Keywords: Adonitol Phase transition Adiabatic calorimetry Oxygen-bomb combustion calorimetry DSC TGA

1. Introduction

Considerable efforts are being expended lately to develop new additives for food and drug from natural polyols because of safe and environmental concerns relating to synthetic industrial additives. Xylitol, sorbitol, erythritol and adonitol are significant natural polyols for food and pharmaceutical industry [1–3]. As natural extracts, they have many advantages such as low cost, no toxic, no erosion and no environmental pollution. Therefore, they are increasingly used to provide sweetness in replace of sugars to various products due to low energy content. Moreover, they reduce the development of dental caries and they do not require insulin or glucose in their metabolism so they are suitable for prevention and treatment of adiposis and diabetics [4–7].

The state and phase transitions of chemicals are very important in chemical engineering and pharmaceutical industry, because they reflect molecular mobility and physicochemical properties. These characteristics have direct effect on the formation of structure, structural changes, time-dependent crystallization and product shelf life [8–10]. It is now recognized that the amorphous solid state offers very interesting possibilities in the control of bioavailability [10–12]. Therefore, heat capacities, phase change data and thermal

ABSTRACT

Adonitol was investigated by adiabatic calorimetry (AC), differential scanning calorimetry (DSC), thermogravity analysis (TGA) and oxygen-bomb combustion calorimetry. The heat capacity was precisely measured in the temperature range from 78 to 400 K by means of a small sample automated adiabatic calorimeter. The melting temperature, the molar enthalpy and entropy of this transition were determined to be $T = 369.08 \pm 0.45$ K, 36.42 ± 0.18 kJ mol⁻¹ and 98.68 ± 0.49 JK⁻¹ mol⁻¹ respectively from the experimental C_p -T curve. The thermodynamic functions [$H_T^0 - H_{298.15}^0$] and [$S_T^0 - S_{298.15}^0$], were derived from the heat capacity data with an interval of 5 K. The standard molar enthalpy of combustion and formation of the compound have been determined to be $\Delta_c H_m^0$ (C_5 H₁₂O₅, cr) = (-2562.4 ± 1.3) kJ mol⁻¹ and $\Delta_f H_m^0$ (C_5 H₁₂O₅, cr) = (-1120.1 ± 1.5) kJ mol⁻¹ respectively by means of a precision oxygen-bomb combustion calorimeter at T = 298.15 K. The thermostability of the compound was further studied by DSC and TGA measurements.

decomposing temperature that characterize the basic thermophysical properties are an important requirement for safe storage and use of these new chemicals. However, the thermodynamic data especially the heat capacities of adonitol have not been published in literature as far as we know.

As a continuation of our earlier work in obtaining the low-temperature heat capacity and thermodynamic data of xylitol and sorbitol [13,14], in the present study, the heat capacity, phase change behavior and thermostability of adonitol were investigated in detail by adiabatic calorimetry (AC), differential scanning calorimetry (DSC) and thermogravity analysis (TGA) methods. The thermodynamic properties including molar enthalpies and entropies of phase transition were determined based on the heat capacity measurements. The thermodynamic functions, [$H_T^0 - H_{298,15}^0$] and [$S_T^0 - S_{298,15}^0$], were calculated from heat capacity data in the temperature range of 78–400 K. The standard molar enthalpy of combustion and the standard molar enthalpy of formation of the compound which reported in literature [15] have been determined by means of a precision oxygen-bomb combustion calorimeter again at *T* = 298.15 K.

was handled in a dry N₂ atmosphere to avoid possible contamination by moisture. GC analyses of the samples gave purities >99.0% in agreement with their specifications. The sample was used without additional purification.

2.2. Adiabatic calorimetry

Heat capacity measurements were carried out in a highprecision automated adiabatic calorimeter described in detail in literature [16-18]. The calorimeter was established by Thermochemistry Laboratory of Dalian Institute of Chemical Physics, Chinese Academy of Sciences in PR China. It mainly consisted of a sample cell, a miniature platinum resistance thermometer, an electric heater, an inner and outer adiabatic shield, two sets of chromel-copel thermocouples and a high vacuum system. Liquid nitrogen was used as the cooling medium.

The sample amount used for the heat capacity measurement is 2.27977 g, which is equivalent to 14.984 mmol based on its molar mass of $152.15 \,\mathrm{g}\,\mathrm{mol}^{-1}$. The measurements were conducted by means of the standard method of intermittently heating the sample and alternately measuring the temperature. Heat capacity of the sample is derived from the total heat capacity subtracting the heat capacity of the calorimeter cell determined in a separate experiment

To verify the reliability of the adiabatic calorimeter, the molar heat capacities for the reference standard material α -Al₂O₃ were measured. The deviations of our experimental results from the recommended values of the National Bureau of Standards (NBS) [19] were within $\pm 0.2\%$ in the entire temperature range of 80–400 K.

2.3. DSC and TG analysis

A differential scanning calorimeter (Model: DSC822^e, METTLER TOLEDO, Switzerland) was used to perform the thermal analysis of adonitol under high purity nitrogen (99.999%) with a flow rate of 40 ml min⁻¹ and heating rate of 10 K min⁻¹. The mass of the sample used in the experiment was 6-8 mg.

The TG measurements of the sample were carried out by a thermogravimetric analyzer (Model: DT-20B, Shimadzu, Japan) under N_2 with a flow rate of 40 ml min⁻¹ and heating rate of 10 K min⁻¹. The mass of the sample used in the experiment was 11.72 mg.

2.4. Oxygen-bomb combustion calorimetry

An isoperibolic calorimeter with a static oxygen bomb (IKA-WERKE C2000 control) was used for measuring of the energy of combustion of adonitol. The accuracy of the commercial calorimeter is close to $\pm 0.01\%$ by combustion experiments of benzoic acid [cr, (-3227.0 ± 0.3) kJ mol⁻¹], 3-methoxybenzoic acid [cr, (-3736.2 ± 0.9) kJ mol⁻¹] and nicotinic acid [cr, (-2731.3 ± 0.5) kJ mol⁻¹] [20,21], provided that the weighing procedure is made at the level of 0.00001 g for the samples and 0.01 g for the water amount in the calorimetric system. The sample of 0.6-0.7 g was pressed and transferred into gelatine capsule (IKA, Germany) of 1 cm³ volume against absorption of air moisture, because the adonitol is easily hygroscopic under high pressure in the bomb. Then, the capsule was placed in the crucible and was burned in oxygen at a pressure 3.04 MPa.

All the necessary weightings for the combustion experiments were made with a precision of $\pm 10^{-5}$ g in a Mettler Toledo ABS-135 analytical balance. For each combustion experiment, the ignition temperature was T = 298.15 K and the final temperature were also close to this temperature.

The energy equivalent of the oxygen-bomb calorimeter, $\varepsilon_{calor} = (8958.05 \pm 0.78) J K^{-1}$ was determined from 10 combustion experiments using NIST 39i benzoic acid with a certified mass

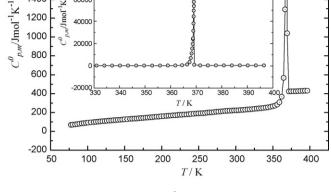

Fig. 1. Experimental molar heat capacity $C_{p,m}^0$ of adonitol as a function of temperature. Outer part: $C_{n,m}^0$ from 78 to 400 K, the whole experiment. Inner part: $C_{n,m}^0$ from 330 to 400 K, the melting process.

energy of combustion of $\Delta_c U = -26,434 \pm 3 \text{ Jg}^{-1}$ under experimental conditions, where the uncertainty quoted is the standard deviation of the mean.

The energy of formation of the aqueous nitric acid produced by oxidation of a trace of nitrogen, which contained in the oxygen bomb, was determined by the neutral titration with a 0.1 mol dm^{-3} of sodium hydroxide solution by using the phenolphthalein as the indicator. A summary of the auxiliary values for the combustion experiments is given in Table 4. Washburn Correction [22] was applied to convert the energy of the actual combustion process to that of the isothermal process, and reduce to standard states.

3. Results and discussion

3.1. Heat capacity

Experimental molar heat capacities of adonitol measured by the adiabatic calorimeter over the temperature range from 78 to 400 K are listed in Table 1 and plotted in Fig. 1. From Fig. 1, a phase transition was observed at the peak temperature of 369.08 K. According to its melting point 374.7 K [23], this transition corresponds to a solid-liquid phase change.

The values of experimental heat capacities can be fitted to the following polynomial equations with least square method [24]:

For the solid phase over the temperature range 78–360 K:

$$C_{p,m}^{0}/JK^{-1} \text{ mol}^{-1} = 170.000 + 98.817x + 23.846x^{2} - 56.366x^{3} - 92.259x^{4} + 71.865x^{5} + 82.678x^{6}$$
(1)

where is the reduced temperature x $x = [T - (T_{max} + T_{min})/2]/[(T_{max} - T_{min})/2]$, T is the experimental temperature, thus, in the solid state (78–360 K), x = [(T/K) - 219]/141, T_{max} is the upper limit (360 K) and T_{min} is the lower limit (78 K) of the above temperature region. The correlation coefficient of the fitting $R^2 = 0.9986$.

For the liquid phase over the temperature range 375–400 K:

$$C_{p,m}^{0} / J K^{-1} mol^{-1} = 428.460 + 3.821x$$
⁽²⁾

where x is the reduced temperature, x = [(T/K) - 387.5]/12.5, T is the experimental temperature, 387.5 is obtained from polynomial $(T_{\text{max}} + T_{\text{min}})/2$, 12.5 is obtained from polynomial $(T_{\text{max}} - T_{\text{min}})/2$. T_{max} and T_{min} are the upper (400 K) and lower (375 K) limit temperature, respectively. The correlation coefficient of the fitting $R^2 = 0.9954.$

Experimental molar heat capacity of adonitol ($M = 152.15 \text{ g mol}^{-1}$).

3.2. The temperature, enthalpy and entropy of solid–liquid phase transition

The standard molar enthalpies and entropies of the solid–liquid phase transition $\Delta_{fus} H_m^0$ and $\Delta_{fus} S_m^0$ of the compound were derived according to Eqs. (3) and (4):

$$\Delta_{fus}H_m^0 = \frac{Q - n \int_{T_i}^{T_m} C_{p,m}^0(s) \ dT - n \int_{T_m}^{T_f} C_{p,m}^0(l) \ dT - \int_{T_i}^{T_f} H^0 \ dT}{n}$$
(3)

$$\Delta_{fus} S_m^0 = \frac{\Delta_{fus} H_m^0}{T_m} \tag{4}$$

where T_i is the temperature that is somewhat lower than the temperature of the onset of a solid–liquid transition and T_f is the temperature slightly higher than that of the transition completion. Q the total energy introduced into the sample cell from T_i to T_f , H^0 the standard heat capacity of the sample cell from T_i to T_f , $C_{p,m}^0(s)$ the standard heat capacity of the sample in solid phase from T_i to T_m , $C_{p,m}^0(l)$ the standard heat capacity of the sample in liquid phase

Table 2

Thermodynamic parameters of adonitol.

from T_m to T_f and n is molar amount of the sample. The heat capacity polynomials mentioned above were used to calculate the smoothed heat capacities, and were numerically integrated to obtain the values of the standard thermodynamic functions above T=298.15 K. The calculated results are listed in Table 2.

3.3. Thermodynamic functions of the compound

The thermodynamic functions of the adonitol relative to the reference temperature 298.15 K were calculated in the temperature range 80–400 K with an interval of 5 K, using the polynomial equation of heat capacity and thermodynamic relationships as follows: Before melting,

$$H_T^0 - H_{298.15}^0 = \int_{298.15}^T C_{p,m}^0(s) \ dT \tag{5}$$

$$S_T^0 - S_{298.15}^0 = \int_{298.15}^T \frac{C_{p,m}^0(s)}{T} \, dT \tag{6}$$

Thermodynamic properties	Melting point, T_m (K)	$\Delta_{fus} H_m^0$ (kJ mol ⁻¹)	$\Delta_{fus}S^0_m$ (J K ⁻¹ mol ⁻¹)
Present work Adiabatic calorimetry DSC	$\begin{array}{c} 369.08 \pm 0.45 \\ 373.61 \pm 0.55 \end{array}$	$\begin{array}{c} 36.42 \pm 0.18 \\ 38.89 \pm 1.17 \end{array}$	$\begin{array}{c} 98.68 \pm 0.49 \\ 104.09 \pm 3.12 \end{array}$
Barone. et al. [23]	374.7	37.6	100.3

After melting,

$$H_T^0 - H_{298.15}^0 = \int_{298.15}^{T_i} C_{p,m}^0(s) \ dT + \Delta_{fus} H_m^0 + \int_{T_f}^T C_{p,m}^0(l) \ dT$$
(7)

$$S_{T}^{0} - S_{298.15}^{0} = \int_{298.15}^{T_{i}} \left[\frac{C_{p,m}^{0}(s)}{T} \right] dT + \frac{\Delta_{fus} H_{m}^{0}}{T_{m}} + \int_{T_{f}}^{T} \left[\frac{C_{p,m}^{0}(l)}{T} \right] dT$$
(8)

where T_i is the temperature at which the solid–liquid phase transition started; T_f is the temperature at which the solid–liquid phase transition ended; $\Delta_{fus} H_m^0$ is the standard molar enthalpy of fusion; T_m is the temperature of solid–liquid phase transition.

The standard thermodynamic functions, $H_T^0 - H_{298.15}^0$, $S_T^0 - S_{298.15}^0$, are listed in Table 3.

3.4. Constant-volume combustion energy, standard molar enthalpy of combustion, and standard molar enthalpy of formation

Results of combustion experiments on adonitol are listed in Table 4. The standard molar energy of combustion $\Delta_c U^0 = (-2561.2 \pm 1.3) \text{ kJ mol}^{-1}$ is used to derive the standard molar enthalpy of combustion $\Delta_c H_m^0$ (C₅H₁₂O₅, cr) = $(-2562.4 \pm 1.3) \text{ kJ mol}^{-1}$ and the standard molar enthalpy of formation $\Delta_f H_m^0$ (C₅H₁₂O₅, cr) = $(-1120.1 \pm 1.5) \text{ kJ mol}^{-1}$ based on the following reaction:

$$C_{5}H_{12}O_{5}(cr) + \frac{11}{2O_{2}(g)} = 5CO_{2}(g) + 6H_{2}O(l)$$
(9)

$$\Delta_c H_m^0 = \Delta_c U^0 + \Delta n \cdot RT \tag{10}$$

$$\Delta n = \sum n_i \text{ (products, g)} - \sum n_i \text{ (reactants, g)}$$
(11)

where $\sum n_i$ was the total molar amount of the gases in products or reactants.

The standard molar enthalpy of formation of the organic compound, $\Delta_f H_n^0$, was calculated by a designed Hess thermochemical cycle according to the reaction (9) as follows:

$$\Delta_{f} H_{m}^{0} (C_{5} H_{12} O_{5}, cr) = [5 \Delta_{f} H_{m}^{0} (CO_{2}, g) + 6 \Delta_{f} H_{m}^{0} (H_{2} O, l)]$$
$$- \Delta_{c} H_{m}^{0} (C_{5} H_{12} O_{5}, cr)$$

In the above formula, the standard molar enthalpies of formation of CO₂ (g) and H₂O (l), recommended by CODATA [25], $\Delta_f H_m^0$ (CO₂, g) = (-393.51 ± 0.13)kJ mol⁻¹, $\Delta_f H_m^0$ (H₂O, l) = (-285.83 ± 0.04) kJ mol⁻¹, were employed in the calculation of $\Delta_f H_m^0$ (C₅H₁₂O₅, cr) values.

3.5. The result of TG and DSC analysis

From the DSC curve in Fig. 2, a sharply endothermic peak corresponding to melting process was observed, with the melting temperature of 373.61 ± 0.55 K and the enthalpy of 38.89 ± 1.17 kJ mol⁻¹, which are slightly higher than the values (369.08 K, 36.42 ± 0.18 kJ mol⁻¹) observed from the adiabatic calorimetric measurements and slightly lower than the values observed from DSC (374.7 K, 37.6 kJ mol⁻¹) from Barone et al. [23]. The results were listed in Table 2. The data from DSC are obtained at a 10 K min⁻¹ scanning rate, in which the sample could not reach thermal balance. However, the data of adiabatic calorimetry are conducted by means of the standard method of intermittently heating the sample and alternately measuring the temperature. The temperature difference between the sample and adiabatic shield was automatically kept to be about 10^{-3} K during the whole experiment. The temperature increment for a heating period was 3 K, and

^a The symbols are defined according to Ref. [20] calorimeter: T_h = 298.15 K; V(bomb) = 0.2605 dm³; p^i (gas) = 3.04 MPa; m^i (H₂O) = 1.00 g. The specific energy of combustion of the gelatine capsule and cotton is 18926.00 and 16666.67 J g⁻¹ (provided by the supplier), respectively; $\rho_{(\text{adonitol})}$ = 1.525 g cm⁻³ calculated using Advanced Chemistry Development (ACD/Labs) Software V8.14 for Solaris (refer to SciFinder Scholar).

^b Masses obtained from apparent masses.

 $\Delta T_c = T_f - T_i - \Delta T_{\rm corr}.$

 $d \Delta U$ (HNO₃), ΔU (cotton), ΔU (bulb), ΔU (ign) is the energy correction of the nitric acid formation, the combustion of the cotton, the combustion of the capsule and the electrical energy of ignition, respectively.

 $\sigma = \sqrt{\sum_{i=1}^{n} (x_i - \bar{x})^2 / n(n-1)}$, in which *n* is the experimental number (*n* = 7); *x_i*, a single value of combustion energies; \bar{x} , the mean value of combustion energies.

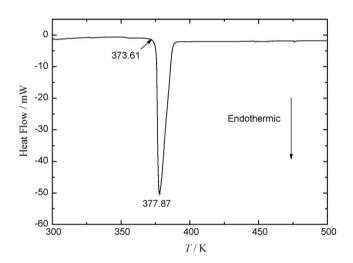

Fig. 2. DSC curve of adonitol under high purity nitrogen with onset temperature 373.61 K and peak temperature 377.87 K.

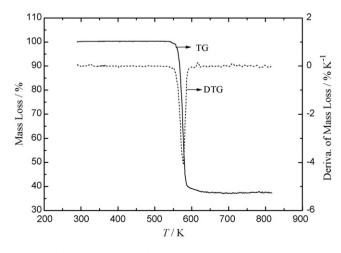

Fig. 3. TG–DTG curve of adonitol under high purity nitrogen.

thermostable below 550 K. It begins to lose weight at 551.55 K, reaches the maximum rate of weight loss at 577.38 K and completely loses its weight when the temperature reaches 601.82 K.

4. Conclusions

The heat capacities of adonitol were measured in the temperature range from 78 to 400 K by a high-precision automated adiabatic calorimeter. From the results of heat capacity experiment, the thermodynamic properties of fusion were completely studied, and the thermodynamic functions $[H_T^0 - H_{298.15}^0]$ and $[S_T^0 - S_{298.15}^0]$, were derived in the range from 78 to 400 K with temperature interval of 5 K. The melting temperature, standard molar enthalpy and entropy of this transition were determined to be 369.08 ± 0.45 K, 36.42 ± 0.18 kJ mol⁻¹ and 98.68 ± 0.49 J K⁻¹ mol⁻¹, respectively. The values of the standard molar enthalpy of combustion and formation of the compound are $\Delta_c H_m^0$ (C₅H₁₂O₅, cr) = (-2562.4 ± 1.3) kJ mol⁻¹ and $\Delta_f H_m^0$ (C₅H₁₂O₅, cr) = (-1120.1 ± 1.5) kJ mol⁻¹ respectively using IKA commercial oxygen-bomb combustion calorimeter.
