3aSC6. The long-term retention of phonetic categories by Japanese immersion graduates. Tetsuo Harada (School of Education, Waseda Univ., 1-6-1 Nishi Waseda, Shinjuku, Tokyo 169-8050, Japan)

English-speaking children in a Japanese immersion program, in which many content subjects are taught in Japanese, were reported to be successful in establishing phonetic categories for single and geminate stops in Japanese, although their categories deviated from those of Japanese monolinguals. However, it is unknown to what extent those children can retain their phonetic categories after they exit the program. Ten participants who had attended a Japanese immersion program in the United States from kindergarten or grade 1 to grade 5 and who were taking a university-level intermediate or advanced Japanese course at the time of data collection were recorded producing Japanese words including both singletons and geminates. Mean closure duration values were obtained, and the ratio of geminates to singletons for the immersion graduates was compared with that of English learners of Japanese having the same proficiency level in a regular Japanese program. The results show that the immersion graduates, who had been exposed to a substantial amount of Japanese at an early age, still retained the phonetic categories and could contrast singletons with geminates in Japanese, although their closure duration tended to be longer than the norm of monolingual Japanese speakers.

3aSC7. The effects of training context on perceptual learning of accented speech. Jessica E. Duke and Sabrina K. Sidaras (Dept. of Psych., Emory Univ., Atlanta, GA 30322)

This study investigates factors influencing adult listeners' perceptual learning of talker-specific and accent-general properties of spoken language. Exposure to foreign accented speech under different training con-

ditions was used to examine mechanisms involved in perceptual learning. Adult native speakers of American English were exposed to English words produced by six native-Spanish-speaking adults. During training, the Spanish-accented words were either grouped by speaker, by word, or were randomized with respect to speaker and word. The different types of training were hypothesized to direct attention to particular characteristics of the accented speech. At test, listeners were asked to transcribe novel words produced by familiar or unfamiliar accented speakers. Regardless of training condition, listeners who had been exposed to Spanish-accented speech during training were more accurate at test than an untrained control group. However, high variability training in which words were randomized led to better transcription performance at test than training with items grouped by speaker or by word. These findings suggest that high variability training may direct attention to the accent-general properties of speech necessary for perceptual learning of accented speech.

3aSC8. Development and validation of an automatic spoken Spanish test.
Nicole Wilson, Elizabeth Rosenfeld, and Jared Bernstein (Ordinate Corp., 800 El Camino Real, Menlo Park, CA 94025)

The development and validation of a fully automatic computer-based test of spoken Spanish is described. The test takes between 15 and 20 min to complete and comprises readings, elicited imitations, opposites, short-answer questions, sentence constructions, and story retellings. The only response modality is spoken Spanish. Sets of vetted items were assembled into tests presented to over 1000 adult non-native Spanish learners and over 1000 native Spanish speakers from several countries. Expert human judgments of the non-native responses showed that the spoken response material carried sufficient information for highly reliable judgments of proficiency. In the development and validation process, over 60 000 responses were transcribed and over 21 000 human judgments were analyzed. The automatic scoring system is described. Its validation includes comparisons of machine scores with interactive human interviews and human ratings of speech recordings. Results suggest that machine scores have virtually the same information that is found in Oral Proficiency Interviews conducted by the U.S. Government raters or by official ACTFL interviews. Correlation between machine scores and combined interview scores ($r = 0.92$) is higher than the interrater reliability of the professional interviewers themselves.

3aSC9. French conversations do not show evidence of phonetic accommodation to a non-native interlocutor.
Caroline Smith (Dept. of Linguist., Univ. of New Mexico, MSC 03 2130, 1 Univ. of New Mexico, Albuquerque, NM 87131-1196)

Although a speech style known as foreigner talk has been described, speech addressed to a reasonably fluent non-native interlocutor may show little or no accommodation by native speakers. This issue is of interest in understanding whether on-line modifications to speech are an important contributor to phonetic variation. Ten native speakers of Parisian French were recorded individually as they performed map tasks, one with another native speaker of French, and another with an American who identified himself as such at the beginning of the conversation, but who spoke French during the task. Previous work has found that French listeners who heard brief extracts from these conversations could not reliably identify which interlocutor was involved. In an attempt to identify other possible differences in speech to natives and non-natives, two prosodic characteristics of the conversations were analyzed, vowel devoicing and the epenthesis of word-final schwas. The hypothesis was that vowel devoicing, which is stylistically marked, would be disfavored in speech to non-natives, while schwa epenthesis, characteristic of a deliberate speech style, would be more frequent. The speakers actually showed similar patterns with both interlocutors, suggesting that variation in these properties is not conditioned by the linguistic status of the interlocutor.

3aSC10. Acoustic correlates of accentedness and intelligibility of Spanish-accented English vowels.
Lynne C. Nygaard, Sabrina K. Sidaras, Jessica E. Duke, and Stig T. Rasmussen (Dept. of Psych., Emory Univ., Atlanta, GA 30322)

The present study investigated the acoustic characteristics of English vowels produced by native speakers of Spanish and the relationship between the acoustic properties of non-native vowel production and perceived accentedness and intelligibility. Twelve native speakers of Spanish were recorded producing monosyllabic words in list format. Individual vowel tokens from a variety of consonant environments were identified and acoustic analyses were conducted, including measures of duration and formant (F1, F2, F3) frequency. Listener ratings of accentedness and intelligibility were obtained from a separate set of sentence-length utterances. The analyses showed that average overall vowel duration as well as the duration of individual vowels was positively correlated with judgments of accentedness and negatively correlated with overall sentence intelligibility. Speakers who were judged to be more accented and less intelligible produced vowels of longer duration than speakers who were judged to be less accented and more intelligible. Analyses of spectral characteristics and comparisons to native English speakers' vowel productions will also be reported. These findings suggest that the temporal properties are one aspect of non-native vowel productions that significantly contribute to the perception of accentedness as well as to the overall intelligibility of individual native Spanish speakers.

3aSC11. Factors influencing L2 vowel perception and production.
Karece Lopez (Dept. of Speech, Commun. Sci., & Theatre, St. Johns Univ., 8000 Utopia Pkwy, Jamaica, NY 11439), Yan Helen Yu (CUNY Grad. School, New York, NY), and Fredericka Bell-Berti (St. Johns Univ., Jamaica, NY 11439)

This study investigates relations among factors expected to influence vowel perception and production in second language learning, including AoA, LoR, L2 education (before coming to and in the US), and language use (in the US). Vowel production will be examined through phonetic transcription, listener identification, and acoustical analysis. Preliminary evidence indicates that, even though our participants arrived in the US after age 12, AoA is still of critical importance in second language learning. Furthermore, and as expected, LoR also contributes to L2 proficiency. AoA and LoR, however, do not account for the ability of all the participants to identify and produce the vowels of English; thus, we must also consider other factors, including L2 education and use. The hypothesis is that L2 educational background and language use influence L2 English speakers' perception and production of English vowels.

3aSC12. Production of English stressed vowels and interstress intervals within and between words in first and second language acquisition.
Michiko M. Sudo and Ikuyo Kaneko (School of Health and Sports Sci., Juntendo Univ., 1-1 Hiragagakuendai, Inbamura, Inbagun, Chiba, 270-1695, Japan, mmsudo@polka.plala.or.jp)

The purpose of this study was to observe the differences between first and second language acquisition in English durational patterns with respect to interstress intervals (ISIs). Production experiments were carried out to investigate the durational patterns used by three groups of speakers: adult native speakers of American English, American third graders, and Japanese learners of English. Two sets of English sentences were devised as the linguistic material, and the sentences in each set differed in the number of nominally unstressed syllables that intervened between a target stressed syllable and the next stressed syllable. These sets of sentences contained two different target stressed vowels, and the ISIs within and between words. The shortest ISIs were produced by adult American speakers regardless of the number of unstressd syllables in the target ISIs. The Japanese learners produced shorter ISIs than the American children in one set of sentences, while in the other set, the American children produced

shorter ISIs than the Japanese. Regarding the durations of target stressed vowels, foot-level shortening was observed in the three subject groups, the American children exhibiting the highest percentage of shortening followed by the American adults and then the Japanese.

3aSC13. Production and perception of American English vowels by native Japanese speakers. Takeshi Nozawa (Ritsumeikan Univ., 1-1-1 Nojihigashi, Kusatsu, Shiga, 525-8577 Japan), Elaina M. Frieda (Auburn Univ., Auburn, AL 36849), and Ratree Wayland (Univ. of Florida, Gainesville, FL 32611-5454)

Native speakers of Japanese (NJ) produced American English vowels in /CVC/ contexts. Twelve native speakers of American English listened to and identified the vowels in the Japanese speakers' productions. In general, the vowels difficult for the NJ subjects to disambiguate in production were also difficult for them to differentiate in perception. An acoustic analysis revealed that the NJ speakers' attempted /i/ and /ɪ/ tokens and /ɑ/ and /ʌ/ tokens largely overlapped in the vowel space, but significant differences in duration were observed between their /i/ and /ɪ/ tokens. These findings agree with the results of our previous studies. In our perception experiment, /ɑ/-/ʌ/ was the most difficult vowel contrast for the same group of NJ speakers to discriminate, and longer /i/ tokens were more correctly identified and shorter /i/ tokens were misidentified more often as /ɪ/. In contrast to the perception experiment, the intelligibility of American English vowels produced by the NJ subjects was not affected by the place of articulation of the preceding consonant or by the voicing status of the following consonant. However, the American English vowels produced by the NJ subjects were less intelligible when a liquid /l/ follows, which may be attributed to their inability to produce /l/ authentically.

3aSC14. Durational characteristics in production of English consonant sequences by Japanese speakers. Kuniyoshi Tanaka (Grad. School of Humanities, Hosei Univ., 2-15-2 Ichigayatamachi, Shinjuku-ku, Tokyo 162-0843, Japan, tanaka22@abox.so-net.ne.jp) and Keiichi Tajima (Hosei Univ., Chiyoda-ku, Tokyo 102-8160, Japan)

Japanese has more limited consonant sequences (e.g., "honda," "nissan") than English (e.g., "script"). This difference becomes a problem for Japanese learners of English when they produce English words that contain consonant sequences. Japanese speakers often avoid these sequences by inserting epenthetic vowels between consonants or following word-final consonants (e.g., English "script" as /su.ku.ri.pu.to/). The present study examines how Japanese speakers produce consonant sequences in English and how speaking rate affects their productions. A group of native Japanese speakers and a control group of native English speakers read English words at normal and slow speaking rates. Segment durations in target consonant sequences were measured, and ratios of segment to word duration and segment to consonant sequence duration were calculated. Preliminary results suggest that the segment durations and ratios are clearly different between the two groups of speakers. For example, in /s/ + consonant sequences, Japanese speakers tend to produce a relatively shorter /s/ and a longer consonant compared to native English speakers. Also, the duration ratios do not seem to vary depending on the speaking rate for either group of speakers. Results will be discussed in terms of timing control in second-language learning. [Work supported by MEXT.]

3aSC15. The speech learning model: English and Japanese voice onset time in mature bilingual talkers. Timothy J. Riney (Intl. Christian Univ., Tokyo, 181-8585, Japan)

With reference to the Speech Learning Model (Flege, 1995 version), this study looked for evidence among mature American and Japanese bilinguals that (a) L1 VOT changed over time and (b) despite minimal L1-L2 phonetic differences, L2 VOT was different from L1 VOT. Five L1 English Americans and 5 L1 Japanese read the same lists of English and Japanese words containing word initial /p/, /t/, and /k/. In all, 880 tokens

(10 talkers ×2 languages ×11 words ×4 tokens) were examined. For both groups and individuals, based on measures of difference and comparisons with age-matched monolinguals (5 American and 13 Japanese), the findings were (a) slight evidence of L1 VOT change, but (b) robust evidence of new L2 categories being formed. By far the most common bilingual pattern observed was L2 compromise VOT, in which the L1 VOT remained close to monolingual VOT and the L2 VOT was positioned about halfway between that of two age-matched monolingual comparison groups.

3aSC16. Phonetic disambiguation by Korean non-native speakers of English. Jiwon Hwang and Giorgos Tserdanelis (Dept. of Linguist., Stony Brook Univ., NY 11794, gtserdanelis@sunysb.edu)

This study examined the effect of pragmatic contrast and auditory priming on the production of contrasts such as "mob∼mop" and "pat∼pet" by 22 Korean non-native speakers of English. Korean speakers played a card arrangement game with a native speaker of English (a confederate). In the pragmatic condition, critical items were arranged to enable the comparison of the same word (e.g. "mob") in two contexts, one where the situation might force subjects to make the contrast of mob and mop and one where the situation facilitates the confederates recognition of mob because there is no contrasting form. An additional auditory priming condition was induced by the confederate saying a phonetically similar word such as "what is below hob?" before the target "mob." Koreans produced more English-like forms when they had to be distinguished from the contrastive item or when they had been auditorily primed. For both b/p and ae/E contrasts, vowel duration was used to signal the distinction in both conditions. Additionally, for the b/p contrast, closure voicing percentage was significantly longer but only in the pragmatic condition. Overall both conditions have similar disambiguating effect, but have different specific consequences for cueing consonant versus vowel contrasts.

3aSC17. Phonetic similarities between English and Korean sibilants: Implications for second language acquisition. Sang Yee Cheon (Dept. of East Asian Lang. and Lit., Univ. of Hawaii at Manoa, 1890 East West Rd., #352, Honolulu, HI 96822)

Recent models of L2 acquisition suggest that foreign accent is determined by the degree of articulatory, acoustic, and perceptual similarity between L1 and L2 sounds. This study examined cross-language perceptual and acoustic similarities between Korean and English voiceless sibilant fricatives: Korean lax aspirated /s/ and tense unaspirated /s*/ versus English alveolar /s/ and palato-alveolar /ʃ/. AX discrimination tests revealed that listeners perceived the non-native contrast in terms of their L1 sound system. To determine acoustic similarity among the fricatives, two acoustic parameters were measured: duration and spectral peak frequency. It was expected that the more acoustically similar two sounds were, the more they would be perceived as the same sound by listeners. However, disparate results were obtained for perceived similarity and acoustic similarity. For instance, Korean lax /s/ and English /ʃ/ before /i/ are acoustically similar, but listeners were easily able to discriminate between them. Perceptual similarity predicts ease of acquisition better than acoustic similarity because a listener's perceptual system incorporates how the sounds are organized in their L1 phonological system. Language teachers need to consider not just degree of similarity between pairs of sounds, but also the differences between the L1 and L2 sound systems as a whole.

3aSC18. Cross-language speech sounds: Differential sensitivity and L2 accent. Miles Munro (Dept. of Cognit. Sci., Univ. of California, Irvine, 3151 Social Sci. Plaza A, Irvine, CA 92697-5100, mmunro@uci.edu)

Individuals vary in their ability to perceive phonetic differences between speech sounds. Individuals also vary in their aptitude for acquiring accurate pronunciation of a second language. The research to be presented

investigates a probable link between the two with the aim that capacity for phonetic perception may constitute a measure of second language aptitude. In a series of tasks manipulating memory and attention load, Native Mandarin speakers for whom English is a second language were tested on their ability to discriminate non-native speech contrasts that cluster around the Mandarin and English phonetic spaces with varying "distances." Each contrast pair is phonemically meaningful in a significant portion of the world's languages (UPSID 451). These scores were then related to measures of degree of accent in English. Related results examining working memory span will also be reported. Accordingly, an explanation of variability in later-learner L2 accent strength is explained as a consequence of idiosyncratic ability to perceive phonetic differences between speech sounds. This cognitive correlate's account is consistent with the notion that a greater ability to perceive small differences between novel phones is crucial to their accurate acquisition and reproduction.

3aSC19. Performance of auditory search with Japanese speech by native speakers and its learners as L2. Noriaki Asemi (Grad. School of Sci. Technol., Kobe Univ., Rokkodai 1-1, Nada-ku, Kobe, 657-8501 Japan, asemi@kobe-u.ac.jp), Ryoko Hayashi (Kobe Univ., Kobe, Japan), and Kazuhiko Kakehi (Chukyo Univ., Toyota, Japan)

Auditory search experiments using normal Japanese speech (NJS) and time-reversed speech (TRS) [Asemi *et al.*, Acoust. Sci. Technol., **24**, 145–147 (2003)] demonstrated fast and accurate judgment of the presence or absence of the target NJS among distracting TRSs. For application of an auditory search to measurement of the ability of auditory comprehension of foreign language, the effects of the learning proficiency of Japanese on the speed and accuracy in the detection of the target NJS were examined through auditory search experiments for native and non-native speakers of Japanese. The experiment comprised two parts: an NJS was the target and TRSs were distractors and vice versa. Subjects were requested to judge the presence or absence of a target speech correctly and as quickly as possible when a target and several distracters were presented simultaneously and diotically. Results showed remarkable differences between the performance of natives and non-native speakers in error rates rather than in the reaction times. Moreover, significant correlations were found between the error rates and the learning experiences only when fewer than three utterances were presented simultaneously. [Work supported by MEXT.]

3aSC20. Neurophysiological basis of temporally cued phonetic contrasts in Japanese and American English listeners. Miwako Hisagi, Valerie Shafer (CUNY-Grad. Ctr., Dept. of Speech and Hearing Sci., 365 Fifth Ave., New York, NY 10016, mhisagi@hotmail.com), and Elyse Sussman (Albert Einstein College of Medicine of Yeshiva Univ., New York, NY)

The present study examined American English (AE) listeners' perception of Japanese (JP) temporally cued contrasts of vowels and consonants. The mismatch negativity (MMN) component of event-related potentials (ERPs) was used as a measure to compare passive (visual-attention condition) and active (auditory-attention condition) discrimination in an oddball paradigm. JP nonsense temporally cued vowel ([tado] vs [taado]) and consonant contrasts ([miʃi] vs [miʃʃi]) were presented to JP listeners, for whom the temporal cues are contrastive, and to AE listeners who have no knowledge of JP. The following results were obtained. (1) With respect to the type of contrast, MMNs were larger for vowel contrasts than consonant contrasts. (2) In the auditory-attention condition both groups showed a robust MMN to vowels. (3) In the visual-attention condition JP also showed a robust MMN, while AE showed a smaller amplitude or absent MMN. This group difference was significant for the vowel contrast. (4) Interestingly, in the auditory-attention condition, AE showed a larger late negativity at frontal sites for vowel contrasts than JP. The results support the hypothesis that first-language perception is an overlearned process that may interfere with second-language speech perception. [Work supported by NSF.]

3aSC21. Vowel perception in second language acquisition. Mariche Garcia Bayonas (Dept. of Romance Lang., at Greensboro, Univ. of North Carolina, 2314 HHRA Bldg., UNCG, P.O. Box 26170, Greensboro, NC 27402-6170)

This study investigates the perception of ten English and five Spanish vowels by native-speakers (NS) and learners (L) at two levels of acquisition, and compares these vowels cross-linguistically. Research on the acquisition of vowels indicates that learners can improve their perception with exposure to the second language (L2) [Bohn and Flege (1990)]. Using Flege's (1995) Speech Learning Model as a theoretical framework, this investigation incorporated a method of adjustment (MOA) task [Johnson *et al.*, (1993)] used to analyze NS perception and production data, to add the dimension of the L2 learner data. The research question was: Are vowels selected differently by NS and L in an MOA task depending on level of proficiency? Spanish learners ($n = 40$) and English learners ($n = 80$) completed MOA tasks in which they were exposed to 120 synthetically produced vowels to analyze spectral variation in the acquisition of both sound systems, and how the learners vowel system may vary from that of the NS. In the MOA tasks they were asked to select which synthesized vowel sounds most resembled the ones whose spelling was presented to them. Results indicated that vowels are selected differently by NS and L, but there are differences among vowels.

3aSC22. Multidimensional category-goodness-difference assimilation of Canadian English /i/ and /ɪ/ to Spanish /i/. Geoffrey Stewart Morrison (Dept. of Linguist., Univ. of AB, Edmonton, AB, T6G 2E7, Canada, gsm2@ualberta.ca)

Morrison [J. Acoust. Soc. Am., **117**, 2401 (2005)] theorized that L1-Spanish learners of English initially identify the Canadian English /i/-/ɪ/ contrast via a multidimensional category-goodness-difference assimilation to Spanish /i/, with more-Spanish-/i/-like vowels (shorter vowels, lower F1 and higher F2) labelled as English /ɪ/ and less-Spanish-/i/-like vowels (longer vowels, higher F1 and lower F2) labelled as English /i/. The L1-Spanish listeners' use of duration is positively correlated with L1-English speakers' productions, but their use of spectral cues is negatively correlated; hence, exposure to English results in increased use of duration cues and reduced use of spectral cues, leading to unidimensional duration-based perception. Since, in L1-English speakers' productions, spectral properties are partially correlated with duration properties, L2-English learners can use duration-based perception as a bootstrap for learning L1-English-like spectral-based perception. Results from a new study are presented. Unlike the previous study, synthetic stimuli in the new study included vowel inherent spectral change (VISC). Results were consistent with the theory above: Vowels that were poor matches for Spanish /i/ because they had converging-VISC were labelled as English /i/, and vowels with no VISC were labelled as English /ɪ/. [Work supported by SSHRC.]

3aSC23. Multiple cue interpretation in non-native phoneme perception: Korean listeners' perception of English /s/ in varied prosodic contexts. Miran Kim (Dept. of Linguist., SUNY at Stony Brook, Add., S201, SBS Bldg, Stony Brook, NY 11794-4376, mrkim@ic.sunysb.edu)

This paper investigates prosodic influences on the non-native perception of English /s/ by Korean listeners, whose phonemic system includes a two-way distinction of fricative, plain /s/ vs. fortis /s*/. English stimuli varied in lexical stress and prosodic domain appear to be relevant to the Korean listeners perceptual responses such that more /s*/ responses to stimuli are obtained with more strengthening effects such as lexical stressed and phrase boundary initial position. Analyses of the relation

between the spectral properties of the stimuli and perception shows that prosodic effects on /sV(C)/ syllables are compatible with the characteristics that have been reported as critical attributes in the distinction of plain and fortis fricatives in Korean. Spectral measurements include F0, H1-H2 (dB), and H1-F2 (dB) values of postfricative vowels, together with the spectral characteristics of frication noise. The relation between prosodic strength in the stimuli and Koreans /s-s*/ perceptual responses implies that Korean listeners interpret prosodic information associated with English /s/ as a part of the segmental properties of English /s/ instead of attributing them to prosodic effects. This leads us to conclude that phonetic information is not limited to a segment-to-segment or prosody-to-prosody transmission, but it can be overlapped in multiple phonetic dimensions.

3aSC24. Identification of English consonants by Korean students.
Byunggon Yang (English Education Dept., Pusan Natl. Univ., 30 Changjundong, Keumjunggu, Pusan 609-735, South Korea)

Previous studies have shown that Korean students have difficulty identifying some English consonants that are not in the Korean sound inventory. The aim of this study was to examine the accuracy score of English consonants correctly identified by 130 college students in order to find out English consonants with listening problems for the Korean students. The subject's task was to identify one of the minimal pairs played in a quiet laboratory classroom. One hundred minimal pairs consisted of syllables with various onsets or codas: stops, fricatives, affricates, liquids, and nasals. Results were as follows: First, types of the correctly identified English consonants varied according to the level of each student's total score. Second, the lower the group level, the lower the accuracy score for each consonant group divided by its manner. Third, those consonants in coda position of the test words were more difficult for the students to identify than those in onset position. Fourth, the subjects showed lower accuracy in the perception of any contrast with a fricative onset or coda. Finally, the students still had problems telling voiced from voiceless consonants, especially in coda position. Future studies will focus on examining students' production data to trace their listening problems.

3aSC25. Identification of English /r/ and /l/ in noise: The effects of baseline performance. Kazuo Ueda (Dept. Appl. Inf. and Commun. Sci., Kyushu Univ., 4-9-1 Shiobaru, Minamiku, Fukuoka 815-8540, Japan, ueda@design.kyushu-u.ac.jp), Ryo Komaki, and Takahiro Adachi (ATR, Soraku-gun, Kyoto 619-0288, Japan)

The effects of baseline performance on identification of English /r/ and /l/ in noise by Japanese listeners were examined. Japanese and American listeners' perception of /r/ and /l/ was measured under various signal-to-noise ratios. Each Japanese listener's baseline performance was also observed with an identification test with a large set of stimuli. Generally, the signal-to-noise ratio had a similar effect across Japanese listeners of different baseline performances, although the overall accuracy was dominated by the baseline. When 15 days of /r/-/l/ identification training in quiet were applied to a group of Japanese listeners, the training effect generalized to identification performance in noise. However, the performance of Japanese listeners did not reach the level that the native listeners exhibited. [Work supported by JSPS and 21st Century COE, Kyushu University.]

3aSC26. Effects of learners' L2 proficiency and acoustic/semantic contexts of stimuli on the phoneme identification training. Yuko Ikuma and Reiko Akahane-Yamada (ATR, 2-2-2, Hikaridai, Seika-cho, Soraku-gun, Kyoto, 619-0288, Japan)

Former studies investigated that word recognition by L2 learners is affected by both acoustic and semantic contexts [Rothwell and Akahane-Yamada, J. Acout. Soc. Am. **112**, 2386 (2002)]. It was also shown that these two context effects lead to different achievement in perception train-

ing [Ikuma and Akahane-Yamada, J. Acout. Soc. Am. **115**, 2393 (2004)]. In this study, native speakers of Japanese were trained to identify English /r/ and /l/ within words or sentences. L2 proficiency level for each trainee was also measured by a short written test regarding vocabulary and grammar. Results showed that training with semantically contextual stimuli improved the identification accuracy for stimuli with semantically contextual cues, but not for stimuli without semantic cues. Furthermore, the L2 proficiency level correlated only with the improvement in identification accuracy of target phonemes embedded in the semantically contextual sentences. These results suggest that L2 learners tend to use semantic cues rather than difficult acoustic cues. However, semantic context may moderate the effect of auditory perception training. Thus, training with semantically neutral stimulus is necessary to improve perception ability even for high proficiency level learners. [Work supported by JSPS.]

3aSC27. Asymmetry in discrimination of an American English contrast, /l-r/, by adult Japanese learners of English. Teruaki Tsushima (Ryutsu Kagaku Univ., 3-1, Gakuen-Nishi-Machi, Nishi-Ku, Kobe, 651-2188, Japan)

The present study provided further evidence on an asymmetry in discrimination of an American English contrast, /l-r/, by Japanese listeners. Experiment 1 ($N=14$) examined stimulus order effects in discrimination of the contrast in the AX discrimination procedure with an ISI of 300 and 1500 ms, using naturally produced stimuli. The results showed discrimination accuracy was significantly lower when /l/ was followed by /r/ than otherwise, under the ISI of 1500 ms. Experiment 2 ($N=17$) examined whether discrimination significantly differed when a typical /l/ was paired with an ambiguous /r/ and vice versa, using synthesized stimuli from a ten-step continuum (i.e., stimulus 1-7 and 4-10). The participants were tested on their identification of the stimuli, and discrimination of the stimulus pairs with the ISI of 300 and 1500 ms. The discrimination sensitivity (i.e., d'), based on the identification performance, was not significantly different between the two pairs. In the discrimination test, however, the sensitivity was significantly lower in the pair including the typical /l/ than in the other, under the ISI of 1500 ms. The results support the hypothesis that categorization of a relatively nativelike speech stimulus (i.e., /l/) in a discrimination task may induce some perceptual assimilation process.

3aSC28. Context really matters!—The influence of input types on L2 speakers' perception of English liquids. Sally Chen and Janice Fon (Grad. Inst. of Linguist., Natl. Taiwan Univ., 1 Roosevelt Rd., Sec. 4, Taipei 106, Taiwan)

This study aims to investigate how different input types can help improve the perception of language learners on L2 sounds. Twenty-four college students of a remedial English class are divided into three groups and are given audio inputs of different types. The first group listens to a wordlist, the second group to a story incorporating all the words on the wordlist, and the third group to a piece of classical music, serving as the control. The wordlist consists of 56 monosyllabic English words with word-initial liquids or liquid-containing clusters. Before the listening task, all three groups are given an online l/r perception test containing all the words on the wordlist (pretest). After the listening task, the same perception test is again administered, including the original 56 words and another 56 phonotactically matched pseudo-V words (posttest). Both accuracy and reaction time are measured for the two perception tests. Preliminary results showed that all participants had significantly higher accuracy and shorter RT for real words in the posttest. The story group showed the biggest improvement for both measures, followed by the wordlist group. The control showed the least improvement.

3aSC29. Categorization of a sibilant+vowel continuum in Japanese, Mandarin, and English. Terrance M. Nearey, Aya Okamoto, Chunling Zhang, and Ron I. Thomson (Dept. of Linguist., Univ. of AB, Edmonton, AB, T6G 2E7, Canada)

A continuum of 168 synthetic sibilant+vowel stimuli was categorized by listeners of three languages (Japanese, Mandarin, and English). The contoid portion of each stimulus consisted of a 190-ms high-pass filtered white noise whose cutoff frequency varied from 1800 to 3800 Hz in 7 steps. (Signals were low-pass filtered at 8500 Hz before resampling to 22.05 kHz for playback.) Each (cascade formant) vocoid portion was 210 ms in duration varying in three $F1$ levels (from 300 to 430 Hz) crossed with four $F2$ levels (from 850 to 2100 Hz, with fixed $F3$ through $F5$). Each of the 84 noise+vocoid patterns was combined with two different $F2$ transition patterns, designed to slightly favor more alveolar or more palatal fricative responses. Appropriate response sets were determined in pilot studies for each language by native speakers on the research team. Corresponding software was designed to allow computer-controlled categorization. Data collection for 9 Japanese, 20 Mandarin, and 4 English listeners is complete (more is planned). Responses to the stimuli spanned at two or three sibilant and several (high-to-mid) vowel categories in each language. Possible effects of language-specific phonotactics on the response patterns will be discussed.

3aSC30. Perceptual cue learning. Grant McGuire (The Ohio State Univ., 222 Oxley Hall, 1712 Neil Ave., Columbus, OH 43210, mcguire@ling.osu.edu)

This paper describes results from an on-going perceptual training study in which native listeners of English are trained perceive a categorical difference between Polish alveopalatal and retroflex sibilants. The stimuli consist of naturally produced, modified two-dimensional stimuli varying by fricative noise and formant transition cues. Subjects are trained to categorize using only the fricative dimension, formant transition dimension, or both dimensions. Testing consists of a two-alternative forced-choice discrimination paradigm and stimulus labeling. Initial results from pilot work and subjects in the fricative dimension training group demonstrate that some listeners can easily attend to either dimension independently for categorization where training focuses attention and sharpens boundaries while others rely heavily on the vocalic cues, only attending reliably to frication noise cues with several training sessions or through verbal instruction. A handful of subjects did not show any improvement due to training; most of these subjects also showed no initial categorization strategy. Moreover, sensitivity to the fricative dimension and boundary increases for all learners (measured in d'), with no corresponding increase or decrease in sensitivity to vocalic cues. Further results from other training conditions will also be reported. [Work supported by NIH-NIDCD.]

3aSC31. Cantonese and Japanese listeners' processing of Russian onset and coda stops. Alexei Kochetov (Dept. of Linguist., Simon Fraser Univ., 8888 Univ. Dr., Burnaby V5A 1S6, Canada, alexei_kochetov@sfu.ca), Connie K. So (Univ. of Western Sydney, Australia), and Nicole Carter (Simon Fraser Univ., Burnaby V5A 1S6, Canada)

The study investigated influences of native phonological and phonetic knowledge on Cantonese and Japanese listeners' processing of non-native stop consonants. Phonologically, Cantonese Chinese has a three-way place contrast in stops in onset and coda positions; Japanese has a similar contrast, however, only in onset position. Phonetically, Cantonese coda stops are acoustically unreleased; Japanese stops followed by devoiced vowels are acoustically similar to released coda stops in other languages, such as Russian. Two groups of listeners, native speakers of Hong-Kong Cantonese and Japanese, were presented with sequences of Russian voiceless stops (VC1#C2V, where C1/C2=/p/, /t/, or /k/). Two tasks were employed: (*i*) identification of onset or coda stops and (*ii*) discrimination of sequences that differed in either onset or coda consonant. Both groups

performed equally well in the identification and discrimination of onset stops. However, Japanese listeners performed significantly better than Cantonese listeners in the identification and discrimination of coda stops. The findings suggest that in non-native listening, the low-level native phonetic knowledge—the acoustic realization of stop place contrasts—can override the higher-level phonological knowledge—syllable structure constraints on the distribution of place features. [Work supported by Social Sciences and Humanities Research Council of Canada.]

3aSC32. Relationships between the intelligibility and acoustic properties of native English and Mandarin-accented English. Rachel Hayes-Harb (Dept. of Linguist., Univ. of Utah, 255 S. Central Campus Dr., Rm. 2330, Salt Lake City, UT 84112), Bruce Smith (Univ. of Utah, Salt Lake City, UT 84112), Tessa Bent (Indiana Univ., Bloomington, IN 47405), and Ann Bradlow (Northwestern Univ., Evanston, IL 60208)

Studies examining effects of talkers' and listeners' linguistic backgrounds on speech intelligibility have produced mixed results, and relatively little is known about which acoustic-phonetic features of native and non-native speech are responsible for many findings. These issues are addressed here via investigation of how acoustic properties of final consonant voicing contrasts influence word intelligibility. Native English and native Mandarin talkers' productions of English words were presented in isolation to native English and native Mandarin listeners in an identification task. Intelligibility findings were related to preceding vowel duration, stop consonant duration, burst duration, and proportion of voicing during stop closure. As expected, native English listeners were more accurate identifying words spoken by native than non-native talkers. In contrast to previous findings of an interlanguage speech intelligibility benefit (ISIB) for sentences, non-native listeners found native speech more intelligible than non-native speech. However, non-native listeners found non-native speech more intelligible than did native listeners. For native talkers, all four acoustic measures contributed significantly to correct identification of voicing contrasts by both native and non-native listeners (with closure voicing most salient). In contrast, for non-native talkers, listeners tended to rely primarily on closure voicing and burst duration. Ramifications for ISIB will be discussed.

3aSC33. English listeners perceptual assimilations for Zulu sounds: Evidence in support of the articulatory organ hypothesis. Andrea Levitt (Wellesley College, 106 Central St., Wellesley, MA 02481, and Haskins Labs., 300 George St., New Haven, CT 06511, alevitt@wellesley.edu), Catherine Best (Univ. Western Sydney, Penrith South NSW 1797, Australia), Louis Goldstein (Yale Univ., New Haven, CT), and Angela Carpenter (Wellesley College, Wellesley, MA 02481)

The articulatory organ hypothesis predicts that listeners' favored perceptual assimilations for non-native sounds will be native sounds that are produced by the same articulatory organ [L. Goldstein and C. Fowler in *Phonetics and Phonology in Language Comprehension and Production*, 159–207 (2003)]. Using discrimination paradigms, we tested English-speaking, adult listeners' perceptual assimilations for four non-native Zulu consonants to see whether assimilations are stronger for sounds articulated with the same vocal-tract organ or those with the same constriction degree. For each Zulu sound, three possible English-language assimilations were provided: a best match, based on the most frequent consonant assimilation provided by the subjects in a previous study [C.T. Best, G.W. McRoberts, and E. Goodell, J. Acoust. Soc. Am. **109**, 775–794 (2001)], an assimilation match where the consonant uses the same articulatory organ, and one where the consonant uses the same constriction degree as the Zulu target. For example, for the bilabial implosive, the best match was /b/ (same articulator and constriction degree), the same organ match /w/, and the same constriction match /d/. Although there were differences in the patterns of responses to the four sounds, overall the results provided support for the articulatory organ hypothesis predictions.

3aSC34. Learning of non-native tonal contrasts with or without tonal context. Valter Ciocca (Div. of Speech & Hearing Sci., Univ. of Hong Kong, 34 Hospital Rd., Hong Kong, vciocca@hkusua.hku.hk), Alexander L. Francis, and Yanhong Zhang (Purdue Univ., West Lafayette, IN 47907-2038)

The learning of non-native (Cantonese) tonal categories by native speakers of another tonal language (Mandarin) was investigated under two learning conditions. For listeners in the tonal context (TC) group, learning occurred by listening to target tones within various carrier phrases. Listeners in the no-context group (NC) were trained using target tones produced as single words. Training stimuli were produced by the same speakers for both groups. A high-variability procedure with feedback was used for training. Sixteen listeners (eight in each group) took part in eight sessions over a period of about 1 month. Categorical perception of Cantonese tones was measured before training (following a brief familiarization session) and after training. For both groups, tone perception was tested for one level- and one contour-tone continua using identification and discrimination procedures. Identification performance before and after training did not differ between the two groups for the level-tone continuum, showing evidence of learning of the (non-native) mid-level category. For the contour-tone continuum, the TC group showed better learning of the (non-native) low-rising/low-level contrast, as well as better perceptual distinction between low-rising and high-rising tones. [Work supported by Hong Kong RGC Grant HKU 7224/03H.]

3aSC35. Native and non-native identification of acoustically modified Mandarin tones. Chao-Yang Lee (School of Hearing, Speech and Lang. Sci., Ohio Univ., Athens, OH 45701), Liang Tao, and Zinny S. Bond (Ohio Univ., Athens, OH 45701)

Lexical tones have been known to be one of the most difficult aspects of tone languages to master for non-native learners. Extending upon Gottfried and Suiter's study [J. Phonetics **25**, 207–231 (1997)] of tone identification in silent center syllables, four experiments examined how well Mandarin tones can be identified with partial acoustic information and whether native and non-native listeners show differences in the use of the limited acoustic information. Twelve minimal tone pairs including all six tonal contrasts in Mandarin were digitally processed to generate four types of stimuli: silent-center, center-only, onset-only, and intact syllables. The stimuli were presented in the original carrier phrase, excised from the carrier phrase, or excised and pasted onto another carrier phrase. Participants included 40 non-native speakers with 1–3 years of Mandarin instruction at Ohio University and 40 native speakers. Both learners and native speakers could identify the tones under all modification conditions at better than chance levels. For both groups, the onset-only syllables were the most difficult. Tone 2 received the fewest correct identifications and longest response times, being confused with tone 3.

3aSC36. Acoustic correlates of English lexical stress produced by native speakers of Mandarin Chinese. Yanhong Zhang and Alexander L. Francis (Program in Linguist., Purdue Univ., West Lafayette, IN 47907)

Native speakers of Mandarin Chinese have difficulty producing native-like English stress contrasts. Acoustically, English lexical stress is multidimensional, involving manipulation of fundamental frequency (f0), duration, amplitude, and vowel quality. Errors in any or all of these correlates could result in poor realization of the stress contrast, but it is unknown which cues are most problematic for Mandarin speakers. Here we compared the use of these correlates in the production of lexical stress contrasts by 20 Mandarin and English speakers. Results showed that Mandarin speakers produced significantly less acceptable stress contrasts, although they did use all four acoustic correlates to distinguish stressed from unstressed syllables. Mandarin and English speakers' use of amplitude and duration were comparable for both stressed and unstressed syllables, but Mandarin speakers signaled stressed syllables with a higher f0 than English speakers. There were also significant differences in formant

patterns across groups, suggesting that Mandarin speakers were able to achieve appropriate vowel reduction in certain unstressed syllables, but not in others. Results suggest that Mandarin listeners' production of lexical stress contrasts in English is influenced in part by native-language experience with Mandarin lexical tones, and in part by similarities and differences between Mandarin and English vowel inventories.

3aSC37. On the characteristics of English speech timing control by Japanese learners. Hajime Tsubaki, Shizuka Nakamura, and Yoshinori Sagisaka (GITI Waseda Univ., 29-7 Bldg. 1-3-10, Nishi-Waseda, Shinjuku-ku, Tokyo 169-0051, Japan, hjm-tsubaki@asagi.waseda.jp)

This paper introduces analysis results of temporal characteristics of English language uttered by Japanese subjects aiming at automatic evaluation of L2 prosody control. As a preliminary study, 11 sentences uttered by about 200 Japanese children were compared with native's speech. The correlation between subjective scores on temporal naturalness and differences in segmental durations were measured in different speech units at every position for sentence by sentence. A wide range of correlation differences were observed such as from -0.70 to 0.23 at unstressed syllables, from -0.33 to 0.19 at stressed syllables, and from -0.70 to -0.04 at function words. The strongest negative correlation -0.70 at unstressed syllables and at function words reflects L1 characteristics of mora-timing characteristics of Japanese. Further analysis results will be given at the conference with additional huge L2 speech database currently under construction. [Work supported in part by Waseda Univ. RISE research project of "Analysis and modeling of human mechanism in speech and language processing" and Grant-in-Aid for and Scientific Research A-2, No. 16200016 of JSPS.]

3aSC38. Acquisition of Japanese pitch-accent by non-native speakers. Tomoko Kozasa (Dept. of Linguist., California State Univ., Fresno, 5245 N Backer Ave., M/S PB92, Fresno, CA 93740-8001)

Vowel duration and $F0$ movement in Japanese pitch-accented words produced by non-native speakers were investigated. Phonemic vowel length and pitch accent are two prosodic properties of Japanese that are problematic for language learners. The vowel length distinction is typically realized by durational differences, and pitch accent involves $F0$ movement from high to low within an accented word. Equal numbers of target words and filler words were produced by 50 speakers by repeating after audio recorded Japanese sentences one at a time. The stimulus sentences were uttered by a native speaker of Tokyo Japanese. Speakers were randomly divided into two groups. For group A, a visual stimulus indicating the native speaker's pitch contour for the target word appeared right after each audio stimulus. Speakers were instructed to follow the visual stimulus as they produced the target word. No visual stimulus was provided to group B. A sufficient durational distinction between long and short vowels was produced by both groups. However, group B failed to produce adequate amount or direction of $F0$ movement. These results suggest that explicitly showing pitch contour to language learners improves their pronunciation of pitch accent.

3aSC39. Native speakers and Korean-speaking advanced learners of English show similar discrimination of English prosodic contours. Hyekyung Hwang and Amy J. Schafer (Dept. of Linguist., Univ. of Hawaii, 569 Moore Hall, 1890 East-West Rd., Honolulu, HI 96822, hyekyung@hawaii.edu)

Previous studies of native versus non-native perceivers argue that phonology can shape perception (e.g., Huang, 2001; Hume et al., 1999). The phonological inventory of prosodic phrasing contours differs between Korean and English. Phonologically, Korean accentual phrases have final rises (within intonation phrases), although this varies at the phonetic level, while English intermediate phrases (ips) can end in falling, rising, or level contours. Previous work has suggested that advanced learners (L2ers) use

ips markedly less effectively than native speakers (L1ers) to recover English syntactic structure (Hwang and Schafer, 2005). This study investigated whether that is due to perceptual differences. L1ers and L2ers listened to pairs of phrases in an AX task that crossed boundary strength (same versus different size) with contour: rising (L*L*H-) versus level (L*L*L- or L*L*) or falling (H*H*L-) versus level (H*H*H- or H*H*). Little variation was found between L1ers' and L2ers' discrimination, and L2ers' discrimination patterns correlated highly with L1ers' ($r = 0.966$). For both groups a falling-level contrast was more salient than a rising-level contrast (in the context tested) and boundary strength contrasts were more difficult than contour contrasts. The results suggest that the L2ers' poor use of ips in comprehension is likely due to difficulty with prosody-syntax mappings.

3aSC40. The effect of phonological knowledge on word learning in second language acquisition. Junko Maekawa (Dept. of Speech-Lang.-Hearing, Univ. of Kansas, 1000 Sunnyside Ave., 3001 Dole Ctr., Lawrence, KS 66045-7555, junko@ku.edu)

Past research in first language (L1) acquisition suggests that phonological knowledge (individual sounds and sound sequences) influences word learning. In second language (L2) word learning, phonological knowledge is dependent on the mapping of L2 sounds to L1. This study explores how the L2-L1 phonological mapping affects L2 word learning for native speakers of Japanese learning English. The learners phonological knowledge was explored through a perceptual discrimination task (same-different task) and a production probe containing English real words and nonwords. L2 word learning was explored through exposure to novel words and comprehension and production testing. The results of the same-different task showed that r-l and θ-s contrasts were the most difficult to perceive, supporting findings from past research. For the production probe, w, t, and s were produced more accurately than r, l, and θ in both real words and nonwords. For L2 word learning, nonwords with w, t, and s were learned more rapidly than nonwords with r, l, and θ in production, but not comprehension. Taken together, phonological knowledge appears to constrain L2 word learning for language expression, but not comprehension. This mirrors the findings for L1 acquisition.

3aSC41. Context effects in recognition of English disyllabic word and nonwords by native and non-native listeners. Robert Felty (Dept. of Linguist. and German, Univ. of Michigan, 3110 Modern Lang. Bldg., 812 E. Washington St., Ann Arbor, MI 48109-1275) and José Benkí (Univ. of Michigan, Ann Arbor, MI 48106)

30 native (L1 = English) and 30 non-native (L1 = German) speakers listened to English CVCCVC words and nonwords mixed with noise. Of the words, half were monomorphemic and half bimorphemic. The j-factor model [Boothroyd and Nittrouer, J. Acoust. Soc. Am. **84**, 101–114 (1988)] was used as a measure of lexical context effects. For both native and non-native speakers, words showed greater context effects than nonwords, though the difference was not as large for non-native speakers. Monomorphemic words also exhibited greater context effects than bimorphemic words, though only for native speakers. In an items analysis, a negative correlation with j was found for lexical frequency and a positive correlation for neighborhood density, for both native and non-native speakers, though more pronounced in native speakers. Misperceptions between native and non-native speakers were also compared, with non-native speakers showing patterns predictable by phonological differences between the two languages. The j-factor results extend previous research using CVC stimuli, providing additional support for its efficacy as a measure of context effects. The differences (and lack there of for non-native speakers) between mono- and bimorphemic words are interpreted as evidence in support of a combinatorial model of lexical access. [Work supported by NIH/NIDCD.]

3aSC42. Recognizing English words by Japanese speakers. Kiyoko Yoneyama (Dept. of English, Daito Bunka Univ., 1-9-1 Takashimadaira, Itabashi, Tokyo, 175-8571, Japan, yoneyama@ic.daito.ac.jp)

Japanese listeners are influence by word frequency and neighborhood density (Yoneyama, 2002) as in other languages such as English. Interestingly, non-native listeners are also affected by word frequency and neighborhood density when they recognize English (e.g., Bradlow and Pisoni, 1999; Imai *et al.*, 2005). Based on the previous studies of neighborhood density by non-native listeners, Yoneyama (2006) investigated whether Japanese listeners learning English employ two types of lexical information (word frequency and neighborhood density) when they recognize English words, as in Imai *et al.* (2005). The results were different from the ones of Imai *et al.* (2005). Japanese listeners were sensitive to both probabilistic phonotactics and word frequency. A strong correlation between probabilistic phonotactics and neighborhood density still predict Japanese listeners can be influenced by neighborhood density in English word recognition. A critical difference between Yoneyama (2006) and Imai *et al.* (2005) is that they did not use the exact same materials, although Yoneyama (2005) selected the words as described in a conference paper of an earlier version of Imai *et al.* (2005). This study reports the results of the experiment in which the materials of Imai *et al.* (2005) were used.

3aSP1. Application of a microphone array to the automatic structuring of meeting recordings. Futoshi Asano, Jun Ogata, and Yosuke Matsusaka (AIST, Central 2 1-1-1 Umezono, Tsukuba, Ibaraki 305-8568, Japan)

A microphone array system applied to the automatic structuring of meeting recordings is introduced. First, speakers in a meeting are identified at every time block (0.25 s) by sound localization using a microphone array, and then the speech events are extracted (structuring). Next, overlaps and insertions of speech events such as "Uh-huh," which greatly reduce the performance of the automatic speech recognition, are separated out. The difficulty in eliminating overlaps and insertions is that the overlapping sections are sometimes very short, and data sufficiently long for conventional separation techniques, such as independent component analysis, cannot be obtained. In this system, a maximum-likelihood beamformer is modified so that all the information necessary for constructing the separation filter, such as speaker location and spatial characteristics of noise, are estimated from the recorded data based he structuring information. Evaluation of the performance of the speech event separation by automatic speech recognition is also presented.

3aSP2. Eigenbeam beamforming for microphone arrays. Jens Meyer and Gary W. Elko (mh acoustics LLC, 25-A Summit Ave., Summit, NJ 07901)

In this talk, we describe a beamforming spherical microphone array consisting of many acoustic pressure sensors mounted appropriately on the surface of a rigid sphere. The associated beamformer is implemented in a two-stage process: a first stage that decomposes of the sound-field into spatially orthonormal spherical harmonics, which are called eigenbeams, and a second stage that combines the eigenbeams to form the overall output beampattern. It is shown that this approach allows for a computationally efficient, flexible, and scalable beamformer structure. As an example of beamforming flexibility, an acoustic zoom feature will be described. This application enables continuous variability of the beamwidth in a simple and elegant manner. Simultaneously, the array beam-pattern can be steered without affecting the beampattern shape. There are many applications for such a feature, one being the coordination of the acoustic and image scenes of microphone and a video camera.

8:45

3aSP3. Effect of low independency on independent component analysis and countermeasures against it. Hidefumi Kobatake (Tokyo Univ. of Agriculture and Technol., 3-8-1, Harumi-cho, Fuchu 183-8538, Japan, kobatake@cc.tuat.ac.jp) and Xuebin Hu (Fuji Photo Film Co., Ltd., Chuo-ku, Tokyo 104-0061, Japan)

Independent component analysis (ICA) is extensively adopted in blind signal separation (BSS). It works well in general. However, processing must be made at every short-time interval and, as a consequence, the assumption of independency cannot always hold due to insufficient data length. This local low-independency can be the cause of degradation in the overall separation performance. In this paper, two approaches to solve that problem caused by local low-independency between source signals are presented. The first one is the combination of ICA-based BSS with beamformer (BF). The BF does not depend on the independence assumption. In the proposed method, ICA and BF are applied in parallel. The frequency components separated by those methods are evaluated by each other and the frequency bin with higher segmental similarity measure is adopted. The second one is a kind of TDD method with a recursive algorithm. A criterion on the performance of separation is introduced. The proposed method has a function to improve the separation filter characteristics recursively. Experiments to evaluate the performance of those methods and demonstrations are given.

3aSP4. Some current challenges in multichannel acoustic signal processing. Walter Kellermann (Univ. Erlangen Nuremberg, Cauerstr. 7, 91058 Erlangen, Germany, wk@LNT.de)

Hands-free human/machine communication involves major challenges for today's state of the art signal processing if the humans should not be forced to carry or wear any technical gear and should be free to move. The spatial domain sampled by multiple loudspeakers for reproduction and multiple microphones for signal acquisition allows for spatialized listening experiences and for

3a THU. AM

spatially selective acoustic scene analysis, respectively. Along with the possibility to serve several human communication partners simultaneously, such systems also introduce the need for localization algorithms. Three main types of impairment have to be addressed by signal processing algorithms to fulfill the promises of the general concept: first, acoustic feedback from the loudspeakers into the microphones; second, ambient noise and undesired pointlike interferers; and, finally, echoes and reverberation as picked up by the human ear when listening to the loudspeaker signals or as recorded by the microphones that actually should record only the direct-path component of the source signal. Accordingly, some of the current challenges in multichannel acoustic echo cancellation, in spatially selective noise and interference suppression, in source separation and localization, and in dereverberation are investigated.

9:25

3aSP5. Sound source tracking for security camera using sensor array utilizing object-related transfer function. Tsuyoshi Usagawa, Toshimichi Takada, and Yoshifumi Chisaki (Grad. School of Sci. and Technol., Kumamoto Univesity, 2-39-1 Kurokami, Kumamoto 860-8555, Japan, tuie@cs.kumamoto-u.ac.jp)

A frequency-domain binaural model has been proposed as a computer model of human auditory system, and it can estimate the direction of arrival (DOA) of target sound source with only two inputs [Nakashima *et al.*, Acoust. Sci & Tech. **21**, 172–178 (2003)]. It utilizes a database of interaural level and phase differences obtained from head-related transfer function (HRTF) for DOA estimation. Since the interaural level and phase differences arise from the diffraction of head, similar ones can be obtained from the diffraction of an object, such as a transparent cover of security camera. In this paper, a source tracking method which utilizes an object-related transfer function is proposed. Three sensors attached on a dome-shaped camera cover are used, and the interchannel level and phase differences obtained from object-related transfer function are used for DOA estimation. The performance of sound source tracking is discussed based on the accuracy of DOA estimation as well as observation latency by the computer simulation. [Research partially supported by the MEXT, Grant-in-Aid for Scientific Research (C), 2006, 18500135 and carried out by the Cooperative Research Project Program of the RIEC, Tohoku University (Grant #H16.A02).]

3aSP6. Low-complexity design schemes for broadband electroacoustic arrays. Michael Goodwin (Creative Adv. Technol. Ctr., 1500 Green Hills Rd., Ste. 205, Scotts Valley, CA 95066, mgoodwin@atc.creative.com)

A variety of methods has been described in the literature for realizing broadband linear electroacoustic arrays, i.e., arrays which exhibit a nearly frequency-invariant response. For example, filter-network beamformers can be designed to achieve a specified beam pattern over a wide frequency range. Some applications, such as low-cost consumer audio products, do not involve strict target pattern requirements and call for lower complexity broadbanding solutions. In this presentation, three broadband array design approaches with low processing overhead and implementation cost are described. The key idea is to configure the array such that its response is essentially a magnification of the response of an individual element; the array geometry and beamformer are designed so as to not introduce directionality. In the first method, the array weights are an approximation of the impulse response of an all-pass filter; in the second method, the array elements are nonuniformly spaced; and, in the third method, arbitrary delays are applied to the elemental signals. Relationships to approaches previously described in the literature are discussed, optimization schemes based on minimizing the array response variation are presented, and the effectiveness of the array designs for realizing a robust broadband wide-angle response is demonstrated.

3aSP7. Three-dimensional microphone array intensity vector sensors for measurement of various acoustical properties in different spatial environment. Khalid H. Miah and Elmer L. Hixson (Univ. of Texas, Austin, TX 78712, miah@mail.utexas.edu)

Precise measurement of different acoustical quantities in different spatial environment has been the key in improving sound-quality and reducing acoustical noise from various sources. In this report, a seven-element 3-D microphone array configuration has been used to measure different acoustical quantities (pressure, particle velocity vectors, intensity vectors, energy density, kinetic and potential energy) in various enclosed environments. Microphones in the array were arranged in an inner and an outer triangular fashion with a reference microphone at the center to address high frequency (1–6 kHz) and low frequency (100–1000 Hz) components of sound signals. Statistical distribution of acoustic field has been used for measurements in large and irregular-shaped room. Statistical distribution of acoustical field using a four-microphone configuration implemented in a previous study (M. W. Budhiantho, Acoustic Velocity Related Distributions dissertation, The University of Texas at Austin, August 1997) has been extended to a seven-microphone configuration in this report. An effort has been made to model acoustical field near the boundaries of an enclosed space (reverberation room). Also 3-D imaging technique of acoustic intensity is also presented in this report.

3aSP8. Acoustic source localization with eye array. Hedayat Alghassi, Shahram Tafazoli, and Peter Lawrence (Dept. of Elec. and Comput. Eng., University of British Columbia, Vancouver, BC V6T 1Z4, Canada, hedayata@ece.ubc.ca)

A novel signal-processing algorithm and array for sound source localization (SSL) in three-dimensional space is presented. This method, which has similarity to the eye in localization of light rays, consists of a novel hemispherical microphone array with 26 microphones on the shell and one microphone in the sphere center. The microphones on the shell map a geodesic hemisphere called two-frequency icosahedron; hence, each microphone has at least four other orthogonal microphones. A signal-processing scheme utilizes parallel creation of a special closeness function for each microphone direction on the shell in the time domain. Each closeness function cell (lens cell) consists of center microphone, shell microphone, and one of its orthogonals. The closeness function output values are linearly proportional to spatial angular difference between the sound source direction and each of the shell microphone directions. By choosing microphone directions corresponding to the highest closeness function values and implementing a linear weighted spatial averaging on them, the sound source direction is estimated. Contrary to traditional SSL techniques, this method is based on simple parallel mathematical calculations

in the time domain with low computational costs. The laboratory implementation of the array and algorithm shows reasonable accuracy in a reverberant room.

10:50

3aSP9. Bayesian space-time processing for acoustic array source estimation using a towed array. James V Candy (Lawrence Livermore Natt. Lab., Univ. of California, P.O. Box 808, L-156, Livermore, CA 94551) and Simon J. Godsill (Univ. of Cambridge, Cambridge CB2 1PZ, UK)

The development of a model-based Bayesian processor for a horizontally towed array using synthesized narrow-band, spatio-temporal data is discussed. The basic processor is developed from the Bayesian perspective, capturing the bearing estimation problem of acoustic sources moving in a surveillance volume. Far-field sources characterized by simplified random motion as well as nonlinear measurement models representing the array motion and propagation of the source signatures contaminated by noise are incorporated into the processor. The entire dynamical system is cast within a Bayesian framework aimed at estimating the underlying posterior filtering distribution of the bearing in a pseudo real-time environment. It is shown that the resulting sequential Bayesian processor is capable of dynamically estimating the instantaneous posterior distribution enabling the extraction of the bearing estimates. The problem solution involves the estimation of the posterior using sequential importance sampling/resampling leading to the development of a particle filter for this problem. The particle filter is simply an empirical representation of the posterior characterized by the weights (probability) and location variables (particles). It is shown how the particle filter successfully extracts the desired signals comparing the results to classical nonlinear processors (e.g., extended/unscented Kalman filters) for this problem.

11:05

3aSP10. A design of array-microphone system using pressure-gradient microphones and two-dimensional finite impulse response filters. Hiroyuki Naono (Matsushita Tech. Information Services Co., Ltd., 25-10 Nishiyama Adachi Yawata city, Kyoto 614-8351 Japan, yql07401@nifty.ne.jp) and Kiyoshi Nishikawa (Kanazawa Univ., Kakuma, Kanazawa-shi, 920-1192 Japan)

Delay-and-sum array microphones consisting of a linear array of microphones can achieve sharp directivity at high frequencies. A disadvantage is that the directivity is frequencydependent. An array microphone using a fan filter is proposed to resolve that problem. However, it is necessary to increase the filter order to form a sharp beam at a low frequency. This paper is reported improvement of the array microphone directivity, realizing a narrow beam with a low order of the filter using a two-dimensional frequency domain design. Using four microphones, a second-order pressure-gradient microphone is formed. The spacing of the microphones is set for high sensitivity and broad bandwidth in the operating frequency range. These microphone units are placed along a line and are cascaded to a two-dimensional fan filter so that the load is distributed. In

the proposed configuration, the second-order pressure-gradient microphone is cascaded with an axially symmetric fan filter. The configuration thereby forms a single broadside beam. Consequently, the directional characteristics of the pressure-gradient microphone are reflected in the array microphone and a sharp directivity, which is frequencyindependent, is obtained over a wide frequency range.

3aSP11. Pressure-sensitive paint as a distributed optical microphone array. James W. Gregory[a], John P. Sullivan (School of Aeronautics and Astronautics, Purdue Univ., 315 N. Grant St., West Lafayette, IN 47907, jim.gregory@alumni.purdue.edu), Sameh S. Wanis, and Narayanan M. Komerath (Georgia Inst. of Technol., Atlanta, GA 30332)

Pressure-sensitive paint is presented and evaluated in this paper as a quantitative technique for measurement of acoustic pressure fluctuations. This work is the culmination of advances in paint technology, which enable unsteady measurements of fluctuations over 10 kHz at pressure levels as low as 125 dB. Pressure-sensitive paint may be thought of as a nanoscale array of optical microphones with a spatial resolution limited primarily by the resolution of the imaging device. Thus, pressure-sensitive paint is a powerful tool for making high-amplitude sound pressure measurements. In this work, the paint was used to record ensemble-averaged, time-resolved, quantitative measurements of two-dimensional mode shapes in an acoustic resonance cavity. A wall-mounted speaker generated nonlinear, standing acoustic waves in a rigid enclosure measuring 216 mm wide, 169 mm high, and 102 mm deep. The paint recorded the acoustic surface pressures of the $(1,1,0)$ mode shape at 1.3 kHz and a sound pressure level of 145.4 dB. Results from the paint are compared with data from a Kulite pressure transducer and with linear acoustic theory. The paint may be used as a diagnostic technique for ultrasonic tests where high spatial resolution is essential, or in nonlinear acoustic applications such as shock tubes. [a] Currently at the Dept. of Aeronautics, U.S. Air Force Academy.

3aSP12. Performance of an infrasound source localization algorithm. Curt Szuberla, Kenneth Arnoult, and John Olson (Geophysical Inst., Univ. of Alaska Fairbanks, 903 Koyukuk Dr., Fairbanks, AK 99775-7320)

We present a performance analysis of a method of acoustic source localization based on time difference of arrival (TDOA) information for an arbitrary array of sensors. The method begins with the construction of a vector containing estimates of time delays for each unique sensor pair in the array via cross correlation. An optimization in the space of geographic location and sound speed is then conducted to minimize the difference between the observed vector and one calculated from a search in that space. The technique uses an analytic method of seeding based on the acoustic analog of a light cone. The source localization procedure is tested as a function of a number of parameters, including array aperture, number of sensors, sample rate, signal-to-noise ratio, and signal type. The technique is shown in application to real and synthetic infrasound signals and its statistical behavior is given.

3aUWa1. Seafloor manipulative experiments during sediment acoustics experiments (SAX99 and SAX04. Michael D. Richardson (Marine Geosciences Div., Naval Res. Lab., Stennis Space Center, MS 39529-5004) and Kevin L. Williams (Univ. of Washington, Seattle, WA 98105-6698)

Seafloor manipulations were performed during Sediment Acoustics Experiments (SAX99 and SAX04) in an attempt to test predictions of high-frequency acoustic backscattering models in sandy environments. Manipulations included alteration of seafloor roughness by raking to mimic the effects of sand ripples on acoustic scattering and placement of marbles, aluminum disks, and shells on the seafloor at different densities to mimic the effects of shelled animals and sand dollars on acoustic scattering (discrete surface scattering). In general, the predictions from scattering models and measured acoustic backscatter strengths were in agreement and the experimental results provide insight into natural phenomena. [Work supported by ONR.]

8:00

3aUWa2. A simple model for time-dependent scattering by changing seafloor roughness. Darrell R. Jackson, Kevin L. Williams, Christopher D. Jones (Appl. Phys. Lab., Univ. of Washington, 1013 NE 40th St., Seattle, WA 98105-6698, drj@apl.washington.edu), Michael D. Richardson, Kevin B. Briggs (Naval Res. Lab., Stennis Space Center, MS 39529-5004), and Anthony P. Lyons (Appl. Res. Lab., State College, PA 16804-0030)

The roughness of sandy seafloors is constantly changing due to biological and hydrodynamic activity. Even when these processes are in equilibrium so that the average acoustic backscattering intensity does not change, the character of successive backscatter echoes changes on time scales from minutes to days, with strong frequency dependence. This change can be characterized by the temporal correlation of the backscattered signal between consecutive pings, expressed as a lag-dependent correlation coefficient. A simple model for roughness change has been developed based upon the diffusion equation. This model assumes that newly created roughness is uncorrelated with existing roughness. It predicts exponential decay of the correlation with e-folding time $1/(DK_B^2)$, where K_B is the Bragg wave number, and D is the horizontal diffusivity. During SAX99 and SAX04, photographic and acoustic observations were made of changing natural and artificially generated roughness. The acoustic observations were made at 40 and 300 kHz, with the higher frequency exhibiting much more rapid decorrelation as predicted by the model. The diffusivities obtained by fitting the model to photographic and acoustic data ranged from roughly 10^{-9} to 10^{-10} m^{2}s^{-1} with the highest diffusivities found at locations where bottom-feeding fish were active. [Work funded by ONR.]

8:15

3aUWa3. Using forward scattering from a rippled sand/water interface to determine its flat surface reflection coefficient: Validation via simulation and use in testing sediment models. Kevin Williams (Appl. Phys. Lab., Univ. of Washington, 1013 NE 40th St., Seattle, WA 98105-6698, williams@apl.washington.edu)

Real-world sediments are inherently rough. At high frequencies (greater than 10 kHz) the roughness is typically sufficient to eliminate any coherent reflection at all but very shallow grazing angles. However, simulation results will be shown that demonstrate that an ensemble average of a large number $[O(50)]$ of forward-scattered signals from different regions of a rippled sand/water interface can be used to estimate the flat surface reflection coefficient for the interface. With this validation in hand, a forward scattering experiment carried out during a sediment acoustics experiment in 2004 (SAX04) will be described. The flat surface reflection coefficients derived from this experiment will be compared with predictions using a fluid and a Biot model for the sand sediment. This comparison indicates that a Biot sediment model is a more accurate predictor for the reflection coefficient. [Work supported by ONR.]

8:30

3aUWa4. High-resolution mapping and backscatter studies in support of the Ripples Program. Barbara Kraft, Christian de Moustier, Brian Calder, and Larry Mayer (Ctr. for Coastal and Ocean Mapping, Univ. of New Hampshire, 24 Colovos Rd., Durham, NH 03824, bjkraft@ccom.unh.edu)

The long-term goal of the Office of Naval Research's RIPPLES DRI is to develop the ability to predict the geometry and evolution of seabed morphology, particularly the presence or absence of ripples which have been shown to affect the sub-seabed penetration of acoustic energy. In support of the RIPPLES and SAX04 programs, high-resolution, multifrequency, multibeam mapping surveys were completed during September and October 2004 within three small areas off Destin, FL. The first survey was completed prior to Hurricane Ivan and followed the burial of minelike targets in the SAX04 field area. The second survey occurred during the SAX04 experiments approximately 6 weeks after Hurricane Ivan made landfall. Ripples were not observed in the bathymetric data from the first survey. Some small-scale features are present in the bathymetry from the second survey; however, most of the ripples generated by Hurricane Ivan had degraded by the time the survey was completed. Large-scale ripple features are present in the bathymetric data that extend off-shore from the SAX04 area. Difference maps of the pre- and post-Hurricane Ivan bathymetry and the acoustic backscatter data show remarkable evidence of sediment deposition and erosion. [Work supported by ONR Grant N00014-04-1-0624.]

3aUWa5. Doppler spreading of aircraft harmonics in a shallow-water channel off Kauai. David Barclay and Michael J. Buckingham (Marine Physical Lab., Scripps Inst. of Oceanogr., UCSD, 9500 Gilman Dr., La Jolla, CA 02093-0238)

In September 2005, during the Makai experiments off Kauai, a light aircraft acted as a moving sound source over a shallow-ocean channel with a coral-sand bottom. Core samples yielded the porosity, bulk density, grain density, and grain size of the sediment. Acoustic sensors (a microphone in the air and a line of hydrophones in the isovelocity water column) recorded the sound of the aircraft as it flew over the sensor station. At least five engine/propeller harmonics, from 80 to 400 Hz, are present in the spectra of the hydrophone signals. Each harmonic exhibits Doppler spreading, with well-defined spectral peaks appearing on either side of the unshifted frequency. Those peaks with the greatest (up- and down-) shifts are associated with the shallow equivalent rays of normal modes in the water column. Two head-wave peaks, associated with slightly steeper rays, are less up- and down-shifted. Least shifted of all, because of their steep equivalent rays, are peaks due to modes supported by the sea surface and the subbottom, a few meters beneath the seabed. The spectral structure in the Doppler-spread harmonics is the basis of Doppler spectroscopy, an inversion technique for recovering the geoacoustic parameters of the seabed. [Research supported by ONR.]

3aUWa6. Using buried vector sensors to examine seabed layering in sandy sediment. Paul C. Hines, John C. Osler, Jeff Scrutton, David M.F. Chapman (Defence R&D Canada Atlantic, P.O. Box 1012, Dartmouth, NS, Canada, B2Y 3Z7), and Anthony Lyons (The Penn State Univ., State College, PA 16804-0030)

There is considerable interest within the underwater acoustics community in quantifying the sound-speed dispersion in sandy sediments at low kiloHertz frequencies. To address this, data were collected during the SAX04 experiment (a US Office of Naval Research Departmental Research Initiative) using projectors and directional (vector) receivers buried in the top 1 m of the seabed, in conjunction with a water-borne source directly above the buried sensor field. Although using buried sensors significantly increased the complexity of the experimental setup, it should enable a direct time-of-flight measurement of acoustic wave speed, which simplifies interpretation of the results. However, initial analysis of the time-of-flight results indicates the existence of a buried layer, which increases the complexity of the data. In this paper, the vector sensors are used to steer beams to confirm the existence of the layer and to isolate the direct and reflected arrivals to improve the estimate of sound speed dispersion. [Work partially funded by US Office of Naval Research.]

3aUWa7. Estimation of received pulse from sea bottom with a transition layer using elastic finite difference time domain method. Takenobu Tsuchiya and Nobuyuki Endoh (Faculty of Eng., Kanagawa Univ., 3-27, Rokkakubashi, Kanagawa-ku, Yokohama, Japan)

Recently, ocean acoustic thermometry is being planned in shallow water. Characteristics of sound propagation in shallow water are influenced by bottom media because sound propagation is affected by acoustic boundary conditions of the water-sediment interface. To investigate characteristics of sound propagation in shallow water, it is necessary to develop an accurate numerical method to model sound propagation. Elastic finite difference time domain method (elastic FDTD) is very accurate and is useful for range-dependent models in shallow water. Therefore, we calculate the sound waveform reflected from the sea bottom with a transition layer in shallow water using elastic FDTD. It is assumed that a 1.5-kHz transducer is placed at 50-m depth. The influence of the sea bottom with the transition layer is calculated for a 400-m range. To determine the influence of thickness of the transition layer to sound propagation, we calculate sound pulses as transition layers of varying thickness. Results show that fluctuation of the pulse amplitude depends on the transition layer thickness if the thickness is greater than one wavelength. A sea bottom with a transition layer clearly affects sound propagation in shallow water.

3aUWa8. Stability of compressional waves in granular media. B. Edward McDonald (Naval Res. Lab., Washington, DC 20375)

Nonlinear compressional waves in a granular medium such as the seafloor are subject to the Hertzian nonlinearity of order 3/2 in the strain rate. As a result, the coefficient of quadratic nonlinearity becomes arbitrarily large at low stress. Two theoretical problems result from the Hertzian nonlinearity: (1) lowest order nonlinearity in the equation of state is no longer quadratic and (2) questions of stability arise when nonlinear steepening occurs arbitrarily fast. A variant of the NPE [McDonald and Kuperman, J. Acoust. Soc. Am. **81**, 1406–1417 (1987)] is used to derive a stability theorem for self-similar waves in a granular medium subject to three-dimensional perturbations. When the dominant nonlinearity is of order n between 1 and 3 (n is not necessarily an integer), the result suggests that wave stability is positively correlated with n. The method of characteristics is used to show that where the coefficient of nonlinearity diverges, the wave slope is forced to zero. [Work supported by the Office of Naval Research.]

3aUWb1. Benchmarking range-dependent seismo-acoustic propagation problems. Peter L. Nielsen, Finn B. Jensen, Mario Zampolli (NATO Undersea Res. Ctr., 19138 La Spezia, Italy), Michael D. Collins (Naval Res. Lab., Washington, DC 20375), and William L. Siegmann (Rensselaer Polytechnic Inst., Troy, NY 12180)

Developing the capability to accurately solve range-dependent problems in ocean acoustics has been going on for many years. A milestone in this development was the ASA benchmark effort in 1990 [J. Acoust. Soc. Am. **87**, 1497–1545 (1990)], where a set of models was applied to generic range-dependent acoustic fluid problems to establish a set of benchmark solutions for model verification purposes. A further benchmarking effort, which included shear waves in the bottom, was published in 1997 [IEEE J. Ocean. Engn. **22**, 226–236 (1997)] involving two seismo-acoustic codes based on spectral-integral techniques and a boundary-element code. Other codes have become available since then for solving general range-dependent elastic problems, either based on marching schemes that ignore backscattering (or adopt a single-scatter approximation) or techniques that solve the full boundary-value problem. In an attempt to establish a set of benchmark solutions for seismo-acoustic problems, we solve several low-frequency elastic problems involving changing bathymetry in multiple layers, and coupling between various wave types, including interface waves. The models in use or used are a parabolic equation model (RAM) and a commercial finite-element model (FEMLAB).

10:15

3aUWb2. Bathymetric and oceanic variability effects on acoustic propagation metrics in a shelf-break environment. Roger Oba (Acoust. Div., Naval Res. Lab., Washington, DC 20375)

The interaction of oceanographic variability and bathymetry on acoustic propagation in the littoral is quite complex, and the relative importance is not readily quantified, especially for data-model comparisons. Sound speeds derived from ocean models could be compared directly to experimental sound-speed data, but this is a crude measure of environmental impact on acoustics. Instead, a 300-Hz source in a three-dimensional parabolic equation (PE) acoustic propagation model provides input to proposed acoustic metrics, especially related to array performance, to assess the effects of experimentally derived bathymetry and tide. The metrics can also be used for comparison of an ocean model and experimentally derived sound-speed profiles. Other acoustic mode metrics can be derived and compared to the more computationally intensive three-dimensional PE derived measures. As an example, the Navy Coastal Ocean Model (NCOM), a mesoscale oceanographic model, predicts sound-speed gridded on the order of 5 m in depth and 200 m in range at 6-h updates for the ASIAEx South China Sea site. This can then be used for metric calculations and data-model comparison. [This research is sponsored by the ONR.]

10:30

3aUWb3. Adaptive predictive-error optimal gridding. Donald R. DelBalzo and Lisa A. Pflug (Planning Systems Inc., 40201 Hwy. 190 E, Slidell, LA 70461)

Transmission loss computations in littoral areas often require a dense spatial and azimuthal grid to achieve acceptable accuracy and detail. The computational cost of accurate predictions in complex areas can be unacceptable for some Naval applications. EAGLE (Efficient Adaptive Gridder for Littoral Environments) was developed to reduce the computational requirements by adapting the fundamental calculation grid to the natural environmental structure. EAGLE produces a nonuniform grid structure within which the underlying data have approximately constant spatial uncertainty, or iso-deviance. The EAGLE point-selection approach is based on a predictive-error metric and least-squares polynomial curve fitting with arbitrary order. This research indicates the degree to which EAGLE grids are related to the underlying coherence properties of the natural environment. The results show significant efficiency enhancements compared to uniform grids of the same accuracy, when the environmental coherence properties are used to control the polynomial order. [Work sponsored by NAVAIR.]

10:45

3aUWb4. The effect of an ocean front on sound propagation in shallow water. Ying-Tsong Lin, Arthur E. Newhall, and James F. Lynch (Woods Hole Oceanogr. Inst., Woods Hole, MA, 02543, ytlin@whoi.edu)

From a perspective of sound propagation, a sloping bottom found in typical shallow-water environments can cause propagating sound to horizontally refract offshore. Additionally, an offshore ocean front can cause horizontal reflection/refraction shoreward. Combining these two effects, sound tends to propagate along the front, and "whispering gallery" modes can be observed. To model this effect, we first derived an analytic solution for the sound field using a point source in a rigid wedge environment that has a front placed offshore. The analytic solution gives us clear physical insight into this problem. For a more complicated environment, we exploited a 3-D acoustic propagation program in the ACOUSTICS TOOLBOX, which uses a vertical mode and horizontal Gaussian beam method. This model shows sound energy trapped ahead of the front with observable frequency and modal dependence. Also, when including the foot of the front, which is commonly seen on the continental shelf and extends inshore along the bottom, the model shows less modal attenuation, which raises the level of the trapped energy.

3aUWb5. Asymptotic expansions for normal modes in transparent wedge. Nick Maltsev (Guzuk Tech. Enterprises, 2443 Wyandotte St., Mountain View, CA 94043)

Asymptotic solutions of exact infinite system of equations for coefficients of angular Fourier harmonics of sound field have been built and computed for an arbitrary transparent wedge. Asymptotic solutions are compared with exact field in the case of two half-spaces and a rectangular wedge.

3aUWb6. Polynomial chaos expansions as extended Markov approximations in the propagation of uncertainty. Dennis Creamer (P.O. Box 660537, Arcadia, CA 91066)

The use of polynomial chaos for incorporating environmental variability into propagation models has been previously investigated where it was found that low-order expansions work quite well when the medium correlation length in the direction of propagation was small, i.e., the Markov approximation is roughly valid. It was suggested that an iterative scheme incorporating extensions of the Markov approximation might be useful. Using the method of successive approximations introduced by Klyatskin and Tatarskii (who used the method for investigating the validity of the Markov approximation), we show how the polynomial chaos equations can be written as a (smaller) set of equations that are basically nested expansions in the correlation function. This allows the use of a closure scheme, which does not involve truncating the expansion and which seems to be simpler to use. Comparisons are made between the approximation schemes in a geometrical optics limit.

3aUWb7. Polynomial chaos expansions for travel time and amplitude uncertainty in acoustic time series in ocean waveguides. Kevin D. LePage (Naval Res. Lab., Code 7144, 4555 Overlook Ave SW, Washington, DC 20375)

Polynomial chaos (PC) techniques have shown themselves to be a powerful technique for the estimation of the statistical properties of ocean acoustic propagation for situations where the vertical and horizontal structure of sound speed uncertainty can be specified in terms of empirical orthogonal functions (EOFs) with known amplitude probability distribution functions. Here we extend the CW solutions for the statistical properties of the normal models describing the acoustic field in the presence of internal waves with Gaussian distributed EOF descriptions to the time domain to describe the scintillation of the acoustic time series. Results are compared to exact solutions as well as to estimates based on the adiabatic approximation. Results show that the PC solutions do a much better job of capturing the true variability of the exact solutions for the time series variability than the adiabatic approximations does. [Work supported by ONR.]

3aUWb8. The propagation of acoustic field uncertainty in an ocean waveguide having finite correlation length sound speed variations. Steven Finette (Acoust. Div., Naval Res. Lab., Washington, DC 20375)

While the physical laws governing wave propagation in ocean waveguides are well understood, the appropriate wave equations typically depend on parameters, fields, boundary, and initial conditions that are, at best, only partially known in any given environment. Incomplete environmental knowledge concerning these quantities is a form of uncertainty that should be characterized and quantified in any simulation-based prediction scheme involving the acoustic field. This talk focuses on the quantification of uncertainty in ocean waveguide propagation using a probabilistic formulation in which both the sound speed and acoustic fields are represented by stochastic basis expansions. An example is discussed for the case of an ocean waveguide with separable depth and range correlation functions describing the sound speed field. The relationship between this example and the propagation of acoustic field uncertainty in an internal wave field is discussed. [Work supported by ONR.]

3pAAa1. An overview of Leadership in Energy and Environmental Design (LEED) certification and acoustical design: Conflicts and synergies. Daniel C. Bruck (BRC Acoust. & Technol. Consulting, 1741 First Ave. South, Ste. 401, Seattle, WA 98134), David Lubman (14301 Middletown Ln., Westminster, CA 92683), and Louis C. Sutherland (27803 Longhill Dr., Palos Verdes, CA 90275)

The LEED program for green building certification acknowledges the importance of acoustics in building quality and design, but currently does not provide for specific credits in acoustics other than in the Innovation in Design category. This paper presents an overview of the LEED approach to sustainable design and discusses the design categories for LEED certification. Conflicts and synergies between the LEED system and acoustical design are discussed, including specific areas in which acoustics can contribute to sustainable design goals, such as recycled materials, energy efficiency, and interior environmental quality. Steps toward integrating acoustics into the LEED system are proposed, which incorporate elements of the Collaborative for High Performance Schools (CHPS) and ANSI S12.60, Acoustical Performance Criteria, Design Requirements, and Guidelines for Schools. The current direction of the U.S. Green Building Council with respect to incorporating acoustics into the LEED program is also presented.

1:25

3pAAa2. Acoustical lessons from four green buildings. Max Richter, Rosamund Hyde (Stantec, 1100-111 Dunsmuir St. Vancouver, BC V6B 6A3, Canada), and Murray Hodgson (University of British Columbia, V6T 1Z3, Canada)

Between 2002–2004, seven green buildings in British Columbia were studied during a Post Occupancy Evaluation (POE) research effort led by Stantec (formerly KEEN Engineering). Using the occupant satisfaction were survey developed by the Center for the Building Environment at UC Berkeley, data on eight aspects of occupant satisfaction were collected, including acoustical satisfaction. The BC buildings generally followed the trends that can be observed in green building acoustical performance, but none of the buildings scored as satisfactory. This year, Stantec and UBC measured four of the building in the original study to determine the acoustical characteristics of the building spaces. From this subsequent study, conclusions can be drawn about the relative acoustical performance of specific green strategies.

1:45

3pAAa3. Acoustical qualities of three Leadership in Energy and Environmental Design (LEED) certified buildings and why some disappoint. Steven D. Pettyjohn (The Acoust. & Vib. Group, 5700 Broadway, Sacramento, CA 95820-1852)

Obtaining points for acoustical qualities in office building or schools is difficult under the current LEED system. For this reason, the selection of partitions to provide speech privacy or prevent speech interference, the design of HVAC systems to meet background sound or vibration goals, or the inclusion of acoustical materials to provide the desired reverberation time is often either left out from the beginning or the first to be cut when budgets are tight. The results of sound tests done as a part of the commissioning of two office complexes and a new combination school, learning center, and administration building are shared. NIC tests were done on fixed and operable wall assemblies, background sound levels were measured in various spaces when due to mechanical and electrical systems and exterior sources, and reverberation time tests were done in conference rooms, classrooms, offices, and auditoria. The reason design goals were not met in two of the three complexes is related to budget cuts and a misunderstanding of the requirements and their importance to the successful use of the facilities. The commissioning process failed to correct the deficiencies.

<center>2:05</center>

3pAAa4. Acoustical evaluation of six "green" office buildings. Murray Hodgson (Acoust. & Noise Res. Group, SOEH-MECH, University of British Columbia, 3rd Fl., 2206 East Mall, Vancouver, BC V6T 1Z3, Canada), Rosamund Hyde, Blair Fulton, and Max Richter (Stantec Consulting Ltd., Vancouver, BC V6B 6A3, Canada)

As part of a project evaluating the performance of six "green" office buildings, detailed acoustical measurements were made to explain the positive and negative comments of building occupants obtained from a questionnaire survey. The objective was to determine how to design better green buildings. This paper presents an overview of the measurement protocol used, the measurements made, the results, and the lessons learned regarding optimal design.

<center>2:25</center>

3pAAa5. Acoustical evaluation of a "green" office building. Murray Hodgson (Acoust. & Noise Res. Group, SOEH-MECH, University of British Columbia, 3rd Fl., 2206 East Mall, Vancouver, BC V6T 1Z3 Canada), Rosamund Hyde, Blair Fulton, and Max Richter (Stantec Consulting Ltd., Vancouver, BC V6B 6A3, Canada)

As part of a project evaluating the performance of six "green" office buildings, detailed acoustical measurements were made on three floors of an office building in order to explain the positive and negative comments of building occupants obtained by a questionnaire survey. The objective was to determine how to design better green buildings. The building contained public spaces, private/closed offices, and open-plan-office areas. This paper presents details of the measurements performed, the results, and the design lessons learned.

<center>2:45</center>

3pAAa6. An overview of sound environmental aspect of Japan's comprehensive assessment system for building environmental efficiency (CASBEE) certifications. Tetsuya Sakuma and Fumiko Yano (Grad. School of Frontier Sci., The Univ. of Tokyo, 5-1-5 Kashiwanoha, Kashiwa-shi, Chiba 277-8563, Japan, sakuma@k.u-tokyo.ac.jp)

In the worldwide trend towards sustainable buildings, a new system called the Comprehensive Assessment System for Building Environmental Efficiency (CASBEE) has been established in Japan, as well as other existing assessment systems such as BREEM, LEED, GB Tool, etc. In particular, CASBEE is intended to evaluate building performance by a single-number index BEE, which is the ratio of environmental qualities to loadings. Concerning sound environment, three items are included in indoor quality evaluation: (1) noise (background noise, equipment noise); (2) insulation (window opening, wall, heavy/light floor impact sound); and (3) absorption; in addition, one item on noise emission outside the building site is included in environmental loading evaluation. However, there are many unclear points on the settings of items, ratings, and weightings, which will make trouble in practical application. In the last 3 years, several large cities have started a certification system using CASBEE for new large-scale buildings. In this presentation, an overview of the assessment system and the statistics of the city of Yokohama will be presented focusing on sound environmental aspect.

<center>3:05–3:25   Break</center>

<center>3:25</center>

3pAAa7. Achieving acoustical satisfaction in a green building. Ethan Salter, Charles M. Salter (Charles M. Salter Assoc., Inc., 130 Sutter St., Ste. 500, San Francisco, CA 94104), Chuck Davis, and Scott Shell (EHDD Architecture, San Francisco, CA 94110)

The Carnegie Institution's Global Ecology Research Center at Stanford University has garnered many accolades, including the AIA's Excellence in Sustainability Award. This building incorporates many "green" and energy-saving design features, mechanical systems, and materials. The occupants of this facility have given it high marks in U.C. Berkeley's Center for the Built Environment's (CBE) survey of buildings. Staff at the Global Ecology Research Center are shown to be more satisfied with their acoustical environment than occupants of other green buildings surveyed by CBE. Measured acoustical data for speech privacy in open plan and enclosed conference rooms will be presented along with descriptions of acoustical design attributes for the building.

<center>3:45</center>

3pAAa8. Relationship between ventilation, air quality, and acoustics in "green" and "brown" buildings. Alireza Khaleghi, Karen Bartlett, and Murray Hodgson (SOEH-MECH, University of British Columbia, 3rd Fl., 2206 East Mall, Vancouver, BC V6T 1Z3, Canada)

This paper discusses a project involving direct monitoring of ventilation, indoor-air quality, and acoustical quality in "green" and "brown" buildings on the UBC campus. The objective was to determine the relationship between these various environmental factors, and the implications of the results for the ventilation-system concept/design, especially in green buildings. The buildings studied, the measurements performed, and the main results are described. The lessons learned about ventilation design are discussed.

4:05

3pAAa9. Acoustic and thermal evaluation low-cost dwelling, a case study in Curitiba, Brazil. Paulo H. Zannin (Mech. Eng. Dept., Federal Univ. of Parana, Rua Benedicto Berillo Fangueiro, 108, Santa Barbara, Curitiba, Parana, CEP, 81540-420, Brazil) and Eduardo Krueger (Cefet of Parana, Rebouas, Curitiba, PR)

The present paper presents acoustic and thermal performance evaluations carried out in low-cost houses located at the Technological Village of Curitiba. Two dwellings were evaluated, which were built according to different building systems: (1) the building system Batistella, built with prefabricated modules and elements, composed of reforestation wood, and (2) the building system Constroyer, composed of EPS plates, framed in a welded iron mesh, with structural plastering. For the thermal performance evaluation, it was verified that the materials used in the envelope were quite significant for controlling heat gains and losses through the building elements as well as for regulating heat storage. In this case, the system with highest thermal inertia presented better results. Results showed that both building systems had poor acoustic performance, characterized by a low weighted apparent sound reduction index of the facade $R'w = 18$ dB. The German DIN 4109 Norm recommends $R'w = 30$ dB. The weighted apparent sound reduction index measured for internal walls was $R'w = 25$ dB and $R'w = 30$ dB, for the building systems Battistela and Constroyer, respectively. The minimum required by German VDI 4100.

4:20

3pAAa10. Indoor occupant productivity perception and environmental sound measurement correlation. Brian J. Landsbeger, Liangcai Tan, and Xin Hu (Dept. of Mech. Eng., UNLV, 4505 Maryland Pkway, Las Vegas, NV 89154)

Occupant comfort and productivity have gained increasing attention by building owners and managers in comparison with traditional concerns about costs associated with building function and operating efficiency. To properly assess building performance, a comprehensive method for measurement and verification of integrated building performance was developed. Indoor sound, temperature, air movement, humidity, lighting, and air quality were measured for 3 days each in ten office buildings and ten schools. Concurrently, a perception questionnaire was completed by a subset of the occupants in the buildings and schools. The resulting questionnaire data were correlated with the physical measurements to determine what measures or combination of measures most accurately indicate worker perception of productivity variation when working under various environmental conditions. This presentation concentrates on correlation of acoustic measures, including dBA, NC, NCB, RC, and RC Mark II to worker perception of noise effects on productivity variation. Also, worker perception of productivity variation due to all measured indoor environmental factors was examined to determine additive effects and interaction between noise and other environmental factors. An ultimate goal of the study is to produce a method to quantitatively determine expected worker productivity variation based on measurable environmental factors.

3pAAb1. Design of the diffuser with hemispheres using 1:10 and real scale models. Shin-ichi Sato and Jin Yong Jeon (School of Architectural Eng., Hanyang Univ., Seoul 133-791, Korea, s_sato@mac.com)

Sound diffusion by a wall structure is one of the main concerns with respect to the sound quality of concert halls. To quantify the sound diffusion of an actual hall from *in situ* measurements, the relationship between the scattering coefficient and the acoustical parameters measured in the laboratory should be investigated first. In this study, the scattering coefficient and acoustical parameters of the diffusers with hemisphere were investigated. The diameter, density, and the arrangement pattern of the hemisphere were investigated in terms of the scattering coefficient and the parameters obtained from the impulse response including temporal diffusion [H. Kuttruff, *Room Acoustics* (Elsevier Science, London, 1991)]. The results of measurements in 1:10 scale reverberation chamber with the same scale diffusers were verified by real scale results. Sound scattering index for reverberation chamber, which quantifies the scattered sound

field, was proposed. The optimum condition of the hemisphere diffuser specification maximizing the effect of scattering on a sound field was also investigated.

1:20

3pAAb2. Augmented-reality virtual-diffusion system: A tool to evaluate listener comfort. Pedro Novo (Acoust. Res. Ctr., Univ. of Salford, M5 4WT, UK, p.novo@salford.ac.uk)

The augmented-reality virtual-diffusion system presented here aims to evaluate the comfort of a subject listening to a nearby speaker located in a room filled with a diffuse crowd. The main parameter to be studied is sound field diffusion and its relation to comfort. To this purpose a virtual diffusion system, based on electro acoustic transducers mounted on the walls, is employed to actively change the properties of the diffuse sound field. The augmented reality factor is introduced through the interaction of the virtual diffusion system with the acoustics of the room. The present paper presents a brief description of the approach chosen to implement the augmented-reality virtual-diffusion system. Diffusion measurements obtained with both virtual and real diffusers are compared. Results regarding

auditory events location evoked by different sound fields and predictions from a cross-correlation-based binaural model employed to model these results are discussed. Initial results relative to comfort evoked by the different sound fields as well as a possible relation between auditory events location and listener comfort are discussed.

1:35

3pAAb3. Simulation of *in situ* measurement of diffusion and scattering coefficients. Diemer de Vries, Martin Kuster, Naziema Joeman, and Eric Schreurs (Lab. of Acoust. Imaging and Sound Control, Delft Univ. of Technol., P.O. Box 5046, 2600 GA Delft, The Netherlands)

Since it has become clear that simulation of the acoustical properties of a room is not successful unless also nonspecular reflections are taken into account, the determination of diffusion and scattering coefficients of boundary profiles is a hot topic in room acoustics research. Measurement of the impulse response of a boundary along a planar array of microphone positions enables us to calculate these coefficients *in situ*, avoiding the drawbacks of laboratory measurements (necessity of scale modeling, limited value of results for practical situations). Array technology makes it also possible to extrapolate the measured responses to the boundary surface, thus creating an acoustical image of the boundary. Next, scattering objects can be virtually added to this image and the impulse response of the modified configuration at the array position can be obtained by inverse extrapolation. This way, the effect of adding an object to a real environment is simulated in a highly realistic way. For several (virtual) modifications of the original boundary, diffusion and scattering coefficients have been calculated and compared. Also, listening tests have been carried out to assess the perceptual significance of the modifications.

1:50

3pAAb4. Effects of specular and diffuse reflections on perceived music quality. Pattra Smitthakorn, Martin A. Gold, Gary W. Siebein, and Bertram Y. Kinzey, Jr. (School of Architecture, Univ. of Florida, 134 ARCH, PO BOX 115702, Gainesville, FL 32611-5702, pattras@ufl.edu)

The purpose of this study was to investigate the effects of temporal distribution of diffuse and specular reflections on the perceived acoustic qualities of music performance. Sets of impulse responses were designed with different temporal distributions of early acoustic energy (specular and diffuse reflections). Then, three types of anechoic sound sources, orchestral music, trumpet, and piano, were convolved with the designed impulse responses. The results from the listening tests revealed that different room environments were needed to acoustically support different source characteristics: (1) A large number of diffuse reflections arriving within 40 and 80 ms of the direct sound improved perceived intimacy, texture, and overall impression for all sound sources; heightened perceived clarity for trumpet and piano; and reduced perceived glare for trumpet. (2) Diffuse reflections arriving between 80 and 160 ms of the direct sound preserved perceived reverberance and reduced perceived echoes as opposed to specular reflections arriving at the same time period. The results of this study indicate that music performance halls should be designed to include diffuse reflections from surfaces within the 80-ms time period to achieve preferred texture, intimacy, clarity, and overall impression and in the 160-ms time period to reduce echoes.

2:05

3pAAb5. The angular distribution of sound incident on a panel or opening. John L. Davy and Thomas K. John (RMIT Univ., GPO Box 2476V, Melbourne, Victoria 3001, Australia, john.davy@rmit.edu.au)

A theoretical method has been developed for predicting the directivity of the sound that is radiated from a panel or opening excited by sound incident on the other side. This directivity needs to be known when predicting the sound level at a particular position due to sound radiation from

a roof, wall, ventilating duct, or chimney flue. The method uses a two-dimensional strip model and the low-frequency result for a square piston. It was found necessary to use a weighting function in order to account for the angular distribution of the incident sound. Initially a cosine squared weighting function with a weighting angle parameter was chosen and the weighting angle parameter was varied in order to obtain the best agreement with experiment for the particular situation. This talk will describe the theoretical development of weighting functions, which are based on the actual physics of each situation. Situations that are covered include an opening or panel on the surface of a room and an opening at the end of a duct. The method will be compared with published experimental results on the directivity of the forced sound radiation from panels and the sound radiation from openings.

2:20

3pAAb6. Spatial coverage of reflector panels predicted with and without edge diffraction. Jonathan Rathsam, Lily M. Wang (Architectural Eng. Program, Univ. of Nebraska-Lincoln, 247 PKI, 1110 S. 67th St., Omaha, NE 68182-0681), and Rendell R. Torres (Rensselaer Polytechnic Inst., Troy, NY 12180-3590)

This investigation concerns the spatial coverage of reflector panels. The specular reflection zone (SRZ) is the spatial coverage predicted by geometrical acoustics, which is commonly used when designing reflector panels. A more accurate prediction of spatial coverage accounting for edge diffraction from the panels is called the effective scattered zone (ESZ). At higher frequencies, the SRZ and the ESZ are typically similar, but notable differences emerge at lower frequencies. In this study a variety of reflector panel arrays will be examined using a boundary element method (BEM) model based on the Kirchhoff-Helmholtz integral equation. The effective scattered zone is studied as a function of incidence angle, distance from array to source and receiver, and ka, the ratio of panel dimension to wavelength. The authors seek rules of thumb to predict configurations in which the SRZ and ESZ differ most notably. [Work supported by National Science Foundation.]

2:35

3pAAb7. Variable reflection acoustic wall system by active sound radiation. Genta Yamauchi and Akira Omoto (Omoto Lab., Dept. of Acoust. Design, Faculty of Design, Kyushu Univ., Shiobaru 4-9-1, Minami, Fukuoka 815-8540, Japan)

For acoustic design of special spaces such as studios, it might be necessary to realize a diffuse reflection from the specific wall surface. Moreover, this requirement often changes according to the time or situation. In this study, a new acoustic wall system is examined; it is a variable reflection acoustic wall system that can address such strict requirements. This system fundamentally comprises a loudspeaker, a pick-up microphone, and absorbent material. Varying the amplitude of the radiation sound that is picked up by the microphone and reradiated by the loudspeaker mounted behind the absorbing material therefore corresponds to varying the reflection performance of the wall system. Several models are proposed. The measurement results show that the proposed models can realize various absorption characteristics. Additionally, these models can realize various radiation characteristics: diffuse reflection and inclined reflection to a desired direction. Furthermore, the frequency characteristic of simulated radiation is changed, so the proposed system can generate reflection coefficient with intended frequency characteristics. The design of an effective feedback canceller between the pick-up microphones is the subject of ongoing research toward practical use of this proposed system.

2:50

3pAAb8. Helmholtz resonator array for low-frequency sound absorption. SangRyul Kim (Acoust. Lab., Korea Inst. of Machinery and Mater., 171 Jang-dong, Yuseong-gu, Daejeon, 305-343, Korea, srkim@kimm.re.kr) and Yang-Hann Kim (Korea Adv. Inst. of Sci. and Technol., Sci. Town, Daejeon, 305-701, Korea)

An array of Helmholtz resonators is often used for reducing low-frequency noise because of the high performance at its resonance frequency. One of the very attractive characteristics of the resonator array is that its effective frequency band is much wider than what can be obtained by a single resonator. This paper discusses a method of designing a Helmholtz resonator array panel for low-frequency sound absorption. First, various experimental results are introduced and studied. Second, based on the experimental results, a theoretical method is presented that can predict reasonably well the panel's absorption characteristics. Any configuration of resonator arrangement can be treated in the method, while all the resonators may or may not be identical. Comparisons between the predicted and experimental results reveal the accuracy of the proposed method. Finally, a numerical optimization is performed to design the Helmholtz resonator array panel. Some examples of optimal designs under some restrictions are also introduced.

3:05

3pAAb9. Concept of active reverberation box. Hisaharu Suzuki, Akira Omoto, and Kyoji Fujiwara (Kyushu Univ., Shiobaru 4-9-1, Minamiku, Fukuoka 815-8540, Japan)

A concept of a small reverberation box is proposed. This box has an active controller that can control the energy flow direction: it is a controller for the sound intensity. Consequently, the box is useful to measure the absorption characteristics of materials, even in a low-frequency range. The controller can create an arbitrary incident condition towards the materials. The measurement procedure with this "active reverberation box" is assumed as follows: (1) The incident angle of the sound is changed by the controller. (2) Impulse responses are measured in some points. (3) Steps 1 and 2 are repeated many times and impulse responses are averaged in an energy domain. (4) The reverberation time is calculated using the averaged impulse response. (5) Absorption characteristics are calculated by comparing the reverberation time of the empty room. The controller is formulized using a pseudo-Hermitian quadratic form of the sound intensity in the box. Numerical examination is performed using the finite difference time domain (FDTD) method. Experimental results demonstrate the effectiveness of the controller's performance. Availability of the active reverberation box is examined using some conventional measurement methods. Numerical results correspond approximately to the absorption coefficients that were taken in a reverberation chamber.

1:05

3pAB1. Vertebrate vocal production: Themes and variations. W. Tecumseh Fitch (Univ. of St. Andrews, St. Andrews, Fife KY169JP, UK)

Most terrestrial vertebrates produce sound using a vocal system of lungs, larynx, and vocal tract, already in place in lungfish ancestral to all tetrapods. Despite the conservative nature of this basic system, there are a wide variety of modifications of the structure of the vocal system that appear to be linked to vocalization. In addition, several clades have evolved novel vocal production systems, including the avian syrinx and the odontocete nasal sac system. In this overview I will focus on the "standard" vertebrate system, discussing modifications of the vocal folds to produce high-pitched (e.g., bats and some primates) or low pitched (e.g., roaring cats) vocalizations, showing endoscopic videos of such unusual vocal folds in action. Moving to the vocal tract, a number of anatomical modifications result in vocal tract elongation, thus lowering formant frequencies. The flexible, dynamic nature of the mammalian vocal tract is illustrated with cineradiographs of vocalizing mammals. Finally, I will discuss the enigmatic existence of air sacs attached to the larynx or vocal tract. Vocal air sacs have evolved in parallel in many different species, in all classes. Despite a variety of plausible hypotheses, the function(s) of these air sacs remains poorly understood.

3pAB2. Simulation of Siberian tiger vocalization. Ingo R. Titze, Fariborz Alipour (The Univ. of Iowa, Iowa City, IA 52242; Natl. Ctr. for Voice and Speech, The Denver Ctr. for the Performing Arts, Denver, CO 80204), Wm. Tecumseh Fitch (Univ. of St. Andrews, St. Andrews, Fife, UK), Eric J. Hunter (The Denver Ctr. for the Performing Arts, Denver, CO 80204), and Edward J. Walsh (Creighton Univ., Omaha, NE)

The excised larynx of a Siberian tiger, which died of natural causes, was studied on a laboratory bench. Pressure-flow relations were determined, as well as modes of vibration of the vocal pads. In addition, CT scans of the animal were made available (from previous health examinations), which allowed the vocal-tract airway to be quantified. The larynx and vocal tract-data were then used to simulate the sound production of the animal. Results showed that multiple tissue modes are excited to produce a tiger roar, and that the production is highly efficient for aerodynamic to acoustic energy conversion. Scaling factors for linear dimensions of the larynx and vocal tract are derived to compare the phonation of this large mammal to human phonation.

3pAB3. Nonlinear phenomena in vertebrate vocal production. Hans-Peter Herzel, Riccardo Zaccarelli, Tobias Riede (Inst. for Theoretical Biol., Invalidenstr. 43, 10115 Berlin, Germany), Juergen Neubauer (UCLA, Los Angeles, CA 90095-1794), and W. Tecumseh FitchIII (Univ. of St. Andrews, KY16 9JU, Scotland, UK)

Nonlinear phenomena such as subharmonics, biphonation (two independent frequencies), and deterministic chaos are widespread in animal communication. Examples from primate vocalizations, African wild dogs, hyena whoops, and bird songs are presented. Despite the variability of size and morphology, vocal production in vertebrates is governed by the same underlying mechanism: vibrating tissues such as vocal folds, membranes, or labia are driven by overcritical airflow. Consequently, sophisticated biomechanical-aerodynamic models of human voice production can serve as a starting point for modeling nonhuman vocal production. However, there is a variety of additional anatomical features in diverse species: pronounced air sacs, extensions of the vocal folds termed ''vocal membranes'' or ''vocal lips,'' or the coordinated action of left and right syrinx in song birds. It is shown that such specific features can induce voice instabilities. For instance, source-tract interactions lead to subharmonics and chaos, and vocal membranes allow multiple ''registers.'' Finally bifurcations in biomechanical models of the syrinx are discussed. [Work supported by the Deutsche Forschungsgemeinschaft (Grant He 2168/7).]

3pAB4. Mosaic and multiple-step evolution of the anatomical foundations for human speech. Takeshi Nishimura (Dept. of Zoology, Kyoto Univ., Kitashirakawa Oiwake-cho, Sakyo, 606-8506 Kyoto, Japan, nishimur@anthro.zool.kyoto-u.ac.jp)

The human vocal tract develops to form a unique configuration with equally long horizontal and vertical cavities. This anatomy contributes greatly to the morphological foundations of human speech. It depends on the reduced growth of the facial length and on the major descent of the larynx relative to the palate. Anatomically, the laryngeal descent is accomplished through both the descent of the laryngeal skeleton relative to the hyoid and the descent of the hyoid relative to the palate. Here, the recent progresses are surveyed in the studies on the developments of the vocal tract anatomy in humans, chimpanzees, and macaques. They showed that humans and chimpanzees fully share the major descent of the larynx with the epiglottis descent. Macaques also show the hyoid descent, but this is not accompanied by the descent of the laryngeal skeleton and epiglottis. It is argued that the major descent of the larynx has probably evolved at least in two steps before the divergence of the human from the chimpanzee lineage, originally to confer an advantage via a function unrelated to speech. Thus, facial flattening has probably evolved only secondarily with anatomical consequences that facilitated speech in the human lineage. [Work supported by JSPS Grant-in-Aid (No. 16000326).]

3pAB5. Birdsong: The role of the vocal tract. Roderick A. Suthers (School of Medicine and Dept. of Biol., Jordan Hall, Indiana Univ., Bloomington, IN 47405, suthers@indiana.edu)

The avian vocal organ, the syrinx, is unique among vertebrates in its morphology and location at or near the base of the trachea. In oscine songbirds, two independent sound sources share the same vocal tract. Despite a growing knowledge of the neural and syringeal mechanisms underlying song, the acoustic role of the suprasyringeal vocal tract in modulating birdsong is still poorly understood. During song, the beak opening, or gape, is typically positively correlated with the dominant frequency of the vocalization, but the mechanism by which beak gape influences vocal tract acoustics is controversial. X-ray cinematography of singing birds reveals song-related movements of the hyoid apparatus and larynx that cause the volume of the upper vocal tract to vary inversely with the songs fundamental frequency. At low fundamental frequencies, the oropharynx and cranial end of the esophagus expand to form a single large chamber, the volume of which is reduced at higher frequencies by collapse of the esophagus and reduction of the oropharyngeal cavity. A computational acoustic model indicates that birds actively tune the volume of their oropharyngeal-esophageal cavity so that its major resonance tracks the fundamental frequency of the song. [Work supported by NIH.]

3pAB6. Odontocete nasalizations: Morphology, physiology, and evolution of sonar signal generation in toothed whales. Ted Cranford (Biol. Dept., San Diego State Univ., 5500 Campanile Dr., San Diego, CA 92182-0001)

The odontocete nasal apparatus contains tissue complexes that generate a variety of sounds. Sounds are produced by moving air across the phonic lips, internal structures that were formed by the invagination of the ancient nasal openings. X-ray computed tomography shows this sound generation complex bilaterally in all odontocetes except in sperm whales, where it is unilateral. Two bottlenose dolphins provided simultaneous bilateral recordings of internal nasal cavity pressure and nasal tissue motion. Small catheters measured pneumatic pressure changes within each bony nasal passage; high-speed video endoscopy recorded motion at both

3p THU. PM

pairs of phonic lips; and two hydrophones revealed acoustic pressure during target discrimination. Sonar pulses can be generated at the left and right phonic lips, independently or simultaneously. Air pressure in both bony nasal passages rises and falls together, even if the activity patterns at the two pairs of lips are different. Increasing pulse repetition rate or sound pressure levels are all normally accompanied by increasing nasal air pressure. The bilateral arrangement of sonar sources in the odontocete nose provides a basis for reinterpretation of previous findings; reevaluation of physiologic limits and on pulse repetition rate, signal bandwidth, frequency composition, and transmission beam geometry; and the evolution of this system.

Contributed Papers

3:05

3pAB7. The creative walrus: Novel sound production via contingency learning. Ronald J. Schusterman, Colleen Reichmuth Kastak (Inst. of Marine Sci., Long Marine Lab., Univ. of California, Santa Cruz, 100 Shaffer Rd., Santa Cruz, CA 95060), Debbie Quihuis (Six Flags Marine World, Vallejo, CA 94589), and Marla M. Holt (Univ. of California, Santa Cruz, Santa Cruz, CA, 95060)

Walruses (*Odobenus rosmarus*) have a range of anatomical specializations that can provide plasticity to their vocal emissions. These include respiratory adaptations related to breath-holding and buoyancy and soft tissue adaptations of the mouth, lips, and tongue related to suction feeding. The aim of this study was to examine the extent to which contingency learning using food reinforcement could modify the sound production of walruses. One male and three female captive walruses participated in the current study. Animals were first trained in air in a series of four experimental steps: (1) induce and reinforce natural sound production, (2) establish stimulus control over sound production and inhibition, (3) establish stimulus control over different sound types by mapping them to different discriminative stimuli, and (4) encourage the production of novel sounds by withholding reinforcement for previously emitted sounds and reinforcing only novel variants. Subsequently, two of the walruses were transferred from airborne to underwater testing. In the absence of additional training, both individuals, when prompted to vocalize, emitted a range of underwater sounds, many of which were qualitatively different from those produced in air and those recorded in baseline conditions under water. Thus, walruses, like cetaceans, can learn to modify their sound production.

3pAB8. Acoustical development of the human baby cry: Anatomical and social factors. Yulri Nonaka, Noriko Kudo, Kazuo Okanoya (Lab. for Biolinguistics, RIKEN Brain Sci. Insitute, 2-1 Hirosawa, Wako, Saitama 351-0198, Japan, ynonaka@brain.riken.jp), Noriko Kudo, Kazuo Okanoya (Chiba Univ.1-33 Yayoi-Cho, Inage, Chiba 263-8522, Japan), Noriko Kudo (JSPS), and Kazuo Okanoya (PRESTO, JST)

We investigated the acoustical development of the human baby cry based on our two-stage hypothesis, which holds that two distinct factors affect the development of the baby cry. First, humans possess the corticobulbar pathway connecting the face motor cortex and the medullary respiratory and vocal centers. This pathway is absent in nonhuman primates and other mammals. We postulate that the myelinization of this pathway would change the acoustic characteristics of the baby cry. Second, after neuroanatomical maturation enabled variable cry patterns, the social relationships with caregivers should differentiate the acoustical patterns of the baby cry. This should lead to family-specific cry patterns. To test the two-stage hypothesis, we recorded ten newborn babies until they were 1 year old. In all babies, the cry pattern was very simple up to 2 weeks, while after 1 month, the pattern became temporally and spectrally complex, suggesting neuroanatomical changes. At three months, we asked the mothers to classify the cries of their own babies into three categories: sleepy, hungry, and wet diaper. There were no acoustic patterns common to their classifications, suggesting that baby cry semantics are family-specific. These results support our two-stage hypothesis of cry development. [Work supported by JST and JSPS.]

3:50

3pAB9. Is the squirrel monkey larynx lateralized biomechanically? Charles H. Brown (Dept. of Psych., Univ. of South Alabama, Mobile, AL 36688, cbrown@usouthal.edu) and Fariborz Alipour (Univ. of Iowa, Iowa City, IA 52242)

Squirrel monkey larynges were dissected, mounted on a pseudotracheal tube, and phonated via the flow of compressed heated and humidified air. Synchronized audio and video signals were digitized and analyzed with a signal processing workstation. Image analysis algorithms measured the change in glottal area due to the movement of the left and right vocal folds, respectively, and measured the change in location of both vocal folds during phonation. The results show that the squirrel monkey larynx is capable of both unilateral and bilateral oscillation. In the unilateral case, oscillation is virtually confined to the left vocal fold. The converse of this has not been observed. In the case of bilateral oscillation, the folds may oscillate synchronously in phase, asynchronously out of phase, or at different fundamental frequencies. The results are consistent with the idea that the biomechanical properties of the left and right vocal folds differ with the left fold capable of oscillation at lower subglottal pressures and greater amplitudes. Changes in vocal fold elongation and adduction change the coupling between the two folds and produce different regimes of oscillation. Squirrel monkeys appear to employ intentional shifts between different regimes of phonation to expand the size of the vocal repertoire.

4:05

3pAB10. Measuring emotional arousal in the voiced sounds of two mammals, the rhesus monkey and African elephant. Joseph Soltis, Christina Wesolek, Anne Savage (Education and Sci., Disney's Animal Kingdom, Lake Buena Vista, FL), Kirsten Leong (Cornell Univ., Ithaca, NY), and John Newman (NICHD, Poolesville, MD)

Emotional arousal is expressed in the voiced sounds of primates and other mammals, but there are no consistent acoustic measures used and few comparative analyses. We apply a representative suite of source and filter measurements to rhesus macaque (*Macaca mulatta*) coo calls on Cayo Santiago, Puerto Rico, and African elephant (*Loxodonta africana*) rumble calls at Disney's Animal Kingdom, Florida, U.S.A. Based on social context, calls were classified into high and low arousal categories. In both species, MANOVA showed that the 15 measures taken together separated calls across arousal categories. In rhesus macaques, high arousal was associated with increased and more variable fundamental frequencies, increased amplitudes in the lower frequencies, and a shift in formant locations. In African elephants, increased arousal was associated with a shift of energy from lower to higher frequencies. In addition, low ranking females expressed a greater magnitude of acoustic change compared to high ranking females. The suite of acoustic features used here may successfully characterize arousal state in a variety of mammals, but the specific acoustic features that reflect arousal and the specific pattern of acoustic response may vary by species and individual. [Work supported by Grant Nos. NIH CM-5-P40RR003640-13 and NSF-IIS-0326395.]

3pAB11. Antiphonal exchanges in female African elephants. Katherine Leighty, Joseph Soltis, Anne Savage (Education and Sci., Disney's Animal Kingdom, Lake Buena Vista, FL), and Kirsten Leong (Cornell Univ., Ithaca, NY)

Female African elephants (Loxodonta africana) engage in antiphonal exchanges of rumble vocalizations. In this study, female African elephants ($N=7$) housed at Disney's Animal Kingdom were outfitted with audio-recording collars and videotaped during 50 1-hour observation sessions

(conducted in 2002). We found that production of the antiphonal response rumble reflected changes in herd affiliation that had taken place since our previous study (2000). Second, we examined response latency and found that females responded more quickly to the rumbles of affiliated partners than to those of a nonaffiliated female. Since affiliated partners spend more time in close proximity by definition, they may engage in higher rates of temporally associated calling simply because nearby stimuli impact them simultaneously or due to a social facilitation effect, not because they are true vocal exchanges. Therefore, we examined antiphonal rumble responses when female pairs were more than 25 m apart. We found that at these distances, affiliated females still exchanged rumbles more frequently, and responded at a decreased latency, than nonaffiliated pairs. Our results provide support for functional hypotheses of African elephant rumble vocalizations that require instances of temporally associated calling in order to be true communicative events. [Work supported by Grant No. NSF-IIS-0326395.]

4:35

3pAB12. Commonality in the vocalizations of order *Perissodactyla*. David G. Browning (Dept. of Phys., Univ. of Rhode Island, Kingston, RI 02881, decibeldb@aol.com) and Peter M. Scheifele (Univ. of Connecticut, Storrs, CT 06269)

As a follow-on to the human genome project, it has been suggested that the next major gene sequencing program may be for the horse as a representative of the relatively small order *Perissodactyla*. This order consists of three families; *Equidae* (equines), *Tapiridae* (tapirs), and *Rhinocerotidae* (rhinos), for a total of 17 species. Both sensual ability and environmental conditions (open plains to dense jungles) vary greatly among this small group; for example, horses have excellent eyesight, tapirs do not. Vocalizations of the various species are compared to determine any common characteristics that might serve as a basis for future association with specific genes. The universal quality appears to be the ability to vary pitch during the vocalization. Other subsets such as braying or whinnying exist among a limited number of species, which suggests that there may be evolutionary trends within the order.

4:50

3pAB13. Application of the source-filter theory to the study of loud-calling in male deer. David Reby (Dept. of Psych., Univ. of Sussex, Brighton BN2 9YU, UK)

I will review recent studies of roaring in red deer males, which illustrate how source-filter theory can be successfully applied to studying mammal vocal signals. Combining anatomical analyses of the vocal apparatus, acoustical analyses, and playback experiments using resynthesized calls, we have shown that (*i*) red deer and fallow deer males have a descended and mobile larynx, an anatomical innovation that was previously believed to be uniquely human and that enables callers to modulate their formants during vocalising; (*ii*) minimum formant frequencies provide an honest indication of body size in red deer roars, (*iii*) stags use rivals' minimum formant frequencies in assessment during male-male contests, and adjust the formants of their own replies in relation to what they hear; and (*iv*) hinds perceive size-related variation in formant frequencies, and pay more attention to roars in which formant spacing indicates larger

males, independently of fundamental frequency. I will then compare the acoustic structure of sexual loud calls in related subspecies (Corsican deer, Wapiti) and species (fallow deer, pere Davids deer), highlighting the variability of source- and filter-related acoustic features in this group. To conclude I will suggest directions for future research in this area.

5:05

3pAB14. Measuring amplitude in North American bison bellows: Environmental, social, and individual impacts. Megan Wyman, Lynette Hart, Brenda McCowan (Univ. of California-Davis, 1025 Haring Hall, One Shields Ave., Davis, CA 95616, mtwyman@ucdavis.edu), and Mike Mooring (Point Loma Nazarene Univ., San Diego, CA 92106)

Communication is a key aspect of any mating system and is a dramatic feature in the mating behavior of North American bison. During their reproductive season, bison bulls defend females from other males by establishing dominance through contests involving multiple signals, the most prominent being the bellow vocalization. While acknowledged that amplitude may be involved in sexual selection, it is rarely measured directly in the field (especially in large mammals) due to difficulties in accurately assessing this parameter. Using strict methodologies accounting for many sources of potential error, the impact that a variety of factors had on bellow amplitude was examined. Amplitude was measured in dB with $L_{a_{max}}$ and $L_{c_{peak}}$ weighting. Parameters *increasing* amplitude (order of decreasing impact): Number of surrounding bulls bellowing, wind levels, and number of surrounding bulls. Parameters *decreasing* amplitude (order of decreasing impact): Distance, head orientation, days spent in rut, time of day, number of copulations, dominance level of bull, and temperature. Since amplitude is correlated with measures of bull quality, condition, and surrounding social environments (beyond physical impacts of distance, etc.), it is likely that amplitude plays a significant role in competition over mates. [Work supported by NSF.]

5:20

3pAB15. Syllable chunking in Bengalese finches in a multi-tutor environment. Miki Takahasi, Iori Tomizawa, and Kazuo Okanoya (Lab. for Biolinguistics, RIKEN Brain Sci. Inst., 2-1 Hirosawa, Wako, Saitama, 351-0198 Japan, mtakahas@brain.riken.jp)

Experiments in birdsong learning have traditionally involved one tutor, usually the father, and the proportion and accuracy of note copying are discussed as indexes of song learning. But in the wild, there are several conspecific males around song-learning pupils. To test song learning under naturalistic situation, 11 male and ten female Bengalese finches were kept in a large flight cage containing ten pot-shaped nests. Seventy-eight chicks were born in this aviary over an 18-month period. We recorded the full songs of male birds after they had matured, and compared the songs between offspring and the original adult males. Most of them learned their songs from one or two tutors and some learned from three or four tutors. When a bird learned from multiple tutors, each of these tutor songs was copied in chunks and within a chunk the order of the song elements was the same as that observed in the tutor male. Furthermore, Bengalese finches change the order of chunks as they sing, and it was possible to express the rule using a finite-state syntax. Therefore, Bengalese finches have an innate universal grammar allowing them to construct a finite-state syntax from multiple sources. [Work supported by JSPS and JST.]

3pBB1. A study on ultrasound parameter specification by temperature rise. Hiroshi Inoue and Chiaki Yamaya (Dept. of Electron. and Elec. Eng., Akita Univ., 1-1 Tegatagakuen-cho Akita-shi, Akita, 010-8502 Japan, inoueh@gipc.akita-u.ac.jp)

So far, temperature rises by absorption of ultrasound have been researched to secure the safety of the ultrasonic diagnostics and the application of ultrasonic therapy. This research is intended to develop a numerical simulation method that is applicable to estimation of medium constants, e.g., the absorption coefficient, using the temperature rise by the ultrasound. The temperature rises have been measured using a micro-thermocouple with high spatial resolution. Three-dimensional simulation using finite-difference time-domain (FDTD) method, which combines ultrasonic propagation and heat conduction, i.e., ultrasonic and temperature fields, is developed. At the first stage, two-dimensional analyses of ultrasonic fields were different from theoretical and experimental values. Therefore, we developed three-dimensional analysis. Time responses and spatial distributions of temperatures of the experiments and simulations were compared. Spatial distributions of temperature that were obtained using the FDTD simulation correspond qualitatively with those obtained by experiment, taking into account the thermocouple artifact. The possibility of estimation of medium constants is therefore suggested.

3pBB2. Modern acoustic microscopy and applications. Lawrence Kessler (Sonoscan, Inc., 2149 E. Pratt, Elk Grove Village, IL 60007)

The concept of acoustic microscopy was first suggested in the late 1930s by S. A. Sokolov and first demonstrated in a one-dimensional scan by Floyd Dunn and W. J. Fry in 1959. The notion of producing images of materials and biological tissues with UHF ultrasound to characterize their microelastic properties has broad appeal, however, most of the modern day (commercial) systems have been used instead for defect detection in manufactured products such as semiconductor devices. This paper will review a spectrum of applications from both the materials and biological worlds.

1:45

3pBB3. Twenty years' development of acoustic microscopy for medicine and biology. Yoshifumi Saijo, Hidehiko Sasaki, Motonao Tanaka (Dept of Medical Eng. & Cardiology, Tohoku Univ, 4-1 Seiryomachi, Aoba-ku, Sendai 980-8575, Japan, saijo@idac.tohoku.ac.jp), Naohiro Hozumi (Aichi Inst. of Technol., Yakusa-cho, Toyota 470-0392, Japan), Kazuto Kobayashi (Honda Electron. Co. Ltd., Oiwacho, Toyohashi 441-3193, Japan), and Floyd Dunn (Univ. of Illinois, Urbana-Champaign, IL)

Since 1985, scanning acoustic microscope (SAM) systems for medicine and biology has been developed and have been equipped for investigation of acoustic properties of various organs at Tohoku University. There are three objectives of SAM for biomedicine. First, it is useful for intraoperative pathological examination because staining is not required. Second, it helps understanding lower frequency ultrasonic images such as echography or intravascular ultrasound because SAM provides microscopic acoustic properties. Third, it provides information on biomechanics of tissues and cells. The most important feature of our SAM is to measure attenuation and sound speed of soft tissues by analyzing the frequency-dependent characteristics of amplitude and phase. Recently, a new-concept acoustic microscopy using a single pulsed wave instead of burst waves used in conventional SAM systems was proposed. Application of SAM has also been broadened and it covers not only myocardium and atherosclerosis in cardiology but also skin, bone, cartilage, tendon, and muscle in dermatology and orthopedic surgery. Higher resolution acoustic microscopy with over 500 MHz enabled us to visualize cultured cells and it can be applied for quality assessment of regenerated skins and cartilage. Impedance acoustic microscopy and 3-D acoustic microscopy are developed for *in vivo* tissue imaging.

3pBB4. VHF/UHF range bioultrasonic spectroscopy system and method. Naoyuki Akashi (Ichinoseki Natl. College of Technol., Ichinoseki 021-8511, Japan, akashi@ichinoseki.ac.jp), Mototaka Arakawa, Hiroyuki Odagawa, Toshio Sannomiya, Jun-ichi Kushibiki (Tohoku Univ., Sendai 980-8579, Japan), Noriyoshi Chubachi (Tohoku Univ., Sendai 980-8579, Japan), and Floyd Dunn (Univ. of Illinois, Urbana, IL 61801)

We developed the bioultrasonic spectroscopy system and method for doing ultrasonic tissue characterization studies in the VHF and UHF ranges. The system can determine the frequency characteristics of bulk acoustic properties of the sound velocity, attenuation, acoustic impedance, and density simultaneously by an ultrasonic transmission line comparison method using pure water as the reference, and using rf tone burst pulse signals. A biological tissue/liquid specimen is sandwiched between the parallel surfaces of buffer rods having ZnO piezoelectric film transducers on their opposite ends. Measurements are conducted with a typical thickness of 0.1 to 1 mm in the frequency range up to 700 MHz, and in the frequencies higher than 500 MHz, with a thin layer of specimen, several micrometers, operating in the multiple interference method. The system was applied for demonstration to measure the acoustic properties of bovine tissues, egg yolk and albumen, and aqueous solutions of biomacromolecules such as bovine hemoglobin and sugars in the frequency range 10 MHz to 1.6 GHz. The system and methodology will enable us to provide basic data for understanding the interaction of high-frequency ultrasonic waves with biological media and to make contributions to the establishment of the scanning acoustic microscope in the fields of biological and medical sciences.

3pBB5. Floyd's contribution to B/A measurement of biological materials. Leon A. Frizzell (Univ. of Illinois, 405 N. Mathews Ave., Urbana, IL 61801)

Ultrasound as used for medical diagnosis and high-intensity therapy is of sufficient amplitude that the effects of nonlinear propagation are important. Critical to modeling and understanding these nonlinear effects is knowledge of the nonlinearity parameter, B/A, for the biological tissues involved. In a series of papers Floyd Dunn and colleagues determined the value of B/A for several biological materials and soft tissues using the thermodynamic and finite amplitude methods. They showed that the B/A value depended directly upon the solute concentration in protein solutions. The value of B/A was around 7 for many soft tissues, including liver, muscle, and brain, but was around 11 for fat. Homogenized liver had a value that was less than that for whole liver, demonstrating an effect of structure. These results provided information regarding the range of B/A for biological materials and its dependence on concentration and structure and suggested the possible use of B/A in tissue characterization.

3pBB6. The impact of Floyd Dunn's research on echocardiography and myocardial tissue characterization. James G. Miller (Dept. of Phys., Washington Univ., St. Louis, MO 63130, james.g.miller@wustl.edu)

By the mid-1970s our lab had demonstrated that alterations in myocardium as a result of mature infarction could be quantified ultrasonically, with increased attenuation correlating with the extent of myocardial damage assessed in the same sites by depletion of creatine kinase. [Mimbs *et al.*, Circ. Res., **41**, 192–198 (1977)]. The Feigenbaum laboratory made the qualitative observation that zones of infarct were "more echo producing" than nearby zones. [Rasmussen *et al.*, Circulation **57**, 230–237 (1978)]. A 1973 article from Floyd Dunn's laboratory [S. Fields and F. Dunn, J. Acoust. Soc. Am. **54**, 809–812 (1973)] provided the basis for understanding these and many future developments in echocardiography and myocardial tissue characterization. In that seminal paper the authors state, "The magnitude of the echoes received is directly related to the preferred orientation and amount of collagen . . . ." We subsequently demonstrated the causal relationships between regional myocardial collagen content and both attenuation and backscatter. We also confirmed the Dunn prediction of anisotropy of attenuation, backscatter, and phase velocity. [Work supported by Grant NIH-R37-HL40302.]

3pBB7. Theoretical analysis of local attenuation approximations when calculating scatterer correlation length. Timothy A. Bigelow (Univ. of North Dakota, 243 Centennial Dr., Stop 7165, Grand Forks, ND 58202) and William D. O'Brien, Jr. (Univ. of Illinois, Urbana, IL 61801)

Determining the correlation length of ultrasound scatterers has shown potential in many tissue characterization applications. Accurate estimates of scatterer correlation length can only be obtained after correcting for focusing, frequency-dependent attenuation along the propagation path (total attenuation), and frequency-dependent attenuation in the region of interest (local attenuation). In order to correct for the local and total attenuation, an approximation is required because uncertainties in tissue attenuation can easily be 0.5 dB/cm-MHz, or greater, even for the same tissue type [J. Acoust. Soc. Am. **64**, 423 (1978)]. Earlier simulation results demonstrated that the most robust approximation for the local attenuation while completely compensating for total attenuation and focusing for weakly focused sources was to assume a finite frequency dependence of ∼0.8 dB/cm-MHz independent of the true attenuation of the tissue for attenuation values between 0.05 and 1 dB/cm-MHz. The goal of the present study was to investigate the theoretical basis for this approximation so that the results could be applied to other ranges of attenuation values. The theoretical analysis was then compared to the simulation results to validate the conclusions. [This work was supported by the University of Illinois Research Board and the University of North Dakota School of Engineering and Mines.]

3pBB8. High-frequency pulse-compression ultrasound imaging using an 18-MHz annular array. Jonathan Mamou, Jeffrey A. Ketterling, and Ronald H. Silverman (F. L. Lizzi Ctr. for Biomed. Eng., Riverside Res. Inst., 156 William St., New York, NY 10038)

High-frequency ultrasound (HFU) allows fine-resolution imaging at the expense of limited depth-of-field (DOF) and shallow acoustic penetration. Coded-excitation imaging allows a significant increase in the signal-to-noise ratio (SNR) and acoustic penetration depth. A 18-MHz, five-element annular array with a focal length of 31 mm and a total aperture of 10 mm was made using a 25-μm thick membrane. To excite the PVDF-TrFe transducer, an optimized 8-μs linear chirp spanning 6 to 30 MHz was uploaded into a waveform generator. The optimal chirp design was deduced from *ex vivo* experiments and computer simulations. Images of a seven-wire phantom were generated. The 25-μm wires were spaced in 1-mm axial and lateral increments. All 25 transmit/receive signal combinations were digitized and postprocessed for compression and synthetic focusing. Compression consisted of linearly filtering the signals with a mismatched filter. The mismatched filter was the time-reversed excitation chirp modulated by a Dolph-Chebyshev window. Marked image-quality improvements were demonstrated in images of *ex vivo* cow eyes. Results of this study demonstrate that the DOF can be improved by a factor of 3 and SNRs, after compression, can be improved by 24 dB.

Contributed Papers

3pBB9. Spatial distributions of acoustic parameters in high-intensity focused ultrasound fields. Vera A. Khokhlova (Ctr. for Industrial and Medical Ultrasound, APL, Univ. of Washington, 1013 NE 40th St., Seattle, WA 98105, vera@apl.washington.edu), Olga S. Bessonova (Moscow State Univ., Moscow 119992, Russia), Michael S. Canney, Michael R. Bailey, and Lawrence A. Crum (Univ. of Washington, Seattle, WA 98105)

Different peak and average acoustic parameters determine the efficiency of different physical mechanisms of high-intensity focused ultrasound (HIFU) interaction with biological tissue. Spatial distributions of these parameters are therefore important for transducer calibration and extrapolation of measurements in water to application in tissue. In the case of linear focusing, all parameters of the acoustic field can be obtained from the spatial distribution of the wave amplitude. However, in nonlinear focused beams, each parameter has its own characteristic spatial structure, which changes with the increase of the HIFU power level. This work compares the focal size and location calculated for the peak positive and peak negative pressure, mean intensity, and effective acoustic energy absorption in water and in tissue. Numerical solutions, obtained with the KZK-type model, are analyzed for various regimes of linear, quasilinear, and strongly nonlinear propagation which includes formation of shocks. The results of simulations are validated by comparison with measurements performed with a fiber-optic probe hydrophone in water and in a tissue-mimicking phantom. The peak positive pressure and effective absorption are finely focused, whereas the negative pressure, responsible for cavitation, is broad and displaced towards the transducer. [Work supported by NSBRI SMS00402, RFBR, and NIH DK43881.]

3pBB11. Infinite periodic model of human lung. Yurii A. Ilinskii, Mark S. Wochner, Mark F. Hamilton, and Evgenia A. Zabolotskaya (Appl. Res. Labs., Univ. of Texas, P.O. Box 8029, Austin, TX 78713-8029)

As described in a companion abstract, an investigation is underway to develop a bioacoustic model of human lung. In parallel with the numerical model described in the companion abstract, a semianalytic model is being developed. The basic unit cell, a truncated octahedron, is the same. In contrast here, the medium is assumed to be infinite in extent. The resulting lattice possesses cubic symmetry, and, for homogeneous deformation, all material properties are determined by a single unit cell. Deformation of the unit cell is determined by the 24 vertices of the polyhedron, only 6 of which are independent. In this presentation we discuss quasistatic deformation of the discretized medium, and thus ignore inertia and energy dissipation. An analytic model for the nonlinear elasticity of collagen and elastin is used to determine the stiffnesses of the springs connecting vertices of the polyhedra. Minimization of the potential energy for a given macroscopic deformation permits calculation of microscopic deformation within the unit cell, which in turn determines the stresses and therefore the elastic constants. Sample calculations will be presented, including the longitudinal and transverse wave speeds in the medium as functions of direction and orientation. [Work supported by ONR and ARL IR&D.]

3pBB10. Finite aperiodic model of human lung. Mark S. Wochner, Yurii A. Ilinskii, Mark F. Hamilton, and Evgenia A. Zabolotskaya (Appl. Res. Labs., Univ. of Texas, P.O. Box 8029, Austin, TX 78713-8029, mwochner@arlut.utexas.edu)

This work is focused on studying the dynamics of the human lung in response to low-frequency sound. The model developed uses individual alveoli as the basic unit cells, which are represented as truncated octahedra [Y. C. Fung, J. Appl. Physiol. **64**, 2132 (1988)]. Having 14 faces, this polyhedron possesses the smallest surface-to-volume ratio of any polyhedron capable of filling three-dimensional space. Unlike previous quasi-static models of this type, typically used to predict elastic properties of the lung, ours is a dynamical model. Mass is concentrated at the vertices of the polyhedra. Viscoelastic properties of the collagen and elastin in lung tissue are taken into account using a Kelvin model that is augmented to account for nonlinear elasticity. The Kelvin elements connect the point masses along the edges and across the faces of the polyhedra. Although not yet taken into account, the model permits inclusion of alveolar ducts by opening or closing selected faces of the polyhedra to accommodate airflow. Numerical simulations of small alveolar clusters subjected to different excitations and geometric constraints will be shown. [Work supported by ONR and ARL IR&D.]

3pBB12. Detecting spatially resolved inertial cavitation with a diagnostic ultrasound system. Caleb H. Farny, Robin O. Cleveland, R. Glynn Holt, and Ronald A. Roy (Dept. of Aerosp. and Mech. Eng., Boston Univ., 110 Cummington St., Boston MA 02215, cfarny@bu.edu)

The onset and presence of inertial cavitation in high-intensity focused ultrasound (HIFU) therapy has been identified as an important indicator of energy deposition for therapy planning. A common technique for detecting inertial cavitation is passive cavitation detection, where broadband noise emissions indicative of inertially driven bubbles collapses are detected using a fixed focus transducer. This technique is suboptimal for clinical applications, because most passive cavitation detector (PCD) transducers are tightly focused and thus afford limited spatial coverage of the HIFU focal region. Here, we report on efforts to use a diagnostic ultrasound system as a PCD by operating in passive mode and filtering out the main HIFU frequencies. This approach allows for spatially resolved detection of inertial cavitation throughout the focal region while being insensitive to scattering from voids or bubbles. [Work supported by the Dept. of the Army and the Center for Subsurface Sensing and Imaging Systems.]

3pBB13. Classification of flow-limiting thrombus in acute coronary syndrome by acoustic microscopy. Hidehiko Sasaki, Yoshifumi Saijo, Takayuki Kanno, and Motonao Tanaka (Dept of Medical Eng. & Cardiology, Tohoku Univ, 4-1 Seiryomachi, Aoba-ku, Sendai 980-8575, Japan)

Virtual histology (VH), based on a power spectral analysis of radio-frequency signal from intravascular ultrasound (IVUS) with neural network, can detect an unstable plaque from all the regions of coronary atherosclerosis. However, it provides limited information on plaque vulnerability because the resolution is larger than 100 m and thrombus is not classified precisely. The objective of the present study is to measure the acoustic properties of flow-limiting thrombus responsible for acute coronary syndrome (ACS) at the microscopic level. A newly developed acoustic microscope with 100-MHz pulsed ultrasound was equipped to measure two-dimensional distribution of attenuation and sound speed. The tissues were obtained from coronary arteries of 26 patients with ACS by intracoronary aspiration catheter. They were sectioned at 5-mm thickness and mounted onto glass slides without cover slips or staining and used acoustic microscopy study. The values of attenuation and sound speed of the red thrombus were significantly higher than those of the platelets-rich thrombus. Both acoustic parameters of old red thrombus were significantly lower than those of the organized thrombus. The acoustic properties provided by acoustic microscopy can classify the flow-limiting thrombus at different pathological stages. The criteria will provide further information for development of a VH-IVUS algorithm.

5:15

3pBB14. Image processing for scanning-type biological ultrasonic microscope considering its beam characteristics. Kazuto Kobayashi (Honda Electron. Co., Ltd. 20 Oyamazuka, Oiwa-cho, Toyohasi, Aichi, Japan), Naohiro Hozumi (Aichi Inst. of Technol., Yakusa Toyota Aichi Japan), and Shigeo Ohtsuki (Tokyo Inst. of Technol., Midori-ku, Yokohama, Kanagawa, Japan)

We have been developing a biological ultrasonic microscope with a high lateral resolution. An acoustic pulse is transmitted by a scanning transducer to a substrate on which a thin slice of a tissue is embedded. The transducer has a minute curvature in order to focus an acoustic beam with a high frequency component. It may be fabricated by MEMS technology; however, from the point of view of engineering, it may not be easy to guarantee the reproducibility of beam pattern as specified. In a high frequency range, a small error in fabrication will lead to a big difference in beam pattern, which strongly affects the observed image. Using newly proposed methodology to observe a well-defined pin-hole, we found that each commercial single probe transducer with the same specification has a unique beam pattern. In addition, the pattern was not always concentric. Consequently, we proposed a method to compensate the image that was obtained using an eccentric beam pattern. A clearer image was successfully obtained after the compensation.

3pMU1. Vibrations of a harp soundbox: Experiment and finite-element analysis. Chris Waltham and Andrzej Kotlicki (Dept. of Phys. & Astron., University of British Columbia, Vancouver BC, Canada V6T 1Z1, cew@phas.ubc.ca)

A medium-sized lever harp of proven design has been built. At each stage of construction, the components have been subjected to experimental modal analysis, using an impact hammer and small accelerometer, and also Chladni patterns. The results have been compared to a corresponding sequence of finite-element calculations. The aim is to build a picture of how the various ingredients—soundboard, veneer, ribs, soundbox, access holes, string tension, etc.—interact with each other to produce an acceptable instrument. Ultimately one would like to create a set of desiderata for the design and manufacture of harp components in a similar manner to that already achieved for, say, the violin.

1:15

3pMU2. The nonlinear motion of harp strings. Chris Waltham and Andrzej Kotlicki (Dept. of Phys. & Astron., University of British Columbia, Vancouver BC, Canada V6T 1Z1, cew@phas.ubc.ca)

The harp is an instrument with a set of plucked strings that excite the sound board directly, without the medium of a bridge. The strings are positioned at an acute angle to the plane of the sound board. The quality of the sound produced depends on the motion of the string and its interaction with the resonances of the sound board. String and sound board motions have been studied using small, infrared position sensors. The results are compared to those of a simple nonlinear model based on the measured elastic properties of the string materials and those of the soundboard. We will also describe the construction and calibration of the position sensors.

3pMU3. On Dagestan tamur acoustical features. Shamil Aliev
(DagDisel Factory, Lenina str. 1, Kaspiisk, Dagestan, Russia), Ernst
Myshinsky, and Alexander Pyshin (Krylov Inst., Saint-Petersburg,
196158, Russia)

The study of the tamur, a national Dagestan two-stringed musical in-
strument played by plucking with narrow body gouged from linden wood,
is presented. Distinctive features of the tamur sound making process are
described. The resonance properties of the tamur body, that is, the me-
chanical resonance system, are determined. Also the resonance properties
of air volume inside the tamur body, that is, an acoustic resonator, are
determined. An interaction of the tamur body mechanical vibration and air
volume inside the body oscillation are discussed. Tamur body sound ra-
diation dependencies on frequency are studied. The resonance properties
of instrument strings and purity of their sounding are determined. The
assessment of efficiency of transformation string oscillations into tamur
sounding board oscillations (body mechanical impedance) is discussed.
The elastic and acoustic constants of linden, that is, the wood material of
the tamur body made by gouge, are determined. The logarithmic decre-
ment of tamur sounding board oscillations is determined. The typical spec-
tra of tamur sounding are analyzed.

**3pMU4. Comparing harmonic reinforcement in the Octet's Mezzo
and a typical Strad-model violin.** Duane Voskuil (Univ. of North
Dakota, Bismarck, ND, dvoskuil@bis.midco.net) and Carleen M.
Hutchins (The New Violin Family Assoc., Wolfeboro, NH)

Many players and listeners maintain the Octet violins have a fuller
sound than conventional instruments. Preliminary data indicate Octet vio-
lins may better embody some resonant intervals that make this more likely.
A theory is presented based on a study comparing the Octet's Mezzo and
a Strad-model violin, concluding that C. M. Hutchin's original design
principle for the Mezzo fortuitously related A0 to A1 as an interval of a
fifth near the two open middle strings, allowing more constructive wave
reinforcement than conventional violins. The theory considers other inter-
vals, seeking to maximize harmonic reinforcement by modifying instru-
ments, (1) so that every bowed note is reinforced by an activated wood or
air resonance by placing the notes fundamental and overtones close
enough to a resonant frequency to activate it, (2) so that two resonances
constructively interfere when they are simultaneously activated because
they are separated by a harmonic interval, and (3) so that as many higher
mode resonances as possible are activated by upper partials of the bowed
notes harmonic series.

2:00

3pMU5. Linearized and nonlinear dynamics of bowed bars. Octavio
Inacio (Escola Sup. de Musica e Artes do Espectaculo, Musical Acoust.
Lab., R. da Alegria, 503, 4000-045 Porto, Portugal,
octavioinacio@esmae-ipp.pt) and Jose Antunes (Instituto Tecnologico e
Nuclear, 2686 Sacavem codex, Portugal)

Friction-excited instruments have been for many decades an inexhaust-
ible source of physical delight. In the last decades, spectacular improve-
ments in computational power and in numerical methods enabled simula-
tions of the self-excited nonlinear regimes with considerable realism and
detail. The authors of the present paper have achieved many such nonlin-
ear simulations, using a powerful modal approach, and decided to inves-
tigate here in detail the characteristics of the linearized and nonlinear
regimes of bowed bars. After stating the theoretical modeling approach for
the nonlinear problem, we derive a corresponding linearized model, from
which the complex eigenvalues and eigenvectors are computed as a func-
tion of the bowing parameters (friction parameters, normal force, and tan-
gential velocity, accounting for the bowing location). We thus obtain plots
of the modal frequencies, damping values, and complex mode shapes, as a

function of the bowing parameters, as well as stability charts for each one
of the system modes. When compared with the nonlinear motion regimes,
these results offer interesting information concerning the stability behavior
of the system, and further insight when addressing the postinstability non-
linear limit-cycle responses. Several differently tuned bars are addressed
in order to assert the configurations leading to optimal playability.

2:15

**3pMU6. Spectral method applied in physical modeling synthesis of
plate.** Lin Zhang (School of Phys., Univ. of Edinburgh, Kings Bldg.,
Edinburgh, EH9 3JZ, UK, lin.zhang@ed.ac.uk)

As a well-applied method in scientific computation, spectral methods
have properties like higher order accuracy, nonlinearity expandability, and
memory saving. By an example, this work will explore the potential of its
application into physical-based sound synthesis With background work of
finite difference on wave equation, spectral differentiation is further ap-
plied in space of discretization of partial difference equation (PDE). Gen-
eral plates (including membrane) percussion models are created numeri-
cally presenting the wave propagation inside of plate. According to two
different dimensions (rectangular and circular), Fourier or Chebyshev in-
terpolations are applied. In addition, stiff system is introduced by adding
sizzlelike partials onto plate model (sizzled cymbals in jazz music) and
complex collision phenomena (for example, ride cymbals). Problems such
as stability condition take an important position in analysis. The algorithm
is to generate high-quality multichannel audio outputs for musical pur-
pose. For the continuity and expandability as application module, parallel
computation programming is taken as the focus of final implementation on
a Sun Bluefire E15K shared memory machine [Work supported by EPCC.]

2:30

3pMU7. Vibrational characteristics of the glassharp. Koichi Uchida
and Kenshi Kishi (Dept. of Electron. Eng., Univ. of Electro-Commun.,
1-5-1 Chofugaoka, Chofu-shi, Tokyo, 182-8585 Japan
coici@crane.ee.uec.ac.jp)

Using the finite-element method (FEM), glassharp vibration was ana-
lyzed. Results show that the glassharp pitch is controllable at the stage of
manufacturing. First, the effects of several factors were studied, such as
geometry approximation, element type, and the number of division on the
accuracy of mode frequencies. Second, it was examined how each mode
frequency changes by the fixed position and length of the glassharp stem.
The results demonstrate that their influences were of no great importance.
Third, the pitch was widely adjustable by changing the swell of the cup.
Particularly, it was finely adjustable by cutting a small circular groove
inside a bottom of the cup instead of a conventional method.

2:45

**3pMU8. Physical modeling of Tibetan singing bowls using dynamic
forcing.** David M. Etlinger (School of Music, Northwestern Univ., 711
Elgin Rd., Evanston, IL 60208)

The geometric simplicity of Tibetan singing bowls produces surpris-
ingly complex vibrational behavior. The curvature of the bowls causes
strong coupling between modes, and the physical parameters of actual
bowls (namely their thickness and deep curvature, as well as their asym-
metrical excitation) produce higher-order effects that cannot be neglected.
In this paper we present a physical model for the bowl's acoustical output.
The model is based on analytical solutions for the natural modes, and
predicts both transient and steady-state behavior. Using the method of
dynamic forcing, we investigate bowl response for linear (striking) and
nonlinear (rubbing) excitation methods, producing audio as well as nu-
merical data. Finally, we use the model to gain insight into aesthetics and
design: by comparing our simulations to actual antique or high-quality
bowls, we can begin to determine what parameters contribute most to
creating the desired sound.

3pNSa1. Field study of sound exposure by personal stereo. Rodrigo Ordoñez, Karen Reuter, and Dorte Hammershøi (Dept. of Acoust., Aalborg Univ., Fredrik Bajers Vej 7-B5, DK-9220 Aalborg Ø, Denmark, rop@acoustics.aau.dk)

A number of large scale studies suggest that the exposure level used with personal stereo systems should raise concern. High levels can be produced by most commercially available mp3 players, and they are generally used in high background noise levels (i.e., while in a bus or train). A field study on young people's habitual sound exposure to personal stereos has been carried out using a measurement method according to principles of ISO 11904-2:2004. Additionally the state of their hearing has also been assessed. This presentation deals with the methodological aspects relating to the quantification of habitual use, estimation of listening levels and exposure levels, and assessment of their state of hearing, by either threshold determination or OAE measurement, with a special view to the general validity of the results (uncertainty factors and their magnitude).

1:15

3pNSa2. Antioxidant use in the prevention of noise-induced hearing loss and ototoxic chemicals in the workplace. Sandra C. MacLean Uberuaga (Alaska Occupational Audiol. & Health Services, 200 West 24th Ave., #196, Anchorage, AK 99503)

There have been discoveries in auditory research as to how the cochlea is injured during noise exposure and how it may sometimes be possible to reverse or prevent acute noise damage with medications. There are two primary mechanisms of damage; mechanical, as delicate tissue structures are torn apart when loud blasts occur above 125–130 dB SPL, and metabolic exhaustion, which commonly results from habitual noise exposure. During metabolic exhaustion toxic waste products (free radicals) form as cells in the cochlea are stressed. Our bodies can react to noise trauma by presenting a defense of antioxidant enzymes. However, when these defenses are overwhelmed, the hair cell is subject to serious damage to its

nuclear DNA, mitochondria, and membranes. This research has been promising in animal studies. We will discuss pharmacological agents that can be used by the ear to synthesize the toxic products. The next step is well-designed human clinical trials in occupational settings where extreme noise levels cause hearing loss despite the seemingly appropriate use of hearing protection devices (e.g., aircraft carrier decks, mining and petroleum industries). Chemicals and agents that can cause hearing loss in the workplace will also be reviewed.

1:30

3pNSa3. Combined effects of occupational exposure to noise and organic solvents on the auditory system. Ikuharu Morioka (School of Health and Nursing Sci., Wakayama Medical Univ., 580 Mikazura, Wakayama, 641-0011 Japan), Yoshihiro Minami, Nobuyuki Miyai, Kazuhisa Miyashita (Wakayama Medical Univ., Wakayama, Japan), Hiroichi Yamamoto (Osaka Occupational Health Service Ctr., Osaka, Japan), and Orawan Kaewboonchoo (Mahidol Univ., Bangkok, Thailand)

Noise exposure is the most common cause of hearing loss. In many work environments where organic solvent exposure occurs, a high level of noise exposure is also common. However, as to the ototoxic effects of organic solvents, the earlier studies focused on the exposure to an organic solvent alone. It is necessary to clarify the combined effects of exposure to noise and organic solvents at the simulated situation of the work environments. The objective of this study was to review the literature on the ototoxic effects of exposure to organic solvents combined with noise. Two organic solvents were selected: methanol, a widely used organic solvents in the occupational field, and styrene, also widely used and a human neurotoxicant. Judging from the results of animal experiments and epidemiologic studies, a synergistical interaction of noise with such organic solvents' ototoxicity was clarified even at the lower concentration where the organic solvent alone showed no ototoxicity in the experimental animals and at the concentration lower than the occupational exposure limits of organic solvents. Consequently, it is important to carefully access the occupational exposure limits when workers are exposed to organic solvents combined with noise, and to take measures against combined exposure.

3pNSb1. Active noise control-like performance of a spherical reflector.
Kunisato Seto, Md. Tawhidul Islam Khan, Kenbu Teramoto (Dept. Mech. Eng., Saga Univ. 1 Honjo-machi, Saga-shi, Saga 840-8502, Japan, kunisato@cc.saga-u.ac.jp), and Hiromitsu Ohta (Natl. Fishery Univ. Shimonoseki 759-6595, Japan)

The principle of cancellation of tonal noise by using a spherical reflector, the designing method of an appropriate reflector for canceling jet screech, the advantage of a spherical compared to a flat reflector for canceling a tonal noise, and a prospective application for an aircraft to protect the fuselage from acoustic fatigue are discussed. The thrust loss due to the new technique was also evaluated directly with a vertical wind tunnel. The change in the aerodynamic structure was optically observed by using a schlieren apparatus along with a high-speed video camera. [Work supported by grant of JSPS, Japan.]

2:15

3pNSb2. A study of subjective effect on active noise control system.
Sayoko Utsumi, Eiji Murai, Yuko Watanabe, and Hareo Hamada (SIE, Tokyo Denki Univ., 2-1200 Muzai-gakuendai, Inzai, Chiba, 270-1382, Japan)

In recent years, the influence of various noises on human beings in our daily life has become a problem. Especially, the low-frequency noise has been considered to have a serious influence on work efficiency of people who are working under the noise exposure. On the other hand, active noise control (ANC) systems have achieved the efficient reduction noise, especially for the low-frequency noise. Actually, a number of successful ANC systems have been reported. Therefore, ANC systems may improve our work efficiency. In this paper, features of various noises are observed to get a representative value to be a sound source for subjective listening tests. Then, the effectiveness of the ANC system is evaluated to observe a physiological reaction of subjects. For that, response times to the short-term memory task will be measured in three different conditions, such as usual condition, under the noise exposure, and that with a running ANC system.

2:30

3pNSb3. Near-field mapping of pressure fields during active noise control of small axial cooling fans. Benjamin M. Shafer, Kent L. Gee, Scott D. Sommerfeldt, and Cole V. Duke (Brigham Young Univ., Provo, UT 84602)

In the past, tonal noise from small axial fans has been globally reduced using active noise control (ANC) with near-field error sensors placed according to a theoretical condition of minimized radiated power [K. L. Gee and S. D. Sommerfeldt, J. Acoust. Soc. Am. **115**, 228–236 (2004)]. The theoretical model, based on mutual coupling of point sources, showed that pressure nulls exist in the near field when the radiated power is minimized. Error sensor placement at these locations should then optimize global ANC. This study comprises an experimental investigation in which the actual locations of these near-field pressure nulls have been measured over a two-dimensional grid with a linear array of microphones. The array consists of 25 quarter-inch microphones with half-inch spacing. This array has been used to map the pressure field from a 60-mm cooling fan during ANC, in addition to a benchmark case, where a small loudspeaker has been mounted in place of the fan. The experimental results are compared to the theoretical pressure null locations in order to determine the efficacy of the point source theoretical model.

2:45

3pNSb4. Active control of free-field sound using near-field energy-based error signals. Ryan T. Chester and Timothy W. Leishman (Acoust. Res. Group, Dept. of Phys. and Astron., Brigham Young Univ., Provo, UT 84602)

Practical efforts to actively control sound often require error sensors located in the acoustic or geometric near field of primary and secondary sources. Unfortunately, when using conventional acoustic pressure sensors, control performance often becomes very sensitive to sensor position, and optimal sensor positions are difficult to ascertain or maintain with changing system conditions. Other types of error sensors or combinations of error sensors may produce fewer position-dependent complications, yielding excellent global sound-field control with greater ease and consistency. This paper compares the use of potential, kinetic, and total energy density error signals in the near field of a primary and secondary source in free space. It also discusses the distinct spatial and spectral uniformities of these quantities and their impact on the active control of sound.

3pNSc1. Can operating room nurses accurately classify noise exposures? Bernadette Stringer and Ted Haines (Dept. of Clinical Epidemiology and Biostatistics, McMaster Univ., ON, Canada)

Worker's qualitative chemical exposure estimates when compared to estimates made by experts or with monitoring devices have been found to be accurate. But almost no research exists on worker's ability to classify noise exposure. This investigation took place within a multi-hospital intervention study in which OR nurses completed a questionnaire at the end of each surgery and answered, "During this surgery could you easily hear: quiet talking, normal talking, or loud talking?" In 255 surgeries, noise was measured using a sound level meter, for a minimum of 15 min, while in 68 surgeries noise was measured for >70% of the surgery. In the 255 surgeries in which noise was measured for 15 min or >, it was found that nurses who heard quiet talking were exposed to 62.8 dB(A) and that nurses who heard normal or loud talking were exposed to 65.1 dB(A), a difference that was statistically significant ($p = 0.019$). In the 68 surgeries where noise measurements lasted more than 70% of the surgery, nurses who heard quiet talking were exposed to 64.0 dB(A), while nurses who heard normal or loud talking were exposed to 67.3 dB(A), a difference that was borderline significant ($p = 0.07$). Nurses can distinguish between noise that interferes with quiet talking during surgery and noise that does not. [Work funded by Ontarios Workplace Safety Insurance Board.]

3:30

3pNSc2. Noise in Canadian hospital operating rooms. Ted Haines and Bernadette Stringer (Dept. of Clinical Epidemiology and Biostatistics, McMaster Univ., ON, Canada)

Noise levels in hospital operating rooms have not been well characterized. Therefore, noise levels were measured using a sound level meter in a sample of surgeries included in a multihospital intervention study, assessing the effectiveness of a recommended work practice to decrease occupational exposure to blood during surgery. The duration of the measurements ranged from 15 min to several hours. Among types of surgery for which at least four measurements were done, the L_{eq} for orthopedic surgery was the highest at 70.1 dB(A) (range 60.8–75.1), followed by 63.7 dB(A) for neurosurgery (range 57.4–68.1), and 62.8 dB(A) (range 58.5–70.3), for general surgery. Gynecological surgery had the lowest L_{eq}, 60.8 dB(A) (range 56.5–62.5). Peak levels were found to be as high as 132.8 and 132.6 dB(A), in general and orthopedic surgery, respectively, and lowest in neurosurgery at 102.6 dB(A). These noise levels are consistent with those from a comprehensive U.S. study, and substantially exceed EPAs recommended level of 45 dB(A) for hospitals. [Work funded by Ontarios Workplace Safety Insurance Board.]

3:45

3pNSc3. Noise levels with the potential to impede communication during surgery. John Oudyk and Bernadette Stringer (Occupational Health Clinics for ON Workers Inc., 848 Main St. E., Hamilton, ON L8M 1L9, Canada)

Surgical teams consist of personnel who may or may not regularly work together, among whom communication can be more difficult because of surgical masks, face shields, or goggles, factors believed to have contributed to a recent serious medication error that occurred when the anaesthetist misunderstood the surgeon's request. In a multihospital, occupational health intervention study a sound level meter was used to measure ambient noise for 15 min or > during 256 surgeries included in the study. Results revealed an L_{eq} of 70.7 dB(A) and peak of 115.8 dB(A) (at the 95th percentile). Since the clarity of words depends on maintaining a signal-to-noise ratio of at least 15 dB(A), personnel working with such noise would likely increase their speaking levels up to 75–85 dB(A), a level substantially higher than normal speech ranging from 55–65 dB(A). Although the effect of noise levels on patient safety, or the health of OR personnel who must raise their voices to be heard, as well as on the overall climate that results when noise is elevated, have not been thoroughly investigated, evidence of negative effects is growing. And, while further characterization of OR noise is justified, this should be carried out to develop tailored interventions that can then be evaluated. [Work was funded by Ontario's Workplace Safety Insurance Board.]

3pNSc4. Comparison of speech communication of renovated classroom by subjective method. Coriolanus Lam, Chun Wah Leung (Dept. of Mech. Eng., The Hong Kong Polytechnic Univ., Hung Hom, Hong Kong, coriolanus.lam@polyu.edu.hk.), and Kai Ming Li (Purdue Univ., IN)

This paper presents measurement results on the acoustical characteristics of two standard and identical classrooms, one of which has been renovated. Several acoustical quantities that affect speech communication have been studied. These quantities were used to predict and quantify the characteristics and the qualities of measured classrooms that focused on speech communication. Subjective method by speech intelligibility tests was conducted in the measurements. Phonetically balanced monosyllabic word tests in both English and Chinese were carried out. In addition, public address messages, both in English and Chinese, from Hong Kong Mass Transit Railway were used as material for the tests. The results indicate that the renovation was beneficial on the quality of speech communication in general except for echo effects and increase in reverberation under several combinations of acoustical settings. These results were used to evaluate the relationship between speech perception quality and speech intelligibility. Besides, it will be used for new classroom designs in Hong Kong for better speech communication. [Work supported by Research

3pNSc5. Case study: Predict acoustical quality of renovated classroom. Coriolanus Lam, Chun Wah Leung (Dept. of Mech. Eng., The Hong Kong Polytechnic Univ., Hung Hom, Hong Kong, coriolanus.lam@polyu.edu.hk), and Kai Ming Li (Purdue Univ., IN)

The study on prediction of acoustical quality of two standard and identical classrooms, one of which has been renovated, was presented. Acoustical back-wall panels and sound-reflecting panels were installed in the renovated classroom. The study was carried out by RAYNOISE under the same conditions and acoustical characteristics of field measurements in the classrooms. Several acoustical quantities such as signal-to-noise ratios, reverberation time, and speech transmission index have been studied. Comparison was focused on the qualities of speech communication between the classrooms with and without renovation. Additional comparison was conducted with the results of field measurements. The results of the present study found that the quality of speech communication varied depending on changes in absorption. The results further implied the limitations and the precautions on application of RAYNOISE for different studies. 3pNSc6. Speech privacy unmasked. David Lubman (14301 Middletown Ln., Westminster, CA 92683) and Louis C. Sutherland (Rancho Palos Verdes, CA 90275)

Background masking noise is widely used to achieve speech privacy between work stations in open offices and in nearby closed (executive) offices. Although speech privacy is often essential, high masking noise levels reduce the abilities of some workers to perform speaking and listening tasks effectively and without strain. Masking noise levels are usually set as high as office inhabitants will tolerate, typically about 45–48 dB (A-weighted). This is 10 to 20 dB higher than noise levels in typical home settings. Many who can communicate effectively in home settings are impaired in offices with background masking noise. People adversely impacted include those with mild or worse hearing disabilities of hearing, speech, and language. Many are older workers and non-native speakers. The current architectural trend to greater inclusiveness underscores the desirability of lower background masking noise levels. Designers can usually achieve speech privacy with lower masking noise levels by specifying partitions with higher noise isolation ratings. Higher sound isolation ratings cost more than higher masking noise levels. But higher costs may be balanced by the benefits of a more inclusive and humane workspace.

4:45

3pNSc7. Objective and subjective evaluation of the acoustic comfort in public classrooms. Paulo H. Zannin, Fabiano B. Diniz, and Daniele Krauser (Mech. Eng. Dept., Federal Univ. of Parana, Rua Benedicto Berillo Fangueiro, 108, Santa Barbara, Curitiba, Parana, CEP, 81540-420, Brazil)

The acoustic comfort of classrooms in a Brazilian public school has been evaluated through interviews with 62 teachers and 464 pupils and measurements of background noise, reverberation time, and sound insulation. Acoustic measurements have revealed the poor acoustic quality of the classrooms. Results have shown that teachers and pupils consider the noise generated and the voice of the teacher in neighboring classrooms as the main sources of annoyance inside the classroom. Acoustic simulations resulted in the suggestion of placement of perforated plywood on the ceiling, for reduction in reverberation time and increase in the acoustic comfort of the classrooms. [Work supported by DAAD, CNPq and FINEP.]

5:00

3pNSc8. Experimental determination of end reflection loss (ERL) over a range of common types and configurations of duct terminations. Alexander P. Michaud and Kenneth A. Cunefare (771 Ferst Dr., Rm. 205, Atlanta, GA 30332)

The two-microphone impedance tube method ASTM E1050 was applied to directly measure the termination impedance of rectangular duct configurations of different aspect ratios and end conditions over a 25- to 500-Hz frequency band. Measured values of the acoustic impedance, and hence the reflection coefficient, of the duct termination permits computation of end reflection loss. ERL is essentially the insertion loss of duct termination. The measurement program is challenging, as the precision required for accurate ERL computation is much higher than that for accurate determination of the reflection coefficient. The measurement program is part of a project to assess the available published data on duct ERL. The ASHRAE Handbook contains a tabulation of ERL data derived from predictions of the radiation impedance of a circular plane piston, and there have been some validation measurements made on a limited set of circular duct configurations and orifice plate terminations. Results to date closely conform to published ERL values. [Work supported by ASHRAE.]

3pNSc9. Classroom acoustics: Future criteria for the design and renovation of learning spaces. Sooch San Souci, Line Guerra, Nicolas Teichner (AiA—Audition, Intelligibility, Acoust., 47 rue Le Corbusier, 92100, Boulogne, France, sooch.sansouci@aiacoustique.com), and Dick Campbell (Bang-Campbell Assoc., Falmouth, MA)

Recent literature suggests that some of today's criteria for classroom acoustics might be in need of revision. This article explores the traditional acoustic classroom criteria as they are applied today, and why several of the design goals for construction or renovation of learning spaces might not be appropriate acoustic targets. The acknowledged quest for optimized acoustics for the enhancement of learning is discussed and related to a series of newer metrics for the measure and modeling of speech level, occupied and unoccupied noise, controlled reverberation, and SNR values presented on a seat-by-seat basis. Based on the measured results of classrooms designed and built in accordance to these newer metrics, our research indicates that these guidelines would incur an average increase of

2% to 8% to current budgets. Specifics involving building costs versus acoustic value are also discussed. Further, research involved in the evaluation of scholastic advantages is underway.

3pNSc10. Speech and noise levels in classrooms—signal, noise, reverberation levels as a metric for acoustic design for learning. Line Guerra, Nicolas Teichner, Sooch San Souci (AiA—Audition, Intelligibility, Acoust., 47 rue Le Corbusier, 92100, Boulogne, France, line.guerra@aiacoustique.com), and Dick Campbell (Bang-Campbell Assoc., Falmouth, MA)

This study attempts to investigate the variance of speech levels in occupied classrooms during learning activities and their relationship to the total noise component (occupied, ambient, and reverberant). The methodology for the construction of a valid data base is presented, which would

apply to criteria such as SNR (signal-to-noise ratio) and correlate to the term SNRL (signal, noise, reverberation levels). The interrelationship of speech and noise in any learning environment requires that the common variables associated with a stated speech level value should be stated along with the speech level value. The significance of the influences on the global value and in some cases the spectra of speech is discussed relative to variables such as the activity, the total occupancy and comportment of the audience, the volume of the room, total occupied noise in proximity to the speaker, speech directivity, effects of head diffraction among seated audience, and the distance from the source. Results from measurements taken in this study in actual classrooms are presented with an emphasis on specificity. This research has produced a strategy for the mapping of the speech-noise environment that significantly supports the use of a modeled SNR value as a goal for design.

3pPA1. Shock-wave−inertial-bubble interaction near an elastic boundary. Georgy Sankin and Pei Zhong (Dept. of Mech. Eng. and Mater. Sci., Duke Univ., Box 90300, Durham, NC 27708)

The interaction of laser-generated single cavitation bubbles (maximum diameter $D_{max}=1.34$ mm) near a silicon rubber membrane with a shock wave (39–75 MPa in peak pressure and 1.7 μs in compressive pulse duration) is investigated. The interaction leads to directional, forced collapse of the bubble with microjet formation along shock wave propagation direction. Maximum jet penetration into the membrane is produced during the bubble collapse phase with optimal shock wave arrival time and stand-off distance s, a condition that ensures that the forced collapse time of the bubble matches with the compressive duration of the shock wave to generate presumably the maximum axial jet velocity toward the boundary. A maximum penetration depth of 0.5 mm is observed at dimensionless proximity γ $(=2s/D_{max})=0.7$ when the bubble establishes contact with the boundary during expansion. At larger γ (≥ 1.2), jet impact is significantly attenuated by the interposing water layer separating the collapsing bubble and the membrane surface. Such interaction may provide a novel acoustic means for *in vivo* microinjection, applicable to targeted delivery of macromolecules and gene vectors to biological tissues.

1:20

3pPA2. In-liquid plasma processing using high-frequency or microwave irradiation. Shinfuku Nomura and Hiromichi Toyota (Dept. Mech., Ehime Univ, Matsuyama, 790-8577, Japan, nomu@eng.ehime-u.ac.jp)

In-liquid plasma is generated by applying high-frequency (27 MHz) or microwave (2.45 GHz) radiation to hydrocarbon liquids or water. In-liquid plasma is expected to replace gas-phase plasma because the reaction rates for chemical deposition of in-liquid plasma are much higher than those for conventional vapor deposition. Moreover, the cooling effect of the liquid mitigates thermal damage to the substrate. In-plasma generation requires the existence of bubbles because this plasma occurs in bubbles in liquid. Two methods exist for generating bubbles. One is to generate vapor bubbles by heating the liquid. The other is to generate acoustic cavitaion bubbles. Sonoplasma is created when acoustic cavitation is used to generate in liquid plasma. This plasma is not arc-discharged plasma, but rather high-frequency or microwave plasma. Therefore, it is useful in many industrial applications. Using this technology as a chemical reactor, synthesis of diamondlike carbon, polycrystalline silicon carbide, and carbon nanotubes, decomposition of waste oils, and the production of hydrogen can be achieved easily in hydrocarbon liquids. Temperatures were measured from the ratio of emission intensities of H_α and H_β. Plasma temperatures in hydrocarbon liquids are higher than those in water.

1:40

3pPA3. Acoustical and optical characterization of air entrapment in piezo-driven inkjet printheads. Detlef Lohse, Jos de Jong, Roger Jeurissen, Michel Versluis (Phys. of Fluids, Univ. of Twente, P.O. Box 217, 7500 AE Enschede, The Netherlands), Hans Reinten, Marc van den Berg, and Herman Wijshoff (Océ Technologies B.V, 5900 MA Venlo, The Netherlands)

Stability of inkjet printers is a major requirement for high-quality printing. However, in piezo-driven inkjet printheads air entrapment can lead to malfunctioning of the jet formation. A voltage pulse applied to a piezoelectric element causes an ink-filled channel to deform, thereby creating a pressure waveform in the ink. Fluid acoustics are involved to guide the waveform energy towards the nozzle and to create pressure and velocity profiles needed for the droplet jetting process. Droplets are jetted every 50 μs, and the typical nozzle size is 30 μm. The piezo actuator is employed to actively monitor the channel acoustics and to identify distortions at

3p THU. PM

an early stage. Modifications of the response of the piezo actuator indicate entrapped air bubbles and these allow us to investigate them. When the signal is employed as a trigger for high-speed imaging, the consequences of the entrained bubbles on the droplet formation can be visualized. [This study has been financed by the Fundamenteel Onderzoek der Materie (FOM) of The Netherlands under Grant. No. 02MFS39 and by Océ Technologies B.V.]

3pPA4. Fully nonlinear model for spherical bubble oscillations between rigid parallel plates. Jianying Cui and Preston S. Wilson (Mech. Eng. Dept., Univ. of Texas, Austin, TX 78712-0292)

Many medical ultrasound applications involve the interaction of intense acoustic waves with bubbles confined by blood vessels or tissue. As a step toward understanding such systems, a bubble confined between two parallel rigid plates was modeled using the image method. The model equation is of Rayleigh-Plesset form, including compressibility of the liquid and accounting for boundary conditions imposed by the plates [Cui *et al.*, Proc. 17th ISNA, edited by Atchley *et al.* (AIP, New York, 2006), pp. 229–232]. An analytical solution for the second harmonic, and fully nonlinear solutions in the quadratic approximation, were reported previously. Here, a hybrid time-frequency algorithm is presented for solving the complete nonlinear model equation. In particular, the effect of the plates is most conveniently dealt with in the frequency domain, whereas the nonlinearity due to the gas law is best handled in the time domain. The procedure was verified for moderate drive amplitudes by comparison with a spectral algorithm for solving the model equation in the quadratic approximation [Cui *et al.*, J. Acoust. Soc. Am. **118**, 1942 (2005)]. Results obtained from the hybrid algorithm will be presented that illustrate the effect of plate separation for different amplitudes and frequencies of acoustic excitation.

2:15

3pPA5. Controlled cavitation in lab-on-a-chip systems. Claus-Dieter Ohl, Ed Zwaan (Phys. of Fluids, Univ. of Twente, Postbus 217, 7500 AE Enschede, The Netherlands), Sèverine Le Gac (Univ. of Twente, 7500 AE Enschede, The Netherlands), and Kinko Tsuji (Shimadzu Europa GmbH, Duisburg, Germany)

Typically cavitation bubble dynamics is studied either in a free, liquid or close to rigid, free or flexible boundaries. Here, we report on a new experimental approach to study cavitation bubbles in confined geometries with sizes comparable to the cavitation bubble (20–100 μm). These fluid environments are fabricated in a polymeric material (PDMS, polydimethylsiloxane) using a conventional molding process from a silicon master (lab-on-a-chip systems). The bubbles are generated by focusing pulsed laser light into the microfluidic systems filled with a light-absorbing dye. The bubble dynamics is recorded stroboscopically and with high-speed photography. We report on bubble dynamics in various geometries such as in triangular, square, and disk-shaped structures. Additionally, we study a cavitation bubble-based micropump, the effect of the channel width on jetting dynamics, and the interaction of the cavitation bubble on suspension cells. The fluid flow is easily visualized by adding microparticles into the liquid. The authors propose that this new experimental approach opens an interesting toolbox in cavitation research.

2:30

3pPA6. Model for the interaction between a bubble and an elastic particle. Todd A. Hay and Mark F. Hamilton (Appl. Res. Labs., Univ. of Texas, Austin, TX 78713-8029, haymaker@mail.utexas.edu)

At the Providence meeting, a model describing the interaction of a spherical bubble with a rigid spherical particle was presented [Hay and Hamilton, J. Acoust. Soc. Am. **119**, 3408 (2006)]. Here, elasticity of the particle is considered. The model accounts for pulsation and translation and is accurate to fifth order in terms of the ratio of characteristic radius to separation distance. The dynamical equations are derived using the Lagrangian formalism of Ilinskii *et al.* [Proc. 17th ISNA, edited by Atchley *et al.* (AIP, New York, 2006), pp. 303–310]. Bubbles and elastic solid particles are considered with radii on the order of microns and driven at

megahertz frequencies. The radial particle motion is quasistatic under these conditions. For moderate bubble pulsations at which the liquid may be considered incompressible, translational motion of the bubble and particle is insensitive to whether the particle is elastic or rigid. Consideration is also given to truncation of the model at fifth order. Derivation of the model equations to arbitrary order was facilitated by the development of a computer algebra program. The importance of including higher-order terms for small separation distances is illustrated. [T.A.H. was supported by an NSF Graduate Research Fellowship.]

3pPA7. Deformation of a single bubble in organic solutions by ultrasound. Hiroshi Itami, Shinobu Mukasa, shinfuku Nomura, Hiromichi Toyota, and Yoshiyuki Takahashi (Dept. of Mech. Eng., Ehime Univ., Matsuyama, 790-8577 Japan)

Behavior of a single bubble under an ultrasound resonant state in a hydrocarbon liquid such as n-dodecane or benzene was observed using a stroboscope and a charge-coupled device (CCD) camera. Although sonoluminescence was not confirmed because of bubble stability limitations, bubble deformation was observed at a situation of stability limitation. Deformation occurred when the bubble contracted to its minimum size. Numerical analyses of deformation growth by Rayleigh-Taylor instability of an oscillated bubble were carried out at the surface. The distortion amplitude of all degrees continued oscillating as the bubble expanded or contracted, and the oscillation frequency increased with the degree. The distortion amplitudes are amplified through the afterbounce by the resonance effect if the oscillation frequency of the distortion amplitude of some degree is approximately equal to the frequency of the afterbounce. The distortion amplitude of all degrees, except for amplified degrees, was dampened by the viscosity effect, and if the distortion amplitudes of all degrees were dampened, the bubble was considered to form a sphere and become stable. A phase diagram of stability of an oscillated bubble showed a function of an ambient bubble radius and the amplitude of forcing pressure.

3pPA8. Observe multibubble cavitations in the ultrasonic cleaning tank. Nakagawa Noritoshi, Wu Chaoqun, and Sekiguchi Yasuhisa (Grad. School of Eng., Hiroshima Univ., 1-4-1 Kagamiyama, Higashi-hiroshima, Japan)

A cylindrical ultrasonic cleaning tank radiated by a PZT with a large horn operated at 27.3 kHz is employed to investigate the manifestations of cavitation in the present research. The characteristics of this cleaning system are analyzed using experimental methods. In this cleaning tank, the nonuniformity of vibration velocity on the radiation surface induces the Eckart streaming, which can eliminate the effect of a standing wave on cleaning efficiency. Fresh tap water and degassed water are employed as test liquids in this research. In tap water, conical streaming is observed as the input voltage of the transducer is increased over 100 V. The structure of conical streaming is anatomized. Its shape varies with the change of input voltage. In degassed water, ultrasonic fireworks are observed and special attention is paid to their subsequences, snowflake bubble clouds and water jet.

3:30

3pPA9. Characterization of in-liquid plasma in a continuous liquid flow. Hiromichi Toyota, Shinfuku Nomura, Shinobu Mukasa, Hiroshi Yamashita (Dept. of Mech. Eng., Ehime Univ., Matsuyama, 790-8577 Japan, toyota@eng.ehime-u.ac.jp), Ayato Kawashima, and Tsunehiro Maehara (Ehime Univ., Matsuyama, 790-8577 Japan)

In-liquid plasma is a useful invention because its chemical reaction rate is several thousand times higher than those of conventional plasma techniques. However, in-liquid plasma is not so familiar now because its fundamental characteristics remain unclear. We investigated characteristics of in-liquid plasma in a continuous liquid flow to facilitate its application as a chemical decomposition or synthesis device. N-dodecane is supplied by the pump and a stable liquid flow is set in the rectangular vessel. Because the flow velocity is insufficient, a nozzle is set 2 mm distant from the microwave electrode tip. The average flow velocity of n-dodecane at the nozzle top is 0–19 m/s and the Reynolds number is as high as 1.2×10^4. A 2.45-GHz microwave is introduced by a monopole antenna electrode inserted into a rectangular cavity resonator. In-liquid plasma is generated and observed in the flowing cavitation bubbles generated from the ultrasonic horn tip. The vessel's inner pressure is adjusted to 65–450 hPa. The temperature in the plasma reached 3600 ± 300 K; it was almost independent of the flow velocity because the physical properties of the plasma are influenced only slightly by the acoustic cavitation stream.

3:45

3pPA10. Microbubble shape oscillations excited through an ultrasound-driven parametric instability. Michel Versluis (Phys. of Fluids, Univ. of Twente, P.O. Box 217, 7500 AE Enschede, The Netherlands), Peggy Palanchon, Dave Goertz, Nico de Jong (Erasmus MC, Rotterdam, 3000 DR Rotterdam, The Netherlands), Ivo Heitman, Sander van der Meer, Benjamin Dollet, and Detlef Lohse (Univ. of Twente, 7500 AE Enschede, The Netherlands)

An ultrasonically driven air bubble can become shape-unstable through a parametric instability. Here, we report time-resolved optical observations of shape oscillations (mode $n = 2$ to 6) of micron-sized single air bubbles for a range of acoustic pressures. The observed mode number n was found to be linearly related to the resting radius of the bubble. Above the critical driving pressure threshold for shape oscillations, which as expected is minimum at the resonance of the volumetric radial mode, the observed mode number n is independent of the forcing pressure amplitude. The microbubble shape oscillations were also analyzed numerically by introducing a small, nonspherical linear perturbation into a Rayleigh-Plesset-type equation model which includes a physical thermal damping mechanism describing heat and mass transport in the thin boundary layer at the bubble-to-water interface. Indeed, a parametric instability is responsible for the shape oscillations, and the Rayleigh-Plesset-type equation captures the experimental observations in great detail.

4:00

3pPA11. Numerical investigation of interactions between ultrasound propagation and cavitation bubbles in shock wave therapy. Marko Liebler, Thomas Dreyer, and Rainer E. Riedlinger (Institut fuer Hoechstfrequenztechnik und Elektronik, Universitaet Karlsruhe, Kaiserstr. 12, D-76131 Karlsruhe, marko.liebler@ihe.uka.de)

Acoustic cavitation in shock wave applications is responsible for several therapeutic effects as well as for undesired side effects. Using a two-phase continuum approach for bubbly liquids, a numerical model is presented to simulate the interactions between nonlinear ultrasound propagation and cavitation bubbles. Numerical results are presented, showing in what manner the presence of cavitation bubbles alters the pressure pulse propagation and how the bubble dynamics can be specifically affected by changing the shock pressure waveform. An increased bubble density leads to significant changes in the tensile part of the pressure waveform. This effect is caused by the changes in medium compressibility due to the oscillating cavitation bubbles. Calculations for the bubble cloud dynamics induced by three pressure waveforms with identical energy but different temporal forms of the tensile part are compared. Simulation results demonstrate that tensile parts with low amplitude but long duration increase the cavitation effect compared to high amplitude but short tensile phases.

Invited Papers

1:05

3pPP1. Auditory grammar: The event construction model and spoken language. Yoshitaka Nakajima (Dept. of Acoust. Design, Kyushu Univ., 4-9-1 Shiobaru, Minami-ku, Fukuoka 815-8540, Japan, nakajima@design.kyushu-u.ac.jp)

Several auditory illusions are accounted for by using the event construction model as presented by Nakajima *et al.* (2000) in order to explain the gap transfer illusion. In this model, the perceptual system detects and processes onsets and offsets of sounds as if they were independent elements. Temporal edges of sounds and their perceptual attributes are combined to construct auditory events

obeying the proximity principle in time and frequency. For example, the onset and offset of a Chinese syllable belonging physically to different tones can be combined if close enough in time and frequency. The listener often hears a syllable with a lexical tone resulting from this illusory connection. Illusory attribution of perceptual features also occurs in nonspeech tones. One demonstration where only an offset of a glide is presented shows the mechanism; a very short illusory tone with no physical counterpart is perceived. Probably, the perceptual system looks for an onset to connect with the offset, but fails and is forced to restore an onset. Our attempts to connect this model to speech perception and pitch perception are presented along with some novel demonstrations. [Work supported by JSPS and 21st Century COE, Kyushu University.]

<center>1:25</center>

3pPP2. The 100- to 150-ms window of auditory temporal processing and its consequences. Pierre Divenyi (Speech and Hearing Res., VA Medical Ctr., Martinez, CA 94553)

Robert Efron (Percept. Psychophys. **14**, 518–530 [1973]) demonstrated that the minimum duration of a percept is between 100 and 130 ms for auditory, vibrotactile, and visual stimuli, suggesting the presence of a most likely centrally located temporal integrator with a time window of about that length. Single-unit studies in the cat auditory cortex also unveiled an integration time of 100-150 ms (C. E. Schreiner and R. V. Urbas, Hear. Res. **21**, 227–241 [1986]). This window corresponds to the lower limit of the longest among Ira Hirsh's three-tiered temporal processing ranges [in *Sensation and Perception*, edited by H. R. Moskovitz *et al.* (Riedel, Dordrecht, 1974), pp. 251–258]. The present study argues that a temporal window of this duration can account for a variety of auditory perceptual results requiring temporal processing, such as temporal order identification, segregation of dynamically changing streams, robust speech intelligibility, and backward masking. Results also show that this window routinely becomes longer with age, with the possibility that the increased length of the window may account for some well-known central auditory processing deficits in aging. [Work supported by NIH, the VA Medical Research, and the 21st Century COE Progam, Kyushu University.]

<center>1:45</center>

3pPP3. Types of illusory continuity of verbal and nonverbal sounds: Some observations leading to their discoveries. Richard M. Warren (Univ. of Wisconsin—Milwaukee, Dept. of Psych., P.O. Box 413, Milwaukee, WI 53201-0413)

When gaps of a few hundred ms in a signal (e.g., speech, music, steady-state tones, tone glides) are replaced by a louder sound capable of masking the missing portion, the signal appears intact; the absent fragment can be perceptually synthesized through reallocation of a portion of the louder sound's auditory representation. General rules and the special rules governing various types of restoration will be discussed, as well as how they were found through a series of observations, inferences, and experiments. [Work supported by NIDCD Grant No. R01 DC000208, and travel expenses provided by the COE Program of Kyushu University.]

<center>2:05</center>

3pPP4. Music sound restoration and the effect of presentation conditions. Takayuki Sasaki (Miyagi Gakuin Women's Univ., Sendai, Japan)

When a music sound in a melody was deleted and replaced by a noise, a missing sound can be restored perceptually. This illusory phenomenon in audition, named music sound restoration, can be proved indirectly by inaccurate judgment of temporal position of the inserted noise. In the present study, music sound restoration was investigated in terms of the temporal position of replaced noise, headphone listening or free field listening, and the listeners' knowledge of the phenomenon. The results showed that the accuracy of the noise location differed between the positions of replaced noise in the melody or within a beat. The perceptual restoration occurred not only in a headphone listening but also in a free-field listening. It was revealed that the accuracy of noise localization elevated when the listeners knew the stimulus construction, but it was still lower than that of a blank. It was also confirmed that a missing sound could be restored perceptually, not only in a melodic sequence but also in a simple sequence such as scale. [This work was supported by JSPS and 21st Century COE, Kyushu University.]

<center>2:25</center>

3pPP5. An analysis of timing microstructure in Mozart's piano sonata K.331. Kengo Ohgushi (1-6-10 Oheyama, Goryo, Nishikyo-ku, Kyoto 610-1102 Japan, ohgushi-19.38@r7.dion.ne.jp)

It is known that a phrase-final lengthening, including a pause, plays an important role both for the intelligibility and the naturalness of speech. This fact is likely to hold true for performance of music. The present study investigates (a) how the phrase-final lengthening appears in performances of Mozart's piano sonata in A Major (K.331) and (b) what are common and individual features of the performances by five groups of pianists, European professional, Chinese student, Korean student, Japanese professional, and Japanese student pianists. One hundred and twelve pianists' performances of the first eight measures are analyzed in terms of the inter-onset intervals (IOIs). The data are averaged for the respective groups. The IOI patterns indicate (a) the final notes of the first half measures as well as the final notes of the second half measures are lengthened, (b) final note lengthening is more prominent in the fourth measure where the first phrase ends than in the other measures, and (c) Japanese student pianists play the rhythm of dotted eighth note and the sixteenth note differently from the pianists of other countries. [Work supported by JSPS and 21st Century COE, Kyushu University.]

3pPP6. Lost silence as a consequence of stream segmentation. Shuji Mori (Cognit. Sci. Lab., ISEE, Kyushu Univ., 6-10-1 Hakozaki, Higashi-ku, Fukuoka 812-8581, Japan)

A sequence of successive tones can be segmented into perceptually distinctive streams by inserting a silent gap or by changing the frequency in mid-sequence. This study demonstrates that a silent gap is perceptually lost when the gap coincides with the frequency change that occurs between tones. Even a 40-ms gap is undetectable when the tonal frequency is shifted from 800 to 3200 Hz. One interpretation of this "lost silence" phenomenon is the prioritization of frequency change as a cue for auditory segmentation. A silent gap and a change in frequency both mark a stream boundary if they are salient. They will be redundant as boundary markers when they coincide with each other; the frequency change will preempt the priority in auditory processing, whereas gap information will receive little processing and eventually become indiscernible. This phenomenon might be related to perceptual ambiguity of the temporal relation of separate streams (Van Noorden, 1975). [Work supported by JSPS.]

3:05

3pPP7. Exclusive allocation of a gap that is shared by two separate sounds. Gerard B. Remijn and Yoshitaka Nakajima (Kyushu Univ., Faculty of Design, 4-9-1 Shiobaru, Minami-ku, 815-8540 Fukuoka, Japan)

When a short temporal gap (40 ms or less) is inserted at the crossing point of two separate sounds of unequal duration, the gap is often allocated only to the shorter sound, whereas the longer sound can be perceptually completed (modal completion). This study shows that the exclusive allocation of the gap to the shorter sound—and the perceptual completion of the longer sound—is most profound when the start of the short sound and the start of the gap are separated by 400 ms or less. A possible explanation for the exclusive allocation of the gap is that within this temporal window, attention is engaged in the formation of a new auditory stream, a process initiated by the shorter sound's onset. When subsequent auditory elements—even a gap—arrive within the temporal window of attentional engagement, these elements will be automatically included in the new stream. [This study was supported by the COE program of Kyushu University, Japan, and the Japan Society for the Promotion of Science.]

3pSA1. Japanese standards and situation of studies about heavy and soft impact sources. Atsuo Hiramitsu (Bldg. Res. Inst., 1 Tachihara, Tsukuba-City, Ibaraki 305-0802, Japan, hiramitu@kenken.go.jp) and Katsuo Inoue (Nihon. Univ, Kanda-Surugadai 1-chome, Chiyoda-ku, Tokyo 101-8308, Japan)

This report describes standards of heavy and soft impact sources. They are used for measurement of floor impact sound insulation of buildings. In Japan, the method for field measurement of floor impact sound level (JIS A 1418) was revised in 2000 and separated into two parts. Part 1 uses a standard light impact source and corresponds to ISO 140-7. Part 2 uses heavy and soft impact sources. At that time, a rubber ball was standardized along with a car-tire source in JIS A 1418-2. Moreover, JIS A 1440-1 and JIS A 1440-2 for laboratory measurement of the reduction of transmitted floor impact sound have been prepared. JIS A 1440-1 corresponds to ISO 140-8, and JIS A 1440-2 uses heavy and soft impact sources. Floor impact sources characteristics are introduced. They include force characteristics, temperature dependence, stability, and others. In addition, among contents of JIS A 1440-2, the measurement method, calculation method, and a laboratory of a box-frame-type reinforced concrete construction are explained. In addition, study examples using a rubber ball are introduced. As examples, we present the·floor impact sound level, the transmitted floor impact sound level, hearing tests on floor impact sound, and evaluation of walking sensations.

1:55

3pSA2. Trends for prediction methods of heavyweight floor impact sound. Takashi Koga (Bldg. Construction Management Div., Kajima Corp., 1-2-7 Moto-Akasaka, Minato-ku Tokyo 107-8388, Japan, tkoga@kajima.com), Katsuo Inoue (Nihon Univ., Tokyo 101-8308, Japan), and Shinji Nakazawa (Tekken Corp., Chiba, 286-0825, Japan)

Trends of building structures of Japanese multifamily dwellings and prediction methods of heavyweight floor impact sound are introduced. Floor impact sound-reduction performance caused by human action like stepping and jumping is considered to be a vital function for Japanese apartment complexes. There are quite a few cases where the floor thickness shall be designed from 200 to 300 mm because of acoustical performance, to assure the required performance. The practical prediction method, the so-called impedance method, was been established in the 1970s, and it has been commonly used. Though there are many buildings that are out of the applicable scope of the ordinal impedance method with the rise of structural design technology, the outline shown is that of the revised practical prediction method that is under discussion by the working group of the Architectural Institute of Japan. And, examples of hybrid method are also introduced that substitute the impedances by numerical vibration calculation results using finite-element method for simplified calculation results of impedance method.

2:15

3pSA3. Correlation of field measurements for footstep force pulse with finite element analysis model for determining vibration response of a building floor. Richard Carman and James Phillips (Wilson, Ihrig & Assoc., 5776 Broadway, Oakland, CA 94618)

An idealized force pulse that simulates footsteps was developed by Galbraith and Barton. Their proposed forcing function was determined from direct force measurements using walkers of different weights walking at various speeds. Unger and White used this idealized footstep pulse to determine the maximum dynamic deflection of a floor for the purpose of building design calculations. These basic concepts were used to revisit the characteristics of the idealized forcing function. During the design phase of an academic research facility, extensive vibration measurements were obtained using an exemplar floor similar in design to that proposed for the new research building. The exemplar floor was modeled using FEA. Its modal characteristics were compared to the field test results and found to be in reasonable agreement. Upon having established confidence in the basic FEA model, the field measurement results of two walkers on the exemplar floor were compared with the FEA results predicted using the Galbraith-Barton footstep pulse. The shape and magnitude of the footstep pulse were iteratively adjusted until the measurement results and FEA results were in good agreement. The results of the FEA analysis and the measurement program behind the model will be presented.

2:35

3pSA4. Influence of lightweight structural design of office buildings on vibration levels due to people walking and operation of mechanical equipment. Steven D. Pettyjohn (The Acoust. & Vib. Group, 5700 Broadway, Sacramento, CA 95820-1852)

West coast buildings typically use lightweight structural designs, even for Class A office building. This means the best floors use lightweight concrete on fluted decks with beam and column spacings of 30 to 35 ft. with open web joists at 10 ft. on center. Class B office building may use columns at 28 and 35 ft. with only two-layers of plywood on wood open web joists at 24 in. on center. The resulting floor/ceiling assemblies are structurally sound but dynamically very live. Some structural damping would be expected from the introduction of partitions, but with the use of large open areas and partial height partitions, damping is limited. These assemblies have relatively low resonance frequencies and are very susceptible to any sinusoidal input force such as people walking or operation of mechanical equipment. Vibration measurements, made on four buildings after complaints were received, show the source of some of these problems. The results are compared with predictions by Murray *et al.* and Ungar *et al.* The lack of composite action between the beams and joists/purlins and the floor appears to be the source of many of the problems. Solutions to the problems in these existing and occupied buildings are discussed.

3pSA5. Heavy and light impact sources to rate impact sound transmission and changes due to applied floor toppings. Alf Warnock and Trevor Nightingale (Acoust. Group, Inst. for Res. in Construction, Natl. Res. Council Canada, Ottawa, K1A 0R6, Canada)

The magnitude and spectrum of the power injected by an impact source depends on the impedance of the source and floor. If standardized impact tests are meant to give ratings that correlate well with subjective impressions of footstep noise, it follows that the impact source used should have the same impedance as an average human foot at least over the range of test frequencies. The ISO tapping machine, the Japanese tire machine, and an 18-cm-diam rubber ball do not satisfy this criterion. Consequently, their impact spectra differ from those from a live walker. Floor toppings, in particular, are ranked differently. Examples of discrepancies will be presented for direct transmission between vertically separated rooms. For horizontally and diagonally separated rooms, flanking transmission controls the impact sound pressure level. The sound pressure level depends not only on the power injected by the source, but also source location relative to the flanking junction because of propagation attenua-

tion across the floor. Sensitivity to source location is similar for different sources (ISO tapping machine and Japanese ball), suggesting that the same source could be used for direct and flanking transmission measurements if the source adequately simulates the impedance of a human foot.

3:25

3pSA6. Evaluation of mid- and high-frequency impact insulation methods. John J. LoVerde and David Wayland Dong (Veneklasen Assoc., 1711 Sixteenth St., Santa Monica, CA 90404)

Impact insulation is currently measured using impact insulation class (IIC) and a standard tapping machine described in ASTM E492 and E1007 (and corresponding ISO metrics and standards). The resultant IIC value does not correlate well with subjective reaction. In previous papers, the authors have focused on the low-frequency thudding from footfalls in lightweight wood construction and shown that the impact sound pressure level (ISPL) in the 63-Hz octave band correlates better with subjective reaction than IIC or other metrics [LoVerde and Dong, J. Acoust. Soc. Am. **112**, 2201 (2002); INCE Inter-Noise 2004 Proceedings, 167 (2004); J. Acoust. Soc. Am. **119**, 3220 (2006)]. Further, the low-frequency ISPL is

controlled by different variables than the mid/high-frequency ISPL. This suggests that a two-metric system would be valuable where the first metric describes the low-frequency performance and the second metric describes the mid/high-frequency performance. Field testing experience is presented showing that IIC does not adequately differentiate the mid/high-frequency performance of various resilient materials. Candidate mid/high-frequency metrics are evaluated to determine if any result in improved methods for evaluation and rank-ordering of floor/ceiling assemblies.

3:40

3pSA7. Flanking impact sound transmission in wood-framed multifamily construction. David Quirt and Trevor Nightingale (Acoust. Group, Inst. for Res. in Construction, Natl. Res. Council Canada, Ottawa, K1A 0R6 Canada)

This paper reports findings from a recently completed study of flanking sound transmission involving the wall/floor junction in wood-framed multifamily buildings. Flanking transmission exists in all buildings, but it can be controlled through good design. The paper examines how common construction details affect flanking paths between horizontally, vertically, and diagonally separated rooms. Variables considered include mounting conditions and orientation of the floor joists, framing of the wall assembly and any associated fire blocking, and mounting and number of layers of gypsum board. Estimates of the apparent sound insulation were obtained by summing the energy transmitted by the direct path through the wall or floor assembly separating the pair of rooms, and all the flanking paths involving the relevant wall-floor junctions. Results indicate that if there is no floor topping (i.e., the subfloor is bare) the apparent sound insulation

for both airborne and impact sources is typically limited by flanking transmission involving the floor. Since, the source room floor is an element common to all impact flanking paths, three different toppings were evaluated as treatment options, and additional layers of gypsum board and resilient mounting were considered as options for the walls. The effectiveness of each option is discussed

3pSA8. Case history building structural vibration isolation for 500 Atlantic Avenue. Gregory Tocci (Cavanaugh Tocci Assoc., Inc., 327F Boston Post Rd., Sudbury, MA 01776), George Wilson, James Phillips (Wilson Ihrig & Assoc., Inc.), Gladys Unger, and James Moore (R.H. Lyon Div. of Acentech)

Vent Building 3 of the new Central Artery Tunnel located at 500 Atlantic Avenue in Boston, Massachusetts is a heavy poured in place concrete structure with its roof situated about 3 ft. below grade. The vent building contains 23 100+-in.-diameter double-width centrifugal fans that, for a number of reasons, are not vibration isolated. The fans exhaust into a cluster of reinforced concrete shafts that rises up to about 250 ft. above grade. The tall stacks have been embedded in a luxury hotel/residential condominium complex that Extell Development Company is currently constructing. The stacks provide both vertical support and seismic support for the building. This paper summarizes the history of work on the project, and compares predicted and measured sound and vibration levels in representative building spaces. [We wish to acknowledge the support of Extell Development Company, Boston, MA for their support of this work.]

3pSC1. Timing variations of frequent utterances occurring in a very large corpus of spontaneous Japanese conversational speech. Nick Campbell (ATR, Kyoto, Japan)

A corpus of spontaneous conversational Japanese speech was collected from volunteer subjects who wore high-quality head-mounted microphones and recorded their daily spoken interactions to minidisk over a period of 5 years. All recordings were transcribed and tagged according to interlocutor type, and a portion representing about 10% was further annotated for speech-act, speaker-state, emotion, and speaking style. This paper presents timing data from the corpus, showing how the same utterance can vary according to speaking style and other factors. It presents the hundred most common utterances in the corpus and relates their durations to spectral and prosodic characteristics that vary according to affect, attitude, intention, and relationship with the listener.

1:25

3pSC2. On the generation and perception characteristics of Japanese timing control. Yoshinori Sagisaka (Waseda Univ. 29-7 Bldg., 1-3-10 Nishi-Waseda, Shinjuku-ku, Tokyo 169-0051 Japan, sagisaka@giti.waseda.ac.jp), Makiko Muto (Univ. of Tokyo, Japan), Hiroaki Kato (NiCT/ATR, Japan), and Minoru Tsuzaki (Kyoto City Univ., Japan)

We have been studying temporal characteristics of Japanese for decades. Not only acoustic measurements but also perceptual studies on temporal modification have revealed the control principles lying behind manifestation of segmental duration characteristics. This talk tries to introduce familiar generation principles such as "mora-timing" and phrasal tempo reset from the viewpoint of humans temporal organization through the understanding of duration statistics. Moreover, by showing perceptual characteristics

including sentential factors, we would like to propose how linguistic units relate to temporal perception and what kind of information form can be considered in temporal cognition process. Some of our recent efforts will also be presented to investigate language-dependent temporal characteristics by observing non-native learners temporal control characteristics. We really expect that we will be able to have a better picture of generation and perception mechanism through the cross check of their characteristic differences between natives and non-natives. [Work supported by Waseda Univ. RISE research project of "Analysis and modeling of human mechanism in speech and language processing" and Grant-in-Aid for and Scientific Research A-2, No. 16200016 of JSPS.]

1:45

3pSC3. Temporal control in Japanese dialects. Haruo Kubozono (Kobe Univ., Nada-ku, Kobe 657-8501 Japan, kubozono@lit.kobe-u.ac.jp)

This paper discusses the extent to which temporal control varies among Japanese dialects. Most dialects of Japanese including Tokyo Japanese are so-called "mora dialects" in which the mora serves as the basic unit of timing. In the periphery of Japan, however, we find a couple of dialects called "syllable dialects" whose basic phonological unit is the syllable rather than the mora. Kagoshima Japanese (KJ) is one such dialect, but little is known about its temporal organization. The main purpose of this paper is to report on the results of an acoustic experiment on this syllable-based dialect and to compare them with those of the experiments about Tokyo Japanese (TJ). This comparison reveals the following four points: (*i*) geminate consonants are considerably longer than single consonants in both TJ and KJ, (*ii*) however, the phonetic duration of words in KJ is not determined by the number of moras involved but by the number of syllables, (*iii*) in KJ, vowels are consistently shorter when they follow geminate consonants than when following single consonants, and (*iv*) unlike English, Korean, and other languages, neither TJ nor KJ shows an effect of vowel shortening in closed syllables.

2:05

3pSC4. Japanese mora-timing and processing: The case of devoiced vowels. Natasha Warner and Naomi Ogasawara (Dept. of Linguist., Univ. of Arizona, P.O. Box 210028, Tucson, AZ 85721-0028, nwarner@u.arizona.edu)

An extensive literature has argued that Japanese speakers compensate for inherent durational differences to keep moras to approximately equal lengths (e.g., Han, 1962; Port *et al.*, 1980; Minagawa-Kawai, 1999; reviewed in Warner and Arai, 2001a). However, near-regularity of moras may not be because of intentional compensation (Warner and Arai, 2001b). This paper examines Japanese listeners processing, rather than production, of one case of irregularly timed moras: vowel devoicing. When Japanese vowels are devoiced, the mora tends to be shorter than usual. If speakers aim for regular timing, one might predict that listeners would also expect moras to be regularly timed and would thus have difficulty processing sequences that deviate from regular mora timing. However, one could predict that listeners are aware of what deviations from regular timing to expect, and thus have no difficulty processing timing deviations. The results, from phoneme monitoring and lexical decision tasks, show that listeners only have difficulty processing devoiced vowels in environments where devoicing would not be expected. In fact, where devoicing would be typical, listeners find devoiced vowels easier to process. This suggests that in processing, knowledge of patterns in the language outweighs any bias toward regularly timed moras.

2:25

3pSC5. Perception and production of long and short vowels in Japanese by children. Takayuki Arai (Dept. of Elec. and Electron. Eng., Sophia Univ., 7-1 Kioi-cho, Chiyoda-ku, Tokyo, 102-8554 Japan), Kyoko Iitaka, and Eriko Ohki (Sophia Univ., Chiyoda-ku, Tokyo, 102-8554 Japan)

Studies have shown that acquisition of reading depends on such phonological processes as verbal short-term memory and temporal processing of speech. An inability to encode phonological representations orthographically may cause reading disabilities, such as dyslexia. Categorical perception is known to be closely associated with phonological encoding. Thus, studies examining the temporal processing of speech sound categorization may be useful in differential diagnoses of reading development and disabilities. The first study examines the perception of long and short Japanese vowels by a group of seven normal six-year-old children and two with delayed phonological development. Subjects were asked to identify vowel length in sets of words. The first vowel in each stimulus word was made to vary with respect to length. Perception by normal and delayed children differed in ways similar to what had been reported in previous English studies. In the second study, the relation between perception and reading of long/short vowels was examined by a group of 125 children ages 4 to 8. Similar settings were used for the second experiment. The results showed that (1) a large developmental change of perception was observed in ages 6–8 and (2) a positive correlation was obtained between perception and reading tasks.

3pSC6. Effects of speaking style on the regularity of mora timing in Japanese. Michael Connolly Brady, Robert F. Port, and Kyoko Nagao (Dept. of Linguist., Indiana Univ., Bloomington, IN 47405)

The regularity of mora timing in Japanese has remained controversial over the years [Warner and Arai, Phonetica **58**, 1–25 (2001)]. It is possible that the degree of regularity varies with speaking style. Four Japanese subjects spoke six-mora proper names with varying syllable structures where the second name had either three simple syllables (e.g., *Tomiko*) or two syllables with a long vowel (e.g., *Tooko*) or a long consonant (e.g., *Tokko*). These were read either in formal sentences, read in conversational style sentences, or used in spontaneous description of pictures of characters having these names. Moras were measured as the intervals between vowel onsets using an automatic vowel-onset detection algorithm. Although all styles suggested regular mora timing, the results show that the styles differ in the degree of temporal compensation for the moras constituted by long vowels and long consonants which are shorter than consonant-vowel syllables. The compensation was clearest in the most formal style of speech.

3pSC7. Representations of within-word structure and Japanese speech timing. Takashi Otake (E-Listening Lab. and Max Planck Inst. for Psycholinguist., 3-35-20, Higashi-Tokorozawa, Tokorozawa, Saitama, 359-0021 Japan)

One complication about the debate of mora timing is that durational units are closely related to syllable structure in which morae can be treated as subunits of syllables. As a consequence, durational properties of the components in three types of syllables, CVN, CVV, and CVQ, can equally be examined from the point of representations of within-word structure. Durational properties in Japanese speech timing undoubtedly play an important role, but knowledge of representations of within-word structure cannot be neglected because it is uniquely language specific. In this presentation it is discussed how knowledge of representations of within-word structure plays a significant role in recognition of morae from the point of psycholinguistic framework, presenting various types of data that were collected from (1) Japanese preschool children (before and after acquiring kana orthography), (2) Japanese monolinguals and Japanese English bilinguals, and (3) Japanese L2 learners (from beginning to advanced whose native language is English). Also reported are data from Telugu (a Dravidian language spoken in India), whose speech segmentation mechanism behaves like that of mora-timed language. It is hoped that knowledge of representations of within-word structure together with the durational properties will facilitate Japanese learners to acquire Japanese speech timing.

3pSC8. DiscourseWare, a blended learning courseware for understanding and producing Japanese audio-visual reactive tokens. Goh Kawai and Takafumi Utashiro (Inst. of Lang. and Culture Studies, Hokkaido Univ., Sapporo, Hokkaido 060-0817 Japan, goh@kawai.com)

We developed blended learning courseware called DiscourseWare for learning Japanese audio-visual reactive tokens. Acquiring proper token choice, timing, frequency, duration, and intonation are emphasized. The courseware consists of interactive computer-based multimedia material and classroom instruction. Lessons start with instructor-led classroom instruction on the types and usage of various reactive tokens. Learners then independently use interactive computer-based courseware to learn how to choose appropriate reactive tokens. The courseware contains videos showing two native speakers conversing using a uncontrolled vocabulary and syntax and at a natural speed. The reactive token being taught is blanked out. Learners solve multiple-choice problems asking which reactive token would be appropriate in that context. Learners increase proficiency in interpreting various prosodic patterns of the same phonetic string. After computer-based training, learners regroup and practice exchanging reactive tokens. Our courseware is accompanied by a syllabus for reactive tokens that might interest researchers of comparative pragmatics as well as language instructors. The conference presentation will include DiscourseWare demonstrations, and before-and-after training comparisons of non-native learners' reactive token productions as assessed through interviews with language teachers.

3pSC9. An issue of rate normalization for learners of Japanese. Yukari Hirata (Dept. of East Asian Lang. and Lit., Colgate Univ., 13 Oak Dr., Hamilton, NY 13346)

This talk explores native and non-native speakers' identification of Japanese phonemic length contrasts in sentences of varying speaking rates. Native Japanese speakers were found to use the rate of the sentence surrounding a target word as a perceptual cue (i.e., to normalize speech rate) to distinguish phonemic vowel and consonant length. This perceptual cue overrode more local cues such as physical duration of the target vowel or consonant. However, when beginning learners of Japanese participated in the same listening tasks, they were unable to normalize speech rate and identify length of vowels and consonants as native speakers did. Specifically, when asked to identify the length of vowels in /mV(V)mV(V)/ (with the first vowel accented) in sentences of slow and fast rates, the learners were least accurate in identifying the long vowel of /mVmVV/ in sentences spoken at a fast rate. The learners' perception was biased by physical duration of vowels and by the presence or absence of pitch accent. Their identification accuracy for long vowels was more affected by speaking rate than that for short vowels. Taken together, these results suggest a need for a training program to help learners of Japanese to cope with speaking rate variations.

3pSC10. Effects of exposure and training on perception of Japanese length contrasts by English listeners. Keiichi Tajima (Dept. of Psych., Hosei Univ., 2-17-1 Fujimi, Chiyoda-ku, Tokyo 102-8160, Japan, tajima@i.hosei.ac.jp), Hiroaki Kato (NICT/ATR, Kyoto 619-0288, Japan), Amanda Rothwell, Reiko Akahane-Yamada (ATR, Kyoto 619-0288, Japan), and Kevin G. Munhall (Queen's Univ., Kingston, ON, Canada)

Native English listeners are known to have difficulty distinguishing Japanese words that contrast in phonemic length, often realized as a contrast in vowel or consonant duration. The present study reports results from a series of experiments investigating the extent to which English listeners' perception of such length contrasts can be modified with exposure to Japanese and with perceptual identification training. Listeners were trained in a minimal-pair identification paradigm with feedback. A pretest and posttest were also administered, using natural tokens of Japanese words containing various vowel and consonant length contrasts, produced in isolation and in a carrier sentence, at three speaking rates, and by multiple talkers. Results indicated that exposure and perceptual training substantially improved identification accuracy. Even though listeners were trained to identify words contrasting in vowel length only, performance also improved for other contrast types. Furthermore, speaking rate strongly affected performance, but training improved performance at all three rates, even though listeners were trained using only stimuli spoken at a normal rate. These results suggest that non-native listeners are highly susceptible to factors that affect the temporal characteristics of speech, but their perceptual strategies can be modified with exposure and training. [Work supported by NICT and JSPS.]

3pSC11. Categorization of phonemic length contrasts in Japanese by native and non-native listeners. Hiroaki Kato (NICT/ATR, 2-2-2 Hikaridai, Seika-cho, Soraku-gun, Kyoto 619-0288, Japan, kato@atr.jp), Keiichi Tajima (Hosei Univ.), Amanda Rothwell, Reiko Akahane-Yamada (ATR), and Kevin Munhall (Queen's Univ.)

Previous studies reported that exposure to Japanese and identification training allowed English listeners to improve their identification accuracy of Japanese words with phonemic length contrasts. However, this does not necessarily mean their perceptual properties approach those of native listeners in all respects. Past perceptual studies have shown that native listeners show, for example, an extremely sharp short-to-long boundary and shift of the boundary to adapt to changes in the temporal context, i.e., typically speaking rate variations. To carefully investigate the effects of training on such properties, the present study analyzed the learners' identification of stimulus continua between word pairs that minimally differed in the length of a phoneme. Overall results showed that English listeners' boundaries tended to be sharpened by the identification training, but only to a limited extent. On the other hand, the results also showed that English listeners' boundaries shifted across different speaking rates in ways that resemble native listeners' adaptation tendencies. The latter result suggests that even non-native listeners can adjust their identification boundaries according to differences in temporal context. Discussion will include both prospects and limitations of listeners' improvement by the perceptual training in this study. [Work supported by NICT and JSPS.]

THURSDAY AFTERNOON, 30 NOVEMBER 2006   MOLOKAI ROOM, 1:00 TO 5:00 P.M.

Session 3pSP

Signal Processing in Acoustics: Various Topics in Signal Processing (Poster Session)

Charles F. Gaumond, Cochair

Naval Research Lab., Code 7142, 4555 Overlook Ave., S.W., Washington, DC 20375-5320

Yoshinobu Kajikawa, Cochair

Kansai Univ., Dept. of Electronics, Faculty of Engineering, 3-3-35 Yamate-cho, Suita-shi, Osaka 564-8680, Japan

Contributed Papers

All posters will be on display from 1:00 p.m. to 5:00 p.m. To allow contributors an opportunity to see other posters, contributors of odd-numbered papers will be at their posters from 1:00 p.m. to 3:00 p.m. and contributors of even-numbered papers will be at their posters from 3:00 p.m. to 5:00 p.m.

3pSP1. Adaptive surround technology for stereo music signals. Yoshitaka Murayama, Akira Gotoh, Jun Ota, Hareo Hamada (DiMAGIC, Sugisho Bldg 3F, 2-4-5 Kanda-Ogawamachi, Chiyodaku, Tokyo 101-0052, Japan), Yuko Watanabe, and Hareo Hamada (Tokyo Denki Univ., Inzai-shi, Chiba, Japan)

Computation of the left and right channel instantaneous difference $(xL - xR)$ is mostly used to obtain the signals for surround sound. This signal is usually referred as the antiphase components. However, there are many problems to using the antiphase components in terms of its applicability in practice as well as the sound quality. For instance, when signals xL and xR are equal, or almost equal, this variation, that is to say, the correlation coefficient value, is high; there is no way to determine the direction vector uniquely, therefore an ambiguity may appear. Instead of the antiphase component's computation, a new method is proposed by using an adaptive signal processing technique. In this paper, it is revealed that natural surround sound signals having no antiphase and uncomfortable feeling are adaptively generated by the proposed method. The other advantages from a signal processing point of view are also discussed. Finally, subjective evaluations on sound quality of a surround sound system are carried out.

3pSP2. A design of fast steering filters based on the adaptive fusion of predesigned finite impulse response filters for microphone array. Masato Nakayama (Grad. School of Sci. and Eng., Ritsumeikan Univ., 1-1-1 Noji Higashi, Kusatsu, Shiga 525-8577, Japan, gr020040@se.ritsumei.ac.jp), Takanobu Nishiura, and Yoichi Yamashita (Ritsumeikan Univ., Kusatsu, Shiga 525-8577, Japan)

With a microphone array, a desired distant-talking speech signal can be acquired selectively by steering the directivity in noisy environments. To form directivity, adaptive beamformers have been proposed as conventional beamformers. They can form null directivity with a small number of transducers. However, adaptive beamformers have a serious drawback: it can't realize the noise-robust adaptation in variable noisy environments, because it has necessary heavy computational costs to train multi-channel adaptive steering filters. To solve this problem, we propose to design the fast steering filters based on the adaptive fusion of predesigned FIR filters in variable noisy environments. The adaptive fusion of predesigned FIR filters is realized by adding (or subtracting) various predesigned FIR filters immediately. Therefore, the proposed method can quickly design the steering filters even in variable noisy environments. In addition, microphone calibration is indispensable for applying the proposed method. Therefore, we also propose the new microphone calibration method based on environmental noise without target signal. Evaluation experiments were con-

ducted in a real acoustic room. As a result of evaluation experiments, we could confirm that the ASR (automatic speech recognition) performance of distant-talking speech was improved on the well-known condition of noise source directions. [Work supported by MEXT of Japan.]

3pSP3. A frequency domain method to estimate the coefficients of feedback control filter. Yusuke Iwamatsu, Masahiro Itou, and Kensaku Fujii (Div. of Comp. Eng., Univ. of Hyogo, 2167 Shosha, Himeji, 671-2280, Japan, er05i005@steng.u-hyogo.ac.jp)

This study proposes a method for repeatedly updating coefficients of a feedback control filter used for canceling a feedback path from a loudspeaker to a noise detection microphone. The coefficients are typically estimated by feeding a sequence of extra noise to the loudspeaker. However, feeding such extra noise under active noise control is undesirable. The proposed method estimates the coefficients without feeding the extra noise. Using the estimation errors involved in the coefficients of the noise control filter instead of the extra noise, the proposed method provides two independent equations and estimates coefficients of the feedback control filter by solving those. The two independent equations are provided through linear prediction using an auxiliary filter. A solution of the equations with two unknowns (a primary noise and the feedback path) provides the coefficients of the feedback control filter, perfectly canceling the feedback path. A salient drawback is that the feedback component is extremely small in comparison to the primary noise that is incident on the noise detection microphone. For that reason, estimation of the coefficients is difficult. This method solves the problem by first estimating the primary noise and then the feedback path.

3pSP4. A new multichannel adaptive algorithm. Masahiro Itoh, Kensaku Fujii (Div. of Comput. Eng., Univ. of Hyogo, 2167 Shosha, Himeji, 671-2280 Japan, er05a003@steng.u-hyogo.ac.jp), and Mitsuji Muneyasu (Kansai Univ., 3-3-35 Yamate-chou, 564-8680 Suita, Japan)

This study presents a new multichannel adaptive algorithm that identifies unknown systems without superposing independent components on reference signals. A problem in such multichannel systems is that the reference signals involve strong cross-correlative components between themselves. These components delay the convergence of the coefficients of adaptive filters. At worst, they can render identification impossible. Usually, this problem is solved by superposing slightly independent components on the reference signals. Various superposition methods are therefore proposed. However, this superposition is perceivable as discordant noise. This study hence examines a new algorithm that exploits the residual components obtained by applying a linear prediction technique to the reference signals. The cross-correlative components thereby decrease and the convergence is hastened. Using this algorithm, however, the residual components are not fed into the unknown systems and adaptive filters. This is a point of great difference from conventional methods. This study also analyzes the performance of the proposed algorithm and derives the convergence condition as a range of step size. Finally, computer simulations are used to verify the derived convergence condition and the increased convergence speed.

3pSP5. Frequency domain simultaneous equations method for active noise control systems. Tadashi Ujino, Kensaku Fujii (Div. of Comput. Eng., Univ. of Hyogo, 2167 Shosha, Himeji, 671-2280 Japan, er06e006@steng.u-hyogo.ac.jp), Mitsuji Muneyasu (Kansai Univ., 564-8680, Suita, Japan), and Yusuke Fujita (Catsystem Corp., 671-1121, Himeji, Japan)

This study proposes a new method for feedforward-type active noise control systems. This method, named the frequency domain simultaneous equations method, is based on a different principle from the filtered-x algorithm requiring a filter modeled on a secondary path from a loudspeaker to an error microphone. Instead of the filter, this method uses an auxiliary filter identifying the overall path consisting of a primary path, a noise control filter, and the secondary path. As seen from the configuration of the overall path, the auxiliary filter can provide two independent equations when two different coefficient vectors are given to the noise control filter. In practical use, the two different coefficient vectors are provided by their own estimation errors. By solving the independent equations, the proposed method can estimate the coefficient vector of the noise control filter minimizing the output of the error microphone. This study first presents computer simulation results demonstrating that the proposed method can automatically recover the noise reduction that is in effect degraded by path changes. Finally, this study applies the proposed method to an experimental system and, by using the system, verifies that the proposed method is functional in practical systems.

3pSP6. Partial differential equation (PDE)-based method of sound source localization. Shigeru Ando and Nobutaka Ono (Univ. of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113-8656 Japan, ando@alab.t.u-tokyo.ac.jp)

We describe the problem of direction and distance estimate of sound sources in free 3-D space. We first derive a partial differential equation (PDE), $\nabla f(\mathbf{r},t) = \{(1/R)f(\mathbf{r},t) + (1/c)\dot{f}(\mathbf{r},t)\}\mathbf{n}(R \equiv |\mathbf{r}|, \mathbf{n} \equiv -\mathbf{r}/R)$, what we call the sound source constraint (SSC). We show that the general solution of the SSC is a diverging spherical wave from a point sounce with arbitrary temporal waveform. The SSC enables the observer to determine the source location (distance R and direction $\mathbf{n}$) from local measurements of the wave field. As the measurements of the wave field, we consider two methods: (1) the weighted temporal integral of arrayed microphone outputs in a finite duration and (2) the weighted spatial integral of pressure distribution in a rectangular or circular area. In both cases, we obtain exact formulas for localizing a single source from a single measurement and multiple sources from the combination of differently weighted measurements.

3pSP7. Effects of microphone and loudspeaker directivity on accuracy of synthesized wave fronts in sound field reproduction based on wave field synthesis. Toshiyuki Kimura, Sadanori Ito, Masaki Nakagawa (Dept. of Comp. and Info. Sci., Tokyo Univ. of Agriculture and Technol., 2-24-16 Naka-cho, Koganei-shi, Tokyo, 184-8588 Japan), and Kazuhiko Kakehi (Chukyo Univ., Kaizu-cho, Toyota-shi, Aichi, 470-0393 Japan)

Sound field reproduction based on wave field synthesis proposed by Camras [M. Camras, J. Acoust. Soc. Am. **43**, 1425–1431 (1968)] is a technique that synthesizes wave fronts of a control area at a listening area using directional microphones and loudspeakers placed at the boundary of those areas. This study evaluates the effects of the directivity of microphones and loudspeakers on the accuracy of synthesized wave fronts. Microphones and loudspeakers were placed at the boundary of both areas that have two cases (a circle with a radius of 2 m and a square 4 m on a side). The number of microphones and loudspeakers were 630 (circle) and 801 (square). The interval of microphones and loudspeakers was less than 2 cm. Therefore, spatial aliasing does not occur if the frequency is less than 8 kHz. Three directional patterns (omnidirectional, unidirectional, and shotgun) were designed as directivity conditions of microphones and loudspeakers. Computer simulation results showed that there is no effect of directivity of loudspeakers and that accurate wave fronts can be reproduced when a unidirectional or shotgun microphone is applied. [Work supported by special grant for education and research of Tokyo Univ. of Agriculture and Technol.]

3pSP8. A study of pinna effect on head-related transfer functions.
Hiromi Sekido, Yuko Watanabe, and Hareo Hamada (Tokyo Denki Univ., 2-1200 Muzai-gakuendai, Inzai, Chiba Prefecture 270-1382, Japan)

For the sound localization, an interaural difference is important. To obtain the desired localization, it is necessary to use a head-related transfer function (refer to HRTF), which is defined as the transfer function between a sound source and a surface of the ear drum. In our previous work, as far as in the case of reproducing the virtual sound source in the horizontal plane, it is confirmed to be capable of remarkable localization by using the numeric data calculated by a rigid sphere head model instead of a dummy head microphone. However, it is necessary to solve the problem of the front back confusion and the sound localization of the vertical plane. For that, it might be essential to add the pinna information to the rigid sphere model, to examine how each part of the pinna is related to the localization.

3pSP9. Sound reproduction system with switching control band range on every listening point.
Yosuke Tatekura and Takeshi Watanabe (Dept. of Eng., Shizuoka Univ., 3-5-1 Johoku, Hamamatsu, Shizuoka, 432-8561, Japan)

We propose a robust multichannel sound reproduction system that utilizes the relationship between the width of the actual listening area and the control frequency of the listening points. The conventional multichannel sound reproduction system uses inverse filters that are designed based on room transfer functions (RTFs) from loudspeakers to listening points in the listening room. However, the sound reproduction accuracy is deteriorated by room environment variations when fixed inverse filter coefficients are used because the condition number relevant to the instability of the matrix composed of the RTFs is large, especially at low frequencies; the inverse filters are unstable at those frequencies. This tendency is more remarkable when listening points are arranged more closely. To resolve the problem, we switch the control band at every listening point to avoid degrading the reproduced sound in low-band frequencies. The control band range of the listening points at both ears is only high band. That of the other listening points is the entire control band. Numerical simulation with real environmental data showed that improvement of the reproduction accuracy is about 6.4 dB on average, even with temperature fluctuations of 5 °C as environmental variations of the listening room.

3pSP10. Frequency scaling reduces individual differences in external-ear transfer functions in developing cats.
Daniel J. Tollin (Dept. Physiol & Biophys., Univ. Colorado Med. Sci., 12800 E. 19th Ave., Aurora, CO 80045, daniel.tollin@uchsc.edu)

There are three cues to sound location: Interaural differences in time and level and monaural spectral shape cues. The ultimate magnitudes of these cues depend largely on the linear dimensions of head and pinnae. During development, the increasing interaural distance associated with a growing head and pinnae result in cues that change substantially and continuously until maturation is complete. These experiments examined whether the intersubject differences in the directional transfer functions (DTFs), the directional components of the head-related transfer functions, of cats during development could be reduced by scaling one set of DTFs on a log-frequency axis. Measurements were made of both the physical dimensions of the head and pinnae and the DTFs of cats aged 4 weeks to adulthood. For each pair of subjects, an optimal frequency scaling factor was computed that minimized the differences in the DTFs. In many cases, the optimal factors for pairs of subjects were proportional to the ratios of the measured physical dimensions of the head and pinnae in those subjects. Although there were still considerable differences in the DTFs even

after scaling, these data support frequency scaling as a potential method of modeling the development of the DTFs in cats. [Work supported by NIH Grant DC006865.]

3pSP11. A method to make a moving virtual sound source.
Ji-Ho Chang and Yang-Hann Kim (KAIST (Korea Adv. Inst. of Sci. and Technol.), 373-1 Kusong-dong, Yusong-gu, Daejeon 305-701, Korea)

This study deals with a method that manipulates the sound field, which is excited by a moving source. That is, the moving source is virtually constructed by array speakers. It is realized by controlling pressure values on boundary of the field. This is, in fact, an attempt to implement the Kirchhoff-Helmholtz integral equation in practice. It is well known that we can generate a certain sound field in a space by controlling pressure values on boundary [S. Ise, Acustica, **85**, 78–87 (1999)]. However, time varying sound field control has not been well addressed. Our aim is to manipulate sound field that is generated by a virtual source moving straightly outside the sound field or traveling around it. To express the method, the simple pure-tone case is considered and then expanded to more general cases. It also handled the problem related to eigenfrequencies at which boundary pressure control is not applicable. Computational and experimental results are introduced as well. [Work supported by BK21 & NRL.]

3pSP12. Partial-differential-equation-based sound source localization: Finite Fourier integral approach and its application to multiple source localization.
Yuya Fujita, Nobutaka Ono, and Shigeru Ando (Dept. of Information Phys. and Computing, Grad. School of Information Sci. and Technol., The Univ. of Tokyo, Tokyo, Japan)

In this paper, a method based on the sound source constraint PDE (partial differential equation) is developed for real complex environments with multiple sources. The sound source constraint PDE is integrated within a finite temporal interval with orthogonal Fourier bases to obtain simultaneous equations including source directions and distances as unknown variables. In them, the fast Fourier transform can be used rigorously and efficiently with least computation time. We show the equations enable us to obtain 3-D locations of up to four sources simultaneously from one spatial gradient observation of sound field. Numerical simulation comparison with the spatio-temporal-gradient-based method was carried out and showed the significant improvement of accuracy. Experimental results using a six proximity microphone array [N. Ono *et al.*, in Proc. ASJ Autumn meetingCvol.IC, pp. 607–608, September, 2004 (in Japanese)] in the real environment will be reported.

3pSP13. Holographic diagnosis: Basic principles and applications.
Jong-Hoon Jeon and Yang-Hann Kim (Ctr. for NOVIC, Dept. of Mech. Eng., KAIST, 373-1 Guseong-dong, Yuseong-gu, Daejeon 305-701, Republic of Korea)

Acoustic signals achieved from a machine often have information on condition of the machine. This means that the location of faults can be found by using acoustic signal. Location of sound source can be found by using techniques such as MFAH (moving frame acoustic holography), which is applicable for pure tone noise and good signal-to-noise ratio, and beamforming, which basically assumes no reflected wave. Faults due to breakdown of rotating parts in a moving vehicle, however, make the above method hard to be directly applicable. The difficulty stems from three characteristics in the fault detection of the moving vehicle. First, the sound source radiates periodic impulsive noise. Second, there exist reflected waves from the ground since the array microphones should be settled between the vehicle and the ground to monitor the bottom side of the vehicle. Last, for the measurement problem, there exists noise due to other parts and wind for the moving vehicle, which degrades coherence among measured signals. In this research, holographic diagnosis, a machine diag-

nosis technique based on holographic approach, is introduced to find the position of faults effectively. The modified version of beamforming that models the moving periodic impulsive noise as a scan function is introduced.

3pSP14. Software-centered implementation of 128-channel loudspeaker array with stock PC and its application. Hiroshi Mizoguchi, Takafumi Nakamura, Hiroshi Takemura (Tokyo Univ. of Sci., 2641 Noda, Chiba 278-8510, Japan), and Satoshi Kagami (DHRC, AIST, Japan)

A huge speaker array system of 128 loudspeakers was constructed and experimented. It was implemented as "software-centered" style, utilizing stock loudspeakers and a PC. No dedicated hardware nor DSP was utilized. Spot forming, instead of beam forming, could be realized by 32 by 4 square layout of the array. Spot means small area of higher sound pressure level. Number of the spot was not limited to one. In the experiment, within 3 m by 3 m area, four spots of different sounds could be simultaneously formed. This spot forming was confirmed by actually measuring spatial distribution of sound pressure level. The effect of the spot was also confirmed auditorily. Since the system was software centered, it was dynamic. By simply changing software parameters, the location of the spot can be easily moved even while the system is running. This movability of the spot was intended to be the basis for visual steering. To realize the system, a simultaneous 128-channel 14-bit DA converter PCI board was developed. The 44.1-KHz sampling rate was achieved by a 2.4-GHz Intel Xeon based PC utilizing the DA board and a real-time OS, named ART-Linux. Approximately 23-μs loop could be realized by the software. It was the world's fastest software loop.

3pSP15. Complex envelope implementation for fast and efficient acoustic holography. Choon-Su Park and Yang-Hann Kim (Ctr. for Noise and Vib. Control, Dept. of Mech. Eng., KAIST, Daejeon 350-701, Republic of Korea)

Acoustic holography allows us to predict the spatial pressure distribution on any surface of interest. To implement this method, we normally use Fourier transform in time and space domain. It is noteworthy that the data size is so huge that it takes a long time to calculate pressure field. Moreover, the reconstructed pressure field is frequently too complex to observe the characteristics of pressure field. One possible candidate is the complex envelope. The complex envelope in time domain is well known and widely used in various fields. We have attempted to extend this method in the space domain, so that we can have a rather compact sound pressure picture that provides the information we need, for example where sound sources are. This belongs to what we call the analysis problem of acoustic holography. We might want to draw some parts in detail but other parts in a rather coarse way. The complex envelope in space certainly meets this objective. First we start with the simplest case. We devise a monopole complex envelope. Then we extend it to finite size source case. Various holography examples are reprocessed according to what we propose and demonstrate how this method is practically fast and how it provides a better picture for analyzing the sound field.

3pSP16. The acoustic information extraction of the indoor impulse response by multiresolution analysis. Wakako Tanaka, Yong Tang, Toru Itakura, and Hideo Shibayama (3-7-5 Toyosu Koutou-ku, Tokyo, 135-8548, Japan, m105072@sic.shibaura-it.ac.jp)

The impulse response is divided into approximation and detail components by the multiresolution analysis. The correlations between the early sound and reflected sounds are estimated respectively for the impulse response and the approximate signal. The approximate signal was calculated as a function of level of the multiresolution analysis. The correlation coefficient of these correlations is over 0.7 under level three. We evaluate the differences of these correlations from the listening test.

3pSP17. Detection for the early reflection in the impulse response by the correlation function. Toru Itakura, Yong Tang, Wakako Tanaka, and Hideo Shibayama (Shibaura Inst. of Technol., Toyosu 3-7-5, Koutoku-ku, Tokyo 135-0061, Japan, m106009@sic.shibaura-it.ac.jp)

Detecting an early reflection sound contained in the impulse response measured in a room, we calculated the correlation factor between the early reflection and the impulse response. Calculating the correlation factor every sampling period, we make the correlation function. For the function, we set a threshold level. We detected the absolute correlation value larger than the threshold level. And, we set the zero value for subthreshold level. Following this algorithm, we generate a new signal with the high correlation factor for the early reflection. We compared the signal with the impulse response by using listening test.

3pSP18. A design of virtual sound field simulator based on acoustic ray tracing and wall impedance. Kiichiro Yamada, Yuki Denda, Masato Nakayama (Grad. School of Sci. and Eng., Ritsumeikan Univ., 1-1-1 Noji Higashi, Kusatsu, Shiga 525-8577, Japan, rs047023@se.ritsumei.ac.jp), and Takanobu Nishiura (Ritsumeikan Univ., Kusatsu, Shiga 525-8577, Japan)

The sound propagation analysis using an architectural scale model is an effective approach for architectural acoustic design of a concert hall, and so on. However, the scale model must be reconstructed together, changing the basic plan of the architectural design. To cope with this problem, an architectural sound field has been virtually designed on the computer by the sound field simulator in recent years. The acoustic ray tracing is one of the simulators based on geometric acoustics. It is an efficient solution from the viewpoints of simulation cost and time. However, it cannot simulate the wall materials, because it employs the delta function as the wall impedance. To overcome this problem, in this paper, we try to design the virtual sound field simulator based on acoustic ray tracing and wall impedance acquired by real measurements. We first measured the reflection characteristics of the wall with impulse response to acquire the wall impedance. Then, we designed the virtual sound field simulator by convoluting the acoustic rays with measured wall impedances. As a result of subjective evaluation experiments, the proposed simulator could realize a more realistic sound field than the conventional acoustic ray tracing. [Work supported by MEXT of Japan.]

3pSP19. A fundamental investigation of the small microphone array system and its applications. Akira Nawa, Yoku Watanabe, and Hareo Hamada (Tokyo Denki Univ., 2-1200 Muzai-gakuendai, Inzai, Choba prefecture 270-1382, Japan)

A purpose of this research is to construct a 3-D sound recording and reproduction system that has a high presence by performing a spatially controlled sound field synthesis technique. For this purpose, it will be required to examine and choose the most suitable sound recording system, since a conventional sound recording system samples only original signal itself, and does not include enough spatial information. In other words, it will be required to examine the system to record the information of the three-dimensional spaces, such as the direction and the distance, and to transform the configuration to become effective to the reproduction system. This paper will deal with a basic examination to construct the microphone array placed in proximity and the recording system, which is able to control the directivities in the three-dimensional spaces, using algorithm based on LMS by FIR filter networks from signals to each microphone.

3pSP20. Blind source separation of musical signals applied to selectable-listening-point audio reconstruction. Kenta Niwa (Grad. School of Information Sci., Nagoya Univ., Furo-cho, Chikusa-ku, Nagoya-city, Aichi, Japan, niwa@sp.m.is.nagoya-u.ac.jp), Takanori Nishino, Chiyomi Miyajima, and Kazuya Takeda (Nagoya Univ., Japan)

An audio reproduction system is being developed to generate binaural signals at user-selected listening positions from audio signals of multiple sound sources recorded with multiple microphones. The system consists of a sound decomposer based on blind source separation (BSS) and a sound recomposer using head-related transfer functions (HRTFs). In this work, musical signals of multiple instruments are separated into the original independent signals of the respective instruments using BSS based on frequency-domain independent component analysis (FD-ICA). HRTFs are then convoluted to the separated sound sources to reconstruct the music sounds of the selected listening point. Preliminary experiments are conducted using two or three sound sources of instruments: flute, violin, and piano generated by a synthesizer. The synthesizer sounds are played through small directional loudspeakers or spherical omnidirectional loudspeakers in a low-reverberant sound-proof room or moderately reverberant lecture room and recorded with multiple microphones. Live music played on real instruments including flute, violin, and trumpet are also recorded in the same rooms. Audio signals of respective instruments obtained by BSS are available on our web site.

3pSP21. Acoustic sound field simulator based on head-related transfer function and three-dimensional mirror-image. Keitaro Kuroda, Yuki Denda, Masato Nakayama (Grad. School of Sci. and Eng., Ritsumeikan Univ., 1-1-1 Noji Higashi, Kusatsu, Shiga 525-8577, Japan, rs016029@se.ritsumei.ac.jp), and Takanobu Nishiura (Ritsumeikan Univ., Kusatsu, Shiga 525-8577, Japan)

The head-related transfer function (HRTF) is the most important factor to simulate an acoustic sound field for the virtual reality technology or the architecture field. However, the HRTF has individual differences on every listener, because it represents the real transfer function between the sound source point in the acoustic field and the listener's ears. In addition, it is impossible to measure the HRTFs on every listener. To solve this problem, we focus on three-dimensional mirror-image. It can represent the virtual transfer function (especially, room reverberation) in an acoustic field by replacing all surface reflections with mirror-image sources. Therefore, we try to design the new acoustic sound field simulator by convoluting the real transfer function of the HRTF and the virtual transfer functions of the three-dimensional mirror-image. By this approach, the proposed simulator may realize the more accurate sound-image localization with room reverberation by three-dimensional mirror-image even if the HRTF of an other listener is employed. As a result of evaluation experiments in some conditions, the proposed simulator could improve the sound-image localization performance especially in an anteroposterior direction more than the conventional simulator based on HRTF. [Work supported by MEXT of Japan.]

3pSP22. Binaural transformation coding with simulated head tracking. Seiichiro Shoji and Anthony I. Tew (Dept. of Electron., Univ. of York, Heslington, York, YO10 5DD UK)

The binaural transformation codec synthesizes generic binaural audio signals and generates accompanying side information. In the decoder the side information is used to personalize the generic signal. The performance of the basic codec is described in another paper; this paper describes the estimated effect on quality of incorporating limited head tracking. Generic HRTFs were used to spatialize two concurrent sound sources spatialized at ±30 or ±80 deg. The generic binaural signal was personalized in the BX decoder and at the same time the individual sound sources were rotated. These induced rotations are equivalent to compensating for head yaw rotations of −80, −40, −20, −10, and −5 deg, and for head pitch rotations of 22.5, 45, and 90 deg. Listening tests based on Recommendation ITU-R BS.1116-1 were used to evaluate the processed

sounds. The tests were conducted using speech, vocals, guitars, and percussion source materials. It was found that the quality of the processed sound tended to degrade as the head yaw rotation increased. However, except for the head yaw condition −80 deg, the quality of the processed sound remained greater than 4.0 on the mean opinion scale. No deterioration of the processed sound was observed for the applied pitch rotations.

3pSP23. Novel method for the efficient individualization of binaural audio signals. Seiichiro Shoji and Anthony I. Tew (Electron. Dept., Univ. of York, Heslington, York, YO10 5DD UK)

A novel coding technique suitable for the transmission of binaural audio signals with concurrent multiple sound sources is proposed in this paper. Existing algorithms typically suffer from audible artefacts, poor localization, or excessive bandwidth. Especially with conventional intra-source coding methods, bandwidth is dependent on the number of sources and becomes greater as the number of sources increases. The proposed binaural transformation (BX) encoder synthesizes binaural signals using generic HRTFs and transmits them to the decoder along with side information. The bandwidth of the side information is independent of the number of sources. Using locally stored HRTFs matching those of the listener, the decoder turns the generic binaural signals into personalized ones. We present two types of BX codec: type A and type B. Psychoacoustic experiments based on Recommendation ITU-R BS.1116-1 were used to compare signals processed by these codecs with the corresponding unprocessed signals. For a variety of source materials (speech, vocals, guitars, and percussion) we show that high mean opinion scores are achievable using the type A codec when its parameters are set appropriately.

3pSP24. Individuality of elevation-angle-sensitive notches in head-related transfer functions. Saho Sekimoto, Yukio Iwaya, and Yôiti Suzuki (Res. Inst. of Elec. Commun./Grad.. School of Information Sci., Tohoku Univ. Katahira 2-1-1 Aoba-ku, Sendai, 980-8577, Japan, saho@ais.riec.tohoku.ac.jp)

Perceived localization can be controlled with high accuracy in the rendered auditory space when listeners' own head-related transfer functions (HRTFs) are used for rendering 3-D spatial audio. However, measurement of a listener's own HRTFs in all directions requires a special measuring apparatus and a long measurement time, which entail a considerable physical load on subjects. Therefore, effective individualization methods of HRTFs must be very useful. In previous studies, a few notches around 6–10 kHz, whose frequencies change depending on the elevation, are inferred as important to determine the perceived elevation [e.g., E. A. G. Shaw and R. Teranishi, J. Acoust. Soc. Am. **44**, 240–249 (1968)]. Therefore, this study examines the individuality of such notches, of which the frequency is elevation-angle sensitive. First, individual HRTFs from all directions are measured for 140 listeners. They are then analyzed using an autoregressive moving average (ARMA) model. Second, the frequencies of these notches are expressed smoothly as a function of the elevation angle using dynamic programming (DP). Results qualitatively clarified the dependency of each frequency on elevation. Moreover, distributions of the notch frequencies show systematic variation as the elevation angle changes.

3pSP25. Objective and subjective evaluation of numerically estimated head-related transfer functions. Shouichi Takane and Koji Abe (Dept. of Electron. and Information Systems, Akita PRef. Univ., 84-4 Ebinokuchi, Tsuchiya, Yurihonjo, Akita, 015-0055 Japan, takane@akita-pu.ac.jp)

In this study, head-related transfer functions (HRTFs) of a dummy head and human subjects are numerically estimated by using the boundary element method (BEM), and their availability for auralization is discussed from the subjective viewpoints. Geometries of their heads are obtained by a 3-D laser scanner. The effect of the torso for the estimation of the HRTFs is also examined and discussed via the 3-D measurement. The estimated

HRTFs are compared for each subject with the measured HRTFs in various objective criteria, such as spectral distortion (SD), signal-to-distortion ratio (SDR), and interaural time/level differences (ITD/ILD). Availability of the estimated HRTFs for the synthesis of the 3-D sound image are then evaluated via hearing experiments. In our previous study [Proceedings of WESPAC IX (2006)], the results of the experiment is insufficient since the low-frequency range of the estimated HRTFs caused the ambiguity in sound localization. In this study, the frequency range of the estimation is extended to as high frequency as possible, and the availability of the estimated HRTFs for auralization is discussed from two viewpoints: the subjective difference between the estimated and measured HRTFs, and some subjective attributes obtained from the hearing of the stimuli convoluted with the estimated HRTFs.

3pSP26. Analysis and modeling of interaction of auditory-visual information. Takahumi Asada, Yuko Watanabe, and Tatsuya Shibata (Grad. School of Information Environment, Tokyo Denki Univ., 2-1200 Muzai Gakuendai Inzai, Chiba, 270-1382 Japan, den03117@nifty.com)

We analyze and model the interaction of movement of the synchronized auditory-visual information. We construct the relationship of movement between virtually sound source and object. We suppose that cubic local contrast model (CLCM) we propose and the optical flow method are useful for analyzing moving image. CLCM is a method that describes the movement of objects from temporal and spatial difference of local contrast between pixels in moving image, and we found CLCM can measure the orientation of camera motion and the moving direction of an object in a moving image. We use the feature of head-related transfer function (HRTF) as the feature of sound movement. We have done two experiments: experiment 1 is that we analyze the data of the interaural amplitude difference (IAD) and interaural phase difference (IPD) between right and left HRTFs of a sphere by local contrast model (LCM); experiment 2 is that we analyze the relationship between the movement of an object in a moving image and a virtual sound source. We discuss the interactive features between auditory and visual information.

3pSP27. The effect of head movement on sound localization using stereo microphones: Comparison with dummy heads. Wataru Endo (Tokyo Inst. Tech., Nagatsuda, Midori-ku, Yokohama 226-8502, Japan, endo@u.ip.titech.ac.jp), Makio Kashino (Tokyo Inst. Tech., Atsugi, Kanagawa 243-0198, Japan), and Tatsuya Hirahara (Toyama Prefectural Univ., Imizu, Toyama 939-0398, Japan)

This study examined the effect of head movement on sound localization with a pair of microphones providing no head-related transfer function (HRTF) information, and with individualized, nonindividualized, and downsized dummy heads providing HRTF information with different degrees of distortion. In an anechoic room, white noise was presented for 5 s from one of 12 loudspeakers. A dummy head or a microphone pair was placed at the observation point. Listeners heard the sound via headphones outside the anechoic room and judged the direction of the source and whether the sound image was extracranial. Without head movement, localization accuracy with the microphone pair was significantly worse than that with dummy heads. When voluntary head movement was allowed and the dummy head was moved in accord with the listener's movement, accuracy with nonindividualized and downsized dummy heads improved nearly to the individualized level. Accuracy with the microphone pair also improved with head movement, but did not reach the level of dummy heads. An extracranial image was perceived with dummy heads in most cases, but not often with the microphone pair even with head movement. Head movement cannot completely compensate for the lack of HRTFs.

3pSP28. A biologically inspired pitch determination algorithm. Arturo Camacho and John G. Harris (Computational Neuro-Eng. Lab, Elec. and Comput. Eng., Univ. of Florida, Gainesville, FL 32611, arturo@cnel.ufl.edu)

A biologically inspired pitch determination algorithm is presented. This algorithm combines existing models of the cochlea and inner-hair-cell based spike generation [Lopez *et al.*, J. Acoust. Soc. Am. **110**, 3107 (2001); Sumner *et al.*, *ibid.* **113**, 893–901 (2003)] to model spike trains in the auditory nerve. The pitch and its salience are then estimated using a method proposed by Cariani [Cariani *et al.*, J. Neurophysiol. **76**, 1698–1716], which computes a summary autocorrelation function over the spike trains. Unlike Cariani's work, where spike trains are obtained experimentally, we simulate the spike trains from biologically inspired models. The main contribution of our approach is to combine models of the auditory system and a pitch estimation method based on neural spike trains. The proposed algorithm was tested using standard synthesized sounds, speech, and singing voices. Results show that this algorithm better matches human performance as compared to traditional pitch detection algorithms used in automatic speech processing.

3pSP29. End-point detection of speech using spectral transition for captioning system. Ayako Koga, Yuki Fujikashi, Takayuki Arai (Dept. of Elec. and Electron. Eng., Sophia Univ., 7-1 Kioi-cho, Chiyoda-ku, Tokyo, 102-8554), Noboru Kanedera (Ishikawa Natl. College of Technol.), and Junko Yoshii (Fujiyama, Inc.)

In recent years, captioning video contents with text translations is increasingly necessary because of the burgeoning use of media internationally, resulting from the rapid development of communication technology. In addition, within one language, video captioning is very important for hearing-impaired people. However, the process of captioning videos, including speech and nonspeech decisions, is often done manually by translators at present. Therefore, an efficient automatic end-point detection of speech for captioning video contents has been proposed. We attempted to detect speech end-points based on acoustic landmarks that identify times when acoustic changes are prominent in the speech signals [K. N. Stevens, Acoust. Phonetics (1998)]. In this study, landmarks were obtained by combining the mean square for the regression coefficients of logarithmic envelopes of $\frac{1}{3}$-oct bands in time, which resembles the parameter proposed by Furui to measure spectral transition [S. Furui, J. Acoust. Soc. Am. **80**(4), 1016–1025 (1986)], with other ones such as the logarithmic power of speech signals. An experiment was carried out using the proposed technique for speech detection. Results showed a high correct rate and introduced the possibility of its application to an efficient video captioning system. [Work partially supported by Open Research Center Project from MEXT.]

3pSP30. Inverse filter analysis of common harmonic structure on Specmurt using Riemann's ζ function. Nobutaka Ono, Shoichiro Saito, Hirokazu Kameoka, and Shigeki Sagayama (Dept. Information Phys. and Computing, Grad. School of Information Sci. and Technol., Univ. Tokyo, 7-3-1 Hongo Bunkyo-ku Tokyo, 113-8656 Japan)

In this paper, based on the interesting relationship between the log-spaced δ function sequence and Riemann's ζ function, the analytical properties of the inverse filter of the common harmonic structure on *specmurt analysis* are discussed. Specmurt [S. Sagayama *et. al.*, in Proc. SAPA (2004)] is a simple and efficient technique for the multi-pitch analysis of polyphonic music signals. If all tones have the same harmonic pattern, the power spectrum on the log-scaled frequency can be regarded as the convolution of the common harmonic structure and the distribution of fundamental frequencies. Based on the model, overtones are effectively suppressed by the inverse filtering of the common harmonic structure in specmurt. Thus, for the stable processing, analytic properties of the inverse filter are significant. Our new finding is that when the common harmonic structure is expressed as a log-spaced δ function sequence with a particular kind of decay, the Fourier transform is exactly equal to Riemann's ζ

function. Interpreting several properties of Riemann's ζ function in a signal processing context gives us the new perspectives like an explicit representation or cascaded decomposition of the inverse filter.

3pSP31. The calculation of sleep apnea syndorome's condition index using the snore noise. Takahiko Ono (Tokyo Univ. of Agriculture and Technol., 3-8-1, Harumicho, Fuchu, Japan), HIroo Yano, Tatsuya Oota (Chiba Inst. of Technol., Chiba, Japan), Yuuji Takasaki, and Sachiko Kurosaki (Oota Kinen Hospital, Kooriyama, Japan)

The polysomnograph analysis is used to measure an apnea hypopnea index (AHI) of sleep apnea syndorome. However, this method needs high grade devices and technique. To compensate the conventional method, the calculation of AHI using only the snore noise of the patient is invented.

3pSP32. Voice activity detection with voice/nonvoice classification using reliable fundamental frequency. Soo-young Suk, Hiroaki Kojima (Information Technol. Res. Inst., AIST, Central 2, Umezono, Tsukuba, Japan, sy.suk@aist.go.jp), and Hyun-Yeol Chung (Yeungnam Univ.)

In this paper, we introduce a voice activity detection (VAD) algorithm to perform voice/nonvoice (V/NV) classification using a fundamental frequency ($F0$) estimator called YIN. Although current speech recognition technology has achieved high performance, it is insufficient for some applications where high reliability is required, such as voice control of powered-wheelchairs for handicapped persons. The proposed VAD, which rejects nonvoice input in preprocessing, is helpful for realizing a highly reliable system. Previous V/NV classification algorithms have generally adopted statistical analyses of $F0$, the zero-crossing rate, and the energy of short-time segments. A combination of these methods, a cepstrum-based $F0$ extractor, has been proposed [S. Ahmadi and S. S. Andreas, IEEE Trans. SAP. **7**, 333–339 (1999)]. The proposed V/NV classification adopts the ratio of a reliable fundamental frequency contour to the whole input interval. To evaluate the performance of our proposed method, we used 1360 voice commands and 736 noises in powered-wheelchair control in a real environment. These results indicate that the recall rate is 97.4% when the lowest threshold is selected for noise classification with precision 97.3% in VAD. The proposed VAD, which rejects nonvoice input in preprocessing, can be helpful to realize a highly reliable system.

3pSP33. Estimation of a talker and listener's positions in a car using binaural signals. Madoka Takimoto (Grad. School of Information Sci., Nagoya Univ., Furo-cho, Chikusa-ku, Nagoya, Aichi, 464-8603 Japan, takimoto@sp.m.is.nagoya-u.ac.jp), Takanori Nishino, and Kazuya Takeda (Nagoya Univ., Japan)

The problem of estimating the location of a sound source is described which is based on signals observed at the entrances of the two ears. The purpose is to specify the talker's and listener's positions within a car using the binaural signal. The talker and the listener sit in two of the four car seats. In this experiment, two kinds of head and torso simulators are used as a talker and a listener. Given information includes the acoustic transfer functions for all positional patterns. Eight patterns of acoustic transfer functions are measured, involving those that have the same positional pattern, but in which the talker faces a different direction. A Gaussian mixture model for each positional pattern is generated. The parameters we used are interaural information such as the envelope of an interaural level difference. The models are evaluated by specifying the positional pattern. Results show that we can specify positions with up to 97% (35/36) accuracy using the binaural signals of two men. Then the input signal was expanded to one with background noise that resembles a real situation, and a model that involves motion of the talker's head was also considered.

3pSP34. An implementation of realtime speech speed control system using hierarchical cascaded integrator and comb filters. Hironobu Takei, Shogo Nakamura, Hiroto Saitoh, and I. Nyoman Sukadana (Tokyo Denki Univ., 2-1200 Muzai Gakuendai, Inzai Chiba, Japan, takei@sp.sie.dendai.ac.jp)

In this paper, our algorithm for speech speed control system and its DSP implementation are described. The system slows or speeds up speech without changing its pitch, which aids learning a foreign language, listening for older people, and so on. The proposed algorithm is based on the phase vocoder, which doesn't need extraction of voiced fragments from a speech signal. And the reconstruction of time-scaled signal involves no smoothing operation between voiced and unvoiced sections. The speech signal is decomposed to bandpassed frequency channels so that the envelope of each of the channels is stretched. Then the stretched envelope is multiplied by the corresponding sinusoidal, and by summing up the channel components the speed controlled signal is reconstructed. Each band has very narrow bandwidth, which requires a large amount of computation with a FIR-based design. To achieve realtime operation of our system, a hierarchical structured cascaded integrator and comb (HSCIC) filter is also introduced, which can have highly sharpened characteristics with only a few multipliers.

3pSP35. On the accuracy of speech source direction identification on the horizontal plane using 3-D audio displays. Hirotoshi Terada, Kazuhiro Kondo, and Kiyoshi Nakagawa (Yamagata Univ., Jounan 4-3-16, Yonazawa, 992-8510, Yamagata, Japan)

This paper describes initial results of speech source direction identification experiments on the horizontal plane. This is an initial study for the sound localization required in order to separate the individual speech source location to increase the intelligibility in remote conference systems. Our focus here was to determine the effect of sound source characteristics on the source direction identification accuracy. Sound sources were located on three target locations (forward, right, and left) and five (45 deg in both right and left added) on the horizontal plane using a real-time virtual acoustic environment rendering system (NASA SLAB). SLAB integrates HRTFs to render the source localization. The sound sources used were conversation speech, white noise, and conversation speech mixed with noise at an SNR of 0 dB. The observers were asked to identify the direction of the rendered sound presented over a headphone. The results showed that the direction identification accuracy of conversational speech is approximately 20% higher than that of white noise in all directions tested. However, the accuracy of mixed conversation and white noise was about the same as the accuracy with white noise only, suggesting that the high-frequency components may be degrading the perceived accuracy.

3pSP36. Multipitch estimation based on correlation between a harmonic structure model and an observed spectrum for mixed audio signals. Yoichi Uchida and Naotoshi Osaka (Tokyo Denki Univ., School of Eng., 2-2 Kanda Nishiki-cho, Chiyoda-ku, Tokyo, 101-8457, Japan, uchida@srl.im.dendai.ac.jp)

In the research of sound source separation and resynthesis, multipitch estimation is an important topic. We propose a multipitch estimation technique for monaural audio signals. It introduces a method of calculating multiple pitches within a frame for a pitched sound signal. First, a harmonic structure is modeled for a pitch M (Hz), using the cases of odd integer multiples of M, even integer multiples of M, and odd integer multiples of $M/2$. Then correlations are derived between each of the harmonic structure models and an observed spectrum. Harmonic structure models are expressed as the summation of Gaussian functions in the frequency domain, where each harmonic has a peak at its center frequency. An evaluation function is dynamically defined to test how well arbitrary values of M fit the observed spectrum. The evaluation function is created by searching for weighted coefficients for the correlation values. Next, a number of maximal peaks equal to the number of sound sources are se-

lected from the spectrum and defined as the estimation pitches. This method was applied to a mixed piano signal, and a mixed audio signal that includes flute, clarinet, and cello. The results are good except at octave unisons.

3pSP37. Transient detection algorithms for speech coding applications. Grzegorz Szwoch, Maciej Kulesza, and Andrzej Czyzewski (Gdansk Univ. of Technol., Narutowicza 11/12, 80-952 Gdansk, Poland)

One of the methods for improving transmitted speech quality is efficient encoding of transients. The majority of currently used speech codecs employ the parametric approach, thus they do not differentiate between transients and other signal components. A sine+noise+transients signal model, proposed earlier as a tool for wideband audio signal encoding, seems to be a promising solution for enhancing signal quality in speech coding. Methods of transient identifying for an efficient transform-domain encoding of transients has to be chosen carefully. Different transient detection algorithms are described in literature, most of them optimized for musical signals. The methods do not ensure efficient transient detection in speech signal, due to the different character of musical signals and speech. This paper provides a comparison of several transient detection methods, mostly based on evaluation of signal energy, that are now primarily used for musical signals. Their efficiency and application to transient detection in speech are evaluated and discussed. Differences between transient detection in wideband musical signals and speech are pointed out. Modifications to existing algorithms are proposed, allowing efficient transient detection and encoding in the proposed, wideband speech codec. [Research funded by the Polish Ministry of Education and Science within Grant No. 3 T11D 004 28.]

3pSP38. Sound source classification using temporal pattern for mixed sounds. Toru Taniguchi, Katsuhiko Shirai (Dept. of Comput. Sci., Waseda Univ., 3-4-1 Okubo, Shinjuku-ku, Tokyo, 169-8555 Japan, tani@shirai.cs.waseda.ac.jp), and Mikio Tohyama (Waseda Univ., Honjo-shi, Saitama 367-0035, Japan)

In speech information processing of real-world environments, how to deal with nonstationary acoustic noise such as background music or speech is a remaining problem while much progress has been made in the speech processing in stationary noise. Music or speech is a sound that has a complex spectral and temporal structure composed of many musical notes or phonemes, and this fact makes it difficult to estimate signals of music or speech separated from a foreground speech. For noise estimation of one-channel sound, only the prior knowledge of temporal or spectral structures of the noises is available besides the signal itself. Therefore, dealing with nonstationary noise of music or speech essentially requires the models representing the temporal and spectral structure of them. In our study, a classification method of nonstationary sounds using sinusoidal decomposition is proposed. In the method a classification of mixed sounds into sound categories, like speech, singing voices, or instruments, is performed based on temporal characteristics of spectral sequences analyzed by a spectral peak tracking algorithm. Temporal features are inspected by statistical analyses and discrimination experiments of sinusoidal sequences. The classification algorithm is evaluated by experiments of classification of mixed sound.

3pSP39. Multiple fundamental frequency estimation assisted by audio watermarking. Yi-Wen Liu (Boys Town Natl. Res. Hospital, 555 North 30th St., Omaha, NE 68131)

The success of computer segregation of sound sources from a single-channel mixture often relies on the estimation of multiple fundamental frequencies. Instead of solving the problem directly, this presented work utilizes audio watermarks to assist sound source segregation. Here, individual sources are assumed to be available for watermark embedding be-

fore mixing. Each source's short-time spectral peaks are aligned to frequency gridpoints labeled with a digital ID [Liu and Smith, "Audio Watermarking Based on Sinusoidal Analysis and Synthesis," International Symposium on Musical Acoustics, Nara, Japan (2004)]. A modified sound source is sinusoidally synthesized afterwards. In this sense, each source is embedded with a watermark. In an experiment, two sound sources are watermarked with two sets of gridpoints P and Q, respectively. Points in P and Q interleave and are spaced 10 cents of a semitone apart. The watermarked sources are then linearly added. To demix them, sinusoidal trajectories found in the mixture are segregated based on whether its frequency more often aligns to P or Q. Then, segregated signals are reconstructed by sinusoidal synthesis. Although the reconstructed signals do not sound like the original sources, the melodies of the original are successfully extracted from the reconstructed in monophonic pitch estimation.

3pSP40. Directions of arrival (DOA) estimation by particle filtering with dominant frequency components in noisy environments. Mitsunori Mizumachi, Norikazu Ikoma, and Katsuyuki Niyada (Kyushu Inst. of Technol., 1-1 Sensui-cho, Tobata-ku, Kitakyushu-shi, Fukuoka 804-8550, Japan)

In noisy environments, DOA estimation is useful for achieving attractive human-machine interfaces in the real world. This article proposes a robust DOA finder based on cross correlations between observed signals by particle filtering with frequency selectivity. The particle filter is flexible for modeling the system because it requires no linearity or Gaussianity on the model. The temporal trajectory of DOAs is modeled using a Markovian state space model. It is estimated through the state estimation procedure using particle filters. Markov modeling is expected to achieve stable DOA estimation in time. It is also a key for the proposed method to selectively use the dominant frequency components, such as formant frequencies of speech, to improve noise robustness. Assuming the quasi-stationarity of noise signals in the presence of a time-varying target speech signal, the dominant frequencies are extracted using a deterministic approach similarly to spectral subtraction. A set of the subband cross-correlation functions at the dominant frequencies is regarded as likelihood and is used for updating particle weights to estimate posterior distribution. The feasibility of introducing both particle filtering and frequency selectivity into DOA estimation was confirmed in several noise conditions.

3pSP41. Azimuth and elevation estimation for multiple sound sources using two-dimensional frequency domain binaural model. Yoshifumi Chisaki, Sho Kawano, and Tsuyoshi Usagawa (Grad. School of Sci. and Technol., Kumamoto Univ., 2-39-1, Kurokami, Kumamoto, 860-8555 Japan, chisaki@cs.kumamoto-u.ac.jp)

Direction of arrival (DOA) estimation for multiple sound sources with only two sensors as the human being does is proposed. The frequency domain binaural model (FDBM) [Nakashima et al., Acoust. Sci. Technol. **24**, 172–178 (2003)] was proposed as one binaural model. The method uses sound diffraction to estimate DOAs and segregate sound sources. The binaural model can estimate one-dimensional DOA, namely, azimuth. However, human beings can estimate not only azimuth of DOA but also elevation of that. In order to achieve an estimate of both azimuth and elevation simultaneously, a new DOA estimation algorithm based on interaural phase and level differences is proposed as a part of frequency domain binaural model. Results of DOA characteristics of the proposed binaural model estimation on multiple sound sources' condition is compared with that of human auditory characteristics. As a result, it was confirmed that performance on accuracy of DOA estimation depends on power level ratio among sound sources. [Research was partially supported by the Ministry of Education, Science, Sports and Culture, Grant-in-Aid for Scientific Research (C), 2006, 18500135 and carried out by the Cooperative Research Project Program of the RIEC, Tohoku University (Grant No. H16.A02).]

3pSP42. Sound source localization using a distributed microphone system in real environments. Kook Cho, Hajime Okumura, Takanobu Nishiura, and Yoichi Yamashita (College of Information Sci. and Eng., Univ. of Ritsumeikan, 1-1-1, Noji-Higashi, Kusatsu-shi, Shiga 525-8577 Japan)

Accurate localization of sound sources is indispensable for high-quality sound capture. The difference of distance from a sound source to two microphones causes a time delay of arrival (TDOA). The cross-power spectrum phase analysis (CSP) method has been proposed to estimate the TDOA based on correlation in signals. The sound source can be localized theoretically as a crossing point of sound directions estimated using two pairs of microphones. However, in a real environment, microphones receive sounds that have originated through reverberation and reflection. This situation makes TDOA estimation difficult, and accurate sound localization is difficult when using only two pairs of microphones. The authors propose a new method of sound localization based on multiple microphones that are widely distributed and placed under the ceiling of a room. A number of pairs of microphones give a series of CSP correlation coefficients as a function of the time delay. The CSP coefficients for hypothetical sound sources are accumulated over all the microphone pairs. The number of microphones is 16. The sound source is localized as a hypothesis that maximizes the accumulated CSP coefficient. Experiment results obtained in a real room show that the proposed method improves the localization accuracy.

3pSP43. Free listening-point synthesizing method in a large microphone array using acoustic transfer function. Mehrdad Panahpour Tehrani, Yasushi Hirano, Shoji Kajita, Kenji Mase (Information Technol. Ctr., Nagoya Univ., Furo-cho, Chikusa-ku, Nagoya 464-8601, Japan), Takanori Nishino, Kazuya Takeda (Grad. School of Information Sci., Furo-cho, Chikusa-ku, Nagoya 464-8603, Japan), and Toshiaki Fujii (Grad. School of Eng., Furo-cho, Chikusa-ku, Nagoya 464-8603, Japan)

In this research a free listening-point synthesizing method is proposed by using the measured acoustic transfer function (ATF) in a large microphone array for future 3-D audiovisual systems. ATFs at the location of far-field microphones are estimated in frequency domain by using a recorded time-stretched pulse (TSP) signal broadcasted by speakers at the location of sources. Then an ATF pool is generated with a chosen density by synthesizing the estimated ATFs for each sound source. The ATF pool contains all the microphones' locations, plus synthesized ATFs with a chosen density from sound sources to any point on the arc which passes all of the microphones. The free listening-point is generated by selecting the ATF for each source from the ATF pool. Then the source microphone sounds are convolved with the chosen ATFs and added. The proposed method is evaluated by an array with 38 microphones in the far field on an arc with $r = 4$ m with 20 cm between each pair of microphones, and two microphones close to two sound sources with 1.5-m distance. Experimental results have been shown for the estimated ATFs and comparison of the synthesized arbitrary listening point with the actually recorded sound for a given point that shows satisfactory results.

3pSP44. On the numerical simulation of sound wave propagation using field programmable gate array device. Takao Tsuchiya (Dept. of Information Systems Design, Doshisha Univ., 1-3 Miyakodani, Tatara, Kyotanabe-shi, Kyoto 610-0321, Japan, ttsuchiy@mail.doshisha.ac.jp), Eiko Sugawara, and Yasusi Inoguchi (Japan Adv. Inst. of Sci. and Technol., 1-1 Asahidai, Nomi, Ishikawa 923-1292, Japan)

Numerical simulation of sound wave propagation using field programmable gate array (FPGA) device is proposed. The two-dimensional digital Huygensf model (DHM) or the transmission line matrix (TLM) model is configured in FPGA device as digital circuits. DHM is a numerical model in which the propagation and scattering of waves are simulated as the sequences of impulses scattering on the transmission line network as Huygens' principle states. The digital equivalent circuit can be easily devel-

oped based on DHM because the formulation of DHM is very simple compared with the finite difference time domain (FDTD) method. In this paper, number of logic cells of the FPGA device required for a DHM element is estimated. To configure DHM elements in the FPGA device as much as possible, the fixed-point operations are applied to the DHM calculations. Numerical precision of DHM using the fixed-point operations is then discussed. The data length required for acoustic field simulation in practical precision is estimated. The capability of the FPGA simulator for room acoustics is discussed.

3pSP45. Signal processing for small-size microphone array system— Application to teleconferencing system. Akira Gotoh, Yoshitaka Murayama, Jun Ota, Hareo Hamada (DiMAGIC, Sugishou Bldg 3F, 2-4-5 Kanda-Ogawamachi, Chiyodaku, Tokyo 101-0052, Japan), Yuko Watanabe, and Hareo Hamada (Tokyo Denki Univ., 2-1200 Muzaigakuendai, Inzai-shi, Chiba, Japan)

A small microphone array system, consisting of two or more closely arranged small microphones and a digital filter network, is newly proposed. A method based on sound field control using multiple-point least-squares filter design contributed to the configuration of a smaller size microphone array system. Several directivity patterns having unique focus directions can be configured by changing each set of optimum filter coefficients. In this paper, a new method of scanning speaker direction using the small microphone array is proposed and several performances used in teleconferencing systems are evaluated.

3pSP46. Sensor signal processing circuit for echolocation using a delta-sigma modulated single-bit digital signal. Shinnosuke Hirata, Minoru K. Kurosawa (Tokyo Inst. of Technol., G2-32, 4259 Nagatsuta, Midori-ku, Yokohama, Japan, shinnosuke.hirata@ip.titech.ac.jp), and Takashi Katagiri (Sutekina Inc. Komagane, Japan)

Ultrasonic sensors are suitable for perception of the environment of mobile autonomous robots. Most bats use echolocation that is a high-quality sensing system by their ultrasonic sensors [S. J. Gaioni, H. Riquimaroux, and N. Suga, "Biosonar behavior of mustached bats swung on a pendulum prior to cortical ablation," J. Neurophysiol. **64**(6), 1801–1817 (1990)]. The echolocation can estimate the distance to the object, its relative velocity, and its scale. But, technological application of echolocation necessitates a large computational requirement because delay of the echo signal from the generated signal is estimated from cross correlation between the generated signal and the echo signal. A new sensor signal processing for echolocation is proposed by using a delta-sigma modulated single-bit digital signal. A delta-sigma modulated single-bit digital signal is a single-bit high-speed data stream. [S.R. Norsworthy, R. Schreier, and G. C. Temes, *Delta-Sigma Data Converters* (IEEE Press, New York, 1997] Using delta-sigma modulated single-bit digital signal processing, multiplication and accumulation of cross-correlation can be changed into logical operations: EXOR, NOT, SUM. Simulations show the possibility of estimation of the distance to the object from correlation of the echo signal with the generated signal converted single-bit data stream, along with reduced computational and circuit-scale requirements.

3pSP47. Modeling of phased antenna array of about 500 microphones, detecting landing airplanes. Gaetano Caronna, Ivan Roselli, and Pierluigi Testa (Dipartimento di Fisica Tecnica, Universit La Sapienza, Via Eudossiana, 18, 00100 Roma, Italy, gaetano.caronna@uniroma1.it)

The University La Sapienza participated recently in the project SAFE-AIRPORT funded within the sixth framework program of the European Commission. This project aimed at developing a phased antenna array of about 500 microphones in order to acoustically detect and track flying airplanes. A preliminary field testing was performed at Rome-Fiumicino airport, however experimental data are not yet fully available. For this

reason, a computer-aided model of the antenna phased array was developed and beam-forming was simulated with real input signals (acoustic emissions from a real landing aircraft with superimposed disturbing, spatially uncorrelated, pink noise of realistic level). Detection range was measured by applying classic shift and sum beamforming. An algorithm was tested in order to increase maximum detection range by exploiting information from more than one temporal frequency, assuming that disturbing environmental noise is uncorrelated on different temporal frequencies. Specific results are reported.

3pSP48. Compressive coding for multichannel audio signals using independent component analysis. Tadashi Mihashi, Tomoya Takatani, Shigeki Miyabe, Yoshimitsu Mori, Hiroshi Saruwatari, and Kiyohiro Shikano (Nara Inst. of Sci. and Technol., 8916-5 Takayama-cho, Ikoma-shi, Nara 630-0192, Japan)

This study addresses a novel compressive coding for multichannel audio signals with independent component analysis (ICA). In recent years, multichannel audio contents are widely spreading, and thus the transmission quantity is increasing. Consequently, audio-signal compression is a problem demanding prompt attention. Conventional compression methods utilizing sparseness assumption among audio-source signals have a problem that the method is likely to distort original sources owing to the lack of sparseness in the mixed signals consisting of two or more sound sources. To solve this problem, we propose an audio-signal compression strategy using ICA; ICA assumes that the source signals are mutually independent, and can estimate the source signals from the mixed signals without *a priori* information by applying an unmixing matrix. The decomposition of mixed signals leads to an enhancement of sparseness among signals. Furthermore, we propose a mechanism to detect time-frequency grids where sparseness is not satisfied, and for the detected grids we directly transmit multichannel signals to mitigate the distortion. The reconstruction process utilizes an inverse projection of the unmixing matrix to make correct lateralization of each sound source. Experimental result shows that the proposed method can compress mixed audio signals more efficiently and achieve a higher quality than the conventional method.

3pSP49. Novel interface using a microphone array for wheelchair control. Akira Sasou and Hiroaki Kojima (Natl. Inst. Adv. Industrial Sci. Technol. (AIST), Central#2,1-1-1, Umezono, Tsukuba, Ibaraki, 305-8568 Japan, a-sasou@aist.go.jp)

This paper describes a novel interface that enables the control of a wheelchair by disabled people without having to use their hands. Thus far, a voice-driven wheelchair has been developed for disabled people who find it difficult to move their hands but are able to speak. Such wheelchairs usually adopt a headset microphone in order to reduce noise interference. However, a headset microphone is not practical because disabled people cannot wear the headset independently. Another problem faced is that the microphone shifts away from the mouth due to involuntary movements. In the proposed system, however, we use a microphone array that is mounted on a wheelchair, so that the disabled people do not need to wear the microphone. The system is also robust to noises and is able to recognize a face's direction by estimating the position of a sound source such as the mouth. For instance, when disabled people need to turn left, they face left and make a sound that is not restricted to voice commands. Thus, the proposed system does not require disabled people to utter clear voice commands. This feature enables the application of the system to more general cases.

3pSP50. Decomposition of the time reversal operator (DORT) for extended objects. Jean-Luc Robert (Philips Res. North America, 345 Scarborough Rd., Briarcliff Manor, NY 1510, jean-luc.robert@philips.com) and Mathias Fink (Universite Paris 7, 75005 Paris, France)

The decomposition of the time reversal operator, known by the French acronym DORT, is widely used to detect, locate, and focus on scatterers in various domains such as underwater acoustics, medical ultrasound, or nondestructive evaluation. In the case of point scatterers, the theory is well understood: the number of nonzero eigenvalues is equal to the number of scatterers, and the eigenvectors correspond to the scatterers' Green function. In the case of extended objects, however, the formalism is not as simple. We show that, in the Fresnel approximation, analytical solutions can be found, and that the solutions are functions called prolate spheroidal wavefunctions. These functions have been studied in optics and information theory as a basis of band-limited and time-limited signals. The theoretical solutions are compared to simulation results and previous experimental results Most importantly, we justify the intuition that for an extended object, the number of nonzero eigenvalues is proportional to the number of resolution cells in the object. The case of 3-D objects imaged by a 2-D array will also be described.

3pUW1. Measurements of temporal coherence of sound transmissions through shallow water. T. C. Yang (Naval Res. Lab., Washington, DC 20375)

Temporal coherence of acoustic signals propagating through fluctuating oceans has received much attention in the literature as the rate of signal coherence loss impacts the sonar performance. This paper presents the measurement results of temporal coherence of acoustic signals propagating through shallow water using data from three experiments in three different parts of the world. The data are broadband signals covering three frequency bands: low frequencies below 1.2 kHz, mid frequencies between 2 and 5 kHz, and high frequencies between 18 and 22 kHz. The source-receiver range covers 3, 5, 10, and 42 km. Measurement issues and environmental impact on the temporal coherence are discussed. The signal coherence time, defined by the time that the signal becomes decorrelated, is deduced from the data. The signal coherence time varies with the source-receiver range and the signal frequency and is significantly influenced by the medium fluctuations. The data can be fit with a simple power law dependence on the range, frequency, and sound speed standard deviations. [This work is supported by the U.S. Office of Naval Research.]

1:15

3pUW2. Comparison of measured signal coherence time in shallow and deep water. T. C. Yang (Naval Res. Lab., Washington, DC 20375)

Temporal coherence of acoustic signals determines the processing of a sonar system for various applications. This paper studies the frequency and range dependence of the temporal coherence time of signal propagation in deep water versus that in shallow water. The signal coherence time has been measured in deep water since the 1970s, in terms of a parameter called the phase rate (the rate of phase change of the signal). Signal coherence time in shallow water has received little attention until only recently. We compare measurement data from more than a dozen of experiments covering a wide range of frequencies at different source-receiver ranges in deep and shallow water. We find that the signal coherence time in both shallow and deep water can be fitted with a universal equation, which exhibits a $\frac{3}{2}$ power frequency dependence and $\frac{1}{2}$ power range dependence. The signal coherence time in shallow water is two to five times longer than the signal coherence time in deep water at the same frequency and range. The signal coherence times are comparable between shallow and deep water if measured in terms of the range-to-depth ratio. [This work is supported by the U.S. Office of Naval Research.]

3pUW3. Spatial coherence of the acoustic field for propagation ranges 500−1000 m in an East China Sea channel. Peter H. Dahl and Jee Woong Choi (Appl. Phys. Lab., Univ. of Washington, Seattle)

Measurements of the vertical spatial coherence at ranges 500–1000 m and for transmission frequencies 2–20 kHz were made as part of the Asian Sea International Acoustics Experiment (ASIAEX) conducted in the East

China Sea (depth 105 m). In an earlier work [J. Acoust. Soc. Am. **115**, 589–599 (2004)], ASIAEX spatial coherence measurements corresponding to arrivals interacting once with the sea surface were modeled using the van Cittert–Zernike theorem in conjunction with model estimates of bistatic scattering scattering from the sea surface. The theorem relates the spatial coherence of an observed field to the distant source intensity distribution associated with this field. Here, the approach from the 2004 work is extended to study the full multiple path arrival involving bistatic scattering from the sea surface, and coherent reflection plus bistatic scattering from the seabed. Model and data comparisons are made for the vertical direction and predications are made for coherence in horizontal, and horizontal-transverse direction.[Work supported by the ONR.]

3pUW4. Statistics of the Parseval sum, match filter, and instantaneous single-frequency transmissions in an ocean waveguide. Mark Andrews (Northeastern Univ., 409 Dana Res. Ctr., Boston, MA 02115-5000), Tianrun Chen, Sunwoong Lee, Nicholas Makris (MIT, Cambridge, MA 02139), and Purnima Ratilal (Northeastern Univ., Boston, MA 02115-5000)

During the ONR Main Acoustic Clutter Experiment of 2003 on the New Jersey Continental Shelf, short duration broadband pulses with 50- to 150-Hz bandwidths were transmitted at 50-s intervals from a moored source array in the 300- to 1500-Hz range. The signals were measured by a towed horizontal receiving array at varying ranges from the source. The broadband data are processed in a variety of ways including the use of Parseval sum and match-filter, and as an instantaneous single frequency transmission. The ping-to-ping fluctuations in the measured acoustic data are a result of changes in the waveguide modal intereference structure due to both motion of the array and presence of time-dependent random internal waves. Our analysis shows that the Parseval sum and match-filter outputs for the direct arrival have significantly smaller standard deviations compared to the instantaneous single frequency transmission. We account for these observations by modeling the broadband acoustic field intensity in both a static waveguide and with Monte Carlo simulations in a fluctuating waveguide, as well as with the use of statistical distributions for the broadband acoustic field. We present an approach for empirically quantifying the range-dependent degradation in the match-filter output in a multimodal waveguide.

3pUW5. Estimation for velocity dispersion of normal modes in a laboratory waveguide. Cao Zhengliang, Wang Suping, and Zhou Shihong (Hangzhou Appl. Acoust. Res. Inst., Hangzhou 310012 China)

As one character of normal modes, velocity dispersion defined as velocity dependent on frequency is related to the environment of a fluid and seabed in a shallow water waveguide. It is important to inverse geoacoustic parameters or analyze normal mode propagation in the waveguide. With waveforms measured by a line array in a laboratory waveguide, velocity dispersion of normal modes is estimated by Prony's

method. Because of the influence of the sum of many modes in a frequency, the estimated dispersions are disordered and discontinued. While a number of modes fewer than that, in fact, are previously selected, the results can be improved on velocity dispersion curves. On the other hand, clear curves can be obtained for the components of waveforms intercepted by an adaptive time window. These results are consistent with that of synthetic waveforms simulated by a normal mode program. Comparing the dispersions estimated from data in different depths, there are abundant high-order modes in this case. [Work supported by SKLF.]

3pUW6. PlaneRay: An underwater acoustic propagation model using ray tracing and plane wave reflection coefficients. Jens M. Hovem and Hefeng Dong (Dept. of Electron. and Telecommunications, Norwegian Univ. of Sci. and Technol., No. 7491, Trondheim, Norway)

Recently there has been a renewed interest in using ray tracing techniques for propagation modeling in underwater acoustics and this paper describes a newly developed model. A special and essential feature of this model is a unique sorting and interpolation routine for efficient determination of a large number of eigenrays and also for range-dependent environments. No rays are traced into the bottom and the bottom interaction is modeled by plane wave reflection coefficients. In the current version of the model the bottom structure consists of a fluid sediment layer over a solid half-space. Important considerations are the accuracy of the ray model and, in particular, how accurate the plane wave reflection coefficients can represent the effects of a layered bottom. This problem is analyzed by comparing the time and frequency domains solution of the ray model with models based on the wave number integration technique. There are two conflicting requirements since ray tracing is valid for high frequencies and the used plane wave reflection coefficient is valid for low frequencies where the sediment layers are thin compared with the acoustic wavelength. A number of illustrative examples are presented.

3pUW7. Ray-based acoustic localization of cavitation in a highly reverberant environment. Natasha A. Chang and David R. Dowling (Dept. of Mech. Eng., Univ. of Michigan, 1231 Beal Rd., 2019 Lay Autolab, Ann Arbor, MI 48109)

Acoustic localization techniques are applied in a water tunnel to study low event rate cavitation in a vortical flow. The measured center frequency and bandwidth of the acoustic pulse from the collapse of a small isolated cavitation bubble are 10 kHz and 200 kHz, respectively, and the measured pulse duration is ~ 15–20 μs. Its timing and exact waveform is not known. An array of 16 receiving hydrophones is used to estimate the source location in the test section of the water tunnel. The direct path signal used for this effort can be buried in background hydrodynamic noise from the water tunnel. Fortunately some of the direct-path signal arrival is distinct enough for acoustic localization. The signal coda is not used in the present effort. The received direct-path signals are cross-correlated between hydrophones to obtain arrival time differences. These arrival time differences are used in conjunction with a simple ray-based acoustic model to estimate the source location in three dimensions. Once the cavitation bubble is located, the signal can be back propagated and part of the free space signal estimated and correlated with high-speed video of cavitation bubble dynamics. [Work sponsored by ONR codes 333 and 321.]

3pUW8. Bistatic invariance for active sonar systems. Lisa Zurk, Jorge Quijano, Manish Velankar (Portland State Univ., P.O. Box 751-ECE, Portland, OR 97207, zurkl@cecs.pdx.edu), and Dan Rouseff (Univ. of Washington, Seattle, WA 98105)

The concept of an invariant time-frequency relationship for passive acoustic intensity has been established through the consideration of interfering normal modes traveling in a shallow water channel. This formulation has received considerable attention in the past and has been applied to the interpretation of passive lofargrams. For bistatic active geometries, the acoustic energy propagates along two distinct pathways: source-to-target and target-to-receiver. In recent work we proposed that this more complicated propagation may also exhibit an invariant structure, thus suggesting potential for improved target tracking through the application of invariant-based track constraints. In this work, further exploration of this phenomenon is presented, with specific attention to the impact of the target scattering matrix that couples energy at the target between incoming and outgoing modes. Simulation results are presented for a variety of underwater environments to examine the effect on the invariant structure. Results are also presented and discussed from spectrograms produced from active sonar data obtained in shallow water environments.

3pUW9. Time-frequency analysis of mode coupling in shallow-water sound propagation. Mohsen Badiey (Ocean Acoust. Lab., Univ. of Delaware, Newark, DE 19716), Valery Grigorev, Boris Katsnelson (Voronezh Univ., Voronezh 394006 Russia), and James Lynch (WHOI, Woods Hole, MA 02543)

Time-frequency (TF) analysis for propagation of broadband sound pulses in shallow water in presence of perturbations of waveguides parameters, such as internal waves, temperature fronts, or bottom variability is considered. Due to waveguide dispersion one can construct a TF diagram for individual normal modes using Gabor transform for each received pulse. If we have a temporal sequence of propagating pulses then we can find a temporal sequence of TF diagrams. It is shown that in the presence of spatial and temporal waveguide perturbations (such as the sound-speed profile in the water column or the sea bottom) structure of a TF diagram and its temporal behavior depends on waveguide parameters, on the source-receiver positions, and on the character of mechanisms influencing the sound propagation, such as mode coupling, horizontal refraction, or adiabatic regime. Dependence of the TF diagram on waveguide variability in geotime provides information about temporal behavior of the perturbations. Structure of TF diagram is analyzed for a shallow-water waveguide model as well as for the SWARM95 experimental data. [Work supported by ONR and RFBR.]

3pUW10. Propagation of impulsive broadband signals in a coastal ocean setting during the 1996 Shelfbreak Primer experiment. Steven E. Crocker (Naval Undersea Warfare Ctr., Newport, RI 02841), James H. Miller, Gopu R. Potty, Georges A. Dossot (Univ. of Rhode Island, Narragansett, RI 02882), and James F. Lynch (Woods Hole Oceanogr. Inst., Woods Hole, MA 02543)

The 1996 Shelfbreak PRIMER experiment provided an opportunity to study the impulse response of a coastal ocean waveguide using broadband acoustic signals from explosive sources. Acoustic transmission paths in the vicinity of the shelfbreak included various orientations ranging from upslope to along-slope, including interactions with a shelfbreak front. Acoustic receptions were acquired with a 16-element vertical line array (VLA). In addition, thermistor string data acquired at the receiving array suggest that a group of high-amplitude, internal waves traversed the test site during this portion of the experiment. Modal decomposition of broadband signal arrivals was performed to investigate variation of the impulse response during source deployments. Variations in the received spectra of individual normal modes were compared with numerical predictions for impulsive broadband signals propagating in range-dependent environments constructed using oceanographic data available for the test site. The potential for mode coupling and three-dimensional effects to shape the modal and spectral distribution of received energy is being investigated. Numerical and experimental results will be discussed. [Work supported by Office of Naval Research.]

3pUW11. Underwater propagation at 16 Hz from French Polynesia to New Zealand: Echoes from islands, banks, and seamounts, and attenuation by seamounts. Marshall V. Hall (9 Moya Crescent, Kingsgrove, New South Wales 2208, Australia, marshallhall@optushome.com.au)

Underwater signals from two nuclear shots fired in Fangataufa and three in Mururoa during 1995/96 were recorded off northern New Zealand, a geoid distance of 4660 km. The signals have been bandpass filtered at 16 Hz and found to contain up to six echoes. The causative scattering seafloor features were estimated from the travel times. For some echoes there was ambiguity in the feature and hence some uncertainty in the deflection angle (DA). Amongst the six echoes, the DA ranged between 20 and 56 deg. In the two Fangataufa signals, echo intensities relative to the intensity of the direct pulse ranged between -44 and -25 dB, and this relative intensity (RI) decreased with increasing DA. The highest feature on the direct path from Fangataufa, a seamount whose peak is 1.6 km deep, appears to have had little effect on the signal. In the three Mururoa signals, there were fewer echoes, and RI did not vary significantly with DA. The highest feature on the direct path from Mururoa was a seamount whose peak is 0.7 km deep. This seamount attenuated the direct signal at New Zealand by approximately 23 dB, as well as paths to features at small angles from the direct.

4:00

3pUW12. Features of the broadband acoustic propagation in very shallow water. Seongwook Lee, Kyu-Chil Park, Jong Rak Yoon (Div. of Electron., Comput. and Telecommunication Eng., Pukyong Natl. Univ., 599-1 Daeyon-3dong, Namgu, Pusan 608-737, Korea), and Phil-Ho Lee (Agency for Defense Development, Jinhae, Gyungnam 645-600, Korea)

In shallow water, acoustic propagation is severely influenced by the property and structure of the bottom. We present the results of acoustic measurement conducted in a very shallow water of about 11-m depth to characterize the features of broadband acoustic propagation. In the measurements using both of the ship and projectors as sources, the signal was received at four hydrophones, two of them were located in the water and another two were located in the sediment. Broadband propagation losses derived from ship noise revealed the frequency band that has high losses around 120–140 Hz. Analysis results on the possible causes of high losses at that frequency band are presented.

3pUW13. A stochastic model for underwater acoustic channel impulse function in the Kauai experiment. Aijun Song, Jing Luo, and Mohsen Badiey (College of Marine Studies, Univ. of Delaware, Newark, DE 19716)

Modeling of underwater acoustic channel impulse function has been of interest to the research community. As is well known, the underwater acoustic wave propagation depends on a number of environmental parameters, such as the sound speed profile along the propagation track, sea surface condition, and source/receiver geometry. The fluctuations of these environmental parameters cause the variability of the acoustic wave propagation in the shallow water region. In this paper, a stochastic model for the channel impulse function is proposed. The characteristics of the each eigenray, such as arrival time, average intensity, and coherence time, are extracted from the Kauai experiment (2003). The correlation between the model parameters and the environmental variability will also be shown.

3pUW14. Measurements of 3-D propagation effects at a shelfbreak front. Kristy A. Moore, James H. Miller, Gopu R. Potty, Georges A. Dossot (Dept of Ocean Eng., Univ. of Rhode Island, 217 Sheet Bldg., Narragansett, RI 02882), Scott M. Glenn ((Rutgers Univ., NB, NJ 08901), and James F. Lynch (Woods Hole Oceanogr. Inst., Woods Hole, MA 02543)

Acoustic data collected on two Webb Slocum gliders deployed by Rutgers University during the Shallow Water Experiment (SW06) on the continental shelf off New Jersey are presented. Acoustic recording systems were attached to the two gliders, which also collected oceanographic data. These gliders periodically surfaced for GPS fixes and data transfer via satellite phone. A major goal of these measurements was to quantify 3-D propagation effects including the horizontal analog to the classical Lloyd's mirror. The Lloyd's mirror effect is produced by the fact that fronts can totally internally reflect sound incident upon them at low grazing angles. The direct and reflected arrivals can add up to produce an interference pattern in range, potentially increasing the received intensity level by 6 dB [Lynch *et al.*, IEEE J. Ocean. Eng., in press]. The gliders crossed the shelfbreak front at ranges of approximately 20 km from the sources and in water depths of approximately 80 m. Measurements of the acoustic arrivals from 224 and 400 Hz tomography sources are compared to 3D modeling results. The increase in the intensity level predicted by the horizontal ray-vertical mode model is discussed. [Work supported by Office of Naval Research.]

4:45

3pUW15. Arrival time change of long distance sound travel in the central Pacific. Hanako Ogasawara, Toshiaki Nakamura (Dept. of Earth and Ocean Sci., Natl. Defense Acad., 1-10-20 Hashirimizu, Yokosuka, Kanagawa 239-8686, Japan), Hiroyuki Hachiya (Chiba Univ., Inage-ku, Chiba 269-8522, Japan), Hidetoshi Fujimori (Japan Agency for Marine-Earth Sci. and Technol., Yokosuka, Kanagawa 237-0061, Japan), and Koichi Mizutani (Univ. of Tsukuba, Tsukuba, Ibaraki 205-8573, Japan)

Ocean acoustic tomography (OAT) is a valuable method for observations of oceanographic phenomena over wide areas. A tomography experiment using seven 200-Hz transceivers at depths around 1000 m was executed in the central equatorial Pacific Ocean during January through December 2000 to monitor ocean phenomena related to El Niño and southern oscillation (ENSO). Because sound that propagates in the ocean takes various paths depending on its incident angle, the sound arrival times showed time lags. Arrival times of the first arrival signals were used to evaluate fluctuations throughout the year. Positional data of transceivers calculated from transponders indicated that major fluctuations of arrival times resulted from location movements of transceivers. The arrival times were corrected by calculating the distance using the positional data to remove distance effects in each transmission. Tidal effects were observed from spectral analyses of the corrected arrival times throughout the experimental period. Reciprocal arrival time differences between one pair of transceivers showed different changes during mid-September through November in comparison to other reciprocal arrival times of several paths. This change might have resulted from some kind of oceanic variation. Acoustic observations are advantageous for detecting various changes over long periods.

4aAA1. Warped-time-stretched pulse: An acoustic test signal robust against ambient noise. Masanori Morise, Toshio Irino, Hideki Banno, and Hideki Kawahara (Wakayama Univ., 930, Sakaedani, Wakayama, 640-8510, Japan, s055068@sys.wakayama-u.ac.jp)

A new acoustic measurement signal that is a hybrid signal of time-stretched pulse (TSP), or lin-TSP, and logarithmic TSP (log-TSP) is proposed. The signal, referred to as warped-TSP [Morise *et al.*, IEICE Trans. Fundamentals, A, **J89-A**(1), 7–14 (2006)], has a single parameter to adjust for better measurements in accordance with ambient noise conditions. It also provides a means to eliminate harmonic distortions produced mainly by loudspeaker systems. In this lecture, the definition and features of the warped-TSP in comparison with the lin-TSP and log-TSP are introduced. The following were shown: (1) the relationship between the parameters, the amplitude frequency characteristics, and the effect on the harmonic distortion components; (2) a method to select the optimal parameters of the warped-TSP for a specific measuring environment; and (3) the experimental results for a series of impulse response measurements under different ambient noise conditions. Those results show that the proposed method outperformed the lin-TSP and log-TSP under all conditions in terms of SNR of the measured impulse response. [This research was supported partly by grants-in-aid for scientific research (15300061 and 15650032) and a grant from the Faculty of Systems Engineering at Wakayama University.]

4aAA2. Simultaneous estimation of reverberation times and their uncertainties from room impulse responses using a single-measurement procedure. Ning Xiang and Tomislav Jasa (Grad. Program in Architecture Acoust., and Dept. of Elec., Comput., and Systems Eng., Rensselaer Polyt. Inst, Troy, NY 12180)

Accurate measurements of reverberation times are of fundamental importance in room acoustics. A number of test procedures for characterizing acoustics in performing arts venues, quantifying acoustic properties of materials in chamber measurements, rely on experimental determination of reverberation times. In addition, decay-time estimation in acoustically coupled spaces has been found to be very demanding. Our recent work has demonstrated that model-based Bayesian approaches [Xiang *et al.*, J. Acoust. Soc. Am. **110**, 1415–1424 (2001); **113**, 2685–2697 (2003); **117**, 3705–3715 (2005)] can be very useful for such analysis in architectural acoustics measurements. This paper discusses the recent development of probabilistic tools for estimating both reverberation (decay) times and their uncertainties within Bayesian framework. This work shows that Bayesian probabilistic inference can be used as a useful tool for sound energy decay analysis in both single-space halls and coupled spaces. Bayesian decay analysis simultaneously provides architectural acousticians with reverberation times, diverse decay times, related derivations, and interdependencies to quantify uncertainties of the estimation from a single measurement of room impulse responses followed by Schroeder backward integrations.

4aAA3. Permissible number of synchronous averaging times to obtain reverberation time from impulse response under time-variance conditions. Fumiaki Satoh, Yukiteru Hayashi (Chiba Inst. of Technol., Tsudanuma 2-17-1, Narashino-chi, Chiba, 275-0016, Japan), Shinichi Sakamoto (Univ. of Tokyo, Meguro-ku, Tokyo, 153-8505, Japan), and Hideki Tachibana (Chiba Inst. of Technol., Narashino-shi, Chiba, 275-0016, Japan)

In the measurement of room impulse response, the synchronous averaging technique and such new methods as the MLS and the swept-sine methods are being widely used to improve the signal-to-noise ratio. In actual measurement conditions, however, the air in a room is continuously moving and the temperature is changing to some degree. The measured value of the reverberation time in such a room tends to be shorter at higher frequencies when applying the synchronous averaging. Therefore, the assumption of a time invariant has to be carefully considered, and, on this point, some research has been conducted to date. We also have reported various research results concerning the impulse response measurement under the time-variance conditions. In this paper, the permissible number of synchronous averaging times for reverberation measurement is studied through some field experiments. In each field, many

3223 J. Acoust. Soc. Am., Vol. 120, No. 5, Pt. 2, November 2006

Fourth Joint Meeting: ASA and ASJ **3223**

time impulse response measurements were taken between a fixed pair of sound source and receiving positions by the swept-sine method, without averaging. After the measurements, the characteristics and the extent of the time-variance under measuring were estimated by a short-term running cross-correlation function between each impulse response. The influence of the time variance on the synchronous averaging result was studied based on the estimated time variance.

4aAA4. Selection of receiving positions suitable for evaluating acoustical parameters. Taeko Akama, Hisaharu Suzuki, and Akira Omoto (Omoto Lab., Dept. of Acoust. Design, Faculty of Design, Kyushu Univ., Shiobaru 4-9-1, Minami, Fukuoka 811-8540, Japan)

Many physical parameters show characteristics of large sound fields such as concert halls. Some of them are adopted in the Annex of ISO 3382. That definition is clearly provided in ISO. However, practical measurement methods for them remain obscure. Our research is intended to examine an effective selection method of receiving positions based on the distribution of acoustical parameters in a real field. For that purpose, impulse responses are measured at more than 1400 seat positions to elucidate the distribution of acoustical parameters in an existing concert hall. The acoustical parameters, which are reverberation time, early decay time, clarity, and center time at each seat, are then calculated for 500-Hz, 1-kHz, and 2-kHz octave bands. The distributions of reverberation time are quite even at all seats. However, the distributions of other parameters show symmetrical patterns at 500 Hz. At 1 and 2 kHz frequencies, the distributions show asymmetrical patterns in this hall. Based on the results obtained in this study, an effective method to select the receiving position can be proposed.

4aAA5. Hybrid measurement method in room acoustics using dodecahedron speakers and a subwoofer. Hideo Miyazaki (Ctr. for Adv. Sound Technologies, Yamaha Corp., 203 Matsunokijima, Iwata, Shizuoka 438-0192, miyazaki@beat.yamaha.co.jp)

A dodecahedron speaker is usually utilized for measurement in room acoustics under the hypothesis of omni directional point source. But generally speakers used for a dodecahedron speaker cannot playback low-frequency sound such as under 100 Hz, which is important especially for auralization, while the one constructed of units with large diameter to support low-frequency sounds cannot be considered as an omni-directional speaker in high frequencies. To meet these requirements, a hybrid system combining a dodeca-hedron speaker and a subwoofer has been developed and actually used for measurements of impulse responses in acoustical design of concert halls. The summary of this method will be presented. The feasibility of this method will be also discussed while evaluating the measurement results in concert halls by changing measurement conditions such as speaker locations and comparing these results with those of conventional methods.

9:15

4aAA6. The perception of apparent source width and its dependence on frequency and loudness. Ingo B. Witew and Johannes A. Buechler (Inst. of Tech. Acoust., RWTH Aachen Univ., Templergraben 55, 52066 Aachen, Germany)

While it is widely accepted that apparent source width (ASW) is an important factor in characterizing the acoustics of a concert hall, there is still a lively discussion on how to refine the physical measures for ASW. A lot of experience has been gathered with interaural-cross-correlation and lateral-sound-incidence measures during the last years. As a result it was learned that different frequencies contribute differently to the perception of ASW and that the level of a sound also influences the perception of the apparent width of a source. With many technical measures having an influence on the perceptual aspect of ASW, the design of psychometric experiments becomes challenging as it is desirable to avoid the interaction of different objective parameters. In the experiments for the study presented, the perception of ASW is investigated for frequencies ranging from 100 Hz to 12.5 kHz at different levels of loudness. It is shown how the frequency and the loudness of a sound influence the perception of ASW.

9:35

4aAA7. Sound source with adjustable directivity. Gottfried K. Behler (Inst. fuer Technische Akustik, RWTH Aachen Univ., D-52056 Aachen, Germany)

Omni-directional sound sources are used to measure room-acoustical parameters in accordance with ISO 3382. To record a detailed room impulse response (RIR) with the aim of auralization, an extended frequency range is required that is not covered by the often-used building acoustics sound sources. To obtain this target, a loudspeaker with dedicated sources for low, mid, and high frequencies was designed, providing a smooth omni-directionality up to 6 kHz and a usable frequency range from 40 Hz up to 20 kHz. However, a realistic auralization of sources like musical instruments is not possible with an omni-directional measured RIR. To include the directional characteristics of instruments in the measuring setup, the directivity of the sound source has to be frequency dependent and must be matched to the (measured) directivity of the real instrument. This can be obtained by using a dodecahedron loudspeaker with independently operating systems and an appropriate complex FIR filtering of the frequency response of each driver. The directivity is a result of parameters like magnitude and phase and the interference sum of all systems. To create the appropriate directivity, optimization algorithms are used to achieve minimum error between measured and adapted directivity.

10:15

4aAA8. Objective measures for evaluating tonal balance of sound fields.   Daiji Takahashi   (Dept. of Urban and Environ. Eng., Kyoto Univ., Kyoto Univ. Katsura, Nishikyo-ku, Kyoto 615-8540, Japan, tkhs@archi.kyoto-u.ac.jp), Kanta Togawa   (FUJITEC Co., Ltd., Hikone Shiga 522-8588, Japan), and Tetsuo Hotta   (YAMAHA Corp., Hamamatsu Shizuoka 430-8650, Japan)

The purpose of this study is to derive objective measures, which can well represent the characteristics of the sound field regarding the tonal balance corresponding to our hearing sense. Two kinds of listening test were conducted in the form of paired comparison, in which subjects were tested using sound fields produced by convoluting some anechoic music sources with some impulse responses. In the first listening test, impulse responses were calculated theoretically for a simple structure of sound field having a direct sound and reflections, and, in the second test, impulse responses were measured at the various seats of existing concert halls. In the latter case, impulse responses which give almost the same reverberance were used for the listening tests. From this investigation, it is found that one objective measure called the DL (deviation of level) has a possibility of an effective measure, which can be used as an appropriate measure for evaluating the tonal balance of sound fields. The index DL is calculated from the data based on the logarithmic scale in both the frequency and magnitude. This fact is not inconsistent with the past findings that human response corresponds to a logarithmic scale of stimulus.

10:35

4aAA9. Measuring impulse responses containing complete spatial information.   Angelo Farina, Paolo Martignon, Andrea Capra, and Simone Fontana   (Industrial Eng. Dept., Univ. of Parma, via delle Scienze 181/A, 43100 Parma, Italy)

Traditional impulse response measurements did capture limited spatial information. Often just omnidirectional sources and microphones are employed. In some cases it was attempted to get more spatial information employing directive transdudcers: known examples are binaural microphones, figure-of-8 microphones, and directive loudspeakers. However, these approaches are not scientifically based and do not provide an easy way to process and visualize the spatial information. On the other side, psychoacoustics studies demonstrated that "spatial hearing" is one of the dominant factors for the acoustic quality of rooms, particularly for theatres and concert halls. Of consequence, it is necessarily to reformulate the problem entirely, describing the transfer function between a source and a receiver as a time/space filter. This requires us to "sample" the impulse response not only in time, but also in space. This is possible employing spherical harmonics for describing, with a predefined accuracy, the directivity pattern of both source and receiver. It is possible to build arrays of microphones and of loudspeakers, which, by means of digital filters, can provide the required directive patterns. It can be shown how this makes it possible to extract useful information about the acoustical behavior of the room and to make high-quality auralization.

10:55

4aAA10. Spherical and hemispherical microphone arrays for capture and analysis of sound fields.   Ramani Duraiswami, Zhiyun Li, Dmitry N. Zotkin, and Elena Grassi   (Perceptual Interfaces and Reality Lab., Inst. for Adv. Comput. Studies, Univ. of Maryland, College Park, MD 20742)

The capture of the spatial structure of a sound field and analysis is important in many fields including creating virtual environments, source localization and detection, noise suppression, and beamforming. Spherical microphone arrays are a promising development to help achieve such capture and analysis, and have been studied by several groups. We develop a practical spherical microphone array and demonstrate its utility in applications for sound capture, room measurement and for beamforming and tracking. To accommodate equipment failure and manufacturing imprecision we extend their theory to handle arbitrary microphone placement. To handle speech capture and surveillance we describe the development of a new sensor, the hemispherical microphone array. For each array the practical performance follows that predicted by theory. Future applications and improvements are also discussed. [Work supported by NSF.]

11:15

4aAA11. High-order wave decomposition using a dual-radius spherical microphone array.   Boaz Rafaely, Ilya Balmages, and Limor Eger   (Dept. of Elec. and Comput. Eng., Ben-Gurion Univ. of the Negev, Beer-Sheva 84105, Israel)

The acoustic performance of an auditorium is influenced by the manner in which sound propagates from the stage into the seating areas. In particular, the spatial and temporal distribution of early reflections is considered important for sound perception in the auditorium. Previous studies presented measurement and analysis methods based on spherical microphone arrays and plane-wave decomposition that could provide information on the direction and time of arrival of early reflections. This paper presents recent results of room acoustics analysis based on a spherical microphone array, which employs high spherical harmonics order for improved spatial resolution, and a dual-radius spherical measurement array to avoid ill-conditioning at the null frequencies of the spherical Bessel function. Spatial-temporal analysis is performed to produce directional impulse responses, while time-windowed space-frequency analysis is employed to detect direction of arrival of individual reflections. Experimental results of sound-field analysis in a real auditorium will also be presented.

4aAA12. Impulse response measurement system and its recent applications. Kazuhiro Takashima, Hiroshi Nakagawa, Natsu Tanaka, and Daiki Sekito (1-21-10, Midori, Sumida-Ku, Tokyo 130-0021, Japan)

Our impulse response measurement system has been developed for ten years. During this decade, the environment related to this measurement has changed significantly. In this article, the features and notes on the measurement system using the sound card, and our brand new system, which is expanded for multichannel inputs, will be presented. Finally, a new technique, which combines multi-channel impulse response measurement and signal processing with microphone array, will be presented. The microphone array was designed for noise analysis for automobile interiors. The array consists of 31 microphones on the surface of an acoustically hard sphere. Moreover, 12 cameras are arranged on the surface of the sphere to take photos. Some applications and future development will be presented.

4aAB1. Development of evoked-potential audiometry in odontocetes. Alexander Supin (Inst. of Ecology and Evolution, 33 Leninsky prospect, 119071 Moscow, Russia)

Evoked-potential methods are widely used for investigation of hearing in whales, dolphins, and porpoises. For this purpose, mostly the auditory brainstem response (ABR) or rhythmic trains of ABRs, the envelope-following response (EFR), are used. Although very productive, these methods require further elaboration. (*i*) Traditionally the EFR is provoked by sinusoidally amplitude-modulated tones (SAM). SAM stimuli have narrow frequency band, which makes them little effective to produce the EFR, because response amplitude depends on the stimulus bandwidth. A solution of the problem is the use of trains of short tone pips instead of SAM tones. Such stimuli produce several times higher EFR than SAM tones. This makes the threshold determination much more confident and precise. The effect is achievable at stimulus bandwidths, which still do not influence negatively the precision of attribution of the threshold to a certain frequency. (*ii*) To extract low-amplitude evoked potentials from noise, the average technique is traditionally used. This operation returns a mean value of averaged traces. Effectively diminishing stationary noise, this method poorly eliminates big artifacts, which may spoil the record even it if appeared once or twice during acquisition. With this respect, computation of the median instead of mean is much more effective.

4aAB2. Towards a predictive model of noise-induced temporary threshold shift for an amphibious marine mammal, the California sea lion (*Zalophus californianus*). David Kastak, Marla M. Holt, Jason Mulsow, Colleen J. Reichmuth Kastak, Ronald J. Schusterman (UCSC Long Marine Lab., 100 Shaffer Rd., Santa Cruz, CA 95060), and Brandon L. Southall (Natl. Marine Fisheries Service, Silver Spring, MD 20910)

A California sea lion that had previously been tested under water was assessed for noise-induced temporary threshold shift (TTS) in air. One hundred ninety-two controlled exposures of octave-band noise centered at 2.5 kHz were conducted over a 3-year period. The noise was varied in level (to 133 dB SPL *re*: 20 μPa) and duration (to 50 min) to generate a variety of equal sound exposure levels (SELs). Behavioral psychophysics was used to measure hearing sensitivity at 2.5 kHz before, immediately following, and 24 h following noise exposure. The levels of threshold shifts obtained ranged up to 30 dB. In cases where TTS exceeded 20 dB, thresholds were obtained at regular intervals until recovery occurred. The average slope of the long-term recovery function was 10 dB per log-(minute). Results show that the threshold shifts correlated with SEL; however, the equal-energy trading rule did not apply in all circumstances, with exposure duration contributing more than exposure level. Repeated testing showed no evidence of a permanent threshold shift at 2.5 kHz or octave higher. The amphibious sea lions appear to be equally susceptible to noise in air and under water, provided that the exposure levels are referenced to the subjects thresholds in both media.

8:30

4aAB3. Electrophysiological investigation of temporal resolution in three pinniped species: Adaptive implications. Jason Mulsow and Colleen Reichmuth Kastak (Univ. of California Santa Cruz, Long Marine Lab., 100 Shaffer Rd., Santa Cruz, CA 95060)

Electrophysiological studies of auditory temporal processing in marine mammals have traditionally focused on the role of highly refined temporal resolution in dolphin echolocation. Studies in manatees, however, have found their temporal resolution to be better than expected, leading to speculation that such capabilities are an adaptation for underwater sound localization. This study measured the ability of auditory brainstem responses to follow rhythmic click stimuli in California sea lions (*Zalophus californianus*), harbor seals (*Phoca vitulina*), and northern elephant seals (*Mirounga angustirostris*). Trains of 640-s clicks were presented in air at repetition rates of 125–1500 per second and averaged rate-following responses were recorded. Rate-following responses were detected in both the harbor seal and the sea lion at rates up to 1000 clicks per second, indicating that pinnipeds, like manatees, possess temporal resolution greater than humans but inferior to dolphins. While this finding might support an underwater sound localization hypothesis, comparable results were obtained in preliminary testing of a dog (*Canis familiaris*), suggesting that increased temporal resolution in pinnipeds may not be the result of the evolutionary pressure of an aquatic environment, but rather a result of increased high-frequency hearing essential to mammalian sound localization. [Work supported by NOPP, ONR, and NMFS.]

4aAB4. Click and tone-pip auditory evoked potentials in a large marine mammal, the northern elephant seal. Dorian S. Houser (BIOMIMETICA, 7951 Shantung Dr., Santee, CA 92071) and James J. Finneran (Space and Naval Warfare Systems Ctr., San Diego, CA 92152)

The use of auditory-evoked potentials (AEPs) to study the hearing of mysticete whales is challenged by access to animals, their large size, and proportionately smaller brain relative to odontocetes. One means by which AEP techniques can be adapted to these larger animals is by application to more readily available proxy species. The northern elephant seal (*Mirounga angustirostris*) is a large pinniped, potentially in excess of 2000 kg, with a thick dermis, large skull, relatively small auditory nerve, and a low-frequency vocal communication system. AEP collection in elephant seals provides similar challenges to those of the mysticetes but at a scale that provides a greater opportunity for success. AEP tests were conducted on northern elephant seals at Año Nuevo State Reserve, the natural haul-out site of the elephant seal. Subjects were chemically immobilized with tiletamine/zolazepam and chemical restraint was maintained with bolus injections of ketamine. Click-evoked potentials were collected from four weanling and two adult male elephant seals and tone-pip-evoked potentials were collected from a 2-year-old female. Results demonstrate that AEPs can be recorded from large pinniped species, providing a step towards the application of similar techniques to larger cetacean species.

4aAB5. Acoustic field measurements and bottlenose dolphin hearing thresholds using single-frequency and frequency-modulated tones. James J. Finneran (U.S. Navy Marine Mammal Program, SPAWARSYSCEN San Diego, Code 2351, 49620 Beluga Rd., San Diego, CA 92152, james.finneran@navy.mil) and Carolyn E. Schlundt (EDO Professional Services, San Diego, CA 92110)

Studies of underwater hearing are often hampered by the behavior of sound waves in small experimental tanks. At lower frequencies, tank dimensions are often not sufficient for free-field conditions, resulting in large spatial variations of sound pressure. These effects may be mitigated somewhat by increasing the frequency bandwidth of the sound stimulus, so effects of multipath interference average out over many frequencies. In this study, acoustic fields and bottlenose dolphin (*Tursiops truncatus*) hearing thresholds were compared for pure-tone and frequency-modulated stimuli. Experiments were conducted in a vinyl-walled, seawater-filled pool approximately $4 \times 5 \times 1.5$ m. Sound stimuli consisted of 500-ms tones at 13 carrier frequencies between 1 and 100 kHz. Frequency-modulated stimuli featured both linear and sinusoidal modulating waveforms with 5%, 10%, and 20% bandwidths. Acoustic fields were measured (without the dolphin present) at three depths over a 60×65-cm grid with a 5-cm spacing. Hearing thresholds were measured using a behavioral response paradigm and up/down staircase technique. Frequency-modulated stimuli with a 10% bandwidth resulted in significant improvements to the sound field without substantially affecting the dolphins hearing thresholds. [Work supported by ONR.]

4aAB6. Hearing frequency selectivity in four species of toothed whales as revealed by the evoked-potential method. Vladimir Popov (Inst. of Ecology and Evolution, 33 Leninsky Prosp., 119071 Moscow, Russia popov_vl@sevin.ru)

Frequency tuning curves were obtained using a tone-tone simultaneous masking paradigm in conjunction with the evoked potential recording. The masker was a continuous tone and the test was a sinusoidal amplitude-modulated (SAM) tonal signal, which evoked the envelope following response (EFR). The EFR was recorded in unanaesthetized animals from a head surface with the use of suction-cup electrodes. The obtained tuning curves featured very sharp tuning with Q(ERB) (quality estimated by the equivalent rectangular bandwidth) from 35 in *Tursiops truncatus* to nearly 50 in *Delphinapterus leucas*. This acuteness is several times better than in humans and many animals. The Q(ERB) dependence on probe frequency could be approximated by regression lines with a slope from 0.18 in *Tur-*

siops trucatus to 0.83–0.86 in *Phocoena phocoena* and *Neophocoena phocoenoides*. Thus, the frequency representation in the odontocete auditory system may be either near constant quality (in Tursiops) or near constant bandwidth (in porpoises). [Work supported by The Russian Foundation for Basic Research and Russian President Grant.]

4aAB7. Growth and recovery of temporary threshold shifts in a dolphin exposed to midfrequency tones with durations up to 128 s. Carolyn E. Schlundt (EDO Professional Services, 3276 Rosecrans St., San Diego, CA 92110, carolyn.melka@edocorp.com), Randall L. Dear (Sci. Applications Intl. Corp., San Diego, CA 92110), Donald A. Carder, and James J. Finneran (Space and Naval Warfare Systems Ctr., San Diego, San Diego, CA 92152)

Auditory thresholds at 4.5 kHz were measured in a bottlenose dolphin (*Tursiops truncatus*) before and after exposure to midfrequency tones at 3 kHz. Experiments were conducted in relatively quiet pools with low ambient noise levels at frequencies above 1 kHz. Behavioral hearing tests allowed for thresholds to be routinely measured within 4 min postexposure, and tracked recovery for at least 30 min postexposure. Exposure durations ranged from 4 to 128 s at sound pressure levels ranging from 149 to 200 dB *re*: 1 μPa. Sound exposure levels ranged from 155 to 217 dB *re*: 1 μPa^2/s. Temporary threshold shifts at 4 min postexposure (TTS$_4$) of up to 23 dB were observed. All thresholds recovered to baseline and pre-exposure levels, most within 30 min of exposure. [Work supported by the U.S. ONR.]

4aAB8. Auditory brainstem response recovery rates during double-pulse presentation in the false killer whale (*Pseudorca crassidens*): A mechanism of automatic gain control? Paul E. Nachtigall (Marine Mammal Res. Program, Hawaii Inst. of Marine Biol., P.O. Box 1106, Kailua, HI 96734), Alexander Ya. Supin (Russian Acad. of Sci., Moscow, Russia), and Marlee Breese (Hawaii Inst. of Marine Biol., Kailua, HI 96734)

The outgoing echolocation pulse and the return echo response can be approximately examined in the auditory system of an echolocating animal by presenting two pulses and determining the forward-masking effect of the first pulse on the response to the second pulse using auditory-evoked potential procedures. False killer whale, *Pseudorca crassidens*, auditory brainstem responses (ABR) were recorded using a double-click stimulation paradigm specifically measuring the recovery of the second (test) response (to the second click) as a function of the length of the interclick interval (ICI) following various levels of the first (conditioning) click. At all click intensities, the slopes of the recovery functions were almost constant: 0.60.8 V per ICI decade. Therefore, even when the conditioning-to-click level ratio was kept constant, the duration of recovery was intensity dependent: the higher intensity the longer the recovery. The conditioning-to-test-click level ratio strongly influenced the recovery time: the higher the ratio, the longer the recovery. This dependence was nearly linear, using a logarithmic ICI scale with a rate of 2530 dB per ICI decade. These data were used for modeling the interaction between the emitted click and the echo in the auditory system during echolocation.

4aAB9. Temporary threshold shifts in the bottlenose dolphin (*Tursiops truncatus*), varying noise duration and intensity. T. Aran Mooney (Dept. of Zoology and Hawaii Inst. of Marlne Biol., Univ. of Hawaii, 46-007 Lilipuna Rd., Kaneohe, HI 96744), Paul E. Nachtigall, Whitlow W. L. Au, Marlee Breese, and Stephanie Vlachos (Univ. of Hawaii, Kaneohe, HI 96744)

There is much concern regarding increasing noise levels in the ocean and how it may affect marine mammals. However, there is a little information regarding how sound affects marine mammals and no published

data examining the relationship between broadband noise intensity and exposure duration. This study explored the effects of octave-band noise on the hearing of a bottlenose dolphin by inducing temporary hearing threshold shifts (TTS). Sound pressure level (SPL) and exposure duration were varied to measure the effects of noise duration and intensity. Hearing thresholds were measured using auditory evoked potentials before and after sound exposure to track and map TTS and recovery. Shifts were frequency dependent and recovery time depended on shift and frequency, but full recovery was relatively rapid, usually within 20 min and always within 40 min. As exposure time was halved, TTS generally occurred with an increase in noise SPL. However, with shorter, louder noise, threshold shifts were not linear but rather shorter sounds required greater sound exposure levels to induce TTS, a contrast to some published literature. From the data a novel algorithm was written that predicts the physiological effects of anthropogenic noise if the intensity and duration of exposure are known.

10:30

4aAB10. Estimates of bio-sonar characteristics of a free-ranging Ganges river dolphin. Tamaki Ura, Harumi Sugimatsu, Tomoki Inoue (Underwater Technol. Res. Ctr., Inst. of Industrial Sci., Univ. of Tokyo, 4-6-1 Komaba, Meguro, Tokyo 153-8505, Japan), Rajendar Bahl (IIT Delhi, New Delhi 110016, India), Junichi Kojima (KDDI R&D Labs. Inc., Saitama 356-8502, Japan), Tomonari Akamatsu (Fisheries Res. Agency, Ibaraki 314-0408, Japan), Sandeep Behera (Freshwater & Wetlands Prog., New Delhi 110003, India), Ajit Pattnaik, Muntaz Kahn (Chilika Dev. Authority, Orissa, India), Sudhakar Kar, Chandra Sekhar Kar (Off. of the Princip. CCF (Wildlife) & Chief Wildlife Warden, Blaubaneswar 751012, India), Tetsuo Fukuchi, Hideyuki Takashi (System Giken Co. Ltd., Kanagawa 253-0085, Japan), and Debabrata Swain (Simpilpal Biosphere and Tiger Reserve, Orissa, India)

This paper reports the first known studies of the bio-sonar characteristics of an isolated free-ranging Ganges river dolphin, *Platanista gangetica*. The animal preferred to roam in a deeper tract of the otherwise shallow river. The click sounds of the dolphin were recorded over a period of 2 days on a 3.2-meter-long high-frequency hydrophone array composed of three hydrophones forming an equispaced linear array and another two hydrophones in conjunction with the central hydrophone forming an SSBL triangular array in a plane perpendicular to the array axis. The array was deployed both in horizontal and vertical configurations. The array structure provided 3-D measurements of the source location through measurement of the interelement time delay. Bio-sonar characteristics such as click duration, bandwidth, and interclick intervals in click trains have been reported. Measurements of dolphin track and the relative click levels on the array hydrophones have been used to obtain a preliminary characterization of the animal's beam pattern.

10:45

4aAB11. Discriminating between the clicks produced by a bottlenose dolphin when searching for and identifying an object during a search task. Sandra Bohn, Stan Kuczaj (Univ. of Southern Mississippi, 118 College Dr., #5025, Hattiesburg, MS 39406, sandra.bohn@usm.edu), and Dorian Houser (BIOMIMETICA, Santee, CA 92071)

Clicks collected from an echolocating bottlenose dolphin completing a search task were compared in order to determine if the clicks produced when the dolphin was acquiring the target differed from the clicks produced when the dolphin was searching for the target. The clicks produced by a free-swimming dolphin completing the search task were recorded using a biosonar measurement tool (BMT), an instrumentation package carried by the dolphin that collected both the outgoing clicks and the returning echoes. A discriminant function analysis classified the clicks as search or acquisition using the variables of peak-to-peak amplitude, duration, peak frequency, center frequency, and bandwidth. The acquisition clicks were classified more accurately than the search clicks. Acquisition clicks and search clicks were significantly different across all five of the variables. These results suggest that the clicks produced by bottlenose dolphins acquiring a target are different than those produced by dolphins searching for a target.

11:00

4aAB12. Echo highlight amplitude and temporal difference resolutions of an echolocating *Tursiops truncatus*. Mark W. Muller, Whitlow W. L. Au, Paul E. Nachtigall, Marlee Breese (Marine Mammal Res. Program, Hawai'i Inst. of Marine Biol., 46-007 Lilipuna Rd., Kaneohe, HI 96744), and John S. Allen III (Univ. of Hawai'i at Manoa, Honolulu, HI 96822)

A dolphin's ability to discriminate targets may greatly depend on the relative amplitudes and the time separations of echo highlights within the received signal. Previous experiments with dolphins have varied the physical parameters of targets, but did not fully investigate how changes in these parameters corresponded with the composition of the scattered acoustic waveforms and the dolphin's subsequent response. A novel experiment utilizes a phantom echo system to test a dolphin's detection response of relative amplitude differences of secondary echo highlights and the time separation differences of all the echo highlights both within and outside the animal's integration window. By electronically manipulating these echoes, the underlying acoustic classification cues can be more efficiently investigated. In the first study, the animal successfully discriminated between a standard echo signal and one with the middle highlight amplitude at -7 dB. When the middle highlight amplitude was raised to -6 dB, the animal's discrimination performance radically dropped to 65%. This study suggests the animal may not be as sensitive to the secondary echo highlights as previously proposed. The experiments were repeated for the trailing highlight amplitude and the time separations between the primary and middle highlights and the middle and trailing highlights.

11:15

4aAB13. A background noise reduction technique for improving false killer whale (*Pseudorca crassidens*) localization. Craig R. McPherson, Owen P. Kenny, Phil Turner (Dept. of Elec. and Comput. Eng., James Cook Univ., Douglas 4811, Queensland, Australia), and Geoff R. McPherson (Queensland Dept. of Primary Industries and Fisheries, Cairns, 4870, Queensland Australia)

The passive localization of false killer whales (*Pseudorca crassidens*) in acoustic environments comprised of discontinuous ambient, anthropogenic, and animal sounds is a challenging problem. A background noise reduction technique is required to improve the quality of sampled recordings, which will assist localization using auditory modeling and signal correlation at extended ranges. The algorithm developed meets this requirement using a combination of adaptive percentile estimation, a median-based tracker, and Gaussian windowing. The results indicate successful improvement of the signal-to-noise ratio, and consequently a significant increase in the detection range of false killer whales in acoustically complex environments.

11:30

4aAB14. Analysis of Australian humpback whale song using information theory. Jennifer L. Miksis-Olds, John R. Buck (School for Marine Sci. and Technol., Univ. of Massachusetts Dartmouth, New Bedford, MA 02744, jmiksis@umassd.edu), Michael J. Noad (Univ. of Queensland, St. Lucia, QLD 4072 Australia), Douglas H. Cato (Defence Sci. & Tech. Org., Pyrmont, NSW 2009 Australia), and Dale Stokes (Scripps Inst. of Oceanogr., La Jolla, CA 92093)

Songs produced by migrating whales were recorded off the coast of Queensland, Australia over 6 consecutive weeks in 2003. Approximately 50 songs were analyzed using information theory techniques. The average length of the songs estimated by correlation analysis was approximately 100 units, with song sessions lasting from 300 to over 3100 units. Song entropy, a measure of structural constraints and complexity, was estimated using three different methodologies: (1) the independently identically distributed model; (2) first-order Markov model; and (3) the nonparametric sliding window match length (SWML) method, as described in Suzuki *et al.* [J. Acoust. Soc. Am. **119**, 1849 (2006)]. The analysis finds the songs of migrating Australian whales are consistent with the hierarchical structure proposed by Payne and McVay (Science **173**, 585−597 (1971)], and

recently confirmed by Suzuki *et al.* for singers on the breeding grounds. Both the SWML entropy estimates and the song lengths for the Australian singers were lower than that reported by Suzuki *et al.* for Hawaiian whales in 1976−1978. These lower SWML entropy values indicate a higher level of predictability within songs. The average total information in the Australian sequence of song units was approximately 35 bits/song. Aberrant songs (10%) yielded entropies similar to the typical songs. [Sponsored by ONR and DSTO.]

8:00

4aBB1. Ultra-high-speed imaging of bubbles interacting with cells and tissue. Michel Versluis, Philippe Marmottant, Sascha Hilgenfeldt, Claus-Dieter Ohl (Phys. of Fluids, Univ. of Twente, P.O. Box 217, 7500 AE Enschede, The Netherlands), Chien T. Chin, Annemieke van Wamel, Nico de Jong (Erasmus MC, 3000 DR Rotterdam, The Netherlands), and Detlef Lohse (Univ. of Twente, 7500 AE Enschede, The Netherlands)

Ultrasound contrast microbubbles are exploited in molecular imaging, where bubbles are directed to target cells and where their high-scattering cross section to ultrasound allows for the detection of pathologies at a molecular level. In therapeutic applications vibrating bubbles close to cells may alter the permeability of cell membranes, and these systems are therefore highly interesting for drug and gene delivery applications using ultrasound. In a more extreme regime bubbles are driven through shock waves to sonoporate or kill cells through intense stresses or jets following inertial bubble collapse. Here, we elucidate some of the underlying mechanisms using the 25-Mfps camera Brandaris128, resolving the bubble dynamics and its interactions with cells. We quantify acoustic microstreaming around oscillating bubbles close to rigid walls and evaluate the shear stresses on nonadherent cells. In a study on the fluid dynamical interaction of cavitation bubbles with adherent cells, we find that the nonspherical collapse of bubbles is responsible for cell detachment. We also visualized the dynamics of vibrating microbubbles in contact with endothelial cells followed by fluorescent imaging of the transport of propidium iodide, used as a membrane integrity probe, into these cells showing a direct correlation between cell deformation and cell membrane permeability.

8:20

4aBB2. Sonoporation: Mechanisms of cell membrane perforation and rapid resealing. Nobuki Kudo and Katsuyuki Yamamoto (Grad. School of Information Sci. and Technol., Hokkaido Univ., Sapporo 060-0814 Japan, kudo@bme.ist.hokudai.ac.jp)

Sonoporation is a technique for making membrane perforation by exposure of cells to ultrasound, and it is an attractive method for realizing nonvirus gene transfection. A continuous or quasicontinuous wave is frequently used for this technique because a higher duty ratio gives higher efficiency of sonoporation. Addition of microbubbles during insonification greatly improves the efficiency of sonoporation, and, especially when microbubbles exist in the vicinity of the cells, ultrasound pulses from diagnostic ultrasound equipment can cause sonoporation. In this study, we examined sonoporation induced by single-shot pulsed ultrasound and the role of microbubbles in induction of cell membrane perforation. Bubble behavior and cell membrane damage were observed using a high-speed camera and light and scanning electron microscopes. Results of observation showed that mechanical stress induced by bubble motion could cause cell membrane perforation. We also studied repair of the perforation using a fluorescence microscope and found that the membrane of mammalian cells has the ability to reseal the perforation within several seconds. [Research partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science, Sports and Culture, Japan.]

8:40

4aBB3. Quantitative imaging of tumor blood flow with contrast ultrasound. Peter N. Burns, Raffi Karshafian, and John Hudson (Dept. Medical Biophys., 2075 Bayview Ave., Toronto ON, M4N 3M5, Canada)

The point at which a solid cancer develops its own blood supply marks the onset of malignant progression. This process, known as angiogenesis, makes oxygen and nutrients available for growth and provides a path for metastatic spread. Angiogenesis is not only of interest as a diagnostic hallmark of malignancy, but also as a target for new therapeutic strategies. Assessing antiangiogenic therapies noninvasively poses problems—flow velocities (<1 mm/s) and vessel diameters (<50 μm) are below resolutions of direct imaging. Vessels are disorganized without the tree-like structure of normal vasculature. We have investigated the potential role of

microbubble disruption-replenishment flow measurement in monitoring antivascular treatment of an animal tumor. The currently used monexponential model incorrectly considers the vasculature a perfect mixing chamber. Simple fractal models of the circulation provide a distribution of vessel diameters which, combined with the geometry of the disruption and detection beams, produce better models of replenishment following acoustic bubble disruption. These not only measure flow, but also predicts differences between organized and disorganized circulations, even with equal flow and vascular volume. If detectable, such differences might be used to characterize vascular organization below the resolution limit of an ultrasound image.

9:00

4aBB4. Dynamics of laser-trapped microbubbles. Hiroyuki Takahira (Dept. of Mech. Eng., Osaka Prefecture Univ., 1-1 Gakuen-cho, Naka-ku, Sakai, Osaka 599-8531, Japan)

A laser-trapping method is utilized for microbubbles. Bubbles of the order of 10 microns in diameter are trapped and manipulated successfully using a dry objective lens with large working distance. The growth or shrinkage of a laser-trapped microbubble and the merger of microbubbles are observed with a high-speed camera to investigate the influence of gas diffusion on the stability of microbubbles. Two kinds of equilibrium radii are found for shrinking microbubbles. The first one is related to the equilibrium surface concentration of surfactant. The other is related to the decrease of the surface tension due to the compression of the surface area at the maximum surfactant concentration. The simulations in which the dynamic surface tension is considered are in good agreement with the experiments. The laser trapping technique is also applied to the motion of a microbubble in a shear flow. It is shown that the bubble escapes from the laser trap being repelled by the optical force in the shear flow. There is overall agreement between the experiments and the simulations in which the buoyancy force, the fluid dynamic forces, and the optical force are taken into account.

9:20

4aBB5. Novel methods of micro-object trapping by acoustic radiation force. Yoshiki Yamakoshi (1-5-1 Tenjin-cho, Kiryushi, Gunma 376-8515 Japan, yamakosi@el.gunma-u.ac.jp)

It is expected that micro object trapping by acoustic radiation force is a useful method in future drug delivery systems in order to concentrate the payloads at desired position. In this paper, two novel methods of micro object trapping are presented. First method is micro object trapping by seed bubbles. This method uses seed bubbles, which have higher sensitivity to the ultrasonic wave, in order to trap micro objects, which are difficult to trap by conventional methods due to low volumetric oscillation under the ultrasonic wave. The Bjerkne's force, which is produced by a secondary wave radiated from the seed bubbles, traps the target objects making bi-layer seed bubbletarget object mass. The Second method is micro bubble trapping by bubble nonlinear oscillation. Two ultrasonic waves with different frequencies (pumping and control waves) are introduced simultaneously. The frequency of the control wave is set to a harmonic frequency of the pumping wave. If the bubbles flow into the cross area of two waves, nonlinear oscillation by high intensity pumping wave generates the Bjerkne's force, producing multiple traps with narrow separation along the control wave propagation direction. In order to demonstrate these methods, experiments using an ultrasonic wave contrast agent are shown.

9:40

4aBB6. Mechanical properties of HeLa cells at different stages of cell cycle by time-resolved acoustic microscope. Pavel V. Zinin (School of Ocean and Earth Sci. and Technol., Univ. of Hawaii, 2525 Correa Rd., Honolulu, HI 96822-2219), Eike C. Weiss, Pavlos Anastasiadis, and Robert M. Lemor (Fraunhofer Inst. for Biomed. Technol., St. Ingbert, Germany)

Scanning acoustic microscopy (SAM), particularly time-resolved acoustic microscopy, is one of the few techniques for study of the mechanical properties of only the cell's interior, cytosol and nucleus. Unfortunately, time-resolved acoustic microscopes typically do not provide sufficient resolution to study the elasticity of single cells. We demonstrate that the high-frequency, time-resolved acoustic microscope developed at the Fraunhofer Institute for Biomedical Technology (IBMT), Germany, is capable of imaging and characterizing elastic properties of micron size structures in cell's cytoskeleton with a theoretical resolution limit of 10 m/s for sound speed measurements. Measurements were performed on cells of the HeLa cell line derived from human cervics carcinoma. SAM measurements of the sound speed of adherent HeLa cells at different states of the cell cycle were conducted. They yielded an average value of 1540 m/s. B-Scan images of HeLa cells at different states of the cell cycle show distinct patterns inside the cell. A method for estimating sound attenuation inside HeLa cells is outlined as such a method is critical for the determination of a cell's viscoelasticity. [Work supported by Alexander von Humboldt Foundation and the European Framework Program 6, Project "CellProm."]

10:00−10:10   Break

10:10

4aBB7. Assessment of shock wave lithotripters via cavitation potential. Jonathan I. Iloreta, Andrew J. Szeri (UC Berkeley, 6119 Etcheverry Hall, M.S. 1740, Berkeley, CA 94720-1740), Yufeng Zhou, Georgii Sankin, and Pei Zhong (Duke Univ., Durham, NC 27708-0300)

An analysis of bubbles in elastic media has been made in order to characterize shock wave lithotripters by gauging the potential for cavitation associated with the lithotripter shock wave (LSW). The method uses the maximum radius achieved by a bubble subjected to a LSW as the key parameter that defines the potential damage a lithotripter could cause at any point in the domain. The maximum radius is determined by an energy analysis. A new index—similar in spirit to the Mechanical Index of Holland and Apfel for diagnostic ultrasound—is proposed for use in gauging the likelihood of cavitation damage.

10:30

4aBB8. Formation of water pore in a bilayer induced by shock wave: Molecular dynamics simulation. Kenichiro Koshiyama, Takeru Yano, Shigeo Fujikawa (Lab. of Adv. Fluid Mech., Hokkaido Univ., Sapporo 060-8628, Japan, koshi@ring-me.eng.hokudai.ac.jp), and Tetsuya Kodama (Tohoku Univ., Aobaku, Sendai 980-8575, Japan)

The irradiation of a shock wave or ultrasound with micro-bubbles has the potential to make transient pores on cell membranes. Although such pores are believed to contribute to the molecular delivery thorough the membrane, the detailed mechanisms of the pore formation with shock waves and the subsequent molecular delivery through the pores into cells are still unclear. To investigate the mechanism at a molecular level, the molecular dynamics simulations of the interaction of the shock wave with a lipid bilayer are conducted. The water penetration into the hydrophobic region by the shock wave is observed in picoseconds. As a next step, structural changes of the bilayer containing water molecules in the hydrophobic region are investigated. The water pore is formed in 3 ns when the large number of water molecules is inserted. The lifetime of the water pore is more than 70 ns. The radius of the water pore is ca. 1.0 nm, which is three times larger than the Stoke's radius of a typical anticancer drug (5FU). Finally, the diffusion of the anticancer drug in the water pore is investigated.

10:45

4aBB9. Ultrasonic spore lysis and the release of intracellular content in a microfluidic channel. Oana C. Marina, Michael D. Ward, John M. Dunbar, and Gregory Kaduchak (MPA-11, Los Alamos Natl. Lab., P.O. Box 1663, MS D-429, Los Alamos, NM, 87545)

Ultrasonic lysis of suspended spores in a microfluidic channel is a promising alternative to conventional spore disruption techniques that include bead beating as the spore lysis gold standard. Our overall research goal is to obtain an automated detection system with complete sample preparation and lysis steps in a microfluidic channel. Previously, much work in this area has focused on organism viability rather than the release of intracellular material. Our research focuses on quantifying the amount of intracellular content (e.g., DNA, proteins, etc.) that is released by acoustic lysis for detection by the sensor. Elucidating the efficacy of acoustics on the release of intracellular material requires reliable methods to quantify the released intracellular content (nucleic acids and proteins). The device used for lysing spores consists of a microfluidic chamber with one acoustically active wall. The chamber depths are in the range of 100–200 m. Channels tested in the 70-kHz to 1-MHz frequency range show that the efficiency of intracellular release depends on the operating frequency of the device and the properties (concentration, composition) of the spore suspensions. Experimental results on viability and released intracellular content are discussed. [Work supported by LANL LDRD.]

11:00

4aBB10. The correlation between cavitation noise power and bubble-induced heating in high-intensity focused ultrasound. Caleb H. Farny, Tianming Wu, R. Glynn Holt, and Ronald A. Roy (Dept. of Aerosp. and Mech. Eng., Boston Univ., 110 Cummington St., Boston, MA 02215, cfarny@bu.edu)

It has been established that inertial cavitation is responsible for elevated heating during high-intensity focused ultrasound (HIFU) application for certain intensity regimes. The contribution of bubble-induced heating can be an important factor to consider, as it can be several times that expected from absorption of the primary ultrasound energy. Working in agar-graphite tissue phantoms with a 1.1-MHz HIFU transducer, an embedded type-E thermocouple, and a 15-MHz passive cavitation detector (PCD), the temperature and cavitation signal near the focus were measured for 5-s continuous wave HIFU insonations. The measured temperature was corrected for heating predicted from the primary ultrasound absorption and the transient thermocouple viscous heating artifact to isolate the temperature rise from the bubble activity. We have found that the temperature rise induced from the bubble activity correlates well with the instantaneous cavitation noise power as indicated by the mean square voltage output of the PCD. The results suggest that careful processing of the cavitation signals could serve as a proxy for measuring the heating contribution from inertial cavitation. [Work supported by the Dept. of the Army (Award No. DAMD17-02-2-0014) and the Center for Subsurface Sensing and Imaging Systems (NSF ERC Award No. EEC-9986821).]

11:15

4aBB11. Membrane permeabilization of adherent cells with laser-induced cavitation bubbles. Rory Dijkink, Claus-Dieter Ohl (Phys. of Fluids, Univ. of Twente, Postbus 217, 7500 AE Enschede, The Netherlands), Erwin Nijhuis, Sèverine Le Gac (Univ. of Twente, 7500 AE Enschede, The Netherlands), and Istvàn Vermes (Medical Spectrum Twente Hospital Group, 7500 KA Enschede, The Netherlands)

Strongly oscillating bubbles close to cells can cause the opening of the cell's membrane, thus to stimulate the uptake of molecules from the exterior. However, the volume oscillations of bubbles induce complex fluid flows, especially when bubble-bubble interaction takes place. Here, we report on an experiment where a single cavitation bubble is created close to a layer of adherent HeLa cells. The interaction distance between the bubble and the cell layer is controlled by adjusting the focus of the pulsed laser light, which creates the cavitation bubble. The dynamics of the bubble and the cells is recorded with high-speed photography. The poration of the cells is probed with different fluorescent stains to distinguish viable and permanent poration and programmed cell death (apoptosis). Quantitative data are presented as a function of the radial distance from the stagnation point. Our main finding is the importance of the asymmetrical collapse and the high-speed jet flow: After impact of the jet onto the substrate a strong boundary layer flow is responsible for shearing the cells.

11:30

4aBB12. Antitumor effectiveness of cisplatin with ultrasound and nanobubbles. Tetsuya Kodama, Yukiko Watanabe, Kiyoe Konno, Sachiko Horie (Res. Organization, Tohoku Univ., 2-1 Seiryo-machi, Aoba-ku, Sendai, Miyagi 980-8575, Japan), Atsuko Aoi (Tohoku Univ., Sendai 980-8575, Japan), Geroges Vassaux (Bart's and The London School of Medicine and Dentistry, UK), and Shiro Mori (Tohoku Univ. Hospital, Sendai 980-8575, Japan)

The potentiation of antitumor effect of cis-diamminedichloroplatinum (II), cisplatin, with ultrasound (1 MHz, 0.6 MPa) and lipid-shelled nanobubbles *in vitro* (EMT6, C26, MCF7, A549) and *in vivo* on s.c. tumor in mice (HT29-expressing luciferase) were evaluated. *In vitro* and *in vivo* antitumor effects were measured by an MTT assay and a real-time *in vivo* imaging, respectively. The effective antitumor effect was seen both *in vitro* and *in vivo* when ultrasound and nanobubbles were used, while other treatment groups with cisplatin with ultrasound did not show the effectiveness. The antitumor effect was not attributed to necrosis but apoptosis, which was confirmed by increase in the activity of the pro-apoptosis signal caspase-3 and Bax. In conclusion, the combination of ultrasound and nanobubbles with cisplatin is an effective chemotherapy of solid tumors and may prove useful in clinical application.

11:45

4aBB13. Sonoporation by single-shot pulsed ultrasound with microbubbles—Little effect of sonochemical reaction of inertial cavitation. Kengo Okada, Nobuki Kudo, and Katsuyuki Yamamoto (Grad. School of Information Sci. and Technol., Hokkaido Univ., Kita 14 Nishi 9, Kita-ku, Sapporo 060-0814, Japan)

Sonoporation is a technique for introducing large molecules into a cell by exposure to ultrasound, and it has a potential application for gene transfection. Although continuous-wave ultrasound is generally used for this technique, we have been using single-shot pulsed ultrasound with microbubbles. To determine the contribution of the sonochemical effect of

4a FRI. AM

inertial cavitation under the condition of single-shot exposure, we compared rates of cell membrane damage in the presence and absence of a free radical scavenger (cysteamine, 5 mM). Cells with microbubbles in their vicinity were exposed to pulsed ultrasound of 1.1 MPa in negative peak pressure under microscopic observation, and the numbers of total and damaged cells in the view field were counted. The damage rates were $8.1\pm4.0\%$ and $10.3\pm6.3\%$ in the presence ($n=17$) and absence (n =25) of the scavenger, respectively, and the average number of total cells was 772 ± 285. Since there was no significant difference, we concluded that the cell membrane damage observed in our exposure condition was not caused by the sonochemical effect but by the mechanical effect of inertial cavitation. [Research was supported by a grant-in-aid for scientific research from the Ministry of Education, Science, Sports and Culture, Japan.]

8:05

4aEA1. Current developments at the National Institute for Standards and Technology in pressure calibration of laboratory standard microphones. Victor Nedzelnitsky, Randall P. Wagner, and Steven E. Fick (National Inst. of Standards and Technol. [NIST], 100 Bureau Dr., Stop 8220, Gaithersburg, MD 20899-8220, victor.nedzelnitsky@nist.gov)

Current research effort aims at improving the apparatus and methods for determining the pressure sensitivities of IEC types LS1Pn and LS2aP laboratory standard microphones. Among the improvements that are being systematically incorporated in an evolving test bed is the capability to operate at adjustable power line frequencies other than the usual 60 Hz. Suitable choices of line frequency relative to frequencies of calibration and adjustable bandpass filter characteristics can be used to improve the signal-to-noise ratios of measurements performed near the usual line frequency and its first few harmonics. This can enable the use of relatively large volume couplers for which uncertainties in microphone front cavity volume and equivalent volume, capillary tube effects, and heat conduction corrections have a lesser influence than they have for small-volume couplers. Another improvement aims to control and to stabilize the ambient static pressure during microphone calibrations, to reduce or eliminate the effects of barometric pressure fluctuations on these calibrations.

8:25

4aEA2. Free-field reciprocity calibration of laboratory standard (LS) microphones using a time selective technique. Knud Rasmussen and Salvador Barrera-Figueroa (Danish Primary Lab. of Acoust. (DPLA), Danish Fundamental Metrology, Danish Tech. Univ., Bldg. 307, 2800 Kgs., Lyngby, Denmark)

Although the basic principle of reciprocity calibration of microphones in a free field is simple, the practical problems are complicated due to the low signal-to-noise ratio and the influence of cross talk and reflections from the surroundings. The influence of uncorrelated noise can be reduced by conventional narrow-band filtering and time averaging, while correlated signals like cross talk and reflections can be eliminated by using time-selective postprocessing techniques. The technique used at DPLA overcomes both these problems using a B&K Pulse analyzer in the SSR mode (steady state response) and an FFT-based time-selective technique. The complex electrical transfer impedance is measured in linear frequency steps from a few kHz to about three times the resonance frequency of the microphones. The missing values at low frequencies are estimated from a detailed knowledge of the pressure sensitivities. Next an inverse FFT is applied and a time window around the main signal is used to eliminate cross talk and reflections. Finally, the signal is transformed back to the frequency domain and the free field sensitivities calculated. The standard procedure at DPLA involves measurements at four distances and the repeatability of the calibrations over time is within ±0.03 dB up to about 1.5 times the resonance frequency of the microphones.

3232   J. Acoust. Soc. Am., Vol. 120, No. 5, Pt. 2, November 2006

Fourth Joint Meeting: ASA and ASJ   **3232**

4aEA3. Microphone calibration by comparison. George S. K. Wong (Acoust. Standards, Inst. for Natl. Measurement Standards, National Res. Council Canada, Ottawa, ON K1A 0R6, Canada)

The absolute method of microphone calibration by the reciprocity method (IEC 61094-2 1992) provides the highest accuracy of approximately 0.04 to 0.05 dB, and the procedure requires three changes of microphone in the "driver-receiver combination" that needs approximately 1 to 2 days. The system capital cost is relatively high. The NRC interchange microphone method for microphone calibration by comparison has been adopted internationally by the International Electrotechnical Commission as IEC 61094-5 (2001-10). With this method, the test microphone is compared with a reference microphone calibrated by the reciprocity method and the procedure requires approximately 3 h. The uncertainty of the comparison method is between 0.08 to 0.09 dB, which satisfies most industrial needs.

4aEA4. Development of a laser-pistonphone for an infrasonic measurement standard. Ryuzo Horiuchi, Takeshi Fujimori, and Sojun Sato (Natl. Metrology Inst. of Japan (NMIJ), AIST, Tsukuba Central 3, 1-1-1 Umezono, Tsukuba, 305-8563, Japan)

Acoustical standards for audio frequencies are based on pressure sensitivities of laboratory standard microphones calibrated using a coupler reciprocity technique. There is a growing need to extend the frequency range downward for reliable infrasonic measurement. The reciprocity technique, however, has limitations on low-frequency calibration (1–20 Hz) because signal-to-noise ratio deteriorates and a sound leak occurs from capillary tubes that equalize the static pressure inside and outside of the coupler. These factors rapidly increase the measurement uncertainty as the frequency is lowered. NMIJ has therefore recently developed a laser-pistonphone prototype, which enables precise calibration of microphones at low frequencies. Compared with the reciprocity technique, the laser-pistonphone produces a higher sound pressure within a cavity by the sinusoidal motion of a piston and has a significantly improved signal-to-noise ratio. Sound pressure is calculated from the piston displacement, which is determined via a Michelson interferometer. A test microphone is inserted into the cavity, exposed to the sound pressure, and its open-circuit voltage is measured. Static pressure equalization is realized through the gap between the piston and its guide. Careful design of the dimensions and relative position of the cavity and piston minimizes sound leakage and friction between them.

4aEA5. Anechoic measurements of particle-velocity probes compared to pressure gradient and pressure microphones. Wieslaw Woszczyk (CIRMMT, McGill Univ., 555 Sherbrooke St. West, Montreal, QC, Canada H3A 1E3, wieslaw@music.mcgill.ca), Masakazu Iwaki, Takehiro Sugimoto, Kazuho Ono (NHK Sci. & Tech. Res. Labs., Setagaya-ku, Tokyo 157-8510, Japan), and Hans-Elias de Bree (R&D Microflown Technologies)

Microflown probes are true figure-of-eight-pattern velocity microphones having extended response down to below the lowest audible frequencies, low noise, and high output. Unlike pressure-gradient microphones, velocity probes do not measure acoustic pressure at two points to derive a pressure gradient. When particle velocity is present, acoustical particle velocity sensors measure the temperature difference of the two closely spaced and heated platinum wire resistors, and quantify particle velocity from the temperature measurement. Microflown probes do not require a membrane and the associated mechanical vibration system. A number of anechoic measurements of velocity probes are compared to measurements of pressure-gradient and pressure microphones made under identical acoustical conditions at varying distances from a point source having a wide frequency response. Detailed measurements show specific response changes affected by the distance to the source, and focus on the importance of transducer calibration with respect to distance. Examples are given from field work using microflown probes to record acoustic response of rooms to test signals. The probe's cosine directional selectivity can be used to change the ratio between early reflections and the diffuse sound since only the $\frac{1}{3}$ of the power in the diffuse sound field is measured with the particle velocity probe.

4aEA6. Sensitivity change with practical use of electret condenser microphone. Yoshinobu Yasuno (Panasonic Semiconductor Device Solutions Co., Ltd. 600, Saedo-cho, Tsuzuki-ku, Yokohama, 224-8539, Japan) and Kenzo Miura (Panasonic Mobile Commun. Eng. Co., Ltd., Yokohama, Japan)

Dr. Sessler and Dr. West invented the electret condenser microphone (ECM) in 1966. It has since been applied in various ways as a sound input device. The ECM has become an important component as a microphone for communications because of its stable sensitivity frequency characteristic. Materials and production methods have been improved continually up to the present. In particular, the ECM reliability is based on the electret's stability. For that reason, the electret surface charge decay is the main factor in ECM sensitivity degradation. This study analyzed the changes of an ECM preserved for 28 years in the laboratory and actually used for an outdoor interphone unit for 29 years. The change of diaphragm stiffness and electret surface voltage were compared with the evaluation result of a heat-acceleration test and verified. A degradation estimate of sensitivity change of ECM was performed. Regarding the life of the electret predicted in the report of former study [K. Miura and Y. Yasuno, J. Acoust. Soc. Jpn. (E) **18**(1), 29–35 (1997)], the validity was verified using actual data from this long-term observation.

10:20

4aEA7. Development of a small size narrow directivity microphone. Masakazu Iwaki, Kazuho Ono, Takehiro Sugimoto   (NHK Sci. & Technol. Res. Labs., 1-10-11 Kinuta, Setagaya-ku, Tokyo, 157-8510, Japan), Takeshi Ishii, and Keishi Inamaga   (Sanken Microphone Co., Ltd, 2-8-8 Ogikubo, Suginami-ku, Tokyo, 167-0051, Japan)

We developed a new microphone that has very sharp directivity even in the low-frequency band. In an ordinary environment of sound pick-up, the energy of background noise is distributed mainly in frequencies lower than 1000 Hz. In such frequencies, a typical cardioid microphone has the directivity pattern close to that of omni-cardiod. Consequently, it is difficult to pick up the objective sounds clearly from background noises. To suppress the noises with very small level, the directivity pattern should be also sharpened in the low-frequency band. In this report, we describe a new method to sharpen directivity for the low-frequency band. The method requires three microphone capsules. One capsule is the main microphone with a very short acoustic pipe. The others compose a second-order gradient microphone to cancel the signal that comes from behind the main microphone. A special feature of this microphone is to control a dip frequency of behind sensitivity without changing the frequency response of the front sensitivity.

10:40

4aEA8. Two-wafer bulk-micromachined silicon microphones. Jianmin Miao and Chee Wee Tan   (Micromachines Ctr., School of Mech. and Aerosp. Eng., Nanyang Technolog. Univ., 50 Nanyang Ave., Singapore 639798, mjmmiao@ntu.edu.sg)

A two-wafer concept is proposed for silicon microphone manufacturing by using bulk-micromachining and wafer bonding technologies. Acoustical holes of the backplate in one wafer are micromachined by deep reactive ion etching and the diaphragm on another wafer is created by wet-chemical etching. The two wafers are then bonded together to form silicon condenser microphones. In order to minimize the mechanical-thermal noise and increase the sensitivity within the required bandwidth, an analytical model based on Zuckerwar's equations has been developed to find the optimum location of the acoustical holes in the backplate of microphones. According to our study, this analytical modeling has shown excellent agreement between the simulated and measured results for the B&K MEMS microphone. Silicon condenser microphones have been further optimized in terms of the air gap, number and location of acoustical holes to achieve the best performance with a low polarization voltage, and easy fabrication for possible commercialization. Details of analytical modeling, fabrication, and measurement results will be presented.

11:00

4aEA9. Infrasound calibration of measurement microphones. Erling Frederiksen   (Bruel & Kjaer, Skodsborgvej 307, 2850 Naerum, Denmark, erlingfred@bksv.com)

Increasing interest for traceable infrasound measurements has caused the Consultative Committee for Acoustics, Ultrasound and Vibration (CCAUV) of BIPM to initiate a key comparison calibration project (CCAUV.A-K2) on pressure reciprocity calibration down to 2 Hz. Ten national metrology institutes, including the Danish Primary Laboratory of Acoustics (DPLA), take part in this project. In addition DPLA has started its own infrasound calibration project, which is described in this paper. The purposes of this project are verification of the CCAUV results and development of methods for calibration of general types of measurement microphone between 0.1 and 250 Hz. The project includes the design of an active comparison coupler, an experimental low-frequency reference microphone, and new methods for its frequency response calibration. One method applies an electrostatic actuator and requires a low-pressure measurement tank, while the other requires an additional microphone, whose design is closely related to that of the reference microphone that is to be calibrated. The overall calibration uncertainty ($k=2$) for ordinary measurement microphones is estimated to less than 0.05 dB down to 1 Hz and less than 0.1 dB down to 0.1 Hz, if the reference is calibrated in the latter mentioned way, i.e., by the related microphones method.

4aEA10. Free-field calibration of 1/4 inch microphones for ultrasound by reciprocity technique. Hironobu Takahashi, Takeshi Fujimori, Ryuzo Horiuchi, and Sojun Sato   (Natl. Metrology Inst. of Japan, AIST, Tsukuba Central 3, 1-1-1 Umezono, Tsukuba, 305-8563 Japan)

Recently, equipment that radiates ultrasound radiation at frequencies far beyond the audible range is increasing in our environment. Such electronic equipment has switching regulators or inverter circuits, and many devices are unintended sources of ultrasound radiation. However, the effects of airborne ultrasound on human hearing and the human body have not been well investigated. To estimate the potential damage of airborne ultrasound radiation quantitatively, it is necessary to establish an acoustic standard for airborne ultrasound because the standard is a basis of acoustic measurement. With the intention of establishing a standard on airborne ultrasound, a free-field calibration system with an anechoic chamber was produced. The principle of free-field calibration techniques is introduced in this presentation. Type WS3 microphones (B&K 4939) were calibrated in the system to examine the calibration ability to be achieved. Results

showed that it can calibrate a microphone from 10 to 100 kHz with dispersion of less than 1 dB. In addition, the effects that were dependent on the uncertainty of the calibration are discussed based on those results.

11:35

4aEA11. An environmentally robust silicon diaphragm microphone. Norihiro Arimura, Juro Ohga   (Shibaura Inst. of Technol.,3-7-5 Toyosu, Koto-ku, Tokyo, 135-8548, Japan), Norio Kimura, and Yoshinobu Yasuno (Panasonic Semiconductor Device Solutions Co., Ltd., Saedo-cho, Tsuzuki-ku, Yokohama, Japan)

Recently, many small microphones installed in cellular phones are the electret condenser microphones (ECMs) that contain an organic film diaphragm. Although FEP of fluorocarbon polymer is generally used as the electret material, silicon dioxide is also used. Recently ECMs have been made small and thin while maintaining the basic sound performance according to the market demand. In addition, environment tests and the reflow soldering mounting process have been adjusted to meet market requirements. On the other hand, the examination satisfied the demand as

the high temperature resistance was insufficient. This paper depicts an examination and a comparison of conventional ECM with the experimental model, a silicon diaphragm condenser microphone produced using the MEMS method. The silicon diaphragm satisfies high-temperature resis-tance and stable temperature characteristics because of its very small co-efficient of linear expansion and it is measured total harmonic distortion (THD) on high pressure sound. Finally, it will be able to be used in high temperature and high pressure sound conditions in the future.

4aMU1. Introduction of the Real World Computing music database. Masataka Goto (Natl. Inst. of Adv. Industrial Sci. and Technol. (AIST), 1-1-1 Umezono, Tsukuba, Ibaraki 305-8568, Japan, m.goto@aist.go.jp)

This paper introduces the *RWC (Real World Computing) Music Database*, a copyright-cleared music database that is available to researchers as a common foundation for research. Shared databases are common in other research fields and have contributed importantly to progress in those fields. The field of music information processing, however, has lacked a common database of musical pieces and a large-scale database of musical instrument sounds. The RWC Music Database was therefore built in fiscal 2000 and 2001 as the world's first large-scale music database compiled specifically for research purposes. It contains six original collections: the *Popular Music Database* (100 pieces), *Royalty-Free Music Database* (15 pieces), *Classical Music Database* (50 pieces), *Jazz Music Database* (50 pieces), *Music Genre Database* (100 pieces), and *Musical Instrument Sound Database* (50 instruments). To address copyright issues, all 315 musical pieces were originally composed, arranged, or performed, and all instrumental sounds were originally recorded. The database has already been distributed to more than 200 research groups and is widely used. In addition, a continuous effort has been undertaken to manually annotate a set of music-scene descriptions for the musical pieces, called *AIST Annotation*, which consists of the beat structure, melody line, and chorus sections.

8:35

4aMU2. Japanese traditional singing on the same lyrics. Ichiro Nakayama (Osaka Univ. of Arts, 469, Higashiyama, Kanan-cho, Minami-Kawachi-gun, Osaka, 585-8555 Japan) and Masuzo Yanagida (Doshisha Univ., Kyo-Tanabe, 610-0321 Japan)

Described is a database of Japanese traditional singing together with supplementary recording of Bel Canto for comparative studies. Singing sounds and spoken speech by the same singers are recorded in pair to form the body of the database. This database covers most of genres of Japanese traditional singing, such as Shinto prayers, Buddist prayers, Nor, Kyogen, Heikyoku, Sokyoku, Gidayu-bushi, Kabuki, Nagauta, Tokiwazu, Kiyomoto, Itchu-bushi, Shinnai, Kouta, Zokkyoku, Rokyoku, Shigin, Ryukyu-clasico, Goze-uta, etc. All the sounds were recorded in anechoic chambers belonging to local institutions, mainly in Osaka and Tokyo, asking 78 professional singers including 18 "Living National Treasures" to sing as informants. The most important point of this database is that an original lyric especially prepared for this recording is commonly used to make comparative studies easy. All the subjects are asked to sing the common lyrics in their own singing styles. Shown here are comparisons of formant shifts in vowels from ordinary speaking to singing for some singers, and comparison of temporal features of fundamental frequency between Japanese traditional singing and Western Bel Canto. [Work supported by the Academic Frontier Project, Doshisha University.]

8:55

4aMU3. Computational intelligence approach to archival musical recordings. Andrzej Czyzewski, Lukasz Litwic, and Przemyslaw Maziewski (Gdansk Univ. of Technol., Narutowicza 11/12, 80-952 Gdansk, Poland)

An algorithmic approach to wow defect estimation in archival musical recordings is presented. The wow estimation is based on the simultaneous analysis of many sinusoidal components, which are assumed to depict the defect. The rough determination of sinusoidal components in analyzed musical recording is performed by standard sinusoidal modeling procedures employing magnitude and phase spectra analysis. Since archival recordings tend to contain distorted tonal structure, the basic sinusoidal modeling approach is often found insufficient, resulting in audible distortions in the restored signal. It is found that the standard sinusoidal modeling approach is prone to errors, especially when strong frequency or amplitude variations of sinusoidal components occur. It may result in gaps or inappropriately matched components, leading to incorrect estimation of the wow distortion. Hence, some refinements to sinusoidal component analysis including interpolation and extrapolation of tonal components are proposed. As it was demonstrated in experi-

4a FRI. AM

ments, due to the nonlinear nature of wow distortion, the enhancement of sinusoidal analysis can be performed by means of a neural network. The paper demonstrates implemented algorithms for parasite frequency modulation in archival recordings together with obtained results. [Work supported by the Commission of the European Communities, within the Integrated Project No. FP6-507336: PRESTOSPACE.]

9:15

4aMU4. Music information retrieval seen from the communication technology perspective. Bozena Kostek (Gdansk Univ. of Technol., Narutowicza 11/12, PL-80-952 Gdansk, Poland)

Music information retrieval (MIR) is a multidiscipline area. Within this domain one can see various approaches to musical instrument recognition, musical phrase classification, melody classification (e.g., query-by-humming systems), rhythm retrieval, high-level-based music retrieval such as looking for emotions in music or differences in expressiveness, and music search based on listeners' preferences. One may also find research that tries to correlate low-level descriptor analysis to high-level human perception. Researchers from musical acoustics, musicology, and music domains on one side, and communication technology on the other side, work together within this area. This may foster a framework for broader and deeper comprehension of contributions from all these disciplines and, in addition, translate the automated access to music information, gathered in various forms around the World Wide Web, as a fully understandable process to all participants regardless of their background. The semantic description is becoming a basis of the next Web generation. Several important concepts have been introduced recently by the researchers associated with the MIR community with regard to semantic data processing including techniques for computing with words. In this presentation some aspects related to MIR are briefly reviewed in the context of possible and actual applications of ontology-based approach to this domain.

9:35

4aMU5. Accompaniment included song waveform retrieval based on framewise phoneme recognition. Yuichi Yaguchi and Ryuichi Oka (Univ. of Aizu, Tsuruga, Ikkimachi, Aizuwakamatsu, Fukushima, 965-8580 Japan)

A novel approach is presented for a retrieval method that is useful for waveforms of songs with accompaniment. Audio signals of songs have some different acoustical characteristics from speech signals. Furthermore, the length per mora of signals is longer than that of speech. Therefore, the authors suggest a sound retrieval system for application to musical compositions, including songs, that extracts framewise acoustical characteristics and uses a retrieval method for absorbing phoneme length. First, the system prepares two sets of phoneme identification functions that have corresponding order, but for which phoneme sets belong to different environments of accompaniment-included or accompaniment-reduced. Next, musical compositions are put into database and the query song wave converts a waveform to a label sequence using framewise phoneme recognition derived by Bayesian estimation that applies each phoneme identification function according to whether it is accompaniment-included or not. Finally, the system extracts an interval area, such as query data, from a database using spotting recognition that is derived using continuous dynamic programming (CDP). Retrieval method results agree well with earlier results [Y. Yaguchi and R. Oka, AIRS2005, LNCS3689, 503–509 (2005)] that applied the same musical composition set without accompaniment.

4aMU6. Design of an impression-based music retrieval system. Kimiko Ohta, Tadahiko Kumamoto, and Hitoshi Isahara (NICT, Keihanna Kyoto 619-0289, Japan, kimiko@nict.go.jp)

Impression-based music retrieval helps users to find musical pieces that suit their preferences, feelings, or mental states from among a huge volume of a music database. Users are asked to select one or more pairs of impression words from among multiple pairs that are presented by the system and to estimate each selected pair on a seven-step scale to input their impressions into the system. For instance, if they want to locate musical pieces that will create a happy impression, they should check the radio button "Happy" in the impression scale: Very happy–Happy–A little happy–Neutral–A little sad–Sad–Very sad. A pair of impression words with a seven-step scale is called an impression scale in this paper. The system calculates the distance between the impressions of each musical piece in a user-specified music database and the impressions that are input by the user. Subsequently, it selects candidate musical pieces to be presented as retrieval results. The impressions of musical pieces are expressed numerically by vectors that are generated from a musical piece's pitch, strength, and length of every tone using n-gram statistics.

4aMU7. Automatic discrimination between singing and speaking voices for a flexible music retrieval system. Yasunori Ohishi, Masataka Goto, Katunobu Itou, and Kazuya Takeda (Grad. School of Information Sci., Nagoya Univ., Furo-cho 1, Chikusa-ku, Nagoya, Aichi, 464-8603, Japan, ohishi@sp.m.is.nagoya-u.ac.jp)

This paper describes a music retrieval system that enables a user to retrieve a song by two different methods: by singing its melody or by saying its title. To allow the user to use those methods seamlessly without changing a voice input mode, a method of automatically discriminating between singing and speaking voices is indispensable. We therefore first investigated measures that characterize differences between singing and speaking voices. From subjective experiments, we found that human listeners discriminated between these two voices with 70% accuracy for 200-ms signals. These results showed that even short-term characteristics such as the spectral envelope represented as MFCC can be used as a discrimination cue, while the temporal structure is the most important cue when longer signals are given. According to these results, we then developed the automatic method of discriminating between singing and speaking voices by combining two measures: MFCC and an $F0$ (voice pitch) contour. Experimental results with our method showed that 68.1% accuracy was obtained for 200-ms signals and 87.3% accuracy was obtained for 2-s signals. Based on this method, we finally built a music retrieval system that can accept both singing voices for the melody and speaking voices for the title.

10:45

4aMU8. Various acoustical aspects of an Asian (South) Indian classical music concert. M. G. Prasad (Dept. of Mech. Eng., Stevens Inst. of Technol., Hoboken, NJ 07030), V. K. Raman (Flautist, Germantown, MD 20874), and Rama Jagadishan (Edison, NJ 08820)

An Asian (South) Indian classical music concert is an integrated acoustical experience for both the audience and the player(s). A typical concert team, either vocal or instrumental, consists of a main vocalist (or an instrumentalist) accompanied by a violinist, up to three percussion instrument players, and a reference drone. The concert is comprised of many songs. Each song has two main parts, namely Alapana and Kriti. The Alapana is an elaboration of a raga (tune) and the Kriti refers to the lyrics of the song. The violinist actively follows and supports the main musician during the concert. The percussion player(s) are provided an opportunity to present a solo of their rhythmic skills. The players and the audience communicate emotionally and intellectually with each other. Elements such as aesthetics, rhythm, skill, and emotional aspects of the players are evaluated and appreciated by the audience. This talk will present various aspects of a concert that brings about an integrated and holistic experience for both the audience and the player(s). Some samples from live vocal and instrumental music concerts will be presented.

11:00

4aMU9. Musical scales, signals, quantum mechanics. Alpar Sevgen (Dept. of Phys., Bogazici Univ., Bebek 34342, Istanbul, Turkey)

Scales, being finite length signals, allow themselves to be treated algebraically: key signatures are related to the "ring" property of the scale labels; cyclically permuted scales and their mirror images have the same number of sharps and flats; and complementary scales (like major and pentatonic) have their sharp and flat numbers exchanged. A search for minimum principles to select among all possible scales those employed in music yields two possibilities: (a) minimize total number of accidentals and (b) minimize frequency fluctuations in a scale. Either of these minimum principles helps filter those scales employed in music from the universe of all scales, setting up very different criteria than the harmonic ratios used by musicians. The notes of the scales employed in music seem to prefer to stay as far apart from each other as possible. Operators that step through the multiplet members of scales with N semitones form a complete set of operators together with those that step through their eigenvectors. The mathematics reveals the discrete Fourier transformations (DFT) and is identical to finite state quantum mechanics of N-level Stern-Gerlach filters worked out by J. Schwinger.

4aNS1. Soundscape in the old town of Naples: Signs of cultural identity. Giovanni Brambilla (CNR Istituto di Acustica "O.M. Corbino" Via del Fosso del Cavaliere 100, 00133 Roma, Italy), Luigi Maffei, Leda De Gregorio, and Massimiliano Masullo (Second Univ. of Naples, 81031 Aversa (Ce), Italy)

Like all cities in Magna Grecia, the ancient Neapolis was built along three main parallel, tight, and straight streets called *decumani*. Since then and during the following centuries, commercial and handicraft activities, as well as social life, have been developed along these streets. The narrow ground rooms forced shopkeepers to occupy the main street to show their merchandise using vocal appeals to magnify their product, and handicrafts to work directly on the street (hammering, sawing, etc.). Music artists had their performance on the streets too. The soundscape in the area was a strong symbol of the Neapolitan cultural identity. Nowadays *decumani* have kept the main features of the past but some of these are overrun by road traffic. To investigate in which way the traffic noise has modified the soundscape perception and cultural identity, sound walks were registered during day and night time. A number of residents were interviewed and laboratory listening tests were carried out. Despite the congested urban environment and high sound levels, preliminary results have shown that part of the residential population is still able to identify the soundscape more related to Neapolitan historical identity.

7:50

4aNS2. Soundscape design in public spaces: Concept, method, and practice. Hisao Nakamura-Funaba and Shin-ichiro Iwamiya (Kyushu Univ., 4-9-1.Shiobaru, Minami-ku, Fukuoka 815-8540, Japan)

Soundscape design of public spaces necessitates consideration of whether a space has important meaning for the user. It is essential to imagine an ideal sound environment of that space. We designed an actual soundscape from the viewpoint of the environment, information, and decoration. In many cases, producing some silence in an environment becomes the first step of soundscape design. There is neither a special technology nor a technique when designing. It merely requires use of a general technology and techniques concerning sound according to location. A key point is knowledge of know how to coordinate these technologies and techniques. For instance, silence was made first at the renewal project of Tokyo Tower observatory through cancellation of its commercial and call broadcasting functions and installation of sound-absorbing panels to the ceiling. Next, suitable and small sounds were added at various points. Guests can take time to enjoy viewing as a result.

4aNS3. The daily rhythm of soundscape. Brigitte Schulte-Fortkamp (TU-Berlin, Einsteinufer 25 TA 7, 10587 Germany, brigitte.schulte-fortkamp@tu-berlin.de) and Andr Fiebig (HEAD acoustics GmbH, 52134 Herzogenrath, Germany)

With respect to people's minds, soundscapes can be considered as dynamic systems characterized by the time-dependent occurrence of particular sound events embedded in specific environments. Therefore, an adequate evaluation of environmental noise will reflect the continually varying acoustical scenery and its specific perception. An acoustical diary shall provide information about the daily routine and subjectively perceived sound exposure of residents. It relies on cognitive and emotional aspects of perceiving and evaluating sounds. It gives insight into evaluating processes and their contextual parameters because of its spontaneous character. It includes and refers to long-term acoustic measurements. Simultaneous measurements for elaborate acoustical analyses will be taken outside the homes regarding the moments of essential sound events. The aim is to collect information about the daily rhythm regarding acoustic events, whereby the focus also should be placed on sound events that are well accepted to deepen the explication of data with respect to the analysis. Procedure and results will be discussed.

4aNS4. Ecological explorations of soundscapes: From verbal analysis to experimental settings. Daniele Dubois (CNRS, 11 rue de Lourmel, 75015 Paris, France) and Catherine Guastavino (McGill Univ., Montreal, QC H3A 1Y1, Canada)

Scientific studies rely on rigorous methods that must be adapted to the object of study. Besides integrating acoustic features, soundscapes as complex cognitive representations also have the properties of being global, meaningful, multimodal, and categorical. Investigating these specificities, new paradigms were developed involving linguistics and ecological psychology to complement the psychophysical approach: cognitive linguistic analyses of discourse to address semantic properties of soundscapes, and categorization tasks and distances from prototypes to investigate their cognitive organization. As a methodological consequence, experimental settings must be designed to ensure the ecological validity of the stimuli processing, (the ''realism'' evaluated from a psychological point of view, stimuli being processed as in a real-life situation). This point will be illustrated with perceptual evaluations of spatial auditory displays for soundscape reproduction. Data processing techniques should also take into consideration the intrinsic properties of the representations they account for. Examples of free-sorting tasks will be presented with measurements in terms of family resemblance of sets of properties defining categories rather than dimensional scales. New ways of coupling physical measurement and psychological evaluations will be presented in order to simulate or reproduce soundscapes in both a realistic and controlled manner for experimental purposes.

4aNS5. Artificial neural network models of sound signals in urban open spaces. Lei Yu and Jian Kang (School of Architecture, Sheffield Univ., Western Bank, Sheffield S10 2TN, UK)

Sound signals, known as foreground sounds, are important components of soundscape in urban open spaces. Previous studies in this area have shown that sound preferences are different according to social and demographic factors of individual users [W. Yang and J. Kang, J. Urban Des., 10, 69–88 (2005)]. This study develops artificial neural network (ANN) models of sound signals for architects at design stage, simulating subjective evaluation of sound signals. A database for ANN modeling has been established based on large-scale social surveys in European and Chinese cities. The ANN models have consequently been built, where individual's social and demographic factors, activities, and acoustic features of the space and sounds are used as input variables while the sound preference is defined as the output. Through the process of training and testing the ANN models, considerable convergences have been achieved, which means that the models can be applied as practical tools for architects to design sound signals in urban open spaces, taking the characteristics of potential users into account. Currently ANN models combining foreground and background sounds are being developed.

4aNS6. Describing soundscape and its effects on people where soundscape is understood as an expansion of the concept of noise engineering. Keiji Kawai (Grad. School of Sci. and Technol., Kumamoto Univ., 2-39-1 Kurokami, Kumamoto 860-8555, Japan, kawai@arch.kumamoto-u.ac.jp)

This study discusses how to describe sound environment and people in terms of ''soundscape'' as an expansion of the ''noise engineering.'' In the framework of the conventional study field of noise evaluation, typically, sound environments are represented by loudness-based indices such as A-weighted sound pressure levels, and the impact of sound environments on people is represented by annoyance response or some physiological metrics. In the case of soundscape studies, however, the description should be expanded beyond what has been used in noise engineering. This matter has already been frequently discussed, but it doesn't seem that much consensus has been achieved concerning it yet. With respect to the effects of sound environment on people, since the concept of soundscape focuses on personal and social meanings of environmental sounds including the historical or aesthetic contexts, the effects are considered to be represented not by a singular concept such as comfortableness or quietness, but by multiple dimensions of emotional and aesthetic concepts. Also, descriptions of sound environment should include some qualitative aspects, such as what types of sounds can be heard at what extent. In this paper, the methodology to describe human-soundscape relationships is discussed through a review of related studies.

9:30

4aNS7. The sound environmental education aided by automated bioacoustic identification in view of soundscape recognition.
Teruyo Oba (Natural History Museum & Inst., Chiba, 955-2 Aoba-cho, Chuo-ku, Chiba-shi, Chiba-ken 260-8682 Japan, oba@chiba-muse.or.jp)

From the 2003–2004 JST projects, where the automated bioacoustic identification device Kikimimi-Zukin was introduced to the nature observation and environmental studies, it was learned that the activities encouraged children to take notice of sounds, become aware of the sound environment, and gain an insight into the soundscape. Sounds are often riddles to us, and hearing is the process to find out the facts and causes. It is more important to let children obtain appropriate clues to differentiate sounds by hearing and thinking for themselves than give them an immediate answer. Program on the Strength of Hearing was formulated to challenge children and have them enjoy hearing to identify, sharing what they hear with others, and observing environment through sounds. Kikimimi-Zukin reinforced the program by a step-by-step guide through the hearing process of scanning, focusing, characterizing, associating with relevant factors, and judging the identity. The experience not only brought them confidence in hearing but incentive to study nature and environment. With Kikimimi-Zukin children collected recordings and relevant information. Using the sound database, the local singing map and three-dimensional sound map were prepared. They facilitated communication on the local sound environment among children and with adults, leading to realization of their inner soundscape.

9:50

4aNS8. Acoustic environmental problems at temporary shelters for victims of the Mid-Niigata Earthquake.
Koji Nagahata, Norio Suzuki, Megumi Sakamoto, Fuminori Tanba (Fukushima Univ., Kanayagawa 1, Fukushima City, Fukushima, 960-1296, Japan, nagahata@sss.fukushima-u.ac.jp), Shin-ya Kaneko, and Tetsuhito Fukushima (Fukushima Medical Univ., Fukushima, 960-1295, Japan)

An earthquake on 23 October 2004 inflicted heavy damage on the Mid-Niigata district. The earthquake isolated Yamakoshi village; consequently, all the village residents were forced to evacuate to temporary shelters in neighboring Nagaoka city for 2 months. Two types of temporary shelters were used: gymnasiums, and buildings with large separated rooms similar to community centers. A questionnaire survey and interviews ($N=95$) were conducted to elucidate problems of the living environment at the temporary shelters. This study analyzed acoustic environmental problems there. Noise-related problems were noted by 40 respondents (46.5%): they were the fifth most frequently cited environmental problems. Several serious complaints, e.g., general annoyance at the shelters and footsteps of refugees at night, were only indicated by respondents who had evacuated to the gymnasiums. However, some problems, e.g., the clamor of children, including crying babies and voices of other refugees, were indicated by respondents irrespective of the type of the shelters to which they had been evacuated. Therefore, buildings like community centers were more desirable for temporary shelters, at least from the perspective of noise problems.

10:10–10:30   Break

10:30

4aNS9. The burden of cardiovascular diseases due to road traffic noise.
Wolfgang Babisch (Dept. of Environ. Hygiene, Federal Environ. Agency, Corrensplatz 1, 14195 Berlin, Germany, wolfgang.babisch@uba.de) and Rokho Kim (WHO/EURO Ctr. for Environment and Health, 53113 Bonn, Germany)

Epidemiological studies suggest a higher risk of cardiovascular diseases, including high blood pressure and myocardial infarction, in subjects chronically exposed to high levels of road or air traffic noise. A new meta-analysis was carried out to assess a dose-response curve, which can be used for a quantitative risk assessment and to estimate the burden of cardiovascular disease attributable to environmental noise in European regions. Noise exposure was grouped according to 5 dB(A)-categories for the daytime outdoor average A-weighted sound pressure level, (L_{day}, 16 h: 6–22 h), which was considered in most studies. Information on night-time exposure (L_{night}, 8 h: 22–6 h or 23–7 h) was seldom available. However, approximations can be made with respect to L_{den} according to the European directive on the assessment and management of environmental noise. The strongest evidence of an association between community noise and cardiovascular endpoints was found for ischaemic heart diseases, including myocardial infarction and road traffic noise. The disability-adjusted life years lost for ischemic heart disease attributable to transport noise were estimated conservatively, assuming the same exposure patterns across the countries with an impact fraction 3% in the western European countries.

10:50

4aNS10. Soundscape, moderator effects, and economic implications.
Cay Hehner (Henry George School of Social Sci., 121 E. 30th St., New York, NY 10016, chehner.hengeoschool@att.net) and Brigitte Schulte-Fortkamp (TU-Berlin, Berlin, Germany)

Soundscape is considered with respect to moderator effects and the contribution of economics. It will be questioned whether soundscapes can work as a moderator concerning noise annoyance. As shown by the different investigations concerning soundscapes, a definition of the meaning of soundscapes is necessary. Evidently, the moderating effect of a given environment and its soundscape has to be discussed on three levels: (1) extension of factors that describe annoyance,(2) peculiar feature of burdensome noise contexts, and (3) discrepancies of the social and economic status of people living in areas where the rebuilding will change the quality of the area. It has to be determined and analyzed to what extent the Georgist method of resources taxation, as recently exemplified, e.g., in Alaska and in Wyoming, can be instrumental in funding soundscapes to moderate noise annoyance as it has been the case in funding free education and allowing the distribution of a citizen's dividend.

4a FRI. AM

4aNS11. Socio-cultural soundscape concepts to support policies for managing the acoustic environment. Michiko So Finegold, Lawrence S. Finegold (Finegold & So, Consultants, 1167 Bournemouth Court Centerville, OH 45459-2647, m-so@pb3.so-net.ne.jp), and Kozo Hiramatsu (Kyoto Univ., Sakyou-ku, Kyoto 606-8501 Japan)

In the past half-century, considerable effort has been invested in the academic, technological, and political arenas to achieve an adequate acoustic environment. Various national and international policy guidance documents have made reasonable progress in establishing a framework for a common approach to minimizing environmental noise, such as documents from various national Environmental Protection Agencies, the World Health Organization, and the European Union. Although these documents have provided useful information for global application, they only address minimizing the negative side of the acoustic environment (i.e., noise), they focus primarily on acoustics issues at the national or international level, and they still have not adequately considered implementation issues related to socio-cultural differences. To deal with the practical problems that exist in the acoustic environment in the context of different cultures, continuing research and new policy guidance are needed to address different local situations and in a variety of cultural contexts. The Soundscape approach has been developing tools for describing the acoustic environment at the local level to address both the positive and negative aspects of the acoustic environment. In this paper, the evolving interdisciplinary aspect of the Socio-Cultural Soundscape will be discussed and key topics for future work will be recommended.

4aNS12. Initial steps for the determination of environmental noise quality—The perception-related evaluation of traffic noise. Klaus Genuit, Sandro Guidati, Sebastian Rossberg, and Andr Fiebig (HEAD Acoust. GmbH, Ebertstrasse 30a, 52134 Herzogenrath, Germany, klaus.genuit@head-acoustics.de)

Directives call for actions against noise pollution and noise annoyance. But, how do we eliminate harmful effects including annoyance due to the exposure of environmental noise without understanding the perception and evaluation of environmental noise? How do we preserve environmental noise quality where it is good (Directive 2002/49/EC) without identifying descriptors for noise quality? Various soundscape approaches based on different methodologies have been developed in the past. But, the measurement procedures must be realizable without much effort in order to achieve acceptance from legislation. Therefore, procedures have to be developed that capture the complexity of human hearing, on the one hand, and are feasible with respect to economy and time, on the other hand. The European project Quiet City (6FP PL516420) is dealing with, among other aspects, vehicle pass-by noise as a typical environmental noise source and its evaluation. Results of the analysis based on subjective assessments and psychoacoustic analyses carried out with respect to the development of an annoyance index will be presented and discussed. Such an index will provide valuable information for effective improvement of noise quality. The final aim is to develop a descriptor valid for complete traffic noise scenarios predicting environmental noise quality adequately.

4aNS13. When objective permissible noise limits of a municipal planning process and a subjective noise ordinance conflict. Marlund Hale (Adv. Eng. Acoust., 663 Bristol Ave., Simi Valley, CA 93065, mehale@aol.com)

In most communities, proposed new building projects are required to conform with planning, community development, zoning, and/or building and safety specifications and standards. In cases of allowable noise exposure and noise limits, where certain of these requirements are quite specific while others are purposefully vague, conflicts between residential and commercial neighbors can lead to extreme disagreement and needless litigation. This paper describes a recent situation occurring in an upscale beach community, the resulting conflict over existing noise sources that comply with the limits of the city planning and permitting process, and the interesting findings of the court following the civil and criminal litigation that followed. Some suggestions are given to avoid these conflicting policy situations.

4aNS14. The complexity of environmental sound as a function of seasonal variation. Hideo Shibayama (3-7-5 Koutou-ku Tokyo, 135-8548, Japan, sibayama@sic.shibaura-it.ac.jp)

Residential land is performed for a surrounding area of a suburban local city. As a result of urbanization, an area of rich natural environments became narrow. For the animals and plants for whom a river and a forest are necessary, it becomes difficult to live. Environmental sound produced by the tiny insects in this area is changing from year to year. Catching the conditions for the developmental observations and environmental preservation in natural environments, we continue to measure the environmental sound as the time-series data. We estimate the complexity for these waveforms of the measured environmental sound in the season when insects chirp and do not chirp. For estimation of the complexity, we evaluate by the fractal dimension of the environmental sound. Environmental sound in early autumn is mainly generated by insects in the grass and on the trees. And, the fractal dimension for the sound waveforms of chirping of insects is up to 1.8.

4aPA1. *In vivo* measurement of mass density and elasticity of cancellous bone using acoustic parameters for fast and slow waves. Takahiko Otani (Faculty of Eng., Doshisha Univ., Kyotanabe 610-0321 Japan)

Cancellous bone (spongy bone) is comprised of a porous network of numerous trabecular elements with soft tissue in the pore space. The effect of decreasing bone density, namely a symptom of osteoporosis, is greater for cancellous bone than for dense cortical bone (compact bone). Two longitudinal waves, the fast and slow waves, are clearly observed in cancellous bone, which correspond to ''waves of the first and second kinds'' as predicted by Biot's theory. According to experimental and theoretical studies, the propagation speed of the fast wave increases with bone density and that of the slow wave is almost constant. Experimental results show that the fast wave amplitude increases proportionally and the slow wave amplitude decreases inversely with bone density. However, the attenuation constant of the fast wave is almost independent of bone density and the attenuation constant of the slow wave increases with   bone   density.   The *in vivo* ultrasonic wave propagation path is composed of soft tissue, cortical bone, and cancellous bone and is modeled to specify the causality between ultrasonic wave parameters and bone mass density of cancellous bone. Then, mass density and elasticity are quantitatively formulated and estimated.

7:55

4aPA2. Is ultrasound appropriate to measure bone quality factors? Pascal Laugier (Univ. Pierre et Marie Curie., UMR CNRS 7623, 15 rue de l'Ecole de medecine, 7506 Paris, France, laugier@lip.bhdc.jussieu.fr)

Theoretical considerations support the concept that quantitative ultrasound variables measured in transmission are mainly determined by bone microstructure and material properties. All these properties are attributes of bone other than its bone mineral density (BMD) that may contribute to its quality and thus to strength or fragility. However, the limitations of this approach for a BMD-independent characterization of bone quality, long questioned, have become indisputable. Such considerations have prompted a research aiming at the development of new methods capable of measuring bone quality factors. New ultrasonic approaches are being investigated that use ultrasonic backscatter, guided waves, or nonlinear acoustics for studying bone microstructure or microdamage. These approaches, combined with sophisticated theoretical models or powerful computational tools, are advancing ideas regarding ultrasonic assessment of bone quality, which is not satisfactorily measured by x-ray techniques.

8:15

4aPA3. Scanning acoustic microscopy studies of cortical and trabecular bone in the femur and mandible. J. Lawrence Katz, Paulette Spence, Yong Wang (Univ. of Missouri-Kansas City, 650 E. 25th St., Kansas City, MO 64108, katzjl@umkc.edu), Anil Misra, Orestes Marangos (Univ. of Missouri-Kansas City, Kansas City, MO 64110), Dov Hazony (Case Western Reserve Univ., Cleveland, OH 44106), and Tsutomu Nomura (Niigata Univ. Grad. School of Medical and Dental Sci., Niigata, Japan)

Scanning acoustic microscopy (SAM) has been used to study the micromechanical properties of cortical and trabecular bone in both the human femur and mandible. SAM images vary in gray level reflecting the variations in reflectivity of the material under investigation. The reflection coefficient, $r = (Z2 - Z1)/(Z2 + Z1)$, where the acoustic impedance (AI), $Z = dv$, d is the materials local density and v is the speed of sound at the focal point; Z2 represents the AI of the material, Z1 that of the fluid coupling the acoustic wave from the lens to the material. Femoral cortical bone consists of haversian systems (secondary osteons) and interstitial lamellae, both of which show systematic variations of high and low AI from lamella to lamella. The lamellar components defining the edges of trabecular cortical bone exhibit the same lamellar variations as seen in cortical bone. Mandibular bone, while oriented perpendicular to the direction of gravitational attraction, exhibits the same cortical and trabecular structural organizations as found in the femur. It also exhibits the same systematic alternations in lamellar AI as found in femoral bone. Both femoral and mandibular cortical bone have transverse isotropic symmetry. Thus, modeling elastic properties requires only five independent measurements.

4aPA4. The interaction between ultrasound and human cancellous bone. Keith Wear (US Food and Drug Administration, 12720 Twinbrook Pkwy., Rockville, MD 20852, keith.wear@fda.hhs.gov)

Attenuation is much greater in cancellous bone than in soft tissues, and varies approximately linearly with frequency between 300 kHz and 1.7 MHz. At diagnostic frequencies (300 to 700 kHz), sound speed is slightly faster in cancellous bone than in soft tissues. A linear-systems model can account for errors in through-transmission-based measurements of group velocity due to frequency-dependent attenuation and dispersion. The dependence of phase velocity on porosity may be predicted from theory of propagation in fluid-filled porous solids. The dependence of phase velocity on frequency (negative dispersion) can be explained using a stratified two-component model. At diagnostic frequencies, scattering varies as frequency to the nth power where $3 > n > 3.5$. This may be explained by a model that represents trabeculae as finite-length cylindrical scatterers.

4aPA5. Dependence of phase velocity on porosity in cancellous bone: Application of the modified Biot-Attenborough model. Suk Wang Yoon and Kang Il Lee (Dept. of Phys. and Inst. of Basic Sci., SungKyunKwan Univ., Suwon 440-746, Republic of Korea)

This study aims to apply the modified Biot-Attenborough (MBA) model to predict the dependence of phase velocity on porosity in cancellous bone. The MBA model predicted that the phase velocity decreases nonlinearly with porosity. The optimum values for input parameters of the MBA model, such as compressional speed c_m of solid bone and phase velocity parameter s_2, were determined by comparing the prediction with the previously published measurements in human calcaneus and bovine cancellous bones. The value of the phase velocity parameter $s_2 = 1.23$ was obtained by curve fitting to the experimental data only for 53 human calcaneus samples with a compressional speed $c_m = 2500$ m/s of solid bone. The root-mean-square error (rmse) of the curve fit was 15.3 m/s. The optimized value of s_2 for all 75 cancellous bone samples (53 human and 22 bovine samples) was 1.42 with the rmse of 55 m/s. The latter fit was obtained by using $c_m = 3200$ m/s. Although the MBA model relies on empirical parameters determined from the experimental data, it is expected that the model can be usefully employed as a practical tool in the field of clinical ultrasonic bone assessment.

4aPA6. Simulation of fast and slow wave propagations through cancellous bone using three-dimensional elastic and Biot's trabecular models. Atsushi Hosokawa (Dept. of Elect. & Comp. Eng., Akashi Natl. Coll. of Tech., 679-3 Nishioka, Uozumi, Akashi, 674-8501 Hyogo, Japan, hosokawa@akashi.ac.jp)

The propagation of ultrasonic pulse waves in cancellous (trabecular) bone was numerically simulated by using three-dimensional finite-difference time-domain (FDTD) methods. In previous research [A. Hosokawa, J. Acoust. Soc. Am. **118**, 1782–1789 (2005)], two two-dimensional FDTD models, the commonly used elastic FDTD model and an FDTD model based on Biot's theory for elastic wave propagation in an isotropic fluid-saturated porous medium, were used to simulate the fast and slow longitudinal waves propagating through cancellous bone in the direction parallel to the main trabecular orientation. In the present study, the extended three-dimensional viscoelastic and Biot's anisotropic models were developed to investigate the effect of trabecular structure on the fast and slow wave propagations. Using the viscoelastic model of the trabecular frame comprised of numerous pore spaces in the solid bone, the effect of the trabecular irregularity, that is the scattering effect, on both the fast and slow waves could be investigated. The effect of the anisotropic viscous resistance of the fluid in the trabecular pore spaces on the slow wave could be considered using Biot's anisotropic model.

Contributed Papers

4aPA7. Ultrasonic characteristics of *in vitro* human cancellous bone. Isao Mano (OYO Electric Co., Ltd., Joyo 610-0101 Japan), Tadahito Yamamoto, Hiroshi Hagino, Ryota Teshima (Tottori Univ., Yonago 683-8503 Japan), Toshiyuki Tsujimoto (Horiba, Ltd., Kyoto 601-8510 Japan), and Takahiko Otani (Doshisha Univ., Kyotanabe 610-0321 Japan)

Cancellous bone is comprised of a connected network of trabeculae and is considered as an inhomogeneous and anisotropic acoustic medium. The fast and slow longitudinal waves are clearly observed when the ultrasonic wave propagates parallel to the direction of the trabeculae. The propagation speed of the fast wave increases with bone density and that of the slow wave is almost constant. The fast wave amplitude increases proportionally and the slow wave amplitude decreases inversely with bone density. Human *in vitro* femoral head was sectioned to 10-mm-thick slices perpendicularly to the femoral cervical axis. These cancellous bone samples were subjected to the ultrasonic measurement system LD-100 using a narrow focused beam. The propagation speed and the amplitude of the transmitted wave both for the fast and slow waves were measured at 1-mm intervals. The local bone density corresponding to the measured points was obtained using a microfocus x-ray CT system. Experimental results show that the propagation speeds and amplitudes for the fast and slow waves are characterized not only by the local bone density, but also by the local trabecular structure.

4aPA8. The effect of hydroxyapatite crystallite orientation on ultrasonic velocity in bovine cortical bone. Yu Yamato, Kaoru Yamazaki, Akira Nagano (Orthopaedic Surgery, Hamamatsu Univ. School of Medicine, 1-20-1 Hamamatsu Shizuoka 431-3192, Japan, yy14@hama-med.ac.jp), Hirofumi Mizukawa, Takahiko Yanagitani, and Mami Matsukawa (Doshisha Univ., Kyotanabe, Kyoto-fu 610-0321, Japan)

Cortical bone is recognized as a composite material of diverse elastic anisotropy, composed of hydroxyapatite (HAp) crystallite and type 1 collagen fiber. The aim of this study is to investigate the effects of HAp orientation on elastic anisotropy in bovine cortical bone. Eighty cubic samples were made from the cortical bone of two left bovine femurs. Longitudinal wave velocity in orthogonal three axes was measured using a conventional pulse echo system. For evaluating the orientation of HAp crystallite, x-ray diffraction profiles were obtained from three surfaces of each cubic sample. The preference of crystallites showed strong dependence on the direction of surface. The C-axis of crystallites was clearly preferred to the bone axial direction. The velocity in the axial direction was significantly correlated with the amounts of HAp crystallites aligning to the axial axis. The HAp orientation and velocity varied according to the microstructures of the samples. The samples with Haversian structure

showed larger preference of crystallites than plexiform samples in the axial direction. These results show clear effects of crystallites orientation on velocity.

4aPA9. Frequency variations of attenuation and velocity in cortical bone *in vitro*. Magali Sasso, Guillaume Haiat (Universite Paris 12, Laboratoire de Mecanique Physique, UMR CNRS 7052 B2OA, 61, avenue du General de Gaulle, 94010 Creteil, France), Yu Yamato (Hamamatsu Univ. School of Medicine, Hamamastu, Shizuoka, 431-3192, Japan), Salah Naili (Universite Paris 12, 94010 Creteil, France), and Mami Matsukawa (Doshisha Univ., Kyotanabe, Kyoto-fu 610-0321, Japan)

The development of ultrasonic characterization devices for cortical bone requires a better understanding of ultrasonic propagation in this heterogeneous medium. The aim of this work is to investigate the frequency dependence of the attenuation coefficient and of phase velocity and to relate them with bone microstructure and anatomical position. One hundred twenty parallelepipedic samples (4–11 mm side) have been cut from three bovine specimens and measured four times with repositioning in transmission with a pair of 8-MHz central frequency transducers. Phase velocity and BUA could be determined with acceptable precision: coefficients of variation of 0.8% and 13%, respectively. Velocity dispersion and BUA values are comprised between −13 and 40 m/s/MHz and 2 and 12 dB/MHz/cm, respectively. Negative dispersion values were measured (similarly to trabecular bone) for 2% of the measured samples. BUA values were found to be smaller in plexiform than in Haversian structure and higher for porotic structure. BUA values were found to be the greatest in the postero-lateral distal part and the smallest in the anterior-medial center part of the bone. The same tendency was found for velocity dispersion. Our results show the sensitivity of the frequency dependence of ultrasound to anatomical position and micro-architectural properties of bone.

4aPA10. 3-D numerical simulations of wave propagation in trabecular bone predicts existence of the Biot fast compressional wave. Guillaume Haiat (Universite Paris 12, Laboratoire de Mecanique Physique, UMR CNRS 7052 B2OA, 61, avenue du General de Gaulle, 94010 Creteil, France), Frederic Padilla, and Pascal Laugier (Universite Pierre et Marie Curie, 75006 Paris, France)

Trabecular bone is a poroelastic medium in which the propagation of two longitudinal waves (fast and slow) has been observed. The 3-D finite-difference time-domain simulations neglecting absorption coupled to 3-D microstructural models of 34 trabecular bone reconstructed from synchrotron radiation microtomography are shown to be suitable to predict both types of compressional wave in the three orthogonal directions. The influence of bone volume fraction (BV/TV) on the existence of the fast and slow waves was studied using a dedicated iterative image processing algorithm (dilation, erosion) in order to modify all 34 initial 3-D microstructures. An automatic criteria aiming at determining the existence of both wave modes was developed from the analysis of the transmitted signals in the frequency domain. For all samples, the fast wave disappears when bone volume fraction decreases. Both propagation modes were observed for BV/TV superior to a critical value for 2, 13, and 17 samples according to the direction of propagation. Above this critical value, the velocity of the fast (slow) wave increases (decreases) with BV/TV, consistent with Biot's theoretical predictions. This critical value decreases when the degree of anisotropy increases, showing coupling between structural anisotropy and the existence of the fast wave.

4aPA11. 3-D numerical simulation of wave propagation in porous media: Influence of the microstructure and of the material properties of trabecular bone. Guillaume Haiat (Universite Paris 12, Laboratoire de Mecanique Physique, UMR CNRS 7052 B2OA, 61, avenue du General de Gaulle, 94010 Creteil, France), Frederic Padilla, and Pascal Laugier (Universite Pierre et Marie Curie, 75006 Paris, France)

Finite-difference time domain simulations coupled to 3-D microstructural models of 30 trabecular bones reconstructed from synchrotron radiation microtomography were employed herein to compare and quantify the effects of bone volume fraction, microstructure, and material properties of trabecular bone on QUS parameters. Scenarios of trabecular thinning and thickening using an iterative dedicated algorithm allowed the estimation of the sensitivity of QUS parameters to bone volume fraction. The sensitivity to bone material properties was assessed by considering independent variations of density and stiffness. The effect of microstructure was qualitatively assessed by producing virtual bone specimens of identical bone volume fraction (13%). Both BUA and SOS show a strong correlation with BV/TV ($r^2 = 0.94$ $p10^{-4}$) and vary quasi-linearly with BV/TV at an approximate rate of 2 dB/cm/MHz and 11 m/s per % increase of BV/TV, respectively. Bone alterations caused by variation in BV/TV (BUA: 40 dB/cm.MHz; SOS: 200 m/s) is much more detrimental to QUS variables than that caused by alterations of material properties or diversity in microarchitecture (BUA: 7.8 dB/cm.MHz; SOS: 36 m/s). QUS variables are changed more dramatically by BV/TV than by changes in material properties or microstructural diversity. However, material properties and structure also appear to play a role.

4aPA12. Singular value decomposition-based wave extraction algorithm for ultrasonic characterization of cortical bone *in vivo*. Magali Sasso, Guillaume Haiat (Universite Paris 12, Laboratoire de Mecanique Physique, UMR CNRS 7052 B2OA, 61, avenue du General de Gaulle, 94010 Creteil, France), Maryline Talmant, Pascal Laugier (Universite Pierre et Marie Curie, 75006 Paris, France), and Salah Naili (Universite Paris 12, 94010 Creteil, France)

In the context of bone status assessment, the axial transmission technique allows ultrasonic evaluation of cortical bone using a multielement probe. The current processing uses the first arriving signal to evaluate the velocity while later contributions are potentially valuable and are not yet analyzed. However, all those contributions interfere, which disrupts the signal analysis. A novel ultrasonic wave extraction algorithm using a singular value decomposition method is proposed. This algorithm aims at characterizing a given energetic low-frequency (ELF) contribution observed *in vivo* at around 1 MHz. To evaluate the performances of the proposed algorithm, a simulated data set was constructed taking into account the influence of noise and of random interfering wavefront. The velocity of the ELF contribution is estimated on simulated datasets and compared to the input velocity. For a signal-to-noise ratio of 10 dB, the mean error associated with this method is 5.2%, to be compared with 34% with a classical signal analysis. The algorithm was also tested on real *in vivo* measurements. Results show the ability to accurately identify and possibly remove this wavefront contribution. Results are promising for multiple ultrasonic parameters evaluation from different wavefront contributions in our configuration.

4aPA13. Direct evaluation of cancellous bone porosity using ultrasound. Peiying Liu, Matthew Lewis, and Peter Antich (Grad. Program of Biomed. Eng., Univ. of Texas Southwestern Medical Ctr. at Dallas, 5323 Harry Hines Blvd, Dallas, TX 75390-9058)

Quantitative measurements of trabecular bone porosity would be a great advantage in diagnosis and prognosis of osteoporosis. This study focused on evaluation of the relationship between ultrasonic reflection and the density and porosity of cancellous bone. Theoretical simulation using MATLAB and Field II ultrasound simulator predicted a linear model of a material's porosity and parameters of the reflected ultrasonic signals. Ex-

perimentally, four plastic phantoms fabricated with different porosities were tested by a 5-MHz ultrasound transducer and the results agreed with simulations. Twelve specimens of bovine cancellous bone were measured. The porosities of these specimens were estimated by calculating the ratio of the mass in air to the wetted mass when they were immersed in water and all the air was removed from the pores. Among all the parameters, the peak value of the reflected ultrasound signal demonstrated highly significant linear correlations with porosity ($R^2 = 0.911$) and density ($R^2 = 0.866$). This encouraging result shows that this technique has the potential to be used to monitor porosity changes noninvasively for clinical purpose such as noninvasive assessment of osteoporotic fracture risk. [Work supported by Pak Foundation.]

4aPA14. Transmission of ultrasound through bottlenose dolphin (*tursiops truncatus*) **jaw and skull bone.** Michael D. Gray, James S. Martin, and Peter H. Rogers (Woodruff School of Mech. Eng., Georgia Inst. of Technol., Atlanta, GA 30332-0405, michael.gray@gtri.gatech.edu)

Measurements of ultrasound transmission through jaw (pan bone) and skull (temporal fossa) samples from an Atlantic bottlenose dolphin were performed as part of an investigation of the feasibility of performing *in vivo* elastography on cetacean head tissues. The pan bone and temporal fossa are both relatively thin and smooth, and are therefore of interest for acoustic imaging of the underlying tissues of the ear and brain, respectively. Field scan data will be presented, showing the influence of the bone on the quality of the focus and overall pressure levels generated by a spherically focused single-element transducer. [Work supported by ONR.]

4aPA15. Assessment of bone health by analyzing propagation parameters of various modes of acoustic waves. Armen Sarvazyan, Vladimir Egorov, and Alexey Tatarinov (Artann Labs., Inc., 1457 Lower Ferry Rd., West Trenton, NJ 08618)

A method for assessment of bone based on comprehensive analysis of waveforms of ultrasound signals propagating in the bone is presented. A set of ultrasound propagation parameters, which are differentially sensitive to bone material properties, structure, and cortical thickness, are evaluated. The parameters include various features of different modes of acoustics

waves, such as bulk, surface, and guided ultrasonic waves in a wide range of carrier frequencies. Data processing algorithms were developed for obtaining axial profiles of waveform parameters. Such profiles are capable of revealing axial heterogeneity of long bones and spatially nonuniform pathological processes, such as osteoporosis. The examination procedure may include either one long bone in the skeleton, like the tibia, radius of the forearm, etc., or several bones in sequence to provide a more comprehensive assessment of the skeletal system. Specifically, for tibia assessment, a multi-parametric linear classifier based on a DEXA evaluation of skeleton conditions has been developed. Preliminary results of the pilot clinical studies involving 149 patients have demonstrated early stages of osteoporosis detection sensitivity of 80% and specificity of 67% based on DEXA data as the gold standard. [Work was supported by NIH and NASA grants.]

4aPA16. Toward bone quality assessment: Interference of fast and slow wave modes with positive dispersion can account for the apparent negative dispersion. James G. Miller, Karen Marutyan, and Mark R. Holland (Dept. of Phys., Washington Univ., St. Louis, MO 63130)

The goal of this work was to show that apparently negative dispersion in bone can arise from interference between fast wave and slow wave longitudinal modes, each of positive dispersion. Simulations were carried out using two approaches, one based on the Biot-Johnson model and the second independent of that model. The resulting propagating fast wave and slow wave modes accumulated phase and suffered loss with distance traveled. Results of both types of simulation served as the input into a phase and magnitude spectroscopy algorithm (previously validated with experimental data) in order to determine the phase velocity as a function of frequency. Results based on both methods of simulation were mutually consistent. Depending upon the relative magnitudes and time relationships between the fast and slow wave modes, the apparent phase velocities as functions of frequency demonstrated either negative or positive dispersions. These results appear to account for measurements from many laboratories that report that the phase velocity of ultrasonic waves propagating in cancellous bone decreases with increasing frequency (negative dispersion) in about 90% of specimens but increases with frequency in about 10%. [Work supported in part by Grant NIH R37HL40302.]

4aPP1. Threshold of hearing for pure tones between 16 and 30 kHz. Kaoru Ashihara (AIST, Tsukuba Central, 6 Tsukuba, Ibaraki 305-8566 Japan, ashihara-k@aist.go.jp)

Hearing thresholds for pure tones were obtained at 2-kHz intervals between 16 and 30 kHz in an anechoic chamber. Measured 50 cm from the sound source, the maximum presentation sound pressure level ranged from 105 to 112 dB depending on the frequency. To prevent the listener from detecting the quantization noise or subharmonic distortions at low frequencies, a pink noise was added as a masker. Using a 3-down 1-up transformed up-down method, thresholds were obtained at 26 kHz for 10 out of 32 ears. Even at 28 kHz threshold values were obtained for 3 ears, but none were observed for a tone at 30 kHz. Above 24 kHz, the thresholds always exceeded 90 dB SPL. Between 16 and 20 kHz thresholds increased abruptly, whereas above 20 kHz the threshold increase was more gradual.

8:55

4aPP2. Do we have better hearing sensitivity than people in the past? Kenji Kurakata and Tazu Mizunami (Natl. Inst. of Adv. Industrial Sci. and Technol. (AIST), 1-1-1 Higashi, Tsukuba, Ibaraki, 305-8566 Japan, kurakata-k@aist.go.jp)

Our hearing sensitivity to tones of various frequencies declines progressively as we become older. ISO 7029 describes a method for calculating expected hearing threshold values as a function of age. However, more than 30 years have passed since the ISO standard source data were published. An earlier paper of the present authors [K. Kurakata and T. Mizunami, Acoust. Sci. Technol. **26**, 381–383 (2005)] compared hearing threshold data of Japanese people in recent years to the ISO standard values. The results of that comparison showed that the age-related sensitivity decrease of Japanese people was smaller, on average, than those described in the standard. A large discrepancy was apparent at 4000 and 8000 Hz: more than 10 dB for older males. In response to that inference, the ISO/TC43/WG1 "threshold of hearing" initiated a project in 2005 to explore the possibility of updating ISO 7029. This paper presents a summary of those comparison results of audiometric data and the work in WG1 for revising the standard.

4aPP3. Reliability and frequency specificity of auditory steady-state response. Masaru Aoyagi, Tomoo Watanabe, Tsukasa Ito, and Yasuhiro Abe (Dept. of Otolaryngol., Yamagata Univ. School of Medicine, 2-2-2 Iida-Nishi, Yamagata, 990-9585, Japan)

The reliability and frequency specificity of 80-Hz auditory steady-state response (80-Hz ASSR) elicited by sinusoidally amplitude-modulated (SAM tones) tones and detected by phase coherence were evaluated as a measure of the hearing level in young children. The 80-Hz ASSR at a carrier frequency of 1000 Hz was monitored in 169 ears of 125 hearing-impaired children and auditory brainstem response (ABR) elicited by tone pips was examined in 93 ears. Both responses were examined during sleep, and the thresholds were compared with the behavioral hearing threshold, which was determined by standard pure-tone audiometry or play audiometry. In 24 ears with various patterns of audiogram, 80-Hz ASSRs were examined at different carrier frequencies, and the threshold patterns were compared with the audiograms to investigate the frequency specificity of ASSR. The correlation coefficient between the threshold of 80-Hz ASSR and pure-tone threshold ($r = 0.863$) was higher than that for ABR ($r = 0.828$). The threshold patterns of 80-Hz ASSR clearly followed the corresponding audiogram patterns in all types of hearing impairment. These findings suggest that 80-Hz ASSR elicited by SAM tones and detected by phase coherence is a useful audiometric device for the determination of hearing level in a frequency-specific manner in children.

4aPP4. Use of perceptual weights to test a model of loudness summation. Lori J. Leibold and Walt Jesteadt (Boys Town Natl. Res. Hospital, 555 N 30th St., Omaha, NE 68131)

We recently examined the contribution of individual components of a multitone complex to judgments of overall loudness by computing the perceptual weight listeners assign to each component in a loudness-matching task [Leibold *et al.*, J. Acoust. Soc. Am. **117**, 2597 (2005)]. Stimuli were five-tone complexes centered on 1000 Hz, with six different logarithmic frequency spacings, ranging from 1.012 to 1.586. When all components fell within the same critical band, weights varied little across components. In contrast, the range of weights increased with increasing frequency separation, with greater weight given to the lowest and highest frequency components. Perceptual weights were largely in agreement with the Moore *et al.* loudness model [J. Audio Eng. Soc. **45**, 224–237 (1997)], except at the widest bandwidth. In the current study we further examined predictions of the loudness model, focusing on the widest frequency-spacing condition. Masked thresholds and jnds for intensity discrimination were measured for each component and were compared to weights. The model predicts more interaction in the widely spaced conditions than simple critical band models, but underestimates the true interactions in conditions where components are widely spaced. Central factors appear to influence loudness, masked thresholds, and intensity discrimination in these conditions. [Work supported by NIH/NIDCD.]

4aPP5. Increased loudness effect at the absolute threshold of hearing. Junji Yoshida, Masao Kasuga (Grad. School of Eng., Utsunomiya Univ., 7-1-2 Yoto, Utsunomiya-shi, Tochigi-ken, 321-8585, Japan), and Hiroshi Hasegawa (Utsunomiya Univ., Tochigi-ken, 321-8585, Japan)

This study investigated the effects of a previous sound on loudness at the absolute threshold of hearing. Change of the absolute threshold of hearing was measured when a pure tone preceded the test tone in the measurement of the threshold. The previous sound at 60 dB SPL was presented first in one ear, followed by the presentation of the test sound in either the contralateral or ipsilateral ear at an interval of 0.5 s. Both the previous and test sounds had the same frequency of 500 Hz, and the same duration of 3 s. The change of the threshold was obtained from the difference between the thresholds with and without the previous sound. The threshold was found to be decreased significantly by approximately 2 dB when the previous sound was presented in the contralateral ear. On the other hand, the threshold was only slightly changed when the previous sound was presented in the ipsilateral ear. These experiment results suggest that loudness was increased by perceiving the previous sound in the contralateral ear.

4aPP6. Induced loudness reduction. Michael Epstein (Auditory Modeling and Processing Lab., Inst. for Hearing, Speech & Lang., Dept. of Speech-Lang. Path. and Aud., Northeastern Univ., Boston, MA 02115) and Mary Florentine (Northeastern Univ., Boston, MA)

Induced loudness reduction (ILR) is a phenomenon by which a preceding higher-level tone (an inducer tone) reduces the loudness of a lower-level tone (a test tone). Under certain conditions, ILR can result in loudness reductions of 10 to 15 phons for pure tones. The strength of this effect depends on a number of parameters including: (1) the levels of both the inducer and test tones; (2) the frequency separation between the inducer and test tones; (3) the durations of the inducer and test tones; (4) the time separation between the inducer and test tones; (5) individual differences; and, possibly (6) the number of exposures to inducers. Because of the sensitivity of ILR to procedural conditions, it is quite important to consider the potential effects of ILR when considering any experimental design in which level varies. The understanding of ILR has also given insight into a number of unexplained discrepancies between data sets that were collected using different procedures. In fact, some of the variability known to affect loudness judgments may be due to ILR. [Work supported by NIH/NIDCD Grant R01DC02241.]

4aPP7. Loudness growth in individual listeners with hearing loss. Jeremy Marozeau and Mary Florentine (Commun. Res. Lab., Inst. for Hearing, Speech & Lang., Northeastern Univ., Boston, MA 02115)

Recent research indicates that there are large individual differences in how loudness grows with level for listeners with sensorineural hearing losses of primarily cochlear origin. Studies of loudness discomfort level suggest that loudness for most of these impaired listeners approaches the loudness experienced by the normal listeners at high levels. Loudness growth at low levels is still controversial. Although it is now well established that loudness at threshold is greater than zero, its exact value is unknown. If this value is the same for normal and impaired listeners, then the loudness growth for the impaired listeners must be steeper in order to catch up to normal at high levels. This phenomenon is called recruitment. If the loudness at threshold for impaired listeners is higher than that for normal listeners, then the impaired listeners will no longer be able to perceive sounds as soft. This phenomenon is called softness imperception. Results from two experiments suggest that: (1) individual differences are more important for impaired listeners than for normal listeners; (2) some impaired listeners seem to show recruitment, others softness imperception; and (3) averaging the results across the impaired listeners will mask these differences. [Work supported by NIH/NIDCD grant R01DC02241.]

4aPP8. Growth of loudness in cochlear implant listening. Robert L. Smith and Nicole Sanpetrino (Inst. for Sensory Res. and Dept. of Biomed. and Chemical Eng., Syracuse Univ., 621 Skytop Rd., Syracuse NY, 13244)

Cochlear implants (CIs) roughly mimic the transformation from sound frequency to cochlear place that occurs in acoustic hearing. However, CIs are relatively less capable of creating the intensive transformations that normal peripheral auditory processing provides. This is partly because CIs have small operating ranges on the order of 10:1 in electric current, compared to the 1 000 000:1 operating range for sound-pressure level (SPL) in acoustic hearing. Furthermore, loudness in acoustic hearing grows as a compressive power function of SPL. In contrast, loudness reportedly grows as a more expansive function of current for CI users, i.e., a power law with a large exponent or an exponential function. Our results, obtained using the minimally biased method of magnitude balance without an arbitrary standard, reveal a previously unreported range of shapes of CI loudness functions, going from linear to power laws with exponents of 5 or more. The shapes seem related in part to the etiology of deafness preceding cochlear implantation, although the shapes can vary with stimulating conditions within a subject. Furthermore, differential sensitivity to changes in current appears to be related to the shape of the corresponding loudness function. Implications for sound processing in electric and acoustic hearing will be discussed.

FRIDAY MORNING, 1 DECEMBER 2006

MOLOKAI ROOM, 8:00 A.M. TO 12:00 NOON

Session 4aSC

Speech Communication: Perception (Poster Session)

Katsura Aoyama, Cochair
Texas Tech. Univ., Health Science Ctr., Dept. of Speech-Language and Hearing Science, Lubbock, TX 79430-6073

Masato Akagi, Cochair
JAIST, School of Information Science, 1-1 Asahidai, Nomi, Ishikawa 923-1292, Japan

Contributed Papers

All posters will be on display from 8:00 a.m. to 12:00 noon. To allow contributors an opportunity to see other posters, contributors of odd-numbered papers will be at their posters from 8:00 a.m. to 10:00 a.m. and contributors of even-numbered papers will be at their posters from 10:00 a.m. to 12:00 noon.

4aSC1. Functional load of segments and features. Mafuyu Kitahara (School of Law, Waseda Univ., 1-6-1 Nishiwaseda, Shinjuku-Ku, Tokyo, Japan)

The present paper proposes a new measure of functional load for segments and features. In a nut shell, it is based on word frequencies and the number of minimal pairs in which the relevant segment/feature is crucial in distinction. For example, minimal pairs distinguished only by /t/ are most frequent in English while those distinguished by /k/ are most frequent in Japanese. As for functional load of features, single-feature contrasts and multiple-feature contrasts are incorporated in the calculation. In Japanese, [high] alone distinguishes the largest number of minimal pairs while [voice] distinguishes words most frequently in cooperation with other features. Word frequency and familiarity database for English and Japanese are used to observe the commonalities and differences in both languages with respect to the proposed measure of functional load. This line of analysis suggests a better account for a certain phonological process being more typical in one language but not in the other. Functional load can be thought of as a part of the top-down information from the lexicon, which interacts with the bottom-up perceptual information in the process of spoken word recognition. Not only the ease of articulation and perceptual salience but also the functional load drives phonological processes.

4aSC2. Cortical representation of processing Japanese phonemic and phonetic contrasts. Seiya Funatsu (The Prefectural Univ. of Hiroshima, 1-1-71 Ujinahigashi, Minami-ku, Hiroshima, 734-8558 Japan), Satoshi Imaizumi (The Prefectural Univ. of Hiroshima, Gakuen-machi Mihara, 723-0053 Japan), Akira Hashizume, and Kaoru Kurisu (Hiroshima Univ., Minami-ku Hiroshima, 734-8551 Japan)

This study investigated how Japanese speakers process phonemic and phonetic contrasts using voiced and devoiced vowel /u/ and /÷u/. During six oddball experiments, brain responses were measured using magnetoencephalography. Under the phonemic condition, a frequent stimulus /ch÷ita/ was contrasted with a deviant /ts÷uta/, and a frequent /ts÷uta/ with a deviant /ch÷ita/. Under the phonetic condition, a frequent /ts÷uta/ was contrasted with a deviant /tsuta/, and a frequent /tsuta/ with a deviant /ts÷uta/. Under the segment condition, vowel segments, /÷u/ and /u/, extracted from spoken words, were contrasted. The subjects were 13 native Japanese speakers. The equivalent current dipole moment (ECDM) was estimated from the mismatch field. Under the phonetic condition, the ECDM elicited by the voiced deviant was significantly larger than that elicited by the devoiced deviant in both hemispheres ($p<0.01$), while there were no significant deviant-related differences in ECDM under the phonemic condition in both hemispheres. Under the segment condition, the ECDM elicited by the voiced deviant and devoiced deviant did not differ significantly in either hemispheres. These results suggested that the

4a FRI. AM

ECDM asymmetries between the voiced and the devoiced deviant observed under the phonetic condition did not originate from the acoustical difference itself, but from the phonetic environment.

4aSC3. Evaluating a model to estimate breathiness in vowels.

Rahul Shrivastav, Arturo Camacho, and Sona Patel (Dept. of Commun. Sci. and Disord., Univ. of Florida, Gainesville, FL 32611)

The perception of breathiness in vowels is cued by changes in aspiration noise (AH) and the open quotient (OQ) [Klatt and Klatt, J. Acoust. Soc. Am. **87**(2), 820–857 (1990)]. A loudness model can be used to determine the extent to which AH masks the harmonic components in voice. The resulting partial loudness (PL) and loudness of AH (noise loudness; NL) have been shown to be good predictors of perceived breathiness [Shrivastav and Sapienza, J. Acoust. Soc. Am. **114**(1), 2218–2224 (2005)]. The levels of AH and OQ were systematically manipulated for ten synthetic vowels. Perceptual judgments of breathiness were obtained and regression functions to predict breathiness from NL/PL were derived. Results show breathiness to be a power function of NL/PL when NL/PL is above a certain threshold. This threshold appears to be affected by the stimulus pitch. A second experiment was conducted to determine if the resulting power function could be used to estimate breathiness in natural voices. The breathiness of novel stimuli, both natural and synthetic, was determined in a listening test. For comparison, breathiness for the same stimuli was also estimated using the power function obtained previously. Results show the extent to which findings can be generalized. [Research supported by NIH/R21DC006690.]

4aSC4. Predicting vowel inventories: The dispersion-focalization theory revisited.

Roy Becker (Dept. of Linguist., Univ. of California Los Angeles, 3125 Campbell Hall, Los Angeles, CA 90095-1543)

A revision of the dispersion-focalization theory (DFT) [Schwartz *et al.*, J. Phonetics **25**, 233–253 (1997)] is presented. Like DFT, the current computational model incorporates the center of gravity effect (COG) of 3.5-Bark spectral integration, but it deviates from DFT in that the COG contributes to the actual values and reliability weights of the perceived formants of vowels. The COG is reinterpreted as a domain of acceleration towards formant merger: the percepts of formants less than 3.5 Barks apart are perturbed towards one another in a nonlinear yet continuous fashion and their weights are increased, but perceptual merger and weight maximization occur only when the acoustic distance is about 2 Bark. Like other dispersion-based models, inventories are evaluated predominantly according to the least dispersed vowel pair, where dispersion is measured as the weighted Euclidean distance between the vowels coordinates (the first two perceived formants). Yet in the current model the weights are determined dynamically, in a well-principled manner. This model improves existing models in predicting certain universal traits, such as series of front rounded vowels in large vowel inventories, as emergent properties of certain local maxima of the inventory dispersion evaluation function, without sacrificing predictive adequacy for smaller inventories.

4aSC5. Matching fundamental and formant frequencies in vowels.

Peter F. Assmann (School of Behavioral and Brain Sci., Univ. of Texas at Dallas, Box 830688, Richardson, TX 75083), Terrance M. Nearey (Univ. of AB, Edmonton, AB, Canada T6E 2G2), and Derrick Chen (Univ. of Texas at Dallas, Richardson, TX 75083)

In natural speech, there is a moderate correlation between fundamental frequency (F0) and formant frequencies (FF) associated with differences in larynx and vocal tract size across talkers. This study asks whether listeners prefer combinations of mean F0 and mean FF that mirror the covariation of these properties. The stimuli were vowel triplets (/i/-/a/-/u/) spoken by two men and two women and subsequently processed by Kawahara's STRAIGHT vocoder. Experiment 1 included two continua, each containing 25 vowel triplets: one with the spectrum envelope (FF) scale factor fixed at 1.0 (i.e., unmodified) and F0 varied over ±2 oct, the other with F0 scale factor fixed at 1.0 and FF scale factors between 0.63 and 1.58. Listeners used a method of adjustment procedure to find the "best voice" in each set. For each continuum, best matches followed a unimodal distribution centered on the mean F0 or mean FF (F1, F2, F3) observed in measurements of vowels spoken by adult males and females. Experiment 2 showed comparable results when male vowels were scaled to the female range and vice versa. Overall the results suggest that listeners have an implicit awareness of the natural covariation of F0 and FF in human voices.

4aSC6. Acoustic cues for distinguishing consonant sequences in Russian.

Lisa Davidson and Kevin Roon (Linguist. Dept., New York Univ., 719 Broadway, 4th Fl, New York, NY 10003, lisa.davidson@nyu.edu)

In Russian, the same consonant sequences are permitted in various environments. Consequently, the presence of a word boundary or reduced vowel can be phonologically contrastive (e.g. [zədɐvatʲ] "to assign," [zdɐvatʲ] "to turn in"), and both learners and experienced listeners likely rely on fine acoustic cues to discriminate the phonotactic structures they hear. In this study, the acoustic characteristics of consonant sequences are examined to establish which cues may distinguish (a) word-initial clusters (C1C2); (b) consonant-schwa-consonant sequences (C1VC2); and (c) sequences divided by a word boundary (C1#C2). For all three sequence types, native Russian speakers produced phrases containing three categories of target sequences: stop+consonant, fricative+consonant, and nasal +consonant. Results show no significant differences in C1 burst duration for initial stops, though a longer interconsonantal duration is a reliable cue to schwa presence in C1VC2. C2 is significantly longer in C#C than in other sequences. For clusters, when C1 is a stop, there are no significant differences in duration with other sequence types, but other C1's are significantly shorter. This suggests that articulatory overlap, which may lead to C1 shortening for fricative or nasal-initial clusters, is reduced in stop-initial clusters to ensure that the stop is released and recoverable. [Research supported by NSF.]

4aSC7. Lipread me now, hear me better later: Crossmodal transfer of talker familiarity effects.

Kauyumari Sanchez, Lawrence D. Rosenblum, and Rachel M. Miller (Dept. of Psych., Univ. of California, Riverside, Riverside, CA)

There is evidence that for both auditory and visual speech perception (lipreading) familiarity with a talker facilitates speech recognition [Nygaard *et al.*, Psychol. Sci. **5**, 42 (1994); Yakel *et al.*, Percept. Psychophys. **62**, 1405 (2000)]. Explanations of these effects have concentrated on the retention of talker information specific to each of these modalities. It could be, however, that some amodal, talker-specific articulatory style information is retained to facilitate speech perception in both modalities. If this is true, then experience with a talker in one modality should facilitate perception of speech from that talker in the other modality. To test this prediction, subjects were given one hour of experience lipreading from a talker and were then asked to recover speech-in-noise from either this same talker or from a different talker. Results revealed that subjects who lipread and heard speech from the same talker performed better on the speech-in-noise task than did subjects who lipread from one talker and then heard speech from a different talker.

4aSC8. Acoustic patterns of Japanese voiced velar stops.

James Dembowski and Katsura Aoyama (Dept. Speech-Lang. & Hearing Sci., Texas Tech Univ. Health Sci. Ctr., 3601 4th St., Lubbock, TX 79430-6073, james.dembowski@ttuhsc.edu)

This presentation focuses on Japanese voiced velar /g/. The phoneme /g/ in VCV contexts is said to be characterized by a distinctive wedge-shaped formant pattern in which F2 and F3 converge toward one fre-

quency in the transition from vowel to stop closure, and then diverge as the vocal tract opens from the stop release to the following vowel. This pattern was examined using acoustic and kinematic data from an x-ray microbeam database of Japanese speakers, which is comparable to the English language x-ray microbeam speech production database [Hashi *et al.*, J. Acoust. Soc. Am. **104**, 2426–2437 (1998)]. Japanese speakers produced the expected wedge-shaped formant pattern in isolated VCV nonsense syllables, but rarely, if ever, produced this pattern in connected speech. In contrast, English speakers more frequently produced the expected formant pattern in connected speech, though the pattern was less reliably present than in isolated VCVs and varied considerably within and across speakers. These observations highlight substantial differences between controlled laboratory speech and meaningful connected speech, as well as differences in the ways that phonemes are manifested by different linguistic communities. These data also potentially illuminate the relationship among phonetic, acoustic, and kinematic levels of speech production.

4aSC9. Finding perceptual categories in multidimensional acoustic spaces.
Eric Oglesbee and Kenneth de Jong (Dept. of Linguist., Indiana Univ., Bloomington, IN 47405, eoglesbe@indiana.edu)

Examining phonetic categorization in multidimensional acoustic spaces poses a number of practical problems. The traditional method of forced identification of an entire stimulus space becomes prohibitive when the number and size of acoustic dimensions becomes increasingly large. In response to this, Iverson and Evans [ICPhS (2003)] proposed an adaptive tracking algorithm for finding best exemplars of vowels in a multidimensional acoustic space. Their algorithm converged on best exemplars in a relatively small number of trials; however, the search method took advantage of special properties of the vowel space in order to achieve rapid convergence. In this paper, a more general multidimensional search algorithm is proposed and analyzed for inherent biases. Then, using the algorithm, the phonetic categorization of /p/ and /b/ in a five-dimensional acoustic space by native speakers of English is tested. Results showed that (a) there were no substantial long-term biases in the search method and (b) the algorithm appeared to identify important acoustic dimensions in the identification of /p/ and /b/ using relatively few trials. [Work supported by NSF BCS-04406540.]

4aSC10. On the perception of epenthetic stops in American English.
Amalia Arvaniti, Ryan Shosted, and Cynthia Kilpatrick (Dept. of Linguist., UCSD, 9500 Gilman Dr., La Jolla, CA 92093, amalia@ling.ucsd.edu)

This study examines the perception of epenthetic stops in American English. Stimuli were created from *prince*, *prints*, *mince*, *mints*, *quince*, and *quints* by removing all traces of /t/ and splicing in 0–72 ms of silence, in 12-ms steps, with or without a following burst. Subjects saw the minimal pairs on screen and selected the word they heard. It was hypothesized that stimuli with bursts and longer closure would result in more *t* responses (*prince* identified as *prints*) and that frequent words (*prince/prints*) would be more difficult to distinguish than infrequent words (*quince/quints*), as our production results suggest that frequent pairs are more likely to be produced similarly. Results from 19 subjects show shorter response times with longer silence intervals, but no effect of burst or stimulus identity. Similarly, stimuli with bursts were not identified as *nts* words more frequently than those without. Generally, stimuli originating from *nts* words were more likely to be identified as such if they contained a burst, while the opposite was true for stimuli from *nce* words.

Finally, frequent words were less likely to be correctly identified than infrequent words, suggesting that /t/ epenthesis is not as widespread throughout the lexicon as generally believed.

4aSC11. Phonetic alignment to visual speech.
Rachel M. Miller, Lawrence D. Rosenblum, and Kauyumari Sanchez (Dept. of Psych., Univ. of California, Riverside, Riverside, CA 92521)

Talkers are known to produce allophonic variation based, in part, on the speech of the person with whom they are talking. This subtle imitation, or phonetic alignment, occurs during live conversation and when a talker is asked to shadow recorded words [e.g., Shockley, *et al.*, Percept. Psychophys. **66**, 422 (2004)]. What is yet to be determined is the nature of the information to which talkers align. To examine whether this information is restricted to the acoustic modality, experiments were conducted to test if talkers align to visual speech (lipread) information. Normal-hearing subjects were asked to watch an actor silently utter words, and to identify these words by saying them out loud as quickly as possible. These shadowed responses were audio recorded and naive raters compared these responses to the actors auditory words (which had been recorded along with the actors visual tokens). Raters judged the shadowed words as sounding more like the actors words than did baseline words, which had been spoken by subjects before the shadowing task. These results show that phonetic alignment can be based on visual speech, suggesting that its informational basis is not restricted to the acoustic signal.

4aSC12. New anthropomorphic talking robot—investigation of the three-dimensional articulation mechanism and improvement of the pitch range.
Kotaro Fukui, Yuma Ishikawa, Takashi Sawa, Eiji Shintaku (Dept. of Mech. Eng., Waseda Univ., 3-4-1 Ookubo, Shinjuku-ku, Tokyo, Japan), Masaaki Honda (Waseda Univ., Saitama, Japan), and Atsuo Takanishi (Waseda Univ., Shinjuku-ku, Tokyo, Japan)

We developed a new three-dimensional talking robot WT-6 (Waseda Talker-No. 6), which generates speech sounds by mechanically simulating articulatory motions as well as aeroacoustic phenomenon in the vocal tract. WT-6 consists of a 17-DOF mechanism (1-DOF lungs, 5-DOF vocal cords, 1-DOF jaws, 5-DOF tongue, and 4-DOF lips). It has 3-D lips, tongue, jaw, and velum, which form the 3-D vocal tract structure. It also has an independent jaw opening/closing mechanism, which controls the relative tongue position in the vocal tract as well as the oral opening. The previous robot, which had a 2-D tongue [J. Acoust. Soc. Am. **117**, 2541 (2005)], was not enough to realize precise closure to produce humanlike consonants such as /s/ or /r/. The new tongue, which could be controlled to form the 3-D shape, makes it possible to produce more realistic vocal tract shape. The vocal cord model was also improved by adding a new pitch control mechanism pushing from the side of the vocal cords. The pitch range becomes broader than the previous robot, which is enough to reproduce normal human speech. Preliminary experimental results showed that synthesized speech quality improves for vowels /a/, /u/ and /o/. Some experimental results and video demonstration of the talking robot will be presented.

4aSC13. The role of familiarity, semantic context, and amplitude-modulation on sentence intelligibility.
Tom Carrell (Univ. of Nebraska—Lincoln, Lincoln, NE 68583, tcarrell@unl.edu) and Dawna Lewis (Boys Town Natl. Res. Hospital, Omaha, NE 68131)

Amplitude modulation has been demonstrated to greatly improve the intelligibility of time-varying sinusoidal (TVS) sentences [Carrell and Opie, Percept. Psychophys. **52** (1992); Barker and Cooke, Speech Commun. **27** (1999); Hu and Wang, Proceedings of ICASSP-02 (2002)]. It has been argued that the improvement is due to a bottom-up process that causes the acoustically independent components of the sentences to be perceptually grouped for further analysis by the auditory system. A recent study [Shapley and Carrell, J. Acoust. Soc. Am. **118** (2005)] indicated that

semantic information did not influence intelligibility levels of TVS or modulated TVS sentences. In virtually all other studies in which speech was distorted or degraded its intelligibility was improved by appropriate semantic context [Miller, *et al.*, JEP **41** (1951)]. It is possible that listeners' unfamiliarity with TVS speech might account for the difference. With one exception every study that has employed this type of stimulus provided the listener with very few practice sentences [Lewis, AAA (2005)]. The present experiment manipulated listeners' familiarity with TVS sentences to test this notion. Participants were presented with high- and low-predictability TVS and modulated-TVS sentences. Familiarity had a large effect on perception and intelligibility. Interpretation of previous findings is reconsidered in this light.

4aSC14. On the relation of apparent naturalness to phonetic perceptual resolution of consonant manner. Robert E. Remez, Claire A. Landau, Daria F. Ferro, Judith Meer, and Kathryn Dubowski (Dept. of Psych., Barnard College, 3009 Broadway, New York, NY 10027)

How does the qualitative experience of speech influence phonetic perception? Our perceptual studies of consonant place and voicing have revealed a dichotomous relation between phonetic sensitivity and naturalness. Auditory quality and phonetic sensitivity sometimes co-vary, while in other conditions phonetic sensitivity is indifferent to huge variation in naturalness. New tests are reported extending the research to the dimension of manner, a contrast correlated with qualitatively distinct acoustic constituents in normal production. Speech synthesis techniques were used to create naturalness variants through (1) variation in the excitation of a synthetic voicing source and (2) variation in the bandwidth of the formant centers. Listeners calibrated the relative naturalness of items drawn from the test series, and the acuity of perceivers to the contrast between fricative and stop manner was estimated with cumulative d' across the series in identification tests. Combined with our prior findings, these new tests show how intelligibility and naturalness can be either perceptually orthogonal or contingent aspects of consonant dimensions, offering a tool to understand normative functions in speech perception. [Research supported by NIH (DC00308).]

4aSC15. Effects of signal levels on vowel formant discrimination for normal-hearing listeners. Chang Liu (Dept. of Commun. Sci. and Disord., Wichita State Univ., Wichita, KS 67260)

The goal of this study was to examine effects of signal levels on vowel formant discrimination. Thresholds of formant discrimination were measured for F1 and F2 of four vowels in isolated vowels and sentences at three intensity levels: 70, 85, and 100 dB SPL for normal-hearing listeners using a three-interval, two-alternative forced-choice procedure with a two-down, one-up tracking algorithm. Results showed that formant thresholds were significantly affected by formant frequency, linguistic context, and signal levels. Thresholds of formant discrimination were increased as formant frequency increased and linguistic context changed from isolated vowels to sentences. The signal level indicated a rollover effect in which formant thresholds at 85 dB SPL are lower than at either 70 or 100 dB SPL in both isolated vowels and sentences. This rollover level effect could be due to reduced frequency selectivity and reduction in active cochlear nonlinearity at high signal levels for normal-hearing listeners. Excitation and loudness models will be explored to account for the level effect on formant discrimination of isolated vowels.

4aSC16. Study on nonaudible murmur speaker verification using multiple session data. Mariko Kojima, Hiromichi Kawanami, Hiroshi Saruwatari, Kiyohiro Shikano (Nara Inst. of Sci. and Technol. 8916-5 Takayama-cho Ikoma-shi, Nara, 630-0192 Japan), and Tomoko Matsui (The Inst. of Statistical Mathematics, Minato-ku, Tokyo, 106-8569 Japan)

A study on speaker verification with nonaudible murmur (NAM) segments using multiple session data was conducted. NAM is different from normal speech and is difficult for other people to catch. Therefore, a text-dependent verification strategy can be used in which each user utters her/

his own keyword phrase so that not only speaker-specific but also keyword-specific acoustic information is utilized. A special device called a NAM microphone worn on the surface of the skin below the mastoid bone is used to catch NAM because it is too low to be recorded using ordinary microphones. However, it is tolerant to exterior noise. This strategy is expected to yield relatively high performance. NAM segments, which consist of multiple short-term feature vectors, are used as input vectors to capture keyword-specific acoustic information well. To handle segments with a large number of dimensions, a support vector machine (SVM) is used. In experiments using NAM data uttered by 19 male and 10 female speakers in several different sessions, robustness against session-to-session data variation is examined. The effect of segment length is also investigated. The proposed approach achieves equal error rates of 0.04% (male) and 1.1% (female) when using 145-ms-long NAM segments.

4aSC17. Sequential contrast or compensation for coarticulation? John Kingston, Daniel Mash, Della Chambless, and Shigeto Kawahara (Linguist. Dept., Univ. of Massachusetts, Amherst, MA 01003-9274)

English listeners identify a stop ambiguous between /t/ and /k/ more often as ''k'' after /s/ than /sh/ (Mann and Repp, 1981). Judgments shift similarly after a fricative ambiguous between /s/ and /sh/ when its identity is predictable from a transitional probability bias but perhaps not from a lexical bias (Pitt and McQueen, 1998; cf. Samuel and Pitt, 2003). In replicating these experiments, we add a discrimination task to distinguish between the predictions of competing explanations for these findings: listeners respond ''k'' more often after /s/ because they compensate for the fronting of the stop expected from coarticulation with /s/ or because a stop with an F3 onset frequency midway between /t/'s high value and /k/'s low value sounds lower after the /s/'s high-frequency energy concentration. The second explanation predicts listeners will discriminate /s-k/ and /sh-t/ sequences better than /s-t/ and /sh-k/ sequences because sequential contrast exaggerates the spectral differences between /s-k/'s high-low intervals and /sh-t/'s low-high intervals and distinguishes them more perceptually than /s-t/'s high-high intervals and /sh-k/'s low-low intervals. Compensation for coarticulation predicts no difference in discriminability between the two pairs because it does not exaggerate differences between the two intervals. [Work supported by NIH.]

4aSC18. Acoustics and perception of coarticulation at a distance. Karen Jesney, Kathryn Pruitt, and John Kingston (Ling. Dept., Univ. of Massachusetts, Amherst, MA 01003-9274)

CVC syllables were recorded from two speakers of American English, in which the initial and final stops ranged over /b,d,g/ and the vowel ranged over /i,I,e,E,ae,u,U,o,O,a/. F2 locus equations differed systematically as a function of the place of articulation of the other stop. These equation's slope and *y* intercepts were used to synthesize initial /g-b/ and /g-d/ continua in CVC syllables in which the final stop ranged over /b,d,g/ and the vowel over /e,o,a/, and the resulting stimuli were presented to listeners for identification. Listeners responded g significantly more often to both continua when the final stop was /d/ rather than /b/; the number of g responses fell between the /d/ and /b/ extremes for final /g/. This difference between final /d/ vs. /b/ is only observed when the intervening vowel is back /o,a/ and is actually reversed weakly when it is front /e/. Listeners also respond g significantly more often when the final stop is /g/ rather than /b/ and the vowel is /o,a/ but not [e]. Segments do coarticulate at a distance, listeners take this coarticulation into account, and perceptual adjustments depend on the segments through which the coarticulation is expressed. [Supported by NIH.]

4aSC19. Diphones, lexical access, and the verbal transformation effect. James A. Bashford, Jr., Richard M. Warren, and Peter W. Lenz (Dept. of Psych., Univ. of Wisconsin—Milwaukee, P.O. Box 413, Milwaukee, WI 53201-0413, bashford@uwm.edu)

When listeners are presented with a repeating verbal stimulus, adaptation occurs and perception of the stimulus is replaced by perception of a competitor. The present study examines the first of these verbal transformations reported by 180 listeners who were presented with lexical and nonlexical consonantvowel (CV) syllables that varied in frequency-weighted neighborhood density (FWND). These stimuli were produced by pairing the six English stop consonants with a set of three vowels. As expected, the majority of initial illusory forms (78%) were neighbors, differing from the stimulus by a single phoneme, and the proportion of lexical neighbors increased with stimulus FWND. Interestingly, FWND had opposite effects upon the lability of consonants and vowels: There was a strong positive correlation [$r = 0.79$, $F(17) = 26.2$, $p < 0.0001$] between FWND and the number of consonant transformations, and in contrast, there was a strong negative correlation [$r = -0.78$, $F(17) = 24.9$, $p < 0.0001$] between FWND and the number of vowel transformations. The implications of these and other findings with these simple diphones will be discussed in relation to current activation-competition theories of spoken word recognition. [Work supported by NIH.]

4aSC20. Acoustic analysis and perceptual evaluation of nasalized /g/ consonant in continuous Japanese. Hisao Kuwabara (Teikyo Univ. of Sci. & Technol., Uenohara, Yamanshi 409-0193, Japan)

It is well known that the /g/ consonant, a velar voiced plosive, in Japanese continuous speech is often nasalized unless it appears at the word-initial position. The nasalized /g/ consonant takes place in dialects mainly spoken in northern districts including the Tokyo area where the standard Japanese is spoken. However, the number of nasalized /g/ consonants is said to be decreasing year by year according to a survey. This paper deals with acoustic and perceptual analysis of this phenomenon. Test materials used in this experiment are read version of Japanese short sentences by NHK's (Japan Broadcasting Corporation) professional announcers. Each sentence includes at least one /g/ consonant that would likely be pronounced as nasalized. An evaluation test reveals that less than 60% of nasalization has been found to occur for /g/ consonants for which 100% nasalization had been observed decades ago. Acoustic analysis for nasalized and non-nasalized /g/ sounds has been performed mainly through waveform parameters. It has been found that the power ratio between consonant and vowel is the most effective parameter for distinguishing nasals from non-nasals, but it is highly speaker dependent.

4aSC21. Production and perception of place of articulation errors. Adrienne M. Stearns and Stefan A. Frisch (Univ. of South Florida, 4202 E. Fowler Ave., PCD1017, Tampa, FL 33620)

Using ultrasound to examine speech production is gaining popularity because of its portability and noninvasiveness. This study examines ultrasound recordings of speech errors. In experiment 1, ultrasound images of participants' tongues were recorded while they read tongue twisters. Onset stop closures were measured using the angle of the tongue blade and elevation of the tongue dorsum. Measurements of tongue twisters were compared to baseline production measures to examine the ways in which erroneous productions differ from normal productions. It was found that an error could create normal productions of the other category (categorical errors) or abnormal productions that fell outside the normal categories (gradient errors). Consonant productions extracted from experiment 1 were presented auditory-only to naive listeners in experiment 2 for identification of the onset consonant. Overwhelmingly, the participants heard normal productions and gradient error productions as the intended sound. Categorical error productions were judged to be different from the intended sound. The only effect of erroneous production on perception appears to be a slight increase in reaction time, which may suggest that error tokens are abnormal in some way not measured in this study.

4aSC22. Role of linguistic experience on audio-visual perception of English fricatives in quiet and noise backgrounds. Yue Wang, Haisheng Jiang, Chad Danyluck (Dept. of Linguist., Simon Fraser Univ., Burnaby, BC, V5A 1S6, Canada), and Dawn Behne (Norwegian Univ. of Sci. and Technol., Trondheim, Norway)

Previous research shows that for native perceivers, visual information enhances speech perception, especially when auditory distinctiveness decreases. This study examines how linguistic experience affects audio-visual (AV) perception of non-native (L2) speech. Native Canadian English perceivers and Mandarin perceivers with two levels of English exposure (early and late arrival in Canada) were presented with English fricative-initial syllables in a quiet and a caf-noise background in four ways: audio-only (A), visual-only (V), congruent AV, and incongruent AV. Identification results show that for all groups, performance was better in the congruent AV than A or V condition, and better in quiet than in caf-noise background. However, whereas Mandarin early arrivals approximate the native English patterns, the late arrivals showed poorer identification, more reliance on visual information, and greater audio-visual integration with the incongruent AV materials. These findings indicate that although non-natives were more attentive to visual information, they failed to use the linguistically significant L2 visual cues, suggesting language-specific AV processing. Nonetheless, these cues were adopted by the early arrivals who had more L2 exposure. Moreover, similarities across groups indicate possible perceptual universals involved. Together they point to an integrated network in speech processing across modalities and linguistic backgrounds. [Work supported by SSHRC.]

4aSC23. Voicing of /h/ in the Texas Instrument MIT (TIMIT) database. Laura Koenig (Haskins Labs, 300 George St., New Haven, CT 06511 and Long Island Univ.-Brooklyn)

Although English /h/ is traditionally described as voiceless, authors have long recognized that voiced allophones exist, especially in unstressed, intervocalic positions. In past work, we have suggested that fully voiced /h/ may be more common in men than women, but our subject population was limited in number and dialectal diversity. In this study, we use the TIMIT database to obtain measures of /h/ production in men and women speaking multiple dialects of American English. Our analysis focuses on the /h/ initiating the word "had" in a sentence produced by all speakers in the database: "She had your dark suit . . . " Each token of /h/ is coded for whether (a) the /h/ is deleted (i.e., auditorily imperceptible); and, if /h/ is present, whether (b) voicing continues unbroken and (c) there is visible aspiration noise in the speech signal. This analysis will provide baseline data on /h/ realization in a common sentence context. We will also carry out follow-up analyses on selected utterances to gain more insight into the effects of phonetic context, stress, and lexical type (e.g., content versus function word) on the characteristics of English /h/. [Work supported by NIH.]

4aSC24. On distinctions between stops and similar-place weak fricatives. James M. Hillenbrand (Speech Pathol. and Audiol., MS5355, Western Michigan Univ., Kalamazoo, MI 49008) and Robert A. Houde (Ctr. for Commun. Res., Rochester, NY 14623)

There is an extensive body of literature on the acoustic properties of both stops and fricatives. However, little attention has been paid to the acoustic features that might distinguish these two sound categories. This is unsurprising in the case of stops versus strong fricatives since these sounds are rarely confused. Stops and weak fricatives, on the other hand, are frequently confused [G.A. Miller and P.E. Nicely, J. Acoust. Soc. Am. **27**, 338–352 (1955)]. The present study was undertaken in a search for acoustic features that might distinguish the stop/weak fricative pairs /b/–/v/ and /d/–/dh/ (i.e., /d/ vs voiced th). Speech material consisted of CV and VCV syllables spoken by five men and five women, using the vowels /a/, /i/, and /u/. A combination of two features reliably separated

the stops from weak fricatives: (1) intensity during the consonant occlusion interval (typically greater for the fricatives), and (2) the rate of increase in mid- and high-frequency energy (above 1 kHz) associated with consonant release (typically greater for the stops).

4aSC25. Salience of virtual formants as a function of the frequency separation between spectral components.

Robert A. Fox, Ewa Jacewicz, Chiung-Yun Chang, and Jason D. Fox (Speech Acoust. and Percpt. Labs, Dept. of Speech and Hearing Sci., Ohio State, 110 Pressey Hall, 1070 Carmack Rd., Columbus, OH 43210-1002)

The center-of-gravity (COG) hypothesis proposed by Chistovich and others for the perception of static vowels suggests that auditory spectral integration may occur when two or more formants fall within a 3.5 bark bandwidth. While several studies have examined the bandwidth limits of such integration, this study examines the extent to which spectral integration is uniform within this putative 3.5-bark range. We examine the perceptual salience of virtual formants produced by modifying the spectral COG of two closely spaced narrow-bandwidth resonances. Three different vowel series were created: [i-ɪ], [ʌ-ɑ] and [ə-ɚ]. A second set of vowels was then created in which one of the formants (F1 in [i-ɪ], F2 in [ʌ-ɑ] and F3 in [ə-ɚ]) was replaced by a virtual formant whose COG matched that of the formant that had been removed. The frequency separation between the two component resonances was then systematically varied between 1.5 and 3.5 barks and a singleinterval 2AFC vowel identification task was used to obtain estimates of vowel quality for each series step. Results will be discussed in terms of whether the spectral integration effects within the 3.5 bark decline as the frequency separation between the resonance components increases. [Work supported by NIDCD R01DC00679-01A1.]

4aSC26. Frequency effects in phoneme processing.

Danny R. Moates, Noah E. Watkins, Zinny S. Bond, and Verna Stockmal (Inst. for the Empirical Study of Lang., Ohio Univ., Athens, OH 45701, moates@ohio.edu)

Are phonological segments activated during word recognition in proportion to their frequency of use? Previous evidence for this hypothesis [Moates *et al.*, *Laboratory Phonology 7*, edited by Gussenhoven and Warner (Mouton de Gruyter, 2002)] used a word reconstruction task. The present study used an online task, the gating task, in which progressively longer fragments of a word are presented to listeners who must identify the word in as few gates as possible. High- and low-frequency segments were contrasted by presenting them in word pairs that differed only in those two segments, e.g., label versus cable, where /l/ is used more frequently than /k/ [M. K. Vitevich and P. A. Luce, Behav. Res. Methods, Instrum. Comput. **36**, 481–487 (2004)]. We constructed 30 pairs of two-syllable words for which the contrasting segments were at the first syllable onset, 30 more for the second syllable onset, and 30 more for the coda of a syllable. Identification judgments were gathered from 120 participants. *t* tests showed high-frequency segments to be identified at significantly earlier gates than their matched low-frequency segments for first onset and coda, but not second onset. These results offer further evidence for sublexical processes in spoken word recognition.

4aSC27. The clustering coefficient of phonological neighborhoods influences spoken word recognition.

Michael Vitevitch (Dept. of Psych., Univ. of Kansas, 1415 Jayhawk Blvd., Lawrence, KS 66045-7556)

Neighborhood density refers to the number of words, or neighbors, that are phonologically related to a given word. For example, the words BAT, MAT, CUT, and CAN (among others) are considered phonological neighbors of the word CAT. In contrast, the clustering coefficient of the neighborhood refers to the proportion of phonological neighbors that are also neighbors of each other. Among the neighbors of CAT, the words BAT and MAT are neighbors of each other, but the words BAT and CAN are not neighbors of each other. Despite the stimulus words having the same number of neighbors overall, the results of an auditory lexical decision task showed that words with a high clustering coefficient (i.e., most neighbors were also neighbors of each other) were responded to more quickly than words with a low clustering coefficient (i.e., few neighbors were also neighbors of each other). These results suggest that some aspects of phonological similarity (i.e., clustering coefficient) might facilitate lexical activation, whereas other aspects of phonological similarity (i.e., neighborhood density) influence a later, decision stage of processing characterized by competition among activated word-forms. [Work supported by NIH.]

4aSC28. The influence of noise and reverberation on vowel recognition: Response time.

Magdalena Blaszak and Leon Rutkowski (Div. of Rm. Acoust. and Psychoacoustics, Adam Mickiewicz Univ., Umultowska 85, 61-614 Poznan, Poland)

This study examines the perceptual effect of two types of noise and reverberation on vowel recognition. Multitalker babble and traffic noise (European Standard EN 1793–3) were generated simultaneously with Polish vowels /a, e, i, o, u, y/ in two different sound fields and an anechoic chamber. The experiment was performed under various conditions of signal-to-noise ratio (-9, -6, -3, 0, $+3$, no noise). A new procedure for listeners' selection based on the Bourdon's psychometrics test was proposed. The effects of noise and reverberation were quantified in terms of (a) vowel recognition scores for young normal-hearing listeners (YNH) and (b) *ease of listening* based on the time of response and subjective estimation of difficulty. Results of the experiment have shown that (a) the response time can be a good measure of the effect of noise and reverberation on the speech intelligibility is rooms, and (b) in this type of experiment, of great significance is the choice of the subjects based on the psychometric tests.

4aSC29. Quantifying the benefits of sentence repetition on the intelligibility of speech in continuous and fluctuating noises.

Isabelle Mercille, Roxanne Larose, Christian Giguère, and Chantal Laroche (Univ. of Ottawa, 451 Smyth Rd., Ottawa, ON, Canada K1H 8M5)

Good verbal communication is essential to ensure safety in the workplace and social participation during daily activities. In many situations, speech comprehension is difficult due to hearing problems, the presence of noise, or other factors. As a result, listeners must often ask the speaker to repeat what was said in order to understand the complete message. However, there has been little research describing the exact benefits of this commonly used strategy. This study reports original data quantifying the effect of sentence repetition on speech intelligibility as a function of signal-to-noise ratio and noise type. Speech intelligibility data were collected using 18 normal-hearing individuals. The speech material consisted of the sentences from the Hearing In Noise Test (HINT) presented in modulated and unmodulated noises. Results show that repeating a sentence decreases the speech reception threshold (SRT), as expected, but also increases the slope of the intelligibility function. Repetition was also found to be more beneficial in modulated noises (decrease in SRT by 3.2 to 5.4 dB) than in the unmodulated noise (decrease in SRT by 2.0 dB). The findings of this study could be useful in a wider context to develop predictive tools to assess speech comprehension under various conditions.

4aSC30. The effect of the spectral shape changes on voice perception.

Mika Ito, Bruce R. Gerratt, Norma Antonanzas-Barroso, and Jody Kreiman (Div. of Head/Neck Surgery, UCLA School of Medicine, 31-24 Rehab Ctr., Los Angeles, CA 90095-1794, jkreiman@ucla.edu)

Researchers have long known that the shape of the vocal source spectrum is an important determinant of vocal quality, but the details regarding the importance of individual spectral features remains unclear. Previous research indicates four spectral features, H1-H2, the spectral slope above 4 kHz, the slope from 1.5–2 kHz, and the slope from 2–4 kHz, account for

virtually all the variability in spectral shapes. The present study provides preliminary evidence about the perceptual importance of these four features. Four series of stimuli were synthesized for each spectral parameter, in which that parameter varied in small steps. Because the perceptual salience of source parameters depends on F0 and on the spectrum of the inharmonic part of the source, series differed in the sex of the speaker (male/female) and in the NSR (noise-free/very noisy). Listeners heard all possible pairs of voices within each series and were asked to determine whether stimuli were same or different. We hypothesize that listeners sensitivity to H1-H2 and the slope of the spectrum from 1.5–2 kHz will be independent of noise, but that sensitivity to changes in the spectral shape above 2 kHz will depend on the amount of noise excitation present in the voice.

4aSC31. The use of auditory and visual information in the perception of stress in speech. James Harnsberger, Daniel Kahan, and Harry Hollien (Inst. for Adv. Study of the Commun. Proc., Univ. of Florida, Gainesville, FL 32611)

Prior work on the acoustic correlates of the perception of psychological stress in speech has suffered from the problem of quantifying and verifying the extent to which a speaker was under stress during articulation. Two experiments were conducted to address this issue. First, stressed and unstressed speech samples were elicited from 78 speakers of American English. Stressed samples were recorded by having subjects read a standard passage while under the threat of the administration of mild electric shock. Both visual and audio recordings were collected. Stress was quantified in terms of four measures: two physiological (pulse rate and galvanic skin response) and two self-report scales. Sentences from the 16 speakers showing the largest differences between the stressed and unstressed conditions were then presented in a paired comparison task to 90 naive listeners, 30 each in three conditions: (1) audio-only presentation of the stimuli, (2) visual-only presentation of the stimuli, and (3) audiovisual presentation of the stimuli. The results indicate that individual listeners are sensitive to stress cues in speech in all three conditions.

4aSC32. Selective attention and perceptual learning of speech. Alexander L. Francis (Dept. of Speech, Lang. & Hearing Sci., Purdue Univ., West Lafayette, IN 47907), Natalya Kaganovich, and Courtney Driscoll (Purdue Univ., West Lafayette, IN 47907)

Phonetic experience can change the perceptual distance between speech sounds, increasing both within-category similarity and between-category distinctiveness. Such warping of perceptual space is frequently characterized in terms of changes in selective attention: Listeners are assumed to attend more strongly to category-differentiating features while ignoring less relevant ones. However, the link between the distribution of selective attention and categorization-related differences in perceptual distance has not been empirically demonstrated. To explore this relationship, listeners were given 6 h of training to categorize sounds according to one of two acoustic features while ignoring the other. The features were voice onset time and onset $f0$, which are normally correlated and can both serve as a cue to consonant voicing. Before and after training, listener's performance on a Garner selective attention task was compared with assessment of the perceptual distance between tokens. Results suggest that training can induce both warping of perceptual space and changes in the distribution of selective attention, but the two phenomena are not necessarily related. Results are consistent with a two-stage model of perceptual learning, involving both preattentive adjustment of acoustic cue weighting and higher-level changes in the distribution of selective attention between acoustic cues. [Work supported by NIH-NIDCD 1R03DC006811.]

4aSC33. Investigation of interaction between speech perception and production using auditory feedback. Masato Akagi, Jianwu Dang, Xugang Lu, and Taichi Uchiyamada (School of Information Sci., JAIST, 1-1 Asahidai, Nomi, Ishikawa 923-1292, Japan)

This study employed an auditory feedback paradigm with perturbed fed-back speech to investigate interaction between speech perception and production by measuring simultaneous fluctuations of speech production organs using the electromyographic (EMG) signals, articulatory movements, as well as spectral analyses, where the articulatory data were obtained by the electromagnetic articulographic (EMA) system. Chinese vowels pair [i]-[y] and Japanese vowels pairs [e]-[a], [e]-[i] and [e]-[u] were chosen as the experimental objects. When the speaker is maintaining the first vowel, the feedback sound is randomly changed from the first vowel to the second one in each pair by manipulating the first three formants. Spectral analysis showed that a clear compensation was seen in the first and second formants of the vowels. Analyses of EMG and EMA signals also showed muscle reactivation and tongue movements to compensate for the perturbations. Latency of the compensating response is about 150 ms to start and about 290 ms for maximum compensation from the onset of the perturbation. According to the measurements, it seems that in most cases the speaker attempts to compensate for the ''error'' caused by the auditory perturbation by a real-time monitoring, and the auditory feedback takes place simultaneously often during speech production.

4aSC34. Cross-ear suppression of the verbal transformation effect: Tweaking an acoustic-phonetic level. Peter W. Lenz, James A. Bashford, Jr., and Richard M. Warren (Dept. of Psych., Univ. of Wisconsin—Milwaukee, P.O. Box 413, Milwaukee, WI 53201-0413, plenz@uwm.edu)

A recorded word repeating over and over undergoes a succession of illusory changes. When two images of the same repeating word are presented dichotically, with a half-cycle delay preventing fusion, the two images of the word each undergo independent illusory transformations at a rate equivalent to that of a single image [Lenz *et al.*, J. Acoust. Soc. Am. **107**, 2857 (2000)]. However, with one phoneme difference (e.g., ''dark'' versus ''dart''), transition rate is dramatically suppressed [Bashford *et al.*, J. Acoust. Soc. Am. **110**, 2658 (2001)]. Rates decrease with extent of feature mismatch at a single phoneme position (roughly 30% reduction with one feature mismatch and 45% with three). Rates also decrease with the number of mismatched phonemes (about 80% rate reduction with three out of four), suggesting a strong acoustic-phonetic basis for verbal transformation suppression. In contrast, semantic relations had no effect (e.g., transformations for ''light'' were suppressed equally by contralateral night and ''might''). Dichotic competition appears to allow us to access and selectively influence a prelexical stage of linguistic analysis. [Work supported by NIH.]

4aSC35. Perceptually balanced filter response for binaural dichotic presentation to reduce the effect of spectral masking. Pandurangarao N. Kulkarni, Prem C. Pandey (Elec. Eng. Dept, Indian Inst. of Technol. Bombay, Powai Mumbai 400076, India, pcpandey@ee.iitb.ac.in), and Dakshayani S. Jangamashetti (Basaveshwar Eng. College Bagalkot, Bagalkot Karnataka 587102, India)

Earlier investigations show that the scheme of binaural dichotic presentation with spectral splitting of speech signal helps in reducing the effect of spectral masking for persons with moderate bilateral sensorineural hearing impairment. Speech perception improved by employing filters with interband crossover gain adjusted between 4 and 6 dB below the pass band gain. The relationship between scaling factors for a tone presented to the two ears, so that perceived loudness is that of a monaural presentation, is investigated for design of comb filters with improved perceptually balanced response. Results from the listening tests show that, for perceptual balance, the sum of the two scaling factors should be constant, indicating that the magnitude response of the comb filters should be complementary on a linear scale.

4aSC36. The organization of bilingual perceptual consonant space: English/Spanish bilingual perception of Malayalam nasal consonants. Jenna Silver and James Harnsberger (Inst. for Adv. Study of the Commun. Proc., Univ. of Florida, Gainesville, FL 32611)

This study examines the capacity of English/Spanish bilinguals to discriminate between consonants that exist in only one of their respective phonetic inventories. Two non-native nasal consonant contrasts were tested: dental versus alveolar and the palatal versus velar, both found in Malayalam. The dental and palatal nasals appear in Spanish, while the alveolar and velar nasals occur in English. Poorer performance in discrimination was interpreted as indicative of a common nasal category subsuming the Spanish dental and English alveolar nasals; better performance was taken as evidence of the maintenance of separate categories from both languages. Two other tests were administered to aid in the interpretation of the discrimination test scores: forced-choice identification and perceptual similarity ratings. The findings of this research will be used to characterize the perceptual consonant space in terms of continuum between two possible bilingual systems: one that collapses similar categories across languages or one that maintains two distinct phonological systems that can be accessed simultaneously. It is believed that bilinguals will be able to discriminate between these contrasts more consistently than their monolingual peers; however, there is no prediction about performance relative to the monolingual group from Malayalam.

4aSC37. Agreement and reliability using reference-matching paradigm in perceptual voice quality rating in Chinese and English. Mandy Ho and Edwin Yiu (Voice Res. Lab., Div. of Speech & Hearing Sci., Univ. of Hong Kong, 5/F Prince Philip Dental Hospital, Hong Kong)

Perceptual voice judgment is commonly used in clinical voice quality evaluation. The use of a referencematching paradigm in perceptual ratings has been shown to improve both agreement and reliability (Yiu *et al.*, in press). This study set out to investigate the agreement and reliability in rating Chinese and English dysphonic stimuli using the reference-matching paradigm. Experiment 1 aimed to synthesize Chinese and English dysphonic stimuli with different breathy and rough severity levels using the HLSyn Speech Synthesizer. Seven representative anchors (references) for each of the rough and breathy series in Chinese and English were chosen by three judges to be used in experiment 2. Acoustic analysis of the anchor series indicated they were of increasing severity. Experiment 2 recruited ten native Chinese and ten native English subjects to rate the quality of Chinese and English dysphonic voice samples using the synthesized anchor as references. Results showed that listeners achieved nearly 90% agreement in rating the Chinese stimuli and 80% agreement in rating the English stimuli regardless of their language background. The study showed that the reference-matching paradigm was a reliable method in rating dysphonic stimuli across listeners with different language backgrounds.

4aSC38. Learning to perceive non-native speech sounds: The role of test stimulus variability. McNeel Jantzen and Betty Tuller (Ctr. for Complex Systems and Brain Sci., Florida Atlantic Univ., 777 Glades Rd., Boca Raton, FL 33431)

Natural speech stimuli used in studies of phonological learning usually include several in talkers and phonetic environments because variability aids learning [e.g., Lively, Logan, and Pisoni, J. Acoust. Soc. Am. (1993)]. The present study investigated whether nonphonetic variability in the synthetic test set has a similar effect. First, a perceptual mapping procedure was performed using a synthetic continuum that ranged from the Malayalam voiced, unaspirated, dental stop consonant to the American English alveolar [d], with three $F0$ contours (low, mid, and high). Subjects identified the stimuli (2AFC) and judged their goodness as exemplars of each category. Subjects then received 15 sessions (one/day) of 2AFC training with feedback using natural stimuli produced by native Malayalam speakers, and performed difference ratings on a subset of pairs from the syn-

thetic stimuli. The perceptual mapping procedure was repeated at 1 and 14 days post-training and results compared with a parallel experiment that included only the midlevel $F0$ contour in the synthetic test set. [Work supported by NSF.]

4aSC39. Influence of the prosody of spoken language on recognition and memory for vocal quality. Sumi Shigeno (Aoyama Gakuin Univ., 4-4-25 Shibuya, Shibuya-ku, Tokyo, 150-8366 Japan)

This study examined whether recognition and memory for vocal quality of a speaker who speaks either a native language or non-native language should be influenced by the prosody of the language that the speaker utters. Voices of 12 speakers were recorded. They were six Japanese people and six Americans and Britons. All speakers uttered short sentences in their respective native languages (i.e., Japanese for Japanese speakers and English for Americans and Britons) and in a non-native language (i.e., English for Japanese speakers and Japanese for Americans and Britons). Ten Japanese participants rated the vocal quality of speakers in the first session. After 1 week the same experiment was again conducted in the second session. Results showed that the performance of identification of speakers as Japanese or as non-Japanese was comparatively accurate even though the ratings on the speakers' voices were varied as the language spoken by the speakers. Ratings of the voices were compared further between two sessions and little difference was found, irrespective of a 1-week blank. Results suggest that the memory for vocal quality is robust, but that the recognition of vocal quality is dependent on the prosody of the language spoken by speakers.

4aSC40. Brain activity during auditory processing affected by expectation of speech versus nonspeech. Yukiko Nota (ATR CIS BAIC, 2-2-2 Hikaridai, Keihanna Sci. City, Kyoto 619-0288, Japan, ynota@atr.jp)

fMRI was used to clarify whether there is any differential brain activity invoked by expectation for speech versus nonspeech sounds. Auditory stimuli were created by acoustically morphing between either sustained vowels or tones, respectively, and a buzz sound. The two sets of interpolation were performed in nine nonlinear steps; the stimuli retained for perceptual experiments were only the three most vowel-like, the three most tone-like, and the three most buzz-like tokens morphed from the vowels. In the "speech expectation" session, subjects were instructed to discriminate the vowel-like and buzz-like stimuli; in the "nonspeech expectation" session, subjects were instructed to discriminate the tone-like and buzz-like stimuli without knowing that the buzz stimuli had been morphed from the vowels. Thus the buzz-like stimuli in both experiments were the same, but the subjects' expectations were different because they were told to expect either speech (vowel-like) or nonspeech (tone-like) stimuli. Comparison of brain activation during processing of the buzz-like stimuli under these two conditions revealed that BA40 and thalamus were more activated in speech expectation, while right BA20 was more activated in nonspeech expectation. These results suggest that subjects' speech/nonspeech expectation for sound stimuli influences brain activity for actual auditory processing. [Work supported by MEXT.]

4aSC41. Representations involved in short-term versus long-term word learning by preschool children with and without phonological disorders. Holly Storkel, Jill Hoover, and Junko Maekawa (Dept. of Speech-Lang.-Hearing, Univ. of Kansas, 1000 Sunnyside Ave., 3001 Dole Ctr., Lawrence, KS 66045-7555, hstorkel@ku.edu)

This study explores whether sublexical (i.e., individual sound) and/or lexical (i.e., whole-word) representations contribute to word learning and whether these contributions change across short-term versus long-term learning. Sublexical representations were indexed by phonotactic probability, the likelihood of occurrence of a sound sequence, whereas lexical representations were indexed by neighborhood density, the number of

similar sounding words. Thirty-four preschool children participated in a short-term word learning task that exposed them to nonwords varying in phonotactic probability and neighborhood density and tested learning of these nonwords. Long-term learning was assessed through comprehension and production of real words varying in phonotactic probability and neighborhood density. Results showed that phonotactic probability and neighborhood density equally influenced short-term word learning. In contrast, long-term word learning was affected primarily by neighborhood density. Thus, both sublexical and lexical representations appeared to play a role in short-term learning, but only lexical representations played a primary role in long-term retention. This pattern held for both children with normal phonological development and children with phonological delays. However, the direction of the effect of neighborhood density for short-term word learning varied by group status, suggesting differences in the use of lexical representations during short-term learning. [Work supported by NIH.]

4aSC42. Changes in formant frequencies associated with postural change in adult male speakers over 50 years old. Michiko Hashi, Tomoki Nanto, and Natsuki Ohta (Prefectural Univ. of Hiroshima, 1-1 Gakuen-cho, Mihara, Hiroshima, Japan)

It is possible that changes of direction of gravity relative to the vocal tract associated with changes in posture influence acoustic characteristics of speech including vowel formant frequencies. Studies examining such effects had produced mixed results and demonstrated the possibility of substantive interspeaker variability in the effect of postural changes on vowel formant frequencies. Recent work by Takakura *et al.* ["Changes in formant frequencies associated with postural change," paper presented at the Fall meeting of Acoustical Society of Japan (2006)], using young adult male speakers, revealed a small number of speakers demonstrating changes in vowel formant frequencies and suggested effect of age. The present study attempts to examine changes of vowel formant frequencies in upright and supine position among older male speakers. Attempts will be made to eliminate the effect of differences in neck position between the postures through the use of a power-bead-based neck stabilizer. The results will be compared with data from young normal speakers in the previous study and inferences will be made relative to speech production models.

4aSC43. The effect of viewing angle on the visual contribution to speech intelligibility in noise. Eugene Brandewie, Douglas Brungart, Nandini Iyer, and Brian Simpson (Air Force Res. Lab., Wright–Patterson AFB, Ohio 45433-7901)

Visual cues are known to assist speech comprehension in noisy environments, but relatively little is known about the impact that viewing angle has on the visual contribution to speech intelligibility. In this experiment, four digital cameras were used to make simultaneous recordings of test phrases from the Modified Rhyme Test at four different viewing angles: 0, 45, 90, and 135 deg. These test phrases were used to measure the effect of viewing angle on the intelligibility of noise-masked speech stimuli that were presented with and without visual cues at seven different signal-to-noise ratios (SNRs). When the face was viewed from the front, the visual cues provided an intelligibility improvement that was equivalent to a 6–10-dB increase in SNR. This visual benefit remained roughly constant for viewing angles up to 90 deg, but it dropped off rapidly (to less than 2 dB) when the viewing angle increased to 135 deg. The results suggest that the visual contribution to speech perception is severely impaired when the observer does not have access to an unobstructed view of the talker's mouth.

4aSC44. Towards estimation of Japanese intelligibility scores using objective voice quality assessment measures. Rui Kaga, Kazuhiro Kondo, Kiyoshi Nakagawa, and Masaya Fuzimori (Yamagata Univ., Jounan 4-3-16, Yonezawa, 992-8510, Yamagata, Japan)

We investigated the use of objective quality measures to estimate the intelligibility of Japanese speech. We initially focused on PESQ (perceptual evaluation of speech quality), which is the state-of-the-art objective assessment method, and can estimate the mean opinion scores (MOS) at an extremely high accuracy. Since we can assume that speech quality is correlated with intelligibility, it should be possible to estimate the intelligibility from the estimated opinion scores or some of its derivatives. We tried to estimate the intelligibility of the Japanese Rhyme Test (DRT). The DRT uses minimal word pairs whose initial phone differs by one phonetic feature. We estimated the MOS of the DRT word samples mixed with noise and tried to correlate this with the measured intelligibility. However, the estimated MOS showed no difference between phonetic features. However, the difference in the estimated MOS between the word pairs seems to differ by a phonetic feature for SNR above 10 dB, which suggests that the estimation of intelligibility by a phonetic feature may be possible. We also plan to selectively use the internal data used to calculate the MOS estimate for better intelligibility estimation.

4aSP1. Adaptive beamforming for multipath environments. Henry Cox (Lockheed Martin, IS&S, AC3DI, 4350 North Fairfax Dr., Ste. 470, Arlington, VA 22203)

Coherent multipaths present a significant challenge to most adaptive beamformers because they violate the common assumption of a rank-one plane wave or geometrically focused signal. When the multipath arrivals that characterize shallow water propagation are resolvable by the array's aperture, the mismatch between the assumed and the true signal spatial structure causes signal suppression. If the amplitude and phase relationships among the various multipaths were known, they could, in principle, be included in a matched field beamforming approach. This is usually impractical due to inadequate knowledge of propagation parameters, especially bottom characteristics, and source/receiver motion. A generalization of the standard MVDR approach, called multirank MVDR, assumes only that the signal lies in a subspace of multiple rank rather than the usual rank-one assumption. An example of a subspace is a small fan of beams that cover the potential multipath directions. The signal may be rank one corresponding to fully coherent multipath or higher rank corresponding to incoherent or partially coherent multipath. The multirank approach is applied to the shallow water multipath problem and compared with the related technique of employing multiple linear constraints. Realistic simulations of alternative beamforming approaches for a large horizontal array are presented. [Work supported by ONR.]

4aSP2. Robust adaptive algorithm based on nonlinear error cost function for acoustic echo cancellation. Suehiro Shimauchi, Yoichi Haneda, and Akitoshi Kataoka (NTT Cyber Space Labs., NTT Corp., 3-9-11, Midori-cho, Musashino-shi, Tokyo, 180-8585, Japan, shimauchi.suehiro@lab.ntt.co.jp)

Motivated by recent progress in the blind source separation (BSS) technique, a robust echo cancellation algorithm is investigated, which would inherently identify the echo path even during double-talk by separating the acoustic echo from the local speech. An adaptive filter has been introduced into acoustic echo cancellers to identify the acoustic echo path impulse response and generate the echo replica. However, most adaptive algorithms suffer from instability during double-talk. Although step-size control cooperating with a double-talk detector (DTD) is a promising approach to stop the adaptation temporarily during double-talk, it cannot handle the echo path change during double-talk. To overcome this problem, novel robust algorithms are derived by applying nonlinearity to the cost function of a conventional echo cancellation algorithm such as the normalized least mean squares algorithm (NLMS) or the affine projection algorithm (APA). Using the simulation results, there is a discussion about how the robustness of the derived algorithms depends on the choice of the nonlinear function and the original algorithm.

4aSP3. Realistic modeling of adaptive beamformer performance in nonstationary noise. Bruce K. Newhall (Appl. Phys. Lab., Johns Hopkins Univ., 11100 Johns Hopkins Rd., Laurel, MD 20723)

Most adaptive beamformers (ABFs) operate under the assumption that the noise field is quasistationary. They estimate the present noise field by averaging, assuming stationarity over the estimation time. The adaptive beamformer responds to slow changes in the noise field across multiple estimation intervals. Unfortunately, in many low-frequency underwater sound applications, the shipping noise may change rapidly, due to nearby ship motion. This motion can be significant during the estimation interval and degrade ABF performance. A realistic model has been developed, including two effects of source motion on horizontal towed arrays. Bearing rate produces a differential Doppler shift across the array. Range rate produces an amplitude modulation as the multipath interference pattern shifts along the array. The ABF model begins with a realization of ship locations and motion based on historical shipping density. Each ship generates realistic random noise composed of tonals in a broadband background. The noise is propagated from each ship to each hydrophone by a normal mode model. For each time sample the position of each ship is updated and propagation recalculated. The ability of a variety of ABF algorithms to reduce shipping noise clutter is simulated and compared.

4aSP4. Multichannel active noise control system without secondary path models using the simultaneous perturbation algorithm.

Yoshinobu Kajikawa and Yasuo Nomura (Faculty of Enginnering, Kansai Univ., 3-3-35, Yamate-cho, Suita-shi, Osaka 564-8680, Japan, kaji@joho.densi.kansai-u.ac.jp)

This paper presents a novel multichannel active noise control (ANC) system without secondary path models. This ANC system uses a simultaneous perturbation algorithm as the updating algorithm and has an advantage that secondary path models (estimation of secondary paths) are not required, unlike the MEFX (multiple error filtered-X)-based ANC. This system can consequently control noise stably because there are not modeling errors that cause system instability. The computational complexity is also very small. Experimental results demonstrate that the proposed multi-channel ANC system can operate stably under the environment where the error microphones always move.

Contributed Papers

4aSP5. Two-microphone system using linear prediction and noise reconstruction.

Hirofumi Nakano, Kensaku Fujii (Dept. of Comput. Eng., Univ. of Hyogo, 2167 Shosya, Himeji 671-2201, Japan, er06j025@steng.u-hyogo.ac.jp), Tomohiro Amitani, Satoshi Miyata (TOA Corp., Takarazuka Hyogo 665-0043, Japan), and Yoshio Itoh (Tottori Univ., Japan)

This study proposes a new adaptive microphone system that is characterized by a linear prediction circuit inserted previous to a noise reconstruction filter corresponding to an adaptive delay used in conventional systems. This insertion provides various advantages to the adaptive microphone system. One is that steering a null for a noise source becomes possible irrespective of the incidence of speech signal. Another is that the new microphone system works as an omnidirectional microphone for the speech signal. Consequently, setting the microphones at arbitrary intervals is possible. For example, building one microphone in a handset and another into a telephone baseset becomes possible, which provides higher noise reduction effect. In practical use, microphone systems must function in reflective surroundings. In this study, such performance of the proposed system is verified first using computer simulations and then using an experimental system put in an ordinary room. This study also presents experimental results verifying that the proposed system can successfully reduce noise incident from the same direction as a speech signal, as well as crowd noise recorded in an airport.

4aSP6. Adaptive beamformer trade-off study of an expendable array for biologic vocalizations.

Juan Arvelo (Appl. Phys. Lab., Johns Hopkins Univ., 11100 Johns Hopkins Rd., Laurel, MD 20723-6099)

Adaptive beamformers exploit the ambient noise anisotropy to increase the array gain against this background, enhance target detection, and increase the resolution of the beam response. A prototype expendable array was developed and tested for high-frequency passive detection and localization of marine mammals. This latest array consists of vertical poly-(vinylidene fluoride) (PVDF) wire elements arranged in a horizontal 6 $\times$6 grid with the corner elements removed for a total of 32 lines. The length of the wires forms a vertical beam response that allows exploitation of the ambient noise directionality in elevation while the horizontal aperture provides full coverage in azimuth. The performance and computational demand of selected adaptive and conventional beamformers are compared in a trade-off study to determine their possible use in this expendable system. This trade-off study accounts for the demand of computational resources in addition to the predicted system performance as adjuncts to ocean observatories. [This effort is partly supported by JHU/APL and the Office of Naval Research (ONR).]

4aSP7. Adaptive matched field processing enhancements to forward sector beamforming.

Jeffrey A. Dunne (Appl. Phys. Lab., Johns Hopkins Univ., 11100 Johns Hopkins Rd., Laurel, MD 20723)

A study was undertaken to examine the potential benefit of adaptive matched field processing (AMFP) to the forward sector capability of single-line, twin-line, and volumetric arrays. Comparisons are made with conventional MFP (CMFP) and adapative and conventional plane-wave beamforming (APWB and CPWB) in order to assess the degree of own-ship noise reduction obtainable and any corresponding improvement to the signal-to-noise ratio (SNR). A minimum variance distortionless response beamformer using dominant mode rejection was implemented, applied to both uniform and distorted array shapes. Significant improvement over CMFP and CPWB in tracking and SNR was seen for modeled data in both cases, with the distorted array showing, not surprisingly, better left-right rejection capability. [Work was undertaken with support from the Defense Advanced Research Projects Agency (DARPA) Advanced Technology Office (ATO).]

4aSP8. Vector sensor array sensitivity and mismatch: Generalization of the Gilbert-Morgan formula.

Andrew J. Poulsen and Arthur B. Baggeroer (MIT, Cambridge, MA 02139, poulsen@mit.edu)

The practical implementation of any sensing platform is susceptible to imperfections in system components. This mismatch or difference between the assumed and actual sensor configuration can significantly impact system performance. This paper addresses the sensitivity of an acoustic vector sensor array to system mismatch by generalizing the approach used by Gilbert and Morgan for an array with scalar, omnidirectional elements [E.N. Gilbert and S.P. Morgan, Bell Syst. Tech. J. **34**, (1955)]. As such, the sensor orientation is not an issue because it does not affect performance for an array of omnidirectional sensors. Since vector sensors measure both the scalar acoustic pressure and acoustic particle velocity or acceleration, the sensor orientation must also be measured to place the vector measurement in a global reference frame. Here, theoretical expressions for the mean and variance of the vector sensor array spatial response are derived using a Gaussian perturbation model. Such analysis leads to insight into theoretical limits of both conventional and adaptive processing in the presence of system imperfections. Comparisons of theoretical results and simulations are excellent. One noteworthy result is the variance is now a function of the steering angle. [Work supported by the PLUSNeT program of the Office of Naval Research.]

4aSP9. Adaptive filtering using harmonic structure of voiced speech for reducing nonstationary known noise. Kenko Ota, Masuzo Yanagida (Doshisha Univ., 1-3, Tarata-Miyakodani, Kyotanabe, Kyoto, 610-0321, Japan, etf1704@mail4.doshisha.ac.jp), and Tatsuya Yamazaki (NICT, 619-0289, Kyoto, Japan, yamazaki@nict.go.jp)

Proposed is an effective method for reducing nonstationary known noise. The objective of this research is to develop a scheme of preprocessing for speech recognition that keeps the same speech recognition rate even in a worse acoustic environment and to realize a TV control system using speech recognition. The basic idea of the proposed method is to estimate the frequency spectrum of noise including sounds from the TV itself and to remove noise components from the frequency spectrum of the received signal. A transfer function from the TV set to the microphone is calculated in an iterative manner estimating the noise signal at the microphone. Traditional ANC techniques do not directly use spectral features such as harmonic structure or fundamental frequency, for example. As the proposed method uses harmonic structure of vocalic segments in command speech, it is expected to have an advantage compared with the traditional adaptive methods. Results of evaluation using speech recognition show that the proposed method significantly improves speech recognition rate compared with conventional spectral subtraction. [Work supported by Knowledge Cluster Project, MEXT, and by Academic Frontier Project Doshisha University.]

4aSP10. Robust matched-field processor in the presence of geoacoustic inversion uncertainty. Chen-Fen Huang, Peter Gerstoft, and William S. Hodgkiss (Marine Physical Lab., Scripps Inst. of Oceanogr., UCSD, La Jolla, CA 92037-0238, chenfen@ucsd.edu)

This presentation examines the performance of a matched-field processor incorporating geoacoustic inversion uncertainty. Uncertainty of geoacoustic parameters is described via a joint posterior probability distribution (PPD) of the estimated environmental parameters, which is found by formulating and solving the geoacoustic inversion problem in a Bayesian framework. The geoacoustic inversion uncertainty is mapped into uncertainty in the acoustic pressure field. The resulting acoustic field uncertainty is incorporated in the matched-field processor using the minimum variance beamformer with environmental perturbation constraints (MV-EPC). The constraints are estimated using the ensemble of acoustic pressure fields derived from the PPD of the estimated environmental parameters. Using a data set from the ASIAEX 2001 East China Sea experiment, tracking performance of the MV-EPC beamformer is compared with the Bartlett beamformer using the best-fit model.

11:10

4aSP11. A study on combining acoustic echo cancelers with impulse response shortening. Stefan Goetze, Karl-Dirk Kammeyer (Dept. of Commun. Univ. of Bremen, Eng., D-28334 Bremen, Germany), Markus Kallinger, and Alfred Mertins (Carl von Ossietzky-Univ., Oldenburg, D-26111 Oldenburg, Germany)

In hands-free video conferencing systems acoustic echo cancelers (AECs) have to face the problem of very high-order impulse responses (IRs), which have to be compensated. Time-domain algorithms for adaptation often suffer from slow convergence (as the NLMS algorithm, e.g.) or high computational complexity (e.g., the RLS). On the other hand frequency-domain algorithms introduce undesired delays [S. Haykin, *Filter Theory*, 2002]. For high-quality hands-free systems IR shortening concepts and IR shaping concepts developed for listening room compensation (LRC) [M.Kallinger and A. Mertins, in Proc. Asilomar, 2005] can be applied to increase speech intelligibility for the near-end speaker. The aim of this study is the synergetic combination of LRC concepts with acoustic echo cancellation. For this scenario two different forms of concatenating the subsystems are possible. Either the AEC filter follows the LRC or vice versa. In the first case the equalization filter reduces the length of the effective IR seen by the AEC filter. Thus, shorter AEC filters can be used which results in faster convergence. However, an estimation algorithm for the room IR is necessary for the LRC subsystem. In the second case the AEC delivers an estimate of the room IR which can be used as an input for the LRC filter. Experimental results confirm the superiority of the new combined approach.

11:25

4aSP12. Krylov and predictive sequential least-squares methods for dimensionality reduction in adaptive signal processing and system identification. James Preisig and Weichang Li (Woods Hole Oceanogr. Inst., Woods Hole, MA 02543)

Rapid time variation of the environment, a large number of parameters which need to be adjusted, and the presence of a reduced subset of the parameters that are relevant at any point in time create significant challenges for adaptive signal-processing algorithms in underwater acoustic applications. In applications such as underwater acoustic communications, the environment is represented by the ''taps'' of the time-varying impulse response. The instability of estimation algorithms or inability to track rapid channel fluctuations are among the problems that are encountered. An approach to addressing these challenges is to dynamically select a subspace in which the adjustment of taps takes place. Here, two algorithms for doing this are presented. The first is based upon using subspace basis vectors, which form a Krylov subspace with respect to the channel input correlation matrix and the channel input/output correlation vector. This method does not use a prediction residual error to select the basis vectors. A second algorithm is a new variant of the matching pursuit algorithm. In this case, ''important'' taps of the channel impulse response are selected to minimize a forward prediction residual error. The properties and performance of these two algorithms are presented and compared using simulation and field data.

11:40

4aSP13. Expectation maximization joint channel impulse response and dynamic parameter estimation and its impact on adaptive equalization. Weichang Li and James C. Preisig (Dept. of Appl. Ocean Phys. and Eng., Woods Hole Oceanograph. Inst., Woods Hole, MA 02543)

Joint estimation of channel impulse response and its dynamic parameters using the expectation maximization (EM) algorithm and its MAP variant is derived for broadband shallow-water acoustic communication channels. Based on state-space channel modeling, the EM algorithms estimate the channel dynamic parameters from the sequence of channel impulse response estimates. The estimated parameters are then used in the Kalman smoother, which estimates the channel impulse response. The stability of the algorithm is shown to be related to an extended persistent excitation (EPE) condition, which requires that both the symbol sequence and the channel estimates be persistently exciting. Modified algorithms are proposed for broadband multipath channels to avoid the issue of insufficient excitation. Efficient suboptimal algorithms are also derived from the EM algorithms that alternatively estimate the parameter and the channel impulse response while allowing slow parameter variations. The performance of these channel estimation algorithms as well as their impact on the subsequent equalizer are demonstrated through experimental data analysis. [Work supported by ONR Ocean Acoustics.]

4aUWa1. Automatic detection performance comparisons of three different fluctuation-based signal processors. Ronald A. Wagstaff (Natl. Ctr. for Physical Acoust., 1 Coliseum Dr., Univ., MS 38677)

The three most common fluctuation-based signal processor (FBP) algorithms achieve gain by exploiting either the reciprocal of the spectral amplitude, the log-differential amplitude, or aligned-phase angles. Two important features of these processors, for the underwater acoustics community, is their ability to detect and automatically identify signals which originated from submerged sources, and to provide unusually large signal-to-noise ratio gains. Similar benefits are of interest to the atmosphere acoustic community. An example is the automatic detection and identification/classification of hostile airborne and ground vehicles by unattended ground sensors (UGS). The three different generic types of FBP algorithms will be defined. The manner in which each exploits fluctuations to achieve gain will be explained. Corresponding performances will be compared using both underwater and atmosphere acoustic data. The ocean acoustic results came from towed array beamformed spectral data and will include spectral plots and grams. Corresponding single sensor spectral results will also be presented for atmosphere acoustic vehicle data. [Work supported by ARDEC and SMDC.]

4aUWa2. Evolution of modern fluctuation-based processing. Ronald Wagstaff (Natl. Ctr. for Physical Acoust., 1 Coliseum Dr., Univ., MS 38677)

Modern fluctuation-based processors (FBPs) are relatively new on the signal processing scene. They started in the mid-1980s with the realization that averaging the reciprocal acoustic powers and inverting the result back, i.e., the harmonic mean, could yield 6- to 8-dB signal-to-noise ratio gain over the corresponding average power. Because of its significant noise attenuation, this processor was designated WISPR, i.e., reduces noise to a whisper. WISPR had a unique, potentially more valuable, capability. Based on the decibel difference, or ratio, between the average power and WISPR, it could be determined whether the received signals were from ships, or from sources of sound that were submerged. After much time and experience with WISPR at sea, acquiring and processing towed array ocean acoustic data, and continuing data processing in the laboratory, the phenomena that were responsible for WISPRs performance, acoustic fluctuations generated near the sea surface, became better understood and WISPRs credibility increased. This led to the development of many other FBPs with similar capabilities, but with significantly enhanced performances. A brief account of post-WISPR development will be presented, including a description of the exploitable parameters, how they are used, and the range of gains that they achieve.

8:30

4aUWa3. A comprehensive unbiased third party evaluation of a signal processor for detecting submerged sources among clutter signals and noise. Ronald Wagstaff (Natl. Ctr. for Physical Acoust., 1 Coliseum Dr., Univ., MS 38677)

The Wagstaff's integration silencing processor, WISPR', was developed to detect and identify signals in the ocean from sources that are submerged well below the sea surface. WISPR is the type of signal processor that exploits the reciprocal of the spectral power amplitude, rather than the amplitude as the average power processor does. Processing the reciprocal of the power represented a significant departure in the prevailing signal processing philosophy that governed most conventional signal processing algorithms that were in use when WISPR first appeared on the scene several years ago. Furthermore, WISPR's claimed submerged-source detection capability made it an attractive candidate for some high interest signal processing applications. Accordingly, one influential national organization considered its potential use in their mission and decided to commission a credible third party laboratory to conduct an unbiased evaluation of the WISPR processor. The emphasis was to be on its performance for automatic unalerted detection of signals from submerged sources. The techniques and evaluation methods used to test the WISPR processor will be described. The results of the evaluation will be presented, and the influence of those results on the development of other, more advanced, fluctuation-based processors will be discussed.

8:45

4aUWa4. The estimated ocean detector: Predicted performance for continuous time signals in a random/uncertain ocean. Jeffrey A. Ballard, R. Lee Culver, Leon H. Sibul (Appl. Res. Lab. and Grad. Program in Acoust., Penn State Univ. P.O. Box 30, State College, PA 16804), Colin W. Jemmott, and H. John Camin (Penn State Univ., State College, PA 16804)

This paper addresses implementation of the maximum likelihood (ML) detector for passive SONAR detection of continuous time stochastic signals that have propagated through a random or uncertain ocean. We have shown previously that Monte Carlo simulation and the maximum entropy method can make use of knowledge of environmental variability to construct signal and noise parameter probability density functions (pdf's) belonging to the exponential class. For these cases, the ML detector has an estimator-correlator and noise-canceller implementation. The estimator-correlator detector computes the conditional mean estimate of the signal conditioned on the received data and correlates it with a function of the received data, hence the name estimated ocean detector (EOD). Here we derive the detector structure for continuous time stochastic signals and Gaussian noise and present receiver operating characteristic (ROC) curves for the detector as a function of the signal-to-noise ratio. [Work supported by ONR Undersea Signal Processing Code 321US.]

4aUWa5. Echo detection enhancement using multiple guide sources in shallow water. David C. Calvo, Charles F. Gaumond, David M. Fromm, and Richard Menis (Naval Res. Lab., Acoust. Div. Code 7145, 4555 Overlook Ave. SW, Washington, DC 20375)

The use of a guide source has been proposed as a way of compensating for multipath by forming a spatial-temporal cross correlation of the received target and guide source signals across a vertical array in the frequency domain [Siderius *et al.*, J. Acoust. Soc. Am. **102**, 3439–3449]. This processing has the effect of creating a virtual receiver at the guide source position. In general, the performance of a virtual receiver degrades if the spatial integration is not carried out over the span of the array with significant signal. In our study, we have pursued an alternative approach of using guide sources which does not require this integration in general. The guide source signal is simply used as a matched filter. Although this does not correspond to a virtual receiver, it is useful as a means of improving active or passive detection of signals in noise. In general, the signal gain using this alternative technique is dependent on the guide source position. To compensate for this, we construct a separable-kernel-receiver filter bank using multiple randomly positioned guide source signals. Improvement of ROC curves in both passive and active scenarios is obtained using experimental and simulated data. [Work sponsored by ONR.]

4aUWa6. Incorporating environmental variability into received signal statistics. H. John Camin, R. Lee Culver, Leon H. Sibul (Appl. Res. Lab. and Grad. Program in Acoust., Penn State Univ., P.O. Box 30, State College, PA 16804), Jeffrey A. Ballard, and Colin W. Jemmott (Penn State Univ., State College, PA 16804)

We have developed a Monte Carlo-based method for estimating the variability of acoustic signal parameters caused by uncertain ocean environments. The method begins with a physics-based model for the environmental properties and uses the maximum entropy (MaxEnt) method to construct probability density functions (pdf's) describing the measured deviations from the model mean. Random realizations of environmental variability, with proper depth correlation, are constructed from the pdf's and added to the mean model parameters. A parabolic equation code (RAM) is used to propagate acoustic energy through each realization of the environment. Fourier synthesis is used to recreate the arrival structure. The method is demonstrated using measurements from the Strait of Gibraltar, which is a particularly complicated region dominated by strong tidal fluctuations and internal waves. During 1996, an international group carried out the Strait of Gibraltar Acoustic Monitoring Experiment (SGAME), in which detailed environmental and 250-Hz acoustic data were collected.

Here, pdf's of the received signal level are compared with results of the Monte Carlo method to demonstrate performance. [Gibraltar data and SVP model provided by Chris Tiemann (ARL:UT) and Peter Worcester (SIO). Work supported by ONR Undersea Signal Processing.]

4aUWa7. Motion compensation of multiple sources. Joung-Soo Park (Agency for Defense Development, P.O. Box18, Jinhae, Kyung-Nam, 645-600, Korea), Jae-Soo Kim (Korea Maritime Univ., Young-Do, Busan, Korea), and Young-Gyu Kim (Agency for Defense Development, Jinhae, Kyung-Nam, 645-600, Korea)

Matched field processing has a advantage of detection of multiple targets. But, if a strong interferer is moving fast near a quiet target, detection of the target is difficult due to the motion effect of the interferer. The motion of the interferer introduces energy spreading and results in poorer detection. A waveguide-invariant-based motion compensation algorithm was proposed to mitigate the motion effect of a dominant signal component, which is estimated by eigenvalue method. The eigenvalue method is good for a strong interferer, but not good for multiple targets. In this presentation, we will propose a steered beam processing method to mitigate the motion effect of multiple targets. We will verify the proposed method with numerical simulations and SwellEx96 data processing.

4aUWa8. Predicting sonar performance using observations of mesoscale eddies. Harry DeFerrari (Div. of Appl. Marine Phys., RSMAS, Univ. of Miami, 4600 Rickenbacker Cswy, Miami, FL 33149)

A predictive relationship has been observed between the location of offshore mesoscale eddies and the performance of active and passive sonar on the shallow water shelf area inside of the eddy. The passage of an eddy produces a prograde front that modifies acoustic propagation by two mechanisms. First, the density gradient serves as a conduit for offshore internal waves to propagate onto the shelf. A long-lived front can result in order of magnitude increases in potential energy of the internal wave field and corresponding increases in sound speed variability. Second, the circulation of the eddy produces a unique sound speed profile that is strongly downward refracting but has a nearly iso-velocity layer near the bottom owing to turbulent mixing. The shape of the profile closely approximates a hyperbolic cosine. Such a profile has mode group velocities that are equal for all refracted modes, thus producing strong focusing and a caustic at the depth of the source at all ranges. The experimental observations are confirmed with oceanographic and acoustic propagation models and, in turn, the models predict FOM fluctuations of as much as 15 dB for passive sonar and 24 dB for active sonar, depending on location of the eddy.

4aUWb1. Phenomenon of Leonid Maximovich Brekhovskikh as a man and a scientist. Nikolay Dubrovskiy (Andreyev Acoust. Inst., Shvernika Ul 4, Moscow 117036, Russia)

Leonid Maximovich Brekhovskikh made phenomenal contributions in acoustics: discovery of the underwater sound channel, development of the fundamental theory of wave propagation in layered media, and working out a tangent plane approximation in the wave scattering theory. Brekhovskikh contributed greatly to the organization of research teams and the dissemination of information on acoustics and oceanography through his popular books and lecturing. He also made a major breakthrough as a public figure and a statesman. He became the first Director of the Acoustics Institute at the age of 36. He served as a secretary of the Russian Academy of Sciences Branch involved in oceanography, geography, and atmospheric physics research. Brekhovskikh's achievements in science and science leadership were marked by multiple highest USSR awards and many international awards. He became an Honorary Fellow of the Acoustical Society of America and the Russian Acoustical Society. He received the Lord Raleigh Medal for the discovery that preserved its urgency for 30 years. Brekhovskikh's phenomenon is regarded here from the viewpoint of his personality as well as specific circumstances of his family and social life.

10:40

4aUWb2. Some aspects of Leonid Brekhovskikh's influence on oceanographic acoustics. W. A. Kuperman and W. Munk (Scripps Inst. of Oceanogr., Univ. of California, San Diego, La Jolla, CA 92093-0238)

Waveguide physics describes the basic features of long-range sound propagation in the ocean. Over the last half century the theory has progressed from describing ideal waveguides to more complicated layered structures to range-dependent structures to time-varying, range-dependent structures. The theme of Brekhovskikh's pioneering work was the development of robust formulations that permitted understanding basic ocean acoustics while also laying the foundation to progress to the next levels of realistic complexity. Early on, he realized that acoustic data were not consistent with known oceanography. His seminal oceanographic experiments established the pervasive presence of mesoscale phenomena, which to this day are still not fully incorporated into rigorous formulations of the forward and inverse acoustics problems. We discuss only a very small part of his work and its subsequent influence.

11:00

4aUWb3. Underwater sound propagation: 49 years with L. M. Brekhovskikh's *Waves in Layered Media*. Oleg A. Godin (CIRES, Univ. of Colorado and NOAA, Earth System Res. Lab., 325 Broadway, Boulder, CO 80305, oleg.godin@noaa.gov)

In his first 10 years of research on wave propagation in layered media, L. M. Brekhovskikh created a theory that remains a basis for physical understanding and mathematical modeling of underwater sound propagation. Summarized in his celebrated book *Waves in Layered Media*, first published in 1957, the theory includes spectral (quasi-plane wave) representations of wave fields, normal mode theory for open waveguides, extensions of the ray and WKBJ methods, and a clear treatment of diffraction phenomena attendant to caustics, lateral waves, and reflection of wave beams and pulses. The book also charted the ways forward that have been and are followed by numerous researchers around the globe. Some of the resulting progress was documented in subsequent editions of *Waves in Layered Media* and in later books L. M. Brekhovskikh coauthored with his students. This paper will discuss diverse, groundbreaking contributions L. M. Brekhovskikh made to the wave propagation theory from the prospective offered by recent developments in underwater acoustics.

11:20

4aUWb4. L. M. Brekhovskikh's studies on nonlinear wave interaction and atmospheric sound. Konstantin Naugolnykh (Univ. of Colorado, NOAA, ESRL/Zeltaech LLD, Boulder, CO)

Nonlinear interaction of waves in a compressible fluid is an underlying factor in many geophysical effects, and L. M. Brekhovskikh made essential contributions to investigation of these phenomena. In particular, he suggested the mechanism of the infrasound generation by stormy areas in the ocean based on the nonlinear interaction of the counter-propagating sea-surface gravity

4a FRI. AM

waves. The estimates of the order of magnitude of sound intensities were made indicating that the main part of the infrasound generated by the surface waves is absorbed in the upper layers of the atmosphere, resulting in the heating of these layers. The other part of the sound energy can be trapped by the atmospheric acoustic waveguide and then returned to earth at distances of hundreds of kilometers, producing the voice of the sea.

11:40

4aUWb5. Tangent-plane approximation by L. M. Brekhovskikh and connected methods in the theory of wave scattering from rough surfaces. Alexander G. Voronovich (NOAA, Earth System Res. Lab., Physical Sci. Div., 325 Broadway, Boulder, CO 80305, alexander.voronovich@noaa.gov)

Starting from pioneering work by Rayleigh in 1907, scattering of waves from rough surfaces was restricted by the case of small Rayleigh parameter. In this case perturbation analysis describing the process of Bragg scattering applies. Apparently, smallness of the roughness is too restrictive for many applications. In 1952 L. M. Brekhovskikh suggested a tangent-plane approximation (TPA). For ideal boundary conditions it represents the first iteration of the appropriate boundary integral equation. However, for more complex situations (e.g., dielectric or solid-fluid interfaces) appropriate boundary integral equations are rather complicated and, even worse, they cannot be readily iterated. The TPA allows bypassing this step providing the answer in closed form for arbitrary boundary conditions and for scalar or vector waves in terms of the local reflection coefficient. Unfortunately, the TPA does not correctly describe the Bragg scattering. However, later it was realized that the TPA allows simple generalization, which treats both low- and high-frequency limits within single theoretical scheme. This is achieved by considering the local reflection coefficient as an operator rather than a factor. New methods going beyond the two classical ones with much wider regions of validity were developed based on this idea. Some of them will be reviewed in this talk.

4pAA1. Impulse response measurements based on music and speech signals. Wolfgang Ahnert, Stefan Feistel, Alexandru Miron, and Enno Finder (Ahnert Feistel Media Group, Berlin, Germany)

All known software based measurement systems, including TEF, MLSSA, SMAART, and EASERA, derive results using predetermined excitation signals like Sweep, MLS, or Noise. This work extends the range of excitations to natural signals like speech and music. In this context selected parameters like frequency range, dynamic range, and fluctuation of the signal and the signal duration are investigated in order to reach conclusions about the conditions required to obtain results comparable with standard excitation signals. Also the limitations of the standard stimuli and the proposed natural stimuli are discussed.

1:15

4pAA2. Assessment of reverberation time in halls through analysis of running music. David Conant (McKay Conant Brook Inc., 5655 Lindero Canyon Rd., Ste. 325, Westlake Village, CA 91362, dconant@mcbinc.com)

The source signal to excite a room's reverberant field sufficient for detailed measurement of reverberation time (RT60) and other measures has been the subject of considerable investigation over several decades. It is generally acknowledged that the best sources are (depending on the researcher) swept tones, MLS, MLS variations, stopped noise, cannon shots, etc. All can be characterized as highly audience unfriendly. In the

interest of obtaining useful approximations of measured midfrequency RT60 in the presence of live audiences, this paper discusses several approaches that may be fruitful while being entirely unobtrusive to the concert experience.

1:30

4pAA3. Comparison of measurement techniques for speech intelligibility. Bruce C. Olson (Olson Sound Design, 8717 Humboldt Ave N, Brooklyn Park, MN 55444, bco@olsonsound.com)

A comparison of measurement techniques for speech intelligibility between two recently released measurement systems is made. EASERA (Electronic and Acoustic System Evaluation and Response Analysis) uses a standard PC and an EASERA Gateway interface attached via Firewire. The software postprocesses a variety of stimuli in order to derive the impulse response for the room under test. This impulse response is then further processed and the results are presented to the user in both graphical and textual presentations. The Ivie Technologies IE-35 is based on a Pocket PC system and uses an external modulated noise source as stimulus to produce an intelligibility score as a single number or average of a series of measurements. This paper will explore a variety of measurements made in the same locations in a room by both systems. Results will also be shown for a variety of other acoustic measures that quantify the acoustical parameters of the room.

4pAA4. Under-balcony acoustics in concert halls: Single source versus an array of multiple sources. Youngmin Kwon and Gary W. Siebein (Architecture Technol. Res. Ctr., Univ. of Florida, 134 ARCH, P.O. Box 115702, Gainesville, FL 32611, ymkwon@ufl.edu)

The conventional measurement protocol using a single omnidirectional sound source may have limits or uncertainty in objective acoustical analysis of a performance hall. This study conducted monaural and binaural impulse response measurements with an array of 16 directional loudspeakers for quantitative acoustical assessment of specifically under-balcony area in a concert hall. The measurements were executed in a real performance hall. The measured time- and frequency-domain responses as well as the results of room acoustical parameters including binaural parameters were compared to the ones measured with a single omnidirectional source. The results were also compared to the ones taken at the main orchestra seating area. The time-domain responses showed a clear distinction particularly in early responses between single source and multiple sources. On the other hand, the magnitude of frequency response showed significantly lower at frequencies above 1 kHz than the one measured at the main area. The results of a binaural parameter, IACC, were found to be marginal between single source and multiple sources but critically different between under-balcony area and main area. Variations were also observed in the results of other room acoustical parameters when compared either between single source and multiple sources or between under-balcony area and main area.

4pAA5. Alternative metrics for the directivity of acoustic sources. Timothy W. Leishman (Acoust. Res. Group, Dept. of Phys. and Astron., Brigham Young Univ., Provo, UT 84602)

While the directivity of an acoustic source at a given frequency is thoroughly characterized by a directivity function over the angular coordinates, it may also be characterized to a lesser degree by a single-number directivity factor. The directivity index (i.e., the logarithmic version of the directivity factor) is a related figure of merit. Recent efforts to quantify the directivity of sources for architectural acoustics measurements have led to several alternatives to these values. One example is the area-weighted spatial standard deviation of radiated levels over a free-field measurement sphere. This paper presents and compares this and other directivity metrics for several types of sources, and discusses their benefits.

4pAA6. Room volume estimation from diffuse field theory. Martin Kuster and Maarten van Walstijn (Sonic Arts Res. Ctr., Queen's Univ. Belfast, BT7 1NN Belfast, Northern Ireland, m.kuster@qub.ac.uk)

Among the parameters relevant in room acoustics, the room volume is one of the most important. The general course in room acoustics research is to use the room volume in the prediction of room acoustic parameters such as reverberation time or total relative sound pressure level. Contrary to this, it has been investigated to what extent the room volume can be retrieved from a measured room impulse response. The approach followed is based on room acoustic diffuse field theory and requires correctly measured room impulse responses with the initial time delay corresponding to the source to receiver distance. A total of ten rooms of varying size and acoustic characteristics have been included. The results in three rooms were unreliable, which was explained by the particular acoustic characteristics. In the remaining rooms the results were numerically useful and consistent between different positions within the same room (relative standard deviation around 20%). The influence of source and receiver directivity is also considered.

4pAA7. *In situ* measurements for evaluating the scattering surfaces in a concert hall. Jin Yong Jeon and Shin-ichi Sato (School of Architectural Eng., Hanyang Univ., Seoul 133-791, Korea, jyjeon@hanyang.ac.kr)

Sound diffusion by a wall structure is one of the main concerns with respect to the sound quality of concert halls. There is a need to develop measurement and evaluation methods for determining the performance of scattering wall surfaces not only in a laboratory but also in actual halls. In this study, the acoustical measurements were conducted in a concert hall which has diffusers with ceramic cubic tiles on the side walls of the stage and the audience area. Binaural impulse responses were measured at all of the seats under two conditions, that is, with and without diffusers. The area which was affected by the diffusive wall was determined and quantified. The condition without diffusers was produced by covering them with the movable reflectors. From the binaural impulse responses, the temporal diffusion [H. Kuttruff, *Room Acoustics*, (Elsevier Science, London, 1991)], which is calculated from the autocorrelation of the impulse response, and other acoustical parameters were analyzed. From the relationship between the scattering coefficient and the acoustical parameters, sound scattering index for real halls, which represents the degree of the diffusion of a hall, was proposed.

4pAA8. Further investigations on acoustically coupled spaces using scale-model technique. Zuhre Su, Ning Xiang (Grad. Program in Architectural Acoust., School of Architecture, Rensselaer Polytechnic Inst., Troy, NY 12180), and Jason E. Summers (Naval Res. Lab., Washington, DC 20024)

Recently, architectural acousticians have been increasingly interested in halls that incorporate coupled-volume systems because of their potential for creating nonexponential sound energy decay. Effects of coupling-aperture configuration and source and receiver locations on energy decay are essential aspects of acoustically coupled spaces that have not yet been extensively investigated. In order to further understand these effects on sound fields in coupled rooms, a systematic experimental study is carried out. An acoustic scale model technique is used in collecting room impulse responses of a two-room coupled system for varying aperture configurations and surface-scattering conditions. Baseline behavior is established by varying aperture area for a fixed aperture shape and analyzing relevant energy-decay parameters at different locations. Effects of aperture shape and number are systematically investigated by varying these parameters while holding coupling area fixed. Similarly, effects of receiver location are systematically investigated by varying the distance of the receiver from the coupling aperture for a fixed aperture configuration. Schroeder decay-function decompositions by Bayesian analysis reveal sensitivities to receiver location and aperture configuration across different frequency bands.

4pAA9. Virtual microphone control: A comparison of measured to created impulse responses of various microphone techniques. Daniel Valente and Jonas Braasch (Rensselaer Polytechnic Inst., 110 8th St., Troy, NY 12180, danvprod@yahoo.com)

A method of rendering sound sources in 3-D space has been developed using virtual microphone control (ViMiC) [J. Acoust. Soc. Am. **117**, 2391]. This method has been used to create a flexible architecture for the creation and rendering of a virtual auditory environment based on microphone techniques. One of the advantages of ViMiC is the ability to simulate coincident, near-coincident, and spaced microphone recording techniques. This allows the user active spatial control over the recorded environment and the ability to shape the final rendering based on his or her specific auditory needs. In order to determine the accuracy of simulating the virtual microphone techniques, measurements of several acoustic

4p FRI. PM

spaces in Troy, NY will be compared to the measurements of generated impulse responses of the same modeled spaces within the ViMiC environment. The data from the measured impulse responses will be used to adapt the ViMiC system in order to create a more realistic auditory rendering. Moreover, the ViMiC system can be improved for use as an educational tool for teaching recording engineers to hear the subtle differences between various microphone techniques.

3:30

4pAA10. The estimation of the room acoustic characteristic using the acoustic intensity method. Yong Tang, Hideo Shibayama, and Takumi Yosida (Dept. of Commun. Eng., Shibaura Inst. of Technol., 3-7-5 Toyosu Koutou-ku, Tokyo, 135-8548 Japan, m603101@sic.shibaura-it.ac.jp)

When a sound radiates in rooms, a lot of reflection sounds are generated. From estimation of the direction where the room reflection sound comes from, we can understand the diffusion situation in the room acoustic field. By using the acoustic intensity method, we can measure the strength and the direction of the sound. In this paper, we estimate the direction of the reflection sound in the time-space by the acoustic intensity method and show the acoustic characteristic of the room.

3:45

4pAA11. Binaural simulation in an enclosure using the phased beam tracing. Cheol-Ho Jeong and Jeong-Guon Ih (NOVIC, Dept. of Mech. Eng., KAIST, Sci. Town, Daejeon 305-701, Korea, chjeong@kaist.ac.kr)

Binaural simulation in an enclosed space is important in the subjective evaluation of the enclosure acoustics in the design or refinement stage. A time domain scheme using the geometrical acoustics technique has been usually used in the binaural processing. However, one can calculate a pressure impulse response by using the phased beam-tracing method, which incorporates the phase information in the beam tracing process. Such phased method employs reflection coefficient and wave number, whereas the conventional method uses absorption coefficient and air attenuation factor. Impulse response can be obtained by the inverse Fourier transformation of the frequency domain result. This feature facilitates the binaural simulation because the convolution with the HRTF can be accomplished by a simple multiplication in frequency domain. Convolutions were conducted for all reflections one by one, and the convolved transfer functions were summed into one transfer function. Consequently binaural room impulse responses at receivers' ear positions can be simulated. The measured binaural room impulse responses in the conference room were compared with the predicted results for octave bands of 125 Hz to 4 kHz. A good agreement with measurement was found, especially in the early part of impulse responses. [Work supported by BK21.]

4:00

4pAA12. Visualization methods of direct and early reflection sounds in small enclosures. Chiaki Koga, Akira Omoto (Omoto Lab., Dept. of Acoust. Design, Faculty of Design, Kyushu Univ., Shiobaru 4-9-1, Minami, Fukuoka 815-8540, Japan), Atsuro Ikeda, Masataka Nakahara (SONA Corp., Nakno-ku, Tokyo, 164-0013, Japan), Natsu Tanaka, and Hiroshi Nakagawa (Nittobo Acoust. Eng. Co., Ltd. Sumida-ku, Tokyo 130-0021, Japan)

Many parameters exist for evaluating large sound fields such as concert halls. However, it is difficult to apply those parameters for evaluation of a small room such as a recording studio because of their different sound fields. Widely useful common parameters have not been established.

Moreover, early reflections are important in small rooms for determining spatial acoustic impressions. Therefore, various methods that visualize spatial acoustic information obtained by early reflection in rooms are proposed. For this study, sound fields (a music studio and a filmmaking studio) were measured using three kinds of different techniques: instantaneous intensity, mean intensity, and a sphere-baffled microphone array. This report compares the information of sound source directions obtained using these methods. Results show that every method can estimate the position of sound sources and important reflections with high accuracy. In the future, we shall propose a method that visualizes spatial acoustic information more precisely by combining the methods and establishing acoustic parameters that are available for evaluating and designing small rooms.

4:15

4pAA13. Acoustic evaluation of worship spaces in the city of Curitiba, Brazil. Cristiane Pulsides, David Q. de Sant'Ana, Samuel Ansay (LAAICA/UFPR, Bloco 4 sala PG-05 81531-990 Curitiba, PR, Brasil, pulsides@gmail.com), Paulo Henrique T. Zannin, and Suzana Damico (LAAICA/UFPR, 81531-990 Curitiba, PR, Brasil)

This article searches acoustic parameters in religious buildings located in the city of Curitiba intending to study its behavior in this kind of facilities. The temples were analyzed according to type of ceremony, architectonic style, and construction date. The research was made through the impulsive response integration method for three energetic parameters: (1) reverberation time (RT); (2) clarity (C80); and (3) definition (D50) according recommendations of the ISO/3382:1997 Standard. Performed in between were six and eight impulsive responses in each room using sweep signals and omnidirectional microphones. The results were than compared with referential values already existing [W. Fasold and E. Veres, *Schallschutz + Raumakustik in der Praxis*, 136 (1998)] for acoustic characterizations. It is possible to observe in the measurements the direct connection between reverberation time and the parameters clarity or definition. Moreover, it is possible also to observe the influence of the geometric ratios and architectural elements of the rooms, getting itself for equivalent volumes and rays of removal of the source, different levels of definition.

4:30

4pAA14. A consideration of the measurement time interval for obtaining a reliable equivalent level of noise from expressway. Mitsunobu Maruyama (Salesian Polytechnic, Oyamagaoka 4-6-8, Machida, Tokyo 194-0215, Japan) and Toshio Sone (Akita Prepectural Univ., Honjo, Akita 015-0055, Japan)

The level of road traffic noise $LA_{eq,T}$ greatly depends on the maximum level during the measurement time interval tau, and the maximum level often appears at the moment when two consecutive heavy vehicles pass through the point adjacent to the observation point. A mathematical model is proposed for simulating the variation in traffic noise, especially from the point of heavy vehicles with passing. The mean time interval between a pair of two consecutive heavy vehicles with the minimum allowable distance is obtained from time-series data and the mean recurrence time h_{ij} which can be calculated from the transition matrix $P[p_{ij}]$. The comparative study is made among the numbers of heavy vehicles from 25 to 300 [vehicles/hour] in traffic flow and the observation distances of 40 to 200 m from the road. The result shows that the measurement time interval required for the acquisition of reliable data is three to four times as long as tau or h_{ij}.

4pABa1. Great ears: Functional comparisons of land and marine leviathan ears. D. R. Ketten (Harvard Med. School, Boston, MA; Woods Hole Oceanograph. Inst., Woods Hole, MA), J. Arruda, S. Cramer, M. Yamato (Woods Hole Oceanograph. Inst., Woods Hole, MA), J. O'Malley (Massachusetts Eye and Ear Infirmary, Boston, MA), D. Manoussaki (Vanderbilt Univ., Nashville, TN), E. K. Dimitriadis (NIH/NIDCD, Bethesda, MD), J. Shoshani (Univ. of Asmara, Asmara, Eritrea), and J. Meng (American Museum of Natural History, New York, NY)

Elephants and baleen whales are massive creatures that respond to exceptionally low frequency signals. Although we have many elephant and whale vocalization recordings, little is known about their hearing. Playback experiments suggest hearing in both proboscideans and mysticetes is tuned similarly to low or even infrasonic signals. This raises several interesting issues. First, they emit and perceive signals in two media, air and water, with radically different physical acoustic properties: 4.5-fold differences in sound speed, three-fold magnitude difference in acoustic impedance, and, for common percepts, whales must accommodate 60-fold acoustic pressures. Also, a commonly held tenet is that upper hearing limit is inversely correlated with body mass, implying there should be virtually no whale-elephant hearing overlap given body mass differences. This study analyzed how inner ears in these groups are structured and specialized for low-frequency hearing. Computerized tomography and celloidin histology sections were analyzed in six baleen whale ($n = 15$) and two elephant species ($n = 7$). The data show mysticetes have a substantially greater hearing range than elephants but that coiling and apical cochlear structures are similar, suggesting common mechanical underpinnings for LF hearing, including cochlear radii consistent with the Whispering Gallery propagation effect. [Work supported by ONR, NIH, WHOI OLI, Seaver Foundation.]

4pABa2. Social context of the behavior and vocalizations of the gray whale *Eschrichtius robustus*. Sarah M. Rohrkasse (School for Field Studies, Ctr. for Coastal Studies, Apartado Postal 15, Puerto San Carlos, BCS, CP 23740 Mexico, sarro101@hotmail.com) and Margaret M. Meserve (Guilford College, Greensboro, NC 27410)

Sound production and surface behavior of the gray whale were investigated at Bahia Magdalena, Mexico to determine if vocalizations have behavioral correlations or are used in specific social contexts. Fifteen-minute sessions of behavioral observations and acoustic recordings of gray whales in various social contexts were collected from February to April 2006 ($n = 30$). Analysis of sound production included proportional use of different call types and acoustic variables of each sound type. Preliminary acoustic analysis found no correlation with social contexts or behaviors, but proportional use of different vocalizations is similar to past studies in Baja [Dahlheim *et al*, *The Gray Whale*, pp. 511–541 (1984), F. J. Ollervides, dissertation, Texas A&M University (2001)]. Initial results indicate significant differences in frequencies of high surface behaviors ($p = 0.0477$) of groups that include mother-calf pairs. As analysis continues, possible correlations between social context and use of sounds could allow for acoustics to be an indicator of group composition, seasonal movements, and social patterns and to help determine the functions of sounds. [Work supported by SFS and NFWF.]

1:45

4pABa3. Ambient noise and gray whale *Eschrichtius robustus* behavior. Francisco Ollervides, Kristin Kuester, Hannah Plekon, Sarah Rohrkasse (School for Field Studies—Ctr. for Coastal Studies, Apartado Postal 15, Puerto San Carlos, BCS, CP 23740 Mexico, follervides@hotmail.com),Kristin Kuester (Univ. of Wisconsin−Madison, Madison, WI 53706), HannahPlekon (Davidson College, Davidson, NC), andSarahRohrkasse (Texas A and M Univ., College Station, TX 77843)

Between 14 February and 13, April 2006, we conducted 31 recording sessions of ambient noise and behavioral sampling of gray whales within Magdalena Bay, Mexico. This breeding lagoon does not have the same Marine Protected Area status compared to the other breeding lagoons of San Ignacio and Guerrero Negro in the Mexican Pacific coast. Poorly monitored guidelines and increasing boat traffic from whale−watching tourism in this area have the potential to affect the surface behavior of these animals and increase average ambient noise levels. Relative ambient noise levelswererecordedandcomparedtoapreviousstudy[Ollervides,2001]todetermine similarities or differences in the 5−year interval between both data sets. Although results are not comparable in decibel levels, probably due to equipment calibration problems, there was a significant difference between the different regions of the bay Kruskal−Wallis ($p = 0.0067$). Activity levels ranged from 0.005–0.196 behaviors/whale/minute. Ambient noise levels ranged from 35.70–64.32 dB Re: 1 Pa. No correlation was found between the ambient noise levels in the bay and the activity level of gray whales (correlation value=0.0126; log correlation value=0.172). Further acoustic processing is currently underway.

2:00

4pABa4. Look who's talking; social communication in migrating humpback whales. Rebecca A. Dunlop, Michael J. Noad (School of Veterinary Sci., Univ. of Queensland, St. Lucia, Qld 4072, Australia. r.dunlop@uq.edu.au), Douglas H. Cato (Defence Sci. and Tech Org., Pyrmont, NSW 2009, Australia), and Dale Stokes (Scripps Inst. of Oceanogr., La Jolla, CA 92037)

A neglected area of humpback acoustics concerns nonsong vocalizations and surface behaviors known collectively as social sounds. This study describes a portion of the nonsong vocal repertoire and explores the social relevance of individual sound types. A total of 622 different sounds were catalogued and measured from whales migrating along the east coast of Australia. Aural and spectral categorization found 35 different sound types, and discriminate functions supported 33 of these. Vocalizations were analyzed from 60 pods that were tracked visually from land and acoustically using a static hydrophone array. Nonsong vocalizations occurred in all pod compositions: lone whales, adult pairs, mother/calf pairs, mother/calf/escorts, and multiple-adult pods. Thwops and wops were likely to be sex-differentiated calls with wops from females and thwops from males. Sounds similar to song-units were almost all from joining pods and yaps were only heard in splitting pods. Other low-frequency calls (less than 60 Hz) were thought to be within-pod contact calls. Higher-frequency cries (fundamental 450–700 Hz) and other calls (above 700 Hz) and presumed underwater blows were heard more frequently in joining

4pABa5. Seasonal ambient noise levels and impacts on communication in the North Atlantic right whale. Susan E. Parks, Christopher W. Clark, Kathryn A. Cortopassi, and Dimitri Ponirakis (Bioacoustics Res. Program, Cornell Univ., 159 Sapsucker Woods Rd., Ithaca, NY 14850, sep6@cornell.edu)

The North Atlantic right whale is a highly endangered species of baleen whale. Acoustic communication plays an important role in the social behavior of these whales. Right whales are found in coastal waters along the east coast of the United States, an area characterized by high levels of human activity. Most of these activities generate noise that is propagated into the coastal marine environment. The goals of this project are to characterize the noise, both natural and anthropogenic, in right whale habitat areas to determine what levels of noise the whales are regularly exposed to, and whether the acoustic behavior of right whales changes in response to increased noise. Continuous recordings were made from autonomous bottom-mounted recorders in three major habitat areas in 2004 and 2005; Cape Cod Bay (December–May), Great South Channel (May), and the Bay of Fundy, Canada (August) to passively detect right whales by recording their vocalizations. Here, we describe the ambient noise levels in these recordings to describe the daily acoustic environment of right whales, how noise varied over diel, weekly, and seasonal time scales, and whether noise levels correlated with any observed changes in acoustic behavior of the whales.

2:30

4pABa6. Blue whale calling in Australian waters. Robert D. McCauley, Chandra P. Salgado Kent (Curtin Univ. of Technol., G.P.O. Box U 1987, Perth 6845, Australia), Christopher L.K. Burton (Western Whale Res. Hillarys 6923, WA Australia), and Curt Jenner (Ctr. for Whale Res. (WA Inc.), Fremantle WA, 6959 Australia)

Calling from the Antarctic true blue whale (*Balaenoptera musculus intermedia*) and the tropical subspecies (brevicauda, or pygmy blue) have been recorded across southern Australia with the pygmy blue calls also recorded along the Western Australian (WA) coast. The subspecies have a believed common downsweep and markedly different longer, tonal calls. The frequency of most energy in the tonal calls is offset between the subspecies suggesting sound-space partitioning. The pygmy blue three-part tonal call is typically 120 s long repeated every 200 s, has several variants, and includes a complex two-source component. The nature of the pygmy blue call allows counts of instantaneous calling individuals, giving relative abundance. These estimates in the Perth Canyon, a localized seasonal feeding area, show patterns in usage of space and through time within and between seasons, such as the sudden departure of animals at a season end, which varies by approximately 2 weeks between years. Sea noise records along the WA coast indicate south-traveling animals arrive midway along the coast in October to November, animals fan out across southern Australian over December through May, then move north in the Austral winter. We have begun converting abundance estimates from relative to absolute for pygmy blue calling rates.

2:45

4pABa7. Acoustical monitoring of finback whale movements on the New Jersey Shelf. Altan Turgut (Naval Res. Lab., Acoust. Div., Washington, DC 20375) and Christopher Lefler (Univ. of California Santa Barbara, Santa Barbara, CA 93106)

Acoustical monitoring of finback whales is performed by using a data set collected over a 3-week period in December of 2003 on the New Jersey Shelf. One-second-duration 20-Hz signals of finback whales were recorded on three vertical line arrays (VLAs) and a bottomed horizontal line array (HLA). One-second-duration pulses are separated by about 10 s and there is an approximately 2-min-long silent period between 10- to 18-min-long pulse trains. A 30- to 60-min silent period after 5 to 10 pulse trains is also common. Modal analysis of individual pulses indicated that most signals contained two acoustic modes. Arrival-time and group-speed differences of these modes are used for remote acoustic ranging. These modal characteristics are also exploited in a broadband matched-field algorithm for depth discrimination. Bearing estimation of individual whales is obtained by performing horizontal beamforming on the HLA data. Range estimation results are verified by time-of-flight triangulation using single hydrophone data from each VLA location. Acoustic monitoring results indicated that most finback whales traveled near the shelf break front where food might be abundant. Relations between silent periods and acoustic range/depth monitoring results are also investigated. [This work was supported by the ONR.]

4pABa8. Analysis of melon-headed whale aggregation in Hanalei Bay, July 2004. David M. Fromm (Naval Res. Lab., 4555 Overlook Ave. SW, Washington, DC 20375-5350), Joseph R. Mobley, Jr. (Univ. of Hawaii at M_noa, Honolulu, HI 96822), Stephen W. Martin (Space and Naval Warfare Systems Ctr. San Diego, San Diego, CA 92152-5001), and Paul E. Nachtigall (Univ. of Hawaii at M_noa, Kailua, HI 96734)

On 3 July 2004, an aggregation of ca. 150–200 melon-headed whales (*Peponocephala electra*) appeared in the shallow waters of Hanalei Bay, Kauai and congregated there for over 27 h. Preceding the whales' appearance and partially coincident with their time in the Bay, midrange (3.5–5 kHz) tactical sonars were intermittently deployed during the Rim of the Pacific 2004 (RIMPAC) joint military exercises being conducted in waters near Kauai by the U.S., Japan, and Australia Navies. An NOAA report (Southall *et al.*, 2006) attributed the active sonar usage as a plausible, if not likely, contributing factor. A detailed timeline and reconstruction of the RIMPAC activities is presented showing the worst-case estimates of the sonar sound levels in the waters surrounding Kauai. A re-examination of available evidence combined with a new report of a simultaneous and similar aggregation in Sasanhaya Bay, Rota, Commonwealth of the Northern Mariana Islands, brings the plausibility conclusion into question. [This work was sponsored by multiple sources. D. Fromm and S. Martin conducted acoustic analyses with funds provided by the U.S. Pacific Fleet. J. Mobley received funding from the U.S. Geological Survey. P. Nachtigall is sponsored by the Office of Naval Research for marine mammal audiometric studies.]

3:30

4pABa9. Midfrequency sound propagation in beaked whale environments. Eryn M. Wezensky, Thomas R. Stottlemyer, Glenn H. Mitchell (Naval Undersea Warfare Ctr., Newport Div., Newport, RI 02841), and Colin D. MacLeod (Univ. of Aberdeen, Aberdeen, U.K.)

Recent mass strandings of beaked whales (*Ziphiidae, Cetacea*) coinciding with the use of midfrequency range (1–10 kHz) active sonar have caused speculation about the potentially adverse effects of these sound sources. Particular questions of the research and regulatory communities concern whether beaked whale sensitivity to midfrequency sound exposure is influenced by oceanographic characteristics present at the time of the mass stranding events. This study investigated the interaction between beaked whale habitat characteristics and the nature of a midfrequency signal by analyzing the oceanographic factors affecting underwater acoustic propagation. Three types of model sites were selected from five specific geographical locations where beaked whales have been regularly recorded or where a mass stranding event has been reported. A ray-trace acoustic propagation model was used to generate transmission loss for a 3-kHz signal over a representative 60-km transect at each locality. Model outputs visually demonstrated how the combination of site/event-specific oceanographic characteristics affects the sound propagation of a moving source. A parametric sensitivity comparison and statistical analysis were conducted to identify influential factors between environmental parameters, source depth, and the resulting transmission loss. Major findings of this study as well as future research direction are discussed. [Research supported by NAVSEA.]

3:45

4pABa10. Examination and evaluation of the effects of fast rise-time signals on aquatic animals. Michael Stocker (Seaflow, Inc., 1062 Ft. Cronkhite, Sausalito, CA 94965)

Increasingly human enterprise is subjecting the ocean environment to acoustic signals to which marine animals are not biologically adapted. This is evidenced by a marked rise in marine mammal strandings, as well as hearing and other physiological damage to fish and other marine organisms as a result of, or coincident to, human-generated noise events. Determining phonotoxic thresholds of marine organisms is complicated by the fact that various marine animals are adapted to sense either pressure gradient or particle motion acoustic energy, or some combination or gradient between the two. This has been addressed to some degree by exposure metrics that consider either net or accumulated acoustical flux densities from various noise sources. This paper examines the role and effects of signal rise time both in terms of physiological impulse response of the exposed organisms, as well as broadband saturation flux densities of fast rise-time signals on animal sense organs. Case studies from the literature will be presented to demonstrate the effects of fast rise time signals on fish. Acoustical signals with high crest factors and fast rise-time components will be compared to signals with dominantly sinusoidal components to illustrate the perceptual effects of these signals on human hearing.

4:00

4pABa11. Noise separation of underwater acoustic vocalization using auditory filter bank and Poisson rate estimation. Owen P. Kenny and Craig R. McPherson (Dept. of Elec. and Comput. Eng., James Cook Univ., Douglas 4811, Queensland, Australia)

Formant vocalization tracking has been achieved using a mammalian periphery model and a Poisson rate estimator. This approach used a set of linear bandpass filters to simulate the mechanical displacement of the basilar membrane. The auditory model simulated neural firing by producing a spike at the positive going zero crossing for each filter output. Poisson

intensity of the neural firing rate is controlled by the dominant frequency components of the signal present in the filter. This approach is extended by incorporating neural synchronization information to separate the formant structure from that of noise. The filter structure is designed to overlap the frequency range of adjacent filters. The presence of a formant structure in adjacent filters controls the interspike intervals of neural firing for both filters, which results in the neural firing from both filters being synchronized. If a noise-only component is present in either filter, then the spiking outputs from the adjacent filters are unsynchronized. Experimental results have shown that incorporating neural synchronization information between adjacent filters has enabled separation of signal components from noise. This technique enables easier signal and noise separation than allowed by traditional methods.

4:15

4pABa12. Using vocalizations of Antarctic seals to determine pupping habitats. T. L. Rogers, C. J. Hogg, M. B. Ciaglia (Australian Marine Mammal Res. Ctr., Zoological Parks Board of NSW/Faculty of Veterinary Sci., Univ. of Sydney, Mosman Australia), and D. H. Cato (Defence Sci. & Technol. Organisation, Pyrmont, Australia)

The Ross and Leopard seal use the floes of the Antarctic pack ice to whelp and raise their pups, But both species are rarely seen in summer throughout the pack ice. We now realize that this is because they are under the water "calling" during the austral summer as part of their breeding display, and so their presence is underestimated in traditional visual surveys. The period of "calling" overlaps with the time that females give birth, so their vocalizations can be used to determine seal distributions during this time. Acoustic recordings were made using sonobuoys deployed during ship based surveys in the pack ice and analyzed to determine the seal distributions. This was used to predict habitat preference of seals by relating their distributions to remotely sensed indices: ice cover, ice floe type, ice thickness, distance to ice edge, distance to shelf break, distance to land, sea surface temperature, and chlorophyll a.

4pABb1. Effective area of acoustic lure surveys for Mexican spotted owls (*Strix occidentalis lucida*). Samuel L. Denes, Ann E. Bowles (Hubbs-SeaWorld Res. Inst., 2595 Ingraham St., San Diego, CA 92109, sdenes@hswri.org), Kenneth Plotkin, Chris Hobbs (Wyle Labs., Arlington, VA 22202), John Kern (Kern Statistical Services, Sauk Rapids, MN 56379), and Elizabeth Pruitt (GeoMarine, Inc., Hampton, VA 23666)

During acoustic lure surveys for birds, topography and ambient noise are likely to be important determinants of detectability. Examinations of propagation were conducted for acoustic lures (human-made calls) and owl responses recorded during acoustic surveys for Mexican spotted owls in the Gila National Forest (2005). Lure surveys were designed based on

formal agency protocols, which assumed a 0.43-km detection range under typical conditions. A total of 558 points was called over a heavily forested, topographically complex 20×24-km area. Real-time measurements of owl calls and lures were made with a calibrated recording system. Ambient noise was collected using an array of 39 Larson-Davis 820 and 824 sound-level meters. The NMSIM (Wyle Laboratories) single-event propagation simulator was used to model propagation of both owl and human calls. The resulting model of survey effort was compared with a simple two-dimensional statistical model. Probability of detecting owls did not fit the expectations of the agency protocol, suggesting that acoustic propagation should be considered during owl surveys. [Work supported by U.S. Air Force ACC/CEVP; USFWS Permit No. TE024429]

4:45

4pABb2. Automated localization of antbirds and their interactions in a Mexican rainforest. Alexander N. G. Kirschel, Travis C. Collier, Kung Yao, and Charles E. Taylor (Univ. of California, Los Angeles, 621 Charles E. Young Dr. South, Los Angeles, CA 90095)

Tropical rainforests contain diverse avian communities incorporating species that compete vocally to propagate their signals to intended receivers. In order to effectively communicate with birds of the same species, birds need to organize their song performance temporally and spatially. An automated identification and localization system can provide information on the spatial and temporal arrangement of songs. Acoustic sensor arrays were tested for the ability to localize the source of songs of antbirds recorded in a Mexican rainforest. Pilot studies with a five-node array arranged in a rough circle with a 20-m diameter located the song of Dusky Antbird (*Cercomacra tyrannina*) with an error of 73 cm and Mexican Antthrush (*Formicarius moniliger*) with an error of 65 cm from the location of a source loudspeaker within the array. An additional source 21 m outside was also localized. Results will be presented for experiments and recordings of individuals at the Mexican rainforest site in October 2006. Locations of birds of the same and different species during vocal performance will provide a greater understanding of how individuals interact spatially with each other based on their vocal performance, from which the role of song in ecological interactions can be inferred.

5:00

4pABb3. Nonintrusive acoustic identification of hermit thrush (*Catharus guttatus*) individuals. Dennis F. Jones (Defence R&D Canada—Atlantic, P.O. Box 1012, Dartmouth, NS, Canada B2Y 3Z7, dennis.jones@drdc-rddc.gc.ca)

From mid-April well into the summer, the secretive hermit thrush (*Catharus guttatus*) can be heard singing throughout the woodlands of Nova Scotia. Its song is distinctive, beginning with a clear introductory note followed by a flurry of flutelike body notes, often cascading and reverberant in character. Despite this fine display of avian virtuosity, few studies have been reported that probe the differences between the calls, songs, and repertoires of individuals. From April 2003 to May 2006, over 3000 songs from several birds were recorded using digital video cameras at study sites in and around the city of Halifax, Nova Scotia. The only birds recorded were those in close proximity to roads and trails. None of the birds were marked, banded, or deliberately disturbed in any way. Although the study birds remained hidden from view most of the time, in the few instances where the birds perched in the open, their behaviors while singing were captured on videotape. All of the birds were readily distinguishable from each other as no two individuals had a single song in common. The most significant finding was that individuals could be reidentified acoustically after 1 week, 3 months, and 1 year had elapsed.

Biomedical Ultrasound/Bioresponse to Vibration and Signal Processing in Acoustics: Elastic Imaging

Peter J. Kaczkowski, Cochair

Univ. of Washington, Applied Physics Lab., 1013 NE 40th Street, Seattle, WA 98105-6698

Tsuyoshi Shiina, Cochair

Univ. of Tsukuba, Graduate School of Systems and Information Engineering, 1-1-1 Tennodai, Tsukuba 305-8573, Japan

Invited Papers

1:00

4pBB1. Present and future of elasticity imaging technology. Tsuyoshi Shiina (Grad. School of Systems and Information Eng., Univ. of Tsukuba, 1-1-1 Tennodai Tsukuba, Japan) and Ei Ueno (Univ. of Tsukuba, Tsukuba, Japan)

Elastic properties of tissues are expected to provide us novel diagnostic information since they are based on tissue characteristics and sensitively reflect its pathological state. So far, various techniques for tissue elasticity imaging have been proposed. However, it was not so easy to satisfy real-time operation and freehand manipulation of probe, which was required for practical equipment. To satisfy these conditions, we developed the combined autocorrelation method (CAM) and recently manufactured a commercial ultrasound scanner, for real-time tissue elasticity imaging by implementing the CAM algorithm, By slightly compressing or relaxing the body through freehand operation, the strain images are obtained with real-time and superimposed on B-mode images with a translucent color scale. In addition, we proposed elasticity scores of malignancy by categorizing patterns of elasticity images of breast tumors into five classes from malignant to benign. As a result of diagnosis based on the elasticity score, it was revealed that even nonexperts could attain precise diagnosis of breast cancer based on elasticity score as well as experts since the criterion on elasticity score is much simpler than conventional B-mode images. Finally, some prospects for the next stages of elasticity imaging technology well be surveyed.

1:20

4pBB2. Real-time tissue elasticity system—Development and clinical application. Takeshi Matsumura, Tsuyoshi Mitake (Hitachi Medical Corp. 2-1, Toyofuta, Hashiwa-Shi, Chiba-Ken, Japan), Tsuyishi Tsuyishi, Makoto Yamakawa, Ei Ueno (Tsukuba Univ.), Nobuhiro Fukunari (Shouwa Univ.), and Kumi Tanaka (Nippon Medical Univ.)

The progress of recent semiconductor technology has a remarkable thing. Thanks to progress of this semiconductor technology, the ultrasound scanner in medicine could come to hold enormousness computing power and has come to realize various complicated processing. At the same time, hardness of human tissue which, as you know, is used by palpation is already the information that is important in a diagnosis. But, we think that it does not have enough objectivity. To increase objectivity by visualizing hardness of

tissue, we adopted ECAM (extended combined autocorrelation method), which was developed by Professor Shiina at Tsukuba University in Japan, and succeeded in developing the commercial ultrasound scanner, which could display a strain image in real time. From a clinical point of view, in the breast region, mammography examination is effective in a diagnosis, but a judgment of permeation degree is not superior in ultrasound image. And in a thyroid gland region, we begin to get experience with availability from a diagnosis of papillary cancer and follicular cancer. So, we would like to have the presentation about the development of a strain imaging function and some of our clinical experiences by using the developed system.

1:40

4pBB3. Elasticity of perfused tissue. Kirk W. Beach (Dept. of Surgery, Univ. of Washington, Box 356410, Seattle, WA 98195-6410), Barbrina Dunmire, and John C. Kucewicz (Univ. of Washington, Seattle, WA 98105-6698)

Elastic imaging intends to measure Young's modulus (tissue stiffness) or bulk modulus (tissue compressibility) of tissue subjected to an applied strain of several percent. Underlying elastic imaging is the assumption of a linear stress/strain relationship without hysteresis or other time-dependent behavior. Perfused tissue is a composite material comprised of a solid matrix of cells, fibers, interstitial fluid (occupying up to 50% of the tissue volume and varying slowly with time), arterioles (pulsating high-pressure spaces that occupy 0.1% of the tissue volume), capillaries, and venules (low-pressure spaces that occupy up to 3% of the tissue volume varying with respiration). This talk will speculate on the nonlinear, nonstationary stress/strain relationships expected from dependent tissues (legs), pressurized tissues (breast tumors), and other living, perfused tissues. The pressure versus strain curve from each tissue voxel allows the measurement of arteriolar and venular volumes and pressures, and interstitial pressure within the tissues. These volumes and pressures may be key to classifying pathologies.

2:00

4pBB4. New developments in transient elastography. Mathias Fink, Mickael Tanter, Ralph Sinkus, and Gabriel Montaldo (LOA, ESPCI, 10 rue Vauquelin, 75005, Paris, France)

An ultra-high-rate ultrasonic scanner has been developed that can give 5000 ultrasonic images per second of the body. With such a high frame rate, the propagation of transient shear waves can be followed, and from the spatio-temporal evolution of the displacement fields, various inversion algorithms allow us to recover the shear modulus map. A discussion on the various inversion algorithms will be presented. In order to obtain unbiased shear elasticity map, different configurations of shear sources induced by radiation pressure of focused transducer arrays are used. Both 2-D and 3-D imaging can obtained with this technique. *In vitro* and *in vivo* results on breast will be presented that demonstrate the interest of elasticity imaging with transient elastography.

2:20

4pBB5. Spectral characteristics of breast vibro-acoustography images. Azra Alizad, Dana H. Whaley, Mathew Urban, Randall R. Kinnick, James F. Greenleaf, and Mostafa Fatemi (Mayo Clinic College of Medicine, Rochester, MN 55905 aza@mayo.edu)

Vibro-acoustography image is a function of the dynamic characteristics of the object at the vibration (difference) frequency (df). The dynamic characteristic of tissue is closely related to pathology. Therefore, it is important to evaluate image features versus df. Here, the influence of df on breast vibro-acoustography images is studied by scanning human breast at various df values ranging from 20 to 90 kHz. The subjects were chosen from a group of volunteers with different breast abnormalities. Images were compared subjectively to study image features and the appearances of breast lesions versus df. It is demonstrated that having a collection of images of the same tissue at different df values generally provides a better perception of the tissue structure and improves lesion identification. In most cases, higher df resulted in a higher signal-to-noise ratio and thus a higher image quality. Finally, a frequency-compounded images was obtained by calculating the weighted sum of images at different df values. It is demonstrated that image compounding normally improves visualization of breast tissue and abnormalities. [Work supported by NIH Grant EB-00535 and Grant BCTR0504550 from the Susan G. Komen Breast Cancer Foundation. Disclosure: Parts of the techniques used here are patented by MF and JFG.]

2:35

4pBB6. Tissue pulsatility imaging: Ultrasonic measurement of strain due to perfusion. John C. Kucewicz, Barbrina Dunmire, Lingyun Huang, Marla Paun (Univ. of Washington Appl. Phys. Lab., 1013 NE 40th St., Seattle, WA 98105-6698), and Kirk W. Beach (Univ. of Washington, Seattle, WA 98195-6410)

Over each cardiac cycle perfused tissues expand and relax by a fraction of a percent as blood rapidly accumulates in the arterial vasculature during systole and then slowly drains through the venous vasculature during diastole. Tissue pulsatility imaging (TPI) is a variation on ultrasonic tissue strain imaging that estimates tissue perfusion from this natural, cyclic tissue expansion and relaxation. TPI is derived in principle from plethysmography, a century-old technology for measuring gross tissue volume change from a whole limb or other isolatable body part. With TPI, the plethysmographic signal is measured from hundreds or thousands of sample volumes within an ultrasound image plane to characterize the local perfusion throughout a body part. TPI measures tissue strain over the cardiac cycle and parametrizes the signal in terms of its amplitude and shape. The amplitude of the strain waveform is correlated with perfusion, and the shape of the waveform is correlated with vascular resistance. Results will be presented from the leg showing the change in the TPI signals as the muscles recover from exercise, from breast tumors, and from the brain as blood flow changes in response to visual stimulation. [Work supported in part by NIH 1-R01EB002198-01 and NIH N01-CO-07118.]

2:50

4pBB7. Using human body shear wave noise for passive elastography.
Karim G. Sabra, Stephane Conti, Philippe Roux, and William A. Kuperman (Scripps Inst. of Ocean., Univ. of California—San Diego, 9500 Gilman Dr., San Diego, CA 92093-0238)

An elastography imaging technique based on passive measurement of shear wave ambient noise generated in the human body (e.g., due to the heart, muscles twitches, and blood flow system) has been developed. This technique merges two recent research developments in medical imaging and physics: (1) recent work on the efficacy of elastographic imaging demonstrating that shear waves are excellent candidates to image tissue elasticity in the human body and (2) theory and experimental verification in ultrasonics, underwater acoustics, and seismology of the concept of extracting coherent Green's function from random noise cross correlations. These results provide a means for coherent passive imaging using only the human body noise field, without the use of external active sources. Coherent arrivals of the cross correlations of recordings of human body noise in the frequency band 2–50 Hz using skin-mounted accelerometers allows us to estimate the local shear velocity of the tissues. The coherent arrivals emerge from a correlation process that accumulates contributions over time from noise sources whose propagation paths pass through both sensors. The application of this passive elastography technique for constructing biomechanical models of *in vivo* muscles' properties will be discussed.

3:20

4pBB8. Dynamic radiation force of acoustic waves on solid elastic spheres.
Glauber T. Silva (Instituto de Computação, Universidade Federal de Algoas, Maceió, AL, 57072-970, Brazil)

The present study concerns the dynamic radiation force on solid elastic spheres exerted by a plane wave with two frequencies (bichromatic wave) considering the nonlinearity of the fluid. Our approach is based on solving the wave scattering for the sphere in the quasilinear approximation within the preshock wave range. The dynamic radiation force is then obtained by integrating the component of the momentum flux tensor at the difference of the primary frequencies over the boundary of the sphere. Effects of the fluid nonlinearity play a major role in dynamic radiation force, leading it to a regime of parametric amplification. The developed theory is used to calculate the dynamic radiation force on three different solid spheres (aluminum, silver, and tungsten). The obtained spectrum of dynamic radiation force presents resonances with larger amplitude and better shape than those exhibited in static radiation force. Applications of the results to some elasticity imaging techniques based on dynamic radiation force will be presented.

3:35

4pBB9. Ultrasonic measurement of displacement distribution inside an object caused by dual acoustic radiation force for evaluation of muscular relax property due to acupuncture therapy.
Yoshitaka Odagiri, Hideyuki Hasegawa, and Hiroshi Kanai (Grad. School of Eng., Tohoku Univ., Sendai 980-8579, Japan, odagiri@us.ecei.tohoku.ac.jp)

Many studies have been carried out on the measurement of mechanical properties of tissues by applying an ultrasound-induced acoustic radiation force. To assess mechanical properties, strain of an object must be generated. However, one radiation force is not sufficient because it also causes translational motion when the object is much harder than surrounding medium. In this study, two cyclic radiation forces are applied to a muscle phantom from two opposite horizontal directions so that the object is cyclically compressed in the horizontal direction. As a result, the object is vertically expanded due to the incompressibility. The resultant vertical displacement is measured using ultrasound. Two concave ultrasonic transducers for actuation were both driven by sums of two continuous sinusoidal signals at two slightly different frequencies of 1 MHz and (1M +5) Hz. Displacement, which fluctuates at 5 Hz, was measured by the ultrasonic *phased tracking method* proposed by our group. Results indicated that the surface of the phantom was cyclically actuated with an amplitude of a tenth of a few micrometers, which well coincided with that measured with laser vibrometer. In addition, upward and downward displacements at the surface and deeper region were found during the increase phase of radiation forces. Such displacements correspond to the horizontal compression.

3:50

4pBB10. A phantom study on ultrasonic measurement of arterial wall strain combined with tracking of translational motion.
Hideyuki Hasegawa and Hiroshi Kanai (Grad. School of Eng., Tohoku Univ., Aramaki-aza-Aoba 6-6-05, Sendai 980-8579, Japan, hasegawa@us.ecei.tohoku.ac.jp)

Correlation-based techniques are often applied to ultrasonic rf echoes to obtain the arterial wall deformation (strain). In such methods, the displacement estimates are biased due to changes in center frequency of echoes. One of the reasons for the change in center frequency is the interference of echoes from scatterers within the wall. In the phased tracking method previously proposed for strain estimation by our group, the estimated displacement contains both the components due to the translational motion and strain. The translational motion is larger than strain by a factor of 10 and, thus, the error in the estimated displacement due to the change in center frequency mainly depends on translational motion and is often larger than the minute displacement due to strain. To reduce this error, in this study, a method is proposed in which the translational motion is compensated using the displacement of the luminal boundary estimated by the phased tracking method before correlating echoes between the frame before deformation and that at the maximum deformation to estimate the strain distribution within the wall. In basic experiments using phantoms made of silicone rubber, the estimation error was much reduced to 15.6% in comparison with 36.4% obtained by the previous method.

4:05

4pBB11. Wave biomechanics of skeletal muscle.
Oleg Rudenko (Dept. of. Blekinge Inst. of Technol., 371 79 Karlskrona, Sweden) and Armen Sarvazyan (Artann Labs., Inc., West Trenton, NJ 08618)

Physiological functions of skeletal muscle, such as voluntary contraction and force development, are accompanied by dramatic changes of its mechanical and acoustical properties. Experimental data show that during contraction, the muscle's Young's modulus, shear viscosity, and anisotropy parameter are changed by over an order of magnitude. None of the existing models of muscle contraction and muscle biomechanics can adequately explain the phenomena observed. A new mathematical model [O. Rudenko and A. Sarvazyan, Acoust. Phys. (6), (2006)], has been developed relating the shear wave propagation parameters to molecular structure of the muscle and to the kinetics of the mechanochemical crossbridges between the actin and myosin filaments. New analytical solutions describing waves in muscle including nonlinear phenomena are found. A molecular mechanism for the dependence of acoustical characteristics of muscle on its fiber orientation and the contractile state is proposed. It is shown that although the anisotropy connected with the preferential direction along the muscle fibers is characterized by five elastic moduli, only two of these moduli have independent values in the muscle. The potential implications of the proposed model in terms of the acoustical assessment of muscle function are explored.

4pBB12. Phase aberration correction for a linear array transducer using ultrasound radiation force and vibrometry optimization: Simulation study. Matthew W. Urban and James F. Greenleaf (Dept. of Physiol. and Biomed. Eng., Mayo Clinic College of Medicine, 200 First St. SW, Rochester, MN 55905, urban.matthew@mayo.edu)

Diagnostic ultrasound images suffer from degradation due to tissues with sound speed inhomogeneities causing phase shifts of propagating waves. These phase shifts defocus the ultrasound beam, reducing spatial resolution and image contrast in the resulting image. We describe a phase aberration correction method that uses dynamic ultrasound radiation force to harmonically excite a medium using amplitude-modulated continuous wave ultrasound created by summing two ultrasound frequencies at f_0 $=3.0$ MHz and $f_0 + \Delta f = 3.0005$ MHz. The phase of each element of a linear array transducer is sequentially adjusted to maximize the radiation force and obtain optimal focus of the ultrasound beam. The optimization is performed by monitoring the harmonic amplitude of the scatterer velocity in the desired focal region using Doppler techniques. Simulation results show the ability to regain a 3.0-MHz focused field after applying a phase screen with an rms time delay of 95.4 ns. The radiation force magnitude increased by 22 dB and the resolution of the field was regained. Simulation results show that the focus of the beam can be qualitatively and quantitatively improved with this method. [This study was supported in part by Grants EB002640 and EB002167 from the NIH.]

4pBB13. Application of the optoacoustic technique to visualization of lesions induced by high-intensity focused ultrasound. Tatiana Khokhlova, Ivan Pelivanov, Vladimir Solomatin, Alexander Karabutov (Intl. Laser Ctr., Moscow State Univ., 119992, Moscow, Russia t_khokhlova@ilc.edu.ru), and Oleg Sapozhnikov (Moscow State Univ., 119992, Moscow, Russia)

Today several techniques are being applied to monitoring of high-intensity focused ultrasound (HIFU) therapy, including MRI, conventional ultrasound, and elastography. In this work a new method for noninvasive monitoring of HIFU therapy is proposed: the optoacoustic method. The optoacoustic technique is based on the excitation of wideband ultrasonic pulses through the absorption of pulsed laser radiation in tissue and subsequent expansion of the heated volume. The excited optoacoustic (OA) pulse contains information on the distribution of optical properties within the tissue—light scattering and absorption coefficients. Therefore, if thermal lesions have different optical properties than the untreated tissue, they will be detectable on the OA waveform. The considerable change in light scattering and absorption coefficients after tissue coagulation was measured using techniques previously developed by our group. Heating induced by HIFU also influences the OA signal waveform due to the rise of thermal expansion coefficient of tissue with temperature. This dependence was measured in order to evaluate the feasibility of the OA technique in temperature monitoring. An OA image of HIFU lesion induced by a 1.1 MHz focused transducer in a liver sample was reconstructed using a 64-element wideband array transducer for OA signal detection.

4pEAa1. Solid-state photo-microphones or pressure sensors by total reflection. Yasushi Suzuki (Gunma Natl. College 08 Tech., 580, Toriba-cho, Maebashi-shi, Gunma, 371-8530 Japan., suzuki@elc.gunma-ct.ac.jp) and Ken'iti Kido (Tohoku Univ., Yokohama-shi, Kanagawa, 226-0017 Japan)

Solid-state photo-microphones or pressure sensors are proposed. These sensors use a new principle, involving the optical total reflection at the boundary surface between glass and air. The critical angle for total reflection changes by the refractive index of air, which depends on the air density. Sound pressure changes the air density. Therefore, the sound pressure is measurable by detecting the intensity of the reflected light from the total reflection area. The sensitivity of the sensor is investigated theoretically. It is expected that the sensor has sufficient sensitivity for practical use, employing laser light and a curved boundary surface with a large radius of curvature. Some experiments are carried out to verify the theoretical investigations. A He-Ne laser or a laser diode is employed as a light source in the experiments. Experimental results show that the sensor has equivalent sensitivity to that which was theoretically estimated, but that sensitivity is very low. The sensor is useful as a pressure sensor, but it is difficult to realize a microphone for general use at the present. The microphones have no diaphragm and the upper limit in the frequency range is extremely high in principle.

4pEAa2. Micromachined microphones with diffraction-based optical interferometric readout. F. Levent Degertekin (G.W. Woodruff School of Mech. Eng., Georgia Inst. of Technol., Atlanta, GA 30332, levent@gatech.edu), Neal A. Hall (Sandia Natl. Labs, Albuquerque, NM 87185-5800), and Baris Bicen (Georgia Inst. of Technol., Atlanta, GA 30332)

A diffraction-based optical method for integrated interferometric detection of micromachined microphone diaphragm displacement is described. With multichip optoelectronics integration, this approach yields highly sensitive optical microphones in mm-cube volumes. Since the microphone sensitivity does not depend on capacitance, this method changes the paradigm for the backplate and gap structure design. As a result, one can use millimeter size diaphragms to achieve wide frequency response and low thermal mechanical noise levels characteristic of precision measurement microphones. Furthermore, the electrical port of the device, which is freed by optical detection, is used for electrostatic actuation of the microphone diaphragm to tune microphone sensitivity and to generate self-characterization signals. Prototype optical microphone structures have been fabricated using Sandia National Laboratories' silicon based SwIFT-Lite[TM] process. Measurements on these diaphragms show an A-weighted diaphragm displacement noise of 2.4 pm and flat electrostatic response up to 20 kHz. These results indicate the feasibility of realizing measurement microphones with 1.5-mm-diam diaphragms, 15-dBA internal noise, and 40-kHz bandwidth. Application of the detection method in a bio-inspired directional microphone for hearing aids is also discussed. [Work partially supported by NIH Grant 5R01DC005762-03, Sensing and Processing for Hearing Aids.]

4pEAa3. Hardware and software technologies for improvement of hearing characteristics of headphone reproduction. Kiyofumi Inanaga and Yuji Yamada (Audio Codec Development Dept., Technol. Development Group, SONY Corp., Shinagawa Tec., 12-15-3, Tokyo, 108-6201 Japan)

This report specifically describes commercialization technology of a headphone system with out-of-head localization applying dynamic head-related transfer functions (HRTFs) that can localize sound easily over a full 360 deg. A source image by output of conventional headphones is localized inside the listener's head. However, the image can be localized outside the listener's head by wearing headphones over a full 360 deg through accurate simulation of the listener's HRTFs. Developments of headphone systems using signal processing technology for data correction have given rise to the static binaural reproduction system (SBRS). The first part of this speech describes its psychoacoustic characteristics and challenges. A rotating dummy-head that is synchronized with the listener's head movement was produced experimentally to create the dynamic binaural reproduction system (DBRS). Using the DBRS, HRTFs synchronize with the listener's head movement. Psychoacoustic characteristics and advantages of the system are also discussed in this report. Further developments were made to realize the commercialization of the DBRS in areas including piezoelectric gyroscope head-tracking technology, headphone technologies that can reproduce real sound characteristics, and simplification of HRTF signal processing employing a simulator with electronic circuits. Finally, future visions for these technologies will be touched upon.

4pEAa4. Piezoelectret microphones: A new and promising group of transducers. Gerhard M. Sessler and Joachim Hillenbrand (Darmstadt Univ. of Technol., Merckstrasse 25, 64283 Darmstadt, Germany, g.sessler@nt.tu-darmstadt.de)

Piezoelectret microphones, first described a few years ago, are transducers based on the strong longitudinal piezoelectric effect of charged cellular polymers. Such microphones have recently been improved in two respects: Firstly, an expansion process was used to increase the piezoelectric d_{33} coefficients of cellular polypropylene (PP) films in the audio frequency range up to 600 pC/N and, secondly, stacking of several films was applied to increase the microphone sensitivity. Transducers with six films now show open-circuit sensitivities of up to 15 mV/Pa, comparable to that of electret microphones. Other characteristics of piezoelectret microphones are their low equivalent noise level of about 26 dB(A) and the very small total harmonic distortion of less than 0.1% at 140 dB SPL. The piezoelectric activity of the PP films and the microphone sensitivities are stable at room temperature but start to decay above 50 °C. Recently, directional piezoelectret microphones with various directional characteristics have been designed. Major advantages of piezoelectret microphones are their simple design, their low harmonic distortion, and their wide frequency range extending into the ultrasonic region.

4pEAa5. Expansion of frequency range for piezoelectric loudspeakers by new transducer construction. Juro Ohga (Shibaura Inst. of Technol., 3-7-5, Toyosu, Koto-ku, Tokyo 135-8548, Japan)

Although simple construction of piezoelectric loudspeakers engenders various merits, expansion of its working frequency range to the very low region is difficult because the mechanically stiff characteristics of conventional piezoelectric ceramic diaphragms prevent their large amplitude operation. This paper proposes two sorts of new piezoelectric loudspeaker construction that are suitable for low-frequency signal radiation. One idea is the use of a tuck-shape diaphragm by a PVDF polymer film bimorph. It has large surface area with a very low resonant frequency. Resonant frequencies and sensitivity frequency characteristics are examined, and control methods of local diaphragm bending are discussed. The other idea is the use of continuous revolution of a piezoelectric ultrasonic motor. It produces a completely controlled large output force because its output mechanical impedance is much greater than that of any conventional transducer or motor. An ultrasonic motor, whose stator is connected to a direct-radiator loudspeaker cone by a rod and whose rotor is burdened by a heavy metal ring, rotates with a constant velocity. Modulation of the velocity by using an audio signal imparts a driving force to the diaphragm because the heavy ring tends to keep a constant velocity. Experimental models suggest that this construction is useful.

4pEAa6. Modal array signal processing using circular microphone arrays applied to acoustic source detection and localization problems. Heinz Teutsch (Avaya Labs, 233 Mt. Airy Rd., Basking Ridge, NJ 07920, teutsch@avaya.com) and Walter Kellermann (Univ. of Erlangen-Nuremberg, Erlangen, Germany)

Many applications of acoustic signal processing rely on estimates of several parameters present in the observed acoustic scene such as the number and location of acoustic sources. These parameters have been traditionally estimated by means of classical array signal processing (CASP) algorithms using microphone arrays. Algorithms for parameter estimation solely based on the paradigm of CASP often suffer from the narrowband assumption underlying the signal model. This restriction limits their usability when wideband signals, such as speech, are present in the wave field under observation. We investigate the parameter estimation problem by applying the notion of wave field decomposition using baffled circular microphone arrays. The obtained wave field representation is used as the basis for "modal array signal processing algorithms." It is shown that by applying the notion of modal array signal processing, novel algorithms can be derived that have the potential to unambiguously detect and localize multiple simultaneously active wideband sources in the array's full field-of-view. Performance evaluations by means of simulations, measurements, and real-time case studies are presented.

4pEAb1. Enhanced voided piezoelectric polymer for underwater acoustic sensors. Juan Arvelo (Appl. Phys. Lab., Johns Hopkins Univ., 11100 Johns Hopkins Rd., Laurel, MD 20723-6099), Ilene Busch-Vishniac, and James West (Johns Hopkins Univ., Baltimore, MD 21218)

A charged voided polymer has been shown to exhibit large piezoelectricity. This material consists of injected air bubbles into polypropylene. This sheet of voided material is then biaxially stretched to elongate the voids. After stretching this material, a strong electric field is applied to cause dielectric breakdown of the gas in the voids, creating electric charges that are trapped in the polymer frame. Since the sides of the voids have opposite charges, they form macroscopic dipoles. When an external force is applied to this material, the voids become narrower, causing stronger dipole strength. A simple model of this voided material was implemented to derive formulas to estimate its piezoelectric constant, electro-mechanical coupling factor, resonance frequency, and sensor sensitivity based on electrical and mechanical properties of the polymer and gas in the voids. These formulas and a survey of available polymers and gases yielded promising combinations that result in more sensitive voided materials that satisfy selected criteria. These criteria include high sensitivity and maximum service temperature, low dissipation factor, and high dynamic compressibility, but low hydrostatic compressibility. This talk will describe the model, derive the formulas, uncover measured properties of candidate polymers and gases, and show calculated sensitivity of selected polymer/gas combinations.

3:30

4pEAb2. Basic study on one-dimensional transducer array using hydrothermally synthesized lead zirconium titanete poly-crystalline film. Akito Endo, Tomohito Hasegawa, Norimichi Kawashima, Shinichi Takeuchi (1614, Kurogane-cho, Aoba-ku, Yokohama, Kanagawa, 225-8502, Japan), Mutsuo Ishikawa, and Minoru Kurosawa (Midori-ku, Yokohama, Kanagawa 226-8502, Japan)

Recently, high-frequency miniature medical ultrasound probes with high resolution were actively developed. However, it is difficult to fabricate such tiny ultrasound probes using piezoelectric ceramic vibrator with thickness less than 100 μm. We deposited a PZT poly-crystalline film on a titanium substrate using the hydrothermal method and developed transducers using the PZT poly-crystalline film for ultrasound probes. In this study, we applied it to a miniature medical one-dimensional (1-D)-array-type ultrasound probe with resonance frequency of 10 MHz. After sputtering of pure titanium on the surface of a hydroxyapatite substrate, the titanium film was etched using the photolithography method to form a 1-D titanium film electrode array with 75 μm element pitch, 40 μm element width, and 4 mm element length to scan an ultrasound beam electronically by sector scan mode using phased-array technique. Thereby we fabricated a miniature 1-D-array-type ultrasound probe. A transmitted ultrasound pulse from 10 MHz commercial ultrasound probe was received by this fabricated 1-D-array type ultrasound probe with hydrothermally synthesized PZT poly-crystalline film vibrators.

3:45

4pEAb3. Analysis of a barrel-stave flextensional transducer using MAVART (model to analyze the vibrations and acoustic radiation of transducers) and ATILA (analysis of transducers by integration of LAplace equations) finite-element codes. Richard A. G. Fleming, Mark Kwiecinski, and Dennis F. Jones (Defence R&D Canada—Atlantic, P.O. Box 1012, Dartmouth, NS, Canada B2Y 3Z7, dennis.jones@drdc-rddc.gc.da)

A small barrel-stave flextensional transducer, designed and tested at Defence Research and Development Canada—Atlantic, is a candidate sound source for underwater coastal surveillance and acoustic communications applications. This high-power transducer has an outside diameter, length, and mass of 5.7 cm, 12.7 cm, and 1.1 kg, respectively. The measured fundamental flexural resonance frequency was 1.8 kHz with a transmitting voltage response of 118 dB/1μPa-m/V and an omnidirectional radiation pattern. Two finite-element models were developed for this transducer using the finite-element codes MAVART (Model to Analyze the Vibrations and Acoustic Radiation of Transducers) and ATILA (Analysis of Transducers by Integration of LAplace equations). Comparisons are made between the calibration measurements and the model predictions. [Work supported in part by Sensor Technology Limited.]

4:00

4pEAb4. Thermal behavior of high-power active devices with the ATILA (analysis of transducers by integration of LAplace equations) finite-element code. Jean-Claude Debus (Institut Superieur de l'Electronique et du Numerique, 41 Bv Vauban, 59046 Lille, Cedex France), John BlottmanIII, and Stephen Butler (Naval Undersea Warfare Ctr. Div. Newport, RI 02841)

Many active devices using piezoelectric ceramics are driven with very high power densities and long pulse lengths. Due to mechanical and dielectric losses in the materials, this produces heat, causing a temperature rise in the devices, which may lead to their mechanical failure. The thermal issues have been shown to be the limiting device design criteria over electric field and mechanical stress limits, yet the effect of the temperature on performance is generally not considered in the numerical models used during the design stage. A coupled electro-mechanical thermal analysis is implemented in the ATILA code. For a steady-state or transient solution, a thermal behavior is weakly coupled to the electromechanical response. The method may take advantage of the order-of-magnitude-greater time constant for thermal effects compared to mechanical behavior. A two-step analysis is performed whereby the electromechanical behavior is first computed, and the resulting dissipated power is then applied as a heat generator to determine the resulting temperature of the device. A high-drive, 31-mode, free flooded ring transducer and a sonar projector serve as validation of the numerical model. The approach addresses both the transient thermal response and the steady temperature profile that results from the high-power, high-duty-cycle drive.

4:15

4pEAb5. Development of multichannel optical sensor and visualization of vibration distribution. Jun Hasegawa and Kenji Kobayashi (Faculty of Eng., Takushoku Univ., 815-1 Tatemachi, Hachioji-shi, Tokyo 193-0985 Japan, jhase@es.takushoku-u.ac.jp)

A multi-channel optical sensor system was developed to measure vibrations simultaneously with high spatial resolution. As sensor elements, optical displacement sensor units were developed not to disturb the natural vibration. Each sensor unit, which consists of the optical fiber bundle and focusing lens, can detect the displacement of the object as the variation of the reflected light power. The sensor unit has a displacement resolution of 10 nm, a dynamic range of more than 90 dB, and a frequency band width of up to 80 kHz. Up to 64 sensor units can be arrayed as one sensor head, which realizes the simultaneous measurement of vibration distribution with the high spatial resolution of 4 mm. A calibrating function under the measurement circumstances was developed. Under calibration mode, the sensor array head is moved by a linear actuator, while the vibration of the object is stopped. Thus the calibrated data of each sensor unit can be

obtained for the displacement magnitude. Measured vibration distributions can be monitored as the three-dimensional animations. With the system developed, several actuators for vibratory micro-injection were measured, and the system could reveal their detailed vibration distributions and could detect the existence of a failure portion of some actuator.

4:30

4pEAb6. Prediction of howling for a sound system in an acoustical environment with both reverberant and direct sounds. Hideki Akiyama and Juro Ohga (Shibaura Inst. of Technol., 3-7-5 Toyosu, Koto-ku, Tokyo 135-8548, Japan, m106003@shibaura-it.ac.jp)

Prediction of howling is a key technology for a howling suppression design for a sound system with a loudspeaker and microphone. A howling occurrence prediction method for a sound system in a reverberant room has already been presented [J. Ohga, J. Sakaguchi, "Prediction of howling of a sound system in a reverberant room," W. C. Sabine Centennial Symposium (ASA, New York, 1994), 2aAAd4]. It is apparently useful for ordinary public address systems whose distances of loudspeakers from microphones are large. However, this result was not perfect because the direct sound component is not negligible in hands-free telephones or teleconference systems whose loudspeakers and microphones are set close to each other. This report gives a quantitative howling occurrence prediction method for a sound system in an acoustical environment with both reverberant and direct sounds. The following design parameters are obtained: (1) the increase of howling occurrence level from the power average value, (2) the level occurrence probability, and (3) the critical level chart given by an equation as a function of direct and reverberant sounds ratio. Prediction results for particular examples are compared with calculations of sound-field transfer functions. Results confirmed that it is practical.

4:45

4pEAb7. Effect of background noise on dialogue in telephony. Koichi Amamoto and Juro Ohga (Sibaura Inst. of Technol., 3-7-5 Toyosu, Koto-ku, Tokyo, 135-8548, Japan, m106006@shibaura-it.ac.jp)

Recent developments of mobile telephones include new sorts of impairments against speech. Conventional evaluation method for impairments by a talker and a few listeners cannot apply to these new ones, because they are brought by long signal delay. The effect of it cannot discriminate by "one-sided" test. This research relates to a speech quality evaluation by conversation between two persons. Variation of conversation stream is observed by addition of pink noise of various levels to a dialogue by microphones and earphones. Length of sentences and frequency of repeats are quantified and their meanings are discussed

5:00

4pEAb8. Best practices for auditory alarm design in space applications. Durand Begault and Martine Godfroy (Human Systems Integration Div., NASA Ames Res. Ctr., Moffett Field, CA 94035)

This presentation reviews current knowledge in the design of auditory caution and warning signals, and sets criteria for development of "best practices" for designing new signals for NASA's Crew Exploration Vehicle (CEV) and other future spacecraft, as well as for extra-vehicular operations. A design approach is presented that is based upon cross-disciplinary examination of psychoacoustic research, human factors experience, aerospace practices, and acoustical engineering requirements. Existing alarms currently in use with the NASA Space Shuttle flight deck are analyzed and then alternative designs are proposed that are compliant with ISO 7731 ("Danger signals for work places Auditory Danger Signals") and that correspond to suggested methods in the literature to insure discrimination and audibility. Parallel analyses are shown for a sampling of medical equipment used in surgical, periop, and ICU contexts. Future development of auditory sonification techniques into the design of alarms will allow auditory signals to be extremely subtle, yet extremely useful in subtly indicating trends or root causes of failures. [Work funded by NASA's Space Human Factors Engineering Project.]

5:15

4pEAb9. Acoustic signal analysis for forensic applications. Durand Begault and Christopher Peltier (Audio Forensic Ctr., Charles M. Salter Assoc., 130 Sutter St., Ste. 500, San Francisco, CA 94104, durand.begault@cmsalter.com)

Acoustical analysis of audio signals is important in many legal contexts for determining the authenticity, originality, and continuity of recorded media; determining the circumstances of events in question that may have been recorded; for determining the audibility of signals; and for identification or elimination of talkers as a match to an unknown exemplar. Recorded media are analyzed in forensic applications using both familiar techniques (waveform and spectral analyses) and more novel methods (e.g., ferro fluid development of media; specialized tape heads with non-standard reproduction characteristics; crystal microscopy; detection and matching to power grid frequencies). Audibility analyses frequently require careful reconstructive field measurements and criteria in excess of normally accepted standards. Voice identification-elimination protocols must account for examiner bias and exemplar quality and can be described using a receiver operator curve (ROC) model. This presentation gives an overview of these techniques and their comparative advantages for specific forensic applications.

5:30

4pEAb10. Without low-pass filter for the 1-bit digital amplifier. Kiyoshi Masuda (Coroprate Res. and Development Group, SHARP Corp., 2613-1 Ichinomoto-cho, Tenri-shi, Nara, Japan) and Yoshio Yamasaki (Waseda Univerity, Okubo, Shinzyuku-ku, Tokyo, Japan)

SHARP collaborated with Waseda University from 1990 for 1-bit digital technology. SHARP had started to receive an order for the 1-bit digital amplifier "SM-SX100" on 20 August 1999. Until today, we have introduced the 1-bit digital amplifier for audio, flat panel TV (LCD TV), and PC. These 1-bit amplifiers provided low-pass filter for the final stage,

which is provided after 1-bit digital switching. We have to achieve more good sound and reduce deterioration of this low-pass filter. We have introduced new 1-bit digital amplifier without this low-pass filter beginning this April. This means we controlled the 1-bit digital signal to directly operate the speaker. We have proved a better effect for sound to compare the new 1-bit digital amplifier with the PWM switching amplifier, the A-class amplifier and the 1-bit digital amplifier with low-pass filter. If we do not measure any improvement for this new 1-bit digital amplifier, it has large radiation noise. We had achieved a reduction to the limit level of FCC, Denanhou, etc.

5:45

4pEAb11. Force-frequency effect of thickness mode langasite resonators. Haifeng Zhang (W317.4 Nebraska Hall, Univ. of Nebraska, Lincoln, NE 68588-0526, hfzhang@bigred.unl.edu), Joseph A. Turner, Jiashi Yang (Univ. of Nebraska, Lincoln, NE 68588-0526), and John A. Kosinski (U.S. Army CECOM, Fort Monmouth, NJ 07703-5211)

Langasite resonators are of recent interest for a variety of applications because of their good temperature behavior, good piezoelectric coupling, low acoustic loss, and high Q factor. The force-frequency effect describes the shift in resonant frequency a resonator experiences due to the application of a mechanical load. A clear understanding of this effect is essential for many design applications such as pressure sensors. In this presentation, the frequency shift is analyzed theoretically and numerically for thin, circular langasite plates subjected to a diametrical force. The results are compared with experimental measurements of the same system for a variety of langasite resonators with various material orientations. In addition, the sensitivity of force-frequency effect is analyzed with respect to the nonlinear material constants. A comparison between the force-frequency effect of langasite and quartz resonators is also made. Finally, the application of such measurements for determining third-order elastic constants is discussed. [Work supported by ARO.]

1:20

4pMU1. A meta-analysis of acoustic correlates of timbre dimensions. Stephen McAdams, Bruno Giordano (CIRMMT, Schulich School of Music, McGill Univ., 555 Sherbrooke St. West, Montreal, QC, Canada H3A 1E3), Patrick Susini, Geoffroy Peeters (STMS-IRCAM-CNRS, F-75004 Paris, France), and Vincent Rioux (Maison des Arts Urbains, F-75020 Paris, France)

A meta-analysis of ten published timbre spaces was conducted using multidimensional scaling analyses (CLASCAL) of dissimilarity ratings on recorded, resynthesized, or synthesized musical instrument tones. A set of signal descriptors derived from the tones was drawn from a large set developed at IRCAM, including parameters derived from the long-term amplitude spectrum (slope, centroid, spread, deviation, skewness, kurtosis), from the waveform and amplitude envelope (attack time, fluctuation, roughness), and from variations in the short-term amplitude spectrum (flux). Relations among all descriptors across the 128 sounds were used to determine families of related descriptors and to reduce the number of descriptors tested as predictors. Subsequently multiple correlations between descriptors and the positions of timbres along perceptual dimensions determined by the CLASCAL analyses were

computed. The aim was (1) to select the subset of acoustic descriptors (or their linear combinations) that provided the most generalizable prediction of timbral relations and (2) to provide a signal-based model of timbral description for musical instrument tones. Four primary classes of descriptors emerge: spectral centroid, spectral spread, spectral deviation, and temporal envelope (effective duration/attack time). [Work supported by CRC, CFI, NSERC, CUIDADO European Project.]

1:40

4pMU2. Perceptual acoustics of consonance and disssonance in multitimbral triads. Roger Kendall (Music Cognition and Acoust. Lab., Program in Systematic Musicology, UCLA, 405 Hilgard Ave., Los Angeles, CA 90095, kendall@ucla.edu) and Pantelis Vassilakis (DePaul Univ., Chicago, IL 60614)

Most studies of consonance and dissonance assume a singular spectrum for the constituent intervals of a dyad. Recently, the principal author conducted experiments evaluating triads consisting of digitally mixed combinations drawn from the MUMS single-note natural-instrument recordings. Results indicated that the main effect of ratings for consonance and dissonance correlated well with studies using artificial signals. However, interaction effects suggested perceptual differences related to the timbral differences across combinations. The present experiment evaluates perceptual and acoustical variables of the ten possible triadic combinations created with C4 as the lower and the ten with C5 as the upper notes. UCLA wind ensemble performers on oboe, flute, and clarinet, combinations designed to span timbral space, were digitally recorded. Analyses include perceptual ratings of consonance and dissonance, similarity, as well as acoustical analysis of roughness using a recently developed model. Since natural performances of any type vary in fundamental frequency, additional experiments will employ emulated oboe, flute, and clarinet (using the Kontakt Silver synthesizer in Sibelius 4) as well as purely synthetic stimuli, in order to ascertain the relationship of time-variant spectral properties to consonance, dissonance, and perceived similarity.

2:00

4pMU3. Multidimensional scaling analysis of centroid- and attack/decay-normalized musical instrument sounds. James W. Beauchamp (School of Music and Dept. of Elect. & Comput. Eng., Univ. of Illinois at Urbana–Champaign, Urbana, IL 61801, jwbeauch@uiuc.edu), Andrew B. Horner (Hong Kong Univ. of Sci. & Technol., Kowloon, Hong Kong), Hans-Friedrich Koehn, and Mert Bay (Univ. of Illinois at Urbana-Champaign, Urbana, IL 61801)

Ten sustained musical instrument tones (bassoon, cello, clarinet, flute, horn, oboe, recorder, alto saxophone, trumpet, and violin) were spectrally analyzed and then equalized for duration, attack and decay time, fundamental frequency, number of harmonics, average spectral centroid, and presentation loudness. The tones were resynthesized both with time-varying harmonic amplitudes and frequencies (dynamic case) and fixed amplitudes and frequencies (static case). Tone triads were presented to ten musically experienced listeners whose tasks were to specify the most dissimilar and most similar pairs in each triad. Based on the resulting dissimilarity matrix, multidimensional scaling (MDS) was used to position the instruments in two- and three-dimensional metric spaces. Two measures of instrument amplitude spectra were found to correlate strongly with MDS dimensions. For both the static- and dynamic-case 2-D solutions, the ratio of even-to-odd rms amplitudes correlated strongly with one of the dimensions. For the dynamic case, spectral centroid variation correlated strongly with the second dimension. Also, 2-D solution instrument groupings agreed well with groupings based on coefficients of the first two components of a principle components analysis representing 90% of the instruments' spectral variance. [This work was supported by the Hong Kong Research Grants Council's CERG Project 613505.]

2:20

4pMU4. Sound synthesis based on a new micro timbre notation. Naotoshi Osaka (School of Eng., Tokyo Denki Univ., 2-2, Kanda-Nishikicho, Chiyoda-ku, Tokyo, 101-8457, Japan, osaka@im.dendai.ac.jp), Takayuki Baba, Nobuhiko Kitawaki, and Takeshi Yamada (Univ. of Tsukuba, Japan)

Timbre has become a major musical factor in contemporary and computer music. However, sufficient timbre theory has not yet been established. The author is challenging to create new timbre theory for music composition. The first step of its construction is to make the timbre descriptive. A micro timbre is defined, which is a perceptual impression of a sound with approximately 50 to 100-ms duration, and describe sound as a micro timbre sequence. This can be used as a new notation system in place of common music notation. In dictation, micro timbre sequence and correspondent duration sequence are perceptually recorded. When synthesizing from this notation, sounds corresponding to the notation systems are either physically synthesized or searched for in a large sound database to generate sound data for a given duration. Two sequential sound data instances are first represented in sinusoidal representations and then are concatenated using a morphing technique. Sounds generated by a stream of water and similar sounds are described using the method as examples. Then scripts describing electronic sounds are introduced and explained. The ability to record, transmit to others, and resynthesize timbre is one of the useful functions of the theory.

2:40

4pMU5. Timbre representation for automatic classification of musical instruments. Bozena Kostek (Gdansk Univ. of Technol., Narutowicza 11/12, PL-80-952 Gdansk, Poland)

Human communication includes the capability of recognition. This is particularly true of auditory communication. Music information retrieval (MIR) turns out to be particularly challenging, since many problems remain still unsolved. Topics that should be included within the scope of MIR are automatic classification of musical instruments/phrases/styles, music representation and indexing, estimating musical similarity using both perceptual and musicological criteria, recognizing music using audio and/or semantic description, language modeling for music, auditory scene analysis, and others. Many features of music content description are based on perceptual phenomena and cognition. However, it can easily be observed that most of the low-level descriptors used, for example, in musical instrument classification are more data- than human-oriented. This is because the idea behind these features is to have data

defined and linked in such a way as to be able to use it for more effective automatic discovery, integration, and reuse in various applications. The ambitious task is, however, to provide seamless meaning to low- and high-level descriptors such as timbre descriptors and linking them together. In such a way data can be processed and shared by both systems and people. This paper presents a study related to timbre representation of musical instrument sounds.

3:15

4pMU6. An attempt to construct a quantitative scale of musical brightness for short melodies implementing timbral brightness. Masashi Yamada (Kanazawa Inst. of Technol., 3-1 Yatsukaho, Hakusan, Ishikawa 924-0838, Japan, m-yamada@neptune.kanazawa-it.ac.jp)

It is known that a major tune is brighter than a minor one, and that music played in a faster tempo and a higher register is brighter than a slower and lower one. However, it has not been clarified how these factors quantitatively determine the musical brightness. On the other hand, it has been clarified that the timbral brightness of a tone corresponds well to the spectral centroid. In the present study, major and minor scales and two short melodies were played with pure tones, and listeners evaluated their musical brightness. For each performance, the spectral centroid was calculated for the overall-term spectrum during the performance on the transformed frequency scale of the ERB rate. The results showed that the musical brightness of the ascending scale increases proportionally as the spectral centroid shown in the ERB rate increases. Using this, a quantitative scale of musical brightness, BM, was constructed. The results also showed that the difference in the musical brightness between major and minor scales corresponded to the transposition of approximately 5 ERB rate, and doubling the speed corresponded to the upper shift of the centroid in approximately 2.5 ERB rate.

3:35

4pMU7. Subjective congruency between a sound effect and a switching pattern of a visual image. Shinichiro Iwamiya, Motonori Arita, and Sun Su (Dept. of Acoust. Design, Kyushu Univ., 4-9-1, Shiobaru, Minami-ku, Fukuoka 185-8540, Japan)

The relationship between the transformation of a visual image and the pitch pattern of sound can create formal congruency between sounds and moving pictures. This effect by switching patterns of enlarging and reducing images that were combined with ascending and descending pitch scales was examined. Rating experiments showed two congruent patterns of the combination of switching and scale patterns; one was a combination of an ascending pitch scale and an enlarging image pattern, and the other a combination of a descending pitch scale and a reducing image pattern. These forms of matching might be based on a Doppler illusion. An additional pair of congruent patterns for combinations of switching and scale patterns was also found: one was a combination of an ascending pitch scale and a sliding movement from left to right, and the other a combination of a descending pitch scale and a sliding movement from right to left. These forms of matching might be based on the correspondence of a progressive sensation. Further, the formal congruency between a pitch pattern and the formal transportation can contribute to integrating auditory and visual information and to making audio-visual products more impressive.

4pMU8. SRA: An online tool for spectral and roughness analysis of sound signals. Pantelis Vassilakis (School of Music, ITD, Libraries, DePaul Univ., 2350 N. Kenmore Ave., JTR 207, Chicago, IL 60614)

SRA performs spectral and roughness analysis on user-submitted 250- to 1000-ms-long portions of sound files (.wav/.aif formats). Spectral analysis incorporates an improved STFT algorithm [K. Fitz and L. Haken, J. Aud. Eng. Soc. **50**(11), 879–893 (2002)] and automates spectral peak-picking using the Loris open source C++ class library [Fitz and Haken (CERL Sound Group)]. Users can manipulate three spectral analysis/peak-picking parameters: analysis bandwidth, spectral-amplitude normalization, and spectral-amplitude threshold. Instructions describe the parameters in detail and suggest settings appropriate to the submitted files and questions of interest. The spectral values obtained from the analysis enter a roughness estimation model [P. N. Vassilakis, Sele. Rep. in Ethnomusicol. **12**, 119–144 (2005)], outputting roughness values for each individual sine-pair in the file's spectrum and for the entire file. The roughness model quantifies the dependence of roughness on a sine-pair's (a) intensity (combined amplitude of the sines), (b) amplitude fluctuation degree (amplitude difference of the sines), (c) amplitude fluctuation rate (frequency difference of the sines), and (d) register (lower sine frequency). Presentation of the roughness estimation model and the online tool will be followed by a discussion of research studies employing it and an outline of future possible applications. [Work supported by DePaul University and Eastern Washington University. Programmed by K. Fitz.]

4pMU9. Further spectral correlations of timbral adjectives used by musicians. Alastair C. Disley, David M. Howard, and Andrew D. Hunt (Dept. of Electron., Univ. of York, Heslington, York, YO10 5DD, UK)

As part of a project to develop a synthesis interface which nontechnical musicians should find intuitive, the adjectives musicians use to describe timbre have been studied in a large-scale listening test covering the timbre space of Western orchestral instruments. These were refined in previous work by the authors (A. C. Disley *et al.* "Spectral correlations of timbral adjectives used by musicians," J. Acoust. Soc. Am. **119**, 3333, (2006)] to a set of ten words which had good common understanding and discrimination between the samples (bright, clear, dull, gentle, harsh, nasal, percussive, ringing, thin, and warm). To help explore potential relationships between these adjectives and spectral features, 20 listeners participated in a further listening experiment, comparing samples in pairs to produce dissimilarity data. Multidimensional scaling produced dimensions which were compared with a large number of spectral and time-domain analyses of the stimuli, suggesting a number of significantly correlated spectral cues with some of the adjectives. These results are compared with previous studies by the authors and others, showing both similarities and differences, suggesting that collective consideration of timbral adjectives is more likely to result in simultaneously applicable theories of acoustic correlates than individual consideration of words.

4pNSa1. Mapping soundscapes in urban quiet areas. Gaetano Licitra (ARPAT, Tuscany Regional Agency for Environ. Protection, Via N. Porpora, 22-50144, Firenze, Italy), Gianluca Memoli (Memolix, Environ. Consultants, 56127 Pisa, Italy), Mauro Cerchiai, and Luca Nencini (ARPAT, 56127 Pisa, Italy)

Innovative action plans in noise-polluted environments require the description of the existing soundscape in terms of suitable indicators. The role of these indicators, giving the "fingerprint" of a fixed soundscape, would be not only to measure the improvement in the sound quality after the action taken, but also to guide the designer in the process, providing a reference benchmark. One of the open questions on new indicators is the way they relate to existing ones and to people's perception. The present work will describe a "Sonic Garden" in Florence, using both the "slope" indicator (constructed from the LA_{eq} time history and related in previous studies to people's perception) and classical psychoacoustical parameters (level, spectral structure, and perceived characteristics such as loudness, sharpness, fluctuation, and roughness). The latter parameters will be acquired using a binaural technique.

1:15

4pNSa2. A questionnaire survey of the attitude of Japanese and foreign residents in Japan to sound masking devices for toilets. Miwako Ueda and Shin-ichiro Iwamiya (Grad. School of Design, Kyushu Univ., Iwamiya Lab. 4-9-1, Shiobaru, Minami-ku, Fukuoka 815-8540 Japan, amaria@white.livedoor.com)

Unique sound masking devices for toilets can be used in women's restrooms in Japan. Such devices function to produce the sound of flushing water without actual flushing. To mask the sound of bodily functions, women tended to flush the toilet continuously while using it, thereby wasting a large amount of water. In the circumstances, sound masking devices have been introduced to public toilets. We have recently conducted a questionnaire survey to clarify the attitude of people toward such sound masking devices for toilets. The results of the survey showed that many Japanese women know such devices and often use them, that foreign women currently living in Japan also know that such devices exist, and that some Japanese men have heard of such devices but never used them. Many Japanese women are quite embarrassed at the thought that someone else can hear them while they are on the toilet. Many noted the necessity of such devices and required a wide range of setting for toilets in public spaces. However, they are not satisfied with the sound quality of the playback toilet flush sounds of currently available devices. The above results suggest that the sound quality of such devices should be improved.

4pNSb1. A review of the vibration and sounds of the crack of the bat and player auditory clues. Robert Collier (Thayer School of Eng., 8000 Cummings Hall, Hanover, NH 03755)

The purpose of this paper is to review the state-of-the-art in the acoustics of baseball. As is well known, the crack of the bat is an important phenomenon of solid wood bats and metal bats. Each has a very different sound signature. At the 148th meeting of the ASA in 2004, the author and coauthors Ken Kaliski and James Sherwood presented the results of laboratory and field tests, which showed

that the spectral characteristics of radiated sound are dependent on the ball-bat impact location and resultant bat vibration of both solid wood and tubular metal bats. These results will be reviewed together with those of other investigators in the context of player auditory clues and the player's response in game situations.

2:35

4pNSb2. Measurements of the impact sound of golf clubs and risk of hearing impairment. Kenji Kurakata (Natl. Inst. of Adv. Industrial Sci. and Technol. (AIST), 1-1-1 Higashi, Tsukuba, Ibaraki, 305-8566 Japan, kurakata-k@aist.go.jp)

The ball-impact sounds of golf clubs with metal heads and of a club with a wood head were measured to investigate their different acoustic properties. Hitting was executed using either a swing machine or a human player. Results of these analyses showed that the metal-head clubs generated sounds around 100 dB ($L_{pA,Fmax}$). This level was 5–15 dB higher than that of the wood-head club. The sounds of the metal-head clubs had greater power in the high-frequency region of 4 kHz and above compared to the wood-head club, which particularly increased the overall sound levels. These results suggest that it would be desirable to develop a metal head with pleasant sound qualities, keeping the sound level lower to minimize hearing damage. Some of these measurement data were published in Japanese in a previous paper [K. Kurakata, J. INCE/J **26**, 60–63 (2002)].

2:55

4pNSb3. New underwater sound system for synchronized swimming: The 9th International Swimming Federation Championships. Takayuki Watanabe, Shinji Kishinaga (YAMAHA Ctr. for Adv. Sound Technologies, 203 Matsunokijima, Iwata, Shizuoka, 438-0192 Japan), Tokuzo Fukamachi (YAMAHA Motor Marine Operations, Arai, Hamana, 438-8501 Japan), and Osamu Maeda (YAMAHA Motor Adv. Technol. Res. Div., Iwata, 438-8501 Japan)

There have been concerns about the differences between underwater sound fields in a temporary fiberglass-reinforced plastic (FRP) pool and in a conventional reinforced concrete (RC) pool. A temporary FRP pool was to be used for competitions at the World Swimming Championships in Fukuoka. We considered three items as key factors for a swimming pool used for synchronized swimming: (1) the sound source itself (output level, fluctuations in frequency characteristics); (2) the effect of materials used in pool construction upon sound source installation conditions; and (3) the effect of the mth mode low-frequency cutoff in "shallow water." To improve basic problems related to the first factor, we developed a new actuator-driven underwater sound system (YALAS), which can eliminate the effect of installation conditions for underwater speakers in the FRP pool. This new underwater system has now seen practical use in competitions. The report summarizes this new underwater sound system and compares the system with conventional systems in terms of its acoustic characteristics. The system can offer music with sufficient audibility in water. We gained a good reputation with competitors because the system showed superior performance to conventional systems in sound volume and quality, and in uniformity of sound distribution.

3:15

4pNSb4. Acoustics of the Great Ball Court at Chichen Itza, Mexico. David Lubman (14301 Middletown Ln., Westminster, CA 92683)

The ball game has played a central role in Mayan religion and culture for 5000 years. Thousands of ball courts have been discovered. The Great Ball Court (GBC) at Chichen Itza is a late development and is architecturally unique. Two remarkable acoustical features were noticed during excavation in the 1920s, but never explained or interpreted. A whispering gallery permits voice communication between temples located about 460 feet (140 m) apart. A profound flutter echo is heard between the two massive parallel walls of the playing field, about 270 ft (82 m) long, 28 ft (8.5 m) high, and 119 ft (36 m) apart. Until recently, most archaeologists dismissed acoustical features at Mayan sites as unintended artifacts. That is now changing. Stimulated by archaeological acoustic studies and reports since 1999, eminent Mayanists Stephen Houston and Karl Taube have reinterpreted certain Mayan glyphs as vibrant sounds and ballcourt echoes, and have famously called for a new archaeology of the senses, especially hearing, sight, and smell [Cambridge Archaeol. J. **10** (2) 261–294 (2000)]. By interpreting architectural, psychoacoustic, and cognitive features of the GBC in the context of ancient Mayan culture, this paper speculates that acoustical effects at the GBC may be original design features.

4pNSb5. Sleep disturbance caused by shooting sounds. Joos Vos (TNO Human Factors, P.O. Box 23, 3769 ZG Soesterberg, The Netherlands, joos.vos@tno.nl)

In the present study relations between the sound level of shooting sounds and the probability of behaviorally confirmed noise-induced awakening reactions were determined. The sounds were presented by means of loudspeakers in the bedrooms of 30 volunteers. The shooting sounds had been produced by a small and a medium-large firearm, and the stimuli consisted of individual bangs or volleys of ten isolated or partly overlapping impulses. Aircraft sound was included as a reference source. The sounds were presented during a 6-h period that started 75 min after the beginning of the sleeping period. The time period between the various stimuli varied between 12 and 18 min, with a mean of 15 min. To cope with at least a relevant portion of habituation effects, each subject participated in 18 nights to be completed within 4 weeks. Preliminary results are presented both for the awakening reactions described above, and for vari-

ous other dependent variables collected with the help of an actimeter or determined by means of subjective rating scales. [Work supported by the Dutch Ministry of Defense.]

4pNSb6. Sound inside a gymnasium. Sergio Beristain (ESIME, IPN, IMA., P.O. Box 12-1022, Narvarte, 03001, Mexico City, Mexico)

A new gymnasium for a sports club was designed taking acoustic confort into consideration, in order to accomodate sports practice, sports events with the public, or musical and drama presentations, taking advantage of its large capacity for the public and performers. The floor plan included room enough for a basketball court with public space on one side, where grades for about 200 people will be permanently installed. Walls were treated in a way that is useful for the sports practice (hard surfaces), with hidden absorption material to reduce the usual reverberant

field inside the court, and to allow for sound events with only the addition of a mat (to protect the floor woodwork) and extra grades and the sound reinforcement system.

4:05

4pNSb7. Occupational and recreational noise exposures at stock car racing circuits. Chucri A. Kardous, Thais Morata, and Luann E. Van Campen (Natl. Inst. for Occupational Safety Health, 4676 Columbia Pkwy., Cincinnati, OH 45226, ckardous@cdc.gov)

Noise in stock car racing is accepted as a normal occurrence but the exposure levels associated with the sport have not been adequately characterized. Researchers from the National Institute for Occupational Safety and Health (NIOSH) conducted an exploratory assessment of noise exposures to drivers, pit crew, team staff, and spectators at three stock car racing events. Area measurements were made during race preparation, practice, qualification, and competition. Personal dosimetry measurements were conducted on drivers, crew members, infield staff, and spectators. Findings showed time-weighted averages (TWA) that ranged from 94 decibels A-weighted (dBA) for spectators to 114 dBA for car drivers. Peak sound-pressure levels exceeded the maximum allowable limit of 140 decibels (dB) during race competitions. Personal exposure measurements exceeded the NIOSH recommended exposure limit (REL) of 85 dBA as an 8-h TWA in less than a minute for one driver during practice, within 2 min

for pit crew and infield staff, and 7 to 10 min for spectators during the race. Hearing protection use was variable and intermittent among crew, staff, and spectators. Among drivers and crew, there was greater concern for communication performance than for hearing protection.

4:20

4pNSb8. Sports acoustics: Using sound from resonant shells, vibrating cylinders, strumming shafts, and water impact to evaluate athletic performance. David G. Browning (Dept. of Phys., Univ. of Rhode Island, Kingston, RI 02881, decibeldb@aol.com) and Peter M. Scheifele (Univ. of Connecticut, Storrs, CT 06269)

The sound from equipment used and/or specific acts during athletic competition, such as hitting a baseball with an aluminum bat, carries beyond the playing field and can provide a nonobtrusive method to evaluate athletic performance—such as where on the bat the ball was hit. Standardized equipment guarantees repeatability, for example, every volleyball resonates at the same frequency. Each major sport can have unique noise interference which in some circumstances can be overwhelming, and the distance from the sound source can vary significantly during a game. Still, it will be shown that useful performance information can be obtained under realistic conditions for at least the following sports: volleyball, softball, baseball, golf, swimming and diving, soccer, and football.

4pPA1. Observables and prediction modeling in the presence of ultra-wideband heterogeneity. John J. McCoy (The Catholic Univ. of America, Washington, DC 20064)

Underlying virtually all propagation and scattering models is an intuitive understanding; the acoustic field is observable using a device of a sufficiently small size to obtain a sufficiently dense set of discrete measurements. This assumes the field variation cuts off at an inner length scale larger than the device size, assuring that no information is lost to the inherent spatial averaging in any measurement. This understanding is faulty in the presence of environment heterogeneity observed on an extreme range of length scales. The reason is that all physical devices have finite accuracy, which limits their ability to capture variation on scales significantly larger than their size, in the presence of variation on intermediate scales. A more refined understanding of the ability to observe a field requires multiple devices, an unbounded hierarchy in the limit, to obtain multiple dense sets of discrete "observables." This, then, suggests a different class of prediction models for environments with ultra-wideband heterogeneity, expressed in multiple sets of discrete variables, each set describing field variation in a limited subband. A framework for formulating these prediction models and their application to a scenario for which environment heterogeneity has no inner scale cutoff is presented.

Contributed Papers

4pPA2. Parameters arising from the Burridge-Keller formulation for poroelastic media, especially for granular media and marine sediments. Allan D. Pierce, William M. Carey, and Paul E. Barbone (Boston Univ., Boston, MA 02215)

It was previously shown [Pierce *et al.* (2006)] that the Burridge-Keller formulation [J. Acoust. Soc. Am. (1981)] rigorously justifies the low-frequency version [(1956a)] of Biot's equations. Implementation involves two microscale problems: (1) incompressible viscous flow driven in a highly irregular space with rigid walls by a uniformly and externally applied apparent pressure distribution and (2) elastostatic deformation of an intricate elastic web caused by the joint influence of a distributed constant body force and by uniform tractions (including an external pressure) on the web's exposed surface. Microscale averages produce the Biot "constants." Theoretical devices of applied mechanics and mathematics yield estimates of these and related parameters. In particular, it is shown that Wood's equation is a reasonable first approximation for the sound speed in sediments in the low-frequency limit. The formulation also yields an estimation for the sound speed in the high-frequency limit, when the viscous boundary layers become thin. The well-known result that the attenuation varies as $f^{1/2}$ in the high-frequency limit also results without the necessity of Biot's heuristic patching theory. Various heuristic approximations due to Gassmann, to Geertsma and Smit, and to Stoll and Bryant are analytically and numerically assessed.

4pPA3. Sound propagation in the mixtures of liquid and solid aggregate; similarities at micro- and nanoscales.. Hasson M. Tavossi (Dept. of Physical and Environ. Sci., Mesa State College, 1100 North Ave., Grand Junction, CO 81504)

Sound propagation phenomena in certain liquid and solid aggregate mixtures, at micrometer scales, in some cases resemble the wave propagation behaviors of materials observed at nanometer and atomic scales. For example, it can be shown that the sound wave dispersion, attenuation, and cutoff-frequency effects depend on the same structural parameters as those observed at nano or atomic levels and are similar at both scales. Therefore, to investigate theoretical models of wave and matter interactions it is more convenient to use, as experimental tools, the readily analyzable models of wave propagation, in mixtures of solid and liquid, constructed at micrometer scales. Theoretical findings on sound propagation in the mixtures of liquid and solid particles at micrometer scales will be discussed. These results show the resemblance to the behavior of acoustic phonons, the lattice thermal vibrations of crystalline structures, at radically different scales. Experimental data on wave dispersion, attenuation, bandpass, and cutoff frequency effects, measured for sound propagation, in inhomogeneous materials consisting of mixtures of solid and liquid will be presented, showing the similarities of wave propagation behaviors at micro- and nanoscales.

4pPA4. Nonlinear surface waves in soil. Evgenia A. Zabolotskaya, Yurii A. Ilinskii, and Mark F. Hamilton (Appl. Res. Labs., Univ. of Texas, P.O. Box 8029, Austin, TX 78713-8029)

Nonlinear effects in surface waves propagating in soil are investigated theoretically. Analytic solutions are derived for the second harmonics and difference frequency waves generated by a bifrequency primary wave propagating at moderate amplitude. The soil is modeled as an isotropic solid. As such, its elastic properties are described by five elastic constants, two at second order in the strain energy density (the shear and bulk moduli) and three at third order. Nonlinear propagation of the surface waves is based on a theory developed previously [Zabolotskaya, J. Acoust. Soc. Am. **91**, 2569–2575 (1992)]. Elements of the nonlinearity matrix associated with the interacting spectral components are expressed in terms of the five elastic constants. It was found convenient to express the nonlinearity matrix for soil as a function of a nonlinearity parameter corresponding to B/A for liquids, particularly for saturated soils exhibiting liquidlike properties. This nonlinearity parameter can vary by several orders of magnitude. For soils with shear wave speeds less than 20% of the compressional wave speeds, the nonlinearity of surfaces waves is found to be independent of the third-order elastic constants and dependent only on the shear modulus. [Work supported by ONR.]

4pPA5. The measurement of the hysteretic nonlinearity parameter of a field soil by the phase shift method: A long-term survey. Zhiqu Lu (Natl. Ctr. for Physical Acoust., The Univ. of Mississippi, Univ., MS 38677)

Soil properties significantly affect the performance of the acoustic landmine detection. The climate and seasonal changes cause the variations of soil properties and smear landmine signature over time. On the other hand, soil is a complicated granular material that exhibits strong nonlinear acoustic behaviors. To understand the weather and seasonal effects on nonlinear acoustic behaviors of soils, a phase shift method is used to measure the hysteretic nonlinearity parameter of a field soil. The technique is based on measuring the variation of phase difference between two transducers, i.e., the phase shift, induced by changing sound level. The hysteretic nonlinear parameter can be extracted from the measured phase shift as a function of sound level or dynamic strain. In a long-term survey, the nonlinearity parameter, sound speed, and environmental conditions such as temperature, moisture, soil water potential, and rainfall precipitation are measured. It is found that the nonlinearity parameter is much more sensitive than sound speed to the climate change. Soil water potential is the predominant factor that affects the nonlinearity parameter and sound speed of the shallow field soil.

4pPA6. Nonlinear acoustic landmine detection: Comparison of soil nonlinearity with soil-interface nonlinearity. Murray S. Korman, Kathleen E. Pauls, Sean A. Genis (Dept. of Phys., U. S. Naval Acad., Annapolis, MD 21402), and James M. Sabatier (Univ. of Mississippi, Univ., MS 38677)

To model the soil-top plate interface in nonlinear acoustic landmine detection, the soil-plate oscillator was developed [J. Acoust. Soc. Am. **116**, 3354–3369 (2004)]. A Lexan plate (2.39 mm thick, 18.5 cm diameter) is clamped at an inside diameter of 11.8 cm between two metal flanges. Dry sifted masonry sand (2-cm layer) is placed over the plate. Turning curves experiments are performed by driving a loudspeaker (located over the sand) by a swept sinusoid. The acceleration versus frequency is measured near resonance on a swept spectrum analyzer using an accelerometer centered on the surface. The corresponding backbone curve exhibits a linear decrease in resonant frequency f versus increasing acceleration, where $a = -a_o(f-f_o)/f_o$. Define a nonlinear parameter $\alpha = 1/a_o$. When the elastic plate is replaced by a "rigid" plate, α decreased from 0.128 to 0.070 (s^2/m), while f_o increased from 191 to 466 Hz. When a cylindrical drumlike mine simulant (rigid walls, thin acrylic top-plate) was buried 2 cm deep in a concrete sand box, "on the mine" results yielded $\alpha = 0.30$ (s^2/m) with $f_o = 147$ Hz, while "off the mine," $\alpha \sim 0.03$ (s^2/m) at $f_o = 147$ Hz. [Work supported by ONR.]

4pPA7. Causality conditions and signal propagation in bubbly water. Gregory J. Orris, Dalcio K. Dacol, and Michael Nicholas (Naval Res. Lab., 4555 Overlook Ave. SW, Washington, DC 20375)

Acoustic propagation through subsurface bubble clouds in the ocean can exhibit signal travel times with enormous variations depending on the acoustic signal frequency, bubble size distribution, and void fraction. Recent theories have predicted large variations in phase speeds and attenuation that have been largely validated for frequencies well below and well above bubble resonance. However, great care must be exercised when

theoretically treating signal propagation at frequencies near resonance, termed the "Anomalous Absorption Regime" nearly 100 years ago in the pioneering work of Sommerfeld [A. Sommerfeld, Physik. Z. **8**, 841 (1975)] while investigating aspects of electromagnetic causality. We will discuss similarities between acoustic propagation in bubbly media and electromagnetic propagation in the presence of a conducting medium. We show that the signal travel time is dependent on the behavior of the dispersion formula in the complex frequency plane and place limits on the range of validity of these formulas, leading naturally to the necessary modifications to the current dispersion formulas to bring them into compliance with causality. Finally, we present theoretical results for the velocity of signals for a representative environment of experimental work carried out at the Naval Research Laboratory. [Work supported by the ONR.]

3:20

4pPA8. Measurements of the attenuation and sound speed in bubbly salt water. Gregory J. Orris, Dalcio K. Dacol, and Michael Nicholas (Naval Res. Lab., 4555 Overlook Ave. SW, Washington, DC 20375)

Bubble clouds were injected from below the surface of a 144-cubic-meter water tank, wherein hydrophones were placed at varying distances from an acoustic source. Measurements were made over a wide range of frequencies to verify and validate the theoretical predictions of the relevant dispersion formula. This work was undertaken under a variety of conditions by varying the relevant environmental parameters: void fraction, temperature, and salinity. Void fractions were varied from roughly 0.02% to 0.1%. Temperatures ranged from 9 °C to 18 °C, and the salinity was varied from zero to approximately 10% of typical oceanic values. Particular attention was paid to tracking the phase of the transmitted signal as the frequency progressed toward resonance starting from 100 kHz. This yielded phase-speed measurements in an essentially free-field environment using a modified version of phase spectral analysis. Time-of-flight measurements gave signal velocities, while the received energy yielded the attenuation. Results are compared to theoretical calculations, leading to the conclusion that current theoretical dispersion formula requires modification. [This work supported by the ONR.]

3:35

4pPA9. Efficient computation of 3-D acoustical scattering from multiple arbitrarily shaped objects using the boundary element method/fast multipole method (BEM/FMM). Nail A. Gumerov and Ramani Duraiswami (Perceptual Interfaces and Reality Lab., Inst. for Adv. Comput. Studies, Univ. of Maryland, College Park, MD 20742)

Many applications require computation of acoustic fields in systems consisting of a large number of scatterers, which may have complex shape. Despite the boundary element method being a well-known technique for solution of the boundary value problems for the Helmholtz equation, its capabilities are usually limited by the memory and speed of computers, and conventional methods can be applicable to relatively small (up to order of 10 000 boundary elements) problems. We developed and implemented an efficient computational technique, based on an iterative solver employing generalized minimal residual method in combination with matrix-vector multiplication speeded up with the fast multipole method. We demonstrate that this technique has $O(N)$ memory and computational complexity and enables solution of problems with thousands of scatterers (millions of boundary elements) on a desktop PC. The test problems solved are of moderate frequency (up to $kD \leqslant 150$, where k is the wavenumber and D is the size of the computational domain). Solution of large scale scattering problems was tested by comparison with the FMM-based T-matrix method applicable for simple shape objects reported earlier [Gumerov and Duraiswami, J. Acoust. Soc. Am., **117**(4), 1744–1761 (2005)], visualization, and physical interpretation of the results.

3:50

4pPA10. Fast acoustic integral-equation solver for complex inhomogeneous media. Elizabeth Bleszynski, Marek Bleszynski, and Thomas Jaroszewicz (Monopole Res., 739 Calle Sequoia, Thousand Oaks, CA 91360, elizabeth@monopoleresearch.com)

We describe elements and representative applications of an integral-equation solver for large-scale computations in acoustic wave propagation problems. In the solver construction we used elements of our previously developed fast integral-equation solver for Maxwell's equations. In comparison with the conventional integral equation approach (method of moments), our solver achieves significant reduction of execution time and memory through the FFT-based matrix compression. One particular aspect of the solver we discuss, pertinent to its high efficiency and accuracy, is an efficient treatment of problems associated with subwavelength discretization. We illustrate the approach and its application on the example of a numerical simulation of acoustic wave propagation through the human head. [Work was supported by a grant from AFOSR.]

4:05

4pPA11. Models for acoustic scattering in high contrast media. Max Denis, Charles Thompson, and Kavitha Chandra (Univ. Massachusetts Lowell, One University Ave., Lowell, MA 01854)

In this work a numerical method for evaluating backscatter from a three-dimensional medium having high acoustic contrast is presented. The solution is sought in terms of a perturbation expansion in the contrast amplitude. It is shown that limitations of the regular perturbation expansion can be overcome by recasting the perturbation sequence as a rational fraction using Padé approximants. The resulting solution allows for an accurate representation of the pressure and allows for the poles in the frequency response to be modeled. The determination of the pulse-echo response for a high-contrast medium is discussed and presented.

4:20

4pPA12. Multiple scattering and visco-thermal effects. Aroune Duclos, Denis Lafarge, Vincent Pagneux (Laboratoire d'Acoustique de l'Universite du Maine, Ave. Olivier Messiaen, 72085 Le Mans, France), and Andrea Cortis (Lawrence Berkeley Natl. Lab., Berkeley, CA 94720)

For modeling sound propagation in a rigid-framed fluid-saturated porous material it is customary to use frequency-dependent density and compressibility functions. These functions, which describe "temporal" dispersion effects due to inertial/viscous and thermal effects, can be computed by FEM in simple geometries and give complete information about the long-wavelength properties of the medium. When the wavelength is reduced, new effects due to scattering must be considered. To study this, we consider solving the sound propagation problem in a 2-D "phononic crystal" made of an infinite square lattice of solid cylinders embedded in a fluid. An exact multiple-scattering solution is first developed for an ideal saturating fluid and then generalized to the case of visco-thermal fluid, by using the concept of visco-thermal admittances. The condition to use this concept is that the viscous and thermal penetration depths are small compared to the cylinder radius. We validate our results in the long-wavelength regime by direct comparisons with FEM data [A. Cortis, "Dynamic parameters of porous media," Ph.D. dissertation (Delft U.P., Delft, (2002)]. When frequency increases, differences appear between the long-wavelength solution and the exact multiple-scattering solution, which could be interpreted in terms of "spatial" dispersion effects.

4:35

4pPA13. Effective parameters of periodic and random distributions of rigid cylinders in air. Daniel Torrent and José Sánchez-Dehesa (Wave Phenomena Group, Nanophotonics Technol. Ctr., Polytechnic Univ. of Valencia, C/Camino de vera s/n., E-46022 Valencia, Spain)

The scattering of sound by finite-size clusters consisting of two-dimensional distributions (periodic and random) of rigid cylinders in air is theoretically studied in the low-frequency limit (homogenization). Analyti-

cal expressions for the effective density and sound speed obtained in the framework of multiple scattering will be reported. For the case of circular-shaped cluster, we have theoretically analyzed the homogenization as a function of the filling fraction, the type of arrangement of the cylinders in the cluster (hexagonal and square lattice), and the number of cylinders in the cluster. When the number of cylinders in the cluster is small we found that for certain ''magic numbers'' their effective parameters (sound speed and density) are the same as those of the corresponding infinite array. [Work supported by MEC of Spain.]

4pPA14. The application of *k*-space acoustic propagation models to biomedical photoacoustics. Benjamin T. Cox (Dept. of Med. Phys. and Bioengineering, Univ. College London, Gower St., London, WC1E 6BT, UK, bencox@mpb.ucl.ac.uk), Simon. R. Arridge, and Paul C. Beard (Univ. College London, Gower St., London, WC1E 6BT, UK)

k−space models for broadband acoustic pulse propagation differ from pseudo−spectral time domain (PSTD) models in their treatment of the time step. By replacing a finite−difference scheme with a propagator, exact for homogeneous media, larger time steps can be taken without loss of accuracy or stability and without introducing dispersion. Three k−space models for modeling photoacoustically generated (PA) pulses are described here. A very simple, exact, model of PA propagation in a homogeneous fluid is used to introduce the k−space propagator, and two models of propagation in heterogeneous media, originally designed for modeling scattering in soft tissue, are adapted for use in photoacoustics [Mast *et al.*, IEEE Trans. UFFC **48**, 341−354 (2001); Tabei *et al.*, J. Acoust. Soc. Am. **111**, 53−63 (2002)]. Our motivation for describing these models comes from biomedical PA imaging, in which one of the current limitations is the assumption that soft tissue has a uniform sound speed. Efficient, accurate, and simple−to−encode forward models such as these are very useful for studying the effects of the heterogeneities encountered in practice. They may also be useful in designing PA imaging schemes that can account for acoustic heterogeneities. [This work was funded by the EPSRC, UK]

4pPA15. Emergence of the acoustic Green's function from thermal noise. Oleg A. Godin (CIRES, Univ. of Colorado and NOAA, Earth System Res. Lab., 325 Broadway, Boulder, CO 80305, oleg.godin@noaa.gov)

Recently proposed applications of noise cross-correlation measurements to passive remote sensing range from ultrasonics and acoustic oceanography to helioseismology and geophysics, at wave frequencies that differ by more than ten orders of magnitude. At the heart of these applications is the possibility to retrieve an estimate of a deterministic Green's function from long-range correlations of diffuse noise fields. Apparently, S. M. Rytov [*A Theory of Electrical Fluctuations and Thermal Radiation* (USSR Academy of Sciences, Moscow, 1953)] was the first to establish theoretically a simple relation between the Green's function and the two-point correlation function of fluctuations of wave fields generated by random sources. He used reciprocity considerations to analyze fluctuations of electromagnetic fields. In this paper, an acoustic counterpart of Rytov's approach is applied to derive exact and asymptotic relations between respective acoustic Green's functions and cross-correlation of thermal noise in inhomogeneous fluid, solid, and fluid-solid media. Parameters of the media are assumed to be time independent, but can be arbitrary functions of spatial coordinates. Theoretical results obtained are compared to those previously reported in the literature.

5:20

4pPA16. Simulation of elastic wave scattering in living tissue at the cellular level. Timothy E. Doyle and Keith H. Warnick (Dept. of Phys., Utah State Univ., 4415 Old Main Hill, Logan, UT 84322-4415, timdoyle@cc.usu.edu)

Elastic wave scattering in biological tissue has been simulated at the cellular level by incorporating a first-order approximation of the cell structure and multiple scattering between cells. The cells were modeled with a concentric spherical shell-core structure embedded in a medium, with the core, shell, and medium representing the cell nucleus, the cell cytoplasm, and the extracellular matrix, respectively. Using vector multipole expansions and boundary conditions, scattering solutions were derived for a single cell with either solid or fluid properties for each of the cell components. Multiple scattering between cells was simulated using addition theorems to translate the multipole fields from cell to cell and using an iterative process to refine the scattering solutions. Backscattering simulations of single cells demonstrated that changes in the nuclear diameter had the greatest effect on the frequency spectra as compared to changes in cell size, density, and shear modulus. Wave field images and spectra from clusters of up to several hundred cells were also simulated, and they exhibited phenomena such as wave field enhancement at the cell membrane and nuclear envelope due to the scattering processes. Relevant applications for these models include ultrasonic tissue characterization and ultrasound-mediated gene transfection and drug delivery.

5:35

4pPA17. Acoustic analog of electronic Bloch oscillations and Zener tunneling. José Sánchez-Dehesa, Helios Sanchis-Alepuz, Yu. A. Kosevich, and Daniel Torrent (Wave Phenomena Group, Polytechnic Univ. of Valencia, C/Camino de Vera s.n., E-46022 Valencia, Spain)

The observation of Bloch oscillations in sound propagation through a multilayer of two different fluidlike components is predicted. In order to obtain the equivalent to the acoustic analog of a Wannier-Stark ladder [E. E. Mendez *et al.*, Phys. Rev. Lett. **60**, 2426–2429 (1988)], a set of cavities with increasing thickness is employed. Bloch oscillations were theoretically predicted as time-resolved oscillations in transmission in direct analogy to electronic Bloch oscillations in semiconductor superlattices [J. Feldmann *et al.*, Phys. Rev. B **46**, R7252–R7255 (1992)]. Finally, an experimental setup is proposed to observe the phenomenon by using arrays of cylindrical rods in air, which acoustically behaves as a fluidlike system with effective sound velocity and density [D. Torrent *et al.*, Phys. Rev. Lett. **96**, 204302 (2006)]. For the proposed system, Bloch oscillations and Zener tunneling are confirmed by using multiple scattering simulations. [Work supported by MEC of Spain.]

4pPA18. Comparison of time reversal acoustic and prefiltering methods of focusing of tone burst signals. Bok Kyoung Choi (Korea Ocean Res. and Development Inst., Sangrok-gu, 426-744, Korea), Alexander Sutin, and Armen Sarvazyan (Artann Labs., Inc., West Trenton, NJ 08618)

The concept of time reversal acoustics (TRA) provides an elegant possibility of both temporal and spatial concentration of acoustic energy in highly inhomogeneous media. TRA-based focusing is typically used for generation of short acoustic pulses, however, in some medical and industrial applications, longer pulses are required. TRA focusing of longer signals leads to an increase of side lobes in temporal and spatial domains. Another method for focusing, known as prefiltering, is based on measurements of the impulse response, which relates the signal at the TRA transmitter to that at the focusing point. After evaluating the impulse response, the excitation signal may be calculated to generate the desired waveform in the focus point. This method allows signal generation with any desired form including long tone-burst signals. Experiments on comparison TRA and prefiltering methods of ultrasound focusing were conducted in the frequency band of 200–1000 kHz. In the experiments, focused acoustic pulses with various forms and duration were generated: triangular, rectan-

4p FRI. PM

gular, and amplitude-modulated tone burst signals. The prefiltering modes provide better temporal compression of the focused signal, and the signal energy outside the main pulse in the prefiltering mode was shown to be much lower than that in standard TRA focusing.

6:05

4pPA19. Modeling quasi-one-dimensional sound propagation in ducts having two propagation media using a cross-sectional averaging theory. Donald Bliss and Lisa Burton (Dept. of Mech. Eng. and Mater. Sci., Duke Univ., Durham, NC 27708)

Sound propagation of quasi-one-dimensional waves through a uniform duct partially filled with porous material has been studied theoretically and experimentally. The porous material makes the effective propagation wave number in the duct complex. A fairly simple theory based on cross-sectional averaging is derived and tested and found to work extremely well up to fairly high frequency. Interestingly, the basic theory depends only on the ratio of cross-sectional areas and the properties of the individual propagation media, but not on the specific configuration of material in a cross section. A higher order correction is developed to achieve excellent accuracy to very high frequency. This correction includes a coefficient that does depend on the specific cross-sectional configuration. Results are compared to exact solutions for layered and annular configurations, and also to experimental measurements with open cell foam as the porous material. An interesting application is to use measured wave numbers to predict the complex effective density and sound speed of porous media samples partially filling the duct. Other applications include fairly simple improved predictions of the behavior of sound in ducts lined with, or partially filled with, bulk reacting absorbing material.

4pPP1. Transmission of bone-conducted sound measured acoustically and psycho-acoustically. Sabine Reinfeldt (Signals & Systems, Chalmers Univ. of Technol., SE-412 96 Goteborg, Sweden), Stefan Stenfelt (Linkoping Univ., SE-581 83 Linkoping, Sweden), and Bo Hakansson (Chalmers Univ. of Technol., SE-412 96 Goteborg, Sweden)

The transcranial transmission is important in the bone-conducted (BC) audiometry where the BC hearing thresholds depend on the stimulation position. It is also important for fitting of BC hearing aids; the transcranial transmission determines the amount of the sound that reaches the contralateral cochlea. Previous reported transcranial transmission results seem to depend on the method used. Here, a comparison between the transcranial transmission measured with BC hearing thresholds and ECSP is performed for both open and occluded ear canal. A BC transducer provided stimulation at both mastoids and the forehead. The ECSP was measured with a probe microphone and the BC hearing thresholds were obtained while masking the nontest ear. The transcranial transmission was determined as the BC hearing threshold or the ECSP for contralateral stimulation relative ipsilateral stimulation. The transmission from the forehead was calculated in a similar way. The transcranial transmission was similar for BC hearing thresholds and ECSP above 800 Hz; this indicates that the ECSP can be used as an estimator of the relative hearing perception by BC. The transcranial transmission results are also similar to vibration measurements of the cochleae made in earlier studies. Hence, vibration measurements of the cochleae can also estimate relative BC hearing.

1:50

4pPP2. Customization of head-related transfer functions using principal components analysis in the time domain. Ki H. Shin and Youngjin Park (Dept. of Mech. Eng., Korea Adv. Inst. of Sci. and Technol. (KAIST), Sci.e Town, Daejeon, 305-701, Republic of Korea)

Pinna responses were separated from HRIRs (head-related impulse responses) of 45 subjects in the CIPIC HRTF (head-related transfer function) database and modeled as linear combinations of five basic temporal shapes (basis functions) by PCA (principal components analysis) accounting for more than 90% of the variance in the original pinna responses per each selected elevation angle in the median plane. By adjusting the weight of each basis function computed for a specific height to replace the pinna response in the KEMAR HRIR at the same height with the resulting pinna response and listening to the filtered stimuli over headphones, four subjects were able to create a set of median HRIRs that outperformed the KEMAR HRIRs in producing elevation effects in the median plane. Since the monoaural spectral features due to the pinna are strongly dependent on elevation instead of azimuth, similar elevation effects could also be generated at different azimuthal positions simply by inserting the customized median pinna responses into the KEMAR HRIRs at other azimuths and varying the ITD (interaural time difference) according to the direction as well as the size of the subject's own head.

4pPP3. An electrophysiological measure of basilar membrane nonlinearity in humans. Christopher J. Plack (Dept. of Psych., Lancaster Univ., Lancaster, LA1 4YF, England) and Ananthanarayan Krishnan (Purdue Univ., West Lafayette, IN 47906)

A behavioral measure of the basilar membrane response can be obtained by comparing the growth in forward masking for maskers at, and well below, the signal frequency. Since the off-frequency masker is assumed to be processed linearly at the signal place, the difference in masking growth with level is thought to reflect the compressive response to the on-frequency masker. The present experiment used an electrophysiological analog of this technique, based on measurements of the latency of wave V of the auditory brainstem response elicited by a 4-kHz, 4-ms pure tone, presented at 65 dB SPL. Responses were obtained in quiet and in the presence of either an on-frequency or an off-frequency (1.8 kHz) pure-tone forward masker. Wave V latency increased with masker level, although the increase was greater for the off-frequency masker than for the on-frequency masker, consistent with a more compressive response to the latter. Response functions generated from the data showed the characteristic shape, with a nearly linear response at lower levels, and 5:1 compression at higher levels. However, the breakpoint between the linear region and the compressive region was at about 60 dB SPL, higher than expected on the basis of previous physiological and psychophysical measures.

2:20

4pPP4. Possible involvement of the spiral limbus in chinchilla cochlear mechanics. William S. Rhode (Dept. of Physiol., 1300 University Ave., Madison, WI 53706, rhode@physiology.wisc.edu)

Differences between cochlear mechanical tuning curves and those of auditory nerve fibers (ANFs) exist. In particular, mechanical transfer functions exhibit a high-frequency plateau; ANFs frequency threshold curves (FTCs) do not. ANF-FTCs may have a low-frequency slope due to a velocity forcing function operating on inner hair cells at low frequencies. Neither basilar membrane velocity nor displacement adequately explain the entire ANF tuning curve. A displacement sensitive interferometer was used to study basilar membrane and spiral limbus mechanics in the 6-kHz region of the chinchilla cochlea. The spiral limbus vibrates at the same phase as the basilar membrane nearly up to the location's characteristic frequency. In the plateau region, the limbus appears to vibrate 0 to 20 dB less than the basilar membrane. The basilar membrane/limbus amplitude transfer function has a low-frequency slope of ~ 3 dB/oct at low frequencies and is ~ 10 dB lower than the basilar membrane amplitude at 1 kHz. It appears that spiral limbus vibration may contribute to the excitation of the cilia of the inner hair cells. [Work supported by NIDCD grant R01 DC001910.]

4pPP5. The effects of antioxidants on cochlear mechanics. Barbara Acker-Mills, Melinda Hill, and Angeline Ebuen (U.S. Army Aeromedical Res. Lab., P.O. Box 620577, Fort Rucker, AL 36362-0577, barbara.acker@us.army.mil)

Several studies have evaluated the effect of N-acetylcysteine (NAC) on temporary threshold shifts (TTSs) in humans. Work at USAARL found that NAC did not reduce TTSs compared to a placebo, but suppressed otoacoustic emissions (OAEs) more than a placebo, indicating that NAC may reduce outer hair cell activity. Kramer *et al.* [JAAA, **17**(4), (2006)] found similar results, where NAC did not affect thresholds in people who had TTSs from exposure to loud music. However, OAEs also did not differ between NAC and placebo. Toppilla *et al.* [XXII Barany Society Meeting (2002)] measured thresholds and balance in people exposed to loud music and found that while NAC did not affect TTS, it reduced noise-induced balance impairment. The current study administered NAC and measured cochlear microphonics, compound action potentials, and OAEs to evaluate cochlear function. The vestibular myogenic potential was measured to assess the effect of NAC on the saccule. The results provide a comprehensive analysis of the effect of NAC on the auditory

system and one component of the vestibular system. [Work supported by the U.S. Army ILIR program. The work is that of the authors and is not necessarily endorsed by the U.S. Army or the Department of Defense.]

4pPP6. Time characteristics of distortion product otoacoustic emissions recovery function after moderate sound exposure. Miguel Angel Aranda de Toro, Rodrigo Ordoñez, and Dorte Hammershøi (Dept. of Acoust., Aalborg Univ., Fredrik Bajers Vej 7 B5, DK-9220, Aalborg, Denmark, maat@acoustics.aau.dk)

Exposure to sound of moderate level temporarily attenuates the amplitude of distortion product otoacoustic emissions (DPOAEs). These changes are similar to the changes observed in absolute hearing thresholds after similar sound exposures. To be able to assess changes over time across a broad frequency range, a detailed model of the recovery time characteristics is necessary. In the present study, the methodological aspects needed in order to monitor changes in DPOAEs from human subjects measured with high time resolution are presented. The issues treated are (1) time resolution of the measurements, (2) number of frequency points required, and (3) effects in fine structures, are they affected with the exposure? [Work supported by the Danish Research Council for Technology and Production.]

3:20

4pPP7. Probability characteristics of neural coincidence detectors in the brainstem. Ram Krips and Miriam Furst (Dept. of Elec. Eng. Systems, Faculty of Eng., Tel Aviv Univ., Tel Aviv 69978, Israel, mira@eng.tau.ac.il)

Auditory neural activity in the periphery is usually described as non-homogeneous Poisson process (NHPP), characterized as either EE or EI, which operates as a coincidence detector. In order to apply a general probabilistic analysis of those brainstem nuclei activity, the stochastic properties of the axons that exit the EE and EI nuclei is essential. An analytical analysis of the probability characteristics of the output of an EE nucleus (EEout) will be presented. Assuming that an EE nucleus receives inputs from two neurons, each behaves as an NHPP with instantaneous rates λ_1 and λ_2, and an output spike is generated if both spike at a coincidence window (Δ) which is relatively small (this matches biological findings). Then EEout is also a NHPP with instantaneous rate $r(t) = \lambda_1(t)\int_{t-\Delta}^{t}\lambda_2(\zeta)\,d\zeta + \lambda_2(t)\int_{t-\Delta}^{t}\lambda_1(\zeta)\,d\zeta$. A similar derivation was applied for an EI nucleus. We found also that the output activity is NHPP for a relatively small coincidence window (Δ). The obtained IR is $r(t) = \lambda_e(t)[1 - \int_{t-\Delta}^{t}\lambda_i(\zeta)\,d\zeta]$, where λ_E and λ_I are the excitatory and inhibitory input IRs. On the other hand, for larger Δ, the output activity is not a Poisson process. Those derivations enable theoretical analysis and performance evaluation of large neural networks, which perform binaural tasks as ITD and ILD.

3:35

4pPP8. Musical expertise and concurrent sound segregation. Benjamin Rich Zendel and Claude Alain (Rotman Res. Inst., Baycrest Ctr. & Dept. of Psych., Univ. of Toronto, Toronto, ON M6A 2E1, Canada)

There is growing evidence suggesting that musical training can improve performance in various auditory perceptual tasks. These improvements can be paralleled by changes in scalp recorded auditory evoked potentials (AEPs). The present study examined whether musical training modulates the ability to segregate concurrent auditory objects using behavioral measures and AEPs. Expert musicians and nonmusicians were presented with complex sounds comprised of six harmonics (220, 440, 660 Hz, etc.). The third harmonic was either tuned or mistuned by 1%–16% of its original value. Mistuning a component of a harmonic complex results in the precept of a second auditory object. Stimuli were presented passively (no response) and actively (participants responded by indicating if they heard one sound or two sounds). Behaviorally both musicians and

4p FRI. PM

nonmusicians perceived a second auditory object at similar levels of mistuning. In both groups, complex sounds generated N1 and P2 waves at fronto-central scalp regions. The perception of concurrent auditory objects was paralleled by an increased negativity around 150 ms post-stimulus onset. This increased negativity is referred to as object-related negativity (ORN). Small differences between musicians and nonmusicians were noted in the ORN. The implication of these results will be discussed in terms of current auditory scene analysis theory.

3:50

4pPP9. Study of auditory temporal processing of language and music in stroke patients. Li Hsieh and Tamara Baubie (Dept. of Commun. Sci. and Disord., Wayne State Univ., 207 Rackham Hall, 60 Farnsworth, Detroit, MI 48202)

This study focused on functional lateralization of temporal processing of language and music for nine stroke patients and nine normal controls. Subjects were asked to discriminate short versus long sounds in ABX tasks, and then to reproduce sequences of short and long sounds they heard. The reproduction tasks consisted of sequences of 3, 4, and 5 sounds. The linguistic stimuli were nonsense CVC syllables, and the musical stimuli were computer-generated musical notes with the timbres of French horn and trombone. Both linguistic and music stimuli were controlled for frequency and intensity, and varied only for duration (i.e., 500 and 750 ms). Our findings are consistent with previous studies; the left hemisphere specializes in linguistics, while the right hemisphere in music. Moreover, both hemispheres appeared to work closely together in processing temporal information. Both left- and right-hemisphere-damaged patients performed worse than controls. Most subjects performed better with music than language. Patients with left posterior lesions performed worse compared to patients with left or right anterior lesions, particularly with linguistic stimuli. Patients with right anterior lesions not only involved with temporal processing in music, but also in linguistic stimuli. Our study provided additional information regarding transient temporal processing in language and music.

4:05

4pPP10. Human bioacoustic biology: Acoustically anomalous vocal patterns used to detect biometric expressions relating to structural integrity and states of health. Sharry Edwards (Sound Health Res. Inst., P.O. Box 267, Sauber Res. Ctr., Albany, OH 45710)

Computerized analyses of acoustically anomalous vocal patterns are being used as biomarkers for predictive, prediagnostic, and efficient management of individual biological form and function. To date, biometrically distinct vocal data have resulted in outcomes that would be considered improbable by contemporary medical standards. For instance, independent EMG conclusions confirmed the regeneration of nerve tissue for a multiple sclerosis patient who used acoustic bioinformation to guide his primary therapy. Another study monitored the amounts of synthetic labor hormones present during induced labor. False labor costs amount to millions of dollars each year in insurance and hospital resources. The use of noninvasive, possibly remote, vocal profiling could ameliorate such costs. Anomalous vocal acoustics are being investigated by many health-related organizations including Pfizer Pharmaceuticals and the Institute of Automatic Control Engineering in Taiwan. Complementary research studying molecular frequencies of cellular chemistry is being done by James Gimjewski, Ph.D., UCLA, Department of Chemistry and Biochemistry. Known as BioAcoustic Biology, this research modality has the potential to advance current health care standards for biological function, disease processes, and metabolism. Organizations such as the Acoustical Society of America are considering standards for technically defining human bioacoustics. This paper would expand that language.

4pSAa1. Analytical model for flow-excited interior cavity resonance and its application to the Stratospheric Observatory for Infrared Astronomy (SOFIA). Jerry H. Ginsberg (G. W. Woodruff School of Mech. Eng., Georgia Inst. of Technol., Atlanta, GA 30332-0405)

The Stratospheric Observatory for Infrared Astronomy (SOFIA) is a joint effort between NASA and the German Space Agency that has installed a 20 000-kg telescope in a modified 747-SP. The modifications entailed constructing bulkheads, one of which is used to provide the active mount for the telescope, and a door that rotates to open as much as one-quarter of the fuselage circumference to the atmosphere. This configuration represents a large compartment that can exhibit acoustic resonances at low frequencies. Concern arose that a Rossiter mode, which is an aerodynamic resonance in which vortices shed from the leading edge of a gap form a coherent standing pattern at certain speeds, would create a strong acoustic source for acoustic and structural modes, whose frequencies might coincide. A model consisting of a two-dimensional hard-walled waveguide having a Rossiter mode source and an elastic plate at one end was analyzed in order to understand these issues. Unlike conventional analyses of interior cabin noise, in which vibrating walls are the acoustic source, the elastic plate represents a compliant boundary that couples with the acoustic modes. The results lead to some general insights to the possibility of a ''triple resonance,'' as well as the role of structural compliance for cavities that are excited by turbulent external flows.

4pSAa2. Energy finite energy analysis for shipboard noise. Raymond Fischer, Leo Boroditsky (Noise Control Eng. Inc., 799 Middlesex Tnpk, Billerica, MA 01821), Layton Gilfroy (DRDC-Atlantic), and David Brennan (Martec Ltd.)

Machinery-induced habitability noise is difficult to model efficiently and accurately. The potential of energy finite-element analysis (EFEA) is compared to other prediction tools such as statistical energy analysis (SEA). This paper will explore the benefits and costs of EFEA with respect to SEA for acoustic modeling. The focus will be on issues relating to structural modeling for EFEA purposes. EFEA techniques will be evaluated to see if they possess the capabilities of verified SEA approaches for predicting habitability and radiated noise, where it is necessary to account for the impact of diverse marine constructions and sources such as the lack of machinery source information with respect to force or moment inputs or the finite impedance of machinery foundations. The effort proposed herein will provide the necessary engineering to research and identify salient features of EFEA that are potentially applicable for the detailed analysis of the acoustic environment and response of surface ships to various excitation sources. The paper will also address the pros and cons of SEA versus energy-finite element analysis (EFEA) methods used to predict the habitability noise of surface ship platforms. [This work is supported by an Office of Navy Research contract.]

4pSAa3. Spectral-based multicoordinate substructuring model for vehicle noise, vibration, and harshness refinement. Teik C. Lim (Mech., Industrial and Nuclear Eng., 598 Rhodes Hall, Box 210072, Univ. of Cincinnati, Cincinnati, OH 45221, teik.lim@uc.edu)

The success of vehicle NVH (noise, vibration, and harshness) refinement often depends on the ability to identify and understand noise and vibration transmission paths within the mid-frequency range, i.e., 200–1000 Hz, throughout the assembled structure. Due to the complexity of the dynamics in this frequency range, most modal or finite element-based methods do not possess the fidelity needed. To address this gap, a multicoordinate substructuring theory applying measured structural-acoustic and vibration spectra is applied. Three forms of substructuring formulation, namely the nondiagonal, block-diagonal, and purely diagonal coupling cases, are developed. The performances of these approaches are studied numerically, and the net effects of these coupling formulations on the predicted joint and free substructure dynamic characteristics, and system response, are determined. Conditions for applying the simpler coupler that can simplify the testing process and overcome computational deficiencies are also derived. When the measured data is noise contaminated, the singular value decomposition (SVD) algorithm is found to be quite helpful. Using an actual vehicle, a comprehensive analysis of the measured and predicted vehicle system responses is performed. The results are employed to develop an understanding of the primary controlling factors and transfer paths and to cascade system requirements to the substructure level.

4pSAa4. Practical application of digital simulation with physical test in vehicle virtual. Toshiro Abe (ESTECH Corp., 89-1 Yamashita-cho, Naka-ku, Yokohama-shi, Kanagawa-ken, Japan 231-0023, toshiro.abe@estech.co.jp)

In the current vehicle design and development program, the Virtual Product Development process (hereafter, VPD process) is the innovation for automotive industry, which improves product quality and shortens time to market. In general, valid CAE applications are the key component of the VPD process as well as physical tests being indispensable to create valid simulation technologies. This presentation explains how physical-test-based CAE leverages the VPD process. In particular, the presentation is based on how physical testing supports the VPD process and why the ESTECH philosophy is that "The essence of CAE lies in its synergy with Testing;" a philosophy that differentiates the company from the competition. To demonstrate these activities, case studies based on automotive dynamic and real time simulation will be presented. In the case studies, vehicle body NVH and brake noise analysis will be used to show the interaction between physical test and computer simulation. Finally, practical application of the VPD process in one of the leading Japanese automotive companies will be shown, where the effectiveness of the front loading in the actual vehicle development program and the actual deployment of VPD process to the Functional Digital Vehicle project in the powertrain design are to be presented.

Contributed Papers

4pSAa5. Active noise control simulations using minimization of energy density in a mock helicopter cabin. Jared Thomas, Stephan P. Lovstedt, Jonathan Blotter, Scott D. Sommerfeldt (Brigham Young Univ., Provo, UT 84602), Norman S. Serrano, and Allan Egelston (Silver State Helicopters, Provo, UT 84601)

Helicopter cabin noise is dominated by low-frequency tonal noise, making it an ideal candidate for active noise control. Previous work in active control of cabin noise suggests an energy density approach to be a good solution [B. Faber and S.D. Sommerfeldt, Global Control in a Mock Tractor Cabin Using Energy Density, Proc. ACTIVE 04, Sept. 2004.] Simulations for active noise control using energy density minimization have been made using recorded data from a Robinson R44 helicopter. Initial computer models show substantial noise reductions in excess of 6 dB at the error sensor are possible. Performance results for computer models and simulations in a mock cab for different control arrangements will be compared.

4pSAa6. Modeling airborne interior noise in full vehicles using statistical energy analysis. Arnaud Charpentier and Phil Shorter (ESI, 12555 High Bluff Dr., Ste. 250, San Diego, CA 92130, arnaud.charpentier@esi-group-na.com)

SEA is particularly well suited for predicting airborne noise in vehicles. The acoustic sources found in such environment are typically spatially distributed around the vehicle and can be well represented with SEA diffuse acoustic loads. Multiple transmission paths contribute to interior noise levels including (1) mass law transmission through trimmed panels, (2) resonant radiation from vibrating structures, and (3) flanking paths through gaskets, seals, and holes. All these transmission mechanisms may be modeled using SEA techniques. Finally, interior trim (including carpet, headliner, seats) is a key contributor to the acoustic performance of modern vehicles. The vehicle sound package has a significant impact on both the strength of the transmissions paths into the vehicle as well as the acoustic absorption in the cabin. Both these effects can be accounted for with SEA through detailed models of the trim. SEA models of full vehicles

are usually validated against experimental results at both component and system levels. The models can then be confidently used to (a) rank key design parameters governing interior levels and (b) quickly evaluate the impact of potential design changes. Example vehicle models and correlation results are presented here.

2:50

4pSAa7. Radiation from vibrating panels at high frequency including an inquiry into the role of edges and drive points. Donald Bliss (Mech. Eng. and Mater. Sci., Duke Univ., Durham, NC 27708)

In the high frequency limit, a vibrating finite panel is shown to have broadband power and directivity characteristics that can expressed analytically by a limited set of parameters. Two-dimensional problems with subsonic structural wave speed are considered. Three basic directivity patterns are identified, associated with right and left traveling waves and the correlation between them. The role of boundary conditions at the panel edge is illustrated, as are the effects of types of forcing. Overall, relatively simple broadband behaviors are revealed. The analytical characterization of the radiation is shown to be particularly straightforward in the high frequency broadband limit. Interestingly, the radiated mean-square pressures are independent of the panel length, indicating the radiation is associated with the edges and the drive point. However, the radiation patterns cannot be explained in terms of simple volumetric sources placed just at the edges and the drive point, showing that the often-stated idea of uncan-

celed volumetric sources at these locations is not correct except under very restricted circumstances. A correct physical interpretation of the radiation is provided both in physical space and in terms of spatial Fourier transforms.

3:05

4pSAa8. Some effect of trim and body panels on the low-frequency interior noise in vehicles. Andrzej Pietrzyk (Volvo Car Corp., Noise and Vib. Ctr., 405 31 Gothenburg, Sweden)

Structure borne noise dominates the interior noise in vehicles at low frequencies. One of the basic vinroacoustic characteristics of the trimmed body is the noise transfer function, i.e., the acoustic response at a selected position in the passenger compartment, e.g., driver's ear due to a mechanical excitation at a selected body mount. Detailed CAE models based on the FE method are today available for calculating this characteristic at low frequencies, corresponding to the engine idling and road excitation. However, the accuracy of CAE predictions of interior noise is still considered insufficient for the so-called analytical sign off, i.e., zero-prototypes vision. The current paper describes some investigations into the contribution of individual body panels to the overall interior noise. Also, the effect of selected interior trim items on the area investigated. Relative errors of prediction at different trim levels and different frequency ranges are discussed. Both experimental and CAE results are provided. The aim is to better understand the way the interior noise in vehicles is created, and how it can be controlled.

4pSAb1. Direct computation of degenerate elastodynamic solution of elastic wave propagation in a thick plate. Jamal Ghorieshi (Eng. Dept., Wilkes Univ., Wilkes-Barre, PA 18766)

The limiting form of elastodynamic solutions as frequency tends to zero leads to the elastostatic eigenvalue equations. However, this limiting procedure is not convenient. It is cumbersome when applied to the solutions obtained using Stokes potentials and, in the case of utilizing Lames potentials, it does not produce static solutions that are a function of position alone. In this paper it is shown that the exact solutions of elastostatic problems can, in general, be obtained in a straightforward manner by the use of harmonic potentials without recourse to any special limiting form of analysis. This method is applied to an infinite, elastic thick plate with traction-free parallel surfaces and the elastostatic eigenvalue equation. It is shown that the problem can be solved exactly in terms of harmonic functions, one of which is a scalar and the other one is a vector. It is noted that results are in agreement with the published solutions.

4pSAb2. Wave propagation characteristics of an infinite fluid-loaded periodic plate. Abhijit Sarkar and Venkata R. Sonti (Indian Inst. of Sci. Mech. Eng., IISc., Bangalore-560012, India)

A 1-D infinite periodic plate with simple supports placed along equidistant parallel lines is considered using the finite-element method. The plate is loaded with a finite-height fluid column covered on the top with a rigid plate. Results show a relation between the propagation constant of the fluid-loaded structure with its *in vacuo* counterpart. Since the acoustic medium is an additional wave carrier, the attenuation bands corresponding to the *in vacuo* structure turn out to be propagating. However, the presence of the fluid can also bring about attenuation regions within the *in vacuo* propagation bands. Primary propagation constants bring additional waves called space harmonics with them. Hence, a localized coincidence effect is seen where a particular harmonic falls below or above the acoustic wave number, leading to propagation or a mass loading effect. Occasionally, a complete attenuation band is created. This is verified by decomposing the

Fourth Joint Meeting: ASA and ASJ   **3288**

single span displacement profile into the space harmonics and also by computing the frequency response function (FRF) for a finite fluid-loaded periodic plate and observing the huge antiresonance dip in frequency in the exact same frequency band where an attenuation band was predicted for the infinite structure.

4pSAb3. The dynamic response of a plate subjected to various edge excitations. Baruch Karp (Faculty of Aerosp. Eng., Technion Israel Inst. of Technol., Haifa 32000, Israel)

Plane strain response of a semi-infinite, elastic plate to harmonic edge excitation is investigated analytically. The exact solution to this problem is obtained as a series expansion of the Rayleigh-Lamb modes of the plate. The variation of energy partition among the propagating modes with frequency of the edge excitation was found for load and displacement (symmetrical) perturbations of uniform and cosine form. The biorthogonality relation was employed in deriving the relative amplitudes of each mode to the given perturbation. The emphasis here is on the sensitivity of the far-field response, represented by propagating waves, to the details of the excitation. Within the frequency range investigated it was found that the plate's response is remarkably insensitive to whether the excitation is load or displacement type. The two types of edge excitation distributions, on the other hand, result in different patterns of energy partition above the first cutoff frequency with similar energy partition only within limited range of frequencies. The effect of the nature of the excitation on the dynamic response of the plate and a possible implication to dynamic equivalence is discussed.

4pSAb4. Measurement of structural intensity using patch near-field acoustical holography. Kenji Saijyou (Fifth Res. Ctr., TRDI, Japan Defense Agency, 3-13-1 Nagase, Yokosuka City, Kanagawa Prefecture, Japan, 239-0826)

Measurement of power flow in a structure, called the structural intensity (SI), is essential for vibration control and noise reduction. The near-field acoustical holography (NAH)-based measurement method is suitable to analyze the interrelationship between SI and acoustic intensity (AI) because NAH-based methods provide measurements of SI and AI simultaneously. Use of NAH requires the measurement of a pressure field over a complete surface located exterior to the structure. Therefore, if the measurement aperture is smaller than the structure, reconstructed results from the pressure on the finite aperture are seriously contaminated. This finite aperture effect prevents implementation of this NAH-based method on an actual large-scale structure such as a ship. Patch NAH and regularization method for SI measurement are applied to overcome this difficulty. This method enables implementation of the NAH-based SI measurement method in a large-scale structure. The effectiveness of this method is demonstrated by experiment.

4:45

4pSAb5. Flexural component and extensional component of vibration energy in shell structure. Taito Ogushi, Manabu Yahara, Masato Mikami, and Naoya Kojima (Dept. of Mech. Eng., Yamaguchi Univ., 2-16-1 Tokiwadai, Ube, Yamaguchi 755-8611, Japan, j008ve@yamaguchi-u.ac.jp)

In this research, the behavior of the flexural component and the extensional component of vibration intensity and their transmission in curved shells are presented. L-shaped shell model was employed as an analysis model of FEM. As FEM analysis methods, both the frequency response analysis and the transitional response analysis were employed. The flexural component and the extensional component of vibration intensity (VI) were calculated by the results of FEM analysis. In the flexural component of the VI, the vibration energy supplied in the flat part decreased at the boundary from the flat part to the curved part and VI vectors flew in circumferential direction in the curved part. In the extensional component of the VI, the vibration energy appeared at the boundary from the flat part to the curved part and most VI vectors flew parallel to the shell axis in the curved part. The total vibration energy of the flexural component and the extensional component was conserved. So, the vibration energy transformed to each other between the flexural component and the extensional component in L-shaped shell.

5:00

4pSAb6. Seismic/acoustic detection of ground and air traffic for unattended ground sensor technology. Peter C. Herdic (Naval Res. Lab., Physical Acoust. Branch, Washington, DC 20375 and SFA Inc., Crofton, MD), Brian H. Houston, Phillip A. Frank, and Robert M. Baden (Naval Res. Lab., Washington, DC 20375)

Human footfall and vehicle traffic create surface waves in soil media that can easily be detected by seismic sensors. Field measurement data have been acquired with a triaxial geophone at several experimental sites. The in-plane-surface wave components dominate the response and decay at a rate of approximately $1/R$, where R is distance. This decay rate is due to the combined effect of spreading $(1/\sqrt{R})$ and damping losses in the soil. Further, the detection range is dependent upon the level of environmental noise, soil compliance, moisture content, and topography. Human detection was achieved in rural environments at distances up to ~30–40 m, and vehicle detection was possible at much greater distances. Seismic signals due to aircraft are small when compared to the acoustic signature. Ground-based microphone measurements clearly show the blade passage frequency tones of propeller airplanes and the broader band signature of turbojet aircraft. Time- and frequency-domain signal-processing methods for the detection and identification will also be introduced. These experimental results will be discussed with particular emphasis placed on wave phenomenon, detection and identification algorithms, and the related physics.

5:15

4pSAb7. Modeling of acoustic and elastic wave phenomena using plane wave basis functions. Tomi Huttunen, Jari P. Kaipio (Dept. of Phys., Univ. of Kuopio, P.O. Box 1627, FI-70211 Kuopio, Finland), and Peter Monk (Univ. of Delaware, Newark, DE 19716)

When simulating acoustic, elastodynamic, or coupled fluid-solid vibration problems using standard finite element (FE) techniques, several elements per wavelength are needed to obtain a tolerable accuracy for engineering purposes. At high wave numbers, the requirement of dense meshes may lead to an overwhelmingly large computational burden, which significantly limits the feasibility of FE methods for the modeling of wave phenomena. A promising technique for reducing the computational complexity is to use plane wave basis functions opposed to the low-order polynomials that are used in conventional FE methods. A possible method for utilizing the plane wave basis is the ultra-weak variational formulation (UWVF). The UWVF method can be used for acoustic Helmholtz problems, elastodynamic Navier problems, or fluid-solid systems characterized by a coupled Helmholtz-Navier model. A comparison of the UWVF technique with a low-order FE method shows reduced computational complexity and improved accuracy.

4pSAb8. Application of vibration energy flow to evaluation of thickness. Akihiko Higashi (Dept. of Maritime Sci. and Technol., Japan Coast Guard Acad., 5-1 Wakaba-cho, Kure, Hiroshima, 737-8512, Japan)

In this study, the possibility of the useful application of the vibration energy flow is investigated. The vibration energy flow means the propagation of the vibration energy of the flexural waves. The vibration energy flow is expressed by the structural intensity. Here, it is easy to input the flexural waves in the thin plates and beam elements. Then, large structures such as ships use many of these thin plates and beam elements. But the usual methods of the evaluation and the inspection of these large structures are inefficient. Then, we investigated the possibility of the evaluation of the changed thickness of the structure by using the vibration energy flow analysis. As the result of analysis, the structural intensity suddenly changes at the position of the changed thickness. The changed quantity of the structural intensity corresponds to the change quantity of the thickness. Then, the evaluation method of the thickness of the structure is proposed. As a result, it was found that the change of the structural intensity indicates the change of the thickness. And the evaluation of the change of thickness of beams could be possible by using the proposed method.

4pSC1. Cross-language perception of voice and affect. Christer Gobl, Irena Yanushevskaya, and Ailbhe N. Chasaide (Phonet. and Speech Lab., School of Linguistic, Speech and Commun. Sci., Trinity College Dublin, Dublin 2, Ireland, yanushei@tcd.ie)

The paper reports on a cross-language study of how voice quality and $f0$ combine in the signaling of affect. Speakers of Irish-English and Japanese participated in perception tests. The stimuli consisted of a short utterance where $f0$ and voice source parameters were varied using the LF-model implementation of the KLSyn88a formant synthesizer, and were of three types: (1) VQ only involving voice quality variations and a neutral $f0$ contour; (2) $f0$ only, with different affect-related $f0$ contours and modal voice; (3) VQ+$f0$ stimuli, where the voice qualities of (1) combine with specific $f0$ contours from (2). Overall, stimuli involving voice quality variation were consistently associated with affect. In (2) only stimuli with high $f0$ yielded high affective ratings. Striking differences emerge between the ratings obtained from the two language groups. The results show that not only were some affects consistently perceived by one language group and not the other, but also that specific voice qualities and pitch contours were associated with very different affects across the two groups. The results have important implications for expressive speech synthesis, indicating that language/culture-specific differences need to be considered. [This work is supported by the EU-funded Network of Excellence on Emotion, HUMAINE.]

4pSC2. An articulatory study of coronal consonants in Arrernte. Marija Tabain (LaTrobe Univ., Melbourne, Australia), Richard Beare (Monash Univ., Melbourne, Australia), Catherine Best (Univ. of Western Sydney, Sydney, Australia), and Louis Goldstein (Haskins Labs., CT)

This paper presents electro-magnetic articulography (EMA) data on the four coronal stops of Arrernte, an Australian language. The stops are: the lamino-dental "th," the apico-alveolar "t," the apico-postalveolar (or "retroflex") "rt," and the lamino-palatal "ty." Jaw, tongue tip (TT), and tongue body (TB) data were collected for two female speakers of the language. Results for the first speaker show a fronted tongue position for the laminal consonants, with the TT reflecting a similar location for both the dental and the palatal. However, for the palatal, the TB position is much higher, whereas for the dental, the TB is very low. For the apical consonants, the TT is not as far forward, and the TB is not quite as high as for the lamino-palatal. For both TT and TB, apico-postalveolar is further back than apico-alveolar. For the second speaker, the TT sensor failed, but in line with the first speaker, the TB sensor showed a higher position for the palatal. The other stops were lower and more forward, with the post-alveolar TB position higher than the laminal or alveolar stop position. For both speakers, the jaw position is lowest for the postalveolar. 4pSC3. Symbolic phonetic features for pronunciation modeling.
Rebecca A. Bates,[a)] , Mari Ostendorf (Dept. of Elec. Eng., Univ. of Washington, Box 352500, Seattle, WA 98195), and Richard A. Wright (Univ. of Washington, Seattle, WA 98195)

A significant source of variation in spontaneous speech is due to intraspeaker pronunciation changes, often realized as small feature changes, e.g., nasalized vowels or affricated stops, rather than full phone transformations. Previous computational modeling of pronunciation variation has typically involved transformations from one phone to another, partly because most speech processing systems use phone-based units. Here, a phonetic-feature-based prediction model is presented where phones are represented by a vector of symbolic features that can be on, off, unspecified, or unused. Feature interaction is examined using different groupings of possibly dependent features, and a hierarchical grouping with conditional dependencies led to the best results. Feature-based models are shown to be more efficient than phone-based models, in the sense of requiring fewer parameters to predict variation while giving smaller distance and perplexity values when comparing predictions to the hand-labeled reference. A parsimonious model is better suited to incorporating new conditioning factors, and this work investigates high-level information sources, including both text (syntax, discourse) and prosody cues. Detailed results are under review with *Speech Communication*. 4pSC4. Acoustic phonetic variability and auditory word recognition by dyslexic and nondyslexic children.
Patricia Keating, Kuniko Nielsen (Phonet. Lab., Linguist., UCLA, Los Angeles, CA 90095-1543, keating@humnet.ucla.edu), Frank Manis, and Jennifer Bruno (USC, Los Angeles, CA 90089)

The hypothesis that dyslexia involves degraded phonological representations predicts impairments in behaviors that rely on these representations, such as auditory word recognition. Normal adult listeners recognize different pronunciations of a word as instances of the same lexical item, but more slowly and less accurately; dylexics should be even more impaired by acoustic phonetic variability. Children with and without dyslexia performed a word recognition task: on each trial, a child hears a target word, then eight probes (matching the target or not), responding yes/no to each probe. On some trials, probes are spoken by multiple talkers who differ in age, sex, speech style, etc.; on some trials the match probes also differ from the target in final stop consonant allophone. Responses are scored for accuracy and speed. Research questions include: Do all children demonstrate less accurate/slower recognition of words spoken by multiple talkers versus by one talker? Do all children demonstrate less accurate/slower recognition of words spoken with different allophones? Do dyslexic children demonstrate less accurate/slower recognition than nondyslexic children and, if so, for all trials, only for multiple talker trials, and/or only for different allophone trials; for all dyslexic children, or only those with particular phonological impairments? [Work supported by NIH.]

4pSC5. Intertalker differences in intelligibility of cochlear-implant simulated speech.
Tessa Bent, Adam B. Buchwald, and David B. Pisoni (Indiana Univ., Dept. of Psychol. and Brain Sci., 1101 E. 10th St., Bloomington, IN 47405, tbent@indiana.edu)

Are the acoustic-phonetic factors that promote highly intelligible speech invariant across different listener populations? Two approaches have been taken to investigate intelligibility variation for a variety of listener populations including hearing-impaired listeners, second language learners, and listeners with cochlear implants: studies on how speaking style affects intelligibility and other research on how inherent differences among talkers influence intelligibility. Taking the second approach, we compared intertalker differences in intelligibility for normal-hearing listeners under cochlear implant (CI) simulation ($n = 120$) and in quiet (n

$=200$). Stimuli consisted of 20 native English talkers' productions of 100 sentences. These recordings were processed to simulate listening with an eight-channel CI. Both clear and CI-processed tokens were presented to listeners in a sentence transcription task. Results showed that the most intelligible talkers in quiet were not the most intelligible talkers under CI simulation. Furthermore, listeners demonstrated perceptual learning with the CI-simulated speech but showed little learning in the quiet. Some of the acoustic-phonetic properties that were correlated with intelligibility differed between the CI-simulated speech and the speech in the quiet. These results suggest that the intertalker variations that result in highly intelligible speech observed in earlier studies are dependent on listener characteristics. [Work supported by NIDCD.]

4pSC6. The effect of phonological neighborhood density and word frequency on vowel production and perception in clear speech.
Rajka Smiljanic, Josh Viau, and Ann Bradlow (Dept. of Linguist., Northwestern Univ., 2016 Sheridan Rd., Evanston, IL 60208)

Previous research showed that phonological neighborhood density and word frequency influence word recognition (Luce and Pisoni, 1998) and vowel production (Wright, 2002; Munson and Solomon, 2004; Munson, to appear), suggesting an interaction of lexical and phonetic factors in speech production and perception Here, we explore whether hyperarticulated, intelligibility-enhancing clear speech shows similar sensitivity to lexical-level structure. Nine American English talkers (five females, four males) produced 40 monosyllabic easy (frequent words with few lexical neighbors) and hard (infrequent words with many lexical neighbors) words in conversational and clear speech. Twenty-four subjects participated in a word-in-noise listening test. Results revealed a large effect of style on intelligibility and vowel production: words were more intelligible and vowels were longer and more dispersed in clear compared to conversational speech. Moreover, the female talkers produced larger vowel spaces than male talkers in both speaking styles. Vowels in hard words were marginally more dispersed than vowels in easy words in both speaking styles. However, within both speaking styles, easy and hard words were equally intelligible and of approximately equal duration. These results showed that phonetic properties of vowels were enhanced equally in clear speech regardless of their lexical properties.

4pSC7. Phoneme dependency of accuracy rates in familiar and unknown speaker identification.
Kanae Amino, Takayuki Arai (Dept. of Elec. and Electron. Eng., Sophia Univ., 7-1 Kioi-cho, Chiyoda-ku, Tokyo, 102-8554 Japan, amino-k@sophia.ac.jp), and Tsutomu Sugawara (Sophia Univ., Chiyoda-ku, Tokyo, 102-8554 Japan)

For perceptual speaker identification, the identification accuracy depends on the speech contents presented to subjects. Our previous studies have shown that stimuli containing nasals are effective for identifying familiar speakers [Amino *et al.*, Acoust. Sci. Tech. **27**(4) (2006)]. We have also presented the possibility that the interspeaker spectral distances reflect perceptual speaker similarities. In the present study, we conducted an experiment in which four unknown speakers were identified by 15 subjects. The stimuli were identical to those used in the previous study, in which ten speakers were identified by familiar listeners, although the speakers were fewer this time. Nine consonants in the CV structure were used as stimuli. The consonants were /d/, /t/, /z/, /s/, /r/, /j/, /m/, /n/, and /nj/; the vowel was restricted to /a/ for all CV syllables to simplify the experiment. The results showed that the nasals /n/ and /nj/ obtained higher scores. Tendencies in the differences among consonants were on the same order as those of the

previous experiment, but the average scores were lower than those for familiar listeners. [Work supported by Grant-in-Aid for JSPS Fellows 17-6901.]

4pSC8. Speech style and stereotypical character in Japanese. Akiko Nakagawa (Grad. School of Cultural Studies and Human Sci., Kobe Univ., 1-2-1 Tsurukabuto, Nada-ku, Kobe 657-8501, Japan, akiko.nakagawa@atr.jp) and Hiroko Sawada (Kyoto Univ., Kyoto 606-8501, Japan)

This study shows that ''stereotypical character'' is necessary to understand Japanese speech communication in addition to existing conceptions such as emotion, communicative strategy, register, and so on. Stereotypical character is here defined as a complex entity, consisting of information about gender, age, social status, physical features, characteristics, and speech style. The necessity of stereotypical character was shown through an auditory experiment involving a total of 70 speech sounds comprised of 15–19 short phrases (mean duration 1.4) selected from recordings of spontaneous speech of four adult female speakers of Japanese. Ten participants were asked to listen to these speech sounds randomly, and to classify them into four speakers. Each of the resulting auditory-perceptual categories was found to contain speech sounds from more than one speaker. Further analyses of these results suggested that the participants classified the speech sounds not according to invariant speaker characteristics but according to virtual stereotypical characters that are common in Japanese society. Therefore, such changeable speaker characteristics as ''busybody'' ''thoughtful,'' ''high-handed,'' and so on, can be elicited through speech sounds by Japanese speakers. [This work was partially supported by the Ministry of Education, Science, Sport, and Culture, Grant-in-Aid for Scientific Research (A), 16202006.]

4pSC9. Perceived vocal age and its acoustic correlates. Hiroshi Kido (Dept. of Commun. Eng., Tohoku Inst. of Technol., Taihaku-ku, Sendai, Japan 989-8577, kidoh@tohtech.ac.jp) and Hideki Kasuya (Intl. Univ. of Health and Welfare, Otawara, Japan 324-8501)

This study investigates relationships between perceived and chronological age of talkers and acoustic correlates of the perceived age. Most of the past studies were primarily concerned with the instability of the vocal-fold vibration extracted from sustained vowels. This study focuses on the dynamic nature of sentence utterances. Talkers included 115 healthy men, aged 20–60 years, who read a short sentence in Japanese. Listeners consisted of 70 men and women, aged 20–40 years, who made direct estimations of age. The results showed a strong correlation ($r = 0.66$) between the perceived and chronological age as well as the tendency toward overestimating the ages of younger talkers and underestimating those of older talkers, supporting past investigations [e.g., R. Huntley *et al.*, J. Voice **1**, 49–52 (1987)]. Acoustic parameters considered were median of the fundamental frequency ($F0$) contour, $F0$ range, declination of $F0$ contour, spectral tilt, median of the boundary frequencies above which irregularities dominate, and speaking rate. From both statistical graphical modeling and regression tree analysis, the speaking rate, $F0$ declination, and spectral tilt were found to be dominant acoustic correlates to the perceived age. [Work supported partly by a Grant-in-Aid for Scientific Research, JSPS (16300061).]

4pSC10. A cross-linguistic study of informational masking: English versus Chinese. Bruce A. Schneider, Liang Li, Meredyth Daneman (Dept. of Psych., Univ. of Toronto at Mississauga, Mississauga, ON, L5L 1C6 Canada, bschneid@utm.utoronto.ca), Xihong Wu, Zhigang Yang, Jing Chen, and Ying Huang (Peking Univ., Beijing, China 10087)

The amount of release from informational masking in monolingual English (Toronto, Canada), and Chinese (Beijing, China) listeners was measured using the paradigm developed by Freyman *et al.* [J. Acoust. Soc. Am. **106**, 3578–3588]. Specifically, psychometric functions relating percent-correct word recognition to signal-to-noise ratio were determined under two conditions: (1) masker and target perceived as originating from the same position in space; (2) masker and target perceived as originating from different locations. The amount of release from masking due to spatial separation was the same for English and Chinese listeners when the masker was speech-spectrum noise or cross linguistic (Chinese speech masking English target sentences for English listeners or English speech masking Chinese target sentences for Chinese listeners). However, there was a greater release from masking for same-language masking of English (English speech masking English target sentences) than for same-language masking of Chinese (Chinese speech masking Chinese target sentences). It will be argued that the differences in same-language masking between English and Chinese listeners reflect structural differences between English and Mandarin Chinese. [Work supported by China NSF and CIHR.]

4pSC11. Cross-linguistic differences in speech perception. Keith Johnson and Molly Babel (UC Berkeley, 1203 Dwinelle Hall, Berkeley, CA 94720-2650)

This research explores language-specific perception of speech sounds. This paper discusses two experiments: experiment 1 is a speeded forced-choice AX discrimination task and experiment 2 is a similarity rating task. Experiment 1 was intended to investigate the basic auditory perception of the listeners. It was predicted that listeners' native languages would not influence responses in experiment 1. Experiment 2 asked subjects to rate the similarity between two tokens on a five-point equal interval scale; the purpose of this experiment was to explore listeners' subjective impression of speech sounds. In experiment 2 it was predicted that listeners' language would affect their responses. The same stimuli were used in both experiments. The stimuli consisted of vowel-fricative-vowel sequences produced by a trained phonetician. Six fricatives were used: /f, th, s, sh, x, h/. These fricatives were embedded in three vowel environments: /a_a/, /i_i/, and /u_u/. Tokens were presented to listeners over headphones with a 100-ms interval. Independent groups of 15 native Dutch and English listeners participated in each of the two experiments. Results suggest that listeners' language influenced responses in both experiments, albeit the result was larger in experiment 2. [Work supported by NIH.]

4pSC12. Neural coding of perceptual interference at the preattentive level. Yang Zhang (Dept. of Speech-Lang.-Hearing Sci., Univ. of Minnesota, Minneapolis, MN 55455), Patricia Kuhl, Toshiaki Imada (Univ. of Washington, Seattle, WA 98195), Toshiaki Imada, and Masaki Kawakatsu (Tokyo Denki Univ., Inzai-shi, Chiba 270-1382, Japan)

Language acquisition involves neural commitment to language-specific auditory patterns, which may interfere with second language learning. This magnetoencephalography study tested whether perceptual interference could occur at the preattentive level. Auditory mismatch field (MMF) responses were recorded from ten American and ten Japanese adult subjects in the passive oddball paradigm. The subjects read self-chosen books and ignored the sounds. Three pairs of synthetic /ra-la/ syllables were used: one cross-category pair varied only in the third formant (F3), and the other two within-category pairs varied only in the second formant (F2). ANOVA results showed a main effect of acoustic dimension with significant interaction with subject groups ($p < 0.01$). As reported earlier, American listeners showed larger but later MMF responses for the F3 change. By contrast, Japanese listeners showed larger and earlier MMFs than Americans for changes in F2. Moreover, Japanese listeners had larger and earlier MMF responses for the changes in F2 as against changes in F3, which was more prominent in the right hemisphere than in the left. These results provided further support for the hypothesis that language experience produces neural networks dedicated to the statistical properties of incoming speech experienced in infancy, which later interfere with second language acquisition.

4pSC13. Russian and Spanish listener's perception of the English tense/lax vowel contrast: Contributions of native language allophony and individual experience. Maria V. Kondaurova (Program in Linguist., Purdue Univ., West Lafayette, IN 47907) and Alexander L. Francis (Purdue Univ., West Lafayette, IN 47906)

We examined the influence of listeners native phonology on the perception of American English tense and lax front unrounded vowels ([i] and [ɪ]). These vowels are distinguishable according to both spectral quality and duration. Nineteen Russian, 18 Spanish, and 16 American English listeners identified stimuli from a *beat-bit* continuum varying in nine spectral and nine duration steps. English listeners relied predominantly on spectral quality when identifying these vowels, but also showed some reliance on duration. Russian and Spanish speakers relied entirely on duration. Three additional tests examined listeners allophonic use of vowel duration in their native languages. Duration was found to be equally important for the perception of lexical stress for all three language groups. However, the use of duration as a cue to postvocalic consonant voicing differed due to phonotactic differences across the three languages. Group results suggest that non-native perception of the English tense/lax vowel contrast is governed by language-independent psychoacoustic factors and/or individual experience. Individual results show large variability within all three language groups, supporting the hypothesis that individual differences in perceptual sensitivity as well as the more frequently cited factors of second language education and experience play an important role in cross-language perception.

4pSC14. An analysis of acoustic deviation manner in spontaneous speech. Norimichi Hosogai, Kanae Okita, Takuya Aida, and Shigeki Okawa (Chiba Inst. of Technol., 2-17-1 Tsudanuma, Narashino, Chiba 275-0016, Japan)

Natural speech typically contains various phenomena deviated from the formal mode such as read speech. It is well known that those paralinguistic phenomena have an important role to give the human emotions and the state of the speakers in speech communication. This study attempts to extract the deviation as an acoustic ''vagueness,'' defined by temporal and dynamical acoustic features of speech. Especially the change of the vagueness during a certain period of speech, such as a 10-minute presentation, is focused. As the acoustic features, it used (*i*) modulation spectrum and (*ii*) syllable speed, which may have relations to the speech clarity and the tempo. For the experiments, 70 academic presentation speech data in the Corpus of Spontaneous Japanese (CSJ) are used. As the experimental results, significant properties in the patterns of the modulation spectrum and the syllable speed are obtained as a difference of the beginning and the ending periods of the presentation. This result will contribute to a human-like speech dialog system.

4pSC15. Nondurational cues for durational contrast in Japanese. Kaori Idemaru (Dept. of East Asian Lang. and Lit., Univ. of Oregon, 1248 Univ. of Oregon, Eugene, OR 97403) and Susan G Guion (Univ. of Oregon, 1290 Eugene, OR 97403)

This study explores potential secondary cues to a durational contrast by examining short and long stop consonants in Japanese. Durational contrasts are susceptible to considerable variability in temporal dimensions caused by changes in speaking rate. In this study, the proposal is examined that multiple acoustic features covary with the stop length distinction and that these features may aid in accessing the percept intended by the speaker, even when the primary cue, closure duration, is unreliable. The results support the proposal, revealing the presence of multiple acoustic features covarying with the short versus long contrast. Not only are there durational correlates to this contrast—the preceding vowel is longer and the following vowel is shorter for geminates than singletons—but there also are nondurational features covarying with this contrast. Greater fundamental frequency and intensity drops are found from the preceding to the following vowel for the geminate than the singleton stops. These results suggest the possibility that systematic variation of these acoustic

features is used in the perceptual categorization of the contrast in addition to the primary cue of closure duration. Moreover, the nondurational correlates are promising candidates for speech-rate resistant features.

4pSC16. Different motor strategies for increasing speaking rate: Data and modeling. Majid Zandipour, Joseph Perkell, Mark Tiede, Frank Guenther (M.I.T., Res. Lab Electron., Speech Commun. Group, 50 Vassar St, Cambridge, MA 02139, majidz@speech.mit.edu), Kiyoshi Honda (ATR Human Information Processing Res. Lab., Kyoto 619-0288, Japan), and Emi Murano (Univ. Maryland Dental School, Baltimore, MD, 21209)

Different motor strategies for increasing speaking rate: data and modeling EMG, kinematic and acoustic signals were recorded from two male subjects as they pronounced multiple repetitions of simple nonsense utterances. The resulting data indicate that the two subjects employed different motor strategies to increase speaking rate. When speaking faster, S1 significantly increased the size of the articulatory target region for his tongue movements, increased the speed of the tongue movements and the rate of EMG rise somewhat, while decreasing the movement duration significantly and movement distance slightly. In contrast, at the fast rate, S2 had the same size articulatory target region and rate of EMG rise as at the normal rate, but decreased the speed, distance, and duration of tongue movement slightly. Each subject had similar dispersions of acoustic targets in $F1-F2$ space at fast versus normal rates, but both shifted target centroids toward the center of the vowel space at the fast rate. Simulations with a biomechanical model of the vocal tract show how modulations of motor commands may account for such effects of speaking rate on EMG, kinematics, and acoustic outputs. [Work supported by NIDCD, NIH.]

4pSC17. Effect of speaking rate on individual talker differences in voice-onset-time. Rachel M. Theodore, Joanne L. Miller, and David DeSteno (Dept. of Psych., 125 NI, Northeastern Univ., 360 Huntington Ave., Boston, MA, 02115-5000, r.theodore@neu.edu)

Recent findings indicate that individual talkers systematically differ in phonetically relevant properties of speech. One such property is voice-onset-time (VOT) in word-initial voiceless stop consonants: at a given rate of speech, some talkers have longer VOTs than others. It is also known that for any given talker, VOT increases as speaking rate slows. We examined whether the pattern of individual differences in VOT holds across variation in rate. For example, if a given talker has relatively short VOTs at one rate, does that talker also have relatively short VOTs at a different rate? Numerous tokens of /ti/ were elicited from ten talkers across a range of rates using a magnitude-production procedure. VOT and syllable duration (a metric of speaking rate) were measured for each token. As expected, VOT increased as syllable duration increased (i.e., rate slowed) for each talker. However, the slopes as well as the intercepts of the functions relating VOT to syllable duration differed significantly across talkers. As a consequence, a talker with relatively short VOTs at one rate could have relatively long VOTs at another rate. Thus the pattern of individual talker differences in VOT is rate dependent. [Work supported by NIH/NIDCD.]

4pSC18. Variation in vowel production. Joseph Perkell, Majid Zandipour, Satrajit Ghosh, Lucie Menard (Speech Commun. Group, Res. Lab. of Electron., Rm. 36-511, M.I.T., Cambridge, MA 02139), Harlan Lane, Mark Tiede, and Frank Guenther (M.I.T., Cambridge, MA 02139)

Acoustic and articulatory recordings were made of vowel productions by young adult speakers of American English—ten females and ten males—to investigate effects of speaker and speaking condition on measures of contrast and dispersion. The vowels in the words teat, tit, tet, tat, tot, and toot were embedded in two-syllable ''compound words'' consisting of two CVC syllables, in which each of the two syllables comprised a real word, the consonants were /p/, /t/ or /k/, the two adjoining consonants were always the same, the first syllable was unstressed and the second stressed. Variations of phonetic context and stress were used to induce

dispersion around each vowel centroid. The compound words were embedded in a carrier phrase and were spoken in normal, clear, and fast conditions. Initial analyses of $F1$ and $F2$ on 15 speakers have shown significant effects of speaker, speaking condition (and also vowel, stress, and context) on vowel contrast, and dispersion around means. Generally, dispersions increased and contrasts diminished going from clear to normal to fast conditions. Results of additional analyses will be reported. [Work supported by NIDCD, NIH.]

4pSC19. Region, gender, and vowel quality: A word to the wise hearing scientist. Richard Wright (Dept. of Linguist., Univ. of Washington, Box 354340, Seattle, WA 98195-4340, rawright@u.washington.edu), Stephanie Bor, and Pamela Souza (Univ. of Washington, Seattle, WA 98105)

Sociophonetic research has established effects of regional accent and gender on spoken vowels. Many gender differences are due to sociolinguistic factors and thus vary by region. The implications for researchers and clinicians are important: gender variation must be controlled for according to the region of the listener and talker population. Moreover, speech perception stimuli used in research and in clinical applications have limited regional application. This poster illustrates these factors using the Pacific Northwest regional accent. The data, collected for a previous study on hearing aid processing, consist of three repetitions of eight vowels produced in real-word /h_d/ (or /_d/) contexts by six males and six females ranging in age from 19 to 60. Formants were measured using an LPC with an accompanying FFT and spectrogram for verification. The results revealed vowel-specific differences in the male and female speech over and above those typically associated with physiologic predictions, and different again from those observed in past studies from different regions. Taken as a whole, these data suggest that speech and hearing researchers should take care in selecting stimuli for general-use speech perception tests. [Work supported by NIDCD training grant (#DC00033) and NIH RO1 (1 RO1 DC006014).]

4pSC20. Acoustic characteristics of vowels in three regional dialects of American English. Ewa Jacewicz, Robert Allen Fox, Yolanda Holt (Speech Acoust. and Percept. Labs., Dept. of Speech and Hearing Sci., The Ohio State Univ., Columbus, OH 43210), and Joseph Salmons (Univ. of Wisconsin—Madison, Madison, WI)

Most of the comparative sociophonetic studies of regional dialect variation have focused on individual vowel differences across dialects as well as speaker variables. The present work seeks to define basic acoustic characteristics of entire vowel systems for three different regional variants of American English spoken in southeastern Wisconsin (affected by the Northern Cities Shift), western North Carolina (affected by the Southern Vowel Shift), and central Ohio (not considered to be affected currently by any vowel shift). Three groups of speakers (men and women) aged 20–29 years were recorded from each geographic area defined by two to three counties (creating a highly homogeneous set of speakers). Acoustic measures for the set of 14 monophthongs and diphthongs in /h_d/ context included vowel space area for each speaker, global spectral rate of change for diphthongized vowels (defined over the first three formant slopes), the amount of frequency change for F1 and F2 at two temporal points located close to vowel onset and offset (vector length), and vowel duration. These measures will establish both systemic and vowel inherent characteristics across the three dialects, serving as a basis for future examination of conditioning factors on vowels in chain shifts. Dialectal differences will be discussed. [Work supported by NIH NIDCD R01 DC006871.]

4pSC21. The rhythmic characterization of two varieties of Portuguese. Verna Stockmal, Emilia Alonso Marks, Audra Woods, and Z. S. Bond (Ohio Univ., Athens, OH 45701)

As spoken in Europe, Portuguese is said to be stress-timed, while Brazilian Portuguese appears to display characteristics of both stress and syllable timing [P. A. Barbosa, D.E.L.T.A. **16**, 369–402 (2000)]. We employed the Ramus *et al.* metric, based on acoustic-phonetic measurements [Ramus *et al.*, Cognition **73**, 265–292 (1999)], to investigate the possibility of distinguishing between the two varieties of the language. Five native speakers of European Portuguese and five native speakers of Brazilian Portuguese recorded the same short prose passage taken from a magazine. The talkers were asked to read at a normal, comfortable rate. The reading time of the passage averaged 60 s, with considerable differences among the talkers. From the vocalic and consonantal intervals, the Ramus metrics, percent vocalic interval and standard deviation of consonantal and vocalic interval, were calculated. The five talkers of the two language varieties differed on the values of these parameters. The values of %V and SD-V showed overlap between the two talker groups, while the BP talkers tended to show lower values for SD-C. Apparently, the rhythmic characterization of the two varieties of the language is not clearly categorical, but rather ranges along a continuum.

4pSC22. Indexical cues to talker sex and individual talker identity extracted from vowels produced in sentence-length utterances. Michael J. Berkowitz (Dept. of Psych., 301 Wilson Hall, Vanderbilt Univ., 111 21st Ave. South, Nashville, TN 37203, michael.j.berkowitz@vanderbilt.edu), Jo-Anne Bachorowski (Vanderbilt Univ., Nashville, TN 37203), and Michael J. Owren (Georgia State Univ., Atlanta, GA 30302)

The purpose of this study was to replicate and extend a previous study of indexical cuing [J.-A. Bachorowski and M. J. Owren, J. Acoust. Soc. Am. **106**, 1054–1063 (1999)] by including more vowel sounds spoken in more diverse contexts. Specific combinations of acoustic parameters that should represent talker sex and individual talker identity were identified using predictions based on known sources of variation in vocal production-related anatomy. This study utilized 100 recordings of sentence-length utterances, produced by each of 43 male and 44 female undergraduates, as well as 22 stock-phrase recordings produced by these same participants. One of five vowel sounds (/æ, ɛ, i, ə, u/) was isolated from each sentence and analyzed for F_0, $F1$, $F2$, $F3$, $F4$, vowel duration, jitter, shimmer, and harmonicity. Classification by talker sex was nearly perfect using a combination of cues related to both vocal-fold and vocal-tract anatomy. The accuracy of classification by individual identity depended strongly on cues relating to vocal tract-variation within sex.

4pSC23. Utterance-final position and projection of femininity in Japanese. Mie Hiramoto and Victoria Anderson (Dept. of Linguist., Univ. of Hawaii, 1890 East-West Rd., Honolulu, HI 96822)

Japanese female speakers frequent use of suprasegmental features such as higher pitch, longer duration, wider pitch range, and more instances of rising intonation *vis-a-vis* male speakers, is recognized as Japanese womens language (JWL) prosody. However, these features normally co-occur with gender-specific sentence-final particles (SFPs) like the strongly feminine "kashira." In this study, we examined the use of pitch and duration in utterances without SFPs, to determine whether JWL prosody is a function of SFPs or of utterance-final position. Eight male and eight female native Japanese speakers were instructed to read prepared sentences as though auditioning for a masculine theater role and then as though auditioning for a feminine role. Results indicate that utterance-final position is the projection point of JWL prosody even in the absence of SFPs. The data used for this study show high pitch, wide pitch range, long duration, and rising intonation at utterance-final positions when produced (by both men and women) in the feminine gender role. Conversely, in the masculine gender

role, both men and women avoid the use of such prosodic features, and may even avoid using rising intonation in interrogative sentences, where the tonal grammar calls for it.

4pSC24. Attitudinal correlate of final rise-fall intonation in Japanese. Toshiyuki Sadanobu (Kobe Univ., Tsurukabuto 1-2-1, Nada, Kobe, 657-8501, Japan)

Abrupt rise and subsequent fall intonation is common at the end of intonation units in Japanese, but its attitudinal correlate has not been fully elucidated yet. This intonation appears in the literature of the 1960's as politicians' way of speech, and nowadays not only politicians but many speakers including older generations often use it. However, this intonation is stigmatized as childish, and many people devalue it as an unintelligent way of speaking by young people. Where does this great gap between reality and image of this intonation come from? This presentation addresses this problem by focusing on natural conversation of Japanese daily life. The conclusions are as follows: (*i*) Rise-fall intonation often appears when the speaker talks about high-level knowledge, whereas it disappears when the speaker talks about their personal experience. (*ii*) Rise-fall intonation at the end of an intonation conveys the speaker's being so occupied with speaking that intonation unit. The childish image comes from the speaker's unawareness of their overall speech because of being occupied with local process. [Work supported by the Ministry of Education, Science, Sport, and Culture, Grant-in-Aid for Scientific Research (A), 16202006, and by the Ministry of Internal Affairs and Communications, SCOPE 041307003.]

4pSC25. Vowel devoicing in Japanese infant- and adult-directed speech. Laurel Fais, Janet Werker (Dept. of Psych., Univ. of BC, 2136 West Mall, Vancouver, BC V6T 1Z4 Canada, jwlab@psych.ubc.ca), Sachiyo Kajikawa, and Shigeaki Amano (NTT Commun. Sci. Labs., Seika-cho, Soraku-gun, Kyoto 619-0237 Japan)

It is well known that parents make systematic changes in the way they speak to infants; they use higher pitch overall, more pronounced pitch contours, more extreme point vowels, and simplified morphology and syntax (Andruski and Kuhl, 1996; Fernald *et al.*, 1989). Yet, they also preserve information crucial to the infants ability to acquire the phonology of the native language (e.g., phonemic length information, Werker *et al.*, 2006). The question examined in this paper is whether information other than phonemic segmental information is also preserved, namely, information concerning the phonological process of vowel devoicing. Devoicing of high vowels between voiceless consonants and word-finally after a voiceless consonant is a regular and well-attested phonological process in Japanese (Shibatani, 1990). A corpus of speech by Japanese mothers addressed to their infants and addressed to another adult was examined, and the degree and frequency with which they apply vowel devoicing in each type of speech was analyzed. Rates of vowel devoicing in speech to adults and infants are compared, accommodations made to infants and to hearing-impaired children are discussed (Imaizumi *et al.*, 1995), and the implications of these accommodations for the acquisition of vowel devoicing by Japanese infants are explored.

4pSC26. Language and gender differences in speech overlaps in conversation. Jiahong Yuan, Mark Liberman, and Christopher Cieri (Univ. of Pennsylvania, Philadelphia, PA 19104)

Language and gender differences in speech overlaps in conversation were investigated, using the LDC CallHome telephone speech corpora of six languages: Arabic, English, German, Japanese, Mandarin, and Spanish. To automatically obtain the speech overlaps between two sides in a conversation, each side was segmented into pause and speaking segments, and the overlap segments during which both sides were speaking were time stamped. Two types of speech overlaps are distinguished: (1) One side takes over the turn before the other side finishes (turn-taking type). (2)

One side speaks in the middle of the other side's turn (backchannel type). It was found that Japanese conversations have more short (less than 500 ms) turn-taking type of overlap segments than the other languages. The average number of such segments per 10 min of conversation for Japanese was 62.6 whereas the average numbers for the other languages ranged from 37.9 to 43.3. There were, however, no significant differences among the languages on the backchannel type of overlaps. Cross-linguistically, conversations between two females contained more speech overlaps (both types) than those between a male and a female or between two males, and there was no significant difference between the latter two.

4pSC27. An acoustic study of laryngeal contrast in three American Indian Languages. Heriberto Avelino (Dept. of Linguist., UC Berkeley, Berkeley, CA 94720-2650)

A contrast between modal and nonmodal phonation is commonly found in American Indian languages. The use of laryngealized voice has been reported in a number of languages from different linguistic families. This paper investigates the acoustics of laryngealized phonation in three indigenous languages spoken in Mexico, Yalalag Zapotec, Yucatec Maya, and Mixe. These languages differ in terms of the use of other features controlled by action of the larynx, i.e., tone. In Zapotec there is a contrast between high, low, and falling tones; Maya has phonemic high and low tones, whereas Mixe does not present phonemic pitch. The results show that the production of phonemic laryngeal vowels differs from language to language. The data suggest that the specific implementation of laryngealization depends in part on the relationship with contrastive tone. The patterns of the languages investigated provide new evidence of the possible synchronization of phonation throughout the vowel. With this evidence, a typology of modal/nonmodal phonation in phonation-synchronizing languages is proposed.

4pSC28. The comparison between Thai and Japanese temporal control characteristics using segmental duration models. Chatchawarn Hansakunbuntheung and Yoshinori Sagisaka (GITI, Waseda Univ., 29-7 Bldg. 1-3-10, Nishi-Waseda, Shinjuku-ku, Tokyo 169-0051, Japan, chatchawarnh@fuji.waseda.jp)

This paper compares the temporal control characteristics between Thai and Japanese read speech data using segmental duration models. The same and the different control characteristics have been observed from phone level to sentence level. The language-dependent and language-independent control factors have also been observed. In phone and neighboring phone level, different characteristics are found. Japanese vowel durations are mainly compensated by only adjacent preceding and following phones, which results from mora timing. Unlike Japanese, Thai vowel durations are affected by two succeding phones. It can be guessed that the differences come from syllabic structures. In word level, most content words tend to have longer phone durations while function words have shorter ones. In phrase level, both languages express duration lengtening of syllable/mora at the phrase initial and final. For language-specific factors, Thai tones express small alteration on phone duration. The comparisions explore the duration characteristics of the languages and give more understanding to be used in speech synthesis and second-language learning research. [Work supported in part by Waseda Univ. RISE research project of "Analysis and modeling of human mechanism in speech and language processing" and Grant-in-Aid for Scientific Research A-2, No. 16200016 of JSPS.]

4pSC29. Articulatory settings of French and English monolinguals and bilinguals. Ian L. Wilson (Univ. of Aizu, Tsuruga, Ikki-machi, Aizu-Wakamatsu City, Fukushima, 965-8580, Japan, wilson@u-aizu.ac.jp) and Bryan Gick (Univ. of BC, Vancouver, BC V6T1Z1 Canada)

This study investigated articulatory setting (AS), a language's underlying posture of the articulators. Interspeech posture (ISP) of the articulators (their position when motionless during interutterance pauses) was used as a measure of AS in Canadian English and Quebecois French.

4p FRI. PM

Optotrak and ultrasound imaging were used to test whether ISP is language specific in monolingual and bilingual speakers. Results show significant differences in ISP across the monolingual groups, with English exhibiting a higher tongue tip, more protruded upper and lower lips, and narrower horizontal lip aperture. Results also show that upper and lower lip protrusion are greater for the English ISP than for the French ISP, in all bilinguals who were perceived as native speakers of both languages, but in no other bilinguals. Tongue tip height results mirror those of the monolingual groups, for half of the bilinguals perceived as native speakers of both languages. Finally, results show that there is no unique bilingual-mode ISP, but instead one that is equivalent to the monolingual-mode ISP of a bilingual's currently most-used language. This research empirically confirms centuries of noninstrumental evidence for AS, and for bilinguals it suggests that differences between monolingual and bilingual modes do not hold at the phonetic level.

4pSC30. Temporal and spectral variability of vowels within and across languages with small vowel inventories: Russian, Japanese, and Spanish. Franzo F. LawII (Speech Acoust. and Percept. Lab., City Univ. of New York—Grad. Ctr., 365 Fifth Ave., New York, NY 10016-4309, flaw@gc.cuny.edu), Yana D. Gilichinskaya, Kikuyo Ito, Miwako Hisagi, Shari Berkowitz, Mieko N. Sperbeck, Marisa Monteleone, and Winifred Strange (City Univ. of New York—Grad. Ctr., New York, NY 10016-4309)

Variability of vowels in three languages with small vowel inventories (Russian, Japanese, and Spanish) was explored. Three male speakers of each language produced vowels in two-syllable nonsense words (VCa) in isolation and three-syllable nonsense words (gaC1VC2a) embedded within carrier sentences in three contexts: bilabial stops in normal rate sentences and alveolar stops in both normal and rapid rate sentences. Dependent variables were syllable duration and formant frequency at syllable midpoint. Results showed very little variation across consonant and rate conditions in formants for /i/ in Russian and Japanese. Japanese short /u, o, a/ showed fronting (F2 increases) in alveolar context, which was more pronounced in rapid sentences. Fronting of Japanese long vowels was less pronounced. Japanese long/short vowel ratios varied with speaking style (isolation versus sentences) and speaking rate. All Russian vowels except /i/ were fronted in alveolar context, but showed little change in either spectrum or duration with speaking rate. Spanish showed a strong effect of consonantal context: front vowels were backed in bilabial context and back vowels were fronted in alveolar context, also more pronounced in rapid sentences. Results will be compared to female productions of the same languages, as well as American English production patterns.

4pSC31. Does infant-directed speech in Tagalog resemble infant-directed speech in American English? Emmylou Garza-Prisby, Shiri Katz-Gershon, and Jean Andruski (Aud. & Speech-Lang. Pathol. Dept., Wayne State Univ., 207 Rackham, 60 Farnsworth St., Detroit, MI 48202)

This study compared the speech of a Filipino mother in infant- and adult-directed speech in order to investigate whether the mother used the acoustic features typically found in the infant-directed speech of American English-speaking mothers. Little acoustic documentation is available on the acoustic features of Tagalog, and no acoustic comparison of speech registers has so far been conducted. Impressionistically, Tagalog-speaking mothers' do not appear to use the features typically found in American mothers speech to their young infants. The mother was recorded talking to her infant and to another adult native speaker of Tagalog. Recordings were made in the mother's home and visits occurred during the first 6 months of the infant's life. Specific acoustic features analyzed include (a) vowel duration, (b) vowel format frequencies, (c) vowel triangle size, (d) rate of speech, (e) fundamental frequency, and (f) F0 range. Morphological and syntactic features were also analyzed, including (g) mean length of utterance and (h) sentence length. Results support a need for further study of speech registers in Filipino mothers.

4pSC32. Restricting relativized faithfulness and local conjunction in optimality theory. Haruka Fukazawa (Keio Univ., 4-1-1 Hiyoshi, Kohoku-ku, Yokohama, Japan)

Within the framework of optimality theory (OT), the two mechanisms, relativized faithfulness and local conjunction, play inevitable roles, especially when a simple constraint ranking fails to account for the data. However, their domain of application are too unrestricted and even overlapping each other. For instance, there are some cases which could be explained both by the ranking with relativized faithfulness and by the one with local conjunction. Syllable-final neutralization in German and geminate devoicing in Japanese loanwords are of interest in this context. The present paper proposes formal restrictions mostly on the local conjunction mechanism: the soundness of constraint combination, the number of constraints involved in a conjunction, and the local domain of conjunction. They not only can simplify the analysis but also give a more principled account for the overlapping cases. In fact, relativized faithfulness approach wins over local conjunction approach both in German neutralization and in Japanese loanwords. It is desirable for the universal grammar to be more restricted. Removing an overlap of theoretical devices is an important step toward the goal.

4pUWa1. Underwater noise as source of information on conditions and dynamics of ocean environments. Alexander V. Furduev (N. N. Andreyev Acoust. Inst., 4 Shvernika St., Moscow 117036, Russia)

Leonid Brekhovskikh wrote in his book *The Ocean and the Human* (1987): ''Ocean noise is as important oceanographic parameter as temperature, current, and wind.'' Brekhovskikh created and headed the Laboratory of Acoustic Methods of Ocean Research in 1956. One of the scientific directions of the Laboratory was investigation of underwater noise both as interference for sound reception and a source of environmental information. Long-term studies on the unique acoustic research vessels created under the initiative of Brekhovskikh resulted in numerous important findings, including ambient noise spectra and envelopes of acoustic fluctuations, depth dependence of noise directivity, and mechanisms of ambient noise generation. Brekhovskikh was always eager to find practical applications of scientific results. Different methods of ensuring noise immunity of hydroacoustic arrays were developed under his supervision. Passive methods of acoustic navigation based on use of natural noise were suggested. Techniques for underwater acoustic monitoring of the ocean based either on ambient noise analysis or reemission of noise from a point away from the receiving system have been developed. The success of the team of scientists headed by Brekhovskikh was determined by the creative atmosphere around him: there was neither competition nor commercial interests. The common goal was knowledge of the ocean.

4pUWa2. Distributed acoustic sensing in shallow water. Henrik Schmidt (Ctr. for Ocean Eng., MIT, Cambridge, MA 02139)

The significance of Leonid Brekhovskikh to the ocean acoustics is undisputed. He was pioneering not only in terms of fundamental understanding of the ocean acoustic waveguide, but also the development of efficient and numerically stable approaches to propagation of sound in a stratified ocean. As such he has been an inspiration to a whole generation of model developers, leading to today's suite of extremely powerful wave theory models, capable of accurately representing the complexity of the shallow-water ocean waveguide physics. The availability of these computational tools have in turn led to major advances in adaptive, model-based signal-processing techniques. However, such computationally intensive approaches are not necessarily optimal for the next generation of acoustic sensing systems. Thus, ocean observation in general is currently experiencing a paradigm shift away from platform-centric sensing concepts toward distributed sensing systems, made possible by recent advances in underwater robotics. In addition to a fully autonomous capability, the latency and limited bandwidth of underwater communication make on-board processing essential for such systems to be operationally feasible. In addition, the reduced sensing capability of the smaller physical apertures may be compensated by using mobility and artificial intelligence to dynamically adapt the sonar configuration to the environment and the tactical situation, and by exploiting multiplatform collaborative sensing. The development of such integrated sensing and control concepts for detection, classification, and localization requires extensive use of artificial intelligence incorporating a fundamental understanding of the ocean acoustic waveguide. No other sources in literature provide this with the clarity and depth that is the trademark of Academician Brekovskikh's articles and classical textbooks. [Work supported by ONR.]

4pUWa3. When the shear modulus approaches zero: Fluids don't bend and Scholte leaves the room. Robert I. Odom (Appl. Phys. Lab., Univ. of Washington, 1013 NE 40th St., Seattle, WA 98105-6698), Donna L. G. Sylvester, and Caitlin P. McHugh (Seattle Univ., Seattle, WA 98122-1090)

The 4×4 linear system of differential equations describing the propagation of the displacements and tractions in an elastic layered medium becomes singular as the shear modulus of the elastic medium approaches zero. There are a number of approximate ways to handle this singularity in order to impart numerical stability to the computation of the elastic waves in a layered medium. For example, one can impose an irrotational constraint on the displacements or introduce a massive elastic interface (MEI). Both of these ways of handling the weak shear strength are approximate, but avoid the need for singular perturbation theory [Gilbert, 1998]. Scholte waves are interface waves that propagate along the interface between an elastic solid and a fluid. They have nodes near or on the interface and decay exponentially into the bounding media. Scholte waves do not occur at the boundary between fluids. As the shear speed in the bounding elastic medium approaches zero, the Scholte waves disappear from the spectrum. We investigate this disappearance by applying singular perturbation theory

to the coupled fluid-elastic system. Among other things, we will address the rate in wave-number space at which the Scholte waves disappear from the spectrum.

4pUWa4. Measurement of the plane-wave reflection coefficient of the ocean bottom and the legacy of Leonid Brekhovskikh. George V. Frisk (Florida Atlantic Univ., 101 N. Beach Rd., Dania Beach, FL 33004) and Luiz L. Souza (Bose Corp., Framingham, MA 01701)

Leonid Brekhovskikh's classic text [*Waves in Layered Media* (Academic, New York, 1980)] inspired the development of several techniques for measuring the plane-wave reflection coefficient of the ocean bottom. Specifically, his application of the geometrical acoustics approximation to the problem of reflection of a spherical wave from a horizontally stratified medium provided the theoretical foundation for evaluating the strengths and weaknesses of various measurement methods. The most popular method assumes that the reflected field also consists of a spherical wave multiplied by the reflection coefficient evaluated at the specular angle. However, Brekhovskikh's work showed that this interpretation is confined to a limited range of angles and bottom structures and, if applied improperly, can lead to unphysical results such as negative bottom loss. This paper describes a technique which circumvents these deficiencies. It consists of measuring the pressure field magnitude and phase versus range due to a cw point source and Hankel transforming these data to obtain the depth-dependent Green's function versus horizontal wavenumber. The reflection coefficient is then obtained from the Green's function using the analytical relationship between the two quantities. The method is demonstrated using 220-Hz data obtained in a near-bottom geometry in the Icelandic Basin. [Work supported by ONR.]

4pUWa5. Field from a point source above a layered half-space; theory and observations on reflection from the seabed. Charles W. Holland (Appl. Res. Lab., The Penn State Univ., State College, PA)

L. M. Brekovskikh's book *Waves in Layered Media* has provided decades of graduate students and researchers alike with a comprehensive and enormously useful reference. One topic from that work, reflection from a point source above a plane-layered medium (the seabed), is discussed here. Both theoretical underpinnings and observations of reflection from a homogeneous halfspace, a transition layer with smoothly varying density and velocity profiles, and discrete layered media are considered for various shallow water sediment fabrics. [Work supported by the Office of Naval Research and NATO Undersea Research Centre.]

<center>2:25</center>

4pUWa6. Plane-wave model and experimental measurements of the directivity of a Fabry-Perot, polymer film, ultrasound sensor. Benjamin T. Cox and Paul C. Beard (Dept. of Med. Phys. and Bioengineering, Univ. College London, Gower St., London, WC1E 6BT, UK, bencox@mpb.ucl.ac.uk)

Optical detection of ultrasound is popular due to the small element sizes that can be achieved. One method exploits the thickness change of a Fabry-Perot (FP) interferometer caused by the passage of an acoustic wave to modulate a laser beam. This detection method can have greater sensitivity than piezoelectric detectors for sub-millimeter element sizes. The directivity of FP sensors and the smallest achievable effective element size are examined here. A plane-wave model of the frequency-dependent directional response of the sensor, based on Brekhovskikh's work on elastic waves in layered media, is described and validated against experimental directivity measurements made over a frequency range of 15 MHz and from normal incidence to 80 deg. In terms of applications, the model may be used to provide a noise-free response function that can be deconvolved from sound field measurements in order to improve accuracy in high-frequency metrology and imaging applications, or, for example, as a predictive tool to improve sensor design. Here, the smallest achievable effective element radius was investigated by comparing the directivity with that of a rigid circular pressure transducer, and found to be $\sim 0.9d$, where d is the thickness of the FP interferometer. [Funding was provided by the EPSRC, UK]

<center>2:40</center>

4pUWa7. The interference head wave and its parametric dependence. Jee Woong Choi and Peter H. Dahl (Appl. Phys. Lab., Univ. of Washington)

The interference head wave that can exist in the presence of a sound-speed gradient in the sediment, is a precursor arrival representing a transition between the first-order head wave and the zeroth-order refracted wave. Using a parabolic equation (PE) simulation, Choi and Dahl [J. Acoust. Soc. Am. **119**, 2660–2668 (2006)] showed how the small shift in the dominant frequency of the interference head wave behaves as a function of the nondimensional parameter zeta, which itself is a function of center frequency, gradient, and range. For example, it was shown that the maximum frequency shift occurring in the vicinity of zeta equals 2. In this work, we investigate the amplitude and additional spectral properties of the interference head wave and analyze the cause of the frequency shift phenomenon using the ray theory. The limitation on the application of ray method also will be discussed. Finally, the conclusion will be verified by the time-dependent simulation using the RAM PE algorithm. [Work supported by the ONR.]

Session 4pUWb

Underwater Acoustics: Session in Honor of Fredrick Fisher

William A. Kuperman, Chair

Scripps Inst. of Oceanography, Univ. of California, San Diego, Marine Physical Lab., La Jolla, CA 92093-0238

Chair's Introduction—3:10

Invited Papers

3:15

4pUWb1. FLIP (Floating Instrument Platform): A major Fred Fisher contribution to ocean science. Fred N. Spiess, Robert Pinkel, William S. Hodgkiss, John A. Hildebrand (Marine Physical Lab., Scripps Inst. of Oceanogr., UCSD 0205, 9500 Gilman Drive; La Jolla, CA 92093-0205, fspiess@ucsd.edu), and Gerald L. D'Spain (UCSD, La Jolla, CA 92093-0205)

Frederick H. Fisher, a loyal and zealous member of the Acoustical Society of America, was an imaginative and effective developer of new techniques for research in both laboratory and seagoing acoustics. Most notable among his contributions was his work in bringing into being and enhancing the usefulness of the spar buoy laboratory, FLIP, from its inception in 1960. Not only did Fred use FLIP in his own research, its existence and many of its ancillary capabilities constituted a base for the seagoing research of others. The authors of this paper have benefited from FLIP's unique capabilities, starting with long-range sound propagation studies in the 1960's and 1970's. FLIP's stability and deep draft structure provided the platform for development of acoustic Doppler techniques for the measurement of ocean currents. Most recently, FLIP has been involved in studies of marine mammal vocalizations and use of multielement arrays to investigate details of shallow-water propagation. Fred's initial studies of sonar bearing accuracy, for which FLIP's construction was funded, and his dedication to advancing FLIP's ability to contribute to ocean science, constitute a legacy that is being utilized today, more than 40 years after FLIP's launching.

3:35

4pUWb2. Absorption of sound in seawater and ocean ambient noise, the scientific passions of Fred Fisher. John A. Hildebrand (Scripps Inst. of Oceanogr., UCSD, La Jolla, CA 92093-0205)

Fred Fisher made seminal contributions to ocean acoustics in the understanding of the absorption of sound in seawater and ocean ambient noise. Laboratory data and long-range sound propagation data revealed excess acoustic absorption in seawater. Fred Fisher spent much of his scientific career, beginning with his Ph.D dissertation, teasing out the contributions of various seawater components to sound absorption, and his work on this topic set the standard for understanding and modeling these phenomena. Ambient noise is an important aspect of underwater signal detection and is the focus of recent concerns about disturbance of marine organisms. Fred Fisher made important contributions to ambient noise studies by conducting measurements of vertical directionality, thereby testing models for ambient noise production. The value of archival ambient noise data and recent increases in ambient noise will be discussed.

Contributed Papers

3:55

4pUWb3. Fred Fisher's high-pressure work with eyewash and epsom salts. Christian de Moustier (Ctr. for Coastal & Ocean Mapping, Chase Ocean Eng. Lab, Univ. of New Hampshire, 24 Colovos Rd., Durham, NH 03824)

Starting in 1957 Fred Fisher led research programs devoted to high-pressure measurements related to the physical chemistry of sound absorption in seawater due to magnesium sulfate and other salts. As he put it, he spent his professional lifetime squeezing epsom salt. His interest in the low-frequency anomalous sound absorption in the ocean below 1 kHz led to the discovery of boric acid as the cause of the low-frequency relaxation. This paper is a short review of Fred Fisher's contributions to our knowledge of sound absorption in seawater, based in part on his carefully hand-written lecture notes and numerous low-pressure discussions.

4:10

4pUWb4. Fred Fisher and research with acoustic vector sensors; Marine Physical Laboratory's vertical array of directional acoustic receivers and ocean noise. Gerald L. D'Spain and William S. Hodgkiss (Marine Physical Lab, Scripps Inst. of Oceanogr., La Jollla, CA 93940-0701)

Fred Fisher had boundless enthusiasm for all topics acoustic. A chance encounter with him in the hallway usually led to a half-hour discussion of the latest research efforts at the lab and recent results he found exciting. In the 1980s, Fred became interested in the problem of identifying the physical phenomena forming the pedestal about the horizontal in vertical directionality measurements of the deep ocean's low-frequency noise field. Two competing mechanisms had been proposed: downslope conversion of coastal shipping and noise from high latitude winds coupling into the deep

4p FRI. PM

sound channel due to the shoaling of the sound channel axis. The relative contributions of these two mechanisms possibly could be separated if the azimuthal ambiguity of a vertical line array of hydrophones somehow could be broken. Therefore, Fred proposed to build a vertical array of "DIFAR" sensors, which led to the design and construction of the Marine Physical Lab's Vertical "DIFAR" Array. This talk will reminisce a bit about Fred as well as present some results from an ambient noise experiment conducted in 1992 on the continental shelf using the Vertical DIFAR Array co-deployed with MPL's freely drifting vector sensors, the Swallow floats. [Work supported by ONR and ONT.]

FRIDAY EVENING, 1 DECEMBER 2006   HAWAII BALLROOM, 7:00 TO 10:00 P.M.

Awards Ceremony

Anthony A. Atchley, President

CITATION FOR THOMAS D. ROSSING

...for contributions to the Society in bringing the joy of scientific discovery and knowledge of acoustics to young people, teachers, and Society members.

HONOLULU, HAWAII • 1 DECEMBER 2006

If you have attended one of his many presentations to high school students at an Acoustical Society meeting, you already know how well deserved this recognition is for Thomas D. Rossing. Students' faces light up every time Tom gets jump ropes to oscillate into their various modes or when he presents any one of a variety of fascinating sound demonstrations pulled from his ever-present suitcase. He truly has the rare ability to capture the interest of an audience of young students and to inspire their curiosity in exploring science. He has that unique skill to bring the joy of acoustics to young students. Likewise, if you have attended any of the special workshops where Tom has spoken, you also already know his dedication to the education of students and teachers. His talks and publications in acoustics over the years focus on this objective, aided by his skill in musical acoustics which provides an additional avenue to interest young students.

Most Acoustical Society members may not have had the pleasure of attending one of Tom's lectures or demonstrations but most members have read *ECHOES* since 1997 when he assumed the position of its editor. In this role he has contributed to increasing ASA members' general knowledge of acoustics through his tireless efforts to disseminate important information to all readers of *ECHOES*. A recent decision was made to publish *ECHOES* online so that it is more widely available and timely for readers. Over the past decade he has tracked down authors to write interesting articles and reported on ASA meetings and other related events in acoustics, including news about members covered in the ''We hear that'' section. Somehow he also finds time to edit the fall issue of the American Physical Society's *Forum on Education* newsletter!

Two other sections in *ECHOES*, ''Scanning the Journals'' and ''Acoustics in the News,'' provide readers with brief summaries of news and technical publications about acoustics that have appeared in a wide variety of publications which many readers would probably have missed reading otherwise. Compiling and writing these two sections of *ECHOES* requires the efforts of someone who likes to read and has a broad background and knowledge about acoustics and other fields of science. Tom possesses these qualities which he obtained through a career that has taken him around the world teaching, presenting papers, conducting research, and writing numerous articles and books.

As a mentor he has influenced scores of young scientists, and his laboratory has been a haven for numerous highly respected acousticians over the years. We do not have the space in this encomium to list all of his accomplishments, but in true ASA style, we refer the interested reader to the encomium written when Tom received the ASA's Silver Medal in Musical Acoustics in November 1992 (Vol. 92, No. 4, Pt. 2). Otherwise you may simply search ''Thomas D. Rossing'' on the web to get a sampling of his major publications.

Tom received a PhD in Physics in 1954 from Iowa State University, followed by 14 years as a member the faculty at St. Olaf College. Later he served as chair of Physics and Distinguished Research Professor at Northern Illinois University. He has been a visiting scientist at more than a dozen national and international universities—most recently at Seoul National University and the Korean Advanced Institute for Science and Technology. He is now a visiting professor at Stanford University. During his career Tom has written many tutorial papers on acoustics, several of which have appeared in *The Physics Teacher* published by the American Association of Physics Teachers (AAPT). Tom served as president of AAPT in 1991 and was awarded their Robert A. Millikan Award in 2000 which recognizes teachers ''who have made a notable and creative contribution to the teaching of physics.''

In 2003 the ASA's Rossing Prize in Acoustics Education was established to recognize outstanding educators in acoustics, funded through a generous donation from Tom. He has served on many ASA committees including Education in Acoustics, Standards, Public Relations, Medals and Awards, and the Technical Committee on Musical Acoustics (Chair 1984-1990). He has also presented two of ASA's tutorial lectures—the most recent one was a demonstration lecture in which he was assisted by ASA members and local high-school teachers.

He has organized many special sessions at Acoustical Society meetings on the subjects of musical acoustics and education in acoustics, including the ''take five'' sessions where presenters describe their favorite techniques and demonstrations for teaching acoustics. Tom also has organized special meetings, including the Catgut Acoustical Society meeting held in 1982 in DeKalb,

Illinois, the International Symposium on Musical Acoustics in Leavenworth, Washington in 1998 and a musical instrument workshop at the ASA's 2005 Spring meeting in Vancouver, Canada. Tom Rossing is the author or co-author of over 400 publications, including 15 books which include *The Science of Sound (3rd edition)*, *The Physics of Musical Instruments* (2nd edition, with Neville Fletcher), *Teaching Sound and Light,* and *Light Sciences Physics and the Visual Arts*. He is the editor for the *Handbook on Acoustics* which will be published in 2007 and co-author of the ASA's *Auditory Demonstrations* CD which is widely used for teaching the perception of sound.

Although Tom is well acquainted with so many fields of science and acoustics, his main love is musical acoustics. He has performed in barbershop quartets at ASA meetings, with his most recent performance at the 75th anniversary banquet in New York City in May 2004 when ASA met to celebrate the founding of the Acoustical Society of America in 1929. This was a good year for acoustics in that it was also the year of Tom Rossing's birth in Madison, South Dakota.

Whether Tom is singing on stage, striking a bell to show its modes, or immersed in some other acoustical demonstration, the smile on his face is a sure sign that he loves acoustics and wants to share that enthusiasm with all listeners. We know that the many readers of this encomium who know how much Tom has contributed to ''bringing the joy of scientific discovery and knowledge of acoustics to young people, teachers, and Society members,'' will share our joy in seeing him recognized by the Society for his many significant contributions to acoustics and to the Acoustical Society of America.

CITATION FOR ALAN H. MARSH

. . . for contributions to the reduction of aircraft noise and for improvement to the quality of acoustical standards.

HONOLULU, HAWAII • 1 DECEMBER 2006

In the mid 1950's the major aircraft manufacturers in the United States were basing their futures on the development of commercial jet aircraft. Introduction of the Comet and Caravelle airplanes from Britain and France had brought a new and worrisome noise source into the communities of the world, causing the domestic airplane industry to begin to think for the first time about control of exterior noise as a major issue in their design considerations. In 1956 Alan Marsh joined Douglas Aircraft Company to begin a distinguished career in noise control engineering as one of the earliest pioneers in the control of aircraft noise.

Alan was born in Rochester, New York, on 21 March 1932, where he lived until enrolling at Williams College. After receiving a Bachelor of Arts degree in Physics from Williams he entered the Electrical Engineering program at the Massachusetts Institute of Technology (MIT). At MIT he came under the spell of enthusiasm for acoustics that Leo Beranek brought out in so many of us. Alan received a Bachelor of Science degree specializing in acoustics from MIT in 1956. Alan's penchant for learning continued after he moved to California and began his career at Douglas. Although he was working many hours of overtime Alan managed to pursue graduate work at the University of California at Los Angeles (UCLA) under the guidance of Alan Powell, then a professor of engineering at UCLA. Alan completed work and received a Master of Science degree in Engineering with a specialty in Aeroacoustics in 1962. His thesis involved the measurement of noise produced by a subsonic air jet impinging on a plane rigid surface.

At Douglas Alan was deeply involved in the earliest efforts to develop practical noise suppression techniques for turbojet engine exhaust noise for the DC-8 series airplanes. At about the same time, the development of the turbofan engine brought new noise control problems because of the strong tonal noise emitted by the turbofans and compressors of these engines. Development of sound-absorbing liners to reduce these noises became one of Alan's major projects. Noise control for these engines is greatly complicated by the high airflows to which materials are exposed, and the durability demands imposed by the airworthiness requirement for airplanes serving the public. Alan has confronted these competing design requirements throughout his career.

Development of reliable measurement instruments and procedures became an early interest for Alan. He became a strong and active participant in the development of standards for equipment and procedures at the national and international level through the standards program of the Acoustical Society of America (ASA), the Society of Automotive Engineers (SAE) Committee A-21 on Aircraft Noise, the International Standards Organization (ISO), and the International Electrotechnical Commission (IEC). He has been an individual expert on the ASA Committees S-1, Acoustics, and S-12, Noise, for many years. For ASA Alan has chaired or been a member of numerous standards working groups, including the standard for acoustical terminology and the development of editorial guidelines for the preparation of standards. For the IEC, Alan has been a U.S. member of the Working Group on Bandpass Filters, the Convener of the Working Group on Sound Level Meters (for the past twenty years), and other working groups, One of his most important contributions has been as the principal author of the SAE Aerospace Recommended Practice on the absorption of sound in air, which is now incorporated in U.S. and international standards for certification of aircraft for noise.

Alan has been a long-time contributor to the activities of the Acoustical Society since becoming a Member in 1956 and a Fellow in 1971. In addition to his service to the Society's standards program he has been Chair of the Technical Committee on Noise, a member of the Publication Policy Committee, an Associate Editor of the *Journal of the Acoustical Society of America*, a member of the Executive Council, and has served as technical chair for several of the semi-annual meetings of the Society. In addition to ASA, Alan was a founding member of the Institute of Noise Control Engineering of the USA for which he has served as President, Vice President, Secretary, Editor-in-Chief of the *Noise Control Engineering Journal*, technical chair and chair of INTER-NOISE Congresses. Alan has been, and currently is, an Officer, and a member of the Board of Directors of the International Institute of Noise Control Engineering.

After leaving Douglas in 1976, Alan formed DyTec Engineering to provide consulting engineering in aircraft and other forms of noise control. He has worked on numerous projects for a

variety of Douglas, Boeing, and other aircraft, as well as other noise control problems, and continues his active participation in acoustical standards development and editorial interests.

For his continuous contributions to the control of aircraft noise, his tireless participation in the development of acoustical standards, and his dedication to the improvement in the editorial quality of technical publications, Alan Marsh is a most deserving recipient of the Acoustical Society of America Silver Medal in Noise.

CITATION FOR HENRY E. BASS

. . . for leadership in physical acoustics and contributions to the understanding of atmospheric sound propagation

HONOLULU, HAWAII • 1 DECEMBER 2006

Henry Ellis Bass is a native Sooner who more than typifies Oklahoma's motto, ''Labor conquers all things.'' Hank's success is cradled in his work ethic and in his insatiable curiosity and vision. His high school academic record earned him college scholarships even while working forty hours a week in support of his family. After his college studies were interrupted by a two-year stint in the Signal Corps, Hank returned to Oklahoma State University to complete his doctorate in physics with an ambitious investigation into rotational relaxation in polar polyatomic gases. Hank joined the Physics faculty of the University of Mississippi (UM) as an Assistant Professor in September 1970. Following promotions through the ranks, he was appointed a Frederick A. P. Barnard Distinguished Professor in 1988. In 1965, he joined the U.S. Army Reserve, serving as a staff officer in the Office of the Assistant Secretary of the Army for Research Development and Acquisition from 1971 until his retirement in 1993 as a Lieutenant Colonel. Hank formed the Physical Acoustics Research Group at the University of Mississippi. The group's reputation and research projects outgrew its facilities and Hank sought financial support for a new laboratory building. As a direct result of these efforts, the U.S. Congress established the National Center for Physical Acoustics (NCPA) in 1986. Hank was appointed Director in 1992.

Hank's research efforts are responsible for several significant findings and developments in physical acoustics. One of Hank's guiding principles is to bring talented people together to develop the best approach to solve a problem. Clear evidence of this approach is that Hank has shared authorship of his 119 peer-reviewed publications with ninety different colleagues. In his second year as Assistant Professor, he invited Hans Bauer to spend a year at UM. Hank recognized the wide applicability of Bauer's work and applied it to the problem of frequency and humidity dependence of sound absorption in the atmosphere. Hank's theoretical and computational models for atmospheric absorption of sound remain a benchmark in the field. His theories formed a major part of the background for the American National Standard, ''Method for Calculation of the Absorption of Sound by the Atmosphere.'' In 1978, Hank received the Acoustical Society's Biennial Award (now the R. Bruce Lindsay Award) in recognition ''for theoretical and experimental research on the effects of molecular relaxation and sound propagation in multicomponent gases.'' In subsequent years, he continued to extend, refine, and apply the fundamental knowledge gained in basic research. He applied the theoretical basis for the prediction of atmospheric absorption to the prediction of the propagation and development of the noise from sonic booms and explosion waves, as well as to the calculation of the acoustic energy production of lightning. Work on the acoustic energy spectrum of tornadoes then led to the development and marketing of the Tornado Alert System™, which identifies imminent tornadoes by their temporal and spectral characteristics.

Hank's study of atmospheric sound absorption led him to investigate ground effects on outdoor sound propagation. He carried out and led pioneering experiments that explored acoustic-to-seismic coupling, surface impedance and effects of ground cover. These experiments ultimately led to important findings on soil porosity, elasticity and near-surface layering including important developments such as long range detection of helicopters using the correlation between acoustic and seismic signals; improved methods for predicting noise propagation over a realistic ground surface; and an acoustic system for buried mine detection that was fully developed by James Sabatier, who, not surprisingly, was Hank's graduate student. In 1981, Hank organized the first International Symposium on Long Range Sound Propagation; particularly significant is the synergy between underwater and atmospheric acousticians that developed out of the symposia leading to new and improved theoretical, numerical and experimental techniques. Hank was also a founding member of NATO Research Study Group 11 that coordinates NATO research on passive acoustic detection.

Hank's directorship brought NCPA into the international arena where it gained a reputation for excellence in physical acoustics research. Because of this reputation, NCPA was chosen as lead institution for the installation of the U.S. Infrasound Monitoring Stations (IMS) that were established to support the United Nations' Comprehensive Test Ban Treaty. Hank assembled a team of infrasound experts from U.S. universities and national labs to oversee the installation of 11 stations, which are part of the global IMS network. Hank fostered the application of these arrays to

widely different phenomena such as earthquakes, volcano eruptions, meteors, and upper atmosphere physics. A nationally important application of the infrasound data was the investigation into the breakup of the space shuttle *Columbia*. Hank's contribution to the IMS carries import for future scientific applications of global-scale acoustics.

Speaking of the future, Hank has always declared, ''graduate students are our greatest product.'' Since 1994, Hank has been the director of the Physical Acoustics Summer School, which brings together graduate students, professionally mature scientists and distinguished lecturers to discuss topics students ordinarily would not encounter in the classroom.

A genuine individual, Hank sincerely appreciates talent and worth in others; his ''do what's best for the whole'' approach has made him a successful leader and administrator. For his students, employees and coworkers, he inspires loyalty and determination. Both things he readily gives in return. Hank is everybody's dad, brother, friend and mentor. As a good Oklahoman, he will help build your home, fix your well, or move your belongings to a new house. He also encourages people to seek their full, albeit hidden, potential. One of the authors of this encomium was an English major working as a secretary. Hank saw the potential and convinced her to switch to Physics. She is now pursuing a Master's.

Hank has an infectious laugh, playful wit and indefatigable curiosity. He motivates, stimulates, and inspires achievement in others. Sometimes, in the halls of NCPA, you can find him walking along with a jaunty gait and a twinkle in his eye all the while softly singing a Mac Davis song from the 80's, ''Oh Lord, its hard to be humble when you're perfect in every way.''

CITATION FOR WILLIAM A. YOST

. . . for contributions understanding pitch perception, sound source localization, and auditory processing of complex sounds.

HONOLULU, HAWAII • 1 DECEMBER 2006

Bill Yost has had a most distinguished career in acoustics, academics, and scientific research. He has made, and continues to make, substantial contributions to Psychological and Physiological Acoustics in the areas of pitch perception and pitch theory, binaural hearing and sound source localization, the detection and discrimination of amplitude modulation, and computational modeling of perception derived from temporal acoustic patterns. He has been a trailblazer in making all of us aware of the importance of sound source determination and segregation for the normal sense of hearing. At the same time, he has been an important person in the life of his home institution of 30 years, Loyola University Chicago, and has contributed significantly and gladly to the Acoustical Society of America, to other scientific and professional organizations and to national panels and government advisory groups. He is the most energetic academic scientist I know. I am proud to have him as a friend and colleague for the past 30 years, and to be able to write about his accomplishments.

Bill received a Ph.D. in Experimental Psychology from Indiana University in 1970, with an emphasis on the quantitative and mathematical study of hearing, in the tradition of behaviorism. Following a National Science Foundation post-doc with Dave Green at the University of California, San Diego, he spent seven years at the University of Florida in Gainesville. He came to Loyola University as Director of the Parmly Hearing Institute and Professor in the Department of Psychology where he thrived professionally and scientifically. Bill quickly transformed the Parmly Hearing Institute from, essentially, a laboratory and resource for the Director, into an internationally known research institute, with 25 faculty, students and staff, and with diverse approaches to hearing science. His research has been continuously funded since 1968 by grants from the National Institutes of Health, National Science Foundation, Air Force Office of Scientific Research, Office of Naval Research, Defense Advanced Research Projects Agency, and the Environmental Protection Agency. Under Bill's direction, the Parmly Hearing Institute received the largest research grant in Loyola University's history from the National Institute of Deafness and Other Communicative Disorders. He has published more than 300 scholarly articles, reports and book chapters. And while he was productive in the laboratory and in the classroom, Bill also served as the president of the ASA, as president of the Association for Research in Otolaryngology, as a Program Director for the National Science Foundation in Sensory Physiology and Perception, and later, as Loyola's Associate Vice President for Research and Dean of the Graduate School. We at The Parmly Hearing Institute are very pleased that now, Bill is ''just a faculty member'' in Psychology. I can think of no other active auditory researcher who has contributed to the diversity, quality and quantity as Bill Yost has contributed to modern psychoacoustic research. These research contributions have matched Bill's talent and energy as a scientific and academic administrator, spokesman, and educator for his field. There are three large themes of Bill Yost's research program: ripple noise processing, binaural signal detection and sound lateralization and localization, and envelope modulation processing including the phenomenon he and his colleagues recently established, known as 'modulation detection interference,' or MDI. There is no new symposium or review of psychoacoustics now that does not have to include or contend with Bill's seminal contributions to pitch perception, sound source localization, and MDI.

Of these several major scientific contributions Bill has made to his field, I focus on the analysis of pitch perception evoked by rippled noise. Rippled noise (sometimes also called repetition noise and cosine noise) is a signal having a sinusoidal amplitude spectrum that evokes a perception of pitch in human and other vertebrate listeners. This signal was originally used in hearing research, in part, because it provided an analog to the sinusoidal spatial frequency grating used in vision research. In effect, rippled noise produces a grating-like excitation pattern over the length of the cochlea, and was thought to permit an experimental investigation of the spatial pattern processing following cochlear frequency analysis. Bill began his experimental research program on rippled noise in 1978 by focusing on its pitch qualities, and the acoustic variables that contribute to pitch value and strength. After quantitatively investigating the effects of spectral modulation depth, component spacing, and harmonic versus inharmonic spectral ripples on pitch and pitch strength, Bill went on to quantitatively model these effects and then on to investigate the spectral dominance regions for evoking ripple noise pitch. More recently, Bill and his colleagues have studied

ripple noise perception neurophysiologically and psychophysically in other species. Most recently, work has focused on the question of time-domain versus frequency-domain processing in the generation of ripple noise pitch using iterated ripple noises. At the same time, Bill and his colleagues have developed an influential time-processing model of ripple noise pitch in which pitch strength is well predicted by the height of the first peak of the stimulus autocorrelation function. This body of work has been cumulative and systematic, resulting in some of the best evidence and theory regarding the temporal processing that may underlie pitch perception, echo processing, and spectral coloration in architectural acoustics. With characteristic energy and commitment, Bill has creatively and persistently exploited ripple noise signals to re-energize temporal pitch theory.

His honors and accomplishments are too numerous to mention in full, but include fellowship in the ASA, the American Speech-Language-Hearing Association, the American Psychological Society, and the American Association for the Advancement of Science. He was awarded an honorary Doctorate by his alma mater, The Colorado College, in 1997, and he serves as a National Associate of the National Academy of Sciences—National Research Council.

It is remarkable that for such an important leader in his field, Bill has also had a rich personal and family life. He and his wife Lee are world travelers, and Bill is a talented athlete on the tennis court, the fairways, and the ski slopes. Bill and Lee have raised two lovely and successful daughters, Kelley and Alyson, and now are enthusiastic new grandparents of Zachary Michael Abrams. Congratulations, Bill, for this richly deserved Silver Medal in Psychological and Physiological Acoustics.

RICHARD R. FAY

WALLACE CLEMENT SABINE AWARD
OF THE
ACOUSTICAL SOCIETY OF AMERICA

William J. Cavanaugh

2006

The Wallace Clement Sabine Award is presented to an individual of any nationality who has furthered the knowledge of architectural acoustics, as evidenced by contributions to professional journals and periodicals or by other accomplishments in the field of architectural acoustics.

PREVIOUS RECIPIENTS

Vern O. Knudsen	1957	Cyril M. Harris	1979
Floyd R. Watson	1959	Thomas D. Northwood	1982
Leo L. Beranek	1961	Richard V. Waterhouse	1990
Erwin Meyer	1964	A. Harold Marshall	1995
Hale J. Sabine	1968	Russell Johnson	1997
Lothar W. Cremer	1974	Alfred C. C. Warnock	2002

SILVER MEDAL IN
ARCHITECTURAL ACOUSTICS

The Silver Medal is presented to individuals, without age limitation, for contributions to the advancement of science, engineering, or human welfare through the application of acoustic principles, or through research accomplishment in acoustics.

PREVIOUS RECIPIENT

Theodore J. Schultz   1976
CITATION FOR WILLIAM JOSEPH CAVANAUGH

. . . for contributions to the practical application of architectural acoustics in building design and to education in architectural acoustics

HONOLULU, HAWAII • 1 DECEMBER 2006

Bill has changed the world as we hear it. Although always eager to redirect credit to his colleagues, most of us know at least some of the roles he played that have helped to define the entire field of architectural acoustics.

William J. Cavanaugh and the Acoustical Society of America (ASA) were both born in 1929– Bill in Boston. He can still recite much of the history of the Bunker Hill Monument that at 8 and 9 years old he would hawk to tourists, and sometimes with a touch of exaggerated ''Bostonese'' that often earned an extra nickel or two. As a growing boy, he juggled various jobs such as delivering newspapers, tomato-packaging at the old Quincy Market; the Depression was ''just fine because no one knew they were poor.'' During World War II he attended The English High School, Boston's public ''prep'' school for students who had dreams of attending nearby MIT, and, as the second oldest of six brothers and a sister grew to be the tallest.

In 1951 Bill earned his Architecture Degree from the Massachusetts Institute of Technology (MIT), and was awarded the American Institute of Architects Student Medal. With four years of Reserve Officer Training Corps (ROTC) at MIT, Bill was immediately ordered to active duty with the U.S. Army Corps of Engineers serving until the Korean War armistice in 1953. He remained in the Army Reserves until 1982, retiring with the rank of Colonel.

Returning from service and recently married to his life-mate, Ginny, he searched for a job in architecture. Settling for a job at Polaroid in their Plant Engineering Department, his MIT class-mate Ranger Farrell suggested that Bill would thrive at the rapidly growing Cambridge office of Bolt Beranek and Newman (BBN) which was established in 1948 to consult on the acoustics of the United Nations Headquarters complex in New York City. Bill joined BBN in February of 1954.

BBN's founding partners, Dick Bolt, Leo Beranek, and Bob Newman as well as many of the extraordinarily talented BBN staff, would have powerfully-positive impacts on Bill's acoustics career and on the entire field of architectural acoustics consulting. Dick Bolt as Professor of Physics and Director of the Acoustics Laboratory was central to all things acoustical, especially around MIT. Leo Beranek stimulated his students at MIT as well as everyone on the BBN staff to publish results of projects and supporting research. Bob Newman, a remarkable and animated teacher, became Bill's immediate mentor, and encouraged Bill's own teaching, always emphasiz-ing expressive language that would be persuasive to architects and engineers, and always with an irrepressible enthusiasm. Bill credits this engaging teaching style as the principal reason that BBN was so successful in architectural acoustics consulting, proving that educated clients are the best clients.

Bill soon began teaching acoustics classes at the MIT School of Architecture, the Boston Architectural Center, the Rhode Island School of Design, and more. Many students became future clients, and some even became acousticians. His passion for ''spreading the word'' eventually, following the untimely death of Bob Newman in 1983, led to the establishment of the Robert Bradford Newman Student Award Fund which sponsors Newman Student Medal Awards for excellence in the study of architectural acoustics and the Theodore J. Schultz Grants for excellence in teaching, both overseen by the Technical Committee on Architectural Acoustics (TCAA) of the Society.

Acoustics books and teaching aids have benefited from Bill's influence as well, in spite of localized pockets of resistance. In the late 1970's, Bill proposed to the Society that the poster sessions on various building types at ASA meetings could be a rich resource for Society publica-tions. Doubts were expressed, but Bill's enthusiasm and persistence were unstoppable. In 1982, ASA architectural acoustics session posters were collected into the first paperback ''Halls for Music Performance: Two Decades of Experience, 1962-1982,'' edited by Rick Talaske, Red Wetherill, and Bill Cavanaugh. The fifth in this ''poster book'' series, ''Halls for Music Perfor-mance: Another Two Decades of Experience, 1982-2002'' was produced in 2003—an elegant hard-cover, color-printed edition. Two more posterbooks in the series are in process. Bill's repu-tation has generated many invitations to write chapters, forewords and articles on architectural acoustics and noise control directed to the building professions following in the footsteps of Wallace Clement Sabine in whose honor the medal that Bill will be receiving today is named.

Immersed in a rapidly growing, diverse and intense environment, Bill's tenure at BBN was the

defining period of his career. His willingness to assist and counsel others at all levels of technical and administrative tasks became a trademark of his leadership style. For example, not long after Bill joined the BBN consulting staff he inherited the unenviable task of collecting timesheets and getting bills out to clients for the architectural acoustics group. Less than ten years later Bill was named Divisional Vice President and Director of BBN's Architectural Technologies Division.

Along with teaching and management matters, he maintained high chargeability on consulting projects and inevitably found an interesting ''wrinkle'' in almost every project. One particularly-heretical wrinkle was the concept that adding background noise could improve acoustics; after all, ''silence is golden.'' However, Bill and his BBN colleagues repeatedly demonstrated the benefits of introducing properly-tailored background sound particularly in the ever growing number of open-plan offices being constructed thoughout the country. Research gleaned from consulting projects as well as from laboratory experiments prompted optimizing the spectra and level of background sound, quantifying other speech-privacy parameters, and developing simplified methods for design and analysis of acoustical privacy problems and, more importantly, explaining the counter-intuitive concept of ''masking'' to clients. The resulting seminal publication was ''Speech Privacy in Buildings,'' by W.J. Cavanaugh, W.R. Farrell, P.W. Hirtle, and B.G. Watters (J. Acoust. Soc. Am. 34, pp. 475-492 (1962)). Many others followed. Speech privacy remains a high priority, especially with new federal mandates for privacy in health-care facilities; the most recent ASA meeting (spring 2006 in Providence, RI) featured special sessions, meetings, and a dinner banquet to celebrate ''Fifty Years of Speech Privacy.''

Most acoustical consulting firms can trace a relationship to BBN, either through alumni or outgrowth firms, which often means a connection to Bill Cavanaugh. Remaining close to his many colleagues, Bill left BBN in 1970 to establish an independent consulting practice. This led almost immediately to a partnership with Lawrence Copley, Cavanaugh Copley Associates (CCA), to handle large consulting assignments particularly acoustical environmental impact studies.

In 1975, Bill and Lawrie mututually decided to terminate the partnership and Bill partnered with Greg Tocci, CCA's only full time employee, to found Cavanaugh Tocci Associates (CTA) which today is a thriving office of 16 professional staff members in Sudbury, MA undertaking consulting and research assignments in architectural, structural, mechanical and environmental acoustics. Throughout the variety of projects ''in and around and away-from buildings,'' Bill's wide experience, his wise counsel, and his overall influence is simply overwhelming.

In addition to speech privacy, Bill is particularly prominent in developing acoustical criteria for cinemas and for outdoor concert venues. In the early 1980's, owners of rapidly growing movie theater chains were vitally interested in improving the acoustical experience for audiences; ensuing evaluations of cinemas across the country led to criteria that are meaningful to most architects and engineers, and are now the foundation for quantifying appropriate sound isolation, HVAC noise, and theater surface treatments. Bill's interest in the thorny problems of neighbor complaints of sound from outdoor amphitheaters led to and continues to influence the entire field of outdoor concert facility design, as well as methods to improve relations with affected communities.

Bill's service to the ASA includes Member of the Executive Council, Chair of the Technical Committee on Architectural Acoustics, and chair or member of administrative committees including Regional Chapters, College of Fellows, Public Relations, Archives and History, and Rules and Governance. He was awarded the ASA Distinguished Service Citation in 1994. Bill served as president of the National Council of Acoustical Consultants (NCAC 1977-79), and was awarded their C. Paul Boner Medal in 1983 for ''Distinguished Contributions to the Acoustical Consulting Profession.'' He also served as president of the Institute of Noise Control Engineering (1993). His work with local chapters and other organizations is legendary, and he has earned a reputation as a skilled negotiator, if not peacemaker, in difficult disputes. At any meeting, Bill is among the best people to locate for almost any kind of assistance.

Ginny, his five children (including Bill, Jr. who died tragically in 1982 while on active duty in the US Air Force), and a growing number of grandchildren are the love of his life. He is also in love with acoustical consulting, and it shows.

His countless friends and admirers, the Technical Committee on Architectural Acoustics, and the entire Acoustical Society of America are proud to congratulate Bill on this richly-deserved Wallace Clement Sabine Medal.

Bill Cavanaugh, CONGRATULATIONS and THANK YOU!

K. ANTHONY HOOVER
LEO L. BERANEK

Architectural Acoustics, Speech Communication, and Psychological and Physiological Acoustics: Psychological Aspects of Speech in Rooms I

John S. Bradley, Cochair
National Research Council, Inst. for Research in Construction, Ottawa, Ontario K1A 0R6, Canada

Hiroshi Sato, Cochair
National Inst. for Advanced Industrial Science and Technology, Inst. for Human Science and Biomedical Engineering, 1-1-1 Higashi, Tsukuba, Ibaraki 305-8566 Japan

Chair's Introduction—7:30

Invited Papers

7:35

5aAA1. Why we should design for optimum reverberation times in rooms for speech communication. J. S. Bradley (Inst. for Res. in Construction, Natl. Res. Council, Montreal Rd., Ottawa, Canada K1A 0R6)

Various texts list recommendations for optimum reverberation times as ideal goals in rooms for speech communication. However, some newer documents, such as ANSI S12.60, talk about maximum recommended reverberation times in rooms for speech communication. The source of the changed approach can be traced to interpretations of experimental results that do not consider the full implications for speech communication in real rooms, and also to the fact that reverberation time is not an ideal predictor of the quality of speech communication. In the extreme, minimizing reverberation times would lead to near anechoic rooms for speech and inadequate signal-to-noise ratios. The need for optimum reverberation times can be explained as a simple need to first achieve adequate signal-to-noise ratios. However, a more complete understanding is obtained by examining the benefits of early-arriving reflections of speech sounds on the intelligibility of the speech to listeners. Attempts to determine optimum reverberation times for normal hearing listeners, which are based on a balance between avoiding excessive reverberation and maintaining adequate signal-to-noise ratios, lead to a range of acceptable values that can vary with the ambient noise level. This discussion will be supported with examples from room acoustics measurements in classrooms and meeting rooms.

7:55

5aAA2. The relation between speech transmission index, clarity, and reverberation time and listening difficulty in the impulse response database of AIJ. Hiroshi Sato (Natl. Inst. of Adv. Industrial Sci. and Technol. (AIST), 1-1-1 Higashi, Tsukuba, Ibaraki 305-8566, Japan), Yoshio Nishikawa (Konoike Co., Ltd., Tsukuba 305-0003, Japan), Hayato Sato, and Masayuki Morimoto (Kobe Univ., Nada, Kobe 657-8501, Japan)

The Speech Communication Research Working Group of AIJ (Architectural Institute of Japan) is collecting information on rooms including digitized impulse responses (IRs) to establish a database for evaluating and designing the speech transmission quality of rooms. This database consists of 966 measured IRs. This study presents the relationships between speech transmission index (STI), clarity (Cx) and reverberation time (T) as measures to consider for the design and evaluation of the speech transmission performance of rooms. The data show a wide range of STI and Cx values for a given T, and the minimum STI at each reverberation time can be obtained by diffused field theory. STI and Cx are seen to be better indicators than T for the design of rooms for speech and that T is not as good. Relationships between STI, Cx, and listening difficulty ratings from previous studies [Proc. of RADS (2004), Proc. of Forum Acusticum, pp. 1713–1718 (2005)] found both STI and Cx can be used as predictors of listening difficulty ratings. Finally, listening difficulty ratings of individual IR in the database are estimated and the distribution of listening difficulty ratings in a variety of rooms are presented as a solid bases to design speech transmission quality of rooms.

8:15

5aAA3. Unifying approaches for modeling and predicting speech intelligibility. Adelbert W. Bronkhorst and Sander J. van Wijngaarden (TNO Human Factors, Kampweg 5, 3769 DE Soesterberg, The Netherlands, adelbert.bronkhorst@tno.nl)

Speech intelligibility is practically always affected by the acoustic environment (reverberation, interfering speech, noise). When speech is processed electronically, distortions introduced by the transmission chain can also deteriorate intelligibility. Furthermore, intelligibility can be strongly influenced by nonacoustic factors such as contextual information, non-nativeness, and hearing impairment. Various intelligibility prediction methods have been developed (including SII, STI, SRS, and PESQ), which cover almost all factors influencing intelligibility. However, each individual method has limited applicability and no attempts have been made to unify them. Recently, the application domains of two widely used methods, the SII and the STI, have been significantly extended. They now, for example, cover interference that fluctuates in level, live speech, and digital transmission channels. These methods are actually very

5a SAT. AM

similar in the way in which they treat frequency-domain effects. Because of this, it is not difficult to fuse the STI and SII into a single method with an unparalleled application domain. Still, important factors such as informational masking and context effects cannot be addressed and more effort should be invested in combining the SII/STI with other, less similar methods (such as the SRS) in order to develop a single, powerful, standard model for predicting speech intelligibility.

8:35

5aAA4. Influence of word familiarity on spoken word recognition. Shigeaki Amano, Tadahisa Kondo (NTT Commun. Sci. Labs., NTT Corp., 2-4 Hikari-dai, Seika-cho, Souraku-gun, Kyoto 6190237, Japan, amano@cslab.kecl.ntt.co.jp), Shuichi Sakamoto, and Yôiti Suzuki (Tohoku Univ., Japan)

Spoken word recognition is affected by many factors including sound pressure level, signal-to-noise ratio, word familiarity, word frequency, and phoneme sequence plausibility. Of these factors, word familiarity is assumed to have a strong effect but has received little attention. One reason for this is that word familiarity data for most words have been unavailable. However, we can now confirm the word familiarity effect because in 1999 Amano and Kondo published a word familiarity database for about 80 000 Japanese words. Experimental results clearly show that spoken words with a high familiarity are recognized better and faster than those with a low familiarity. In addition, word familiarity correlates with the recognition score of spoken words much better than word frequency, which was previously regarded as an influential factor in word recognition. Because the word familiarity effect is so strong, it is very important to control the familiarity of spoken words to obtain stable and reasonable results when assessing the speech hearing ability of individuals, and when measuring speech clarity in communication media and public spaces.

8:55

5aAA5. Development of word lists for word intelligibility tests in Japanese. Shuichi Sakamoto, Yôiti Suzuki (Res. Inst. of Elec. Commun., Grad. School of Info. Sci., Tohoku Univ., 2-1-1, Katahira, Aoba-ku, Sendai, 9808577, Japan, saka@ais.riec.tohoku.ac.jp), Shigeaki Amano, and Tadahisa Kondo (NTT Corp., Seika-cho, Soraku-gun, Kyoto, 6190237, Japan)

Speech intelligibility tests are widely used to evaluate personal speech hearing ability accurately. Although various lists have been proposed for the tests, almost all lists in Japan do not properly consider word difficulty as an aspect of speech recognition. Consequently, even if these tests are performed under identical conditions, correct results cannot be obtained. We have been developing word lists for word intelligibility tests to cope with these problems. We control word familiarity, which strongly affects word recognition scores, to equalize difficulty in recognition between word lists. Words are divided into four word-familiarity ranks. Twenty lists of 50 words are constructed in each rank by considering phonetic balance. Moreover, to compensate slight differences in intelligibility scores among word lists within the same word-familiarity rank, the relationship between the difference of word familiarity and signal-to-noise ratio (SNR) is estimated. Then this relationship is used to compensate the difference of the intelligibility score. The other compensation method is based on speech recognition threshold (SRT). The intelligibility score of each word can be equalized by changing the SNR according to the difference of the SRT of the word. The effectiveness of these compensation methods is discussed.

9:15

5aAA6. Binaural and spatial factors affecting speech intelligibility in rooms. H. Steven Colburn, Suzanne Carr, and Rui Wan (Hearing Res. Ctr. and Dept. of Biomed. Eng., Boston Univ., 44 Cummington St., Boston, MA 02215, colburn@bu.edu)

Prominent complaints of hearing-impaired listeners relate to the difficulties they experience in complex acoustic environments, particularly environments with multiple sources and reverberation. Available data and some theoretical ideas about the nature of the difficulties with speech intelligibility in these environments will be reviewed with impaired listeners in mind. The effects of the spatial characteristics of the sound sources and the room on the binaural signals and their processing is the primary focus of this presentation. Listeners with normal hearing as well as listeners with hearing impairments, with and without hearing aids, will be considered. Theoretical topics to be discussed include the effects of reverberation on interaural differences and on temporal modulation patterns, including the consequences for performance as predicted by standard models of binaural processing. [Work supported by NIH R01 DC00100.]

9:35

5aAA7. The effect of noise on novel word learning in sequential bilingual children. Pui Fong Kan, Kathryn Kohnert, and Peggy Nelson (Dept. of Speech-Lang.-Hearing Sci., Univ. of Minnesota, 164 Pillsbury Dr. SE, Minneapolis, MN 55455)

Preschool children must learn in noisy environments (Picard and Bradley, 2001), but young children are more negatively affected by background noise than are adults (Elliott, 1979). Young second-language learners are more negatively affected by noise than are monolingual children (Crandell et al., 1996; Nelson et al., 2005). Background noise may be still more detrimental in the case of preschool children who speak one language (L1) at home and who start to learn a second language (L2) in nursery school. In this present study we examine the effect of noise on fast-mapping skills in L1 (Hmong) and L2 (English). In the fast-mapping task each child was briefly presented with 5 novel words–counterbalanced in Hmong and in English–in a quiet setting over two different sessions. Another 5 novel Hmong and English words were presented to each child in two sessions in the presence of babble background noise. During each session the children were tested immediately after their exposure to the novel words. The results confirmed (1) that the children demonstrated–in both L1 and L2–better skills in quiet than in noise and (2) that the childrens fast-mapping skills were positively correlated with their pre-existing L1 and L2 language skills.

10:15

5aAA8. The effects of fluctuating interaural cues on the segregation of speech in rooms.   Douglas Brungart and Nandini Iyer (Air Force Res. Lab., 2610 Seventh St., Bldg 441, WPAFB, OH 45433, douglas.brungart@wpafb.af.mil)

Spatial separation is known to improve the segregation of talkers in anechoic environments, but relatively little is known about the role spatial cues play in speech segregation in reverberant rooms. One might expect the random disruptions in the interaural time and level differences (ILDs and ITDs) that occur in reverberant environments to eliminate many of the intelligibility benefits that normally occur for spatially separated speech. However, the precedence effect often leads to a robust perception of spatial location even in extremely echoic environments. This can result in an apparent separation between talkers that may facilitate selective attention to the location of the target speech even in a highly reverberant room. Also, random fluctuations in ITD and ILD may lead to differences in the apparent source widths of the target and masking sounds, which might serve as a segregation cue. In this talk, we examine the effects fluctuating interaural difference cues have on the segregation of target speech from competing speech or noise. The results suggest that differences in apparent source width can be used to segregate competing speech signals even when the target and masking signals appear to originate from the same direction relative to the listener.

10:35

5aAA9. The intelligibility advantage of clear speech in noise and reverberation backgrounds: Effects of speaking rate.   Jean C. Krause   (Commun. Sci. and Disord. Dept., Univ. of South Florida, 4202 E. Fowler Ave., PCD 1017, Tampa, FL 33617, jkrause@cas.usf.edu)

Clear speech refers to a speaking style that is significantly more intelligible than conversational speech for a variety of listeners and backgrounds, including roomlike backgrounds such as noise and reverberation [Payton *et al.*, J. Acoust. Soc. Am. **95**, 1581–1592 (1994)]. Although typically spoken more slowly than conversational speech [e.g., Uchanski *et al.*, J. Speech Hear. Res. **39**, 494–509 (1996)], talkers can produce clear speech at normal rates with training [Krause and Braida, J. Acoust. Soc. Am. **112**, 2165–2172 (2002)]. Whether this form of clear speech (clear/normal speech) provides similar intelligibility benefits to clear (clear/slow) speech in all situations has not been fully characterized, though some results [Krause and Braida, Iranian Audiol. **2**, 39–47 (2003)] suggest that the amount of benefit is more dependent on talker and environment. To investigate this possibility for roomlike degradations, the intelligibility advantage provided by clear/slow and clear/normal speech was evaluated by groups of eight normal-hearing listeners at five signal-to-noise ratios (-4, -2, 0, $+2$, and $+4$ dB) and three levels of reverberation (0, 0.18, and 0.6 s). Results for four talkers will be reviewed in order to illustrate the effects of speaking rate and speaking style on speech intelligibility in rooms.

10:55

5aAA10. Separating and understanding a talker from a mixture in reverberant spaces.   Barbara G. Shinn-Cunningham, Madhusudana Shashanka, and Scott Bressler   (677 Beacon St., Boston, MA 02215)

Many studies show that reverberant energy can interfere with the ability to understand a listener by smearing out the temporal modulations and distorting the spectral content that convey speech meaning. However, the amount of distortion caused by the reverberation in everyday settings often is not severe enough to degrade speech understanding when there is only one talker in a room. Despite this, even modest reverberation can have an enormous impact on the ability to understand the same talker when there is another sound source in the environment. One factor that likely contributes to the problem of understanding a talker in a mixture of sounds in reverberant spaces is that it is difficult to separate the target talker from the competing sounds. This talk will explore the ways in which reverberant energy degrades the ability to separate sounds in a mixture. The effects of reverberation on different cues for source segregation, including pitch and location, will be discussed. [Work supported by AFOSR and NIH.]

11:15

5aAA11. Preprocessing speech against reverberation.   Takayuki Arai   (Dept. of Elec. and Electron. Eng., Sophia Univ., 7-1 Kioi-cho, Chiyoda-ku, Tokyo, 102-8554 Japan)

Although short reverberation in a room may help speech perception, it is known that long reverberation causes degradation in speech comprehension. This is especially true for elderly people, the hearing-impaired, and non-native listeners. In order to prevent intelligibility degradation, we can apply a signal processing technique to the public address system of a room before speech signals are radiated through the loudspeakers. So far, we have developed several such preprocessing techniques. The two main techniques are modulation filtering [Kusumoto *et al.*, Speech Commun. **45**, 101–113 (2005)] and steady-state suppression [Arai *et al.*, Acoust. Sci. Technol. **23**, 229–232 (2002)]. Both techniques essentially enhance the temporal dynamics of speech between 1 and 16 Hz [Arai *et al.*, J. Acoust. Soc. Am. **105**, 2783–2791 (1999)]. Steady-state suppression, which suppresses steady-state portions of speech, reduces overlap-masking and improves speech intelligibility for young, elderly, and non-native listeners in reverberant environments [e.g., Hodoshima *et al.*, J. Acoust. Soc. Am. **119**, 4055–4064 (2006)]. This technique is more effective when speech-rate slowing is applied in advance [Arai *et al.*, Acoust. Sci. Tech. **26**, 459–461 (2005)]. Intelligibility with this technique exceeds a simple speech-rate slowing approach. [Work partially supported by JSPS.KAKENHI (16203041).]

5a SAT. AM

5aAA12. Failure of the precedence effect in children and in persons with hearing loss. Ruth Litovsky (Univ. of Wisconsin Waisman Ctr., 1500 Highland Ave., Madison, WI 53705)

Children spend a vast majority of time in reverberant environments. However, their auditory system appears not to be as fully equipped as that of adults for coping with reverberation. In our studies we simulate simple aspects of reverberation by exploiting a well-known auditory illusion known as the precedence effect (PE). Stimuli consist of clicks or speech, pairs of source (lead), and its first-arriving reflection (lag). Results from typically developing normal-hearing children ages 3–10 suggest that the PE undergoes significant maturation during childhood. In addition, we studied 10-year-old children with specific language impairment (SLI), who are delayed on expressive and receptive language. Performance was similar to that of younger, language-age-matched children, suggesting that the PE could be a useful clinical tool for measuring nonverbal temporal information processing. The PE was also used to study deaf adults with bilateral cochlear implants. Results suggest that binaural sensitivity is only available when the cochlea can be directly stimulated, but in free field the temporal smearing caused by the microphone leads to degraded and abnormal PE. Taken together, these studies suggest that a basic and necessary auditory function, that of suppressing echoes, fails under numerous circumstances, in children and in deaf, bilateral cochlear implant users.

SATURDAY MORNING, 2 DECEMBER 2006　　　　　　　　LANAI ROOM, 8:00 A.M. TO 12:00 NOON

Session 5aAB

Animal Bioacoustics: Animal Bioacoustics Poster Session (Poster Session)

Sheryl L. Coombs, Cochair
Bowling Green State Univ., Dept. of BioScience, Life Science Bldg., Bowling Green, OH 43403

Yutaka Hosokawa, Cochair
Ryukyu Univ., Dept. of Physiology, 207 Uehara, Nishihara-chu, Okinawa 903-0215, Japan

Contributed Papers

All posters will be on display from 8:00 a.m. to 12:00 noon. To allow contributors an opportunity to see other posters, contributors of odd-numbered papers will be at their posters from 8:00 a.m. to 10:00 a.m. and contributors of even-numbered papers will be at their posters from 10:00 a.m. to 12:00 noon.

5aAB1. Reconstruction of bat sonar beams using a multichannel microphone array. Peter Stilz, Wiebke Pflästerer, and Hans-Ulrich Schnitzler (Tierphysiologie, Universität Tübingen, Auf der Morgenstelle 28, 72076 Tübingen, Germany, peter.stilz@uni-tuebingen.de)

We reconstruct the sonar beams emitted subsequently by flying bats from recordings of a two-dimensional microphone array. Based on the bats' position in space, which can be accessed through a infrared 3D-video system, and the simultaneous recordings of 16 small microphones, the sonar beams emitted by the bats and the sonar footprints on arbitrary planes can be estimated. For the interpolation of a continuous sonar beam at different frequency bands, directional frequency responses, atmospheric and geometric attenuation, and different lag times are taken into account for each microphone. Mean and maximum call intensities can be analyzed and various analysis parameters can be adjusted, different visualizations are available, and numerical data are exported. The system provides access to estimations of the maximum intensity of each call in front of the bat, beam width, shape, and intensity for arbitrary frequency bands, the aiming of the beam, and the bat's scanning behavior on its flight path.

5aAB2. A new low-power acoustic bat detector for long-duration observations. Matt Heavner (Univ. of Alaska Southeast, 11120 Glacier Hwy., Juneau, AK 99801)

A new small, low-power, long-duration, field-deployable computer for the acoustic monitoring of bats in Southeast Alaska has been developed. Parker *et al.*, (1997) report the northern geographic limit of four bat spe-

cies to be Southeast Alaska. (A fifth species, *E. fuscus*, goes much farther north.) The relationship of the bats to forest management practices, the habitat usage of the bats, and population size and trends are all very poorly known for bats in Southeast Alaska. Long duration monitoring of several different types of area (such as old-growth versus recently logged forest) will provide knowledge to improve management practices in regards to bat ecology in Southeast Alaska. With the motivations just described, the hardware, development methods, and analysis software designed to develop an improved detector are presented. Tradeoffs between computation power, power consumption, cost, and other factors will be discussed. The project has benefitted in several direct ways from the system design requirement of modularity. [Work supported by Alaska epartment of Fish & Game.]

5aAB3. Development of networked weatherproof remote sensing embedded Linux system for bioacoustical evaluation. Hiroki Kobayashi, Yoshihiro Kawasaki, and Shinichi Watanabe (Matsushima Lab., Dept. of Geosystem Eng., The Univ. of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, 113-8656, Japan, tt56958@mail.ecc.u-tokyo.ac.jp)

The purpose of this research is to develop a real-time evaluation technology of bioacoustic diversity in a remote location by networked Linux embedded system. The hardware is designed to operate 24 h a day, 7 days a week, 365 days a year under severe environment, such as extremely high moisture and temperature environment in subtropical forest. Three stages of the hardware development were completed at this point. At first, a wired long-lived bioacoustic monitoring system in subtropical forest in Iriomote Island, Japan was developed and succeeded to operate continuously for the

past 2 years based on an unmanned condition with less than 1000 US dollars annual budget. Based on this development, a wired multifunctional monitoring system with infrared cameras and microclimate monitoring sensors was developed and evaluated with less than 4000 US dollars. At last, with FOMA (Freedom of Mobile Multimedia Access) mobile information technology offered by Japanese mobile phone operator NTT DoCoMo, a multifunctional bioacoustic monitoring system with two-way communication system which operates passive and active observation for Iriomote Cat was developed with less than 8000 US dollars. [Work supported by NTT DoCoMo.]

5aAB4. Can birds discriminate between simple sounds and natural vocalization with different degrees of reverberation. Sandra H. Blumenrath and Robert J. Dooling (Dept. of Psych., Univ. of Maryland, College Park, MD 20742)

Birds in natural habitats using long-range acoustic signals experience substantial acoustic alterations of their signals when transmitted from a sender to a receiver. The main degradation comes from reflections of the emitted sounds from surfaces in and around the transmission pathway. These reverberations cause tails of echoes and affect frequency and amplitude modulation within the sounds' original time frame. Humans discriminate among reverberant and nonreverberant speech segments and use the nature of reverberation in determining the location of the sound source. Using operant conditioning and psychophysical methods, we investigated the ability of several species of small birds to discriminate between nondegraded sounds and sounds artificially reverberated to varying degrees, while holding other sound aspects constant. Birds were able to easily discriminate between nonreverberant sounds and sounds reverberated to various extents. By comparing the birds' performance on stimuli varying along different dimensions of reverberation, we can make predictions as to the birds ability to use reverberations as acoustic cues in distance estimation and locating sound sources. [Work supported by NICD DC000198 (to R.J.D.) and DC004664.]

5aAB5. Perception of budgerigar (*Melopsittacus undulatus*) warble elements. Hsiao-Wei Tu and Robert J. Dooling (Dept. of Psych., Univ. of Maryland, College Park, MD 20742)

The warble song of budgerigar (*Melopsittacus undulatus*) contains various classes of vocal elements, including contact calls, alarm calls, harmonic calls, etc. Previous work has shown that budgerigars can discriminate different call types according to both acoustic and functional features; however, there is no evidence on how well birds can distinguish subtle differences within and between each category. Using operant conditioning and psychophysical methods, budgerigars were trained to discriminate among different warble elements. In general, birds were able to discriminate quite easily between all warble elements, even those with high spectral cross correlations. Humans, on the other hand, had difficulty distinguishing among warble elements that were similar to one another. The relative discriminability of warble elements within and across categories is used to more precisely define the functional categories of warble elements in understanding vocal communication in this species. [Work supported by NIDCD DC000198 to R.J.D. and P30 DC004664.]

5aAB6. Voices of the dead: Complex nonlinear vocal signals from the larynx of an ultrasonic frog. Roderick A. Suthers (School of Medicine and Dept. of Biol., Indiana Univ., Bloomington, IN 47405, suthers@indiana.edu), Peter M. Narins (Univ. of California, Los Angeles, CA 90095), Wen-Yu Lin (Univ. of Illinois, Urbana, IL 61801), Hans-Ulrich Schnitzler, Annette Denzinger (Univ. Tuebingen, D-72076 Tuebingen, Germany), Chun-He Xu (Chinese Acad. of Sci., Shanghai, P. R. China), and Albert S. Feng (Univ. of Illinois, Urbana, IL 61801)

Most anurans are highly vocal but their vocalizations are stereotyped and simple with limited repertoire sizes compared to other vocal vertebrates, due presumably to the limited mechanisms for fine vocal motor control. We recently reported that the call of the concave-eared torrent frog

(*Amolops tormotus*) is an exception in its seemingly endless variety, musical warbling quality, extension of call frequency into the ultrasonic range, and the prominence of nonlinear features such as period doubling. We now show that the major spectral features of its calls, responsible for this frog's vocal diversity, can be generated by forcing pressurized air through the larynx of euthanized males. Laryngeal specializations for ultrasound appear to include very thin portions of the medial vocal ligaments and the reverse sexual size dimorphism of the larynx being smaller in males than in females. The intricate morphology of the vocal cords, which changes along their length, suggests that nonlinear phenomena likely arise from complex nonlinear oscillatory regimes of separate elastically coupled masses. *Amolops* is thus the first amphibian for which the intrinsic nonlinear dynamics of its larynx, a relatively simple and expedient mechanism, can account for the species call complexity, without invoking sophisticated neuromuscular control.

5aAB7. Comparative analysis of head-banging behavior in the subterranean termites *Coptotermes formosanus* and *Reticulitermes flavipes* using high-speed imaging. Tom Fink, Lichuan Gui, Yong Wang, Zhonghua Cao (Natl. Ctr. for Physical Acoust., One Coliseum Dr., University, MS 38677), Adarsh Jaiswal, Orwa Tahaineh, Roger Hasse, John Seiner (Natl. Ctr. for Physical Acoust., University, MS 38677), and Alan Lax (U.S. Dept. Agriculture, Blvd. New Orleans, LA 70124)

Disturbed soldiers of *Coptotermes formosanus* (FST) readily head-bang (HB) only in their galleries and carton nests while *Reticulitermes flavipes* (Rf) will also readily HB in an artificial chamber. The head-banging motion was examined using the Photron FASTCAM-ultima APX video camera at 10 000 frames per second. Termites were placed in a 0.25-in. diameter hole in a wood block and induced to HB by touching them with a small brush. A PCB Piezotronics 352B accelerometer was used to detect HB-induced vibrations. These vibration signals were then received by the Photron Multi-Channel-Data-Link apparatus, which then superimposes the vibration waveform on the video frames corresponding to the head movement. Thus, movement of the head can be correlated with the vibrations produced. Time between successive HB is about 70 ms or more in FST vs 40 ms or less in Rf despite the much larger head of Rf. Upward and downward head velocities in FST are, respectively, 100 and 240 mm/s, while the respective values for *Reticulitermes* are over 200 and about 400 mm/s. Acceleration for FST is about 400 m/s or up to 700 m/s^2 for *Reticulitermes*. Both species may show head rebounding after the initial contact with the substratum.

5aAB8. Underwater auditory localization by harbor seals (*Phoca vitulina*). Anaïs Bodson, Lars Miersch, and Guido Dehnhardt (General Zoology & Neurobiology, Univ. of Bochum, ND 6/33, D-44780 Bochum, Germany, bodson@marine-science-center.de)

The underwater sound localization acuity of a swimming harbor seal was measured in the horizontal plane. The stimulus was either a double sound (two 6-kHz pure tones lasting 0.5 s separated by an interval of 0.2 s) or a single continuous sound of 1.2 s. Testing was conducted in a 10-m-diameter underwater half-circle with hidden loudspeakers. The animal was trained to swim along the diameter of the half-circle and to change its course towards the sound source right after the signal was given. The seal indicated the sound source by touching its assumed position at the half-circle. The deviation of the seal's choice from the actual sound source was measured by means of video analysis. In trials with the double sound the seal localized the sound sources with a mean deviation of 2.8° and in trials with the single sound with a mean deviation of 4.5°. In a second experiment minimum audible angles of the animal were determined as a function of frequency (2, 4, 6, 8, and 16 kHz resulting in MAAs of 9.4°, 9.6°, 9.8°, 13.0°, and 13.5°, respectively). Intraspecific differences of the MAA will be presented for five additional harbor seals.

5aAB9. Evaluation of the auditory capabilities of marine mammals using a portable auditory-evoked potential system. Kristen A. Taylor, Paul E. Nachtigall, T. Aran Mooney, Michelle M. Yuen (Marine Mammal Res. Program, Hawaii Inst. of Marine Biol., Univ. of Hawaii, P.O. Box 1106, Kailua HI 96734), and Alexander Ya Supin ((Russian Acad. of Sci., Moscow, Russia)

There is growing concern about the increasing amounts of acoustic pollution in our oceans. Anthropogenic noise sources span a large range of frequencies and amplitudes. The extents to which these noise sources adversely impact marine mammals is poorly understood yet they are of particular significance given that the acoustic environment is crucial for many aspects of marine mammal life. Past and present experiments have addressed the effects of different sounds on the hearing capabilities of captive dolphins. However, only a few individuals from a small number of species have been tested. Our research group has created a portable system that is capable of measuring the hearing thresholds of marine mammals using auditory-evoked potential (AEP) techniques. This portable system has enabled us to obtain audiograms of otherwise inaccessible marine mammal species. This system will also allow us to measure the hearing of stranded animals as well as begin to quantify the normal variations in hearing between different ages and genders of animals in captivity.

5aAB10. Optical imaging of neural activity in the right and left guinea pig auditory cortices evoked by repeated sound. Yutaka Hosokawa (Dept. of Physiol., Ryukyu Univ., Nishihara-tyo, Okinawa, 903-0215 Japan) and Junsei Horikawa (Toyohashi Univ. of Technol., Toyohashi, 441-8580 Japan)

Processing of spectral and temporal information in the right and left auditory cortices of guinea pigs anesthetized with ketamine and xylazine was investigated using an optical imaging technique with a voltage-sensitive dye (RH795). Tonotopical organization in the primary (AI) and the dorsocaudal (DC) fields in the left and the right auditory cortices were compared, as visualized by superimposition of the areas activated by tones at 2, 4, 8, and 16 kHz. In 65% of 31 animals, the distance between 2- and 16-kHz isofrequency bands was longer in the left than in the right AI; it was shorter in the left than in the right DC. Repetition rate transfer functions (RRTFs) in AI measured with repeated sounds (420 Hz repetition rates) were low pass, with a sharp drop-off above 10 Hz. In contrast, RRTFs in DC were bandpass with a peak at 8 or 10 Hz. The cutoff frequencies of RRTF were different for each of the left and right cortices.

5aAB11. The physoclistous swim bladder of chaetodontid butterflyfishes: Implications for acoustic function. Christopher Woods, Jacqueline Webb (Dept. of Biol., Villanova Univ., Villanova, PA 19085; jacqueline_webb@mail.uri.edu), and Darlene Ketten (Woods Hole Oceanogr. Inst., Woods Hole, MA 02543)

Butterflyfishes (genus *Chaetodon*) have a swim bladder lateral line connection (laterophysic connection, LC), hypothesized to convert sound-induced oscillations of the swim bladder into fluid flow in the lateral line system and/or ear. Evaluation of LC function is dependent upon an understanding of swim bladder acoustics, which is a function of swim bladder anatomy. We used several anatomical methods (including CT) to describe swim bladder and tunica externa and tunica interna morphology (including gas gland/*rete mirabile* complex and the oval, responsible for gas secretion and resorption) in *Chaetodon* and *Forcipiger*. Swim bladder and tunica externa morphology differ between *Chaetodon* spp. with different LCs morphologies. A perforated transverse diaphragm divides the gas volume into two compartments. The gas gland/*rete mirabile* complex is in the ventral midline of the anterior compartment; it varies in morphology and is largest in species with a direct LC. The oval, defined by an extensive capillary network, occupies the entire tunica interna of the posterior compartment, so that diaphragm position determines oval size. These data raise questions about swim bladder structure-function relationships with respect to the reception and transduction of acoustic stimuli in coral reef fishes. [Work supported by NSF Grant IBN-0132607 to J.F.W.]

5aAB12. The temporal resolution of goldfish hearing: An auditory evoked potential study of gap detection. Jianqiang Xiao and Christopher Braun (Dept. of Psych., Hunter College, 695 Park Ave., New York, NY 10021, jxiao@hunter.cuny.edu)

Temporal processing in goldfish (*Carassius auratus*) was studied by measuring auditory evoked potentials (AEP) using gaps in continuous band-limited Gaussian noise. Long (>100 ms) silent gaps in high amplitude noise (30 dB SL) evoked distinct offset and onset responses, lasting 6090 ms. Offset and onset responses overlapped with shorter gaps and became difficult to distinguish for gaps <10 ms. The gap-response waveform was modeled as the sum of offset and temporally-shifted onset responses from the same animals (using 120-ms gaps). This model predicted the waveform of gap responses nearly perfectly for gaps longer than 6 ms. Waveforms evoked by shorter gaps (<6 ms) did not accurately fit this model, suggesting that one or both components of the gap response were inhibited or altered. Nonetheless, clear responses were evoked by gaps shorter than 1 ms at this intensity, while longer gaps (up to 10 ms) were required for detection in a low-intensity noise background. This study extends and confirms prior reports that the temporal resolution for goldfish is on the order of 1 ms, but there is also evidence for longer integration processes, over a period of several ms. [Work supported by Grants S06GM60654, R03MH067808, RR03037 (NIH).]

5aAB13. The effects of source distance and orientation on lateral line stimulation patterns and source localization by Lake Michigan mottled sculpin. Sheryl Coombs and Paul Patton (Dept. of Biological Sci., JP Scott Ctr. for Neurosci., Mind, and Behavior, Bowling Green State Univ., Bowling Green, OH 43403)

Visually deprived, Lake Michigan mottled sculpin respond to small dipole sources (sinusoidally vibrating spheres) with an initial orienting response and subsequent approach and strike behaviors. Lateral line canal neuromasts, but not superficial neuromasts, are required for the initial orienting response. Computational (potential flow) models reveal that stimulation patterns across lateral line canals vary in complex ways when the orientation (axis of vibration) and distance of the dipole source are varied. The body location where lateral line stimulation is maximal (the excitatory peak) might seem to provide a reliable cue of source location. However, this cue is (1) confounded by the relative amplitude, number, and body location of excitatory peaks when source orientation is varied and (2) degraded by both an increase in peak width and a reduction in peak amplitude when source distance is increased. Behavioral measures of orienting accuracy for equally detectable sources at two distances (3 and 6 cm) and horizontal orientations (parallel or orthogonal to the long axis of the fish) reveal that localization abilities are degraded by increases in source distance. Although varying source orientation does not produce dramatic deficits in orienting accuracy, more subtle effects were observed that may relate to information encoded in spatial excitation patterns.

5aAB14. The use of multimodal communication during courtship in Malawi cichlids. Adam R. Smith and Moira J. van Staaden (Dept. of Biological Sci. and J. P. Scott Ctr. for Neurosci., Mind & Behavior, Bowling Green State Univ., Bowling Green, OH 43403)

The cichlids of Lake Malawi are often considered the quintessential example of a species radiation driven primarily by sexual selection and

relying on visual cues. However, the description of sound production by courting males in several species raises the possibility that acoustic signaling may play a significant role in the selection process. This study describes the mating calls from multiple species in the genera *Melanochromis* and *Metriaclima* in order to discern if there is active selection of call characteristics between closely related species or whether differences are more likely the result of drift. Variation in total call duration and fundamental frequency within genera often exceeded that between genera, particularly between the sister species *Melanochromis johanni* and *Melanochromis cyaneorhabdos*. This suggests that mating calls may indeed be subject to divergent sexual selection in closely related species. Moreover, *in situ* sound recordings from Lake Malawi indicate that this behavior is of ecological relevance and not simply an artifact of laboratory conditions. Together, these results suggest that current models of sexual selection in Malawian cichlids may benefit from consideration of previously ignored sensory modalities. The plasticity inherent in such multimodal processing may prove of particular importance to the species-rich African cichlid radiation.

5aAB15. Reaction of plaice (*Pleuronectes platessa*) and cod (*Gadus morhua*) to low-frequency sound in an experimental tank. Christina Mueller-Blenkle (FRS Marine Lab., P.O. Box 101, Aberdeen AB11 9DB, UK) and Karin Luedemann (Institut fr Angewandte Fischbiologie, 22083 Hamburg, Germany)

Anthropogenic sound in the sea is an increasing problem and more knowledge on the influence of sound on fish needs to be collected. For this reason experiments are carried out in an experimental tank 10 m in diameter to examine the reaction of juvenile and adult cod and plaice to sound. Pure tones from the frequency range of offshore wind turbines are artificially emitted in typical wind turbine sound levels of 130 and 140 dB *re* 1 Pa. A sound gradient in the tank enables the fish to avoid highest sound levels. The number of fish in the vicinity of the sound source is determined in regular time intervals before, during, and after the 24-h period of sound exposure. Changes in numbers of fish can be seen in the periods with and without sound in many experiments. Reactions of plaice are ambiguous, pointing to both avoidance of or attraction to the sound. In the majority of the experiments carried out on cod, avoidance behavior to the sound can be seen with strongest reactions at 25, 60, and 90 Hz. The results indicate potential avoidance behavior of cod to the operational noise of offshore wind farms.

9:05

5aBB1. Microbubble spectroscopy of ultrasound contrast agents. Sander van der Meer, Benjamin Dollet (Phys. of Fluids, Univ. of Twente, P.O. Box 217, 7500 AE Enschede, The Netherlands), Chien T. Chin, Ayache Bouakaz, Marco Voormolen, Nico de Jong (Erasmus MC, 3000 DR Rotterdam, The Netherlands), Michel Versluis, and Detlef Lohse (Univ. of Twente, 7500 AE Enschede, The Netherlands)

We present a new optical characterization of the behavior of single ultrasound contrast bubbles. The method consists of insonifying individual bubbles several times successively sweeping the applied frequency and recording movies of the bubble response up to 25 million frames per second with an ultra-high-speed camera operated in a segmented mode. The method, termed microbubble spectroscopy, enables one to reconstruct a resonance curve of the oscillating bubble in a single run. We analyze the data through a linearized model for coated bubbles. The results confirm the significant influence of the shell on the bubble dynamics: shell elasticity increases the resonance frequency by about 50%, and shell viscosity is responsible for about 70% of the total damping. The obtained value for shell elasticity is in quantitative agreement with previously reported values. The shell viscosity decreases significantly with the dilatation rate, revealing the nonlinear behavior of the phospholipid coating.

9:20

5aBB2. High-frequency response of polymer shell contrast agents. Jeffrey A. Ketterling, Jonathan Mamou (Lizzi Ctr. for Biomed. Eng., Riverside Res. Inst., 156 William St., New York, NY 10038), John S. AllenIII (Univ. of Hawaii-Manoa, Honolulu, HI 96822), Orlando Aristizábal, Rene G. Williamson, and Daniel H. Turnbull (NYU School of Med., New York, NY 10016)

Ultrasound contrast agents were originally designed for use at low MHz frequencies; however, recent experimental evidence suggests that many of these agents may also be useful for contrast imaging at frequencies above 20 MHz. Three polymer shelled agents (mean diameters of 0.56, 1.1, and 3.4 μm) from POINT Biomedical were investigated to determine their optimal high-frequency responses. A flow phantom was constructed to restrict the flow of a dilute contrast agent solution to a small volume. The focus of a 40-MHz single-element transducer from a Visual Sonics V770 was positioned within the flow phantom. Radio-frequency backscatter data from individual contrast agents were digitized under a variety of pulse durations (1–15 cycles) and pressure levels (1.4–7.6 MPa). Echo signals from individual bubbles were windowed, and spectra were calculated. Each of the POINT agents reflected energy at the 40-MHz fundamental; however, only the 1.1-μm-diameter agent displayed characteristics of a harmonic response under longer excitations (15 cycle) and medium pressure settings (2.5 to 5 MPa). Experimental results were com-

pared to theoretical calculations for the case of the polymer shell remaining intact during excitation and for free gas nuclei that result from a ruptured shell.

9:35

5aBB3. Optical observations of the collapsing behavior of polymer micro-capsule irradiated in the ultrasonic sound field. Tetsuo Yamato, Kenji Yoshida, Wataru Kiyan, and Yoshiaki Watanabe (Faculty of Eng., Doshisha Univ., 610-0321 1-3 Tataramiyakotani Kyotanabe Kyoto Japan)

For the medical use, it is important to understand the micro-capsule behavior during collapsing under the ultrasonic sound field. In this report, the behavior of micro-capsule collapse was observed using the high-speed video camera system (HPV-1, SHIMADZU: maximum recording rate; 1 000 000 frames/second). By using this system, the detail phenomena can be observed. The micro-capsule leaked the internal gases through a small pin hole on the surface of the micro-capsule while repeating asymmetrical vibration. The internal gases were emitted during the positive period of driving sound pressure and returned again in the micro-capsule during the negative period. By repeating the outflow and inflow of internal gases, the stress was cumulated on the shell. Therefore, the small pin hole developed into the big one, then, the micro-capsule emitted a large amount of internal gases and the capsule was collapsed. After the collapsing, only the shell was remained. From the results, it was found for the effect of the shell, that is, the micro-capsule radius shrunk in positive pressure phase, however it hardly expanded in negative pressure phase. These phenomena were numerically simulated by the vibration model, which the effect of the shell was removed only when shrinking. This simulation results qualitatively agreed with observation results.

9:50

5aBB4. Thermal effect of microbubbles in the focused ultrasound field. Yukio Kaneko, Naoyuki Iida, Shu Takagi, and Yoichiro Matsumoto (Dept. of Mech. Eng., The Univ. of Tokyo, Tokyo, Japan)

High-intensity focused ultrasound (HIFU) has been developed for the treatment of tumor, and additionally the medical applications with microbubbles such as ultrasound imaging have attracted much attention. In the field of the bubble dynamics, it is known that the microbubble is an energy converter of ultrasound mechanical energy to heat when subjected to an acoustic field. The goal is the tissue heating enhanced by microbubbles. In this study, the relationship between the heating effect and the behavior of microbubbles is analyzed. The temperature rise was measured by a thermocouple and a thermal liquid crystal sheet, and the bubble behavior was simultaneously observed with a camera. The ultrasound frequency is 2.2 MHz and the intensity is 100–2000 W/cm^2. The temperature rise became larger as the number density of microbubbles (Levovist) around the focal region increased. As the number density became too large, the conversion efficiency from ultrasound energy to heat became smaller because the shielding effect of ultrasound by the existence of too many bubbles became larger. From these results, it is indicated that it is important to choose the optimal conditions of microbubbles and ultrasound in order to control the heat deposition from microbubbles.

10:25

5aBB5. Engineering the acoustic response of lipid-based microbubbles: Simulations and high speed optical imaging results. Eleanor Stride (Dept. of Mech. Eng., UCL, Torrington Pl., London WC1E 7JE, UK, e_stride@meng.ucl.ac.uk), Rob Eckersley, Kevin Chetty, Charles Sennoga, and Jo Hajnal (Imperial College, London, W12 0NN, UK)

Gas microbubbles coated with a surfactant or polymer shell have become well established as contrast agents for ultrasound imaging and are under investigation for therapeutic applications such as targeted drug delivery. The purpose of this study was to examine the effect of modifying the microbubbles' coating composition upon their response to ultrasound excitation. Using a high speed camera operating at 3 MHz, the radial oscillations from the commercial contrast agent SonoVueTM and four in-house microbubble preparations were measured under controlled insonation conditions (four-cycle Gaussian pulse; center frequency 0.5 MHz; peak negative pressure 30–70 kPa). The results indicate that microbubble response varies as the lipid structure and functional components in the coating change. These findings have been compared with simulation results using the generalized model for microbubble dynamics developed by the authors, in order to quantify the observed effects of changing the shell composition upon the microbubbles viscoelastic and diffusion characteristics. Both microbubble shrinkage and variable shell viscoelasticity can have significant implications for the acoustic response. This in turn can affect contrast specific imaging methods, especially those involving multipulse sequences such as pulse inversion. Similarly, these phenomena may affect the microbubble destruction threshold and hence the efficiency of drug delivery procedures.

10:40

5aBB6. The use of homemade microbubbles in detection of organ bleeding and enhancement of high-intensity focused ultrasound therapy. Wenbo Luo, Vesna Zderic, and Shahram Vaezy (Dept. of Bioengineering, Univ. of Washington, Seattle, WA 98195)

We investigated the feasibility of using homemade microbubbles in detection of internal bleeding, and for optimization of high-intensity focused ultrasound (HIFU) therapy. Homemade microbubbles were produced by sonicating albumin and dextrose saline solution with the presence of perfluorocarbon gas. Microbubbles were injected intravenously to reveal rabbit kidney and liver injuries. HIFU treatments were performed on liver lacerations for hemostatis and on intact liver for lesion production, with or without homemade microbubbles. The mean size of homemade microbubble was 4.7 um (range 1.2–7.1 μm). The concentration of microbubbles was 3.1*108 bubble/ml. Kidney and liver injuries were revealed by mosaic color flow at the injury sites. In treatment, the average hemostasis times normalized with the bleeding rate were 39 s/ml*min for HIFU only and 21 s/ml*min for HIFU+microbubbles treatments. The presence of microbubbles reduced 44 percent ($p<0.05$) time in producing the first formation of the blood coagulum. The HIFU lesion depth was reduced by 35 percent because microbubbles shield the postfocal region from HIFU exposure. Homemade microbubbles oscillate and collapse in ultrasound field, generating mosaic pattern thus revealing the bleeding site. It also shows potential in promoting HIFU hemostasis and shielding deep-tissue regions from HIFU exposures.

10:55

5aBB7. The effects of encapsulation on growth and dissolution of a contrast microbubble. Kausik Sarkar and Pankaj Jain (Mech. Eng., Univ. of Delaware, Newark, Delaware, sarkar@me.udel.edu)

Micron-size gas bubbles are intravenously injected into patients body at the time of ultrasound imaging to improve image contrast. The bubbles are encapsulated by a thin layer (4–10 nm) of protein, lipids, and other surface active materials, to prevent their premature dissolution in the blood. We will present a model for the dissolution of the microbubble that accounts for the effects of encapsulation. The encapsulation hinders the permeability of the gas-liquid surface and its elasticity balances the surface tension-induced stress. Both these effects will be explicitly modeled. The model behavior will be discussed for variations of the material parameters and conditions (encapsulation permeability and elasticity, mole fraction of the osmotic agent and liquid saturation). The encapsulation significantly affects the bubble growth and dissolution including their time scales.

5aEA1. Wideband piezoelectric rectangular loudspeaker using a tuck-shaped polyvinylide-fluoride bimorph. Taira Itoh, Juro Ohga (Shibaura Inst. of Technol., 3-7-5, Toyosu, Koto-ku, Tokyo 135-8548, Japan, m106011@shibaura-it.ac.jp), Toshitaka Takei (Take T Co.), and Nobuhiro Moriyama (Kureha Co.)

A bimorph sheet of polyvinylide-fluoride (PVDF) film was applied to a flat rectangular loudspeaker as a folded zigzag-tack shape diaphragm whose size is, e.g., 260–144 mm with various depths. These loudspeakers, which we call bimorph tuck loudspeakers, are characterized by their moderate size, wide frequency range, light weight, and lack of magnetic flux radiation. This study examines the electro-acoustic transducer characteristics of these loudspeakers. Their sensitivity and resonance frequency were measured using a flat-panel baffle. Their electrical properties and sound field characteristics were also examined. A speaker's resonance frequency was estimated theoretically as a function of tuck depth. The measured resonance frequencies were, for example, 200, 160, 90, and 60 Hz. These low resonance frequencies are satisfactory for full-range loudspeaker use. Frequency characteristics of output sound pressure were also measured. They still include some irregularities that are attributable to a local bending resonance of the diaphragm. This paper examines the control methods for those irregularities.

8:15

5aEA2. Digital measurement method for dynamic distortion of loudspeakers. Keiichi Imaoka and Juro Ohga (Shibaura Inst. of Technol., 3-7-5 Toyosu, Koutou-ku, Tokyo, 135-8548, Japan, m605101@sic.shibaura-it.ac.jp)

Though many sorts of measuring methods using digital signal processing techniques have been developed, most of them are only for measurements in a linear range. There is still no suitable digital measuring method for nonlinear distortion of acoustical devices. An accurate and convenient nonlinear distortion measurement system should be developed for evaluation of electroacoustical transducers. A new digital distortion measuring method for acoustical devices is presented briefly. This method applies a Pink-TSP signal (time stretched pulse, i.e., quickly swept sinusoidal signal), whose frequency band is partially eliminated, to an acoustical system to be measured. The detected component produced in the rejected band is picked up by a bandpass filter and measured as a distortion. First, two kinds of small size electrodynamic loudspeaker units were measured by using the dynamic distortion measurement system mentioned above. Next, distortion characteristics of mechanical single resonant system models whose component shows amplitude-dependent nature were examined. This paper describes the relationship between distortion characteristics and quality factor, input signal level, and nonlinear parameters. The difference in distortion of two kinds of loudspeakers is detected by this measurement. It is seen that the resonant phenomenon has an influence on distortion characteristics.

8:30

5aEA3. Effect of acoustical load parameters for frequency response of headphones. Megumi Kobayashi, Juro Ohga, Wataru Onoda (Shibaura Inst. of Technol., 3-7-5 Toyosu, Koto-ku, Tokyo, 135-8548 Japan), and Ikuo Oohira (Ashida Sound Co., Ltd. Shinagawa-ku, Tokyo, 141-0032 Japan)

This report describes experimental and theoretical analyses for characteristics of headphones to examine the effect of significant parameters for design. Though various types of headphones are being used, the standard design procedure is still not established, because physical relationship between headphone construction and the human ear is not understood satisfactorily. The authors measured frequency response of various headphones by using IEC 60318 artificial ear and IEC 60959 head and torso simulator (HATS), and also measured the response by human ears by inserting a miniature microphone for comparison. By these examinations, a few mechanoacoustical parameters important for design were picked out. Especially, the effect of acoustical leakage shall be noted. Design parameters for supra-aural and intraconcha headphones will be reported.

8:45

5aEA4. High-output microsized earplug driver system for extreme acoustic environments. Keehoon Kim, Andrew Kostrzewski (Physical Optics Corp., 20600 Gramercy Pl., #100, Torrance, CA 90501, kkim@poc.com), and Reginald Daniels (Air Force Acoust. Res. Lab., Wright–Patterson AFB, OH 45433)

Hearing protection is critical when aircraft flight operations create a high-noise environment (130–150 dB) for aircrew and service members. Untreated aircraft noise causes noise-induced hearing loss (NIHL) and poses risks of similar hearing damage in the future. The authors have developed a new microsized smart material actuator (MSMA), a high-output earplug driver for active noise reduction (ANR) hearing protection, based on highly efficient microstructured acoustic exciters. The MSMA consists of a microscale earplug (MEP) with a proprietary acoustic structure, a protective MEP package, and a compact actuation amplifier easily connected to an external ANR controller. Performance tests show that the system produces over 130 dB into a 1-cc trapped cylindrical volume, 6 mm in diameter by 7 mm long, without significant phase delay or noticeable discontinuities in frequency response.

Fourth Joint Meeting: ASA and ASJ   **3329**

200- to 400-μm-thick bulk silicon proof mass, and suspended by surface micromachined polysilicon springs. Motion of the diaphragm is detected using an integrated polysilicon surface micromachined grating-based optical interferometer. Initial dynamic characterization of these structures in vacuum shows a fundamental resonant frequency of 250 Hz. Based on the high force sensitivity of these structures combined with interferometric motion detection, 1-μg/$\sqrt{\text{Hz}}$ detection resolution in the 1-Hz frequency range is estimated. Microfabricated structures employing electrostatic actuation electrodes for the diaphragm are also presented, which enable force feedback operation for high dynamic range and enhanced dc stability. These characteristics may make these sensors well-suited for seismic and inertial navigation applications.

9:15

5aEA6. Finite-element modeling of thin-film damping in micromachined microphones employing diffraction based optical readout. Neal A. Hall, Murat Okandan (Sandia Natl. Labs., Albuquerque, NM 87185), and F.L. Degertekin (Georgia Inst. of Technol., Atlanta, GA 30332)

Micromachined microphones with diffraction-based optical displacement detection have been presented in detail previously [J. Acoust. Soc. Am. **118**(5), 3000–3009 (2005)]. In addition to providing superior diaphragm displacement detection sensitivity over miniature capacitive sensors, optical approaches have the advantage of removing mechanical design constraints on the microphone backplate perforation architecture as well as constraints on the diaphragm-backplate gap thickness. Taking advantage of this freedom to tailor design the frequency response function and thermal noise characteristics of miniature high-performance microphones requires a sophisticated damping model to navigate this new design space. A finite-element model in ANSYS based on the modal projection method is employed to study the dynamics of new optical microphone structures. The model extracts the frequency-dependent resistance and stiffening characteristics of the film using modal displacement profiles of the diaphragm. Simulated frequency response functions and thermal-mechanical noise limits agree well with those measured on fabricated structures. Most notably, 1.5-mm-diameter diaphragm structures with under 1 μPa/$\sqrt{\text{Hz}}$ thermal noise and over 20-kHz bandwidth have been successfully designed, fabricated, and characterized. [The authors would like acknowledge the IC Postdoctoral Research Fellowship Program.]

9:30

5aEA7. Design optimization of a microelectromechanical piezoresisitive microphone for use in aeroacoustic measurements. Brian Homeijer, Ben Griffin, Toshi Nishida, Lou Cattafesta, and Mark Sheplak (Univ. of Florida, 231 MAE-A Bldg., Gainesville, FL 32611-6250, sheplak@ufl.edu)

A microelectromechanical systems (MEMS)-based piezoresistive microphone optimimum design is presented, with a focus on improving the minimum detectable pressure over many current technologies without sacrificing bandwidth. This microphone design addresses many of the problems associated with previous piezoresistive microphones. Here, a novel nonlinear circular composite plate mechanic model was employed to determine the stresses in the diaphragm, which was designed to be in the compressive quasibuckled state. With this model, the inherent in-plane stresses that occur in the microelectronic fabrication process can be used to increase the sensitivity of the device. Ion-implanted doped silicon was chosen for the piezoresistors and a fabrication recipe was made which minimizes the inherent noise characteristics of the material. The piezoresistors are arranged in a Wheatstone bridge configuration with two resistors oriented for tangential current flow and two for radial current flow. A lumped element model was created to describe the dynamic characteristics of the microphone diaphragm and the cavity/vent structure. The geometry for this device was optimized using a sequential quadratic programming scheme performed using the aforementioned novel device characteristics. Results indicate a dynamic range in excess of 120 dB for devices possessing resonant frequencies beyond 120 kHz.

9:45

5aEA8. A two-dimensional mechanical resonator array filter with reduced sensitivity to disorder. John A. Judge, Joseph F. Vignola (Mech. Eng. Dept., The Catholic Univ. of America, Washington, DC 20064, judge@cua.edu), and Scott A. Mathews (The Catholic Univ. of America, Washington, DC 20064)

The structural acoustics of perfectly periodic arrays of coupled mechanical resonators are characterized by frequency passbands, outside of which waves do not propagate across the array, but in which wave propagation is attenuated only by dissipation. Arrays of high-Q micromechanical resonators, with sufficiently high resonant frequencies, can thus be used as filters for rf band electrical signals. However, small deviations from periodicity, such as the disorder induced by finite fabrication tolerances, are known to have significant consequences for energy propagation across such arrays. This is particularly true in narrow passband applications, in which resonators are weakly coupled, and the passband energy transmission can be significantly degraded. In this work, a two-dimensional array of resonators is demonstrated that is less sensitive to disorder than equivalent one-dimensional arrays, improving filter performance without the need for improved manufacturing tolerances. The concept is explained in terms of a simple model, and the design of a prototype array is described, including a statistical investigation of disorder effects using finite-element analysis. Experimental measurements are reported demonstrating improved performance of the two-dimensional array (relative to one-dimensional arrays), by comparing laser Doppler vibrometry measurements of equivalent 2-D and 1-D arrays created in silicon wafers using laser microfabrication.

5aEA9. Methods of fitting a nonaudible murmur microphone for daily use and development of urethane elastmer duplex structure type nonaudible murmur microphone. Yoshitaka Nakajima and Kiyohiro Shikano (Grad. School of Information Sci., Nara Inst. of Sci. and Technol., 8916-5 Takayama, Ikoma, Nara, 630-0101 Japan)

Nonaudible murmur (NAM) microphones capturing vibrations directly from the skin without mediation by the air enable the sampling of nonaudible murmur with almost the same amplification rate as normal speech. Because they are filtered through the human body, they are robust against air-conducted noises. Soft silicone has been used, which has acoustic impedance close to human flesh, as a sound medium between the electrode of the condenser microphone and the skin by fixing it in a neckband style. We replaced the soft silicone with urethane elastomer, which has self-adhesiveness, to develop a NAM microphone that is easily wearable in everyday life without expendable supplies or supporting devices. It can be fixed to the skin, and it also decreases body movement noises. But miniaturized or sticking-type NAM microphones increased the mixture of air-conducted noises from the back of the microphone and from a gap between the skin and the rim of the microphone. To solve this problem, we created a duplex structure inside the urethane elastomer wrapping condenser microphone and outside the urethane elastomer for fixation and noise proofing to develop a miniaturized sticking-type NAM microphone that was again robust against air-conducted noise.

10:30

5aEA10. Throat-contact microphone with an elastomer-supported piezoelectric diaphragm. Daisuke Yoshioka, Hiroaki Okano, Juro Ohga (Shibaura Inst. of Technol., 3-7-5, Toyosu, Koutou-ku, Tokyo, 135-8548, Japan), Ikuo Oohira (Ashida Sound Co., Ltd., Shinagawa-ku, Tokyo, 141-0032, Japan), and Masato Miyoshi (NTT Commun. Sci. Labs., Seika-cho, "Keihanna Sci. City," Kyoto, 619-0237, Japan)

Throat-contact microphones are free from environmental acoustical noise because they pick up only local vibration of the throat. This paper proposes a new piezoelectric throat-contact microphone using an elastomer-supported diaphragm. It is smaller and lighter than conventional

electromagnetic throat-contact microphones, which have a magnet and coil. Transducer characteristic and parameters are examined in this paper to establish design procedures for such microphones. Frequency characteristics of output signals and electrical impedance for the microphones and their transducing components are presented. The piezoelectric diaphragm is supported by a few elastomer boundaries.

10:45

5aEA11. A study of bone conduction and its applications for audio signal transmission. Yusuke Watabe, Kochi Yui, Yuko Watanabe, and Hareo Hamada (Tokyo Denki Univ., 2-1200 Muzai-gakuendai, Inzai, Chiba Prefecture 270-1382, Japan)

Human can perceive a sound in two different ways: one is sound transmission through the ear canal, another is that through the skull. The bone conduction technology has been used mainly for hearing impaired listeners and as communication tools in the military organization. Recently, because of a rapid improvement of the bone conduction device, its technology has spread in the field of audio. However, the relationship between the physical characteristic and the subjective responses of bone conduction are not clearly understood. For example, the effect of attachment position and excitation force of bone conduction loudspeakers has been still under discussion. In addition, since the bone conduction units also generate the airborne sound, listeners can hear the sound composed of both the bone conduction sound and the airborne sound. In our previous work, by using of a loudness curve and a threshold of hearing, a fundamental performance of the bone conduction was discussed. In this paper, further investigation will be carried out in order to establish a transmission system of the bone conduction, and the airborne sound on the eardrum that is caused by the vibration of the bone conduction loudspeaker will be measured.

11:00

5aEA12. Acoustic communication system using bone conduction elements. Kenji Muto (Tokyo Metropolitan College of Industrial Technol., 8-52-1 Minamisenju, Arakawa-ku, Tokyo, Japan, muto@kouku-k.ac.jp), Guoyue Chen (Akita Prefectural Univ.), Kunihiko Takano (Tokyo Metropolitan College of Industrial Technol.), Kikuo Asai, and Kimio Kondo (Natl. Inst. of Multimedia Education)

This study examines an acoustic communication system constructed using a bone conduction speaker and a bone conduction microphone. This system is a headset that places a bone conduction speaker to the user's cheek, and a bone conduction microphone to the other cheek. A user can thereby hear a voice through the bone conduction speaker while hearing a voice of a loudspeaker and surrounding noise when using it for teleconferencing. It can transmit the voice of the remote loudspeaker using the external ear, but the user can hear the translated voice through bone conduction. However, the sound of the bone conduction speaker and the surrounding sound are mixed with the speaker's voice using the bone conduction microphone. The vibration level of the bone conduction microphone from the bone conduction speaker was about 0 dB, although it was the same level as the level of the speaker's voice. The vibration level from surrounding sound was about -3 dB, although it was a smaller level than the level of the speaker's voice. This device removed mixed sounds using the echo canceller [K. Muto *et al.*, Proc. Inter-noise (2004), p. 248]. The echo elimination level was about 12 dB. [This work was supported by JSPS KAKENHI 17300283.]

5aMU1. Observing the effects of waveguide model elements in acoustic tube measurements. Tamara Smyth (Simon Fraser Univ., Surrey, BC, Canada) and Jonathan Abel (Universal Audio Inc., Santa Cruz, CA)

The theory of digital waveguide synthesis and its use in modeling virtual musical instruments, and in particular for cylindrical and conical bores, is well documented. Current models rely on certain approximations, however, particularly in cases where the theory provides no exact closed form solution, such as the reflection and transmission occurring at the bore's open end. In this research, we observe, from a time domain, waveguide model perspective, how the theory corresponds to actual acoustic measurements. We consider four simple acoustic tube structures, incorporating both open and closed boundary conditions for both a simple cylinder and a cylinder with a conical flare, allowing us to isolate, and observe, the filtering effects of each model component.

5aMU2. Ingoing and outgoing waves in time-domain simulation of wind instruments. Eric Ducasse (Laboratoire de Mecanique Physique, UMR CNRS 5469, Universite Bordeaux I, 351 cours de la Liberation, F-33405 Talence Cedex, France)

An extension of a recently published work [Ducasse, J. Acoust. Soc. Am. **112**, 3031–3041 (2002)] is presented. Two-port modeling is an efficient tool for time-domain simulation of sound propagation in wind instruments. It requires the separation of ingoing and outgoing waves contributing to the acoustic field in any cross section of the air column. This separation is achieved by using a multimodal approach, where uncoupled traveling modes appear in the case of cylindrical waveguides: the propagation of the plane mode is straightforwardly modeled by a delay line and the impulsional response of any other mode is the sum of a delayed Dirac pulse and a closed-form dispersive term. Although mode coupling occurs in acoustic pipes with nonuniform cross section, the scattering matrix can be directly obtained. When a multimodal approach is not adequate, the time-domain responses of complex elements are numerically calculated by introducing either nonreflecting boundary conditions (NRBCs) or perfectly matched layers (PMLs) in a finite-element method. The examples of (*i*) the reflection matrix of a bell, as seen from the body, and (*ii*) a piece of pipe containing an obstacle (e.g., the register hole) illustrate the method.

5aMU3. Differences between cylindrical and conical brass instruments; the nonlinear propagation point of view from experiments and simulations. Joel Gilbert (Laboratoire d'Acoustique de l'Universite du Maine, CNRS, avenue Olivier Messiaen, 72085 Le Mans Cedex 9, France, joel.gilbert@univ-lemans.fr)

The brightness of the sound generated by brass instruments is due to the essential nonlinearity of the wave propagation in the pipe. The bright instruments such as the trumpet and the trombone are different from brass instruments such as saxhorns or flugelhorns. The bright instruments have a cylindrical pipe segment just downstream of the mouthpiece. The conical bore of the saxhorns implies a faster decay of the wave, which reduces the nonlinear wave steepening. In this talk, theoretical and experimental results of brassiness associated with brass instruments having different bores, from mainly cylindrical ones to mainly conical ones, will be shown. The theoretical results come from simulations of periodic regimes using a theoretical background based on generalized Burger's equations.

5aMU4. Motion of brass players' lips during very loud playing. Seona Bromage, Murray Campbell, Samuel Stevenson (School of Phys., Univ. of Edinburgh, Edinburgh EH9 3JZ, UK, d.m.campbell@ed.ac.uk), John Chick (Univ. of Edinburgh, Edinburgh EH9 3JL, UK), and Joël Gilbert (Laboratoire d'Acoustique de l'Université du Maine, 72085 Le Mans Cedex9, France)

When a crescendo is played on a trumpet, horn, or trombone, the timbre changes markedly at the fortissimo level: there is a dramatic increase in the relative amplitudes of the high- frequency harmonics, and the resulting sound is often described as "brassy." Shock-wave generation in the air column of the instrument as a consequence of nonlinear steepening of the wavefront is the generally accepted explanation of this phenomenon. It has, however, also been suggested that saturation of the lip opening could play a role in the timbre change. This study compares the motion of the lips at lower dynamic levels and during extremely loud playing, using a high-speed digital camera and instruments with different sizes of mouthpiece. Curves illustrating the variation of the open lip area as a function of time at different dynamic levels are presented, together with waveforms and spectral analyses of both the radiated sound and the pressure in the mouthpiece. The results suggest that there is no qualitative change in the time-dependent behaviour of the opening area of the lips when the instrument enters the brassy regime.

5aMU5. Input impedance measurements of alto saxophones with a calibration error analysis. Antoine Lefebvre and Gary Scavone (Music Tech. Area, McGill Univ., Montral H3A 1E3, Canada)

Recent investigations are presented for the measurement of acoustic input impedance of wind music instruments. Initial efforts have focused on measurements of alto saxophones using a two-microphone, three-calibration tube procedure. We first present the design of the impedance probe, as well as the data sampling and analysis procedures. We then discuss the relationship between errors in the calculated calibration parameters and the resulting measured transfer functions. Finally, we compare the input impedances of Yamaha Z and Selmer Series II alto saxophones for several low register fingerings. We note several instances where the Yamaha saxophone possesses significantly stronger fundamental resonances than the Selmer saxophone.

Contributed Papers

5aMU6. Interactive program for computer-aided design of woodwind musical instruments. Héctor Alfonso Cordourier-Maruri and Felipe Orduña-Bustamante (CCADET-UNAM, Circuito Exterior CU, CP 04510, México DF, México, felipe@aleph.cinstrum.unam.mx)

Current scientific knowledge on the acoustics of woodwind instruments allows accurate physical modeling of the sound generation mechanisms, and the acoustic interaction with the air column. These physical models can be incorporated into computer software, in order to evaluate not only the tuning, voicing, and other tonal characteristics of existing instrument designs, but also to estimate the potential effects of proposed modifications, and to anticipate the characteristics of new designs. This presentation describes the development of an interactive computer program for the acoustic design, evaluation, and auralization of woodwind musical instruments. The program displays a graphical user interface that allows convenient entry of air column data, including constant and variable cross-section segments, open and closed fingerholes, and air column terminations. It also implements different types of sound excitation mechanisms, which include jet-driven (flutelike) and single reed (clarinet-like) models. The program can produce input impedance and reflection function data for further acoustic analysis, and synthetic sounds that approximate the musical tones that can be expected form the actual instru-

ment. The software has been validated by comparative analysis of calculated versus measured air columns, and simulated versus actual (recorded) flute tones.

10:35

5aMU7. Control parameters inversion using genetic algorithms applied to numerical impedance synthesis for woodwinds. Laura Perichon, Olivier Carriere, Jean-Pierre Hermand, Matthias Meyer (Environ. Hydroacoustics Lab, Optics and Acoust. Dept., ULB-CP 194/05, 50 Av. F.D. Roosevelt, B-1050 Brussels, Belgium), and Philippe Guillemain (Ctr. Natl. pour la Recherche Scientifique, 13402 Marseille cedex 20, France)

Woodwind sound synthesis in real time has been achieved using different computational techniques, especially the so-called numerical impedance model based only on acoustical variables. The impedances of the excitation mechanism and of the resonator are approximated by IIR filters and related by a nonlinear coupling. The control parameters can be reduced to a number of three including the length of the resonator, the mouth pressure, and a mask parameter. In this paper we present preliminary inversion results for the latter two parameters in the case of a clarinet. The inversion algorithm is based on differential evolution metaheuristics with a number of prior conditions on the correlated parameters. A cost function based on time-domain correlation has been implemented, allowing us to obtain better results in terms of signal matching than with conventional descriptors extraction. The technique has proved its effectiveness on the sustained part of synthesized sounds and a regularization method is presented to allow us to invert attack and decay parts as well as real analogically recorded signals. Results will be of main interest for tuning control parameters in real-time model-based synthesis.

10:50

5aMU8. Virtual wind instruments based on pulse forming synthesis. Michael Oehler (Inst. for Appl. Musicology and Psych., Duerener Strasse 98, 50931 Cologne, Germany, oehler@iamp.info) and Christoph Reuter (Univ. of Cologne, 50923 Cologne, Germany)

A new synthesis method for wind instruments is presented, the digital pulse forming. The core of that principle is that every wind instrument sound can basically be put down to its excitation impulses, which independently of the fundamental always behave according to the same principles. By controlling the pulse width and shape it is possible to generate all sound nuances that can be produced on a real wind instrument. Based on the 1975 found principles of generating wind-instrument-like spectra with typical stable formant areas and spectral gaps evoked by the excitation pulses of double-reeds or lips [J. P. Fricke, Fortsch. Akust. **4**(DAGA75), 407–411 (1975)], a virtual wind instrument, the Digital Variophon, is developed. The resulting software-based version of the original Variophon, the first analog wind synthesizer using the pulse forming principles, is a further step towards the intended scientific experiment system for analyzing and synthesizing (wind) instrument sounds. Trumpet, bassoon, and oboe modules are already digitally implemented in a flexible, realtime sound generating and analyzing framework. Acoustic analyses and hearing experiments show extensive concordance between the original instruments and the Digital Variophon. [Work supported by DFG.]

11:05

5aMU9. Flow regimes at the output of oboe double-reeds. Christophe Vergez (LMA, CNRS UPR-7051, 31 chemin Joseph-Aiguier, 13402 Marseille, cedex 20, France) and Reneé Caussé (IRCAM)

Measurements of the quasistatic nonlinear characteristic curve for double reeds show systematic deviations from an elementary model of a reed instrument based on a spring model associated to a Bernoulli flow input into the reed. These deviations were previously explained by the pressure recovered by the flow as it expands in the conically divergent output duct of the reed. We will show measurements of the pressure recovery inside the reed as well as detailed flow profiles that can explain the different regimes observed for the pressure recovery (laminar and turbulent). An extension of these measurements to oscillating regimes allows us to observe some qualitative differences in the flow, suggesting an important influence of the dynamic terms in the Navier-Stokes equation in these kinds of regimes.

11:20

5aMU10. Wolf notes in brass wind instruments. Thomas R. Moore and Isaac E. W. Codrey (Dept. of Phys., Rollins College, Winter Park, FL 32789)

It has been recently reported that experiments using artificial lips have shown that damping the bell vibrations of a trumpet can result in changes in the sound spectrum. New data now suggest that these effects are enhanced when the fundamental frequency of the note is near a resonance frequency of the bell vibration. This effect results in a situation that is analogous to the wolf note commonly found on stringed instruments. Although the physics of the process is still poorly understood, the effect appears not to be related to a change in impedance of the air column.

5aNS1. Sound field modeling in a street canyon with a diffusion equation. Judicaël Picaut, Stéphane Colle, and Michel Bérengier (LCPC, Section Acoustique Routière et Urbaine, Rte. de Bouaye, BP 4129, 44341 Bouguenais Cedex, France)

The transport theory of sound particles is applied to the sound field modeling in an empty street canyon with partially diffusely reflecting facades. A diffusion equation is then derived to predict the sound field distribution and the sound decay in the street. The main parameter, namely the diffusion coefficient, is a function of the street width and the acoustic reflection laws of both building facades. For a single rectangular street, analytical solutions can be found. For more complex urban spaces, a finite-element based approach is proposed. Several numerical examples are given, like the sound propagation in a street with a nonuniform cros section, and in street intersections, for point and line sources. In comparison with ray-tracing-based models, the diffusion model requires less computation time and could be applied to the calculation of a sound map for large urban areas. However, at the present time, the diffusion coefficient can be calculated only for simple building reflection laws, like the Lambert's one.

7:55

5aNS2. Prediction of road traffic noise using two-dimensional numerical analysis. Shinichi Sakamoto (Inst. of Industrial Sci., The Univ. of Tokyo, 4-6-1 Komaba, Meguro-ku, Tokyo 153-8505, sakamo@iis.u-tokyo.ac.jp), Akinori Fukushima (NEWS Environ. Design, Inc., Hyougo, Kobe 652-0802), Tomonao Okubo, and Kohei Yamamoto (Kobayasi Inst. of Physical Res., Kokubunji, Tokyo 185-0022, Japan)

For acoustically complicated road structures such as semi-underground roads and special areas in which a viaduct road and a flat road with noise barriers exist together, prediction of road traffic noise is complicated because of multiple reflections and diffractions that occur inside the road structures. For such road structures, an energy-based engineering model cannot be applied and noise propagation should be addressed through introduction of wave theory. When the road structures have almost identical cross-sectional shape along the road, two-dimensional (2-D) wave-based numerical analyses are applicable. In the prediction model of road traffic noise, the ASJ-RTN Model 2003, published by the Acoustical Society of Japan (ASJ), the application of 2D wave-based numerical analysis was introduced as a prediction method for such complicated road structures. Comparisons between calculations by BEM and FDM and field measurements and experiments for three actual road structures were conducted. Consequently, calculation results agreed well with measured ones. Therefore, the validity of the calculation methods was confirmed. This research was discussed in the Research Committee of Road Traffic Noise in ASJ. Measurement data were provided by Nippon Expressway Company and the Nagoya Expressway Public Corporation.

8:15

5aNS3. Modeling outdoor sound propagation in mountainous areas. Dick Botteldooren, Timothy Van Renterghem, and Bram de Greve (Acoust. Group, Dept. of Information Technol., Ghent Univ., St. Pietersnieuwstraat 41, 9000 Gent, Belgium, dick.botteldooren@ugent.be)

Detailed modeling of outdoor sound propagation in mountainous area imposes special requirements. The strong gradients in ground surface create propagation conditions that may lead to noise levels much higher than expected at some distance from the source partly due to a focusing effect. Meteorological conditions are particular: main winds following the valley, strong temperature gradients often including stable inversion, slope winds, etc. Because of these particular conditions, efficient modeling of outdoor sound propagation in mountainous area requires adaptations to be made to general purpose models. In this paper we will present possibilities for making time-domain models terrain following and consider options to decrease the memory requirements. For the higher frequency range and distances one is generally interested in, these adaptations are insufficient. Hence, a Green's function parabolic equation model is added to the toolbox. To tackle the problem in three dimensions, a number of two-dimensional slices connecting the receiver point to all (segments of) sources considered is made. Propagation results for each slice are added. Numerical simulations are compared to field measurements made close to an Alpine highway.

5aNS4. Measurements of acoustic impedance and their application to sound propagation calculations and audible simulations.
Teruo Iwase (Faculty of Eng., Niigata Univ., 8050 2nocho, Niigata City, 950-2181, Japan), Yu Murotuka (Niigata Univ., Niigata City, 950-2181, Japan), and Koichi Yoshihisa ((Meijo Univ., Tempaku-ku, Nagoya, 468-8502, Japan)

Acoustic impedance is an important value that determines the boundary condition of each sound field, but collections of actual values are not sufficient for evaluation of many sound fields. First, measurements using a particle velocity sensor for acoustic impedance were tested on various fields. Such measurement results were applied to calculations of sound propagation. Frequency characteristics of sound propagation were obtained along such surfaces as fields of lawns and snow, and areas paved by porous asphalt for drainage. Those characteristics showed fair correspondence with inspected field measurement results. Then, fine calculations in the frequency domain were converted to the impulse response for each sound field model. Convolution operations based on the impulse response and on voice, music, and some noise sources readily produced an ideal sound field to the audible sound file. Furthermore, simulations of the noise, including noise reduction effects from a car running through a drainage pavement area, were executed as advanced applications. Our measurement method of acoustic impedance is inferred to be useful. Calculated sound propagation characteristics based on the measured acoustic impedance correspond to actual propagation characteristics. Audible simulation will be effective as a future means of sound-field evaluation. [Research supported by KAKENHI.]

5aNS5. Quiet heights and pulse tails: The modal structure of near ground to near ground sound propagation in the nocturnal duct. Roger Waxler (NCPA, Univ. of Mississippi, University, MS 38677, rwax@olemiss.edu)

On clear nights over land a temperature inversion forms, creating an acoustic duct in the first few hundred meters of the atmosphere. Assuming a flat, locally reacting ground surface and a stratified atmosphere, the sound field can be expressed as a superposition of independently propagating vertical modes [J. Acoust. Soc. Am. **112** (6), 2540–2552 (2002) and **115** (4), 1437–1448 (2004)]. The modes account for refraction due to sound-speed gradients as well as for the compliance and resistance of the ground. For typical nocturnal ducts and ground surfaces one finds two types of modes: a surface mode and a set of higher modes. The surface mode is more slowly propagating and more rapidly attenuated than the higher modes. The higher modes' amplitudes all have a sharp minimum several meters above the ground. Two consequences of this modal structure have been observed: At long ranges, narrow-band signals have a range-independent quiet height at which sound levels are reduced by 10 to 15 dB from the levels on the ground [J. Acoust. Soc. Am. **119** (1) 86–95 (2006)] while impulsive signals develop a bandlimited low-frequency tail [J. Acoust. Soc. Am. **88** (1), 455–461 (1990)].

5aNS6. Influence of short-term variations of meteorological parameters on sound propagation outdoors. Philippe Blanc-Benon, Benjamin Cotte (LMFA, UMR CNRS 5509, Ecole Centrale de Lyon, 69134 Ecully Cedex, France), Benoit Gauvreau, and Michel Berengier (Laboratoire Central des Ponts et Chausses, BP 4129, 44341 Bouguenais Cedex, France)

Predicting long-range sound propagation over a nonurban site with complex propagation media requires the knowledge of micrometeorological fields in the lower part of the atmospheric boundary layer. In the framework of road traffic noise characterization there is a need for reliable sound pressure level predictions for specific propagation conditions that must be representative of time and space (small scale and site effects) characteristics of the acoustic situation. Outdoor measurements involving roughly 100 meteorological and acoustic sensors have been carried out during 3 months in 2005 in the southwest of France. This large database enables us to study the variability of meteorological parameters (wind speed, temperature, etc.) on different time scales. Scaling parameters in the atmospheric surface layer (such as the friction velocity and the Monin-Obukhov length) are estimated every 15 min, which allows looking at relatively short-term variations. Some longer-term effects, from days to months, are studied too. These include occurrences of meteorological configurations and variation of ground parameters. The effect of meteorological variability on sound propagation is studied using parabolic equation simulations. Comparisons between numerical predictions and experimental data will be discussed.

5aNS7. Effect of atmospheric absorption on aircraft noise propagation in various world regions during the year. Yasuaki Okada, Koichi Yoshihisa (Meijo Univ., 1-501 Shiogamaguti, Tempaku-ku, Nagoya, 468-8502, Japan), and Teruo Iwase (Niigata Univ., Niigata, 950-2102, Japan)

The attenuation of sound due to atmospheric absorption depends strongly on environmental temperature and humidity. For that reason, it varies in response to changing meteorological conditions on a variety of time scales. To perform long-term prediction of outdoor sound propagation more accurately, it is necessary to examine the fluctuation of the attenuation coefficients for atmospheric absorption during the year. Large variations occur according to the time and place in actual meteorological conditions, on which the attenuation coefficients depend strongly. The attenuation coefficients for atmospheric absorption were calculated from hourly meteorological data obtained at ten international airports throughout the world during a year using the calculation method described in ISO 9613-1. Calculated results show that the variability characteristics of the attenuation coefficients during the year depend strongly upon both the sonic frequency and the place. The effects of atmospheric absorption on aircraft noise propagation were examined using the calculated attenuation coefficients. Results showed that the A-weighted sound pressure levels and sound spectra of aircraft noise vary strongly because of the changes in atmospheric absorption, which depend on actual meteorological conditions of various world regions.

5aNS8. Acoustic travel-time tomography of temperature and wind velocity fields in the atmosphere. Vladimir E. Ostashev (NOAA, Earth System Res. Lab., Boulder, CO, and Dept. of Phys., New Mexico State Univ., Las Cruces, NM), Sergey N. Vecherin (New Mexico State Univ., Las Cruces, NM), D. Keith Wilson (U.S. Army Engineer Res. and Development Ctr., Hanover, NH), Astrid Ziemann, Manuela Barth, and Klaus Arnold (Inst. of Meteorol., Univ. of Leipzig, Germany)

Acoustic tomography of the atmosphere allows one to reconstruct (estimate) temperature and wind velocity fields in the atmosphere and to monitor the evolution of these turbulent fields in time. In the present paper, we report on a progress in construction of a state-of-the-art array for acoustic tomography of the atmosphere, which will allow us to measure travel times of sound propagation between different pairs of sources and receivers within a few meters above the ground. Using these travel times, the turbulent fields will then be reconstructed using different inversion algorithms. The array is being built at the Boulder Atmospheric Observatory, CO, in a collaborative effort between several organizations in the U.S. Furthermore, we discuss several inverse algorithms for estimation of the turbulent fields, including recently developed time-dependent stochastic inversion. Finally, some of these algorithms were used to reconstruct temperature and wind velocity fields in indoor and outdoor tomography experiments carried out by scientists from the Institute of Meteorology, University of Leipzig, Germany. Examples of the reconstructed fields are given. [Work supported by ARO, Grants DAAD19-03-1-0104 and W911NF-06-1-0007.]

5aNS9. A comprehensive noise study for the city of Lincoln, Nebraska. Dominique Cheenne, Connie Lee, Michael Cappiello, Sam Lalk, Coleman Martin, and Philip Muzzy (Dept. of Audio Arts & Acoust., Columbia College Chicago, Chicago, IL 60610)

A comprehensive noise study to define the soundscape of the city of Lincoln, NE, has been undertaken by the students enrolled in the Acoustics Program at Columbia College, Chicago. The study includes (1) a global review of best practices in the field of environmental noise control using a perspective emphasizing close attention to effective and proven solutions that can be implemented via policies and effective legislation, (2) the creation of a large-scale outdoor noise propagation computer model that incorporates all primary traffic arterial and readily identifiable noise sources, (3) a comprehensive large-scale testing of noise levels using specially modified noise dosimeters allowing for determination of Leq, and Ldn over 24-h intervals, and (4) a large scale attitudinal survey of the population using a web-based survey engine that allows for the geographical location of the respondents. The results of the survey are used to refine the density of the test locations and the scale resolution of the software model, as well as to provide city and county officials with a targeted course of action pertaining to regulations and noise abatement policies. The project is expected to last 3 years with up to 1200 test locations being analyzed.

5aNS10. Effect of parameters on modeling low-frequency propagation of petrochemical plant noise over water. Frank Brittain (Bechtel Corp., 2255 Peavine Valley Rd., Reno, NV 89523, fhbritta@bechtel.com) and Xiao Di (Univ. of Mississippi, University, MS 38677)

Modeling noise is vital to designing petrochemical plants to meet community noise limits. Models are used to specify equipment noise, choose add-on controls, and confirm limits will be met. For propagation over land, there are substantial variations of actual levels from the long-term average computed using ISO 9613-2. Commercial modeling software based on ISO 9613-2 excludes propagation over water, where levels are often higher and more variable than at the same distance over land. Over water, higher levels and variability arise primarily from wind, thermal inversions, and lack of attenuations from ground clutter. Often a petrochemical plant and receivers are separated by a large body of water, which reduces modeling accuracy. To better understand propagation over water, full-wave Green's Function-Parabolic Equation (GF-PE) software was used to predict levels between 50 m and 10 km for various lapse rates (temperature increase with elevation) as well as inversion, source, and receiver heights. Plots of attenuation with distance and contours in a vertical plane are presented for 63 Hz. Rates of attenuation considerably less than −6 dB

per distance doubling for spherical spreading were found; these and implications for design are discussed. The potential application of GF-PE to verify algorithms for outdoor propagation is indicated.

5aNS11. Bauxite refinery community noise control and prediction. Jose Augusto Nepomuceno (Acustica & Sonica, R. Fradique Coutinho, 955, sala 01, Sao Paulo, 05416-011 SP, Brasil, janepomuceno@yahoo.com) and Aljan Machado (Alcoa Brasil)

Alumar in the city of Sao Luis in Brazil is one of the largest bauxite processing plants in the world including refinery and reduction plants. The Alumar refinery will expand from approximately 1.4 million mtpy to approximately 3.5 million mtpy and the expansion is expected to be completed in the first half of 2008. Since the year 2000 the authors worked in collaborative way with the in-plant and community noise control and prediction program for the expansion project. The program included noise measurement in the existing plant, development of the Bauxite Refinery Noise Control Manual, several noise control guidelines, and noise modeling to predict community noise impact. The plant is surrounded by different land uses as residential, industrial, rural, and natural permanent protection. Using computer modeling it was studied how the refinery expansion could impact the community areas and what will be the critical equipment requiring special noise limits. The validation process predicted measured results in the range of +2.2 dB(A). The paper presents the noise program results obtained by the year 2006.

5aNS12. Statistical models for fading and coherence of sound in urban environments. D. Keith Wilson (U.S. Army Engineer Res. and Development. Ctr., 72 Lyme Rd., Hanover, NH 03755, d.keith.wilson@erdc.usace.army.mil), Rafael Bey-Hernandez (U.S. Army Engineer Res. and Dev. Ctr., Hanover, NH 03755), and Vladimir E. Ostashev (NOAA/Earth System Res. Lab., Boulder, CO 80305)

Urban environments typically produce strong, multipath scattering. It is often desirable to characterize the effects of the scattering with statistical models for signal fading and coherence. This paper discusses initial efforts to develop such models. Random configurations of buildings, with varying sizes and number densities, are synthesized. Sound waves are then propagated through the random configurations. The first and second moments of the sound field are calculated by averaging results from the random realizations. Most of the propagation calculations are done by a ray-tracing technique, which is very fast but does not include diffraction. Due to multiple scattering, cases where a receiver is in a full acoustic shadow are infrequent. We also compare the ray tracing to finite-difference, time-domain calculations, which provide a full-wave solution that includes diffraction as well as multiple scattering. Initial results show

that the wave extinction and coherence diminish exponentially with distance, as is the case for turbulent scattering. The extinction and coherence decay rate increases with the number of buildings and size, but appears to be independent of frequency. We compare the signal probability density functions to statistical fading models developed for radio-wave scattering in urban environments.

11:30

5aNS13. A review on barrier diffraction theories and related insertion loss comparisons in highway noise models. Ning Shu (AZTEC Eng., 4561 East McDowell Rd., Phoenix, AZ 85008), Louis F. Cohn, Roswell A. Harris, and Teak K. Kim (Univ. of Louisville, Louisville, KY 40292)

This paper presents a review on diffraction theories for highway noise barriers. Insertion loss based on different diffraction theories was investigated with two highway noise models, STAMINA and TNM 2.5. STAMINA implements the Kurze and Anderson empirical diffraction formula while TNM 2.5 deploys a simplified MacDonald analytical model. Quantitative analysis indicates that from the perspective of diffraction theory, the average difference of insertion loss between TNM and STAMINA for a point source is about 3 dB(A). To improve the prediction accuracy of TNM, it is recommended that the MacDonald solution, but with real and image sources, should be deployed.

11:45

5aNS14. An acoustic technique for monitoring off-highway vehicle (OHV) use with sound level meter data: Camparison with Trailmaster records. Tina Yack, Ann Bowles (Hubbs-SeaWorld Res. Inst., 2595 Ingraham St., San Diego, CA 95616, tyack@hswri.org), Keith Slauson, William Zielinski (USDA Forest Service, Arcata, CA 95521), and Kenneth Plotkin (Wyle Labs., Arlington, VA 22202)

Off-highway vehicle (OHV) use is of growing interest to land managers. Trail counters are typically used to monitor OHV activity, but accuracy of this technique remains relatively untested. As part of an ongoing study comparing the distribution of American martens (*Martes americana*) with OHV use in the Lake Tahoe Basin, verifiable OHV detections were collected using two techniques, (1) photographs from Trailmaster 1500 camera systems (TMs) placed across roads/trails and (2) continuous 2-s, A-weighted equivalent-continuous sound levels (LAeq2s) collected using Larson-Davis 720 Sound Level Meters (SLMs) placed either near roads/trails or paired with TM animal detection stations. Events were identified in the SLM data by comparing time-history profiles collected in the field with profiles of known snowmobile passes. Errors in SLM event counts were assessed using independent observer logs and compared with the TM records. SLMs were consistently more reliable detectors of snowmobile use. During the Winter 2004 season, TM records were reliably matched to SLM logs only 48% of the time. TMs consistently missed passes and overestimated events compared to SLMs. In conclusion, SLMs proved to be more sensitive and reliable detectors of OHV activity. These results have implications in both wildlife research and land management applications.

5aPA1. Amplification of acoustic intensity of a pulse wave propagating through a tube having a temperature gradient. Tetsushi Biwa (Dept. of Mech. Syst. Design, Tohoku Univ., Aoba-ku, Sendai, 980-8579, Japan), Yusuke Tashiro, Masatoshi Shinmei (Nagoya Univ., Chikusa-ku, Nagoya, 464-8603, Japan), and Taichi Yazaki (Aichi Univ. of Education, Igaya-cho, Kariya, Japan)

Ceperley has theoretically pointed out that when acoustic traveling waves pass through a long duct with a positive temperature gradient, the acoustic intensity is amplified as a result of the thermodynamic cycles that the gas undergoes. Even though he only observed damping of the acoustic intensity in the experiment, his idea serves as a starting point of new acoustic devices known as thermoacoustic Stirling heat engines. For a further progress of the thermoacoustic technology, experimental verification of his idea is of great importance. In this paper, we report on the thermoacoustic amplification of acoustic intensity using pulse waves traveling in a long tube equipped with a differentially heated regenerator. A reservoir filled with pressurized air and a solenoid valve were used to generate the acoustic pulse running in one direction in the tube with length 60 m. A series of pressure transducers was used to determine the axial distribution of the acoustic intensity. Use of a pulse wave enabled us to see

the frequency dependence of the amplification rate of acoustic intensity very easily. We found that the amplification rate was essentially determined by the ratio of thermal boundary layer thickness to the pore radius of the regenerator.

7:45

5aPA2. Pattern formation in thermoacoustic resonators. German J. de Valcarcel (Dept. de Optica, Universitat de Valencia, Dr. Moliner 50, 46100 Burjassot, Spain), Victor J. Sanchez-Morcillo, and Isabel Perez-Arjona (Universidad Politecnica de Valencia, 46730 Grao de Gandia, Spain)

The phenomenon of pattern formation is ubiquitous in the dynamics of extended nonlinear systems. Patterns arise from the interplay of external forcing, dissipation, nonlinearity, and spatial coupling. These factors are also present in many acoustic systems. However, under usual conditions where the elastic nonlinearity dominates, the development of shock fronts in nonlinear regime strongly limits the possibility of a simple analysis. Viscous media, where thermal nonlinearity dominates over the elastic one and wave distortion is inhibited at short distances, are good candidates for acoustic systems presenting patterns with similar characteristics as those found in other fields, such as hydrodynamics or optics. A model describing

the evolution of pressure and temperature variations in a resonator with plane walls containing a viscous medium is presented. The large aspect ratio of the resonator allows the transverse spatial coupling, mediated by sound diffraction and temperature diffusion. The homogeneous solutions show bistability at some values of the parameters, in agreement with experimental results reported in the bibliography. We show by means of linear stability analysis that the homogeneous solutions develop spatial instabilities leading to the spontaneous generation of spatial patterns. The analytical predictions are confirmed by a numerical analysis. [Support from Spanish MEC, Project FIS2005-07931-C03-02/03, is acknowledged.]

5aPA3. Anharmonic acoustic resonators in miniature thermoacoustic cooler. H. El-Gendy, L. Lyard, and O. G. Symko (Dept. of Phys., Univ. of Utah)

In optimizing miniature thermoacoustic coolers for high cooling power density, the acoustic resonator has to be able to sustain very high amplitude acoustic oscillation at the resonant frequency of the driver in order to pump heat up a temperature gradient. Nonlinear effects in cylindrical-shaped resonators lead to acoustic saturation; acoustic energy is dissipated in higher harmonics, thus limiting the intensity of the fundamental mode. To overcome this limitation, noncylindrical resonators were studied here. Conical, exponential, and halfcosine shapes were used. They produce high-amplitude sound waves with essentially no shock waves. Such resonators were chosen here to operate at around 4 kHz, the resonant frequency of the piezoelectric driver. They are easily adapted to the miniature refrigerator. Moreover, they provide an impedance match, which is shape dependent, between the driver and the resonator. Tests at sound intensity levels up to 170 dB show essentially no distortion of the acoustic waveform. Results of their performance will be discussed. [Work supported by ONR and the State of Utah.]

5aPA4. A study for applying lower temperature heat source to loop-tube thermoacoustic cooling system. Yousuke Imamura, Shin-ichi Sakamoto, and Yoshiaki Watanabe (Faculty of Eng., Doshisha Univ., 610-0321 1-3 Tataramiyakotani Kyotanabe Kyoto, Japan)

To realize the generation of self-sustained sound in lower temperature heat source, a 5-μm in thickness rubber membrane was applied in the loop-tube thermoacoustic cooling system. It is known that the existence of dc flow acts as the negative effect for the loop-tube. The membrane reduces a loss of thermal energy supplied to the prime mover by suppressing the dc flow. So it is considered that lower temperature difference between both the edges of the stack can be realized by using presented system. The locating position of the membrane was moved, and then the temperature differences of the stack were observed. The experiments were carried out on the condition that the thermal energy supplied to the prime mover was constant. It was found that the temperature difference is affected by the position of the membrane. When the membrane was set at the approximate antinode of pressure, the lowest temperature difference was realized. In this condition, the temperature difference with the membrane was 430 K, which was 160 K lower than without the membrane. These results suggest that a lower temperature heat source can be available by setting the membrane on the loop-tube thermoacoustic cooling system.

8:30

5aPA5. Marginal instability of thermoacoustic oscillations of a gas in a tube. Nobumasa Sugimoto and Masatomi Yoshida (Dept. of Mech. Sci., Grad. School of Eng. Sci., Osaka Univ., Toyonaka, Osaka 560-8531, Japan, sugimoto@me.es.osaka-u.ac.jp)

This paper examines a marginal condition of instability of thermoacoustic oscillations of a gas in a tube with one end open and the other closed by a flat wall, subjected to a smooth temperature distribution axially. Assuming a boundary layer is thin compared with the tube radius, the linear theory is developed in the framework of the first-order theory in its

thickness. An idea of the method of renormalization enables us to obtain analytical solutions and to derive the marginal condition when the temperature distribution is parabolic. Solving the condition numerically, the marginal curve for the temperature ratio is displayed graphically against the tube radius relative to the boundary-layer thickness. It is found that the temperature ratio has a minimum and that the curve has two branches with respect to the minimum. While the left branch for viscous mode extends to infinity, the right branch, close to the curve for neutral oscillations, asymptotes a certain temperature ratio as the tube radius increases. Such results should be compared with the ones obtained by Rott in the case of a step distribution. Spatial mode of oscillations is also displayed in the marginal state and some discussions on the energy balance are included.

8:45

5aPA6. Direct observation of thermoacoustic energy conversion. Yusuke Tashiro (Dept. of Crystalline Mater. Sci., Nagoya Univ., Furo-cho Nagoya 464-8603, Japan, tashiro@mizu.xtal.nagoya-u.ac.jp), Tetsushi Biwa (Tohoku Univ., Aoba-ku Aramaki Sendai 980-8579, Japan), and Taichi Yazaki (Aichi Univ. of Education, Kariya 448-8542, Japan)

A gas column starts to oscillate when the externally imposed temperature gradient exceeds a critical value. Also, when an acoustic wave propagates through a differentially heated regenerator, the acoustic intensity is thermally amplified. Such thermoacoustic phenomena attract considerable interest not only because it becomes possible to develop pistonless Stirling heat engines, but because an alternative approach to understand a heat engine has been proposed based on energy flows. In this work, we report the direct observation of the thermoacoustic energy conversion in a tube filled with atmospheric air to test the validity of the proposal. A gas column was partly heated by an electrical heater and driven by an oscillating piston at 1.00 Hz to assure good thermal contact with the surrounding tube wall. We simultaneously measured pressure and velocity oscillations to determine the acoustic intensity. As a result, we found the amplification of acoustic intensity in the region with a positive temperature gradient. This supports the proposed approach. Further test was made by comparing the acoustic power produced per unit length and the thermodynamic cycles of the gas, the latter of which was also experimentally determined from measurements of temperature and pressure.

9:00

5aPA7. Study on a thermoacoustic cooling system to drive the fundamental resonance frequency by connecting a triggered tube. Hideo Yoshida, Shin-ichi Sakamoto, and Yoshiaki Watanabe (Ultrasonic Labs., Doshisha Univ., 1-3 Miyakodani Tatara, Kyotanabe City, Kyoto 610-0321 Japan, dtf0166@mail4.doshisha.ac.jp)

A thermoacoustic cooling system to drive a looped-tube with the fundamental resonance frequency by connecting a triggered tube is proposed. The heat pump is located in the triggered-tube. The existence of dc flows, which is caused by harmonics in the looped tube, has been pointed out as negative effects. The presented thermoacoustic cooling system, however, connected the triggered-tube is expected to suppress the harmonics and to improve cooling effect, so that the length of the triggered tube is designed to have the fundamental resonance frequency. It is well known that the phase relation between sound pressure and particle velocity is important, and approximately in-phase relation is the best position for cooling effect. In the presented system, the sound energy is supplied from the looped tube. It is important to know the best connecting position where the phase relation is approximately in phase. The sound pressures were observed, then the phase relations were calculated by two-sensor power method. By using results, the best position of the triggered tube was decided. It is confirmed that the presented system can realize the suppression of harmonics and the decrease of outlet temperature. It is also confirmed that the decrease of temperature has the higher effects compared with the looped tube in the same environmental conditions.

5aPA8. Determination of complex propagation constant, acoustic intensity, and acoustic power in an arbitrarily terminated pipe using laser Doppler anemometry. Ki Won Jung and Anthony A. Atchley (Grad. Program in Acoust., Penn State Univ., University Park, PA 16802, kuj102@psu.edu)

Microphones are widely used to determine acoustical parameters, such as the complex propagation constant and acoustic intensity and power, of sound fields. It is less common to use measurements of acoustic particle velocity for the same purpose. Precise measurement of acoustic particle velocity can be achieved using laser Doppler anemometry (LDA). Although this measurement technique requires optical access to the region of interest and the use of seeding particles, in some circumstances it can be less invasive and offer greater flexibility than measuring pressure fields with microphones. The focus of this research is to use LDA to determine the complex propagation constant, acoustic intensity, and power inside a constant cross-section circular pipe. The measured particle velocities are fit to a counterpropagating plane-wave model to determine the complex amplitudes and propagation constant. Other acoustic quantities, such as the radial-dependent acoustic intensity and the cross-sectional-averaged acoustic power, can then be calculated. The complex propagation constant is compared with the theoretical value based on thermoviscous boundary layer theory. The acoustic intensity and power are compared with numerical solutions to Rott's wave equation. [Work supported by the Penn State Graduate Program in Acoustics.]

9:30

5aPA9. Spectral gaps and discrete transmission in slender tubes. Manvir S. Kushwaha (Inst. of Phys., Univ. of Puebla, P.O. Box J-45, Puebla, Pue. 72570, Mexico), A. Akjouj, B. Djafari-Rouhani, L. Dobrzynski, and J. Vasseur (Univ. of Sci. and Technol. of Lille-I, France)

Extensive band structure and transmission spectra for the longitudinal (acoustic) wave propagation in a system made up of N' dangling side branches (DSBs) periodically grafted at each of the N equidistant sites on a slender tube are reported. A periodic pattern of large stop bands is obtained for the airy DSB on a slender tube. The emphasis is laid on the interesting result of huge gaps and discrete transmission spectrum due only to the DSB grafted at a *single* site ($N=1$) on the slender tube. Designing the system with open tubes allows achievement of lowest gap below a threshold frequency and extending up to zero—thereby providing an entirely discrete band structure and transmission spectrum. This should have important consequences for the suppression of low-frequency noise and for designing filters and transducers.

9:45

5aPA10. The effects of turbulence on an undular bore. Pablo Luis Rendon (CCADET, Universidad Nacional Autonoma de Mexico, Ciudad Universitaria, Mexico D.F. 04510, Mexico, rendon@aleph.cinstrum.unam.mx)

The Korteweg-de Vries-Burgers (KVB) equation is the simplest equation to incorporate simultaneously the effects of nonlinearity, damping, and dispersion, and is of the form $\eta_t + \eta, \eta_x + \eta_{xxx} = \delta, \eta_{xx}$. It has been found that the steady solution to this equation exhibits all the characteristics of the undular bore, with $\eta(x,t)$ the surface profile. An examination of the effects of turbulence on undular bores, and of whether this turbulence can effectively alter the overall shape of the bore, is conducted through numerical simulation of the KVB equation. [The author thanks the Universidad Nacional Autonoma de Mexico for funding this project through a PAPIIT (IN116205) grant.]

5aPA11. Resonant aero-acoustic excitation of cavity depth modes. Boris M. Efimtsov, Alexey Yu. Golubev (TsAGI, 17 Radio St., 107005 Moscow, Russia), and Anders O. Andersson (Boeing MC 67-ML, Seattle, WA 98118)

Results are generalized of parametric experimental investigations of resonant aero-acoustic excitation of the depth modes of a flow-grazed cavity at low-subsonic (U50 m/s) and transonic flows (0.7M1.045). Special attention is given to the fundamental mechanisms responsible for this phenomenon. The conditions for these mechanisms to manifest themselves and interact are predicted. Observations are made of the relations between the characteristic flow and cavity parameters at which the maximum resonant aero-acoustic response of the cavity depth mode takes place. These relations take into account the distinction between the flow velocity and the characteristic spreading velocity of the disturbances downstream of the wall discontinuity as well as the distinction between the cavity depth and the characteristic linear scale in the Helmholtz number connected with the edge effect for sound waves in the vicinity of the cavity gap. Experimental data illustrating the reliability of these relations are presented. The extent of the Strouhal-number region where the cavity mode excitation can be treated as an aero-acoustic resonance is determined.

10:30

5aPA12. Single transducer parametric sound source. Bastian Epp and Volker Mellert (Univ. of Oldenburg, Faculty V, Inst. of Phys., D-26111 Oldenburg, Germany)

The idea of using the nonlinear effects of the propagation of sound waves with finite amplitude to build up highly directed sound sources is well known. In underwater acoustics, such parametric arrays are widely used. There are also attempts to build up parametric arrays in air to generate highly directed air-borne sound. To be able to use nonlinear effects in air as a carrier medium, one needs high amplitudes of the propagating sound wave. Consequently, a superposition of single sound sources (arrays) is often reported in the literature to increase the size, and so the directivity, of the sound source as well as the acheived sound pressure level. A major disadvantage of using arrays is the problem of slightly varying resonance frequencies and phase characteristics of the single source components as well as a complicated superposition of single directivity patterns. It is difficult to investigate basic properties of wave propagation and the nature of distortion in such a way. In this work, a single, high-power ultrasound transducer was used to radiate sound waves with finite amplitude, able to generate extraneous frequency components in air. Using only a single transducer, it was possible to investigate basic properties of nonlinear wave propagation in air.

10:45

5aPA13. Scale model experiments over curved rough surfaces. James Chambers and Andrew Whelan (Natl. Ctr. for Physical Acoust., The Univ. of Mississippi, 1 Coliseum Dr., University, MS 38677)

Previous research has indicated that the propagation of sound over a curved surface can be drastically altered by the presence of continuous small scale roughness that is smaller than the acoustic wavelength. This effect can alter sound levels in the shadow zone from +6 to −20 dB relative to levels past a similar smooth surface depending on the frequency of interest. These findings were originally observed for a single radius of curvature and a limited range of roughness sizes. The work has been revisited for a larger range of radii of curvature and roughness sizes with comparable results. The results for this problem as well as the related one of propagation in an upwardly refracting medium will be discussed. [Work supported by the Army Research Laboratory.]

5a SAT. AM

5aPA14. Low-frequency pulse propagation over irregular terrain.
Xiao Di and Kenneth E. Gilbert (Natl. Ctr. for Physical Acoust., Univ. of Mississippi, University, MS 38677)

The shape of a low-frequency pulse that propagates to the far side of a hill depends primarily on two physical mechanisms: a diffracted wave and a surface wave. Both of these mechanisms depend on frequency, so that the pulse shape and frequency spectrum of the received pulse differ significantly from those near the source. As is well known, diffraction acts like a low-pass filter. The surface wave has a more complicated frequency dependence that depends on the terrain, the frequency dependence of the ground impedance, and the near-ground sound speed profile. For a given range, these parameters determine a frequency band that contains most of the surface wave energy. The surface wave thus functions as a low-frequency bandpass filter. The combined effects of diffraction and surface wave propagation on pulse propagation over a hill are studied using a parabolic equation model and a piecewise linear mapping to flatten the irregular terrain. Numerical calculations are presented for selected terrain features, ground impedances, and sound speed profiles. [Research supported by the U.S. Army Armament, Research Development and Engineering Center (ARDEC).]

5aPA15. Proper orthogonal decomposition for sensitivity analysis and classification of outdoor sound propagation. Chris Pettit (Aerosp. Eng. Dept., U.S. Naval Acad., 590 Holloway Rd., MS 11-B, Annapolis, MD 21402, pettitcl@usna.edu) and D. Keith Wilson (U.S. Army Cold Regions Res. and Eng. Lab., Hanover, NH 03755)

Simulations of outdoor sound propagation are compromised by many sources of uncertainty and error. A key step in validating computational acoustics models, which may be interpreted as the act of assessing predictive skill, is estimating ensemble sound pressure variability due to uncertainties in the parameters that define the propagation conditions. This paper describes elementary steps toward achieving this goal. The atmospheric surface layer is represented through Monin-Obukhov similarity theory and the acoustic ground properties with a relaxation model. Randomness is assumed across appropriate ranges of the governing parameters. The parameters are modeled herein as independent random variables, but future efforts will extend this formulation to include random field models of the parameters with varying levels of correlation. Sound propagation is predicted with the parabolic equation method. Latin hypercube sampling (LHS) and proper orthogonal decomposition (POD) are employed to develop low-dimension representations, i.e., reduced order models, of the sound pressure random field. Sensitivity of the sound pressure field is studied via the model-induced sensitivity of the POD mode coefficients to the system parameters as well as statistical dependence on the number of LH samples. Attention is also given to connecting the POD coefficients to documented indicators of refraction conditions.

5aPA16. Analysis of the effect of small currents on ray stability and caustic formation in a layered moving fluid medium. David Bergman (Lockheed Martin Maritime Systems and Sensors, 199 Borton Landing Rd., Moorestown, NJ 08570)

In studies of underwater sound it is usually sufficient to treat the medium of propagation as a static inhomogeneous medium. Including current and time-dependent changes adds to the overall understanding of the behavior of sound in underwater environments. The quiescent medium approach combines the movement of the fluid with the local sound speed to create an effective sound speed profile. Recently it has been demonstrated that the effects of small-scale fluid motion on the propagation of sound in the ocean can be of the same order of magnitude as that of the static sound speed profile [J. A. Colosi, J. Acoust. Soc. Am. **119**, 705–708 (2006)]. The stability of the acoustic ray equation in a moving fluid medium depends on the first and second derivatives of the sound speed profile and fluid velocity [D. R. Bergman, Waves Random Complex Media **15**(4), 417–435 (2005)]. In this presentation the effects of weak but rapidly changing currents on the stability and intensity of the acoustic field are investigated for environments with low Mach number. The main result will show that in real underwater environments small currents cannot be ignored when modeling or analyzing the propagation of sound.

5aPA17. Complex drag coefficient and complex Nusselt number for oscillatory flow. Jin Liu (United Technologies Res. Ctr., East Hartford, CT 06108) and Steven L. Garrett (Penn State Univ., State College, PA 16804)

Characterizing and choosing the optimal porous material for efficient heat transfer while minimizing viscous loss is important for improving the efficiency of thermoacoustic machines. The pressure drop for oscillating flow through porous media has both a viscous (real) part and an inertial (imaginary) part, making the drag coefficient for oscillatory flow a complex number [J. Liu, J. Acoust. Soc. Am. **115**, 2380 (2004)]. Similarly, a phase difference exists between the oscillating pressure and the oscillating temperature. A complex Nusselt number is therefore required to characterize heat transfer for oscillating pressure. For the first time, the complex Nusselt number will be related to the thermoviscous f-function favored by thermoacousticians. This identification also allows the heat transfer coefficient for oscillating flow to be determined experimentally, at sufficiently low amplitudes, without requiring the measurement of temperatures or the use of heat exchangers. At low frequencies, the real part of the complex Nusselt number converges to the steady-state (dc) heat transfer coefficient. At high frequencies, it recovers the results published by other researchers interested in the behavior of heat exchangers used in oscillating flows. [Work supported by the ONR.]

5aPP1. The significance of relative loudness in listener identification of pipe organ stops. Alastair C. Disley and David M. Howard (Dept. of Electron., Univ. of York, Heslington, York, YO10 5DD, UK)

As part of a wider study of the factors affecting listener identification of pipe organ stops, the authors' previous research [A. C. Disley and D. M. Howard, "Onset transient significance in listener identification of pipe organ stops," J. Acoust. Soc. Am. **119**, 3333, abstract only (2006)] has suggested that the relative loudness of a stop as presented to a listener may have a significant effect on its identification. Recordings of a representative selection of pipe organ stops were played to a group of 43 organists in a formal listening test. Each stop was presented twice, once at its original amplitude and once at an increased amplitude equal for all stops. Listeners were asked to classify each example using nine general categories of organ stops. The results suggest that increased amplitude improves listener recognition for some stops (particularly open flute stops), but produces significant misidentification of other stops, especially those with the greatest difference between the original and increased amplitude. These results suggest that caution should be employed when considering equalizing sample amplitudes in similar listening experiments.

9:05

5aPP3. Remembering what's missing: Modeling phoneme restoration and other complex forms of auditory induction as the triggering of a memory. Justin Aronoff (Neurosci. Program, Univ. of Southern California, HNB 27, Los Angeles, CA 90089, aronoff@usc.edu)

Although phoneme restoration is often spoken about and modeled as a unique phenomenon specific to language, the effect is very similar to restoration effects found with well-learned musical melodies. This suggests that both of these effects may be the result of a natural characteristic of learned temporal patterns, rather than a special mechanism. A recurrent connectionist network was designed to test this hypothesis. The network contained ten input and output nodes, which represented notes in a melody. The model was trained on sets of simple melodies, each consisting of eight randomly selected sequential notes. To test that the model was learning and identifying the melodies, the network was trained to predict the next note in the tune, which could only be accomplished by maintaining a representation of the sequence of prior notes. After the network learned the melodies, the fourth sequential note in each tune was removed and replaced by activation across all the input nodes, simulating noise. The model demonstrated accurate restoration, performing significantly better than chance, both at the noise position and over the notes that followed, suggesting that sequence learning may be sufficient to explain phoneme restoration and other forms of complex auditory induction.

8:50

5aPP2. Influence of attack transient and decay times of percussive sounds on the echo threshold. Hari V. Savitala and Jonas Braasch (Rensselaer Polytechnic Inst., 110 8th St., Troy, NY 12180, hari.savitala@gmail.com)

The human ability to localize a direct sound source in the presence of reflected sounds is well known as the precedence effect. The echo threshold defines the time delay of the reflection, above which the reflection becomes audible as a separate event. For musical instruments, various attack transient and decay times affect the echo threshold, but often a constant echo threshold of 50 ms is assumed for music. The aim of this study is to determine in more detail how the parameters of a test sound affect the echo threshold. For this purpose, 12 adult listeners with normal hearing participated in a psychoacoustic experiment to determine the echo threshold for various percussive and nonpercussive instrument sounds. In the headphone-based experiment, the lead was placed with an interaural time difference (ITD) of ± 300 μs, while the lag was presented from the opposite side. Interstimulus interval (ISI) values of 0, 1, 2, 5, 10, 25, 50, and 100 ms were tested. The results of the experiment showed a large variation of the echo threshold. The smallest value of 7.50 ms was found for the castanet and the largest of 75.00 ms for a free-reed organ pipe.

9:20

5aPP4. Auditory priming releases Chinese speech from informational masking. Zhigang Yang, Jing Chen, Xihong Wu, Yanhong Wu (Dept. of Psych., Natl. Key Lab. on Machine Percept., Peking Univ., Beijing, China, 100871), Bruce Schneider, and Liang Li (Univ. of Toronto at Mississauga, Mississauga, ON, Canada L5L 1C6)

Before an English speech sentence is presented, hearing or reading the sentence without the last key word improves recognition of the last key word if the full-length speech sentence is presented under speech masking but not under noise masking. This phenomenon suggests a content priming effect on releasing speech from informational masking. To determine whether the priming effect extends to tonal Chinese speech, and, in particular, whether it can be induced by the target talkers voice, in the present study, listeners were presented with either same-voice/different-sentence primes or same-voice/same-sentence primes before hearing the target sentence in either two-talker-speech masking or noise masking. Under speech masking, each of the two prime types significantly improved recognition of the last key word in the full-length target sentence, but the content priming is stronger than the voice priming. Under noise masking, same-voice/same-sentence primes had a weak but significant priming effect, but same-voice/different-sentence primes had only a negligible priming effect. These results suggest that both content and voice cues can be used by listeners to release Chinese speech from informational masking, but only

content cues are useful for releasing Chinese speech from energetic masking. [Work supported by China NSF and Canadian IHR.]

5aPP5. Auditory memory for frequency in sequential interference. Jeffrey J. DiGiovanni and Dennis T. Ries (School of Hearing Speech and Lang. Sci., Ohio Univ., Athens, OH 45701)

Percepts within working memory are weakened by the presence of intervening stimuli that lie along the same perceptual dimension. To this end, the effect of sequential interference on the storage of frequency information within auditory working memory was measured. The difference limen for frequency was measured by the method of constant stimuli for two diotic and two dichotic conditions. The first diotic condition served as a control and consisted of two 300-ms stimuli separated by 5 s. The frequency of the referent (first tone) was roved over a 100-Hz range centered at 435 Hz. Listeners indicated whether the target (second tone) was higher or lower in frequency than the referent. The second diotic condition added four interfering tones between the referent and the target. In the third condition, the interferers and referent/target pair were lateralized to opposite ears via the Stenger effect. In condition four, the phase of the interferers differed between ears by 180 deg. Results indicate (1) the addition of interferers increased the difference limen for frequency, and (2) when the interferer and target/referent pair differed along a single localization dimension, the effect of the interferers was reduced.

5aPP6. Speech recognition in coherently-amplitude modulated noise. Imran Dhamani, K. Naveen, and B. Rajashekhar (Dept. of Speech and Hearing, MCOAHS, MAHE, Manipal, Karnataka, India, imrandhamani@yahoo.co.in)

Comodulation masking release is a phenomenon that improves the detectability of a masked pure tone or speech signal by addition of a coherently amplitude-modulated energy above and/or the signal frequency. The majority of the studies done on comodulation masking release have studied threshold detection for a pure tone, or speech identification at or near threshold levels with a favorable signal-to-noise ratio. Moreover, various studies examining comodulation masking release under conditions of reduced frequency selectivity in listeners with cochlear hearing impairment indicate absence or reduced comodulation of masking release effect (Hall et al., 1984; Hall and Grose, 1985; Moore et al., 1993). In the current study, the speech recognition task was studied for the CMR effect at supra-threshold level and unfavorable signal-to-noise ratio of -10 dB. Results indicated absent CMR effect at supra-threshold level for the word recognition task for normal-hearing individuals.

5aPP7. Modulation detection thresholds for cochlear implants: Dependence on stimulation site and stimulus level. Bryan E. Pfingst, Rose A. Burkholder, Catherine S. Thompson (Kresge Hearing Res. Inst., Dept. of Otolaryngol., Univ. of Michigan, Ann Arbor, MI 48109-0506, bpfingst@umich.edu), and Li Xu (Ohio Univ., Athens, OH 45701)

Amplitude modulation of pulse trains is the strategy of choice for transmission of temporal-envelope information in most modern auditory prostheses. Previous studies by Fu, Colletti, and Shannon have shown high negative correlations between modulation detection thresholds (MDTs) (measured at only one site in the electrode array) and speech recognition with cochlear or brainstem auditory prostheses. The objective of this study was to characterize MDTs across the parameter space used in cochlear prosthesis speech processors: all usable stimulation sites at multiple stimulus levels. Across-site patterns of MDTs varied considerably from subject to subject. In general, sites with the poorest MDTs were located in the basal third of the scala-tympani electrode array, but this pattern did not hold for all subjects or all stimulus conditions. The mean MDT for two levels (30% and 70% of dynamic range) was highly correlated with the

mean for five levels. Mean MDTs at these two levels averaged over four adjacent electrodes in any of five segments of the electrode array were negatively correlated with speech recognition scores. This study suggests that in order to adequately characterize a subject's modulation detection acuity, it is necessary to sample MDTs at multiple sites and levels. [Work supported by NIH/NIDCD.]

5aPP8. Lateralization of sine tones—Interaural time versus interaural phase. Peter X. Zhang and William M. Hartmann (Dept. of Phys. and Astron., Michigan State Univ., 4230 BPS Bldg., East Lansing, MI 48824)

Five listeners estimated the lateral positions of 50 sine tones in a headphone experiment designed to determine whether the human sense of sound location correlates better with the interaural phase difference (IPD) or the interaural time difference (ITD). In any experimental block the IPD values ranged from -150 to $+150$ degrees, and the frequencies were chosen such that the ITDs ranged from -1000 to $+1000$ microseconds. The frequencies were all in the range where human listeners are known to be able to lateralize tones based on the ITD in the waveform fine structure. It was found that the lateralization responses correlated with the ITD much better than with the IPD. The average variance was five times smaller for the ITD hypothesis compared to the IPD hypothesis, and only the ITD hypothesis led to a well-fitting (compressive) function. For the ITD function, individual compressive exponents varied considerably and averaged 0.75. For the IPD function the exponents were too small to be meaningful. Comparison with previous lateralization studies indicates the importance of presenting the entire range of stimulus parameters in all experimental blocks because it appears that listeners tend to use the entire range of allowable responses in any block. [Work supported by the NIDCD.]

5aPP9. Influence of visual stimuli in the sound quality evaluation of loudspeaker systems. Alex Karandreas and Flemming Christensen (Sound Quality Res. Unit, Dept. of Acoust., Aalborg Univ., Fredrik Bajers Vej 7 B5, DK-9220 Aalborg, Denmark)

There is currently an increasing demand to evaluate sound quality attributes of products and to understand to what extent they influence a user's overall impression, since there is usually more than one modality stimulating this evaluation. The present study uses loudspeakers as an example and evaluates the overall impression in relation to hearing and vision. In order to quantify the bias that the image of a loudspeaker has on the sound quality evaluation done by a naive listening panel, loudspeaker sounds of varied degradation are coupled with positively or negatively biasing visual input of real loudspeakers, and in a separate experiment by pictures of the same loudspeakers. In order to choose loudspeakers that provide a sufficient range of visual bias a preliminary visual-only experiment has been conducted. From the ongoing experiments it is possible to evaluate how much the auditory perception of a loudspeaker can be biased from visual input and study how the two modalities interact. Results from the experiments are presented.

5aPP10. Head-related transfer functions via the fast multipole accelerated boundary element method. Nail A. Gumerov, Ramani Duraiswami, and Dmitry N. Zotkin (Perceptual Interfaces and Reality Lab., Inst. for Adv. Comput. Studies, Univ. of Maryland, College Park, MD 20742)

Computation of head-related transfer functions (HRTF) via geometrical meshes and numerical methods has been suggested by a number of authors. An issue facing this approach is the large computational time needed for high frequencies, where the discretization must include hundreds of thousands of elements. Conventional computational methods are unable to achieve such computations without excessive time or memory. We use a newly developed fast multipole accelerated boundary element

method (FMM/BEM) that scales linearly both in time and memory. The method is applied to the mesh of the widely used KEMAR manikin and its HRTF computed up to 20 kHz. The results are compared with available experimental measurements.

11:20

5aPP11. Perceptual measurement of sound level differences between TV programs and advertisements. Eiichi Miyasaka (Musashi Inst. of Technol., 3-3-1, Ushikubo-Nishi, Tsuzuki-ku, Yokohama, Japan) and Takahiro Kamada (Pioneer Co., Tsurugashima, Saitama, Japan)

In order to investigate loudness difference between TV program materials and advertisements (CMs) inserted in the materials, sound levels of CMs broadcast in five terrestrial broadcasting stations throughout a day were quantitatively measured and a perceptual experiment was performed. The averaged sound levels (ASLs) and the standard deviations (SDs) of 4262 CMs were concentrated on -7 dB and 5 dB, respectively. Next, three types of CMs with different ASLs and SDs were used to the perceptual experiment. These ASLs and SDs were (-5.1 and 1.8 dB for CM-1), (-7.1 and 4.9 dB for CM-2), (-14.2 and 10.1 dB for CM-3), respectively. The reference sound as a main program material was speech uttered by a NHK female announcer with duration of 10 s. The ASL and the SD were -6.5 and 10.1 dB, respectively. The transformed up-down method was used for 12 observers with normal hearing. The results show that all CMs were perceived at least 3 to 5 dB louder than the reference for a half of the observers. These results show that there is large perceptual discrepancy between CMs and the main program materials. [Work supported by The Okawa Foundation.]

5aSA1. Recent developments and applications of energy finite- element analysis. Kuangcheng Wu (Dept. of Signatures and Hydrodynamics, Northrop Grumman Newport News, Newport News, VA 23607) and Nickolas Vlahopoulos (Univ. of Michigan, Ann Arbor, MI 48109)

The energy finite-element analysis (EFEA) comprises a finite-element-based solution for vibration and acoustic modeling that uses energy-based variables for formulating the governing differential equations. This presentation covers the main points in the derivation of energy finite-element analysis (EFEA), validation through comparison with test data, and case studies that demonstrate the computational capabilities of the EFEA. The EFEA can be applied in various engineering disciplines as it will be demonstrated by the case studies. Thus, it comprises a general purpose simulation method for vibration and acoustic analysis of complex systems. [Work support for this research is provided by ONR code 331.]

8:50

5aSA2. Fast finite-element analysis for damping of automotive structures having elastic bodies, viscoelastic bodies, porous media, and gas. Takao Yamaguchi (Dept. of Mech. System Eng., Gunma Univ., 1-5-1 Tenjin-cho, Kiryu, Gunma 376-8515, Japan) and Yoshio Kurosawa (Fuji Heavy Industries, ltd., Sano-shi, Gunma, 327-0512 Japan)

A numerical method is proposed to calculate damping properties for automotive soundproof structures involving solid bodies, porous media, and air in two-dimensional regions. Both effective density and bulk modulus have a complex quantity to represent damped sound fields in the porous media. Particle displacements in the media are discretized using a finite-element method. For damped solid bodies, displacements are formulated using conventional finite elements including complex modulus of elasticity. Displacement vectors as common unknown variables are solved under coupled condition between solid bodies, porous media, and gas. Further, by applying an asymptotic method to a complex eigenvalue problem, explicit expressions of modal loss factor for the mixed structures are derived. The proposed methods yield appropriate results for some typical problems and this method diminishes computational time for large-scaled finite-element models. Moreover, it is found that damping can be coupled in the mixed structures. An expression to calculate a share of dissipated energy for each element in mixed structures is also derived. Damping behaviors in sound bridge phenomena are analyzed using the proposed method.

5a SAT. AM

5aSA3. Vibro-acoustic analysis using hybrid finite element, boundary element, and statistical energy analysis models. Phil Shorter and Vincent Cotoni (ESI US R&D, 12555 High Bluff Dr., Ste. 250, San Diego, CA 92130, pjs@esi-group-na.com)

This paper presents an overview of the theory and application of the hybrid FE-SEA method. The method provides a rigorous way to model the fully coupled response of a vibro-acoustic system across a broad frequency range using a combination of FE, BEM, and SEA. The theory of the method will be discussed and results from the following applications will be presented: (i) modeling the transmission loss and radiation efficiency of trimmed automotive subassemblies; (ii) creating efficient models of structure-borne noise in an automotive body-in-white; (iii) modeling structure-borne noise transmission in a commercial aircraft fuselage; and (iv) modeling the response of a satellite antenna to broadband acoustic loading.

9:30

5aSA4. Simulation of borehole acoustic measurements with adaptive finite elements for the accurate and efficient assessment of rock formation properties. Christian Michler, Leszek Demkowicz, and Carlos Torres-Verdin (Inst. for Comput. Eng. and Sci., Univ. of Texas, 201 East 24th St., Austin, TX 78712, c.michler@ices.utexas.edu)

Borehole acoustic measurements are routinely used to probe *in situ* properties of rock formations. The numerical simulation of such measurements involves numerous outstanding challenges, such as the modeling of large spatial variations of rock porosity and anisotropy, material diffractions, source-sensor effects, and the need for a reflectionless truncation of the computational domain. To simulate borehole acoustic measurements, a new axisymmetric finite-element formulation in the frequency domain has been developed and successfully tested. The formulation couples acoustic phenomena within the fluid-filled borehole with elasticity in both the probed rock formations and the measurement tool. One of the central components of our formulation is the automatic adaptivity of element size and approximation order of the finite-element spatial discretization. No user interaction is necessary to control the adaptivity. Such a formulation enables accurate simulation results in the presence of large contrasts of material properties. A novel combination of the perfectly matched layer enhanced with finite-element adaptivity effectively truncates the computational domain. Several challenging benchmark problems are presented that confirm the accuracy, reliability, and efficiency of our method to reproduce complex waveforms excited by monopole and dipole sources in a fluid-filled borehole that penetrates layered media.

9:45

5aSA5. Perfectly matched layers for the numerical approximation of the radiation boundary condition in structural acoustic finite element tools. Mario Zampolli, Alessandra Tesei, Finn B. Jensen (NATO Undersea Res. Ctr., La Spezia, Italy), and John B. BlottmanIII (Naval Undersea Warfare Ctr., Newport, RI 02841)

The Berenger perfectly matched layer (PML) is one of a variety of numerical techniques for approximating the Sommerfeld radiation boundary condition. In acoustics, the PML is a nonphysical finite thickness layer of fluid or solid material that surrounds the physical computational domain of interest and acts as an anisotropic absorber of the outgoing waves. The absorption coefficients in the PML are such that the acoustic energy is dissipated selectively only in the direction perpendicular to the interface between the PML and the physical domain. The study presented here shows that the appropriate choice of PML absorbing functions can have a beneficial effect on the convergence of frequency domain acoustic finite-element tools. In the context of elastic target scattering computations, it is shown how the PML can be applied in direct contact with the wet surface of convex elastic targets. Other examples from low-frequency geoacoustic benchmarking applications demonstrate the adaptability of the PML to a variety of geometries and to problems where the radiation condition must be imposed across inhomogenous layers. The numerical results obtained with the finite-element/PML tool are compared to results from finite-element/infinite-element codes and to results from parabolic equation models.

5aSA6. Reconstruction of vibro-acoustic response of a plate using Helmholtz equation least-squares method. Huancai Lu and Sean F. Wu (Mech. Eng. Dept., Wayne State Univ., 5050 Anthony Wayne Dr., Detroit, MI 48202, huancai.lu@gmail.com)

A numerical investigation of reconstructing the vibro-acoustic responses of an arbitrary structure subject to vibration excitations based on the Helmholtz equation least-squares (HELS) method is presented. It is emphasized that in many engineering applications, the exact solution to a general vibrating structure does not exist, and the HELS method is one way of getting approximate solutions in a cost-effective manner. In this study, the test object is a simply supported, unbaffled thin plate. The reason for selecting this simply supported plate is that the analytic solutions to the plate vibrations are readily available. The field acoustic pressures generated by the Rayleigh integral are taken as input to HELS algorithms to reconstruct the normal velocity and normal acoustic intensity on the plate surface using Tikhonov regularization associated with generalized cross-validation methods. The reconstructed normal surface velocities are compared with the benchmark values, and the out-of-plane vibration patterns at the first five natural frequencies are compared with natural modes of the simply supported plate. The effects of measurement aperture, stand-off distance, and location of the origin of the coordinate system on the resultant accuracy of reconstruction are examined. [Work supported by NSF.]

10:30

5aSA7. Application of the short-time Fourier transform and the two-dimensional Fourier transforms to detect damage in plates. Jamal Assaad, Faysal El Youbi, Sebastien Grondel, and Emmanuel Moulin (IEMN-DOAE, 59313 Valenciennes, cedex 9, France)

Lamb waves are widely used in the fields of characterization and non-destructive testing of structures. Usually, the full characterization of the structures requires two kinds of information: the first one is related to the material quality, the other one aims at the evaluation of the structure health, i.e., the detection of localized damage or defects. Time-frequency analyses or two-dimensional Fourier transforms (2DFT) have been used separately to solve such a problem. The purpose in this work is therefore to present a dual signal processing approach based on the relationship between the STFT (short-time Fourier transform) and the 2DFT amplitudes that allows a better interpretation and identification of Lamb modes. This relationship will be numerically verified by a two-dimensional finite-element method. Experimentally, a 3-mm-thick aluminum plate with an emitter and a receiver are considered. The emitter consists of two piezo-electric transducers while the receiver consists of a 32 multi-electrode piezoelectric transducer. This receiver has been developed especially to increase signal-to-noise ratio at the reception. In order to simulate damages a hole with different diameter was introduced in the plate center. The application of this dual signal processing has located conversion modes phenomenon.

10:45

5aSA8. Sound radiation from finite plates excited by a space-time stream of random impulses. Katsuji Akamatsu (Machinery Acoust., 1-1-2-314 Obanoyama Shinohara, Nada-ku, Kobe 657-0015, Japan, akamatsu@s4.dion.ne.jp), Takao Yamaguchi (Gunma Univ., Kiryu 376-8515, Japan), and Junichi Kanazawa (Musashino Damping Technol., Tachikawa 190-0002, Japan)

Sound radiation from baffled finite elastic plates that are subjected to impulses occurring at random points on the surface, at random intervals, and with random strength is analyzed. The plate response is obtained in the Stieltjes integral form of the plate impulse response function with respect to the occurrence of impulses. The total sound power radiated from the plate is formulated according to Heckl's approach. Explicit expressions for the expected value of the plate response and the radiated sound power are derived for the case in which the stream of impulses is uncorrelated. An approximate solution for the radiated sound power is obtained by assuming light damping of plates and by neglecting modal coupling effects. For comparison, the exact and approximate solutions are evaluated numerically for a plate with constant loss factors. The analysis is applied to the prediction of rainfall noise by expressing the expected value of the exciting force in terms of the size of raindrops, their terminal velocity, and the rainfall rate.

11:00

5aSA9. Dynamic analysis of shuttle bus generated vibration in an airport rental car center with an elevated roadway. James Phillips (Wilson, Ihrig & Assoc., 5776 Broadway, Oakland, CA 94618, jphillips@wiai.com)

A finite-element analysis (FEA) model was developed for a new rental car center at an international airport in the United States. Incorporated into the structure was an elevated roadway for shuttle buses transporting rental car customers. Of concern was possible vibration transmitted into occupied portions of the structure from shuttle buses. Measurements were conducted on an existing elevated roadway at the airport in order to determine dynamic force inputs to be applied in the FEA model developed to predict the vibration response inside the rental car center. Impulse response measurements were conducted and then the vibration response of the roadway was measured during shuttle bus passbys. The results of these tests were used to derive the dynamic forces generated by the moving buses on the structure. A finite-element analysis (FEA) model of the elevated roadway was also developed. This model was used to verify the derived dynamic force levels and to verify the modeling approach applied to the rental car center.

11:15

5aSA10. Parametric relations for porous foams and their use in optimization of structural acoustic performance of multilayer trim components. Eleonora Lind and Peter Goransson (KTH Aeronautical and Vehicle Eng., MWL, SE-10044 Stockholm, Sweden, eleonora@kth.se)

Lightweight porous acoustic multilayer trim components have traditionally been specified in terms of sound absorption and sound transmission loss performance targets. Importantly, the material specification of the trim component developed only for absorption and sound transmission loss may be suboptimal in terms of, e.g., sound radiation behavior. This highlights the necessity for accurate, computationally efficient, and robust simulation method, which should form an integral part of a multidisciplinary optimization tool. In addition, for such optimization to be physically meaningful the design parameters used should be based on relations between microstructural dimensions and properties, and the corresponding macroscopic parameters describing porous materials. This paper discusses recent results from research focused on the parametrization of porous foams, i.e., continuous links between micro-dimensions, elasticity, density, and flow resistivity, used in higher order 3-D finite element simulations of multilayer components for structural-acoustic applications. In addition to the microdimensions, also the thicknesses of individual layers have been used as design parameters, with the overall weight as the design objective. Acoustic and vibration targets, velocity of the radiating surface, radiation efficiency, transmission, etc., as well as upper and lower bounds of the microdimensions, have been used as constraints.

5aSCa1. Making young ears old and old ears even older: Simulating a loss of synchrony. Ewen MacDonald, Kathy Pichora-Fuller, Bruce Schneider, and Willy Wong (Univ. of Toronto, Toronto, ON Canada M5S 3G9)

Age-related changes in the auditory system have been attributed to three independent factors: OHC damage, changes in endocochlear potentials, and loss of neural synchrony. In previous studies, a jitter algorithm has been used to simulate the loss of synchrony in young adults (Mac-Donald *et al.*, 2005). In this study, the effect of jitter on old adults with good audiograms in the speech range is explored. SPIN-R sentences were presented in two SNR and three processing conditions: intact, jitter, and smear. The parameters of the jittering algorithm were the same as those used with young adults. The parameters of smearing algorithm were chosen to match the spectral distortion produced by jitter algorithm. While both the jitter and smear conditions resulted in a significant decline in word identification, the decline was largest in the jitter condition. Psychometric functions were fitted to the data and compared to previous work with young adults. The comparison supports the hypothesis that loss of synchrony can adversely affect speech intelligibility in noise, and is consistent with the hypothesis that loss of synchrony occurs with age. As well, the comparison suggests that the effect of jitter may be linear.

5aSCa2. Adult age differences in the use of envelope cues to identify noise-vocoded words with a varying number of frequency bands. Signy Sheldon, Kathy Pichora-Fuller, and Bruce Schneider (Univ. of Toronto at Mississauga, Rm. CCIT 4163, 3559 Mississauga Rd., Mississauga, ON, L5L1C6, Canada, signy.sheldon@utoronto.ca)

Older adults with good audiograms have difficulty understanding speech in noise. Age-related differences have been found on some temporal processing measures such as gap detection; however, older adults are believed to have well-preserved ability to use envelope cues to identify words. Following Shannon *et al.* (1995), we used noise-vocoded speech such that the amplitude envelope of speech was retained in frequency bands but filled with noise, thereby obliterating fine structure cues within each band. In experiment 1, younger and older listeners heard a list of words. Each word was presented first with one vocoded frequency band, and the number of bands was incremented until the listener correctly identified the word. The average number of bands required for correct identification was found to be identical for both age groups. In experiment 2, both age groups identified words in four blocked noise-vocoded conditions (16, 8, 4, and 2 bands). Younger adults outperformed older adults. Al-

though older adults were as able as younger adults to use envelope cues cumulatively in experiment 1, they were less able to use these cues without the benefit of repetition.

5aSCa3. Audiovisual perception of voicing with age in quiet and cafe noise. Dawn Behne (Dept. of Psych., Norwegian Univ. of Sci. and Technol., 7491 Trondheim, Norway), Yue Wang (Simon Fraser Univ., Burnaby, BC V5A 1S6, Canada), Magnus Alm, Ingrid Arntsen, Ragnhild Eg, and Ane Valsø (Norwegian Univ. of Sci. and Technol., 7491 Trondheim, Norway)

Research has shown that voicing is difficult to discern in noisy environments. While voicing may be difficult to resolve from visual cues, acoustic cues for voicing are relatively robust. This study addresses these factors with normally aging audiovisual perception. Identification responses were gathered with 19–30-year-old and 49–60-year-old adults for audiovisual (AV) CVs differing in voicing and consonant place of articulation. Materials were presented in quiet and in cafe noise (SNR=0 dB) as audio-only (A), visual-only (V), congruent AV, and incongruent AV. Results show a tendency toward use of visual information with age and noise for consonant place of articulation. Notably for voicing, incongruent AV materials that had one voiced component, regardless if it was A or V that was voiced, were consistently perceived as voiced in both age groups and regardless of noise. Only if the A and V components were both voiceless was the syllable perceived as voiceless. These findings indicate the influence of age and noise in the use of perceptual information to identify place of articulation. That voicing is robustly salient from either audio or visual information, despite the unlikely presence of strong visual cues for voicing, indicates a possible bias toward the perception of voicing.

5aSCa4. Energy suppression of steady-state portions of vowels while maintaining the energy of consonants better improves speech intelligibility for elderly listeners in reverberation. Yusuke Miyauchi and Takayuki Arai (Dept. of Elec. and Electron. Eng., Sophia Univ., 7-1 Kioi-cho, Chiyoda-ku, Tokyo 102-8554 Japan, m-yuusuk@sophia.ac.jp)

In a reverberant environment, overlap-masking renders speech perception difficult. Arai itet al. proposed that energy suppression of steady-state portions of speech improves speech intelligibility with young subjects [Acoust. Sci. Technol. 23, 229–232 (2002)]. Audibility degrades with age. Therefore, reverberation can be a more critical barrier to speech perception by elderly listeners. To investigate the effect of suppressing reverberation for elderly people, a listening test was conducted with 25 elderly

3346   J. Acoust. Soc. Am., Vol. 120, No. 5, Pt. 2, November 2006

Fourth Joint Meeting: ASA and ASJ   **3346**

subjects (mean age: 73.3 years) using the following three types of speech: (a) speech without energy suppression of steady-state portion, (b) speech with the suppression of steady-state portions of speech, and (c) speech with the suppression only of vowels, while maintaining the energy of consonants. As expected, speech intelligibility by method (b) (46.7%) was markedly improved from (a) (42.2%), but method (c) (52.0%) improved it more. Because the energy of consonants is less than that of vowels, overlap-masking attendant on previous vowels would largely affect perception of subsequent consonants. These results suggest that suppressing the steady-state portions of vowels while maintaining the energy of consonants serves elderly persons well to improve speech intelligibility in a reverberant environment. [Work supported by JSPS.KAKENHI (16203041).]

5aSCa5. Older adult's identification and memory of synthetic and natural speech in noise. Candice Q. McCarty and Aimee Surprenant (Purdue Univ., 703 Third St., West Lafayette, IN 47907)

This research tested older adult's performance on identification and recall when presented sentences taken from the Speech Perception in Noise Test [Bilger *et al.*, J. Speech Hear. Res. **27**, 32–48 (1984)] synthesized using AT&T Natural Voices speech synthesizer. Performance on synthesized speech was compared to identification and recall of natural speech in noise. In experiment 1, participants were instructed to identify the final word of high- and low- predictability natural and synthesized sentences presented at three signal-to-noise ratios. The results showed that natural speech was easier to identify than synthesized speech at every speech-to-noise ratio for high and low predictability sentences. In addition, replicating Pichora-Fuller *et al.* [J. Acoust. Soc. Am. **97**, 593–608 (1995)], pure tone thresholds were significantly correlated with identification performance for both natural and synthetic speech. In experiment 2, participants were given a sentence span task in which they were presented two to five natural and synthesized sentences and asked to recall the final words. These experiments show that, even with high context, synthetic speech is more difficult to understand and remember than natural speech. These results highlight concerns about the use of synthesized speech in assistive devices, particularly for elderly listeners. [Work supported by NIH.]

5aSCa6. Spectral shape discrimination and speech identification in noise in elderly hearing-impaired listeners. Mini Shrivastav (Dept. of Commun. Sci. and Disord., Univ. of Florida, 336 Dauer Hall, Gainesville, FL 32611)

Elderly hearing-impaired listeners have difficulties in the recognition and discrimination of consonants, particularly those that share the same manner of articulation. An important cue that distinguishes the manner of articulation of these consonants is spectral shape. A previous study (Shrivastav *et al.*, 2006) found a moderate predictive relation between spectral-shape discrimination thresholds and syllable identification scores of elderly hearing-impaired listeners, when all stimuli were presented in quiet. The present study examined the contribution of spectral-shape discrimination abilities to speech-identification performance of elderly hearing-impaired listeners in the presence of background noise. The study included a group of elderly hearing-impaired listeners, with a group of young normal-hearing adults included for comparison purposes. Listeners were tested on a series of speech-identification and spectral-shape discrimination tasks, while ensuring that all stimuli were at least minimally audible to all the hearing-impaired listeners. The contribution of spectral-shape discrimination abilities to speech-identification performance in background noise was examined and compared to the results in quiet for young normal-hearing and older hearing-impaired listeners.

5aSCa7. The use of subsegmental information in sentence comprehension with or without formant transitions by normal-hearing and hearing-impaired listeners. Jae Hee Lee and Diane Kewley-Port (Dept. of Speech and Hearing Sci., 200 S. Jordan Ave., Bloomington, IN, 47405, jaejalee@indiana.edu)

Using a noise replacement paradigm, Lee and Kewley-Port [J. Acoust. Soc. Am., **119**, (2006)] examined sentence comprehension by young normal-hearing (YNH) and elderly hearing-impaired (EHI) listeners when sentences were processed to present only subsegmental information (i.e., either steady-state or formant transitions) in sentences processed in four different ways. Results showed that correct word responses by EHI listeners were more affected by the type of information in the four conditions compared to YNH listeners. To compare the use of subsegmental information between listener groups who were carefully matched for audibility and age, new analyses of correctly identified phonemes and different word-error patterns were made for both correct and incorrect word responses. Correlation analyses examined the relations among correct and incorrect word responses, phoneme scoring, hearing thresholds, and age. Despite a larger number of incorrect answers by EHI listeners, word-error patterns, as well as an ability to extract phonemes using subsegmental information, were similar between YNH and EHI listeners. Analyses for EHI listeners showed correct word responses were strongly correlated with correct phoneme identification and with hearing thresholds, but not with age. [Work supported by NIHDCD-02229.]

5aSCa8. Auditory-visual integration and lipreading abilities of older adults with normal and impaired hearing. Mitchell S. Sommers (Dept. of Psych., Washington Univ., Campus Box 1125, St. Louis, MO 63130, msommers@wustl.edu), Nancy Tye-Murray, and Brent Spehar (Washington Univ. School of Medicine, St. Louis, MO 63130)

The current study investigated how age-related hearing impairment affects lipreading and auditory-visual integration in older (above age 65) individuals. The performance of 53 normal-hearing and 24 mild-to-moderate hearing-impaired older adults was compared on auditory-only (A), visual-only (V), and auditory-visual (AV) speech perception, using consonants, words, and sentences as stimuli. All testing was conducted in the presence of individually specified multi-talker background babble, to obtain approximately equivalent A-only performance across the groups. In addition, we compared normal-hearing and hearing-impaired individuals on measures of auditory enhancement, visual enhancement, and auditory visual integration that were derived from the A, V, and AV performance scores. In general, normal-hearing and hearing-impaired older adults performed similarly on measures of visual-only and auditory-visual speech perception. The one exception to this finding was that hearing-impaired adults performed significantly better than normal-hearing participants on visual-only identification of words. Measures of visual enhancement, auditory enhancement, and auditory-visual integration did not differ as a function of hearing status. Overall, the results of the current study suggest that despite increased reliance on visual speech information, hearing-impaired older adults do not exhibit better visual-only speech perception or auditory-visual integration than age-matched normal-hearing individuals.

5aSCa9. Effects of intermodal timing difference and speed difference on auditory-visual speech perception. Akihiro Tanaka (Dept. of Psych., Univ. of Tokyo, 7-3-1 Hongo, Bunkyo-ku, 113-0033 Tokyo, Japan, tanaka@L.u-tokyo.ac.jp), Shuichi Sakamoto, Komi Tsumura, and Yo-iti Suzuki (Tohoku Univ., Sendai 980-8577, Japan)

Previous studies have shown that lipreaders possess insufficient sensitivity to intermodal timing differences and adapt to the timing difference when it is kept constant. This study investigated effects of intermodal timing differences and speed differences on auditory-visual speech perception. We used 20 minimal pairs of Japanese four-mora words such as *mizuage* (catch landing) versus *mizuame* (starch syrup). We administered intelligibility tests to younger and older adults. Words were presented

under visual-only, auditory-only, and auditory-visual (AV) conditions. Effects of AV asynchrony by time-expanded speech (speed difference) on AV benefit (i.e., the superiority of AV performance over auditory-only performance) were compared with those by intermodal timing shift (timing difference). Results showed that the AV benefit declined as the timing difference and speed difference increased. Results also revealed that younger adults adapted to the timing difference but did not adapt to the speed difference. Older adults adapted neither to the timing difference nor to the speed difference. These results suggest that intermodal lag adaptation in younger adults requires a constant timing difference between a talker's moving image and voice. These results might be useful for design of a multimodal speech-rate conversion system.

5aSCa10. Description of mouth shapes used in traditional Japanese sign language by comparison to those of speech utterance. Yumiko Fukuda (Natl. Rehabilitation Ctr. for the Disabled, Tokorozawa, Japan, fukuda@rehab.go.jp) and Shizuo Hiki (Waseda Univ., Tokorozawa, Japan)

Mouth shapes used in traditional Japanese sign language were described systematically through comparison to those in uttered speech. A framework of mouth shape descriptions that had been proposed by the present authors included (1) projection of mouth shapes of Japanese vowels and semi-vowels to the lip articulation plane of the three-dimensional IPA vowel chart and (2) grouping of discriminating consonants in lip-reading on the IPA articulation matrix. It was transferred to a coordinate consisting of contractions of muscles involved in mouth movement. In traditional Japanese sign language, the mouth shape, when added as a part of facial expression, modifies meaning of the word conveyed by a hand gesture. Those mouth shapes were extracted from conversations among native signers and were symbolized by their respective degrees of closing, rounding, and pulling corners, and by categories borrowed from Japanese vowels and some consonants. Using the extended framework, those mouth shapes that were elected for visual discrimination ranged more widely than those elected to discriminate phonemes aurally. Video pictures were retrieved according to their symbols from an electronic dictionary of 250 basic sign words and 1500 exemplary sentences of their meanings, as edited by the Japanese sign language research group, NRCD.

5aSCa11. Audiovisual speech integration in children with autism spectrum disorders. Julia R. Irwin (Haskins Labs., 300 George St., New Haven, CT 06511)

Children with autism spectrum disorder (ASD) appear to be less influenced by visual speech information than typically developing children, as measured by their responses to mismatching auditory and visual (McGurk) stimuli. This study examined whether this reduction in sensitivity to the McGurk effect is due to eye gaze aversion, a hallmark of ASD. Children with ASD and typically developing controls (TD) were presented with videotaped consonant-vowel (CV) stimuli. Stimuli were digitally edited to create either an audiovisual (AV) match (AV /ma/ or /na/) or mismatch (audio /ma/ and visual /ga/). Responses were considered visually influenced if participants reported hearing /na/ for the mismatched stimuli. Using eye-tracking methodology, only trials where participant's gaze was fixated on the speaker's face during consonantal closure were included in analyses. Initial analyses reveal, when fixated on the speaker's face, children with ASD show significantly less visual influence relative to typically developing controls. It is proposed that the reduced influence of visual speech information in ASD is best understood at the level of visual speech processing, perhaps arising from a lack of experience with speaking faces. Implications for understanding visual speech processing in typical development and developmental disability are discussed. [Work supported by NIH grant DC-00403 (Cathi Best, PI.]

5aSCa12. Auditory temporal order judgments in children with specific language impairment and autism spectrum disorder. Sheryl Rosen, Mark De Ruiter, and Li Hsieh (Wayne State Univ., 207 Rackham, 60 Farnsworth, Detroit, MI 48202)

The Tallal repetition test (TRT) measures the ability of listeners to detect, associate, sequence, and remember complex patterns of stimuli (serial memory) The TRT contains sequencing and serial memory subtests with varying short and long interstimulus intervals (ISIs) Three groups of 12 children were tested using a modified version of the TRT. Subject groups consisted of 7- to 10-year old children with typical development (TD), autism spectrum disorder (ASD), and specific language impairment (SLI). The TRT contained both tone and CV syllable stimuli to assess temporal processing. As ISI increased, performance improved for both children with TD and SLI in both tone and syllable sequencing tasks, but not for children with ASD, especially in the tone task. Children with TD and those with ASD performed better than those with SLI across most subtests, especially in tasks with short ISIs. Analysis of performance in the serial memory portion of the TRT revealed a predicted pattern of decreased performance as stimuli elements increased. Overall, children with TD and those with ASD appear to have superior auditory temporal order judgment abilities when compared to children with SLI. The linguistic relevance factor shall be considered in assessment and training of various disordered populations.

5aSCa13. Perception of synthesized syllables and sentences by listeners with hearing loss. Corine Bickley, Amanda Dove, Andrea Liacouras, and Jolene Mancini (Dept. of Hearing Speech and Lang. Sci., Gallaudet Univ., 800 Florida Ave NE, Washington DC 20002)

The goal of this project is to create a set of synthesized speech materials that yields listening results equivalent to those that would be obtained using recorded naturally spoken materials, such as the CUNY Nonsense Syllable Test and the CASPERsent set of topic-specific sentences. One research interest of the RERC-HE is the following: Can synthesized speech be used as a substitute for recorded human speech in aural rehabilitation and in hearing aid research? The listeners in this study are both adults with normal hearing and with hearing loss. We have tested two listeners with normal hearing and four with hearing loss using nonsense syllables synthesized with DECtalk. The patterns of errors in their identification of phonemes follow expected patterns when subjects' responses were analyzed with respect to their audiometric profiles and the acoustic characteristics of the synthesized phonemes. The same group of listeners is now being tested using sentences from the CASPERsent lists synthesized with two commercially available text-to-speech systems: DECtalk, which uses a formant-type synthesizer, and ATT Natural Voices, which uses a concatenative synthesizer. Results of these listening tests will be presented. [This project is funded through the Rehab Engineering Research Center—Hearing Enhancement through the NIDRD.]

5aSCa14. Effects of dichotic listening for hearing impaired people. Ai Sasaki, Atsunobu Murase, Shuichi Sakamoto, Yôiti Suzuki (Res. Inst. of Electron. Commun., Grad. School of Info. Sci., Tohoku Univ. Katahira 2-1-1, Aoba-ku, Sendai, 980-8577 Japan, asasaki@ais.riec.tohoku.ac.jp), Tetsuaki Kawase, and Toshimitsu Kobayashi (Tohoku Univ., Aoba-ku, Sendai, 980-8577 Japan)

Methods applying the dichotic listening algorithm have been proposed and examined for application in hearing aids. Murase *et al.* (2005) proposed an algorithm in which dichotic listening was simply implemented by a set of complementary high-pass and low-pass filters. One filter is for either the right or left channel; the other filter is used for the other channel. This study examined two unsolved problems with this algorithm. One is the reason why this algorithm is effective. The other is probable degradation of sound localization that occurs because interaural level differences and interaural time differences is only slightly available with this signal processing. This problem is considerable when the sounds come from frontal incidence. Regarding the first problem, intelligibility tests were

performed using the low-frequency-boosted sounds. The intelligibility scores under the dichotic listening conditions should be higher than those under the diotic listening conditions if the effectiveness of this algorithm is attributable to the reduction of upward spread of masking. Results suggest that this dichotic listening reduced the upward spread of masking. Regarding degradation of performance of sound localization, sound localization test results suggest that time-intensity trading might recover degradation with dichotic listening algorithm.

5aSCa15. Effects of auditory training on hearing aid acclimatization. Jack M. Scott III (Texas Medical & Surgical Assoc., 8440 Walnut Hill Ln., Ste. 500, Dallas, TX 75231, jack.scott@texasmedsurg.com)

New hearing-aid users may experience a gradual improvement in speech performance over time that typically plateaus 6–12 weeks following hearing aid fitting. The delayed improvement may be due to neural reorganization of the auditory system following the introduction of amplified auditory input. Unfortunately, 30 days is the typical duration for most hearing aid trial periods; therefore, many individuals may be returning their hearing aids before being able to evaluate the full benefit of amplification. Prior to amplification, listeners with hearing impairment may experience difficulty perceiving subtle high-frequency changes in speech known as second-formant transitions. Second-formant transitions provide cues in discriminating consonant sounds. The purpose of this study was to determine if intensive high-frequency discrimination training for new hearing-aid users could facilitate improvements in speech perception. Speech recognition was evaluated for consonant identification, speech feature perception, and sentence identification in quiet and in noise before and after 10 days of training discrimination of frequency sweeps at 2 kHz. Improvements were found in sentence identification. These results have implications for the use of auditory training to improve speech recognition for newly amplified listeners with hearing impairment.

5aSCa16. Vowel production in Swedish children with cochlear implants. Tina Ibertsson, Birgitta Sahlen, and Anders Lofqvist (Dept. Logoped., Phoniatrics & Audiol., Clinical Sci., Lund, Univ. Hospital, SE-221 85 Lund, Sweden)

This study analyzed vowel production of Swedish children with cochlear implants. Swedish has a rich vowel system with nine vowels. Minimal word pairs were used as linguistic material. The age of the children varied between 6 and 13 years. The age at implantation was 1.2–10 years. The first two formants were measured for each vowel. To estimate the vowel space, the average Euclidean distance in the $F1$–$F2$ plane between each vowel and the mean first and second formant frequencies of all the vowels was calculated for each child. Preliminary results from 15 children with cochlear implants and 11 control subjects with normal hearing show no difference between the two groups, due to a large amount of variability in the group with cochlear implants. The relationship between the vowel space and the speech perception of each child with a cochlear implant was analyzed using correlations. Results show no strong correlation between the two measures, again due to the variability within the group. [Work supported by the Sunnderdahl Foundation.]

5aSCa17. Sentence duration and mode of communication in cochlear implanted children. Nicole L. Wiessner, Emily A. Tobey (Callier Adv. Hearing Res. Ctr., Univ. of Texas at Dallas, 1966 Inwood Rd., Dallas, TX 75235), and Ann E. Geers (Univ. of Texas Southwestern Medical Ctr. at Dallas, Dallas, TX 75390)

This study investigates the relationships between mode of communication and speech duration in cochlear implanted (CI) children with 4–6 years experience with their device. One hundred thirty-six CI children between the ages of 8 and 9 years old repeated sentences of three, five, and seven syllables (McGarr, 1983). Durations were examined according to syllable length, low versus high context sentences, and the communication

modality of the child's classroom. Findings suggest that communication modality is more strongly associated with duration than sentence context or length. Significantly shorter sentence durations were found for CI children taught with an auditory-oral emphasis than CI children taught using an emphasis of speech and some form of manual sign system. [Work supported by the NIH.]

5aSCa18. Interpolation of vocal-tract shape during stop closures from transition segments in vowel-consonant-vowel syllables. Milind S. Shah and Prem C. Pandey (Dept. of Elec. Eng., Indian Inst. of Technol., Bombay, Powai Mumbai 400076, India, pcpandey@ee.iitb.ac.in)

Children with prelingual profound hearing impairment have great difficulty in acquiring speech. Speech-training systems providing visual feedback of vocal-tract shape are found to be useful for improving vowel articulation. Vocal-tract shape estimation, based on LPC and other analysis techniques, generally fails during stop closures, and this restricts its effectiveness in speech training for production of consonants not having visible articulatory efforts. A technique based on two-dimensional surface modeling of the area values, estimated by LPC analysis, during the vowel-consonant and consonant-vowel transitions preceding and following the stop closure, has been investigated for interpolating the area values during the stop closures. Surface modeling was based on least-squares bivariate polynomials and Delaunay triangulation methods. Syllables of the type /aCa/, /aCi/, /iCa/, /iCi/, and /uCu/ with stop consonants /p/, /b/, /t/, /d/, /k/, and /g/ were analyzed for the estimation of place of stop closure. For bilabial, alveolar, and velar stops, the place could be estimated consistently with conic polynomial surface interpolation. Estimation of place, based on Delaunay surfaces, was consistent for bilabial and velar stops. However, cubic polynomial surface interpolation results were less consistent in estimating the place of constriction.

5aSCa19. Child voice and noise; acoustic effects of a day at the day-care related to background noise levels. Anita McAllister (INR, Speech Pathol., Linkoping Univ., Sweden), Svante Granqvist, Johan Sundberg, Peta Sjolander (Royal Inst of Technol.), and Mechtild Tronnier (Linkoping Univ.)

Several studies have found that high background noise levels are detrimental to health parameters. In particular, this seems to apply to developing voices were future vocal habits are established. Thus, it is important to study vocal function and environmental effects on the developing child voice. This study analyzed the effects of background noise on children's voices, specifically vocal intensity, and fundamental frequency. The investigated vocal parameters were (1) the relationship of background noise levels to F0 and vocal intensity, (2) F0 and vocal intensity variations over the day, and (3) F0 perturbation variations over the day. Ten 5-year-old children from three day-cares participated, six boys and four girls. The audio signal was recorded by two microphones mounted in front of the subjects' ears. By adding these signals it is possible to separate the voice from background noise. The material analyzed contained data from three 60-min recordings per child from morning, noon, and afternoon during a normal day at the day-care. Generally high mean background noise levels were found (82.6 dBA). Preliminary results suggest a correlation between high background noise and high F0 and vocal intensity in the children's voices, particularly for boys. F0 perturbation tends to increase during the day.

5aSCa20. Acoustic correlates of primary motor speech disorders in children during oral and hand tasks. Beate Peter and Carol Stoel-Gammon (Univ. of Washington, 1417 N.E. 42nd St., Seattle, WA 98195)

Primary child speech disorders have been subclassified variously. One proposed subtype, childhood apraxia of speech (CAS), results from motor programming deficits in speech production, and associated characteristics include limited phoneme inventory, variability in production, and diffi-

culty with speech prosody, e.g., monostress and monopitch. The purpose of this study was to identify acoustic correlates of oral and limb movements, derived from the hypothesis of a generalized timing deficit, that characterize this disorder subtype differentially from other disorder subtypes. Twelve children (age 4;7 to 6;6), of which eight were labeled with CAS, and 12 age- and gender-matched peers participated in a variety of oral motor and hand tasks. *K*-means clustering generated three disorder subgroups in the sample of participants with speech disorders, two of which were populated with CAS labels. Distinguishing characteristics included accuracy of vowel duration in a nonword imitation task, accuracy of clap interval duration in a clapped rhythm imitation task, rate of syllable repetition, durations of unstressed but not stressed vowel durations, and breath group duration. Taken together, these results are consistent with the view that deficits in timing accuracy, movement speed, and breath support underlie at least one subtype of idiopathic speech disorder.

5aSCa21. Changes in acoustic characteristics of /r/ following production training using electropatatography. Anna Schmidt (School of Speech Pathol. & Audiol., Kent State Univ., Kent, OH 44242)

Visual feedback using electropalatography (EPG) is an effective method for changing production of speech sounds in children. Differences in tongue placement and general acceptability of production have been demonstrated with EPG training for tongue to palate contact. Little is known, however, about changes in the spectral characteristics of speech sounds following training. The current study examined pre- and post-EPG patterns for /r/ in prevocalic, intervocalic, and postvocalic positions in sentences with 5 weeks of intensive EPG training. In particular, pre- and post-spectral characteristics of /r/ were examined for differences pre- and post-treatment. Subjects were four children (aged 9–10). These children exhibited distorted /r/ despite several years of traditional speech therapy but learned to produce perceptually acceptable /r/ with EPG. Spectral characteristics for /r/ productions in the same sentences by four typically developing children were used for comparison. Differences will be discussed in terms of acoustic characteristics as well and changes in tongue position.

5aSCa22. Physiologic and behavioral classification of delayed speech: Syllable repetition tasks. Jennell C. Vick, Christopher A. Moore, Lakshmi Venkatesh (Dept. of Speech & Hearing Sci., Univ. of Washington, 1417 NE 42nd St., Seattle, WA 98105, jennell@washington.edu), Thomas F. Campbell, Heather Leavy Rusiewicz (Univ. of Pittsburgh, Pittsburgh, PA), Lawrence D. Shriberg (Univ. of Wisconsin—Madison, Madison, WI), and Jordan R. Green (Univ. of Nebraska—Lincoln, Lincoln, NE)

As part of a large-scale study that aims to create a data-driven model of speech delay of unknown origin (SD) in preschool children, this investigation analyzed two- and three-syllable nonword repetitions by 50 3- to 5-year-old children, half of whom are typically developing (TD). The syllable repetition task was composed of four different words, bama, bada, bamana, and manaba, selected both for articulatory simplicity and to maximize displacement of the external articulators for kinematic analyses. While children in the TD group were significantly more accurate in both two- and three-syllable repetitions than children in the SD group, neither group was able to repeat three-syllable nonwords with particular acumen. Children in the TD group were 55% accurate, while children in the SD group were only 22% accurate. Measures of repetition accuracy, acoustics, nasalence, external articulatory kinematics, and respiration contribute to a hierarchical agglomerative clustering model that generates hypotheses about potential subclinical categories within the SD and TD groups.

5aSCa23. Changes of voice characteristics under noisy conditions: Acoustic and fiberscopic studies of school teachers. Noriko Kobayashi (School of Allied Health Sci., Kitasato Univ., 1-15-1, Kitasato, Sagami-hara, Kanagawa, 228-8555 Japan, noriko@ahs.kitasato-u.ac.jp) and Takashi Masaki (Kitasato Univ, Sagamihara, 228-8555 Japan)

It has been known that incidence of vocal pathology was high in school teachers as they had to use a great amount of voice and loud phonation in noisy school settings with the children's loud voices. Vocal hygiene programs and voice therapy are effective treatments for these cases. The final goal of the treatment should be to obtain the skills to use efficient and healthy phonation even in abusive and noisy environments. In our study, two school teachers with vocal nodules, two speech therapists who were trained to keep proper phonation even in noisy environments, and ten college students with no laryngeal pathology (control group) spoke eight sentences in two environments: a quiet environment and one with meaningful multitalker babble (MMB). Acoustic analyses and fiberscopic examination revealed higher sound pressure and F0 levels and laryngeal constriction in MMB for the teachers before therapy and the students, whereas two speech therapists kept similar F0 levels and the nonconstricted laryngeal condition in both environments. A teacher who had voice therapy produced less constricted voice with MMB than the pretherapy recording. The results suggested the efficacy of voice therapy with MMB for teachers to obtain efficient and healthy voice in their noisy work environments.

5aSCa24. Effect of speech task on intelligibility in speakers with dysarthria. Kate Bunton (Dept. of Speech, Lang., and Hearing Sci., Univ. of Arizona, P.O. Box 210071, Tucson, AZ 85721-0071, bunton@u.arizona.edu)

There is some evidence that speech intelligibility varies across speech task for speakers with dysarthria. Primary differences have been related to the linguistic level of the material being evaluated (e.g., single words, sentences, conversation). While conversational speech is the most socially valid context for evaluating speech intelligibility, quantifying intelligibility in conversation limits its clinical use. The present study assessed intelligibility in speakers with dysarthria across four speech production tasks: single words, sentence production, passage reading, and spontaneous speech. Speakers varied with regard to the type of dysarthria, including hypokinetic, hyperkinetic, spastic, and mixed. Results show that all speakers were significantly less intelligible during spontaneous speech than the other structured speech production tasks (e.g., single words, sentences, and reading). Mean differences varied across speech severity level but did not vary across dysarthria type. These data indicate that speech production task is an important variable to consider during the evaluation of dysarthria and highlight the importance of developing techniques to measure the intelligibility of conversational speech. [Work supported by NIH Grant R03 DC005902.]

5aSCa25. Acoustic features of speech after glossectomy. Yuichi Ishimoto (School of Media Sci., Tokyo Univ. of Technol., 1404-1 Katakura, Hachioji, Tokyo 192-0982, Japan, ishi@media.teu.ac.jp) and Noriko Suzuki (Showa Univ., Ohtaku, Tokyo 145-8515, Japan)

The tongue serves an important role in speech production. Speech disorders due to tongue resection often occur and cause communication difficulties after surgery, according to the extent of the resected area. Such patients typically require appropriate speech therapy and palatal augmentation prosthesis. However, diagnosis of the speech in such patients has been based largely on subjective evaluation by clinicians. Acoustic features in glossectomee have yet to be clarified, and there is no objective estimation method for speech intelligibility. This study aims to clarify acoustic features associated with speech disorders after glossectomy and to develop a computerized evaluation system. The speech data were analyzed using the improved cepstrum method and compared with varying degrees of speech intelligibility. The vowel /i/ was selected as the speech sample because it is the high front vowel. The results showed that spectral

envelopes of the Japanese vowel /i/ with low speech intelligibility exhibit two peaks in the second formant (F2) region from 1500 to 3000 Hz. This suggests that the spectral features in the F2 region of the vowel /i/ are important clues to determine speech intelligibility.

5aSCa26. New generation aids for laryngectomy patients. Andrzej Czyzewski, Piotr Odya (Gdansk Univ. of Technol., Narutowicza 11/12, PL-80-952 Gdansk, Poland), and Bozena Kostek (Inst. of Physiol. and Pathol. of Hearing, Warsaw, Poland)

The artificial larynx has many disadvantages. The produced speech is monotonous and sounds artificially. In addition, produced speech intelligibility is usually poor. The major problem is a background noise caused by the device. In fact, the artificial larynx is only a simple vibrator, a construction of which has been almost unchanged since the 1950s. The aim of the presented project is to design a new generation of devices for laryngectomy patients. There are two different approaches to solve this task. The first one focuses on the artificial larynx. Some major improvements in the construction of the device might be easily introduced. Hence, the artificial larynx engineered was equipped with a digital processor and an amplifier. The spectral subtraction algorithm for noise reduction was used. In this method, an average signal spectrum and average noise spectrum are estimated and subtracted from each other, thus average signal-to-noise ratio (SNR) is improved. The main problem to be solved was that both the noise and the speech signal have the same excitation source and consequently are strongly correlated for voiced sounds. The second approach uses a PDA (portable digital assistant) to generate synthetic speech. The proposed new generation devices helping laryngectomy patients are presented in the paper.

5aSCa27. A speech communication aid system for total laryngectomies using voice conversion of body transmitted artificial speech. Keigo Nakamura, Tomoki Toda, Hiroshi Saruwatari, and Kiyohiro Shikano (Nara Inst. of Sci. and Technol., 8916-5, Takayama-cho, Ikoma-shi, Nara, 630-0192 Japan, kei-naka@is.naist.jp)

There are several problems associated with using existing electrolarynxes. For example, the loud volume of the device itself might disturb smooth interpersonal communication, and its generated speech is also unnatural. To improve the quality of speech communication using such a medical device, this paper proposes a novel speech communication aid system for total laryngectomies. This system detects articulated speech caused by a new sound source as an alternative to the existing electrolarynx through the soft tissues of the head with a nonaudible murmur (NAM) microphone attached to the surface of the skin [Nakajima et al, Proc. Interspeech 2005, pp. 293–296 (2005)]. The new sound source outputs signals of extremely low energy that cannot be heard by people near the speaker. Such body-transmitted artificial speech is converted to a more natural voice by statistical voice conversion [T. Toda and K. Shikano, Proc. Interspeech 2005, pp. 1957–1960 (2005)]. The performance of the proposed system is evaluated in terms of objective and subjective measures using body-transmitted artificial speech simulated by a non-disabled speaker. Experimental results show that body-transmitted artificial speech is consistently converted to a much more natural and intelligible voice. [Work supported by SCOPE-S.]

5aSCa28. Development of a hands-free electrolarynx for persons whose larynx have been removed. Mitsuo Hashiba (Hokkaido Industrial Res. Inst., N19W11, Kita-ku, Sapporo, 060-0819, Japan), Yasunori Sugai (Densei Inc., Chuo-ku, Sapporo, 060-0002, Japan), Takashi Izumi (Hokkaido Tokai Univ., Minami-ku, Sapporo, 005-8601, Japan), Shuichi Ino, and Tohru Ifukube (The Univ. of Tokyo, Meguro-ku, Tokyo, 153-8904, Japan)

An electrolarynx is a useful speech-substitute device for patients who have lost laryngeal function. Unfortunately, the voices produced by a conventional electrolarynx are completely flat, unlike a human voice. For that reason, we developed a pitch-controlled electrolarynx that allows patients

to control a voice intonation using their exhalation [N. Uemi and T. Ifukube, "Design of a new electrolarynx having a pitch control function," IEEE RO-MAN'94, 198–203 (1994)]. This pitch-controlled electrolarynx has been manufactured and more than 3000 patients have used the device since 1998. However, many patients have strongly requested that we design a hands-free electrolarynx so that they can perform daily life functions and work in their office without their hands occupied by the electrolarynx control during use. In response to that request, we designed some models of a hands-free electrolarynx that is attachable to the patient's neck. Furthermore, by comparing the models based on evaluation tests regarding its sound quality and usability, a thermo-plastic brace was found to be the best for attachment to the neck. Although our hands-free electrolarynx has not yet been equipped with the pitch-control function, it was ascertained that it is useful for taking notes while talking on the phone, and so on.

5aSCa29. Modeling aspects of vocal fold oscillations with validation to clinical data. Sarah A. Bentil (Dept. of Mech. Eng., Univ. of Hawaii Manoa, Honolulu, HI 96822), Todd Reed, John S. AllenIII (Univ. of Hawaii Manoa, Honolulu, HI 96822), and Yuling Yan (Stanford Univ. School of Medicine, Stanford, CA 94305)

We investigate vocal fold vibrations in patients with muscle tension dysphonia (MTD) and Parkinson's diseases (PD) using a refined two mass model [I. Steinecke and H. Herzel, J. Acoust. Soc. Am. **97**(3), 1874–1884 (1995)] and clinical data obtained from acoustic recordings and high-speed digital imaging (HSDI) of the larynx. The two-mass model with empirical parameters is able to reproduce some of the behaviors revealed from functional, image-based analyses of vocal fold dynamics in both normal and abnormal states. In particular, the glottal area waveform (GAW) is used to describe the vocal fold vibratory behavior, which is derived from HSDI data using an analytical framework developed by the Yan research group [Yan et al., J. Voice **19**(2), 161–175 (2005); IEEE Trans. Biomed. Eng., (2006)]. Further, a comparison of the two-mass model predictions and the GAW and acoustic data was performed using signal processing techniques including fast fourier transforms, wavelet transforms, and spectrograms. These analyses deliver a comprehensive quantitative representation of the dynamic characteristics of the vocal folds and may provide new insights into the mechanism of abnormal voice productions such as in MTD and PD. [Research is sponsored by NSF Grant #0627992.]

5aSCa30. Preshearing effects on viscoelastic properties of collagen-based vocal fold injectables. Sarah A. Klemuk (Dept. of Speech Pathol. & Audiol., Univ. of Iowa, 336C SHC, Iowa City, IA 52242, sarah-klemuk@uiowa.edu) and Ingo R. Titze (Univ. of Iowa, Iowa City, IA 52242)

A criterion for developing a biomaterial is that its viscoelastic properties correspond to native tissues. This criterion is particularly important for vocal fold tissues. Collagen-based injectables are routinely used to repair paralyzed or scarred vocal folds and restore vocalization, yet reported viscoelastic properties are inconsistent. The present study evaluated the effects of preshearing samples on their viscoelastic measurements. Non-cross-linked bovine collagen (Zyderm II[TM]) and micronized dermal tissue (Cymetra[TM]) were presheared by extruding directly through a mechanically operated syringe with different needle sizes. Preshear rates ranged from 31 to 5600/s for orifice radii of 1.21 to 0.0955 mm, respectively. Sandpaper-coated, parallel plate attachments on a stress-controlled rheometer were used to measure elastic moduli and dynamic viscosities from 0.01 to 10 Hz. A 3–10-fold reduction in elastic modulus and a 2–4-fold reduction in dynamic viscosity occurred for preshear rates exceeding 1000/s compared to rates of 31 and 131/s. These results suggest a change in the molecular structure and the viscoelastic compatibility of vocal fold injectables when sufficiently presheared. [Work supported by NIH.]

5aSCa31. Spasmodic dysphonia in Japan: 1486 Botulinum toxin injections for 260 spasmodic dysphonia patients. Masanobu Kumada (Kumada Ear-Nose-and-Throat Clinic, L-First Bldg. 3F, 4-2-6 Nishi-Azabu, Minato-Ku, Tokyo, 106-0031 Japan) and Takeo Kobayashi (Teikyo Univ. Ichihara Hospital)

Botulinum toxin injection is a very effective treatment for spasmodic dysphonia. We experienced 1486 injections for 260 patients in past 15 years in Japan. Here we show statistics of these injections. We use type A toxin that is produced by Clostridium Botulinum. This toxin affects the neuro-muscular junction as a blocker of release of Ach, which leads to inversible parasis of a muscle. Mainly, we inject the toxin paracutaneously on the neck to the vocalis muscle using a partly covered needle that works as an EMG electrode. Mainly we have four options: 2.5 i.u. unilaterally (38% of 256 patients), 2.5 i.u. for each laterality bilaterally (16%), 5.0 i.u. unilaterally (29%), and 5.0 i.u. for each laterality bilaterally (5%). Its effectiveness persisits for 17.3 weeks on average. The longest effectiveness we have ever experienced is more than 1 year. A small percentage of the injections are not effective; it can be thought that the injected toxin does not reach the neuromuscular junction even when the needle is in the muscle: neuromuscular junctions contribute a part of the muscle and EMG signals do not tell us where these junctions are. Mainly, the side effects are breathy hoarseness and misdiglutition, which persist a week or so.

5aSCa32. Collagen injection as an adjunct to arytenoid adduction. Miwako Kimura, Takaharu Nito (Dept. of Otorhinolaryngology, The Univ. of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, 1138655, Japan, mkimu-tky@umin.ac.jp), Niro Tayama (Intl. Medical Ctr., Shinjuku-ku, 162-8655, Tokyo, Japan), and Roger Chan (Texas Univ., TX)

Dysphonia associated with laryngeal paralysis may be identified in the short term postoperatively or may develop years after successful arytenoid adduction. In selected cases, collagen injection of vocal fold improves phonation after arytenoid adduction. Our experience with the use of collagen injection to supplement arytenoid adduction is reported. Forty patients were treated with transoral collagen injection into the atrophic vocal fold after arytenoid adduction at The University of Tokyo from January 1990 to December 2005. These patients all had a diagnosis of unilateral vocal fold paralysis. Voice quality (GRBAS scale) and the other examinations for vocal function demonstrated measurable improvement after treatment. After arytenoid adduction, maximum phonation time (MPT) improved from 5 to 11 s and mean flow rate (MFR) as an aerodynamic examination improved from 772 to 322 ml/s. Voice quality, especially roughness, improved from 1.8 to 0.8 after collagen injection. MPT (from 11 to 14 s) and MFR (from 322 to 233 ml/s) showed overall improvement after collagen injection. We will report the ease with which transoral collagen injection was accomplished and how better voice quality was attained without the more extensive surgery. In the session techniques of anesthesia, injection, and patient selection are discussed.

5aSCa33. Numerical simulation of sound originated from the vocal tract in soft neck tissues. Makoto Otani, Tatsuya Hirahara (Dept. of Intelligent Systems Design Eng., Toyama PRef. Univ., Imizu, Toyama 939-0398, Japan, otani@pu-toyama.ac.jp), and Seiji Adachi (Fraunhofer Inst. for Bldg. Phys., 70569 Stuttgart, Germany)

A nonaudible murmur (NAM), a very weak speech sound produced without vocal vibration, can be detected by a special NAM microphone attached to the neck, thereby providing a new communication tool for use with functional speech disorders. The microphone is a condenser microphone covered with soft-silicone impression material that provides good impedance matching with soft tissues that are found in the neck. The NAM detected with the NAM microphone, however, is insufficiently clear because higher-frequency components are suppressed severely. A production mechanism of the NAM as well as transfer characteristics of the NAM in soft tissues of a neck should be clarified to improve the NAM clarity. As a first step, sound propagation from the vocal tract to the neck surface is simulated using a head model scanned with magnetic resonance imaging and finite difference method. Results show that soft-meat-tissue-conducted sound has fewer higher-frequency components than an air-conducted sound. The decay of transfer characteristics is approximately -10 dB/oct in the audible range, which is roughly parallel to the spectral characteristics of the measured NAM. [Work supported by SCOPE-S.]

Session 5aSCb

Speech Communication: Production I (Poster Session)

Dani M. Byrd, Cochair
Univ. of Southern California, Linguistics, 3601 Watt Way, GFS 301, Los Angeles, CA 90089-1693

Contributed Papers

All posters will be on display and all contributors will be at their posters from 11:00 a.m. to 12:00 noon.

5aSCb1. Computer graphics facial animation of Japanese speech using three-dimensional dynamic visemes. Makoto J. Hirayama (Kanazawa Inst. of Technol., 7-1 Ohgigaoka, Nonoichi Ishikawa, 921-8501 Japan, mako@infor.kanazawa-it.ac.jp)

Speech production makes not only acoustic signals but also visual images of the face especially for the jaw, lips, teeth, and tongue. To reproduce realistic facial images during Japanese speech, a three-dimensional computer graphics model of Japanese visemes was made. These visemes were extracted from the video database of images around lips during speech captured by two high speed (up to 300 frames per second) cameras [M. J. Hirayama, Proc. ICPhS 2003 (2003), pp. 3157–3161]. Most of the visemes are created as static shapes. They are for five vowels, semi-vowels, and some consonants. For explosives by labials (/p/ /b/ /n/) or tongue (/t/ /d/ /n/), dynamic information, that is, multiple shapes and timing information were assigned for each viseme. By placing these visemes onto a time axis at the timing of phonemes of a sentence, then interpolating shapes in between by using a spline interpolation technique on speech articulators' motion graphs, computer graphics animation was made by ray-tracing rendering. [A part of this work was supported by Japan MEXT Academic Frontier Project.]

5aSCb2. A photoglottographic (PGG) method with external lighting and sensing. Kiyoshi Honda (LPP-UMR7019, CNRS/Univ. Paris 3, Paris F75005 France, and ATR, Kyoto 619-0288, Japan, honda@atr.jp), Shinji Maeda (CNRS/ENST, Paris, F75634 Cedex13 Paris, France), Stephane Hans (Service ORL, F75015 Paris, France), and Lise Crevier-Buchman (CNRS/Univ. Paris 3, Paris F75005 France)

Photoglottography (PGG) is a moderately invasive technique to observe glottal movements and vocal-fold vibrations. A light guide is inserted into the pharynx and transglottal light is detected by a photosensor placed on the outer skin below the glottis, or conversely the sensor is placed inside the pharynx and the subglottal cavity is illuminated from outside with a light source. This report evaluates a noninvasive PGG method, in which the hypopharynx is illuminated with a light guide placed on the neck skin at the level between the hyoid bone and thyroid cartilage and a photosensor on the skin near the cricoid cartilage. The light passed through the skin illuminates the lumen of the hypopharynx and the photosensor detects indirect (diffusion) light through the glottis during glottal adduction. Choosing an appropriate location for the light source and photosensor, glottal adduction pattern is observed for voiceless stops and fricatives in low as well as high vowel context. Thus, our diffusion-light

PGG potentially overcomes the tongue-position dependency of the detected signals, which has been a major caveat of the conventional PGG methods.

5aSCb3. Evaluation of a photonasography. Angélique Amelot (LPP, 19 rue des Bernardins 75005 Paris, angelique.amelot@univ-paris3.fr), Kiyoshi Honda, Shinji Maeda (ENST, 75013 Paris, France), Lise Crevier-Buchman (HEGP, 75015 Paris, France), and Patricia Basset (LPP, 75005 Paris, France)

A photonasographic (PNG) technique was tested to evaluate velopharyngeal port (VP) opening/closing during speech. This system uses a photodetector placed in the pharynx via a nostril and a fiberscope in another nostril pointing to the back wall of the nasopharynx. With this setting, the light is reflected from the walls, passes through the open port, and is sensed by the photodetector. In a pilot experiment, a native French speaker read sequences C1V1C1 V2C1V1, where C1=/n/ or /t/ and V1,2=/a/, /i/, /A/, /E/, or /O/, as /tatA ta/. The obtained PNG data compare qualitatively well with the velum position data, on the same corpus, derived from the naso-fiberscopic video images. When NPG detects a VP opening, the fiberscope data correspondingly indicate a lowering of the velum and inversely. PNG, as well as the velum position data, show that VP is open at the onset of a nasal phoneme and is closed just after the offset of that nasal phoneme. Moreover, VP is not completely closed during the first and second phoneme in the sequence [ninini] and [nanana], indicating their nasalization. The combination of a well-set fiberscopic light-source and photodetector appears to give a good estimation of the degrees of VP opening.

5aSCb4. An MRI-based 3-D tongue atlas for tongue modeling. Chao-Min Wu and Han Tiet Goh (Dept. of Elec. Eng., Natl. Central Univ., 300, Chun-Da Rd., Chung-Li, Taiwan 320)

The main objective of this study is to build an MRI-based 3-D tongue atlas with an established available spatial transformation technique. The subjects for the MRI data were eight male and eight female college students (19–28 years old) who are native speakers of mandarin with Taiwanese accent without speech disorders. The oral MR images (axial: TR, 400 ms; TE, 10 ms; FOV 24×24; image matrix, 256×256 for 35 slices with 2-mm thickness) were acquired using a GE SIGNA 1.5-T scanner in the University Hospital of Chung Shan Medical University. The axial MR images of the human tongue were first segmented with snakes active contour method, then the 3-D tongues of each subject were reconstructed with morphology-based gray-level interpolation. Finally, these 3-D tongues were spatial transformed into a 3-D tongue atlas with thin-plate spline method. The 3-D tongue atlases for male and female subjects and mor-

phometric studies, such as subject-to-subject, subject-to-atlas, and male-to-female, of these two atlases will be presented. Implication of these data related to tongue modeling will also be discussed. These information will be used as the basis for future research on tongue modeling and underlying physiological mechanism of normal and disordered speech production.

5aSCb5. Direct measurement of glottal volume velocity using high-speed, stereoscopic, particle imaging velocimetry. David A. Berry, Juergen Neubauer, and Zhaoyan Zhang (The Laryngeal Dynam. Lab., UCLA Div. of Head and Neck Surgery, 1000 Veteran Ave., Rm. 31-24, Los Angeles, CA 90095-1794)

Despite its central importance as the glottal source in several long-standing models of voice production, the glottal volume velocity signal has been relatively little studied. In particular, few direct measurements of the glottal volume velocity signal have been made. One common method for estimating the glottal volume velocity signal has been linear inverse filtering of the oral acoustic output. However, a major assumption of linear inverse filtering, and of the linear source-filter theory of speech production in general, is that the glottal source and the vocal tract are independent of each other. The accuracy of this assumption has been questioned, particularly at extremes of fundamental frequency and intensity. In order to test the limits of linear inverse filtering, direct, instantaneous measurements of glottal volume velocity have been made using high-speed, stereoscopic, particle imaging velocity on a self-oscillating, physical model of vocal-fold vibration. These direct measurements are contrasted with results from linear inverse filtering.

5aSCb6. Lip protrusion and tongue position in French vowels produced by blind speakers and sighted speakers. Lucie Menard, Annie Leclerc, Jerome Aubin, and Annie Brasseur (Phonet. Lab., UQAM, Case Postale 8888, succ. Ctr.-Ville, Montreal, H3C 3P8, Canada)

The influence of visual experience in speech production was investigated through a study of the French vowels /i y u a/. Articulatory and acoustic recordings of ten repetitions of the vowels in CVC syllables embedded in carrier sentences were conducted in three consonant environments (/b d g/) and two prosodic conditions (neutral and under contrastive emphasis). Six congenitally blind adults and six sighted adults were recorded. All participants were native speakers of Canadian French and had no history of speech disorder. The audio signal, lip movement, and tongue shapes were recorded using a digital camera and an ultrasound system. The minimal (for /i a/) or maximal (for /y u/) horizontal position of the upper lip was tracked and the front-back position of the tongue was measured for each vowel. Formant frequencies were extracted using LPC analyses. Results show that, despite similar acoustic differences, the rounded and unrounded vowels are less differentiated along the protrusion dimension for blind speakers compared to sighted speakers. It is suggested that this variability is related to a trade-off between lip protrusion and tongue position. Significant interaction effects between consonant environment and vowel category are discussed for each speaker group. [Work supported by SSHRC, NSERC.]

5aSCb7. Tongue muscle fiber tracking during tongue protrusion and rest. Hideo Shinagawa, Emi Z. Murano (Dept. of Biomed. Sci., Univ. of Maryland Dental School, 666 W. Baltimore St., Baltimore, MD 21201, hshinagawa@umaryland.edu), Jiachen Zhuo, Rao P. Gullapalli (Univ. of Maryland Medical Ctr., Baltimore, MD 21201), Bennett Landman, Jerry L. Prince (Johns Hopkins Univ., Baltimore, MD 21218), and Maureen Stone (Univ. of Maryland Dental School, Baltimore, MD 21201)

Diffusion tensor imaging (DTI) has recently become a promising tool to investigate not only the nerve structure of the brain, but also integration of the peripheral muscle structure. The purpose of this study was to represent the functional deformation of tongue muscles with DTI by exam-

ining two conditions, tongue protrusion and rest. Three normal volunteers participated in the study. They were recorded at rest and wearing a custom made tongue retaining device (TRD), often used for patients with sleep apnea. The TRD held the tongue immobile in protruded position. In both positions, the tongue muscle structure and functional deformation could be visualized. In particular, the deformation of the genioglossus (GG) muscle, which is generally fan shaped, was clearly visible. The fibers of GG anterior muscle were more vertical with the TRD. The DTI technique has the potential to reveal not only myoarchitecture but also functional deformation of the tongue *in vivo*. With a little ingenuity, it might be possible to conquer the MRI sensitivity to small motion artifacts or improve tongue muscle stabilization to track the muscle fiber architecture during sustained speech. [Work supported by JSPS and NIH.]

5aSCb8. The effects of the false vocal folds on laryngeal pressures and flows. Li Sheng (Dept. of Biomed. Eng., School of Life Sci. and Technol., Xi'an Jiaotong Univ., Xi'an 710049), Ronald C. Scherer (Bowling Green State Univ., Bowling Green, OH 43403), Wan MingXi, Wang SuPin, and Qi LiYun (Xi'an Jiaotong Univ., Xi'an 710049)

As a laryngeal constriction, the false vocal fold (FVF) gap (the distance between the medial edges of the FVFs) may create important effects on phonation by altering the pressures within and flows through the larynx. The computational code FLUENT was used to examine the effects on pressures and flows for FVF gaps ranging from 0.02 to 2.06 cm, for three glottal angles (uniform and convergent/divergent 40 deg) and two minimal glottal diameters (0.04 and 0.06 cm), for constant subglottal pressure (8 cm H_2O). The specific design of the FVFs followed prior literature. Results suggest three important ranges of FVF gaps: (1) when the FVF gap was 1.5–2 times the minimal glottal diameter, pressures were lower throughout the larynx, and flows were higher through the larynx (less flow resistance); (2) for smaller FVF gaps, intralaryngeal pressures increased and flows decreased; (3) for greater FVF gaps, pressures and flows were unaffected. Also, (4) the divergent glottal angle gave the greatest flows, (5) flow separation locations for the divergent glottis moved downstream as the FVF gap decreased, and (6) the FVFs straightened the flow for narrow gaps. Thus, the status of the FVFs needs to be considered for voice production and synthesis.

5aSCb9. Acoustic and aerodynamic effects of false folds and epiglottis. Fariborz Alipour, Sanyukta Jaiswal, and Eileen Finnegan (Dept. Speech Path. and Audiol., Univ. of Iowa, Iowa City, IA 52242)

Excised larynx research usually excludes the false folds in an effort to reveal the true vocal folds. The purpose of this study was to examine the aerodynamic and acoustic effects of the false folds and epiglottis on excised larynx phonation. Canine larynges were mounted over a tapered tube on the excised larynx bench that supplied pressurized, heated, and humidified air. Glottal adduction was accomplished by passing sutures that simulated lateral cricoarytenoid muscle activation. First, the excised larynx with intact false folds and epiglottis was subjected to a series of pressure-flow experiments with tension and adduction as major control parameters. Then, the epiglottis and false folds were successively removed and the experiment was repeated for each condition. The subglottal pressure, EGG, flow rate, audio signal, and sound pressure level were recorded during each experiment. Glottal flow resistance was calculated from the pressure and flow signals, while the EGG signal was used to extract fundamental frequency. It was found that these additional structures have positive contribution to the glottal resistance and sound intensity of the larynx. Also, vocal fold elongation and glottal medial compression caused an increase in the glottal resistance. [Work supported by NIDCD Grant No. DC03566.]

5aUW1. Notes on broadband seabed geoacoustic inversion in shallow water. Ji-Xun Zhou and Xue-Zhen Zhang (Georgia Inst. of Technol., Atlanta, GA 30332-0405 and Inst. of Acoust., Chinese Acad. of Sci., Beijing, 100080, China)

With increasing interest in shallow-water environments, where bottom interaction is a dominant effect, there is a need to acquire accurate information about seabed geoacoustic parameters. Due to the difficulties and high costs of directly measuring seabed parameters at low frequencies (LF) in shallow water (SW), seabed geoacoustic inversion from long-range propagation has become an active research area. Much progress on this subject, notably on inversion methods, has been made in the last two decades, mainly through the use of powerful numerical codes and data processing tools. Despite this, seabed geoacoustic inversion often fails to yield systematic LF seabed parameters in a broad band (such as speed/attenuation vs frequency) that are required for seabed geoacoustic modeling or for sonar performance prediction in the SW environment. This paper will discuss several basic concepts and technical issues related to SW geoacoustic inversion, including filter phase shifting, speed-attenuation coupling, hidden depth, and sea-surface effects. It shows that inverting the broadband seabed acoustic parameters is a delicate task that can often be subject to errors. These issues should be considered in designing experiments that test seabed geoacoustic inversion methods or in interpreting experimental results. [Work supported by ONR and NNSF of China.]

5aUW2. Efficient use of *a priori* data in sediment inversions through the use of null space. Gopu R. Potty, James H. Miller (Dept. of Ocean Eng., Univ. of Rhode Island, Narragansett, RI 02882), Ying-Tsong Lin, and James F. Lynch (Woods Hole Oceanogr. Inst., Woods Hole, MA)

We present improved inversions for sediment parameters by incorporating *a priori* information about the environment. This improvement is achieved by projecting a desirable solution into the null space of the inversion and including this null space contribution along with the standard non-null space contribution. We use singular value decomposition (SVD) to define the null space of the inversion and elucidate our projection method. The desirable solution, which is projected into the null space, is constructed based on previous data from cores, geophysical surveys, and historic data. This approach introduces user bias into the solution; the projection onto the null space supplies a safety net by showing which aspects of this bias are justified by the data. The user bias can be considered as additional data which, when incorporated, can lead to meaningful solutions. Effectiveness of probing the null space will be compared to the more conventional nonlinear inversion schemes. This approach will be tested using field data collected as part of the Shelfbreak Primer experiment. [Work supported by ONR.]

5aUW3. Robust source localization and geoacoustic inversion in the Haro Strait Primer. Rashi Jain, Zoi-Heleni Michalopoulou (Dept. of Mathematical Sci., New Jersey Inst. of Technol., Newark, NJ 07102), and Alex Tolstoy (A. Tolstoy Sci., McLean, VA 22101)

Gibbs sampling, a Markov chain Monte Carlo technique, has been shown to be a powerful tool for geoacoustic inversion and source localization. By providing estimates of posterior joint distributions, it offers a global optimization route for multidimensional estimation that reports uncertainty and covariance in addition to point estimates. In this work, Gibbs sampling is applied for extracting time delays from recorded time series during the Haro Strait primer experiment. Employing time delay estimates and using a linear approximation to the inverse problem and then regularization, estimates are obtained for source and receiver location and some environmental parameters. Simultaneously processing receptions at all three vertical line arrays for localization of each source reduces ambiguities in the estimation process. Similarly, using received signals corresponding to several sources, array element localization for a single array, a difficult problem for this particular data set, becomes more precise. Multiple data sets are used in the inversion and consistent results validate the robustness of the approach. Estimated bathymetry is in agreement with bathymetric maps for the region. [Work supported by ONR.]

5aUW4. Coherent noise processing and geoacoustic inversion. Peter Gerstoft, Chen-Fen Huang, and William S. Hodgkiss (Marine Physical Lab., Univ. of California San Diego, San Diego, CA 92093-0238)

Ocean acoustic noise can efficiently be processed to extract Green function information from noise [Roux *et al.*, J. Acoust. Soc. Am. (2004), Siderius *et al.*, *ibid.* (2006)]. By cross-correlating the ambient noise field from two sensors, it is possible to extract the impulse response between the two sensors including bottom and subbottom bounces. When this noise processing is used on a vertical array, it can give valuable information about the subbottom near the array. This information will be then used to constrain a classical geoacoustic inversion procedure where we use a distant towed source to obtain the geoacoustic bottom parameters.

8:50

5aUW5. Geoacoustic inversion based on both acoustic pressure and particle velocity. A. Vincent van Leijen (NLDA, P.O. Box 10.000, 1780 CA, Den Helder, The Netherlands, av.vanleijen@kim.nl), Jean-Pierre Hermand (ULB, B-1050 Bruxelles, Belgium), and Kevin B. Smith (NPS, Monterey, CA 93943)

Conventional inversion schemes for environmental assessment depend on an objective function that exploits amplitude or phase information of acoustic pressure data alone. This work investigates the potential of vector sensors for geoacoustic inversion by defining an objective function that

5a SAT. AM

3355 J. Acoust. Soc. Am., Vol. 120, No. 5, Pt. 2, November 2006

Fourth Joint Meeting: ASA and ASJ **3355**

also takes into account acoustic particle motion. Calculations are performed on synthetic broadband data for a shallow water environment (South Elba) with an optimization scheme based on different metaheuristics. Differences in the inversion process, including sensitivity of the cost function to environmental parameters and convergence speed of the optimization algorithm, are presented by comparing inversion results for a sparse pressure-only array and a vector sensor array.

9:05

5aUW6. Geophysical parameter inversion in a range-dependent environment. Woojae Seong, Keunhwa Lee, Kyungsup Kim (Dept. of Ocean Eng., Seoul Natl. Univ., Seoul, 151-742, Korea), and Seongil Kim (Agency for Defense Development, Jinhae, Korea)

Matched-field inversion technique is applied for estimation of geophysical parameters of the ocean bottom in a range-dependent shallow water. In the experiment (MAPLE-4), conducted off the coast of the East Sea during May 2005, narrow-band multitone cw acoustic data were obtained from the towed moving source along a weakly range-dependent track, from 2 to 18 km apart from the L-shaped receiver array. In the inversion, complex density model based on Biot model is used to invert for parameters including porosity and permeability. Inversion results are compared with existing geological survey data. In addition, the effect of range dependency resulting from the seafloor slope and the existing bottom intrusion is examined.

9:20

5aUW7. Bayesian inversion of propagation and reverberation data. Peter L. Nielsen (NATO Undersea Res. Ctr., Viale S. Bartolomeo 400, 19138 La Spezia, Italy) and Stan E. Dosso (Univ. of Victoria, Victoria, BC, Canada V8W 3P6)

A Bayesian matched-field inversion approach to infer geoacoustic and scattering properties of the seabed is applied to simulated propagation and reverberation data received on a towed horizontal array. The approach is based on the method of fast Gibbs sampling (FGS) of the posterior probability density to estimate uncertainties in both geoacoustic and scattering parameters for broadband acoustic data in realistic shallow-water environments. The FGS is linked to an acoustic propagation model that simultaneously provides complex acoustic pressure at short propagation ranges and long-range reverberation intensity. The inversion algorithm is initially applied to long-range reverberation data alone to assess the geoacoustic information content of reverberation in terms of marginal posteriori probability densities for the environmental parameters. A reduction in uncertainty for the extracted geoacoustic and scattering parameters is demonstrated by a simultaneous inversion of the propagation and reverberation horizontal array data.

5aUW8. On the use of acoustic particle velocity fields in adjoint-based inversion. Matthias Meyer, Jean-Pierre Hermand (Université libre de Bruxelles, Belgium & Royal Netherlands Naval College, The Netherlands), and Kevin B. Smith (Naval Postgraduate School, Monterey, CA)

Following the recent interest in the use of combined pressure and particle motion sensors in underwater acoustics and signal processing, some general aspects regarding the modeling and multipath phenomenology of acoustic particle velocity fields in shallow water environments have been studied. In this paper we will address a number of issues associated with the incorporation of vector sensor data (pressure and particle velocity) into adjoint-based inversion schemes. Specifically, we will discuss the ability of a semi-automatic adjoint approach to compute the necessary gradient information without the need for an analytic model of the adjoint particle velocity field. Solutions to the forward propagation of acoustic pressure are computed using an implicit finite-difference parabolic equation solver while the particle velocity is calculated locally at each grid point. Some numerical examples of vector sensor inversion results are provided. [Work supported by Royal Netherlands Navy.]

5aUW9. Sensitivity analysis of a geoacoustic parametrized model and its application to inversion of seabed properties. Jin-Yuan Liu and Chung-Ray Chu (No. 70 Lien-hai Rd. Kaohsiung 804, Taiwan)

The work first aims to analyze the parametrized geoacoustic model proposed by Robins [J. Acoust. Soc. Am. **89**, 1686–1696 (1991)], in which the density and sound speed distributions vary with respect to depth as a generalized-exponential and an inverse-square function, respectively. The model contains a set of parameters that, by appropriate selection, may fit well the realistic geoacoustic variations [E. L. Hamilton, J. Acoust. Soc. Am. **68**, 1313–1340 (1990)]. By choosing the plane-wave reflection field as an objective function, each model parameter is carefully analyzed to determine its range and sensitivity. Then, numerical simulation is employed to establish an inversion procedure, in conjunction with the application of acoustic wave reflection from a nonuniform seabed. Finally, a field experiment is designed and implemented to estimate the seabed acoustic properties based upon the model parameter inversion.

5aUW10. Characterization of sediment dynamics in an estuary environment using acoustic techniques. Jean-Pierre Hermand, Laura Perichon (Environ. Hydroacoustics Lab., Optics and Acoust. Dept., ULB-CP 194/05, 50 AV. F.D. Roosevelt, B-1050 Brussels, Belgium), and Michel Verbanck (Univ. Libre de Bruxelles, B-1050 Brussels, Belgium)

In recent years, acoustic-based methods have been developed to characterize the dynamical behavior of loose sediments and bed deposits in very shallow water environments. In this paper, we present preliminary results on the estimation of the dynamic changes in an estuarine environment using data from dual-frequency echosounding at high resolution and contemporaneous hydrological measurements including suspended matter concentration, density subbottom profiling, and data assimilation based on a sediment transport model. Those measurements are being conducted in the lower estuary of the Scheldt (Belgium) at the Sint Anna site where strong tide and season-dependent phenomena can be observed. This allows us to construct a ground-truthed, time-dependent geoacoustic model of the environment, i.e., a characterization of sound speed, density, and attenuation in function of time and depth. Synthetic acoustic data generated by that model will then be used to test inversion methods for monitoring sediment dynamics in real time.

10:35

5aUW11. Geoacoustic model for the New Jersey Shelf by inverting airgun data. Yong-Min Jiang, N. Ross Chapman (School of Earth and Ocean Sci., Univ. of Victoria, P.O. Box 3055, Victoria, BC V8W 3P6, Canada), and Mohsen Badiey (Univ. of Delaware, Newark, NJ 19716)

This paper describes geoacoustic inversion of airgun data acquired during the SWARM95 experiment. Hybrid optimization and Bayesian inversion techniques were applied to three airgun data sets recorded by a vertical line array. Optimization results are used to show the consistency of the estimates from all of the shots in terms of histograms and standard deviations of the inverted geoacoustic model parameters. The inversion results from the Bayesian approach are used to show the uncertainties of the estimates in terms of marginal distributions, MAP estimates, and credibility intervals. In the Bayesian inversion, full data error covariance matrices were estimated by ensemble averaging the covariance of the residuals of the measured and modeled data of inversions from many shots. The numbers of shots in the ensemble averages were determined by checking the temporal coherence of the signal. Statistical tests were used to test the validity of the assumptions in the Bayesian approach after incorporating full data error covariance matrices. With these inversion techniques, equivalent geoacoustic models with/without shear wave estimates are extracted for this experimental site. The frequency dependence of the p-wave attenuation, and the correlation between the geoacoustic parameters are obtained from the inversion results. [Work supported by ONR.]

5aUW12. Mismatch effects on passive matched-field, thick-sediment inversion. Donald R. DelBalzo, Robert S. Linzell, and Lisa A. Pflug (Planning Systems Inc., 40201 Hwy. 190 E, Slidell, LA 70461)

Acoustic field predictions in shallow-water areas can be severely limited by environmental uncertainty, especially in sediment property characteristics. Direct methods of obtaining geophysical data are expensive, so inverse methods, which invert signals from controlled active sources, have recently become popular. This work assesses the impact of environmental mismatch on low-frequency (<100 Hz) matched-field correlations on broadband signals from surface ships with unknown source levels at unknown ranges. A range-staggered technique is employed to create a range-dependent sediment description, with ever-increasing confidence as additional ships are analyzed. Matched-phase techniques are applied in a simulated shallow-water environment with a single vertical array and high signal-to-noise ratios. The simulations indicate significant potential for passive, range-dependent, thick-sediment characterizations out to ranges of tens of water depths in shallow water, despite reasonable mismatch conditions in the water and in the sediments. [Work sponsored by SPAWAR.]

5aUW13. To obtain geo-acoustic parameters by the acoustic inversion technique using subbottom profiler. Chung-Wu Wang and Cheng-Che Lee (China College of Marine Technol. and Commerce, No. 212, Sec. 9, Yan-Ping N. Rd.,Taipei, Taiwan, ROC)

The fast sound speed at sea surface in the water surrounding Taiwan causes strong refraction. If the water depth is shallower than 5000 m, the sound ray will reflect at the bottom, causing severe bottom losses. Therefore, geo-acoustic parameters are important for acoustic studies in the water surrounding Taiwan. In the past, researchers used single-pulse sonar of 3.5 kHz to obtain geo-acoustic parameters by the spectral ratio technique. Now the sediment exploration has already advanced and used the Chirp Sonar system on Taiwanese Research Vessels such as Ocean Researcher I (OR I) and Ta-Kuans TOPAS system. This paper presents the results of attenuation coefficients in ocean bottoms using the acoustic inversion technique on the chirp sonar data collected by OR I. The results are compared with the core data, and the error is within 15%.

11:20

5aUW14. The resolution of a nonlinear ocean acoustic inverse problem. Robert I. Odom and Andrew A. Ganse (Appl. Phys. Lab. and Dept. of Earth and Space Sci., Univ. of Washington, 1013 NE 40th St., Seattle, WA 98105-6698)

For a strictly linear inverse problem the model resolution matrix is a simple product of the linear system matrix and its generalized inverse. How much the model resolution differs from the identity is an indication of bias in the inverted model. Nonlinear inverse problems lead to higher order resolution operators, which allow one to quantify the effect of ignoring the nonlinearity in the inverse problem. In addition, the trade-off between resolution and variance is examined for the nonlinear inverse problem. Ocean acoustic inverse problems for ocean and/or bottom structure are intrinsically underdetermined, because some continuous quantity such as sound speed or temperature is estimated from a finite number of data values, and the model is generally discretely parametrized to be numerically tractable. Discretizing the model has the positive effect of regularizing an intrinsically ill-posed problem. However, discretizing an intrinsically nonlinear problem extracts a penalty. Higher order resolution operators may contribute even when they should be identically zero. (For example, in a quadratically nonlinear model, cubic and higher order resolution operators should be zero, but won't be zero as a result of the discretization.) Modal propagation in an ocean acoustic waveguide is used to illustrate the issues. [Work supported by ONR.]

11:35

5aUW15. Adapting results in filtering theory to inverse theory, to address the statistics of nonlinear geoacoustic inverse problems. Andrew A. Ganse and Robert I. Odom (Appl. Phys. Lab. and Dept of Earth and Space Sci., Univ. of Washington, 1013 NE 40th St., Seattle, WA 98105)

The intrinsically non-Gaussian statistics of nonlinear inverse problems, including ocean geoacoustic problems, is explored via analytic rather than numerical means. While Monte Carlo Bayesian methods do address the non-Gaussian statistics in nonlinear inverse problems, they can be very slow, and intuitive interpretation of the results are at times problematic. There is great theoretical overlap between recursive filters/smoothers, such as the extended Kalman filter, and methods of linear and nonlinear geophysical inversion. The use of recursive filters in inversion is not in itself new, but our interest is in adapting statistical developments from one to the other. Classic analytic methods in both filtering theory and inverse theory assume Gaussian probability distributions, but newer nonlinear filters do not all make this assumption and are explored for their potential application to nonlinear inverse problems. The similarities and differences between the frameworks of filtering theory and inverse theory are laid out in a series of geoacoustic inverse problem examples. Recent work in nonlinear filters handles non-Gaussian probability densities that are constrained to a particular form, and also derives analytic expressions for higher order moments of these density functions. The application of these developments to geoacoustic inverse problems is addressed. [Work supported by ONR.]

5pAA1. Calibration of consonant perception in room reverberation.
Kanako Ueno (Inst. of Industrial Sci., Univ. of Tokyo, 4-6-1 Komaba, Meguro-ku, Tokyo, 153-8505, Japan), Norbert Kopco, and Barbara Shinn-Cunningham (Boston Univ., 677 Beacon St., Boston, MA 02215)

Many studies of sound perception often assumed that our auditory sensory processes are relatively static, rather than plastic. However, in everyday environments, we naturally and fluidly compensate for interfering effects of background noise and room reverberation. In order to investigate how listeners calibrate auditory perception to such acoustic interference, a listening experiment was performed to measure the effect of sudden changes of reverberation on the identification of consonants. Test sounds were generated by convolving two types of binaural room impulse responses (BRIRs) measured in large real rooms with speech tokens. As a control condition, pseudo-anechoic BRIRs with negligible reverberation energy were used. Listeners were asked to identify the consonant in a vowel-consonant target. The target was preceded by a carrier phrase consisting of vowel-consonant pairs from the same talker. In some cases, the target and carrier phrase were processed by the same BRIRs, while in others the BRIR's processing target and carrier differed. Consistent effect of calibration was observed in one of the simulated rooms, but not in the other, suggesting that the ability to compensate for the effects of reverberation depends on the specific pattern of reverberation produced in a given room. [Work supported by AFOSR and NSF.]

5pAA2. Sentence context influences vowel perception in reverberant conditions. Janine Wotton (Dept. of Psych., Gustavus Adolphus College, 800 W. College Ave., St. Peter, MN 56082, jwotton2@gac.edu), Kristin Welsh, Crystal Smith, Rachel Elvebak, Samantha Haseltine (Gustavus Adolphus College, St. Peter, MN 56082), and Barbara Shinn-Cunningham (Boston Univ., Boston, MA 02115)

Sentences recorded with a Mid-western accent were convolved with head-related impulse responses that included different room reverberation conditions. The stimuli were presented binaurally through headphones in an echo-attenuated chamber and subjects ($n=23$) typed the sentences they heard. The target word was one of a vowel pair (cattle/kettle, jam/gem, gas/guess, past/pest) embedded as the second word in one of three sentence types. The neutral sentence provided little context for the word. Target words in sentences that provided strong contextual cues could be congruent or incongruent with the expectations of the subject, for example, "The cattle/kettle grazed in the meadow." Subjects made significantly more errors in the incongruent sentences compared to the neutral (Wilcoxon$=3.572$ $p<0.05$) or congruent sentences (Wilcoxon$=3.56$ $p<0.05$). When the target word was in a congruent sentence subjects performed equally well in reverberant or pseudo-anechoic conditions (Wilcoxon$=1.298$) but they made more errors in the reverberant condi-

tion for both neutral (Wilcoxon$=3.359$, $p<0.05$) and incongruent sentences (Wilcoxon$=2.241$, $p<0.05$). Results suggest that reverberation may cause listeners to rely more heavily on linguistic context to determine word meaning. [Work supported by NOHR, AFOSR.]

5pAA3. Perceptual compensation for reverberation: Effects of noise-context bandwidth. Simon J. Makin, Anthony J. Watkins, and Andrew P. Raimond (School of Psych., The Univ. of Reading, Earley Gate, Reading RG6 6AL, UK, s.j.makin@reading.ac.uk)

Perceptual compensation for reverberation is observed when the reverberation is applied to a test word (from a "sir"-to-"stir" continuum) and its context (e.g., "next you'll get_to click on") are varied independently. Increasing reverberation in test words decreases listeners' "stir" responses, as reverberation "fills the gap" that cues the [t]. Compensation occurs when the context's reverberation is commensurately increased, and "stir" responses increase back to the level found with minimal test-word reverberation. Compensation is strongest with speech contexts but also occurs with some noise-like contexts, including "signal-correlated noise" that has the wideband temporal envelope of the original speech. Also effective is a wideband noise that is given the temporal envelope seen at the output of a single auditory filter in response to speech. A narrow-band version of this "auditory-filtered" noise is not effective, but when contexts are made by summing of three or five of these bands, their effectiveness increases correspondingly. Compensation appears to be informed by the "tails" that reverberation adds at offsets, so it merely requires contexts with suitable temporal-envelope fluctuations. However, effects seem confined to the context's frequency region, so the crucial offsets need to be in a wide range of frequency bands. [Work supported by EPSRC.]

5pAA4. Aural localization of speech stimuli. Evelyn Way (Talaske, 105 N. Oak Park Ave, Oak Park, IL 60301, evelyn@talaske.com)

Localization error was tested for a variety of signals to answer the question: do humans aurally localize different speech stimuli with a different localization blur? A series of tests was conducted comparing the effect of the sentence length, gender of the talker, and frequency content of the signals on localization. Results were applied to ongoing research into constructing an aurally accurate telepresence system.

5pAA5. Quantifying the effects of room acoustics on speech intelligibility in very low signal-to-noise ratio environments. Jarrod E. Whittington (Grad. Program in Archictectural Acoust., Rensselaer Polytechnic Inst., Troy, NY 12180, whittj@rpi.edu) and John S. Bradley (Inst. for Res. in Construction, Ottawa, K1A OR6 Canada)

The intelligibility of speech transmitted from closed offices to adjacent spaces is strongly affected by the signal-to-noise ratio at the receiver position and the acoustical characteristics of the spaces involved. Previous studies have suggested that the effect of room acoustics on speech intelligibility in closed offices and rooms is negligible and can be ignored (as with intelligibility quantifiers such as the articulation index). The purpose of this study is to show that in conditions of very low signal-to-noise (i.e., when high speech privacy is a primary concern), the influence of room acoustics rises dramatically. To this end, multiple subjects were given tests of speech intelligibility in simulated sound fields. Speech samples were presented to subjects with seven levels of signal-to-noise and four different reverberation times. The results from these tests show that as reverberation time increases, speech intelligibility decreases much more sharply for very low (-8 dB) signal-to-noise situations than in higher ($+10$ dB) signal-to-noise situations. This suggests an important relationship between room acoustics and speech privacy/security.

2:15

5pAA6. The effect of a preprocessing approach improving speech intelligibility in reverberation considering a public-address system and room acoustics. Nao Hodoshima, Takayuki Arai (Dept. of Elec. and Electron. Eng., Sophia Univ., Tokyo 102-8554, Japan), and Peter Svensson (Norwegian Univ. of Sci. and Technol., Trondheim NO-7491, Norway)

This study evaluates a preprocessing approach for reducing reverberation effects when the input signal is not ideal, dry speech, but rather a realistic speech signal picked up by a close microphone in a room. And this study shows how the situation affects the input and the further approach compared to a dry signal as the input. Steady-state suppression, as described by Arai *et al.* [Acoust. Sci. Technol. **23**, 229–232 (2002)], was used as a preprocessing approach that processes a speech signal before it is radiated from loudspeakers. A lecture was simulated in two different halls (reverberation times of 1.2 and 1.8 s) in which public address systems were installed. The simulation software CATT-Acoustic was used and impulse responses were calculated for the input to the preprocessing approach and for a listener position. Stimuli for a syllable identification test were prepared by convolving speech signals with the calculated impulse responses. Speech signals were given with and without steady-state suppression. The inclusion of natural and electroacoustical impulse responses makes the study of steady-state suppression more realistic and tests its robustness. [Work supported by JSPS (176911).]

5pAA7. Improving speech intelligibility in reverberant rooms. Douglas F. Winker and Elmer L. Hixson (Dept. of Elec. and Comp. Eng., Univ. of Texas, Austin, TX 78712)

Speech intelligibility in rooms with long reverberation times has long been a problem for acousticians. This problem is exacerbated when the option for acoustic treatments is not an option for a variety of reasons. In this study, a constant-beamwidth, wide-bandwidth (CBWB) loudspeaker array was used to improve speech intelligibility in two multipurpose rooms where treatment was not an option. A CBWB loudspeaker array was designed with independent beam pattern control on both the horizontal and vertical axes. A wide horizontal beam pattern and narrow vertical pattern were designed to achieve constant coverage from 500 Hz to 4 kHz. The array incorporates four separate arrays, two with nested elements, and linear-phase FIR filters to maintain constant beamwidth over the three octaves of interest. Room simulations were conducted with CATT-Acoustic and the array was implemented and compared to a source with a

more conventional coverage pattern. The STI method was used to measure speech intelligibility at several positions throughout the rooms. The study showed an improvement in speech intelligibility and a reduction in measured reverberation times.

5pAA8. Experimental investigations of the influence of room acoustics on the teacher's voice. Malte Kob, Anja Kamprolf, Christiane Neuschaefer-Rube, Oliver Goldschmidt (Chair of Phoniatrics and Pedaudiology, RWTH Aachen Univ., Pauwelsstr. 30, 52074 Aachen, Germany, mkob@ukaachen.de), and Gottfried Behler (RWTH Aachen Univ., 52066 Aachen, Germany)

Teachers belong to the group of professional voice users who often suffer from voice disorders. One reason for a significantly increased prevalence of voice problems can be poor room acoustical conditions in the classrooms. In this study, four rather reverberant and loud classrooms in a primary school in Aachen were analyzed using measurements of the reverberation time, T_{20}, and the speech transmission index, STI. About half of the school's teachers were investigated with respect to their voice status by using phoniatric, logopedic, and objective voice analysis methods. The prevalence of voice problems in this group was found to exceed previous studies where subjective voice quality was rated. In a second part of this joint project the change of voice quality during the teachers' working day was analyzed. Two of the four rooms were acoustically optimized. Members of two groups of teachers with and without voice problems were recorded before and after teaching in either one of the acoustically poor rooms or one of the newly renovated rooms. The preliminary results indicate changes of the voice quality in most subjects with respect to one or more voice parameters. Further studies shall prove the significance of the room influence.

5pAA9. Human voice phoneme directivity pattern measurements. Brian F. G. Katz, Fabien Prezat, and Christophe d'Alessandro (Percept. Située, LIMSI-CNRS, BP 133, F91403 Orsay, France)

The application of directivity patterns to radiating sources into computer simulations and auralizations is common for loudspeaker models. Few applications include the directivity patterns of natural sources, partly due to the lack of sufficient data. This work presents the results of a detailed measurement study on human voice directivity in three-dimensions. Unlike previous studies that have used average directivity data over read phrases, this work presents results that are measured for a number of sustained individual phonemes. Details of the measurement protocol and posttreatment processing are presented. Comparisons are made relative to phoneme, f0, spectral characteristics, and associated mouth geometry for several talker subjects. Studies have also been made on the directivity of the singing voice. Specifically, the variations in directivity relative to level (piano, fortissimo, etc.) and projection as controlled by the singer have been investigated. Results of this work are applicable to speech production research, talker simulator design, room acoustic sound field prediction, and virtual reality systems with talking avatars.

3:30

5pAA10. Case study for voice amplification in a highly absorptive conference room using a negative absorption tuning by the Yamaha Active Field Control system. Takayuki Watanabe (YAMAHA Commercial Audio Systems, Inc., 6600 Orangethorpe Ave., Buena Park, CA 90620)

The Yamaha Active Field Control (AFC) enhances and varies acoustical conditions from the room acoustics using the acoustical feedback in a system, which is properly tuned to the installed room acoustics. The system is primarily used to improve auditory impressions of reverberance, loudness by enhancement of reverberation in time, and energy in a music venue. Here, a negative absorption tuning is demonstrated as beneficial to

the presentation room for a simple spoken speech used with a relatively excessive absorption at a middle-sized multiuse conference room. The space occupies 1100 ft² with a ceiling height of 9 ft. It is designed for demonstration of sound equipment as well as lecture without audio equipment. Since the acoustics in the room are highly absorptive (average absorption coefficient, 0.3), considering a primary use for product demonstration, it causes a flutter echo between longitudinal walls due to less sound energy in a late field. We demonstrate here a system adjustment of the AFC system emphasizing voice amplification as well as an acoustical solution to a defect of a fluttering echo here. Acoustical descriptors such as RT, echo diagram, and SPL are discussed for a tuned room acoustics with the AFC system.

Contributed Poster Papers

Poster papers 5pAA11 to 5pAA14 will be on display from 1:00 p.m. to 4:45 p.m. Authors will be at their posters from 3:45 p.m. to 4:45 p.m.

5pAA11. Slowed speech spreading into reverberant environments; steady-state suppression improves speech intelligibility. Yuki Nakata, Yoshiaki Murakami, Nao Hodoshima, and Takayuki Arai (Dept. of Elec. and Electrons Eng., Sophia Univ., 7-1 Kioi-cho, Chiyoda-ku, Tokyo, 102-8554 Japan)

Speech intelligibility is often decreased in reverberant environments. For improving speech intelligibility under reverberant environments, Arai *et al.* [Acoust. Sci. Technol. **23**, 229–232 (2002)] suggested steady-state suppression, which suppresses steady-state portions of speech to reduce overlap-masking (causing degradation intelligibility) and improves speech intelligibility as preprocessing. Previous studies showed that speech intelligibility was improved through this processing under some reverberant environments [Hodoshima *et al.*, J. Acoust. Soc. Am. **119**(6), 4055–4064 (2006)]. On the other hand, speech intelligibility is known to be increased greatly by speaking slowly [Bolt and MacDonald, J. Acoust. Soc. Am. **21**(6), 577–580 (1949)]. However, it is not optimal for improving speech intelligibility in terms of reducing overlap masking because vowels causing major parts of overlap masking are expanded by speaking slowly. Therefore, in the current study, we investigated the effects of steady-state suppression on speech perception with a decreased speech rate from 6 to 4 and 5 morae/s. Results showed that the slowest speech (4 morae/s) with steady-state suppression was the most intelligible. Also, steady-state suppression improved speech intelligibility at a speech rate of 4 morae/s in each reverberant condition (reverberation times of 1.5, 2.0, and 2.5 s). [Work partially supported by JSPS.KAKENHI (16203041).]

5pAA12. Suppression of speech intelligibility loss through a modulation transfer function-based speech dereverberation method. Masashi Unoki, Masato Toi, Yohei Shibano, and Masato Akagi (School of Information and Sci., JAIST, 1-1 Asahidai, Nomi, Ishikawa, 923-1292 Japan, unoki@jaist.ac.jp)

The concept of modulation transfer function (MTF) can successfully be applied to evaluate the quality of speech transmission in the room acoustics [Houtgast and Steeneken, J. Acoust. Soc. Am. **77**, 1069–1077 (1985)]. We previously proposed a speech dereverberation method based on the MTF concept, which consisted of MTF-based power envelope inverse filtering and the carrier regeneration in the filterbank [Unoki *et al.*, EuroSpeech2003 (2003)]. This paper evaluates how the proposed method can suppress the loss of speech intelligibility caused by reverberation, by comparing various methods. We have carried out massive simulations of dereverberation for reverberant speech signals to objectively evaluate these methods. We also subjectively evaluated the methods via listening tests. In these simulations, artificial reverberations were convolved with a clean speech signal in which the impulse responses in the room acoustics can be approximated from the exponential decay as a function of reverberation time with a white-noise carrier. The results of both evaluations show that, in addition to reducing the averaged log-spectrum distortion by about 1 dB, the proposed method reduces the loss of speech intelligibility by about 30%. [Work supported by a Grant-in-Aid for Science Research from the Japanese Ministry of Education (No. 18680017).]

5pAA13. Word and mora intelligibility in "Familiarity-controlled word-lists 2003 (FW03)." Tadahisa Kondo, Shigeaki Amano (NTT Commun. Sci. Labs., NTT Corp., 3-1 Morinosato-Wakamiya, Atsugi, Kanagawa, 2430198, Japan, tkondo@brl.ntt.co.jp), Shuichi Sakamoto, and Yôiti Suzuki (Tohoku Univ., Aoba-ku, Sendai, Miyagi, 9808577, Japan)

"Familiarity-controlled Word-lists (FW03)" was developed to make it possible to perform intelligibility tests on the same person repeatedly and/or under several different conditions. FW03 consists of 20 lists of 50 words in four word familiarity ranks. These words were selected taking phonetic balance into consideration to maximize their variety of initial moras and vowel-consonant sequences. To confirm that all FW03 word lists from a particular familiarity rank present the same hearing difficulty, we measured the word intelligibility of all the words in FW03. Sixteen subjects listened to 4000 words spoken by four speakers with seven signal-to-noise ratios. The mean intelligibility scores for the lists were significantly different even for the same familiarity rank. The intelligibility was apparently influenced by some specific moras and their position in words. These results suggest that it is difficult to equalize the word intelligibility of the lists even when the word familiarity is controlled more precisely. We therefore examined several methods for equalizing the intelligibility among the lists such as controlling the sound pressure level for each word when operating an actual intelligibility test. The effectiveness of these methods is discussed with detailed analyses of word and mora intelligibility in FW03.

5pAA14. Influence of Deutlichkeit value and reverberation time on improved speech intelligibility in reverberant environments because of steady-state suppression. Nahoko Hayashi, Nao Hodoshima, Takayuki Arai (Dept. of Elec. and Electron. Eng., Sophia Univ., 7-1 Kioi-cho, Chiyoda-ku, Tokyo 102-8554 Japan, nhayash@sophia.ac.jp), and Kiyohiro Kurisu (TOA Corp., Takarazuka, Hyogo 665-0043 Japan.)

To improve speech intelligibility in reverberant environments, Arai *et al.* proposed "steady-state suppression (SSS)" as preprocessing [Arai *et al.*, Acoust. Sci. Technol. **23**, 229–232 (2002)]. In this study, a perceptual experiment under artificial reverberant conditions with simulated impulse responses was conducted to elucidate the effect of the Deutlichkeit (D) value and reverberation time (RT) on improvements of speech intelligibility because of SSS. Artificial impulse responses were simulated with white noise multiplied by a decay curve. The advantage of this method is that the simulated impulse responses have mutually similar frequency characteristics; consequently, we can evaluate them using only the D value and RT regardless of their different frequency characteristics. Two parameters, the energy of the impulse response 50 ms from the direct sound and the attenuation rate of the decay curve, were controlled to obtain several impulse responses having certain D value and RT. Results show that SSS improved speech intelligibility in the conditions of low D value, even if RT was long or short. We could also interpret these results as indicating that processing is effective when the original speech intelligibility is less than 60%. [Work supported by JSPS.KAKENHI (16203041).]

5pBB1. Measurement of thrombi volume using a transesophageal echocoardiography movie. Masami Aoki (Grad. School of Sci. and Technol., Chiba Univ., 1-33 Yayoi-cho Inage-ku, Chiba, 263-8522, Japan), Tadashi Yamaguchi, and Hiroyuki Hachiya (Chiba Univ., Chiba, Japan)

In a total knee replacement operation, thrombi are formed by blood stasis in the deep venous of inferior limbs. They can cause pulmonary thromboembolism. The current judgment method of the existence of thrombi in the orthopedics field is visual observation using transesophageal echocoardiography (TEE). Therefore, we attempted to devise a quantitative measurement method of the volume of thrombi from TEE movies using multiple signal processing. It is necessary to extract a contour of the right atrium area at each frame of a TEE movie to measure the amount of thrombi that reach the lungs. Therefore, we propose processing that combines the modified brain extraction technique (BET) and vector moving method. The modified BET enables high-precision contour extraction. Vector moving performs the fast contour extraction. In addition, the fiber structure extraction technique (FSET) is used to extract the thrombi information in the right atrium. Similarly to speckle reduction, FSET can extract anomalous information from echo images. Using these processes, we observed a small periodic change that is synchronized with the heartbeat and the large time change that is synchronized with breathing.

1:15

5pBB2. Auscultation in high-noise environments using hybrid electromechanical and ultrasound-Doppler techniques. Adrianus J. M. Houtsma, Ian P. Curry (U.S. Army Aeromedical Res. Lab., Fort Rucker, AL 36362), John M. Sewell, and William N. Bernard (Active Signal Technologies, Inc., Linthicum Heights, MD 21090)

Medical evacuation of battlefield casualties or traffic accident victims by air typically takes place in very noisy environments. Auscultation of patients, e.g., to support chest intubation or to detect a pneumothorax, is therefore difficult or impossible to perform. A conventional acoustic stethoscope will not function very well in background noise levels beyond 80 dB. Electronic stethoscopes, in combination with mechanical impedance-matched transducer designs, can extend this range to about 90 dB, but this is not enough for helicopter noise levels that can reach 110 dB. The use of an ultrasound transmitter and receiver, however, provides an essentially noise-free auscultation channel since transportation vehicles do not produce acoustic energy at ultrasound carrier frequencies of 2–3 MHz. Clean and noise-free heart and breath sounds have been obtained in broadband noise fields of intensities as high as 120 dB. A hybrid stethoscope has been developed that allows auscultation by ultrasound-Doppler as well as electromechanical means. Pros and cons of making Doppler sounds subjectively similar to conventional sounds by nonlinear signal processing will be discussed, as well as potentially functional and meaningful aspects of Doppler signals that are not found in conventional stethoscope sounds.

1:30

5pBB3. Color and pulsed Doppler signatures of vascular bleeding. Wenbo Luo, Vesna Zderic, and Shahram Vaezy (Dept. of Bioengineering, Univ. of Washington, Seattle, WA 98195)

To develop ultrasound-based methods for detection and localization of internal vascular bleeding, we investigated the bleeding signatures using color and pulsed Doppler. Under ultrasound guidance, femoral arteries ($n = 13$) and veins ($n = 12$) in seven pigs were catheterized with 6, 9, and 11 F catheters. Color and pulsed Doppler were acquired from the injury site and the surrounding positions after withdrawal of the catheter. The bleeding rates were 3.8–38 ml/s. Color Doppler revealed that the injured vessels were in spasm. The checkered color pattern at the injury site indicated flow turbulence. Pulsed Doppler spectrum of the color jet (extravasated blood) represented a unique arterial bleeding pattern with increased baseline velocity (from 0 up to 25.8 cm/s) and elevated systolic velocity (from 23.2 up to 62.5 cm/s) at the puncture site, as compared to the normal arterial pattern. Venous bleeding showed a narrow-band vibration signal at the bleeding site. Local blood turbulence contained multiple velocity components which were illustrated as checkered color in color Doppler. Pulsed Doppler spectrum showed increased baseline due to turbulence and elevated velocity due to narrowed vessel. In future studies pulsed Doppler radio-frequency data will be used to analyze bleeding patterns for detection and localization of internal bleeding.

5pBB4. Basic study on angular dependence of ultrasonic scattering from wire phantom mimicking myocardium. Teppei Onodera, Hideyuki Hasegawa, and Hiroshi Kanai (Grad. School of Eng., Tohoku Univ., Sendai 980-8579, Japan, onodera@us.ecei.tohoku.ac.jp)

It is reported that the ultrasonic scattering from myocardium varies periodically during a cardiac cycle. One of the reasons is considered to be the change of the angle between the ultrasonic beam and the direction of myocardial fibers. Therefore, it is expected that ultrasonic scattering from myocardium quantitatively characterizes the condition of myocardium. To investigate the angle dependence of ultrasonic scattering in relation to the fiber direction, in this study, ultrasonic echoes from a wire phantom (thinner than a wavelength in diameter) that mimics myocardium were measured as a function of the insonification angle. Two ultrasonic transducers of 7 MHz were employed for transmitting and receiving ultrasonic pulses. Focal points of these transducers were set at the same point on the phantom. A custom-made experimental system can change the azimuth and elevation angles while keeping the focal points at the same point. Measured ultrasonic scattering showed a significant change depending on the azimuth angle. Such changes depending on the azimuth angle were decreased by increasing the elevation angle. These preliminary findings support the hypothesis that the change in the angle between the ultrasonic beam and myocardial fibers due to the heartbeat varies the ultrasonic scattering property.

5pMU1. A hybrid approach for simulating clarinetlike systems involving the lattice Boltzmann method and a finite difference scheme. Andrey Ricardo da Silva and Gary Scavone (Computational Acoust. Modeling Lab., McGill Univ., 555 Sherbrooke St. W., Montreal, CA H3A 1E3, Canada, andrey.dasilva@mail.mcgill.ca)

The lattice Boltzmann (LB) method is becoming an increasingly important technique for the simulation of problems involving the interaction between acoustic and fluid fields. New LB algorithms allow the representation of moving boundaries at low Mach numbers. In this work we present the implementation of a hybrid model involving one such LB algorithm coupled to a finite difference scheme to simulate the fluid-structure interaction at the reed of a two-dimensional clarinetlike system. The results of the simulation for different input pressures and reed parameters are compared with the results provided by the related literature. [The first author was supported by CAPES (Brazil).]

5pMU2. Three-dimensionality and temporal variability of the jet flow in organ pipes. Shigeru Yoshikawa, Yumiko Sakamoto (Dept. of Acoust. Design, Grad. School of Kyushu Univ., Fukuoka 815-8540 Japan), Andreas Bamberger (Albert-Ludwigs-Univ. Freiburg, D-79104 Freiburg, Germany), and Judit Angster (Fraunhofer Inst. for Bldg. Phys., D-70569 Stuttgart, Germany)

Flow visualization by the particle image velocimetry (PIV) is expected to provide quantitative information based on high resolution from the use of sheetlike laser pulses. This PIV technique is applied to investigate the difference in jet-flow structure of organ pipes when the ear (small plate standing at each side of the mouth) is used or not. The experimental results given by PIV are also compared with those by the hot-wire anemometry. Two-dimensionality and laminar-flow condition tend to be maintained when the ear is used. However, when the ear is not applied, the deviation from laminar flow and the resulting three-dimensionality are apparent halfway between the flue and the edge (*re* less than 1800). The ear seems to block the entrainment from the mouth side. Moreover, it is shown that the magnitude of jet velocity is significantly reduced at the phase when the jet deflects innermostly to the pipe with the ear and at the phase when the jet deflects outermostly from the pipe without the ear. These 3D and temporal variability of the jet flow should be examined in more detail in the context of harmonic structure of organ tones and vortex-sound theory on flue instruments.

1:40

5pMU3. Vortex sound and the flute. Andreas Bamberger (Phys. Institut der Universitaet Freieburg, Hermann Herder Str. 3, 79104 Freiburg, Germany)

The flute is investigated for its aeroacoustical properties based on the vortex sound theory. Particle image velocimetry (PIV) is used for quantitative flow determination of the jet-edge interaction. The Endoscopic-PIV offers a nonobstructive view of the system over all phases. The evaluation of the source term through the vorticity is done according to M. Howe (1975). The acoustic flow across the embouchure is determined by excitation through the foot. The flute is operated near 1200 Hz with various jet speeds. Finally the acoustic radiation power in the far field is determined to be compared with the source terms. The following findings are presented: (*i*) The space integrated and time averaged power of the coherent source terms turns out to be positive, i.e., emitting acoustic energy. (*ii*) There is a dominant contribution near the labium. (*iii*) The source term power compares favorably with the far field power, which is well below 1% of the total input power. The results demonstrate that the vorticity of the upper and lower shear layers of the jet cancels to a great extent, except for regions where the transverse amplitude of the jet is large.

5pMU4. Sound generation in flutelike instruments: Simulation and analysis. Helmut Kuehnelt (Inst. of Musical Acoust., Univ. of Music and Performing Arts Vienna, Singerstrasse 26a, A-1010 Vienna, Austria)

Three-dimensional flow-acoustic simulations using the lattice Boltzmann method were used to study the sound generation in flutes and recorders. Theory suggests that the fluctuating Coriolis force in the mouth of the instrument caused by the fluctuating vorticity distribution of the jet is the main source of sound. A numerical experiment was undertaken to clarify this hypothesis for flute instruments. In the mouth of the instrument an equivalent temporal fluctuating force was imposed in a quiescent fluid. Although this force excited fluid dynamic effects in the mouth not present at mean flow, it nevertheless induced a standing wave in the instrument with a sound pressure whose amplitude differed only less than 1 dB from the playing situation. This shows the cardinal role of the Coriolis force for the sound generation in flutes. The temporal and spatial structure of the Coriolis force distribution and the vortex sound power generated will be compared for flute and recorder. Especially the spatial structure differs systematically for the two types of instruments. Implications for the design of flute head joints will be discussed.

5pMU5. Particle image velocimetry measurement and vortex sound analysis of high-amplitude acoustically generated flows in open ended tubes. David Skulina (Acoust. and Fluid Dynam. Group, School of Phys., Univ. of Edinburgh, Scotland)

Periodic vortex shedding induced by an acoustic field has been observed by several authors at orifices and at the open ends of tubes. It is a well-known dissipative mechanism and affects the sound field at the open end of a tube and the efficiency with which a standing wave can be maintained within it. This has obvious implications in the playability and design of musical wind instruments. To quantify the losses associated with vortex generation and shedding at the open end of a tube a method for the evaluation of PIV velocity maps using vortex sound theory is outlined. Comparison between the results of the vortex sound calculations and the velocity fields measured from the PIV vector maps allows both qualitative and quantitative descriptions of the acoustical effect of vortex shedding on losses over the acoustic cycle. It is found that the net acoustical losses due to the interaction of vortices with the acoustic field are most significant in a region within 2.5 mm of the open end. Out of this region, vortices act as a net source of sound, but are of lesser magnitude. [Work supported by EPSRC.]

5pMU6. Synthetic percussion. Stefan Bilbao (Dept. of Music, Rm. 7306B, James Clerk Maxwell Bldg., King's Bldg., Mayfield Rd., Edinburgh EH3 9JZ, Scotland)

The widespread availability of fast small computers has removed many of the restrictions that governed the development of sound synthesis methods in the past, and, in particular, those based on physical modeling of musical instruments. Even relatively complex models can now produce sound output in something approaching real time, if not real time itself. As an example, various models of strings and 2-D percussion instruments, simulated using direct time domain methods, are presented here. Various issues are discussed, including interconnections of various vibrating objects, extensions of percussion instruments involving acoustic "preparation," the modeling of nonlinearities, multichannel output, algorithmic complexity, and operation counts, as well as current work towards developing real time implementations. Sound examples are presented.

3:10

5pMU7. Simulation of piano strings and a soundboard by a large deformation theory. Isoharu Nishiguchi, Masataka Sasaki, and Aki Yamamoto (Kanagawa Inst. of Technol., 1030 Shimoogino, Atsugi, Kanagawa, Japan 243-0292, nishiguc@sd.kanagawa-it.ac.jp)

Three-dimensional finite element analyses of piano strings and a soundboard are presented in which a large deformation theory is adopted. In the large deformation theory, the momentum balance of a body is preserved in the course of the deformation and the changes of direction and amplitude of axial force due to deformation are taken into account. It is shown that the secondary partials appear in the spectrum of the velocity component in the axial direction as well as the transverse direction. A hammer is modeled by masses with springs and dashpots. Gap elements are employed to simulate the contact and detachment between the hammer model and a string. It is demonstrated that multiple reflections between hammer and agraffe can be reproduced by the method. Modeling of the interaction among strings, a bridge, and a soundboard is also discussed in which the crown and the preloading of the soundboard are taken into account.

3:30

5pMU8. Physical modeling of the piano. N. Giordano (Dept. of Phys., Purdue Univ., West Lafayette, IN 47907, giordano@purdue.edu)

As part of an ongoing project we have constructed a computational model of the piano. This model uses Newton's laws to compute the motion of the hammers, strings, soundboard, and room air, yielding the sound pressure that reaches a listener. The model is based heavily on corresponding experimental studies of hammers, strings, and soundboard properties. To date we have focused on the modern piano, but our basic modeling approach can also be used to investigate how changes in the instrument would change the resulting tones. After reviewing the model, we describe studies of the sound produced by models of historical pianos, i.e., the type of piano made in the late 1700s or early 1800s, and compare those tones with the tone of a modern instrument.

5pMU9. Numerical dispersion of finite difference method. Yoshimitsu Takasawa (Univ. of Electro-Commun. 1-5-1 Chofugaoka, Chofu, Tokyo, Japan, takasawa@ice.uec.ac.jp)

The partial frequencies of the transverse vibrations of a string, which has stiffness ϵ and is assumed to be hinged at both ends, form an inharmonic series and obey the equation $f_n = f_0 n (1 + \pi^2 \epsilon n^2)^{1/2}$, where f_0 is the fundamental frequency. For musical synthesis, the equations of a physical model can be simulated in the time domain using numerical methods. The most straightforward approach can be said to be the finite difference method. The equations are formulated in discrete form using discrete positions $i\Delta x$ and discrete time steps $n\Delta t$. In the finite difference method, two problems must be taken into account. The first is numerical stability: it must be roughly $\gamma > N$. Here, $\gamma = f_e/2f_0$, $f_e = 1/\Delta t$ is the sampling frequency, and $N = L/\Delta x$ is the segment number of the string. The second is the numerical dispersion. It has been shown that some undesirable dispersive effects might be present in the solution if a finite difference scheme is used. This numerical dispersion can be formularized as the equation $f_n \approx f_0 n [1 + \pi^2 \{\epsilon - \frac{1}{12}(1/N^2) - 1/\gamma^2)\} n^2 - \pi^4/6\{\epsilon/N^2 - \frac{1}{60}(1/N^4 - 1/\gamma^4)\} n^4]^{1/2}, n \leq N-1$.

5pMU10. Imaging vibrations and flow using electronic speckle pattern interferometry. Thomas R. Moore (Dept. of Phys., Rollins College, Winter Park, FL 32789)

Electronic speckle pattern interferometry has been used to measure sub-micrometer displacements and visualize the deflection shapes of harmonically vibrating objects for many years; however, to date the technique has not been widely used within the community of musical acousticians. The cost of the equipment, the need for effective vibration isolation, and the complexity of the hardware are usually cited as the reasons why this technique has not been more widely utilized in the study of musical instruments. To alleviate these concerns, a speckle pattern interferometer has been designed that is relatively inexpensive, easy to assemble, and very robust. Construction of the interferometer will be discussed, and applications to problems in musical acoustics will be presented.

5pMU11. Psychoacoustic experiments with virtual violins. Claudia Fritz, Ian Cross (Faculty of Music, Univ. of Cambridge, West Rd., Cambridge, CB3 9DP, UK), Brian C. J. Moore, and Jim Woodhouse (Univ. of Cambridge, Cambridge, CB3 9DP, UK)

This study is the first step in the psychoacoustic exploration of why some violins sound better than others. A method was used that enabled the same performance to be replayed on different "virtual violins," so that the relationships between acoustical characteristics of violins and perceived qualities could be explored. Recordings of real performances were made using a bridge-mounted force transducer, giving an accurate representation of the signal from the violin string. These were then played through filters corresponding to the admittance curves of different violins. Initially, the limits of performance in detecting changes in acoustical characteristics have been characterized. Thresholds were measured for the detection of different modifications of a violins acoustical response, such as a shift in frequency or an increase in amplitude of one or several modes, using a three-interval forced-choice discrimination task. Thresholds were higher for an input of a musical phrase than for a single note, but depended strongly on the choice of the note. The lowest threshold corresponded to a simultaneous shift in frequency of 1.5%, or an increase in level of 3 dB, of several modes, but thresholds appear to be dependent on the musical training of the listeners.

5pMU12. Use of the energy decay relief (EDR) to estimate partial-overtone decay times in a freely vibrating string. Nelson Lee and Julius O. SmithIII (Ctr. for Comput. Res. in Music and Acoust. (CCRMA), The Knoll, 660 Lomita, Stanford, CA 94305-8180, USA, nalee@stanford.edu)

The energy decay relief (EDR) was proposed by J. M. Jot [IEEE, ICASSP (1992)] for displaying the impulse response of artificial reverberation systems. The EDR is a frequency-dependent generalization of Manfred Schroeder's energy decay curve (EDC), defined at time n as the sum of squared impulse-response samples from time n until decay is complete. The EDR is similarly defined for each band in a uniform filter bank, typically implemented using the short-time Fourier transform (STFT). In this work, we apply the EDR to the problem of estimating decay times for the partials of a freely vibrating string. Previously, such decay times have been measured based on STFT magnitude data. We show that the EDR has certain advantages over the STFT, such as being less sensitive to "beating" in the amplitude envelopes of the partial overtones. Results in the context of virtual acoustic guitar modeling will be presented.

Contributed Paper

5pMU13. Numerical analysis of the 48-key experimental piano. Kenji Hasegawa, Isoharu Nishiguchi, and Masataka Sasaki (Kanagawa Instutute of Technol., 1030 Shimoogino, Atsugi, Kanagawa, 243-0292, Japan, s064817@cce.kanagawa-it.ac.jp)

An experimental piano has been built as a part of research program for students in the 4th grade. Though the main purpose of the building was to use the piano in vibrational and acoustical experiments, it was also intended to deepen the understanding of the structures of a piano by newly designing and building a piano that was different from existing pianos. The range covered by the piano is 4 oct (key nos. 21–68). After the sizes and arrangements of the strings were determined, the metal frame that sustains the tension of the strings was designed. The deformation and the stress were evaluated by the FEM. In this paper, the design and results of numerical analysis of the strings and soundboard are reported.

5pNSa1. A predictive noise model for the resurfacing of Nebraska Highway 2. Dominique Cheenne, Connie Lee, Michael Cappiello, Sam Lalk, Coleman Martin, and Philip Muzzy (Dept. of Audio Arts & Acoust., Columbia College Chicago, Chicago, IL 60610)

A detailed investigation of the noise soundscape resulting from traffic on a 3-mile segment of Nebraska Highway 2 prior to resurfacing work was undertaken by the students enrolled in the Acoustics Program at Columbia College, Chicago. Noise data were acquired at six different locations using established protocols and included daytime and nighttime conditions. The test data were compared to the predictions from an outdoor noise propagation computer model and the results were found to be within ± 2 dB for all locations under consideration. The computer model was then used to assess expected noise conditions under various concrete and asphalt scenarios for resurfacing. Data show that reductions of up to 6 dB in the overall noise levels may be achievable depending on the choice for the surface of the roadway.

1:15

5pNSa2. Experimental determination of the correction for noise levels assessed in front of a facade. Gianluca Memoli (Memolix Environ. Consultants, Pisa, Italy), Stylianos Kephalopoulos, Marco Paviotti (Joint Res. Ctr. of the European Commission, Ispra, Italy), and Gaetano Licitra (Tuscany Region Agency for Environ. Protection, Firenze, Italy)

The assessment of noise levels, in the proximity of a building or on its facade, is a requirement of the European Environmental Noise Directive 2002/49/EC concerning environmental noise produced by road and railway traffic, airports, and industries. One of the problems that concerns both theoretical models and measurements is to estimate the correction due to reflections. Several works in the past have approached this problem, now stated by international standards, which suggest using a $+3$ or $+6$-dB correction in function of the microphone position. A complete set of measurements have been performed in the framework of the IMAGINE project for road traffic, in different urban situations, in order to determine

the real intereference pattern in terms of coherence length. A careful treatment of the acquired data highlighted a dependence of corrective factors on the distance from the building facade that cannot be neglected. Practical solutions and uncertainties also will be discussed in this work.

1:30

5pNSa3. An exact point-source starting field for the Green's function parabolic equation in outdoor sound propagation. Kenneth Gilbert and Xiao Di (Univ. of Mississippi, Natl. Ctr. for Physical Acoust., Coliseum Dr., Universtiy, MS 38677)

A method for exactly representing a point source in a Green's function parabolic equation calculation is presented. The method is no more difficult to use than standard starting-field formulations and has the several advantages: (1) the point-source solution is essentially exact; (2) only the propagating Fourier components are used; and (3) there is no limitation on the source height, which can be taken to be at $z = 0$, if necessary. The method is derived analytically and examples of the numerical implementation are given. [Research supported by U.S. Army Armament, Research Development and Engineering Center (ARDEC).]

1:45

5pNSa4. Predicted effects of forest stand age on acoustic propagation. Michelle Swearingen (Construction Eng. Res. Lab., P.O. Box 9005, Champaign, IL 61826, michelle.e.swearingen@erdc.usace.army.mil)

A theoretical study on the impact of forest stand age on acoustic propagation will be presented. A Red Pine forest was simulated at 10, 20, 30, 40, and 80 years of age, with assumptions that it was being maintained for utility pole harvest. Forest parameters, such as density, height, and diameter of trees, were used to predict vertical sound-speed profiles and then acoustic propagation. The resulting spectra were weighted to simulate low-frequency (30 Hz) and midfrequency (500 Hz) blast signatures. Spectra and sound-exposure levels (SEL) were examined to determine whether the forest stand age has a significant impact on acoustic propagation within a forest.

5pNSb1. Noise emissions from powered hand tools: A consumer alert!.　Charles Hayden and Edward Zechmann　(NIOSH, 4676 Columbia Pkwy., C27, Cincinnati, OH 45226)

　　Existing standards for acquiring sound power levels of powered hand tools specify, for the most part, that sound levels be gathered in the unloaded test condition. However, there is an increase in sound level when the power tool is tested in the loaded condition. There are two purposes for gathering sound power level data: (1) determination of hearing loss hazard or irritation and (2) part of an engineering design optimization effort. The former is the focus of the National Institute for Occupational Safety and Health efforts. Sound power level data were gathered in the loaded and unloaded conditions from a variety of electrically powered hand tools. A model was then used to estimate the A-weighted sound pressure level at the operator's ear from the A-weighted sound power (LWA) measurements of powered hand tools. The magnitude of LWA is found to be a reasonable predictor of the magnitude of sound pressure level exposure that a powered hand tool operator might experience across a variety of acoustical environments. This presentation explores the methods used to gather sound power levels, an evaluation of the model, and an examination of differences found between loaded and unloaded tool test conditions.

2:40

5pNSb2. Protocol for measuring dishwasher sound power levels.　Kevin Herreman and Richard Godfrey　(Owens Corning Corp., 2790 Columbus Rd., Rte. #16, Granville, OH 43023, kevin.herreman@owenscorning.com)

　　A leading retailer of home appliances came to the OC acoustics laboratory to evaluate the noise generated by dishwashers sold in their stores. A protocol based on a methodology used in Europe was used. It was modified to account for North American building standards. The standard provides an overall sound power level determination for the complete dishwasher cycle with and without the drying portion of the cycle. As a result customers making a purchasing decision can compare the noise performance of the various products using the same yard stick.

3:00

5pNSb3. Noise exposure limits and measurements for earphones.　K. Allen Woo　(Plantronics, Inc., 345 Encinal St., Santa Cruz, CA 95060)

　　There are noise exposure concerns regarding the use of audio earphones and telephone receivers. The permissible noise exposure limits have been defined for the occupational environment for many years, for instance, the US Code of Federal Regulations, 29CFR1910.95, Occupational noise exposure and the Directive 2003/10/EC of European Parliament on Minimum Health and Safety Requirements. Those permissible noise exposure limits are defined for noise exposure in an ''open-field'' environment. An open-field environment is an environment where the noise sources are at a distance from a person's ear. The sound or noise field can be a combination or any of a free field, or partially reflected, diffused, and reverberant fields. Nonetheless, the noise exposures from earphones are not in an open field. They are localized at or inside the user's ear. Conventional open-field noise exposure measurement methods do not apply. During the last 15 years or so, a few different test methods for measuring noise exposure from earphone or telephone receivers were developed. The standards of ITU-T P.360, UL 60950-1, IEEE 269, and EN 50332 were developed mostly by the telephone industry. This presentation addresses the common permissible noise exposure limits, how to relate the limits to earphones, and how to measure them.

3:20

5pNSb4. Sound quality evaluation of transient sounds in precision information equipments. Masao Yamaguchi (Res. & Development Ctr., Toshiba Tec Corp., 6-78, Minami-cho, Mishima-shi, Shizuoka-ken, 411-8520 Japan), Sho Shirakata, and Takeshi Toi (Chuo Univ., Bunkyo-ku, Tokyo 112-8511, Japan)

These days, sound quality in mechanical products has become a very important factor in addition to reduction of the sound pressure level. A new method is proposed for sound quality evaluation including the transient sound in precision information equipment taking MFP (multifunction peripheral), for example. The MFP has many functional parts and a lot of operational modes, so single copy mode and ten times continuous copies mode in monochrome are taken into account. Since the operational sound including the transient sound is changed with time in one cycle, it is necessary to identify high contribution sound section to decide the sound quality by pair comparison method and SD method with original, filtered, and edited sounds. As a result, sound quality of the transient sound is influenced by the cycle time, the rhythm, the sound pressure, and the frequency characteristics. As the single copy mode, main uncomfortable sound can be estimated at the steady-state sound section caused by a rotational component. On the other hand, for the ten times continuous copies mode, it can be estimated at the particular transient sound section in one cycle caused by collision with mechanical parts, which is different from the single copy mode.

3:40

5pNSb5. Sound source identification for precision information equipment having many kinds of sound sources. Sho Shirakata (Dept. of Precision Mech., Chuo Univ., 1-13-27 Kasuga, Bunkyo-ku, Tokyo 112-8551, Japan), Masao Yamaguchi (Toshiba Tec Corp., Shizuoka-ken, 411-8520, Japan), and Takeshi Toi (Chuo Univ., Tokyo 112-8551, Japan)

These days, precision information equipment having multifunction with high qualities in an office environment is demanded. Sound quality in this equipment has become a very important factor in addition to reduction of the sound-pressure level. MFP (multifunction peripheral) has many functional parts and operational modes, so it makes uncomfortable transient sounds in one cycle. The primary sound section to decide the sound quality of the MFP was estimated by sound quality evaluation as in previous research. Main uncomfortable sounds could be confirmed at the steady-state sound section as the single copy mode and at the particular transient sound section in one cycle as the ten-times continuous copies mode. So, it is necessary to identify the position of uncomfortable sound sources at each mode for comfortable sound design. Principal component analysis (PCA) using acceleration measured by accelerometers and sound pressure measured by microphones is applied to identify the number of sound sources. Sound-pressure distribution in one cycle from the MFP having many kinds of sound sources can be measured by microphone array at each moment. As a result, the sound source position can be identified by using PCA and sound-pressure distribution.

5pNSb6. The role of noise audits in characterizing and reducing consumer product noise. David L. Bowen (Acentech Inc., 33 Moulton St., Cambridge, MA 02138)

Consumer products often share some common traits that impact both the measurement techniques that can be employed, as well as the noise control options that are available. These traits include their relatively small size (except for the special case of automobiles), low profit margin, and quick time to market. Their small size implies that existing units or prototypes can usually be set up for acoustical measurements inside a modestly sized reverberation room. The low profit margin implies that design solutions, rather than adding ''acoustical'' materials, are the preferred route to a quieter product, but the quick time to market can sometimes work against this approach. This talk will focus on a sound power based ''noise audit'' technique that is useful for characterizing and rank ordering the potential noise sources in a product, in order to devise the most effective noise reduction strategies. Case studies will be used to illustrate the use of this engineering technique applied to the particular case of consumer products, where the design trend is often towards lighter, stiffer components and faster rotating parts, all of which tend to increase noise.

4:20

5pNSb7. Consumers, products, and noise: The economic, social, and political barriers to reducing noise in consumer products sold in North America. Leslie Blomberg (Noise Pollution Clearinghouse, Box 1137, Montpelier, VT 05601)

The paper examines the economic, social, and political barriers to reducing noise in consumer products sold in North America. Included in the economic issues are the cost of noise control and whether or not consumers are willing to pay more for a quieter product. An equally important economic barrier, however, is that the marketplace currently does not have an effective mechanism to reward builders of quieter products, even if noise treatments were cost effective. There is very little information available to consumers about the noise levels of consumer products. Without their informed decisions in the marketplace, no signal reaches the manufacturers. Complicating this problem is the consolidation of the consumer product manufacturing sector and the consolidation in the retail sector. The social barriers include the public's attitude towards noise (that it is an unavoidable cost of living in a technologically advance society) and the failure to see noise as a pollutant (that it is merely something unwanted). Political barriers include an absence of government involvement in consumer product noise, in terms of regulation, labeling, as well as a general concern for the issue.

4:40

5pNSb8. Evaluation of noise intensity level using an eccentric press during the production of metallic closure: Findings according to different positions surrounding the press. Paulo H. T. Zannin (Lab. de Acustica Ambiental, Industrial e Conforto Acustico, Dept. Eng. Mecanica, Univ. Federal do Parana, C. Politecnico, Curitiba, Pr, Brazil, 81531-990) and Samuel S. Ansay (Univ. Federal Tecnologica do Parana, Centro, Curitiba, Pr, Brazil, 80230-901)

This study was performed to evaluate the differences in noise level produced by an eccentric press, during the manufacturing of metallic clo-sures for steel cans. The primary objective of the study was to establish a rank of sound-intensity level and sound-power level as well as the global noise level emitted by this particular press. Ten different areas in the surface surrounding the press were evaluated regarding both the sound power and the sound intensity of each measurement. Each site was mea-sured twice to increase accuracy. The ten areas sampled were sweeping using intensity probe. We have found the surface area to demonstrate the lowest noise level was at S1 and the highest one was at S10 (p value 0.0005). In conclusion, our study demonstrates adequately the global noise level as well as in specific sites, indicating areas requiring special treat-ment for noise reduction in this environment.

5pPA1. Optimizing seismo-acoustic sonar source array configuration for maximum radiated Rayleigh wave energy. Anthony N. Johnson (Dept. of Appl. Mathematics, Naval Postgraduate School, Monterey, CA 93943), Clyde L. Scandrett, and Steven R. Baker (Naval Postgraduate School, Monterey, CA 93943)

A three-dimensional (3-D) continuum mechanics approach to the de-velopment of a time-dependent finite element model for optimizing the position and excitation of a seismo-acoustic sonar source array to detect the presence of buried landmines will be presented. Various source con-figurations will demonstrate the use of constructive and destructive inter-ference, which maximizes the radiated energy of unidirectional Rayleigh waves while suppressing the radiation of body waves. Radiation charac-teristics are analyzed in a linear, horizontally stratified (isotropic and ho-mogeneous within each layer) half-space with a discrete number of tran-sient seismic sources. Results for Rayleigh wave strengths are presented in both a homogeneous half-space and a layered medium.

1:30

5pPA2. Nonlinear acoustic experiments involving landmine detection: Status and future. Murray S. Korman (Phys. Dept., U.S. Naval Acad., Annapolis, MD 21402) and James M. Sabatier (Univ. of Mississippi, University, MS 38677)

In past experiments [J. Acoust. Soc. Am. **116**, 3354–3369 (2004)], airborne sound at two primary tones, f_1 and f_2 (closely spaced near reso-nance), undergo acoustic-to-seismic coupling. Due to interactions with the buried plastic landmine, a scattered surface profile can be measured. Par-ticle velocity profiles at f_1, f_2, and $f_1-(f_2-f_1)$ exhibit single peaks; those at $2f_1-(f_2-f_1)$, f_1+f_2, and $2f_2+(f_2-f_1)$ involve higher-order mode shapes. For some combination frequencies the "on target" to "off target" contrast ratio can improve by over 20 dB. Near resonance, the bending (softening) of a family of increasing amplitude tuning curves, involving the vibration over the landmine, exhibits a linear relationship between the peak particle velocity and corresponding frequency. Hyster-esis effects and slow dynamic behavior have also been observed. The interaction between the top-plate interface of a buried landmine and the soil above it appears to exhibit many characteristics of the mesoscopic/nanoscale nonlinear effects that are observed in geomaterials like rocks (sandstone). In linear detection schemes the natural inhomogeneous soil layering can generate some false alarms. Recent "off target" versus. "on target" tuning curve measurements show a substantial increase in nonlin-earity, suggesting this to be a good false alarm discriminator. [Work sup-ported by ONR.]

1:45

5pPA3. Phase inversion and two-frequency interaction in nonlinear time-reversal acoustic method of land mine detection. Alexander Sutin (Artann Labs., Trenton / Stevens Inst. of Technol., Hoboken, NJ), Brad Libbey (U.S. Army RDECOM CERDEC NVESD, Fort Belvoir, VA 22060), and Armen Sarvazyan (Artann Labs., Inc., West Trenton, NJ 08618)

Seismic waves are known to generate a nonlinear response in soil, but data show that the presence of a mine increases the nonlinearities due to interactions of the mine and soil system. The nonlinear effects were inves-tigated by two methods. The first, phase inversion, uses two short, broad-band TRA focused signals with opposite signs. These are broadcast se-quentially and the responses are added in post processing. This results in cancellation of the linear response leaving the nonlinear system compo-nents. The second method relies on two-frequency intermodulation. In this case time-reversed seismic energy at 280 and 350 Hz was used to excite the system while the response was analyzed at the sum frequency, 630 Hz. The experiments demonstrate that the presence of the mine increases non-linearity by 12 dB for the phase-inversion method and by 6 dB for two-frequency interactions in comparison with intact sand. These results sup-port the hypothesis that the interface between mine body and surrounding sand significantly increases the nonlinear response as compared to sand alone. Work was supported by U.S. Army RDECOM CERDEC Night Vision and Electronic Sensors Directorate.

5pPA4. Time-reversal acoustic focusing of waves produced by seismic vibrators. Alexander Sutin, Victor Kurtenoks (Artann Labs., Trenton/ Stevens Inst. of Technol., Hoboken, NJ), James Sabatier, Rick Burgett, Mike ONeil, Slava Aranchuk (Univ. of MS, University, MS 38677), Brad Libbey (U.S. Army RDECOM CERDEC Night Vision and Electron. Sensors Directorate, Fort Belvoir, VA), and Armen Sarvazyan (ARTANN Labs., Inc., NJ 08618)

A land mine detection system has been developed based on excitation of seismic waves by four mechanical shakers and measurements of ground vibration by a 16-beam, scanning laser Doppler vibrometer (LDV). Time-reversal acoustic (TRA) focusing was applied to concentrate seismic waves using the above system. Linear swept frequency signals and orthogonal initial signals in the frequency band of 100–500 Hz were used in outdoor testing. The system impulse response from any shaker to the LDV output was computed by cross correlating the original and recorded signals. With orthogonal signals, the system impulse responses between multiple shakers and the LDV were measured simultaneously, thus reducing the overall measurement time. Each shaker then reradiates the time-reversed impulse responses focusing the seismic energy to a point on the ground. Experiments demonstrate that the TRA focusing provided a high concentration of elastic wave energy in the test area with typical focusing spots about 20 cm in diameter. [Work supported by U.S. Army RDECOM CERDEC Night Vision and Electronic Sensors Directorate.]

5pPA5. Acousto-optic interactions at a surface perturbed by acoustic and gravity waves. James Churnside, Hector Bravo (ESRL/Zeltech, 325 Broadway, Boulder, CO), Konstantin Naugolnykh, and Joseph Fuks (Univ. of Colorado, Boulder, CO)

We studied the acousto-optic interaction at a water surface perturbed by an underwater sound source. Using a coherent optical detection technique, we measured the power spectra of the scattered light. Filtering of the power spectra allowed us to detect the sound-induced perturbations of the surface in the presence of surface waves, even though the amplitude of the waves was much larger than the acoustic perturbations of the surface. The theory of scattering by a surface perturbed by sound and by surface waves is developed and that theory is compared with the experimental results.

5pPA6. Improvement of dispersion of nanometer-sized diamond particles for precise polishing by ultrasound exposure. Takeyoshi Uchida, Tsuneo Kikuchi (Natl. Metrology Inst. of Japan, Natl. Inst. of Adv. Industrial Sci. and Technol., Japan), Yoshikazu Setoyama, Norimichi Kawashima, and Shinichi Takeuchi (Toin Univ. of Yokohama)

A novel acoustic dispersion method for fine diamond particles was investigated by our group. Nanometer-sized diamond particles for abrasive agents should be dispersed sufficiently in water without aggregation. The particles usually aggregate immediately after their manufacture. The dispersants and dispersion equipment are used for dispersion of the particles. However, these dispersion methods present problems in their dispersion characteristics and reaggregation because such methods do not improve the essential surface characteristics. We suggested the acoustic dispersion method. We reported in 2005 at the IEEE Conference in Rotterdam that nanometer-sized diamond particles with 5-nm primary particle size were dispersed using ultrasound. The particles with 5-nm primary particle size are anticipated for use as future abrasive agents. Particles with 50-nm primary particle size are actually used at present as abrasive agents. Therefore, in this study, we investigated the dispersion of particles with primary particle sizes of 20, 50, 80, and 150 nm. Results show that the aggregated particles were disaggregated to nanometer-sized particles. Zeta potentials of the diamond particles were increased by ultrasound. These results suggest the improvement of dispersion of nanometer-sized diamond particles in water.

5pPA7. Observation of living samples in a C-mode configuration with an ultrasonic phase conjugator. Tatsuya Seki and Masahiro Ohno (Chiba Inst. of Technol., 2-17-1 Tsudanuma, Narashino, Chiba 275-0016, Japan)

Ultrasonic images of living samples have been obtained in a C-mode configuration with phase conjugation (time-reversal) processes. A phase conjugator for 10-MHz ultrasound was realized by the field-mixing in a PZT block pumped with 20-MHz electric fields. Samples, relatively thick (mm to cm) living materials, were placed between an ultrasonic transmitting/receiving transducer and the phase conjugator and were scanned to form C-mode transmission images. Ultrasonic tone-burst pulses radiated onto the sample were led into the PZT block and were converted to their phase conjugate waves, which, for their time-reversing nature, acted to cancel the wavefront deformation introduced by the thick living samples. In the experiment, images were obtained at a frequency of 10 MHz for several samples such as chicken liver, poke meat, and some model samples made of agarose gel, both by the phase conjugate method and by the conventional one. Images by the phase conjugate method showed relatively good accordance with the real ultrasonic attenuation distribution, while those by the conventional method were very sensitive to the shapes or the discontinuities of samples.

5pPA8. Propagation and interaction of phase conjugate ultrasound waves in moving media. V. Preobrazhensky, P. Pernod, and Yu Pyl'nov (Joint European Lab. LEMAC: Institut d'Electronique et de Micro-electronique et de Nanotechnologie IEMN-DOAE-UMR CNRS 8520, Ecole Centrale de Lille, BP48, 59651 Villeneuve d'Acsq, Cedex, France, Wave Res. Ctr. of General Phys. Inst. RAS and Moscow State Inst. of Radio Eng., Electron. Automation, Moscow, Russia, vladimir.preobrajenski@iemn.univ-lille1.fr)

Wave phase conjugation is known as an effective tool for compensation of phase distortions arising during wave propagation in inhomogeneous media. Backpropagation of the phase conjugate wave (PCW) towards the emitter restores the phase of the primary wave on its source. This feature of PCW results from reversibility of wave processes in stationary media. The presence of flows or of moving objects in a medium breaks the time-reversal invariance of the wave process and leads, in particular, to the phase shift of the emitted and conjugate waves on the source. In the present paper the theory of PCW propagation in nonlinear and moving inhomogeneous media is developed on the basis of the modified KZK approximation. Applications of the wave phase conjugation for new methods of ultrasonic velocimetry and nonlinear diagnostics of flows are considered.

5pPA9. Ultrasonic scattering in polycrystalline material with elongated grains. Goutam Ghoshal and Joesph A. Turner (Dept. of Eng. Mech., W317.4 Nebraska Hall, Univ. of Nebraska-Lincoln, Lincoln, NE 68588-0526)

The scattering of elastic waves in polycrystalline materials is relevant for ultrasonic materials characterization and nondestructive evaluation (NDE). Ultrasonic attenuation and diffuse backscatter measurements have been especially useful for extracting microstructural information such as grain size and for detecting flaws in materials. Accurate interpretation of experimental data requires robust scattering models. Such models often assume constant density and uniform grain size such that the scattering for grains with mainly spherical geometry is well understood. However, many structural materials are processed in such a way that the microstructure has grain elongation (e.g., from rolling). The scattering of elastic waves in such media must be understood well for design of effective materials inspection methods and for quantitative data analysis. For materials with grain elongation, the appropriate spatial correlation function is no longer

isotropic such that closed-form solutions for attenuation cannot be achieved. Here, attenuation and diffuse backscatter expressions are derived as a function of wave propagation direction with respect to the axis of grain elongation. Numerical results are presented for materials of common interest under assumptions of statistical homogeneity. These results are anticipated to impact ultrasonic nondestructive evaluation of polycrystalline media. [Work supported by U.S. DOE.]

5pPA10. Accurate time domain computation of linear wave propagation using Chebyshev collocation and matrix diagonalization. Lixi Huang (Dept of Mech. Eng., The Univ. of Hong Kong, Pokfulam Rd., Hong Kong)

Accurate time domain computation of the wave propagation phenomena is of great interest to many fields of studies. The spectral method of Chebyshev collocation is adopted for smooth problems of linear waves. Space differentiation is discretized by Chebyshev derivative matrices and the wave equation is cast as a second-order ordinary differential equation in time domain. The general boundary conditions involving pressure and acoustic particle velocity are discretized and absorbed into the system equations for the unknown vector containing all grid points. The system equations are solved accurately by the method of matrix diagonalization, which involves the finding of the eigenvalues and eigenvectors for the appropriate combinations of the damping and stiffness matrices. For this solution, the time step for stable and accurate computation is only limited by the consideration of round-off errors when the exponential functions are evaluated. Comparison is made with analytical solutions in the one-dimensional case, and good agreement is obtained. The only perceived drawback would be the size of matrices that can be alleviated by the use of domain decomposition approaches. The physical meaning of the eigenvalues derived from the discretization procedure is discussed.

5pPA11. Ultrasonic characterization of microstructure evolution during processing. Liyong Yang and Joseph A. Turner (Dept. of Eng. Mech., Univ. of Nebraska-Lincoln, Lincoln, NE 68588, jaturner@unl.edu)

Many cold-working processes for polycrystalline metals cause alignment of the grains with a single symmetry axis. This type of microstructure is called fiber texture. The existence of a preferred orientation of the grains has a significant influence on the propagation and scattering of ultrasonic waves, which are often used for material inspection. Knowledge of the wave attenuation of such textured materials is of both theoretical and practical interest to nondestructive testing and materials characterization. In this article, the quantitative relations between fiber texture and wave attenuations of hexagonal crystals are presented. The texture is characterized by a Gaussian distribution function that contains a single parameter that governs the transition of the texture from perfectly aligned crystals to statistically isotropic. Under this assumption, the materials of interest have a varying degree of transverse isotropy representative of processing conditions. Simple expressions for the attenuations of the three modes of waves are given in a concise, generalized representation. Finally, numerical results are presented and discussed in terms of the directional, frequency, and texture dependence. The results presented are expected to improve the understanding of the microstructure evolution during thermomechanical processing. [Work supported by U.S. DOE.]

4:15

5pPA12. Shaped sound focusing using multiple sources: An acoustical ring. Jin Young Park and Yang-Hann Kim (Ctr. for Noise and Vib. Control at KAIST, Japan, jypark1979@kaist.ac.kr)

Shaped sound focusing is defined as the generation of acoustically bright shape in space using multiple sources. The acoustically bright zone is a spatially focused region with relatively high acoustic potential energy level. In view of the energy transfer, acoustical focusing is essential because acoustic energy is very small to use other types of energy. In clinical uses, for example, there are several approaches for using thermal energy

from focused ultrasonic wave energy, so-called high intensity focused ultrasound, concerning point-focusing not regional focusing. If sound shape can be controlled, it offers various kinds of solutions for clinical uses and others because a regional focusing is essentially needed to reduce a treatment time and enhance the performance of transducers. For making the shaped-sound field, control variables, such as a number of sources, excitation frequency, source positioning, etc., should be considered according to geometrical sound shape. To verify these relations between them, a wave-number domain matching method is suggested because the wave-number spectrum can provide the information of the source from the phase and magnitude of the wave-number spectrum. In this presentation, discussions about shaped sound focusing and how to make this sound field are provided for the case of an acoustical ring.

4:30

5pPA13. Noncontact acoustic manipulation using a standing wave field in air. Teruyuki Kozuka, Kyuichi Yasui, Toru Tuziuti, Atsuya Towata, and Yasuo Iida (Natl. Inst. of Adv. Industrial Sci. and Technol. (AIST), Shimoshidami, Moriyan-ku, Nagoya 463-8560, Japan, kozuka-t@aist.go.jp)

A noncontact manipulation technique is necessary to develop micromachine technology, biotechnology, and new materials processing. The authors have developed an acoustic manipulation technique to transport particles in water [T. Kozuka, Proceedings of WCU2003, Paris, 483–486 (2003)]. Although it is more difficult to generate a strong sound field in air than in a liquid, many researchers are actively studying the trapping of particles, droplets, and aerosols in air using ultrasound. Nevertheless, many of the resultant studies only trap and observe objects; they do not transport them. This paper describes an advanced manipulation technique to transport small objects in air using that scheme. A standing-wave field was generated by two sound beams (40 kHz) using bolted Langevin transducers. The beams' axes cross each other. Expanded polystyrene chips were trapped at nodes of the sound pressure in the crossing sound beams. The trapped position was shifted by changing the phase difference of the two sound beams. In addition, transportation at constant speed of the trapped target was realized by a slight difference in ultrasonic frequency between the two sound beams. This system is also applicable to liquid droplets and aerosols in air.

4:45

5pPA14. Propagation phase and zeros in the complex frequency plane. Yoshinori Takahashi (Kogakuin Univ., Tokyo, Japan, takahashi@acoust.rise.waseda.ac.jp), Mikio Tohyama (Waseda Univ., Tokyo, Japan), and Kazunori Miyoshi (Kogakuin Univ., Tokyo, Japan)

This paper describes the transfer function (TF) including the coherent sound field as the distance between source and observation points increases, from a point of view of the number of zeros on a complex frequency plane. The propagation phase could be estimated according to the linear-regression analysis for narrow frequency-band frequency characteristics of the minimum-phase component [Inst. Electron. Inf. Commun. Eng. Jpn., **J89-A**(4) 291–297 (2006) (in Japanese with English figures)]. This paper analyzes zeros of the TFs for the coherent and reverberant fields based on the modal and random sound field theory. Consequently the distribution of zeros could be estimated in the transition from the coherent to the reverberant conditions.

5:00

5pPA15. Using instabilities in the long wavelength transverse optical mode to generate nuclear fusion. Brian Naranjo and Seth J. Putterman (Phys. Dept., UCLA, 1-129 Knudsen Hall, Los Angeles, CA 90095)

Various crystals such as lithium niobate or lithium tantalate display a phase transition due to an instability in the long wavelength transverse optical mode. These low-temperature phases develop huge electric fields which can accelerate ions to energies where nuclear fusion is observed [Nature **434**, 1115–1117 (2005)]. [Research funded by DARPA, ONR, NSF.]

5pSC1. Finite-element method analysis of acoustic characteristics of the vocal tract with the nasal cavity during phonation of Japanese /a/. Hiroki Matsuzaki and Kunitoshi Motoki (Faculty of Eng., Hokkai-Gakuen Univ., S-26 W-11, Chuo-ku, Sapporo 064-0926, Japan)

For this study, the transfer functions and active sound intensities of a vocal tract model with and without a nasal cavity were computed using a three-dimensional finite-element method (FEM). The models were based on vowel data obtained by magnetic resonance imaging (MRI) of the vocal tract with a nasal cavity during phonation of the Japanese /a/. The oral cavity was also coupled with the nasal cavity in a three-dimensional volume of radiation. Effects of wall impedance were also examined. Coupling of the nasal cavity to the oral cavity indicated the following aspects. Additional peaks appeared below 3 kHz for the lossless condition. However, they disappeared in the simulation for the soft wall condition. The sound energy circulation did not occur in the simulation for the soft wall condition. Regarding effects of the wall boundary condition on the spectral envelope, three-dimensional simulations confirmed the upward shift of lower formant frequencies. However, disagreement of the formant frequencies between simulated and real speech should be investigated further by adjusting the wall boundary condition to a more realistic one.

5pSC2. Using tagged cine-MRI and finite-element method to lower bound the number of independently controllable motor units in the tongue. Caroline Essex-Torcaso, William S. Levine (Dept. of Elec. and Comput. Eng., Univ. of Maryland), Maureen Stone, Emi Z. Murano (Univ. of Maryland School of Dentistry, Baltimore, MD 21201), Vijay Parthasarathy, and Jerry L. Prince (Johns Hopkins Univ.)

The biomechanical structure of the tongue is unusual in that there is no rigid structure, such as a bone, for the muscles to act against. In order to understand these biomechanics and their control, a mathematical model has been created. This model has the form of a nonlinear controllable incompressible elastic structure that undergoes large deformations. The model was used to solve a simplified two-dimensional inverse problem. For a simple speech motion (/i-u/), the trajectories of specific points within the tongue were tracked by means of tagged cine MRI. These points correspond to finite element nodes and were used as input to the simplified model. The remaining unknowns in the model are the set of muscle activations that produce the observed motion. Because there is no such set of activations, the set that best approximates the observed motion in a least squares sense was chosen. The results indicate that there must be independently controllable compartments in SL and GG in order to produce this

movement. Three methods were used to improve the representation of the tongue and the resolution of the model: refinement of the number of elements, refinement of the number of muscle activations, and the inclusion of dynamics.

5pSC3. Simulation of phonation control using a tensile vocal-fold model. Chao Tao, Yu Zhang, and Jack J. Jiang (Dept. of Surgery, Div. of Otolaryngol. Head and Neck Surgery, Univ. of Wisconsin Med. School, Madison, WI 53792-7375)

The vocal folds act as an energy transducer that converts aerodynamic power into acoustic power. Therefore, modeling the vocal-fold vibration could provide valuable information for voice synthesis. In previous vocal-fold lumped models, the vocal-fold was simplified as a spring oscillator; the restoring force due to lateral deflection of vocal-fold tissue is represented by equivalent lateral springs. However, the vocal-fold tissue actually contains an intricate extracellular matrix, composed of longitudinal elastin, which lies parallel to the vocal fold. Thyroarytenoid, lateral cricoarytenoid, and cricothyroid muscles control the elongation of these longitudinal elastin and further determine the voice pitch, dysphonia, and rough voice. In this study a tensile vocal-fold model is proposed to simulate vocal-fold vibration. In this model the lateral tissue deflection is represented by lateral spring and the longitudinal elastin elongation is described by nonlinear longitudinal springs. Differential equations are developed to describe the tensile vocal-fold model. The fundamental frequency and phonation threshold pressure are predicted by the proposed vocal-fold model. Numerical simulations prove that the proposed tensile vocal-fold model can accurately describe the muscles control on phonation pitch and so on. [Work supported by NIH.]

5pSC4. A new aerodynamic critical parameter of the speech production: Phonation threshold flow. Jack J. Jiang and Chao Tao (Dept. of Surgery, Div. of Otolaryngol. Head and Neck Surgery, Univ. of Wisconsin Med. School, Madison, WI 53792-7375, jiang@surgery.wisc.edu)

In this paper, the implications of phonation threshold flow (PTF) as an addition to the aerodynamic parameters of speech production system are studied. PTF, the minimum airflow volume velocity able to sustain stable vocal-fold vibration, could have utility in clinical vocal disease assessment just like phonation threshold pressure (PTP) [I. R. Titze, J. Acoust. Soc. Am. **83**, 1536–1552 (1988)]. Furthermore, because glottal airflow can be more easily measured noninvasively than subglottal pressure, PTF could be more suitable for routine clinical assessment than PTP. Theoretical

3371   J. Acoust. Soc. Am., Vol. 120, No. 5, Pt. 2, November 2006

Fourth Joint Meeting: ASA and ASJ   **3371**

5p SAT. PM

studies indicate that PTF is a sensitive aerodynamic parameter dependent on tissue properties, glottal configuration, and vocal-tract loading. Accordingly, this theory suggests that PTF is reduced by the following: decreasing tissue viscosity, decreasing mucosal wave velocity, increasing vocal-fold thickness, or decreasing prephonatory glottal area. A divergent glottis and low vocal-tract resistance also reduce phonation threshold flow. Finally, the significance of PTF for investigation of the distribution of energy in a vocal-fold vibration system and the potential for application of the PTF parameter are assessed. [Work supported by NIH.]

5pSC5. Lung pressure dependence of glottal sound source.

Hideyuki Nomura and Tetsuo Funada (Div. of Elec. Eng. and Comput. Sci., Kanazawa Univ., Kakuma-machi, Kanazawa-shi 920-1192, Japan, nomu@t.kanazawa-u.ac.jp)

The present study investigates the lung pressure dependence of the vibration of vocal cords using numerical experiments based on our proposed glottal sound source model. The glottal sound source model is described as a coupled problem between unsteady glottal jets and mechanical vocal cords. The vocal cord is assumed to be an elastic cover with effective mass of vocal cord. To simulate the mechanical properties of vocal cords, the elastic cover is supported by distributed small mechanical elements of a spring and damper. The speech production process can be predicted by alternately solving the motion of glottal jets and the vocal cords' vibration. Results of this simulation show that the fundamental frequency of vocal cords' vibration and the propagation velocity of the mucosal wave first increase and then remain constant with lung pressure. The threshold lung pressure of 200–400 Pa and the propagation velocity of mucosal waves is of the order of 1 m/s, which are consistent with measured values. These results suggest that our proposed model is suitable for description of a glottal sound source.

5pSC6. Direct computational method of including piriform fossae and nasal cavity in a time-domain acoustic model of the vocal tract.

Parham Mokhtari (NICT, ATR Cognit. Information Sci. Labs., 2-2 Hikaridai Seikacho, Kyoto 619-0288 Japan, parham@atr.jp)

Frequency-domain simulations of the human vocal tract (VT) have previously shown the importance of including the piriform fossae, which impart a pole and two zeros in the 4–5-kHz frequency range and thereby contribute to speaker individualities. The literature has also shown that time-domain simulation of VT acoustics can result in high-quality synthesis naturally including interactions between the time-varying glottal area and the supraglottal VT. In the present work, the time-domain model of [S.Maeda, Speech Commun. **1**, 199–229 (1982)] was extended to include both left and right piriform fossae as side-branches connected to the main VT, in addition to the nasal tract and sinuses. Departing from Maeda's original implementation owing to the complexity of including more than one side branch, the variables representing acoustic pressure and volume velocity at the piriform fossae and nasal tract junctions were analytically eliminated, and the resulting large system of linear equations were solved simultaneously at each simulation sample. This direct method runs at only a few times real-time on a 1.8-GHz notebook PC, while achieving a more natural sound quality in speech synthesis and control over timbral (or voice quality) features that contribute to each speaker's individuality. [Work supported by NiCT and SCOPE-R of Japan.]

5pSC7. Measures of intraoral pressure pulse shape during stop consonants.

Jorge C. Lucero (Dept. of Mathematics, Univ. Brasilia, Brasilia DF 70910-900, Brazil, lucero@unb.br) and Laura L. Koenig (Haskins Labs, New Haven, CT)

To maintain voicing during a stop consonant, adult speakers typically perform articulatory actions that increase supraglottal volumes and slow the rate at which of intraoral pressure (Pio) rises. In an influential study, Müller and Brown [in *Speech and Language: Advances in Basic Research*

and Practice 4, edited by N. Lass (Academic, New York, 1980), pp. 318–389] proposed a quantitative measure of Pio pulse shape, based on the difference between (a) the slope from pressure at closure to average pressure and (b) from average pressure to pressure at release. We recently applied these techniques to data from women and child speakers of English and observed some shortcomings in Müller and Brown's measurement technique, such that the slope difference angle did not clearly reflect the actual pressure pulse shape. The purpose of this paper is to explore new methods of analyzing intraoral pressure contours, based on fitting a mathematical model to the pressure pulse shapes. It will report our progress and compare our results with the previous technique.

5pSC8. Estimation of area function for three-dimensional vocal tract using finite-element method.

Keita Mochizuki and Takayoshi Nakai (The Grad. School of Electron. Sci. and Technol., Shizuoka Univ., 3-5-1, Johoku, Hamamatsu-shi, Shizuoka, 432-8561 Japan)

Numerous studies have obtained a vocal tract area function using data obtained from magnetic resonance imaging (MRI). However, this approach often results in increased error between formant frequencies derived by recorded voice and estimated frequencies derived by MRI. Two factors engender error: creating the vocal tract model and estimating the area function from the vocal tract model. Generally, the errors from those two factors are not considered independently. This study is intended to establish precise estimation of the area function automatically from a vocal tract model. Pressure contours and sound intensity in the vocal tract are obtained using the finite-element method (FEM); the vocal tract area function is obtained from them. The precision is assessed by comparing the formant frequencies that are derived using the FEM with our method. Results show that the vocal tract area function can be estimated precisely from three-dimensional MRI.

5pSC9. Linear stability analysis of an aeroelastic model of phonation.

Zhaoyan Zhang, Juergen Neubauer, and David Berry (UCLA, 31-24 Rehab Ctr., 1000 Veteran Ave., Los Angeles, CA 90095)

This study presents a linear stability analysis of a two-dimensional aeroelastic model of phonation, which incorporates the interaction between the glottal flow and the vocal folds. The model consists of a wall constriction (shaped by the medial surface of vocal the folds), which is situated in a rigid pipe with an applied potential flow. The vocal-fold constriction is modeled as a plane-strain linear elastic layer. An eigenvalue problem is formulated and the eigenvalues of the coupled system and the eigenshape of the vocal fold surface are calculated. Both linear divergence and flutter instabilities are possible. Phonation onset frequency and pressure are investigated as a function of glottal channel width, vocal fold geometry, and vocal fold material properties. Based on aeroelasticity theory, this model allows the prediction of the effects of changing geometric and viscoelastic properties of the vocal folds on phonation onset.

5pSC10. Comparison of vocal tract shaping patterns derived from articulatory fleshpoint data and MRI-based area functions.

Brad H. Story and Kate Bunton (Dept. of Speech, Lang., and Hearing Sci., Speech Acoust. Lab., Univ. of Arizona, Tucson, AZ 85721)

A recent addition to the University of Wisconsin x-ray microbeam (XRMB) database [Westbury, UW-Madison, 1994] (XRMB) is a speaker from whom MRI-based vocal tract area functions have been previously obtained. The purpose of this study was to compare principal components derived from collections of vocal tract shapes for vowels obtained with these two different techniques. For the XRMB data, midsagittal cross-distance functions representative of each of 11 vowels were first obtained from tongue and jaw pellet positions and the hard palate profile of the speaker. A principal components analysis was then performed on the set of cross-distance functions. Results indicated that the first two orthogonal components (referred to as modes) accounted for more than 90% of the

variance. The shape of these two modes was shown to be similar to those previously determined from the same speakers set of MRI-based area functions. The XRMB-based modes were then used to develop a database-lookup technique where mode coefficients could be determined for time frames throughout a series of vowel sequences. Finally, a procedure is described for using the time-dependent mode coefficients obtained from the XRMB data as input for an area function model of the vocal tract. [Work supported by NIH R01-DC04789.]

5pSC11. Temporal structures of articulatory movements: A contrastive study of stop consonants in Japanese, Korean, and Chinese. Tokihiko Kaburagi and Yoshitaka Nakajima (Faculty of Design, Kyushu Univ., 4-9-1 Shiobaru, Minami-ku, Fukuoka 815-8540 Japan, kabu@design.kyushu-u.ac.jp)

Stop consonants of Japanese, Korean, and Chinese were studied from an articulatory perspective, particularly in relation to the temporal structure of articulatory movements. In general, acoustical features of stop consonants, such as the amount of aspiration, voice onset time (VOT), and so on, are largely controlled by interarticulatory movements of the tract and glottis. In this study, several speakers were instructed to produce stop consonants of their native tongues. Then, states of the articulators were monitored using an electroglottograph (EGG) and pressure and flow sensors. While the EGG tracked vibratory patterns of the glottis, the pressure and flow sensors were used to measure the air pressure inside the vocal tract and the amount of air flowing out of the mouth. It is noteworthy that these languages have different sets of stops: the voiced and unvoiced stops of Japanese; the aspirated, weak, and strong stops of Korean; and the aspirated and nonaspirated stops of Chinese. Temporal structures of interarticulatory movements were analyzed from the observed data. Their respective acoustical consequences were compared among these languages. [Work supported by JSPS and 21st Century COE, Kyushu University.]

5pSC12. The relation of the temporal variation of F2 to articulator movement. Benjamin V. Tucker (Dept. of Linguist., Univ. of Arizona, P.O. Box 210028, Tucson, AZ 85721-0028, bvt@u.arizona.edu) and Brad H. Story (Univ. of Arizona, Tucson, AZ 85721)

The second formant frequency (F2) has been shown to serve a prominent role in speech perception. The specific relation of the temporal variation of F2 to tongue and lip motion is, however, less well understood. Using the x-ray microbeam database (Westbury *et al.*, 1994), data from six males and six females were extracted for six vowel to vowel (VV) transitions (iu, ia, ua, au, ai, ui). Time-dependent displacements of the lower lip pellet, four tongue pellets, and a jaw pellet were extracted from each of the VV transitions for each speaker. Also extracted for each VV were F1, F2, and F3. Jaw movement was decoupled from the movement of the other fleshpoints following Westbury (1994). Correlations were then calculated between each flesh point and each of the formants on both the x and the y axis of movement. An analysis of the correlation results indicates that F2 was most highly correlated with articulator movement on both the x and y axes.

5pSC13. Processing of Japanese vowel devoicing and the effect of speech rate. Naomi Ogasawara (Dept. of Linguist., Univ. of Arizona, Douglass 200E, P.O. Box 210028, Tucson, AZ 85721-0028, naomi703@email.arizona.edu)

Vowel devoicing (or reduction) in Japanese is an interface between the phonetic and phonological levels (Vance, 1987; Yoshida, 2002). The phonological rule for vowel reduction defines that high vowels (/i, u/) undergo reduction when between voiceless consonants or between a voiceless consonant and a pause. However, there are some cases of vowel reduction that do not fit the rule. A high vowel adjacent to a voiced consonant sometimes becomes reduced, especially in casual speech (Arai, 1999). Even a nonhigh vowel can undergo reduction (Arai, 1999; Vance, 2004). In this study,

the effect of speech rate on the processing of reduced vowels is examined, particularly for vowels that are only likely to be reduced in casual, fast speech. How do listeners recognize vowels that are reduced in fast speech, or the words containing them? A lexical decision experiment showed that listeners found it easier to process fast speech containing reduced vowels than careful speech of isolated words containing them. They also found vowel reduction acceptable for nonhigh vowels in fast speech. This suggests that listeners use knowledge of both phonology and speech rate variability in processing connected speech.

5pSC14. Korean coda cluster simplification: Articulatory study. Minjung Son (Dept. of Linguist., Yale Univ., 370 Temple St., New Haven, CT 06520, and Haskins Labs., 300 George St., #900, New Haven, CT 06511)

Korean exhibits optional coda cluster reduction in lateral-stop (C1C2) sequences. However, this phenomenon has not been tested on the basis of articulatory data. The present study examines articulatory movement using EMMA. For two speakers of Seoul-Korean (e.g., JL and SL), clusters such as /Vlk/ and /Vlp/ followed by /ta/ were elicited at a normal rate along with control tokens (e.g., /Vkta/, /Vpta/, /Vlta/). The stimuli were presented with the relevant word in isolation. Results indicated that neither speaker showed /p/ and /l/ reduction, although there was interspeaker variation in /k/ reduction. While no /k/ reduction occurred in C1C2 for JL, SL demonstrated categorical /k/ reduction in 19% of production, where a longer closure duration of a tongue tip gesture was observed (e.g., possible compensatory lengthening) when it was compared with the control /VltV/; this fails to be addressed in impressionistic transcription and OT analyses [June 11th ICKL, pp. 382–390 (1998); Cho, CLS **35**, 43–57 (1999)]. Lastly, the duration of gestural formation of /k/ in the sequence containing /lk/ was longer than that of /p/ in the sequence containing /lp/, which can be articulatorily supporting evidence to explain more /l/ deletion before /k/ than /p/ in Cho (1999). [Work supported by NIH.]

5pSC15. Intrusive vowels in Cruceno Spanish. Cynthia Kilpatrick, Kathryn McGee (Dept. of Linguist., Univ. of California, San Diego, 9500 Gilman Dr. #0108, La Jolla, CA 92093-0108), and James Kirby (Univ. of Chicago, Chicago, IL 60637)

Intrusive vowels are short vowels appearing within consonant clusters that are not treated phonologically like full vowels. Though reported in many languages, few quantititative studies have examined these vowels. Here, an acoustic study of intrusive vowels in obstruent+tap clusters in the Spanish of Santa Cruz, Bolivia is reported. The results support earlier studies in that the intrusive vowel quality resembles that of the following nucleic vowel, rather than a neutral vowel, and intrusive vowels are significantly longer in clusters with voiced obstruents than in those with voiceless ones. However, results do not fully support all previous phonetic descriptions and related theoretical assumptions. In particular, a significant difference is not found in intrusive vowel length based on variables such as place of articulation of the obstruent, quality of the nucleic vowel, or placement of stress in relation to the cluster. In addition, where previous work finds no significance for position in the word, the present work finds that intrusive vowels are significantly longer in word-medial clusters than in word-initial clusters. The data further suggest that the articulation of obstruent+tap does not require an intrusive vowel, as has previously been claimed, as not all obstruent+tap clusters include an intrusive vowel.

5pSC16. Ultrasound study of velar-vowel coarticulation. Sylvie M. Wodzinski and Stefan A. Frisch (Dept. of CSD, Univ. of South Florida, 4202 E. Fowler Ave., PCD1017, Tampa, FL 33620)

In velar fronting, the closure location for a velar consonant is moved forward along the palate due to vowel context. This study is a replication and extension of a previous study on velar fronting [Wodzinski and Frisch, J. Acoust. Soc. Am. **114**, 2395 (2003)]. In this study, ten participants

produced sentences containing monosyllabic words with /k/ onsets and nine different American English vowels. Ultrasound was used to make measurements of lingual-palatal constriction location at the midpoint of stop closure. Participants were recorded using a head-stabilizing apparatus and an acoustically transparent standoff was used between the ultrasound probe and the jaw. Velar closure location was quantified by the angle of elevation from the horizontal axis of the ultrasound probe to the center of the velar closure. The articulatory frontness of the following vowel was quantified using the frequency of $F2$ at the vowel midpoint. A strong negative correlation between velar closure angle and the following vowel $F2$ was seen for all ten participants. The coarticulatory pattern suggests that each velar-vowel combination results in a distinct closure location for the velar. Implications for models of speech production will be discussed.

5pSC17. Introducing diphthongs to the vowel space. Anna Bogacka (Adam Mickiewicz Univ., Poznan, Poland)

The aim of the study is to provide information on a new vowel space of Polish learners of British English, specifically about acoustic properties of diphthongs. Polish does not have diphthongs, though it has vowel plus glide sequences comparable to English rising diphthongs. Polish has neither vowel duration distinctions nor vowels which are qualitatively identical to the ones appearing in English diphthongs. Studying diphthongs offers the possibility of examining the interplay of substitutions of qualitative and quantitative features. Eight dipthongs were taken into account. The conditioning criteria were quality, duration, occurrence of glottal stops, and degree of nasalization. Twenty subjects were recorded reading 61 sentences with diphthongs embedded in real words. The paper discusses challenges in segmentation. Reported are non-native properties of formant and timing relations and systematic differences in alternations applied to: simple vowels versus diphthongs, rising versus centering diphthongs, and initial versus final phases of diphthongs. Specifically, nasal vocalization was found to depend on the presence or absence of a following fricative, but to be independent of a stressed or unstressed position. The finding is explained by resorting to Polish prosody, which is not stress timed. Suggestions for using the findings in second language instruction will also be offered.

5pSC18. Cues to stop place in stop-liquid clusters. Edward Flemming (Dept. of Linguist. and Philosophy, M.I.T., 77 Massachusetts Ave., 32-D808, Cambridge, MA 02139, flemming@mit.edu)

The acoustic correlates of stop place contrasts in prevocalic position have been studied intensively, but much less is known about stop place contrasts in consonant clusters. An understanding of the nature and distribution of cues to contrasts across a variety of contexts is important to the phonological analysis of the distribution of contrasts. This study extends the characterization of stop place contrasts to stop-liquid clusters /br, dr, gr, bl, gl/, based on acoustic analysis of American English. We examine how well established cues relating to burst duration, burst spectrum, and formant transitions generalize to the stop-liquid context. The relative perceptual weight of burst and formant transitions will be assessed through identification of cross-spliced stimuli.

5pSC19. Acoustic analysis of pressed voice. Carlos Ishi, Hiroshi Ishiguro, and Norihiro Hagita (ATR/IRC Labs., 2-2 Hikaridai, Kyoto 619-0288, Japan)

Pressed voice (''rikimi'' in Japanese) is a voice quality related to the vibratory patterns of the vocal folds. It was recently shown that pressed voice carries important paralinguistic information in Japanese, indicating emotional or attitudinal state of the speaker. In the present work, several acoustic features are investigated, aiming for an appropriate acoustic characterization and an automatic detection of pressed voices. Analysis of pressed voice samples extracted from natural conversational speech firstly shows that irregularity in periodicity (such as in creaky and harsh voices)

is a common but not a strictly determinant feature of pressed voices. Spectral analysis shows that parameters related to spectral slope are effective to identify part of the pressed voice samples, but fail when vowels are nasalized or double-beating occurs in a glottal cycle. Temporal analyses of pressed and nonpressed creaky voices indicate that diplophonia (simultaneous production of two separate tones, when vocal folds oscillate out of phase) frequently occurs in nonpressed creaky voices, while it rarely appears in pressed ones. Further temporal analysis of EGG (electroglottograph) waveforms of acted speech showed the same trends obtained for natural speech, indicating that information about the absence of diplophonia can potentially be used for pressed voice detection.

5pSC20. Determining Bayesian evidence and decay time estimates in acoustically coupled volumes. Tomislav Jasa (Dept. of Elec. Eng., The University of British Columbia, Vancouver, BC, Canada V6T 1Z2) and Ning Xiang (Rensselear Polytechnic Inst., Troy, NY 12180)

Sound energy decay analysis is an important element in understanding acoustical properties of coupled volumes in architectural acoustics. A Bayesian model formulation using Monte Carlo algorithms [Xiang and Goggans, J. Acoust. Soc. Am. **110** 1415–1424 (2001); Jasa and Xiang, *ibid.* **117**, 3707(A) (2005)] has been applied to estimating both the decay times and decay order required in sound energy decay analysis. The need to focus on model selection in a Bayesian model formulation of sound energy decay analysis was presented by Jasa and Xiang [J. Acoust. Soc. Am. **119**, 3343(A) (2006)] along with a discussion of the limitations of the existing Monte Carlo algorithms used for this purpose. This paper will present some recent algorithms that can overcome the limitations of a Monte Carlo approach to model selection and show how these algorithms can be applied to determining both the proper model and decay time estimates for acoustically coupled rooms.

5pSC21. Acoustic analysis and synthesis of laughter. Toshiaki Haga, Masaaki Honda, and Katsuhiko Shirai (Dept. of Sci. and Eng., Univ. of Waseda, 3-4-1 Okubo, Rm. 55S-609, Shinjuku-ku, Tokyo 169-8555, Japan)

Laughter is an important emotional expression in speech. The production is characterized simply by quasiperiodic glottal opening/closing gesture with relatively constant articulatory configuration. The acoustic consequence, however, is complicated and appears in the temporal characteristics of voiced-unvoiced category and pitch, the spectral envelope, and the segmental duration. In this study, acoustic parameters that characterize laughter were investigated from acoustical and perceptual points of view. Laughter /hahaha/ was selected as a typical laughter from conversational speech recording and the acoustic characteristics were compared with those of normally uttered speech /hahaha/. The acoustic analysis was performed in terms of pitch in average and its intrasegmental pattern, the spectral tilt and formant bandwidth, and the segmental duration of the vowel /a/ and the consonant /h/. Then, perceptually significant acoustic features were investigated by using means of replacement of the acoustic parameters of the normally uttered speech by those of the laughter in speech analysis-synthesis system. The results showed that an increased pitch in average and distinct intrasegmental pitch pattern as well as spectral envelope with broad bandwidths are significant features to characterize the laughter. The laughter synthesis by rule was also investigated by manipulating these acoustic parameters.

5pSC22. A study of manual articulatory feature-based transcription of conversational speech. Karen Livescu (Comput. Sci. and Artificial Intelligence Lab., MIT, Cambridge, MA), Xuemin Chi, Lisa Lavoie (MIT, Cambridge, MA), Ari Bezman (Dartmouth College, Hanover, NH), Nash Borges, and Lisa Yung (Johns Hopkins Univ., Baltimore, MD)

This study investigates the manual labeling of speech, and in particular conversational speech, at the articulatory feature level. A detailed transcription, including subtleties such as overlapping or reduced gestures, is useful for studying the great pronunciation variability in conversational

speech. This type of labeling also facilitates the testing of automatic feature classifiers, such as those used in articulatory approaches to automatic speech recognition. For this study, approximately 100 utterances drawn from the SWITCHBOARD database have been transcribed using eight articulatory tiers rather than the traditional single phonetic tier. The tiers include: place and degree for up to two constrictions, nasality, glottal state, lip rounding, and vowel quality. Two transcribers have labeled this set of utterances in a multipass strategy, allowing for correction of errors. Preliminary analysis shows a high degree of intertranscriber agreement. Further analysis of the data is being performed to address a number of questions, such as: How quickly and reliably can this type of transcription be done? What are its advantages and disadvantages relative to purely phone-based transcription? What characteristics of the utterances correspond to high or low transcriber agreement? What can be learned from the data regarding articulatory phenomena such as reduction and asynchrony?

5pSC23. Changes in vocal tract resonance during a pitch cycle. Hironori Takemoto, Tatsuya Kitamura (NICT/ATR Cognit. Information Sci. Labs., 2-2-2 Hikaridai, Seika-cho, Soraku-gun Kyoto, 619-0288, Japan, takemoto@atr.jp), and Seiji Adachi (Fraunhofer Inst. for Bldg. Phys., 70569 Stuttgart, Germany)

Vocal tract (VT) resonances during a pitch cycle were examined using area functions of the five Japanese vowels extracted from MRI data of a male subject. The volume-velocity distribution within the VT at each formant was calculated by a transmission line model, as a function of the glottal area. Our previous study showed that in glottal closure condition the fourth formant was provided by the laryngeal cavity (LC) and the other formants by the VT excluding LC, the VT proper (VTp). During the early stage of glottal opening, the fourth formant disappeared, as it had been provided by the closed-tube resonance of LC. After glottal opening, the single volume-velocity node of the first formant moved to the middle pharynx, shortening the effective VT length and thus increasing its frequency. At the other formants, a node appeared at the junction between LC and VTp, and the VT resonance during the glottal opening condition could therefore be approximated by the VTp. This result indicates that the VTp was responsible for most of the VT resonances throughout a period, while LC provided the fourth formant in the glottal closure period. [Work supported by NICT and MEXT KAKENHI of Japan.]

5pSC24. A study on generation of the voice bar in voiced stops. Jianwu Dang (School of Information Sci., Japan Adv. Inst. of Sci. and Technol., Japan), Takayoshi Nakai (Shizuoka Univ., Japan), Yongnan Piao (Japan Adv. Inst. of Sci. and Technol., Japan), and Shinobu Masaki (ATR, Japan)

The voice bar of the voiced stops is generally considered as a radiation sound from the vibration of the laryngeal wall while the mouth is closed. In this study, we investigated the mechanisms involved in generation of the voice bar of the voiced stops by means of acoustic and mechanical measurements and MRI observations for three Japanese speakers. Radiated sounds from the mouth and the nostrils were recorded separately, while vibration of the laryngeal wall was measured by an accelerometer. The correlation of the nostril radiation to the voice bar is higher than that of the laryngeal wall vibration to the voice bar. It implies that the major component of the voice bar is likely radiated from the nostrils but not the laryngeal wall, where the nostrils' radiation is possibly caused by a trans-velar coupling of the yielding velum. The authors have proposed a two-layer board model to imitate the transvelar function. To obtain physiological evidences, articulation of stop-vowel sequences was observed by MRI movies. It found that the thickness of the velum varies with the adjacent vowels. Applying this measurement to the two-layer board model, the generation of the voice bar was evaluated by comparing the simulations and observations.

5pSC25. Sound radiations from nostrils for voiced speech and their individuality. Takayoshi Nakai and Masashi Yamamoto (Faculty of Eng., Shizuoka Univ., 3-5-1 Johoku, Hamamatsu, Japan, 432-8561tdtnaka@ipc.shizuoka.ac.jp)

This study is intended research to analyze sound radiations from the nostrils for voiced speech and explore their characteristics. Sound pressure near the nostril, vibration acceleration of the nose, and sound pressure in front of the mouth were observed using a three-channel A-D converter. The ratio of radiations from the nostril and the mouth, RRNM, was observed. Speech materials included nasal sounds /ma/ and /na/; five vowels; and /cvcv/(c=b, d, g, v=a, i, u, e, and o). There are ten male subjects. For initial buzzes, RRNM showed individuality: it is from 0 to −15 dB lower than for /m/. For medial buzzes, RRNM is mostly lower than for initial buzzes. Transitions from buzz to vowel and from vowel to buzz were mostly fast, but their transitions are slow and smooth in some cases. Frequency analyses revealed that radiation from the nostrils consists mainly of fundamental frequency, and the second and third harmonics.

5pSC26. Spectral characteristics of period doubled phonation. Jody Kreiman and Bruce R. Gerratt (Div. of Head/Neck Surgery, UCLA School of Medicine, 31-24 Rehab Ctr., Los Angeles, CA 90095-1794, jkreiman@ucla.edu)

Period doubling (also called subharmonic phonation, bifurcated phonation, F0 series) occurs frequently in both pathological and normal phonation. In this kind of phonation, the most obvious acoustic characteristic is that vocal pulses appear in pairs, with alternate pulses differing in period and often in amplitude. Attempts at modeling period doubling by varying period and amplitude did not capture its characteristic quality, leaving the question of which acoustic variables underlie our perception of period doubling. Acoustic analyses of 50 period doubled voices were undertaken to determine what acoustic features might underlie the constant percept associated with period doubling. Every voice examined did show alternation between short/long and large/small glottal pulses. However, alternations in amplitude were not consistently linked to alternations in period. Voices additionally showed a consistent pattern of alterations in pulse shape, so that the A and B pulses consistently differed in H1-H2. Results suggest that the consistent vocal quality associated with period doubling is due to combined alternations in period and spectral tilt. Amplitude alternations appear to be acoustic artifacts of the period and spectral alternations.

5pSC27. On the vocalization of nonspeech sounds: Implicit mechanisms. Rodrigo Segnini (Shimojo Implicit Brain Function Project, JST-ERATO, 3-1 Morinosatowakamiya, Atsugi, Kanagawa, Japan 243-0198, rsegnini@shimojo.jst.go.jp) and Takemi Mochida (NTT Sensory and Motor Res. Group, Atsugi, Kanagawa, Japan 243-0198)

When humans vocalize nonspeech sounds, as when imitating other sound-producing mechanisms, how effective is this vocalization? The human vocal tract is adept at producing speech sounds, allowing verbal communication despite variations in these sounds due to differences in size, shape, and dynamics of this mechanism among individuals. In contrast, nonspeech sounds that were not originally produced by the human vocal tract derive from even more structurally different mechanisms—those of animal calls or machinery sounds, for example. Through experiment, we determined that in imitative tasks of such nonspeech sounds, subjects were intuitively able to produce distinguishing articulatory movements for each sound under different conditions, even when lacking auditory feedback. These results reveal a nontrivial coherence between articulatory events and the intended sound despite the noted differences with the original production mechanism and the resulting acoustic mismatch. The authors would like to express sincere appreciation to Makio Kashino for enriching discussion and support in the realization of this project.

5pSC28. Basic processes underlying speaking and singing: Preliminary acoustic and aerodynamic comparisons. Amee P. Shah (Dept. of Health Sci., Cleveland State Univ., 2121 Euclid Ave., MC 431-B, Cleveland, OH 44115)

Intuitively, we think speech and singing are different. Perceptually, we hear the difference. Aesthetically, we appreciate the difference. Psychologically, we benefit from the positive effect of singing. The important question is whether this perceived difference is purely perceptual or is it grounded in physiological reality? It is important to identify the difference between speaking and singing if indeed there is one as it can shed light on our theoretical understanding of normal auditory perception and vocal production processes. Addressing this question has practical applications as well, as the findings could yield valuable information for working with clients in the fields of speech pathology and vocal music training. In addressing this question, the present investigation targeted broad areas to identify the differences between speech and singing. Specifically, respiration (the mechanics of breathing), articulation (the movements of the oral musculature), phonation (vocal-fold movement and air pressures), and acoustic attributes (temporal and spectral measures) were compared across speaking and singing. Surprisingly, and somewhat counterintuitively, results showed that speaking and singing are not as different as they are perceived to be. Results of preliminary acoustic and aerodynamic comparisons will be discussed as they help better understand the processes of singing and speaking.

5pSC29. The articulation of consonants in Kinyarwanda's sibilant harmony. Rachel Walker, Dani Byrd, Sungbok Lee, Celeste DeFreitas (Dept. of Linguist., USC, 3601 Watt Way, GFS 301, Los Angeles, CA 90089-1693, rwalker@usc.edu), and Fidele Mpiranya (Univ. of Chicago, Chicago, IL 60637)

Kinyarwanda's sibilant harmony causes alveolar /s, z/ to become retroflex when preceding a retroflex fricative within a stem. Intervening coronal stops block sibilant harmony, but bilabial and velar consonants are transparent. This study investigates the production of Kinyarwanda's sibilant fricatives and also examines transparent and opaque consonants in the system. Articulatory kinematic data were collected for a native speaker of Kinyarwanda using electromagnetic articulography. This allowed calculation of the mean angle for receivers affixed to the tongue tip and blade over the target consonant intervals. Average mean angle reliably and robustly distinguished alveolar and retroflex fricatives, with alveolars showing a lower tip relative to blade. No significant difference in mean angle was found for /t/ in contexts where it blocked retroflex sibilant harmony versus ones where it preceded an alveolar fricative, confirming that /t/ does not participate in the harmony. However, in contexts where /m/ and /k/ are perceived as transparent to sibilant harmony, their mean tip-blade angle was significantly different from contexts where harmony did not occur. Furthermore, mean angle during transparent /m/ showed no significant difference from mean angle during retroflex fricatives, suggesting that tongue tip-blade angle conducts strongly and systematically through transparent consonants but without perceptible effect. [Work supported by NIH, USC URP.]

5pSC30. Validity of the Nasometer measuring the temporal characteristics of nasalization. Youkyung Bae, David P. Kuehn, and Seunghee Ha (Dept. of Speech and Hearing Sci., Univ. of Illinois at UC, 901 S. Sixth St., Champaign, IL 61820, yousong@uiuc.edu)

Patients with oral-nasal resonance imbalance may present different characteristics not only in the amplitude but also in the temporal aspects of nasalization. Although nasalance has been the most commonly derived measure from the Nasometer (KayPENTAX), the Nasometer also might be useful in providing another important measure, time. Such measurements, however, should be validated in relation to a separate external criterion procedure. This study examined the validity of the Nasometer measuring the temporal characteristics of nasalization. Fourteen adult American English speakers produced three rate-controlled nonsense speech samples:

/izinizi/, /azanaza/, and /uzunuzu/. Acoustic data recorded through the Nasometer were compared to those recorded through a standard audio recording setup which served as an external criterion procedure. Four timing variables pertinent to nasalization were measured from the digitized acoustic signals: nasal onset, nasal consonant, nasal offset, and total nasalization. No significant differences were found between the two instrumental conditions in any of four timing variables measured, which suggests the Nasometer can be used as a valid tool to measure the temporal features of nasalization. This study also provided a valid way of segmenting speech tasks using the Nasometer and confirmed the significant effect of different vowel contexts on the temporal characteristics of nasalization.

5pSC31. Pitch determination and sinusoidal modeling for time-varying voiced speech. Masashi Ito and Masafumi Yano (Res. Inst. of Elec. Commun., Tohoku Univ., 2-1-1 Katahira. Aoba-ku, Sendai 980-8577, Japan, itojin@riec.tohoku.ac.jp)

A voiced speech signal consists of sinusoidal components of which amplitude and frequency are time varying. Usually the signals are analyzed by assuming that they are stationary within a local analysis window, so they include inevitable errors. To solve this problem, we have proposed a method termed local vector transform (LVT), in which amplitude and phase of the sinusoidal components were approximated by quadratic functions uniquely determined from input spectrum. Two types of experiments were carried out to evaluate the validity of this method. First, time-varying pitch frequencies (F0s) of natural utterances were investigated. F0 determined by LVT greatly improved the accuracy compared to the conventional pitch determination algorithms: cepstrum, autocorrelation, and instantaneous frequency estimation. Second, LVT is applied to the sinusoidal modeling and the amplitude and phase were estimated for every component. The results apparently showed that the signal obtained by LVT was very close to the input. This was quantified by a signal to residual power ratio (S/R). For both of synthesized and naturally uttered speech signals, LVT showed the higher S/R compared to the conventional algorithm. These results indicate that the proposed algorithm is highly effective for pitch determination and sinusoidal modeling for time-varying speech signals.

5pSC32. The effect of stress on consonant vowel (CV) coarticulation: Decoupling of the CV bond. Augustine Agwuele, Harvey Sussman, and Bjorn Lindblom (Dept. of Linguist., Univ. of Texas, Austin, TX 78712)

Two common sources of variation in the speech signal arise from (1) naturally imposed speaking conditions (e.g., stress, tempo), overlaid onto (2) inherent contextual influences. Coarticulatory analyses are affected by both sources of variation, but rarely are they dissociated. The focus of this study was to derive quantitative methods to assess the effect of emphatic vowel stress on preceding stop consonant onsets, apart from, and independent of, anticipatory effects of changing vowel contexts. Three speakers produced V1CV2 tokens, with emphatic stress either on V1 or V2; C =/bdg/. There were six V1 and 10 V2 vowel contexts. Novel methods were applied to both standard locus equation scatterplots and multiple regression analyses to isolate F2 midvowel (Hz) and F2 onset (Hz) adjustments as a function of emphatic stress. The analyses show how stress differentially affects the V-midpoints and C-onsets for labial /b/ relative to lingual stops /dg/.

5pSC33. Intrinsic vowel F0 and speech rate. Ian Maddieson (Univ. of New Mexico/Univ. of California, Berkeley Dept. of Linguist., Univ. of New Mexico, MSC 03 2130, Albuquerque, NM 87131)

A relation between vowel height and F0 such that, other things being equal, F0 is a little higher in a high vowel than a low vowel appears to be a phonetic universal. However, the cause of this relationship remains unclear. An insight might be gained from ways in which the relationship changes under transformations of speech rate. Ten speakers of American

English were recorded saying sentences containing words such as "bead" and "bad" at fast and slow rates. For the majority of the subjects the intrinsic F0 difference was greater in fast speech, contrary to expectation. The difference cannot be explained by changes in vowel quality between the conditions.

5pSC34. Tongue dorsum location and tongue root retraction in alveolar and palatal clicks in the endangered language N/uu. Amanda L. Miller, Johanna Brugman, Jonathan Howell (Dept. of Linguist., Cornell Univ., 203 Morrill Hall, Ithaca, NY 14853), and Bonny Sands (Northern Arizona Univ., AZ)

Traill (1985) describes Xoo clicks as having velar posterior constriction locations (PCL). Miller *et al.* (to appear) show that the PCLs of Khoekhoe alveolar and palatal clicks are uvular and uvulo-pharyngeal. Ladefoged and Maddieson (1996) discuss clicks involving a uvular posterior release location (PRL) (and an implied velar PCL). An ultrasound investigation of velar and uvular pulmonic stops, alveolar and palatal velar clicks, and palatal uvular clicks, in the endangered language N/uu is presented. Results are for 15 repetitions of each consonant in the u context by four of the remaining speakers. The alveolar click has the tongue dorsum (TD) between the velar and uvular stops, and tongue root retraction (TRR) like the uvulars. The TD in the palatal click is also similar to the velar and uvular stops, but there is no TRR. The TD in the uvular palatal click is at the uvulo-phraryngeal location, and there is TRR similar to the uvular stop, in both the closure and the release. TRR in the alveolar-uvular and palatal-uvulo-pharyngeal clicks explains their phonological patterning with uvulars. The lack of TR retraction in the palatal click explains its patterning with velars. [Work supported by NSF, BCS #0236735.]

5pSC35. Acoustic evidence for the lenis/fortis contrast in California Northern Paiute. Molly Babel (UC Berkeley, 1203 Dwinelle Hall, Berkeley, CA 94720-2650, mbabel@berkeley.edu)

California Northern Paiute (CNP) is spoken in the communities on the eastern slopes of the Sierra Nevada Mountains in northern California. CNP is the southernmost dialect of Northern Paiute, a language belonging to the Western Numic branch of Uto-Aztecan. CNP is a severely endangered language spoken by fewer than ten fluent speakers. CNP has a phonemic contrast that is distinct from that of any other Numic language. CNP has three series of stops: lenis, fortis, and voiced fortis. Previous descriptions of CNP have used only impressionistic judgments to categorize the phoneme series. This paper presents the first acoustic evidence for the lenis/fortis contrast in CNP. Field recordings from five native speakers of CNP were analyzed in this investigation. The lenis/fortis contrast was examined by measuring the closure duration using cues from the waveform and spectrogram in a digital signal processing program. Results of duration measurements support the impressionistic evidence and suggest a voiced and voiceless fortis series in addition to a single lenis series in the phonemic inventory of CNP. This research has implications for the acquisition of categories by second language learners who are first language speakers of a language that does not have such a contrast.

5pSC36. Articulation without acoustics: A case study of Oneida utterance-final forms. Bryan Gick (Dept. of Linguist., University of British Columbia, E270-1866 Main Mall, Vancouver, BC V6T 1Z1, Canada), Karin Michelson (Univ. at Buffalo, Buffalo, NY 14260), and Bosko Radanov (University of British Columbia, Vancouver, BC V6T 1Z3, Canada)

Whether the targets of speech production are primarily articulatory or acoustic has been controversial [Guenther *et al.*, J. Acoust. Soc. Am. **105**(5), 2854–2865 (1999)]. While it has been observed that tongue movements occur even in contexts where they may be acoustically obscured [Browman and Goldstein, LabPhonI: 341–376 (1990); Tiede *et al.*, J. Acoust. Soc. Am. **110**(5), 2, 2657 (2001)], the question of whether natural languages can systematically encode articulations in the absence of acoustic consequences has remained open. A study was conducted to investigate a purported phonological process in the endangered Oneida (Iroquois) language whereby utterance-final forms exhibit fixed sequences having this property. Ultrasound, video, and acoustic data were collected from two native speakers of Oneida in a field setting. Preliminary results indicate that speakers' tongue positions are significantly different during different utterance-final vowel articulations despite these vowels being completely inaudible. Results confirm claims that the Oneida phenomenon is in fact a case of articulation without acoustics, and indicate that it is indeed possible for articulations to be retained even in the systematic absence of auditory goals. [Work supported by NSERC.]

5pSC37. Automatic detection of vowel nasalization using knowledge-based acoustic parameters. Tarun Pruthi and Carol Y. Espy-Wilson (Dept. of Elec. Eng. and Inst. of Systems Res., Univ. of Maryland, College Park, MD 20742, tpruthi@umd.edu)

Researchers in the past have suggested several acoustic correlates of nasalization including extra pole-zero pairs near the first formant ($F1$), a reduction in $F1$ amplitude, and an increase in F1 bandwidth. Even though these correlates have been known for a long time, considerable work is still needed to automate the extraction of acoustic parameters (APs) for nasalization. This work looked at 37 different APs which were pared down to 8 APs based on F statistic obtained by ANOVA. In preliminary experiments, an accuracy of 69.79% has been obtained for the task of discriminating between oral and nasalized vowels on the TIMIT database using a support vector Machine (SVM)-based classifier. The classification was done on a frame basis, and a segment was declared nasalized if more than 30% of the frames were found to be nasalized. Note that all vowels adjacent to nasal consonants were assumed to be nasalized. Thus, the accuracy may actually be higher since some vowels before nasal consonants may not be nasalized. Further, these results were obtained by using a linear kernel in SVMs. We hope the results would improve when a radial basis function kernel is used. [Work supported by Honda and NSF Grant BCS0236707.]

5pSC38. A novel method for the measurement of vowel formant frequencies and its application to the analysis of Japanese vowels over a wide range of ages. Hideki Kasuya (Dept. of Speech, Lang. and Hearing Sci., Intl. Univ. of Health and Welfare, Otawara, Japan 324-8501, kasuyah@snow.ucatv.ne.jp), Kanae Ohta, Hiroki Mori (Utsu-nomiya Univ., Utsunomiya, Japan 321-8585), Toshisada Deguchi, Ghen Ohyama (Tokyo Gakugei Univ., Tokyo, Japan 184-8501), and Yukimasa Muraishi (Univ. of Tokyo, Tokyo, Japan 164-8654)

The first three formant frequencies of the Japanese vowels, measured over a wide range of ages of talkers by one of the authors in 1968, have widely been cited in many speech textbooks and research papers. We decided to update those old data, measured by sound spectrograms, by using a more advanced method. We developed an iterative method for measuring vowel formant frequencies based on an autoregressive with exogenous input (ARX) speech production model that incorporates both voice source and vocal-tract models [J. Acoust. Soc. Jpn. **58**, 386–397(2002)]. In using this method to measure vowel formant frequencies of high-pitched voice, the procedure for determining the initial value of the open quotient (OQ) of the source model was carefully investigated, since it affects significantly the estimation of the lower first formant frequency. Estimated OQs of the vowel /a/ of a talker were found to be stable against various initial values and so were used for analyzing the other vowels of the same talker. Perceptual confirmation of phonetic quality of resynthesized vowels with the fundamental frequency perturbed was also of great importance for accurate measurement. This procedure was successfully applied to 320 male and female talkers, aged 6–24 years.

5pSC39. Spectral properties of Japanese whispered vowels referred to pitch. Hideaki Konno, Hideo Kanemitsu (Hokkaido Univ. of Education, Hakodate 040-8567, Japan, konno@cc.hokkyodai.ac.jp), Jun Toyama, and Masaru Shimbo (Hokkaido Info. Univ., Ebetsu 069-8585, Japan)

Whispered speech can communicate the same linguistic information as ordinary speech in spite of the great difference of their respective acoustic characteristics. In this respect, whispering is an interesting object for studying speech perception and recognition. In this study, we investigate the spectral properties of five whispered Japanese vowels uttered in isolation and having different pitch. Pitch of ordinary whispered vowels was measured in terms of the manner in which the talkers were listening to pure tones while uttering and adjusting its frequency so that the pitch matched the utterance. For other samples, talkers changed the pitch of utterances to match the given pure tones. Acoustic analyses were carried out on formant frequencies, a spectral tilt, and a peak frequency of wide-ranging spectral shape using second-order LPC method called a global peak. Preliminary results show a tendency of upward shift of $F1$, $F2$, and global peaks, and flattened spectral tilts on overall vowels with increasing pitch. The intended pitch by a talker is not correspondent to a specific formant frequency. Results of pitch comparison tests among samples and pitch matching test with pure tones will also be discussed. [Work supported by MEXT Japan.]

5pSC40. Detecting nonlinearity in voice production systems. Yu Zhang, Chao Tao, and Jack J. Jiang (Dept. of Surgery, Div. of Otolaryngol. Head and Neck Surgery, Univ. of Wisconsin Med. School, Madison, WI 53792-7375)

Many biomedical systems exhibit some form of nonlinear behavior, such as saturation in response to certain inputs. Linear description may not be sufficient to describe the complex nonlinear phenomena, including bifurcation and chaos. The determination of nonlinearity from time series has become an important topic for the analysis and modeling of biomedical systems. In this study, we will apply nonlinear dynamic modeling based on Volterra kernel function to describe the nonlinearity of voice signals. Three nonlinear parameters including nonlinearity-to-linearity amplitude ratio (NLAR), nonlinearity-to-linearity parameter ratio (NLPR), and nonlinear order are employed. Sufficiently lower NLAR and NLPR, and a nonlinear order approaching 1 can be found in periodic voice signals, demonstrating the linear mechanism of periodic voice production. However, aperiodic voices show sufficiently high NLAR and NLAR, and a nonlinear order above 2, indicating the dominant role of nonlinearity in disordered voice production. Furthermore, the effects of the signal length and noises on these three parameters are investigated. These three nonlinear parameters show the robustness of short signal length and noise perturbations, demonstrating their potential applications in measuring the nonlinearity of disordered voice production systems. [Work supported by NIH.]

5pSC41. Concurrent speech disturbs word generation: Semantic, associative, and grammatical processes in picture naming: A pictureword interference study. Masumi Watanabe (Dept. of SLP, Tama Rehabilitation Acad., 1-642-1 Nekabu, Ome, Tokyo, Japan 198-0004), Kazuhiko Kakehi (Cyukyo Univ., Kaizu-cho, Toyota, Japan, 470-0393), Joanne Arciuli, David Vinson, Gabriella Vigliocco (Univ. College London, London WC1H 0AP, UK), and Noriko Iwasaki (UC Davis, Davis, CA 95616)

In pictureword interference (PWI), a picture of an object to be named is presented with a distracter word. Most PWI studies showed semantic interference between a target picture and distracter word (noun). Recently, Vigliocco et al. (2005) studied grammatical effect in naming a picture of action. They found that generation of an inflected form of an Italian verb was disturbed by a distracter in the same grammatical class. In experiment 1 of the present study, naming an object with an auditorily presented noun or verb distracter in Japanese was investigated, and grammatical class but not semantic effect was found, which is incongruent with previous find-

ings. Analyzing the distracters revealed that familiarity of the verbs was lower than that of nouns, and half of nouns classified as semantically close were associative (e.g., garage versus car). In experiment 2, familiarity was matched across distracters, and association effect was examined separately. To see time course of interference, stimulus onset asynchrony (SOA) was changed from -300 to $+200$ ms. Again, grammatical effect was observed, and associative as well as semantic effect was found for negative SOAs. Possible factors producing grammatical and associative effects in PWI will be discussed cross-linguistically.

5pSC42. Quantifying the Lombard effect in different background noises. Christian Giguère, Chantal Laroche, Émilie Brault, Julie-Catherine Ste-Marie, Marianne Brosseau-Villeneuve, Bertrand Philippon, and Véronique Vaillancourt (Univ. of Ottawa, 451 Smyth Rd., Ottawa, ON, Canada K1H 8M5)

The Lombard effect of increasing one's vocal effort in the presence of background noise has been quantified by Pearsons et al. (1977) as a 0.6-dB increase in speech levels for each dB increase in the background noise up to a ceiling level. Lombard speech has also been investigated in other studies with variable results. This study reports data on the effect of different noises on (1) the slope of the function relating speech levels and noise levels and (2) the spectral structure of speech. Twenty normal-hearing adults were asked to read aloud ten sentences from the hearing in noise test (HINT) to an experimenter seated 1 m away, in quiet and in various noises (white, speech spectrum, babble, and restaurant) presented in the sound field at 60 and 75 dBA. Preliminary findings show that increases in speech levels in natural environmental noises (restaurant and babble) most closely follow Pearsons' data, with a slope of 0.6 dB. In contrast, artificial noises (speech spectrum and white) were associated with lower slopes (0.2 and 0.4 dB, respectively). Findings of this study could be useful in a wider context of modeling the complete speech communication process from talker to listener.

5pSC43. Frequency modulated feedback of ones own voice can cause dysfluence of speech. Xu Yizhong (Res. Inst. for Electron. Sci., Hokkaido Univ., N12-W6 Kita-ku, Sapporo 060-0812, Japan), Akira Toyomura, Sachiko Koyama, and Shinya Kuriki (Hokkaido Univ., Sapporo 060-0812, Japan)

Delayed auditory feedback (DAF) can cause speech dysfluency (e.g., stuttering) in healthy normal subjects. In previous studies, feedback frequency was changed linearly or to a constant value in FAF. In this study, we introduce frequency-modulated feedback of pitch in a sine-wave manner. The modulation depth of pitch ($F0$) of auditory feedback voice was six semitones, and the modulation frequencies of sinewaves were set at 0.05, 0.1, 0.5, 0.9, 2, 4, 6, 8, 10, 12, 14, and 16 Hz. In addition to the FAF experiment, we conducted DAF experiments with delay times of 50, 200, and 400 ms. Participants (18 Chinese and 18 Japanese) were instructed to read sentences as they listened to the altered feedback voice through a headphone under each condition. Speech dysfluency was apparent under all FAF and DAF conditions for both groups. Only when the modulation frequency was 14 Hz did Chinese subjects show significantly larger disturbance than Japanese in FAF. A significant greater disturbance of Chinese in DAF was observed when the delay time was 50 ms. These results indicate that frequency modulation can cause speech dysfluency, as does DAF. [Work supported by the 21st century COE (Center of Excellence) Program.]

5pSC44. An online customizable music retrieval system with a spoken dialogue interface. Sunao Hara, Chiyomi Miyajima, Katsunobu Itou,[a] and Kazuya Takeda (Grad. School of Information Sci., Nagoya Univ., Furo-cho, Chikusa-ku, Nagoya, 464-8601, Japan, hara@sp.m.is.nagoya-u.ac.jp)

In this paper, we introduce a spoken language interface for music information retrieval. In response to voice commands, the system searches for a song through an internet music shop or a "playlist" stored in the local PC; the system then plays it. To cope with the almost unlimited size

of the vocabulary, a remote server program with which a user can customize their recognition grammar and dictionary is implemented. When a user selects favorite artists, the server program automatically generates a minimal set of recognition grammars and a dictionary. The system then sends them to the interface program. Therefore, on average, the vocabulary is less than 1000 words for each user. To perform a field test of the system, we implemented a speech collection capability, whereby speech utterances are compressed in free lossless audio codec (FLAC) format and are sent back to the server program with dialogue logs. Currently, the system is available to the public for experimental use. More than 100 users are involved in field testing. In our presentation, we will report details of the system and the results of field tests, which include motorcycle environments. [a]Currently at Graduate School of Computer and Information Sciences, Hosei University, Tokyo 184-8584, Japan.

5pSC45. Database construction and analysis of user speech with real environment spoken guidance systems. Hiromichi Kawanami, Manabu Kida, Tobias Cincarek, and Kiyohiro Shikano (Grad. School of Information Sci., Nara Inst. of Sci. and Technol., 8916-5 Takayama-cho, Ikoma-shi, Nara, 630-0101, Japan, kawanami@is.naist.jp)

A spoken guidance information system "Takemaru-kun" has developed and been operated in a public city center in Ikoma city, Nara, Japan since November 2002. The system employs the example-based response selection strategy and answers to users' questions about the hall facility, the city, sightseeing, etc. with CG agent animation. Following the success of the system, two new spoken systems "Kita-chan" and "Kita-chan robot" were developed and were set on a railway station since March 2006. "Kita-chan robot" is being operated with a robotlike agent. All user speech of the systems is recorded and two year's data of "Takemaru-kun" and one month's data of "Kita-chan" systems are manually transcribed and labeled by age and gender. Proper answers are also given to each utterance. In this paper, details of the three user speech databases are described and analytical results concerning numbers of inputs and response accuracy and age group and gender are reported.

5pSC46. A speech communication environment using open source software library for active sound image control. Yuichiro Kitashima, Kazuhiro Kondo, and Kiyoshi Nakagawa (Yamagata Univ., Jounan 4-3-16, Yonezawa, 992-8510, Yamagata, Japan)

This paper describes a three-dimensional (3-D) conference system using an open source software library on conventional PCs. We will attempt to use both 3-D graphics and audio to construct a virtual conference environment for effective communication between remote parties. A rough prototype system was developed using OpenGL and OpenAL. The system uses local files for voice output, whose image location is rendered according to the user input. We initially evaluated the perceived sound image location accuracy of the rendered sound image using the prototype. Users were asked to identify the location of the rendered sound image from among four choices: front, back, left, and right. The users were able to identify the left and right images correctly at virtually 100%, but the front and back identification were lower than 10% for some sounds, particularly male speech. We plan to implement audio-streaming functions to achieve real-time audio conferencing and evaluate the benefits of 3-D audio for conferences. We would also like to implement HRTF (head-related transfer function) and RTF (room transfer function) for improved audio image localization, especially to achieve accurate elevation perception.

5pSC47. Khmu voice register: Acoustic analysis and perceptual experiments. Arthur S. Abramson, Patrick W. Nye (Haskins Labs., 300 George St., New Haven, CT 06511, arthur.abramson@uconn.edu), and Theraphan L-Thongkum (Chulalongkorn Univ., Bangkok 10330, Thailand)

Khmu has phonological voice registers, i.e., bundles of phonetic properties pertinent to the syllable. Auditory observations claim clear voice and high pitch for register 1 and breathy voice and low pitch for register 2. Although Suai registers were in flux [Abramson *et al.*, Phonetica **61**, 147–171 (2004)], it was understood that Khmu Rawk had a stable distinction. Words were recorded by 25 native speakers. Acoustic analysis yielded F0 and overall amplitude contours, frequencies of F1 and F2 in quasi-steady states of the vowels, relative intensities of higher harmonics to that of the first harmonic, and vowel durations. When circumstances caused early attention to perception testing, the words of only eight speakers had been analyzed. Since the only significant factor that had emerged by then was F0 contour, the synthetic stimuli were made with a series of seven contours. The labeling by 32 native speakers yielded two categories, demonstrating the sufficiency of F0 as an acoustic cue. The completed acoustic analysis showed a significant effect of the harmonic ratios for the women, suggesting a conservative bias. The language is shifting toward tonality. Further perception testing must be done for phonation-type effects. [Work supported by NIH and the Thailand Research Fund.]

5pUW1. Modeling scattering from simple three-dimensional bathymetric features using wave-field superposition. John A. Fawcett (DRDC Atlantic, P.O. Box 1012, Dartmouth, N.S., Canada, B2Y 3Z7, john.fawcett@drdc-rddc.gc.ca)

In the method of wave-field superposition a set of point sources inside or outside of a scattering region can be used to represent the exterior or interior acoustic fields. A method is presented that represents a simple bathymetric feature as a closed scattering region in an otherwise flat water-seabed environment. In particular, the feature is taken to be azimuthally symmetric about the vertical axis, thus allowing the three-dimensional scattering problem to be solved in terms of a set of two-dimensional problems. These problems are solved using the method of wave-field superposition. Numerical examples are presented. As well, a benchmark solution in the case that the surrounding medium has only a density jump at the seabed is derived and compared with the more general numerical approach.

5pUW2. Finite-difference modeling of scattering from shallow buried objects in sea floor. Inger Helene Moen and Hefeng Dong (Acoust. Group, Dept. of Electron. and Telecommunications, NTNU, O.S. Bragstads plass 2B, 7091 Trondheim, Norway)

An object buried in the sea floor positioned close to the water/sediment surface can, when exposed to an incident wave, be a source of interface wave generation. The amplitude of a surface wave tends to dominate at greater distances, and surface waves can thus be a viable tool for detecting shallow buried objects. In this paper, the 2-D velocity-stress finite-difference formulation of Virieux [Geophysics **51**, 889–901 (1986)] is adopted to model the wave propagation from a point source located above the sea floor in an open ocean environment. The wave responses from an object situated below the surface are computed and analyzed, with respect to various object depths, properties, and sizes. A second consideration of the paper is the analysis of the artificial reflections from the model boundaries. The perfectly matched layer absorbing boundaries is a widely used technique that has been shown to be very efficient and has therefore been implemented in order to reduce the grid reflections. The numerical results show that the amplitude of the surface wave decreases with the depth of the object, and that interface waves can be of great importance for detection and identification of shallow buried objects in the sea floor.

5pUW3. Time-frequency analysis of backscattered echoes from absorbing spherical shells. Hui Ou, Xudong Wang, Vassilis L. Syrmos (Dept. of Elec. Eng., Univ. of Hawaii at Manoa, Honolulu, HI 96822), and John S. AllenIII (Univ. of Hawaii at Manoa, Honolulu, HI 96822)

The backscattering of tone bursts by spherical shells immersed in water has been investigated by several researchers. For a very thin shell, the backscattering specular echo is followed by enhanced echoes. The mechanism of these enhanced echoes has been attributed to a subsonic surface guided wave from recent ray synthesis analysis [P. L. Marston and N. H. Sun, J. Acoust. Soc. Am. **96**, 1862–1874 (1992)]. In this study, time-frequency analysis is performed on the scattering signal. A discrete Wigner distribution function is employed to express the information content in the scattered sound in relation to the size and material of the shell [G. C. Gaunaurd and H. C. Strifors, IEEE **84**, 1231–1248 (1996)]. The simulation results support that the time delay between the echoes is determined by the outer radius of the shell as well as the shell material (with or without absorption), or the Rayleigh velocity of the shell material. Furthermore, the backscattered enhancement occurs at different ranges in frequency domain due to various shell materials, which provide a potential method to determine the shell material properties. The relationship of this work to target discrimination methods for sonar applications is highlighted. [Work supported by ONR.]

5pUW4. Numerical and experimental investigations of transformations of near-field to far-field scattering measurements. John A. Fawcett, Juri Sildam, and Mark V. Trevorrow (DRDC Atlantic, P.O. Box 1012, Dartmouth, NS, Canada, B2Y 3Z7, john.fawcett@drdc-rddc.gc.ca)

Due to the size of a target and measurement constraints, the measurements of monostatic acoustic scattering are often made in the near field of the target. For many applications, it is an estimate of the far-field target scattering strength, which is desired. In this presentation some model-based inversion techniques, which can be used to predict far-field monostatic target strengths as a function of aspect angle, are derived. In particular, a set of near-field measurements is used in an inversion scheme to compute coefficients for either a linear array of point scatterers or for a generalized Kirchhoff model of the target. The resulting model is then used to predict the far field scattering amplitudes. Simulated and experimental data are used to illustrate the accuracy of the proposed methods.

5pUW5. Scattering in swell-contaminated seas: A semiempirical approach. Roger C. Gauss and Joseph M. Fialkowski (Naval Res. Lab., Code 7144, Washington, DC 20375-5350)

Acoustic scattering from the undersea air-sea interface is driven by its surface roughness. In modeling this scattering, 2-D spectral models such as the Pierson-Moskowitz model are used to represent the roughness contribution. However, these spectral models typically assume fully developed wind-driven seas. In practice, seas are not always fully developed and swell is often present. In general, scattering depends on the full roughness spectrum and so can be sensitive to its peak behavior. This paper describes low-to-midfrequency (< 10 kHz) bistatic scattering strength and coherent surface-loss models that are acoustically constrained by backscatter data and oceanographically constrained by coincidentally measured wave spectra. To match the latter, a semiempirical surface-wave spectral model is developed whose key parameters (strength, exponent, and peak) are expressed solely in terms of significant wave height and wind speed. It is shown that including the non-wind-wave contributions is essential to accurately modeling interface scattering in general at low frequencies, and forward scattering at all frequencies. [Work supported by ONR and PEO C4I & Space (PMW-180).]

5pUW6. Modeling reverberation time series for shallow water clutter environments. Kevin D. LePage (Naval Res. Lab., Code 7144, 4555 Overlook Ave. SW, Washington, DC 20375), Charles W. Holland (The Penn State Univ., State College, PA 16801), and Peter Neumann (Planning Systems Inc., Reston, VA 20191)

The phenomenon of clutter in shallow water environments can be modeled from a variety of viewpoints. One approach we have taken is to model reverberation time series for heterogeneous environments with a variety of scattering mechanisms to see if some of the characteristics of resulting estimates model the characteristics of experimentally observed clutter. Here we show reverberation time series estimates for the Straits of Sicily that seem to capture some of the clutter behavior observed during the Boundary 04 experiment conducted in conjunction with the NATO Undersea Research Centre. Of particular interest is the appearance of coherent time-frequency striation patterns in both the modeled and observed reverberation, with compact time supported but broadband clutter features superimposed by the presence of environmental discontinuities. 5pUW7. Mechanism for sea bottom reverberation in long range sonar in a range-dependent continental shelf environment. Ameya Galinde and Purnima Ratilal (Northeastern Univ., 409 Dana Res. Ctr., Boston, MA 02115)

The statistically stationary background reverberation in long-range sonar data acquired in the New Jersey Continental shelf during the ONR 2003 Main Acoustic Clutter Experiment is mainly due to seafloor scattering. We compare three mechanisms or models for scattering from the sea bottom in a range-dependent waveguide with the experimental data. They are the Rayleigh-Born volume scattering model, a rough surface scattering model, and an empirical Lambertian model. Each of these models has a different decay rate as a function of range and different frequency dependence. These models are compared to the measured background reverberation as a function of range from the sonar system and at various frequency bandwidths from 300 to 1500 Hz to determine which mechanism or model for seafloor scattering best describes the data.

5pUW8. "Through-the-sensor" monostatic bottom loss and bottom backscatter measurements at mid-frequencies. Martin Barlett and Walter Brown (Appl. Res. Labs., Univ. of Texas, P.O. Box 8029, Austin, TX 78713, barlett@arlut.utexas.edu)

Determinations of bottom backscatter and bottom loss parameters for the seafloor at mid-frequencies are of interest for understanding the performance of modern tactical sonar systems. A variety of techniques exist for measuring bottom scattering properties, but many of these methods require significant resources and/or time to perform. Over the last several years, a through-the-sensor approach for making bottom backscatter measurements using standard tactical sonars has been developed. Recently, these techniques have been extended to monostatic bottom loss estimates. In this presentation, a description of the overall approach to these measurements, advantages and limitations of these techniques, and examples of through-the-sensor bottom backscatter and bottom loss measurements made from data collected through a tactical sonar system will be given.

5pUW9. Validating physics-based clutter from seafloor roughness and biologic scattering. Juan Arvelo, Charles Monjo, Bruce Newhall (Appl. Phys. Lab., Johns Hopkins Univ., 11100 Johns Hopkins Rd., Laurel, MD 20723-6099), Adam Frankel (Marine Acoust. Inc., Annapolis, MD 21401), Richard Love (Fort Worth, TX 76179), and William T. Ellison (Marine Acoust. Inc., Litchfield, CT 06759)

Two physics-based clutter models were developed for comparison and to study the merits and limitations of both approaches. The stochastic approach [Newhall and Arvelo, J. Acoust. Soc. Am. **118**, 2041 (2005)] makes use of perturbation theory, to relate the mean seafloor scattering strength to the mean surface wavenumber spectrum, and the extrapolation of this spectrum to the Bragg wavenumber to generate the clutter distribution from the seafloor roughness. The semi-deterministic approach [Monjo and Arvelo, J. Acoust. Soc. Am. **118**, 2041 (2005)] is based on 2-D power-law fractal realizations of the ocean floor, coherent modal addition, and the microscale bathymetric slopes. Biologic scattering was later included where spatial distribution and nonstationarity of schools of fish and individual marine mammals are realistically represented [Frankel *et al.* J. Acoust. Soc. Am. **119**, 3437 (2006)] through individual-based modeling of their movements, school size, and target strengths. Clutter distributions from both approaches are compared against each other, for selected test cases, and against clutter measurements. [This effort was funded by the Maritime Sensing Program of the Office of Naval Research (ONR Code MS 321).]

5pUW10. Ocean bottom scattering: characterization with chirp sonar. Jorge Quijano, Lisa Zurk (Portland State Univ., P.O. Box 751-ECE, Portland, OR 97207, zurkl@cecs.pdx.edu), Altan Turgut (Naval Res. Lab/DC, Washington, DC 20375), and D. J. Tang (Appl. Phys. Lab., Seattle, WA 98105)

Shallow water acoustic propagation in the mid-frequency range (~ 1–10 kHz) is strongly affected by scattering from the ocean bottom. In general, this scattering is a combination of rough surface scattering from the water-sediment interface and sediment layers, as well as volume scattering from embedded inhomogeneities. It is necessary to develop an understanding of the spatial and temporal characteristics of the acoustic field to optimize Navy sonar performance. Although there has been a growth of research activity in this area, the validity of different modeling approaches still remains an open research question. One promising tool for bottom sediment characterization is a chirp sonar. These sonars can produce high-quality data in which time of arrival is often associated with location of subbottom sediment layers to produce sediment profiles. However, features of the acoustic scattering such as multiple scattering or particle resonances can have complicated signatures that are not straightforward to

interpret. In this work, the effect of these signatures on the chirp sonar data is studied through application of a numerical FDTD model applied to a variety of ocean bottom geometries. Results obtained from the chirp sonar system are presented and compared with ocean bottom scattering models.

5pUW11. Using the ultrasound standing wave in vibroacoustography for surface roughness imaging applications. Farid G. Mitri and Mostafa Fatemi (Dept. of Physiol., and Biomed. Eng., Ultrasound Res. Lab., Mayo Clinic College of Medicine, 200 First St. SW, Rochester MN 55905)

The surface roughness (of about 20 microns) of an acrylic block immersed in water was measured using the acoustic emission pressure field (in the kHz range) induced by the dynamic radiation force of ultrasound (2 MHz). The dynamic radiation force is produced by mixing two beams of different frequencies to excite the probed object. The acoustic emission is a result of object vibration at the difference frequency of the incident ultrasound beams and is detected by a low-frequency hydrophone placed nearby the block. Due to the presence of the block, an ultrasound standing wave field is generated as a result of multiple reflections between the transducer and the block's surface. The acoustic emission by the block's surface varies according to its relative position to the transducer. This variation is used to form an image of the surface roughness at two difference frequencies $\Delta_f = 9.9$ and 22.4 kHz. To have a one-to-one map between the surface roughness and the image, the surface variation has to lie within the distance from a maximum to its nearest minimum in the standing wave. Images obtained here demonstrate that vibroacoustography may be used as a powerful tool for the nondestructive inspection and imaging of surface roughness [Mitri *et al.*, Appl. Phys. Lett. **88**, 234105 (2006)]. [Work supported by NIH.]

5pUW12. Tower-based breaking wave noise measurements. Steven L. Means and Jeffrey A. Schindall (Naval Res. Lab., Code 7120, 4555 Overlook Ave. SW, Washington, DC 20375, means@wave.nrl.navy.mil)

A tower-based sea surface noise experiment began collecting data January 2006 in the shallow waters (25 m) approximately 75 km off the coast of Savannah, Georgia. A 32-phone, three nested-aperture, vertical hydrophone array was deployed nominally 100 m from a Navy tower that stands 50 m above the water surface. A high-resolution video camera was mounted near the top of the tower along with a dual-polarized marine-band radar to record the location, size, and lifetime of the surface expressions of the breaking waves above of the array. The array is cabled back to the tower for power and signal collection. The tower is microwave-linked to shore for internet-based control and data retrieval. To date, measurements have been made in wind speeds ranging from 5–21 m/s and wave heights of 1–3.4 m over a 6-month period. Empirical relationships between the time-frequency structures of the generated noise, obtained on the endfire beam of the array, and the size of the surface expressions of the breaking waves will be given for a range of environmental conditions. [Work supported by ONR base funding at NRL.]

5pUW13. Numerical simulation of noise generated by wave breaking in a tank. Xuemei Chen, Steven L. Means, Bill G. Szymczak (Acoust. Div., Naval Res. Lab., 4555 Overlook Ave. SW, Washington, DC 20375, xchen@wave.nrl.navy.mil), and Joel C. W. Rogers (Brooklyn Polytechnic Univ., Brooklyn, NY)

A coupled hydro-acoustic source model in relating the physical parameters of wave breaking to the source quantities has been developed. The physical processes of wave formation and breaking are modeled using a generalized hydrodynamics formulation with the initial wave profile cal-

culated by boundary integral method. Hydrodynamic parameters, such as pressure variations and air cavity shapes, etc., will be provided through the simulation. In the acoustic simulation, an algorithm has been developed in handling wave propagation in irregular regions, such as the bubbly liquid generated by wave breaking. To validate the modeling, an experiment on wave formation, propagation, and breaking is carried out in a wave tank. The waves are generated mechanically with a computer controlled vertically oscillating wedge. Favorable agreement is found upon comparing prediction and measurement. [Work supported by ONR.]

5pUW14. Long-term trends in ocean noise. D. Benjamin Reeder, Rommel Pucan, and Curtis A. Collins (Naval Postgraduate School, 833 Dyer Rd., SP-222 Bldg. 232, Monterey, CA 93943)

The effect of ocean noise, particularly from anthropogenic sources such as Navy sonar systems, on marine mammal hearing, behavior, and reproduction is of great concern. However, relatively few studies exist to make a definitive conclusion regarding rising ambient noise levels, due largely to the dearth of information over sufficiently long time periods for a sufficient number of geographical locations. A few studies have estimated that ocean noise is rising at a rate of approximately 3–5 dB per decade at some frequencies in some locations. This study is based upon ambient noise measurements from U.S. Navy sonobuoys deployed by operational units between 1993 and 2004. Data and analysis are presented for three areas of the ocean—the Northwestern Atlantic Ocean, the Greenland-Iceland-United Kingdom (GIUK) gap, and the Mediterranean Sea. Analysis of this data demonstrates a less significant increase, and in some cases, a decrease, in ocean noise for these three ocean areas at frequencies between 50 and 2000 Hz. Ocean noise levels in this study are comparable to measured ocean noise levels reported in the literature during the 1960's.

5pUW15. Vessel noise measurements underwater in the Haro Strait, WA. Scott Veirs (Beam Reach Marine Sci. and Sustainability School, 6537 16th St. NE, Seattle, WA 98115, scott@beamreach.org) and Val Veirs (Colorado College, Colorado Springs, CO 80903)

In the recent listing of southern resident orcas as endangered under the Endangered Species Act, disturbance by vessels is cited as a risk factor for the population and a factor in the designation of critical habitat. To help determine whether vessel noise underwater is disturbing orcas as they use sound to navigate, forage, or communicate, the source level of common large vessels transiting Haro Strait was measured. Since large vessels are the dominant source of underwater sound for the southern residents (based on water volume ensonified and duration of exposure at a given receive level), it is convenient that all commercial vessels longer than 65 ft are now required to broadcast their location, speed, and other data in real-time. The automatic identification system (AIS) broadcasts data every 2 s via VHF that can be received and decoded with specialized radio receivers that are now coming on the market. AIS was used to log range, speed, and relative bearing while simultaneous recordings were made of the received sound pressure levels using calibrated hydrophones and photographs were taken. From these observations, the broadband and spectrum source level of each vessel was calculated as a function of bearing relative to vessel axis.
