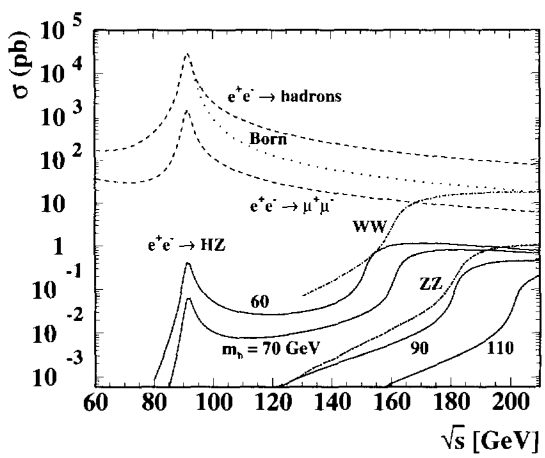

Figure 3: Cross sections for the Higgs-strahlung process in the SM for fixed values of m_{H^0} (full lines) and for other SM processes which contribute to the background, as a function of $\sqrt{s}$.

The SM Higgs boson can also be produced by W^+W^- fusion in the t-channel [23], $e^+e^- \to \overline{\nu}_e\nu_e H^0$, but at current energies this process has a small contribution to the cross section, except for Higgs masses which cannot be reached by the Higgs-strahlung process. The W^+W^- fusion process may extend slightly the ultimate range of sensitivity at LEP2 [20].

In the MSSM, the main production mechanisms of the neutral Higgs bosons h^0 and A^0 are [24] the Higgs-strahlung process $e^+e^- \to h^0Z^0$ and the pair-production process $e^+e^- \to h^0A^0$. As in the SM case, the fusion process plays a marginal role at current energies. Furthermore, the production of the heavy neutral CP-even Higgs boson H^0 is suppressed over most of the parameter space currently accessible. The cross sections for the Higgs-strahlung and pair-production processes may be expressed in terms of $\sigma_{\rm SM}$ given in Eq. (1) and the angles α and β introduced before:

$$\sigma(e^+e^- \to Z^0h^0) = \sin^2(\beta-\alpha)\sigma_{\rm SM} \qquad (2)$$

$$\sigma(e^+e^- \to A^0h^0) = \cos^2(\beta-\alpha)\overline{\lambda}\sigma_{\rm SM}\ , \qquad (3)$$

with the kinematic factor $\overline{\lambda} = \lambda^{3/2}_{A^0h^0}/[\lambda^{1/2}_{Z^0h^0}(12M_Z^2/s + \lambda_{Z^0h^0})]$ and $\lambda_{ij} = [1-(m_i+m_j)^2/s][1-(m_i-m_j)^2/s]$. The cross sections are complementary due to the MSSM suppression factors $\sin^2(\beta-\alpha)$ and $\cos^2(\beta-\alpha)$. At small $\tan\beta$ the process $e^+e^- \to Z^0h^0$ has the larger cross section while at large $\tan\beta$ it is $e^+e^- \to h^0A^0$, unless the latter is suppressed kinematically.

In models with ***two Higgs field doublets*** (2HD models), including the MSSM, charged Higgs bosons are expected to be produced in pairs [19,25], $e^+e^- \to H^+H^-$, and the cross section is fixed at the tree level by the mass $m_{H^\pm}$:

$$\sigma(e^+e^- \to H^+H^-) = \frac{2G_F^2M_W^4s_W^4}{3\pi\ s}$$
$$\times\left[1 + \frac{v_ev_H}{4s_W^2c_W^2(1-M_Z^2/s)} + \frac{(a_e^2+v_e^2)v_H^2}{64s_W^4c_W^4(1-M_Z^2/s)^2}\right]\beta_H^3 \quad (4)$$

with $c_W = \cos\theta_W$, $v_H = -1+2s_W^2$, and $\beta_H = (1-4m^2_{H^\pm}/s)^{1/2}$.

Higgs boson decay:

In the case of the ***SM Higgs boson***, the most relevant decay branching ratios [22,26] are summarized in Fig. 4. For masses below about 135 GeV, decays to fermion anti-fermion pairs dominate, and $H^0 \to b\overline{b}$ has the largest branching ratio. Decays to $\tau^+\tau^-$, $c\overline{c}$, and gluon pairs (*via* loops) are below 10%. The decay width is less than 10 MeV. For larger masses, the W^+W^-, Z^0Z^0 final states dominate [10] and the decay width rises rapidly with mass, reaching about 1 GeV for $m_{H^0} = 200$ GeV and 100 GeV for $m_{H^0} = 500$ GeV.

In the MSSM, the couplings of the neutral Higgs bosons to quarks, leptons, and gauge bosons are modified with respect to those of the SM Higgs boson by factors which depend upon the mixing angles α and β. These factors, valid at leading order, are summarized in Table 1. The decays are discussed in [19,24]. Some features relevant to current searches are discussed below.

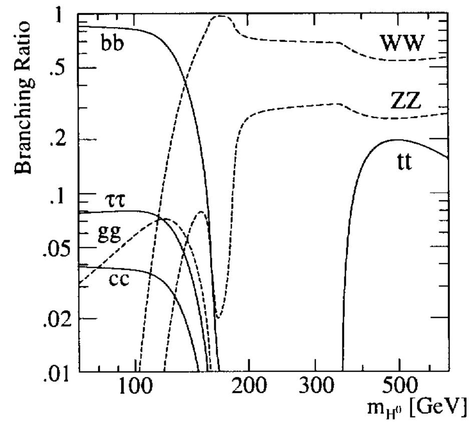

Figure 4: Branching ratios for the main decay modes of the SM Higgs boson [10].

Table 1: Factors relating the SM Higgs couplings to the corresponding couplings in the MSSM.

	"Up" fermions	"Down" fermions	Vector bosons
SM-Higgs:	1	1	1
MSSM h^0:	$\cos\alpha/\sin\beta$	$-\sin\alpha/\cos\beta$	$\sin(\beta-\alpha)$
H^0:	$\sin\alpha/\sin\beta$	$\cos\alpha/\cos\beta$	$\cos(\beta-\alpha)$
A^0:	$1/\tan\beta$	$\tan\beta$	0

- The h^0 boson will decay mainly to fermion pairs since the mass is smaller than about 135 GeV. The A^0 boson also decays predominantly to fermion pairs, independently of its mass, since its coupling to vector bosons is zero at leading order (see Table 1). For $\tan\beta > 1$, decays to $b\overline{b}$ and $\tau^+\tau^-$ pairs are preferred, with branching ratios of about 90% and 8%, respectively, while the decays to $c\overline{c}$ and gluon pairs are suppressed. Decays to $c\overline{c}$ may become important for $\tan\beta < 1$.
- The decay $h^0 \to A^0A^0$ may become dominant if it is kinematically allowed [25].
- Other possible decays are into SUSY particles such as sfermions, charginos or neutralinos, which may lead to invisible or barely visible final states. The branching fractions can be large, even dominant in parts of the MSSM parameter space, thus requiring a different search strategy.

Charged Higgs bosons in 2HD models decay mainly *via* $H^+ \to \tau^+\nu_\tau$ if $\tan\beta$ is large. For small $\tan\beta$, the decay to $c\overline{s}$ is dominant at low mass, and the decay to $H^+ \to t^*\overline{b} \to W^+b\overline{b}$ is dominant for $H^\pm$ masses larger than about 130 GeV [27].

IV. The search environment at LEP

During the first phase of LEP, the experiments ALEPH, DELPHI, L3, and OPAL analysed over four million Z^0 decays each. They have set lower bounds of approximately 65 GeV on the mass of the SM Higgs boson, and of about 45 GeV on the masses of the h^0, A^0 (valid for $\tan\beta > 1$) and also for $H^\pm$ bosons. At energies above the Z^0 resonance (the LEP2 phase) the experimental environment is different in many respects. The signal-to-background ratio at LEP2 is more favorable (see Fig. 3), despite the additional backgrounds from the processes $e^+e^- \to W^+W^-$ and Z^0Z^0. The latter have kinematic properties similar to the signal process $e^+e^- \to H^0Z^0$, but since at LEP2 the Z^0 boson is on the mass shell, constrained kinematic fits allow a good overall signal-to-background ratio to be achieved. Furthermore, since neutral Higgs bosons decay preferentially to $b\bar{b}$, the LEP Collaborations have considerably upgraded their b-tagging capabilities for the LEP2 phase. Jets with B hadrons are recognized by the presence of secondary decay vertices or tracks with large impact parameters, identified by means of high-precision silicon microvertex detectors. Other indicators for B hadron decays are high-p_T leptons ($\ell = e, \mu$) from $b \to c\ell^-\bar{\nu}_\ell$ decays and several jet properties.

The following final states provide good sensitivity for neutral Higgs bosons (here h^0 may designate either the SM Higgs boson or the light CP-even neutral scalar in the MSSM).

(a) The ***four-jet final state*** is produced by the processes $(h^0 \to b\bar{b})(Z^0 \to q\bar{q})$ and $(h^0 \to b\bar{b})(A^0 \to b\bar{b})$. In the SM it occurs with a branching ratio of 58%. In the first process, the invariant mass of two of the jets is close to M_Z, while the other two jets contain B hadrons. In the second process, the Z^0 mass constraint cannot be used, but B hadrons are expected in all four jets. The Higgs mass can be reconstructed with a typical resolution of 2.5 GeV.

(b) The ***missing-energy final state*** is produced mainly by the process $(h^0 \to b\bar{b})(Z^0 \to \nu\bar{\nu})$. In the SM it occurs with a branching ratio of 17%. The signal has two jets with B hadrons, substantial missing transverse momentum and missing mass compatible with M_Z. A similar event topology would also occur in h^0Z^0 and h^0A^0 if the h^0 or the A^0 boson decayed into "invisible" SUSY particles (*e.g.*, neutralinos), or in the W^+W^- fusion process leading to $b\bar{b}\nu_e\bar{\nu}_e$ events. The reconstruction of the Higgs boson requires good knowledge of the detector acceptance and energy resolution; it is achieved with a typical resolution of 3 GeV, but the distribution usually has a pronounced non-Gaussian tail.

(c) The ***leptonic final states*** are produced in the processes $(h^0 \to b\bar{b})(Z^0 \to e^+e^-, \mu^+\mu^-)$. In the SM the branching ratios add up to 6%. The two leptons reconstruct to M_Z and the two jets contain B hadrons. Although the branching ratio is small, this channel adds considerably to the overall search sensitivity since it has low background and good mass resolution, typically 1.5 GeV, if m_{h^0} is taken to be the mass recoiling against the reconstructed Z^0 boson.

(d) The ***tau final states*** are produced in the SM and MSSM processes $(h^0 \to \tau^+\tau^-)(Z^0 \to q\bar{q})$, $(h^0 \to q\bar{q})(Z^0 \to \tau^+\tau^-)$, $(h^0 \to \tau^+\tau^-)(A^0 \to q\bar{q})$, and $(h^0 \to q\bar{q})(A^0 \to \tau^+\tau^-)$. In the SM they occur with a branching ratio of about 10% in total. These channels play an important role in some subsets of the MSSM parameter space where the decays to $b\bar{b}$ are suppressed.

To summarize, the conjunction of constrained kinematic fits and sophisticated b tagging allows the searches at LEP2 to be conducted with increased sensitivity. With the inclusion of the abundant four-jet final states, which had to be discarded at LEP1 from searches for the SM Higgs boson, about 95% of the signal cross section is utilized.

Searches for the charged Higgs process $e^+e^- \to H^+H^-$ make use of the decays $H^+ \to c\bar{s}$ and $\tau^+\nu_\tau$. The process $e^+e^- \to W^+W^-$ constitutes a high background at $m_{H^\pm} \approx M_W$.

In the SM and the MSSM, the signal and background rates are predicted channel by channel. The corresponding search results can thus be combined for a better overall sensitivity. Furthermore, datasets from different LEP energies and experiments can also be added. The combined LEP data are used to test two hypotheses: the *background-only* ("b") hypothesis, which assumes no Higgs boson to be present in the mass range investigated, and the *signal + background* ("$s + b$") hypothesis, where Higgs bosons are assumed to be produced according to the model under consideration. A global *test-statistic* X is constructed [28] which allows the experimental result $X_{\rm observed}$ to be classified between the b-like and $s + b$-like situations. It utilizes the number of selected events and various distributions which provide discrimination between signal and background (*e.g.*, the reconstructed mass or b-tag variables). The test-statistic takes into account experimental details such as detection efficiencies, signal-to-background ratios, resolution functions, and provides a single value for a given model hypothesis (*e.g.*, the test-mass m_{H^0} in the SM).

To set the scale for X, a large number of Monte Carlo experiments are generated, separately for the b and the $s + b$ hypotheses, and separately for each model hypothesis (*e.g.*, m_{H^0}). The resulting distributions of $X(m_{H^0})$ are normalized to become probability density functions, and integrated to form the confidence levels $\mathrm{CL}_b(m_{H^0})$ and $\mathrm{CL}_{s+b}(m_{H^0})$. The integration starts in both cases from the b-like end and runs up to $X_{\rm observed}$; thus $\mathrm{CL}_b(m_{H^0})$ and $\mathrm{CL}_{s+b}(m_{H^0})$ express the probabilities that the outcome of an experiment is more b-like or less $s + b$-like, respectively, than the outcome represented by the set of selected events.

The 95% CL lower limit for the SM Higgs mass is defined as the lowest value of the test mass m_{H^0} which yields* $\mathrm{CL}_s(m_{H^0})$=$\mathrm{CL}_{s+b}(m_{H^0})/\mathrm{CL}_b(m_{H^0}) = 0.05$. The quantity $1 - \mathrm{CL}_b(m_{H^0})$ is an indicator for a possible signal: a SM Higgs boson with true mass m_0 would produce a pronounced drop in this quantity for $m_{H^0} \approx m_0$. Values of $1 - \mathrm{CL}_b < 5.7 \times 10^{-7}$ would indicate a five-standard deviation (5σ) discovery.

If values of $X_{\rm observed}$ (and thus the integration bounds) are obtained from Monte Carlo simulations of the real experiment, the average expected confidence levels $\langle 1 - \mathrm{CL}_b(m_{H^0})\rangle$ and $\langle \mathrm{CL}_s(m_{H^0})\rangle$ are obtained. Of particular interest are $\langle 1 - \mathrm{CL}_b(m_{H^0})\rangle$ from simulated $s + b$ experiments and

$\langle CL_s(m_{H^0}) \rangle$ from simulated b experiments, since these indicate the expected ranges of sensitivity of the available data set for discovery and exclusion, respectively.

V. Latest results

We summaries below the search results obtained recently by the LEP Collaborations, the CDF, DØ, and other experiments. Some of the LEP results presented are obtained by combining [29] preliminary data from the four experimental groups [30] according to the procedure outlined above.

Results relevant to the SM and the MSSM:

(a) For the ***SM Higgs boson***, the confidence levels $1 - CL_b$ and CL_s obtained from combining the data of the four LEP experiments are shown in Fig. 5 [29]. One can see in the upper part that the observed behavior of $1 - CL_b$ (full line) is compatible with the expected behaviors for background within 2σ (light-shaded band). The expected behavior in the presence of a signal (dashed line) indicates that the data have sensitivity for a 5σ discovery ($1 - CL_b < 5.7 \times 10^{-7}$) up to $m_{H^0} \approx 98$ GeV. In the lower part of the figure, the curves of CL_s observed (full line) and expected from background (dashed line) follow each other closely, as anticipated in the absence of a signal. The curves cross the value $CL_s = 0.05$ in the vicinity of $m_{H^0} = 103$ GeV. After cross checking with several test-statistics, the value 102.6 GeV is quoted in Ref. 29 as the 95% CL lower bound for the SM Higgs mass.

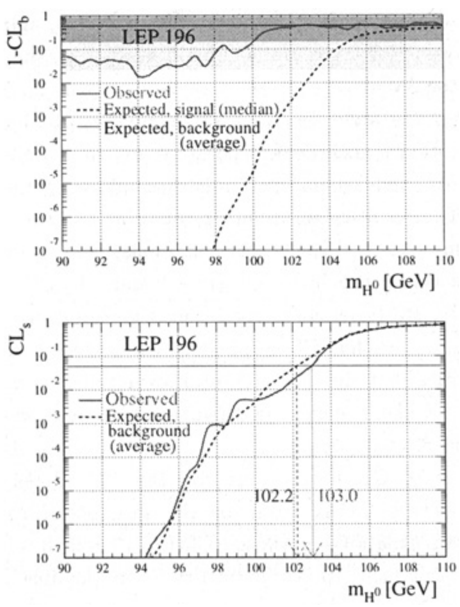

Figure 5: The confidence levels $1 - CL_b$ (upper) and CL_s (lower part), observed and expected, as a function of the test mass m_{H^0}, obtained from combining [29] preliminary data of the four LEP experiments. The dark (light) shaded areas represent the ±one- (two-) standard deviation bands around the expected average (0.5) from simulated *background only* experiments.

At the Tevatron, the SM Higgs boson would be produced primarily by gluon fusion, $gg \to H^0$ [31]. However, the signal processes providing best sensitivity to masses below 140 GeV are those where a Higgs boson is produced in association with a $W^\pm$ or Z^0 boson, or in association with heavy quarks, $p\overline{p} \to W^\pm H^0 X$, $Z^0 H^0 X$, $Q\overline{Q} H^0 X$ [32]. The Run I data samples, of about 110 pb^{-1} from both CDF and DØ, are far too small for a discovery of the SM Higgs boson but allow upper bounds to be set on the cross section. For $m_{H^0} > 70$ GeV, these bounds are higher by an order of magnitude at least than the SM prediction [33,34].

(b) For the ***MSSM Higgs bosons h^0 and A^0***, the search results are used to test a 'constrained' MSSM where universal SUSY-breaking masses m_{SUSY} and M_2 are assumed for sfermions and gauginos, respectively, at the electroweak scale. With these assumptions, the number of MSSM parameters is reduced to only six [4,19]. All masses, cross sections, and decay branching ratios can be calculated by fixing m_{SUSY}, M_2, $\tan\beta$, m_{A^0}, the Higgs mixing parameter μ, and the trilinear coupling A_t which controls stop mixing. The top mass has also an impact on the predictions through loop corrections.

Although more general parameter scans have been reported [35,36], most interpretations of the results are limited to less general scenarios (*e.g.*, those proposed in Ref. 20), where some of the parameters are fixed: m_{SUSY}=1 TeV/c^2, M_2=1.6 TeV/c^2, $\mu = -100$ GeV, and $m_t = 175$ GeV. Two separate cases are considered, with $A_t = 0$ and $\sqrt{6}$ TeV, which correspond to *no mixing* and *large stop-mixing*. The remaining parameters, m_{A^0} and $\tan\beta$, are scanned independently.

The current LEP limits in the MSSM parameter space [29], valid for *large mixing*, are shown in Fig. 6 in the $(m_{h^0}, \tan\beta)$ and $(m_{A^0}, \tan\beta)$ projections (for *no mixing* the available parameter space is more restricted). The current 95% CL bounds are: $m_{h^0} > 84.3$ GeV, $m_{A^0} > 84.5$ GeV. Furthermore, values of $\tan\beta$ from 0.8 to 1.9 are excluded for the parameter sets considered; however, that exclusion can be reduced considerably in other scenarios [37].

The CDF experiment has searched for the process $p\overline{p} \to b\overline{b}X \to b\overline{b}b\overline{b}$ [33] where a particle $X(\equiv h^0, H^0, A^0)$ is radiated from a b quark and decays subsequently to $b\overline{b}$. This process is enhanced in the MSSM at large $\tan\beta$ where the Yukawa coupling to the b quark is large. The domains excluded by CDF are indicated in Fig. 6 together with the limits from LEP.

Interpretations in models beyond the SM and the MSSM:

Any model, to be acceptable, has to reproduce the available precision electroweak data. 2HD models with any number of additional singlet or doublet fields satisfy this criterion. This has been demonstrated [38] for 2HD models of class II where the "up" and "down" fermions couple to separate Higgs doublets. In the case of higher representations (*e.g.*, triplet fields) the parameters can also be tuned to obtain agreement, in particular to preserve the value of $\rho = M_W^2/M_Z^2 \cos^2\theta_W$

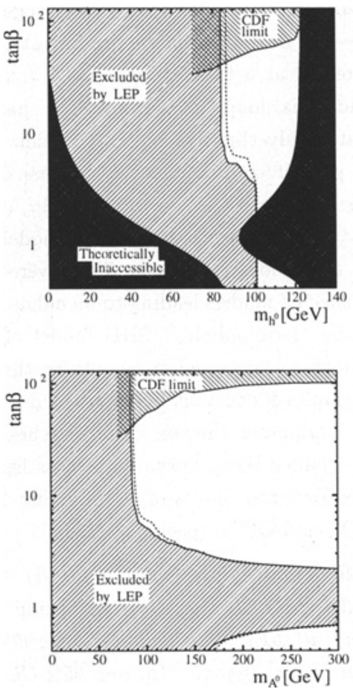

Figure 6: The 95% CL bounds on m_{h^0}, m_{A^0}, and $\tan\beta$, for the case of large mixing, from combining the data of the four LEP experiments up to $\sqrt{s}$ = 196 GeV [29]. The dashed lines indicate the expected limits. The exclusions at large $\tan\beta$ from the CDF experiment [33] are also indicated.

and to avoid excessive rates of flavor-changing neutral currents. Search results are discussed below in theoretical contexts which are more general than the SM and the MSSM.

(a) The searches for $e^+e^- \to h^0Z^0$ and h^0A^0 have been used to derive ***model-independent bounds*** for the rates of *generic processes* where h^0 and A^0 can be any CP-even and CP-odd scalar particles [36,40]. In deriving these limits it is generally assumed that the decay properties of the generic particles are identical to those of the SM Higgs boson. Models with CP violation [39] and non-SM decay properties have also been addressed [40].

(b) The searches for ***charged Higgs bosons*** are guided by predictions of 2HD models. The mass $m_{H^{\pm}}$ is not constrained. In the LEP searches [41] it is assumed that the decay modes $H^+ \to c\overline{s}$ and $\tau^+\nu_\tau$ fully exhaust the decay width, but the relative branching ratio is unknown. They therefore include the $e^+e^- \to H^+H^-$ final states $(c\overline{s})(\overline{c}s)$, $(\tau^+\nu_\tau)(\tau^-\overline{\nu}_\tau)$ and $(c\overline{s})(\tau^-\overline{\nu}_\tau) + (\overline{c}s)(\tau^+\nu_\tau)$. The current combined limits from LEP [29] are reproduced in Fig. 7 as a function of the branching ratio $B(H^+ \to \tau^+\nu_\tau)$. The lowest value, independent of the branching ratio, is currently 77 GeV.

At the Tevatron, charged Higgs bosons may be produced in the decay of the top quark, $t \to bH^+$. While the SM requires the top quark to decay almost exclusively via $t \to bW^+$, in 2HD models the process $t \to bH^+$ may compete with the SM process if $m_{H^+} < m_t - m_b$ and if $\tan\beta$ is either large (> 30) or less than one. To search for $H^{\pm}$, the DØ experiment has adopted an indirect "disappearance technique [42]," optimized for the detection of the SM background process $t \to bW^+$. The CDF Collaboration reported on a direct search for the process $t \to H^+b \to \tau^+\nu_\tau b$ [43] and on an indirect approach [44] in which the rate of di-leptons and lepton+jets in $t\overline{t}$ decay is compared to the SM prediction. The 2HD model of class II is assumed by both collaborations, and that the H^+ decays into three channels: (i) $c\overline{s}$, which is dominant at low $\tan\beta$ and small $m_{H^{\pm}}$, (ii) $t^*b \to W^+b\overline{b}$, dominant at low $\tan\beta$ and for $m_{H^{\pm}} \approx m_t + m_b$ [27], and (iii) $\tau^+\nu_\tau$, dominant at high $\tan\beta$. The results are summarized in Fig. 8, where the LEP limits of Fig. 7 are also reproduced. All these limits are subject to potentially large theoretical uncertainties [45].

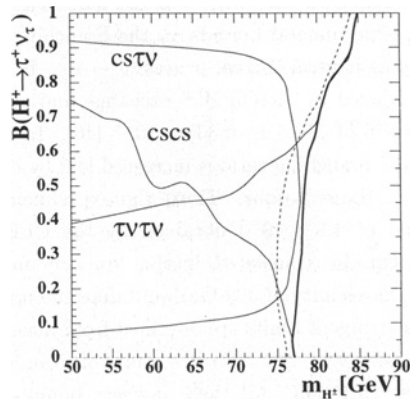

Figure 7: The 95% CL bounds on $m_{H^{\pm}}$ as a function of the branching ratio $B(H^+ \to \tau^+\nu_\tau)$, from combining the data collected by the LEP experiments at energies up to 196 GeV [29]. The expected exclusion limit is indicated by the dashed line and the observed limits, channel-by-channel (light) and total (heavy), by the full lines.

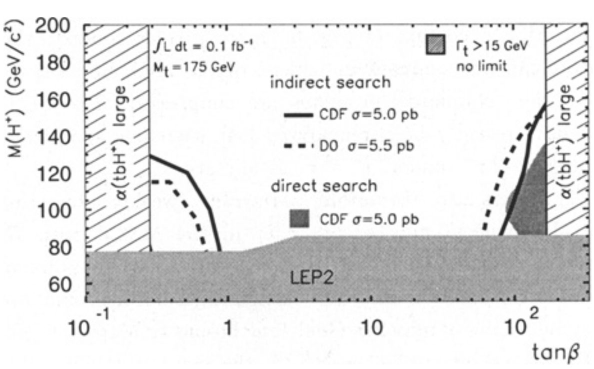

Figure 8: Summary of the 95% CL exclusions in the $(m_{H^+}, \tan\beta)$ plane obtained by the DØ [42] and CDF [43] collaborations, using various indirect and direct observation techniques. The limits quoted by the two collaborations were obtained assuming slightly different $t\overline{t}$ cross sections and using different statistical procedures. The LEP limits from Fig. 7 are also reproduced.

Indirect limits in the $(m_{H^\pm}, \tan\beta)$ plane can also be derived using experimental bounds on the branching ratio of the flavor-changing neutral current process $b \to s\gamma$. In the SM, this process is induced by virtual $W^\pm$ exchange and gives rise to a branching ratio of $(3.28 \pm 0.33) \times 10^{-4}$ [46]. In 2HD models of class II, the branching ratio is increased [47] by contributions from charged Higgs bosons. Thus, the experimental 95% CL upper bound of 4.5×10^{-4} obtained by the CLEO Collaboration [48] can be translated into a lower bound on $m_{H^\pm}$, which is in the vicinity of 300 GeV and depends moderately on $\tan\beta$. Less stringent limits are obtained from measurements of the $b \to s\gamma$ and $b \to \tau^-\overline{\nu}_\tau X$ rates and from tau-lepton decay properties at LEP [49]. All these indirect bounds are model-dependent and may be invalidated, *e.g.*, by sparticle loops or anomalous couplings.

(c) Higgs bosons with ***double-electric charge***, $H^{\pm\pm}$, are predicted by several models [50,19] *e.g.*, with triplet scalar fields. The OPAL Collaboration has searched for the process $Z^0 \to H^{++}H^{--}$ in final states with four prompt electrons or muons. An alternative selection, sensitive to long-lived $H^{\pm\pm}$ and giving rise to isolated tracks with ionization energy loss typical for two electron charges, was also used. By combining the two searches, $H^{\pm\pm}$ bosons with mass less than $M_Z/2$ could almost completely be excluded [51].

(d) The addition of a ***singlet scalar field*** to the MSSM [52], gives rise to two additional neutral scalars, one CP-even and one CP-odd. The radiative corrections to the masses are similar to those in the MSSM and arguments of perturbative continuation to the GUT scale lead again to an upper bound of about 135-140 GeV for the mass of the lightest neutral CP-even scalar. The DELPHI Collaboration has used the searches for neutral Higgs bosons to constrain such models [53].

(e) Higgs bosons can be produced by ***Yukawa processes*** in which they are radiated from a massive fermion, *e.g.*, b or $\tau^\pm$. The CDF search for this process [33] has already been discussed in the MSSM context of Fig. 6. In a broader context, this process can be dominant in regions of the 2HD model space where the "standard" processes are suppressed. The LEP1 data have recently been reanalyzed [54], searching specifically for $b\bar{b}b\bar{b}$, $b\bar{b}\tau^+\tau^-$, and $\tau^+\tau^-\tau^+\tau^-$ final states.

(f) Decays into ***"invisible" particles*** (weakly interacting neutral particles) may occur, *e.g.*, in the MSSM with R-parity conservation, if the Higgs bosons decay to pairs of neutralinos [55]. In a different context, Higgs bosons could also decay into pairs of massless Goldstone bosons or Majorons [56]. In Higgs-strahlung, $e^+e^- \to h^0Z^0$, the mass of the invisible Higgs boson can be inferred from the Z^0 boson which is reconstructed in the $Z^0 \to e^+e^-$, $\mu^+\mu^-$, and $q\bar{q}$ final states, and using the beam energy constraint. Assuming the SM production rate, the LEP experiments exclude the existence a Higgs boson of mass less than about 95 GeV decaying exclusively to invisible final states [57].

(g) ***Photonic final states*** from the processes $Z^0/\gamma^* \to H^0\gamma$ and $H^0 \to \gamma\gamma$ do not occur in the SM at the tree level, but may be present at a low rate due to $W^\pm$ and top-quark loops [58]. Additional loops, *e.g.*, from SUSY particles, would increase the rates only slightly [59], but models with anomalous couplings predict enhancements by orders of magnitude. Searches for the processes $e^+e^- \to (H^0 \to b\bar{b})\gamma$, $(H^0 \to \gamma\gamma)q\bar{q}$, and $(H^0 \to \gamma\gamma)\gamma$ have been used to set model-independent limits on such anomalous couplings. They were also used to constrain very specific models leading to an enhanced $H^0 \to \gamma\gamma$ rate, such as the "fermiophobic" 2HD model of class I [60], where all fermions are assumed to couple to the same scalar field, and the couplings can thus be suppressed simultaneously by appropriate parameter choices. The searches at LEP [61] exclude a fermiophobic Higgs boson with mass less than about 95 GeV. At the Tevatron, limits of 82 GeV and 78.5 GeV are obtained by CDF and DØ, respectively [33,62].

Note: Very Recent Results (March 2000)

Very recently, the LEP Higgs working group updated their results including all LEP data collected in 1999 [63]. They report no indication for a signal. The new 95% CL mass bounds, replacing the ones quoted in this section, are the following. For the SM Higgs boson, $m_{H^0} > 107.7$ GeV; for the h^0 and A^0 bosons of MSSM, $m_{h^0} > 88.3$ GeV and $m_{A^0} > 88.4$ GeV; finally, for charged Higgs bosons in 2HD models, $m_{H^\pm} > 78.6$ GeV.

VI. Outlook

The LEP collider is scheduled to stop producing data in the year 2000. At the Tevatron, the Run I sensitivity is rather limited for Higgs boson searches, but a powerful luminosity upgrade is in preparation. Performance studies [8] provide a high motivation for collecting large data samples in excess of 10 fb^{-1} per experiment. Such samples will extend the combined sensitivity of CDF and DØ well beyond the LEP reach and allow large domains in the MSSM parameter space to be investigated.

The Large Hadron Collider (LHC) will deliver proton-proton collisions at 14 TeV energy in the year 2005. The ATLAS and CMS detectors have been optimized for Higgs boson searches [9]. The discovery of the SM Higgs boson will be possible over the full canonical mass range between 100 GeV and 1 TeV. This broad range is covered by a variety of production and decay processes. The LHC experiments will provide full coverage of the MSSM parameter space *via* their searches for the h^0, H^0, A^0, and $H^\pm$ bosons and by detecting the h^0 boson in cascade decays of SUSY particles. The discovery of several Higgs bosons is possible over extended domains of the parameter space. Decay branching fractions can be determined, and masses measured with accuracies between 10^{-3} (at 400 GeV mass) and 10^{-2} (at 700 GeV).

It is conceivable that a high-energy e^+e^- linear collider will be realized after the year 2010. Initially it could run at energies up to 500 GeV, with 1 TeV and more in perspective [10]. One of the prime goals of such a collider is to extend the precision measurements, typical of e^+e^- colliders, to the Higgs sector. The Higgs couplings to fermions and vector bosons can be measured through production cross sections and decay branching ratios, with precisions of a few percent. The MSSM parameters can be studied in great detail. At the highest collider energies and luminosities, the self-coupling of the Higgs fields can be studied directly through final states with two Higgs bosons [64].

At a future $\mu^+\mu^-$ collider [11], the Higgs bosons can be generated as s-channel resonances. Mass measurements with precisions of a few MeV would be possible and the widths could be obtained directly from Breit-Wigner scans. The heavy CP-even and CP-odd Higgs bosons H^0 and A^0, degenerate over most of the MSSM parameter space, could be disentangled experimentally.

Finally, if Higgs bosons are not discovered at the TeV scale, both the LHC and the future lepton colliders will be in a position to test alternative theories of electroweak symmetry breaking such as those with strongly interacting vector bosons [65], expected in theories with dynamical symmetry breaking [66].

Notes and References

* The ratio CL_s replaces CL_{s+b} in order to avoid situations where a downward fluctuation of the event count would exclude even the b-like hypothesis. In such situations, the exclusion of the $s+b$ hypothesis would incorrectly appear as an exclusion of a signal for which there is insufficient experimental sensitivity.

STANDARD MODEL H^0 (Higgs Boson) MASS LIMITS

These limits apply to the Higgs boson of the three-generation Standard Model with the minimal Higgs sector. For a review and a bibliography, see the above Note on 'Searches for Higgs Bosons' by P. Igo-Kemenes.

Limits from Coupling to $Z/W^\pm$

Limits on the Standard Model Higgs obtained from the study of Z^0 decays rule out conclusively its existence in the whole mass region $m_{H^0} \lesssim 60$ GeV. These limits, as well as stronger limits obtained from e^+e^- collisions at LEP at energies up to 172 GeV, and weaker limits obtained from other sources, have been superseded by the most recent data of LEP. They have been removed from this compilation, and are documented in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review of Particle Physics.

In this Section, unless otherwise stated, limits from the four LEP experiments (ALEPH, DELPHI, L3, and OPAL) are obtained from the study of the $e^+e^- \rightarrow H^0 Z$ process, at center-of-mass energies reported in the comment lines.

A recent combination (LEP 00B) of preliminary, unpublished results relative to data taken at LEP in the Summer of 1999 at energies up to 202 GeV gives the limit $m_{H^0} > 107.7$ GeV.

[1] Search for $e^+e^- \rightarrow H^0 Z$ in the final states $H^0 \rightarrow q\bar{q}$ with $Z \rightarrow \ell^+\ell^-$, $\nu\bar{\nu}$, $q\bar{q}$, and $\tau^+\tau^-$, and $H^0 \rightarrow \tau^+\tau^-$ with $Z \rightarrow q\bar{q}$.

[2] Search for $e^+e^- \rightarrow H^0 Z$ in the final states $H^0 \rightarrow q\bar{q}$ with $Z \rightarrow \ell^+\ell^-$, $\nu\bar{\nu}$, $q\bar{q}$, and $\tau^+\tau^-$, and $H^0 \rightarrow \tau^+\tau^-$ with $Z \rightarrow \ell^+\ell^-$, $\nu\bar{\nu}$, and $q\bar{q}$.

[3] ABE 98T search for associated $H^0 W$ and $H^0 Z$ production in $p\bar{p}$ collisions at $\sqrt{s}$= 1.8 TeV with $W(Z) \rightarrow q\bar{q}^{(\prime)}$, $H^0 \rightarrow b\bar{b}$. The results are combined with the search in ABE 97W, resulting in the cross-section limit $\sigma(H^0 + W/Z)\cdot B(H^0 \rightarrow b\bar{b})<(23–17)$ pb (95%CL) for m_H= 70–140 GeV. This limit is one to two orders of magnitude larger than the expected cross section in the Standard Model.

H^0 Indirect Mass Limits from Electroweak Analysis

For limits obtained before the direct measurement of the top quark mass, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review. Other studies based on data available prior to 1996 can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review. For indirect limits obtained from other considerations of theoretical nature, see the Note on "Searches for Higgs Bosons."

Because of the high current interest, we mention here the following unpublished result (LEP 00, and update, presented by A. Straessner at the 2000 Electroweak Rencontres de Moriond) although we do not include it in the Listings or Tables: m_H= 66.5^{+60}_{-33} GeV. This is obtained from a fit to LEP, SLD, W mass, top mass, and neutrino scattering data available in the Spring of 2000, with $1/\alpha^{(5)}(m_Z)$= 128.878 ± 0.090. The 95%CL upper limit is 188 GeV.

[4] CHANOWITZ 99 studies LEP/SLD data on 9 observables related $\sin^2\theta^\ell_{\rm eff}$, available in the Spring of 1998. A scale factor method is introduced to perform a global fit, in view of the conflicting data. m_H as large as 750 GeV is allowed at 95% CL.

[5] D'AGOSTINI 99 use m_t, m_W, and effective $\sin^2\theta_W$ from LEP/SLD available in the Fall 1998 and combine with direct Higgs search constraints from LEP2 at E_{cm}=183 GeV. $\alpha(m_Z)$ given by DAVIER 98.

[6] FIELD 99 studies the data on b asymmetries from $Z^0 \rightarrow b\bar{b}$ decays at LEP and SLD (from LEP 99). The limit uses $1/\alpha(M_Z)$= 128.90 ± 0.09, the variation in the fitted top quark mass, m_t=$171.2^{+3.7}_{-3.8}$ GeV, and excludes b-asymmetry data. It is argued that exclusion of these data, which deviate from the Standard Model expectation, from the electroweak fits reduces significantly the upper limit on m_H. Including the b-asymmetry data gives instead the 95%CL limit $m_H < 284$ GeV. See also FIELD 00.

[7] CHANOWITZ 98 fits LEP and SLD Z-decay-asymmetry data (as reported in ABBANEO 97), and explores the sensitivity of the fit to the weight ascribed to measurements that are individually in significant contradiction with the direct-search limits. Various prescriptions are discussed, and significant variations of the 95%CL Higgs-mass upper limits are found. The Higgs-mass central value varies from 100 to 250 GeV and the 95%CL upper limit from 340 GeV to the TeV scale.

[8] HAGIWARA 98B fit to LEP, SLD, W mass, and neutrino scattering data as reported in ALCARAZ 96, with m_t = 175 ± 6 GeV, $1/\alpha(m_Z)$= 128.90 ± 0.09 and $\alpha_s(m_Z)$= 0.118 ± 0.003. Strong dependence on m_t is found.

[9] DEBOER 97B fit to LEP and SLD data (as reported in ALCARAZ 96), as well as m_W and m_t from CDF/DØ and CLEO $b \rightarrow s\gamma$ data (ALAM 95). $1/\alpha(m_Z)$ = 128.90 ± 0.09 and $\alpha_s(m_Z)$ = 0.120 ± 0.003 are used. Exclusion of SLC data yields m_H=241^{+218}_{-123} GeV. $\sin^2\theta_{\rm eff}$ from SLC (0.23061 ± 0.00047) would give m_H=16^{+16}_{-9} GeV.

[10] DEGRASSI 97 is a two-loop calculation of M_W and $\sin^2\theta^{\rm lept}_{\rm eff}$ as a function of m_H, using $\sin^2\theta^{\rm lept}_{\rm eff}$ 0.23165(24) as reported in ALCARAZ 96, m_t = 175 ± 6 GeV, and $1/\alpha(m_Z)$=128.90 ± 0.09.

[11] DITTMAIER 97 fit to m_W and LEP/SLC data as reported in ALCARAZ 96, with m_t = 175 ± 6 GeV, $1/\alpha(m_Z^2)$ = 128.89 ± 0.09. Exclusion of the SLD data gives m_H = 261^{+224}_{-128} GeV. Taking only the data on m_t, m_W, $\sin^2\theta^{\rm lept}_{\rm eff}$, and $\Gamma^{\rm lept}_Z$, the authors get m_H = 190^{+174}_{-102} GeV and m_H = 296^{+243}_{-143} GeV, with and without SLD data, respectively. The 95% CL upper limit is given by 550 GeV (800 GeV removing the SLD data).

[12] RENTON 97 fit to LEP and SLD data (as reported in ALCARAZ 96), as well as m_W and m_t from $p\bar{p}$, and low-energy νN data available in early 1997. $1/\alpha(m_Z)$ = 128.90 ± 0.09 is used.

[13] ELLIS 96C fit to LEP, SLD, m_W, neutral-current data available in the summer of 1996, plus m_t = 175 ± 6 GeV from CDF/DØ . The fit yields m_t = 172 ± 6 GeV.

[14] GURTU 96 studies the effect of the mutually incompatible SLD and LEP asymmetry data on the determination of m_H. Use is made of data available in the Summer of 1996. The quoted value is obtained by increasing the errors *à la* PDG. A fit ignoring the SLD data yields 267^{+242}_{-135} GeV.

MASS LIMITS FOR NON-STANDARD MODEL HIGGS BOSONS

This section covers the following cases:

(i) Neutral scalar and pseudoscalar Higgs bosons in the MSSM,
(ii) Neutral Higgs bosons in extended Higgs models,
(iii) Charged Higgs bosons, and
(iv) Doubly-charged Higgs bosons

H_1^0 (Higgs Boson) MASS LIMITS in Supersymmetric Models

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [H_1^0 and H_2^0, where we define $m_{H_1^0} < m_{H_2^0}$], a pseudoscalar (A^0), and a charged Higgs pair ($H^\pm$). H_1^0 and H_2^0 are also called h and H in the literature. There are two free parameters in the theory which can be chosen to be m_{A^0} and $\tan\beta = v_2/v_1$, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H_1^0} \leq m_Z$, $m_{H_2^0} \geq m_Z$, $m_{A^0} \geq m_{H_1^0}$, and $m_{H^\pm} \geq m_W$. However, as described in the Review on Supersymmetry in this Volume these relations are violated by radiative corrections.

The mass region $m_{H_1^0} \lesssim 45$ GeV has been by now entirely ruled out by measurements at the Z pole. The relative limits, as well as other by now obsolete limits from different techniques, have been removed from this compilation, and can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review. Unless otherwise stated, the following results assume no invisible H_1^0 or A^0 decays.

A recent combination (LEP 00B) of preliminary, unpublished results relative to data taken at LEP in the Summer of 1999 at energies up to 202 GeV gives the limit $m_{H_1^0} > 88.3$ GeV.

[15] ABBIENDI 00F search for $e^+e^- \rightarrow H_1^0 A^0$ in the final states $b\bar{b}b\bar{b}$, $b\bar{b}\tau^+\tau^-$, and $A^0A^0A^0 \rightarrow b\bar{b}b\bar{b}b\bar{b}$, and $e^+e^- \rightarrow H_1^0 Z$. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 1.63 TeV and Higgsino mass parameter μ=−0.1 TeV are assumed. m_t=175 GeV is used. The cases of maximal and no-stop mixing are examined. Limits obtained from scans of the Supersymmetric parameter space can be found in the paper.

[16] ABREU 00G search for $e^+e^- \rightarrow H_1^0 A^0$ in the final states $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$, and $e^+e^- \rightarrow H_1^0 Z$. $m_{A^0} > 20$ GeV is assumed. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 0.2 TeV, and Higgsino mass parameter μ=−0.2 TeV are assumed. m_t=175 GeV is used. The scenarios of no-stop mixing, and of mixing with the maximal impact on the Higgs mass limit, are examined.

[17] ACCIARRI 99U searched for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$, and $e^+e^- \to H_1^0 Z$. Universal scalar mass and SU(2) gaugino mass of 1 TeV and Higgsino mass parameter $\mu=-0.1$ TeV are assumed. The cases of minimal and maximal stop mixing are examined.

[18] BARATE 98A search for $e^+e^- \to H_1^0 A^0$ in the final states $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$ and combine with BARATE 99B limit on $e^+e^- \to H_1^0 Z$. The limit is for M_{SUSY}= 1 TeV with minimal/maximal stop mixing. See paper for the result from a scan in more general MSSM parameters.

[19] ABBIENDI 99E search for $e^+e^- \to H_1^0 A^0$ in the final states $b\bar{b}b\bar{b}$, $q\bar{q}\tau^+\tau^-$, and $6b$ and $e^+e^- \to H_1^0 Z$ for various final states. M_{top}=175 GeV, M_{SUSY}=1 TeV, and minimal/maximal scalar top mixing. See paper for results of more general scans.

[20] ABREU 99I search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$, and $b\bar{b}\tau^+\tau^-$ and $e^+e^- \to H_1^0 Z$ for various final states. The limit is for the universal scalar mass of 1 TeV, SU(2) gaugino mass of 1.6 TeV, and higgsino mass parameter $\mu=-100$ GeV, with typical/maximal/no-stop mixing. m_t= 173.9 GeV.

[21] ABREU 98E search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$ and $q\bar{q}\tau^+\tau^-$. The results from the SM Higgs search described in the same paper are also used to set these limits. m_{top} = 175 GeV, M_{SUSY} = 1 TeV, and maximal scalar top mixings.

[22] ACCIARRI 98M search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$, and $e^+e^- \to H_1^0 Z$. m_{top} = 175 GeV, M_{SUSY} = 1 TeV, SU(2) gaugino mass of 1 TeV and various scalar top mixing scenarios.

[23] ACKERSTAFF 98S search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$, $q\bar{q}\tau^+\tau^-$, and $6b$ and combine with ACKERSTAFF 98H limit on $e^+e^- \to H_1^0 Z$. m_{top} = 175 GeV, M_{SUSY} = 1 TeV, SU(2) gaugino mass of 1 TeV and maximal scalar stop mixing. The more general scan of the MSSM parameter space does not reduce the limit significantly.

[24] ACCIARRI 97N search for $e^+e^- \to H_1^0 A^0$ in four-jet final states. Cross-section limits are obtained for $|m_{H_1^0} - m_{A^0}|$ = 0, 10, and 20 GeV.

[25] BARATE 97P search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$ and combine with BARATE 97O limit on $e^+e^- \to H_1^0 Z$. m_{top} = 175 GeV and M_{SUSY} = 1 TeV, and maximal scalar top mixings. The invisible decays $H_1^0 \to \tilde{\chi}^0\tilde{\chi}^0$ are not allowed in the analysis, as ruled out in the relevant kinematic region by BUSKULIC 96K.

A^0 (Pseudoscalar Higgs Boson) MASS LIMITS in Supersymmetric Models

Limits on the A^0 mass from e^+e^- collisions arise from direct searches in the $e^+e^- \to A^0 H_1^0$ channel and indirectly from the relations valid in the minimal supersymmetric model between m_{A^0} and $m_{H_1^0}$. As discussed in the "Note on Supersymmetry," these relations depend on the masses of the t quark and $\tilde{t}$ squarks. The limits are weaker for larger t and $\tilde{t}$ masses, while they increase with the inclusion of two-loop radiative corrections. Some specific examples of these dependences are provided in the footnotes to the listed papers. Unless otherwise stated, two-loop radiative corrections have been included, where relevant, in the limits presented here.

Limits obtained at the Z pole have been made obsolete by more recent results from higher energy e^+e^- collision data at LEP. Together with other by now obsolete results, they have been omitted from this compilation, and can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review. Unless otherwise stated, the following results assume no invisible H_1^0 or A^0 decays. Limits quoted for a given value of E_{cm} may include data from lower energies.

A recent combination (LEP 00B) of preliminary, unpublished results relative to data taken at LEP in the Summer of 1999 at energies up to 202 GeV gives the limit $m_{A^0} > 88.4$ GeV.

[26] ABBIENDI 00F search for $e^+e^- \to H_1^0 A^0$ in the final states $b\bar{b}b\bar{b}$, $b\bar{b}\tau^+\tau^-$, and $A^0A^0A^0 \to b\bar{b}b\bar{b}b\bar{b}$, and $e^+e^- \to H_1^0 Z$. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 1.63 TeV and Higgsino mass parameter $\mu=-0.1$ TeV are assumed. m_t=175 GeV is used. The cases of maximal and no-stop mixing are examined. Limits obtained from scans of the Supersymmetric parameter space can be found in the paper.

[27] ABREU 00G search for $e^+e^- \to H_1^0 A^0$ in the final states $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$, and $e^+e^- \to H_1^0 Z$. $m_{A^0} > 20$ GeV is assumed. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 0.2 TeV, and Higgsino mass parameter $\mu=-0.2$ TeV are assumed. m_t=175 GeV is used. The scenarios of no-stop mixing, and of mixing with the maximal impact on the Higgs mass limit, are examined.

[28] ACCIARRI 99U search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$, and $e^+e^- \to H_1^0 Z$. Universal scalar mass and SU(2) gaugino mass of 1 TeV and Higgsino mass parameter $\mu=-0.1$ TeV are assumed. The cases of minimal and maximal stop mixing are examined.

[29] BARATE 98A search for $e^+e^- \to H_1^0 A^0$ in the final states $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$ and combine with BARATE 99B limit on $e^+e^- \to H_1^0 Z$. The limit is for M_{SUSY}= 1 TeV with minimal/maximal stop mixing. See paper for the result from a scan in more general MSSM parameters.

[30] ABBIENDI 99E search for $e^+e^- \to H_1^0 A^0$ in the final states $b\bar{b}b\bar{b}$, $q\bar{q}\tau^+\tau^-$, and $6b$ and $e^+e^- \to H_1^0 Z$ for various final states . M_{top}=175 GeV, M_{SUSY}=1 TeV, and minimal/maximal scalar top mixing. See paper for results of more general scans.

[31] ABREU 99I search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$, and $b\bar{b}\tau^+\tau^-$ and $e^+e^- \to H_1^0 Z$ for various final states. The limit is for the universal scalar mass of 1 TeV, SU(2) gaugino mass of 1.6 TeV, and higgsino mass parameter $\mu=-100$ GeV, with typical/maximal/no-stop mixing. m_t= 173.9 GeV.

[32] ABREU 98E search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$ and $q\bar{q}\tau^+\tau^-$. The results from the SM Higgs search described in the same paper are also used to set these limits. m_{top} = 175 GeV, M_{SUSY} = 1 TeV, and maximal scalar top mixings.

[33] ACCIARRI 98M search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$, and $e^+e^- \to H_1^0 Z$. m_{top} = 175 GeV, M_{SUSY} = 1 TeV, SU(2) gaugino mass of 1 TeV and various scalar top mixing scenarios.

[34] ACKERSTAFF 98S search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$, $q\bar{q}\tau^+\tau^-$, and $6b$ and combine with ACKERSTAFF 98H limit on $e^+e^- \to H_1^0 Z$. m_{top} = 175 GeV, M_{SUSY} = 1 TeV, SU(2) gaugino mass of 1 TeV and maximal scalar stop mixing. The more general scan of the MSSM parameter space does not reduce the limit significantly.

[35] DREES 98 (and Erratum in DREES 98B) use the CDF third-generation leptoquark search results (ABE 97F) to constrain possible Higgs production in association with $b\bar{b}$ in $p\bar{p}$ collision. In the framework of MSSM, m_A less than 130 GeV is excluded for $\tan\beta$=100. No significant limit is obtained for $\tan\beta < 80$.

[36] ACCIARRI 97N search for $e^+e^- \to H_1^0 A^0$ in four-jet final states. Cross-section limits are obtained for $|m_{H_1^0} - m_{A^0}|$ = 0, 10, and 20 GeV.

[37] BARATE 97P search for $e^+e^- \to H_1^0 A^0$ in the final state $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$ and combine with BARATE 97O limit on $e^+e^- \to H_1^0 Z$. m_{top} = 175 GeV and M_{SUSY} = 1 TeV, and maximal scalar top mixings. The invisible decays $H_1^0 \to \tilde{\chi}^0\tilde{\chi}^0$ are not allowed in the analysis, as ruled out in the relevant kinematic region by BUSKULIC 96K.

H^0 (Higgs Boson) MASS LIMITS in Extended Higgs Models

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the Note on 'Searches for Higgs Bosons' at the beginning of this Chapter). See the footnotes or the comment lines for details on the nature of the models to which the limits apply.

[38] ABBIENDI 99E search for $e^+e^- \to H^0 A^0$ and $H^0 Z$ at E_{cm} = 183 GeV. The limit is with m_H=m_A in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the m_H–m_A plane. The limit includes searches at lower energy between m_Z and 172 GeV.

[39] ABBIENDI 99O search for associated production of a $\gamma\gamma$ resonance with a $q\bar{q}$, $\nu\bar{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at 189 GeV. The limit is for a H^0 with SM production cross section and B($H^0 \to f\bar{f}$)=0, for all fermions f. See their Fig. 4 for limits on $\sigma(e^+e^- \to H^0 Z^0)\times$B$(H^0 \to \gamma\gamma)\times$B$(X^0 \to f\bar{f})$ for various masses.

[40] ABBOTT 99B search for associated production of a $\gamma\gamma$ resonance and a dijet pair. The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. Limits in the range of $\sigma(H^0 + Z/W)\cdot$B$(H^0 \to \gamma\gamma)$= 0.80–0.34 pb are obtained in the mass range m_{H^0}= 65–150 GeV.

[41] ABREU 99P search for $e^+e^- \to H^0\gamma$ with $H^0 \to b\bar{b}$ or $\gamma\gamma$, and $e^+e^- \to H^0 q\bar{q}$ with $H^0 \to \gamma\gamma$. See their Fig. 4 for limits on $\sigma\times$B. Explicit limits within an effective interaction framework are also given.

[42] ABREU 99Q search for $e^+e^- \to H^0 Z$ with H^0 decaying invisibly at E_{cm} between 161 and 183 GeV. The limit assumes SM production cross section, and holds for any B($H^0 \to$ invisible). In the case of invisible decays in the MSSM, the excluded region of the (M_2, $\tan\beta$) plane overlaps the exclusion region from direct searches for charginos and neutralinos (ABREU 99E in the Supersymmetry Listings). See their Fig. 6(d) for limits on a Majoron model.

[43] BARATE 99C search for $e^+e^- \to H^0 Z$ with H^0 decaying invisibly at $\sqrt{s}$ between 161 and 184 GeV, and update the search for $Z^0 \to H^0 Z^*$ at m_Z. The limit assumes SM

production cross section, and B($H^0 \to$ invisible)= 100%. See their Fig. 6 for limit on the ZZH^0 coupling vs. m_{H^0}.

[44] BARATE 99O search for $e^+e^- \to H^0 Z$ with H^0 decaying invisibly at E_{cm}=189 GeV. The limit assumes SM production cross section and B($H^0 \to$ invisible)=100%. See their Fig. 7 for limits on the ZZH^0 coupling vs. m_{H^0}.

[45] ACCIARRI 98B searches for $e^+e^- \to ZH^0$ events, with $Z \to$ hadrons and H^0 decaying invisibly. The limit assumes SM production cross section, and B($H^0 \to$ invisible)=1. For limits under other assumptions, see their Fig. 5b.

[46] ACKERSTAFF 98S search for $e^+e^- \to H^0A^0$ and H^0Z at E_{cm} between 130 and 172 GeV. The limit is for $m_H = m_A$. The limit is 41 GeV for all values of tanβ. See also their Fig. 10 for the exclusion limit in the m_H-m_A plane.

[47] ACKERSTAFF 98Y search for associate production of a $\gamma\gamma$ resonance and a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- annihilation at E_{cm}=183 GeV. The limit assumes SM production cross section and B($H^0 \to \gamma\gamma$)=1. See their Fig. 3 for limit on $\sigma(H^0)\cdot$B($H^0 \to \gamma\gamma$)/$\sigma(H^0_{SM})$. Supersedes ACKERSTAFF 98B.

[48] GONZALEZ-GARCIA 98B use DØ limit for $\gamma\gamma$ events with missing E_T in $p\overline{p}$ collisions (ABBOTT 98) to constrain possible ZH or WH production followed by unconventional $H \to \gamma\gamma$ decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limits on the anomalous couplings.

[49] KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no $H^0_1 ZZ$ coupling and obtain $m_{H^0_1} \gtrsim$ 5 GeV or $m_{A^0} \gtrsim$ 5 GeV for tanβ > 50. Other Higgs bosons are assumed to be much heavier.

[50] ACCIARRI 96J give B($Z \to H^0$ + hadrons)×B($H^0 \to \gamma\gamma$) < 2.3–6.9 × 10^{-6} for 20 <m_{H^0} <70 GeV.

[51] ACCIARRI 96J give B($Z \to H^0\gamma$)×B($H^0 \to q\overline{q}$) < 6.9–22.9 × 10^{-6} (95%CL) for 20 <m_{H^0} <80 GeV.

[52] ALEXANDER 96H give B($Z \to H^0\gamma$)×B($H^0 \to q\overline{q}$) < 1–4 × 10^{-5} (95%CL) and B($Z \to H^0\gamma$)×B($H^0 \to b\overline{b}$) < 0.7–2 × 10^{-5} (95%CL) in the range 20 <m_{H^0} <80 GeV.

[53] See Fig. 4 of ABREU 95H for the excluded region in the $m_{H^0} - m_{A^0}$ plane for general two-doublet models. For tanβ >1, the region $m_{H^0}+m_{A^0} \lesssim$ 87 GeV, m_{H^0} <47 GeV is excluded at 95% CL.

[54] PICH 92 analyse H^0 with m_{H^0} <$2m_\mu$ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and $\pi^{\pm}$, η rare decays are shown in Figs. 3,4. The considered mass region is not totally excluded.

$H^{\pm}$ (Charged Higgs) MASS LIMITS

Unless otherwise stated, the limits below assume B($H^+ \to \tau^+\nu$)+B($H^+ \to c\overline{s}$)=1, and hold for all values of B($H^+ \to \tau^+\nu_\tau$), and assume H^+ weak isospin of T_3=+1/2. In the following, tanβ is the ratio of the two vacuum expectation values in two-doublet models (2HDM).

The limits are also applicable to point-like technipions. For a discussion of techniparticles, see the Review of Dynamical Electroweak Symmetry Breaking in this Review.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current measurements, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review.

Searches in e^+e^- collisions at and above the Z pole have conclusively ruled out the existence of a charged Higgs in the region $m_{H^+} \lesssim$ 45 GeV, and are now superseded by the most recent searches in higher energy e^+e^- collisions at LEP. Results by now obsolete are therefore not included in this compilation, and can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the $e^+e^- \to H^+H^-$ process. Limits from $b \to s\gamma$ decays are usually stronger in generic 2HDM models than in Supersymmetric models.

'OUR LIMIT' is taken from the LEP Higgs Boson Searches Working Group (LEP 99B), where the combination of the results of ABBIENDI 99E, ABREU 99R, ACCIARRI 99B, BARATE 99D was performed.

A recent combination (LEP 00B) of preliminary, unpublished results relative to data taken at LEP in the Summer of 1999 at energies up to 202 GeV gives the limit $m_{H^{\pm}_1}$ > 78.6 GeV.

		[66] BUSKULIC	95	ALEP	$b \to \tau\nu_\tau X$

[55] The limit improves to 71.6 GeV for B($\tau\nu$)> 0.2 (see Fig. 4).

[56] ABBOTT 99E search for a charged Higgs boson in top decays in $p\overline{p}$ collisions at E_{cm}=1.8 TeV, by comparing the observed $t\overline{t}$ cross section (extracted from the data assuming the dominant decay $t \to bW^+$) with theoretical expectation. The search is sensitive to regions of the domains tan$\beta \lesssim$ 1, 50 <m_{H^+}(GeV) $\lesssim$ 120 and tan$\beta \gtrsim$ 40, 50 <m_{H^+}(GeV) $\lesssim$ 160. See Fig. 3 for the details of the excluded region.

[57] ACKERSTAFF 99D measure the Michel parameters ρ, ξ, η, and $\xi\delta$ in leptonic τ decays from $Z \to \tau\tau$. Assuming e-μ universality, the limit m_{H^+} > 0.97 tanβ GeV (95%CL) is obtained for two-doublet models in which only one doublet couples to leptons.

[58] ABE 97L search for a charged Higgs boson in top decays in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV, with $H^+ \to \tau^+\nu_\tau$, τ decaying hadronically. The limits depend on the choice of the $t\overline{t}$ cross section. See Fig. 3 for the excluded region. The excluded mass region extends to over 140 GeV for tanβ values above 100.

[59] ACCIARRI 97F give a limit m_{H^+} > 2.6 tanβ GeV (90%CL) from their limit on the exclusive $B \to \tau\nu_\tau$ branching ratio.

[60] AMMAR 97B measure the Michel parameter ρ from $\tau \to e\nu\nu$ decays and assmes e/μ universality to extract the Michel η parameter from $\tau \to \mu\nu\nu$ decays. The measurement is translated to a lower limit on m_{H^+} in a two-doublet model m_{H^+} > 0.97 tanβ GeV (90% CL).

[61] COARASA 97 reanalyzed the constraint on the ($m_{H^{\pm}}$,tanβ) plane derived from the inclusive $B \to \tau\nu_\tau X$ branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.

[62] GUCHAIT 97 studies the constraints on m_{H^+} set by Tevatron data on $\ell\tau$ final states in $t\overline{t} \to (Wb)(Hb)$, $W \to \ell\nu$, $H \to \tau\nu_\tau$. See Fig. 2 for the excluded region.

[63] MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large $B_c \to \tau\nu_\tau$ background to $B_u \to \tau\nu_\tau$ decays. Stronger limits are obtained.

[64] STAHL 97 fit τ lifetime, leptonic branching ratios, and the Michel parameters and derive limit m_{H^+} > 1.5 tanβ GeV (90% CL) for a two-doublet model. See also STAHL 94.

[65] ALAM 95 measure the inclusive $b \to s\gamma$ branching ratio at $\Upsilon(4S)$ and give B($b \to s\gamma$)< 4.2 × 10^{-4} (95% CL), which translates to the limit m_{H^+} >[244 + 63/(tanβ)$^{1.3}$] GeV in the Type II two-doublet model. Light supersymmetric particles can invalidate this bound.

[66] BUSKULIC 95 give a limit m_{H^+} > 1.9 tanβ GeV (90%CL) for Type-II models from $b \to \tau\nu_\tau X$ branching ratio, as proposed in GROSSMAN 94.

		[68] GORDEEV	97	SPEC	muonium conversion
		[69] ASAKA	95	THEO	
>30.4	95	[70] ACTON	92M	OPAL	$T_3(H^{++})$= +1
>25.5	95	[70] ACTON	92M	OPAL	$T_3(H^{++})$= 0
none 6.5–36.6	95	[71] SWARTZ	90	MRK2	$T_3(H^{++})$ = +1
none 7.3–34.3	95	[71] SWARTZ	90	MRK2	$T_3(H^{++})$ = 0

[67] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[68] GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F$ < 0.14 (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}}$ > 210 GeV if the Yukawa copulings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

[69] ASAKA 95 point out that H^{++} decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does not apply.

[70] ACTON 92M from $\Delta\Gamma_Z$ <40 MeV.

[71] SWARTZ 90 assume $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ (any flavor). The limits are valid for the Higgs-lepton coupling g($H\ell\ell$) $\gtrsim$ 7.4 × 10^{-7}/[m_H/GeV]$^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

Heavy Bosons Other Than Higgs Bosons, Searches for

We list here various limits on charged and neutral heavy vector bosons (other than W's and Z's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axigluons.

W_R (Right-Handed W Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B, and COLANGELO 91. $g_R = g_L$ assumed. [Limits in the section MASS LIMITS for W' below are also valid for W_R if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, *i.e.*, the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89B. Limits on the W_L-W_R mixing angle ζ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

[2] ACKERSTAFF 99D limit is from τ decay parameters. Limit increase to 145 GeV for zero mixing.

[3] BARENBOIM 98 assumes minimal left-right model with Higgs of $SU(2)_R$ in $SU(2)_L$ doublet. For Higgs in $SU(2)_L$ triplet, m_{W_R} >1100 GeV. Bound calculated from effect of corresponding Z_{LR} on electroweak data through Z-Z_{LR} mixing.

[4] The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L-K_S mass difference.

[5] STAHL 97 limit is from fit to τ-decay parameters.

[6] ALLET 96 measured polarization-asymmetry correlaton in $^{12}N\beta^+$ decay. The listed limit assumes zero L-R mixing.

[7] KUZNETSOV 95 limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94B.

[8] KUZNETSOV 94B limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed.

[9] BHATTACHARYYA 93 uses Z-Z' mixing limit from LEP '90 data, assuming a specific Higgs sector of $SU(2)_L \times SU(2)_R \times U(1)$ gauge model. The limit is for m_t=200 GeV and slightly improves for smaller m_t.

[10] SEVERIJNS 93 measured polarization-asymmetry correlation in $^{107}In\,\beta^+$ decay. The listed limit assumes zero L-R mixing. Value quoted here is from SEVERIJNS 94 erratum.

[11] IMAZATO 92 measure positron asymmetry in $K^+ \to \mu^+ \nu_\mu$ decay and obtain ξP_μ > 0.990 (90%CL). If W_R couples to $u\overline{s}$ with full weak strength (V^R_{us}=1), the result corresponds to m_{W_R} >653 GeV. See their Fig. 4 for m_{W_R} limits for general $|V^R_{us}|^2 = 1 - |V^R_{ud}|^2$.

[12] POLAK 92B limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Supersedes POLAK 91.

[13] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.

[14] COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.

[15] POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Superseded by POLAK 92B.

[16] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.

[17] LANGACKER 89B limit is for any ν_R mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.

[18] BALKE 88 limit is for $m_{\nu_{eR}} = 0$ and $m_{\nu_{\mu R}} \leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.
[19] JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point e^+ spectrum in the decay of the highly polarized μ^+.
[20] STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay e^+ spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.
[21] BERGSMA 83 set limit $m_{W_2}/m_{W_1} > 1.9$ at CL = 90%.
[22] CARR 83 is TRIUMF experiment with a highly polarized μ^+ beam. Looked for deviation from $V-A$ at the high momentum end of the decay e^+ energy spectrum. Limit from previous world-average muon polarization parameter is $m_{W_R} > 240$ GeV. Assumes a light right-handed neutrino.
[23] BEALL 82 limit is obtained assuming that W_R contribution to K_L^0–K_S^0 mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

Limit on W_L-W_R Mixing Angle ζ

Lighter mass eigenstate $W_1 = W_L\cos\zeta - W_R\sin\zeta$. Light ν_R assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

[24] ACKERSTAFF 99D limit is from τ decay parameters.
[25] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.
[26] The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L-K_S mass difference.
[27] MISHRA 92 limit is from the absence of extra large-x, large-y $\overline{\nu}_\mu N \rightarrow \overline{\nu}_\mu X$ events at Tevatron, assuming left-handed ν and right-handed $\overline{\nu}$ in the neutrino beam. The result gives $\zeta^2(1-2m^2_{W_1}/m^2_{W_2}) < 0.0015$. The limit is independent of ν_R mass.
[28] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed.
[29] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.
[30] First JODIDIO 86 result assumes $m_{W_R}=\infty$, second is for unconstrained m_{W_R}.

THE W' SEARCHES

Written October 1997 by K.S. Babu, C. Kolda, and J. March-Russell (IAS/Princeton).

Any electrically charged gauge boson outside of the Standard Model is generically denoted W'. A W' always couples to two different flavors of fermions, similar to the W boson. In particular, if a W' couples quarks to leptons it is a leptoquark gauge boson.

The most attractive candidate for W' is the W_R gauge boson associated with the left-right symmetric models [1]. These models seek to provide a spontaneous origin for parity violation in weak interactions. Here the gauge group is extended to $SU(3)_C \times SU(2)_L \times SU(2)_R \times U(1)_{B-L}$ with the Standard Model hypercharge identified as $Y = T_{3R} + (B-L)/2$, T_{3R} being the third component of $SU(2)_R$. The fermions transform under the gauge group in a left-right symmetric fashion: $q_L(3,2,1,1/3) + q_R(3,1,2,1/3)$ for quarks and $\ell_L(1,2,1,-1) + \ell_R(1,1,2,-1)$ for leptons. Note that the model requires the introduction of right-handed neutrinos, which can facilitate the see-saw mechanism for explaining the smallness of the ordinary neutrino masses. A Higgs bidoublet $\Phi(1,2,2,0)$ is usually employed to generate quark and lepton masses and to participate in the electroweak symmetry breaking. Under left-right (or parity) symmetry, $q_L \leftrightarrow q_R$, $\ell_L \leftrightarrow \ell_R$, $W_L \leftrightarrow W_R$ and $\Phi \leftrightarrow \Phi^\dagger$.

After spontaneous symmetry breaking, the two W bosons of the model, W_L and W_R, will mix. The physical mass eigenstates are denoted as

$$W_1 = \cos\zeta\, W_L + \sin\zeta\, W_R, \qquad W_2 = -\sin\zeta\, W_L + \cos\zeta\, W_R \quad (1)$$

with W_1 identified as the observed W boson. The most general Lagrangian that describes the interactions of the $W_{1,2}$ with the quarks can be written as [2]

$$\mathcal{L} = -\frac{1}{\sqrt{2}}\overline{u}\gamma_\mu\left[\left(g_L\cos\zeta\, V^L P_L - g_R e^{i\omega}\sin\zeta\, V^R P_R\right)W_1^\mu + \left(g_L\sin\zeta\, V^L P_L + g_R e^{i\omega}\cos\zeta\, V^R P_R\right)W_2^\mu\right]d + h.c. \quad (2)$$

where $g_{L,R}$ are the $SU(2)_{L,R}$ gauge couplings, $P_{L,R} = (1 \mp \gamma_5)/2$ and $V^{L,R}$ are the left- and right-handed CKM matrices in the quark sector. The phase ω reflects a possible complex mixing parameter in the W_L-W_R mass-squared matrix. Note that there is CP violation in the model arising from the right-handed currents even with only two generations. The Lagrangian for leptons is identical to that for quarks, with the replacements $u \rightarrow \nu$, $d \rightarrow e$ and the identification of $V^{L,R}$ with the CKM matrices in the leptonic sector.

If parity invariance is imposed on the Lagrangian, then $g_L = g_R$. Furthermore, the Yukawa coupling matrices that arise from coupling to the Higgs bidoublet Φ will be Hermitian. If in addition the vacuum expectation values of Φ are assumed to be real, the quark and lepton mass matrices will also be Hermitian, leading to the relation $V^L = V^R$. Such models are called *manifest* left-right symmetric models and are approximately realized with a minimal Higgs sector [3]. If instead parity and CP are both imposed on the Lagrangian, then the Yukawa coupling matrices will be real symmetric and, after spontaneous CP violation, the mass matrices will be complex symmetric. In this case, which is known in the literature as *pseudo-manifest* left-right symmetry, $V^L = (V^R)^*$.

Indirect constraints: In minimal version of manifest or pseudo-manifest left-right symmetric models with $\omega = 0$ or π, there are only two free parameters, ζ and M_{W_2}, and they can be constrained from low energy processes. In the large M_{W_2} limit, stringent bounds on the angle ζ arise from three processes. (i) Nonleptonic K decays: The decays $K \rightarrow 3\pi$ and $K \rightarrow 2\pi$ are sensitive to small admixtures of right-handed currents. Assuming the validity of PCAC relations in the Standard Model it has been argued in Ref. 4 that the success in the $K \rightarrow 3\pi$ prediction will be spoiled unless $|\zeta| \leq 4 \times 10^{-3}$. (ii) $b \rightarrow s\gamma$: The amplitude for this process has an enhancement factor m_t/m_b relative to the Standard Model and thus can be used to constrain ζ yielding the limit $-0.01 \leq \zeta \leq 0.003$ [5]. (iii) Universality in weak decays: If the right-handed neutrinos are heavy, the right-handed admixture in the charged current will contribute to β decay and K decay, but not to the μ decay. This will modify the extracted values of V^L_{ud} and V^L_{us}. Demanding that the difference not upset the three generation unitarity of the CKM matrix, a bound $|\zeta| \leq 10^{-3}$ has been derived [6].

If the ν_R are heavy, leptonic and semileptonic processes do not constrain ζ since the emission of ν_R will not be kinematically allowed. However, if the ν_R is light enough to be emitted in μ decay and β decay, stringent limits on ζ do arise. For example, $|\zeta| \leq 0.039$ can be obtained from polarized μ decay [7] in the large M_{W_2} limit of the manifest left-right model. Alternatively, in the $\zeta = 0$ limit, there is a constraint $M_{W_2} \geq 484$ GeV from direct W_2 exchange. For the constraint on the case in which M_{W_2} is not taken to be heavy, see Ref. 2. There are also cosmological and astrophysical constraints on M_{W_2} and ζ in scenarios with a light ν_R. During nucleosynthesis the process $e^+e^- \to \nu_R\overline{\nu}_R$, proceeding via W_2 exchange, will keep the ν_R in equilibrium leading to an overproduction of ^{4}He unless M_{W_2} is greater than about 1 TeV [8]. Likewise the ν_{eR} produced via $e_R^- p \to n\nu_R$ inside a supernova must not drain too much of its energy, leading to limits $M_{W_2} > 16$ TeV and $|\zeta| \leq 3 \times 10^{-5}$ [9]. Note that models with light ν_R do not have a see-saw mechanism for explaining the smallness of the neutrino masses, though other mechanisms may arise in variant models [10].

The mass of W_2 is severely constrained (independent of the value of ζ) from K_L–K_S mass-splitting. The box diagram with exchange of one W_L and one W_R has an anomalous enhancement and yields the bound $M_{W_2} \geq 1.6$ TeV [11] for the case of manifest or pseudo-manifest left-right symmetry. If the ν_R have Majorana masses, another constraint arises from neutrinoless double β decay. Combining the experimental limit from ^{76}Ge decay with arguments of vacuum stability, a limit of $M_{W_2} \geq 1.1$ TeV has been obtained [12].

Direct search limits: Limits on M_{W_2} from direct searches depend on the available decay channels of W_2. If ν_R is heavier than W_2, the decay $W_2^+ \to \ell_R^+\nu_R$ will be forbidden kinematically. Assuming that ζ is small, the dominant decay of W_2 will be into dijets. UA2 [13] has excluded a W_2 in the mass range of 100 to 251 GeV in this channel. DØ excludes the mass range of 340 to 680 GeV [14], while CDF excludes the mass range of 300 to 420 GeV for such a W_2 [15]. If ν_R is lighter than W_2, the decay $W_2^+ \to e_R^+\nu_R$ is allowed. The ν_R can then decay into $e_R W_R^*$, leading to an $eejj$ signature. DØ has a limit of $M_{W_2} > 720$ GeV if $m_{\nu_R} \ll M_{W_2}$; the bound weakens, for example, to 650 GeV for $m_{\nu_R} = M_{W_2}/2$ [16]. CDF finds $M_{W_2} > 652$ GeV if ν_R is stable and much lighter than W_2 [17]. All of these limits assume manifest or pseudo-manifest left-right symmetry. See [16] for some variations in the limits if the assumption of left-right symmetry is relaxed.

Alternative models: W' gauge bosons can also arise in other models. We shall briefly mention some such popular models, but for details we refer the reader to the original literature. The *alternate* left-right model [18] is based on the same gauge group as the left-right model, but arises in the following way: In E_6 unification, there is an option to identify the right-handed down quarks as $SU(2)_R$ singlets or doublets. If they are $SU(2)_R$ doublets, one recovers the conventional left-right model; if they are singlets it leads to the alternate left-right model. A similar ambiguity exists in the assignment of left-handed leptons; the alternate left-right model assigns them to a $(1,2,2,0)$ multiplet. As a consequence, the ordinary neutrino remains exactly massless in the model. One important difference from the usual left-right model is that the limit from the K_L–K_S mass difference is no longer applicable, since the d_R do not couple to the W_R. There is also no limit from polarized μ decay, since the $SU(2)_R$ partner of e_R can receive a large Majorana mass. Other W' models include the un-unified Standard Model of Ref. 19 where there are two different SU(2) gauge groups, one each for the quarks and leptons; models with separate SU(2) gauge factors for each generation [20]; and the $SU(3)_C \times SU(3)_L \times U(1)$ model of Ref. 21.

Leptoquark gauge bosons: The $SU(3)_C \times U(1)_{B-L}$ part of the gauge symmetry discussed above can be embedded into a simple $SU(4)_C$ gauge group [22]. The model then will contain leptoquark gauge boson as well, with couplings of the type $\{(\overline{e}_L\gamma_\mu d_L + \overline{\nu}_L\gamma_\mu u_L)W'^\mu + (L \to R)\}$. The best limit on such leptoquark W' comes from nonobservation of $K_L \to \mu e$, which requires $M_{W'} \geq 1400$ TeV; for the corresponding limits on less conventional leptoquark flavor structures, see Ref. 23. Thus such a W' is inaccessible to direct searches with present machines which are sensitive to vector leptoquark masses of order 300 GeV only.

MASS LIMITS for W' (A Heavy-Charged Vector Boson Other Than W) in Hadron Collider Experiments

Couplings of W' to quarks and leptons are taken to be identical with those of W. The following limits are obtained from $p\overline{p} \to W'X$ with W' decaying to the mode indicated in the comments. New decay channels (*e.g.*, $W' \to WZ$) are assumed to be suppressed. UA1 and UA2 experiments assume that the $t\overline{b}$ channel is not open.

[31] For bounds on W_R with nonzero right-handed mass, see Fig. 5 from ABACHI 96C.

[32] ABE 97G search for new particle decaying to dijets.

[33] ABACHI 95E assume that the decay $W' \to WZ$ is suppressed and that the neutrino from W' decay is stable and has a mass significantly less $m_{W'}$.

[34] ABE 95M assume that the decay $W' \to WZ$ is suppressed and the (right-handed) neutrino is light, noninteracting, and stable. If m_ν=60 GeV, for example, the effect on the mass limit is neglibible.

[35] ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes $\Gamma(W')/m_{W'} = \Gamma(W)/m_W$ and $B(W' \to jj) = 2/3$. This corresponds to W_R with $m_{\nu_R} > m_{W_R}$ (no leptonic decay) and $W_R \to t\overline{b}$ allowed. See their Fig. 4 for limits in the $m_{W'}$–$B(q\overline{q})$ plane.

[36] RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.

[37] ABE 91F assume leptonic branching ratio of 1/12 for each lepton flavor. The limit from the $e\nu$ ($\mu\nu$) mode alone is 490 (435) GeV. These limits apply to W_R if $m_{\nu_R} \lesssim 15$ GeV and ν_R does not decay in the detector. Cross section limit $\sigma \cdot B <$ (1–10) pb is given for $m_{W'}$ = 100–550 GeV; see Fig. 2.

[38] ALITTI 91 search is based on two-jet invariant mass spectrum, assuming $B(W' \to q\overline{q})$ = 67.6%. Limit on $\sigma \cdot B$ as a function of two-jet mass is given in Fig. 7.

[39] ALBAJAR 89 cross section limit at 630 GeV is $\sigma(W')\,B(e\nu) <$ 4.1 pb (90% CL).

[40] See Fig. 5 of ANSARI 87D for the excluded region in the $m_{W'}$–$[(g_{W'q})^2\, B(W' \to e\overline{\nu})]$ plane. Note that the quantity $(g_{W'q})^2\, B(W' \to e\overline{\nu})$ is normalized to unity for the standard W couplings.

[41] ARNISON 86B find no excess at large p_T in 148 $W \to e\nu$ events. Set limit $\sigma \times B(e\nu)$ <10 pb at CL = 90% at E_{cm} = 546 and 630 GeV.

[42] ARNISON 83D find among 47 $W \to e\nu$ candidates no event with excess p_T. Also set $\sigma \times B(e\nu)$ <30 pb with CL = 90% at E_{cm} = 540 GeV.

THE Z' SEARCHES

Written October 1997 by K.S. Babu, C. Kolda, and J. March-Russell (IAS/Princeton).

If the Standard Model is enhanced by additional gauge symmetries or embedded into a larger gauge group, there will arise new heavy gauge bosons, some of which generically are electrically neutral. Such a gauge boson is called a Z'. Consider the most general renormalizable Lagrangian describing the complete set of interactions of the neutral gauge bosons among themselves and with fermions, which is that of the Standard Model plus the following new pieces [1,2,3]:

$$\mathcal{L}_{Z'} = -\frac{1}{4}\widehat{F}'_{\mu\nu}\widehat{F}'^{\mu\nu} - \frac{\sin\chi}{2}\widehat{F}'_{\mu\nu}\widehat{F}^{\mu\nu} + \frac{1}{2}\widehat{M}^2_{Z'}\widehat{Z}'_\mu\widehat{Z}'^\mu + \delta\widehat{M}^2\,\widehat{Z}'_\mu\widehat{Z}^\mu - \frac{\widehat{g}'}{2}\sum_i \overline{\psi}_i\gamma^\mu(f^i_V - f^i_A\gamma^5)\psi_i\widehat{Z}'_\mu \quad (1)$$

where $\widehat{F}_{\mu\nu}, \widehat{F}'_{\mu\nu}$ are the field strength tensors for the hypercharge $\widehat{B}_\mu$ gauge boson and the Z' respectively before any diagonalizations are performed, ψ_i are the matter fields with Z' vector and axial charges f^i_V and f^i_A, and $\widehat{Z}_\mu$ is the electroweak Z boson in this basis. (See the Review on "Electroweak Model and Constraints on New Physics" for the Standard Model pieces of the Lagrangian.) The mass terms are assumed to come from spontaneous symmetry breaking via scalar expectation values. The above Lagrangian is general to all abelian and non-abelian extensions, except that $\chi = 0$ for the non-abelian case since then $\widehat{F}'_{\mu\nu}$ is not gauge invariant. Most analyses take $\chi = 0$ even for the abelian case.

Going to the physical eigenbasis requires diagonalizing both the gauge kinetic and mass terms, with mass eigenstates denoted Z_1 and Z_2, where we choose Z_1 to be the observed Z boson. The interaction Lagrangian for Z_1 has the form, to leading order in the mixing angle ξ ($s_W \equiv \sin\theta_W$, etc.):

$$\mathcal{L}_{Z_1} = -\frac{e}{2s_W c_W}\left(1 + \frac{\alpha T}{2}\right)\overline{\psi}_i\gamma^\mu\left\{\left(g^i_V + \xi\tilde{f}^i_V\right) - \left(g^i_A + \xi\tilde{f}^i_A\right)\gamma^5\right\}\psi_i Z_{1\mu} \quad (2)$$

where

$$\xi \simeq \frac{-\cos\chi(\delta\widehat{M}^2 + \widehat{M}^2_Z s_W\sin\chi)}{\widehat{M}^2_{Z'} - \widehat{M}^2_Z\cos^2\chi + \widehat{M}^2_Z s^2_W\sin^2\chi + 2\,\delta\widehat{M}^2\,s_W\sin\chi} \,. \quad (3)$$

We have made the identifications $g^i_A = T^i_3$, $g^i_V = T^i_3 - 2Q^i s^2_*$, $\tilde{f}^i_{V,A} = (\widehat{g}' s_W c_W / e\cos\chi) f^i_{V,A}$, and s^2_W is identified to be the $s^2_{M_Z}$ defined in the "Electroweak Model and Constraints on New Physics" review. Note that the value of the weak angle

THE Z' SEARCHES

Written October 1997 by K.S. Babu, C. Kolda, and J. March-Russell (IAS/Princeton).

If the Standard Model is enhanced by additional gauge symmetries or embedded into a larger gauge group, there will arise new heavy gauge bosons, some of which generically are electrically neutral. Such a gauge boson is called a Z'. Consider the most general renormalizable Lagrangian describing the complete set of interactions of the neutral gauge bosons among themselves and with fermions, which is that of the Standard Model plus the following new pieces [1,2,3]:

$$\mathcal{L}_{Z'} = -\frac{1}{4}\widehat{F}'_{\mu\nu}\widehat{F}'^{\mu\nu} - \frac{\sin\chi}{2}\widehat{F}'_{\mu\nu}\widehat{F}^{\mu\nu} + \frac{1}{2}\widehat{M}^2_{Z'}\widehat{Z}'_\mu\widehat{Z}'^\mu + \delta\widehat{M}^2\,\widehat{Z}'_\mu\widehat{Z}^\mu - \frac{\widehat{g}'}{2}\sum_i \overline{\psi}_i\gamma^\mu(f^i_V - f^i_A\gamma^5)\psi_i\widehat{Z}'_\mu \quad (1)$$

where $\widehat{F}_{\mu\nu}, \widehat{F}'_{\mu\nu}$ are the field strength tensors for the hypercharge $\widehat{B}_\mu$ gauge boson and the Z' respectively before any diagonalizations are performed, ψ_i are the matter fields with Z' vector and axial charges f^i_V and f^i_A, and $\widehat{Z}_\mu$ is the electroweak Z boson in this basis. (See the Review on "Electroweak Model and Constraints on New Physics" for the Standard Model pieces of the Lagrangian.) The mass terms are assumed to come from spontaneous symmetry breaking via scalar expectation values. The above Lagrangian is general to all abelian and non-abelian extensions, except that $\chi = 0$ for the non-abelian case since then $\widehat{F}'_{\mu\nu}$ is not gauge invariant. Most analyses take $\chi = 0$ even for the abelian case.

Going to the physical eigenbasis requires diagonalizing both the gauge kinetic and mass terms, with mass eigenstates denoted Z_1 and Z_2, where we choose Z_1 to be the observed Z boson. The interaction Lagrangian for Z_1 has the form, to leading order in the mixing angle ξ ($s_W \equiv \sin\theta_W$, etc.):

$$\mathcal{L}_{Z_1} = -\frac{e}{2s_Wc_W}\left(1+\frac{\alpha T}{2}\right)\overline{\psi}_i\gamma^\mu\left\{\left(g^i_V + \xi\tilde{f}^i_V\right) - \left(g^i_A + \xi\tilde{f}^i_A\right)\gamma^5\right\}\psi_i Z_{1\mu} \quad (2)$$

where

$$\xi \simeq \frac{-\cos\chi(\delta\widehat{M}^2 + \widehat{M}^2_Z s_W\sin\chi)}{\widehat{M}^2_{Z'} - \widehat{M}^2_Z\cos^2\chi + \widehat{M}^2_Z s^2_W\sin^2\chi + 2\,\delta\widehat{M}^2\,s_W\sin\chi} \,. \quad (3)$$

We have made the identifications $g^i_A = T^i_3$, $g^i_V = T^i_3 - 2Q^i s^2_*$, $\tilde{f}^i_{V,A} = (\widehat{g}'s_Wc_W/e\cos\chi)f^i_{V,A}$, and s^2_W is identified to be the $s^2_{M_Z}$ defined in the "Electroweak Model and Constraints on New Physics" review. Note that the value of the weak angle that appears in the vector coupling is shifted by the S and T oblique parameters:

$$s_*^2 = s_W^2 + \frac{1}{s_W^2 - c_W^2}\left(\frac{1}{4}\alpha S - c_W^2 s_W^2 \alpha T\right) \ . \tag{4}$$

Recall that $\rho = 1 + \alpha T$ defines the usual ρ parameter. In the presence of Z–Z' mixing, the oblique parameters receive contributions [4]:

$$\begin{aligned} \alpha S &= 4\xi c_W^2 s_W \tan\chi \\ \alpha T &= \xi^2 \left(\frac{M_{Z_2}^2}{M_{Z_1}^2} - 1\right) + 2\xi s_W \tan\chi \\ \alpha U &= 0 \end{aligned} \tag{5}$$

to leading order in small ξ. These contributions are in addition to those coming from top quark and Higgs boson loops in the Standard Model. (This is in contrast to the "Electroweak Model and Constraints on New Physics" Review in which oblique parameters are defined to be zero for reference values of m_t and M_H.) Note that nonzero Z–Z' contributions to S arise only in the presence of kinetic mixing.

The corresponding $Z_2\overline{\psi}\psi$ interaction Lagrangian is:

$$\mathcal{L}_{Z_2} = -\frac{e}{2 s_W c_W}\overline{\psi}_i \gamma^\mu \left\{ (h_V^i - g_V^i \xi) - (h_A^i - g_A^i \xi)\gamma^5 \right\} \psi_i Z_{2\mu} \tag{6}$$

with the following definitions:

$$\begin{aligned} h_V^i &= \tilde{f}_V^i + \tilde{s}(T_3^i - 2Q^i)\tan\chi \\ h_A^i &= \tilde{f}_A^i + \tilde{s} T_3^i \tan\chi \\ \tilde{s} &= s_W + \frac{s_W^3}{c_W^2 - s_W^2}\left(\frac{1}{4c_W^2}\alpha S - \frac{1}{2}\alpha T\right) \end{aligned} \tag{7}$$

where the last equation defines a weak angle appropriate for the Z_2 interactions.

If the Z' charges are generation-dependent, there exist severe constraints in the first two generations coming from precision measurements such as the K_L–K_S mass splitting and $B(\mu \to 3e)$ owing to the lack of GIM suppression in the Z' interactions; however, constraints on a Z' which couples differently only to the third generation are somewhat weaker. (It will be assumed in the Z-pole constraint section that the Z' couples identically to all three generations of matter; all other results are general.) If the new Z' interactions commute with the Standard Model gauge group, then per generation, there are only five independent $Z'\overline{\psi}\psi$ couplings; we can choose them to be $\tilde{f}_V^u$, $\tilde{f}_A^u$, $\tilde{f}_V^d$, $\tilde{f}_V^e$, and $\tilde{f}_A^e$. All other couplings can be determined in terms of these, *e.g.*, $\tilde{f}_V^\nu = (\tilde{f}_V^e + \tilde{f}_A^e)/2$.

Canonical models: One of the prime motivations for an additional Z' has come from string theory in which certain compactifications lead naturally to an E_6 gauge group, or one of its subgroups. E_6 contains two U(1) factors beyond the Standard Model, a basis for which is formed by the two groups $\mathrm{U(1)}_\chi$ and $\mathrm{U(1)}_\psi$, defined via the decompositions $E_6 \to \mathrm{SO(10)} \times \mathrm{U(1)}_\psi$ and $\mathrm{SO(10)} \to \mathrm{SU(5)} \times \mathrm{U(1)}_\chi$; one special case often encountered is $\mathrm{U(1)}_\eta$ where $Z_\eta = \sqrt{\frac{3}{8}}Z_\chi + \sqrt{\frac{5}{8}}Z_\psi$. The charges of the SM fermions under these U(1)'s, and a discussion of their experimental signals, can be found in Ref. 5.

It is also common to express experimental bounds in terms of a toy Z' usually denoted $Z_{\rm SM}$. This $Z_{\rm SM}$, of arbitrary mass, couples to the SM fermions identically to the usual Z.

Almost all analyses of Z' physics have worked with one of these canonical models and have assumed zero kinetic mixing at the weak scale.

Experimental constraints: There are three primary sets of constraints on the existence of a Z' which will be considered here: precision measurements of neutral-current processes at low energies, Z-pole constraints on Z–Z' mixing, and direct search constraints from production at very high energies. In principle, one usually expects other new states to appear at the same scale as the Z', including its symmetry-breaking sector and any additional fermions necessary for anomaly cancellation. However, because these states are highly model-dependent, we will not include searches for them, or Z' decays to them, in the bounds that follow.

Low-energy constraints: After the breaking of the new gauge group and the usual electroweak breaking, the Z of the Standard Model can mix with the Z', with mixing angle ξ defined above. As already discussed, this Z–Z' mixing implies a shift in the usual oblique parameters [S, T, U defined in Eq. (5)]. Current bounds on S and T translate into stringent constraints on the mixing angle, ξ, requiring $\xi \ll 1$; similar constraints on ξ arise from the LEP Z-pole data. Thus we will only consider the small-ξ limit henceforth.

Whether or not the new gauge interactions are parity violating, stringent constraints can arise from atomic parity violation (APV) and polarized electron-nucleon scattering experiments [6]. At low energies, the effective neutral-current Lagrangian is conventionally written:

$$\mathcal{L}_{\rm NC} = \frac{G_F}{\sqrt{2}}\sum_{q=u,d}\left\{C_{1q}(\overline{e}\gamma_\mu\gamma^5 e)(\overline{q}\gamma^\mu q) + C_{2q}(\overline{e}\gamma_\mu e)(\overline{q}\gamma^\mu\gamma^5 q)\right\} \tag{8}$$

APV experiments are sensitive only to C_{1u} and C_{1d} (see the "Electroweak Model and Constraints on New Physics" Review for the nuclear weak charge, Q_W, in terms of the C_{1q}) where in the presence of the Z and Z':

$$C_{1q} = 2(1+\alpha T)(g_A^e + \xi\tilde{f}_A^e)(g_V^q + \xi\tilde{f}_V^q) + 2r(h_A^e - \xi g_A^e)(h_V^q - \xi g_V^q) \tag{9}$$

where $r = (M_{Z_1}/M_{Z_2})^2$. The r-dependent terms arise from Z_2 exchange and can interfere constructively or destructively with the Z_1 contribution. In the limit $\xi = r = 0$, this reduces to the Standard Model expression. Polarized electron scattering is sensitive to both the C_{1q} and C_{2q} couplings, again as discussed in the "Electroweak Model and Constraints on New Physics" Review. The C_{2q} can be derived from the expression for C_{1q} with the complete interchange $V \leftrightarrow A$.

Table 1: Expansion coefficients for shifts in Z-pole observables normalized to the Standard Model value of the observable [7,3].

$\mathcal{O}$	$\mathcal{A}_{\mathcal{O}}^{S}$	$\mathcal{A}_{\mathcal{O}}^{T}$	$\mathcal{B}_{\mathcal{O}}^{Vu}$	$\mathcal{B}_{\mathcal{O}}^{Au}$	$\mathcal{B}_{\mathcal{O}}^{Vd}$	$\mathcal{B}_{\mathcal{O}}^{Ve}$	$\mathcal{B}_{\mathcal{O}}^{Ae}$
Γ_Z	−0.49	1.35	−0.89	−0.40	0.37	0.37	0
R_ℓ	−0.39	0.28	−1.3	−0.56	0.52	0.30	4.0
σ_h	0.046	−0.033	0.50	0.22	−0.21	−1.0	−4.0
R_b	0.085	−0.061	−1.4	−2.1	0.29	0	0
R_c	−0.16	0.12	2.7	4.1	−0.59	0	0
$\overline{A}_e$	−24.9	17.7	0	0	0	−26.7	2.0
$\overline{A}_b$	−0.32	0.23	0.71	0.71	−1.73	0	0
$\overline{A}_c$	−2.42	1.72	3.89	−1.49	0	0	0
M_W^2	−0.93	1.43	0	0	0	0	0

Stringent limits also arise from neutrino-hadron scattering. One usually expresses experimental results in terms of the effective 4-fermion operators $(\overline{\nu}\gamma_\mu\nu)(\overline{q}_{L,R}\gamma^\mu q_{L,R})$ with coefficients $(2\sqrt{2}G_F)\epsilon_{L,R}(q)$. (Again, see the "Electroweak Model and Constraints on New Physics" Review.) In the presence of the Z and Z', the $\epsilon_{L,R}(q)$ are given by:

$$\begin{aligned}\epsilon_{L,R}(q) = &\frac{1+\alpha T}{2}\left\{(g_V^q \pm g_A^q)[1+\xi(\tilde{f}_V^\nu \pm \tilde{f}_A^\nu)] + \xi(\tilde{f}_V^q \pm \tilde{f}_A^q)\right\} \\ &+ \frac{r}{2}\left\{(h_V^q \pm h_A^q)(h_V^\nu \pm h_A^\nu) - \xi(g_V^q \pm g_A^q)(h_V^\nu \pm h_A^\nu)\right. \\ &\left. - \xi(h_V^q \pm h_A^q)\right\} \ . \end{aligned} \qquad (10)$$

Again, the r-dependent terms arise from Z_2-exchange.

Z-pole constraints: Electroweak measurements made at LEP and SLC while sitting on the Z resonance are generally sensitive to Z' physics only through the mixing with the Z unless the Z and Z' are very nearly degenerate, a possibility we ignore. Constraints on the allowed mixing angle and Z couplings arise by fitting all data simultaneously to the *ansatz* of Z–Z' mixing. For any observable, $\mathcal{O}$, the shift in that observable, $\Delta\mathcal{O}$, can be expressed (following the procedure of Ref. 7) as:

$$\frac{\Delta\mathcal{O}}{\mathcal{O}} = \mathcal{A}_{\mathcal{O}}^{S}\,\alpha S + \mathcal{A}_{\mathcal{O}}^{T}\,\alpha T + \xi\sum_i \mathcal{B}_{\mathcal{O}}^{(i)}\tilde{f}^i \qquad (11)$$

where i runs over the 5 independent $Z'\overline{\psi}\psi$ couplings listed earlier (assuming a Z' couplings commute with the generation and gauge symmetries of the Standard Model; this is the only place where we enforce such a restriction). The coefficients $\mathcal{A}_{\mathcal{O}}^{S,T}$ and $\mathcal{B}_{\mathcal{O}}^{(i)}$, which are functions only of the Standard Model parameters, are given in Table 1. The first 5 observables are directly measured at LEP and SLC, while $\overline{A}_e$, $\overline{A}_b$ and $\overline{A}_c$ are measured via the asymmetries $\overline{A}_{FB}^{(0,f)} = \frac{3}{4}\overline{A}_e\overline{A}_f$ and $A_{LR}^0 = \overline{A}_e$ as defined in the "Electroweak Model and Constraints on New Physics" Review. As an example, the shift in $\overline{A}_e$ due to Z' physics is given by

$$\frac{\Delta\overline{A}_e}{\overline{A}_e} = -24.9\,\alpha S + 17.7\,\alpha T - 26.7\,\xi\,\tilde{f}_V^e + 2.0\,\xi\,\tilde{f}_A^e \ . \qquad (12)$$

High-energy indirect constraints: At $\sqrt{s} < M_{Z_2}$, but off the Z_1 pole, strong constraints on new Z' physics arise from measurements of deviations of asymmetries and leptonic and hadronic cross sections from their Standard Model predictions. These processes are sensitive not only to Z–Z' mixing but also to direct Z_2 exchange primarily through γ–Z_2 and Z_1–Z_2 interference; therefore information on the Z_2 couplings and mass can be extracted that is not accessible via Z–Z' mixing alone.

Far below the Z_2 mass scale, experiment is only sensitive to the scaled Z_2 couplings $(\sqrt{s}/M_{Z_2})\cdot h_{V,A}^i$ so the Z_2 mass and overall magnitude of the couplings cannot both be extracted. However as $\sqrt{s}$ approaches M_{Z_2} the Z_2 exchange can no longer be approximated by a contact interaction and the mass and couplings can be simultaneously extracted.

Z' studies done before LEP relied heavily on this approach; see, *e.g.*, Ref. 8. LEP has also done similar work using data collected above the Z peak; see, *e.g.*, Ref. 9. For indirect Z' searches at future facilities, see, *e.g.* Refs. 10 and 11.

Direct-search constraints: Finally, high-energy experiments have searched for on-shell Z' (here Z_2) production and decay. Searches can be classified by the initial state off of which the Z' is produced, and the final state into which the Z' decays; we will not include here exotic decays of a Z'. Experiments to date have been sensitive to Z' production via their coupling to quarks ($p\overline{p}$ colliders), to electrons (e^+e^-) or to both (ep).

For a heavy Z' ($M_{Z_2} \gg M_{Z_1}$), the best limits come from $p\overline{p}$ machines via Drell-Yan production and subsequent decay to charged leptons. For $M_{Z_2} > 600\,\mathrm{GeV}$, CDF [12] quotes limits on $\sigma(p\overline{p} \to Z_2X)\cdot B(Z_2 \to \ell^+\ell^-) < 0.04\,\mathrm{pb}$ at 95% C.L. for $\ell = e + \mu$ combined; DØ [13] quotes $\sigma\cdot B < 0.025\,\mathrm{pb}$ for $\ell = e$. For $M_{Z_2} < 600\,\mathrm{GeV}$, the mass dependence is complicated and one should refer to the original literature. For studies of the search capabilities of future facilities, see *e.g.* Ref. 10.

If the Z' has suppressed, or no, couplings to leptons (*i.e.*, it is leptophobic) then experimental sensitivities are much weaker. In particular, searches for a Z' via hadronic decays at DØ [14] are able to rule out a Z' with quark couplings identical to those of the Z only in the mass range $365\,\mathrm{GeV} < M_{Z_2} < 615\,\mathrm{GeV}$; CDF [15] cannot exclude even this range. Additionally, UA2 [16] finds $\sigma\cdot B(Z' \to jj) < 11.7\,\mathrm{pb}$ at 90% C.L. for $M_{Z'} > 200\,\mathrm{GeV}$ and more complicated bounds in the range $130\,\mathrm{GeV} < M_{Z'} < 200\,\mathrm{GeV}$.

For a light Z' ($M_{Z'} < M_Z$) direct searches in e^+e^- colliders have ruled out any Z' unless it has extremely weak couplings to leptons. For a combined analysis of the various pre-LEP experiments see Ref. 8.

MASS LIMITS for Z' (Heavy Neutral Vector Boson Other Than Z)

Limits for Z'_{SM}

Z'_{SM} is assumed to have couplings with quarks and leptons which are identical to those of Z, and decays only to known fermions.

[43] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \rightarrow$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.
[44] ABE 97S find $\sigma(Z')\times B(e^+e^-,\mu^+\mu^-)$< 40 fb for $m_{Z'}$ > 600 GeV at $\sqrt{s}$= 1.8 TeV.
[45] ERLER 99 give 90%CL limit on the Z-Z' mixing $-0.0041 < \theta < 0.0003$. ρ_0=1 is assumed.
[46] ABE 97S find $\sigma(Z')\times B(e^+e^-)$< 350 fb for $m_{Z'}$ > 350 GeV at $\sqrt{s}$= 1.8 TeV.
[47] VILAIN 94B assume m_t = 150 GeV.
[48] ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes B($Z' \rightarrow q\overline{q}$)=0.7. See their Fig. 5 for limits in the $m_{Z'}$–B($q\overline{q}$) plane.
[49] RIZZO 93 analyses CDF limit on possible two-jet resonances.
[50] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. They fix m_W = 80.49 ± 0.43 ± 0.24 GeV and m_Z = 91.13 ± 0.03 GeV.

Limits for Z_{LR}

Z_{LR} is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the W'). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

[51] ERLER 99 give 90%CL limit on the Z-Z' mixing $-0.0009 < \theta < 0.0017$.
[52] ABE 97S find $\sigma(Z')\times B(e^+e^-,\mu^+\mu^-)$< 40 fb for $m_{Z'}$ > 600 GeV at $\sqrt{s}$= 1.8 TeV.
[53] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \rightarrow$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.
[54] CHAY 00 also find $-0.0003 < \theta < 0.0019$. For g_R free, $m_{Z'}$ > 430 GeV.
[55] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_{LR} and Z_χ.
[56] ABREU 99A give 95%CL limit on the Z-Z' mixing $|\theta|$ < 0.0031. For the limit contour in the mass-mixing plane, see their Fig. 16. Data taken at $\sqrt{s}$= 130–172 GeV.
[57] CASALBUONI 99 discuss the discrepancy between the observed and predicted values of Q_W(Cs). It is shown that the data are better described in a class of models including the Z_{LR} model.
[58] CZAKON 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds $|\theta|$ < 0.0042.
[59] ERLER 99 assumes 2 Higgs doublets, tranforming as 10 of SO(10), embedded in E_6.
[60] BARENBOIM 98 also gives 68% CL limits on the Z-Z' mixing $-0.0005 < \theta < 0.0033$. Assumes Higgs sector of minimal left-right model.
[61] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.
[62] BARATE 97B gives 95% CL limits on Z-Z' mixing $-0.0017 < \theta < 0.0035$. The bounds are computed with α_s = 0.120 ± 0.003, m_t = 175 ± 6 GeV, and $M_H = 150^{+150}_{-90}$ GeV. Data taken at $\sqrt{s}$=20–136 GeV.
[63] ABE 97S find $\sigma(Z')\times B(e^+e^-)$< 350 fb for $m_{Z'}$ > 350 GeV at $\sqrt{s}$= 1.8 TeV. See their Fig. 3 for the mass bound of Z' decaying to all allowed fermions and supersymmetric fermions.
[64] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.
[65] ADRIANI 93D give limits on the Z-Z' mixing $-0.002 < \theta < 0.015$ assuming $m_{Z'}$ > 310 GeV.
[66] ALTARELLI 93B limit is from LEP data available in summer '93 and is for m_t = 110 GeV. m_H = 100 GeV and α_s = 0.118 assumed. The limit improves for larger m_t (see their Fig. 5). The 90%CL limit on the Z-Z' mixing angle is in Table 4.
[67] RIZZO 93 analyses CDF limit on possible two-jet resonances.
[68] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim$ 1 MeV. A specific Higgs sector is assumed. See also GRIFOLS 90D, RIZZO 91.
[69] BARBIERI 89B limit holds for $m_{\nu_R} \leq$ 10 MeV. Bounds depend on assumed supernova core temperature.

Limits for Z_χ

Z_χ is the extra neutral boson in SO(10) → SU(5) × U(1)$_\chi$. $g_\chi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[70] ERLER 99 give 90%CL limit on the Z-Z' mixing $-0.0020 < \theta < 0.0015$.

[71] ABE 97S find $\sigma(Z')\times B(e^+e^-,\mu^+\mu^-) <$ 40 fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.

[72] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[73] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_{LR} and Z_χ.

[74] ROSNER 00 discusses the possiblitiy that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_χ.

[75] ABREU 99A give 95%CL limit on the Z-Z' mixing $|\theta| < 0.0033$. For the limit contour in the mass-mixing plane, see their Fig. 16. Data taken at $\sqrt{s}$= 130–172 GeV.

[76] ERLER 99 assumes 2 Higgs doublets, tranforming as 10 of SO(10), embedded in E_6.

[77] CHO 98 limit is from constraints on four-Fermi contact interactions obtained from low-energy electroweak experiments, and assumes no Z-Z' mixing.

[78] CHO 98B use various electroweak data to constrain Z' models assuming m_H=100 GeV. ρ=1 is not assumed. See their Eq. (4.8) for their fit in mass-mixing plane, and Table 10 for limits assuming E_6-motivated Higgs sector.

[79] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[80] Z-Z' mixing is assumed to be zero. $\sqrt{s}$= 57.77 GeV.

[81] BARATE 97B gives 95% CL limits on Z-Z' mixing $-0.0016 < \theta < 0.0036$. The bounds are computed with $\alpha_s = 0.120 \pm 0.003$, $m_t = 175 \pm 6$ GeV, and $M_H = 150^{+150}_{-90}$ GeV. Data was taken at $\sqrt{s}$= 20–136 GeV.

[82] ABE 95 limit is obtained assuming that Z' decays to known fermions only. See their Fig. 3 for the mass bound of Z' decaying to all allowed fermions and supersymmetric fermions.

[83] ABREU 95M limit is for α_s=0.123, m_t=150 GeV, and m_H=300 GeV. For the limit contour in the mass-mixing plane, see their Fig. 13.

[84] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[85] ADRIANI 93D give limits on the Z-Z' mixing $-0.004 < \theta < 0.015$ assuming the ABE 92B mass limit.

[86] ALTARELLI 93B limit is from LEP data available in summer '93 and is for m_t = 110 GeV. m_H = 100 GeV and α_s = 0.118 assumed. The limit improves for larger m_t (see their Fig. 5). The 90%CL limit on the Z-Z' mixing angle is in their Fig. 2.

[87] FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos $\Delta N_\nu < 0.5$ and is valid for $m_{\nu_R} < 1$ MeV.

[88] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[89] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim$ 1 MeV).

[90] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

Limits for Z_ψ

Z_ψ is the extra neutral boson in $E_6 \to SO(10) \times U(1)_\psi$. $g_\psi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[94] ERLER 99 give 90%CL limit on the Z-Z' mixing $-0.0013 < \theta < 0.0024$.

[95] CHO 98 limit is from constraints on four-Fermi contact interactions obtained from low-energy electroweak experiments and assumes no Z-Z' mixing.

[96] CHO 98B use various electroweak data to constrain Z' models. See their Eq. (4.9) for their fit in mass-mixing plane.

[97] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[98] BARATE 97B gives 95% CL limits on Z-Z' mixing $-0.0020 < \theta < 0.0038$. The bounds are computed with $\alpha_s = 0.120 \pm 0.003$, $m_t = 175 \pm 6$ GeV, and $M_H = 150^{+150}_{-90}$ GeV. Data taken at $\sqrt{s}$= 20–136 GeV.

[99] See ABE 95 Fig. 3 for the mass bound of Z' decaying to all allowed fermions and supersymmetric fermions.

[100] ABREU 95M limit is for α_s=0.123, m_t=150 GeV, and m_H=300 GeV. For the limit contour in the mass-mixing plane, see their Fig. 13.

[101] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[102] ADRIANI 93D give limits on the Z-Z' mixing $-0.003 < \theta < 0.020$ assuming the ABE 92B mass limit.

[103] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[104] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim$ 1 MeV).

[105] GRIFOLS 90D limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also RIZZO 91.

Limits for Z_η

Z_η is the extra neutral boson in E_6 models, corresponding to $Q_\eta = \sqrt{3/8}\,Q_\chi - \sqrt{5/8}\,Q_\psi$. $g_\eta = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[123] CHO 98B use various electroweak data to constrain Z' models.

LEPTOQUARK QUANTUM NUMBERS

Written December 1997 by M. Tanabashi (Tohoku U.).

Leptoquarks are particles carrying both baryon number (B) and lepton number (L). They are expected to exist in various extensions of the Standard Model (SM). The possible quantum numbers of leptoquark states can be restricted by assuming that their direct interactions with the ordinary SM fermions are dimensionless and invariant under the SM gauge group. Table 1 shows the list of all possible quantum numbers with this assumption [1]. The columns of $SU(3)_C$, $SU(2)_W$, and $U(1)_Y$ in Table 1 indicate the QCD representation, the weak isospin representation, and the weak hypercharge, respectively. Naming conventions of leptoquark states are taken from Ref. 1. The spin of a leptoquark state is taken to be 1 (vector leptoquark) or 0 (scalar leptoquark).

Table 1: Possible leptoquarks and their quantum numbers.

Leptoquarks	Spin	$3B+L$	$SU(3)_c$	$SU(2)_W$	$U(1)_Y$
S_1	0	−2	$\bar{3}$	1	1/3
$\tilde{S}_1$	0	−2	$\bar{3}$	1	4/3
S_3	0	−2	$\bar{3}$	3	1/3
V_2	1	−2	$\bar{3}$	2	5/6
$\tilde{V}_2$	1	−2	$\bar{3}$	2	−1/6
R_2	0	0	3	2	7/6
$\tilde{R}_2$	0	0	3	2	1/6
U_1	1	0	3	1	2/3
$\tilde{U}_1$	1	0	3	1	5/3
U_3	1	0	3	3	2/3

If we do not require leptoquark states to couple directly with SM fermions, different assignments of quantum numbers become possible.

The Pati-Salam model [2] is an example predicting the existence of a leptoquark state. In this model a vector leptoquark appears at the scale where the Pati-Salam SU(4) "color" gauge group breaks into the familiar QCD $SU(3)_C$ group (or $SU(3)_C \times U(1)_{B-L}$). The Pati-Salam leptoquark is a weak isosinglet and its hypercharge is 2/3 (U_1 leptoquark in Table 1). The coupling strength of the Pati-Salam leptoquark is given by the QCD coupling at the Pati-Salam symmetry breaking scale.

Bounds on leptoquark states are obtained both directly and indirectly. Direct limits are from their production cross sections at colliders, while indirect limits are calculated from the bounds on the leptoquark induced four-fermion interactions which are obtained from low energy experiments.

The pair production cross sections of leptoquarks are evaluated from their interactions with gauge bosons. The gauge couplings of a scalar leptoquark are determined uniquely according to its quantum numbers in Table 1. The magnetic-dipole-type and the electric-quadrupole-type interactions of a vector leptoquark are, however, not determined even if we fix its gauge quantum numbers as listed in the table [3]. We need extra assumptions about these interactions to evaluate the pair production cross section for a vector leptoquark.

If a leptoquark couples to fermions of more than a single generation in the mass eigenbasis of the SM fermions, it can induce four-fermion interactions causing flavor-changing-neutral-currents and lepton-family-number violations. Non-chiral leptoquarks, which couple simultaneously to both left- and right-handed quarks, cause four-fermion interactions affecting the $(\pi \to e\nu)/(\pi \to \mu\nu)$ ratio [4]. Indirect limits provide stringent constraints on these leptoquarks. Since the Pati-Salam leptoquark has non-chiral coupling with both e and μ, indirect limits from the bounds on $K_L \to \mu e$ lead to severe bounds on the Pati-Salam leptoquark mass. For detailed bounds obtained in this way, see the Boson Particle Listings for "Indirect Limits for Leptoquarks" and its references.

It is therefore often assumed that a leptoquark state couples only to a single generation in a chiral interaction, where indirect limits become much weaker. This assumption gives strong constraints on concrete models of leptoquarks, however. Leptoquark states which couple only to left- or right-handed quarks are called chiral leptoquarks. Leptoquark states which couple only to the first (second, third) generation are referred as the first (second, third) generation leptoquarks in this section.

[124] ABBOTT 00C search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The limit above assumes B(μq)=1. For B(μq)=0.5 and 0, the bound becomes 180 and 79 GeV respectively. Bounds for vector leptoquarks are also given.

[125] ABBOTT 98E search for scalar leptoquarks using $e\nu jj$, $eejj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The limit above assumes B(eq)=1. For B(eq)=0.5 and 0, the bound becomes 204 and 79 GeV, respectively.

[126] ABBOTT 98J search for charge −1/3 third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. The quoted limit is for scalar leptoquark with B(νb)=1.

[127] ABE 98S search for scalar leptoquarks using $\mu\mu jj$ events in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. The limit is for B(μq)= 1. For B(μq)=B(νq)=0.5, the limit is > 160 GeV.

[128] ABE 97F search for third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV. The quoted limit is for scalar leptoquark with B(τb) = 1.

[129] ABBOTT 99J search for leptoquarks using $\mu\nu jj$ events in $p\overline{p}$ collisions at E_{cm}= 1.8TeV. The quoted limit is for a scalar leptoquark with B(μq) = B(νq) = 0.5. Limits on vector leptoquarks range from 240 to 290 GeV.

[130] ABBOTT 97B, ABE 97X search for scalar leptoquarks using $eejj$ events in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The limit is for B(eq)=1.

[131] Limit is for charge −1/3 isospin-0 leptoquark with B(ℓq) = 2/3.

[132] First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.

[133] Limits are for charge −1/3, isospin-0 scalar leptoquarks decaying to $\ell^- q$ or νq with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.

[134] KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of de^+ and $u\overline{\nu}$ ($s\mu^+$ and $c\overline{\nu}$). See paper for limits for specific branching ratios.

[135] BARTEL 87B limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint B(X → $c\overline{\nu}_\mu$) + B(X → $s\mu^+$) = 1.

[136] BEHREND 86B assumed that a charge 2/3 spinless leptoquark, χ, decays either into $s\mu^+$ or $c\overline{\nu}$: B($\chi \rightarrow s\mu^+$) + B($\chi \rightarrow c\overline{\nu}$) = 1.

MASS LIMITS for Leptoquarks from Single Production

These limits depend on the q-ℓ-leptoquark coupling g_{LQ}. It is often assumed that $g_{LQ}^2/4\pi$=1/137. Limits shown are for a scalar, weak isoscalar, charge −1/3 leptoquark.

[137] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 13 and Fig. 14. ADLOFF 99 also search for leptoquarks with lepton-flavor violating couplings. ADLOFF 99 supersedes AID 96B.

[138] Limit from single production in Z decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes B(ℓq) = 2/3. The limit is 77 GeV if first and second leptoquarks are degenerate.

[139] ABREU 99G limit obtained from process $e\gamma \rightarrow LQ + q$. For limits on vector and scalar states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 4 and Table 2.

[140] DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 5–8 and Table 1 for detailed limits.

[141] AID 96B also search for leptoquarks with lepton-flavor violating couplings. For limits on states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 2, Fig. 3, and Table 2.

[142] DERRICK 93 search for single leptoquark production in ep collisions with the decay eq and νq. The limit is for leptoquark coupling of electromagnetic strength and assumes B(eq) = B(νq) = 1/2. The limit for B(eq) = 1 is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

[143] BARATE 00I search for deviations in cross section and jet-charge asymmetry in $e^+e^- \rightarrow \overline{q}q$ due to t-channel exchange of a leptoquark at $\sqrt{s}$=130 to 183 GeV. Limits for other scalar and vector leptoquarks are also given in their Table 22.

[144] ABBIENDI 99 limits are from $e^+e^- \rightarrow q\overline{q}$ cross section at 130–136, 161–172, 183 GeV. See their Fig. 8 and Fig. 9 for limits in mass-coupling plane.

[145] ABE 98V quoted limit is from B($B_s \rightarrow e^\pm\mu^\mp$)< 8.2 × 10^{-6}. ABE 98V also obtain a similar limit on M_{LQ} > 20.4 TeV from B($B_d \rightarrow e^\pm\mu^\mp$)< 4.5 × 10^{-6}. Both bounds assume the non-canonical association of the b quark with electrons or muons under SU(4).

[146] ACCIARRI 98J limit is from $e^+e^- \rightarrow q\overline{q}$ cross section at $\sqrt{s}$= 130–172 GeV which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 4 and Fig. 5 for limits in the mass-coupling plane.

[147] ACKERSTAFF 98V limits are from $e^+e^- \rightarrow q\overline{q}$ and $e^+e^- \rightarrow b\overline{b}$ cross sections at $\sqrt{s}$ = 130–172 GeV, which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 21 and Fig. 22 for limits of leptoquarks in mass-coupling plane.

[148] DEANDREA 97 limit is for $\tilde{R}_2$ leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange. DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane.

[149] DERRICK 97 search for lepton-flavor violation in ep collision. See their Tables 2–5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

[150] GROSSMAN 97 estimate the upper bounds on the branching fraction $B \rightarrow \tau^+\tau^-$ (X) from the absence of the B decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.

[151] JADACH 97 limit is from $e^+e^- \rightarrow q\overline{q}$ cross section at $\sqrt{s}$=172.3 GeV which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.

[152] AID 95 limit is for the weak isotriplet spin-1 leptoquark with the electromagnetic coupling strength. For the limits of leptoquarks with different quantum number, see their Table 2. AID 95 limits are from the measurements of the Q^2 spectrum measurement of $ep \rightarrow eX$.

[153] KUZNETSOV 95B use π, K, B, τ decays and μe conversion and give a list of bounds on the leptoquark mass and the fermion mixing matrix in the Pati-Salam model. The quoted limit is from $K_L \rightarrow \mu e$ decay assuming zero mixing. See also KUZNETSOV 94, DESHPANDE 83, and DIMOPOULOS 81.

[154] MIZUKOSHI 95 calculate the one-loop radiative correction to the Z-physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.

[155] BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the Z. m_H=250 GeV, $\alpha_s(m_Z)$=0.12, m_t=180 GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to $\overline{e}_L t_R$, $\overline{\mu} t$, and $\overline{\tau} t$, see Fig. 2 in BHATTACHARYYA 94B erratum and Fig. 3.

[156] DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion insteractions from π, K, D, B, μ, τ decays and meson mixings, *etc.* See Table 15 of DAVIDSON 94 for detail.

[157] KUZNETSOV 94 gives mixing independent bound of the Pati-Salam leptoquark from the cosmological limit on $\pi^0 \rightarrow \overline{\nu}\nu$.

[158] LEURER 94, LEURER 94B limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in $\pi_{\ell 2}$ decay provides a much more stringent bound. See also SHANKER 82.

[159] MAHANTA 94 gives bounds of P- and T-violating scalar-leptoquark couplings from atomic and molecular experiments.

[160] DESHPANDE 83 used upper limit on $K_L^0 \rightarrow \mu e$ decay with renormalization-group equations to estimate coupling at the heavy boson mass. See also DIMOPOULOS 81.

[161] From $(\pi \rightarrow e\nu)/(\pi \rightarrow \mu\nu)$ ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling $4g^2/M^2$ $(\overline{\nu}_{eL}\, u_R)$ $(\overline{d}_L\, e_R)$with g=0.004 for spin-0 leptoquark and g^2/M^2 $(\overline{\nu}_{eL}\, \gamma_\mu u_L)$ $(\overline{d}_R\, \gamma^\mu e_R)$ with $g\simeq$ 0.6 for spin-1 leptoquark.

MASS LIMITS for Diquarks

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none 290–420	95	[162] ABE	97G CDF	E_6 diquark
none 15–31.7	95	[163] ABREU	94O DLPH	SUSY E_6 diquark

[162] ABE 97G search for new particle decaying to dijets.

[163] ABREU 94O limit is from $e^+e^- \to \overline{c}\overline{s}cs$. Range extends up to 43 GeV if diquarks are degenerate in mass.

MASS LIMITS for g_A (axigluon)

Axigluons are massive color-octet gauge bosons in chiral color models and have axial-vector coupling to quarks with the same coupling strength as gluons.

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
>365	95	[164] DONCHESKI	98 RVUE	$\Gamma(Z \to$ hadron)

> 29		[170] ROBINETT	89 THEO	Partial-wave unitarity
none 150–310	95	[171] ALBAJAR	88B UA1	$p\overline{p} \to g_A X$, $g_A \to$ 2jets
> 20		BERGSTROM	88 RVUE	$p\overline{p} \to \Upsilon X$ via $g_A g$
> 9		[172] CUYPERS	88 RVUE	Υ decay
> 25		[173] DONCHESKI	88B RVUE	Υ decay

[164] DONCHESKI 98 compare α_s derived from low-energy data and that from $\Gamma(Z \to$ hadrons)/$\Gamma(Z \to$ leptons).

[165] ABE 97G search for new particle decaying to dijets.

[166] ABE 95N assume axigluons decaying to quarks in the Standard Model only.

[167] ABE 93G assume $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 10$.

[168] CUYPERS 91 compare α_s measured in Υ decay and that from R at PEP/PETRA energies.

[169] ABE 90H assumes $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 5$ $(\Gamma(g_A) = 0.09 m_{g_A})$. For $N = 10$, the excluded region is reduced to 120–150 GeV.

[170] ROBINETT 89 result demands partial-wave unitarity of $J = 0$ $t\overline{t} \to t\overline{t}$ scattering amplitude and derives a limit $m_{g_A} > 0.5\ m_t$. Assumes $m_t > 56$ GeV.

[171] ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution. $\Gamma(g_A) < 0.4\ m_{g_A}$ assumed. See also BAGGER 88.

[172] CUYPERS 88 requires $\Gamma(\Upsilon \to g g_A) < \Gamma(\Upsilon \to ggg)$. A similar result is obtained by DONCHESKI 88.

[173] DONCHESKI 88B requires $\Gamma(\Upsilon \to g q\overline{q})/\Gamma(\Upsilon \to ggg) < 0.25$, where the former decay proceeds via axigluon exchange. A more conservative estimate of < 0.5 leads to $m_{g_A} > 21$ GeV.

X^0 (Heavy Boson) Searches in Z Decays

Searches for radiative transition of Z to a lighter spin-0 state X^0 decaying to hadrons, a lepton pair, a photon pair, or invisible particles as shown in the comments. The limits are for the product of branching ratios.

[174] BARATE 98U obtain limits on $B(Z \to \gamma X^0)B(X^0 \to \ell\overline{\ell}, q\overline{q}, gg, \gamma\gamma, \nu\overline{\nu})$. See their Fig. 17.

[175] See Fig. 4 of ACCIARRI 97Q for the upper limit on $B(Z \to \gamma X^0;\ E_\gamma > E_{min})$ as a function of E_{min}.

[176] ACTON 93E give $\sigma(e^+e^- \to X^0\gamma)\cdot B(X^0 \to \gamma\gamma) < 0.4$ pb (95%CL) for $m_{X^0} = 60 \pm 2.5$ GeV. If the process occurs via s-channel γ exchange, the limit translates to $\Gamma(X^0)\cdot B(X^0 \to \gamma\gamma)^2 < 20$ MeV for $m_{X^0} = 60 \pm 1$ GeV.

[177] ABREU 92D give $\sigma_Z \cdot B(Z \to \gamma X^0) \cdot B(X^0 \to$ hadrons) <(3–10) pb for m_{X^0} = 10–78 GeV. A very similar limit is obtained for spin-1 X^0.

[178] ADRIANI 92F search for isolated γ in hadronic Z decays. The limit $\sigma_Z \cdot B(Z \to \gamma X^0) \cdot B(X^0 \to$ hadrons) <(2–10) pb (95%CL) is given for m_{X^0} = 25–85 GeV.

[179] ACTON 91 searches for $Z \to Z^* X^0$, $Z^* \to e^+e^-$, $\mu^+\mu^-$, or $\nu\overline{\nu}$. Excludes any new scalar X^0 with $m_{X^0} < 9.5$ GeV/c if it has the same coupling to ZZ^* as the MSM Higgs boson.

[180] ACTON 91B limits are for m_{X^0} = 60–85 GeV.

[181] ADEVA 91D limits are for m_{X^0} = 30–89 GeV.

[182] ADEVA 91D limits are for m_{X^0} = 30–86 GeV.

[183] AKRAWY 90J give $\Gamma(Z \to \gamma X^0)\cdot B(X^0 \to$ hadrons) < 1.9 MeV (95%CL) for m_{X^0} = 32–80 GeV. We divide by $\Gamma(Z) = 2.5$ GeV to get product of branching ratios. For nonresonant transitions, the limit is $B(Z \to \gamma q\overline{q}) < 8.2$ MeV assuming three-body phase space distribution.

MASS LIMITS for a Heavy Neutral Boson Coupling to e^+e^-

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none 55–61		[184] ODAKA	89 VNS	$\Gamma(X^0 \to e^+e^-) \cdot B(X^0 \to$ hadrons) $\gtrsim$ 0.2 MeV

none 39.8–45.5		[188] ADEVA	84 MRKJ	$\Gamma(X^0 \to e^+e^-)$=10 keV
>47.8	95	[188] ADEVA	84 MRKJ	$\Gamma(X^0 \to e^+e^-)$=4 MeV
none 39.8–45.2		[188] BEHREND	84C CELL	
>47	95	[188] BEHREND	84C CELL	$\Gamma(X^0 \to e^+e^-)$=4 MeV

[184] ODAKA 89 looked for a narrow or wide scalar resonance in $e^+e^- \to$ hadrons at E_{cm} = 55.0–60.8 GeV.

[185] DERRICK 86 found no deviation from the Standard Model Bhabha scattering at E_{cm}= 29 GeV and set limits on the possible scalar boson e^+e^- coupling. See their figure 4 for excluded region in the $\Gamma(X^0 \to e^+e^-)$-m_{X^0} plane. Electronic chiral invariance requires a parity doublet of X^0, in which case the limit applies for $\Gamma(X^0 \to e^+e^-)$ = 3 MeV.

[186] ADEVA 85 first limit is from 2γ, $\mu^+\mu^-$, hadrons assuming X^0 is a scalar. Second limit is from e^+e^- channel. E_{cm} = 40–47 GeV. Supersedes ADEVA 84.

[187] BERGER 85B looked for effect of spin-0 boson exchange in $e^+e^- \to e^+e^-$ and $\mu^+\mu^-$ at E_{cm} = 34.7 GeV. See Fig. 5 for excluded region in the $m_{X^0} - \Gamma(X^0)$ plane.

[188] ADEVA 84 and BEHREND 84C have E_{cm} = 39.8–45.5 GeV. MARK-J searched X^0 in $e^+e^- \to$ hadrons, 2γ, $\mu^+\mu^-$, e^+e^- and CELLO in the same channels plus τ pair. No narrow or broad X^0 is found in the energy range. They also searched for the effect of X^0 with $m_X > E_{cm}$. The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for $\Gamma(X^0 \to e^+e^-) = 2$ MeV if X^0 is a spin-0 doublet. The second limit of BEHREND 84C was read off from their figure 2. The original papers also list limits in other channels.

Search for X^0 Resonance in e^+e^- Collisions

The limit is for $\Gamma(X^0 \to e^+e^-) \cdot B(X^0 \to f)$, where f is the specified final state. Spin 0 is assumed for X^0.

[202] ABREU 99H refutes the hypothesis that the excess reported in BUSKULIC,D 96 is a sign of new physics at over 99%CL.

[203] ACKERSTAFF 98X search for $e^+e^- \to XY \to$ 4jets at $\sqrt{s}$= 130–184 GeV. The upper limits on $\sigma(e^+e^- \to XY)$, which are well below the excess reported by BUSKULIC,D 96, are shown in their Fig. 5.

[204] ACKERSTAFF 98Y search for $e^+e^- \to XY$, with $X \to \gamma\gamma$, $Y \to f\overline{f}$ where $f\overline{f}$ may be $q\overline{q}$, $\ell\ell$, or $\nu\overline{\nu}$ at $\sqrt{s}$= 183 GeV. The upper limits on $\sigma(e^+e^- \to XY) \times B(X \to \gamma\gamma)$ are shown in their Fig. 4.

[205] ALEXANDER 97B search for the associated production of two massive particles decaying into quarks in e^+e^- collisions at $\sqrt{s}$=130–136 GeV. The 95%CL upper limits on $\sigma(e^+e^- \to XY)$ range from 2.7 to 4.5 pb for $95 < m_X + m_Y < 120$ GeV.

[206] BUSKULIC,D 96 observed an excess of four-jet production cross section in e^+e^- collisions at $\sqrt{s}$=130–136 GeV and find an enhancement in the sum of two dijet masses around 105 GeV.

Heavy Particle Production in Quarkonium Decays

Limits are for branching ratios to modes shown.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$<1.5 \times 10^{-5}$	90	[207] BALEST	95 CLE2	$\Upsilon(1S) \to X^0\gamma$, $m_{X^0} < 5$ GeV
$< 3 \times 10^{-5}$–6×10^{-3}	90	[208] BALEST	95 CLE2	$\Upsilon(1S) \to X^0\overline{X}^0\gamma$, $m_{X^0} < 3.9$ GeV
$<5.6 \times 10^{-5}$	90	[209] ANTREASYAN	90C CBAL	$\Upsilon(1S) \to X^0\gamma$, $m_{X^0} < 7.2$ GeV
		[210] ALBRECHT	89 ARG	

[207] BALEST 95 two-body limit is for pseudoscalar X^0. The limit becomes $< 10^{-4}$ for $m_{X^0} < 7.7$ GeV.

[208] BALEST 95 three-body limit is for phase-space photon energy distribution and angular distribution same as for $\Upsilon \to gg\gamma$.

[209] ANTREASYAN 90C assume that X^0 does not decay in the detector.

[210] ALBRECHT 89 give limits for $B(\Upsilon(1S), \Upsilon(2S) \to X^0\gamma) \cdot B(X^0 \to \pi^+\pi^-, K^+K^-, p\overline{p})$ for $m_{X^0} < 3.5$ GeV.

Axions (A^0) and Other Very Light Bosons, Searches for

AXIONS AND OTHER VERY LIGHT BOSONS

Written October 1997 by H. Murayama (University of California, Berkeley) Part I; April 1998 by G. Raffelt (Max-Planck Institute, München) Part II; and April 1998 by C. Hagmann, K. van Bibber (Lawrence Livermore National Laboratory), and L.J. Rosenberg (Massachusetts Institute of Technology) Part III.

This review is divided into three parts:

Part I (Theory)
Part II (Astrophysical Constraints)
Part III (Experimental Limits)

AXIONS AND OTHER VERY LIGHT BOSONS, PART I (THEORY)

(by H. Murayama)

In this section we list limits for very light neutral (pseudo) scalar bosons that couple weakly to stable matter. They arise if there is a global continuous symmetry in the theory that is spontaneously broken in the vacuum. If the symmetry is exact, it results in a massless Nambu–Goldstone (NG) boson. If there is a small explicit breaking of the symmetry, either already in the Lagrangian or due to quantum mechanical effects such as anomalies, the would-be NG boson acquires a finite mass; then it is called a pseudo-NG boson. Typical examples are axions (A^0) [1], familons [2], and Majorons [3,4], associated, respectively, with spontaneously broken Peccei-Quinn [5], family, and lepton-number symmetries. This Review provides brief descriptions of each of them and their motivations.

One common characteristic for all these particles is that their coupling to the Standard Model particles are suppressed by the energy scale of symmetry breaking, *i.e.* the decay constant f, where the interaction is described by the Lagrangian

$$\mathcal{L} = \frac{1}{f}(\partial_\mu \phi) J^\mu, \qquad (1)$$

where J^μ is the Noether current of the spontaneously broken global symmetry.

An axion gives a natural solution to the strong CP problem: why the effective θ-parameter in the QCD Lagrangian $\mathcal{L}_\theta = \theta_{eff}\frac{\alpha_s}{8\pi}F^{\mu\nu a}\widetilde{F}^a_{\mu\nu}$ is so small ($\theta_{eff} \lesssim 10^{-9}$) as required by the current limits on the neutron electric dipole moment, even though $\theta_{eff} \sim O(1)$ is perfectly allowed by the QCD gauge invariance. Here, θ_{eff} is the effective θ parameter after the diagonalization of the quark masses, and $F^{\mu\nu a}$ is the gluon field strength and $\widetilde{F}^a_{\mu\nu} = \frac{1}{2}\epsilon_{\mu\nu\rho\sigma}F^{\rho\sigma a}$. An axion is a pseudo-NG boson of a spontaneously broken Peccei–Quinn symmetry, which is an exact symmetry at the classical level, but is broken quantum mechanically due to the triangle anomaly with the gluons. The definition of the Peccei–Quinn symmetry is model dependent. As a result of the triangle anomaly, the axion acquires an effective coupling to gluons

$$\mathcal{L} = \left(\theta_{eff} - \frac{\phi_A}{f_A}\right)\frac{\alpha_s}{8\pi}\, F^{\mu\nu a}\, \widetilde{F}^a_{\mu\nu}\,, \qquad (2)$$

where ϕ_A is the axion field. It is often convenient to *define* the axion decay constant f_A with this Lagrangian [6]. The QCD nonperturbative effect induces a potential for ϕ_A whose minimum is at $\phi_A = \theta_{eff} f_A$ cancelling θ_{eff} and solving the strong CP problem. The mass of the axion is inversely proportional to f_A as

$$m_A = 0.62 \times 10^{-3}\text{eV} \ \times (10^{10}\text{GeV}/f_A)\,. \qquad (3)$$

The original axion model [1,5] assumes $f_A \sim v$, where $v = (\sqrt{2}G_F)^{-1/2} = 247$ GeV is the scale of the electroweak symmetry breaking, and has two Higgs doublets as minimal ingredients. By requiring tree-level flavor conservation, the axion mass and its couplings are completely fixed in terms of one parameter ($\tan\beta$): the ratio of the vacuum expectation values of two Higgs fields. This model is excluded after extensive experimental searches for such an axion [7]. Observation of a narrow-peak structure in positron spectra from heavy ion collisions [8] suggested a particle of mass 1.8 MeV that decays into e^+e^-. Variants of the original axion model, which keep $f_A \sim v$, but drop the constraints of tree-level flavor conservation, were proposed [9]. Extensive searches for this particle, A^0(1.8 MeV), ended up with another negative result [10].

The popular way to save the Peccei-Quinn idea is to introduce a new scale $f_A \gg v$. Then the A^0 coupling becomes weaker, thus one can easily avoid all the existing experimental limits; such models are called invisible axion models [11,12]. Two classes of models are discussed commonly in the literature. One introduces new heavy quarks which carry Peccei–Quinn charge while the usual quarks and leptons do not (KSVZ axion or "hadronic axion") [11]. The other does not need additional quarks but requires two Higgs doublets, and all quarks and leptons carry Peccei–Quinn charges (DFSZ axion or "GUT-axion") [12]. All models contain at least one electroweak singlet scalar boson which acquires an expectation value and breaks Peccei–Quinn symmetry. The invisible axion with a large decay constant $f_A \sim 10^{12}$ GeV was found to be a good candidate of the cold dark matter component of the Universe [13](see Dark Matter review). The energy density is stored in the low-momentum modes of the axion field which are highly occupied and thus represent essentially classical field oscillations.

The constraints on the invisible axion from astrophysics are derived from interactions of the axion with either photons, electrons or nucleons. The strengths of the interactions are model dependent (*i.e.*, not a function of f_A only), and hence one needs to specify a model in order to place lower bounds on f_A. Such constraints will be discussed in Part II. Serious experimental searches for an invisible axion are underway; they typically rely on axion-photon coupling, and some of them assume that the axion is the dominant component of our galactic halo density. Part III will discuss experimental techniques and limits.

Familons arise when there is a global family symmetry broken spontaneously. A family symmetry interchanges generations or acts on different generations differently. Such a symmetry may explain the structure of quark and lepton masses and their mixings. A familon could be either a scalar or a pseudoscalar. For instance, an SU(3) family symmetry among three generations is non-anomalous and hence the familons are exactly massless. In this case, familons are scalars. If one has larger family symmetries with separate groups of left-handed and right-handed fields, one also has pseudoscalar familons. Some of them have flavor-off-diagonal couplings such as $\partial_\mu \phi_F \bar{d} \gamma^\mu s / F_{ds}$ or $\partial_\mu \phi_F \bar{e} \gamma^\mu \mu / F_{\mu e}$, and the decay constant F can be different for individual operators. The decay constants have lower bounds constrained by flavor-changing processes. For instance, $B(K^+ \rightarrow \pi^+ \phi_F) < 3 \times 10^{-10}$ [14] gives $F_{ds} > 3.4 \times 10^{11}$ GeV [15]. The constraints on familons primarily coupled to third generation are quite weak [15].

If there is a global lepton-number symmetry and if it breaks spontaneously, there is a Majoron. The triplet Majoron model [4] has a weak-triplet Higgs boson, and Majoron couples to Z. It is now excluded by the Z invisible-decay width. The model is viable if there is an additional singlet Higgs boson and if the Majoron is mainly a singlet [16]. In the singlet Majoron model [3], lepton-number symmetry is broken by a weak-singlet scalar field, and there are right-handed neutrinos which acquire Majorana masses. The left-handed neutrino masses are generated by a "seesaw" mechanism [17]. The scale of lepton number breaking can be much higher than the electroweak scale in this case. Astrophysical constraints require the decay constant to be $\gtrsim 10^9$ GeV [18].

There is revived interest in a long-lived neutrino, to improve Big-Bang Nucleosynthesis [19] or large scale structure formation theories [20]. Since a decay of neutrinos into electrons or photons is severely constrained, these scenarios require a familon (Majoron) mode $\nu_1 \rightarrow \nu_2 \phi_F$ (see, *e.g.*, Ref. 15 and references therein).

Other light bosons (scalar, pseudoscalar, or vector) are constrained by "fifth force" experiments. For a compilation of constraints, see Ref. 21.

It has been widely argued that a fundamental theory will not possess global symmetries; gravity, for example, is expected to violate them. Global symmetries such as baryon number arise by accident, typically as a consequence of gauge symmetries. It has been noted [22] that the Peccei-Quinn symmetry, from this perspective, must also arise by accident and must hold to an extraordinary degree of accuracy in order to solve the strong CP problem. Possible resolutions to this problem, however, have been discussed [22,23]. String theory also provides sufficiently good symmetries, especially using a large compactification radius motivated by recent developments in M-theory [24].

AXIONS AND OTHER VERY LIGHT BOSONS: PART II (ASTROPHYSICAL CONSTRAINTS)

(by G.G. Raffelt)

Low-mass weakly-interacting particles (neutrinos, gravitons, axions, baryonic or leptonic gauge bosons, *etc.*) are produced in hot plasmas and thus represent an energy-loss channel for stars. The strength of the interaction with photons, electrons, and nucleons can be constrained from the requirement that stellar-evolution time scales are not modified beyond observational limits. For detailed reviews see Refs. [1,2].

The energy-loss rates are steeply increasing functions of temperature T and density ρ. Because the new channel has to compete with the standard neutrino losses which tend to increase even faster, the best limits arise from low-mass stars, notably from horizontal-branch (HB) stars which have a helium-burning core of about 0.5 solar masses at $\langle\rho\rangle \approx 0.6 \times 10^4\,\mathrm{g\,cm^{-3}}$ and $\langle T\rangle \approx 0.7 \times 10^8\,\mathrm{K}$. The new energy-loss rate must not exceed about $10\,\mathrm{ergs\,g^{-1}\,s^{-1}}$ to avoid a conflict with the observed number ratio of HB stars in globular clusters. Likewise the ignition of helium in the degenerate cores of the preceding red-giant phase is delayed too much unless the same constraint holds at $\langle\rho\rangle \approx 2 \times 10^5\,\mathrm{g\,cm^{-3}}$ and $\langle T\rangle \approx 1 \times 10^8\,\mathrm{K}$. The white-dwarf luminosity function also yields useful bounds.

The new bosons X^0 interact with electrons and nucleons with a dimensionless strength g. For scalars it is a Yukawa coupling, for new gauge bosons (*e.g.*, from a baryonic or leptonic gauge symmetry) a gauge coupling. Axion-like pseudoscalars couple derivatively as $f^{-1}\bar\psi\gamma_\mu\gamma_5\psi\,\partial^\mu\phi_X$ with f an energy scale. Usually this is equivalent to $(2m/f)\bar\psi\gamma_5\psi\,\phi_X$ with m the mass of the fermion ψ so that $g = 2m/f$. For the coupling to electrons, globular-cluster stars yield the constraint

$$g_{Xe} \lesssim \begin{cases} 0.5 \times 10^{-12} & \text{for pseudoscalars [3]}\ , \\ 1.3 \times 10^{-14} & \text{for scalars [4]}\ , \end{cases} \tag{1}$$

if $m_X \lesssim 10\,\mathrm{keV}$. The Compton process $\gamma + {}^4\mathrm{He} \to {}^4\mathrm{He} + X^0$ limits the coupling to nucleons to $g_{XN} \lesssim 0.4 \times 10^{-10}$ [4].

Scalar and vector bosons mediate long-range forces which are severely constrained by "fifth-force" experiments [5]. In the massless case the best limits come from tests of the equivalence principle in the solar system, leading to

$$g_{B,L} \lesssim 10^{-23} \tag{2}$$

for a baryonic or leptonic gauge coupling [6].

In analogy to neutral pions, axions A^0 couple to photons as $g_{A\gamma}\mathbf{E}\cdot\mathbf{B}\,\phi_A$ which allows for the Primakoff conversion $\gamma \leftrightarrow A^0$ in external electromagnetic fields. The most restrictive limit arises from globular-cluster stars [2]

$$g_{A\gamma} \lesssim 0.6 \times 10^{-10}\,\mathrm{GeV}^{-1}\ . \tag{3}$$

The often-quoted "red-giant limit" [7] is slightly weaker.

The duration of the SN 1987A neutrino signal of a few seconds proves that the newborn neutron star cooled mostly by neutrinos rather than through an "invisible channel" such as right-handed (sterile) neutrinos or axions [8]. Therefore,

$$3 \times 10^{-10} \lesssim g_{AN} \lesssim 3 \times 10^{-7} \tag{4}$$

is excluded for the pseudoscalar Yukawa coupling to nucleons [2]. The "strong" coupling side is allowed because axions then escape only by diffusion, quenching their efficiency as an energy-loss channel [9]. Even then the range

$$10^{-6} \lesssim g_{AN} \lesssim 10^{-3} \tag{5}$$

is excluded to avoid excess counts in the water Cherenkov detectors which registered the SN 1987A neutrino signal [11].

In terms of the Peccei-Quinn scale f_A, the axion couplings to nucleons and photons are $g_{AN} = C_N m_N/f_A$ ($N = n$ or p) and $g_{A\gamma} = (\alpha/2\pi f_A)(E/N - 1.92)$ where C_N and E/N are model-dependent numerical parameters of order unity. With $m_A = 0.62\,\mathrm{eV}\,(10^7\,\mathrm{GeV}/f_A)$, Eq. (3) yields $m_A \lesssim 0.4\,\mathrm{eV}$ for $E/N = 8/3$ as in GUT models or the DFSZ model. The SN 1987A limit is $m_A \lesssim 0.008\,\mathrm{eV}$ for KSVZ axions while it varies between about 0.004 and 0.012 eV for DFSZ axions, depending on the angle β which measures the ratio of two Higgs vacuum expectation values [10]. In view of the large uncertainties it is good enough to remember $m_A \lesssim 0.01\,\mathrm{eV}$ as a generic limit (Fig. 1).

In the early universe, axions come into thermal equilibrium only if $f_A \lesssim 10^8\,\mathrm{GeV}$ [12]. Some fraction of the relic axions end up in galaxies and galaxy clusters. Their decay $a \to 2\gamma$ contributes to the cosmic extragalactic background light and to line emissions from galactic dark-matter haloes and galaxy

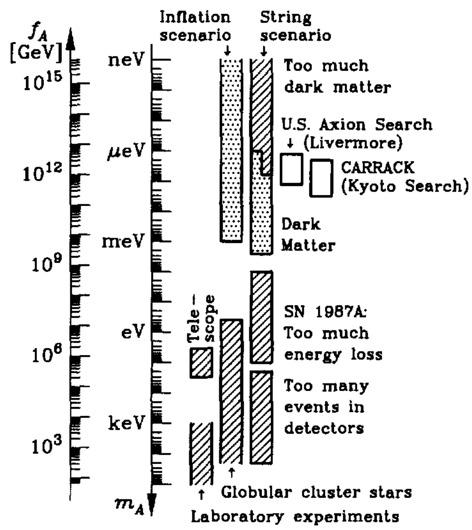

Figure 1: Astrophysical and cosmological exclusion regions (hatched) for the axion mass m_A or equivalently, the Peccei-Quinn scale f_A. An "open end" of an exclusion bar means that it represents a rough estimate; its exact location has not been established or it depends on detailed model assumptions. The globular cluster limit depends on the axion-photon coupling; it was assumed that $E/N = 8/3$ as in GUT models or the DFSZ model. The SN 1987A limits depend on the axion-nucleon couplings; the shown case corresponds to the KSVZ model and approximately to the DFSZ model. The dotted "inclusion regions" indicate where axions could plausibly be the cosmic dark matter. Most of the allowed range in the inflation scenario requires fine-tuned initial conditions. In the string scenario the plausible dark-matter range is controversial as indicated by the step in the low-mass end of the "inclusion bar" (see main text for a discussion). Also shown is the projected sensitivity range of the search experiments for galactic dark-matter axions.

clusters. An unsuccessful "telescope search" for such features yields $m_a < 3.5\,\mathrm{eV}$ [13]. For $m_a \gtrsim 30\,\mathrm{eV}$, the axion lifetime is shorter than the age of the universe.

For $f_A \gtrsim 10^8\,\mathrm{GeV}$ cosmic axions are produced nonthermally. If inflation occurred after the Peccei-Quinn symmetry breaking or if $T_{\rm reheat} < f_A$, the "misalignment mechanism" [14] leads to a contribution to the cosmic critical density of

$$\Omega_A h^2 \approx 1.9 \times 3^{\pm 1}\,(1\,\mu\mathrm{eV}/m_A)^{1.175}\,\Theta_{\rm i}^2 F(\Theta_{\rm i}) \qquad (6)$$

where h is the Hubble constant in units of $100\,\mathrm{km\,s^{-1}\,Mpc^{-1}}$. The stated range reflects recognized uncertainties of the cosmic conditions at the QCD phase transition and of the temperature-dependent axion mass. The function $F(\Theta)$ with $F(0) = 1$ and $F(\pi) = \infty$ accounts for anharmonic corrections to the axion potential. Because the initial misalignment angle $\Theta_{\rm i}$ can be very small or very close to π, there is no real prediction for the mass of dark-matter axions even though one would expect $\Theta_{\rm i}^2 F(\Theta_{\rm i}) \sim 1$ to avoid fine-tuning the initial conditions.

A possible fine-tuning of $\Theta_{\rm i}$ is limited by inflation-induced quantum fluctuations which in turn lead to temperature fluctuations of the cosmic microwave background [15,16]. In a broad class of inflationary models one thus finds an upper limit to m_A where axions could be the dark matter. According to the most recent discussion [16] it is about 10^{-3} eV (Fig. 1).

If inflation did not occur at all or if it occurred before the Peccei-Quinn symmetry breaking with $T_{\rm reheat} > f_A$, cosmic axion strings form by the Kibble mechanism [17]. Their motion is damped primarily by axion emission rather than gravitational waves. After axions acquire a mass at the QCD phase transition they quickly become nonrelativistic and thus form a cold dark matter component. Battye and Shellard [18] found that the dominant source of axion radiation are string loops rather than long strings. At a cosmic time t the average loop creation size is parametrized as $\langle \ell \rangle = \alpha t$ while the radiation power is $P = \kappa\mu$ with μ the renormalized string tension. The loop contribution to the cosmic axion density is [18]

$$\Omega_A h^2 \approx 88 \times 3^{\pm 1}\left[(1 + \alpha/\kappa)^{3/2} - 1\right]\,(1\,\mu\mathrm{eV}/m_A)^{1.175}\;, \qquad (7)$$

where the stated nominal uncertainty has the same source as in Eq. (6). The values of α and κ are not known, but probably $0.1 < \alpha/\kappa < 1.0$ [18], taking the expression in square brackets to 0.15–1.83. If axions are the dark matter, we have

$$0.05 \lesssim \Omega_A h^2 \lesssim 0.50\;, \qquad (8)$$

where it was assumed that the universe is older than 10 Gyr, that the dark-matter density is dominated by axions with $\Omega_A \gtrsim 0.2$, and that $h \gtrsim 0.5$. This implies m_A = 6–2500 μeV for the plausible mass range of dark-matter axions (Fig. 1).

Contrary to Ref. 18, Sikivie *et al.* [19] find that the motion of global strings is strongly damped, leading to a flat axion spectrum. In Battye and Shellard's treatment the axion radiation is strongly peaked at wavelengths of order the loop size. In Sikivie *et al.*'s picture more of the string radiation goes into kinetic axion energy which is redshifted so that ultimately there are fewer axions. In this scenario the contributions from string decay and vacuum realignment are of the same order of magnitude; they are both given by Eq. (6) with Θ_i of order one. As a consequence, Sikivie *et al.* allow for a plausible range of dark-matter axions which reaches to smaller masses as indicated in Fig. 1.

The work of both groups implies that the low-mass end of the plausible mass interval in the string scenario overlaps with the projected sensitivity range of the U.S. search experiment for galactic dark-matter axions (Livermore) [20] and of the Kyoto search experiment CARRACK [21] as indicated in Fig. 1. (See also Part III of this Review by Hagmann, van Bibber, and Rosenberg.)

In summary, a variety of robust astrophysical arguments and laboratory experiments (Fig. 1) indicate that $m_A \lesssim 10^{-2}$ eV.

The exact value of this limit may change with a more sophisticated treatment of supernova physics and/or the observation of the neutrino signal from a future galactic supernova, but a dramatic modification is not expected unless someone puts forth a completely new argument. The stellar-evolution limits shown in Fig. 1 depend on the axion couplings to various particles and thus can be irrelevant in fine-tuned models where, for example, the axion-photon coupling strictly vanishes. For nearly any m_A in the range generically allowed by stellar evolution, axions could be the cosmic dark matter, depending on the cosmological scenario realized in nature. It appears that our only practical chance to discover these "invisible" particles rests with the ongoing or future search experiments for galactic dark-matter.

AXIONS AND OTHER VERY LIGHT BOSONS, PART III (EXPERIMENTAL LIMITS)

(by C. Hagmann, K. van Bibber, and L.J. Rosenberg)

In this section we review the experimental methodology and limits on light axions and light pseudoscalars in general. (A comprehensive overview of axion theory is given by H. Murayama in the Part I of this Review, whose notation we follow [1].) Within its scope are searches where the axion is assumed to be dark matter, searches where the Sun is presumed to be a source of axions, and purely laboratory experiments. We restrict the discussion to axions of mass $m_A < O(\text{eV})$, as the allowed range for the axion mass is nominally $10^{-6} < m_A < 10^{-2}$ eV. Experimental work in this range predominantly has been through the axion-photon coupling $g_{A\gamma}$, to which the present review is confined. As discussed in Part II of this Review by G. Raffelt, the lower bound derives from a cosmological overclosure argument, and the upper bound from SN1987A [2]. Limits from stellar evolution overlap seamlessly above that, connecting with accelerator-based limits which ruled out the original axion. There it was assumed that the Peccei-Quinn symmetry-breaking scale was the electroweak scale, *i.e.*, $f_A \sim 250$ GeV, implying axions of mass $m_A \sim O(100\,\text{keV})$. These earlier limits from nuclear transitions, particle decays, *etc.*, while not discussed here, are included in the Listings.

While the axion mass is well determined by the Peccei-Quinn scale, *i.e.*, $m_A = 0.62$ eV $(10^7\,\text{GeV}/f_A)$, the axion-photon coupling $g_{A\gamma}$ is not: $g_{A\gamma} = (\alpha/\pi f_A)\,g_\gamma$, with $g_\gamma = (E/N - 1.92)/2$, where E/N is a model-dependent number. It is noteworthy however, that two quite distinct models lead to axion-photon couplings which are not very different. For the case of axions imbedded in Grand Unified Theories, the DFSZ axion [3], $g_\gamma = 0.37$, whereas in one popular implementation of the "hadronic" class of axions, the KSVZ axion [4], $g_\gamma = -0.96$. The Lagrangian $L = g_{A\gamma}\mathbf{E}\cdot\mathbf{B}\,\phi_A$, with ϕ_A the axion field, permits the conversion of an axion into a single real photon in an external electromagnetic field, *i.e.*, a Primakoff interaction. In the case of relativistic axions, $k_\gamma - k_A \sim m_A^2/2\omega \ll \omega$, pertinent to several experiments below, coherent axion-photon mixing in long magnetic fields results in significant conversion probability even for very weakly coupled axions [5].

Below are discussed several experimental techniques constraining $g_{A\gamma}$, and their results. Also included are recent but yet-unpublished results, and projected sensitivities for experiments soon to be upgraded.

III.1. Microwave cavity experiments: Possibly the most promising avenue to the discovery of the axion presumes that axions constitute a significant fraction of the dark matter halo of our galaxy. The maximum likelihood density for the Cold Dark Matter (CDM) component of our galactic halo is $\rho_{\rm CDM} = 7.5 \times 10^{-25}{\rm g/cm}^3 (450\,{\rm MeV/cm}^3)$ [6]. That the CDM halo is in fact made of axions (rather than *e.g.* WIMPs) is in principle an independent assumption, however should very light axions exist they would almost necessarily be cosmologically abundant [2]. As shown by Sikivie [7], halo axions may be detected by their resonant conversion into a quasi-monochromatic microwave signal in a high-Q cavity permeated by a strong magnetic field. The cavity is tunable and the signal is maximum when the frequency $\nu = m_A(1 + O(10^{-6}))$, the width of the peak representing the virial distribution of thermalized axions in the galactic gravitational potential. The signal may possess ultra-fine structure due to axions recently fallen into the galaxy and not yet thermalized [8]. The feasibility of the technique was established in early experiments of small sensitive volume, $V = O(1\,{\rm liter})$ [9,10] with High Electron Mobility Transistor (HEMT) amplifiers, which set limits on axions in the mass range $4.5 < m_A < 16.3\,\mu$eV, but at power sensitivity levels 2–3 orders of magnitude too high to see KSVZ and DFSZ axions (the conversion power $P_{A\to\gamma} \propto g^2_{A\gamma}$). A recent large-scale experiment ($B \sim 7.5\,{\rm T}, V \sim 200\,{\rm liter}$) has achieved sensitivity to KSVZ axions over a narrow mass range $2.77 < m_A < 3.3\,\mu$eV, and continues to take data [11]. The exclusion regions shown in Fig. 1 for Refs. [9–12] are all normalized to the best-fit Cold Dark Matter density $\rho_{\rm CDM} = 7.5 \times 10^{-25}{\rm g/cm}^3 (450\,{\rm MeV/cm}^3)$, and 90% CL. Recent developments in DC SQUID amplifiers [12] and Rydberg atom single-quantum detectors [13] promise dramatic improvements in noise temperature, which will enable rapid scanning of the axion mass range at or below the DFSZ limit. The region of the microwave cavity experiments is shown in detail in Fig. 2.

III.2. Telescope search for eV axions: For axions of mass greater than about 10^{-1} eV, their cosmological abundance is no longer dominated by vacuum misalignment or string radiation mechanisms, but rather by thermal production. Their contribution to the critical density is small, $\Omega \sim 0.01\,(m_A/{\rm eV})$. However, the spontaneous-decay lifetime of axions, $\tau(A \to 2\gamma) \sim 10^{25}{\rm sec}(m_A/{\rm eV})^{-5}$ while irrelevant for μeV axions, is short enough to afford a powerful constraint on such thermally produced axions in the eV range, by looking for a quasi-monochromatic photon line from galactic clusters. This line, corrected for Doppler shift, would be at half the axion mass and its width would be consistent with the observed virial motion,

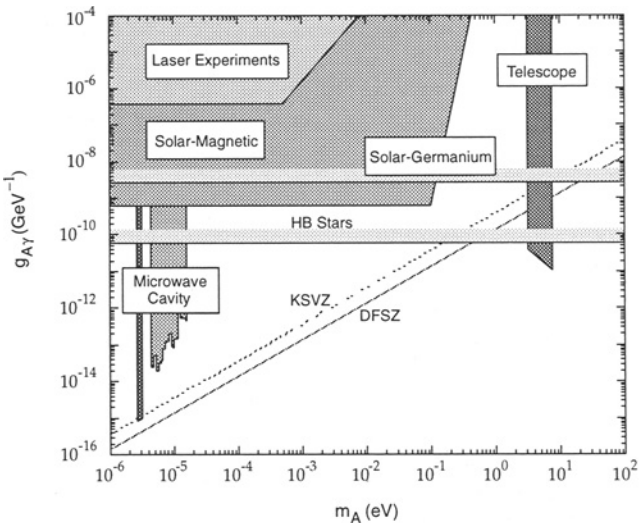

Figure 1: Exclusion region in mass vs. axion-photon coupling $(m_A, g_{A\gamma})$ for various experiments. The limit set by globular cluster Horizontal Branch Stars ("HB Stars") is shown for Ref. 2.

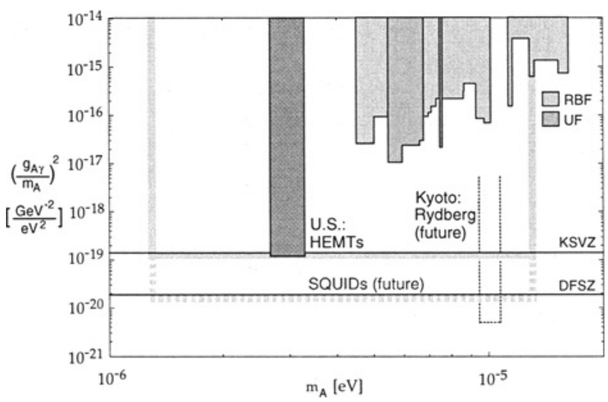

Figure 2: Exclusion region from the microwave cavity experiments, where the plot is flattened by presenting $(g_{A\gamma}/m_A)^2$ vs. m_A. The first-generation experiments (Rochester-BNL-FNAL, "RBF" [9]; University of Florida, "UF" [10]) and the US large-scale experiment in progress ("US" [11]) are all HEMT-based. Shown also is the full mass range to be covered by the latter experiment (shaded line), and the improved sensitivity when upgraded with DC SQUID amplifiers [12] (shaded dashed line). The expected performance of the Kyoto experiment based on a Rydberg atom single-quantum receiver (dotted line) is also shown [13].

typically $\Delta\lambda/\lambda \sim 10^{-2}$. The expected line intensity would be of the order $I_A \sim 10^{-17}(m_A/3\,{\rm eV})^7{\rm erg\,cm^{-2}arcsec^{-2}\AA^{-1}sec^{-1}}$ for DFSZ axions, comparable to the continuum night emission.

The conservative assumption is made that the relative density of thermal axions fallen into the cluster gravitational potential reflects their overall cosmological abundance. A search for thermal axions in three rich Abell clusters was carried out at Kitt Peak National Laboratory [14]; no such line was observed between 3100–8300 Å (m_A = 3–8 eV) after "on-off field" subtraction of the atmospheric molecular background spectra. A limit everywhere stronger than $g_{A\gamma} < 10^{-10}\mathrm{GeV}^{-1}$ is set, which is seen from Fig. 1 to easily exclude DFSZ axions throughout the mass range.

III.3. A search for solar axions: As with the telescope search for thermally produced axions above, the search for solar axions was stimulated by the possibility of there being a "1 eV window" for hadronic axions (*i.e.*, axions with no tree-level coupling to leptons), a "window" subsequently closed by an improved understanding of the evolution of globular cluster stars and SN1987A [2]. Hadronic axions would be copiously produced within our Sun's interior by a Primakoff process. Their flux at the Earth of $\sim 10^{12}\mathrm{cm}^{-2}\mathrm{sec}^{-1}(m_A/\mathrm{eV})^2$, which is independent of the details of the solar model, is sufficient for a definitive test via the axion reconversion to photons in a large magnetic field. However, their average energy is $\sim$ 4 keV, implying an oscillation length in the vacuum of $2\pi(m_A^2/2\omega)^{-1} \sim O(\mathrm{mm})$, precluding the mixing from achieving its theoretically maximum value in any practical magnet. It was recognized that one could endow the photon with an effective mass in a gas, $m_\gamma = \omega_{\mathrm{pl}}$, thus permitting the axion and photon dispersion relationships to be matched [15]. A first simple implementation of this proposal was carried out using a conventional dipole magnet with a conversion volume of variable-pressure helium gas and a xenon proportional chamber as the x-ray detector [16]. The magnet was fixed in orientation to take data for $\sim$ 1000 sec/day. Axions were excluded for $g_{A\gamma} < 3.6 \times 10^{-9}\mathrm{GeV}^{-1}$ for $m_A <$ 0.03 eV, and $g_{A\gamma} < 7.7 \times 10^{-9}\mathrm{GeV}^{-1}$ for 0.03 eV< m_A <0.11 eV (95% CL). A more ambitious experiment has recently been commissioned, using a superconducting magnet on a telescope mount to track the Sun continuously. A preliminary exclusion limit of $g_{A\gamma} < 6 \times 10^{-10}\mathrm{GeV}^{-1}$ (95% CL) has been set for $m_A <$ 0.03 eV [17].

Another search for solar axions has been carried out, using a single crystal germanium detector. It exploits the coherent conversion of axions into photons when their angle of incidence satisfies a Bragg condition with a crystalline plane. Analysis of 1.94 kg-yr of data from a 1 kg germanium detector yields a bound of $g_{A\gamma} < 2.7 \times 10^{-9}\mathrm{GeV}^{-1}$ (95% CL), independent of mass up to $m_A \sim$ 1 keV [18].

III.4. Photon regeneration ("invisible light shining through walls"): Photons propagating through a transverse field (with E||B) may convert into axions. For light axions with $m_A^2 l/2\omega \ll 2\pi$, where l is the length of the magnetic field, the axion beam produced is colinear and coherent with the photon beam, and the conversion probability Π is given by $\Pi \sim (1/4)(g_{A\gamma}Bl)^2$. An ideal implementation for this limit is a laser beam propagating down a long, superconducting dipole magnet like those for high-energy physics accelerators. If another such dipole magnet is set up in line with the first, with an optical barrier interposed between them, then photons may be regenerated from the pure axion beam in the second magnet and detected [19]. The overall probability $P(\gamma \to A \to \gamma) = \Pi^2$. Such an experiment has been carried out, utilizing two magnets of length l= 4.4 m and B= 3.7 T. Axions with mass $m_A < 10^{-3}$ eV, and $g_{A\gamma} > 6.7 \times 10^{-7}\mathrm{GeV}^{-1}$ were excluded at 95% CL [20,21]. With sufficient effort, limits comparable to those from stellar evolution would be achievable. Due to the $g_{A\gamma}^4$ rate suppression however, it does not seem feasible to reach standard axion couplings.

III.5. Polarization experiments: The existence of axions can affect the polarization of light propagating through a transverse magnetic field in two ways [22]. First, as the $E_{\|}$ component, but not the $E_{\perp}$ component will be depleted by the production of real axions, there will be in general a small rotation of the polarization vector of linearly polarized light. This effect will be a constant for all sufficiently light m_A such that the oscillation length is much longer than the magnet ($m_A^2 l/2\omega \ll 2\pi$). For heavier axions, the effect oscillates and diminishes with increasing m_A, and vanishes for $m_A > \omega$. The second effect is birefringence of the vacuum, again because there can be a mixing of virtual axions in the $E_{\|}$ state, but not for the $E_{\perp}$ state. This will lead to light which is initially linearly polarized becoming elliptically polarized. Higher-order QED also induces vacuum birefringence, and is much stronger than the contribution due to axions. A search for both polarization-rotation and induced ellipticity has been carried out with the same magnets described in Sec. (III.4) above [21,23]. As in the case of photon regeneration, the observables are boosted linearly by the number of passes the laser beam makes in an optical cavity within the magnet. The polarization-rotation resulted in a stronger limit than that from ellipticity, $g_{A\gamma} <$ $3.6 \times 10^{-7}\mathrm{GeV}^{-1}$ (95% CL) for $m_A < 5 \times 10^{-4}$ eV. The limits from ellipticity are better at higher masses, as they fall off smoothly and do not terminate at m_A. There are two experiments in construction with greatly improved sensitivity which while still far from being able to detect standard axions, should measure the QED "light-by-light" contribution for the first time [24,25]. The overall envelope for limits from the laser-based experiments in Sec. (III.4) and Sec. (III.5) is shown schematically in Fig. 1.

			[20] ZHITNITSKII	79		Heavy axion

[3] ALTEGOER 98 looked for X^0 from π^0 decay which penetrate the shielding and convert to π^0 in the external Coulomb field of a nucleus.
[4] ADLER 97 bound is for massless A^0.
[5] KITCHING 97 limit is for B($K^+ \rightarrow \pi^+ A^0$)·B($A^0 \rightarrow \gamma\gamma$) and applies for $m_{A^0} \simeq 50$ MeV, $\tau_{A^0} < 10^{-10}$ s. Limits are provided for $0 < m_{A^0} < 100$ MeV, $\tau_{A^0} < 10^{-8}$ s.
[6] ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ATIYA 93. The limit is for massless stable A^0 particles and extends to m_{A^0}=80 MeV at the same level. See paper for dependence on finite lifetime.
[7] AMSLER 94B and AMSLER 96B looked for a peak in missing-mass distribution.
[8] The MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of X^0 decay modes. It applies to $\tau(X^0) > 10^{-23}$ sec.
[9] ATIYA 93B looked for a peak in missing mass distribution. The bound applies for stable A^0 of m_{A^0}=150–250 MeV, and the limit becomes stronger (10^{-8}) for m_{A^0}=180–240 MeV.
[10] NG 93 studied the production of X^0 via $\gamma\gamma \rightarrow \pi^0 \rightarrow \gamma X^0$ in the early universe at $T \simeq 1$ MeV. The bound on extra neutrinos from nucleosynthesis $\Delta N_\nu < 0.3$ (WALKER 91) is employed. It applies to $m_{X^0} \ll 1$ MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier X^0.
[11] ALLIEGRO 92 limit applies for m_{A^0}=150–340 MeV and is the branching ratio times the decay probability. Limit is $< 1.5 \times 10^{-8}$ at 99%CL.
[12] ATIYA 92 looked for a peak in missing mass distribution. The limit applies to m_{X^0}=0–130 MeV in the narrow resonance limit. See paper for the dependence on lifetime. Covariance requires X^0 to be a vector particle.
[13] MEIJERDREES 92 limit applies for $\tau_{X^0} = 10^{-23}$–10^{-11} sec. Limits between 2×10^{-4} and 4×10^{-6} are obtained for m_{X^0} = 25–120 MeV. Angular momentum conservation requires that X^0 has spin ≥ 1.
[14] ATIYA 90B limit is for B($K^+ \rightarrow \pi^+ A^0$)·B($A^0 \rightarrow \gamma\gamma$) and applies for m_{A^0} = 50 MeV, $\tau_{A^0} < 10^{-10}$ s. Limits are also provided for $0 < m_{A^0} < 100$ MeV, $\tau_{A^0} < 10^{-8}$ s.
[15] KORENCHENKO 87 limit assumes m_{A^0} = 1.7 MeV, $\tau_{A^0} \lesssim 10^{-12}$ s, and B($A^0 \rightarrow e^+ e^-$) = 1.
[16] EICHLER 86 looked for $\pi^+ \rightarrow e^+ \nu A^0$ followed by $A^0 \rightarrow e^+ e^-$. Limits on the branching fraction depend on the mass and and lifetime of A^0. The quoted limits are valid when $\tau(A^0) \gtrsim 3. \times 10^{-10}$s if the decays are kinematically allowed.
[17] YAMAZAKI 84 looked for a discrete line in $K^+ \rightarrow \pi^+ X$. Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.
[18] ASANO 82 at KEK set limits for B($K^+ \rightarrow \pi^+ A^0$) for m_{A^0} <100 MeV as BR $< 4. \times 10^{-8}$ for $\tau(A^0 \rightarrow n\gamma\text{'s}) > 1. \times 10^{-9}$ s, BR $< 1.4 \times 10^{-6}$ for $\tau < 1. \times 10^{-9}$s.
[19] ASANO 81B is KEK experiment. Set B($K^+ \rightarrow \pi^+ A^0$) $< 3.8 \times 10^{-8}$ at CL = 90%.
[20] ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 (3 < m <40 MeV) contradicts experimental muon anomalous magnetic moments.

A^0 (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

$<3. \times 10^{-4}$	90		[31] ALAM	83 CLEO	$\Upsilon(1S) \rightarrow A^0\gamma$
$<9.1 \times 10^{-4}$	90		[32] NICZYPORUK	83 LENA	$\Upsilon(1S) \rightarrow A^0\gamma$
$<1.4 \times 10^{-5}$	90		[33] EDWARDS	82 CBAL	$J/\psi \rightarrow A^0\gamma$
$<3.5 \times 10^{-4}$	90		[34] SIVERTZ	82 CUSB	$\Upsilon(1S) \rightarrow A^0\gamma$
$<1.2 \times 10^{-4}$	90		[34] SIVERTZ	82 CUSB	$\Upsilon(3S) \rightarrow A^0\gamma$

[21] BALEST 95 looked for a monochromatic γ from $\Upsilon(1S)$ decay. The bound is for $m_{A^0} <$ 5.0 GeV. See Fig. 7 in the paper for bounds for heavier m_{A^0}. They also quote a bound on branching ratios 10^{-3}–10^{-5} of three-body decay $\gamma X \overline{X}$ for $0<m_X < 3.1$ GeV.

[22] The combined limit of ANTREASYAN 90C and EDWARDS 82 excludes standard axion with $m_{A^0} < 2m_e$ at 90% CL as long as $C_\Upsilon C_{J/\psi} > 0.09$, where C_V ($V = \Upsilon$, J/ψ) is the reduction factor for $\Gamma(V \rightarrow A^0\gamma)$ due to QCD and/or relativistic corrections. The same data excludes $0.02 < x < 260$ (90% CL) if $C_\Upsilon = C_{J/\psi} = 0.5$, and further combining with ALBRECHT 86D result excludes $5 \times 10^{-5} < x < 260$. x is the ratio of the vacuum expectation values of the two Higgs fields. These limits use conventional assumption $\Gamma(A^0 \rightarrow ee) \propto x^{-2}$. The alternative assumption $\Gamma(A^0 \rightarrow ee) \propto x^2$ gives a somewhat different excluded region $0.00075 < x < 44$.

[23] The first DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 3 \times 10^{-13}$ s/MeV and $m_{A^0} < 20$ MeV.

[24] The second DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 5 \times 10^{-13}$ s/MeV and $m_{A^0} < 20$ MeV.

[25] The third DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} > 7 \times 10^{-12}$ s/MeV and $m_{A^0} < 200$ MeV.

[26] $\tau_{A^0} < 1 \times 10^{-13}$s and $m_{A^0} < 1.5$ GeV. Applies for $A^0 \rightarrow \gamma\gamma$ when $m_{A^0} < 100$ MeV.

[27] $\tau_{A^0} > 1 \times 10^{-7}$s.

[28] Independent of τ_{A^0}.

[29] BOWCOCK 86 looked for A^0 that decays into e^+e^- in the cascade decay $\Upsilon(2S) \rightarrow \Upsilon(1S)\pi^+\pi^-$ followed by $\Upsilon(1S) \rightarrow A^0\gamma$. The limit for $B(\Upsilon(1S) \rightarrow A^0\gamma)B(A^0 \rightarrow e^+e^-)$ depends on m_{A^0} and τ_{A^0}. The quoted limit for m_{A^0}=1.8 MeV is at $\tau_{A^0} \sim 2. \times 10^{-12}$s, where the limit is the worst. The same limit $2. \times 10^{-3}$ applies for all lifetimes for masses $2m_e < m_{A^0} < 2m_\mu$ when the results of this experiment are combined with the results of ALAM 83.

[30] MAGERAS 86 looked for $\Upsilon(1S) \rightarrow \gamma A^0$ ($A^0 \rightarrow e^+e^-$). The quoted branching fraction limit is for $m_{A^0} = 1.7$ MeV, at $\tau(A^0) \sim 4. \times 10^{-13}$s where the limit is the worst.

[31] ALAM 83 is at CESR. This limit combined with limit for $B(J/\psi \rightarrow A^0\gamma)$ (EDWARDS 82) excludes standard axion.

[32] NICZYPORUK 83 is DESY-DORIS experiment. This limit together with lower limit 9.2×10^{-4} of $B(\Upsilon \rightarrow A^0\gamma)$ derived from $B(J/\psi(1S) \rightarrow A^0\gamma)$ limit (EDWARDS 82) excludes standard axion.

[33] EDWARDS 82 looked for $J/\psi \rightarrow \gamma A^0$ decays by looking for events with a single γ [of energy $\sim$ 1/2 the $J/\psi(1S)$ mass], plus nothing else in the detector. The limit is inconsistent with the axion interpretation of the FAISSNER 81B result.

[34] SIVERTZ 82 is CESR experiment. Looked for $\Upsilon \rightarrow \gamma A^0$, A^0 undetected. Limit for 1S (3S) is valid for m_{A^0} <7 GeV (4 GeV).

A^0 (Axion) Searches in Positronium Decays

Decay or transition of positronium. Limits are for branching ratio.

$<2 \times 10^{-4}$	90	MAENO	95 CNTR	o-Ps $\rightarrow A^0\gamma$ m_{A^0}=850–1013 keV
$<3.0 \times 10^{-3}$	90	[35] ASAI	94 CNTR	o-Ps $\rightarrow A^0\gamma$ m_{A^0}=30–500 keV
$<2.8 \times 10^{-5}$	90	[36] AKOPYAN	91 CNTR	o-Ps $\rightarrow A^0\gamma$ ($A^0 \rightarrow \gamma\gamma$), $m_{A^0} < 30$ keV
$<1.1 \times 10^{-6}$	90	[37] ASAI	91 CNTR	o-Ps $\rightarrow A^0\gamma$, $m_{A^0} < 800$ keV
$<3.8 \times 10^{-4}$	90	GNINENKO	90 CNTR	o-Ps $\rightarrow A^0\gamma$, $m_{A^0} <$ 30 keV
$<(1\text{–}5) \times 10^{-4}$	95	[38] TSUCHIAKI	90 CNTR	o-Ps $\rightarrow A^0\gamma$, m_{A^0} = 300–900 keV
$<6.4 \times 10^{-5}$	90	[39] ORITO	89 CNTR	o-Ps $\rightarrow A^0\gamma$, $m_{A^0} < 30$ keV
		[40] AMALDI	85 CNTR	Ortho-positronium
		[41] CARBONI	83 CNTR	Ortho-positronium

[35] The ASAI 94 limit is based on inclusive photon spectrum and is independent of A^0 decay modes.

[36] The AKOPYAN 91 limit applies for a short-lived A^0 with $\tau_{A^0} < 10^{-13} m_{A^0}$ [keV] s.

[37] ASAI 91 limit translates to $g^2_{A^0 e^+e^-}/4\pi < 1.1 \times 10^{-11}$ (90%CL) for $m_{A^0} < 800$ keV.

[38] The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of A^0 decay modes.

[39] ORITO 89 limit translates to $g^2_{A^0 ee}/4\pi < 6.2 \times 10^{-10}$. Somewhat more sensitive limits are obtained for larger m_{A^0}: $B < 7.6 \times 10^{-6}$ at 100 keV.

[40] AMALDI 85 set limits $B(A^0\gamma)$ / $B(\gamma\gamma\gamma) < (1\text{–}5) \times 10^{-6}$ for m_{A^0} = 900–100 keV which are about 1/10 of the CARBONI 83 limits.

[41] CARBONI 83 looked for orthopositronium $\rightarrow A^0\gamma$. Set limit for A^0 electron coupling squared, $g(eeA^0)^2/(4\pi) < 6. \times 10^{-10}$–$7. \times 10^{-9}$ for m_{A^0} from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from $g-2$ experiments.

A^0 (Axion) Search in Photoproduction

VALUE	DOCUMENT ID	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •		
	[42] BASSOMPIE... 95	$m_{A^0} = 1.8 \pm 0.2$ MeV

[42] BASSOMPIERRE 95 is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of e^+e^- pairs in the region $m_{e^+e^-} = 1.8 \pm 0.2$ MeV. They obtained bounds on the production rate A^0 for $\tau(A^0) = 10^{-18}$–10^{-9} sec. They also found an excess of events in the range $m_{e^+e^-}$ = 2.1–3.5 MeV.

A^0 (Axion) Production in Hadron Collisions

Limits are for $\sigma(A^0)$ / $\sigma(\pi^0)$.

[43] AHMAD 97 reports a result of APEX Collaboration which studied positron production in ^{238}U+^{232}Ta and ^{238}U+^{181}Ta collisions, without requiring a coincident electron. No narrow lines were found for $250 < E_{e^+} < 750$ keV.

[44] LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy e^+e^--line at $\sim$ 635 keV in ^{238}U+^{181}Ta collision. Limits on the production probability for a narrow sum-energy e^+e^- line are set. See their Table 2.

[45] GANZ 96 (EPos II Collaboration) has placed upper bounds on the production cross section of e^+e^- pairs from ^{238}U+^{181}Ta and ^{238}U+^{232}Th collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of e^+e^- pairs. These limits rule out the existence of peaks in the e^+e^- sum-energy distribution, reported by an earlier version of this experiment.

[46] KAMEL 96 looked for e^+e^- pairs from the collison of ^{32}S (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity m_{ee} >2 MeV.

[47] BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of e^+e^- or $\mu^+\mu^-$ from the produce A^0. See Fig. 5 for the excluded region in m_{A^0}-x plane. For the standard axion, 0.3 <x<25 is excluded at 95% CL. If combined with BLUEMLEIN 91, 0.008 <x<32 is excluded.

[48] MEIJERDREES 92 give $\Gamma(\pi^- p \to nA^0) \cdot B(A^0 \to e^+e^-)/\Gamma(\pi^- p \to \text{all}) < 10^{-5}$ (90% CL) for m_{A^0} = 100 MeV, $\tau_{A^0} = 10^{-11}$–10^{-23} sec. Limits ranging from 2.5×10^{-3} to 10^{-7} are given for m_{A^0} = 25–136 MeV.

[49] BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for $A^0 \to e^+e^-$, 2γ are found. Fig. 6 gives the excluded region in m_{A^0}-x plane ($x = \tan\beta = v_2/v_1$). Standard axion is excluded for $0.2 < m_{A^0} < 3.2$ MeV for most $x > 1$, 0.2–11 MeV for most $x < 1$.

[50] FAISSNER 89 searched for $A^0 \to e^+e^-$ in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass $2m_e$–20 MeV is excluded. Lower limit on f_{A^0} of $\simeq 10^4$ GeV is given for $m_{A^0} = 2m_e$–20 MeV.

[51] DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass ~ 1.1, ~ 2.1, and ~ 9 MeV, lifetimes 10^{-16}–10^{-15} s decaying to e^+e^- and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A **A22** 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with π^0 Dalitz decay. DEBOER 89B is a reply which contests the criticism.

[52] EL-NADI 88 claim the existence of a neutral particle decaying into e^+e^- with mass 1.60 ± 0.59 MeV, lifetime $(0.15 \pm 0.01) \times 10^{-14}$ s, which is produced in heavy ion interactions with emulsion nuclei at ~ 4 GeV/c/nucleon.

[53] FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for $A^0 \to \gamma\gamma$. A standard axion decaying to 2γ is excluded except for a region $x \simeq 1$. Lower limit on f_{A^0} of 10^2–10^3 GeV is given for m_{A^0} = 0.1–1 MeV.

[54] BADIER 86 did not find long-lived A^0 in 300 GeV π^- Beam Dump Experiment that decays into e^+e^- in the mass range m_{A^0} = (20–200) MeV, which excludes the A^0 decay constant $f(A^0)$ in the interval (60–600) GeV. See their figure 6 for excluded region on $f(A^0)$-m_{A^0} plane.

[55] BERGSMA 85 look for $A^0 \to 2\gamma$, e^+e^-, $\mu^+\mu^-$. First limit above is for m_{A^0} = 1 MeV; second is for 200 MeV. See their figure 4 for excluded region on f_{A^0}–m_{A^0} plane, where f_{A^0} is A^0 decay constant. For Peccei-Quinn PECCEI 77 A^0, m_{A^0} <180 keV and τ >0.037 s. (CL = 90%). For the axion of FAISSNER 81B at 250 keV, BERGSMA 85 expect 15 events but observe zero.

[56] FAISSNER 83 observed 19 1-γ and 12 2-γ events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.

[57] FAISSNER 83B extrapolate SIN γ signal to LAMPF ν experimental condition. Resulting 370 γ's are not at variance with LAMPF upper limit of 450 γ's. Derived from LAMPF limit that $[d\sigma(A^0)/d\omega \text{ at } 90°]\, m_{A^0}/\tau_{A^0} < 14 \times 10^{-35}$ cm^2 sr^{-1} MeV ms^{-1}. See comment on FRANK 83B.

[58] FRANK 83B stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-A0 are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450 γ's. See comment on FAISSNER 83B.

[59] HOFFMAN 83 set CL = 90% limit $d\sigma/dt\, B(e^+e^-) < 3.5 \times 10^{-32}$ cm^2/GeV^2 for $140 < m_{A^0} < 160$ MeV. Limit assumes $\tau(A^0) < 10^{-9}$ s.

[60] FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since 2-γ peak rate remarkably decreases if iron wall is set in front of the decay region.

[61] FAISSNER 81 see excess μe events. Suggest axion interactions.

[62] FAISSNER 81B is SIN 590 MeV proton beam dump. Observed 14.5 ± 5.0 events of 2γ decay of long-lived neutral penetrating particle with $m_{2\gamma} \lesssim 1$ MeV. Axion interpretation with η-A^0 mixing gives $m_{A^0} = 250 \pm 25$ keV, $\tau_{(2\gamma)} = (7.3 \pm 3.7) \times 10^{-3}$ s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83B, FRANK 83B, and BERGSMA 85. Also see in the next subsection ALEKSEEV 82, CAVAIGNAC 83, and ANANEV 85.

[63] KIM 81 analyzed 8 candidates for $A^0 \to 2\gamma$ obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is $(0.86\sim 5.6) \times 10^{-3}$ s depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.

[64] FAISSNER 80 is SIN beam dump experiment with 590 MeV protons looking for $A^0 \to e^+e^-$ decay. Assuming $A^0/\pi^0 = 5.5 \times 10^{-7}$, obtained decay rate limit 20/(A^0 mass) MeV/s (CL = 90%), which is about 10^{-7} below theory and interpreted as upper limit to $m_{A^0} < 2m_{e^-}$.

[65] JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events [σ(production)σ(interactaction) $< 7. \times 10^{-68}$ cm^4, CL = 90%]. Second limit is from nonobservation of axion decays into 2γ's or e^+e^-, and for axion mass a few MeV.

[66] SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.

[67] BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either 2γ or e^+e^-. No signal found. CL = 90% limits for model parameter(s) are given.

[68] COTEUS 79 is a beam dump experiment at BNL.

[69] DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.

[70] BELLOTTI 78 first value comes from search for $A^0 \to e^+e^-$. Second value comes from search for $A^0 \to 2\gamma$, assuming mass $< 2m_{e^-}$. For any mass satisfying this, limit is above value$\times$(mass^{-4}). Third value uses data of PL 60B 401 and quotes σ(production)σ(interaction) $< 10^{-67}$ cm^4.

[71] BOSETTI 78B quotes σ(production)σ(interaction) $< 2. \times 10^{-67}$ cm^4.

[72] DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.

[73] MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).

[74] VYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

A^0 (Axion) Searches in Reactor Experiments

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[75] ALTMANN	95	CNTR	Reactor; $A^0 \to e^+e^-$
	[76] KETOV	86	SPEC	Reactor, $A^0 \to \gamma\gamma$
	[77] KOCH	86	SPEC	Reactor; $A^0 \to \gamma\gamma$
	[78] DATAR	82	CNTR	Light water reactor
	[79] VUILLEUMIER	81	CNTR	Reactor, $A^0 \to 2\gamma$

[75] ALTMANN 95 looked for A^0 decaying into e^+e^- from the Bugey 5 nuclear reactor. They obtain an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma) \times B(A^0 \to e^+e^-) < 10^{-16}$ for m_{A^0} = 1.5 MeV at 90% CL. The limit is weaker for heavier A^0. In the case of a standard axion, this limit excludes a mass in the range $2m_e < m_{A^0} < 4.8$ MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances Z^0 in the (m_{X^0}, f_{X^0}) plane.

[76] KETOV 86 searched for A^0 at the Rovno nuclear power plant. They found an upper limit on the A^0 production probability of $0.8\,[100\text{ keV}/m_{A^0}]^6 \times 10^{-6}$ per fission. In the standard axion model, this corresponds to m_{A^0} >150 keV. Not valid for $m_{A^0} \gtrsim$ 1 MeV.

[77] KOCH 86 searched for $A^0 \to \gamma\gamma$ at nuclear power reactor Biblis A. They found an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$ (CL=95%). Standard axion with m_{A^0} = 250 keV gives 10^{-5} for the ratio. Not valid for m_{A^0} >1022 keV.

[78] DATAR 82 looked for $A^0 \to 2\gamma$ in neutron capture ($np \to dA^0$) at Tarapur 500 MW reactor. Sensitive to sum of I = 0 and I = 1 amplitudes. With ZEHNDER 81 [(I = 0) − (I = 1)] result, assert nonexistence of standard A^0.

[79] VUILLEUMIER 81 is at Grenoble reactor. Set limit m_{A^0} <280 keV.

A^0 (Axion) and Other Light Boson (X^0) Searches in Nuclear Transitions

Limits are for branching ratio.

[80] DEBOER 97C reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into e^+e^- would explain the excess of events with large opening angles.

[81] TSUNODA 95 looked for axion emission when ^{252}Cf undergoes a spontaneous fission, with the axion decaying into e^+e^-. The bound is for m_{A^0}=40 MeV. It improves to 2.5×10^{-5} for m_{A^0}=200 MeV.

[82] MINOWA 93 studied chain process, ^{139}Ce $\to$ ^{139}La* by electron capture and M1 transition of ^{139}La* to the ground state. It does not assume decay modes of A^0. The bound applies for m_{A^0} < 166 keV.

[83] HICKS 92 bound is applicable for $\tau_{X^0} < 4 \times 10^{-11}$ sec.

[84] The ASANUMA 90 limit is for the branching fraction of X^0 emission per ^{241}Am α decay and valid for $\tau_{X^0} < 3 \times 10^{-11}$ s.

[85] The DEBOER 90 limit is for the branching ratio ^{8}Be* (18.15 MeV, 1^+) $\to$ ^{8}BeA^0, $A^0 \to e^+e^-$ for the mass range m_{A^0} = 4–15 MeV.

[86] The BINI 89 limit is for the branching fraction of ^{16}O*(6.05 MeV, 0^+) $\to$ ^{16}OX^0, $X^0 \to e^+e^-$ for m_X = 1.5–3.1 MeV. $\tau_{X^0} \lesssim 10^{-11}$ s is assumed. The spin-parity of X is restricted to 0^+ or 1^-.

[87] AVIGNONE 88 looked for the 1115 keV transition $C^* \to CuA^0$, either from $A^0 \to 2\gamma$ in-flight decay or from the secondary A^0 interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for $m_{A^0} < 1.1$ MeV.

[88] DATAR 88 rule out light pseudoscalar particle emission through its decay $A^0 \to e^+e^-$ in the mass range 1.02–2.5 MeV and lifetime range 10^{-13}–10^{-8} s. The above limit is for $\tau = 5 \times 10^{-13}$ s and $m = 1.7$ MeV; see the paper for the τ-m dependence of the limit.

[89] The limit is for the branching fraction of $^{16}O^*(6.05\ \text{MeV}, 0^+) \to {}^{16}O X^0$, $X^0 \to e^+e^-$ against internal pair conversion for $m_{X^0} = 1.7$ MeV and $\tau_{X^0} < 10^{-11}$ s. Similar limits are obtained for $m_{X^0} = 1.3$–3.2 MeV. The spin parity of X^0 must be either 0^+ or 1^-. The limit at 1.7 MeV is translated into a limit for the X^0-nucleon coupling constant: $g^2_{X^0NN}/4\pi < 2.3 \times 10^{-9}$.

[90] The DOEHNER 88 limit is for $m_{A^0} = 1.7$ MeV, $\tau(A^0) < 10^{-10}$ s. Limits less than 10^{-4} are obtained for $m_{A^0} = 1.2$–2.2 MeV.

[91] SAVAGE 88 looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N, 17.64 MeV state $J^P = 1^+$ in ^{8}Be, and the 18.15 MeV state $J^P = 1^+$ in ^{8}Be. This experiment constrains the isovector coupling of A^0 to hadrons, if $m_{A^0} = (1.1 \to 2.2)$ MeV and the isoscalar coupling of A^0 to hadrons, if $m_{A^0} = (1.1 \to 2.6)$ MeV. Both limits are valid only if $\tau(A^0) \lesssim 1 \times 10^{-11}$ s.

[92] Limits are for $\Gamma(A^0(1.8\ \text{MeV}))/\Gamma(\pi M1)$; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of e^+e^- pairs. Valid for $\tau_{A^0} < 2 \times 10^{-11}$s. ^{6}Li isovector decay data strongly disfavor PECCEI 86 model I, whereas the ^{10}B and ^{14}N isoscalar decay data strongly reject PECCEI 86 model II and III.

[93] SAVAGE 86B looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N. Limit on the branching fraction is valid if $\tau_{A^0} \lesssim 1. \times 10^{-11}$ s for $m_{A^0} = (1.1$–$1.7)$ MeV. This experiment constrains the iso-vector coupling of A^0 to hadrons.

[94] ANANEV 85 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% masses below 470 keV (Li* decay) and below $2m_e$ for deuteron* decay.

[95] CAVAIGNAC 83 at Bugey reactor exclude axion at any $m_{^{97}\text{Nb}^*\text{decay}}$ and axion with m_{A^0} between 275 and 288 keV (deuteron* decay).

[96] ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% mass-ranges m_{A^0} <400 keV (Li* decay) and 330 keV $< m_{A^0} <$ 2.2 MeV. (deuteron* decay).

[97] LEHMANN 82 obtained $A^0 \to 2\gamma$ rate $< 6.2 \times 10^{-5}$/s (CL = 95%) excluding m_{A^0} between 100 and 1000 keV.

[98] ZEHNDER 82 used Goesgen 2.8GW light-water reactor to check A^0 production. No 2γ peak in Li*, Nb* decay (both single p transition) nor in n capture (combined with previous Ba* negative result) rules out standard A^0. Set limit m_{A^0} <60 keV for any A^0.

[99] ZEHNDER 81 looked for $Ba^* \to A^0 Ba$ transition with $A^0 \to 2\gamma$. Obtained 2γ coincidence rate $< 2.2 \times 10^{-5}$/s (CL = 95%) excluding m_{A^0} >160 keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.

[100] CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

A^0 (Axion) Limits from Its Electron Coupling

Limits are for $\tau(A^0 \to e^+e^-)$.

VALUE (s)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •

none 6×10^{-14}–9×10^{-11}	95	[107] DAVIER 86	BDMP	$eN \to eA^0N$ ($A^0 \to ee$)
none 3×10^{-13}–1×10^{-7}	90	[108] KONAKA 86	BDMP	$eN \to eA^0N$ ($A^0 \to ee$)

[101] The listed BROSS 91 limit is for $m_{A^0} = 1.14$ MeV. $B(A^0 \to e^+e^-) = 1$ assumed. Excluded domain in the τ_{A^0}–m_{A^0} plane extends up to $m_{A^0} \approx 7$ MeV (see Fig. 5). Combining with electron $g-2$ constraint, axions coupling only to e^+e^- ruled out for $m_{A^0} < 4.8$ MeV (90%CL).

[102] GUO 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with $g-2$ constraint, axions coupling only to e^+e^- are ruled out for $m_{A^0} < 2.7$ MeV (90% CL).

[103] BJORKEN 88 reports limits on axion parameters (f_A, m_A, τ_A) for $m_{A^0} < 200$ MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.

[104] BLINOV 88 assume zero spin, $m = 1.8$ MeV and lifetime $< 5 \times 10^{-12}$ s and find $\Gamma(A^0 \to \gamma\gamma)B(A^0 \to e^+e^-) < 2$ eV (CL=90%).

[105] Assumes $A^0\gamma\gamma$ coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for $m_{A^0} < 15$ MeV.

[106] Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for $m_{A^0} < 15$ MeV are shown in their figure 3.

[107] $m_{A^0} = 1.8$ MeV assumed. The excluded domain in the τ_{A^0}–m_{A^0} plane extends up to $m_{A^0} \approx 14$ MeV, see their figure 4.

[108] The limits are obtained from their figure 3. Also given is the limit on the $A^0\gamma\gamma$–$A^0e^+e^-$ coupling plane by assuming Primakoff production.

Search for A^0 (Axion) Resonance in Bhabha Scattering

The limit is for $\Gamma(A^0)[B(A^0 \to e^+e^-)]^2$.

<2500	90	MILLS 87	CNTR	$m_{A^0} = 1.8$ MeV
		[118] VONWIMMER...87	CNTR	

[109] HALLIN 92 quote limits on lifetime, 8×10^{-14} – 5×10^{-13} sec depending on mass, assuming $B(A^0 \to e^+e^-) = 100\%$. They say that TSERTOS 91 overstated their sensitivity by a factor of 3.

[110] HENDERSON 92C exclude axion with lifetime $\tau_{A^0} = 1.4 \times 10^{-12}$ – 4.0×10^{-10} s, assuming $B(A^0 \to e^+e^-)$=100%. HENDERSON 92C also exclude a vector boson with $\tau = 1.4 \times 10^{-12}$ – 6.0×10^{-10} s.

[111] WU 92 quote limits on lifetime $> 3.3 \times 10^{-13}$ s assuming $B(A^0 \to e^+e^-)$=100%. They say that TSERTOS 89 overestimate the limit by a factor of $\pi/2$. WU 92 also quote a bound for vector boson, $\tau > 8.2 \times 10^{-13}$ s.

[112] WIDMANN 91 bound applies exclusively to the case $B(A^0 \to e^+e^-)$=1, since the detection efficiency varies substantially as $\Gamma(A^0)_{\text{total}}$ changes. See their Fig. 6.

[113] JUDGE 90 excludes an elastic pseudoscalar e^+e^- resonance for 4.5×10^{-13} s $< \tau(A^0) < 7.5 \times 10^{-12}$ s (95% CL) at $m_{A^0} = 1.832$ MeV. Comparable limits can be set for $m_{A^0} = 1.776$–1.856 MeV.

[114] See also TSERTOS 88B in references.

[115] The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B, footnote 3.

[116] VANKLINKEN 88 looked for relatively long-lived resonance ($\tau = 10^{-10}$–10^{-12} s). The sensitivity is not sufficient to exclude such a narrow resonance.

[117] MAIER 87 obtained limits $R\Gamma \lesssim 60$ eV (100 eV) at $m_{A^0} \simeq 1.64$ MeV (1.83 MeV) for energy resolution $\Delta E_{cm} \simeq 3$ keV, where R is the resonance cross section normalized to that of Bhabha scattering, and $\Gamma = \Gamma^2_{ee}/\Gamma_{\text{total}}$. For a discussion implying that $\Delta E_{cm} \simeq 10$ keV, see TSERTOS 89.

[118] VONWIMMERSPERG 87 measured Bhabha scattering for $E_{cm} = 1.37$–1.86 MeV and found a possible peak at 1.73 with $\int \sigma dE_{cm} = 14.5 \pm 6.8$ keV·b. For a comment and a reply, see VANKLINKEN 88B and VONWIMMERSPERG 88. Also see CONNELL 88.

Search for A^0 (Axion) Resonance in $e^+e^- \to \gamma\gamma$

The limit is for $\Gamma(A^0 \to e^+e^-)\cdot\Gamma(A^0 \to \gamma\gamma)/\Gamma_{\text{total}}$

[125] MITSUI 96 looked for a monochromatic γ. The bound applies for a vector X^0 with C=−1 and m_{X^0} <200 keV. They derive an upper bound on eeX^0 coupling and hence on the branching ratio B(o-Ps $\to \gamma\gamma X^0$)< 6.2×10^{-6}. The bounds weaken for heavier X^0.
[126] SKALSEY 95 looked for a monochromatic γ without an accompanying γ in e^+e^- annihilation. The bound applies for scalar and vector X^0 with C = −1 and m_{X^0} = 100–1000 keV.
[127] SKALSEY 95 reinterpreted the bound on γA^0 decay of o-Ps by ASAI 91 where 3% of delayed annihilations are not from $^3S_1$ states. The bound applies for scalar and vector X^0 with C = −1 and m_{X^0} = 0–800 keV.
[128] ADACHI 94 looked for a peak in the $\gamma\gamma$ invariant mass distribution in $\gamma\gamma\gamma\gamma$ production from e^+e^- annihilation. The bound applies for m_{X^0} = 70–800 keV.
[129] ADACHI 94 looked for a peak in the missing-mass mass distribution in $\gamma\gamma$ channel, using $\gamma\gamma\gamma\gamma$ production from e^+e^- annihilation. The bound applies for m_{X^0} <800 keV.
[130] ADACHI 94 looked for a peak in the missing mass distribution in $\gamma\gamma\gamma$ channel, using $\gamma\gamma\gamma\gamma$ production from e^+e^- annihilation. The bound applies for m_{X^0} = 200–900 keV.

Searches for Goldstone Bosons (X^0)

[131] DIAZ 98 studied models of spontaneously broken lepton number with both singlet and triplet Higgses. They obtain limits on the parameter space from invisible decay $Z \to H^0A^0 \to X^0X^0X^0X^0X^0$ and $e^+e^- \to ZH^0$ with $H^0 \to X^0X^0$.
[132] BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit $x_e^2 < 2\times10^{-4}$ (95%CL) is found for the effective anomalous magneton parametrized as $x_e(G_F/8\pi\sqrt{2})^{1/2}$.
[133] ALBRECHT 90E limits are for B($\tau \to \ell X^0$)/B($\tau \to \ell\nu\overline{\nu}$). Valid for m_{X^0} < 100 MeV. The limits rise to 7.1% (for μ), 5.0% (for e) for m_{X^0} = 500 MeV.
[134] ATIYA 90 limit is for m_{X^0} = 0. The limit B < 1×10^{-8} holds for m_{X^0} < 95 MeV. For the reduction of the limit due to finite lifetime of X^0, see their Fig. 3.
[135] BOLTON 88 limit corresponds to $F > 3.1\times10^9$ GeV, which does not depend on the chirality property of the coupling.
[136] CHANDA 88 find v_T < 10 MeV for the weak-triplet Higgs vev. in Gelmini-Roncadelli model, and $v_S > 5.8\times10^6$ GeV in the singlet Majoron model.
[137] CHOI 88 used the observed neutrino flux from the supernova SN 1987A to exclude the neutrino Majoron Yukawa coupling h in the range $2\times10^{-5} < h < 3\times10^{-4}$ for the interaction $L_{int} = \frac{1}{2}ih\overline{\psi}_\nu^c\gamma_5\psi_\nu\phi_X$. For several families of neutrinos, the limit applies for $(\Sigma h_i^4)^{1/4}$.
[138] PICCIOTTO 88 limit applies when m_{X^0} < 55 MeV and τ_{X^0} > 2ns, and it decreases to 4×10^{-7} at m_{X^0} = 125 MeV, beyond which no limit is obtained.
[139] GOLDMAN 87 limit corresponds to $F > 2.9\times10^9$ GeV for the family symmetry breaking scale from the Lagrangian $L_{int} = (1/F)\overline{\psi}_\mu\gamma^\mu(a+b\gamma_5)\psi_e\partial_\mu\phi_{X^0}$ with $a^2+b^2 = 1$. This is not as sensitive as the limit $F > 9.9\times10^9$ GeV derived from the search for $\mu^+ \to e^+X^0$ by JODIDIO 86, but does not depend on the chirality property of the coupling.
[140] Limits are for $\Gamma(\mu \to eX^0)/\Gamma(\mu \to e\nu\overline{\nu})$. Valid when m_{X^0} = 0–93.4, 98.1–103.5 MeV.
[141] EICHLER 86 looked for $\mu^+ \to e^+X^0$ followed by $X^0 \to e^+e^-$. Limits on the branching fraction depend on the mass and and lifetime of X^0. The quoted limits are valid when $\tau_{X^0} \lesssim 3.\times10^{-10}$ s if the decays are kinematically allowed.
[142] JODIDIO 86 corresponds to $F > 9.9\times10^9$ GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian $L_{int} = (1/F)\,\overline{\psi}_\mu\gamma^\mu\psi_e\partial^\mu\phi_{X^0}$.
[143] BALTRUSAITIS 85 search for light Goldstone boson(X^0) of broken U(1). CL = 95% limits are B($\tau \to \mu^+X^0$)/B($\tau \to \mu^+\nu\nu$) <0.125 and B($\tau \to e^+X^0$)/B($\tau \to e^+\nu\nu$) <0.04. Inferred limit for the symmetry breaking scale is m >3000 TeV.
[144] The primordial heavy neutrino must decay into ν and familon, f_A, early so that the red-shifted decay products are below critical density, see their table. In addition, $K \to \pi f_A$ and $\mu \to ef_A$ are unseen. Combining these excludes $m_{heavy\nu}$ between 5×10^{-5} and 5×10^{-4} MeV (μ decay) and $m_{heavy\nu}$ between 5×10^{-5} and 0.1 MeV (K-decay).

Majoron Searches in Neutrinoless Double β Decay

Limits are for the half-life of neutrinoless $\beta\beta$ decay with a Majoron emission. Previous indications for neutrinoless double beta decay with majoron emission have been superseded. No experiment currently claims any such evidence. Also see the recent rviews ZUBER 98 and FAESSLER 98B.

				CNTR	[152] VERGADOS	82

[145] BERNATOWICZ 92 studied double-β decays of ^{128}Te and ^{130}Te, and found the ratio $\tau(^{130}\text{Te})/\tau(^{128}\text{Te}) = (3.52\pm0.11)\times10^{-4}$ in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of ^{128}Te of $(7.7\pm0.4)\times10^{24}$ year. We calculated 90% CL limit as $(7.7-1.28\times0.4=7.2)\times10^{24}$.
[146] ARNOLD 99 use enriched ^{96}Zr and give a limit based on the matrix elements of STAUDT 90.
[147] DANEVICH 98 use cadmium tungstate crystals, enriched to 83% in ^{116}Cd. The spectrum was analysed in the region of expected majoron emission. Using a variety of nuclear matrix elements, they obtain a limit $\langle g_{\nu\chi}\rangle < (1\text{–}3)\times10^{-4}$.
[148] DANEVICH 98 obtain a limit on the 0ν decay with emission of 2 majorons.
[149] LUESCHER 98 report a limit for the 0ν decay with Majoron emission of ^{136}Xe using Xe TPC. This result is more stringent than BARABASH 89. Using the matrix elements of ENGEL 88, they obtain a limit on $\langle g_{\nu\chi}\rangle$ of 2.0×10^{-4}.
[150] See Table 1 in GUENTHER 96 for limits on the Majoron coupling in different models.
[151] TANAKA 93 also quote limit 5.3×10^{19} years on two Majoron emission.
[152] VERGADOS 82 sets limit $g_H < 4\times10^{-3}$ for (dimensionless) lepton-number violating coupling, g_H, of scalar boson (Majoron) to neutrinos, from analysis of data on double β decay of ^{48}Ca.

Invisible A^0 (Axion) MASS LIMITS from Astrophysics and Cosmology

$\nu_1 = \nu_2$ is usually assumed (ν_i = vacuum expectation values). For a review of these limits, see RAFFELT 90C and TURNER 90. In the comment lines below, D and K refer to DFSZ and KSVZ axion types, discussed in the above minireview.

[153] MOROI 98 points out that a KSVZ axion of this mass range (see CHANG 93) can be a viable hot dark matter of Universe, as long as the model-dependent $g_{A\gamma}$ is accidentally small enough as originally emphasized by KAPLAN 85; see Fig. 1.

[154] BORISOV 97 bound is on the axion-electron coupling $g_{ae} < 1 \times 10^{-13}$ from the photo-production of axions off of electric fields in the outer layers of neutron stars.

[155] KACHELRIESS 97 bound is on the axion-electron coupling $g_{ae} < 1 \times 10^{-10}$ from the production of axions in strongly magnetized neutron stars. The authors also quote a stronger limit, $g_{ae} < 9 \times 10^{-13}$ which is strongly dependent on the strength of the magnetic field in white dwarfs.

[156] KEIL 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and pion-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.

[157] RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).

[158] ALTHERR 94 bound is on the axion-electron coupling $g_{ae} < 1.5 \times 10^{-13}$, from energy loss via axion emission.

[159] CHANG 93 updates ENGEL 90 bound with the Kaplan-Mahohar ambiguity in $z{=}m_u/m_d$ (see the Note on the Quark Masses in the Quark Particle Listings). It leaves the window $f_A{=}3{\times}10^5$–$3{\times}10^6$ GeV open. The constraint from Big-Bang Nucleosynthesis is satisfied in this window as well.

[160] BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from 2γ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.

[161] KIM 91C argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an *upperbound* rather than a lowerbound.

[162] RAFFELT 91B argue that previous SN 1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.

[163] RESSELL 91 uses absence of any intracluster line emission to set limit.

[164] ENGEL 90 rule out $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$, which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to $2.5 \times 10^{-3}\,\text{eV} \lesssim m_{A^0} \lesssim 2.5 \times 10^4$ eV. The constraint is loose in the middle of the range, i.e. for $g_{AN} \sim 10^{-6}$.

[165] RAFFELT 90D is a re-analysis of DEARBORN 86.

[166] The region $m_{A^0} \gtrsim 2$ eV is also allowed.

[167] ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.

[168] MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2–4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88B.

[169] RAFFELT 88B derives a limit for the energy generation rate by exotic processes in helium-burning stars $\epsilon < 100\ \text{erg}\,\text{g}^{-1}\,\text{s}^{-1}$, which gives a firmer basis for the axion limits based on red giant cooling.

[170] RAFFELT 87 also gives a limit $g_{A\gamma} < 1 \times 10^{-10}\ \text{GeV}^{-1}$.

[171] DEARBORN 86 also gives a limit $g_{A\gamma} < 1.4 \times 10^{-11}\ \text{GeV}^{-1}$.

[172] RAFFELT 86 gives a limit $g_{A\gamma} < 1.1{\times}10^{-10}\ \text{GeV}^{-1}$ from red giants and $< 2.4{\times}10^{-9}\ \text{GeV}^{-1}$ from the sun.

[173] KAPLAN 85 says $m_{A^0} < 23$ eV is allowed for a special choice of model parameters.

[174] FUKUGITA 82 gives a limit $g_{A\gamma} < 2.3 \times 10^{-10}\ \text{GeV}^{-1}$.

Search for Relic Invisible Axions

Limits are for $[G_{A\gamma\gamma}/m_{A^0}]^2\rho_A$ where $G_{A\gamma\gamma}$ denotes the axion two-photon coupling, $L_{\text{int}} = \frac{G_{A\gamma\gamma}}{4}\phi_A F_{\mu\nu}\tilde{F}^{\mu\nu} = G_{A\gamma\gamma}\phi_A \mathbf{E}\cdot\mathbf{B}$, and ρ_A is the axion energy density near the earth.

$<2 \times 10^{-41}$	95	[178] WUENSCH	89	CNTR	m_{A^0} = (11.3–16.3)10^{-6} eV

[175] Based on the conversion of halo axions to microwave photons. Limit assumes ρ_A=0.45 GeV cm^{-3}. At 90%CL this result excludes a version of KSVZ axions as dark matter in the halo of our Galaxy, for the quoted axion mass range.

[176] KIM 98 calculated the axion-to-photon couplings for various axion models and compared them to the HAGMANN 90 bounds. This analysis demonstrates a strong model dependence of $G_{A\gamma\gamma}$ and hence the bound from relic axion search.

[177] HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.

[178] WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with $[G_{A\gamma\gamma}/m_{A^0}]^2 = 2 \times 10^{-14}\ \text{MeV}^{-4}$ (the three generation DFSZ model) and $\rho_A = 300\ \text{MeV/cm}^3$ that makes up galactic halos gives $(G_{A\gamma\gamma}/m_{A^0})^2\ \rho_A = 4 \times 10^{-44}$. Note that our definition of $G_{A\gamma\gamma}$ is $(1/4\pi)$ smaller than that of WUENSCH 89.

Invisible A^0 (Axion) Limits from Photon Coupling

Limits are for the axion-two-photon coupling $G_{A\gamma\gamma}$ defined by $L = G_{A\gamma\gamma}\phi_A \mathbf{E}\cdot\mathbf{B}$.

Related limits from astrophysics can be found in the "Invisible A^0 (Axion) Mass Limits from Astrophysics and Cosmology" section.

$<2.5 \times 10^{-6}$		[186] SEMERTZIDIS	90		$m_{A^0} < 7 \times 10^{-4}$ eV

[179] MASSO 00 studied limits on axion-proton coupling using the induced axion-photon coupling through the proton loop and CAMERON 93 bound on the axion-photon coupling using optical rotation. They obtained the bound $g_p^2/4\pi < 1.7 \times 10^{-9}$ for the coupling $g_p\bar{p}\gamma_5 p\phi_A$.

[180] AVIGNONE 98 result is based on the coherent conversion of solar axions to photons via the Primakoff effect in a single crystal germanium detector.

[181] Based on the conversion of solar axions to X-rays in a strong laboratory magnetic field.

[182] Experiment based on proposal by MAIANI 86.

[183] Experiment based on proposal by VANBIBBER 87.

[184] LAZARUS 92 experiment is based on proposal found in VANBIBBER 89.

[185] RUOSO 92 experiment is based on the proposal by VANBIBBER 87.

[186] SEMERTZIDIS 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to $m_{A^0} = 4 \times 10^{-3}$ where $G_{A\gamma\gamma} < 1 \times 10^{-4}\ \text{GeV}^{-1}$.

Limit on Invisible A^0 (Axion) Electron Coupling

The limit is for $G_{Aee}\partial_\mu\phi_A\bar{e}\gamma^\mu\gamma_5 e$ in GeV^{-1}, or equivalenty, the dipole-dipole potential $\frac{G_{Aee}^2}{4\pi}\ ((\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2) - 3(\boldsymbol{\sigma}_1\cdot\boldsymbol{n})\ (\boldsymbol{\sigma}_2\cdot\boldsymbol{n}))/r^3$ where $\boldsymbol{n}{=}\boldsymbol{r}/r$.

The limits below apply to invisible axion of $m_A \leq 10^{-6}$ eV.

$<6.6 \times 10^{-5}$	95	[187] VOROBYOV	88		Induced magnetism

[187] These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor.

[188] These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either of them.

[189] WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

Invisible A^0 (Axion) Limits from Nucleon Coupling

Limits are for the axion mass in eV.

VALUE (eV)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<745	90	[190] KRCMAR	98	CNTR	Solar axion

[190] KRCMAR 98 looked for solar axions emitted by the M1 transition of thermally excited ^{57}Fe nuclei in the Sun, using their possible resonant capture on ^{57}Fe in the laboratory, following MORIYAMA 95B. The mass bound assumes m_u/m_d=0.56 and the flavor-singlet axial-vector matrix element $S=3F-D\simeq 0.5$.

Axion Limits from T-violating Medium-Range Forces

The limit is for the coupling g in a T-violating potential between nucleons or nucleon and electron of the form $V=\frac{g\hbar^2}{8\pi m_p}(\boldsymbol{\sigma}\cdot\hat{\mathbf{r}})\left(\frac{1}{r^2}+\frac{m_A c}{\hbar r}\right)e^{-m_A cr/\hbar}$

	[194] RITTER	93		torsion pendulum
	[195] VENEMA	92		nuclear spin-precession frequencies
	[196] WINELAND	91	NMR	

[191] NI 99 searched for a T-violating medium-range force acting on paramagnetic Tb F_3 salt. See their Fig. 1 for the result.

[192] POSPELOV 98 studied the possible contribution of T-violating Medium-Range Force to the neutron electric dipole moment, which is possible when axion interactions violate CP. The size of the force among nucleons must be smaller than gravity by a factor of 2×10^{-10} (1 cm/λ_A), where $\lambda_A=\hbar/m_A c$.

[193] YOUDIN 96 compared the precession frequencies of atomic ^{199}Hg and Cs when a large mass is positioned near the cells, relative to an applied magnetic field. See Fig. 3 for their limits.

[194] RITTER 93 used a torsion pendulum to study the influence of bulk mass with polarized electrons on the pendulum.

[195] VENEMA 92 looked for an effect of Earth's gravity on nuclear spin-precession frequencies of ^{199}Hg and ^{201}Hg atoms.

[196] WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine resonances in stored $^9Be^+$ ions using nuclear magnetic resonance.

LEPTONS

e

$J = \frac{1}{2}$

e MASS

The mass is known much more precisely in u (atomic mass units) than in MeV; see the footnote. The conversion from u to MeV, 1 u = 931.494013±0.000037 MeV/c^2 (MOHR 99, the 1998 CODATA value), involves the relatively poorly known electronic charge.

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
0.510998902±0.000000021	[1] MOHR	99	RVUE	1998 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •				
0.51099907 ±0.00000015	[2] FARNHAM	95	CNTR	Penning
0.51099906 ±0.00000015	[3] COHEN	87	RVUE	1986 CODATA value
0.5110034 ±0.0000014	COHEN	73	RVUE	1973 CODATA value

[1] MOHR 99 (1998 CODATA) value in atomic mass units is 0.0005485799110(12).

[2] FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped $^{12}C^{+6}$ ion. The result is m_e = 0.0005485799111(12) u, where the figure in parenthesis is the 1σ uncertainty in the last digit. The uncertainty after conversion to MeV is dominated by the uncertainty in the electron charge.

[3] COHEN 87 (1986 CODATA) value in atomic mass units is 0.000548579903(13). See footnote on FARNHAM 95.

$(m_{e^+} - m_{e^-})$ / m_{average}

A test of *CPT* invariance.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
<8 × 10^{-9}	90	[4] FEE	93	CNTR	Positronium spectroscopy
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<4 × 10^{-8}	90	CHU	84	CNTR	Positronium spectroscopy

[4] FEE 93 value is obtained under the assumption that the positronium Rydberg constant is exactly half the hydrogen one.

$|q_{e^+} + q_{e^-}|/e$

A test of *CPT* invariance. See also similar tests involving the proton.

VALUE	DOCUMENT ID		TECN	COMMENT
<4 × 10^{-8}	[5] HUGHES	92	RVUE	
• • • We do not use the following data for averages, fits, limits, etc. • • •				
<2 × 10^{-18}	[6] SCHAEFER	95	THEO	Vacuum polarization
<1 × 10^{-18}	[7] MUELLER	92	THEO	Vacuum polarization

[5] HUGHES 92 uses recent measurements of Rydberg-energy and cyclotron-frequency ratios.

[6] SCHAEFER 95 removes model dependency of MUELLER 92.

[7] MUELLER 92 argues that an inequality of the charge magnitudes would, through higher-order vacuum polarization, contribute to the net charge of atoms.

e MAGNETIC MOMENT ANOMALY

$\mu_e/\mu_B - 1 = (g-2)/2$

For the most accurate theoretical calculation, see KINOSHITA 81.

VALUE (units 10^{-6})	DOCUMENT ID		TECN	CHG	COMMENT
1159.6521869±0.0000041	[8] MOHR	99	RVUE		1998 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •					
1159.652193 ±0.000010	[8] COHEN	87	RVUE		1986 CODATA value
1159.6521884±0.0000043	VANDYCK	87	MRS	−	Single electron
1159.6521879±0.0000043	VANDYCK	87	MRS	+	Single positron

[8] The CODATA value assumes the $g/2$ values for e^+ and e^- are equal, as required by *CPT*.

$(g_{e^+} - g_{e^-})$ / g_{average}

A test of *CPT* invariance.

VALUE (units 10^{-12})	CL%	DOCUMENT ID		TECN	COMMENT
− 0.5± 2.1		[9] VANDYCK	87	MRS	Penning trap
• • • We do not use the following data for averages, fits, limits, etc. • • •					
< 12	95	[10] VASSERMAN	87	CNTR	Assumes $m_{e^+} = m_{e^-}$
22 ±64		SCHWINBERG	81	MRS	Penning trap

[9] VANDYCK 87 measured $(g_-/g_+)-1$ and we converted it.

[10] VASSERMAN 87 measured $(g_+ - g_-)/(g-2)$. We multiplied by $(g-2)/g = 1.2 \times 10^{-3}$.

e ELECTRIC DIPOLE MOMENT

A nonzero value is forbidden by both *T* invariance and *P* invariance.

[11] ABDULLAH 90 and COMMINS 94 use the relativistic enhancement of a valence electron's electric dipole moment in a high-Z atom.

e^- MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45**, 1 June, Part II (1992), p. VI.10).

Most of these experiments are one of three kinds: Attempts to observe (a) the (K) shell x ray produced when an electron decays without additional energy deposit, e.g., $e^- \rightarrow \nu_e \overline{\nu}_e \nu_e$ ("disappearance" experiments), (b) the 255.5 keV gamma ray produced in $e^- \rightarrow \nu_e \gamma$, and (c) nuclear de-excitation gamma rays after the electron disappears from an atomic shell and the nucleus is left in an excited state. The last can include both weak boson and photon mediating processes. We use the best "disappearance" limit for the Summary Tables. The best limit for the specific channel $e^- \rightarrow \nu\gamma$ is much better.

Note that we use the mean life rather than the half life, which is often reported.

μ MASS

The mass is known much more precisely in u (atomic mass units) than in MeV. The conversion from u to MeV, 1 u = 931.494013±0.000037 MeV/c^2 (MOHR 99, the 1998 CODATA value), involves the relatively poorly known electronic charge.

Where m_μ/m_e was measured, we have used the 1986 CODATA value for m_e = 0.51099906 ± 0.00000015 MeV.

[13] In the three LEE 59 events, the sum of energies E(e^+) + E(e^-) + E(e^+) was 51 MeV, 55 MeV, and 33 MeV.

NEUTRINO MASS

Written February 1998 and updated October 1999 by B. Kayser (NSF).

There is now rather convincing evidence that neutrinos have nonzero masses. This evidence comes from the apparent observation of neutrino oscillation. Let us recall the physics of this phenomenon, and its relation to neutrino mass.

In the decay

$$W^+ \to \ell^+ \nu_\ell \tag{1}$$

of a W boson into a charged lepton of "flavor" $\ell(e, \mu$, or $\tau)$, the accompanying neutrino is referred to as ν_ℓ, the neutrino of flavor ℓ. Neutrinos of different flavor are different objects. When an energetic ν_ℓ undergoes a charged-current weak interaction, it produces a charged lepton ℓ of the same flavor as the neutrino [1].

If neutrinos have masses, then a neutrino of definite flavor, ν_ℓ, need not be a mass eigenstate. Indeed, if leptons behave like quarks, the ν_ℓ is a coherent linear superposition of mass eigenstates, given by

$$|\nu_\ell\rangle = \sum_m U_{\ell m} |\nu_m\rangle \ . \tag{2}$$

Here, the ν_m are the mass eigenstates, and the coefficients $U_{\ell m}$ form a matrix U known as the leptonic mixing matrix. There are at least three ν_m, and perhaps more. However, it is most often assumed that no more than three ν_m make significant contributions to Eq. (2). Then U is a 3×3 matrix, and according to the electroweak Standard Model (SM), extended to include neutrino masses, it is unitary.

The relation Eq. (2) means that when, for example, a W^+ decays to an e^+ and a neutrino, the neutrino with probability $|U_{e1}|^2$ is a ν_1, with probability $|U_{e2}|^2$ is a ν_2, and so on. This behavior is an exact leptonic analogue of what is known to occur when a W^+ decays to quarks.

If each neutrino of definite flavor is a coherent superposition of mass eigenstates, then a neutrino of one flavor can spontaneously change into one of another flavor as it propagates [2]. This is the phenomenon referred to as neutrino oscillation.

To understand neutrino oscillation, let us consider how a neutrino born as the ν_ℓ of Eq. (2) evolves in time. First, we apply Schrödinger's equation to the ν_m component of ν_ℓ in the rest frame of that component. This tells us that [3]

$$|\nu_m(\tau_m)\rangle = e^{-iM_m\tau_m}|\nu_m(0)\rangle \ , \tag{3}$$

where M_m is the mass of ν_m, and τ_m is time in the ν_m frame. In terms of the time t and position L in the laboratory frame, the Lorentz-invariant phase factor in Eq. (3) may be written

$$e^{-iM_m\tau_m} = e^{-i(E_m t - p_m L)} \ . \tag{4}$$

Here, E_m and p_m are respectively the energy and momentum of ν_m in the laboratory frame. In practice, our neutrino will be extremely relativistic, so we will be interested in evaluating the phase factor of Eq. (4) where $t \approx L$, where it becomes $\exp[-i(E_m - p_m)L]$.

Imagine now that our ν_ℓ has been produced with a definite momentum p, so that all of its mass-eigenstate components have this common momentum. Then the ν_m component has $E_m = \sqrt{p^2 + M_m^2} \approx p + M_m^2/2p$, assuming that all neutrino masses M_m are small compared to the neutrino momentum. The phase factor of Eq. (4) is then approximately

$$e^{-i(M_m^2/2p)L} \ . \tag{5}$$

Alternatively, suppose that our ν_ℓ has been produced with a definite energy E, so that all of its mass-eigenstate components have this common energy [4]. Then the ν_m component has $p_m = \sqrt{E^2 - M_m^2} \approx E - M_m^2/2E$. The phase factor of Eq. (4) is then approximately

$$e^{-i(M_m^2/2E)L} \ . \tag{6}$$

Since highly relativistic neutrinos have $E \approx p$, the phase factors (5) and (6) are approximately equal. Thus, it doesn't matter whether our ν_ℓ is created with definite momentum or definite energy.

From Eq. (2) and either Eq. (5) or Eq. (6), it follows that after a neutrino born as a ν_ℓ has propagated a distance L, its state vector has become

$$|\nu_\ell(L)\rangle \approx \sum_m U_{\ell m} e^{-i(M_m^2/2E)L} |\nu_m\rangle \ . \tag{7}$$

Using the unitarity of U to invert Eq. (2), and inserting the result in Eq. (7), we find that

$$|\nu_\ell(L)\rangle \approx \sum_{\ell'} \left[\sum_m U_{\ell m} e^{-i(M_m^2/2E)L} U^*_{\ell' m} \right] |\nu_{\ell'}\rangle \ . \tag{8}$$

We see that our ν_ℓ, in traveling the distance L, has turned into a superposition of all the flavors. The probability that it has flavor ℓ', $P(\nu_\ell \to \nu_{\ell'}; L)$, is obviously given by

$$P(\nu_\ell \to \nu_{\ell'};\ L) = |\langle \nu_{\ell'} | \nu_\ell(L)\rangle|^2 = \left| \sum_m U_{\ell m} e^{-i(M_m^2/2E)L} U^*_{\ell' m} \right|^2 \ . \tag{9}$$

If it should turn out that the number of neutrino flavors, N, is greater than three, and that the N neutrinos of definite flavor are made up out of N light neutrino mass eigenstates, then the neutrino oscillation probability will still be given by this equation, but with U an $N \times N$, rather than 3×3, unitary matrix.

The mixing matrix U is often called the "Maki-Nakagawa-Sakata matrix" in recognition of the very insightful early work of these three authors on neutrino mixing and oscillation [2].

The quantum mechanics of neutrino oscillation leading to the result Eq. (9) is somewhat subtle. It has been analyzed using wave packets [5], treating a propagating neutrino as a virtual particle [6], evaluating the phase acquired by a propagating mass eigenstate in terms of the proper time of propagation [3], requiring that a neutrino's flavor cannot change unless the neutrino travels [4], and taking different neutrino mass eigenstates to have both different momenta and different energies [7]. The subtleties of oscillation are still being explored.

Frequently, a neutrino oscillation experiment is analyzed assuming that only two neutrino flavors, ν_e and ν_μ for example, mix appreciably. Then the mixing matrix U takes the form

$$U = \begin{pmatrix} \cos\theta_{e\mu} & \sin\theta_{e\mu} \\ -\sin\theta_{e\mu} & \cos\theta_{e\mu} \end{pmatrix} , \qquad (10)$$

where $\theta_{e\mu}$ is the ν_e–ν_μ mixing angle. Inserting this matrix into Eq. (9), we find that

$$P(\nu_e \to \nu_\mu;\ L) = \sin^2 2\theta_{e\mu} \sin^2\left(\Delta M^2_{21} L/4E\right) . \qquad (11)$$

Here, $\Delta M^2_{21} \equiv M^2_2 - M^2_1$, where ν_1 and ν_2 are the mass eigenstates which make up ν_e and ν_μ. If the omitted factors of $\hbar$ and c are inserted into the argument $\Delta M^2_{21} L/4E$ of the oscillatory sine function, it becomes 1.27 ΔM^2_{21} (eV^2)L (km)/E (GeV). The probability that a ν_e will retain its original flavor during propagation over a distance L is simply

$$P(\nu_e \to \nu_e;\ L) = 1 - P(\nu_e \to \nu_\mu;\ L) . \qquad (12)$$

When ν_e, ν_μ, and ν_τ all mix, but two of the three corresponding mass eigenstate neutrinos ν_m are nearly degenerate, neutrino oscillation is described by an expression nearly identical to the "two-neutrino formula" of Eq. (11). To be more precise, suppose that $|\Delta M^2_{21}| \ll |\Delta M^2_{31}| \cong |\Delta M^2_{32}|$, where $\Delta M^2_{mm'} \equiv M^2_m - M^2_{m'}$ is the splitting between the squared masses of mass eigenstates ν_m and $\nu_{m'}$. That is, ν_2 and ν_1 form a pair with a much smaller splitting than that between ν_3 and this pair. Now, suppose an oscillation experiment has L/E such that $|\Delta M^2_{31}|L/E$ is of order unity, so that $|\Delta M^2_{21}|L/E \ll 1$. For this experiment, it follows from Eq. (9) and the unitarity of U that [8]

$$P(\nu_\ell \to \nu_{\ell' \neq \ell};\ L) \cong |2U_{\ell 3}U_{\ell' 3}|^2 \sin^2\left(\Delta M^2_{31} L/4E\right) . \qquad (13)$$

Because $|\Delta M^2_{21}|L/E \ll 1$, this experiment cannot "see" the splitting between ν_2 and ν_1, so these two mass eigenstates behave as if they were a single one. Thus, in this experiment there appear to be only two mass eigenstates altogether, so it is no surprise that the expression for neutrino oscillation, Eq. (13), is very similar to the "two-neutrino" result of Eq. (11).

In a beam of neutrinos born with flavor ℓ_a, neutrino oscillation can be sought in two ways: First, one may seek the *appearance* in the beam of neutrinos of a different flavor, ℓ_b. Secondly, one may seek a *disappearance* of some of the original ν_{ℓ_a} flux, or an L- or E-dependence of this flux.

Clearly, no oscillation is expected unless L/E of the experiment is sufficiently large that the phase factors $\exp(-iM^2_m\ L/2E)$ in Eq. (9) differ appreciably from one another. Otherwise, $\mathrm{P}(\nu_\ell \to \nu_{\ell'}; L) = |\sum_m U_{\ell m} U^*_{\ell' m}|^2 = \delta_{\ell\ell'}$. Now, with omitted factors of $\hbar$ and c inserted, the relative phase of $\exp(-iM^2_m\ L/2E)$ and $\exp(-iM^2_{m'} L/2E)$ is 2.54 $\Delta M^2_{mm'}$(eV^2) L(km)/E(GeV). Thus, for example, an experiment in which neutrinos with $E \approx 1$ GeV travel 1 km between production and detection will be sensitive to $\Delta M^2 \gtrsim 1$ eV^2.

A more direct way than neutrino oscillation experiments to search for neutrino mass is to look for its kinematical effects in decays which produce a neutrino. In the decay $X \to Y\ell^+\nu_\ell$, where X is a hadron and Y is zero or more hadrons, the momenta of ℓ^+ and the particles in Y will obviously be modified if ν_ℓ has a mass. If ν_ℓ is a superposition of mass eigenstates ν_m, then $X \to Y\ell^+\nu_\ell$ is actually the sum of the decays $X \to Y\ell^+\nu_m$ yielding every ν_m light enough to be emitted. Thus, if, for example, one ν_m is much heavier than the others, the energy spectrum of ℓ^+ may show a threshold rise where the ℓ^+ energy becomes low enough for the heavy ν_m to be emitted [9]. However, if neutrino mixing is small, then the decays $X \to Y\ell^+\nu_m$ yield almost always the neutrino mass eigenstate which is the dominant component of ν_ℓ. The kinematics of ℓ^+ and Y then reflect the mass of this mass eigenstate.

From kinematical studies of the particles produced in ^{3}H $\to$ ^{3}He $e^-\,\overline{\nu}_e, \pi \to \mu\nu_\mu$, and $\tau \to n\pi\nu_\tau$, various upper bounds on neutrino mass have been obtained. In the case of the decay ^{3}H $\to$ ^{3}He $e^-\,\overline{\nu}_e$, the upper bound on the neutrino mass is derived from study of the e^- energy spectrum. It should be noted that in several experiments, the observed spectrum is not well fit by the standard theoretical expression, either with vanishing or nonvanishing neutrino mass. However, progress is being made in understanding the spectral anomalies [10].

Neutrinos carry neither electric charge nor, as far as we know, any other charge-like quantum numbers. To be sure, it may be that the reason an interacting "neutrino" creates an ℓ^-, while an "antineutrino" creates an ℓ^+, is that neutrinos and antineutrinos carry opposite values of a conserved "lepton number." However, there may be no lepton number. Even then, the fact that "neutrinos" and "antineutrinos" interact differently can be easily understood. One need only note that, in practice, the particles we call "neutrinos" are always left-handed, while the ones we call "antineutrinos" are right-handed. Since the weak interactions are not invariant under parity, it is then possible to attribute the difference between the interactions of "neutrinos" and "antineutrinos" to the fact that these particles are oppositely polarized.

If the neutrino mass eigenstates do not carry any charge-like attributes, they may be their own antiparticles. A neutrino which is its own antiparticle is called a Majorana neutrino, while one which is not is called a Dirac neutrino.

If neutrinos are of Majorana character, we can have neutrinoless double beta-decay ($\beta\beta_{0\nu}$), in which one nucleus decays to another by emitting two electrons and nothing else. This process can be initiated through the emission of two virtual W bosons by the parent nucleus. One of these W bosons then emits an electron and an accompanying virtual "antineutrino." In the Majorana case, this "antineutrino" is no different from a "neutrino," except for its right-handed helicity. If the virtual neutrino has a mass, then (like the e^+ in nuclear β-decay), it is not fully right-handed, but has a small amplitude, proportional to its mass, for being left-handed. Its left-handed component is precisely what we call a "neutrino," and can be absorbed by the second virtual W boson to create the second outgoing electron. This mechanism yields for $\beta\beta_{0\nu}$ an amplitude proportional to an effective neutrino mass $\langle M\rangle$, given in a common phase convention by [11]

$$\langle M\rangle = \sum_m U_{em}^2 M_m \ . \tag{14}$$

Experimental upper bounds on the $\beta\beta_{0\nu}$ rate are used to derive upper bounds on $\langle M\rangle$. Note that, owing to possible phases in the mixing matrix elements U_{em}, the relation between $\langle M\rangle$ and the actual masses M_m of the neutrino mass eigenstates can be somewhat complicated. The process $\beta\beta_{0\nu}$ is discussed further by P. Vogel in this *Review*.

If neutrinos are their own antiparticles, then their magnetic and electric dipole moments must vanish. To see why, recall that CPT invariance requires that the dipole moments of the electron and its antiparticle be equal and opposite. Similarly, CPT invariance would require that the dipole moments of a neutrino and its antiparticle be equal and opposite. But, if the antiparticle of the neutrino is the neutrino itself, this means that the dipole moments must vanish [12].

If neutrinos are not their own antiparticles, then they can have dipole moments. However, for a Dirac neutrino mass eigenstate ν_m, the magnetic dipole moment μ_m predicted by the Standard Model (extended to include neutrino masses) is only [13]

$$\mu_m = 3.2\times 10^{-19} M_m(\text{eV})\mu_B \ , \tag{15}$$

where μ_B is the Bohr magneton.

Whether neutrinos are their own antiparticles or not, there may be *transition* magnetic and electric dipole moments. These induce the transitions $\nu_m \to \nu_{m'\neq m}\gamma$.

A Majorana neutrino, being its own antiparticle, obviously consists of just two states: spin up and spin down. In contrast, a Dirac neutrino, together with its antiparticle, consists of four states: the spin-up and spin-down neutrino states, plus the spin-up and spin-down antineutrino states. A four-state Dirac neutrino may be pictured as comprised of two degenerate two-state Majorana neutrinos. Conversely, in the field-theory description of neutrinos, by introducing so-called Majorana mass terms, one can split a Dirac neutrino, D, into two nondegenerate Majorana neutrinos, ν and N. In some extensions of the SM, it is natural for the D, ν, and N masses, M_D, M_ν, and M_N, to be related by

$$M_\nu M_N \approx M_D^2 \ . \tag{16}$$

In these extensions, it is also natural for M_D to be of the order of $M_{\ell \text{ or } q}$, the mass of a typical charged lepton or quark. Then we have [14]

$$M_\nu M_N \sim M_{\ell \text{ or } q}^2 \ . \tag{17}$$

Suppose now that $M_N \gg M_{\ell \text{ or } q}$, so that N is a very heavy neutrino which has not yet been observed. Then relation Eq. (17), known as the seesaw relation, implies that $M_\nu \ll M_{\ell \text{ or } q}$. Thus, ν is a candidate for one of the light neutrino mass eigenstates which make up ν_e, ν_μ, and ν_τ. So long as N is heavy, the seesaw relation explains, without fine tuning, why a mass eigenstate component of ν_e, ν_μ, or ν_τ will be light. Interestingly, the picture from which the seesaw relation arises predicts that the mass eigenstate components of ν_e, ν_μ, and ν_τ are Majorana neutrinos.

There are three reported indications that neutrinos actually oscillate in nature, and thus have mass. There is rather convincing evidence that the atmospheric neutrinos oscillate, fairly strong evidence that the solar neutrinos do, and so-far unconfirmed evidence that the neutrinos studied by the LSND experiment do as well.

The atmospheric neutrinos are produced in the earth's atmosphere by cosmic rays, and then detected in an underground detector. Incident on this detector are neutrinos coming from all directions, created in the atmosphere all around the earth. The most compelling evidence that something very interesting happens to these atmospheric neutrinos en route to the detector is the fact that the detected upward-going atmospheric ν_μ flux U (coming from all directions below the horizontal at the detector) differs from the corresponding downward-going flux D. Suppose that neither neutrino oscillation nor any other mechanism decreases or increases the ν_μ flux as the neutrinos travel from their points of origin to the detector. Then, as illustrated in Fig. 1, any ν_μ that enters the sphere S defined in the figure caption will later exit this sphere. Thus, since we are dealing with a steady-state situation, the total ν_μ fluxes entering and exiting S per unit time must be equal. Now, for neutrino energies above a few GeV, the flux of cosmic rays which produce the atmospheric neutrinos is isotropic. Consequently, these neutrinos are being created at the same rate all around the earth. Owing to this spherical symmetry, the equality between the ν_μ fluxes entering and exiting S must hold at any point of S, such as the location of the detector. Now, as shown in Fig. 1, a ν_μ *entering* S through the detector must be part of the downward-going flux D. One *exiting* S through the detector must be part of the upward-going flux U. Thus, the equality of the ν_μ fluxes entering and exiting S at the detector implies that $D = U$. (It is easily shown that this equality must hold not only for the integrated downward and upward fluxes, but angle by angle. That is, the flux coming down from zenith angle θ_Z must equal that coming up from angle $\pi - \theta_Z$.)

The underground Super-Kamiokande detector (Super-K) finds that for multi-GeV atmospheric muon neutrinos [15],

$$\frac{\text{Flux Up}(-1.0 < \cos\theta_Z < -0.2)}{\text{Flux Down}(+0.2 < \cos\theta_Z < +1.0)} = 0.52 \pm 0.05 \ , \tag{18}$$

in strong disagreement with the requirement that the upward and downward fluxes be equal. Thus, some mechanism must be changing the ν_μ flux as the neutrinos travel to the detector.

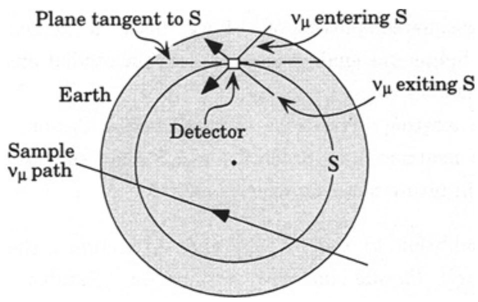

Figure 1: Atmospheric muon neutrino fluxes at an underground detector. S is a sphere centered at the center of the earth and passing through the detector.

The most attractive candidate for this mechanism is neutrino oscillation. Since the atmospheric ν_e flux is compatible with up-down symmetry, the electron neutrinos do not seem to be involved significantly in this oscillation. All of the detailed Super-K atmospheric neutrino data are well described by the hypothesis that $\nu_\mu \to \nu_\tau$ oscillation is occurring, with [16]

$$2 \times 10^{-3}\text{eV}^2 \lesssim \Delta M^2 \lesssim 6 \times 10^{-3}\text{eV}^2 \qquad (19)$$

and

$$\sin^2 2\theta \approx 1 \ . \qquad (20)$$

Other experiments favor roughly similar regions of parameter space [17].

The order of magnitude of the splitting ΔM^2 in Eq. (19) may be understood by noting that for $E \sim 1$ GeV, upward-going neutrinos have $L/E \sim 10^4$km/1 GeV, while downward-going ones have $L/E \sim 10$ km/1 GeV. Thus, if $\Delta M^2 \sim 10^{-3}$ eV^2, the argument $[1.27\Delta M^2(\text{eV}^2)L(\text{km})/E(\text{GeV})]$ of the oscillatory factor in Eq. (11) (applied to the relevant observation channel) exceeds unity for the upward-going neutrinos, but is quite small for the downward-going ones. As a result, the upward-going muon neutrinos oscillate away into neutrinos of another flavor, but the downward-going ones do not. This explains why the flux ratio of Eq. (18) is less than unity.

Conceivably, upward-going muon neutrinos are disappearing, not as a result of neutrino oscillation, but through neutrino decay. This possibility is theoretically less likely than oscillation. However, it is interesting to note that it is not at all excluded by the present data [18]. Of course, neutrino decay, like neutrino oscillation, implies neutrino mass.

The flux of solar neutrinos has been detected on earth by several experiments [19] with different neutrino energy thresholds. In every experiment, the flux is found to be below the corresponding prediction of the Standard Solar Model (SSM) [20]. The discrepancies between the observed fluxes and the SSM predictions have proven very difficult to explain by simply modifying the SSM, without invoking neutrino mass [21]. Indeed, we know of no attempt which has succeeded despite very serious and clever attempts [22–24]. By contrast, all the existing observations can successfully and elegantly be explained if one does invoke neutrino mass. The most popular explanation of this type is based on the Mikheyev-Smirnov-Wolfenstein (MSW) effect—a matter-enhanced neutrino oscillation [25].

The neutrinos produced by the nuclear processes that power the sun are electron neutrinos ν_e. With some probability, the MSW effect converts a ν_e into a neutrino ν_x of another flavor. Depending on the specific version of the effect, ν_x is a ν_μ, a ν_τ, a ν_μ–ν_τ mixture, or perhaps a sterile neutrino ν_s. Since present solar neutrino detectors are sensitive to a ν_e, but wholly, or at least largely, insensitive to a ν_μ, ν_τ, or ν_s, the flavor conversion accounts for the low observed fluxes.

The MSW $\nu_e \to \nu_x$ conversion results from interaction between neutrinos and solar electrons as the neutrinos travel outward from the solar core, where they were produced. When, for example, the neutrino mixing is small, the conversion requires that, somewhere in the sun, the total energy of a ν_e of given momentum, including the energy of its interaction with the solar electrons, equal the total energy of the ν_x of the same momentum, so that we have an energy level crossing. Given the typical density of solar electrons, and the typical momenta of solar neutrinos, the condition that there be a level crossing requires that

$$M^2_{\nu_x} - M^2_{\nu_e} \equiv \Delta M^2_{\nu_x\nu_e} \sim 10^{-5}\text{eV}^2 \ , \qquad (21)$$

where M_{ν_e}, continuing to assume small mixing, is the mass of the dominant mass eigenstate component of ν_e, and similarly for M_{ν_x}.

The observed solar neutrino fluxes can also be explained by supposing that on their way from the sun to the earth, the electron neutrinos produced in the solar core undergo vacuum oscillation into neutrinos of another flavor [26]. Assuming that only two neutrino flavors are important to this oscillation, the oscillation probability is described by an expression of the form given by Eq. (11). To explain the observed suppression of the solar ν_e flux to less than half the predicted value at some energies, and to accommodate the observation that the suppression is energy-dependent, the argument $[1.27\Delta M^2(\text{eV}^2)L(\text{km})/E(\text{GeV})]$ of the oscillatory factor in Eq. (11) must be of order unity when L is the distance from the sun to the earth, and $E \simeq 1$ MeV is the typical energy of a solar neutrino. Perhaps this apparent coincidence makes the vacuum oscillation explanation of the solar neutrino observations less likely than the MSW explanation. To have $[1.27\Delta M^2(\text{eV}^2)L(\text{km})/E(\text{GeV})] \sim 1$, we require that $\Delta M^2 \sim 10^{-10}$ eV^2.

In addition to measuring the solar neutrino fluxes, one can explore the physics of the solar neutrinos by studying the solar ν_e energy spectrum [27], by probing the dependence of the solar ν_e flux on whether it is day or night, and on the time of night [28], and by measuring the solar ν_e flux as a function of the season of the year. The Super-K experiment is doing all of these things [29].

The solar neutrino experiments, and the comparison between their results and theoretical predictions, are discussed in some detail by K. Nakamura in this *Review.*

The LSND experiment [30] has studied neutrinos from stopped positively-charged pions, which decay via the chain

$$\pi^+ \to \mu^+\nu_\mu \quad \hookrightarrow e^+\nu_e\overline{\nu}_\mu \tag{22}$$

We note that this chain does not produce $\overline{\nu}_e$, but an excess of $\overline{\nu}_e$ over expected background is reported by the experiment. This excess is interpreted as arising from oscillation of the $\overline{\nu}_\mu$ which the chain does produce into $\overline{\nu}_e$. Since the experiment has $L(\text{km})/E(\text{GeV}) \sim 1$, the implied mass splitting is $\Delta M^2 \gtrsim 1$ eV^2. LSND finds supporting evidence for its reported oscillation in a study of the neutrinos from the decay

$$\pi^+ \to \mu^+\nu_\mu \tag{23}$$

of positively-charged pions in flight [31].

Other experiments do not observe the oscillation seen by LSND, and allow only some of the $(\Delta M^2, \sin^2 2\theta)$ region favored by LSND. However, these other experiments do not exclude the oscillation interpretation of the LSND data [32,33].

Suppose we assume that the behavior of the atmospheric, solar, and LSND neutrinos are all to be understood in terms of neutrino oscillation. What neutrino masses are then suggested?

If there are only three neutrinos of definite flavor, ν_e, ν_μ, and ν_τ, made up out of just three neutrinos of definite mass, ν_1, ν_2, and ν_3, then there are only three mass splittings $\Delta M^2_{mm'}$, and they obviously satisfy

$$\Delta M^2_{32} + \Delta M^2_{21} + \Delta M^2_{13} = (M_3^2 - M_2^2) + (M_2^2 - M_1^2) + (M_1^2 - M_3^2) = 0 \ . \tag{24}$$

Now, as we have seen, the ΔM^2 values required to explain the atmospheric, solar, and LSND oscillations are of three different orders of magnitude. Thus, they cannot possibly obey the constraint of Eq. (24). Hence, to explain all three of the reported neutrino oscillations, one must introduce a fourth neutrino. Since this neutrino is known to make no contribution to the width of the Z^0 [34], it must be a neutrino which does not participate in the normal weak interactions—a "sterile" neutrino.

One four-neutrino scheme which accounts for all three reported oscillations contains the following neutrino mass eigenstates: A nearly degenerate pair, ν_3, ν_2, with $M_3 \approx M_2 \sim 1$ eV, and a much lighter pair, ν_1, ν_0, with the mass of ν_0, M_0, roughly 3×10^{-3} eV, and $M_1 \ll M_0$. The mass splitting $M_3^2 - M_2^2$ is chosen to be $\sim 4 \times 10^{-3}$ eV^2 to explain the oscillation of the atmospheric neutrinos. Interpreting that oscillation as $\nu_\mu \to \nu_\tau$ with near maximal mixing, we take ν_2 and ν_3 to be approximately 50–50 mixtures of ν_μ and ν_τ. The splitting $M_0^2 - M_1^2 \approx M_0^2 \sim 10^{-5}$ eV^2 allows us to interpret the solar neutrino observations in terms of the MSW effect. We take ν_1 to be largely ν_e, and ν_0 to be largely a sterile neutrino ν_s, so that the MSW effect converts ν_e to a sterile neutrino. Finally, the mass-squared splitting of ~ 1 eV^2 between the heavier pair and the lighter one enables us to explain the oscillation reported by LSND [35].

The existing indications of neutrino oscillation, and the possible neutrino-mass scenarios which they suggest, will be probed in future neutrino experiments.

In addition to the ν_e, ν_μ, and ν_τ sections, the *Review of Particle Physics* includes sections on "Number of Light Neutrino Types," "Heavy Lepton Searches," and "Searches for Massive Neutrinos and Lepton Mixing." Also see other recent reviews [36].

Number of Light Neutrino Types

The neutrinos referred to in this section are those of the Standard SU(2)×U(1) Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with $m_\nu < m_Z/2$. The limits are on the number of neutrino families or species, including ν_e, ν_μ, ν_τ

THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

Revised August 1999 by D. Karlen (Carleton University).

The most precise measurements of the number of light neutrino types, N_ν, come from studies of Z production in e^+e^- collisions. The invisible partial width, $\Gamma_{\rm inv}$, is determined by subtracting the measured visible partial widths, corresponding to Z decays into quarks and charged leptons, from the total Z width. The invisible width is assumed to be due to N_ν light neutrino species each contributing the neutrino partial width Γ_ν as given by the Standard Model. In order to reduce the model dependence, the Standard Model value for the ratio of the neutrino to charged leptonic partial widths, $(\Gamma_\nu/\Gamma_\ell)_{\rm SM} = 1.991\pm0.001$, is used instead of $(\Gamma_\nu)_{\rm SM}$ to determine the number of light neutrino types:

$$N_\nu = \frac{\Gamma_{\rm inv}}{\Gamma_\ell}\left(\frac{\Gamma_\ell}{\Gamma_\nu}\right)_{\rm SM} . \qquad (1)$$

The combined result from the four LEP experiments is $N_\nu = 2.984 \pm 0.008$ [1].

In the past, when only small samples of Z decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in N_ν was reduced by using Standard Model fits to the measured hadronic cross sections at several center-of-mass energies near the Z resonance. Since this method is much more dependent on the Standard Model, the approach described above is favored.

Before the advent of the SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy e^+e^- colliders by measuring the cross section of the process $e^+e^- \to \nu\overline{\nu}\gamma$. The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [2], leading to a 95% CL limit of $N_\nu < 4.8$. This process has a much larger cross section at center-of-mass energies near the Z mass and has been measured at LEP by the ALEPH, DELPHI, L3, and OPAL experiments [3]. These experiments have observed several thousand such events, and the combined result is $N_\nu = 3.00 \pm 0.08$. The same process has been measured by the LEP experiments at center-of-mass energies approaching 100 GeV above the Z mass, in searches for new physics. Combined, the measured cross section is 0.965 ± 0.028 of that expected for 3 light neutrino generations [1].

Experiments at $p\overline{p}$ colliders also placed limits on N_ν by determining the total Z width from the observed ratio of $W^\pm \to \ell^\pm\nu$ to $Z \to \ell^+\ell^-$ events [4]. This involved a calculation that assumed Standard Model values for the total W width and the ratio of W and Z leptonic partial widths, and used an estimate of the ratio of Z to W production cross sections. Now that the Z width is very precisely known from the LEP experiments, the approach is now one of those used to determine the W width.

Massive Neutrinos and Lepton Mixing, Searches for

SEARCHES FOR MASSIVE NEUTRINOS

Revised April 2000 by D.E. Groom (LBNL).

Searches for massive neutral leptons and the effects of nonzero neutrino masses are listed here. These results are divided into the following main sections:

A. Heavy neutral lepton mass limits;
B. Sum of neutrino masses;
C. Searches for neutrinoless double-β decay (see the note by P. Vogel on "Searches for neutrinoless double-β decay" preceding this section);
D. Other bounds from nuclear and particle decays;
E. Solar ν experiments (see the note on "Solar Neutrinos" by K. Nakamura preceding this section);
F. Astrophysical neutrino observations;
G. Reactor $\overline{\nu}_e$ disappearance experiments;
H. Accelerator neutrino appearance experiments;
I. Disappearance experiments with accelerator and radioactive source neutrinos.

Direct searches for masses of dominantly coupled neutrinos are listed in the appropriate sections on ν_e, ν_μ, or ν_τ, where it is assumed that the mass eigenstates ν_1, ν_2, and ν_3 predominately couple to ν_e, ν_μ, and ν_τ, respectively. Note that the assumptions made in these Listings, that ν_2 predominately couples to ν_μ and ν_3 to ν_τ, may not be true. Searches for massive charged leptons are listed elsewhere, and searches for the mixing of $(\mu^- e^+)$ and $(\mu^+ e^-)$ are given in the muon Listings.

Discussion of the current neutrino mass limits and the theory of mixing are given in the note on "Neutrino Mass" by Boris Kayser just before the ν_e Listings.

In many of the following Listings (*e.g.* neutrino disappearance and appearance experiments), results are presented assuming that mixing occurs only between two neutrino species, such as $\nu_\tau \leftrightarrow \nu_e$. This assumption is also made for lepton-number violating mixing between two states, such as $\nu_e \leftrightarrow \overline{\nu}_\mu$ or $\nu_\mu \leftrightarrow \overline{\nu}_\mu$. As discussed in Kayser's review, the assumption of mixing between only two states is valid if (a) all mixing angles are small or (b) there is a mass hierarchy such that one ΔM^2_{ij}, *e.g.* $\Delta M^2_{21} = M^2_{\nu_2} - M^2_{\nu_1}$, is small compared with the others, so that there is a region in L/E (the ratio of the distance L that the neutrino travels to its energy E) where $\Delta M^2_{21} L/E$ is negligible, but $\Delta M^2_{32} L/E$ is not.

In this case limits or results can be shown as allowed regions on a plot of $|\Delta M^2|$ as a function of $\sin^2 2\theta$. The simplest situation occurs in an "appearance" experiment, where one searches for interactions by neutrinos of a variety not expected in the beam. An example is the search for ν_e interactions in a detector in a ν_μ beam. For oscillation between two states, the probability that the "wrong" state will appear is given by Eq. 11 in Kayser's review, which may be written as

$$P = \sin^2 2\theta \, \sin^2(1.27\Delta M^2 L/E) \; , \qquad (1)$$

where $|\Delta M^2|$ is in eV^2 and L/E is in km/GeV or m/MeV. In a real experiment L and E have some spread, so that one must average P over the distribution of L/E. As an example, let us make the somewhat unrealistic assumption that $b \equiv 1.27L/E$ has a Gaussian distribution with standard deviation σ_b about a central value b_0. Then:

$$\langle P \rangle = \tfrac{1}{2} \sin^2 2\theta [1 - \cos(2b_0 \Delta M^2) \exp(-2\sigma_b^2 (\Delta M^2)^2)] \qquad (2)$$

The value of $\langle P \rangle$ is set by the experiment. For example, if 230 interactions of the expected flavor are detected and none of the wrong flavor are seen, then $P = 0.010$ at the 90% CL.* We can then solve the above expression for $\sin^2 2\theta$ as a function of $|\Delta M^2|$. This function is shown in Fig. 1.† Note that:

(a) since the fast oscillations are completely washed out by the resolution for large $|\Delta M^2|$, $\sin^2 2\theta = 2\langle P \rangle$ in this region (If b is taken as much smaller than experimental resolution, Eq. (2) can be used in Monte Carlo calculations to avoid the pathology if Eq. (1) at large Δm^2);
(b) the maximum excursion of the curve to the left is to $\sin^2 2\theta = \langle P \rangle$ with good resolution, with smaller excursion for worse resolution. This "bump" occurs at $|\Delta M^2| = \pi/2b_0$ eV^2;
(c) for large $\sin^2 2\theta$, $\Delta M^2 \approx (\langle P \rangle / \sin^2 2\theta)^{1/2}/b_0$; and, consequently,
(d) the intercept at $\sin^2 2\theta = 1$ is at $\Delta M^2 = \sqrt{\langle P \rangle}/b_0$.

The intercept for large $|\Delta M^2|$ is a measure of running time and backgrounds, while the intercept at $\sin^2 2\theta = 1$ depends also on the mean value of L/E. The wiggles depend on experimental features such as the size of the source, the neutrino energy distribution, and detector and analysis features. Aside from such details, the two intercepts completely describe the exclusion region: For large $|\Delta M^2|$, $\sin^2 2\theta$ is constant and equal to $2\langle P \rangle$, and for large $\sin^2 2\theta$ the slope is known from the intercept. For these reasons, it is (nearly) sufficient to summarize the results of an experiment by stating the two intercepts, as is done in the

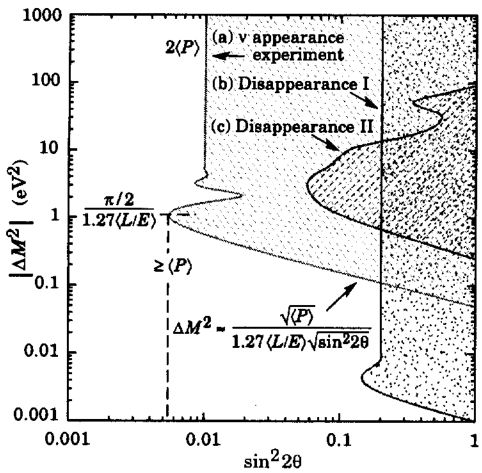

Figure 1: Neutrino oscillation parameter ranges excluded by two hypothetical experiments
(a and b) described by Eq. (2) and one real one (c). Parameters for the first two cases are given in the footnotes. In case (a) one searches for the appearance of neutrinos not expected in the beam. The probability of appearance, in this case 0.5% at some specified CL, is set by the number of right-flavor events observed and/or information about the flux and cross sections. Case (b) represents a disappearance experiment in which the flux is known in the absence of mixing. In case (c), the information comes from measured fluxes at two distances from the target [4].

following tables. The reader is referred to the original papers for the two-dimensional plots expressing the actual limits.

If a positive effect is claimed, then the excluded region is replaced by an allowed band or allowed regions. This is the case for the LSND experiment [2] and the SuperKamiokande analysis of R(μ/e) for atmospheric neutrinos [3].

In a "disappearance" experiment, one looks for the attenuation of the beam neutrinos (for example, ν_k) by mixing with at least one other neutrino eigenstate. (We label such experiments as $\nu_k \not\to \nu_k$.) The probability that a neutrino remains the same neutrino from the production point to detector is given by

$$P(\nu_k \to \nu_k) = 1 - P(\nu_k \to \nu_j) \ , \qquad (3)$$

where mixing occurs between the kth and jth species with $P(\nu_k \to \nu_j)$ given by Eq. (1) or Eq. (2).

In contrast to the detection of even a few "wrong-flavor" neutrinos establishing mixing in an appearance experiment, the disappearance of a few "right-flavor" neutrinos in a disappearance experiment goes unobserved because of statistical fluctuations. For this reason, disappearance experiments usually cannot establish small-probability (small $\sin^2 2\theta$) mixing.

Disappearance experiments fall into two general classes:

I. Those in which the beam neutrino flux is known, from theory or from other measurements. Examples are reactor $\overline{\nu}_e$ experiments and certain accelerator experiments. Although such experiments cannot establish very small-$\sin^2 2\theta$ mixing, they can establish small limits on ΔM^2 for large $\sin^2 2\theta$ because L/E can be very large. An example, based on the Chooz reactor measurements [5], is labeled "Disappearance I" in Fig. 1.‡

II. Those in which attenuation or oscillation of the beam neutrino flux is measured in the apparatus itself (two detectors, or a "long" detector). Above some minimum $|\Delta M^2|$ the equilibrium is established upstream, and there is no change in intensity over the length of the apparatus. As a result, sensitivity is lost at high $|\Delta M^2|$, as can be seen by the curve labeled "Disappearance II" in Fig. 1 [4]. Such experiments have not been competititive for a long time. However, a new generation of long-baseline experiments with a "near" detector and a "far" detector with very large L, *e.g.*, MINOS, will be able to use this strategy to advantage.

Finally, there are more complicated cases, such as analyses of solar neutrino data in terms of the MSW parameters [6]. For a variety of physical reasons, an irregular region in the $|\Delta M^2|$ vs $\sin^2 2\theta$ plane is allowed. It is difficult to represent these graphical data adequately within the strictures of our tables.

Experimental two-neutrino mixing limits and positive signals are shown on the following page.

Footnotes and References

* A superior statistical analysis of confidence limits in the $\sin^2 2\theta$–$|\Delta M^2|$ plane is given in Ref. 1.

† Curve generated with $\langle P \rangle = 0.005$, $\langle L/E \rangle = 1.11$, and $\sigma_b/b_0 = 0.08$.

‡ Curve parameters $\langle P \rangle = 0.1$, $\langle L/E \rangle = 237$, and $\sigma_b/b_0 = 0.5$. For the actual Chooz experiment [5], $\langle L/E \rangle \approx 300$ and the limit on $\langle P \rangle$ is 0.09.

TWO-FLAVOR OSCILLATION PARAMETERS AND LIMITS

Written April 2000 by H. Murayama (LBNL).

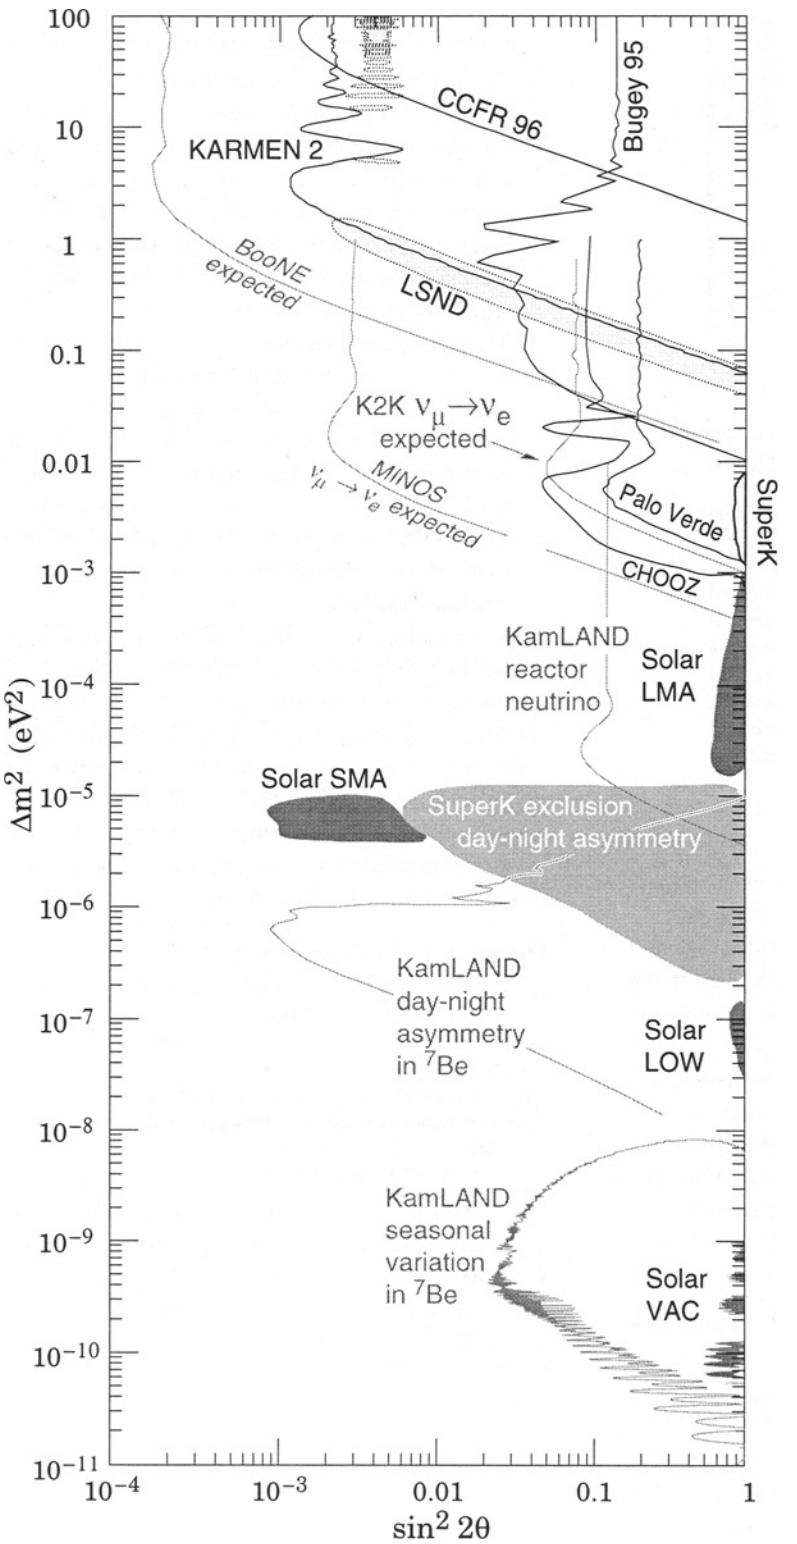

Figure 1: The most important exclusion limits as well as preferred parameter regions from neutrino oscillation experiments in the context of two-flavor oscillations. Beware that the plot shows oscillation modes on different pairs of neutrinos at the same time. All of them are 90% confidence limits unless otherwise noted. From the top,

- CCFR 96 limit is on ν_μ to ν_e oscillation from ROMOSAN 97
- KARMEN 2 excluded region and LSND preferred region are for $\bar{\nu}_e$ appearance from $\bar{\nu}_\mu$ taken from Klaus Eitel, New J. Phys. **2**, 1 (2000), Fig. 12
- Bugey 95 limit is on $\bar{\nu}_e$ disappearance from ACHKAR 95
- CHOOZ limit is on $\bar{\nu}_e$ disappearance from APOLLONIO 99, Fig. 9
- Palo Verde limit is on $\bar{\nu}_e$ disappearance from BOEHM 00, Fig. 3, curve (b)
- SuperKamiokande preferred region is on $\overset{(-)}{\nu}_\mu$ disappearance from FUKUDA 98C
- Solar neutrino preferred regions (solar LMA, solar SMA, solar LOW, and solar VAC) are on ν_e disappearance from J.N. Bahcall, P.I. Krastev, and A.Yu. Smirnov, Phys. Rev. **D58**, 096016 (1998) based on solar neutrino rates only at 99% CL
- SuperKamiokande exclusion is based on the absence of day-night asymmetry in the neutrino rate from FUKUDA 99, Fig. 2, at 99% CL
- Some projected improvements by near-future experiments on ν_e oscillations are shown in grey

Note that the plot shows only half of the parameter space $\Delta m^2 \cos 2\theta > 0$, while the other half $\Delta m^2 \cos 2\theta < 0$ should show different regions excluded/preferred, especially for solar neutrino oscillations (de Gouvêa *et al.*, hep-ph/0002064) once experiments report their data. References in upper-case letters are given at the end of the Listings for "Massive Neutrinos and Lepton Mixing."

(A) Heavy neutral leptons

Stable Neutral Heavy Lepton MASS LIMITS

[7] These results assume that neutrinos make up dark matter in the galactic halo.

[8] Limits based on annihilations in the sun and are due to an absence of high energy neutrinos detected in underground experiments.

[9] MORI 92B results assume that neutrinos make up dark matter in the galactic halo. Limits based on annihilations in earth are also given.

[10] REUSSER 91 uses existing $\beta\beta$ detector (see FISHER 89) to search for CDM Dirac neutrinos.

[11] ENQVIST 89 argue that there is no cosmological upper bound on heavy neutrinos.

(B) Sum of neutrino masses

Revised April 1998 by K.A. Olive (University of Minnesota).

The limits on low mass ($m_\nu \lesssim 1$ MeV) neutrinos apply to $m_{\rm tot}$ given by

$$m_{\rm tot} = \sum_\nu (g_\nu/2) m_\nu \ ,$$

where g_ν is the number of spin degrees of freedom for ν plus $\overline{\nu}$: $g_\nu = 4$ for neutrinos with Dirac masses; $g_\nu = 2$ for Majorana neutrinos. Stable neutrinos in this mass range make a contribution to the total energy density of the Universe which is given by

$$\rho_\nu = m_{\rm tot} n_\nu = m_{\rm tot}(3/11) n_\gamma \ ,$$

where the factor 3/11 is the ratio of (light) neutrinos to photons. Writing $\Omega_\nu = \rho_\nu/\rho_c$, where ρ_c is the critical energy density of the Universe, and using $n_\gamma = 412$ cm^{-3}, we have

$$\Omega_\nu h^2 = m_{\rm tot}/(94 \ {\rm eV}) \ .$$

Therefore, a limit on $\Omega_\nu h^2$ such as $\Omega_\nu h^2 < 0.25$ gives the limit

$$m_{\rm tot} < 24 \ {\rm eV} \ .$$

The limits on high mass ($m_\nu > 1$ MeV) neutrinos apply separately to each neutrino type.

Limit on Total ν MASS, $m_{\rm tot}$

(Defined in the above note), of effectively stable neutrinos (i.e., those with mean lives greater than or equal to the age of the universe). These papers assumed Dirac neutrinos. When necessary, we have generalized the results reported so they apply to $m_{\rm tot}$. For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85.

Limits on MASSES of Heavy Stable Right-Handed ν (with necessarily suppressed interaction strengths)

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
> 10	[14] OLIVE	82	COSM	G_R/G_F <0.1
>100	[14] OLIVE	82	COSM	G_R/G_F <0.01

[14] These results apply to heavy Majorana neutrinos and are summarized by the equation: m_ν >1.2 GeV (G_F/G_R). The bound saturates, and if G_R is too small no mass range is allowed.

(C) Searches for neutrinoless double-β decay

LIMITS FROM NEUTRINOLESS $\beta\beta$ DECAY

Revised September 1999 by P. Vogel (Caltech).

Neutrinoless double beta decay, if observed, would signal violation of the total lepton number conservation. The process can be mediated by an exchange of light Majorana neutrino, or by an exchange of other particles. As long as only a limit on its lifetime is available, limits on the effective Majorana neutrino mass, and on the lepton-number violating right-handed current admixture can be obtained, independently on the actual mechanism. These are considered in the following three tables.

The derived quantities are nuclear model-dependent, so the half-life measurements are given first. Where possible, we list the references for the nuclear matrix elements used in the subsequent analysis. Since rates for the more conventional $2\nu\beta\beta$ decay serve to calibrate the theory, results for this process are also given. As an indication of the spread among different ways of evaluating the matrix elements, we show in Fig. 1 some representative examples for the most popular nuclei.

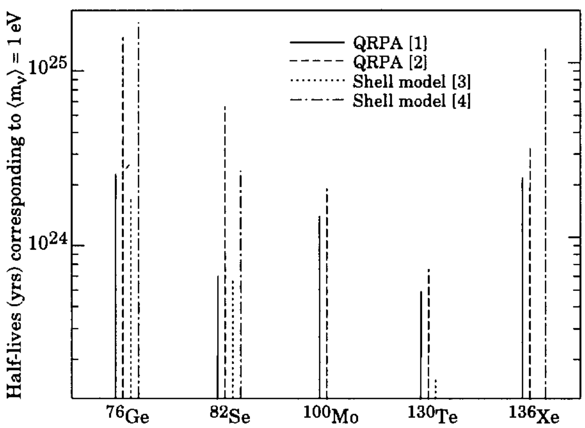

Figure 1: Half-lives (in years) calculated for $\langle m_\nu \rangle = 1$ eV by various representative methods and different authors for the most popular double-beta decay candidate nuclei. Solid lines are QRPA from [1], dashed lines are QRPA from [2] (recalculated for $g_A = 1.25$ and $\alpha' = -390$ MeV fm^3, dotted lines are shell model [3], and dot-and-dashed lines are shell model [4].

To define the limits on lepton-number violating right-handed current admixtures, we display the relevant part of a phenomenological current-current weak interaction Hamiltonian:

$$H_W = (G_F/\sqrt{2}) \times (J_L \cdot j_L^\dagger + \kappa J_R \cdot j_L^\dagger + \eta J_L \cdot j_R^\dagger + \lambda J_R \cdot j_R^\dagger) + \text{h.c.} \qquad (1)$$

where $j_L^\mu = \bar{e}_L \gamma^\mu \nu_{eL}$, $j_R^\mu = \bar{e}_R \gamma^\mu \nu_{eR}$, and J_L^μ and J_R^μ are left-handed and right-handed hadronic weak currents. Experiments are not sensitive to κ, but quote limits on quantities proportional to η and λ.* In analogy to $\langle m_\nu \rangle$ (see Eq. 17 in the "Neutrino mass" at the beginning of the Neutrino Particle Listings), the quantities extracted from experiments are $\langle \eta \rangle = \eta \sum U_{1j} V_{1j}$ and $\langle \lambda \rangle = \lambda \sum U_{1j} V_{1j}$, where V_{ij} is a matrix analogous to U_{ij} (see Eq. 2 in the "Neutrino mass"), but describing the mixing among right-handed neutrinos. The quantities $\langle \eta \rangle$ and $\langle \lambda \rangle$ therefore vanish for massless or unmixed neutrinos. Also, as in the case of $\langle m_\nu \rangle$, cancellations are possible in $\langle \eta \rangle$ and $\langle \lambda \rangle$. The limits on $\langle \eta \rangle$ are of order 10^{-8} while the limits on $\langle \lambda \rangle$ are of order 10^{-6}. The reader is warned that a number of earlier experiments did not distinguish between η and λ. Because of evolving reporting conventions and matrix element calculations, we have not tabulated the admixture parameters for experiments published earlier than 1989.

See the section on Majoron searches for additional limits set by these experiments.

Footnotes and References

* We have previously used a less accepted but more explicit notation in which $\eta_{RL} \equiv \kappa$, $\eta_{LR} \equiv \eta$, and $\eta_{RR} \equiv \lambda$.

[15] AALSETH 99 limit is based on 74.84 active mol-yr of data using enriched Ge detectors at several locations. It is not competive with BAUDIS 99B.

[16] ARNOLD 99 measure directly the 2ν decay of Zr for the first time, using the NEMO-2 tracking detector and an isotopically enriched source. The lifetime is more accurate than the geochemical result of KAWASHIMA 93.

[17] BAUDIS 99B is a continuation of the work of BAUDIS 97. The limit is based on a subset of data using a pulse shape event selection. The exposure time is 24.2 kg-yr. The more stringent limit, in parentheses, results from unphysical data (measured rate significantly below expected background), while the smaller value is the experimental sensitivity as defined by FELDMAN 98. This work supersedes BAUDIS 97 as the most stringent result.

[18] ALESSANDRELLO 98 report limits using an array of 20 cryogenic detectors of 340 grams of TeO_2 each. Supersedes ALESSANDRELLO 96B.

[19] LUESCHER 98 report a limit for the 0ν decay of ^{136}Xe TPC. Supersedes VUILLEUMIER 93.

[20] LUESCHER 98 report a limit for the 2ν decay of ^{136}Xe using Xe TPC. Supersedes VUILLEUMIER 93.

[21] ALSTON-GARNJOST 97 report evidence for 2ν decay of ^{100}Mo. This decay has been also observed by EJIRI 91, DASSIE 95, and DESILVA 97.

[22] BARABASH 97 measure limits for β^+, EC, and ECEC decay of ^{92}Mo to the ground and excited states of ^{92}Ru, respectively. Limits are not competive compared to $\beta^-\beta^-$ searches as far as sensitivity to $\langle m_\nu \rangle$ or RHC admixtures is concerned.

[23] BAUDIS 97 limit for 0ν decay of enriched ^{76}Ge using Ge calorimeters supersedes GUENTHER 97.

[24] DESILVA 97 result for 2ν decay of ^{100}Mo is in agreement with ALSTON-GARNJOST 97 and DASSIE 95. This measurement has the smallest errors.

[25] DESILVA 97 result for 2ν decay of ^{150}Nd is in marginal agreement with ARTEMEV 93. It has smaller errors.

[26] DESILVA 97 do not explain whether their efficiency for 0ν decay of ^{150}Nd was calculated under the assumption of a $\langle m_\nu \rangle$, $\langle \lambda \rangle$, or $\langle \eta \rangle$ driven decay.

[27] GUENTHER 97 half-life for the 2ν decay of ^{76}Ge is not in good agreement with the previous measurements of BALYSH 94, AVIGNONE 91, and MILEY 90.

[28] ARNOLD 96 measure the 2ν decay of ^{116}Cd. This result is in agreement with EJIRI 95, but has smaller errors. Supersedes ARNOLD 95.

[29] BALYSH 96 measure the 2ν decay of ^{48}Ca, using a passive source of enriched ^{48}Ca in a TPC.

[30] EJIRI 96 use energy and angular correlations of the 2β-rays in efficiency estimate to give limits for the 0ν decay modes associated with $\langle m_\nu \rangle$, $\langle \lambda \rangle$, and $\langle \eta \rangle$, respectively. Enriched ^{100}Mo source is used in tracking calorimeter. These are the best limits for ^{100}Mo. Limit is more stringent than ALSTON-GARNJOST 97.

[31] TAKAOKA 96 measure the geochemical half-life of ^{130}Te. Their value is in disagreemnt with the quoted values of BERNATOWICZ 92 and KIRSTEN 83; but agrees with several other unquoted determinations, e.g., MANUEL 91.

[32] BARABASH 95 cannot distinguish 0ν and 2ν, but it is inferred indirectly that the 0ν mode accounts for less than 0.026% of their event sample. They also note that their result disagrees with the previous experiment by the NEMO group (BLUM 92).

[33] BELLOTTI 87 searches for γ rays for 2^+ state decays in corresponding Xe isotopes. Limit for ^{130}Te case argues for dominant $0^+ \to 0^+$ transition in known decay of this isotope.

[34] GEORGADZE 95 result for this and other modes are also give in DANEVICH 95. Result for 2ν decay omitted because of authors' caveats.

[35] In PIEPKE 94, the studied excited states of ^{116}Sn have energies above the ground state of 1.2935 MeV for the 2^+ state, 1.7568 MeV for the 0^+_1 state, and 2.0273 for the 0^+_2 state.

[36] BERNATOWICZ 92 finds ^{128}Te/^{130}Te activity ratio from slope of ^{128}Xe/^{132}Xe vs ^{130}Xe/^{132}Xe ratios during extraction, and normalizes to lead-dated ages for the ^{130}Te lifetime. The authors state that their results imply that "(a) the double beta decay of ^{128}Te has been firmly established and its half-life has been determined ... without any ambiguity due to trapped Xe interferences... (b) Theoretical calculations ... underestimate the [long half-lives of ^{128}Te ^{130}Te] by 1 or 2 orders of magnitude, pointing to a real supression in the 2ν decay rate of these isotopes. (c) Despite [this], most $\beta\beta$-models predict a *ratio* of 2ν decay widths ... in fair agreement with observation." Further details of the experiment are given in BERNATOWICZ 93. Our listed half-life has been revised downward from the published value by the authors, on the basis of reevaluated cosmic-ray ^{128}Xe production corrections.

[37] AVIGNONE 91 reports confirmation of the MILEY 90 and VASENKO 90 observations of $2\nu\beta\beta$ decay of ^{76}Ge. Error is 2σ.

[38] BELLOTTI 91 uses difference between natural and enriched ^{136}Xe runs to obtain $\beta\beta0\nu$ limits, leading to "less stringent, but safer limits."

[39] TURKEVICH 91 observes activity in old U sample. The authors compare their results with theoretical calculations. They state "Using the phase-space factors of Boehm and Vogel (BOEHM 87) leads to matrix element values for the ^{238}U transition in the same range as deduced for ^{130}Te and ^{76}Ge. On the other hand, the latest theoretical estimates (STAUDT 90) give an upper limit that is 10 times lower. This large discrepancy implies either a defect in the calculations or the presence of a faster path than the standard two-neutrino mode in this case." See BOEHM 87 and STAUDT 90.

[40] MILEY 90 claims only "suggestive evidence" for the decay. Error is 2σ.

[41] KIRSTEN 83 reports "2σ" error. References are given to earlier determinations of the ^{130}Te lifetime.

$\langle m_\nu \rangle$, The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double β Decay

$\langle m_\nu \rangle = |\Sigma\ U^2_{1j} m_{\nu_j}|$, where the sum goes from 1 to n and where n = number of neutrino generations, and ν_j is a Majorana neutrino. Note that U^2_{ej}, not $|U_{ej}|^2$, occurs in the sum. The possibility of cancellations has been stressed. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

[42] In AALSETH 99, the range given in the limit reflects the spread of the corresponding nuclear matrix elements. This limit is not competive with BAUDIS 99B.

[43] ARNOLD 99 limit based on the nuclear matrix elements of STAUDT 90.

[44] BAUDIS 99B derive a limit for $\langle m_\nu \rangle$ using the matrix elements of STAUDT 90. The uncertainty given for $\langle m_\nu \rangle$ reflects theoretical uncertainty in the matrix element calculations. The less restrictive limit is based on the quoted experimental sensitivity while the lower value in parentheses makes use of measured rates significantly below background.

[45] LUESCHER 98 limit for $\langle m_\nu \rangle$ is based on the matrix elements of ENGEL 88.

[46] ALSTON-GARNJOST 97 obtain the limit for $\langle m_\nu \rangle$ using the matrix elements of ENGEL 88. The limit supersedes ALSTON-GARNJOST 93.

[47] BAUDIS 97 limit for $\langle m_\nu \rangle$ is based on the matrix elements of STAUDT 90. This is the most stringent bound on $\langle m_\nu \rangle$. It supersedes the limit of GUENTHER 97.

[48] EJIRI 96 obtain the limit for $\langle m_\nu \rangle$ using the matrix elements of TOMODA 91.

[49] DANEVICH 95 is identical to GEORGADZE 95.

[50] VUILLEUMIER 93 mass range from parameter range in the Caltech calculations (ENGEL 88). On the basis of these calculations, the BALYSH 92 mass range would be < 2.2–4.4 eV.

[51] BERNATOWICZ 92 finds these majoron mass limits assuming that the measured geochemical decay width is a limit on the 0ν decay width. The range is the range found using matrix elements from HAXTON 84, TOMODA 87, and SUHONEN 91. Further details of the experiment are given in BERNATOWICZ 93.

[52] ELLIOTT 92 uses the matrix elements of HAXTON 84.

Limits on Lepton-Number Violating ($V+A$) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later. $\langle \lambda \rangle = \lambda \sum U_{ej} V_{ej}$ and $\langle \eta \rangle = \eta \sum U_{ej} V_{ej}$, where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

[53] GUENTHER 97 limits use the matrix elements of STAUDT 90. Supersedes BALYSH 95 and BALYSH 92.

[54] EJIRI 96 obtain limits for $\langle \lambda \rangle$ and $\langle \eta \rangle$ using the matrix elements of TOMODA 91.

[55] DANEVICH 95 is identical to GEORGADZE 95.

[56] VUILLEUMIER 93 uses the matrix elements of MUTO 89.

[57] BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the 0ν width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on η. Further details of the experiment are given in BERNATOWICZ 93.

[58] BRITTON 92B is from a search for additional peaks in the e^+ spectrum from $\pi^+ \to e^+\nu_e$ decay at TRIUMF. See also BRITTON 92.

[59] BRYMAN 83B obtain upper limits from both direct peak search and analysis of $B(\pi \to e\nu)/B(\pi \to \mu\nu)$. Latter limits are not listed, except for this entry (i.e. — we list the most stringent limits for given mass).

[60] Analysis of $(\pi^+ \to e^+\nu_e)/(\pi^+ \to \mu^+\nu_\mu)$ and $(K^+ \to e^+\nu_e)/(K^+ \to \mu^+\nu_\mu)$ decay ratios.

[61] Analysis of $(K^+ \to e^+\nu_e)$ spectrum.

Kink search in nuclear β decay

High-sensitivity follow-up experiments show that indications for a neutrino with mass 17 keV (Simpson, Hime, and others) were not valid. Accordingly, we no longer list the experiments by these authors and some others which made positive claims of 17 keV neutrino emission. Complete listings are given in the 1994 edition (Physical Review **D50** 1173 (1994)) and in the 1998 edition (The European Physical Journal **C3** 1 (1998)). We list below only the best limits on $|U_{ex}|^2$ for each m_{ν_x}. See WIETFELDT 96 for a comprehensive review.

[62] DRAGOUN 99 analyze the β decay spectrum of ^{241}Pu in the energy range 0.2–9.2 keV to derive limits for the admixture of heavy neutrinos. It is not competive with HOLZSCHUH 99.

[63] HOLZSCHUH 99 use an iron-free β spectrometer to measure the ^{63}Niβ decay spectrum. An analysis of the spectrum in the energy rage 33–67.8 keV is used to derive limits for the admixture of heavy neutrinos.

[64] HINDI 98 obtain a limit on heavy neutrino admixture from EC decay of ^{37}Ar by measuring the time-of-flight distribution of the recoiling ions in coincidence with x-rays or Auger electrons. The authors report upper limit for $|U_{ex}|^2$ of ≈ 3% for m_{ν_x}=500 keV, 1% for m_{ν_x}=550 keV, 2% for m_{ν_x}=600 keV, and 4% for m_x=650 keV. Their reported limits for $m_{\nu_x} \le$ 450 keV are inferior to the limits of SCHRECKENBACH 83.

[65] In the beta spectrum from tritium β decay nonvanishing or mixed $m_{\overline{\nu}_1}$ state in the mass region 0.01–4 keV. For m_{ν_x} <1 keV, their upper limit on $|U_{ex}|^2$ becomes less

[66] KALBFLEISCH 93 extends the 17 keV neutrino search of BAHRAN 92, using an improved proportional chamber to which a small amount of ^{3}H is added. Systematics are significantly reduced, allowing for an improved upper limit. The authors give a 99% confidence limit on $|U_{ex}|^2$ as a function of m_{ν_x} in the range from 13.5 keV to 17.5 keV. See also the related papers BAHRAN 93, BAHRAN 93B, and BAHRAN 95 on theoretical aspects of beta spectra and fitting methods for heavy neutrinos.

[67] MORTARA 93 limit is from study using a high-resolution solid-state detector with a superconducting solenoid. The authors note that "The sensitivity to neutrino mass is verified by measurement with a mixed source of ^{35}S and ^{14}C, which artificially produces a distortion in the beta spectrum similar to that expected from the massive neutrino."

[68] This limit was taken from the figure 3 of APALIKOV 85; the text gives a more restrictive limit of 1.7×10^{-3} at CL = 90%.

[69] SCHRECKENBACH 83 is a combined measurement of the β^+ and β^- spectrum.

[70] SHROCK 80 was a retroactive analysis of data on several superallowed β decays to search for kinks in the Kurie plot.

[71] Application of test to search for kinks in β decay Kurie plots.

[72] ABREU 97I long-lived ν_x analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity except at 3.5 GeV, where the limit is the same as at 6 GeV.

[73] HAGNER 95 obtain limits on heavy neutrino admixture from the decay $\nu_h \to \nu_e e^+ e^-$ at a nuclear reactor for the ν_h mass range 2–9 MeV.

[74] BARANOV 93 is a search for neutrino decays into $e^+e^-\nu_e$ using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron. The limits are not as good as those achieved earlier by BERGSMA 83 and BERNARDI 86, BERNARDI 88.

[75] BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89C, and WENDT 87.

[76] OBERAUER 87 bounds from search for $\nu \to \nu' ee$ decay mode using reactor (anti)neutrinos.

[77] COOPER-SARKAR 85 also give limits based on model-dependent assumptions for ν_τ flux. We do not list these. Note that for this bound to be nontrivial, x is not equal

to 3, i.e. ν_x cannot be the dominant mass eigenstate in ν_τ since m_{ν_3} <70 MeV (ALBRECHT 85I). Also, of course, x is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.

[78] BERGSMA 83B also quote limits on $|U_{e3}|^2$ where the index 3 refers to the mass eigenstate dominantly coupled to the τ. Those limits were based on assumptions about the D_s mass and $D_s \rightarrow \tau\nu_\tau$ branching ratio which are no longer valid. See COOPER-SARKAR 85.

[79] ASSAMAGAN 98 obtain a limit on heavy neutrino admixture from π^+ decay essentially at rest, by measuring with good resolution the momentum distribution of the muons. However, the search uses an ad hoc shape correction. The authors report upper limit for $|U_{\mu x}|^2$ of 0.22 for m_ν = 0.53 MeV, 0.029 for m_ν = 0.75 MeV, and 0.016 for m_ν = 1.0 MeV at 90%CL.

[80] BRYMAN 96 search for massive unconventional neutrinos of mass m_{ν_x} in π^+ decay.

[81] ARMBRUSTER 95 study the reactions $^{12}C(\nu_e,e^-)\,^{12}N$ and $^{12}C(\nu,\nu')\,^{12}C^*$ induced by neutrinos from π^+ and μ^+ decay at the ISIS neutron spallation source at the Rutherford-Appleton laboratory. An anomaly in the time distribution can be interpreted as the decay $\pi^+ \rightarrow \mu^+\nu_x$, where ν_x is a neutral weakly interacting particle with mass ≈ 33.9 MeV and spin 1/2. The lower limit to the branching ratio is a function of the lifetime of the new massive neutral particle, and reaches a minimum of a few × 10^{-16} for $\tau_x \sim 5$ s.

[82] From experiments of π^+ and π^- decay in flight at PSI, to check the claim of the KARMEN Collaboration quoted above (ARMBRUSTER 95).

[83] $\pi^+ \rightarrow \mu^+\nu_\mu$ peak search experiment.

[91] VAITAITIS 99 search for $L^0_\mu \rightarrow \mu X$. See paper for rather complicated limit as function of m_{ν_x}.

[92] ABREU 97I long-lived ν_x analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity except at 3.5 GeV, where the limit is the same as at 6 GeV.

[93] VILAIN 95C is a search for the decays of heavy isosinglet neutrinos produced by neutral current neutrino interactions. Limits were quoted for masses in the range from 0.3 to 24 GeV. The best limit is listed above.

[94] BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89C, and WENDT 87.

[95] See also limits on $|U_{3x}|$ from WENDT 87.

[96] COOPER-SARKAR 85 also give limits based on model-dependent assumptions for ν_τ flux. We do not list these. Note that for this bound to be nontrivial, x is not equal to 3, i.e. ν_x cannot be the dominant mass eigenstate in ν_τ since m_{ν_3} <70 MeV (ALBRECHT 85I). Also, of course, x is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.

(E) Solar ν Experiments

SOLAR NEUTRINOS

Revised January 2000 by K. Nakamura (KEK, High Energy Accelerator Research Organization, Japan).

The Sun is a main-sequence star at a stage of stable hydrogen burning. It produces an intense flux of electron neutrinos as a consequence of nuclear fusion reactions which generate solar energy, and whose combined effect is

$$4p + 2e^- \to {}^4\text{He} + 2\nu_e + 26.73 \text{ MeV} - E_\nu , \quad (1)$$

where E_ν represents the energy taken away by neutrinos, with an average value being $\langle E_\nu \rangle \sim 0.6$ MeV. Each neutrino-producing reaction, the resulting flux, and contributions to the event rates in chlorine and gallium solar-neutrino experiments predicted by the recent Bahcall, Basu, and Pinsonneault standard solar model (SSM) calculation [1] are listed in Table 1. This SSM is regarded as the best with helium and heavy-element diffusion. Figure 1 shows the energy spectra of solar neutrinos from these reactions quoted from Ref. 1. Recently, the SSM has been shown to predict accurately the helioseismological sound velocities with a precision of 0.1% rms throughout essentially the entire Sun, greatly strengthening confidence in the solar model [1,2].

Observation of solar neutrinos directly addresses the SSM and, more generally, the theory of stellar structure and evolution which is the basis of the SSM. The Sun as a well-defined neutrino source also provides extremely important opportunities to investigate nontrivial neutrino properties such as nonzero mass and mixing, because of the wide range of matter density and the very long distance from the Sun to the Earth. In fact, the currently available solar-neutrino data seem to require such neutrino properties, if one tries to understand them consistently.

So far, five solar-neutrino experiments have published results. Three of them are radiochemical experiments using ^{37}Cl

Table 1: Neutrino-producing reactions in the Sun (the first column) and their abbreviations (second column). The neutrino fluxes and event rates in chlorine and gallium solar-neutrino experiments predicted by Bahcall, Basu, and Pinsonneault [1] are listed in the third, fourth, and fifth columns respectively.

* 1 SNU (Solar Neutrino Unit) = 10^{-36} captures per atom per second.

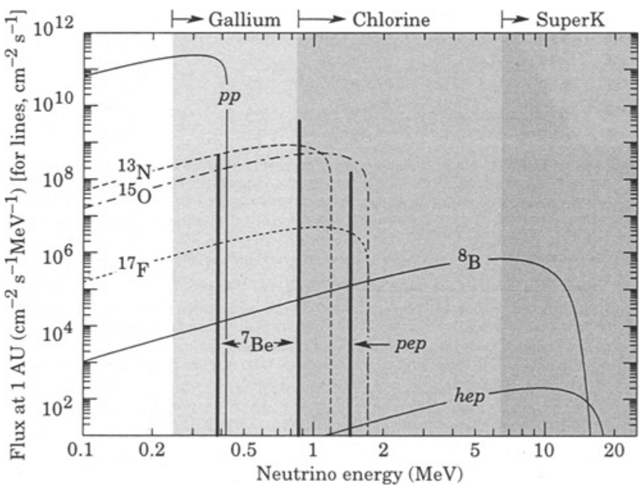

Figure 1: The solar neutrino spectrum predicted by the standard solar model. The neutrino fluxes from continuum sources are given in units of number cm^{-2}s^{-1}MeV^{-1} at one astronomical unit, and the line fluxes are given in number cm^{-2}s^{-1}. Spectra for the pp chain, shown by the solid curves, are courtesy of J.N. Bahcall (1999), and reflect updates in BAHCALL 98C. Spectra for the CNO chain are shown by the dotted curves, and are courtesty of J.N. Bahcall (1995).

(Homestake in USA) or ^{71}Ga (GALLEX at Gran Sasso in Italy and SAGE at Baksan in Russia) to capture neutrinos: $^{37}\text{Cl}\ \nu_e \to {}^{37}\text{Ar}\ e^-$ (threshold 814 keV) or $^{71}\text{Ga}\ \nu_e \to {}^{71}\text{Ge}\ e^-$ (threshold 233 keV). The produced ^{37}Ar and ^{71}Ge are both radioactive nuclei, with half lives ($\tau_{1/2}$) of 34.8 days and 11.43 days, respectively. After an exposure of the detector for two to three times $\tau_{1/2}$, the reaction products are extracted and introduced into a low-background proportional counter, and are counted for a sufficiently long period to determine the exponentially decaying signal and a constant background. In the chlorine experiment, the dominant contribution comes from ^{8}B neutrinos, but ^{7}Be, *pep*, ^{13}N, and ^{15}O neutrinos also contribute. At present, the most abundant *pp* neutrinos can be detected only in gallium experiments. Even so, almost half of the capture rate in the gallium experiments is due to other solar neutrinos.

The other experiments are real-time experiments utilizing νe scattering in a large water-Čerenkov detector (Kamiokande and Super-Kamiokande in Japan). These experiments take advantage of the directional correlation between the incoming neutrino and the recoil electron. This feature greatly helps the clear separation of the solar-neutrino signal from the background. Due to the high thresholds (7 MeV in Kamiokande and 5.5 MeV at present in Super-Kamiokande) the experiments observe pure ^{8}B solar neutrinos because *hep* neutrinos contribute negligibly according to the SSM. (However, the recent Super-Kamiokande results on the recoil-electron energy spectrum at $>$ 13 MeV raised some discussion on the possibility of an enhanced *hep* neutrino contribution [3,4].)

In May, 1999, a new realtime solar-neutrino experiment, SNO (Sudbury Neutrino Observatory) started observation. This experiment uses 1000 tons of heavy water (D_2O) to measure solar neutrinos through both inverse β decay ($\nu_e d \to e^- pp$) and neutral-current interactions ($\nu_x d \to \nu_x pn$). In addition, νe scattering events will be measured.

Solar neutrinos were first observed in the Homestake chlorine experiment in the late 1960's. From the very beginning, it was recognized that the observed capture rate was significantly smaller than the SSM prediction provided nothing happens to the electron neutrinos after they are created in the solar interior. This deficit has been called "the solar-neutrino problem."

The Kamiokande-II Collaboration started observing the ^{8}B solar neutrinos at the beginning of 1987. Because of the strong directional correlation of νe scattering, this result gave the first direct evidence that the Sun emits neutrinos (no directional information is available in radiochemical solar-neutrino experiments.) The observed solar-neutrino flux was also significantly less than the SSM prediction. In addition, Kamiokande-II obtained the energy spectrum of recoil electrons and the fluxes separately measured in the daytime and nighttime. The Kamiokande-II experiment came to an end at the beginning of 1995.

GALLEX presented the first evidence of *pp* solar-neutrino observation in 1992. Here also, the observed capture rate is significantly less than the SSM prediction. SAGE, after the initial confusion which is ascribed to statistics by the group, observed a similar capture rate to that of GALLEX. Both GALLEX and SAGE groups tested the overall detector response with intense man-made ^{51}Cr neutrino sources, and observed good agreement between the measured ^{71}Ge production rate and that predicted from the source activity, demonstrating the reliability of these experiments. The GALLEX Collaboration formally finished observations in early 1997. Since April, 1998, a newly defined collaboration, GNO (Gallium Neutrino Observatory) resumed the observations.

Super-Kamiokande is a 50-kton second-generation solar-neutrino detector, which is characterized by a significantly larger counting rate than the first-generation experiments. This experiment started observation in April 1996. The average solar-neutrino flux is smaller than, but consistent with, the Kamiokande-II result. However, the flux measured in the nighttime shows an excess over that measured in the daytime [5,6], though the significance is not yet high. Super-Kamiokande also observed the recoil-electron energy spectrum [7]. Its shape showed an excess at the high-energy end ($>$ 13 MeV) compared to the SSM expectation, though its statistical significance is not very high. More recent results indicate that the high-energy excess is reduced with the accumulation of statistics.

The most recent published results on the average capture rates or flux from solar-neutrino experiments are listed in Table 2 and compared to the results from SSM calculations which are taken from "Lepton Particle Listings (E) Solar ν Experiments" in this edition of "Review of Particle Physics." In these calculations, BAHCALL 98C [1], BRUN 98 [12], BAHCALL 95B [14], and DAR 96 [13] take into account helium and heavy-element diffusion, but other calculations do not. SSM calculations give essentially the same results for the same input parameters and physics. This statement applies to the most recent BAHCALL 98C [1] and BRUN 98 [12] models. The BAHCALL 98C model [1] differs from the BAHCALL 95B model [14] in that BAHCALL 98C [1] uses the nuclear fusion rates systematically reevaluated and recommended by Adelberger *et al.* [24], and other best available input data. The ^{7}Be$(p,\gamma)^8$B cross section adopted by Adelberger *et al.* [24] is 15% lower than the value used by BAHCALL 95B [14]. This is the principal reason why the ^{8}B neutrino flux and the ^{37}Cl and ^{71}Ga capture rates calculated by the BAHCALL 98C model [1] are lower than those calculated by the BAHCALL 95B model [14]. The BAHCALL 95B [14] model and the TURCK-CHIEZE 93B [15] model differ primarily in that BAHCALL 95B [14] includes element diffusion. The DAR 96 [13] model differs significantly from the BAHCALL 95B [14] model mostly due to the use of nonstandard reaction rates, different treatments of diffusion, and the equation of state.

All results from the present solar-neutrino experiments indicate significantly less flux than expected from SSM calculations except those of DAR 96 [13]. The DAR 96 [13] model predicts the ^{8}B solar-neutrino flux which is consistent with the Kamiokande-II and Super-Kamiokande results, but even this model predicts ^{37}Cl and ^{71}Ga capture rates significantly larger than the Homestake, GALLEX, and SAGE results.

Is there any possible consistent explanation of all the results of solar-neutrino observations in the framework of the standard solar model? This is difficult because the Homestake result and the Kamiokande result, taken at face value, are mutually

Table 2: Recent results from the five solar-neutrino experiments and a comparison with theoretical solar-model predictions. Solar model calculations are also presented. The evolution of these results over the years gives some feeling for their robustness as the models have become more sophisticated and complete.

* 1 SNU (Solar Neutrino Unit) = 10^{-36} captures per atom per second.
† "3σ" errors.

inconsistent if one assumes standard neutrino spectra. That is, with the reduction factor of the ^{8}B solar-neutrino flux as determined from the Kamiokande result, the Homestake ^{37}Cl capture rate would be oversaturated, and there would be no room to accommodate the ^{7}Be solar neutrinos. This makes astrophysical solutions untenable because ^{8}B nuclei are produced from ^{7}Be nuclei in the Sun.

Several authors made more elaborate analyses using the constraint of observed solar luminosity, and found (see for example, Refs. 25–28)

- that both the comparison of the Kamiokande and gallium results and the comparison of the gallium and chlorine results also indicate strong suppression of the ^{7}Be solar-neutrino flux, and
- that not only the SSM but also nonstandard solar models are incompatible with the observed data.

In view of the above situation, it is attractive to invoke nontrivial neutrino properties. Neutrino oscillation in matter (MSW mechanism) is particularly attractive in explaining all the experimental data on the average solar-neutrino flux consistently, without any *a priori* assumptions or fine tuning. Several authors made extensive MSW analyses using all the available data and ended up with similar results. For example, Bahcall, Krastev, and Smirnov [28] analyzed the solar-neutrino data as of 1998 in terms of two-flavor oscillations. In addition, they analyzed the case of vacuum oscillations. They obtained the following solutions for the BAHCALL 98C [1] SSM: Using only the total event rates in the five solar-neutrino experiments, there are three MSW solutions and one vacuum-oscillation solution at the 99% confidence level for oscillations into active neutrinos (ν_μ or ν_τ).

- Small mixing-angle (SMA) solution:
  $\Delta m^2 = 5.4 \times 10^{-6}$ eV^2, $\sin^2 2\theta = 6.0 \times 10^{-3}$
- Large mixing-angle (LMA) solution:
  $\Delta m^2 = 1.8 \times 10^{-5}$ eV^2, $\sin^2 2\theta = 0.76$
- LOW (low probability or low mass) solution:
  $\Delta m^2 = 7.9 \times 10^{-8}$ eV^2, $\sin^2 2\theta = 0.96$
- Vacuum (VAC) solution:
  $\Delta m^2 = 8.0 \times 10^{-11}$ eV^2, $\sin^2 2\theta = 0.75$.

In the case of oscillations into sterile neutrinos, only the SMA and VAC solutions are allowed at the 99% confidence level with the best-fit parameters similar to the ones given above.

Bahcall, Krastev, and Smirnov [28] also made global analyses using all of the available solar-neutrino data, *i.e.*, total event rates plus the Super-Kamiokande recoil-electron energy spectrum and day-night asymmetry. At the 99% confidence level, acceptable solutions are found to be SMA (oscillations into both active and sterile neutrinos) and VAC. The LMA and LOW solutions are marginally ruled out.

Assuming that the solution to the solar-neutrino problem will really be provided by neutrino oscillations, how can one discriminate various solutions? The MSW SMA solution causes an energy-spectrum distortion. In the Super-Kamiokande and SNO observations, the flux will be more suppressed at lower energies. The MSW LMA solution predicts the day-night flux difference, a hint of which is seen in the recent Super-Kamiokande results [6]. However, the LMA solution gives almost no spectrum distortion. Thus, should LMA be a correct solution, one needs to explain the high-energy excess in the recoil-electron spectrum observed by Super-Kamiokande [7], if it turns out to be a real effect, due to a very large contribution from *hep* neutrinos or from other possibilities [4]. The VAC solution is characterized by seasonal variation of the flux, which is different from the trivial variation due to the eccentricity of Earth's orbit [29,30]. Also, the VAC solution can explain the high-energy excess of the recoil-electron spectrum observed by Super-Kamiokande [30].

SNO's observations of solar-neutrino flux by neutral-current reactions will give decisive evidence for neutrino oscillations into active neutrinos, if that flux is consistent with the SSM prediction and larger than the flux measured by charged-current reactions. On the other hand, the signal for oscillations into sterile neutrinos will be the same amount of reduction of the fluxes measured by neutral- and charged-current reactions.

An important task of the second-generation solar neutrino experiments is the measurement of monochromatic ^{7}Be solar neutrinos. If the VAC solution is correct, the flux of ^{7}Be neutrinos shows larger seasonal variations than the flux of ^{8}B neutrinos. The ^{7}Be neutrino flux will be measured by a new experiment, Borexino, at Gran Sasso *via* νe scattering in 300 tons of ultra-pure liquid scintillator with a detection threshold as low as 250 keV. The Borexino detector is expected to be completed in 2001.

KamLAND, which is under construction at Kamioka and will be completed in 2001, is a multi-purpose neutrino experiment with 1000 tons of ultra-pure liquid scintillator. This experiment will also observe ^{7}Be neutrinos if the detection threshold can be lowered to a level similar to that of Borexino. However, one of the primary purposes of this experiment is the observation of oscillations of neutrinos produced by power reactors. The sensitivity region of KamLAND includes the MSW LMA solution. Thus, the LMA solution may be proved or excluded by KamLAND.

The second-generation solar-neutrino experiments, Super-Kamiokande, SNO, and Borexino, as well as KamLAND, will provide a variety of data with high statistical accuracy. It is hoped that these experiments will solve the long-standing solar-neutrino problem in coming years.

[100] ABDURASHITOV 99B is a detailed report of the SAGE solar-neutrino experiment during the period January 1990 through December 1997, and updates the ABDURASHITOV 94 result. However the data in the period November 1993 through June 1994 were not used in determining the neutrino capture rate due to some uncertainty with respect to experimental control. A total of 211 ^{71}Ge events were observed.

[101] FUKUDA 99 results are for a total of 503.8 live days with Super-Kamiokande between 31 May 1996 and 25 March 1998, with threshold $E_e > 6.5$ MeV, and replace FUKUDA 98B results. The day-night solar-neutrino flux asymmetry is given as $N/D-1=0.047\pm0.042\pm0.008$. The results are also given for night fluxes subdivided into five data sets according to nadir of the Sun at the time of the neutrino event. FUKUDA 99 set an absolute flux-independent exclusion region in the two-neutrino oscillation parameter space from the absence of a significant day-night variation. Except for $+0.6\%/-0.5\%$, the systematic errors are common to day and night fluxes.

[102] FUKUDA 99B reports the energy spectrum of recoil electrons from elastic scattering of solar neutrinos for a total of 503.8 live days of Super-Kamiokande observation. A comparison of the observed spectrum with the expectation is in poor agreement at the 4.6% confidence level.

[103] HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is $118.4 \pm 17.8 \pm 6.6$ SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300 ^{71}Ge events were observed.

[104] CLEVELAND 98 is a detailed report of the ^{37}Cl experiment at the Homestake Mine. The average solar neutrino-induced ^{37}Ar production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

[105] FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold $E_e > 9.3$ MeV (first 449 days), > 7.5 MeV (middle 794 days), and > 7.0 MeV (last 836 days). These results update the HIRATA 90 result for the average ^{8}B solar-neutrino flux and HIRATA 91 result for the day-night variation in the ^{8}B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

(F) Astrophysical neutrino observations

Neutrinos and antineutrinos produced in the atmosphere induce μ-like and e-like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as μ/e. It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical μ/e, $R(\mu/e)$, or that of experimental to theoretical μ/total, $R(\mu/\text{total})$ with total = $\mu+e$, is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions.

$R(\mu/e)$ = (Measured Ratio μ/e) / (Expected Ratio μ/e)

[106] ALLISON 99 result is based on an exposure of 3.9 kton yr, 2.6 times the exposure reported in ALLISON 97, and replaces that result.

[107] FUKUDA 98 result is based on an exposure of 25.5 kton yr. The analyzed data sample consists of fully-contained e-like events with $0.1\ \mathrm{GeV}/c<p_e$ and μ-like events with $0.2\ \mathrm{GeV}/c<p_\mu$, both having a visible energy < 1.33 GeV. These criteria match the definition used by FUKUDA 94.

[108] FUKUDA 98E result is based on an exposure of 25.5 kton yr. The analyzed data sample consists of fully-contained single-ring events with visible energy > 1.33 GeV and partially contained events. All partially contained events are classified as μ-like.

[109] FUKUDA 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.

[110] DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95 also report $R(\mu/e) = 0.99 \pm 0.13 \pm 0.08$ for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.

[111] FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained e-like events with $0.1 < p_e < 1.33$ GeV/c and fully-contained μ-like events with $0.2 < p_\mu < 1.5$ GeV/c.

[112] FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy > 1.33 GeV and partially contained μ-like events.

[113] BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atomospheric neutrinos) as $0.36 \pm 0.02 \pm 0.02$, as compared with expected fraction $0.51 \pm 0.01 \pm 0.05$. After cutting the energy range to the Kamiokande limits, BEIER 92 finds $R(\mu/e)$ very close to the Kamiokande value.

$R(\nu_\mu)$ = (Measured Flux of ν_μ) / (Expected Flux of ν_μ)

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$0.74\pm0.036\pm0.046$	[114] AMBROSIO	98	MCRO	Streamer tubes
	[115] CASPER	91	IMB	Water Cherenkov
	[116] AGLIETTA	89	NUSX	
0.95 ± 0.22	[117] BOLIEV	81		Baksan
0.62 ± 0.17	CROUCH	78		Case Western/UCI

[114] AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of ±0.13. With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields $\sin^2 2\theta$=1.0 and $\Delta(m^2) \sim$ a few times 10^{-3} eV^2. However, the fit to the observed zenith distribution gives a maximum probability for χ^2 of only 5% for the best oscillation hypothesis.

[115] CASPER 91 correlates showering/nonshowering signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowering ($\approx \nu_\mu$ induced) fraction is $0.41 \pm 0.03 \pm 0.02$, as compared with expected 0.51 ± 0.05 (syst).

[116] AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define ρ = (measured number of ν_e's)/(measured number of ν_μ's). They report ρ(measured)=ρ(expected) $= 0.96^{+0.32}_{-0.28}$.

[117] From this data BOLIEV 81 obtain the limit $\Delta(m^2) \leq 6 \times 10^{-3}$ eV^2 for maximal mixing, $\nu_\mu \not\rightarrow \nu_\mu$ type oscillation.

$R(\mu$/total) = (Measured Ratio μ/total) / (Expected Ratio μ/total)

[130] FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_\mu > 1.6$ GeV, the observed flux of upward through-going muons is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13}$ cm^{-2} s^{-1} sr^{-1}. The zenith-angle dependence of the flux does not agree with no-oscillation predictions. For the $\nu_\mu \rightarrow \nu_\tau$ hypothesis, FUKUDA 99C obtained the best fit at $\sin^2 2\theta$=0.95 and $\Delta(m^2)$=5.9 $\times 10^{-3}$ eV^2. FUKUDA 99C also reports 68% and 99% confidence-level allowed regions for the same hypothesis.

[131] FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13}$ cm^{-2} s^{-1} sr^{-1}. This is compared to the expected flux of $(0.73 \pm 0.16$ (theoretical error)$) \times 10^{-13}$ cm^{-2} s^{-1} sr^{-1}. The flux of upward through-going muons is taken from FUKUDA 99C. For the $\nu_\mu \rightarrow \nu_\tau$ hypothesis, FUKUDA 99D obtained the best fit in the physical region at $\sin^2 2\theta$=1.0 and $\Delta(m^2)$=3.9 $\times 10^{-3}$ eV^2. FUKUDA 99D also reports 68% and 99% confidence-level allowed regions for the same hypothesis. FUKUDA 99D further reports the result of the oscillation analysis using the zenith-angle dependence of upward-stopping/through-going flux ratio. The best fit in the physical region is obtained at $\sin^2 2\theta$=1.0 and $\Delta(m^2)$=3.1 $\times 10^{-3}$ eV^2.

[132] AMBROSIO 98 result is only 17% probable at maximum because of relatively low flux for $\cos\theta < -0.8$.

[133] FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric-neutrino data which include the 25.5 kton yr data used by FUKUDA 98 (sub-GeV) and FUKUDA 98E (multi-GeV). Inside the physical region, the best fit was obtained at $\sin^2 2\theta$=1.0 and $\Delta(m^2)$=2.2$\times 10^{-3}$ eV^2. In addition, FUKUDA 98C gave the 99% confidence interval, $\sin^2 2\theta > 0.73$ and $3 \times 10^{-4} < \Delta(m^2) < 8.5 \times 10^{-3}$ eV^2. FUKUDA 98C also tested the $\nu_\mu \rightarrow \nu_e$ hypothesis, and concluded that it is not favored.

[134] HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_\mu > 1.6$ GeV, the observed flux of upward through-going muon is

$(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. This is compared to the expected flux of (2.46 ± 0.54 (theoretical error)) $\times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. For the $\nu_\mu \to \nu_\tau$ hypothesis, the best fit inside the physical region was obtained at $\sin^2 2\theta$=1.0 and $\Delta(m^2)$=3.2 × 10^{-3} eV^2.

[135] HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande's contained events (FUKUDA 94) and upward-going muon events. The best fit was obtained at $\sin^2 2\theta$=0.95 and $\Delta(m^2)$=1.3 × 10^{-2} eV^2.

[136] CLARK 97 obtained this result by an analysis of fully contained and partially contained events in the IMB water-Cerenkov detector with visible energy > 0.95 GeV.

[137] FUKUDA 94 obtained this result by a combined analysis of sub-and multi-GeV atmospheric neutrino events in Kamiokande.

[138] BECKER-SZENDY 92 uses upward-going muons to search for atmospheric ν_μ oscillations. The fraction of muons which stop in the detector is used to search for deviations in the expected spectrum. No evidence for oscillations is found.

[139] BERGER 90B uses the Frejus detector to search for oscillations of atmospheric neutrinos. Bounds are for both neutrino and antinuetrino oscillations.

[140] FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of E_μ > 1.6 GeV, the observed flux of upward through-going muon is (1.74 ± 0.07 ± 0.02) × 10^{-13} cm^{-2}s^{-1}sr^{-1}. The zenith-angle dependence of the flux does not agree with no-oscillation predictions. For the $\nu_\mu \to \nu_\tau$ hypothesis, FUKUDA 99C obtained the best fit at $\sin^2 2\theta$=0.95 and $\Delta(m^2)$=5.9 × 10^{-3} eV^2. FUKUDA 99C also reports 68% and 99% confidence-level allowed regions for the same hypotheis.

[141] FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is (0.39 ± 0.04 ± 0.02) × 10^{-13} cm^{-2}s^{-1}sr^{-1}. This is compared to the expected flux of (0.73 ± 0.16 (theoretical error)) × 10^{-13} cm^{-2}s^{-1}sr^{-1}. The flux of upward through-going muons is taken from FUKUDA 99C. For the $\nu_\mu \to \nu_\tau$ hypothesis, FUKUDA 99D obtained the best fit in the physical region at $\sin^2 2\theta$=1.0 and $\Delta(m^2)$=3.9 × 10^{-3} eV^2. FUKUDA 99D also reports 68% and 99% confidence-level allowed regions for the same hypothesis. FUKUDA 99D further reports the result of the oscillation analysis using the zenith-angle dependence of upward-stopping/through-going flux ratio. The best fit in the physical region is obtained at $\sin^2 2\theta$=1.0 and $\Delta(m^2)$=3.1 × 10^{-3} eV^2.

[142] AMBROSIO 98 result is only 17% probable at maximum because of relatively low flux for $\cos\theta < -0.8$.

[143] FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric-neutrino data which include the 25.5 kton yr data used by FUKUDA 98 (sub-GeV) and FUKUDA 98E (multi-GeV). Inside the physical region, the best fit was obtained at $\sin^2 2\theta$=1.0 and $\Delta(m^2)$=2.2×10^{-3} eV^2. In addition, FUKUDA 98C gave the 99% confidence interval, $\sin^2 2\theta$ > 0.73 and $3\times10^{-4} < \Delta(m^2) < 8.5\times10^{-3}$ eV^2. FUKUDA 98C also tested the $\nu_\mu \to \nu_e$ hypothesis, and concluded that it is not favored.

[144] HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of E_μ > 1.6 GeV, the observed flux of upward through-going muon is $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. This is compared to the expected flux of (2.46 ± 0.54 (theoretical error)) $\times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. For the $\nu_\mu \to \nu_\tau$ hypothesis, the best fit inside the physical region was obtained at $\sin^2 2\theta$=1.0 and $\Delta(m^2)$=3.2 × 10^{-3} eV^2.

[145] HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande's contained events (FUKUDA 94) and upward-going muon events. The best fit was obtained at $\sin^2 2\theta$=0.95 and $\Delta(m^2)$=1.3 × 10^{-2} eV^2.

[146] CLARK 97 obtained this result by an analysis of fully contained and partially contained events in the IMB water-Cerenkov detector with visible energy > 0.95 GeV.

[147] FUKUDA 94 obtained this result by a combined analysis of sub-and multi-GeV atmospheric neutrino events in Kamiokande.

[148] BERGER 90B uses the Frejus detector to search for oscillations of atmospheric neutrinos. Bounds are for both neutrino and antinuetrino oscillations.

$\Delta(m^2)$ for $\sin^2(2\theta) = 1$ ($\nu_\mu \to \nu_s$)

ν_s means ν_τ or any sterile (noninteracting) ν.

[156] APOLLONIO 99 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use $\overline{\nu}_e p \to e^+ n$ in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. This is the most sensitive search in terms of $\Delta(m^2)$ for $\overline{\nu}_e$ disappearance.

[157] BOEHM 00 is a disappearance search for neutrino oscillations at 0.75 and 0.89 km distance from Palo Verde reactors. The detection reaction is $\overline{\nu}_e p \to e^+ n$ in a segmented Gd loaded scintillator target. Result is less restrictive than APOLLONIO 99.

[158] ACHKAR 95 bound is for *L*=15, 40, and 95 m.

[159] VIDYAKIN 94 bound is for *L*=57.0 m, 57.6 m, and 231.4 m. Supersedes VIDYAKIN 90.

[160] AFONIN 86 and AFONIN 87 also give limits on $\sin^2(2\theta)$ for intermediate values of $\Delta(m^2)$. (See also KETOV 92). Supersedes AFONIN 87, AFONIN 86, AFONIN 85, AFONIN 83, and BELENKII 83.

[161] VIDYAKIN 87 bound is for *L* = 32.8 and 92.3 m distance from two reactors.

[162] This bound is from data for *L*=37.9 m, 45.9 m, and 64.7 m.

<0.19	90	[172] ZACEK	85		Gösgen reactor
<0.16	90	[173] GABATHULER	84		$\overline{\nu}_e p \to e^+ n$

[163] ACHKAR 95 bound is from data for *L*=15, 40, and 95 m distance from the Bugey reactor.

[164] BOEHM 00 search for neutrino oscillations at 0.75 and 0.89 km distance from Pao Verde reactors.

[165] APOLLONIO 99 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors.

[166] GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River by observing $\overline{\nu}_e p \to e^+ n$ in a Gd loaded scintillator target. Their region of sensitivity in $\Delta(m^2)$ and $\sin^2 2\theta$ is already excluded by ACHKAR 95.

[167] The VYRODOV 95 bound is from data for *L*=15 m distance from the Bugey-5 reactor.

[168] The VIDYAKIN 94 bound is from data for L=57.0 m, 57.6 m, and 231.4 m from three reactors in the Krasnoyark Reactor complex.

[169] Several different methods of data analysis are used in AFONIN 88. We quote the most stringent limits. Different upper limits on $\sin^2 2\theta$ apply at intermediate values of $\Delta(m^2)$. Supersedes AFONIN 87, AFONIN 85, and BELENKII 83.

[170] VIDYAKIN 87 bound is for L = 32.8 and 92.3 m distance from two reactors.

[171] This bound is from data for L=37.9 m, 45.9 m, and 64.7 m distance from Gosgen reactor.

[172] ZACEK 85 gives two sets of bounds depending on what assumptions are used in the data analysis. The bounds in figure 3(a) of ZACEK 85 are progressively poorer for large $\Delta(m^2)$ whereas those of figure 3(b) approach a constant. We list the latter. Both sets of bounds use combination of data from 37.9, 45.9, and 64.7m distance from reactor. ZACEK 85 states "Our experiment excludes this area (the oscillation parameter region allowed by the Bugey data, CAVAIGNAC 84) almost completely, thus disproving the indications of neutrino oscillations of CAVAIGNAC 84 with a high degree of confidence."

[173] This bound comes from a combination of the VUILLEUMIER 82 data at distance 37.9m from Gosgen reactor and new data at 45.9m.

[178] ATHANASSOPOULOS 98 is a search for the $\nu_\mu \to \nu_e$ oscillations using ν_μ from π^+ decay in flight. The 40 observed beam-on electron events are consistent with $\nu_e C \to e^- X$; the expected background is 21.9±2.1. Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability (0.26 ± 0.10 ± 0.05)%. Although the significance is only 2.3σ, this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillations from μ^+ decay at rest. See also ATHANASSOPOULOS 98B.

[179] LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

[180] LOVERRE 88 reports a less stringent, indirect limit based on theoretical analysis of neutral to charged current ratios.

[182] LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

[183] ATHANASSOPOULOS 98 report (0.26 ± 0.10 ± 0.05)% for the oscillation probability; the value of $\sin^2 2\theta$ for large Δm^2 is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate $\sin^2 2\theta$ and Δm^2. See also ATHANASSOPOULOS 98B.

[184] VILAIN 94C limit derived by combining the ν_μ and $\overline{\nu}_\mu$ data assuming CP conservation.

[185] LOVERRE 88 reports a less stringent, indirect limit based on theoretical analysis of neutral to charged current ratios.

[186] ANGELINI 86 limit reaches 13×10^{-3} at $\Delta(m^2) \approx 2$ eV^2.

[187] BERNARDI 86B is a typical fit to the data, assuming mixing between two species. As the authors state, this result is in conflict with earlier upper bounds on this type of neutrino oscillations.

[188] 15ft bubble chamber at FNAL.

[189] FREEDMAN 93 is a search at LAMPF for $\overline{\nu}_e$ generated from any of the three neutrino types ν_μ, $\overline{\nu}_\mu$, and ν_e which come from the beam stop. The $\overline{\nu}_e$'s would be detected by the reaction $\overline{\nu}_e p \to e^+ n$. FREEDMAN 93 replaces DURKIN 88.

[190] ATHANASSOPOULOS 96 is a search for $\overline{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly from π^+ decay at rest. $\overline{\nu}_e$ could come from either $\overline{\nu}_\mu \to \overline{\nu}_e$ or $\nu_e \to \overline{\nu}_e$; our entry assumes the first interpretation. They are detected through $\overline{\nu}_e p \to e^+ n$ (20 MeV $< E_{e^+} <$ 60 MeV) in delayed coincidence with $np \to d\gamma$. Authors observe 51 ± 20 ± 8 total excess events over an estimated background 12.5 ± 2.9. ATHANASSOPOULOS 96B is a shorter version of this paper.

[191] ATHANASSOPOULOS 95 error corresponds to the 1.6σ band in the plot. The expected background is 2.7 ± 0.4 events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18} \pm 0.07)$%. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

[192] HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\overline{\nu}_\mu \to \overline{\nu}_e$ and obtains only upper limits.

[203] ESKUT 98B search for $\tau^- \rightarrow \mu^- \nu_\tau \overline{\nu}_\mu$ or $h^- \nu_\tau \overline{\nu}_\mu$, where h^- is a negatively charged hadron. The μ^- sample is somewhat larger than in ESKUT 98, which this result supersedes. Bayesian limit.
[204] ASTIER 99 limits are based on data corresponding to ~ 950000 ν_μCC interactions in the 1995, 1996, and (most) 1997 runs. This is a "blind" analysis using the FELDMAN 98 classical CL approach, and other algorithms have also been improved since ALTEGOER 98B.
[205] ALTEGOER 98B is the NOMAD 1995 data sample result, searching for events with $\tau^- \rightarrow e^- \nu_\tau \overline{\nu}_e$, hadron$^-$ ν_τ, or $\pi^- \pi^+ \pi^-$ decay modes using classical CL approach of FELDMAN 98.
[206] ESKUT 98 search for events with one μ^- with indication of a kink from τ^- decay in the nuclear emulsion. No candidates were found in a 31,423 event subsample.
[207] LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

$\nu_e \rightarrow (\overline{\nu}_e)_L$

This is a limit on lepton family-number violation and total lepton-number violation. $(\overline{\nu}_e)_L$ denotes a hypothetical left-handed $\overline{\nu}_e$. The bound is quoted in terms of $\Delta(m^2)$, $\sin(2\theta)$, and α, where α denotes the fractional admixture of $(V+A)$ charged current.

QUARKS

QUARK MASSES

Written by A. Manohar (University of California, San Diego).

A. Introduction

This note discusses some of the theoretical issues involved in the determination of quark masses. Unlike the leptons, quarks are confined inside hadrons and are not observed as physical particles. Quark masses cannot be measured directly, but must be determined indirectly through their influence on hadron properties. As a result, the values of the quark masses depend on precisely how they are defined; there is no one definition that is the obvious choice. Though one often speaks loosely of quark masses as one would of the electron or muon mass, any careful statement of a quark mass value must make reference to a particular computational scheme that is used to extract the mass from observations. It is important to keep this scheme dependence in mind when using the quark mass values tabulated in the data listings.

The simplest way to define the mass of a quark is by making a fit of the hadron mass spectrum to a nonrelativistic quark model. The quark masses are defined as the values obtained from the fit. The resulting masses only make sense in the limited context of a particular quark model. They depend on the phenomenological potential used, and on how relativistic effects are modelled. The quark masses used in potential models also cannot be connected with the quark mass parameters in the QCD Lagrangian. Fortunately, there exist other definitions of the quark mass that have a more general significance, though they also depend on the method of calculation. The purpose of this review is to explain the most important such definitions and their interrelations.

B. Mass parameters and the QCD Lagrangian

The QCD Lagrangian for N_F quark flavors is

$$\mathcal{L} = \sum_{k=1}^{N_F} \overline{q}_k \left(i\not{D} - m_k \right) q_k - \tfrac{1}{4} G_{\mu\nu} G^{\mu\nu} \ , \qquad (1)$$

where $\not{D} = (\partial_\mu - igA_\mu)\,\gamma^\mu$ is the gauge covariant derivative, A_μ is the gluon field, $G_{\mu\nu}$ is the gluon field strength, m_k is the mass parameter of the $k^{\rm th}$ quark, and q_k is the quark Dirac field. The QCD Lagrangian Eq. (1) gives finite scattering amplitudes after renormalization, a procedure that invokes a subtraction scheme to render the amplitudes finite, and requires the introduction of a dimensionful scale parameter μ. The mass parameters in the QCD Lagrangian Eq. (1) depend on the renormalization scheme used to define the theory, and also on the scale parameter μ. The most commonly used renormalization scheme for QCD perturbation theory is the $\overline{\rm MS}$ scheme.

The QCD Lagrangian has a chiral symmetry in the limit that the quark masses vanish. This symmetry is spontaneously broken by dynamical chiral symmetry breaking, and explicitly broken by the quark masses. The nonperturbative scale of dynamical chiral symmetry breaking, Λ_χ, is around 1 GeV. It is conventional to call quarks heavy if $m > \Lambda_\chi$, so that explicit chiral symmetry breaking dominates, and light if $m < \Lambda_\chi$, so that spontaneous chiral symmetry breaking dominates. The c, b, and t quarks are heavy, and the u, d and s quarks are light. The computations for light quarks involve an expansion in m_q/Λ_χ about the limit $m_q = 0$, whereas for heavy quarks, they involve an expansion in Λ_χ/m_q about $m_q = \infty$. The corrections are largest for the s and c quarks, which are the heaviest light quark and the lightest heavy quark, respectively.

At high energies or short distances, nonperturbative effects such as chiral symmetry breaking are unimportant, and one can in principle analyze mass-dependent effects using QCD perturbation theory to extract the quark mass values. The QCD computations are conventionally performed using the $\overline{\rm MS}$ scheme at a scale $\mu \gg \Lambda_\chi$, and give the $\overline{\rm MS}$ "running" mass $\overline{m}(\mu)$. The μ dependence of $\overline{m}(\mu)$ at short distances can be calculated using the renormalization group equations.

For heavy quarks, one can obtain useful information on the quark masses by studying the spectrum and decays of hadrons containing heavy quarks. One method of calculation uses the heavy quark effective theory (HQET), which defines a HQET quark mass m_Q. Other commonly used definitions of heavy quark masses such as the pole mass are discussed in Sec. C. QCD perturbation theory at the heavy quark scale $\mu = m_Q$ can be used to relate the various heavy quark masses to the $\overline{\rm MS}$ mass $\overline{m}(\mu)$, and to each other.

For light quarks, one can obtain useful information on the quark mass ratios by studying the properties of the light pseudoscalar mesons using chiral perturbation theory, which utilizes the symmetries of the QCD Lagrangian Eq. (1). The quark mass ratios determined using chiral perturbation theory are those in a subtraction scheme that is independent of the quark masses themselves, such as the $\overline{\rm MS}$ scheme.

A more detailed discussion of the masses for heavy and light quarks is given in the next two sections. The $\overline{\rm MS}$ scheme applies to both heavy and light quarks. It is also commonly used for predictions of quark masses in unified theories, and for computing radiative corrections in the Standard Model. For this reason, we use the $\overline{\rm MS}$ scheme as the standard scheme in reporting quark masses. One can easily convert the $\overline{\rm MS}$ masses into other schemes using the formulæ given in this review.

C. Heavy quarks

The commonly used definitions of the quark mass for heavy quarks are the pole mass, the $\overline{\rm MS}$ mass, the Georgi-Politzer mass, the potential model mass used in ψ and Υ spectroscopy, and the HQET mass.

The strong interaction coupling constant at the heavy quark scale is small, and one can compute the heavy quark propagator using QCD perturbation theory. For an observable particle such as the electron, the position of the pole in the propagator is the definition of the particle mass. In QCD this definition of the quark mass is known as the pole mass m_P, and is independent of the renormalization scheme used. It is known that the on-shell quark propagator has no infrared divergences in perturbation theory [1], so this provides a perturbative definition of the quark mass. The pole mass cannot be used to arbitrarily high accuracy because of nonperturbative infrared effects in QCD. The full quark propagator has no pole because the quarks are confined, so that the pole mass cannot be defined outside of perturbation theory.

The $\overline{\rm MS}$ running mass $\overline{m}(\mu)$ is defined by regulating the QCD theory using dimensional regularization, and subtracting the divergences using the modified minimal subtraction scheme. The $\overline{\rm MS}$ scheme is particularly convenient for Feynman diagram computations, and is the most commonly used subtraction scheme.

The Georgi-Politzer mass $\widehat{m}$ is defined using the momentum space subtraction scheme at the spacelike point $-p^2 = \widehat{m}^2$ [2]. A generalization of the Georgi-Politzer mass that is often used in computations involving QCD sum rules [3] is $\widehat{m}(\xi)$, defined at the subtraction point $p^2 = -(\xi+1)m_P^2$. QCD sum rules are discussed in more detail in the next section on light quark masses.

Lattice gauge theory calculations can be used to obtain heavy quark masses from ψ and Υ spectroscopy. The quark masses are obtained by comparing a nonperturbative computation of the meson spectrum with the experimental data. The lattice quark mass values can then be converted into quark mass values in the continuum QCD Lagrangian Eq. (1) using lattice perturbation theory at a scale given by the inverse lattice spacing. A recent computation determines the b-quark pole mass to be 5.0 ± 0.2 GeV, and the $\overline{\rm MS}$ mass to be 4.0 ± 0.1 GeV [4].

Potential model calculations of the hadron spectrum also involve the heavy quark mass. There is no way to relate the quark mass as defined in a potential model to the quark mass parameter of the QCD Lagrangian, or to the pole mass. Even in the heavy quark limit, the two masses can differ by nonperturbative effects of order $\Lambda_{\rm QCD}$. There is also no reason why the potential model quark mass should be independent of the particular form of the potential used.

Recent work on the heavy quark effective theory [5–9] has provided a definition of the quark mass for a heavy quark that is valid when one includes nonperturbative effects and will be called the HQET mass m_Q. The HQET mass is particularly useful in the analysis of the $1/m_Q$ corrections in HQET. The HQET mass agrees with the pole mass to all orders in perturbation theory when only one quark flavor is present, but differs from the pole mass at order α_s^2 when there are additional flavors [10]. Physical quantities such as hadron masses can in principle be computed in the heavy quark effective theory in terms of the HQET mass m_Q. The computations cannot be done analytically in practice because of nonperturbative effects in QCD, which also prevent a direct extraction of the quark masses from the original QCD Lagrangian, Eq. (1). Nevertheless, for heavy quarks, it is possible to parametrize the nonperturbative effects to a given order in the $1/m_Q$ expansion in terms of a few unknown constants that can be obtained from experiment. For example, the B and D meson masses in the heavy quark effective theory are given in terms of a single nonperturbative parameter $\overline{\Lambda}$,

$$\begin{aligned} M(B) &= m_b + \overline{\Lambda} + \mathcal{O}\left(\frac{\overline{\Lambda}^2}{m_b}\right) , \\ M(D) &= m_c + \overline{\Lambda} + \mathcal{O}\left(\frac{\overline{\Lambda}^2}{m_c}\right) . \end{aligned} \tag{2}$$

This allows one to determine the mass difference $m_b - m_c = M(B) - M(D) = 3.4$ GeV up to corrections of order $\overline{\Lambda}^2/m_b - \overline{\Lambda}^2/m_c$. The extraction of the individual quark masses m_b and m_c requires some knowledge of $\overline{\Lambda}$. An estimate of $\overline{\Lambda}$ using QCD sum rules gives $\overline{\Lambda} = 0.57 \pm 0.07$ GeV [11]. The HQET masses with this value of $\overline{\Lambda}$ are $m_b = 4.74 \pm 0.14$ GeV and $m_c = 1.4 \pm 0.2$ GeV, where the spin averaged meson masses $(3M(B^*) + M(B))/4$ and $(3M(D^*) + M(D))/4$ have been used to eliminate the spin-dependent $\mathcal{O}(\overline{\Lambda}^2/m_Q)$ correction terms. The errors reflect the uncertainty in $\overline{\Lambda}$ and the unknown spin-averaged $\mathcal{O}(\overline{\Lambda}^2/m_Q)$ correction. The errors do not include any theoretical uncertainty in the QCD sum rules, which could be large. A quark model estimate suggests that $\overline{\Lambda}$ is the constituent quark mass (≈ 350 MeV), which differs significantly from the sum rule estimate. In HQET, the $1/m_Q$ corrections to heavy meson decay form-factors are also given in terms of $\overline{\Lambda}$. Thus an accurate enough measurement of these form-factors could be used to extract $\overline{\Lambda}$ directly from experiment, which then determines the quark masses up to corrections of order $1/m_Q$.

The quark mass m_Q of HQET can be related to other quark mass parameters using QCD perturbation theory at the scale m_Q. The relation between m_Q and $\widehat{m}_Q(\xi)$ at one loop is [12]

$$m_Q = \widehat{m}_Q(\xi)\left[1 + \frac{\widehat{\alpha}_s(\xi)}{\pi}\frac{\xi+2}{\xi+1}\log(\xi+2)\right] , \tag{3}$$

where $\widehat{\alpha}_s(\xi)$ is the strong interaction coupling constant in the momentum space subtraction scheme. The relation between m_Q and the $\overline{\rm MS}$ mass $\overline{m}_Q$ is known to two loops [13],

$$\begin{aligned} m_Q = \overline{m}_Q(\overline{m}_Q)\Bigg[1 &+ \frac{4\overline{\alpha}_s(\overline{m}_Q)}{3\pi} \\ &+ \left(13.44 - 1.04\sum_k\left(1 - \frac{4}{3}\frac{\overline{m}_{Q_k}}{\overline{m}_Q}\right)\right)\left(\frac{\overline{\alpha}_s(\overline{m}_Q)}{\pi}\right)^2\Bigg] , \end{aligned} \tag{4}$$

where $\overline{\alpha}_s(\mu)$ is the strong interaction coupling constants in the $\overline{\rm MS}$ scheme, and the sum on k extends over all flavors Q_k lighter than Q. For the b-quark, Eq. (4) reads

$$m_b = \overline{m}_b\left(\overline{m}_b\right)\left[1 + 0.09 + 0.05\right] , \tag{5}$$

where the contributions from the different orders in α_s are shown explicitly. The two loop correction is comparable in size and has the same sign as the one loop term. There is presumably an error of order 0.05 in the relation between m_b and $\overline{m}_b(\overline{m}_b)$ from the uncalculated higher order terms.

D. Light quarks

For light quarks, one can use the techniques of chiral perturbation theory to extract quark mass ratios. The light quark part of the QCD Lagrangian Eq. (1) has a chiral symmetry in the limit that the light quark masses are set to zero, under which left- and right-handed quarks transform independently. The mass term explicitly breaks the chiral symmetry, since it couples the left- and right-handed quarks to each other. A systematic analysis of this explicit chiral symmetry breaking provides some information on the light quark masses.

It is convenient to think of the three light quarks u, d and s as a three component column vector Ψ, and to write the mass term for the light quarks as

$$\overline{\Psi} M \Psi = \overline{\Psi}_L M \Psi_R + \overline{\Psi}_R M \Psi_L, \tag{6}$$

where M is the quark mass matrix M,

$$M = \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_d & 0 \\ 0 & 0 & m_s \end{pmatrix}. \tag{7}$$

The mass term $\overline{\Psi} M \Psi$ is the only term in the QCD Lagrangian that mixes left- and right-handed quarks. In the limit that $M \to 0$, there is an independent SU(3) flavor symmetry for the left- and right-handed quarks. This $G_\chi = \mathrm{SU}(3)_L \times \mathrm{SU}(3)_R$ chiral symmetry of the QCD Lagrangian is spontaneously broken, which leads to eight massless Goldstone bosons, the π's, K's, and η, in the limit $M \to 0$. The symmetry G_χ is only an approximate symmetry, since it is explicitly broken by the quark mass matrix M. The Goldstone bosons acquire masses which can be computed in a systematic expansion in M in terms of certain unknown nonperturbative parameters of the theory. For example, to first order in M one finds that [14,15]

$$\begin{aligned} m_{\pi^0}^2 &= B\,(m_u + m_d)\ , \\ m_{\pi^\pm}^2 &= B\,(m_u + m_d) + \Delta_{em}\ , \\ m_{K^0}^2 = m_{\overline{K}^0}^2 &= B\,(m_d + m_s)\ , \\ m_{K^\pm}^2 &= B\,(m_u + m_s) + \Delta_{em}\ , \\ m_\eta^2 &= \frac{1}{3} B\,(m_u + m_d + 4m_s)\ , \end{aligned} \tag{8}$$

with two unknown parameters B and Δ_{em}, the electromagnetic mass difference. From Eq. (8), one can determine the quark mass ratios [14]

$$\begin{aligned} \frac{m_u}{m_d} &= \frac{2m_{\pi^0}^2 - m_{\pi^+}^2 + m_{K^+}^2 - m_{K^0}^2}{m_{K^0}^2 - m_{K^+}^2 + m_{\pi^+}^2} = 0.56\ , \\ \frac{m_s}{m_d} &= \frac{m_{K^0}^2 + m_{K^+}^2 - m_{\pi^+}^2}{m_{K^0}^2 + m_{\pi^+}^2 - m_{K^+}^2} = 20.1\ , \end{aligned} \tag{9}$$

to lowest order in chiral perturbation theory. The error on these numbers is the size of the second-order corrections, which are discussed at the end of this section. Chiral perturbation theory cannot determine the overall scale of the quark masses, since it uses only the symmetry properties of M, and any multiple of M has the same G_χ transformation law as M. This can be seen from Eq. (8), where all quark masses occur only in the form Bm, so that B and m cannot be determined separately.

The mass parameters in the QCD Lagrangian have a scale dependence due to radiative corrections, and are renormalization scheme dependent. Since the mass ratios extracted using chiral perturbation theory use the symmetry transformation property of M under the chiral symmetry G_χ, it is important to use a renormalization scheme for QCD that does not change this transformation law. Any quark mass independent subtraction scheme such as $\overline{\mathrm{MS}}$ is suitable. The ratios of quark masses are scale independent in such a scheme.

The absolute normalization of the quark masses can be determined by using methods that go beyond chiral perturbation theory, such as QCD sum rules [3]. Typically, one writes a sum rule for a quantity such as B in terms of a spectral integral over all states with certain quantum numbers. This spectral integral is then evaluated by assuming it is dominated by one (or two) of the lowest resonances, and using the experimentally measured resonance parameters [16]. There are many subtleties involved, which cannot be discussed here [16].

Another method for determining the absolute normalization of the quark masses, is to assume that the strange quark mass is equal to the SU(3) mass splitting in the baryon multiplets [14,16]. There is an uncertainty in this method since in the baryon octet one can use either the Σ–N or the Λ–N mass difference, which differ by about 75 MeV, to estimate the strange quark mass. But more importantly, there is no way to relate this normalization to any more fundamental definition of quark masses.

One can extend the chiral perturbation expansion Eq. (8) to second order in the quark masses M to get a more accurate determination of the quark mass ratios. There is a subtlety that arises at second order [17], because

$$M\left(M^\dagger M\right)^{-1} \det M^\dagger \tag{10}$$

transforms in the same way under G_χ as M. One can make the replacement $M \to M(\lambda) = M + \lambda M \left(M^\dagger M\right)^{-1} \det M^\dagger$ in all formulæ,

$$\begin{aligned} M(\lambda) &= \mathrm{diag}\,(m_u(\lambda)\,,\ m_d(\lambda)\,,\ m_s(\lambda)) \\ &= \mathrm{diag}\,(m_u + \lambda m_d m_s\,,\ m_d + \lambda m_u m_s\,,\ m_s + \lambda m_u m_d)\ , \end{aligned} \tag{11}$$

so it is not possible to determine λ by fitting to data. One can only determine the ratios $m_i(\lambda)/m_j(\lambda)$ using second-order chiral perturbation theory, not the desired ratios $m_i/m_j = m_i(\lambda = 0)/m_j(\lambda = 0)$.

Dimensional analysis can be used to estimate [18] that second-order corrections in chiral perturbation theory due to the strange quark mass are of order $\lambda m_s \sim 0.25$. The ambiguity due to the redefinition Eq. (11) (which corresponds to a second-order correction) can produce a sizeable uncertainty in the ratio m_u/m_d. The lowest-order value $m_u/m_d = 0.56$ gets corrections of order $\lambda m_s(m_d/m_u - m_u/m_d) \sim 30\%$, whereas m_s/m_d gets a smaller correction of order $\lambda m_s(m_u/m_d - m_u m_d/m_s^2) \sim 15\%$. A more quantitative discussion of second-order effects can be found in Refs. 17,19,20. Since the second-order terms have a single parameter ambiguity, the value of m_u/m_d is related to the value of m_s/m_d.

The ratio m_u/m_d is of great interest since there is no strong CP problem if $m_u = 0$. To determine m_u/m_d requires fixing λ in the mass redefinition Eq. (11). There has been considerable effort to determine the chiral Lagrangian parameters accurately enough to determine m_u/m_d, for example from the analysis of the decays $\psi' \to \psi + \pi^0, \eta$, the decay $\eta \to 3\pi$, using sum rules, and from the heavy meson mass spectrum [16,21–24]. A recent paper giving a critique of these estimates is Ref. 25.

Eventually, lattice gauge theory methods will be accurate enough to be able to compute meson masses directly from the QCD Lagrangian Eq. (1), and thus determine the light quark masses. For a reliable determination of quark masses, these computations will have to be done with dynamical fermions, and with a small enough lattice spacing that one can accurately compute the relation between lattice and continuum Lagrangians.

The quark masses for light quarks discussed so far are often referred to as current quark masses. Nonrelativistic quark models use constituent quark masses, which are of order 350 MeV for the u and d quarks. Constituent quark masses model the effects of dynamical chiral symmetry breaking, and are not related to the quark mass parameters m_k of the QCD Lagrangian Eq. (1). Constituent masses are only defined in the context of a particular hadronic model.

E. Numerical values and caveats

The quark masses in the particle data listings have been obtained by using the wide variety of theoretical methods outlined above. Each method involves its own set of approximations and errors. In most cases, the errors are a best guess at the size of neglected higher-order corrections. The expansion parameter for the approximations is not much smaller than unity (for example it is $m_K^2/\Lambda_\chi^2 \approx 0.25$ for the chiral expansion), so an unexpectedly large coefficient in a neglected higher-order term could significantly alter the results. It is also important to note that the quark mass values can be significantly different in the different schemes. For example, assuming that the b-quark pole mass is 5.0 GeV, and $\overline{\alpha}_s(m_b) \approx 0.22$ gives the $\overline{\rm MS}$ b-quark mass $\overline{m}_b(\mu = m_b) = 4.6$ GeV using the one-loop term in Eq. (4), and $\overline{m}_b(\mu = m_b) = 4.3$ GeV including the one-loop and two-loop terms. The heavy quark masses obtained using HQET, QCD sum rules, or lattice gauge theory are consistent with each other if they are all converted into the same scheme. When using the data listings, it is important to remember that the numerical value for a quark mass is meaningless without specifying the particular scheme in which it was obtained. All non-$\overline{\rm MS}$ quark masses have been converted to $\overline{\rm MS}$ values in the data listings using one-loop formulæ, unless an explicit two-loop conversion is given by the authors in the original article.

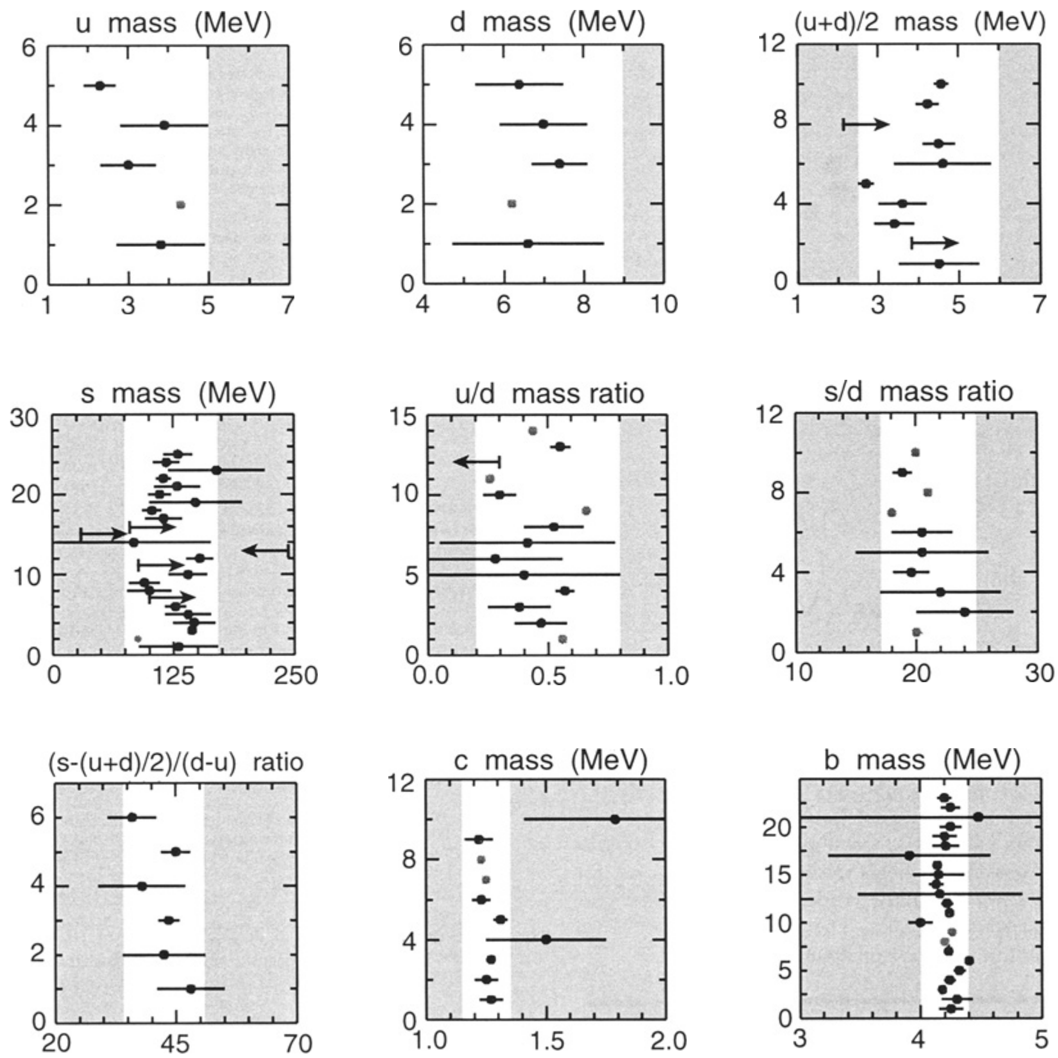

Figure 1: The values of each quark mass parameter taken from the Data Listings. Points from papers reporting no error bars are colored grey. Arrows indicate limits reported. The grey regions indicate values excluded by our evaluations; some regions were determined in part though examination of Fig. 2.

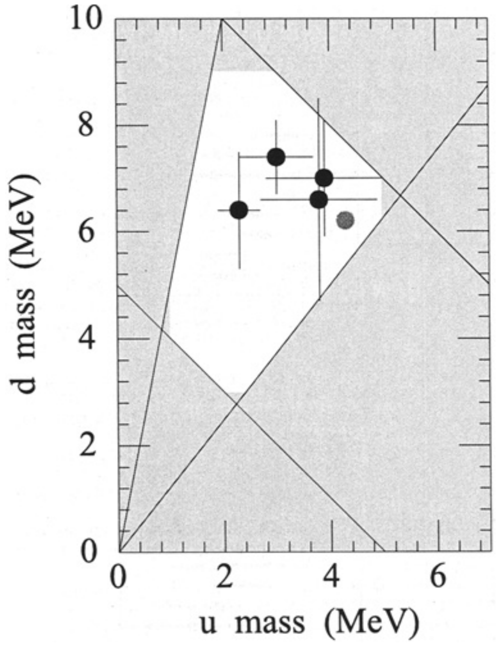

Figure 2: The allowed region (shown in white) for up quark and down quark masses. This region was determined in part from papers reporting values for m_u and m_d (data points shown) and in part from analysis of the allowed ranges of other mass parameters (see Fig. 1). The parameter $(m_u + m_d)/2$ yields the two downward-sloping lines, while m_u/m_d yields the two rising lines originating at (0,0). The grey point is from a paper giving no error bars.

u $I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass m = 1.5 to 5 MeV   Charge = $\frac{2}{3}$ e $I_z = +\frac{1}{2}$

m_u/m_d = 0.20 to 0.70

d $I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass m = 3 to 9 MeV   Charge = $-\frac{1}{3}$ e $I_z = -\frac{1}{2}$

m_s/m_d = 17 to 25

$\overline{m} = (m_u + m_d)/2$ = 2 to 6 MeV

s $I(J^P) = 0(\frac{1}{2}^+)$

Mass m = 60 to 170 MeV   Charge = $-\frac{1}{3}$ e   Strangeness = −1

$(m_s - (m_u + m_d)/2)/(m_d - m_u)$ = 34 to 51

LIGHT QUARKS (*u*, *d*, *s*)

OMITTED FROM SUMMARY TABLE

u-QUARK MASS

The *u*-, *d*-, and *s*-quark masses are estimates of so-called "current-quark masses," in a mass- independent subtraction scheme such as $\overline{\rm MS}$. The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of *d* and *u* masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the *u* quark could be essentially massless. The *s*-quark mass is estimated from SU(3) splittings in hadron masses.

We have normalized the $\overline{\rm MS}$ masses at a renormalization scale of μ = 2 GeV. Results quoted in the literature at μ = 1 GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 1 and 2.

[16] AOKI 00 obtain the light quark masses from a quenched lattice simulation of the meson and baryon spectrum with the Wilson quark action.

[17] AOKI 99 obtain the light quark masses from a quenched lattice simulation of the meson spectrum with the Staggered quark action employing the regularization independent scheme.

[18] STEELE 99 obtain a bound on the light quark masses by applying the Holder inequality to a sum rule. We have converted their bound of $(m_u+m_d)/2 \geq 3$ GeV at μ=1 GeV to μ=2 GeV.

[19] BECIREVIC 98 compute the quark mass using the Alpha action in the quenched approximation. The conversion from the regularization independent scheme to the $\overline{\rm MS}$ scheme is at NNLO.

[20] DOSCH 98 use sum rule determinations of the quark condensate and chiral perturbation theory to obtain $9.4 \leq (m_u+m_d)(1\text{ GeV}) \leq 15.7$ MeV. We have converted to result to μ=2 GeV.

[21] EICKER 97 use lattice gauge computations with two dynamical light flavors.

[22] GOUGH 97 use lattice gauge computations in the quenched approximation. Correcting for quenching gives $2.1 < \overline{m} < 3.5$ MeV at μ=2 GeV.

[23] GUPTA 97 use Lattice Monte Carlo computations in the quenched approximation. The value for two light dynamic flavors at μ = 2 GeV is 2.7 ± 0.3 ± 0.3 MeV.

[24] LELLOUCH 97 obtain lower bounds on quark masses using hadronic spectral functions.

[25] BIJNENS 95 determines m_u+m_d (1 GeV) = 12 ± 2.5 MeV using finite energy sum rules. We have rescaled this to 2 GeV.

s-QUARK MASS

See the comment for the u quark above.

We have normalized the $\overline{\rm MS}$ masses at a renormalization scale of μ = 2 GeV. Results quoted in the literature at μ = 1 GeV have been rescaled by dividing by 1.35.

[26] AOKI 00 obtain the light quark masses from a quenched lattice simulation of the meson and baryon spectrum with the Wilson quark action. We have averaged their results of m_s= 115.6 ± 2.3 and m_s= 143.7 ± 5.8 obtained using m_K and m_ϕ, respectively, to normalize the spectrum.

[27] AOKI 99 obtain the light quark masses from a quenched lattice simulation of the meson spectrum with the Staggered quark action employing the regularization independent scheme. We have averaged their results of m_s=106.0 ± 7.1 and m_s=129 ± 12 obtained using m_K and m_ϕ, respectively, to normalize the spectrum.

[28] BARATE 99R obtain the strange quark mass from an analysis of the observed mass spectra in τ decay. We have converted their value of $m_s(m_\tau)$= 176^{+46}_{-57} MeV to μ=2 GeV.

[29] MALTMAN 99 determines the strange quark mass using finite energy sum rules.

[30] NARISON 99 uses sum rules to order α_s^3 for ϕ meson decays.

[31] BECIREVIC 98 compute the quark mass using the Alpha action in the quenched approximation. The conversion from the regularization independent scheme to the $\overline{\rm MS}$ scheme is at NNLO.

[32] CHETYRKIN 98 uses spectral moments of hadronic τ decays to determine m_s(1 GeV)=200 ± 70 MeV. We have rescaled the result to μ=2 GeV.

[33] CUCCHIERI 98 obtains the quark mass using a quenched lattice computation of the hadronic spectrum.

[34] DOMINGUEZ 98 uses hadronic spectral function sum rules (to four loops, and including dimension six operators) to determine m_s(1 GeV)< 155 ± 25 MeV. We have rescaled the result to μ=2 GeV.

[35] DOSCH 98 use sum rule determinations of the quark condensate and chiral perturbation theory to obtain m_s(1 GeV)> 121 ± 12 MeV. We have converted the result to μ=2 GeV.

[36] LEBED 98 obtain lower bounds of 41, 90, and 139 MeV for m_s(1 GeV) using dispersion relations and chiral perturbation theory. The numbers assume the chiral perturbation theory form factor is accurate to 5%, 1%, and 0.05%, respectively. We have used the first number converted to μ=2.

[37] MALTMAN 98 uses τ-decay-like sum rules involving electromagnetic spectral data to determine m_s(1 GeV)=113 ± 107 MeV. We have rescaled the result to μ=2 GeV.

[38] MALTMAN 98B uses spectral moments of hadronic τ decays to determine m_s(1 GeV)< 220 ± 110 MeV. We have rescaled the result to μ=2 GeV.

[39] CHETYRKIN 97 obtains 205.5 ± 19.1 MeV at μ=1 GeV from QCD sum rules including fourth-order QCD corrections. We have rescaled the result to 2 GeV.

[40] COLANGELO 97 is QCD sum rule computation. We have rescaled m_s(1 GeV) > 120 to μ = 2 GeV.

[41] EICKER 97 use lattice gauge computations with two dynamical light flavors.

[42] GOUGH 97 use lattice gauge computations in the quenched approximation. Correcting for quenching gives 54 $< m_s <$ 92 MeV at μ=2 GeV.

[43] GUPTA 97 use Lattice Monte Carlo computations in the quenched approximation. The value for two light dynamical flavors at μ = 2 GeV is 68 ± 12 ± 7 MeV.

[44] LELLOUCH 97 obtain lower bounds on quark masses using hadronic spectral functions.

[45] CHETYRKIN 95 uses QCD sum rules at next-to-leading order. We have rescaled m_s(1 GeV) = 171 ± 15 to μ = 2 GeV.

[46] JAMIN 95 uses QCD sum rules at next-to-leading order. We have rescaled m_s(1 GeV) = 189 ± 32 to μ = 2 GeV.

[47] For NARISON 95C, we have rescaled m_s(1 GeV) = 197 ± 29 to μ = 2 GeV.

[48] NEFKENS 92 results for $m_s-(m_u+m_d)/2$ are 111 ± 10 MeV from meson masses and 163 ± 15 MeV from baryon masses.

[49] DOMINGUEZ 91 uses QCD sum rules with Λ_{QCD} = 100–200 MeV and the SVZ value for the gluon condensate. We have rescaled m_s(1 GeV) = 194 ± 9 to μ = 2 GeV.

[50] BARDUCCI 88 uses a calculation of the effective potential for $\overline{\psi}\psi$ in QCD, and estimates for $\Sigma(p^2)$. We have rescaled m_s(1 GeV) = 118 to μ = 2 GeV.

[51] KREMER 84 obtain m_u+m_s=245 ± 10 MeV at Q^2 = 1 GeV^2 using SVZ values for quark condensates; they obtain m_u+m_s=270 ± 10 MeV at Q^2 = 1 GeV^2 using factorization values for quark condensates.

[52] GASSER 82 uses chiral perturbation theory for the mass ratios, and uses QCD sum rules to extract the absolute values. We have rescaled m_s(1 GeV) = 175 ± 55 to μ = 2 GeV.

[53] GAO 97 uses electromagnetic mass splittings of light mesons.

[54] LEUTWYLER 96 uses a combined fit to $\eta \rightarrow 3\pi$ and $\psi' \rightarrow J/\psi\ (\pi,\eta)$ decay rates, and the electromagnetic mass differences of the π and K.

[55] CHOI 92 result obtained from the decays $\psi(2S) \rightarrow J/\psi(1S)\pi$ and $\psi(2S) \rightarrow J/\psi(1S)\eta$, and a dilute instanton gas estimate of some unknown matrix elements.

[56] DONOGHUE 92 result is from a combined analysis of meson masses, $\eta \rightarrow 3\pi$ using second-order chiral perturbation theory including nonanalytic terms, and $(\psi(2S) \rightarrow J/\psi(1S)\pi)/(\psi(2S) \rightarrow J/\psi(1S)\eta)$.

[57] DONOGHUE 92B computes quark mass ratios using $(\psi(2S) \rightarrow J/\psi(1S)\pi)/(\psi(2S) \rightarrow J/\psi(1S)\eta)$, and an estimate of L_{14} using Weinberg sum rules.

[58] GERARD 90 uses large N and η-η' mixing.

[59] LEUTWYLER 90B determines quark mass ratios using second-order chiral perturbation theory for the meson and baryon masses, including nonanalytic corrections. Also uses Weinberg sum rules to determine L_7.

[60] MALTMAN 90 uses second-order chiral perturbation theory including nonanalytic terms for the meson masses. Uses a criterion of "maximum reasonableness" that certain coefficients which are expected to be of order one are ≤ 3.

[61] CHOI 89 uses second-order chiral perturbation theory and a dilute instanton gas estimate of second-order coefficients in the chiral lagrangian.

[62] KAPLAN 86 uses second-order chiral perturbation theory including nonanalytic terms for the meson masses. Assumes that less than 30% of the mass squared of the pion is due to second-order corrections.

[63] GASSER 82 uses chiral perturbation theory for the meson and baryon masses.

[64] LANGACKER 79 result is from a fit to the meson and baryon mass spectrum, and the decay $\eta \to 3\pi$. The electromagnetic contribution is taken from Socolow rather than from Dashen's formula.

[65] LANGACKER 79B result uses LANGACKER 79 and also ρ-ω mixing.

[66] WEINBERG 77 uses lowest-order chiral perturbation theory for the meson and baryon masses and Dashen's formula for the electromagnetic mass differences.

c-QUARK MASS

The c-quark mass is estimated from charmonium and D masses. It corresponds to the "running" mass m_c ($\mu = m_c$) in the $\overline{\rm MS}$ scheme. We have converted masses in other schemes to the $\overline{\rm MS}$ scheme using one-loop QCD pertubation theory with $\alpha_s(\mu{=}m_c) = 0.39$. The range 1.0–1.6 GeV for the $\overline{\rm MS}$ mass corresponds to 1.2–1.9 GeV for the pole mass (see the "Note on Quark Masses").

[1] VILAIN 99 obtain the charm quark mass from an analysis of charm production in neutrino scattering.

[2] DOMINGUEZ 94 uses QCD sum rules for $J/\psi(1S)$ system and finds a pole mass of 1.46 ± 0.07 GeV.

[3] LIGETI 94 computes lower bound of 1.43 GeV on pole mass using HQET, and experimental data on inclusive B and D decays.

[4] LUKE 94 computes lower bound of 1.46 GeV on pole mass using HQET, and experimental data on inclusive B and D decays.

[5] NARISON 94 uses spectral sum rules to two loops, and $J/\psi(1S)$ and Υ systems.

[6] TITARD 94 uses one-loop computation of the quark potential with nonperturbative gluon condensate effects to fit $J/\psi(1S)$ and Υ states.

[7] ALVAREZ 93 method is to fit the measured x_F and p_T^2 charm photoproduction distributions to the theoretical predictions of ELLIS 89C.

[8] NARISON 89 determines the Georgi-Politzer mass at $p^2 = -m^2$ to be 1.26 ± 0.02 GeV using QCD sum rules.

[9] NARISON 87 computes pole mass of 1.46 ± 0.05 GeV using QCD sum rules, with $\Lambda(\overline{\rm MS})$ = 180 ± 80 MeV.

[10] GASSER 82 uses SVZ sum rules. The renormalization point is μ = quark mass.

b-QUARK MASS

The b-quark mass is estimated from bottomonium and B masses. It corresponds to the "running" mass m_b ($\mu = m_b$) in the $\overline{\rm MS}$ scheme. We have converted masses in other schemes to the $\overline{\rm MS}$ scheme using one-loop QCD pertubation theory with $\alpha_s(\mu{=}m_b) = 0.22$. The range 4.1–4.5 GeV for the $\overline{\rm MS}$ mass corresponds to 4.5–4.9 GeV for the pole mass (see the "Note on Quark Masses").

[1] HOANG 00 uses a NNLO calculation of the vacuum polarization function to determine spectral moments of the masses and electronic decay widths of the Υ mesons.
[2] BENEKE 99 uses a calculation of the $b\overline{b}$ production cross section and the mass of the Υ meson at NNLO.
[3] BRANDENBURG 99 obtain a b-quark mass of $m_b(M_Z) = 2.56 \pm 0.27^{+0.28}_{-0.38}{}^{+0.49}_{-1.48}$ from a study of three-jet events at the Z. We have converted this to $\mu{=}m_b$.
[4] HOANG 99 uses a NNLO calculation of the vacuum polarization function to determine spectral moments of the masses and electronic decay widths of the Υ mesons.
[5] MELNIKOV 99 compute the quark mass using Υ sum rules at NNLO.
[6] PENIN 99 compute the quark mass using Υ sum rules at NNLO.
[7] ABREU 98I determines the $\overline{\rm MS}$ mass $m_b = 2.67 \pm 0.25 \pm 0.34 \pm 0.27$ GeV at $\mu{=}M_Z$ from three jet heavy quark production at LEP. ABREU 98I have rescaled the result to $\mu = m_b$ using $\alpha_s{=}0.118 \pm 0.003$.
[8] KUEHN 98 uses a calculation of the vacuum polarization function, including resumming threshold effects, to determine spectral moments of the masses of the Υ mesons. We have converted their extracted value of 4.75 ± 0.04 for the pole mass to the $\overline{\rm MS}$ scheme.
[9] GIMENEZ 97 uses lattice computations of the B-meson propagator and the B-meson binding energy $\overline{\Lambda}$ in the HQET. Their systematic (second) error for the $\overline{\rm MS}$ mass is an estimate of the effects of higher-order corrections in the matching of the HQET operators (renormalon effects).
[10] JAMIN 97 apply the QCD moment method to the Υ system. They also find a pole mass of 4.60 ± 0.02.
[11] RODRIGO 97 determines the $\overline{\rm MS}$ mass $m_b = 2.85 \pm 0.22 \pm 0.20 \pm 0.36$ GeV at $\mu{=}M_Z$ from three jet heavy quark production at LEP. We have rescaled the result.
[12] NARISON 95B uses finite energy sum rules to two-loop accuracy to determine a b-quark pole mass of 4.61 ± 0.05 GeV.
[13] VOLOSHIN 95 uses moments of the total cross section for $e^+e^- \rightarrow b$ hadrons. We have converted the value of of 4.827 ± 0.007 MeV for the pole mass to the $\overline{\rm MS}$ scheme using the two-loop formula.
[14] DAVIES 94 uses lattice computation of Υ spectroscopy. They also quote a value of 5.0 ± 0.2 GeV for the b-quark pole mass. The numerical computation includes quark vacuum polarization (unquenched); they find that the masses are independent of n_f to within their errors. Their error for the pole mass is larger than the error for the $\overline{\rm MS}$ mass, because both are computed from the bare lattice quark mass, and the conversion for the pole mass is less accurate.
[15] LIGETI 94 computes lower bound of 4.66 GeV on pole mass using HQET, and experimental data on inclusive B and D decays.
[16] LUKE 94 computes lower bound of 4.60 GeV on pole mass using HQET, and experimental data on inclusive B and D decays.
[17] NARISON 94 uses spectral sum rules to two loops, and $J/\psi(1S)$ and Υ systems.
[18] TITARD 94 uses one-loop computation of the quark potential with nonperturbative gluon condensate effects to fit $J/\psi(1S)$ and Υ states.
[19] DOMINGUEZ 92 determines pole mass to be 4.72 ± 0.05 using next-to-leading order in $1/m$ in moment sum rule.
[20] NARISON 89 determines the Georgi-Politzer mass at $p^2{=}{-}m^2$ to be 4.23 ± 0.05 GeV using QCD sum rules.
[21] REINDERS 88 determines the Georgi-Politzer mass at $p^2 = -m^2$ to be 4.17 ± 0.02 using moments of $\overline{b}\gamma^\mu b$. This technique leads to a value for the mass of the B meson of 5.25 ± 0.15 GeV.
[22] NARISON 87 determines the pole mass to be 4.70 ± 0.14 using QCD sum rules, with $\Lambda(\overline{\rm MS}) = 180 \pm 80$ MeV.
[23] GASSER 82 uses SVZ sum rules. The renormalization point is μ = quark mass.

$m_b - m_c$ MASS DIFFERENCE

The mass difference $m_b - m_c$ in the HQET scheme is 3.4 ± 0.2 GeV (see the "Note on Quark Masses").

VALUE (GeV)	DOCUMENT ID	
• • • We do not use the following data for averages, fits, limits, etc. • • •		
≥ 3.29	[24] GROSSE	78

[24] GROSSE 78 obtain $(m_b - m_c) \geq 3.29$ GeV based on eigenvalue inequalities in potential models.
