### ABSTRACT

The phase equilibria in the  $\text{Cr}_2\text{V}_4\text{O}_{13}$ – $\text{CrVMoO}_7$  system at temperatures up to  $1000^\circ\text{C}$  over the entire component concentration range have been studied by DTA and X-ray powder diffraction. It has been found that there is a solid solution of  $\text{MoO}_3$  in  $\text{Cr}_2\text{V}_4\text{O}_{13}$  in this system. The  $\text{Mo}^{6+}$  ions are incorporated in the  $\text{Cr}_2\text{V}_4\text{O}_{13}$  lattice, replacing  $\text{V}^{5+}$  ions, and this substitution gives rise to excessive positive charges the compensation of which leads to the reduction of  $\text{Cr}^{3+}$  to  $\text{Cr}^{2+}$ . All the results are shown in the form of a phase diagram.

### INTRODUCTION

Studies on the  $\text{Cr}_2\text{O}_3$ – $\text{V}_2\text{O}_5$ – $\text{MoO}_3$  system and studies on the phase equilibria in the  $\text{CrVO}_4$ – $\text{MoO}_3$  system [1–3] have shown that the system components react with each other in the solid state to form an unknown phase with the formula  $\text{CrVMoO}_7$ . The properties of this phase have not so far been studied in every respect. It is known, however, that the phase melts incongruently at  $820 \pm 5^\circ\text{C}$  with formation of solid  $\text{Cr}_2\text{O}_3$ . Its X-ray pattern in the  $2\theta$  range  $12$ – $65^\circ$  (Co  $K\alpha$ ) and its density are also known [3].

Investigation of another two-component system, i.e.  $\text{Cr}_2\text{O}_3$ – $\text{V}_2\text{O}_5$  has demonstrated that, as well as  $\text{CrVO}_4$ , there is another phase,  $\text{Cr}_2\text{V}_4\text{O}_{13}$ , whose existence has not as yet been unequivocally determined [4–6]. It has been found that  $\text{Cr}_2\text{V}_4\text{O}_{13}$  is stable up to  $640^\circ\text{C}$  when it starts to decompose in the solid state at a relatively slow rate yielding  $\text{CrVO}_4$  and  $\text{V}_2\text{O}_5$ . The density of  $\text{Cr}_2\text{V}_4\text{O}_{13}$  has been determined and its X-ray pattern is known [6].

In another investigation it was determined that  $\text{MoO}_3$  is incorporated into the  $\text{Cr}_2\text{V}_4\text{O}_{13}$  lattice to form a solid solution [7]. It has been established that the mechanism of formation of the solution consists of incorporating the  $\text{Mo}^{6+}$  ions in place of  $\text{V}^{5+}$  in the  $\text{Cr}_2\text{V}_4\text{O}_{13}$  lattice, compensation of the excessive positive charges probably taking place by the reduction of an equivalent number of  $\text{Cr}^{3+}$  ions to  $\text{Cr}^{2+}$  [8]. In the three-component system,  $\text{Cr}_2\text{O}_3$ – $\text{V}_2\text{O}_5$ – $\text{MoO}_3$ , besides  $\text{CrVMoO}_7$ , there are also phases of the

$\text{Cr}_{2-x}^{3+}\text{Cr}_x^{2+}\text{V}_{4-x}\text{Mo}_x\text{O}_{13}$ -type, which are formed by the three oxides, with  $0.500 < x_{\text{max}} < 0.581$ .

As  $\text{CrVMoO}_7$  and  $\text{Cr}_2\text{V}_4\text{O}_{13}$  are recently discovered phases, it seemed expedient to establish how the phase equilibria are formed in the system composed of the components of interest. Until now, we have only determined what kinds of phase equilibria are established in the solid state [9]. The purpose of the studies presented here was to produce a complete diagram of the phase equilibria being established up to  $1000^\circ\text{C}$  in the system of interest.

## EXPERIMENTAL

Analytically pure  $\text{V}_2\text{O}_5$ , obtained commercially, was used in the experiments. The  $\text{MoO}_3$  and  $\text{Cr}_2\text{O}_3$  used were obtained by the thermal decomposition of ammonium molybdate and ammonium dichromate, respectively. The decomposition of  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$  was carried out at  $120\text{--}550^\circ\text{C}$  for over 10 h; the decomposition of  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$  was first carried out at  $100^\circ\text{C}$ , and then at  $150^\circ\text{C}$ , the decomposition product being also roasted at  $1000^\circ\text{C}$  for 72 h. X-ray powder diffraction analysis of the preparations obtained by this method showed  $\text{MoO}_3$  and  $\text{Cr}_2\text{O}_3$ , respectively, only.

Appropriate weights of the oxides were homogenised by grinding, pastilling and roasting in air, as follows:  $400^\circ\text{C} \rightarrow 500^\circ\text{C}$  (24 h)  $\rightarrow 600^\circ\text{C}$  (24 h)  $\rightarrow 620^\circ\text{C}$  (9 h)  $\rightarrow 635^\circ\text{C}$  (9 h  $\times$  3). After each heating cycle, the preparations were slowly cooled to ambient temperature, ground, examined by DTA and X-ray powder diffraction, then repastilled and reheated until the samples were obtained in the equilibrium state. The conditions necessary to attain the equilibrium state were established in separate experiments carried out during the synthesis of the preparations, verifying the model of the solid solution of  $\text{MoO}_3$  in  $\text{Cr}_2\text{V}_4\text{O}_{13}$  [7]. The attainment of equilibrium was verified by X-ray powder diffraction of selected samples following two successive roasting cycles. Two identical results indicated that equilibrium had been achieved.

The phase composition of the preparations was ascertained by X-ray powder diffraction (DRON-3, Co  $K\alpha$ ) and from ASTM data [10], and from publications [3,6].

DTA studies were carried out on a F. Paulik–J. Paulik–L. Erdey derivatograph in quartz crucibles, in air at  $20\text{--}1000^\circ\text{C}$  at a heating rate of  $10^\circ\text{C min}^{-1}$ . The weight of the samples was 1000 mg in each case. When the phase diagram was constructed, the solidus lines were determined on the basis of the temperatures at which the effect begins to be recorded on the DTA curves, whereas the liquidus lines were marked, where possible, based on the temperatures at which a suitable effect starts, or else, in other cases, on the

temperatures of the apex of these effects. The accuracy of the temperature reading, determined by repetitions, was found to be  $\pm 5^\circ\text{C}$ .

## RESULTS AND DISCUSSION

Table 1 shows the compositions of the initial oxide mixtures and the compositions in terms of the components of the system under consideration, as well as the results from X-ray powder diffraction of the products obtained from the final roasting cycle. X-ray powder diffraction showed that in the initial mixtures with  $\text{MoO}_3$  up to 15.38%, the equilibrium products were mono-phase containing a solid solution of  $\text{MoO}_3$  in  $\text{Cr}_2\text{V}_4\text{O}_{13}$  only. The diffraction patterns showed that, apart from the absence of  $\text{MoO}_3$ , the reflection set characterizing the solid solution was shifted, from the position of lines related to the matrix, towards smaller angles, corresponding, therefore, to higher interplanar distances. This fact is also proved by the existence of the solid solution  $\text{MoO}_3$  in  $\text{Cr}_2\text{V}_4\text{O}_{13}$ .

TABLE 1

The composition of starting mixtures and the X-ray powder diffraction results of the preparations at equilibrium

Composition of samples			Phase composition at equilibrium	
Mol% oxides in starting mixtures		MoO <sub>3</sub>	In terms of components of the system, mol% CrVMoO <sub>7</sub>	at equilibrium
Cr <sub>2</sub> O <sub>3</sub>	V <sub>2</sub> O <sub>5</sub>

27.78	38.89	33.33	75.00	CrVMoO <sub>7</sub> , Cr <sub>2</sub> V <sub>4</sub> O <sub>13</sub> (s.s.)
27.27	36.36	36.36	80.00	CrVMoO <sub>7</sub> , Cr <sub>2</sub> V <sub>4</sub> O <sub>13</sub> (s.s.)
26.74	33.72	39.54	85.00	CrVMoO <sub>7</sub> , Cr <sub>2</sub> V <sub>4</sub> O <sub>13</sub> (s.s.)
26.19	30.95	42.86	90.00	CrVMoO <sub>7</sub> , Cr <sub>2</sub> V <sub>4</sub> O <sub>13</sub> (s.s.) (v. little)
25.61	28.05	46.34	95.00	CrVMoO <sub>7</sub> , Cr <sub>2</sub> V <sub>4</sub> O <sub>13</sub> (s.s.) (traces)

At over 15.38 mol% MoO<sub>3</sub> in the initial mixtures, as well as Cr<sub>2</sub>V<sub>4</sub>O<sub>13</sub>(s.s.), the equilibrium preparations contained another phase in the CrVMoO<sub>7</sub> system.

In order to determine whether the solubility of MoC<sub>3</sub> in Cr<sub>2</sub>V<sub>4</sub>O<sub>13</sub> increases at higher temperatures, i.e. close to the temperatures of the solidus lines, equilibrium samples containing 15.38 mol% and 17.65 mol% MoO<sub>3</sub> in the initial mixtures were, in addition, heated for 3 h at 590 °C and then rapidly cooled to ambient temperature. X-ray powder diffraction of the preparations obtained in this way showed that their compositions are not essentially different from those of the slowly cooled samples at equilibrium. However, the intensity of the diffraction lines characterising Cr<sub>2</sub>V<sub>4</sub>O<sub>13</sub>(ss) was increased, whereas the intensity of the reflections characterising the CrVMoO<sub>7</sub> phase was decreased. This indicates that the solubility of MoO<sub>3</sub> in Cr<sub>2</sub>V<sub>4</sub>O<sub>13</sub> is slightly higher at 590 °C than at ambient temperature and does not exceed 17.65 mol% in the initial mixture.

Three endothermic effects were recorded in the DTA curves of the preparations at equilibrium. With monophasic preparations, i.e. containing up to 15.38 mol% MoO<sub>3</sub> in the initial mixtures, the effects recorded were analogous with those observed in the DTA curve of pure Cr<sub>2</sub>V<sub>4</sub>O<sub>13</sub>, the matrix solution (Fig. 1). It has been found from published investigations [6], that the Cr<sub>2</sub>V<sub>4</sub>O<sub>13</sub> phase is stable only up to 640 °C (below the melting point) at which temperatures it starts to decompose in the solid state

The decomposition products form a eutectic mixture melting as low as at 650 °C [6], although the initial velocity of the decomposition is not high and the Cr<sub>2</sub>V<sub>4</sub>O<sub>13</sub> which has not decomposed melts incongruently at 740 °C. This

Fig. 1. The DTA curve of Cr<sub>2</sub>V<sub>4</sub>O<sub>13</sub>(s.s.) containing 11.11 mol% MoO<sub>3</sub> in the initial mixture.

is confirmed by the second thermal effect recorded in the DTA curve (Fig. 1).

The third thermal effect is related to the melting of  $\text{CrVO}_4$ , the solid product of reaction (2).

With  $\text{Cr}_2\text{V}_4\text{O}_{13}(\text{s.s.})$ , as well as  $\text{CrVO}_4(\text{s})$  and  $\text{V}_2\text{O}_5(\text{s})$ , free  $\text{MoO}_3$  appears in the decomposition products. However, this molybdenum(VI) oxide can also form a solid solution with  $\text{V}_2\text{O}_5$  by being incorporated into its crystal lattice [11,12]. The solubility limit of  $\text{MoO}_3$  in  $\text{V}_2\text{O}_5$  is considerable; according to Bielański and Najbar, it is 30 mol% [11]. Hence, the decomposition of  $\text{Cr}_2\text{V}_4\text{O}_{13}(\text{s.s.})$  seems to involve the formation of another solid solution, i.e. of  $\text{MoO}_3$  in  $\text{V}_2\text{O}_5$ , as well as  $\text{CrVO}_4$ . However, this could not be confirmed experimentally due to the very small temperature range in which the areas comprising  $\text{V}_2\text{O}_5(\text{s.s.})$ , one of the stable equilibrium phases, occur.

In preparations whose X-ray powder diffraction pattern has shown that at equilibrium up to  $640^\circ\text{C}$  two phases remain, i.e.  $\text{Cr}_2\text{V}_4\text{O}_{13}(\text{s.s.})$  and  $\text{CrVMoO}_7$ ,  $\text{Cr}_2\text{V}_4\text{O}_{13}(\text{s.s.})$  is responsible for the first two effects; on the other hand, the third unsymmetrical effect is related to the incongruent melting of  $\text{CrVMoO}_7$  [3]

Figure 2 shows a phase diagram of the  $\text{Cr}_2\text{V}_4\text{O}_{13}$ – $\text{CrVMoO}_7$  system. The ranges of coexistence of solid phases with liquid have been determined on the basis of the thermal effects recorded on the DTA curves, whereas the phases remaining at equilibrium with liquid were established experimentally: samples chosen from particular diagram areas were, in addition, heated for 3 h at  $600^\circ\text{C}$ ,  $700^\circ\text{C}$ ,  $720^\circ\text{C}$ ,  $750^\circ\text{C}$ ,  $800^\circ\text{C}$ ,  $850^\circ\text{C}$ ,  $900^\circ\text{C}$  and  $950^\circ\text{C}$ , then cooled rapidly to ambient temperature and analysed by X-ray powder diffraction. The compositions of samples subjected to such an examination are marked on the diagram (Fig. 2).

It follows from the phase diagram that  $\text{Cr}_2\text{V}_4\text{O}_{13}$ – $\text{CrVMoO}_7$  is a real two-component system over the entire component concentration range until the decomposition temperature of  $\text{Cr}_2\text{V}_4\text{O}_{13}(\text{s.s.})$ , i.e. up to  $640^\circ\text{C}$ . The range of existence of solid solution at ambient temperature is at least 15.38 mol%  $\text{MoO}_3$  in the initial mixture. Above  $640^\circ\text{C}$ ,  $\text{Cr}_2\text{V}_4\text{O}_{13}(\text{s.s.})$  ceases to be a thermodynamically stable phase and, at equilibrium in the solid state in a very small temperature range, either the products of its decomposition ( $\text{CrVO}_4(\text{s})$  and  $\text{V}_2\text{O}_5(\text{s.s.})$ ) or three solid phases ( $\text{CrVO}_4(\text{s})$ ,  $\text{V}_2\text{O}_5(\text{s.s.})$  and  $\text{CrVMoO}_7(\text{s})$ ) remain. Both  $\text{CrVO}_4$  and  $\text{CrVMoO}_7$  melt incongruently and  $\text{Cr}_2\text{O}_3$ , being a solid product of both reactions, finally remains at equilibrium with the liquid (Fig. 2).

The experimental results could not always precisely fix the existence range for all areas, because of the small temperature ranges within which they are

Fig. 2. Phase diagram of the  $\text{Cr}_2\text{V}_4\text{O}_{13}$ - $\text{CrVMoO}_7$  system.

confined. Nevertheless, the position of neighbouring areas and the results of our other investigations [3,6,13] enable the extent of these areas to be deduced. The curves outlining these areas are marked in the diagram with dotted lines.
