

**Note**

**Isobaric heat capacities of five dimethylsiloxane oligomers at 303.15 and 323.85 K from sound velocity and pVT data**

IAN A. McLURE

*Department of Chemistry, The University, Sheffield S3 7HF (England)*

(Received 30 November 1976)

The isothermal compressibilities  $\beta_T$  derived from recent measurements in this laboratory of the specific volumes  $V$  and isochoric thermal expansion coefficients  $\gamma_v$  of the first five members of the dimethylsiloxane (DMSO) oligomeric series differ from values calculated by Weissler<sup>1</sup> from his velocity of sound data using the equation

$$\beta_T = (V/W^2) + (TV\alpha_p^2/c_p) \quad (1)$$

where  $W$  is the velocity of sound,  $T$  is temperature, and  $\alpha_p$  and  $c_p$  are the isobaric thermal expansivity and specific isochoric heat capacity, respectively. Subsequent study has revealed that the discrepancy arises, at least in the case of the first member of the series — hexamethyldisiloxane, from errors in the  $c_p$  and  $\alpha_p$  data used by Weissler. A comparison showing the quantities involved at 303.15 K is given in Table I where  $(V/W^2)$  is shown more conventionally as the isentropic compressibility  $\beta_s$ . Weissler quoted his  $c_p$  results for no substances other than hexamethyldisiloxane and so the analysis given in Table I cannot be repeated for the other four DMSO oligomers discussed here. However, it seems likely that similar weaknesses beset all his  $\beta_T$  values. Nevertheless, his  $W$  values appear accurate and, together with more recent DMSO  $pVT$  data, they permit the calculation of  $c_p$  at the two

TABLE I

COMPARISON OF THERMODYNAMIC DATA ON HEXAMETHYLDISILOXANE AT 303.15 K

	Weissler	Recent data
$c_p$ (J K <sup>-1</sup> g <sup>-1</sup> )	1.88	1.930 <sup>a</sup>
$v$ (cm <sup>3</sup> g <sup>-1</sup> )	1.3271	1.3212 <sup>b</sup>
$\alpha_p$ (mK <sup>-1</sup> )	1.60	1.407 <sup>b</sup>
$\beta_s$ (GPa <sup>-1</sup> )	1.741	1.73 <sup>c</sup>
$\beta_T$ (GPa <sup>-1</sup> )	2.287	2.134 <sup>b</sup>

<sup>a</sup> According to D. W. Scott et al.<sup>2</sup>. <sup>b</sup> From ref. 3. <sup>c</sup> Obtained from Weissler's  $W$  and  $V$  from ref. 3.

temperatures — 303.15 and 323.85 K — at which  $W$  has been measured. Although  $c_p$  is much better obtained calorimetrically, no such data appear to exist and it is to fill this gap that the present report is made.

Table 2 contains the results and some of the intermediate quantities. The different DMSO oligomers are denominated in column 1 by Wilcock's notation whereby M<sub>2</sub>D<sub>*x*-2</sub> is the open-chain DMSO oligomer containing *x* silicon atom<sup>6</sup>; *x* can be regarded as a measure of the chain-length of the oligomer. Columns 2 and 4 contain the  $\beta_s$  and  $\beta_T$  calculated from the  $pVT$  data from this laboratory ( $\beta_T = \alpha_p/\gamma_v$ ). All of the coefficients refer effectively to zero pressure. Columns 3 and 5 contain the analogous quantities reported by Weessler; his measurements of  $c_p$  were carried out at 303.15 K only and thus he records only  $\beta_T(303.15\text{ K})$ . Column 6 contains  $c_p$  calculated via eqn (1). Finally column 7 contains molar isobaric heat capacities  $C_p$  calculated using molar masses based on H = 1.008<sub>0</sub>, C = 12.011, O = 15.999<sub>4</sub>, and Si = 28.08<sub>6</sub>. It is difficult to assess the effect of the accumulated errors of all the quantities appearing in the expression for  $c_p$ , but taking the uncertainty in the accuracy of  $\beta_T$  and  $\beta_s$ , the least well determined of the set, as around  $\pm 1-2\%$  it seems safe to take the error in  $c_p$  to be around  $\pm 5\%$ . The difference ( $\beta_T - \beta_s$ ) diminishes with chain-length and thus the inaccuracy in  $c_p$  increases with chain-length. The materials used in the  $pVT$  studies were all pure single substances but in Weessler's work M<sub>2</sub>D<sub>4</sub> was a viscosity-characterised cut containing M<sub>2</sub>D<sub>4</sub> as a principal component only. Although this does not noticeably affect the trend of  $W$  or  $\beta_s$  with chain-length, it should be borne in mind as representing the limit of the calculation of  $c_p$  from Weessler's data.

From the results in Table 2 a comparison can be made with the  $c_p(M_2)$  studies at the Bureau of Standards<sup>2</sup>; the present values at 303.15 and 323.85 K are higher by

2.4 and 4.8%, respectively (Weissler's value at 303.15 K is 2.6% lower than the Bartlesville value). Despite this discrepancy, it is believed that the present results are no more than 5% inaccurate with one exception to be discussed now.

The chain-length dependence of oligomer heat capacity is better discussed in terms of the specific heat capacities  $c_p$ , rather than of the molar heat capacities  $C_p$ , in which the molar mass plays a distracting role. Figure 1 shows  $c_p$  as a function of chain-length  $x$ ; the error bars reflect the  $\pm 5\%$  inaccuracy limit given earlier. It is clear that the  $c_p$ - $x$  curve is smooth save for  $c_p(M_2D_3)$ ; the two values shown fall below the best line through the others, this is believed to be due to a slightly low  $\gamma_v(M_2D_3)$  the effect of which becomes more serious at high  $x$  as already noted. Interestingly, the limiting value quoted by Weissler for material of molar mass 4000 of  $c_p(303.15\text{ K}) = 1.63\text{ J K}^{-1}\text{ g}^{-1}$  is close to the asymptotic value to which our values are tending. The drop in  $c_p$  with  $x$  is expected for an oligomeric series.

A plausible case can be made out for taking tetramethylsilane as the first member of the DMSO series. Thus on extrapolating the  $c_p$ - $x$  curve back to  $x = 1$  one might expect to obtain the value for  $C_p$  (tetramethylsilane). The value obtained by a 13 K extrapolation of the results of Aston et al.<sup>5</sup> is approximately  $2.4\text{ J K}^{-1}\text{ g}^{-1}$  and it can be seen on the figure that this value is not inconsistent with the trend of the  $c_p(x)$  function.

Fig. 1. Specific isobaric heat capacities for dimethylsiloxane oligomers. Ordinate,  $c_p$  ( $\text{J K}^{-1}\text{ g}^{-1}$ ); abscissa, DMSO chain-length  $x$ .

## ACKNOWLEDGEMENT

The author thanks Dr. A. J. Pretty for carrying out some of the calculations discussed here.
