Myoepithelial cell (MEC) is the component of various secretory glands including salivary and breast glands and it is located between the basement membrane and the luminal cells. The MEC has pinocytic vesicles, microfilaments and dense bodies resembling smooth muscle cells and they are recognized immunohistochemically by the positivity of myofilaments. Since the beginning, its function as a contractile cell which facilitates the excretion of the products of both salivary and breast glands is well known. With the scientific advances in molecular and biologic studies, new functions were added. The studies in this area are controversial since some have indicated a tumour suppressor function and others a tumour facilitating function for the MEC. In order to increase some knowledge to this subject, we have investigated the immunoprofile of benign MEC in areas of in situ carcinoma ex-pleomorphic adenoma (ISCXAP) comparing with the MEC in areas of pleomorphic adenoma (PA) source of the malignant tumour. Tissue samples from 4 cases of ISCXAP have been selected for immunohystochemistry study using MEC markers (SMA, calponin, CK14, p-63), extracellular matrix protein (laminin) and protease inhibitor (maspin). The results revealed that all MEC markers plus laminin and maspin are stronger expressed in benign MEC of ISCXAP areas than in benign MEC of pleomorphic adenoma . These results have led us to conclude that MEC which surrounds the malignant epithelial component of ISCXAP is phenotypically altered and more differentiated than the benign MEC of pleomorphic adenoma and probably, exerts, at this moment of the oncogenesis process, a tumour suppressive function. Further studies are necessary in order to clarify if the MEC is also implicated in the transition of in situ to invasive carcinoma.

P 352

CD10 EXPRESSION USEFULNESS IN DIFFERENTIAL DIAGNOSIS OF PRIMARY AND METASTATIC CLEAR CELL TUMOURS OF SALIVARY GLANDS

Alos L, Morente V, Garrido M, Mozos A, Ordi J, Cardesa A.
Department of Pathology, Hospital Clinic, IDIBAPS, University of Barcelona, Spain.

INTRODUCTION: The expression of CD10, or common acute lymphoblastic leukemia antigen, has been widely studied in normal tissues and neoplasms. CD10 is characteristically expressed in renal clear cell carcinomas, a neoplasm with tendency to metastatize in the head and neck region. Its positivity has been shown to be helpful in the differential diagnosis with other tumours with clear cells in other organs such as the ovary. However, the expression of CD10 in clear cell neoplasms of salivary gland origin has not been previously studied in detail.
PURPOSE OF THE STUDY: To study the expression of CD10 in primary clear cell tumours of salivary glands and metastatic renal cell carcinoma, in order to determine the uselfulness of this marker for the differential diagnosis.
MATERIAL AND METHODS: Thirty-five tumours of salivary glands with a major clear cell component were selected. Thirty-two were primary tumours and three were metastatic renal clear cell carcinomas. The immunohistochemical study for CD10 (Novocastra Laboratories. Newcastle, UK. Dilution 1:25) was performed in all cases from from formalin-fixed and paraffin embedded material.
RESULTS: All primary tumours composed of myoepithelial cells showed a strong and diffuse cytoplasmic CD10 positivity: myoepitheliomas (4/4), myoepithelial carcinomas (3/3), and epithelial-myoepithelial carcinomas (3/3). CD10 was also positive in other primary tumours with clear cells: mucoepidermoid carcinomas (3/6) showed a predominant apical and luminal positivity in glandular differentiated areas; some acinic cell carcinomas (2/8) and oncocytomas (1/3) had a cytoplasmic pattern.Three salivary gland clear cell carcinomas and two sebaceous differentiated tumours were negative for CD10. Metastatic renal clear cell carcinomas showed a strong membrane positivity (3/3).
CONCLUSION: CD10 is expressed in a variety of primary tumours of salivary glands, with a cytoplasmic or luminal pattern; whereas this marker shows a strong membrane positivity in metastatic renal cell carcinoma. The different immunoreactivity pattern may be useful for differentiating renal cell carcinoma metastasis from other primary salivary gland tumours.

EXTRA PAROTID PARAPHARYNGEAL SPACE TUMOR WITH BIPHASIC PATTERN.

DINU* Carmen, TOUBLANC* Marianne, WASSEF** Michel, GEHANNO*** Pierre, HÉNIN* Dominique
*Pathology department, ***ENT department, Bichat hospital; **Pathology department, Lariboisière hospital, Paris, France.

A 54 year old woman presented with a nodular lesion of the parapharyngeal space. This lesion was well-circumscribed hypoechogene on echography, separated from the parotid gland by a narrow band of fat tissue on CT scan. On MRI a possible connection with the parotid gland and a T2 moderate hypersignal were noticed. At surgery the tumor appeared as a firm encapsulated greyish nodule, 3,5 x 5,5 cm, without connection with the parotid gland.
Microscopically, tumor was predominantly composed of spindle cells intermixed with mature adipose tissue and epithelial cells, forming small solid nests with squamoid features, rarely tubes or microcysts. No necrosis was observed. Both epithelial and spindle cells were strongly positive for AE1/AE3. Spindle component was PS100 + and faintly smooth muscle actin +. Proliferation index was less than 3% . Cells were not stained by CD34, desmine, GFAP and CD99 antibodies. Diagnosis of ectopic hamartomatous thymoma was first proposed on account of location at the skull base without connection with parotid gland, predominant spindle shaped pattern and squamoid features, but PS100 positivity was unusual. On serial sections cartilage tissue was found, leading to the diagnosis of pleomorphic adenoma.
Tumors in the parapharyngeal space (PPS) are rare and constitute less than 0.5% of head and neck neoplasm. Of these, pleomorphic adenoma (PA) is the most common (40%) followed by schwannoma and paraganglioma. PA can arise either de novo from accessory salivary glands or from the deep lobe of the parotid gland and extend through the stylomandibular tunnel into the PPS. Typical PA has a biphasic appearance resulting from the intimate admixture of epithelium and myoepithelial cells, and generally contain myxochondroid areas and sometimes adipous tissue. Some pleomorphic adenomas are extremely cellular, the tumor cells being either round or spindle shaped. The myoepithelial component is immunoreactive for keratins, myosin, fibronectin, PS-100 and often for actin. The main differential diagnosis include ectopic hamartomatous thymoma, biphasic

synovial sarcoma, schwannoma, malignant peripheral nerve sheath tumor and myoepithelioma of soft tissue.
Conclusion: Immunohistochemical study is important for the diagnosis of parapharyngeal space tumor with biphasic pattern.

PRIMARY AMYLOIDOSIS OF THE LARYNX
PAGLIARI Angelo Virgilio °, KLINGER Francesco *, KLINGER Marco *
° U.O. ORL - Azienda Ospedaliera di Crema
* Istituto di Chirurgia Plastica e Ricostruttiva
Università degli Studi di Milano-I.C. Humanitas

Introduction In 1851 Virchow coined the word amyloid to describe the strachlike reaction of a waxy material when treated with iodine and sulphuric acid. Amyloidosis is defined as a pathologic proteinaceous substance deposited between the cells of tissues and organs leads to various clinico-pathologic conditions. Localized and idiopathic amyloidosis in the head and neck is a rare and benign process.
Methods We present a clinical case of a 63 years female with hoarseness due to a laryngeal mass and also a review of literature regarding localized amyloidosis. A laryngoscopic examination revealed a smooth, non ulcerated submucosal mass involving the ventricle, false cord extended to vocal process. Physical and laboratory evaluation showed no evidence of systemic amyloidosis or multiple myeloma. The lesion was treated by endoscopic laser excision.
Results At light microscope amyloid is a homogeneous acellular eosinophilic and extracellular material with haematoxylin and eosin stains. It stains metachromatically purple red with crystal violet and characteristically manifests a Congo red staining of its fibrils with apple-green birefrigence. Amyloid stains dark brown with iodine. Exposure of the Congo red to potassium permanganate and diluite sulphuric acid may be used to partly subclassify amyloid. Immunohistochemical examination revealed a polyclonal staining pattern of light chain of immunoglobulins.
Conclusion Localized amyloidosis of head and neck region is rare. Borow in 1873 first reported amyloidosis of the larynx and at the present about 350 cases were reported in literature. It should be recognized, understood, evaluated and properly treated.

ANGIOLEIOMYOMA OF THE NECK MIMICKING THYROGLOSSAL DUCT CYST
SALERNO Angela*, MARLIA Enrico°, FONTI Giulio°.
*Servizio di Anatomia e Istologia Patologica e Citodiagnostica. Ospedale Maggiore. Bologna.
°Unità Operativa di Chirurgia Generale. Ospedale G. Dossetti. Bazzano (Bologna). ITALY

INTRODUCTION. Angioleiomyoma (AL) is an uncommon benign tumour composed of smooth muscle cell and vascular endothelium. After Shout reported the first 11 cases in 1937, about another thousand have been reported and most authors have accepted that angioleiomyoma originates from the smooth muscle in the wall of vascular channels. In 1973 Morimoto proposed to subdivide AL into capillary (solid), cavernous and venous type. Clinically AL is more frequent in female; they are usually located in lower extremities and present as a solitary, painful cutaneous or subcutaneous mass of solid type. Only about 10% of AL arises in the head and neck area and they usually present as a painless mass of venous or cavernous type. Frequently imaging study or cytological examination is not helpful for preoperative diagnosis. Recurrence is rare.
PURPOSE OF THE STUDY. In this paper we report the case of an angioleiomyoma of the neck mimicking a thyroglossal duct cyst and to our knowledge this is the first case described in this location.
METHODS. A 67-year-old male presented with a painless mass of the neck. Physical examination revealed a 2 cm subcutaneous solid mass in the upper neck. There was neither associated lymphadenopathy nor abnormality of the skin. Ultrasound examination showed a 20 x 15 x 21 mm solid hyperechogenic mass, with hypoechogenic peripheral rim. The preoperative diagnosis was of a thyroglossal duct cyst. The patient underwent surgery and a 2 cm solid mass was found attached to the geniohyoid muscle but without relation with the hyoid bone.
RESULTS. Histologic examination showed a well demarcated nodule composed of smooth muscle with thick-walled venous vessels with inner layers of smooth muscle and without lamina elastica. The tumour contained also mature fat cells. Immunohistochemistry for smooth muscle actin was positive and confirmed the diagnosis of angioleiomyoma of venous type.
CONCLUSION. AL is a rare benign tumour in head and neck area. This lesion is difficult to diagnose before surgery, especially when it occurs as a painless mass and is in a site where other lesions are more frequent. Surgical excision is necessary to make a correct diagnosis and gives good results with rare recurrence.

P 356
EWING /PNET FAMÝLY SARCOMA ARISING FROM BRANCHIAL CYST WALL
DERVISOGLU Sergulen, OZ Buge, SAR Mehmet

INTRODUCTION:The Ewing sarcoma family tumors (ESFT) include Ewing sarcoma, peripheral primitive neuroectodermal tumor, neuroepithelioma, atypical Ewing sarcoma, and Askin tumor. ESFT research is ongoing to further characterize the biology of the EWS/FL1 fusion protein and it's role in transformation, cell growth and chemosensitivity. Unusual location of such tumors may cause diagnostic problems and cytogenetic analysis on tumor tissue samples may solve the problem in diagnostic approach. We present an ESFT arising from a branchial cleft cyst and discussed the diagnostic difficulties.
CASE: A 21 year old female complained dysphagia for 2 years duration. During the last 2 months a mass was palpated on the right side of the neck. Physical examination revealed cystic cervical, nontender mass with 4x3x3cm diameters, located along the lower one third of the anterior border of the sternocleidomastoid muscle between the muscle and overlying skin. Histopathological examination of the excised mass showed cystic wall lined with partially stratified squamous and respiratory epithelium. Lymphoid tissue was seen in the cyst wall in accordance with branchial cleft cyst. Next to this lymphoid area a malignant neoplasm consisting primitive cells arranged in cords and with a vague nesting pattern was observed. Immunohistochemical studies showed CD99 positivity, while cytokeratin, CD45, NSE, S-100, chromagranin, synaptophysin, smooth muscle actin, and desmin were all negative.Cytogenetic analysis performed by using RT-PCR technique on paraffin embedded tumor tissue demonstrated the chimeric fusion transcripts EWS/FLI-1 and confirmed the diagnosis of ESFT.
CONCLUSION:This location was unique when we rewieved the English written literature as far as we could reach .
Because the ESFT is a rare tumor in extraskeletal site it is often not considered in clinical differential diagnosis until a biopsy reveals a small blue round cell tumor.Especially unusal presentation like the presented case, a panel of immunohistochemistry may not be helpful in all instances. Cytogenetic analysis may solve the problem if the material belongs to a tumor with a known characteristic transformation. In our case EWS/FL-1 fusion which is present in 85% of ES/PNET cases was helpful in dignostic approach.

Because of the cystic nature and branchial cyst association malignancy was not in the differential diagnosis clinically, consultation with an oncologist is critical.

SPINDLE CELL PROLIFERATION IN FOLLICULAR ADENOMA OF THE THYROID. CASE REPORT IN PATIENT TREATED FOR HIGH GRADE LYMPHOMA

Manfrin E°, Martignoni G*, Remo A°, Reghellin D°, Dalfior D°, Eccher A°, Bonetti F°.
°Department of Pathology, University of Verona
*Department of Pathology, University of Sassari

Introduction: Spindle cell proliferations of the thyroid are rare and they include anaplastic carcinoma and mesenchimal tumors. There are few reports of spindle cell change in epithelial tumors of the thyroid as such as have been described in follicular adenoma and papillary carcinoma.
Purpose: to report the clinical and pathological features of a thyroid adenoma with diffuse spindle cell change in a patient treated for high grade lymphoma.
Methods: In 2003, a 31-year-old woman was admitted to "G.B.Rossi" hospital of Verona University and underwent chemotherapy because of high grade lymphoma. In 2004, she received bone marrow transplantation (BMT). During follow-up, a Positron Emission Tomography (PET) was performed and a suspicious single nodule in the thyroid was detected. Following fine needle aspiration cytology (FNAC) was not conclusive and the nodule was surgically removed.
Summary: Cytologically, the lesion was composed by cohesive, plump spindle cells with amphophylic cytoplasm, irregular nuclei with granular cromatin. No bizarre nuclei nor necrosis or mitoses were detected. On gross examination, the nodule was 2.5 cm in diameter, with whitish cut surface and a well-defined capsule. Histologically, it was composed, almost completely (90%), of spindle cells growing in diffuse, haphazard pattern, surrounding residual thyroid follicles. There was no vascular neither capsular invasion. Immunohistochemically, spindle cells were strongly positive with TTF-1, CK8-18 and vimentin, positive with keratin, but negative with CD34, S-100, desmin, HMB-45 and calcitonin. Spindle cells showed weak and focal immunoreactivity for thyroglobulin. Immunoistochemical results demonstrated the follicular origin of the lesion and suggested a diagnosis of spindle metaplastic transformation in follicular adenoma.
Conclusion: Spindle cell adenoma of thyroid is an extremely rare lesion. In our case FNAC was not conclusive and histological examination was necessary for a correct diagnosis. An association between spindle cell adenoma and the treatment for lymphoma cannot be ruled out.

Fibronectin is one of the extracellular matrix glycoprotein, that plays an important role in cancer invasion and progression. Our purpose was to evaluate fibronectin expression and its possible prognostic value in laryngeal cancer. Forty-one patients (six female and thirty-five male) surgically treated for laryngeal cancer were included in the study. The expression and distribution of fibronectin was immunohistochemically determined by using monoclonal antibody against fibronectin. Low expression of fibronectin was detected around the individual carcinoma cells, but large amounts were present in the invasive tumour front and the cancer surrounding stroma was strongest positive for fibronectin. By univariate analysis the level of fibronectin expression on the border of the invasive tumour front was proved to be correlated with tumor stage ($p=0,03$). There was a significant association between the defect of ECM and overall survival ($p>0,05$). These observation indicates that testing the distribution and the expression of ECM seems to be useful to evaluate the histological grading of malignancy of laryngeal cancer and to be helpful to prognosticate the overall survival while measured on the border of tumour proliferative front in laryngeal patients. The results demonstrate that fibronectin amount may be useful in evaluating the invasion potential of the tumour.

P 359
MALT LYMPHOMA IN SJOGREN'S SYNDROME

KATIÆ Vuka, KRASIÆ Dragan, BURIÆ Nikola, TRENKIÆ Marija, KATIÆ Katarina.
Institute of Pathology, Medical Faculty of Niš University, Niš, Serbia and Montenegro

Introduction and aim: Sjogren's syndrome is a chronic autoimmune and rheumatic disorder with prominent sicca complaints from the mucous membranes because of lack of proper exocrine secretions. A large number of autoantibodies have been reported in Sjogren's syndrome where the antibodies are correlated with the extent and severity of disease. It is world-wide disease and may occur in all ages.However, the peak incidence is in the fourth and fifth decades of life with a female/male ratio of 9:1. Mucosa Associated Lymphoid Tissue (MALT) accounts for about 7,2% of all of non-Hodgkin's lymphomas.Most arise at sites without lymphoid tissue and appear following a period of chronic inflammation. This is the result of autoimmune disease as occurs in the thyroid or salivary glands, or in the stomach following local bacterial infection. In contrast to many reports on MALT lymphoma induced H.pylori chronic infection, on MALT lymphoma in salivary glands induced autoimmune disease there are a few data, that is the reason for our study.
Material and methods: Five patients with tumours of the parotid glands and surrounding lymph nodes, were surgically treated and sent to pathologist for histological analysis.Formaldehyde-fixed and paraffin- emmbedded tumorous tissue were cut and stained with H&E,AB-PAS, Van Gieson's and immunohistochemical LSAB2 methods. For immunohistochemical analysis, antibodies to cytokeratin and to CD20 and CD45RO antigens were used.
Results: MALT lymphoma in the salivary glands has a mean age incidence 56 years with a female to male ratio of 3:1. Macroscopical characteristics are not specific. Histological characteristic of MALT lymphoma was the presence of lymphoid follicles and diffuse infiltrate of lymphocytes occupying the marginal zone and both infiltrating and replacing glandular epithelium (pathognomonic lymphoepithelial lesion). The marginal zone, more developed, contained a mixed population of cells, with plasma cells and many mature B-cells,including centrocytoid and monocytoid B-cells.The pathognomonic lymphoepithelial lesions were more numerous than in
gastric MALT lymphoma. Immunohistochemically, lymphoepithelial lesions and B-cell origin of MALT lymphoma were confirmed.
Conclusion: MALT lymphoma in Sjogren's syndrome is autoimmune genesis.Characteristics of
MALT lymphomas induced by chronic H.pylori infections are symilar to characteristics of MALT lymphoma in Sjogren's syndrome.

INTRODUCTION
Micropapillary carcinoma (MC) of the bladder, first described in 1994, is a rare and highly aggressive variant of urothelial cell carcinoma (UCC) that accounts for 0.6% to 1% of all urothelial carcinoma. Histologically, the micropapillary component (MPC) is characterized by superficial pattern of slender, filiform processes or small papillary clusters of tumor cells and a deep pattern of tight infiltrating clusters contained within tissue retraction spaces. Herein, we report two additional cases of MC of the bladder including one with a long follow-up.
CASE 1:
A 68-year-old man presented with macroscopic hematuria. Ultrasonography and cystoscopy showed a sessile papillary tumor of 4 cm involving the anterior wall. The transurethral excision was complete. Microscopic findings demonstrated a grade G3 TCC with focal superficial and deep MPC (20%). Evidence of vascular invasion without muscular extension was found. A complementary BCG therapy was delivered. Four months later, the tumor relapsed and complete transurethral resection showed a recurrent pTa G1 UCC without MPC. He benefited from a second BCG therapy cure. He is now free of disease since more than six years.
CASE 2:
A 70-year-old man, treated for terminal chronic renal failure of unknown cause, exhibited a gross hematuria. Ultrasonography coupled with cystoscopy were consistent with a multifocal papillary tumor. The pathological examination after complete transurethral resection revealed a G3 papillary UCC with extensive MPC (60%) which infiltrate the lamina propria. The resection did not include muscle tissue. No cystectomy nor BCG therapy were scheduled due to his poor general condition. Currently, the follow-up is only one month.
DISCUSSION
While MC of the bladder is considered as a highly aggressive tumor with a high grade and stage at presentation, its prognosis is not very well documented due to the low number of cases in the literature. We report two additional cases including one with a favourable clinical course, the follow-up is too short for the second one. The prognosis depends on the extent of the invasion and on the proportion of the MPC. Deep muscle biopsies are recommended to rule out invasion when MPC is encountered. BCG therapy benefit should be better evaluated. A review of a large number of cases is needed to conclude whether or not the prognosis of patient with MC is poorer than that of patients with UCC G3 bladder cancer.

P 361

PROGNOSTIC IMPACT OF INVASIVE PATTERN, SQUAMOUS DIFFERENTIATION AND SARCOMATOID TRANSFORMATION IN TRANSITIONAL CELL CARCINOMA OF THE UPPER URINARY TRACT

Cord Langner1, Peter Rehak2, Richard Zigeuner3
1Institute of Pathology, 2Department of Surgery, Division of Biomedical Engineering & Computing and 3Department of Urology, Medical University of Graz, Austria

Introduction
Initial tumour stage and grade and extent of surgery have been documented as major prognostic factors in patients with upper tract transitional cell carcinoma (TCC). Our study aimed to evaluate the prognostic impact of other histopathological factors, such as invasive pattern, squamous differentiation and sarcomatoid transformation, in a large series of consecutive patients.
Methods
239 consecutive patients underwent surgery for upper urinary tract TCC between 1984 and 2004 at our institution. Patients with non-invasive TCCs (pTa) and multifocal (both pelvic and ureteral) TCCs were excluded. H&E slides of the remaining 188 cases (133 pelvic and 55 ureteral TCCs) were systematically re-evaluated regarding invasive pattern (nodular, trabecular and infiltrative), squamous differentiation and sarcomatoid transformation. The prognostic impact (regarding metastasis-free survival) was analyzed using the Kaplan-Meier method and the log-rank test. For multivariate analysis a Cox proportional hazard regression model including tumour stage and grade was used.
Results
The pattern of invasion was nodular in 47%, infiltrative in 31% and trabecular in 22% of cases, respectively. Squamous differentiation was identified in 22%, sarcomatoid transformation and marked tumour cell anaplasia were noted in 8% of cases, respectively. Follow-up data were available from 182/188 (97%) patients. After a mean follow-up of 4.1 years, metastatic disease was noted in 80/182 (44%) patients. Mean time to progression was 22 months. Significant prognostic factors in univariate analysis were pattern of invasion ($p<0.001$), squamous differentiation ($p=0.009$) and sarcomatoid transformation ($p=0.002$). In multivariate analysis, infiltrative pattern of invasion ($p<0.001$, risk ratio [RR]=7.1, 95% confidence interval [CI]=2.4-19.8) and pT category > 1 ($p<0.001$, RR=4.0, 95%CI=1.9-8.3) proved to be independent predictors with respect to metastasis-free survival, whereas for sarcomatoid transformation only a trend was noted ($p=0.06$).
Conclusions
The infiltrative pattern of invasion proved to be a new independent predictor of metastasis-free survival in upper tract TCCs, whereas squamous differentiation and sarcomatoid transformation lacked independent influence on patient outcome.

P 362

PROGNOSTIC IMPACT OF TUMOUR STAGE, GRADE AND ANGIOINVASION IN TRANSITIONAL CELL CARCINOMA OF THE UPPER URINARY TRACT

Cord Langner1, Peter Rehak2, Richard Zigeuner3
1Institute of Pathology, 2Department of Surgery, Division of Biomedical Engineering & Computing and 3Department of Urology, Medical University of Graz, Austria

Introduction
Initial tumour stage and grade and extent of surgery have been documented as major prognostic factors in patients with upper tract transitional cell carcinoma (TCC). However, data are limited due to small sample size and the new two-tired grading system of the WHO has not yet been systematically tested with respect to prognostic significance. Therefore, our study aimed to evaluate possible conventional prognostic factors, such as tumour stage and grade as well as angioinvasion, in a large series of consecutive patients.
Methods
239 consecutive patients underwent surgery for upper urinary tract TCC between 1984 and 2004 at our institution. Patients with non-invasive TCCs (pTa) and multifocal (both pelvic and ureteral) TCCs were excluded. The slides of the remaining 188 cases (133 pelvic and 55 ureteral TCCs) were systematically re-evaluated regarding pT-category, tumour grade according to the recent revision of the WHO classification and angioinvasion (L1, V1). The prognostic

impact (regarding metastasis-free survival) was analyzed using the Kaplan-Meier method and the log-rank test. For multivariate analysis a Cox proportional hazard regression model was used.
Results
Follow-up data were available from 182/188 (97%) patients. After a mean follow-up of 4.1 years, metastatic disease was noted in 80/182 (44%) patients. Mean time to progression was 22 months. Significant prognostic factors in univariate analysis were pT-stage > 1 (p<0.001), high tumor grade (p<0.001) and angioinvasion (p<0.0001). No significant prognostic influence was observed for tumour location. In multivariate analysis, pT-stage > 1 (p<0.001, risk ratio [RR]=4.7, 95% confidence interval [CI]=2.3-9.5) and angioinvasion (p<0.001, RR=4.9, 95%CI=2.7-8.9) proved to be independent predictors with respect to metastasis-free survival, whereas for high tumour grade only a trend was noted (p=0.09).
Conclusions
Advanced tumour stage and presence of angioinvasion were independent predictors of metastasis-free survival in upper tract TCCs. No impact was seen for tumour localization (pelvic vs. ureteral), thus supporting the current concept of the TNM system to summarize pelvic and ureteral TCCs in one tumour category.

P 363
CORRELATION BETWEEN APOPTOSIS AND HISTOLOGICAL GRADE OF TRANSITIONAL CELL CARCINOMA OF URINARY BLADDER
Bahram Mofid,Mohammad Reza Jalali Nadoushan, Hamideh Peivareh

Purpose: TO evaluate the relationship between histological Grade and Apoptotic Index (AI) in TCC of urinary bladder .

Methods & Materials: Formalin-fixed and paraffin-embedded tissue blocks from 75 patients with TCC who underwent Transurethral resection (TUR) were studied. One 3 micron sections were provided from each TUR samples. In one section after Hematoxylin and Eosin (H&E) staining, grade was determined according to WHO/ISUP criteria. The apoptotic cells were determined using a terminal deoxynucleotidyl transferase (TdT) mediated dUTP biotin nick end labeling (TUNEL) technique. Apoptotic index was then obtained as the percent of TUNEL positive cells from observations of at least 1000 cells in each section.

Results: Forty-nine patients were men and 26 were women. The mean age was 56.34,,b9 years. The mean AI was 2.30,,b0.50. The relationship between grade and AI was significant (P=0.000, rs=0.551). A higher grade was associated with a higher AI.

Conclusion : The AI has a direct correlation with bladder TCC grade. For determination of definite role of it in prognosis, other analytical studies are needed.

Key Words: Transitional cell carcinoma, Grade, Apoptotic Index, Tunnel

P 364
THE RELATIONSHIP BETWEEN C-ERB B2 ONCOPROTEIN OVER EXPRESSION AND HISTOLOGIC GRADE ON TRANSITIONAL CELL CARCINOMA OF URINARY BLADDER
Jalali Nadoushan Mohammad Reza,Jouian Neda,Zaeri Farid
Shahed University

Background and Objective: Transitional cell carcinoma of urinary bladder is the fourth most common cancer in men and eighth in women. Similar to other cancers, this cancer needs to determination of prognosis and type of treatment, after diagnosis. Several parameters such as clinical and pathological parameters, chromosomal and genetically abnormalities and molecular factors in cells surface have rules in determination of prognosis. In this research, for the first time in Iran, abundance of c-erb B-2 oncoprotein and it's relation with tumor grade were evaluated.
Material and Method: A prospective cross-sectional study was performed in paraffin embedded tissue from 75 patients with TCC of urinary bladder. Two 3m sections were provided. In one section, according to WHO/ISUP grading system, grade of tumor was determined, by H&E staining. In the other section, the presence of c-erb B-2 oncoprotein was determined by IHC Method.
Results: Increasing in number of patient with c-erb B-2 protein over expression, was associated to increase in grade of tumor, and a meaningful relation between over expression of c-erb B-2 and grade of tumor was found.
Conclusion: c-erb B-2 oncoprotein over expression had a direct relation with tumor grade. Results of this study are the same as often previous; therefore c-erb- B-2 oncoprotein over expression could be a prognostic factor in TCC of urinary bladder. Other studies for confirmation of this hypothesis are recommended.

P 365
IMMUNOHISTOCHEMICAL EXPRESSION OF CK 7, CK20, P53, AND MIB1 IN UROTHELIAL LESIONS
Molinié Vincent (1), Lebret Thierry (2), Hervé Jean Marie (2), Botto Henry (2). Pathology department (1), Hôpital saint Joseph, Paris, and Urology department (2) Hôpital Foch, Suresnes, France.

Morphological aspect in vesical lesion is sometimes difficult to distinguish from a reactional dystrophy, and it could be difficult to distinguish low and high grade carcinoma, specilally in G2 tumour. In these cases immunohistochemistry with p53 and Mib1 may be useful.
Aim of the study : to evaluate the expression CK 20 in the diagnosis of urothelial carcinoma, and to compare to the expression of p53 and Mib1 and CK 7.
Materials and methods : 69 cases of urothelial carcinoma (54 TUR and 15 biopsies), interesting 3 reactional dystrophic lesions, 32 low grade urothelial carcinoma, 34 high grade urothelial carcinoma ; corresponding in 59 superficial tumours (38 pTa, 16 pT1a, 5pT1b) and 8 infiltrative tumours (pT2). For each cases one paraffin block of representative with normal urothelium were tested with CK 7 (Immunotech, 1/50); CK 20 (Immunotech, 1/50); p53 (Dako, 1/80) and Mib1 (Ki67, Dako, 1/100), after antigenic restoration, on an automate stainer Nexes Ventana ®.
Results : Normal superficial cells expressed CK7 in 98,5% of the cases. With CK 20, in normal urothelium, and low grade tumors, only superficial cells were stained. In high grade tumours all the height of the urothelium was stained. CK 20 expression was correlated with grade p = 0,01 (WHO 73: G1 vs G2 vs G3 or WHO 2004: High grade vs Low grade), but not with stage p = 0,15. Expression of p53 and Mib1 varied from 5 to 90%. Mib1expression was strongly correlated with grade : p = 0,013 (WHO 2004: High grade vs Low grade or WHO 73: G1 vs G2 vs G3) and with stage p = 0,05. p53 expression was correlated neither with the grade p = 0,58 nor stage p = 0,18.
Conclusion : High expression of CK 20 and Mib1 is found in high grade urothelial carcinoma and in CIS. This should be exercised in using CK 20 and Mib1 immunohistochemical staining for the diagnosis of papillary urothelial tumour of intermediate grade (G2, OMS 73), or in case of atypical plane lesion

P 366
SIGNIFICANCE OF P21 AND C-MYC EXPRESSION IN BLADDER UROTHELIAL LESIONS

Badawy Afkar, El-hindawy Aly, Khattab Hany*, Abo-Shousha Tarek, El-Shahat Noha, and Omran Zeinab.
Pathology department, Theodor Bilharz Research Institute and * Faculty of Medicine, Cairo University, Egypt.

Immuno-histochemical tissue expression of the anti-proliferative marker P21 and the oncogenic marker C-myc were estimated in 40 cases with non-neoplastic and neoplastic urinary bladder lesions with or without schistosomal infection to assess the significance of their urothelial expression as a diagnostic tool in patients with higher risk of developing cancer bladder and as a prognostic indicator in malignant lesions. P21 expression was detected randomly in normal urothelial nuclei, while 50% of simple cystitis cases and all cases with premalignant changes were positive for P21 immuno-reactivity expressed into about 16% of urothelial cells. Eighty five percent of malignant cases expressed P21 in 48-55% of urothelial cells without significant variance between different histologic tumor types. Extent of P21 expression inversely correlated with bilharzial association, upgrading of malignancy and tumor invasiveness.

C-myc was detected in 50% of normal urothelium (as cytoplasmic staining), in 80% of simple chronic cystitis cases (75% cytoplasmic, 25% cytoplasmic and nuclear expression), and in all cystitis cases with premalignant changes (as cytoplasmic and nuclear expression). Eighty nine percent of cancer cases were C-myc positive with predominance of nuclear expression to be seen in 16.7% and mixed with cytoplasmic expression in another 58.3% of positive cases. Malignancy upgrading and invasiveness raised C-myc positivity. In conclusion: P21 expression increases in an attempt to check cellular proliferation, but when the matter is out of hand, P21 is down- regulated, while the increase in the oncogen C-myc goes ahead. Loss of P21 and increased C-myc expression in a malignant lesion is a predictor of malignancy progress to higher grade or stage.

P 367

IMMUNOHISTOCHEMICAL PROGNOSTIC FACTORS OF UROTHELIAL CARCINOMA.

Frank G.A., Zavalishina L.E., Andreeva Yu.
Hertsen Research Oncological Institute, Moscow, Russian Federation

AIMS : Immunohistochemical study structural component of extracellular matrix and cellular adheson mollecules in bladder urothelial carcinoma of different grade.
METHODS : Using formalin – fixed and paraffin – embedded tissue, we examined by immunohistochemical method tenascine, collagen IV, laminin, E-cadherin, beta-catenin, CD44 in 39 cases of urothelial carcinoma: G1 – 15, G2 – 12 and G3. Staining intensity of E-cadherin, beta-catenin and CD44 were evaluated using a 0 to 3+ scale.
RESULTS: The strong positive staining (3+) with antibody to E-cadherin was observed in most of cases G1 carcinoma. Low intensive (0/1+) reaction was found in all cases G3 urothelial carcinoma. Immunohistochemical staining with antibody to beta-catenin was the same in localisation and inteisity of expression with E-cadherin: G1 carcinoma – 3+ and 2+ in 80%, G2 – 2+ in 40% and 1+ in 60%, G3 – 0/1+ in 100% cases. It is impotant, that it was low expression E-cadherin and beta-catenin (0/1+) in a few cases high-grade urothelial carcinoma.
CD44 level was high in tumor cells in G1 and low – in extracellular matrix. But in G3 cases we observed strong reaction in extracellular matrix and low reaction – in tumor cells membrane.
Expression collagen IV and laminin was high intensivety around tumor complexes in G1 carcinoma, but low – in cases G3. The overexpression of tenacsine was found only in bladder carcinoma G1.
CONCLUSAON: Our data suggest, that expression E-cadherin, beta-catenin, CD44, tenascine, collagen IV and laminin may play a role of prognostic factores in urothelial carcinoma and they correlate with different level of malignancy. .

Introduction: Superficial tumors of the bladder present 2 prognostic problems: a risk of recurrence and a risk of progress in grade and in stage. Predictive factors of recurrence and of tumoral progress were identified.These factors are essentially endoscopical and pathological ones. Recent works underlined the prognostic value of the immunohistochemical study of the markers of cellular proliferation and of apoptosis in these tumors.
Aims: To study a series of superficial tumors of the bladder and to assess the prognostic significance of p53, Ki67, PCNA and bcl2 in these tumors.
Materials and methods: We studied 59 bladder tumors: 43 pTa and 16 pT1. All Patients had cystoscopy 3 months after the resection and tumors that did not recur had a minimum follow up of 5 years.
Results: Age more than 65 years (p = 0,001), multifocality (p = 0,022) and tumoral size ¡Ý 3 cm (p = 0,022) were correlated with the recurrence. The expression of p53 was correlated with the recurrence in the year following the tumoral resection (p = 0,035). That of of Ki67 was correlated with the histological grade (p = 0,03) and stage (p = 0,002).
Conclusion : Our results suggest to practise regular endoscopic controls during the first year following the resection of the primitive tumor if it expresses p53. The immunohistochemical expression of Ki67 being correlated with the grade, this marker could help to better classify the tumors of intermediate grade.

EXPRESSION OF TETRANECTIN IN INVASIVE AND NON-INVASIVE PAPILLARY BLADDER CANCER

BRUNNER Andrea, ENSINGER Christian, CHRISTIANSEN Michael*, HEISS Simone, MIKUZ Gregor, TZANKOV Alexandar
Institute of Pathology, Medical University of Innsbruck
Department of Clinical Biochemistry, Statens Serum Institute, Copenhagen*

Introduction: Tetranectin is a plasma protein, which can be detected immunohistochemically in many normal cells. It is able to bind to the kringle-4 region of plasminogen and to participate in proteolytic processes that are considered to play an important role during tumor invasion and metastasis. Tetranectin expression was reported in breast, gastric and colon cancer being associated with a reduced survival in breast cancer.
The aim of the study was to investigate the expression of tetranectin in the normal bladder and bladder cancer.
Material and methods: Expression of tetranectin was studied in 20 invasive and non-invasive bladder tumors, including 9 low grade (5 grade 1, 4 grade 2 tumors) and 11 high grade tumors (3 grade 2, 8 grade 3 tumors) and in normal urothelium by means of immunohistochemistry using a monoclonal antibody against human tetranectin.
Results: Tetranectin was detected in normal urothelial cells, in the extracellular matrix, in inflammatory cells, in the smooth muscle of the bladder wall and in endothelial cells.
Non-invasive bladder tumors showed a weak tetranectin expression in superficial and intermediate cells.
In invasive tumors high expression of tetranectin was found in the invasive tumor component.
The extracellular matrix stained positive for tetranectin in non-invasive and invasive tumors, exhibiting a more intense staining around invasive tumor.
Conclusion: Stromal tetranectin expression is observed in the normal bladder and bladder cancer. The significance of this finding remains to be clarified.
The observed high cytoplasmic expression in invasive tumor cells suggests a potential role for tetranectin during invasion of bladder cancer.

2 Department of Pathology, Asklepeion Voula Hospital, Athens GR 166 73 Greece

Minichromosome maintenance (MCM) proteins are components of the prereplicative complex and thus essential for eukaryotic DNA replication. Their presence only in proliferating cells suggests a role as a novel proliferation marker. There is no previous study investigating MCMs in muscle-invasive bladder carcinomas. We analyzed immunohistochemically the expression of MCM-2 and MCM-5 proteins in 65 patients with muscle-invasive urothelial bladder carcinomas, in relation with clinicopathological parameters, patients' overall and disease-free survival and the expression of the conventional proliferation index Ki-67 and other cell-cycle modulators (p53, pRb, p21WAF1 and p27Kip1).
MCM-2 and MCM-5 levels were significantly higher in high grade ($p<0.0001$), advanced stage ($p=0.001$) and non-papillary tumors ($p<0.0001$). MCM-2 and MCM-5 protein ex-pression significantly associated with the conventional proliferation index Ki-67 ($p=0.0001$ for each protein). MCM-2 or MCM-5 expression positively correlated with p53 labeling index ($p=0.014$ and $p=0.009$ respectively). Also median p21WAF1 labeling index was higher in MCM-5 high expressors ($p=0.028$). Finally, both MCM-2 and MCM-5 associated significantly with adverse patients` outcome in both univariate ($p=0.0072$ and $p=0.0074$ respectively) and multivariate ($p=0.0001$) analysis.
In conclusion, MCM-2 and MCM-5 proteins appear to be reliable proliferative indices and useful prognostic markers in patients with muscle-invasive urothelial bladder carcinomas.

P 372
QUALITATIVE AND QUANTITATIVE ANALYSIS OF ANGIOGENIC FACTORS IN TRANSITIONAL CELL BLADDER CARCINOMA: RELATIONSHIP WITH CLINICAL COURSE AT 10 YEARS FOLLOW-UP

NESI Gabriella1, BARTOLETTI Riccardo2, CAI Tommaso2, GIRARDI Lucia Roberta1, SARDI Iacopo3, RIZZO Michelangelo2, TADDEI Gian Luigi1
1Department of Human Pathology and Oncology, University of Florence, Italy; 2Department of Urology, University of Florence, Italy; 3Department of Paediatrics (Onco-Haematology Unit), University of Florence, Italy

Aims: Many authors have shown that tumour hypoxia exerts its own influence on malignant progression by inducing angiogenetic factors and new blood vessels toward and within the tumour. This event usually suggests poor prognosis and/or aggressive tumour behaviour. The objective of this study is to compare molecular analysis of angiogenetic factors with microvessel density (MVD) in bladder cancer.
Materials and methods: Twenty-nine consecutive patients underwent transurethral or open surgery for bladder tumours. Neoplastic tissue samples, normal-appearing bladder mucosa and blood samples were taken from each patient. All the tissues underwent mRNA extraction and Northern Blot analysis, marked with specific probes for inducible Nitric Oxide Synthase (iNOS), Cycloxygenase-2 (COX-2) and Vascular Endothelial Growth Factor (VEGF), and evaluated by gel-electrophoresis. MVD, a quantitative analysis for neoangiogenesis, was also evaluated by using CD31 immunohistochemical assay and compared with molecular analysis and patient follow-up. Two follow-ups for recurrence or progression were performed at 74 months and 10 years from surgery, respectively.
Results: Pathological evaluation demonstrated the presence of superficial transitional cell carcinoma (sTCC) in 15 patients, while 14 had an invasive bladder tumour (iBT). At both 74 months and 10 years follow-up, all patients with lower MVD had a shorter survival time. No significant results were obtained by comparing disease progression or survival rate with VEGF, iNOS and COX-2 levels. A proportional increase of VEGF expression and MVD associated with poor prognosis was the expected outcome of our study. These results were disregarded at both the first and the second follow-up. A strong correlation between MVD >20 and survival rate was noted both in sTCC ($p=0.024$) and iBT ($p<0.001$) patients.
Conclusions: These results confirm that MVD could be considered a good prognostic factor. The angiogenetic cytokine overexpression found in control tissue samples of sTCC could have clinical significance in either a macroscopically unidentified diffuse carcinogenetic process or a systemic immune response against tumour cells.

P 373
MICROSATELLITE INSTABILITY AND SOMATIC DOWN-REGULATION OF MISMATCH REPAIR CHARACTERIZE SOLID MUSCLE-INVASIVE

TRANSITIONAL CELL CARCINOMA OF THE BLADDER

Alfredo Blanes(1) and Salvador J. Diaz-Cano(1,2)
(1) University of Malaga School of Medicine, Spain
(2) King's College Hospital-GKT School of Medicine, London, UK

Background: Histologic patterns have been demonstrated prognostically useful in transitional cell carcinomas (TCC) of the bladder, but no information is available on the prognoistic significance and genetic profile of muscle-invasive TCC by infiltration pattern. The contribution of DNA mismatch repair abnormalities to this profile remains unknown.
Design: The predominant infiltration patterns of 72 muscle-invasive TCC was assessed in the deep compartment and classified as "solid" (diffuse infiltration effacing the muscle fibers, 45 cases) or "single-file" (tumor infiltration dissecting the muscle and inducing an intense stromal reaction, 27 cases). Tumors were studied by compartments (superficial and deep to muscularis mucosa), DNA being extracted from both compartments to analyze the microsatellite pattern of TP53, RB1, WT1, and NF1 by polymerase chain reaction-denaturing gradient gel electrophoresis. Mitotic indexs, Ki67 index, in-situ end labelling (ISEL) and DNA ploidy analyses were evaluated in the same areas. Statistical differences were tested using ANOVA and Fisher's exact test. Mismatch repair was assessed by mlh1 and msh2 sequencing and immunostaining in TCC with >2 abnormal microsatellite loci.
Results: Single file TCC showed lower cell turnover (Ki67 index 14.94±4.28, ISEL 14.1±10.0), lower incidence of aneuploid DNA content, and shorter mean survival (20 months) than solid TCC (Ki67 index 20.65±4.94, ISEL index 20.2±22.7, and 37-month survival, respectively).
The genetic profile was demonstrated significantly different for RB1 (p=0.0003) and NF1 (p=0.0023) only. Single-file TCC showed a low incidence of genetic deletions/single nucleotide polymorphism(s), not involving RB1 locus, and very occasionally NF locus (2 cases, 13%). A significant decrease of mlh1/msh2 protein expression (absence of any of these proteins) with no gene mutations were identified in TCC with high microsatellite instability and solid growth pattern.
Conclusions: 1. Somatic down-regulation of mismatch repair proteins (mlh1/msh2) in solid muscle-invasive TCC results in microsatellite instability characterized by deletion/single nucleotide polymorphism(s) in RB1 and NF1. 2. This microsatellite instability profile correlates with the higher cellular turnover (both proliferation and apoptosis) and longer survival observed in patients with solid TCC (as compared with those of single-file TCC).

CYTOKERATIN 20 EXPRESSION IN UROTHELIAL CARCINOMA OF THE BLADDER: A HIGH-THROUGHPUT TISSUE MICROARRAY ANALYSIS CONFRONTING THE PRIMARY TUMOR AND ITS METASTASIS.

C. Mallofré, M. Castillo*, A. Gaspa, A. Petit , E. Campo .
Dpt. of Pathology, Hospital Clínic de Barcelona i Hospital Universitari de Bellvitge*

Introduction
Cytokeratin 20 (CK20) expression has been reported in a high percentage of urothelial carcinomas (UC) of the bladder, with no clear correlation with stage or grade, and it has poorly been studied in metastatic carcinoma.
The aim of our study was to determine whether CK20 was consistently expressed in metastatic UC.
Material and Methods
We studied all the cistectomy cases performed in our department from 1995 until 2004 with a diagnosis of UC, and found 45 cases which had developed metastatic disease. A Tissue Microarray (TMA) was built with duplicates of 0,6 mm cores of the 45 primary UC and their metastasis (31 nodal, 4 pulmonary, 4 osseous, 4 peritoneal and 2 to the urogenital area). CK20 immunohistochemistry was performed on 5mm sections (clon Ks20.8, Dako, dilution: 1/400).
Results
CK20 was positive in 45,4% of the primary UC and in 42,9% of the metastasis. In 54% of the cases, primary and metastatic disease showed the same pattern of expression (23% both positive, 31% both negative), while in 19% of cases there was a loss of CK20 expression in the metastasis compared to primary tumor. Unexpectedly, 27% of the primary UC were negative for CK20 and their metastasis were positive.
Conclusions
CK20 is generally considered a good marker of UC of the bladder, specially in combination with CK7. In our series, less than half of the primary UC express CK20, probably owing to high-grade histology. Furthermore, there is a decrease of CK20 expression in metastatic disease compared to primary UC. We think that CK20 is a good marker of UC of the bladder, specially in combination with CK7, and specially in low-grade and low-stage UC.

EXPRESSION OF CELL CYCLE PROTEINS IN BLADDER CARCINOMA

A. Goussia (1), V. Kordela (2), E. Sintou-Mantela (1), A. Zioga (1), I. Panelos (1), A. Charchanti (3), S. Dimou (1), N.J. Agnantis (1), M. Bai (1)
Department of Pathology (1) and Department of Anatomy-Histology-Embryology (3), Medical faculty, University of Ioannina, Department of Pathology, General Hospital of Preveza (2), Greece

The cell cycle is known to be deregulated in cancer. We therefore analyzed the immunohistochemical expression of cell cycle related proteins p53, Rb, p21, p16, p27 and cyclin D1 in 128 cases of transitional cell bladder carcinomas. The proliferation status was determined by Ki67, cyclin A and cyclin B1 protein expression. The expression of the proteins was correlated with clinicopathological parameters.
High expression of p53, p21 and cyclin D1 proteins (>10% of neoplastic cells)was detected in 64.7%, 16.5% and 32.5% of the cases, respectively. Low expression (<10% of neoplastic cells) of pRb, p16 and p27 proteins was found in 55.65%, 22.10% and 9% of the cases, respectively. Expression of Ki67, cyclin A and cyclin B1 proteins was found in all cases. Significant positive correlations were found between a) p53 and p21, Ki67, cyclin A, cyclin B1, b) pRb and Ki67, cyclin A, c) p21 and cyclin D1, cyclin A, when their expression was compared as continuous variables.
The following combined p53/p21 expression patterns (p53 pathway) were observed: p53+p21+ (13.91%), p53+/p21- (53.04%), p53-/p21+ (3.48%), p53-/p21- (29.56%). The combined Rb/p16/cyclin D1 expression patterns (Rb pathway) were: Rb+/p16+/cyclin D1+ (9.63%), Rb+/p16+/cyclin D1- (25.3%), Rb+/p16-/cyclin D1- (3.6%), Rb+/p16-/cyclin D1+ (7.23%), Rb-/p16+/cyclin D1+ (15.67%), Rb-/p16+/cyclin D1- (26.5%), Rb-/p16-/cyclin D1- (10.84%), Rb-/p16-/cyclin D1+ (1.20%). A significant correlation was found between combined p53/p21 expression patterns and cyclin A (p=0.002) and cyclin D1 (p<0.0001) expression. Moreover, cyclin A expression was correlated with combined Rb/p16/cyclin D1 expression patterns(p=0.040).
High expression of p53, Ki67, cyclin A and cyclin B1 (>10% of neoplastic cells) was negatively correlated with the papillary morphology of the tumor (p=0.026, p<0.0001, p<0.0001 and p=0.001, respectively) and positively with tumor grade (p=0.014, p<0.0001, p=0.002 and p=0.027, respectively) and T-stage (p=0.014, p<0.0001, p=0.004 and p=0.025, respectively).

These results suggest that alterations of cell cycle regulatory proteins are common in bladder carcinomas and may act in cooperative or synergistic ways to promote tumor progression.

P 376
HER-2/NEU OVEREXPRESSION AND AMPLIFICATION IN METASTATIC UROTHELIAL CARCINOMA OF THE BLADDER.
M. Castillo, A. Gaspa*, A. Petit *, C. Mallofré*. Dpt. of Pathology, Hospital Universitari de Bellvitge i Hospital Clínic de Barcelona*

Introduction
Studies reporting Her2Neu expression, both immunohistochemical and by fluorescence in situ hibridization (FISH) have shown varying results: some authors have suggested that Her2Neu gene amplification rates are low, in comparison with protein overexpression. The pattern of expression of Her2Neu in metastatic disease has not been almost studied.
The aim of our study was to determine Her2Neu status by immunohistochemistry (IHC) and FISH in metastatic bladder cancer.
Material and Methods
We studied all the cistectomy cases performed in our department from 1995 until 2004 with a diagnosis of UC, and found 45 cases which had developed metastatic disease. A Tissue Microarray (TMA) was built with duplicates of 0,6 mm cores of the 45 primary UC and their metastasis (31 nodal, 4 pulmonary, 4 osseous, 4 peritoneal and 2 to the urogenital area). FISH was performed using the Pathvysion kit (Vysis, Abbott), and IHC was performed on 5mm sections (CB11, Ventana) and evaluated as 0, 1+, 2+, and 3+.
Results
Only 6% of the primary UC and 8,6% of the metastasis show amplification by FISH, and correspond to the 3+ results by IHC. 91,1% and 3% of the primary neoplasms and 80% and 11,4% of the metastatic tumors are IHC negative and show 2+ positivity for Her2Neu, but none of them are amplified by FISH.
Conclusions
Her2Neu is not frequently amplified in bladder carcinoma, not even in metastatic disease. All the cases with a 2+ IHC result are not amplified in our series, and perhaps the performance of FISH is not necessary in those cases.

Department of Pathology, Veterans Administration Hospital of Athens, Greece (3)

Introduction: Primary bladder adenocarcinomas (PBAs) represent a small fraction of bladder tumors (1-2%). Their differential diagnosis from other metastatic adenocarcinomas can be difficult on histological basis alone, and the combined use of Cytokeratin (CK) 7 & 20 does not always seem to resolve the problem. Relatively new, urothelial specific diagnostic markers, such as Uroplakin-III (UPIII), are commercially available for immunohistochemistry.
Purpose: To investigate the possible diagnostic value of UP-III immunohistochemical detection in PBAs, as well as, in a small number of lesions with true glandular differentiation, arising in the bladder.
Methods: Seven cases of PBA, one villous adenoma with mucin producing cells and two cases of enteric type urothelial metaplasia were retrieved from our files. The material was re-evaluated and stained with monoclonal antibodies against CK7, CK20 and UPIII using appropriate positive and negative controls, according to standard procedures. A streptavidin-biotin based detection system was employed, using diaminobenzidine as chromogen. The staining reaction was assigned semiquantitatively; the cut-off point was set at 5%.
Results: Regarding the panel of CK7/20 four PBAs were (+/+); one (+/-); two (-/+). The adenoma and the metaplastic lesions were (+/+). UPIII was positive in almost all cases (9/10), including (6/7) PBAs regardless of their histologic subtype. The staining pattern was cytoplasmic with focal membrane accentuation. The staining intensity and the percentage of positive cells were variable.
Conclusions: UPIII seemingly represents a valid, constant diagnostic immunohistochemical marker for PBA and can contribute to their differential diagnosis, providing evidence for their urothelial origin, even in cases with frankly enteric phenotype.

P 378
LOH AND FISH ANALYSIS FOR THE DETECTION OF BLADDER CANCER FROM VOIDED URINE SPECIMENS: A PRELIMINARY STUDY REPORT
FRIGERIO Simona (1), PADBERG Barbara (1), STREBEL Räto (2), LENGGENHAGER Daniela (1), MESSTHALER Angelika (1), ABDOU Marie-Therèse (1), MOCH Holger (1), JOHN Hubert (2) and ZIMMERMANN Dieter (1)
Department of Pathology (1), and Department of Urology (2), University Hospital Zürich, Switzerland

Introduction: Successful treatment of bladder cancer depends largely on early detection of primary and recurrent disease. As cytology alone is too unreliable to serve as a basis for therapy decision, improved laboratory tests are needed. Today, loss of heterozygosity (LOH) and fluorescence in situ hybridization (FISH) are the most promising assays to detect early tumor-specific genetic alterations in cytological specimens. We chose to set up and validate a LOH method, which involves analysis at 10 microsatellite loci on chromosomes 8p, 9q, 9p, 13q, 16q and 17p. Ambiguous cases were additionally analysed by FISH.
Methods: Matched biopsies and urines from patients scheduled for tumor resection were collected prospectively and examined by routine histology and cytology. LOH analysis was performed using fluorescence-labeled primers and capillary electrophoresis. FISH analysis was done according to the manufacturer's recommendations (UroVysion, Vysis).
Results: Preliminary analysis were performed on 62 urine samples from patients with histological confirmed diagnosis of bladder cancer (carcinoma in situ pTis: 8; non-invasive papillary pTa: 10 G1, 22 G2, 3 G3; invasive papillary pT1: 2 G2, 9 G3 and pT2: 8 G3). Chromosomal aberrations were detected in 47 urine samples (76%), while 15 were LOH negative (mostly pTa G1-2 tumors). Remarkably, the sensitivity of LOH for low grade tumors (G1-2) was superior to cytology (69% vs. 26%). Most genetic aberrations were associated with losses at 9p and 9q, confirming a pivotal role of these regions for bladder tumorigenesis, while LOH on chromosome 8p, 13q, 16q and 17p rather correlated with advanced tumor grade and stage. To date, FISH analysis was performed on 13 urines. There were 10 histologically positive carcinoma cases (2 pTa G1-2, 2 pTa G3, 3 pT1-2 G3 and 3 pTis), of which 7 exhibited chromosomal instabilities, while 3 were scored as normal. Out of 3 histologically tumor-free cases, 2 were FISH-negative and 1 FISH-positive. Comparing

the two methods, identical LOH and FISH positive as well as negative results were documented in 7 histologically corresponding cases. Clinical follow-up is currently ongoing for the other 6 ambiguous cases.
Conclusions: Preliminary data show that both LOH and FISH analysis improve the sensitivity of voided urine specimens for the detection of bladder cancer.

DETECTION OF PRIMARY UROTHELIAL CARCINOMA IN VOIDED URINE SPECIMEN USING FOUR PROBE FISH ASSAY COMBINED WITH AUTOMATED MICROSCOPIC SYSTEM, A PROSPECTIVE STUDY

PAJOR Gábor(1), KNEIF Maria(1), CSALA Judit(1), FARKAS László M.D.(2), SOMOGYI László M.D.(2), PAJOR László M.D.(1), SÜLE Norbert M.D.(1)
(1) Department of Pathology, University of Pécs Medical School
(2) Department of Urology, University of Pécs Medical School

INTRODUCTION: The gold standard to diagnose urinary cancer is urinary cytology combined with cystoscopy. The low-grade urothelial cancer and early detection of recurrences are the greatest diagnostic challenges and many attempts are made to make the urinary cytology screening more sensitive and specific especially in these two critical cases. The literature is flooded with different methods including different immunologic and genetic testings like microsatellite instability assays and FISH. It seems that FISH assays will play an important role in the future in the cytology laboratory.
PURPOSE: Determination of the effectiveness of an automated microscopic system in the detection of chromosomal changes in uroepithelial cancer.
METHODS: We have analyzed 19 patients with primary uroepithelial cancer. Conventional urinary cytology coupled with cystoscopy and biopsy in each case was performed. From the collected voided urine we have analyzed three preparations processed with three methods. After optimizing the cell count in cyto-chamber we used the alcohol fixed specimen for FISH analysis. The preparations were evaluated by Zeis Axioplan2 automated microscope combined with Metasystem/Metacyte-Metafer4 software and/or manually counted (150-300 cells).
RESULTS: Histologically evident uroepithelial carcinoma was present in 16 cases (grade I/II/III: 3/8/5 respectively). The cytology evaluation of the voided urine specimen could prove the presence of neopastic cells in 10 cases (62.5%) and was suspicious in 4 cases (25%). One result was negative and one was unsatisfactory. Automated detection system could identify surprising number of chromosomal abnormality even in histologically negative cases (average 31 cell; 7.81%). The number of cells carrying chromosomal abnormality was significantly lower in low grade vs. high grade tumors (G1:45 cells; 5,18% vs.G2:248,5; 16,77% and G3:146,8; 17,39%). Similar correlation could be observed in in situ vs. invasive (pTa:78 cells, 7,41%;vs. pT1:272,67, 19,67%; pT2:102,5, 16,3%). The control manual counts gave similar results.
CONCLUSION: Using Zeis Axioplan2 automated microscope combined with Metasystem/Metacyte-Metafer4 software is a powerful method to detect chromosomal changes in voided urine cytology specimen. The criteria defining positive diagnosis need to be adjusted, because the original Urovysion criteria was established on manual evaluation which required only the presence of 25 morphologically abnormal cells.

P 380
LIMPHOEPITHELIOMA-LIKE CARCINOMA OF THE BLADDER. CASE REPORT AND REVIEW OF THERAPEUTIC MANAGEMENT

TERRASA fernando, GARCÍA magdalena, ARRIVI antonio, REBASSA miguel.

Introduction
Lymphoepithelioma-like carcinoma (LELC) of bladder is an extremely rare tumor. In the bladder, Zuckerberg and col. first describe this tumor as a part of a series of carcinoma simulating lymphoma. The origin of this tumor is unknown although it is suspected that it originates from modified urothelial cells. Initially it was classified as a neoplasm with a poor prognosis, but actually it is recognized its sensitivity to chemotherapy and a more long-term prognosis when compared with other types of carcinomas of bladder of equivalent stage and grade.
Case report
We present, a case of LELC diagnosed and treated at our Institution. The case is that of a 70 years old male with two years history of hematuria. A transurethral resection (TUR) of the bladder tumor was carried out after multiple inconclusive imaging studies, cystoscopy and urine cytologies. The histologic diagnosis of LELC with tumor infiltration of the muscle layer, led to 4 cycles of chemotherapy treatment with cysplatin and ethoposide based regimens, and no additional surgical interventions. 18 months later, the patient was well and free of disease.
Results and conclusion:
Microscopically, the tumor showed a neoplastic cell proliferation composed of sheets and nests of atypical cells with scarce eosinophilic cytoplasm and large vesicular nuclei with prominent nucleoli and numerous mitosis. The tumor invaded into the muscle layer of the bladder, and was accompanied by a prominent inflammatory reaction. The bladder mucosa was focally ulcerated, and we did not identify areas of carcinoma in situ or conventional bladder carcinoma elsewhere. Immunohistochemically, tumor cells showed strongly positive cytoplasmic staining for Keratin (CK) AE1/AE3 and epithelial membrane antigen; and were focally positive for CK 7 and 8. Neoplastic cells were negative for CK 20. Immunostaining for Epstein-Barr virus was negative. All these findings are concordant with those of reported LELC cases in this location. Invasive LELC of bladder, according to the criteria of Amin et al., are classified as pure (all lymphoepithelial elements), predominant (more than half) or focal (less than half). It is well established that the two first types, are tumors that respond well to chemotherapy. It is important to recognize these tumors, and distinguish them for conventional transitional tumors with focal LELC differentiation, in order to administrate appropriate treatment and avoid cystectomy in these patients.

PRIMARY SMALL CELL NEUROENDOCRINE CARCINOMA OF THE URINARY BLADDER : AN IMMUNOHISTOCHEMICAL STUDY OF 15 CASES.

TRIAU Stéphane(1), KOFFI Emmanuel(1), LAVOINE Eric(2), JOSSELIN Nicolas(1), SAINT-ANDRE Jean-Paul(1), ROUSSELET Marie-Christine(1).
(1) Department of Pathology, University Hospital, 4 rue Larrey, 49933 Angers Cedex 09 France. (2) Pathology Center, 2 rue de l'Appentis, 49022 Angers, France.

Introduction : Primary small cell neuroendocrine carcinoma (SCC) of the urinary bladder is a very rare entity (0.5% of urinary bladder tumors). Its morphology may overlap with poorly differentiated urothelial carcinoma but SCC must be clearly distinguished because of differences in treatment and prognosis. We investigated the immunohistochemical expression of epithelial growth factor receptor (EGFR) and some other markers in a series of 15 SCC.
Methods : We studied synaptophysin, CD56, chromogranin A and B, cytokeratin (34betaE12) p16, p53 and EGFR reactivity in 15 consecutive cases diagnosed between 1990 to 2005 on

transurethral resection (9 cases), radical cystectomy (1 case) or both (5 cases). Ten cases were fixed in formalin, 5 in Bouin's fluid.
Results : In 13 cases (87%), the SCC was associated with an urothelial carcinoma which was a minor component in all but one case and was invasive in 8 cases, in situ in 2 cases or both in 3 cases. A reactivity with 2 or more neuroendocrine markers was observed in all cases. Synaptophysin was positive in all cases, CD56 in 13 cases (87%), chromogranin A in 12 cases (80%) and B in 9 cases (60%). 34betaE12 was always negative on SCC but was expressed by the urothelial carcinoma component while p16 was positive on both components in all cases. All tumors fixed in formalin presented a high expression of p53. Nine SCC (60%) expressed EGFR in at least 5% to more than 50% of cells.
Conclusion : In poorly differentiated tumors of urinary bladder, neuroendocrine markers must be used with 34betaE12 to differentiate SCC from poorly differentiated urothelial carcinoma. As in small cell carcinoma of the lung, we found an over-expression of p53 and p16 that might be related to a disruption of the Rb pathway. EGFR is expressed in a majority of SCC of the urinary bladder thus suggesting a possible therapeutic role for EGFR inhibitors.

Indroduction: Adenocarcinoma (AC) of the bladder is a rare entity and has several architectural variants: the “enteric-type” is the most common one and shares morphological and immunophenotypic features with conventional colorectal carcinoma. Although the occurrence of neuroendocrine (NE) differentiation in ACs from various sites, lung, colon and prostate, among the most relevant has been widely reported, in the bladder only rare case reports have been documented. cells, as known in colorectal, prostatic (but not in urothelial) carcinomas, among others.
The purpose of this study was to investigate the occurrence of NE differentiation in bladder AC and non–neoplastic glandular lesions.
Methods: Sixteen primary bladder ACs (6 urachal) and 4 urothelial carcinomas with glandular differentiation (UGCC) were collected. The UGCC had high grade urothelial carcinoma areas admixed with enteric-type glands (5-80% of the tumor). ACs were subclassified into enteric-type (7), mucinous (6) and NOS (3 cases) variants. To classify a case as “urachal adenocarcinoma” we applied the criteria proposed by Johnson and coworkers [1985]. In addition 20 glandular cystitis, 3 urachal cysts, 15 urothelial carcinomas and 3 small cell carcinomas were also collected as control groups. NSE, synaptophysin and chromogranin A immunostainings were performed. Clinico-pathological and outcome data were available for all but one case.
Results: Panendocrine markers gave heterogeneous results: NSE was negative, synaptophysin was focally positive in two cases, and chromogranin-A revealed NE differentiated cells in 12/20 cases (60%) (all enteric-type and mucinous carcinoma variants). All urachal cysts and 70% of glandular cystitis also had chromogranin-A reactive cells. Control urothelium and urothelial carcinomas (but not 3/3 small cell carcinoma) were chromogranin-A negative. No correlation was found between NE differentiation and clinical (including outcome) or pathological parameters. At follow up, 50% of patients had fatal outcome. In patients died of disease, the mean survival was 40 months (ra

PARAGANGLIOMA OF THE URINARY BLADDER: REPORT OF THREE CASES
KILICASLAN Isin*, OZTURK A. Sanem*, MIROGLU Cengiz**, BOZBORA Alp***, UYSAL Veli*
*Istanbul University, Istanbul Faculty of Medicine, Department of Pathology
**Sisli Etfal Training and Research Hospital, Department of Urology
***Istanbul University, Istanbul Faculty of Medicine, Department of General Surgery

We present three cases of urinary bladder paraganglioma. One of them is a tumor resection of a patient with typical micturition attacks. The other two are transurethral resection materials consultated to our department. One of these two patients was diagnosed as urothelial carcinoma and the other one was diagnosed as adenocarcinoma and urothelial carcinoma in two different pathology departments. As we learned later, one of these patients had an hipertension attack during the biopsy procedure.
Microscopical examination of all three cases revealed the typical cellular and vascular arrangement of paragangliomas. Focal pleomorphism was remarkable in one of the cases. Submucosal invasion was detected in the transurethral resection materials. In the partial cystectomy material the tumor was located in the muscular layer. The negative immunohistochemical reaction of the tumor cells with pancytokeratin, cytokeratin 7 and cytokeratin 20 helped to rule out urothelial carcinoma. The tumor cells showed diffuse immunoreactivity with chromogranin A, synaptophysin and neuron specific enolase and the sustentacular cells stained positive for S100 protein. Based on these immunohistochemical findings we diagnosed the tumors as paraganglioma. The Ki67 proliferation index of the tumors were 1-2%.
The invasion of lamina propria and the muscular layer of paragangliomas is the misleading point of the transurothelial resection materials. The pathologist must take paraganglioma into consideration in the differential diagnosis of these materials not to miss out the cases.

P 384
PARAGANGLIOMA OF URINARY BLADDER
GHAINI M.Hossein, FROOTAN Kazem, SAKI Soheil

Urinary bladder is a rare site of paraganglioma. We describe a paraganglioma of the urinary bladder in a 51-year-old female who presented with painless gross hematuria. Abdominal ultrasonography revealed a protruding well-defined mass, about 3Cm. in diameter over the left lateral wall of the urinary bladder. The tumor was not completely resected by transurethral resection of bladder tumor (TURBT) due to involvement of the bladder wall. Histologic examination of the tumor indicated clustersof polygonal chromaffin cells, arranged in nests (zellballen). Although there was marked pleomorphism and atypia in nuclei, no evidence of recuurence or metastasis has seen since about 1 year. There is no reliable method for predicting their clinical behavior, so long-term follow-up is required. We also provide a brief review of the literature for comparison.

P 385
SARCOMATOID TRANSITIONAL CELL CARCINOMA OF URACHUS:A CASE REPORT
SETARESHENAS Roya,AZIZI Rasoul,
Assistant Professors of Iran Medical Science University.

Tumors of urachus duct which is remnant of embryonic

allantoic duct are rare.We report a case of transitional cell carcinoma of urachus in a 54 Y/O man with chief complaint of abdominal wall mass.The mass had adhesion to anterior abdominal wall and also extension to dome of bladder.By operation the mass and small part of wall of bladder were excised.

Cut section of mass showed a cyst inside,with tumoral lesion around.Histilogically the tumor was transitinal cell carcinoma of variable degrees and also sarcomatoid pattern in some areas.Smooth muscles of urachus wall and also bladder wall were invaded by tumor,but surgical margins and two detected lymph nodes were free.

It seems that this patient is the first reported case of sarcomatoid carcinoma of urachus.

P 386

SARCOMATOID TRANSITIONAL CARCINOMA OF URACHUS(A CASE REPORT)

SETARESHENAS Roya,AZIZI Rasoul

Urachus duct which is remnant of embryonic allantois duct,may show neoplastic lesions rarely.The most common tumor of urachus is adenocarcinoma,but squamous cell carcinoma and transitional cell carcinoma(TCC) has also been reported.

We report a case of sarcomatoid TCC of urachus in a 54 year old male who presented with abdominal wall mass.

Abdominal CT-Scan and sonography detected a mass in lower abdomen between umbilicus and symphisis of pubis with minor attachment to bladder.Cystoscopy was normal.

Operation consisted of exicion of mass and small part of bladder wall.Cut section of mass showed a cyst inside with tumoral lesion including necrosis around,surrounded by muscular and fatty tissues.

Microscopically the tumor was TCC with variable degrees and also sarcomatoid patterin some areas. Smooth muscle of urachus and bladder wall were invaded by tumor but striated muscles,surgical margins and 2 detcted lymph nodes were free.

It seems this is the first reported case of sarcomatoid carcinoma of urachus.

P 387

HISTOPATHOLOGIC ASSESSMENT OF ANGIOGENIC RESPONSE IN DIFFERENT URINARY BLADDER LESIONS.

NOSSEIR Mona, AKL Maha.
Pathology Department. Theodor Bilharz Research Institute

This study was designed to evaluate the angiogenic activity in chronic bladder lesions (chronic cystitis and schistosomal cystitis) in comparison to bladder tumors, as well as its relation to the stage of invasiveness of bladder carcinoma. The pattern and state of vascularization of bladder lesions could provide novel therapies using anti-angiogenic agents.
Methods: The current study included 75 cases of urinary bladder lesions representing 12 cases of chronic non-specific cystitis, 12 cases of schistosomal cystitis, 31 cases of transitional cell carcinoma (TCC), 13 cases of squamous cell carcinoma (Sqcc), 7 cases of urothelial dysplasia; in addition to 5 control cases of apparently normal bladders. All cases were first diagnosed and studied by hematoxylin and eosin. Then all were assessed for the expression of both basic fibroblast growth factor (bFGF); within epithelial cells, endothelial cells, fibroblasts and macrophages, and Factor VIII-related antigen (von Willebrand Factor ,vWF); delineating endothelial cells at the wall of blood vessels, using a standard immunohistochemical technique. Positive expression for bFGF was scored as 3+,2+&1+, while microvascular density (MVD) was calculated through counting the microvessels positively stained for Factor VIII-related antigen in five successive hot spots. Results: Expression of bFGF and MVD were significantly higher in malignant bladder cases, especially in advanced stages, compared to chronic cystitis cases. Schistosomal cystitis cases showed marked angiogenic activity. Conclusion: High angiogenic response in non-invasive early stage of bladder cancer could predict recurrence and metastatic potentiality. Tumor invasive capability is directly correlated to the increase in its angiogenic activity. Marked angiogenesis in schistosomal cystitis could provide a favorable environment for tumorigenesis, thus they are commonly recorded in association.

ADENOCARCINOMA OF THE URINARY BLADDER ASSOCIATED WITH SCHISTOSOMIASIS IMMUNOHISTOCHEMICAL PROFILE

NADJI mehredad**, SHOMAN sohair*, EISSA saad*, NASSIRI mahdy**.
Departments of Pathology, NCI, Egypt* and University of Miami, Florida, USA**.

INTRODUCTION
Primary nonurachal intestinal adenocarcinomas of the urinary bladder are frequently associated with chronic irritation of bladder mucosa and a background of intestinal metaplasia and/or intestinal type cystitis glandularis.
PURPOSE OF THE STUDY
The morphology and immunophenotype of 102 cases of bladder adenocarcinoma associated with schistosomiasis were reviewed, and special attention was paid to the presence of associated metaplastic or preneoplastic changes.
MATERIAL & METHODS
One hundred two partial or radical cystectomy specimens performed at the National Cancer Institute, Cairo, Egypt with the diagnosis of primary adenocarcinoma were studied. Biographic data and clinical information including clinical stage, type of therapy and follow-up were reviewed. The histopathology of tumor, pathologic stage and variation in cell type was recorded in all samples. Special attention was paid to the status of non-involved bladder mucosa for the presence of intestinal metaplasia and/or cystitis glandularis. Five representative paraffin blocks from each case were selected for immunohistochemical studies.
Four micron paraffin sections were stained by a standard labeled streptavidin-biotin method using antibodies against cytokeratin 7 and cytokeratin 20 (M7018 and M7019), p53 (M3566), HER-2/ neu (A0485) and Cathepsin D (A0561) [DakoCytomation, Carpinteria, CA], heat-induced antigen retrieval using citrate buffer in a vegetable steamer. DAB was used as chromogen in the presence of hydrogen peroxide. The presence, pattern and intensity of immunohistochemical reactions were evaluated in both tumor cells and in non-neoplastic epithelium.
RESULTS
The tumors occurred predominantly in trigone, lateral, or posterolateral walls. None of the tumors involved bladder dome or the anterior wall. The study cohort consisted of 64 male and 38 female patients (male-female ratio, 1.7:1.0) ages 25 to 78 (mean, 50.3 years). Most frequent presenting symptoms were hematuria and irritation. In all patients, partial or radical cystectomy was performed followed by radiation therapy. The clinical stage of disease and the follow up data are as follows; 73 patients (72%) presented with advanced disease (T3 and T4), 56 of whom (78%) were either dead from the disease or alive with cancer during the 36month follow up period. Five patients with the predominant signet ring cell type adenocarcinoma were all dead of the disease in less than 15 months after the diagnosis.

P 389

PREVALENCE OF P53 AND KI-67 IMMUNOREACTIVITY IN CHRONIC URINARY BLADDER LESIONS

BADAWY Afkar, NOSSEIR Mona,and MOUSSA Mona.
Pathology Department, Theodor Bilharz Research Institute.Cairo,Egypt.

Early detection of alterations affecting p53 and/ or ki-67 control pathways will affect the clinical course of the disease and tumor progression.
The aim of this study was to investigate the expression of mutant p53 oncoprotein and the proliferative marker ki-67 in a series of non-neoplastic and neoplastic urinary bladder lesions with or without schistosomal infection using immunohistochemical staining on formalin-fixed, paraffin embedded sections. Its relation to traditional prognostic indicators (grades and stages) of malignant lesions was assessed.
Cystoscopic biopsies from (66) cases, received in the Pathology Department of TBRI were examined including; 22 cases of chronic cystitis (16 were schistosomal in etiology and 10 were associated with premalignant changes) and 44 cases of malignancy (34 cases of transitional cell carcinoma (TCC) and 10 cases of squamous cell carcinoma (SqCC)). Four normal controls were also added. Grades and stages of malignant cases according to World Health Organization Scheme were studied in sections stained with Hx.&E.. Scoring of the immunohistochemical nuclear expression of p53 and ki-67 for all cases was performed . Results were compared with those of control bladder specimens. Nuclear staining for p53 could not be detected in normal urothelium or in cases with cystitis (whether bilharzial or not) , but it was expressed in presence of premalignanant changes with significant over-expression in bilharzial versus non bilharzial cases. p53 over-expression accentuated in malignant lesions and correlated with upgrading of malignancy. Ki-67 was variably expressed in hyperplastic urothelium of cystitis cases, over-expressed in premalignant and malignant lesions with significant correlation to schistosomal association in malignant cases, to grade of tumor differentiation, and to p53 overexpression.
Assessment of both markers can yield prognostic information that is more powerful than what behavior alone can provide.

P 390

E-CADHERIN AND EPITHELIAL MEMBRANE ANTIGEN EXPRESSION IN SCHISTOSOMAL URINARY BLADDER LESIONS .

BADAWY Afkar and HAMMAM Olfat.
Department of Pathology, Theodor Bilharz Research Institute. Cairo, Egypt.

Urothelial immunohistochemical tissue expression of the epithelial cell-to-cell adhesive molecules: E-cadherin and Epithelial Membrane Antigen (EMA) were assessed in 66 cases with chronic urinary bladder lesions (benign, premalignant, and malignant) with or without schistosomal infestation to estimate a possible role of schistosomiasis in disruption of these adhesive antigens with its consequent relationship to pathological prognostic features of bilharzial related bladder carcinoma versus non bilharzial one. Normal urothelium expressed E-cadherin and EMA as uniformly membranous immunostaining of high intensity, localized to epithelial cell membranes. The staining intensity of both E-cadherin and EMA declined in chronic non specific cystitis, with significant limitation in extent of positively stained urothelial cells in chronic schistosomal cystitis. In advance, both antigens were expressed in a heterogenous pattern with loss of staining in basal urothelial layers and its preservation in superficial cells in cystitis cases with dysplastic changes. In malignant cases, the extent and intensity of staining of both antigens significantly diminished with alteration of their membranous immunoreactivity into heterogenous staining pattern and even cytoplasmic or nuclear accumulation which was more evident in T.C.C than in Sq.C.C cases. Upgrading and invasiveness of malignancy correlated with changing pattern of expression of E.M.A and E-cadherin, and with loss of urothelial positivity extent and intensity of E-cadherin rather than EMA. Schistosomal association in malignant cases correlated with more diminution in staining intensity of both antigens, and with advanced alteration in their pattern of expression which may facilitate tumor invasiveness and explain presentation of schistosomal associated cancer bladder at advanced stages.

In conclusion, it is the altered expression of E-cadherin and EMA that reflect neoplastic urothelial process rather than percentage of stained cells or their staining intensity. Schistosomal cystitis progressively minimize EMA and E-cadherin secretion than do non specific cystitis with advanced alteration in their expression pattern when complicated by malignancy process versus non schistosomal related bladder malignancy. Assessment of E-cadherin and EMA immunoreactivity may be a useful histologic prognostic marker in schistosomal cystitis and schistosomal related cancer bladder.

P 391

COMPARATIVE PATHOLOGIC ANALYSIS OF RENAL NEOPLASMS DEVELOPED IN PATIENTS WITH ERDS AND BACKGROUND RENAL CHANGES

SULE Norbert, YAKUPOGLU Ulkem, SHEN S. Steven, KRISHNAN Bhuvaneswari, TROUNG D. Luan

INTRODUCTION:
Patients with end-stage renal disease (ESRD) show increased incidence of acquired cystic kidney disease (ACK) and development of renal tumors. In a recent study demonstrated prominent calcium oxalate (CO) deposition in these carcinomas.
PURPOSE:
Complete phenotypic and immunologic profiling of benign and malignant neoplasm and determination the extent of CO deposition in the tumors and parenchyma.
METHODS:
We performed a retrospective analysis in a 13-year period to identify ACK-associated renal neoplasms. We compared the main pathologic features, immunologic profile and proliferative rate of the malignant and benign tumors. The severity of CO deposition was semiquantitated (0-4+) under polarizing microscope. RCC Marker, CD10, EMA and kidney specific cadherin (KSC) stains were performed and the intensity was graded (0-4+). The number of proliferating cell was determined by Ki-67 in 10 high power fields.
RESULT:
We identified 30 renal cell carcinomas with background changes of ESRD. Two histologic appearances were dominant: clear cell carcinoma (13, 43.33%) and oxalate type (8, 26.67%). We also identified 4 papillary (13.3%), 1 chromophobe (3.33%) and 1 sarcomatoid carcinoma (3.33%). Three tumors were necrotic and were not classified in either group. CO deposition was present in 8 neoplasms. Immunologic profile of the clear cell and the 3 necrotic tumors, which probably represented also clear cell carcinoma judged by the residual morphological features, showed EMA positivity (>3+; 76.92% and 100%, respectively); oxalate and sarcomatoid type had dual expression of RCC marker (>3+; 62.5% and 100%, respectively) and CD10 (>3+; 100% both). Papillary carcinoma expressed strongly EMA (4+; 100%) and had and intermediate CD10 intensity (2+; 100%). Chromophobe type displayed a combined expression of EMA and KSC (4+ each). No increased mitotic activity was detected. In the kidneys we identified 21 adenomas: one necrotic and 20 with either oxalate (8, 38.09%) or papillary phenotype (12, 57%). CO was identified in 4 cases, all associated with oxalate phenotype. Cystic changes were

present in all kidneys and combined with CO crystals in 11 cases.
CONCLUSION:
CO deposition in ACK-associated renal lesions is common. Distinct, recently described tumor morphology is evident, which defies the current classification. Proximal tubular cell differentiation in conjunction with ESRD-mediated high serum level of CO may be important in the pathogenesis

P 392
MORPHOLOGIC, ULTRASTRUCTURAL AND HISTOCHEMICAL STAINING CHARACTERISTICS OF CHROMOPHOBE RENAL CELL CARCINOMAS

Bahram Shahgoli(1), Natasha Djurdjevic(2),Slobodan Bojovic(2)
Department of pathology, University Clinical-hospital center "Zvezdara" Belgrade,Serbia&Montenegro

Morphologic, ultrastructural and histochemical staining characteristics of
Chromophobe Renal Cell Carcinoma
Introduction: Approximately 5% of renal cell carcinoma in surgical series are chromophobe renal cell carcinoma.It is rare in the first two decades of life.Althought obesity,smoking,hypertension and exposure to industrial chemicals have been implicated as risk factors in the genesis.An association with von Hippel-Lindau disease is seen in occasional cases.Associations also exist with tuberous sclerosis and autosomal dominant polycystic kidney disease.The genetic hallmark of chromophobe renal cell carcinoma is the loss of multiple chromosomes.
Case: 70 years old male presented with complaint of hematuria and pain in the flank.Ultrasonography and computerized tomographic scan show a solid mass in the left kidney.The diagnosis was obtained of the hematoxylin and eosin (H&E), histochemical stained slides and ultrastructural findings..
Results: On gross examination a well –circumscribed,solid tan mass is identified.Microscopically ,characterized by mosaic pattern composed of large and small cells with reticular cytoplasm,well-defined thick cytoplasmic membranes.The Hale's colloidal iron stain colors the cytoplasm blue.Ultrastructurally,the cytoplasm of chromophobe cells is crowded with many small vesicles.
Conclusion: The eosinophilic variant of chromophobe cell renal cell carcinoma was recognized.This variant shares the ultrastructural and colloidal iron staining features of the typical variant but in H&E stained slides often closely resembles renal oncocytoma.For this reason,it is worthwhile routinely to collect specimens for electron microscopy from renal tumors,especially those which do not have the yellow color characteristic of clear cell renal cell carcinoma.

P 393
YOLK SAC TUMORS : A REPORT OF 9 CASES
MNIF Hela, KHABIR Abdelmajid, AYADI Lobna, GHARIANI Mekki, BAHLOUL ALI, BOUDAWARA SELLAMI Tahya

Introduction
A single institution review of epidemiological, clinico-pathological and immunocytochemical features, and prognosis of yolk sac tumor
Materiels and Methods
We report a retrospective study performed of 9 cases of yolk sac tumor accessioned at the pathologic anatomy and cytology laboratory of the University Teaching Hospital of Sfax between 1983 and 2003.
Results:
Presentation occurred at a median age of 18 months (range 8 months to 24 months).The interval between children¡¯s first symptoms and diagnosis was 2,2 months (rang 1 to months). Clinical presentation occurred most often (88, 88%) with testicular lump. Seven patients had stage I and two patients had stage II according to the Baden classification.
The anatomopathological study confirmed the diagnostic. The germinal testicular tumor presented a structors that showing the yolk sac of the human embryon. Two pathognomical histological signs were most often presents (66, 66): the Schiller Duval body and hyaline globules. The immunohistochemical study showed that this tumor over expressed the ¦Á-foetoprotein (AFP) in 100% of the cases. The radical orchidectomy was indicated in all cases. It was associated with chemotherapy in advanced tumors.
Prognostic factors included age, clinical stage, rate of AFP, vascular or lymph node involvements, local extension, tumor¡¯s size, proliferated molecular factors = AND¡¯s index, proliferated cellular nuclear Antigen PCNA, ki 6l and molecular genetically factor= oncogen hst-1
Conclusion:
The testicular tumors in pr¨¦pubertal children and especially the yolk sac tumors have an excellent prognosis the overall 5 years survival range 95 to 100%.
Prospective study will be effective to establish a therapeutical consensus between differents equips.

Athens,Greece.

INTRODUCTION
Solitary fibrous tumor is a rare spindle-cell neoplasm of uncertain histogenesis and with potentially aggressive behaviour.It usually arises on serosal surfaces with infrequent involvement of other sites.Renal and paratesticular SFTs are extremely rare and only 9 intrarenal,intrapelvic and parapelvic and 3 paratesticular cases have been reported in the international literature respectively.
AIM
Two cases of SFTs,one large renal and one paratesticular are reported with review of the literature and emphasis on the differential diagnosis from other mesenchymal or epithelial spindle cell neoplasms.
MATERIALS - METHODS
Case 1.A 79 years old man was operated for an asymptomatic solid tumor of the left kidney at CT-scan.The tumor was 12 cms in greatest diameter,well circumscribed,round,with smooth surface,firm consistency,whorled appearance and grey-white in colour with hemorrhagic areas without involvement of the pyelocalycic system.
Case 2.A 27 years old male had a palpable,nodular,painless left intrascrotal mass.At operation,a well circumscribed 3 cms binodular tumor between the tunica vaginalis and the dartos was removed.Sections were examined with H+E,PAS,PAS-D and the immunophenotype was determined with the Envision-HRP method for the detection of MCK,Vimentin,Desmin,a-SMA,CD31,CD34,CD99,CD68,Bcl-2,HMB-45,GFAP,NSE,NF,Ki-67 and C-kit.
RESULTS
Both tumors were encapsulated,non-invasive,composed of spindle cells with storiform,diffuse or fascicular growth pattern of varying cellular density and scattered wide collagen bundles.The renal tumor at the centre was vascular with loosely arranged cells and an atypical mitosis.Additional features:myxoid areas with scattered multinucleated cells,a marked chronic perivascular inflammation and focal

hyalinization of the vascular walls.The neoplastic cells of both tumors were Vimentin,CD34 and CD99 positive.Bcl-2 expression was either diffuse in the paratesticular SFT or reduced/absent in the central vascular area of the renal SFT.NSE and CD68 focal positivity was observed in the paratesticular SFT.Ki67<2% and <2 mitoses per 10 HPF.
CONCLUSIONS
SFT has a characteristic growth pattern and immunophenotype(Vimentin,CD34,CD99,Bcl-2 +)which enables differential diagnosis from other tumors of fibroblastic,myofibroblastic or epithelial origin.Follow-up,even after complete excision is recommended as it may recur or even metastise regardless of cellular atypia.

P 395
MYCOPLASMOSIS OF MALE UROGENITAL TRACT IN IRAN
AMIRMOZAFARI Nour , HARIRI Ali
Azad University, Lahijan Branch, Microbiology Department, Lahijan, Iran

Mycoplasma are the smallest bacteria capable of growth in artificial media. Their contribution to male urogenital infections and infertility are lesser known. The most common complaints of male patients who refer to urologists include urogenital tract irritations and infertility problems. Although the cause of these complications are very diverse and multifactorial, urogenital infections with Mycoplasma and Ureaplasma are among the known etiological factors. Very little attention has been paid to these infections in the male patients in Iran. A total of 302 clinical samples including semen, urethral secretions, and first urine drops were enriched and cultured for Mycoplasma. We also sought to compare the isolation rate for the bacteria by the filteration (0.45 um pore size) versus non-filteration (multi-antibiotic use) method of enrichment. The bacteria were cultured from 27 of these samples. Of these, 11 were contaminated with Mycoplasma hominis, 9 with Ureaplasma urealyticum, and the remaining 7 individuals were co-infected with both of these bacteria. Six percent of the sperm secretions, 10% of the first urine drop samples, and 11% of the urethral discharges were culture positive. Co-infections were seen only in the first urine drops. Overall, Mycoplasma and Ureaplasma were cultured in 8.9% of the male samples collected. This points to the relatively high prevalence of mycoplasmosis among sexually active male population in Iran. It also emphasizes a probable detrimental role mycoplasmosis plays in the overall quality of sperm cells.

MOLECULAR AND IMMUNOHISTOCHEMICAL STUDY OF CELL CYCLE REGULATORS IN URINARY BLADDER TUMORS
RAMOS David1, YURAKH Andriy1, LÓPEZ-GUERRERO José Antonio2, CALABUIG-FARIÑAS Silvia, PELLÍN Antonio, RUBIO José2, SOLSONA Eduardo2, LLOMBART-BOSCH Antonio1
Department of Pathology, University of Valencia1. Fundación Instituto Valenciano de Oncología2. Valencia, Spain.

INTRODUCTION: The optimal management of patients with bladder neoplasms requires the assessment of multiple predictive markers in addition to classical clinical and pathologic (grade and stage) factors. PURPOSE: Our main goal was to quantify diverse molecular and immunohistochemical (IHC) markers in order to accurately predict the clinical evolution of these patients in terms of tumor recurrence, progression and survival. METHODS: Clinical and pathologic data from 84 patients were collected including all tumor grades and stages. DNA from all these cases was analyzed for the presence of loss of heterozygosity (LOH) of the 9p21 locus; homozygous deletions (HD) and promoter methylation of the p14ARF, p16INK4A and p15INK4B genes; gene amplification of the MDM-2, CCND1 and CDK4; and P53 mutations; by means of diverse PCR-based techniques. Paraffin-embedded material from the cases was also studied at the IHC level by means of p53, Ki-67 (MIB1), p14, p16, p21, p27, pRb, MDM-2, and cyclin D1 antibodies using the avidin-biotin peroxidase procedure. Statistical analyses were performed with a specific software program package (STATISTICA version 6.0, Statsoft Inc, USA). RESULTS: In univariate studies, HD of the p14ARF, p15INK4A, and p16INK4B genes showed a statistical correlation with recurrence prediction; whereas CDK4 and CCND1 amplifications together with Ki-67 labeling index (LI), p27, p53, p16 and pRb immunoexpression were statistically associated with tumor progression. Likewise, LOH of the 9p21 locus along with p14, p53 and cyclin D1 protein expression showed strong statistical correlation with relapse-free survival (RFS). In multivariate studies, tumor stage and Ki-67 LI appeared to be independent prognostic factors in relation to overall survival, whereas HD of the 9p21 locus was related to RFS. CONCLUSION: Three factors demonstrated in the present study independent prognostic significance: clinical tumor stage, overexpression of Ki-67 antigen and HD of the 9p21 locus.

HEAVY EOSINOPHILIC INFILTRATE OF THE BREAST
JM Radhi, C Otero, S Reid
Department of Pathology, Diagnostic Imaging and Surgery, McMaster University, Hamilton Ontario, Canada

Introduction: Significant eosinophilic infiltrate of the breast is encountered in eosinophilic mastitis granulomatous mastitis, Churg-Strauss syndrome, Crohn's disease, parasitic infection and rarely in carcinoma.
Aim: Our aim is to identify cases of breast reported with heavy or significant eosinophilic infiltrates.
Materials & Methods: Seven cases were identified after reviewing all breast cases reported during the period of 1999-2005. Three cases diagnosed as granulomatous mastitis, one eosinophilic mastitis, two ductal carcinoma and one gynecomastia. The ductal carcinoma cases exhibited florid eosinophilic infiltrates with periductal fibrosis and destruction. One case associated with prior history of herbal medication.
Conclusion: Significant eosinophilic infiltrate is identified in cases of mastitis and rarely in ductal carcinoma. Although eosinophils can degranulate and release toxic inhibiting factors into tumours, they are uncommonly encountered in breast carcinoma.

P 398
FEMALE MALIGNANT BREAST TUMORS IN CAMBODIA
MONCHY Didier, HOU SEREY Vannak, SOK KIM Eng
Pathology Department, Institut Pasteur du Cambodge
Phnom Penh Cambodia

Background: Little is known about breast cancer in Cambodian women living in Cambodia.
Objectives: To describe the various histological types of invasive breast cancers, their frequency, grade and stage.
Methods: We selected all breast biopsies and surgical specimens that were processed during 2003 and 2004 in our newly set up laboratory in Phnom Penh. Tissue samples were embedded after 10% formalin fixation and sections were stained by H&E. Pathology reports were written according to international recommendations. Carcinomas were graded

using the Nottingham modification of the Bloom-Richardson system and staging was established according to the 2003 TNM classification. Detection of hormone receptors by immunohistochemistry was not available in Cambodia at this time.
Results: A total of 107 ladies from Phnom Penh and different provinces in Cambodia, aged 16 to 76, presented with malignant tumors of whom 12 (11.2%) had biopsy then surgery, 81 (75.7%) directly had surgery and 14 (13.1%) solely had biopsy. Lesions included 96 (89.7 %) carcinomas, nine (8.4 %) Phylloides tumors and two (1.9%) lymphomas. The mean age of patients with carcinoma was 48.2 (23-76). Among these patients, invasive ductal type was the most frequent, identified in 79 ladies (82.3%) and high histological grade was found in 74.7% of cases. Radical surgery was performed in 63 of the 79 affected patients and proportions of T1, T2, T3 and T4 were respectively 9.6%, 41.2%, 15.9% and 33.3%. Lymphadenectomy was performed in 31 of 63 patients (49.2%) and lymph node metastases were observed in 26 of 31 (83.9%). Medullary carcinomas accounted for 11.4% (11/96) of the ladies, whose mean age was 46.4 (40-59). Metaplastic, papillary, mucinous and mixed histological types of carcinoma were rare and no case of invasive lobular carcinoma was diagnosed.
Conclusion: Our findings demonstrated a high frequency of medullary carcinomas and malignant phylloides tumors in Cambodian ladies. In contrast, no case of lobular carcinoma was found. The fact that most of our cases were at late stage of the disease, may suggest that early detection of the disease should be strengthened in Cambodia. In addition, standardized surgical procedures should be established so that lymphadenectomy, for instance, is systematically performed at the time of tumor excision.

P 399
TUMOUR GRADE AND TUMOUR MARKER EXPRESSION IN INVASIVE BREAST CARCINOMA WITH INTRA-DUCTAL COMPONENT.
Lacerda M.*; Figueiredo P.*; Schmitt F.**
*C.R.O.C.I.P.O.F.G. –Coimbra –Portugal
** I.P.A.T.I.M.U.P.-Porto - Portugal

Introduction: Ductal carcinoma in-situ is regarded as a precursor to invasive breast cancer. Trying to find steps in this progression. we compared the grade and expression of some tumour markers (ER, PR, c-erb-B2, MIB-1, P53 and Bcl-2) of both components in 74 cases of invasive carcinoma with an intra-ductal component. Materials and methods: Both components (intra-ductal and invasive) were classified independently according the guidelines of the European Commission Working Group on Breast Screening Pathology. The results of the staining were analyzed in the intra-ductal and in the invasive components separately. We worked with the cut-off limits generally accepted.
Statistical analysis: For comparison between the two components the chi-square test was used. Statistically significant differences were assumed when $P<0.05$.
Results: 1)Tumour grade – a): high grade of the intra-ductal and grade of the invasive component: in 28% cases the invasive component was grade 3; in 57% cases the invasive component was grade 2 and in 14,3% the invasive component was grade 1;b)intermediate grade plus low grade of the intra-ductal component: in 34% cases the invasive component was grade 2; in 56,6% the invasive component was grade 1. Only in 5 cases (9,4%) the invasive component was grade 3. 2) ER expression: in 62,2% cases both components were ER+ and in 27% cases both components were ER-. 3) PR expression: in21, 6% cases both components were RP+ and in 66,2% both components were RP- 4) c-erb-B2: in 17,6% cases c-erb-B2 was over-expressed in both components; in 77% cases c-erb-B2 was negative in both components. In no one case we observed c-erb-B2negative in the intra-ductal component and over-expression in the invasive component. 5) MIB-1: in 12,2% cases MIB-1 was high in both components but in 18,9% cases its expression move on to low in the invasive component; in 64,9% cases MIB-1 was low in both components. 6) P53 expression: in 66,2%cases both components were P53+ and in 10,8%cases P53- in both components. 6) Bcl-2 expression: in 27% cases Bcl-2 both components were Bcl-2+ and in 63,5% cases both components were Bcl-2-.
Conclusion These results allow us to conclude that the step between in-situ and invasive carcinoma, seems to occur independently of tumour grade. The tumour markers that we studied were not clearly associated with the progression from in-situ to invasive; the expression of these tumour markers are almost identical in the two components.

P 400
ROUND/OVAL SHAPE IN BREAST LESIONS. A MARKER OF BENIGN LESION? CYTO-HISTOLOGICAL STUDY OF 544 CASES FROM THE VERONA BREAST SCREENING PROGRAM.
Manfrin E1, Mariotto R2, Dalfior D1, Remo A1, Reghellin D1, Eccher A1, Bonetti F.1
1 Department of Pathology, University of Verona (Italy), 2 Breast Screening Unit ULSS 20 Verona (Italy)

Introduction: The round/oval shape is a radiological feature suggesting a diagnosis of benign breast lesion.
Purpose: To evaluate the pathologic and mammographic correlation of round/oval-shaped breast lesions.
Methods: Between 1999 and 2004, we studied the cytological and histological features of breast lesions with ultrasonographic and/or mammographic circular shape within the Verona Breast Screening Program (BSP).
Results: Out of 544 round breast lesions, 125 (22,9%) were malignant and 419 (77,1%) benign. Malignant lesions were all invasive; histotype was ductal: 105 cases (84%), lobular: 13 cases (10,4%), mucinous: 4 cases (3,2%), medullary: 2 cases (1,6%), tubular: 1 case (0,8%). The TNM of malignancy was pT1: 102 cases (81,6%); pT2: 18 cases (14,4%); pT3: 2 cases (1,6%) and pT4: 3 cases (2,4%).
Nodal status, available in 98% of cases, was N+: 24.4% and N-:75.6%. All benign lesions were investigated with cytology and so stratified: fibroadenoma: 188 (44,9%); cyst: 53 (12,6%); benign lesion, NAS: 54 (12,9%); fibrocystic change: 32 (7,6%); steatonecrosis: 17 (4%); adenosis: 15 (3,6%); adipose nodule: 12 (2,9%); papilloma: 7 (1,7%); intramammary lymph node: 5 (1,2%) and other(focal fibrosis, granulomas, abscess): 36 (8,6%). Surgery was performed in 14 cytological benign lesions; histology was benign in 9 cases, atypical in 5.
Conclusion: In our series, round/oval-shaped breast lesions were malignant in 23% of cases. The most frequent histotype was infiltrating ductal cell carcinoma. The most common benign lesion was fibroadenoma. From our data we conclude that follow-up is not adequate in breast lesions with round-oval imaging, but further investigations are necessary. BREAST SCREENING PROGRAM IN VERONA. CYTO-HISTOLOGICAL FINDINGS OF FIVE YEARS OF ACTIVITY AND COMPARISON WITH OTHER SCREENING PROGRAMS IN EUROPE.
Manfrin E1, Mariotto R2, Remo A1, Reghellin D1, Dalfior D1, Eccher A1, Bonetti F1.
1Department of Pathology, University of Verona (Italy), 2 Breast Screening Unit ULSS 20 Verona (Italy)

Breast Screening Program (BSP) for women with age comprised between 50 and 69 years started in Verona in

1999. Compared with the "classic" screening, the Verona program has a different organization, similar to that of a Breast Clinic, and operates in a building exclusively devoted to the BSP. First level mammograms and all second level exams (US, FNAC, core biopsy, mammotome) are performed in the same structure by a staff composed of two radiologists, two cytopathologists, four technicians and two nurses. All women are submitted to a double projection mammography; the Radiologists perform real time interpretation of mammograms. Results are immediately communicated. Negative patients are dismissed after reassurances; suspicious patients are immediately submitted to second level examination. FNAC is evaluated for adequacy and a diagnostic report is immediately given to the Radiologist. Core-biopsy and mammotome specimens are centrally collected in Pathology Department of University of Verona. Result of histological exams are communicated within two days. Results: In the first five years of activity (1999-2004) 55.000 women have been evaluated by screening. The participation rate was 61% in initial screening, 89% in subsequent screening. Among 513 cases sent to surgery, 424(83%) were malignant, 24(5%) atypical hyperplasia, 65(12%) benign. The ratio benign vs. malignant was 0.18. The detection rate for cancer was 9.6‰ in the first round and 4.9‰ in the following rounds. The pre-operative diagnosis of malignancy was done in 85% of cases with FNAC and in 15% of cases with core biopsy/mammotome. The TNM of malignancy was pTis: 23.4%, pT1:63.9%, pT2:10.3%, pT3:0.9%, pT4:1.4%. Nodal status was N+:21% and N- :79%. Surgery was conservative in 80% with 20% mastectomy. TNM(M0) staging was St0:23.4%; StI:54.5%, StII:15.3%, StIII:6.8%, StIV:0. Interval cancers rate was 8.6%.Conclusions: Compared with other screening program, the results of the Verona screening program are all within the preferred results of the European guidelines. The peculiar organization of the program, with its centralized integrated radio-pathological activity seems a major factor for a successful screening program.(Supported by Fondazione Cassa Risparmio VR-VI-BL-AN.Bando 2004. Progetto Cr. Mammella)

P 402

MALE BREAST CARCINOMA : A CLINICO-PATHOLOGICAL STUDY OF 21 CASES

MNIF Hela, MAKNI Saloua, FAKHFAKH Ines, SELLAMI Ahmed, BOUDAWARA SELLAMI Tahya

Introduction:
Breast carcinoma rarely occurs in males and information regarding this pathology are limited. The aims of this study were to document epidemiological, clinico-pathological and immunocytochemical features of this cancer and to establish which factors would predict prognosis.
Materiels and Methods:
A retrospective study was performed of 21 cases of male breast carcinoma accessioned at the pathological anatomy and cytology laboratory of the University Teaching Hospital of Sfax between 1992 and 2003.
Results:
The patients' mean age was 65,4 years. The average duration of signs and symptoms before the diagnosis was 10,4 months. Presentation occurred most often (85,7%) with self-detected lump. Clinically the majority of the cases presented advanced cancers. Three patients had stage 0, 5 had stage II, 4 had stage III, 9 had stage IV disease. Histology found: 13 canalar infiltrating carcinoma, 3 neuroendocrin carcinoma, 1 papillary carcinoma and 4 ductal carcinoma in situ. Four Paget's disease were diagnosted. The histological grad of SBR was precised: 2 patients had grad I, 8 had grad II, 7 had grad III. Lymph node involvement was found in 52,3% of the cases. Immunohistochemicaly data were reviewed: 65% of tumors were oestrogen receptor positive, 80% were progesterone receptor positive, 23,5% over expressed CerbB2, 40% over expressed Bcl2 and P53 and 15% exprimed vimentin. The overall 5 years corriged survival was 61,9%. The disease stage, high histological grad, lyph node involvement and the over expression of the biological biomarkers (receptor of oestrogen, P53, , CerbB2, vimentine) were correlated with poor prognosis.
Conclusion:
The poor prognosis of male breast cancer is related to older age at diagnosis in advanced stage of disease at presentation.We find that to get better prognosis, it is important to improve medical and technical means, to increase information and to promote early detection.

PRELIMINARY ANALYSIS OF THE HISTO-PROGNOSTIC POWER OF A HETEROGENEITY INDEX FOR BREAST CANCER

Venus Sharifi-Salamatian, Lab. d'Analyse d'Image en Pathologie Cellulaire (AIPC) Hôpital Saint-Louis, Paris, France
Joelle Simony-Lafontaine,Majida Esslimani, Nadine Lequeux, Laboratoire d'Anatomie Pathologique, Centre Regional de Lutte Contre le Cancer (CRLCC), Montpellier, France

In 1998, the Kananaskis Tumour Heterogeneity working group conjectured that there should be a correlation between the level of intratumoral heterogeneity and the seriousness of a carcinoma. This group emphasized the need for a reproducible and quantifiable measure of heterogeneity to test this hypothesis.
In this paper, we use a recently developed Intratumoral Spatial Heterogeneity Index (ISHI) complying with the Kananaskis group requirements. This index has been shown to be very useful in characterisation of breast cancer tumours. In particular it was shown that the ISHI for various blocks of a single tumour was invariable, regardless of the fact that various blocks differ in size and in number of marked cells. We present in this paper our preliminary results about the histo-prognostic ability of the ISHI.
The ISHI has been derived on a set of 78 blocks coming from 56 breast carcinoma patients and labelled by monoclonal anti-MIB-1 marker. A complete analysis of the ISHI and its correlation with SBR grade assigned by a pathologist has been conducted and some interesting results are obtained. The analysis shows clearly that blocks coming from patient with a SBR grade I, have also low level of heterogeneity (ISHI close to 1). ISHI separates well (as validated by a statistical test) SBR grade I from grade II and III, but grade II and III are not well separated.
We conducted a survival analysis of a sub-sample of 37 breast carcinoma patients with 10 to 12 years of follow-up, to evaluate the histo-pronostic value of the ISHI. For this purpose we divided the set of 37 patients into three equal size sets containing patients with decreasing value of ISHI; group 1 with low heterogeneity (ISHI between 1 and 0.9), group 2 with medium heterogeneity (ISHI between 0.9 and 0.82), group 3 with large heterogeneity (ISHI from 0.82 to 0.67). We therefore compared the survival curve of the 3 group. It appears that no mortality has been reported in group 1 (with low heterogeneity) and that the survival curve of the group 3 is clearly below the group 2 and 1 (as validated by a logrank statistical test). This could be seen as a preliminary validation of the histo-pronostic value of the ISHI.
Even if the number of samples used in this study is not enough to reach to a definitive answer, however this gives some indications that motivate us to conduct a larger scale survival study.

3. Programa de Patología Molecular. Citogenetic Laboratory. CNIO. Spain.
4. Department of Pathology. La Paz Hospital. Madrid. Spain.

INTRODUCTION: Tumours from women with germline BRCA1 mutations have a basal-like phenotype: estrogen receptor (ER) negative, HER2 negative, cytokeratin 5 (CK5) and/or epidermal growth factor receptor (EGFR) positive. Moreover, they show high cyclin E expression and frequently show medullary features.

AIMS: To investigate whether or not atypical medullary sporadic breast carcinomas have a basal-like phenotype.

MATERIAL and METHODS: We studied a group of 39 sporadic invasive breast cancers that displayed features of atypical medullary carcinoma according to the 2003 WHO criteria, and a series of 76 consecutive sporadic breast tumors (as a control group). They were analysed inmunohistochemically for ER, PR, p53, Her2neu, ki-67, cyclin E, CK5 and EGFR expression. Cyclin E alterations were also analysed by fluorescence in situ hybridization (FISH). Both studies were performed on paraffin-embedded tumours included in tissue-microarrays (TMA).

RESULTS: In the medullary carcinoma group, 100% and 92,3 % of the cases were negative for Her2neu and ER whereas 28,2%, 61,5% and 66,7% were positive for EGFR, CK5/6 and cyclin E, respectively. The three ER positive cases were negative for both CK5/6 and EGFR. Interestingly, we observed that cyclin E gene was amplified in 15,4% of the cases. On the other hand, in the control group 76,3% and 22,3% of the cases were negative for Her2neu and ER, respectively. We found positivity for CK 5/6 and EGFR in 8 (10,5%) and 11 (14,5%) cases, respectively but only 5 (6,6%) cases fulfilled all the criteria to be included in the basal-phenotype group. Cyclin E was overexpressed in 36,8% of the cases but no gene amplification was found.

CONCLUSION: These data indicate that as well as in BRCA1-mutated tumours, sporadic invasive breast cancers with medullary features show the characteristics of the basal phenotype. Interestingly, medullary breast tumours show a high percentage of cyclin E gene amplification , a fact not previously been reported in breast tumours.

WIDESPREAD BREAST CANCER METASTASES TO THE UTERUS AND LEIOMYOMA - REPORT OF TWO CASES

Background: Breast carcinoma is the most common malignancy in the female population. Frequent sites of metastases include lymph nodes, liver, lung and bone. Widespread gynecologic and leiomyoma metastases from breast carcinoma is a well-known but extremely rare phenomenon and had only been reported sporadically in the literature.

We present two cases of gynecologic and leiomyoma metastases from invasive ductal and lobular carcinoma of the breast respectively. Immunohistochemical studies including CEA, estrogen, progesteron, C-erb–2 and human milk fat globulin was performed for differential diagnosis.

Case I: An 62-year old multigravid woman with a history of breast cancer and tamoxifen therapy presented with abnormal uterine bleeding. After the diagnosis of malignancy was made on cervical smear, biopsies were taken from cervix and endometrium, which revealed an infiltrating moderately differentiated ductal adenocarcinoma consistent with breast metastasis. A total abdominal hysterectomy, bilateral salpingo-oophorectomy, and pelvic lymph node sampling were performed. The uterus measured 10x6x4 and it was markedly distorted with multiple gray-white cervical, intramural and endometrial tumor nodules with the maximum diameter of 3 cm. Final pathology examination revealed metastatic ductal carcinoma of the breast including vagina, cervix, endometrium, myometrium and fallopian tubae.

Case II: A 49-year-old multigravid woman was admitted to the hospital with the complaint of uterine bleeding and abdomino-pelvic pain. Her gynecologic history was unremarkable, however, 4 months previously, she was underwent a right sided modified radical mastectomy for invasive lobular carcinoma. At the time of admission, her physical and genital examinations showed no abnormalities except multiple leiomyomas. After the vaginal hysterectomy and bilateral salpingo-oophorectomy; microscopic examination revealed metastatic foci of invasive lobular carcinoma in the leiomyoma and ovary

Conclusion: Metastases to the female genital tract from extragenital cancers are uncommon. It should be kept in mind that abnormal uterine bleeding may be the first sign of metastatic disease in a woman with a history of malignant disease as in our cases.

IMMUNOHISTOCHEMICAL EXPRESSION OF P21 WAF1/CIP1, BAG-1, BAX, MCL-1 PROTEINS IN BREAST CARCINOMAS. CORRELATION WITH PROGNOSTIC FACTORS

1L Zakhartseva, 2I Shchepotin, 2O Lobanova
1Kiev City Oncology Hospital
2National Medical University

Introduction Identification of apoptosis factors and cell proliferation carries valuable information about specific features of tumor clinics, treatment sensitivity and survival of patients. Cell cycle progression is governed by cell cycle regulators and inhibitors such as cyclin dependent kinases, p21 WAF1/Cip1, BAG-1, BAX, and Mcl-1.

Material and methods Immunohistochemical analysis for estrogen/progesterone receptors (ER/PR), c-erb B2, p21 WAF1/Cip1, BAG-1, BAX, Mcl-1 was performed on formalin-fixed infiltrating ductal (81%) and lobular (19%) breast carcinomas of 64 patients with

Ò1-2 N0 M0 G2-3. They were undergone mastectomy and chemotherapy therapy taking into account c-erb B2 expression. Two groups of patients were studied in terms of survival. The first group with more than 3 years survival (53), the second – less than 3 years (11).

Results The tumors of the first group of patients had positive reaction ER/PR in 83% cases, c-erb B2 in 18%, p21 WAF1/Cip1 – 75% (tumor having more then 20% staining cells were considered to be positive), BAG-1and BAX in 100% in c-erb B2 positive tumors and 25% in c-erb B2 negative tumors , Mcl-1 in 20% in c-erb B2 positive tumors and 36% in c-erb B2 negative tumors. The tumors of the second group patients had positive reaction ER/PR in 38%cases, c-erb B2 in 25%, p21 WAF1/Cip1 – 83%, BAG-1 and BAX in 30%, Mcl-1 in 20%.
Conclusion Higher expression of BAG-1, BAX, Mcl-1, as well as ER/PR, is indicates good prognostic factors of survival.

INCREASED LEVEL OF FATTY ACID SYNTHASE AND PROGESTERONE RECEPTOR PROTEINS IN PREMALIGNANT MAMMARY LESIONS AND IN SITU CARCINOMA

ESSLIMANI-SAHLA Majida1,2, KRAMAR Andrew3, SIMONY-LAFONTAINE Joelle2, THEZENAS Simon3, LAVAILL Roselyne2, BIBEAU Frederic 2, BALDET Pierre4, MAUDELONDE Thierry1,4, CHALBOS Dany1 and ROCHEFORT Henri1,4
1INSERM U540, Endocrinologie Moléculaire et Cellulaire des Cancers; Departments of 2Pathology and 3Biostatistics, Cancer Center Val d'Aurelle; 4CHU; Montpellier, France

While progestins increase the risk of breast cancer after menopause (the WHI trials 2002 and 2004), the mechanism of this effect is unclear. One approach is to estimate the level of proteins related to progestin action in different mammary preinvasive lesions compared to adjacent normal mammary glands, in an attempt to define at which stage of carcinogenesis progestin action could be increased. We previously found that Fatty acid synthase (FAS) was overexpressed in invasive breast cancer and induced by progestins and growth factors. FAS was then described by others as corresponding to a mammary and prostate nutritional oncogene.
We now estimate by immunohistochemistry, FAS and progesterone receptor (PgR) expression in "benign" breast disease (BBD) of increasing histological risk according to Dupont and Page (non proliferative, proliferative without atypia, proliferative with atypia) and in situ breast carcinomas (of lobular and ductal subtypes). This study was performed in archive paraffin embedded tissues from 116 patients with 164 BBD and in situ carcinomas, compared to their adjacent normal ducts and lobules, using a rabbit polyclonal FAS antibody (raised by D. Chalbos in our laboratory) and a PgR monoclonal antibody (clone PgR636-Dako). The expression level of these markers was quantified by computer image analyser. A statistical analysis was performed to compare staining level in normal glands to that in the different lesions and to correlate FAS and PgR levels with MIB-1 proliferation index and clinical parameters (age, menopausal status and hormone therapies).
Results will be given showing at which premalignant lesion the expression level of these two markers was found to be significantly increased.

P 408
THE STATUS OF C-ERBB-2/HER-2/NEU AND EXPRESSION OF E-CADHERIN IN INVASIVE LOBULAR AND DUCTAL CARCINOMAS OF THE BREAST

TURASHVILI Gulisa 1, BOUCHAL Jan 1, BURKADZE George 2, KOLAR Zdenek 1
1 - Institute of Pathology and Laboratory of Molecular Pathology, Palacky University, Olomouc, Czech Republic
2 - Department of Pathology, Tbilisi State Medical University, Tbilisi, Georgia

Introdution. E-cadherin (E-CD) is considered to be the most important cell adhesion molecule in mammary gland. Some studies suggest that downregulation of E-CD and subsequent loss of cellular adhesiveness correlate with poor prognosis and metastasis but this is not confirmed by other studies. Many investigations suggest that E-CD protein is not expressed in invasive lobular (ILC) in comparison with invasive ductal carcinoma (IDC) of the breast. A few papers report that E-CD mediated cell adhesion system can be disrupted by oncoprotein c-erbB-2/HER-2/neu in c-erbB-2-positive breast carcinomas despite ductal or lobular type. Purpose of study. To evaluate the relationship between expression of HER-2/neu and E-CD in ILC and IDC and analyze an association with lymph node positivity. Methods. We reviewed 106 cases of breast cancer: 91 IDC and 15 ILC including 3 pleomorphic lobular carcinomas (PLC). All cases were examined in our laboratory for suspicioion for c-erbB-2 overexpression. Nottingham histologic grade, immunohistochemical staining for estrogen and progesterone receptors (ER and PR), proliferating cell nuclear antigen (PCNA), E-CD; fluorescense in situ hybridization for HER-2/neu gene amplification; and lymph node positivity were evaluated. Results. HER-2/neu gene amplification was observed in 60.5% of IDC and 26.7% of ILC including one case of PCL and positively correlated with higher histological grade and lymph node positivity. Strong positivity for PCNA was observed in 84.2% of IDC and positively correlated with histological grade and HER-2/neu positivity. IDCs were negative for ER in 50%, and PR in 57.8% of cases. ILCs were negative for ER in 40%, PR in 46.7% of including one case of PLC. ER/PR-negativity was associated with histological grade, HER-2/neu gene amplification and lymph node positivity. Majority (80%) of ILC including two cases of PLC showed negative staining for E-CD. E-CD expression was lost in 10 cases (26.3%) of 38 IDCs and positively correlated with histological grade, HER-2/neu gene amplification and lymph node positivity. Conclusion. The loss of E-CD expression can be a feature of some typical invasive ductal carcinomas of the breast. E-CD negativity seems to be associated with higher histological grade, HER-2/neu gene amplification and lymph node positivity suggesting that c-erbB-2 may act as a regulator of E-CD expression in most human breast carcinomas in vivo.

Background: Treatment with trastuzumab (T) has shown excellent clinical response in patients with HER2-overexpressing breast cancer (BC). However, the exact mechanisms of action of T has not been fully characterized and appears to be complex. The objective of this study was to dertermine, in vivo, whether the immune response is a mechanism of action of T in human BC.
Material and Methods : 23 patients with BC characterized as 3+ HER2 by immunochemistry (IHC) were enrolled to receive T + docetaxel (D) primary systemic therapy (PST) as

part of the 'TAXHER01' trial. Following surgery, they were 9 (40%) pathological complete response (pCR). The remaining 14 BC displayed partial (N =13) or no (N=1) pathological response. Additionally, 23 BC treated with D-containing PST, and 23 BC treated with anthracycline-containing PST were analyzed as non-T groups. Each cases of the 2 control subgroups was chosen to be matched (same pathological response) with those of the case group. Of these 69 surgical specimens, residual tumors areas or pCR areas were blindly analyzed by morphology and IHC. B-lymphocytes were stained with anti-CD20. T-lymphocytes were stained with CD3, CD4 and with CD8. Macrophages were stained with CD68. Dendritic cells were stained with PS100 and CD1a. Natural Killer (NK) cells were stained with CD56 and with NK1. Potential cytolytic cells were stained with Granzyme B and with TIA-1. HER2 status was also analyzed by IHC on residual tumor cells. These analyses were performed by 2 independent pathologists.
Results : All residual tumor cells from the cases group were HER2 postive on IHC and there were no differences in HER2 status before and after T PST in the case group. The number, topography, and activation status of various type of immunocompetent cells were generally different between the case group and the two control groups. Significantly more NK cells were in contact with tumor cells in the case group than in controls. In addition, there was significantly greater expression of Granzyme B and Tia1 by lymphoid cells in the case group than in controls.

Conclusion : This study provides evidence in favor of the immune response as one of the mechanisms of action of T in BC. NK cells in particular, that are able to mediating antibody-dependent cell toxicity against antibody-coated cells via their expression of FcãRIII, seemed to play an important role. This finding may have further implications for the management of T treatment in BC.

IMMUNOHISTOCHEMICAL DETECTION OF ERBB RECEPTORS OVEREXPRESSION IN HUMAN BREAST CARCINOMAS

Ravazoula P,Lykaki-Karatza E, Koumoundourou D, Androutsopoulos G, Michail G, Kourounis G.
Departments of Pathology, Radiology and Obstretrics-Gyneacology, School of Medicine, University Hospital of Patras, Greece

Abstract
ErbB receptors are expressed in various tissues, in which they are involved in the control of diverse biological processes such as proliferation, differentiation, migration and apoptosis. Cerbb-2 overexpression has been implicated in many types of human cancers and is associated with poor prognosis.
The aim of our study is to identify the expression of cerbB-3, cerbB-4 and cerbB-2 in human breast carcinomas.
Materials and Methods: The study comprised 47 breast cancer specimens of 47 women with follow up period 3-10 years. Histological examination showed 3 in situ ductal carcinomas and 44 ductal invasive carcinomas common type (11 grade I, 23 grade II and 10 grade III). Eight out of 44 women with invasive carcinoma had a recurrent disease. Immunohistochemistry was carried out by using polyclonal antibodies against cerbB-3 and cerbB-4 (Santa Cruz Biotechnology) and a monoclonal antibody against cerbB-2 (Biogenex). Tumors were scored by the proportion of tumor cells stained.
Results: Expression of cerbB-3 was evident in all in situ and in 10 (22,72%) invasive carcinomas. One out of the 10 women with invasive carcinoma had a local recurrence (9%). CerbB-4 expression was evident in 1 in situ carcinoma and in 28 (63,6%) invasive carcinomas. Seven out of the 28 women with invasive carcinoma had a recurrent disease (24,13%). CerbB-2 expression was evident in all in situ and in 7 invasive carcinomas (~15%). Two out of the seven women with invasive carcinoma had a recurrent disease (28,57%).
Conclusions: Our results demonstrate that erbB receptors are expressed early in human breast carcinoma. ErbB-2 and erbB-4 overexpression is correlated with recurrent disease.

P 411
CERB B2 OVEREXPRESSING BREAST CANCER CEELS REVEAL DISTINCTIVE NUCLEAR FEATURES BY IMAGE CYTOMETRY

DR.BALOGLU H,DR.YILDIRIM S,HAHOLU A,DR.YILMAZ I,DR.BERBER U,DR.,DR.CERMIK H,DR.ERGUR R*.
DEPTARTMENT OF PARTHOLOGY & OBGYN* GATA-HEH,ISTANBUL,TURKEY.

Background: To understand if CerbB2 over-expressing breast cancer cells have distinctive phenotypic features.
Design: N0 Grade II twelve invasive breast cancer cells showing heterogenous CerbB2 protein over-expression were included in the study. For measurements, 100 CerbB2 immunoreactive tumor cells, and 100 non-reactive tumor cells were selected for each case from their paraffin embedded tumor tissue sections stained immunohistochemically with mouse antihuman CerbB2 antibody (BioGenex, CA, USA). Nuclear area, nuclear perimeter, and nuclear form factor of these selected cells were determined on SAMBA 4000 image analysis workstation. Discriminative analysis was performed whether measured parameters are accurate to identify CerbB2 positive and negative cellular phenotype.
Results: Nuclear area was found to be the most distinctive feature for CerbB2 over-expression second to the nuclear perimeter ($p<0,05$). CerbB2 expressing cells have bigger nuclear area and bigger nuclear perimeter significantly ($p<0,05$).
Conclusion: CerbB2 protein expression was found consistent with distinct nuclear features in invasive breast carcinoma cells that may be identified by image cytometry.

P 412
EXPRESSION OF HEDGEHOG SIGNALING COMPONENTS IN BREAST CANCER

KOLLMANN Karoline,BLAAS Leander, ALINGER Beate, ESTERBAUER Harald, ABERGER Fritz, DIETZE Otto, HAUSER-KRONBERGER Cornelia
Department of Pathology, General Hospital Salzburg and Department of Molecular Biology, University of Salzburg, Austria.

The hedgehog signal transduction pathway plays an important instructional role during the development of vertebrates. This pathway includes hedgehog ligands (Sonic hedgehog, Shh; Desert hedgehog, Dhh; Indian hedgehog, Ihh) binding to the membrane receptor patched (ptch) and the trans-membrane protein smoothened with its intracellular effectors (Gli1, Gli2, Gli3). Mutations of the receptor ptch are known to induce human tumours, i.e. the basal cell carcinoma (BCC).
Lately, hedgehog has been described to play a crucial role in the carcinogenesis, differentiation and proliferation of breast cancer.
The aim of the present study has been to reveal the expression of single components of the hedgehog pathway in normal tissues, precancerous lesions, non-invasive and invasive cancer of the breast.
Formalin fixed and paraffin embedded human normal (n=3) tissue, precancerous lesions (atypical hyperplasia, DCIS; LCIS n=15) and invasive ductal and lobular carcinoma tissues (n=25) have been investigated. Additionally breast cancer tissue arrays and breast cancer cell lines were analyzed for the expression of components of the hedgehog pathway using immunohistochemistry. The ligands (Shh, Dhh, Ihh), the

receptor Patched and the transcriptionfactors (Gli1, Gli2, Gli3) as main partners of an activated pathway were analyzed. Twelve breast cancer cell lines (MDA-231, SK-BR-3, BT-20, MDA-361, HS-578, T-47 D, ZR 751, MCF-7, HBL-100, 734B, MTSV 1-7, ALAB) have been examined by real-time polymerase chain reaction for the quantification of mRNA.
The results suggest a constitutively activated hedgehog pathway in all breast carcinoma tissues. Furthermore, there are differences in the expression of the hedgehog components. Invasive ductal carcinomas apparently show an increased expression of Shh, Gli1, Gli2, Gli3 and Ptch. In addition to the over-expressed components in invasive ductal carcinoma, ductal carcinomas in situ indicate an intensive staining of Ihh. Shh, Ihh, Gli1, Gli2, Gli3, and Ptch are expressed in invasive lobular carcinomas and in LCIS.
Elucidation of the role of hedgehog signalling pathway in breast cancer could contribute to a new therapeutic approach by obstructing the hedgehog pathway cascade with cyclopamine or antibody therapy.

P 413
A MODIFIED APPROACH FOR EVALUATION OF ERBB2 (HER2) GENE COPY NUMBER IN MODERATELY AMPLIFIED INVASIVE DUCT CARCINOMAS (IDC) OF THE BREAST
MRHALOVA Marcela, NERADOVA Marie, KODET Roman
Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University in Prague, V Uvalu 84, Prague 5 – Motol, 150 06, Czech Republic

INTRODUCTION: In IDC of the breast ERBB2 gene FISH status is reported as a ratio of a total number of ERBB2 signals and a total count of chromosome 17 centromere signals (ERB/CEP17). Using this system, interpretation of borderline findings may be difficult. PURPOSE: To introduce a more accurate approach to describe ERBB2 gene status in cases with a borderline ERBB2 gene amplification. METHODS: We investigated ERBB2 gene status in tissue imprints (92 IDC) and histological sections (127 IDC) using FISH PathVysion (Abbott/Vysis). We evaluated 100 tumor cells in each case and classified the nuclei according to the number of ERBB2 signals in three categories: without the gene amplification, with a moderate (<10 signals) and with a strong (>10 signals) amplification. The evaluation of ERBB2 signals was performed relatively to the number of CEP17 signals in each counted cell. The IDCs were classified as strongly amplified if more than 10% of tumor cells had the strong amplification. A case with a moderate amplification was defined as having more than 10% of tumor cells with the gene moderately amplified. SUMMARY OF THE RESULTS: A group of tumors which were by our system of evaluation strongly amplified had the ERB/CEP17 ratio >2 (101 IDC; 2,11-16,14; median 6,81), and a group of tumors without amplification had the ratio <2 (90 IDCs; 0,84-1,90; median 1,07). However, in 28 cases classified as moderately amplified by our system the ERB/CEP17 ratio varied from 1,18 to 4,77 (median 1,96) – 10 cases with imprints 1,18-2,96 (median 1,84), 18 patients with tissue sections 1,30-4,77 (median 2,12 – reflecting the cutting of the nuclei). We found that neither approach to FISH evaluation of borderline cases has a correlate to the protein status. CONCLUSION: In a majority of IDCs the ERB/CEP17 ratio describes ERBB2 gene status in a comparable way with our system. In cases with a borderline ERBB2 gene amplification ERB/CEP17 ratio may lead to misinterpretation of the result. Evaluation of histological sections should be done with a caution because centromeres may be cut off dysproportionally to the ERBB2 signals resulting in an increase of ERB/CEP17 ratio. On the other hand, ERB/CEP17 ratio may hide a minor tumor cell clone with a strong amplification. From this reason it is more useful to report the percentage of tumor cells with a strong and with moderate amplification. The result must be carefully confronted with the ERBB-2 protein status. FNM MZO 00064203

P 414
ESTROGEN RECEPTOR BETA EXPRESSION IN HIGH GRADE BREAST CANCER PATIENTS MAY PREDICT METASTASIS AND MORTALITY
VELA Teresa, PÉREZ Victor, MORA Arcelia, DUBON Elsa, HERNÁNDEZ-RODRÍGUEZ Norma; Instituto Nacional de Cancerología, México, México

Background: The two isoforms of estrogen receptor (ER)alpha and beta are involved in breast tumorigenesis and progression. ER alpha is a well established prognostic and predictive factor for anti-estrogen therapies in breast cancer, and predicts a favorable disease outcome, ER beta potential as a clinical prognostic marker remains to be defined. The aim of this study was to identify the potential of ER beta as a predictor of metastases and mortality in high grade breast cancer patients.
Methods: In a group of 50 patients with confirmed diagnostic of ductal carcinoma and a SBR of 8-9, we assesed by immunoblotting and IHQ (using specific monoclonal antibodies directed against ER alpha and ER beta) the distinct expression pattern of this ER isoforms in primary tumor samples. Chi-square and log rank tests were used to determine differences between proportions of each ER isoform and mortality and survival distributions respectively. A P value <0.05 were considered significant.
Results: The median follow up of this case series was 80 months (2-107) months.Twenty-three (46%)of 50 patients developed metastases, and 25 of 50 (50%) were positive for expression of ER alpha and ER beta respectively. We found a high frequency of metastasis (13 of 25; 52%) among those cases that express ER beta. Similar to 17 of 25 (68%)observed in ER alpha negative samples. This relationship was very significant (P=0.0000) when compared to the rest of the group. We also found a statistically significant correlation between patients with positive ER beta and negative ER alpha and higher mortality (P=0.03 and P=0.0038 respectively).
Conclusions: These findings suggest that ER beta expression in high grade samples from ductal carcinoma histologic subtype may be used as a poor prognostic marker in breast cancer patients.

P 415
NY-BR-1 REPRESENTS A NEW DIFFERENTIATION ANTIGEN IN INVASIVE BREAST CANCER, WHICH REMAINS STABLE DURING METASTATIC PROCESS.
THEURILLAT Jean-Philippe, JAEGER Dirk, SASSE Bernd, FREI Claudia, MOCH Holger, VARGA Zsuzsanna

NY-BR-1 is believed to represent a new differentiation antigen in breast cancer that represents a potential target antigen for antibody based therapies. We investigated immunohistochemical expression of NY-BR-1 invasive breast cancer cases by using a monoclonal antibody. The retrospective study involved 124 invasive breast cancer cases comprising well (G1), moderately (G2), and poorly (G3) differentiated carcinomas. Lymph node metastases were examined in 38 cases. NY-BR-1 was detected in all normal breast samples and all ductal carcinoma in situ components (100%). Among invasive carcinomas, NY-BR-1 was detected in 76% of G1 , 63% of G2 and 51% of G3 carcinomas. Expression profile of NY-BR-1 remained remarkably stable in the lymph node metastases. Our data could provide further evidence that NY-BR-1 is a differentiation antigen by being ubiquitously expressed in normal breast tissue and ductal carcinoma in situ, and its expression was decreasingly detected by dedifferentiation. NY-BR-1 might possibly play

an invasion suppression function at least in a subset of breast cancer cases. As NY-BR-1 exhibits organ specificity, it might be of practical use at routine practice by unknown primaries. Whether NY-BR-1 could be seen as a potential target for immunotherapy, needs to be investigated by further studies.

P 416
THE MULTIFUNCTIONAL ROLE OF SMAD2 PROTEIN IMMUNOHIS-TOCHEMICAL EXPRESSION IN INVASIVE BREAST CARCINOMAS

Mylona E, Liapis G, Alexandrou P, Athanassiadou S, Nikolaou I, Markaki S, Keramopoulos A, Nakopoulou L
2nd Department of Pathology, "Attikon" Hospital, National and Kapodis-trian University of Athens, Athens, Greece

Introduction: Smad2 participates in the Transforming Growth Factor- beta (TGFbeta) signaling pathway, where, in a complex with other Smad proteins, cooperates with transcription factors to regulate expression of defined genes. The purpose of the present study was to investigate the expression of phosphorylated smad2 (pSmad2) in association with clinicopathological parameters and various biological markers of prolif-eration and invasion.
Methods: A two step immunohistochemical method (Envision) was applied on paraffin embedded sections from 164 patients with invasive breast carcinomas to detect the expression of the proteins pSmad2, Ki-67, topoisomerase II alpha (topoII alpha), Extracellular Signal Regulated Kinase-2 (ERK2), catenin p120, Matrix Metalloporteinases (MMP)-14, -2 and Tissue Inhibitor of Metalloproteinase-2 (TIMP-2). The results were subjected to statistic analysis.
Results: pSmad2 protein was detected in the nuclei in the 68.1% of ma-lignant cells and in the fibroblasts of the tumor (55.2%). Nuclear pSmad2 was inversely correlated with histological grade (p=0.047) and the normal immunoexpression of catenin p120 (p=0.028). Both nuclear and stromal pSmad2 were inversely correlated with lymph nodal status (p=0.054 and p=0.053 respectively), Ki67 (p=0.003 and p=0.043 re-spectively) and topoIIa (p=0.021 and p=0.035 respectively), whereas their relation with MMP-14 of tumor cells (p=0.012 and p=0.008 respec-tively) and ERK2 of tumor fibroblasts (p=0.008 and p<0.0001 respectively) was found to be parallel. Stromal pSmad2 was further positively related with MMP-14 of stromal cells (p=0.006) and TIMP-2 of cancer cells (p=0.022) and nuclear pSmad2 with MMP-2 of stromal cells (p=0.038).
Conclusion: In the present study, pSmad2 was found to play both tumor suppressive and invasive role, probably via its collaboration with MAP kinase pathway.

P 417
PROGNOSTIC SIGNIFICANCE OF THE IMMUNOHISTOCHEMICAL EXPRESSION OF VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF)-C AND ITS RECEPTOR, FLT-4, IN INVASIVE BREAST CARCINOMA

Mylona E, Alexandrou P, Giannopoulou I, Nikolaou I, Athanassiadou S, Markaki S, Keramopoulos A, Nakopoulou L
2nd Department of Pathology, "Attikon" Hospital, National and Kapodistrian University of Athens, Athens, Greece

Introduction: The vascular endothelial growth factor (VEGF) family currently includes five members. Among them, VEGF-C is a ligand for VEGF receptor-3 (VEGFR-3 or flt-4). Both show some selectivity toward lymphatic endothelial cells but their role in cancer is largely unknown. The aim of the present study was to investigate the role of VEGF-C and its receptor, flt-4, in invasive breast carcinomas through their correlation with classic clinicopathological parameters, biological markers indicative of aggressive tumor phenotype, such as proliferation markers (Ki67, topoII alpha), invasion markers [Metalloproteinase(MMP)-11 and abnormal e-cadherin], c-erbB-2 and patients' survival.
Methods: Immunohistochemistry was applied on paraffin embedded sections from 169 patients with invasive breast carcinomas to detect the expression of the proteins VEGF-C, flt-4, c-erbB-2, Ki67, topoisomerase II alpha (topoII alpha), (MMP-11) and e-cadherin. Results were subjected to statistic analysis.
Results: VEGF-C was detected in the cytoplasm and the membrane of malignant cells in 86% and 32% of the cases respectively, whereas flt-4 was found to be expressed in the nuclei of cancer cells (41.4 %) and tu-mor fibroblasts (65%). Membranous VEGF-C showed a parallel correlation with proliferation markers Ki67 and topoII alpha (p-0.006 and p=0.026 respectively), stromal MMP-11 (p=0.012) and abnormal e-cadherin (p=0.035) and it was further found to be an independent prognosticator of patients' shortened disease-free survival (p=0.03), while cytoplasmic VEGF-C had an independent unfavorable effect on patients' overall survival (p=0.016). Flt-4, on the other hand, when detected in the nuclei of malignant cells showed a parallel correlation with topoII alpha (p=0.039), whereas stromal flt-4 was positively associated with c-erbB-2 (p=0.017) and a shortened overall survival of postmenopausal patients (p=0.058). Patients who expressed simultaneously membranous VEGF-C and stromal flt-4 were found to have the worst prognosis as far as both disease-free and overall survival is concerned (p=0.012 and p=0.039 respectively).
Conclusion: VEGF-C and its receptor, flt-4, were associated with biological markers indicative of aggressive tumor phenotype. Furthermore, VEGF-C seems to exert an unfavorable effect on patients' survival, suggesting that it may be an independent prognosticator for invasive breast carcinomas.

P 418
HER2 OVEREXPRESSION PREDICTS SURVIVAL IN STAGE II AND III OF BREAST CANCER PATIENTS TREATED WITH NEOADJUVANT DOCETAXEL PLUS EPIRUBICIN

Daniel Guimarães Tiezzi, Jurandyr Moreira de Andrade, Alfredo Ribeiro-Silva, Marcelo Guimarães Tiezzi, Heitor Ricardo Cosinski Marana, Fábio Eduardo Zola, Joaquim Moraes Sarmento-Filho.
Departments of Obstetrics & Gynecology and Pathology, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Brazil

Objective: The study was designed to evaluate the importance of biological markers to predict response to neoadjuvant chemotherapy and the overall survival in stage II and III of breast cancer patients. Patients and methods: Fifty-two patients received preoperative docetaxel (75 mg/m²) in combination with epirubicin (50 mg/m²) in i.v. infusion in D1 every 3 weeks after incisional biopsy. They received adjuvant chemotherapy with CMF or FEC according the axillary status following definitive breast surgery. Clinical and pathologic response rates were determined after preoperative therapy. We evaluated the response rate to neoadjuvant chemotherapy and the prognostic significance of clinicopathologic and immunohistochemical parameters (p53, HER2, p21, RE and RP). Median patient age was 50 years with a median follow up of 46 moths from time of diagnosis. Results: Preoperative treatment achieved clinical response in 73% and complete pathologic response in 5.7%. The p53 overexpression was associated with an increased rate of objective response (P= 0.04). Among all clinicopathologic and immunohistochemical parameters, only HER2 overexpression, the axillary status (>2 positive LN) and age (under 41 years old) were associated with decrease in disease free survival (P= 0.004, P= 0.001 and P< 0.0001, respectively). The overall survival was reduced in HER2 overexpression patients (P= 0.02) and in patients with

more than seven axillary lymph node metastasis (P= 0.03).
Conclusions: p53 overexpression is associated with a higher objective response rate and HER2 overexpression is associated with poor prognostic in stage II and III of breast cancer patients treated with neoadjuvant taxanes/anthracyclin based chemotherapy.

P 419
IMMUNOHISTOCHEMICAL ANALYSIS OF CHROMOGRANINE A, SYNAPTOPHYSINE AND KI67 IN PURE MUCINOUS BREAST CARCINOMA.
Mrad K, Kacem D, Driss M, Sassi S, Abbes I, Dhouib R, A. Bouziani*,
Ben Romdhane K.
Institut Salah Azaiez, 1006, Bab Saadoun, (*) HMPIT, Tunis, Tunisia

Introduction : Breast mucinous carcinoma (BMC) are characterized by their favourable prognosis but they are not completely homogenous at microscopic level.
Aim of the study : to analyse endocrine differentiation and ki67 in BMC.
Material and method : Only pure BMC are eligible for the study. They were classified as follows according to the proportion of tumor cells/the whole tumor surface : A:<20%, B: 20-50%, C>50% and the presence (1) or absence (2) of cytoplasmic mucus. The following parameters were analyzed: age, follow-up, tumor size, lymph node status, Elston and Ellis grade. Immunohistochemical study of the following antibodies (Dako, dilution : 1/50) was performed : chromogranine A, synaptophysine and Ki67 (clone KiS5).
Results : Endocrine markers are positive in 7 cases. Chromogranine A is positive in 4 cases and synaptophysine in 5 cases with co-expression of the two markers in 2 cases. Two phenotype groups are distinguished :
- group I : immunolabeling of more than 50% of the cells (1+ to 3+)
- group II : immunolabeling of a low number of cells (20% : 1 case, few cells : 2 cases) with high intensity (2+ and 3+).

Expression of neuroendocrine markers is more frequent when the stroma is less abundant (type B and C) and when the cells contain cytoplasmic mucous (type 1). There's no difference for other parameters (size, lymph node, Elston and Ellis grade, survival).
Rates of Ki67 expression was distributed as follows : <1% : 11 cases, <10% : 7 cases, >20% : 4 cases. The rate is not correlated to the cellular type, neither to the the proportion of tumor cells/tumor surface
Conclusion : Endocrine differentiation doesn't influence the outcome of the tumor. The low rate of Ki67 expression could explain the favourable course of the tumor.

P 420
AN IMMUNOHISTOCHEMICAL STUDY OF EXTRAMAMMARY PAGET'S DISEASE
SCHELFOUT Katrien, TJALMA Wiebren, VAN DEN EYNDEN Gert, NAIK Raj, LOPES Tito, VAN MARCK Erik, MONAGHAN John, COLPAERT Cecile

Introduction: Extramammary Paget's disease (EPD) has diverse histogenetic pathways, some lesions originating primarily from cutaneous adnexal structures (primary EPD), while others resulting from secondary involvement of the skin by a subjacent carcinoma (secondary EPD). In primary EPD, most Paget cells seem to be cytokeratin (CK) 7+/CK 20-/gross cystic disease fluid protein (GCDFP-15)+, while CK20+/GCFDP-15- Paget cells suggests the presence of a subjacent cancer with a corresponding immunophenotype, most often a rectal carcinoma or a transitional cell carcinoma (TCC). Mammary and extramammary Paget cells share histopathological similarities. The receptor complex of heregulin-alpha consisting of HER2/neu, HER3 and HER4, is present in almost all cases of mammary Paget's disease. Published studies report a variable (0-88%) overexpression of HER2/neu in EPD. Expression of HER3 and HER4 in EPD has not been studied before.
Aim: To immunophenotype 15 cases of EPD and evaluate the expression of HER2, HER3 and HER4.
Methods: Immunohistochemical stains were performed on formalin-fixed, paraffin–embedded tumour tissue from 15 patients with EPD, using antibodies to CK7, CK20, GCDFP-15, TAB250, CB11, HER3 and HER4. HER2 oncogene amplification was assessed by fluorescence in situ hybridization (FISH).
Results: Mean age at diagnosis was 68.3 years (range 38-84). The EPD involved the vulva and/or perineum or urethra in all females (n=9). In the males (n=6), the EPD was located in perianal, scrotal and/or inguinal regions and symphysis. Eleven tumours were intraepithelial and 4 were invasive. Four patients had a subjacent cancer: 2 rectal carcinomas, 1 in situ TCC and 1 mucinous/endometrioid carcinoma of the vagina. The CK7+/CK20-/GCDFP-15+ immunophenotype was found in 6 cases, all without an associated carcinoma, and CK20+/GCDFP-15- in another 6 cases, including 1 associated TCC and 2 associated rectal carcinomas. The CK7+/CK20-/GCDFP-15- immunophenotype was found in 3 cases, including 1 associated mucinous/endometrioid carcinoma. Three cases of EPD showed HER2/neu oncogene amplification. HER3 and HER4 was expressed in 7 and 9 cases respectively, pointing at a role for heregulin-alpha in the chemotaxis of extramammary Paget cells.
Conclusion: We confirm that immunophenotyping of EPD with CK7, CK20 and GCDFP-15 is valuable in predicting the risk of an associated cancer. New therapies targetting the frequently expressed HER3 and HER4 might be promising.

VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF)-A IMMUNOHISTOCHEMICAL EXPRESSION IS ASSOCIATED WITH AN AGGRESSIVE PHENOTYPE IN INVASIVE BREAST CARCINOMA
Mylona E., Giannopoulou I., Alexandrou P., Athanassiadou S., Nikolaou I., Zoumpouli C., Nakopoulou L.
2nd Department of Pathology, "Attikon" Hospital, National and Kapodistrian University of Athens, Athens, Greece.

Introduction: Angiogenesis is a complex process which includes the protelolysis of the basal vascular membrane and intercellular matrix, migration and proliferation of endothelial cells and the formation of tubular structures. Tumor growth is dependent on angiogenesis that is regulated by peptide growth factors of which vascular endothelial growth factor (VEGF)-A is one of the most selective and potent. In the present study we investigated the role of VEGF-A in invasive breast carcinoma through its correlation with classic clinicopathological parameters (menopausal status, tumor size, histologic type, grade, lymph nodal status, stage of the disease, ER, PR), biological markers indicative of aggressive tumor phenotype (p53, c-erbB-2) and invasiveness [Membrane type1- Matrix Metalloproteinase (MT1-MMP)] and patients' survival.
Methods: A three step immunohistochemical method (ABC/HRP) was applied on paraffin embedded sections from 162 patients with invasine breast carcinoma to detect the expression of the proteins VEGF-A, p53, c-erbB-2 and MT1-MMP. Results were subjected to statistic analysis.
Results: VEGF-A was detected in the cytoplasm of malignant cells and the tumor stroma in 49.6% and 48.4% of the cases respectively. Cytoplasmic VEGF-A showed a parallel correlation with accumulative, non functional p53 and c-erbB-2 (p=0.007 and p=0.028 respectively). Additionally, parallel was found to be the correlation between cytoplasmic VEGF-A and MT1-MMP in cancer and stromal cells

(p=0.018 and p=0.020 respectively) as well as MT1-MMP of vascular endothelial cells (p=0.018). VEGF-A was found to have no significant relation to the clinicopathological parameters and patients' disease free or overall survival.
Conclusion: VEGF-A expression seems to be associated with the emergence of an aggressive tumor phenotype through its correlation with p53 and c-erbB-2. Moreover, VEGF-A correlation with MT1-MMP indicates its participation in angiogenesis, which further supports its contribution to the aggressive behavior of breast carcinoma.

P 422
NATURE OF C-KIT ALTERATIONS IN BREAST CANCER. A PUTATIVE NEW PROGNOSTIC AND THERAPEUTIC FACTOR
Isabel Arranz, Sebastian Luna and Dolores Bautista.
Department of Pathology. Hospital Regional Carlos Haya. Málaga. Spain.

Mutations of protooncogen c-kit (CD117)are believed to have a pathogenetic role in several neoplasms. Detected in most gastrointestinal stromal tumors (GIST), are highly relevant for treatment, determining a target for tyrosine kinase receptors inhibitors as Imatinib. C-kit mediated signal pathway is important for the development of breast cancer cell lines and c-kit gene expression seems to be lost in most breast neoplasms. However, an increase of c-kit expression has been associated with aggressiveness and poor outcome. The mechanism of these changes of expression and its importance in breast cancer biology and treatment have not been determined.
In order to study the nature and relevance of c-kit alterations in breast cancer, we have analyzed 85 invasive ductal carcinoma for c-kit expression at protein level, by immunohistochemistry (IHC) using a polyclonal antibody from DAKO, and at mRNA level by Quantitative RT-PCR. We also analyzed DNA for point mutations in exons 9, 11, 13 and 17 of the gene.
Normal ductal epithelia was always positive for c-kit protein but most neoplastic samples lost this expression when analyzed by IHC. However, 11 (12'9%)tumors showed overexpression of the protein, most of them (7 out of 11) of high histologic grade (WHO grade III). None of these cases contained point mutations when DNA was analysed, and the single detected mutation was present in a case negative by IHC. mRNA expression of c-kit in tumor tissues did not correlate with protein expression patterns nor presence of point mutation, suggesting a different origin. The nature, mechanism and significance of c-kit overexpression in breast cancer will be discussed.

P 423
PHYLLODES TUMOURS OF BREAST: A RETROSPECTIVE STUDY OF 18 CASES
GHARIANI Mekki, BAHRI Ibticem, AYADI Lobna, KHABIR A, SELLAMI Ahmed, BOUAZIZ Younes, BOUDAWARA SELLAMI Tahya

Introduction:
Phyllodes tumours (PT) are rare accounting for 0,3 to 1% of all primitive tumours of the breast. They constitute a spectrum of tumours ranging from benign to malignant form.
Objective:
The purpose of this study is to discuss the clinic and pathologic characteristics, the course and the prognosis of PT of breast.
Material and methods:
We report a retrospective study of 18 cases of PT diagnosed in the pathology department of Habib Bourguiba Hospital (Sfax-Tunisia) over a five years period (1999 - 2003)
Results:
The mean age of patients was 40 years (extremes: 17 and 60 years). Most patients (72,3%) gave a history of a slowly enlarging mass. The mammographic aspect was in favour of a benign tumour in ??? cases (71,4%). Macroscopically, the tumour size ranged from 1,5 to 22 cm (mean size : 7,9 cm). 11 PT were benign (61,2%), 4 borderline (22,2%) and 3 malignant (16,6%). A tumorectomy was carried out in 17 cases followed by a mastectomy in 4 cases. One benign PT and one borderline PT recurred after a follow up of 12 and 24 months. Two borderline PT and one phyllode sarcoma metastasised after a mean follow up of 12 months. A complete remission was observed in 15 case (83,3%) with a mean follow up of 32 months (extremes : 2 and 60 months).
Conclusion:
PT are usually benign but relapses and metastases are not uncommon. The clinical course can not be predicted reliably from histologic grading.

INDUCTION OF APOPTOSIS PREDICTS THE RESPONSE TO THE NEOADJUVANT CHEMOTHERAPY IN LOCALLY ADVANCED BREAST CANCER
Daniel Guimarães Tiezzi, Jurandyr Moreira de Andrade, Alfredo Ribeiro-Silva, Francisco José Cândido dos Reis, Heitor Ricardo Cosiski Marana, Sérgio Bighetti, Antônio Plácido Pereira.
Departments of Obstetrics & Gynecology and Pathology, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Brazil

Objective: This study was designed to evaluate the relationship between the apoptosis induced by chemotherapy and the clinical response in breast cancer. Patients and methods: We studied the Apoptotic Index (AI) and the overexpression of the protein p53 in 44 breast tumors from patients submitted to neoadjuvant chemotherapy. Objective response (OR) to primary chemotherapy was observed in thirty-seven (84%) and no response (NR) in seven. The AI was measured by the rate of apoptotic cells identified by morphological criteria in hematoxylin and eosin stain. The p53 protein expression was evaluated by the immunoperoxidase technique. The cases were interpreted as positive if more than 2/3 of tumors cells exhibited a dark brown nuclear staining. Results: The median AI change (AI initial – AI post-chemotherapy) observed in the patients with objective response was 0.84 while in patients with no response the median AI change was -0.01 (r= 0.40; P= 0.006). P53 protein overexpression was observed in 16.6% of OR patients and 42.8% of NR patients (r= -0.32; P= 0.034). The median AI change in p53-positive cases was 0.75, and in p53-negative cases, it was 1.72 (r= 0.44; P= 0.0029). Conclusion: We find a positive correlation between the increase in the AI and the clinical response and a negative correlation between the p53 expression and the clinical response, in patients with breast cancer submitted to neoadjuvant chemotherapy.

P 425
ADHESIVENESS IN SHORT-TERM PRIMARY CULTURES DERIVED FROM INFILTRATING DUCTAL BREAST CANCER AND THEIR ASSOCIATION WITH CLINICOPATHOLOGICAL VARIABLES
Bértolo C1, Guerrero D1, Vicente F2, Martínez-Peñuela JM3, Córdoba A3, Miranda C2, Ojer A1, Balen E2, Lera JM2
1Centro de Investigación Biomédica, Servicio Navarro de Salud. 2Servicio de Cirugía General y Digestiva, Hospital de Navarra. Servicio Navarro de Salud. 3Servicio de Anatomía Patológica, Hospital de Navarra. Servicio Navarro de Salud.

INTRODUCTION: Breast cancer is the most commonly diagnosed non-skin malignancy in women, being its incidence

and death rates increasing world-wide. E-cadherin adhesion molecule is involved in morphogenesis, maintenance of tissue cytoarchitecture and cellular migration. Short-term primary cultures isolated from ductal breast tumors are more reliable as a tool to study the specific cellular behaviour than commercial cell lines.
PURPOSE OF THE STUDY: We have studied the possible correlation between E-cadherin expression and pathological variables (histologic grade, c-erbB2 amplification…), metastasis, disease-free and survival time periods. The role of E-cadherin and histologic grade in growth pattern and metastatic properties of short-term primary cultures were also evaluated.
PATIENTS AND METHODS: We studied 30 patients that were preoperatively diagnosed with infiltrating ductal breast cancer and were informed about the study and gave their consent. The infiltrating ductal breast cancer tumors (IDC) were classified according to TNM stage, Nottingham prognostic index combined histological grade (NPI) and histologic grade (G1, G2, G3). Cells fractions were isolated and maintained for a short-period of time in 19 viable epithelial cultures derived from breast tumors. Tumor cell invasion was evaluated using a modified Boyden chamber invasion assay. E-cadherin expression was evaluated by immunohistochemistry and Western Blotting.
RESULTS: The median follow-up value was 33.2 months. 63.3% of the tumors were cultured, and their growth rate is associated with G3 (P= 0. 009). Lack of expression of E-cadherin by Western Blot is directly correlated to invasion properties (P= 0.027) and inversely correlated to c-erbB2 overexpression (P=0.008). There is no association between cell invasion and metastasis in vivo (P=0.51). E-cadherin expression did not associate with estrogen and progesterone receptor expression (P= 0.35, P=0.16, respectively) or growth rate (P=0.65). Histological grade is closely associated with ER and PR status (P=0.003, P=0.041, respectively), proliferative index (P=0.005) and overall survival (P=0.009).
CONCLUSIONS: 1. Viability of cultures is closely associated to unfavourable histological grade 2. E-cadherin expression is correlated with invasive properties in cell cultures.

P 426

CARDIOMEGALY AND MYOCARDIAL INFARCTION IN AN INFANT OF A DIABETIC MOTHER

HERVA Riitta, HIRVIKOSKI Pasi, VÄÄRÄSMÄKI Marja and AIKIO Outi
Oulu University Hospital, Oulu, Finland

Introduction
Pregnancy in diabetic women is a risk state that involves increased somatic size or macrosomia, an increased incidence of perinatal death and prematurity, hypertrophy of the islets of Langerhans with B-cell hyperplasia and hyperinsulinemia, and an increased frequency of congenital malformations.Today, diabetes is the most common chronic disease complicating pregnancy and its occurrence is especially high in Finland. The onset of diabetes occurs at an increasingly young age and vascular complications are thus becoming more common. The strain on maternal care services is also increasing. We describe an unhappy case with many complications of diabetic pregnancy.
Case report
The case consists of the second pregnancy and delivery of a 27-year-old female. The mother has had insulin-treated DM1 for 17 years. The first pregnancy in 2003 ended in birth at 38 + 2 weeks. The weight of the baby was 4435g. During the present pregnancy the patient's diabetes was in satisfactory control after the first trimester. In the third trimester, however, she developed pre-eclampsia. Emergency Caesarean section was done at 38 + 3 weeks because of CTG changes. The weight of the male baby was 5370g (+4SD) and length 59cm. Apgar score was 3/5/7 at 1/5/15 minutes. The infant's appearance was typical of diabetic macrosomia. Thorax X-ray and ultrasonography showed a hypertrophic heart. The baby died at 13 hours of age. Autopsy revealed ventricular and septal myocardial hypertrophy and mild obstruction of the outflow canal. There was a recent infarction in the septal myocardium and disorganized structure. The islets of Langerhans in the pancreas were hyperplastic and increased.
Conclusions
In Finland insulin-treated diabetes complicates about 4-5/1000 births. Many pregnant women have had diabetes long enough to develop diabetic vascular complications because the onset of diabetes occurs at a young age. Although hypertrophic cardiomyopathy is uncommon, the findings and the outcome of the present case indicate the importance of third trimester echocardiographic monitoring of fetal heart function when the mother has diabetes.

Department of Neuropathology Polish Academy of Sciences, Warsaw, Poland4

Detection of respiratory chain (RC) complex deficits in spectrophotometric assay of muscle and fibroblasts consists an important contribution to diagnosis of mitochondrial disorders (MD). However RC complexes may show defective activity in several disorders not primarily related to genes/proteins involved in structure and function of the RC.
Out of 300 skeletal muscle and fibroblast samples obtained from children suspected for MD 130 showed RC dysfunction in spectrophotometric assay. In 51 patients eventually molecular genetic studies of mtDNA and nDNA confirmed the diagnosis of MD. In 27 patients with RC complex deficits other diagnosis was finally confirmed. The diagnoses include: Duchenne and Becker muscular dystrophy, spinal muscular atrophy, myotubular myopathy, glycogen storage disease type II, vanishing white matter leukodystrophy, Lowe syndrome, LCHAD deficiency, Fanconi Bickel syndrome, hereditary fructose intolerance and others. Histological and histochemical assessment of skeletal muscle in children with RC complex deficits revealed: diagnostic pattern of mitochondrial or other non-mitochondrial disease; non-specific lesions; or normal morphology. The mechanisms of RC deficits in patients with diagnoses other than MD are probably diverse and subject to further investigation.
Conclusions: Repiratory chain defects may be associated with various „non mitochondrial'' disordes. Morphological examination remains useful in differential diagnosis of secondary respiratory chain defects. Disregard of morphological examination may lead to misdiagnosis.

P 428

DISEASE OF LETTERER-SIWE: A CASE REPORT

CHEDDADI F.

The Langerhans'cell histiocytosis has an incidence of 5 per million and often occurs in childhood with a male predominance.
Its clinical translation and its forecast are very variable and depend on the age of occurred (lower than two years) and of the organs reached. Pathologies of benign evolution and pathologies of bad forecast are thus defined.

The Langerhans'cell histiocytosis is characterized by a more or less polymorphic inflammatory infiltrate but always containing cells of lang¨¦rhans with notched nucleus which express the CD1a antigen intensely.
The diagnosis of LCH per defect is not posed any more with the advent of the antibody 010.It is necessary to avoid the diagnosis by excess met more and more in inflammatory pathologies or an increase in the histiocytes is observed.
It acts, in the observation which we report of a 4 month old nourrisson which presents:
- a cutaneous eruption generalized prevailing on the level of the folds of inflection,
- three masses of three cm large axis each one, occupying the right and left skull area,
- a hypertrophic gingivitis with early dental eruption,
- a chronic diarrhea,
and a multiple gaps of the dome of the skull with osseous lysis of the internal table.
The diagnosis of LCH was posed on fragments biopsic coming from the left skull mass, gum and the bone.
The cutaneous, oral and osseous attack concomitant realize the board of LCH in its traditional form multi focal and multi systemic and which returns within the framework of the clinical entities of bad forecast.
The marking of the molecule of adherence (¦ÁE¦Â7) could not be done for a digestive attack search.
Conclusion: the disease of LETTERER - SIWE is rare. The majority of the LCH cases corresponds to a focal disease (eosinophilic granulom solitary).the role of the histopathology in the diagnosis of the LCH largely profited from the Ag CD1a.
Unfortunately there are not criteria histopathologic of bad forecast from where major importance of confrontation anatomo-clinic.

P 429
OVERCOMING THE BLOOD BRAIN BARRIER WITH HIGH DOSE ENZYME REPLACEMENT THERAPY IN THE MURINE MUCOPOLYSACCHARIDOSIS VII MODEL OF LYSOSOMAL STORAGE DISEASE
VOGLER Carole, GRUBB Jeffrey, LEVY Beth, GALVIN Nancy, TAN Yun, KAKKIS Emil, PAVLOV Nadine, SLY William S.
Department of Pathology and Edward A. Doisy Department of Biochemistry and Molecular Biology, Saint Louis University School of Medicine, 1402 South Grand Blvd., St. Louis, MO 63104, USA and Division of Medical Genetics, Department of Pediatrics, Harbor-UCLA Research and Education Institute, Torrance CA USA and BioMarin Pharmaceutical Inc., Novato, CA USA

Enzyme replacement therapy (ERT) with recombinant enzyme is effective in reducing lysosomal storage in patients with several of the lysosomal storage diseases although improvement in CNS disease has been limited because the blood brain barrier restricts access of enzyme to the CNS. ERT with recombinant beta-glucuronidase (GUS) is not yet available for human MPS VII. However, there is a good murine model for this disorder in which glycosaminoglycan storage in the CNS produces severe cognitive disability. Studying this model, we found that the CNS is accessible to and improved by infused recombinant human GUS (rhGUS) in the newborn period but not improved by treatment begun after age 2 weeks. We recently reported that this enzyme delivery to brain in the newborn period is dependent on transcytosis of phosphorylated enzyme across the blood brain barrier by the mannose 6-phosphate/IGF-2 receptor. Down-regulation of this receptor mediated delivery system by age 2 weeks appears to explain the lack of response in the adult MPS VII mouse. In the current study we asked whether the obstacle to enzyme delivery to the CNS in the adult could be overcome by administering much higher doses of enzyme than used in conventional trials. We measured reduction in lysosomal storage for doses of 0.3-40 mg/kg body weight of rhGUS administered i.v. for 1 – 13 weeks to MPS VII mice tolerant to GUS. Mice treated for only 3 weeks with 0.3-5 mg/kg enzyme weekly had a slight reduction in meningeal storage but no change in storage in neurons. When mice received doses of 1-4 mg/kg/week for 13 weeks, there was a dose-based therapeutic effect on meninges, parietal neocortical and hippocampal neurons and glia. Only mice treated with 4 mg/kg showed a response in both neocortex and hippocampus. However, doses of 20-40 mg/kg GUS given 3 times over 1 week failed to reduce storage in any area of the CNS except the meninges. On the other hand, mice given 20 mg/kg weekly for 4 weeks, showed a decrease in neuronal, glial and meningeal storage and, on average, 2.5% of wild type GUS activity in brain. Our results indicate therapeutic enzyme can be delivered across the blood brain barrier in the adult MPS VII mouse if 1) one administers higher doses of enzyme than used in conventional ERT trials and 2) if these high doses of enzyme are administered over a sufficient period of time. These results have important implications for ERT for human lysosomal storage diseases.

SOLID PSEUDOPAPILLARY TUMOR OF THE PANCREAS IN CHILDREN
NICULESCU Liviu 1,CITU Rafira 2,ARDELEANU Carmen 3,PETRESCU Amelia 4
1.University of Medicine and Pharmacy "Carol Davila",2."Grigore Alexandrescu" Children Hospital,3."Victor Babes" Institute of Pathology, 4."Prof Dr.Th.Burghele" Clinical Hospital,Bucharest,Romania

Introduction:Solid pseudopapillary tumors of the pancreas are rare and their origin is unknown.The aim of this work is to report a new case diagnosed at a child.Thus ,we present the case of 14 years old girl hospitalised for complaining of severe epigastric pain. The radiological examination demonstated a well- demarcated pancreatic mass.The sugeons decided to remove the tumor.
Macroscopically examination carried out the removed tumor showed a 5 cm.diameter,well circumscribed and capsulated tumor with a gray-whitish colour on cut surface,soft consistency and haemorrhage zones.
Material and methods: Fragments of the tumor were fixed in formaldehyde 10% included in paraffin and the sections were stained with HE,VG and immunohistochemical markers like Vimentine (VIM), progesteron receptors(PR),neuron-specific enolase(NSE) and glucagone.
Results:The histological examination revealed proliferation of uniform cells with basophilic cytoplasm without atypia arranged in nests;between nests we observed giant multinucleated cells ,cholesterol crystals within a haemorrhagic stroma and pseudopapillary features.Immunohistochemical analysis : VIM positives, PR diffuse positives,NSE diffuse positives,glucagone positives
Conclusions: All these findings plead for the diagnosis of solid pseudopaillary epithelial tumor of the pancreas.

P 431
SOME IMMUNOPATHOLOGICAL CHARACTERISTICS OF EPITHELIAL CHANGES IN JUVENILE POLYPS OF COLON AND RECTUM IN CHILDREN
A. S. Tertychnyy, D. M. Konovalov, N. S. Marenich, A. G. Talalaev, Russian State Medical University, Moscow, Russia

The aim of this study was to outline variants of morphological epithelial changes in solitary juvenile colorectal polyps.
Material and methods: Formalin fixed paraffin embedded tissues were obtained from 30 patients with solitary juvenile polyps (JP) of colon and rectum. Patients were 6 months - 9

years old (median age 4.3 years). Localization of polyps was the rectum (n=22) and sigmoid colon (n=8). Size of JP varied from 0.5 to 5.0 cm (median 3.4 cm). H&E, histochemical (van Gieson, periodic acid Shiff (PAS) and Gomori's aldehyde fushcin - Alcian-blue (GAF-AB) stains and immunohistochemical (expression of Ki-67, p53 and carcinoembryonic antigen (CEA)) analyses were performed.

Results: The following morphological variants of epithelial changes were observed: in 25/30 JP comprised reactive regenerative changes within focal complex glandular structures, with high mitotic counts and expression of Ki-67. 22/30 cases showed hypertrophic epithelial changes, consisting of enlarged and pseudostratified goblet cells, suggestive of so called transitional mucosa. In 19/30 cases we observed focal cytoplasmic expression of CEA. 12/30 cases showed eosinophilic epithelial changes consisting of glands with abundant eosinophilic cytoplasm and centrally located small round nuclei. Expression of Ki-67 and CEA was negative in this group. In 7/30 cases we observed Paneth cell metaplasia, and in 5/30 cases, mild dysplasia with expression of p53 in less than 10% of nuclei in polyp glands.

Conclusion: JP showed a board spectrum of epithelial changes that might represents degenerative, regenerative and metaplastic processes. The main diagnostic pitfall is early dysplasia. Level of expression of p53 in JP may aid in differential diagnosis between reactive, regenerative changes and dysplasia.

HETEROTOPIC ORAL GASTROINTESTINAL CYST : REPORT OF A CASE

Nona Zabolinejad,MD*,Mehran Hiradfar**
*Department of Pathology,**Department of Pediatric Surgery
Dr. Sheikh Children Hospital,Mashhad-IRAN

Heterotopic gastrointestinal cyst of the oral cavity is an extremely rare lesion which fewer than 40 cases have been reported in the English language literature. They usually involve the soft tissue of the floor of the mouth and the tongue. The lining of these lesions resembles gastric or intestinal mucosa. In this report we describe an oral heterotopic gastrointestinal cyst of tongue in a 1-month-old boy and discuss its pathogenesis.

P 433

A CASE OF A COMPLETE PYLORIC PANCREATIC HETEROTOPIA AT CHILD CAUSING GASTROESOPHAGEAL REFLUX

NICULESCU Liviu 1, CATU Rafira 2 , ARDELEANU Carmen 3, PETRESCU Amelia 4
1."Carol Davila" University of Medicine and Pharmacy ,Bucharest,Romania 2.“Grigore Alexandrescu” Children Hospital, Bucharest, Romania 3.“Victor Babes” Institute, Bucharest, Romania 4.“Prof.Dr. Th. Burghele”Hospital, Bucharest, Romania

Introduction and aim: Heterotipic pancreas is usually found incidentally. Despite many cases having been reported heterotopic pancreas causes diagnostic difficulties for clinicians.Authors report a case of 1 year 1 month baby boy hospitalized for a history of vomiting, bleeding, gastroesophageal reflux and weight loss.
Plain abdominal radiograph showed a “trumpeting elephant” image.Endosonographical examination revealed a pyloric mass and a surgery was conducted to explore the area for tumor ablation.
Macroscopic examination showed a small tumor with a diameter of 6mm, firm, yellow, sharply circumscribed from the surrounding tissues, located beneath a mucosa;central umbilication was present.
Material and methods: Fragments of the tumor were fixed in formalin 10%, embedded in paraffin and sections were stained with HE. Immunohistochemical tests have been done:CD 56, Chromogranine, Glucagone, Insuline, Somatostatine, Sinaptophizine and VIP.
Results: Microscopic examination revealed a tumor proliferation consisting of acini‘s group, pancreatic ducts, Langerhans island on the pyloric sub- mucous and hypertrophyc muscular layer. The tumor was positive for insuline, glucagone, VIP,CD 56
Conclusions:The morphological appearance and immunohistochemical results enabled us to the diagnosis of complet form of heteritopic pancreas.It is important to differentiate between a cancer, an ectopic pancreas , a metastasis of a tumour and a pancreatic metaplasia of gastric mucoasa. Thus,an ectopic pancreas must be considered in the differential diagnosis of gastroesophageal reflux.

P 434

IDENTIFICATION OF THE MOTILIN CELLS IN DUODENAL EPITHELIUM OF PREMATURE INFANTS

NISHIKUBO T1), YAMAKAWA A2), NISHINO M3), NAKAJIMA M4), TAKAHASHI Y5), NAKAYAMA M6), KITAJIMA H7) AND FUJIMURA M7)
1)Neonatal Intensive Care Unit, 2)Clinical Laboratory Division, and 3)Department of Pediatrics, Nara Prefectural Hospital, 4)Department of Pediatrics and 5)Neonatal Intensive Care Unit, Nara Medical University Hospital, Nara, 6)Department of Pathology and 7)Neonatal Intensive Care Unit, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan

Introduction: Motilin is one of the gastrointestinal hormones, and originates in the endothelial cells of the upper small intestine. Motilin regulates the gastrointestinal motility via migrating motor complex (MMC) activity. Most preterm infants of <32 weeks gestation are considered to lack MMC activity.
Purpose: The aim of the present study was to examine the presence of motilin in the duodenal epithelial cells of premature infants of <32 weeks gestation.
Methods: Specimens from 10 deceased infants (gestational age: 26.4 • } 2.7 weeks and birthweight: 808 • } 303 g) were examined as subjects. All infants died of severe cardiopulmonary disorder or intraventricular hemorrhage (grade IV). The average survival period was 3.1 • } 1.9 days. Autopsies were performed and formalin-fixed duodenums were immunostained with rabbit antiserum to motilin by the labeled streptavidin-biotin (LSAB) method. An adult duodenum obtained by pancreatoduodenectomy was also examined for the presence of motilin as a positive control specimen. An absorption test using motilin peptide was performed to prove the specificity of the binding with rabbit antiserum to motilin.
Results: Motilin-containing cells were detected in the adult specimen, and the binding by rabbit antiserum to motilin was completely inhibited by excess amounts of motilin peptide, indicating that this binding was specific to motilin. All 10 infants had presence of motilin antigen in the epithelial cells of their duodenums.
Conclusion: This preliminary study indicates that the immunohistological analysis is specific to detect motilin-containing cells, and certifies the presence of motilin in duodenal epithelial cells of premature infants of <32 weeks gestation, including one at only 22 weeks gestation.

KARYOMETRIC ANALYSIS OF THYMOCYTES IN DOWN SYNDROME

MIHAILOVIC Dragan, KUTLESIC Cedo, DJORDJEVIC Biljana, MIJOVIC Zaklina, GOVEDAREVIC Nenad
Institute of Pathology, University of Nis, Serbia

Introduction. Down syndrome (trisomy 21) is the most common numeric aberration of autosomal chromosomes in man; the incidence in newborn is about 1 in 700. Intrauterine growth retardation is a consistent finding in infants with Down¡¦s syndrome. The common anomalies, in order of frequency, are cardiac defects, duodenal obstruction, talipes equinovarus, cataracts, imperforate anus, cleft lip or palate, congenital megacolon, and meningomyelocele. Endocrine disorders in patients with Down¡¦s syndrome include hypothyroidism, occasionally associated with precocious puberty or diabetes mellitus. T-cell immunodeficiency in Down syndrome has been well documented.
Purpose of the study. To estimate nuclear size and integrated optical density of thymic lymphocytes in patients with Down¡¦s syndrome and control group.
Material and Methods. During the years 1988 to 2000, fourteen cases of Down¡¦s syndrome were found (eight male and six female). Ten babies without congenital anomalies, died with respiratory distress syndrome, were analyzed as a control group. Karyotyping was performed in all cases during life. After standard pediatric autopsy, 5 ƒÝm thick sections were stained with hematoxilin and eosin. Karyometric analysis was done using ImageJ software, NU-1 microscope (Carl Zeiss, Jena, Germany), at objective x63 (NA=0.65), after manual editing of a binary image.
Five nuclear variables were estimated: mean number of lymphocyte nuclei per visual field, area, perimeter, circularity, and integrated optical density (IOD), in both cortex and medulla.
Results.In the thymic cortex, the mean number of lymphocyte nuclei was significantly lower in patients with Down syndrome. Integrated optical density of thymocyte nuclei was significantly higher in Down syndrome patient, compared to control group. Thymocytes nuclei were smaller in Down syndrome patients, but this difference was not statistically significant.
Conclusions. In Down syndrome patients the thymus is usually small and may be dysplastic with lymphocyte depletion; a small, contracted cortex and loss of corticomedullary demarcation resemble thymic involution. Large Hassall¡¦scorpuscles with calcification and cystic change in the thymus has been suggested as a marker for Down syndrome. The present results suggest altered gene expression in excessive genetic material, disordered maturation of cortical lympohocytes, with decreased number and increased chromatin density.

MORPHOLOGIC AND ULTRASTRUCTURAL FEATURES OF SOFT PALATE AND PHARYNGEAL MUSCLES IN CHILDREN WITH CLEFT PALATE
CECCHETTI Denise, *LUCCHESI Paolo, POLLINA Luca Emanuele, **SANSEVERO Stefano, **MASSEI Alessandro, FUNEL Niccola, BEVILACQUA Generoso, VIACAVA Paolo
Division of Surgical, Molecular and Ultrastructural Pathology, Department
of Oncology, University of Pisa, Pisa, Italy
* Department of Human Morphology and Applied Biology, University of Pisa, Pisa, Italy
** Department of Plastic Surgery, Hospital of Pisa, Pisa, Italy

Introduction. Palate and lip muscle alterations in patients with cleft are poorly known. Few studies have focused attention on lip muscle, while very rare data are reported on the pathologic features of palate muscles. The morphological alterations of palate and pharyngeal muscles in infants with cleft palate could be responsible for a persistent postsurgical velopharyngeal insufficiency with consequent inadequate functional recovery especially for speech and swallowing.
Purpose. Based on this, we decided to analyze the histologic features of the superior pharyngeal constrictor muscle and right and left palatopharyngeal muscles in a series of 11 patients affected by isolated cleft palate and 9 patients affected by unilateral or bilateral cleft lip and palate. In 4 cases ultrastructural analysis was also performed. Methods. A muscle biopsy was done during palatoplasty. Muscle sections were stained with hematoxylin-easin, modified Gomori trichrome, PAS and NADH-TR. The analyzed parameters were: organization and type of muscle fibers, presence of ragged red fibers, characteristics of nuclei, degree of fibrosis, presence of adipose tissue and inflammatory infiltrate.
Results. Our results showed the presence in both type of muscle of dystrophic-like alterations such as variability of fiber size, increase of connective tissue and presence of adipose tissue. No ragged red fiber, inflammatory infiltrate or neurogenic atrophy was observed. Electron microscopy evidenced focal areas of disruption of myofibrils containing amorphous materials. Conclusions. The marked alterations of palate muscles in children with cleft suggest that muscle damage could represent a significant pathogenetic factor in this type of malformation. The degree of muscle alterations may be responsible for a persistent postsurgical velopharyngeal insufficiency despite successful surgical repair. Muscular biopsy during palatoplasty could offer useful functional prognostic information in patients with cleft lip and palate.

P 437
HYPOPHYSEAL DUPLICATION WITH FRONTONASAL AND CNS MALDEVELOPMENT
González-Obeso E.(1), Morales C (2), Mariño A (1), García-Fernández E (1), Rodríguez JI(2).
Department of Pathology. La Paz University Hospital. Madrid. Spain.
(1) Tranee resident; (2) Medical Doctor.

INTRODUCTION: Hypophyseal duplication is an uncommon malformation that appears isolated or associated with craniofacial malformations. About 24 cases have been reported since 1880.
PURPOSE OF THE STUDY: To present a new case and review the central nervous system (CNS) and craniofacial anomalies associated with hypophyseal duplication in the autopsy cases reported in literature.
METHODS: Clinical reports, scanner images, and autopsy study of a girl (46, XX) 2 months and 20 days old.
RESULTS: The propositus had frontonasal malformation (hypertelorism, broad nasal bridge, bifid nasal tip and bifid anterior cranium), macrostomia, retrognathia, and bifid tongue. She also presented maxilomandibular bony fussion, as well as fussion of the tongue to the palate and to the inferior lip by a hairy polyp, both corrected surgically.
In the cranium, the sella turcica was broadened, with little prominence of the clinoid apophyses, and with two cavities that contained two complete hypophyses with two infundibules. The three cranial fosae where narrowed antero-posteriorly.
The CNS had both olfactory bulbs and corpus callosum agenesis, anomalous morphology of the brain stem and spinal cord, and neuronal heterotopia in occipital white matter and leptomeningeal heterotopia.
CONCLUSIONS: There are seven previous autopsy cases of hypophyseal duplication that associate, in order of frequency, the following frontonasal malformations: hypertelorism (6 cases), an intraoral mass –epignatus- (4), bifid tongue (3), duplication of the anterior groove of the spinal cord (1), and "V" shaped hairline (1). The associated anomalies of the CNS reported were broadened sella turcica and hypothalamic anomalies (7); corpus callosum agenesis (5) and olfactory bulbs agenesis (2), and glial and/or neuronal heterotopias (1).
The present case has several common features with the one described by Hori et al. in 1983, that, in addition, had cleft palate, abnormal circle of Willis, duplication of the spinal

cord groove extended to the thoracic level, but it had no olfactory bulbs agenesis.
There are several hypothesis about the origin of the hypophyseal duplication and the associated malformations, yet none of them is definitive.

2. Department of Children Surgery, Papageorgiou Hospital Thessaloniki Greece

EFSTRATIOU Ioannis, ZAVITSANAKIS Athanassios, NEOFYTOU Andreas, PETROPOULOS Anastassios.
Melanotic neuroectodermal tumor of infancy in the retroauricular region: a case report.
Melanotic neuroectodermal tumor of infancy (MNTI) is a very rare neoplasm arising in the first year of life and localized mainly in the craniofacial region. It grows rapidly and has a high rate of recurrence.
We report a case of MNTI because of its unusual extraosseous localization. The tumor has been investigated by means of histology and immunhistochemistry,
A 10 month-old male infant presented with a swelling of the left retroauricular region. Ultrasonography showed a soft tissue lesion 1 cm in diameter with poor vascularisation without destruction of the scull. A dermoid cyst was suspected.
The surgical specimen measured 1,5x1x0,5 cm and had a whitish focally black color with elastic consistency.
Histologically the tumor consisted of alveolar nests and tubules within fibroblastic tissue. These formations were composed of two cell populations, large melanin-containing cells around smaller neuroblast-like cells with smashed nuclei. Immunhistochemically the melanocyte-like cells expressed cytokeratin and HMB-45. The smaller ‘blue cells’ didn’t stain for any marker due to the smudging artefact. Histological and immunhistochemical characteristics of the tumor confirm the diagnosis of MNTI. Six months later the patient has no evidence of recurrence.
MNTI is a dysembryogenetic tumor of neural crest occurring commonly in the maxilla and in the mandible. In our case the tumor had a very infrequent site. The vast majority of these tumors behave in a benign fashion after local excision. However follow-up for at least 2 years is necessary because of the high recurrence rate.

P 439
DIFFERENTIATED MELANOTIC NEUROECTODERMAL TUMOR OF INFANCY
PARK So Yeon, HYUN Chang-Lim, LEE Youn Kyung, LEE Hye Seung, CHUNG Jin Haeng, CHI Je Geun, CHOE Gheeyoung
Department of Pathology, Seoul National University Bundang Hospital, Seoul National University College of Medicine

A three-month-old male infant was admitted due to left temporal mass. He was born at full term by vaginal delivery. His birth weight was 2.8 kg and his head circumference was within normal limits. A mass was noted on left temporal area at the age of one month, and the mass progressively increased in size. Brain CT revealed an extra- and intra-dural tumor with calcification and destruction of overlying calvaria. Temporoparietal craniotomy with near-total removal of the tumor was done. On operation, the tumor involved left temporal bone, periosteum, dura and cerebral cortex. Microscopically, the tumor consisted of lobules and solid clusters of monomorphous small cells admixed with gland-like or tubular arrangements of pigmented epithelium. Both pigmented melanin-containing epithelial cells and a small-cell component resembling neuroblasts were present, and the diagnosis of melanotic neuroectodermal tumor of infancy (MNTI) was made. The patient received 18 cycles of ¡°8 drugs in 1 day¡± chemotherapy for 15 months. Follow-up CT disclosed a residual mass attached to the petrous bone with a peritumoral cyst. The mass showed strong contrast enhancement. Second operation was done 11 years after the first operation, and the residual mass was excised. The surgical specimen of second operation was a 3 cm-sized, pigmented mass with focal calcification. Microscopically, the tumor consisted of two different components. In the center of the tumor, pigmented epithelial cells formed clusters, glands or tubules. In the peripheral region of the tumor, lobules of mature ganglion cells, immature ganglion cells and abundant neuropil were surrounded by pigmented epithelial cells and fibrovascular septa. Compared to the original tumor, the residual tumor revealed extensive maturation of neuroblast-like small cells. We diagnosed this case as a differentiated MNTI.
MNTI is a rare but well-documented lesion of neuroectodermal derivation. Maturation of the neural elements has been reported only occasionally. To the authors' knowledge, this case is the first one of MNTI in which neuronal differentiation of the neuroblastic cells is convincingly demonstrated in a residual tumor over 10 years, and in which chemotherapy might have induced differentiation of the neuroblastic cells.

P 440
1H MRS STUDY OF THE BRAIN IN NORMAL CHILDREN AND IN CHILDREN WITH SEIZURE DISORDERS
ROGOZHYN Vladimir, ROZHKOVA Zina, KIRILLOVA Lyudmila
Radiological Center of the Academy of Medical Sciences of Ukraine, Kiev, Ukraine

Purpose: We propose the quantitative indicators for the characteristics of regional and age-related peculiarities of brain metabolism in normally developing children and in children with seizure disorders.
Materials and Methods: Two groups of children are examined by 1H MRS using 1.5T Magnetom Vision (SIEMENS). The 1st group (NG) consists of 10 healthy children (in the age from 1 months to 16 years). The 2nd group (PG) includes 24 developmentally delayed children with seizure disorders (in the age from 2 weeks to 10 years). In all children 12x12 spectral matrixes in supraventricular region parallel to the canthomeatal line are obtained. 2DCSI 1H spectra are recorded with: TR/TE=1500/135 ms, NS = 1.
Results: In each voxel of the spectral matrix we introduce two indicators: the metabolite content AM as the peak area and the metabolite concentration CM as the ratio of the peak area to the sum of all the peak areas S: CM=AM/S. We describe the metabolic state in each voxel by the triad T* ={ACho, ACr, ANAA}, where ACho, ACr, and ANAA are the peak areas of the signals from Cho, Cr and NAA. For each of the areas we assign three values: 1, 2 and 3, to obtain six symbolic spectral configurations:1* ={1,2,3}, 2* = {2,1,3}, 3* ={1,3,2}, 4* ={3,2,1}, 5* ={3,1,2} and 6* ={2,3,1}. We analyzed the temporal alterations of the triad distributions during neurodevelopment. In the NG during infancy (from 1month to 1 year) the most frequent configurations in gray and white matter are 3*, 4* and 5*. During childhood (from 1year to 11 years) in the NG triads 1* and 2* dominate in all voxels of VOI. In the PG in the electrically defined seizure focus the triads 5* and 6* are observed. Signal of lactate is elevated only in children of PG, who had seizures immediately before MRS-examination.

Conclusion: The triad distributions in developing brain give us a quantitative way for the estimation neurodevelopmentally abnormalities.

P 441

THE CHILD'S CEREBRAL TUMORS

Hanane Rais, Fatiha Benadra, Badiaa Belaabidia
Department Of Pathology, CHU Mohammed VI - Marrakec-Morroco

The child's cerebral tumors (CCT) are rare. They represent 20% of the child's malignant tumors. They constitute the second malignant tumors in pediatrics after the leukemias 34,5% and the first cancer strong tumor, just before the lymphoma 7-10%. The object is to value through a set of 52 cases of CCT the epidemiological and pathologic features of this pathology. It is a retrospective review (survey carrying) on 210 cases of cerebral tumors collected to the service of anatomy pathology between June 2001 and August 2004.
The CCT represent 24,76% of the cerebral tumors. The median age at diagnosis was 8.9 years (range 2-16 years). The sex-ratio was 2 with a masculine predominance. The cerebral tumors of the posterior fossa cerebral occupied the first rank with 68.18%. The médulloblastoma represents 51,9% followed of the astrocytoma 19,23%. The CCT are highly heterogenous, so in every case the histological diagnosis should be obtained. They distinguish themselves to the one of the adult by a particular topographic and histological distribution: Big frequency of the tumors of the posterior fossa cerebral, clean predominance of the astrocytoma, médulloblastoma. Their diagnosis require an anatomo-clinical and radiological confrontation. Prognostic factors are the degree of histologic malignancy and the extent of surgical resection.

ENCEPHALOCELE ASSOCIATED TO AN AGENESIS AND A LIPOMA OF CORPUS CALLOSUM : A CASE REPORT.

ELBAKKOURI Jalila (1), RAIS Hanane(1), ALATAWNA Hind (1), ELATTAR Hicham(1), LOQA C. (2), BELAABIDIA Badia (1), AIT BENALI (2).
(1) Department of anatomopathology – (2) department of neurosurgery.
CHU Mohammed VI - Marrakech

Lipomatous hamartomas are rare disorders affecting the central nervous system. Forty percent of all lipomas develop in the anterior third of the corpus callosum. In 48% of the cases, there is partial agenesia of the corpus callosum. In 50% of the cases, there is no clinical expression.

We report the case of a 30 months old boy with frontal tumefaction since his birth. The neurological examination was normal. There were no associated malformations. The brain computed tomography scanning showed a lipoma and an agenesis of the corpus callosum. An hydrocephaly of the temporal and occipital corns has been found. Surgery was indicated. The mass was composed of typical adipose tissue in which a large number of blood vessels were present. The evolution was marked by post-surgery meningitis.

Our purpose was to describe a very rare association of an encephalocele, agenesis and lipoma of the corpus callosum.

P 443

IMMUNOHISTOCHEMICAL EXPRESSION OF CELL CYCLE REGULATORS IN PEDIATRIC EMBRYONAL BRAIN TUMOURS

STEFANAKI Kalliopi,ARGYRAKOS Theodore,VAN VLIET-CONSTANTINIDOU Catherine,MOSCHOVI Maria,PATERELI Amalia,SAKELLIADIS Emmanuel ,HADJIGEORGI Christiana,SFAKIANOS George,PRODROMOU Fivos,KARENTZOU Ourania.
Dept.of Pathology,Computerized Tomography,Neurosurgery of "Aghia Sophia Children's Hospital,Dept.of Oncology-Haematology First Pediatrics Clinics of Athens University,Athens Greece

Background:Embryonal brain tumours in children are aggressive neoplasms with overlapping clinical and histological features.The distinction between Medulloblastomas(MB)and Atypical Teratoid Rhabdoid tumours(ART)has prognostic and therapeutic value.
The purpose of this study was to investigate the immunophenotypic features and the expression of cell cycle regulators,p27,Cyclin D3,Cyclin E,in 35 pediatric embryonal brain tumours in correlation with Ki-67 and p53,bcl-2 proteins.
Our material comprised 29 MB and 6 ART.The Streptavidin-Biotin HRP method was performed on paraffin sestions for the detection of Synaptophysin(SY),GFAP,Neurofilaments(NF),EMA,Cytokeratin AE1/AE3,Cytokeratin 8,Vimentin(VIM),Smooth muscle actin(SMA),Desmin,Ki-67/MIB-1,P53(DO7),bcl-2,p27(1B4),Cyclin D3,Cyclin E with monoclonal antibodies.
The immunophenotype of MB was:29+/29 SY,9+/29NF,5+/29 GFAP,0/29 EMA and AE1/AE3,while the ART were:6+/6 VIM,5+/6 EMA,6+/6 AE1/AE3 and Cytokeratin 8,4+/6 NF,5+/6 GFAP,4+/6 SMA.
High expression of Ki-67(>25%)and p27(>50%)was observed in 89,6%(26/2)]and 79%(23/29) of MB respectively with increasing p27 expression in areas of neuroblastic differentiation.Cyclin D3 and Cyclin E were detected in 25%(6/24)and 62,5%(15/24)of MB.
High Ki-67/high p27 was observed in 68,9%(20/29) of MB with detection of Cyclin E in 65%(13/20) and a parallel Cyclin D3 expression in 3 MB.P-53 and bcl-2 proteins were detected in 75%(22/29)and 27,5%(8/29) of MB respectively.
High Ki-67(>25%) and p53(>10%)expression was revealed in all ART,while high bcl-2 and p27 expression was observed in 5. Cyclin E and Cyclin D3 were detected in 6 and 1 ART respectively.
In conclusion,the complex immunophenotype including the detection of epithelial markers contributes significantly in the differential diagnosis of ART from MB.
The parallel high Ki-67/p27 expression in correlation with Cyclin E detection in a considerable number of MB and ART suggests that dysregulation of G1/S transition may play an important role in their pathogenesis.

P 444

CHILDREN'S KAPOSI'S SARCOMA IN CAMEROON(CENTRAL AFRICA) WITHIN THE ONGOING AIDS EPIDEMIC AN ENDEMIC AREA

NKEGOUM Blaise(1),GESSAIN Antoine(2),DOUMBE Pierre(3)
1- Service of Pathology, University Teatching Hospital-Yaondé-Cameroon email: nkegoum@yahoo.fr
2-Unit of Viral Oncology,Pasteur Institute-Paris-France
3-Department of Pediatric,Unit of Children oncology-Yaoundé-Cameroon

Background: Cameroon (Central Africa) was known to be an endemic area af Kaposi's sarcoma even before the unset of AIDS epidemic. Jensen and al reported 16 cases of Kaposi's sarcoma in cameroonian children between 1968 and 1974. An increase in the incidence of Kaposi's sarcoma have being noted in AIDS patients
allover the world nowadays. The aim of this study was to show the anatomoclinical aspects of Kaposi's sarcoma within the ongoing AIDS epidemic in Cameroon.

Materials and methods: we carried out this retrospective study over a period of 18 years (from 1987 to 2004).All cases of children Kaposi's sarcoma were retrieved. We noted:
- the total number of Kaposi's sarcoma within the period of study,
- the ages and gender of the patients,
- the clinical signs,
- the HIV status,
- the pathological aspects,
- the treatment received and the evolution under treatment.
Results: among the 575 cases of Kaposi's sarcoma noted, 4% were aged 0 to 15 years. The youngest patient was aged 3 months and was HIV positive. The male to female ratio was 3/1. The most common site of involvement was cervical lymph nodes. All the chidren presented with fever and weight loss. Skin and lymph nodes were simultaneously involved in 2 cases. Only 4 cases of HIV positive serology were observed in this serie of children and their mothers. The pathological aspect most frequently observed was advanced stage Kaposi's sarcoma. Less than 10 children received fulldose of chemotherapy made up of cyclophosphamide, vincristine and prednisone. Only one child survived 9 years after chemotherapy.
CONCLUSION: Children Kaposi's sarcoma is still a rare disease in Central Africa for the moment.

P 445
INTRAMEDULLARY OSTEOID OSTEOMA: A CASE REPORT.
ELBAKKOURI Jalila (1), BELAABIDIA B. (1), KASSIMI Nabil (2), OULED SAID (2).
(1) department of anatomopathology -
(2) department of Paediatric Surgery.
CHU Mohammed VI - Marrakech

Osteoid osteoma is a benign bone tumour. It accounts for 2 to 3% of the whole of bones tumours. The intramedullary localization is rare and poses diagnosis problems at the radiological stage.
We report the case of an 8 years old boy without particular pathological antecedents. He has consulted for pains of the left leg appeared 6 months before. Plane radiographes objectified a medullary tibial hyperdensity and a cortical thickening. The computed tomography showed intramedullary calcifications.
A biopsy exerèse of the tumour was carried out. The anatomo-pathological examination confirmed the diagnosis of the osteoid osteoma.

Intramedullary osteoid osteoma is rare. It poses a real radiological diagnosis problem. Its final diagnosis is anatomo-pathological. The characteristics of our case are the unusual localization of the osteoid osteoma associated with intense reactive bone sclerosis.

P 446
CONGENITAL BILATERAL ADRENAL NEUROBLASTOMA WITH MULTIPLE METASTASES: A CASE REPORT
SPASEVSKA Liljana, JANEVSKA Vesna, PETRUSEVSKA Gordana, JOVANOVIC Rubens, RISTOVSKI Milco, BANEV Saso
Institute of Pathology, Faculty of Medicine, Skopje, R. Macedonia

We report a case of bilateral congenital neuroblastoma (NB) with multiple metastases found at autopsy.
The neonatus was born by normal vaginal delivery in a local hospital at 40 weeks of gestation and weighted 3000g. Maternal history was unremarkable. His abdomen was markedly distended, suspected to congenital malformation. Prenatal ultrasound was not peformed. He was urgently transported to the Central Hospital but died on the way two hours after birth.

Postmortem examination, revealed a relatively well demarcated huge tumors in the both adrenal glands with necrosis and hemorrhage. The kidneys were not involvded by tumors. The left tumor measured 4x4x2cm and weighed 120g and the right tumor measured 6x4x2cm , weighed 140g. The left tumor was ruptured with massive intraabdominal bliding (300ml). Multiple metastatic nodules in the liver (500g), lung and in the brain were noted. The other organs were grossly unremarkable. Microscopically the tumors were composed of small poorly differentiated neuroblasts with minimal stroma and without fibrillary background. The diffuse pattern of growth was accompanied with necrosis, hemorrhage, angiomatoid and pseudovascular formations. The tumor cells were immunoreactive for neuron specific enolase, chromogranin and synaptophysin, while desmin, MIC2, and leucocyte comman antigen were negative. The microscopical findings of the liver, lung and brain were similar. A diagnosis of NB with multiple metastases was made. The NB was classified on the basis of INPC (Shimada) classification as one of the stroma-poor tumors, poorly differentiated, with mitosis karyorrhexis index of less than 200 - faborable histology.

P 447
RENAL DYSPLASIA. ANALYSIS AND CLASSIFICATION OF 16 POST-NATAL CASES.
SALERNO Angela.
Servizio di Anatomia e Istologia Patologica e Citodiagnostica. Ospedale Maggiore. Bologna. ITALY

INTRODUCTION.
Renal dysplasia (RD) is the major cause of renal failure in children. It consists of a heterogeneous group of disorders with different etiologies and it is classified according to well-recognised histopathologic criteria. RD may affect the whole kidney or may be focal or segmental and may have a broad spectrum of severity. RD shows usually unilateral involvement of a kidney. Most forms of dysplasia have associated cysts suggesting common etiopathogenetic mechanisms. One of them is the disruption of renal branching morphogenesis. The more frequent forms of RD include the isolated multicystic dysplastic kidney, the dysplastic kidney from early fetal ureteric obstruction and the dysplastic kidney associated with a genetic syndrome.
PURPOSE OF THE STUDY.
To evaluate the clinical data and the microscopic feature of the post-natal dysplastic kidneys submitted to the Pathology Department in the last ten years according to the most used classification (Osathanondh and Potter 1964) and using a semiquantitative evaluation, devised by Tarantal et al. in 2001 in their experimental model, to grade dysplasia.
METHODS.
Clinical data and pathological material of 16 patients with RD registered between 1995 and 2005 were retrieved and reviewed.
RESULTS.
The 16 patients included 11 males and 5 females. Their ages ranged from 1 to 29 months with a mean age of 10 months (ten patients were less than 12- months old). Only one patient had bilateral RD (postmortem case) and 7 out of 16 had segmental disease. The malformations most frequently associated were ureter duplication (9 cases) and ureteral stenosis or atresia (4 cases). The microscopic features of the renal parenchyma including renal architecture, cyst, alterations in collecting tubules, primitive ductal structures, fibromuscular rings, changes in the metanephric mesenchyme, growth of primitive glomeruli and tubules and evidence of islands of cartilage has been scored. Cysts were very scanty in 2 cases and cartilage was absent in 9 cases (5 females). The dysplasia was less severe in female patients. Chronic inflammation was usually present.
CONCLUSION.

The prevailing classification of RD takes into account the clinical manifestations and the pathological changes but a completely satisfying classification system, encompassing new data from molecular studies on morphogenesis and traditional histology, is still missing.

P 448
EVALUATION OF PROGNOSTIC IMPORTANCE OF THE 2001 SIOP PROTOCOL IN CHILDREN WITH NEPHROBLASTOMAS. A PRELIMINARY STUDY.
Jozef Kobos*, Katarzyna Taran**
*Department of Pathology of the Age of Development and Department of Pathology Konopnicka Memorial Hospital Medical University of Lodz, Poland
** Department of General Pathology and Department of Pathology Konopnicka Memorial Hospital Medical University of Lodz, Poland

The application of modern complex therapeutic protocols in children with Wilms' tumor caused a spectacular increase in the curing rate up to 85-90% cases. Histopathological classification is a vital part of these protocols and morphological diagnosis determines the schedule of subsequent treatment.
The new Revised SIOP Working Classsification of renal Tumor of Childhood (2001) was introduced in our center.
For our research we used formalin-fixed and paraffin-embedded archival material from 48 patients with nephroblastomas cured in our Hospital.
For histopathological evaluation of tumors we applied the previously used system and also the new Revised SIOP Working Classsification of renal Tumor of Childhood (2001). Statistical analysis was based on Kaplan-Meier survival method and Kruskal-Wallis as well as Chi2 tests.
The aim of our study was to correlate the prognostic importance of both classifications.
Results:
The presence of regular and irregular blastemal component in evaluated nephorblastomas was related to poor prognosis. Children with Wilms' tumor with low differentiated epithelial component did similiarly as patients with nephroblastomas which contained regular and irregular blastemal component. The application of the former classification showed the correlation between the histological grade of the tumor and the presence of metastases and relapses as well as with the presence of deaths from the disease.
The use of new SIOP (2001) classification also showed a strong correlation between the histological grade of the tumor and the presence of deaths from the disease.
Conclusion:
The new SIOP classification is an excellent tool in both the diagnosis and treatment of children with Wilms' tumor. The subdivision of cases fulfilling criteria for intermediate-risk tumors depending on either high or low epithelial differentiation might be useful for further prognostic analysis.

2-Mother and Child Health Institute of Serbia "dr Vukan Cupic", Belgrade

SUMMARY: Cyclin-dependent kinase (CDK) inhibitors represented by the INK4 family (including p16(INK4a), p15(INK4b), p18(INK4c), and p19(INK4d) are regulators of the cell cycle shown to be aberrant in many types of human cancer. AIM: The aim of our study was to investigate p16 protein expression in Wilms tumor, to compare it with the expression in normal renal tissue as well as to see if there is a correlation between p 16 expression in Wilms tumor with tumor stage, histological type and prognostic group. METHODS: 28 cases of Wilms tumor (2 cases with metastasis) and 2 samples of normal kidney tissue were studied using streptavidin-biotin-complex technique. P16 expression levels were semiquantitatively scored. RESULTS: The expression of p16 was observed in the majority of cases (96%). There was statistically significant relationship between p16 expression and tumor stage (p=0.015) that is, tumors of higher stage (III/IV/V) more often expressed p16 then tumors of lower stage (I/II). Expression of p16 was detected in various histological types of Wilms tumor, but there was no statistically significant association (p=0.82). p16 was found more frequently in high risk tumors then in tumors with good prognosis (p=0.02). P16 immunostaining was observed in two cases of metastasis. CONCLUSION: Although, p16 is inhibitor of CDK, the results of our investigation show that nephroblastoma cells may proliferate in the presence of elevated levels of p16.

P 450
ROLE OF THE ? TYPE COLLAGEN IN FORMING OF CONNECTIVE TISSUE ELEMENTS OF HUMAN FETAL KIDNEYS AT IUGR CASES IN 20-22 WEEKS OF GESTATION
SYSOENKO Olexander, RESHETNIKOVA Olga, MOROZOV Sergiy
Department of Pathologic Anatomy, Medical University, Lugansk, Ukraine.

It is suggested that fetal intrauterine growth retardation (IUGR) may lead to hypertension in adults. Alteration of kidneys tissue maturation may play an important role in the pathogenesis of a hypertension too. The aim of present study was to determine the distribution of the III type collagen in forming of connecting tissue of the fetal kidneys in cases of IUGR. Methods: 20 pairs of fetal kidneys (including 10 pairs of kidneys in cases of IUGR) from the late medical abortions because of psychotherapeutic reasons at 20-22 weeks of gestation were weighted, studied macroscopically and microscopically, and then the distribution of the III type collagen with the help of antibodies was investigated. Results have shown that kidneys in IUGR group have macroscopic and histological signs of both organ and tissue growth restriction. The intensity of the III type collagen expression and the area of its distribution increased, mainly in the perivascular connective tissue, kidneys cortex and medulla's stroma. Conclusion: Fetal IUGR is accompanied with the lesion of renal tissue formation. The intensified synthesis of collagen ? may be a marker of tissue remodeling when connective tissue formation and sclerosis outrun the parenchyma elements growth and maturation.

PENTALOGY OF CANTRELL : AN EARLY CASE REVEALED AT 12 W.G.
Loget Philippe (1, 2), Mouchel François (1,3), Mouchel Jack (1,3), Krizeck Marie-Christine (1,4), Martin Dominique (1) Chevé Marie.Thérèse (1), Foulet-Rogé Armelle (2)
1: Prenatal Diagnosis Center of Le Mans, 2: Service d'anatomie pathologique, Hôpital Le Mans. 3 Clinique du Tertre Rouge, Le Mans, 4 : Laboratoires de biologie associés, unité de cytogénétique, Nantes.

We present the case of a 39 years old female foetus with termination of pregnancy at 14 W.G. for a polymalformation syndrome with: a midline supra umbilical wall defect, ectopia cordis, anterior diaphragmatic defect, defect of the lower sternum and omphalocele.

The G4P1A1 woman (2 miscarriages), with no history of systemic illness or familial disease, showed at the first obstetric ultra sonogram (12 W.G.) an increased nuchal translucency (6 mm), omphalocele, wall defect with ectopia cordis evocative of the Pentalogy of Cantrell. The autopsy showed a normal growth male foetus (Karyotype: 46, XY), with the full spectrum of the Pentalogy and also club feet, nuchal oedema without cystic hygroma, persistent left vena cava and probably a septal ventricular defect. The X ray films were normal.
The Pentalogy was first described by Cantrell in 1958 with five cases. The full Pentalogy occurs rarely and such early cases are very rare. The pathogenesis has not been elucidated. Cases are generally sporadic even if some families, monozygotic twins and rare chromosomal abnormalities (triploidy and trisomy 18) have been described.
We present this case because of its rarity and to stress on the importance of the examination of the foetus even in very early termination of pregnancy for an appropriate genetic counseling.

P 452
HISTOPATHOLOGICAL AND HISTOCHEMICAL STUDY OF THE EFFECTS OF TEUCRIUM POLIUM ON THE KIDNEY IN RAT
TALAEI KHOZANI Tahereh , DEHGHANI Farzaneh, PANJEHSHAHIN Mohammad Reza, KARBALAY-DOOST Saeed, Anatomy Department, Shiraz Medical School, Shiraz University of Medical Sciences

Teucrium Polium is commonly used in Iran traditional medicine for decreasing of blood sugar level. The aim of this project was to study of the effects of Teucrium Polium water extract on histologic structure of kidney in male rats. To examine such effects, 50 Spragu-Dawly rats were divided randomly to four experimental and one control groups. Experimental groups were fed with Teucrium Polium water extract (4gr/kg, 3gr/kg, 2 gr/kg, 1gr/kg) for 14 days. The rats were scarified, their kidneys were removed, and fixed, histological sections were prepared and stained with PAS/alcian blue and toluidin methods.
The results indicated that histological structure did not change but the extract affected on extracellular matrix. There was a mild precipitate of metachromatic material around the renal tubules of the cortex. Increasing amount of acidic glycoconugates and metachromatic components were observed in extracellular matrix of medulla and it was dose dependent.
It seems that this extract causes some kinds of changes in renal extracellular matrix, therefore it is recommended that this extract should be used cautiously and it needs more research to find its complications.
Keywords: Teucrium Polium, kidney

P 453
ESTIMATION OF GLOMERULAR VOLUME ON GLYCEROL-INDUCED ACUTE RENAL FAILURE IN RAT
DEHGHANI Farzaneh, DEZFULIAN Rahman, PANJEHSHAHIN Mohammad Reza, ZAHIRI Shahla Anatomy Department, Shiraz Medical School, Shiraz University of Medical Sciences

Backgroud:The use of stereological methods in evaluation of volume changes in vital organs such as kidney is very important. In this study, the volume of glomeruli in glycerol-induced acute renal failure in rat was determined.
Methods: 48 Sprague-Dawley male rats were divided into 2 groups (1control, 1experiment). Experimental group 10ml/kg of 50% glycerol was injected intramuscularly. And control group the same volume of saline was injected. After 48h, animals were dissected under deep anesthesia, and right kidneys were fixed by vascular perfusion. Microscopic slides were stained with H-E. Glomerular volumes were calculated using projecting microscope, point counting and cavalieri principal.
Finding: The results indicated that renal failure induced-glycerol didn't effect on glomerular volume
Conclusions:It seems that estimation glomerular volume can not be useful variable in identifying of acute renal failure induced glycerol, but further investigation is needed to clarify the issue.
Key Word:Kidney, Stereology, Mean Volume

P 454
POLYOMA (BK) VIRUS INFECTION IN TRANSPLANTED PATIENTS.
Cinzia Giacometti, Fiorella Calabrese, Francesco Marchini*, Paolo Rigotti** and Marialuisa Valente.
Institute of Pathological Anatomy, * Division of Nephrology, **Clinica Chirurgica 3, Department of Medical and Surgical Sciences, University of Padua, Medical School, Padova, Italy

INTRODUCTION: Polyoma (BK) virus nephropathy was first described in 1971. In immunocompetent patients it has a high prevalence but a low morbidity. Urinary tract is usually affected. Ureteric stenosis, hemorrhagic cystitis and interstitial nephritis had been described in renal graft before introducing cyclosporine A and Induction therapy. Afterwards BK infection was rarely reported for decades.
MATERIAL AND METHODS. From July 2001 to May 2003 132 adult patients underwent kidney transplantation at the University of Padua. Among these 7 patients developed BK infection with histological proven interstitial nephritis. The patients were 5 males and 2 females, mean age 42 years. Time interval between transplant and infection ranged from 6 to 79 months (mean 25,5). Triple therapy was performed in all cases : FK-506, Mycophenolate Mofetil and Steroids was performed in 5, Cyclosporine, Mycophenolate Mofetil and Steroids in 1 case and Cyclosporine, Rapamycin and Steroids in 1 case. Biopsy was performed in all cases due to increase in serum creatinine level. Diagnosis was suspected at histology on haematoxylin and eosin stain and confirmed by PCR method. Three patients experienced graft loss.
CONCLUSIONS. Polyoma (BK) infection is becoming more frequent in renal grafts. This may be related either to new immunosuppressive agents or to total level of immunosuppression. Reaching biopsy diagnosis following creatinine elevation, is usually too late in order to allow graft survival, because nephrotoxicity of antiviral therapy. Role of surveillance biopsies and PCR on bioptic material for earlier viral detection should be considered in heavily immunosuppressed transplanted patients.

P 455
TWO CASES OF CRYPTOCOCCOSIS DIAGNOSED ON KIDNEY GRAFT BIOPSY
MEHRENBERGER Marion (1),RIBES David (1), PILLET Adèle (1), ROSTAING Lionel (1), DURAND Dominique (1), BROUSSET Pierre (2), MODESTO Anne (2).
(1)Service de Néphrologie Dialyse et Transplantation, Hôpital Rangueil, 1, Avenue J. Poulhes, TSA 50032 Toulouse Cedex 9, France
(2) Service d'Anatomie et Cytologie Pathologiques, Hôpital Purpan, 1, Place Dr Baylac, TSA 50032, 31 059 Toulouse cedex, France

Cryptococcus neoformans accounts for 4% of the fungal infections after renal transplantation, and mortality remains high despite therapy (30 to 60%). Diagnosis relies on isolation of the yeast or its capsular antigen in biological samples. We report on two cases of neuromeningeal cryptococcosis that have been diagnosed on histologic study of renal graft biopsy.

Mrs D, 62-year-old, had received a kidney graft for polykystic disease . Immunosuppression associated thymoglobulins, mycophenolate mofetil, tacrolimus and steroïds. Two years after transplantation, a graft biopsy performed for nephrotic syndrom and progressive renal failure revealed an allograft glomerulopathy, with arterial fibrosis and membranoproliferative pattern. Immunofluorescence was positive for IgM deposits. Hepatitis serologies were negative. Suspecting chronic rejection, she received anti CD20 antibody therapy. Two months later, she died from a terrifying (foudroyant?) meningoencephalitis of unknown origin. Diagnosis was made on post-mortem graft analysis,which revealed cryptococcal yeasts in small renal vessels. It was secondary confirmed by blood cultures.
Mr S, 46-year-old, had chronical replicative hepatitis C, and type III cryoglobulinemia. Twenty years prior before, he had been transplanted for childhood malformative uropathy, and was treated by azathioprine, ciclosporine and steroïds. In 2003, azathiopine was replaced by mycophenolate mofetil because of chronic allograft nephropathy. One year later, he presented a neuromeningeal cryptococcosis, diagnosed on lumbar puncture. The same month, immunosuppression discontinuation and end-stage graft failure led to transplantectomy. Endovascular cryptococcal yeasts were noted on transplant biopsy. Antifungal therapy led to complete recovery.
Histologic diagnosis of C. Neoformans infection must be evocated in front of capsulated yeast that are strongly Periodic Schiff Acid positive . They are typically stained by Grocott coloration and Alcian Blue staining.
Cryptococcal infection occurs in cell immunity deficient patients, such as AIDS, prolonged steroid therapy, malignancies, sarcoïdosis and transplantation,especially under heavy immunosuppressive therapy. Because of its systemic spreading, the pathologist must be able to recognize such yeasts in peripheral organs, such as kidney graft in transplanted patients.

UNUSUAL DIFFERENTIAL DIAGNOSIS FOR VASCULAR ACUTE REJECTION : EARLY RENAL GRAFT PYELONEPHRITIS

MEHRENBERGER Marion (1), LAVAYSSIERE Laurence (1), ROSTAING Lionel (1), MODESTO Anne (2), BROUSSET Pierre (2), DURAND Dominique (1)
(1)Service de Néphrologie Dialyse et Transplantation, Hôpital Rangueil, 1, Avenue J. Poulhes, TSA 50032 Toulouse Cedex 9, France
(2) Service d'Anatomie et Cytologie Pathologiques, Hôpital Purpan, 1, Place Dr Baylac, TSA 50032, 31 059 Toulouse cedex, France

Accelerated acute rejection occurs within a few days after renal transplantation, due to preformed cytotoxic antibodies. It is often responsible for early graft loss. Histologic studies show evidence of vascular lesions with thrombosis, and polymorphonuclear leukocytes infiltrating glomeruli. We report on a case of acute graft pyelonephritis that mimicked an accelerated acute rejection.
Mrs B., a 34-year-old woman, developed 32 % panel-reactive antibodies to HLA class I after a prior kidney transplantation for lupic nephropathy. Fourteen years later, she underwent a second renal allograft, with a pre-transplantation negative crossmatch , but a low positive crossmatch against B lymphocytes, on a one-year-old serum . The patient received anti-thymocyte globulins, mycophenolate mofetil, tacrolimus and steroïds. After initial normalization of renal function, she became anuric on the 5th day. Clinical examination and Doppler ultrasound of the graft were normal . There was no fever, nor biological markers of inflammation or haemolysis. Bacteriological screening returned negative. The patient received two steroïd pulses and two plasma exchanges for suspected accelerated acute rejection.
Graft biopsy, performed on the 8th day, showed major polymorphonuclear (PN) cell infiltration of glomeruli, invading urinary space,as well as numerous PN casts stating the diagnosis of pyelonephritis. Interstitium examination revealed diffuse oedema, but only moderate PN leukocytes infiltrate. Rare glomerular thrombi were noted. The following day, urine and blood cultures returned positive for Escherichia Coli, and inflammatory markers elevated. Infection and renal function improved under antibiotherapy.
Urinary tract infections are the most frequent infections in renal transplant recipients, favored by immunosuppression and urologic surgery. Although most of them are benign, they can sometimes threaten graft function, especially in early post-transplant period . In such cases, the differential diagnosis with acute rejection can be difficult, because of attenuation of physical and biological signs by steroid therapy , and
then relies on kidney graft biopsy.

RELATIONSHIP BETWEEN POLY (ADP-RIBOSE) POLYMERASE WITH COLD ISCHEMIA AND DELAYED RENAL FUNCTION IN TRANSPLANT. DEMONSTRATION IN A PARP-1 KNOCKOUT MOUSE MODEL.

O'VALLE Francisco, GOMEZ-MORALES Mercedes, Del MORAL Raimundo MG, BENITEZ Maria del Carmen, AGUILAR Mariano, MARTIN-OLIVA David, OLIVER F Javier, Del MORAL Raimundo G.
Department of Pathology, San Cecilio University Hospital, Granada. Institute of Parasitology and Biomedicine, CSIC, Granada, Spain.

Kidney allografts undergo pre-transplant cold ischemia and consequent ischemia-reperfusion injury (IR). Poly (ADP-Ribose) Polymerase (PARP-1) overactivation leads to massive NAD+ consumption and ATP depletion with induction of cellular necrosis under ischemic conditions, which may lead to an increase in acute tubular necrosis (ATN) and a delay in total recovery of renal function (RFR) of the transplanted organ. Objetive: Our aim was to demonstrate that the expression of PARP-1 are relationship with ischemia, develop of acute tubular necrosis and delayed of renal function.
Material and Methods: We studied the semiquantitative nuclear expression of PARP-1 in tubular cells by immunohistochemistry with the monoclonal antibody PAR01 in kidney transplant biopsies from expanded-criteria donors (ECD) (N=166), and allografts with ATN (N=94), and by immunohistochemical and western blot expression of parp-1 in knockout mice ischemia /[45 min.]/reperfusion [6 and 48 hours] model.
Results: In 50% of ATN biopsies, more than 50% of tubular nuclei were immunostained for PARP-1. PARP-1 expression was higher in ATN biopsies than in those from ECD (2.40 ± 0.74 vs 0.92 ± 1.13, p=0.0001 Mann-Whitney). PARP-1 showed a statistically significant relationship with the time required to achieve effective diuresis (Rho:0.608, P=0.0001 Spearman test), with serum creatinine, and with duration of cold ischemia (Rho:0.650, P<0.0001 Spearman test); these relationships were stronger in the biopsies with ATN (Rho: 0.774; Rho:0.806, P=0.0001 Spearman test, respectively). In IR experimental model we induced tubular lesion in PARP-1wild-type mice and we reduced the severity of renal injury in PARP-1 knockout mice and in PARP-1 wild-type mice chemical blocks with PARP inhibitor.
In conclusion, multivariate analysis demonstrated that PARP-1 expression and cold ischemia duration in kidney biopsies with ATN predicted the short-term RFR (delay in total recovery of renal function, and serum creatinine in the first

month) It is proposed that PARP-1 plays a pivotal role in the pathophysiology of I/R injury of the human kidney.

BK –VIRUS NEPHROPATHY FREQUENCY IN RENAL TRANSPLANT BIOPSIES.

ÇAKALAĐAOĐLU Fulya, ERBARUT Ýpek, TUĐLULAR Serhan*, KAYA Handan.
Department of Pathology, Division of Nephrology-Department of Internal Medicine*, Marmara University School of Medicine. Ýstanbul-Turkey.

BK virus nephropathy is the most common type of viral disease following renal transplantations. Although the frequency is differs according to the transplantation centres, the rate is between 1.5% and 20%. The diagnosis can be established histologically by renal allograft biopsy.
The aim of this study is to search the frequency rate of the BK-virus nephropathy which causes the graft rejection in our cases.
The material of this study consists of the graft rejection cases that we received in last two years. The biopsies are diagnosed routinely according to the Banff criterias. We have found 5 cases (15.6%) of BK virus in 32 cases. All of the cases have been treated by immunosuppresive drugs following the transplantation surgery. Biopsies have been performed because of the disturbance of the renal functions. Only one case have had urinary examination.
Morphological diagnosis of BK virus nephropathy has been followed by serological examination.
The most frequent morphological changes with our BK virus infection are basophilia, nuclear inclusions, nuclear enlargement, on the tubul epithelium. Decoy cell has not been found in the only case who had urinary examination.
The treatment of immunosuppresion of the cases with BK virus nephropathy has been reduced and antiviral treatment has been started.
BK virus nephropathy should be kept in mind in the differential diagnosis of transplant rejection and drug toxicity.

Miss KA, born in 1983, eldest child of six with consanguineous parents of first degree followed on hemodialysis since 2000 for chronic renal insufficiency developed after ignored initial nephropathy: (focal segmental glomerulosclerosis ?). Family history: * a sister dead at 4years ago in a swollen syndrome, * another 20 years ago sister has renal insufficiency and * a brother of 16years ago has proteinuriea higher than 3g/24h. TRANSPLANTATION of KA in June 2003 with the kidney of her mother of 43years ago. Good evolution under immunosuppressor therapy.
EVOLUTION of the transplant :* At 6 months (01/01/04) after surgery, occurrence of a arterial stenosis of the renal graft successfully cured. *At 18 months (01/01/05) after transplantation,occurrence of hématuria with progressive increased creatinin and serum urea suggesting acute rejection or toxicity in Cyclosporine?Two biopsy were performed
Renal biopsy 1: extra-capillary diffuse glomerulonephritis with linear IgG and C3deposits , leading to diagnosis of a quickly progressive glomerulonephritis by anti-glomerular basement membrane(GBM) antibody developed in ignored Autosomal Recessive Alport 's Syndrome . No recovery even after plasmatic exchanges and bolus of solumedrol and endoxan .Renal Biopsy 2 performed one month and half after the first one showed important lesions of chronicity.
Patient given in hemodialysis. Discussion: For this rare complication the diagnosis is against all new transplantation and must lead to the meeting of a genetic council

TYPE III COLLAGENOFIBROTIC GLOMERULOPATHY ASSOCIATED WITH IGA MESANGIAL DEPOSITS

Mihaela Gherghiceanu,
"Victor Babes" National Institute of Pathology
E. Mandache
"Dr. Carol Davila" Hospital of Nephrology. Bucharest. Romania

The collagenofibrotic glomerulopathy is a recently described entity that is characterized by massive accumulation of banded collagen fibers in glomerular mesangial and subendothelial zones. Abnormal accumulations of banded collagen are an ultrastructural pathologic hallmark of nail-patella glomerulopathy. In this disease the banded collagen occur predominantly within the glomerular basement membranes, whereas in the collagenofibrotic glomerulopathy the abnormal collagen fibers occur predominantly in the subendothelial zone and mesangium.
Collagenofibrotic glomerulopathy is a rare disease that usually presents with nephrotic syndrome and renal insufficiency. It has been first reported in 1979 by Masaaki Arakawa. In 1993 M-C. Gubler et al. reported 10 children with collagenofibrotic glomerulopathy who had evidence for familial renal disease with an autosomal recessive transmission.
The pathogenesis of this disease is unknown. Some patients have elevated serum levels of type III procollagen suggesting up regulation of collagen synthesis.
A case of collagenofibrotic glomerulopathy has been diagnosed in a series of over 500 renal biopsies. This is the first internationally reported association of type III collagenofibrotic glomerulopathy and IgA mesangial deposits. A 22-year-old male was admitted with recurrent macroscopic hematuria. Physical examination revealed normal blood pressure and no edema. Laboratory values - normal blood tests. Hematuria: 30-60/mm3. Proteinuria: 250 mg/24h
The diagnostic was established after performing immunohistochemistry on frozen sections, light microscopy and a thorough electron-microscopic investigation. The light microscopy showed slight mesangial proliferation. The immunofluorescence emphasized IgA mesangial deposits. These IgA deposits have been clearly identified as dense paramesangial spots in electron microscopy too. In electron microscopy, type III collagen fibers, having a diameter of about 100 nm and a standard periodicity, were found arranged as clusters in the mesangial matrix and less in the sub endothelial area. Only a few fibers were found in the glomerular capillary basement membrane and in the capsular basement membrane. Not all the glomeruli showed type III collagen fibers. In the renal interstitial area, especially around the glomeruli, the strips of collagen fibers were more conspicuous then usual.

P 461

THE MORPHOMETRIC STUDY OF IMMUNOFLUORESCENT C3D INTERSTITIAL DEPOSITS IN IGA GLOMERULONEPHRITIS

E. Mandache (a, b), Mihaela Gherghiceanu (a), M. Penescu (b),
(a)"Victor Babes" National Institute of Pathology, Bucharest, Romania

(b)"Carol Davila" Clinical Hospital of Nephrology, Bucharest, Romania

The IgA glomerulonephritis (IgAGN) is one of the most common primary glomerulonephritis and has a variable and difficult to predict evolution toward the end-stage nephrosclerosis. The deposition of C3d complement component in peritubular capillaries (PTCs) indicates a variant type of acute rejection while C3d deposition in primary glomerulonephritis (GN) is poorly documented.
The aim of this study is to examine C3d expression in peritubular capillaries (PTCs) and its correlation with the severity of renal injury in IgA glomerulonephritis. Since these interstitial, immunofluorescent deposits have tiny and poorly structured shapes our investigation applied some computerized morphometry programs. Thus we could demonstrate the occurrence of the C3c IF deposits in strict connection with the peritubular capillaries in either cross or longitudinal section. Polyclonal FITC conjugated rabbit anti-human C3c and C3d antibodies were used for direct immunofluorescent evaluation of the C3c and C3d deposits in 24 kidney biopsies with IgA glomerulonephritis.
The study revealed that the C3d deposits in peritubular capillaries were associated with known predictor aspects for rapid progression of IgAGN such as: glomerular sclerosis (63,6%), atrophic tubules (90,9%) and interstitial sclerosis (81,8%). The intensity of the C3c glomerular immunofluorescent deposits was related with active lesions. Thus, the predictive value of C3d deposition on PTCs in IgAGN is worth to be taken into consideration as an unfavorable outcome of the disease and request further long run investigations.

P 462
MEMBRANOPROLIFERATIVE GLOMERULONEPHRITIS COMPLICATING DIABETIC NEPHROPATHY

L.Grcevska (1), G.Petrusevska (2), S.Kostadinova (2), S.Dzikova (1)
1. Department of Nephrology, Clinical Center, Skopje, Macedonia
2. Institute of Pathology, Faculty of Medicine, Skopje, Macedonia

Renal diseases other than diabetic nephropathy (DN) can be found in diabetic patients. Various forms of primary and secondary glomerular diseases were reported, but membranoproliferative glomerulonephritis (MPGN) is rare. We noted 4 patients with MPGN associated with DN at our Department for the past 3 years.
Two of the patients had enlarged lobular glomeruli due to mesangial and endocapillar hypercellularity. Intraglomerular cells consisted of monocytes, rare neutrophils, mesangial and endothelial cells. Mesangial matrix was enlarged with focal hyaline-sclerotic areas. The silver methenamine staining showed duplication of glomerular basement membrane (GBM). Visceral epithelium was hypertrophic and adherent to parietal epithelium. Interstitial edema with slight fibrosis was visible. Intrarenal blood vessels presented hyaline insudative changes. This was followed with deposition on immunofluorescence of granular deposits of IgA, IgM, IgG, C3, C4 and Fibrinogen. The whole histopathology in these two patients suggested nodular form of DN with diffuse MPGN.
The other two patients presented diffuse diabetic glomerulosclerosis. Inflammatory cellular mesangial proliferation with intracapillary influx of neutrophils was also present, with duplication and partial destruction of GBM. Part of the glomeruli presented diffuse changes, and the rest presented segmental changes. Tubular epithelium showed degenerative changes and the interstitium was edematous with diffuse mononuclear cell infiltration. Changes of intrarenal blood vessels affected only the vascular poles. The immunofluorescent analyses showed granular deposits for the above mentioned antibodies.
The renal structure and function in both diseases are similar. Pathological changes in DN include thickening of all renal extracellular basement membranes and the mesangial matrix. Mesangial expansion is related to proteinuria, hypertension and declining GFR. Interstitial volume may be increased in insulin-dependent diabetes mellitus particularly in areas containing sclerotic glomeruli or marked tubular atrophy. Parallel findings were documented for type I MPGN in which the increased mesangial volume was related to decreased GFR, increased glomerular permeability to protein and hypertension. The cortical interstitial volume is correlated with functional abnormalities both in DN and MPGN. Besides these similaritites, hyperperfusion injury characteristic for DN, can also be found in MPGN.

P 463
THE ROLE OF VIRAL INFECTION IN ORIGIN AND PROGRESSION OF PRIMARY GLOMERULONEPHRITIS AND SOME NEPHROPATHIES

V.A. Varshavsky (1), E.P. Golitsyna (1), P.N. Rybin (2), D.N. Fedorov (1)
(1) I.M. Sechenov Moscow Medical Academy, 119992, Moscow
(2) N.N. Burdenko Main Military Clinical Hospital, 105229, Moscow

It is known that viral infection has a high profile in origin and progression of glomerulonephritis and noninflammatory nephropathies in children and adults.
The aim of our study was to determine the role of different viruses in development of glomerulonephritis and some nephropathies.
Methods and materials. 136 biopsies from patients (aged from 1,5 to 58 years) with unspecified viral presence (group I) and 68 biopsies from patients with proven viral infection (group II) were studied. Biopsies were examined by means of light microscopy, immunohystochemistry and electron microscopy. Viral typing was performed by means of PCR and IFA.
Results and discussion. Electron microscopy has revealed viral inclusions in 70 of 136 cases from group I. 12 types of viruses were determined in 68 cases of group II. It was revealed that single viruses as well as viral associations (from two to three viral types) play a role in progression of glomerulonephritis and noninflammatory nephropathies. The most commonly encountered were Herpes simplex virus (HSV), adenoviruses, hantaviruses and their associations. The correlation analysis between type of virus and morphology of nephropathy was performed. The most common morphological form of glomerulonephritis was mesangioproliferative glomerulonephritis (31 cases): in 30 cases single-type virus was revealed (adenovirus type 8 or 11, HSV type 1 or 2, Coxsackie-virus, RS-virus, hantaviruses (Hantaan and Puumala viruses), and cytomegalovirus). Membranoproliferative glomerulonephritis was revealed in 15 cases: membranoproliferative glomerulonephritis type I with 2 virus type combination was diagnosed in 7 most serious cases. Parvovirus B19 was revealed exceptionally in segmental-focal sclerosing glomerulonephritis and arteriolohyalinosis (6 cases). Herpes simplex virus type II was found in 1 case of segmental-focal sclerosing glomerulonephritis. Antiviral therapy resulted in strongly beneficial effect.
Conclusion. As a result of our study we confirmed viral infection participation in development and/or progression of glomerulonephritis and some nephropathies. However further investigations are needed in order to determine the role of viruses as an etiological factor, or as disease progression factor originated from corticosteroid therapy of.

DYNAMIC GD-ENHANCED MRI, IN VIVO ¹H MRS AND T₂ RELAXOMETRY STUDY OF HUMAN KIDNEYS

ROGOZYN Vladimir, ROZHKOVA Zina, Vozianov Sergei
Radiological Center of the Academy of Medical Sciences of Ukraine, Kiev, Ukraine

Purpose:We propose quantitative analysis of Gd-enhanced MRI (time-intensity curves), in vivo ¹H MRS, and T₂-relaxation time for differential diagnosis of renal tumors.
Materials and Methods: 44 patients are examined by 1.5 T Magnetom Vision System (SIEMENS). MRI are obtained after i.v. bolus of 0.1 mM/kg body weight of Gadovist 1.0 (Schering) with breath-hold sequence: FLASH-2D sequence:FA=70^o,TR/TE=160/6ms,TA=22s which was repeated every minute for 10 minutes. ¹H MR-spectra are recorded with SVS-STEAM sequence:TR/TE = 1500/60 ms. In T₂-relaxation time measurement the ¹H MR-spectra are recorded in and outside of the tumors with SVS-STEAM sequence:TR/TE = 1500/60,80,100,140ms.
Results:The following enhancement patterns were established for the normal renal medulla (NRM, maximal signal intensity (mSI) in the 2-4 min after Gadovist 1.0 injection), renal cell carcinoma (RCC, mSI in the 1min), and the transitional cell carcinoma (TCC, flat curve, enhancement weaker than in the NRM). In the case of angiomyolipoma the enhancement was not different from the RCC. From ¹H MR spectra the peak areas of main metabolite signals: water (4.7ppm), lipids(1.5,2.3-2.5,5.4ppm), creatine+creatinine(Cr,3.0ppm), choline-containing compounds(Cho), and betaine (3.25-3.9ppm) are obtained. For NRM the following mean values of T₂ are calculated: T₂^{NRM}(Wat)=(114.3+-9.6)ms before and (92.4+-3.5)ms after Gadovist 1.0 injection. The following mean values of T₂ are obtained: for RCC the mean values of T₂^{RCC}(Wat)=(83.2+-4.7)ms before and (61.7+-5.2)ms after Gadovist 1.0 injection, and for TCC T₂^{TCC}(Wat)=(72.6+-4.3)ms before and (53.7+-4.2)ms after Gadovist 1.0 injection.
Conclusion: This work is very helpful for study of kidney metabolism and for differential diagnosis of renal tumors.

P 465

TWO FAMILIAL CASES OF ANCA-ASSOCIATED VASCULITIS

Honsova E, Rihova Z, Jancova E, Lodererova A.

Antineutrophil cytoplasmatic autoantibodies (ANCA) directed to proteinase 3 (PR3-ANCA) or myeloperoxidase (MPO-ANCA) are closely associated with systemic necrotizing vasculitides (AAV). However, ANCA alone are not sufficient, as based on clinical and experimental data, and other, probably exogenous factors, seem necessary for disease induction. Besides, various genetic factors are most likely involved in disease susceptibility.
Case Reports
We report on two familial cases of AAV. In the first family, the father had presented with an acute renal failure due to PR3-ANCA-associated disease three years before his daughter had exactly the same manifestation. However, at the time of his admission to the hospital she had already had E.N.T. involvement, which was later attributed to Wegener´s granulomatosis. There were also very similar morphological features in their kidney biopsies. The second family involved two sisters, who were diagnosed with microscopic polyangiitis (MPO-ANCA associated) with a more gradual decline of renal function within four months of each other. The younger sister actually suggested the diagnosis of her sibling based on her symptoms and probably saved her a significant amount of renal function.
Conclusion
As in other autoimmune diseases, the etiology of AAV is heterogenous and basically unknown. Different predisposing factors probably play differential etiopathogenic roles in various groups of AAV. The two familial cases support the hypothesis that genetic predisposition plays an important, although not yet fully understood role.

P 466

FREQUENCY OF DETECTION OF EPSTEIN-BARR VIRUSES (EBV) IN THE RENAL BIOPSIES: VALUE OF ULTRASTRUCTURAL FINDINGS AND POLIMERASE CHAIN REACTION.

REZNIKOVA Galina, MATSIONIS Alexandre,
KIRICHENKO Yury, POVILAITITE Patrisia.
Rostov Regional Bureau of Pathology

Introduction. Concomitant viral infection exerts negative influence on the basic process and treatment of chronic renal pathologies. Intranuclear virion-like inclusions are often seen during diagnostic electron microscopy of renal biopsies, but it is difficult to identify these unusual inclusions for lack of specificity of its ultrastructure. We used within one year not only electron microscopy, but also polimerase chain reaction (PCR) and immunohistochemistry for analysis of all renal biopsies.
Aim. The purpose of the present study was the revelation and exact identification of viruses in the renal biopsies and also characteristic of accompanying alterations.
Methods. Renal biopsies with preliminary diagnosis chronic glomerulonephritis (n=145) were the subjects of the study. The material was prepared by the standard methods for light microscopy, immunohistochemistry and electron microscopy (EM-208/Philips). Identification of EBV was confirmed by PCR, we isolated DNA from non-fixed or formalin-fixed, paraffin-embedded tissue.
Results. In the biopsy samples DNA of EBV was detected by PCR most frequently (16 positive reactions, 10% of cases). For the same period DNA of a Herpes-virus (1-2 types) was found out in one case, and in one case DNA of cytomegalovirus. Ultrastructural analysis of these samples showed the specific alterations of nucleus - small or large electron dense chromatin formations with a light halo, numerous nuclear bodies, inner nuclear membranes thickening. The same abnormal nucleus ultrastructure was in the mesangial and visceral epithelial cells and in the interstitial monocytes. Light microscopic examination has detected presence of numerous limphocytes in the inflammatory infiltrate of the interstitium. Immunohistochemical examination of EBV antigen (Dako anti-EBV primary antibody, clone LMP) has demonstrated distribution of LMP in the cytoplasm of the glomerular podocytes, rarely in the infiltrating cells and in the tubular epithelial cells. The most frequent forms of basic pathology - amyloidosis, minimal change glomerulopathy and membranous glomerulonephropathy, are accompanied by tubulointerstitial alterations.
Conclusion. Our results show the high level of concomitant EBV infection in the renal biopsy samples from patients with chronic renal pathologies. Ultrastructural identification of intranuclear inclusions is helpful for early determination of EBV and other Herpesviruses in the renal tissue.

P 467

COMPUTERIZED ANALYSIS OF RENAL CORPUSCLE MORPHOLOGY IN RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS

CARUNTU Irina-Draga(1), HARTAN Alexandra(1), SAJIN Maria(2), DOBRESCU Gioconda(1)

(1) University of Medicine and Pharmacy "Gr.T.Popa" Iasi, Romania
(2) University of Medicine and Pharmacy "Carol Davila" Bucuresti, Romania

Purpose: The evaluation by computerized morphometry of the morphologic elements characterizing the renal corpuscles in rapidly progressive glomerulonephritis (RPGN), pointing out several gravity stages that induce a quantitative-type classification and justify distinct attitudes in the clinical approach.
Material and methods: We analyzed 10 cases diagnosed by renal biopsy as RPGN. The measurements were automatically performed on 100 renal corpuscles (10 per biopsy), relying on the procedure COREN, developed by us for running under KS400 (Zeiss) software. COREN exploits the RGB segmentation to accurately individualize the corpuscle (cor) and its entities presenting interest for the quantitative analysis: capillaries (cap), nuclei (nuc), connective tissue of the mesangium and crescent (cot), Bowmann space (bos). For each considered corpuscle (i=1 to 100), COREN measures the areas (square microns) of the corpuscle (denoted by A(i)cor) and of the aforementioned entities (denoted by A(i)x, where x=cap, nuc, cot, bos), computes the corresponding percentages relative to A(i)cor (denoted by P(i)x=A(i)x/A(i)cor) and stores the results in a data base. Next, for each case (c=1 to 10), COREN extracts the adequate information from the data base and calculates the mean values per case denoted by A(c)cor, A(c)x and P(c)x=A(c)x/A(c)cor. Finally, COREN provides the mean values characterizing the entire lot of biopsies, denoted by Acor, Ax and Px=Ax/Acor.
Results: For the analyzed biopsies we have obtained the following mean areas: Acor=3485, Acap=460, Anuc=355, Acot=2140, Abos=260, which, in percentage terms, yield Pcap=13,2%, Pnuc=10,2%, Pcot=61,4%, Pbos=7,4% and 7,7% for other elements (i.e. erythrocytes). Based on appropriate comparisons between the above values and the values corresponding to the 10 reported cases (not reproduced here for brevity reasons), we have studied the role of P(c)x in the classification of the cases, reflecting different gravity degrees, which cannot be rigorously evaluated by the usual microscopic exam. Further evolutions of our cases have shown that the proposed separation in classes is fully motivated from the point of view of the medical practice.
Conclusions: The morphometric approach opens new perspectives for the analysis of the renal biopsy in the sense of refining the diagnosis and, consequently, the therapy. Future researches should focus on the general validity of the classification criteria, by enlarging the number of studied cases.

Department of Histology and Embryology, University of Medical Sciences, Poznan, Poland

Excessive physical exercise may lead to disturbance of the entire homeostasis in the body, including the damage not only in skeletal muscles but also in many distant organs. Among the mechanisms responsible for the exercised-induced changes could be an oxidative stress or angiotensin II. We previously showed that acute exercise led to apoptosis in kidney but not as a result of oxidative stress. In this study, we examined the role of angiotensin II and its receptors AT1 and AT2 in mediating exercised-induced apoptosis in kidney. We clearly demonstrated that an acute physical exercise induced apoptosis in renal distal tubular cells. Moreover, those cells displayed an increased expression of both AT1 and AT2 angiotensin II receptors and p53 protein. These results suggest that angiotensin II could upregulate p53 expression via both AT1 and AT2 receptors in renal distal tubular cells what might be a crucial mediating mechanism of apoptosis occurrence in kidney after excessive exercise.

P 469
ROLE OF INDUCED NITRIC OXIDE SYNTHASE (I-NOS) IN UNILATERAL OBSTRUCTIVE NEPHROPATY

BAHAR AKKAYA1, H.ELIF PESTERELI1, SHERIEF LABIB2, ASSEM EL SHERIEF2

Background: Obstructive nephropathy leads to tubulointerstitial fibrosis and loss of function. Nitric oxide has been shown to have antifibrotic properties. We explored induced nitric oxide synthase (i-NOS) expression in kidneys from rats underwent obstruction- release of unilateral ureteral obstruction.
Methods: Experiments were performed using a total 63 male Sprague-Dawley rats. The rats were either subjected to left proximal unilateral ureteric obstruction (UUO) or sham operation. The duration of UUO differed according to the group (1 day, 7 days, or 14 days obstruction). At each time point (1, 7 and 14 days) groups of rats (n =5) were sacrificed without relieving the obstruction to evaluate the severity of the obstructive injury. Other rats had their obstruction relieved and were left for another 15 days before sacrifice to evaluate the extent of structural recovery. Controls animals (n = 5) were sacrificed in parallel at each time point. Paraffin sections were stained CD68 and iNOS expression and assessed by immunohistochemistry.
Results: A significant increase in cortical interstitium macrophage number on CD68 immunolabelling was shown between obstruction- release and control group. By contrast no differences were observed on renal cortical and medullar interstitium in control groups. A significant difference in macrophage infiltration in cortex and medulla interstitium was found between obtruction-release group and control group. (p¡Ü0.05)
Significant increase on iNOS expression in cortex and medulla tissue of obstruction release group compared to control group was observed. (p¡Ü0.05) On the contrary, difference on i-NOS expression in cortex of control group compared to medulla of control group was found. But a significant increase on iNOS expression in medulla tissue of obstruction release group compared to cortex at the same group was detected.
Conclusion: In kidneys with UUO an expression of iNOS in medulla and cortex was increased. These results provide evidence for the iNOS expression in the renal cortex induced by inflammatory cytokines at medulla tissue of UUO kidneys. It is suggested a possible link in the pathogenesis of post ¨Cobstruction renal fibrosis.

A RENAL INTRAVASCULAR LARGE B- CELL LYMPHOMA REVEALED BY PROTEINURIA.

ZIDANE Merzouka (1), BABINET François (2), ROUSSELET Marie-Christine (1), SAINT-ANDRÉ Jean-Paul (1).
(1)Department of Pathology, University Hospital, 49933 Angers Cedex 09. France

(2)Nephrology, Center Hospital, 72037 Le Mans cedex 01. France

Intravascular lymphoma is a rare subtype of large B-cell lymphoma. The lumina of small vessels are plugged with large lymphoid cells, especially in the brain, skin or lungs, without tumor mass or leukemia. Symptoms are non specific, related to vascular occlusion, and clinical diagnosis is difficult unless a microscopic examination of an affected organ is performed. This lymphoma has a propensity to rapid systemic dissemination and many cases have been diagnosed only at autopsy.
Case report : a 73-year-old male with a medical history of hypertension, repeated pulmonary embolism, heart deficiency and mellitus diabetes was hospitalized for a 38°C fever and weight loss without adenopathy, neither hepatosplenomegaly or neurological symptoms. Laboratory investigation disclosed proteinuria near the nephrotic range (2.2 to 3.3 g/24 hours), a severe inflammatory syndrome (C-reactive protein 115 mg/l, fibrinogen 7.3 g/l) and a mild elevation of serum lactate dehydrogenase (LDH) (473 UI/l). Immunoserology was negative (ANCA, antinuclear antibody). A kidney biopsy showed large atypical lymphoid cells only localized in glomerular capillaries, without other glomerular changes and a mild chronic interstitial nephritis. Tumor cells were immunostained by the CD45, CD20 and CD79a antibodies but negative for CD5 and CD10. There was no other tumor localization on brain, spine, skeletal, thorax and abdominal imaging as well as on bone marrow aspiration and biopsy. Laboratory tests quite suddenly worsened with a high LDH titer (> 1000 UI/l), hemoglobin concentration at 7 g/dL, and signs of microangiopathic haemolysis. Combination chemotherapy was initiated and after six cycles, the patient was alive and well, with normal laboratory tests. Nine months after the diagnosis, a second renal biopsy showed focal hyaline scars in glomeruli with no residual lymphoma cells.
Comments: this case of intravascular large B-cell lymphoma appeared limited to the kidney, and, as in a few other reported cases, revealed by proteinuria. An early diagnosis by renal biopsy was followed by combination chemotherapy usually effective in high-grade non-Hodgkin's lymphoma and leading to complete remission.

CONTRIBUTIONS TO THE KNOWLEDGE OF THE EVOLUTIVE POTENTIAL OF THE METANEFROGEN MESENCHYMA

Dragoi S.G., Trasca E.T., Rodica Silca, Melinte P.R., Popescu M., Riza L
Academic Hospital Filantropia Craiova
University of Medicine and Pharmacy from Craiova, Romania

Introduction. Oscar Hertwig (1881) proposed the term of mesenchyma as a morphogenetic entity instead of mezoblast. Today, it must be defined as an ancestral system endowed with variable differentiation potentialities in fundamental structures (cardiac, angiogenetic, nefrogenetic).
Purpose of the study. The purpose of this paper is to submit anatomic arguments for the knowledge of the differentiation ability of the metanefrogen mesenchyma.
Materials and methods. Our research has been achieved on human material (6 embryos, 4 fetus, 5 new born). We used classical micro anatomical staining techniques (Hematoxilin Eosine, Van Gieson, Gomori, PAS, Giemsa).
Results. The knowledge of the evolutive potentialities of the metanefrogen mesenchyma has been achieved due to our efforts in understanding the genesis and the evolution of the tubular and vascular nefron structures. By analyzing the serried section through tissue fragments in different stages of metanefrogenesis, we observed the existence of the dual differentiation potentiality of the metanefrogen mesenchyma – a part generated the walls of the Muller-Bowman capsule and of the contort and Henle renal tubes; another part formed the glomerular capillaries.
Conclusions. We consider that the differentiation of the metanefrogen mesenchyma is determined by the inductive action of the urethral bud for the genesis of the nefron and tubular structures and by the neural crest migrated cells for the formation of the nefron vascular structures.
Key words: metanefrogen mesenchyma, Bowman capsule, nefron

PROSPECTIVE STUDY OF EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) AND C-KIT EXPRESSION IN NON SMALL CELL LUNG CANCER (NSCLC) AND NEURO-ENDOCRINE CARCINOMAS (NEC)

Patrick Saint-Blancard (1), Hélène Laize (2), Jacques Margery (2), Joël Guigay (2)
Service d'Anatomie Pathologique, (2) Service des Maladies Respiratoires.
Hôpital d'Instruction des Armées Percy, 101, avenue Henri Barbusse, 92141 Clamart, France.

The new target therapies are designed molecular missiles, aimed at specific cancer cellular command centers. Kit (CD117), the product of the proto-oncogene c-kit, is a tyrosine-kinase transmembrane receptor. Kit positivity is in fact a definitive feature of GIST. EGFR is another important cellular receptor, with EGFR-targeted agents such as gefinitib, OSI-774, and cetuximab in current development.
We decided to analyse the CD117 and EGFR immunohistochemical profiles of majors types of lung tumors on surgical specimens or lung biopsies. This prospective study of expression of EGFR and c-kit was assessed on 49 adenocarcinomas, 8 squamous tumors and 8 small cell lung carcinomas (SCLC) or neuro-endocrine carcinomas (NEC). Material was formalin-fixed, paraffin-embedded tissue , obtained by thoracoscopic wedge biopsies, bronchial biopsies or resection specimens.
44/49 adenocarcinomas, 6/8 squamous epitheliomas, and 1/8 SCLC or NEC, revealed increased expression of EGFR. 5/49 adenocarcinomas, 1/8 squamous epitheliomas, and 5/8 SCLC or NEC, revealed increased expression of c-kit CD117 immunoreactivity was also more frequent for the patients with SCLC or NEC lung carcinomas (p=0.001). For 46 adenocarcinomas, 6 squamous carcinomas and 6 SCLC or NEC, we evaluated if the expression of EGFR or CD117 immunoreactivity was correlated with differents variables as clinicopathological characteristics (gender, tobacco's status), therapy (surgery or chemotherapy) or response to chemotherapy. Statistical analysis used a Fisher's exact test. None of the tested parameters was significative for the squamous carcinomas or adenocarcinomas. There was no statistical link between tobacco's status and EGFR overexpression.CD117 immunoreactivity was correlated with a good response to chemotherapy and a lack of progression for the patients with SCLC or NEC (p=0.07).
The success of imatinib in the treatment of metastatic GIST has stimulated interest in understanding the functional sence of kit immunoexpression in others tumors. This therapeutic's way could be attractive for the SCLC or the NEC, as they often overexpress c-kit. Although a recent study with a little number of patients with SCLC was negative, it should be interesting to assess this molecule's efficacy in the other NEC.

P 473
PROGNOSTIC VALUE HER-2/NEU ONCOGENE AND ESTROGENE RECEPTOR EXPRESSION IN NSCLC PATIENTS

Jasminka Jakic-Razumovic, M.D., Ph.D, Ivan Aleric, M.D. Ph.D. 1

Department of Pathology, Clinical Hospital Center Zagreb, Croatia, Clinical Hospital for pulmonary diseases Jordanovac, Zagreb, Croatia 1

Introduction: Lung cancer is the leading cause of cancer mortality worldwide. Patients prognosis partially depends on some traditional patohistological parameters and clinical stage, but in recent time many studies try to find some additional risk factors which would be able to divide patients with better disease-free and overall survival from those who will have early tumor recurrence and metastatic disease. Patients and methods: Clinical information and pathological slides and paraffin blocks from 132 consecutive patients with non-small cell lung carcinoma (NSCLC) were collected to evaluate HER-2/neu oncogene and oestrogen receptor (ER) expression, as well as their correlation with patients survival. All tumors were reviewed to verify histological parameters as histological type, tumor and nuclear grade, quantity of lymphocytic infiltrates, mitotic rate, and degree of tumor necrosis. Additionally, clinical data as sex, smoking habits, preoperative clinical stage, and overall survival were collected. HER-2/neu and ER status were determined immunohistochemicaly and correlated with clinical and pathohistological data. Results: The results showed statistically significant correlation between HER-2/neu and nuclear grade (p=0,010). Additionally correlation between ER expression and histological type of tumor (p=0,043), and mitotic rate (p=0,008) was found. Kaplan-Meier analysis showed statistically significant correlation of patients overall survival with TNM status (p<0,0001) and degree of tumor necrosis (p=0,0153). Cox proportional hazards regression analysis showed that male gender (p=0.01214), histological type (p=0.0303), high degree of necrosis (p=0.0064), and higher histological grade (p=0.0370) had significant influence on patient's survival. Relative risk of death was 2.7 times higher for male gender, 2.2 times for adenocarcinomas in comparison with squamous carcinoma, and 3.4 times higher for tumors with prominent necrosis in comparison with tumors without necrosis. Conclusion: Our findings indicate that some traditional histological parameters are important for determination of NSCLC patient's prognosis, but that ER and HER-2/neu expression might be of potential usage in clinical practice for assessment of certain group of patients who might benefit of specific treatment.

P 474

EVALUATION OF EPIDERMAL GROWTH FACTOR RECEPTOR AND C-ERBB2 IN DIFFERENT TYPE OF NON SMALL CELL CARCINOMA OF LUNG

FAHKRJOU ASHRAF M.D.,MONTAZERI VAHID M.D.

INTRODUCTOIN:The aim of this study was to evaluate the effects of EGFR(epidermal growth factor receptor) and c-erbB2 in the different type of non small cell lung cancer ,and to compare the results with normal lung tissue and different stages of tumor.
METHOD: For this study ,79 paraffin blocks were obtained for 64 patients having a confirmed pathological report of non small cell lung cancer and 15 normal lung tissue as a control group.All of specimens were stained with monoclonal antibodies against EGFR and c-erbB2.
Results:In this study 30 patients with SCC(sqamous cell carcinoma) , 30 patients with AC(adenocarcinoma),2 cases of large cell cacinoma and 2 patients with carcinoid tumorwere selected.In 27(90%) patients with SCC ,EGFR was positive and in 20(66%) patients with adenocarcinoma,c-erbB2 was positive.None of large cell carcinoma and carcinoid tumor were positive for these factors.
CONCLUSION:According to the results of this research there is sinificant difference between SCC and AC of lung that can help for adjuvant treatment after surgery of tumor.
key words:Lung cancer,non small cell cancer,c-erbB2,EGFR.

PROGNOSTIC SIGNIFICANCE OF KI67, CD44,AND CD 105 TUMOUR MARKERS IN SURGICALLY TREATED NON-SMALL CELL LUNG CANCER (NSCLC)

Maria CHORTIS, Evangelia VLETSI, Nikolaos TRAKAS, Nikolaos MAOUNIS, Phillipos PALAMIDAS, Stella LEGAKIS, Stella ZOUGRIS, Heleni ANAGNOSTOPOULOU,Laura MANOLIA, Nikolaos TAMVAKIS
Department of Pathology , Sismanoglio General Hospital, Athens, Greece.

Introduction:Given the fact of an ominous prognosis in surgically treated non-small cell lung cancer (NSCLC), even in early stage cases, more specific prognostic factors could be of help in the preoperative categorisation of these neoplasms.
Aim of the study:We examined the expression of Ki67 (nuclear proliferation index), CD44 (adhesive molecule) and CD105 (vascular index)in surgically treated NSCLC and correlated these markers with histological type, stage and size of the tumour.
Material and methods:41 specimens of surgically treated NSCLC were included in this study, 23 adenocarcinomas (56.1%),13 squamus (31.7%)and undifferentiated (12.2%).22 patients were staged as Ia-Ib (61.1%)and 14 as IIa-IIb (38.95%)
Immunohistochemical staining was perfofmed on paraffin sections.Our results were correlated to the clinical and pathological parametres(size,histology,stage).The evaluation of CD105 vessels positivity was based on microvessel density technique (MVD).
Results:All results were statistically assessed using Pearson chi2 score.Statistical significance was observed in Ki67 expression in adenocarcinomas (p<0.014)which could be explained by an increased agressiveness of this type of cancer.CD105 was also overexpressed and correlated to a more advanced stage of disease which apparently seems to be related to a worse disease prognosis.CD44 did not present with significant statistical advantage and awaits further investigation considering the fact that a larger number of cases may be apparently required to provide us with more conclusive results.

P 476

PROGNOSTIC SIGNIFICANCE OF NK CELLS AND TNFA IN SURGICALLY TREATED NON-SMALL CELL LUNG CARCINOMAS

RIGAS Angelos1, STYLIANOU Paraskevi1, CHORTI Maria2, TRAKAS Nikos2, LEGAKI Stella2, PALAMIDAS Filippos1, MAOUNI Niki3, ANAGNOSTOPOULOU Helen2, ZIOTOPOULOS Panayiotis1, TAMVAKIS Nikolaos2. 1 1st Department of Respiratory Medicine, Sismanoglion General Hospital, Athens, GREECE; 2 Pathology Department, Sismanoglion General Hospital, Athens, GREECE; 3 Cytology Department, Sismanoglion General Hospital, Athens, GREECE.

Aim: To assess the prognostic significance of NK cells (CD56) and TNFa in biopsy specimens with non-small cell lung cancer (NSCLC).
Materials and methods:104 patients who underwent surgery because of NSCLC were investigated as follows: tumors were classified as squamous cell carcinoma (n=53) or adenocarcinoma (n=51), and age, tumor stage, and tumor size were assessed. Expression of TNFa in lung cancer cells and the NK cells were estimated with the use of monoclonal antibodies. Samples showing >10% of TNFa positive tumor cells were considered positive. Samples with 20-30% infiltration with CD56 were considered positive and >30% strongly positive for the NK cells.Results were assessed

statistically using Pearson chi square. Life tables were estimated by Kaplan-Meier statistics and survival curves were compared using the long-rank test (SPSS 10.0).
Results: 28 samples (26.9%) were TNFá positive and 76 samples (73.1%) were TNFá negative. The survival for negative samples was 56,97 months and 37,52 for positive (p=0.01). There was also a positive correlation between the TNFá expression and more advanced stages IIIA and IIIB (p=0.01). 43 (43%) specimens were CD56 negative, 44 (44%) CD56 positive and 13 (13%) were strongly positive. There was no correlation of CD56 positive expression with the stage and survival (p=0,1000/p=0,2392 respectively). No relation was found with the size of the tumour, the histological type and the age.
Conclusion: The current study could support a role for TNFa as a prognostic factor for patients with non-small cell lung cancer.

EXPRESSION OF MATRIX METALLOPROTEINASES 7 AND 9 IN NON-SMALL CELL LUNG CANCER; RELATION TO CLINICOPATHOLOGICAL FACTORS, PROGNOSIS AND BETA-CATENIN

PIRINEN Risto (1), LEINONEN Tero (1), BOHM Jan (1), JOHANSSON Risto (2), ROPPONEN Kirsi (1), KOSMA Veli-Matti (1)
1) Department of Pathology and Forensic Medicine,
2) Department of Oncology
University of Kuopio and Kuopio University Hospital, Kuopio, Finland

INTRODUCTION: Lung tumour aggressiveness is based on its invasive and metastatic properties probably regulated by different cell–cell and cell-matrix interactions. Matrix metalloproteinases have an important role in many physiological processes and cancer cell behaviour.
PURPOSE OF THE STUDY: The present study was undertaken to analyze the expression and prognostic value of MMP-7 and MMP-9 in non-small cell lung cancer (NSCLC). The relationship of MMP-7 with beta-catenin was also evaluated.
MATERIAL AND METHODS: The study consists of 212 patients with resected NSCLC. The representative tumour samples were collected and stained immunohistochemically. The expression of MMP-7 and MMP-9 was evaluated in both tumour cells and peritumoural stromal tissue. Results were compared to beta-catenin expression and clinicopathological factors of the patients.
RESULTS: The normal bronchial epithelium was either MMP-7 negative or showed weak positivity mainly in apical cells. In MMP-9 stainings the positive staining signal was noted through the whole bronchial epithelium. The dysplastic epithelium was seen in 11 cases. Three out of 11 cases were weakly positive for MMP-7, whereas high MMP-9 staining was seen in all cases throughout the dysplastic epithelium. A high staining of MMP-7 and MMP-9 in tumour cells was noted in 62 (30%) and 113 (57%) cases, respectively. Expression of MMP-7 in cancer cells was associated with histological type of tumour (p=0.022). High cancer cell associated MMP-7 was related to less advanced tumour (p=0.037) and better tumour differentiation (p=0.005). High MMP-7 was also correlated with normal beta-catenin expression in tumour cells (p=0.001). High MMP-9 expression in tumour cells was related to poor tumour differentiation (p=0.016). The stromal signal for MMP-9 was observed in 58 (32%) cases and was linked with higher tumour grade (p=0.031). In survival analyses the significant predictors of survival were histological type of tumour and tumour stage (p=0.0009 and 0.0012, respectively). MMP-7 or MMP-9 expressions were not related to patient`s outcome.
CONCLUSION: The results indicate that in NSCLC high MMP-9 expression both in cancer cells and tumour stroma is a sign of more aggressive tumour, while high MMP-7 expression correlates with less advanced disease.

4.Professor Assistant of Pathology Dept of PUCRS, Porto Alegre, Brasil.
5.Professor of Post-Graduation Programme of UFRJ, Rio de Janeiro, Brasi.

Introduction: Despite improvements on diagnosis and treatment, the prognosis of non small cell lung cancer (NSCLC) still is reserved. There has been much research on new biological parameters and prognostic markers for innumerable malignancies. Studies have demonstrated that angiogenesis can be considered as an independent prognostic factor in several neoplasias including those from lung. Computed assisted analysis of angiogenesis has been performed in some types of tumours by assessment of the number of tumour vessels. This study, however, includes also the area of tumour vessels with image analysis in NSCLC as well as survival rates in Brazilian patients. Purpose: To accomplish the tumour vascular area measurement and the microvessel count with computed assistance through microscopic images from NSCLC, and verify the correlation between these measurements and patient survival in a 5-year period. Material and methods: Paraffin blocks from 107 surgical specimens for NSCLC from Pavilhao Pereira Filho - Santa Casa (Porto Alegre, Brazil). Immunohistochemistry with anti-CD34 monoclonal antibody (QB-End10; Dako Corporation) was performed on paraffin-embedded tissue sections in order to highlight the vessels. The tumour vascular area and the microvessel count were obtained through Image Pro Plus - 3.0 program. 6 images (200x) from 3 hot spots have been taken from each case, totalling 18 images per case. With this software, the vascular area and the number of tumour vessels images have been obtained. The vascular area of each case was assumed as the mean value of its all 18 images. The cases were then separated into high or low vascular area groups, the cut-off being the mean from all 107 cases. Similar process has been made to the microvessel count method. Results: the 5-year survival rate of high vascular area group was 21.7 months „b 2.5, significantly lower (P<0.0001) than the low vascular area cases, 38.9 months „b 3.0. The correlation coefficient between the microvessel area and the microvessel count was 0.5 (P=0.001). The tumour vascular area showed higher correlation to survival (correlation coefficient: 0.48 / P= 0.001) than the tumour microvessel count (correlation coefficient:0.2 / P=0.03). Conclusion The tumour vascular area measurement with computed assistance can be used as a prognostic marker in NSCLC.

P 479
THE IMPACT OF IMMUNOHISTOCHEMICAL DETECTION OF POSITIVE LYMPH NODES ON STAGING AND PROGNOSIS IN EARLY LUNG CANCER

ERSEV Ayse, TEZEL Cagatay, KIRAL Hakan, UREK Senol, DUDU Canan, ARMAN Bulent

Detection of micrometastatic disease is an interesting topic about lung cancer. In early stage, some researchers showed its prognostic impact on survival. Therefore we conducted a study to determine whether the detection of mediastinal lymph node spread by immunohistochemical analysis affects the risk of recurrence and metastasis.
Between 1997 and 2003 21 patients underwent complete resection with mediastinoscopy and systemic nodal dissection for early stage (Stage I and II) lung cancer in our clinic. 426 lymph nodes from 21 patients were analysed. Epithelial spesific antigen Ab-9 and Keratin Pan Ab-1 were used as immunohistochemical markers. Based on nodal spread four of the 21 patients (19.04%) were upstaged after the immunohustochemical analysis. One patient with stage IB (T2N0) were upstaged to IIIA (T2N2); two patients staged as IIB (T2N1) were upstaged to IIIA (T2N2). only one of the 11 patients who had pN0(i)developed local recurrence. On the other hand three of four patients who had both pN1(i) and pN2(i) disease, developed either local recurrence or metastatic disease. Statistical analysis showed that the lymphatic dissemination detected with immunohistochemical analysis was associated with reduced disease-free-survival.
Our study provides some verification that patients with lymphatic micrometastasis have a reduced disease free survival. These results suggest that adjuvant therapies may have a role in early stage lung cancer. Before the new TNM staging system will be commonly used more information is needed to understand the prognostic impact of micrometastatic dissemination.

P 480
DIFFERENTIAL DIAGNOSTIC OF SMALL-CELLED LUNG CANCER USING PLOIDOMETRY
Fedorina TA, Yugina OV
Samara State Medical University, Samara, Russia

Background. The problem of early differential diagnostics of small-celled and non-small-celled lung cancer is particularly important in the light of different approaches to clinical management depending on a tumor type.
Aim: to use ploidometry research for studying the epithelial cell clones in the lung tumors to determine objective criteria of diagnostics of small-celled and non-small-celled lung cancers.
Methods. Computer ploidometry test was carried out for nuclei of epithelial cells in bronchial biopsy specimens, taken from 50 patients with small-celled and squamous cells carcinomas in different stages of cancerogenesis. Bronchial epithelium nuclei taken from 10 healthy individuals were used as control. Histological preparations of 8 micron thickness, stained by Feulgen's technique, were subject of the research. Nuclei's ploidy was defined by means of the computer image analyzer "Imager-CH" ("Avtan-San" software version). The "tissue ploidy standart" (2c) was used for obtaining the data of 1856 bronchial epithelium nuclei. Inter-phase cell nuclei of clones of normal bronchi epithelium, small-celled and squamous cells carcinomas in different stages of differentiation were the subjects of investigation.
Results: In comparison with the average ploidy value of the normal bronchial epithelial cells nuclei, the average ploidy index increases 1,7 times in small-celled cancers. 2 times in well differentiated squamous cells carcinomas and 2,5 times in poorly differentiated squamous cells carcinomas. The study results showed that tumor cells proliferative activity and nuclei ploidy increase in parallel with the increased disdifferentiation of squamous cells carcinomas. In routine diagnostics of bronchial biopsy specimens morphological identification between small-celled and poorly differentiated squamous cells carcinomas is particularly complicated and equally important for further clinical management. The average ploidy of nuclei significantly differs between clones of small-celled and squamous cells cancers (4.2 c versus > 6.3 c) which makes the ploidy index a useful differential diagnostic criteria.
Conclusions: Computer ploidometry may be used in differential diagnostics of small-celled and squamous cells lung cancers. Use of ploidometry data in morphological diagnostics of lung tumors can be an objective tool for taking justified clinical decisions.

P 481
THYMUS TUMORS ON OPEARTIVE TISSUE MATERIAL
STOJSIC Jelena1, RADOJICIC Jelena1, ADZIC Tatjana1, JOVANOVIC Dragana1, TODOROVIC Vera2, DRNDAREVIC Neda2 Institute for Lung Diseases and Tuberculosis, Belgrade, Serbia1
Institute for Medical Research, Belgrade, Serbia2

Background: Thymus tumors are the most frequent tumors of anterior mediastinum. It is a great challenge for surgical pathologist to estimate a precise type of thymus tumor.
Methods: We analysed 75 operated tumors of anterior mediastinum of thymus origin in last fourteen years. Thymus tumors were classified and reclassified according to the most recent classification. Thymus cysts were included in a group of anterior medisatinum operated tumors of thymus origin.
Results: Only on 14 (18.6%) preoperative percutaneuos needle biopsies pathohistological diagnosis of thymoma was established. They measured approximatively 79mm in the greatest diameter. Operated tumors were mostly encapsulated by smooth capsule, lobulated by wide septas, mostly solid or partly cystic. Eleven of them penetrated capsula and involved surrounding tissues. The most frequent was thymoma of A type - 18 (24%), then of AB type – 12 (16%), of B1 – 8 (10.66%), of B2 - 4 (5.33%) and B3 – 4 (5.33%), of C type 6 (8%). Also 3 Hodgkin lymphoma and 3 germ cell were diagnosed, each of 4%. One thymolipoma and one carcinoid tumor of thymus were also estimated – each of 1.33%. Very frequent were diagnosed thymus cysts – 15 (20%).
Conclusion: Preoperative percutaneuos needle biopsies is helpful to distinguish thymus tumors from to other tumors of anterior mediastinum, especially mesenchimal tumors and Hodgkin and B and T non Hodgkin lymphoma. According to their morphology and immunophenotype the precise pathohistological diagnosis could be established and adequate therapy, operated or else oncologic, applied. On small tissue samples the tumor biological behaviour, penetration of thymus capsula and involving of surrounding tissues, can not be estimated. It is only possible on operated thymus tumors.

P 482
MUCINOUS CYSTIC TUMOR OF THE THYMUS: A DOCUMENT OF AN EXTREMELY UNCOMMON CASE
HARADA Hiroshi, YANO Hirohisa, TAKAMORI Shinzo*, MATSUO Toshihiro*
Department of Pathology, Kurume University School of Medicine
Department of Surgery, Kurume University School of Medicine*

Pure epithelial benign neoplasms without lymphoid element are extremely rare in the thymus, although several examples of thymic adenocarcinoma have been described in the literature. We recently encountered a cystic tumor almost purely composed of goblet cell-like mucus-producing cells of the thymus arising in a middle aged Japanese male and describe herein its histological features with brief discussion regarding to the histogenesis. The patient was a 54-year-old male, who was pointed out of enlargement of the

mediastinum in 2004. But he had no complaint such as pain and remained untreated approximately for a year. At the initial presentation to our hospital in early 2005, computed tomography revealed a tumor of the medistinum and surgical removal of the thymus was performed. Gross specimen presented a unilocular cystic lesion containing abundant mucin, which was surrounded by thymic tissue and measured 8x5.5x4.5cm. Dense fibrous tissue occasionally associated with calcification intervened between the lesion and the thymic tissue. Microscopic examination revealed a cystic tumor consisting of bland mucus-producing cells resembling goblet cells and forming tiny daughter cysts within the dense fibrous capsule. In some areas, pseudostratified columnar cells were recognized as well as flattened cells showing slight atypia and nuclear enlargement in the basal layer. No destructive growth or infiltration into surrounding thymic tissue was observed. Thus, the tumor should be regarded as a mucinous cystic tumor of the thymus, probably • gmucinous cyst adenoma• h. Immunohistochemically, tumor cells showed positive reaction for AE1/AE3, CAM 5.2, but negative for 34betaE12 and involucrin. Only a few cells were reactive for p63. Two hypotheses are to be discussed on histogenesis; this tumor is likely considered to have developed from a thymic cyst on basis of pseudostratified columnar cells occasionally identified among mucinous cells. Otherwise, it might have a close relationship to mucoepidermoid carcinoma rarely found also in the thymus, although definite evidence of squamous differentiation was not confirmed. Anyway, the present case is an extremely common neoplasm which has not been described.

P 483

EXPRESSION OF OCT4 AND CELL CYCLE-REGULATORY PROTEINS IN SEMINOMA AND EMBRYONAL CARCINOMA ORIGIN IN THE MEDIASTIUM

Pao-Hsien Chu, Shih-Ming Jung, The First Cardiovascular Department; Department of Pathology, Chang Gung Children Hospital and University, Taipei, Taiwan

Background. Primary germ cell tumor is a relatively rare tumor usually located in the anterior mediastinum. A previous study has postulated that OCT4 is a nuclear transcription factor that is expressed in pluripotent embryonic germ cells. The cell cycles in the germ cell tumors have not been well documented. This study attempted to identify and characterizations of OCT4 expression and cell cycles in the specific germ cell tumors, seminoma and embryonal carcinoma.

Methods. A retrospective study conducted between 1983 and 2005 included 10 consecutive patients with seminoma and embryonal carcinoma in the mediastinum whose tumors had been surgically excised. Overexpressions of OCT4, Ki-67, p16, p53 and p63 genes were studied by immunohistochemistry.

Results. Of the 10 seminoma and embryonal carcinoma in the mediastiun patients, all were men (age 26.8 ¡Ó 15.5 y). Clinical presentations included asymptomatic (38%), chest pain (49%), and dyspnea (13%). The study group contained 10 (100%) men, with a mean age of 26.8 ¡Ó 15.5 years and follow-up 37.2 +/- 18 months. Over-expression of the OCT4 (66.7¡Ó38.3%), p53 (68.6¡Ó31.3%), and p16 (55.5¡Ó34.7%) were considerably higher than Ki-67 (31.4¡Ó27.6%).

Conclusions. This work first examined the immunohistochemical over-expression of OCT4 and cell cycle (Ki-67, p16 and p53) in seminoma and embryonal carcinoma in the mediastinum. This approach demonstrates OCT4 is highly sensitive and specific for the diagnosis; and distinguishes the potential roles of cell cycle in the development of seminoma and embryonal carcinoma.

P 484

CLINICOPATHOLOGIC STUDY OF THYMOMAS (ABOUT 40 CASES)

BRAHAM Emna, ISMAIL Olfa, AYADI Aida, KILANI Tarek* and EL MEZNI Faouzi
Service d'Anatomie Pathologique,
Service de Chirurgie, Hôpital A Mami, Ariana, Tunisia.

INTRODUCTION

Thymomas are primary tumors that arise from epithelial cells of the thymus. They account for more than 50% of anterior médiastinal masses and approximatively 20% of all médiastinal tumours. These neoplasms are most commonly associated with parathymic syndromes, especially myasthenia gravis.

PURPOSE:

We present the clinical and histologic features of thymomas and review the literature.

METHODS

From January 1994 until December 2004, microscopic slides of 40 cases of thymomas were reviewed retrospectively and reclassified according to the new World Health Organization histologic classification. The stage was determined according to Masaoka's classification. Clinical records were collected from medical folders.

RESULTS

There were 23 females and 17 males. Mean age was 51,05 years (range14-76). At presentation 4 patients were asymptomatic and 7 presented with myasthenia gravis. Diagnosis was achieved on surgical specimen in 29 cases and on biopsy in 11 cases .The distribution of histologic subtype was type A (n=1), type AB (n=7), type B1 (n=6), type B2 (n=17), type B3 (n=6), micronodular thymoma (n=2), metaplastic thymoma (n=1). 10 patients were in stage I, 10 in stage II, 8 in stage IIIa, 5 in stage IIIb, 5 in stage IVa and 1 in stage IVb.

CONCLUSION

The predominant histological type in our study was B2 and half of patients were stage I and II of Masaoka. Surgery was the mainstay of treatment, and complete resection with clinical stage seem the most important prognostic factors in this disease.

INTRODUCTION

Peripheral neuroblastic tumors include neuroblastoma, ganglioneuroblastoma and ganglioneuroma. These tumors were classified on depending of neuroblastic differentiation and the degree of schwannian stroma. Ganglioneuroma was a mature and benign form of them. It was rare slow-growing tumor, localized commonly in the posterior mediastinum and retroperitoneum

PURPOSE

The aim of the study is to describe the clinical and pathological characteristics of mediastinal ganglioneuroma in our institution.

METHODS

We retrospectively analyzed seven cases of mediastinal ganglioneuroma diagnosed between January 1993 and December 2004. Medical records and microscopic slides were reviewed.
RESULTS
Patients were 2 males and 7 females. Mean age was 22.14 years (4-84 years) and there were 4 pediatric cases. The most common symptoms were cough and chest pain. One patient presented with Claude-Bernard-Horner's syndrome. Two presented supraclavicular lump and one patient was fortuitously diagnosed. CT scan showed posterior mediastinal mass with dumbbell type in one case. Six patients underwent total tumorectomy. In macroscopy, 5 tumors were firm in consistency, one was soft and other was cystic with calcifications. The mean size was 5.9 cm (3.5 – 9 cm). In histological examination, tumors were composed of nerve fibers and mature ganglion cells. Lymphocytes were observed in 4 cases, fibrous capsule in three cases and calcifications in one case.
CONCLUSION
Ganglioneuromas tend to develop in children and young adults. They are asymptomatic in 50% of cases and symptoms are related to the mass effect. The mean tumor size reported in literature is 8 cm. In our study, tumors were litter and paradoxically the most of them were symptomatic (6 cases).
The definitive diagnosis is histological and the presence of neuroblasts excludes ganglioneuroma. So, complete surgical resection is necessary for ultimate diagnosis and it' is the best chance of cure.

NEUROGENIC TUMORS OF THE MEDIASTINUM IN ADULTS: A REPORT OF 44 CASES.
ISMAIL Olfa, KLAI Khedija, SMATI Belhassen*, AYADI Aida, DJILANI Habiba*,
KILANI Tarek* and EL MEZNI Faouzi.
Department of pathology
Department of thoracic surgery, Hôpital A Mami, Ariana, Tunisia.

INTRODUCTION
Neurogenic tumors originate in the embryonic neural crest cells, which constitute the ganglia, paraganglionic and parasympatic systems. In mediastinum, they are relatively uncommon, though they represent 20% of all primary mediastinal tumors in adults and occur almost exclusively in the middle and posterior compartments.
PURPOSE
We retrospectively reviewed our institutional experience of mediastinal neurogenic tumors in adults with emphasis on the clinical and pathologic characteristics.
METHODS
Between January 1993 and January 2005, 44 mediastinal neurogenic tumors were diagnosed in patients older than 14 years. Clinical records (demographic data, clinical presentation, diagnostic investigations, operative procedures and follow up) were analysed and all microscopic slides were re-examined. Comparison for parameters to distinguish malignant forms to benign, was made by X2 test.
RESULTS
Patients were 16 males and 28 females and ranged from 14 to 84 years of age. 9 patients were asymptomatic, otherwise, chest pain was the main symptom. 4 patients presented a thoracic lump and three a Recklinghausen disease. The tumors had the following characteristics: 38 of them were located in the post medistinum and 3 tumors showed an intraspinal extention, the so called dumbbell-type. They were 36 benign and 8 malignant tumors with 21 schwannomas, 10 neurofibromas, 7 malignant peripheral nerve tumors, 3 ganglioneuromas, one ganglioneuroblastoma and 2 paragangliomas. Resected was performed for all benign tumors and 4 cases of malignant tumors.
With a X2 test, we founded that tumor size¡Ý 8 cm, extension in TDM, dyspnea, thoracic lump and general status alteration were the predictive factors for malignancy.
CONCLUSION
Most studies of mediastinal neurogenic tumors compared pediatric and adult forms and age seem the most important clinical parameter for distinguishing between histological type and rate of malignancy for these tumors. In adult population, it appears that tumor size and some symptoms were the predictive factors of malignancy, especially
general status alteration that seem the only independant factor.

4Department of Biochemistry, Afyon Kocatepe University Faculty of Medicine

ABSTRACT:
Objectives: To show the effects of smoke exposure in rabbits to the histopathological changes in lungs, oxidant-antioxidant status, and the effects of melatonin on these changes.
Methods: Four groups each with five rabbits are formed. A glass box (80x80x80 cm) is used. Group 1 (control) is exposed to cigarette smoke, group 2 (melatonin) is given melatonin only, group 3 (smoke+melatonin) is both exposed to smoke and given melatonin in a duration of 1 month for 1 hour daily and group 4 (control) is the control group. Then lung tissues are examined histopathologically . Protein sulfhydryls (SH), carbonyl, prostaglandin F2á (PG F2á), melandialdehyde (MDA), glutathion peroxidase (GPX), superoxide dismutase (SOM) levels in blood are measured.
Results: Histopathologically intraparenchimal vascular congestion and thrombosis, intraparenchimal hemorrhage, respiratory epithelial proliferation, macrophages in alveolar and bronchial lumens, and bronchoalveolar hemorrhage scores were significantly higher in group 1(smoke) than group 4(control). The scores of bronchoalveolar hemorrhage is significantly decreased in group 3(smoke+melatonin) than group 1 (smoke). Levels of SH and PG F2á were significantly higher and levels of SOD were significantly lower in group 1(smoke) than group 4(control). Carbonyl levels were significantly lower in group 3(smoke+melatonin) than group 1(smoke).
Conclusion: Exposure to cigarette smoke causes severe histopathological changes and negatively effects the oxidant-antioxidant status on rabbits. Melatonin treatment has no healing effect on histopathological changes and oxidant-antioxidant status.

TRANSTHORACIC FINE NEEDLE BIOPSY OF THE LUNG
REPŠE-FOKTER Alenka, KERN Izidor

BACKGROUND AND AIMS: Transthoracic fine needle biopsy of the lung is one of the basic invasive diagnostic procedures in patients with lung diseases. It is safe, cost effective and successful, especially in detecting of malignant diseases. Our objective was to assess the correlation between cytologic and histologic diagnoses.

MATERIAL AND METHODS: We analysed cytologic and histologic diagnoses of 39 patients in whom transthoracic fine needle biopsy of the lung was performed between January 2002 and December 2004.
RESULTS: The patients were 31 – 84 years old (mean 59). The cell samples were insufficient for cytologic diagnosis in 8 cases (20,5%), 5 of them were insufficient also for histologic diagnosis. In 13 out of 31 representative cases cytologic diagnoses were correctly interpreted as benign changes (41,9%). There were two cases of hamartoma and two cases of abscedent inflammation among benign lesions, remaining 9 were reported as non-specific benign changes. In 5 patients cytologic diagnoses were suspicious for carcinoma. In three of them histologic diagnosis confirmed epidermoid carcinoma, in one mesotelioma. One of cytologically suspicious cases was suspicious also after histologic examination. 13 out of 31 representative cases were correctly diagnosed as malignant. Among malignant lesions 4 were adenocarcinomas, 3 epidermiod carcinomas, 2 non-small cell carcinomas and 2 small cell carcinomas. Histologic examination of the two malignant tumors with very unusual cytomorphologic picture revealed synovial sarcoma in one case and PNET in the other.

CONCLUSION: Transthoracic fine needle biopsy of the lung and cytologic examination is a reliable method in distinguishing benign or malignant nature of lung lesions. It is successful also in differentiation of malignant tumors. However, histologic examination is more reliable in further classification of benign changes.

P 489
DIFFUSE PULMONARY OSSIFICATION: A FORGOTTEN ENTITY IN CHRONIC LUNG DISEASE
Ruiz E.(1), Gonzalez-Obeso E.(1), Nistal M.(2).
(1) Trainee resident; (2) MD, pHD.
Department of Pathology. Universitary Hospital La Paz. Madrid. Spain

INTRODUCTION: Diffuse pulmonary ossification (DPO) is an uncommon chronic process characterized by progressive metaplastic lung parenchima ossification. Clinical course is usually asymptomatic, although mild symptoms and restrictive pulmonary physiology have been described in some cases.
OBJECTIVE: To present two cases of DPO and correlate the clinical, radiographical, and pathological features of this entity.
METHODS: Lung biopsies and adult autopsies performed at the University Hospital of La Paz from 1966 to 2004 were reviewed to identify the cases of DPO. One case of DPO was identified out of 9,964 lung biopsies and the other out of 4,051 adult autopsies.
RESULTS: The biopsy was obtained from a 72 year-old man clinically diagnosed of pulmonary restrictive disease. The other case was a 81 year-old man with biventricular hipertrophy and a peacemaker who died of bilateral bronchoneumonia. Radiographically, both patients presented signs that could sugest DPO. Histologically, lungs from both patients presented a nodular pattern of DPO (lamellar deposits of calcified osteoid material located within the alveolar spaces). Even though, the underlying pathology of the first patient has been associated to the dendriform or branching pattern of DPO.
CONCLUSIONS: DPO is an unusual entity seen incidentally at autopsy. Since it is hardly ever considered by clinical physicians, it is rarely diagnosed. A better understanding of the process of DPO formation, its associated diseases, and radiographical appearance is important in order to avoid misdiagnosis with other types of calcium accumulation in the lungs.

P 490
CENTRAL AND PERIPHERAL AIRWAYS EXPRESSION OF NF-KBP65 AND HDAC2 IN NONSMOKERS, ASYMPTOMATIC SMOKERS AND COPD
ISAJEVS Sergejs, TAIVANS Immanuels, KOPEIKA Uldis, STRAZDA Gunta
Department of Pathology, Faculty of Medicine, University of Latvia

Introduction. Airways inflammation and oxidant/antioxidant imbalance is a major cause of lung damage in COPD. An oxidative stress lead to redox-sensitive transcription factor nuclear factor-kB (NF-kB) activation, which regulates the transcription of inflammatory mediators. The molecular mechanism by which inflammatory genes are switched off is mediated by chromatin deacetylation by histone deacetylase (HDAC2).
Purpose of the study. The aim of our research was to compare inflammatory changes in central and peripheral airways in nonsmokers, asymptomatic smokers and in smokers with COPD.
Patients and methods. The study population was composed of 17 subjects undergoing lung resection for a solitary peripheral carcinoma. They have been subdivided into three groups: 5 subjects was nonsmokers and had normal lung function, 5 subjects were smokers with normal lung function and 7 subjects had COPD (FEV1/VC<70%). Immunohistochemical methods were used to identify NF-kB p65 and HDAC2 positive cells. The alveolar destruction index was calculated by formula DI (destruction index)={D/(D+N)}*100%, where D-is destroyed, but N-normal alveolar walls.
Results and discussion. Asymptomatic smokers had more NF-kBp65 positive cells in central compared to peripheral airways and alveolar walls. Subjects with COPD had more NF-kBp65 positive cells in alveolar walls and peripheral airways compared to central airways. The NF-kBp65 was activated both in macrophages and bronchial epithelial cells. In nonsmokers NF-kBp65 expression was found mostly in cytoplasm, but in smokers in cell nucleus. In central airways of asymptomatic smokers there was a positive correlation between the number of NF-kBp65 positive cells (p=-0,04; r=0,65) and smoked pack-years. In patients of all groups there was a positive correlation between macrophages in alveolar walls and destruction index (p=-0.04; r-=0,68). HDAC2 was expressed in all inflammatory cells. HDAC2 expression was suppressed in smokers.
Conclusion. It has been suggested that NF-kB was activated both in asymptomatic smokers and in smokers with COPD. In COPD NF-kBp65 positive cells mostly infiltrate alveolar walls and peripheral airways. The HDAC2 activity was suppressed in smokers.

P 491
PARTICULARITY OF CHRONIC DIFFUSE LUNG DISEASE IN PATIENTS LIVED AT RADIOACTIV-POLLUTED TERRITORIES OF SEMIPALATINSK REGION
Sagindikova G., Kogan E.

Aim. To study diseases, mortality and morphological peculiarities of chronic diffusion diseases of lung in persons lived at radioactive-polluted territories of Semipalatinsk region over a long period of time.
Materials and methods. The analysis of 631 postmortem examination reports with the diagnosis chronic diffusion disease of lungs and archival paraffin autopsy, surgical and biopsy material from 300 patients with CDLD who lived near to polygon and were exposed to the radiation over a long period of time since childhood up to 2003 (annual dose of the irradiation exceeded 0,1 bar). Light microscopy with painting by haemotoxilin and eosin; Van-Gison were performed;

chromogranin À (DAKO) were studied by immunohistochemically.
Results. In the presence of CDLD except known morphology particularities we can point to: sclerosis of walls of bronchus and interstitial; vessel pathology with development of hemosiderosis; accumulation of dust as an indirect index of deposit of radionuclide; hyperplasia of neuroendocrine cells; displease of bronchus epithelium.
Conclusion. The analysis of diseases, mortality, and decrease of these indexes after closing of the polygon and morphology data and information from the literature showed that radiation has a very high mean in pathogenesis of CDLD.

P 492
THE FIRST YEAR OF TRANSBRONCHIAL BIOPSY (TBB) AFTER LUNG TRANSPLANTATION (LT). THIRTEEN YEARS EXPERIENCE.
E.Caballero-Mendoza*,R Vilallonga,I de Torres, M Ferran, R Broto, J Ancer*,S Ramon y Cajal,J Majo. Hospital Vall Hebron, Barcelona, Spain. * Pathology Department, Faculty of Medicine, UANL, Monterrey, Mexico.

Objective.
To analyze the evolution of the mean, indications and diagnostics of 700 TBB performed in the first year from 241 lung transplants performed between 1990 and 2003
Design.
We divided our TBB database for LT into two groups, the historical group (HG) (80 LT& 345 TBB, between 1990 to 1997), and the recent group (RG) (161 LT & 355 TBB, between 1998 to 2003). Each of them were divided into early postransplant period (EPT) (<45 days), and late postransplant period (LPT) (45 to 365 days). We also considered wether the biopsy was clinically indicated (Bcli) or it was a survillance biopsy (Bsurv)
Results.
There is a current decrease in the mean TBBs, principaly in the LPT, in both Bsurv and Bclin compared the HG and RG. The frecuency of TBB in EPT were similar in Bsurv and Bclin in the HG and RG
Historic Group: TBB* 345 (I:4.3); EPT 114 (I:1.42); LTP* 231 (I:2.88); B surv* 163 (I:2.06); B surv EPT 45 (I:0.56); B surv LTP* 118(I:1.47); B clin 182 (I:2.27);B clin EPT 69 (I:0.86); B clin LPT* 113 (I:1.41).
Recent Group: TBB* 355 (I:2.2); EPT 214 (I:1.32); LTP* 141 (I:0.85); B surv* 150 (I:0.93); B surv EPT 88 (I:0.54); B surv LTP* 62(I:0.38); B clin 205 (I:1.27);B clin EPT 126 (I:0.78); B clin LPT* 79 (I:0.49).
* $p<0.05$
In Bcli, in TBB from the recent group we can see an increase of diagnostic biopsies of acute rejection (AR) from 32 to 61 cases (17.6% in HG vs 29.8% in RG, $p<0.05$) and bronchitis/bronchiolitis from 3 to 17 cases (1.6 in HG vs 8.3% in RG, $p<0.05$) and decrease of non-diagnostic biopsies (ND) from 38 to 26 cases (20.9% in HG vs 12.7% in RG, $p<0.05$).
In Bsurv observed an increase of AR diagnostics from 32 to 48 cases (19.6% in HG vs 32% in RG, $p<0.05$) and bronchitis/bronchiolitis from 4 to 20 cases (2.5% in HG vs 13.3% in RG, $p<0.05$)
Conclusions.
1) We are currently managing LT with less TBB before.
2) Present better definitions of clinical settings (i.e. chronic airway rejection) see to improve the percentage of diagnostics in B cli
3) Better recent biopsy protocolization provides Bsurv with some wortwhile indications, not only in the early PT period, but also in late non far PT period

P 493
DISCREPANCIES OF CLINICAL AND POSTMORTEM DIAGNOSIS IN PULMONARY CASES.
Kleina Regina, Aboltins Arnis

The aim of our study is to analyze frequency and reasons of undiagnosed lung diseases in hospitals of Riga (Latvia) during 1999-2004.
Material and methods.We have evaluated autopsy protocols, histological specimens, cases reports of 51 patients with nonspecific inflammation processes and tuberculosis. All dates were evaluated with SPSS 10 program.
Results. In State Center of Pathology (Riga) in six years were made 3600 necropsies. The level of uncoincidence between clinical and pathological diagnosis was 10, 6 %. The comparison of clinical cause of death and autopsy diagnosis showed misdiagnosis of lung diseases in 16, 1 % of cases. Between undiagnosed lungs diseases were: 64 % with lobar pneumonia (LP), 19 % -bronchopneumonia (BP), 5 %-chronic bronchitis (CHB), 12 % -tuberculosis (T). Hospitalization time of patients with LB. was 5days. These were cases with such complications as empyema and purulent meningitis. BP. cases were mainly with abscesses. Persons dead due to CHB were very old people. In misdiagnosis of T. clinical doctors ignored bone tuberculosis in anamnesis and T. was not proved by X- ray examinations.
Instead of lung diseases clinical doctors had diagnosed pathologies of CNS (33, 3 %), coronary heart disease (12%), gastrointestinal system 18, 5% and other pulmonary problems (28%). Duration of patient's hospitalization was average 2, 6 days; ratio male to female was 1, 9:1, average age of men -49, female 60 years. Diagnostic difficulties were also due to severe concomitant diseases of liver and cardiovascular system.
Conclusions. Misdiagnoses of lung diseases were mainly due to short hospitalization time of patient. Doctors ignored patients complains and overlooked X-ray findings, leukocytosis, high ESR, coughing, dyspnoe.

P 494
EXPRESSION OF EXTRACELLULAR MATRIX METALLOPROTEINASE INDUCER (EMMPRIN) IN INTERSTITIAL LUNG DISEASES.
CAULET-MAUGENDRE Sylvie*, GUILLOT Stéphanie**, MARTIN-CHOULY Corinne**, JOUNEAU Stéphane***, DELAVAL Philippe***,LAGENTE Vincent**.
* Laboratoire d'Anatomie Pathologie, ** INSERM U620, Université de Rennes 1, *** Service de Pneumologie, CHU RENNES. France.

Background : Extracellular matrix metalloproteinase inducer (EMMPRIN) is a transmembrane glycoprotein, member of the immunoglobulin superfamily, which stimulates the production of various matrix metalloproteinases (MMPs) from mesenchymal cells. Several MMPs (MMP-1, MMP-2, MMP-9, MMP-14) are involved in lung tissue remodeling and fibrotic processes in experimental and human interstitial lung diseases, as Usual Interstitial Pneumonia (UIP), Non Specific Interstitial pneumonia (NSIP), Chronic Organizing Pneumonia (COP or BOOP), diffuse alvolar damage (DAD), or sarcoidosis.
Purpose of the study : This study aimed to analyse the EMMPRIN expression in various human interstitial lung inflammatory diseases, with or without fibrosis, to precise the cellular source and relationships between EMMPRIN, inflammation and fibrosis.
Methods : The expression was evaluated by immunohistochemistry on surgical lung biopsies in 14 UIP (7 idiopathic or IPF and 7 with associated disease), 4 other interstitial pneumonia (1 NSIP, 1 COP, 2 without specific histologic pattern), 5 DAD, 5 sarcoidosis, 5 pneumoconiosis at early stages, 5 localized fibro-bullous disease and 4 histological normal tissues.
Results : In normal lung, EMMPRIN was slightly expressed in alveolar macrophages and in bronchiolar epithelial cells. In all cases, EMMPRIN was mainly localized in alveolar and

tissue macrophages and bronchiolar cells, with an increased cytoplasmic staining in interstitial pneumonia. In UIP and DAD, pneumocytes of type II present in areas of fibrosis (honeycomb pattern or fibroblastic foci) expressed EMMPRIN according a membranous pattern, along the basement membrane and the cellular interfaces. Pneumocytes of type I, observed in preserved areas of UIP or in all other diseases, were never stained.
Conclusion : EMMPRIN, as an inducer of MMPs, is implicated in the migration/proliferation and phenotype change of the fibroblasts to myofibroblasts with subsequent accumulation and remodeling of extracellular matrix. In UIP and DAD, the increase and peculiar expression of EMMPRIN demonstrated that both the inflammatory (macrophages with activation) and epithelial (alveolar epithelial cells with injury/activation) pathways play a major role in the development of fibrosis. This could be underlined in these two interstitial pneumonia for therapeutical research, because their dramatic evolution towards fatal fibrosis with no or limited response to classical anti-inflammatory drugs.

P 495
METAPLASTIC CHANGES IN BRONCHIAL GLANDS ON THE PLACE OF THE PREVIOUS BIOPSY
GAJANIN Radoslav, BABIC Bozana, KLEM Istvan, ERI Zivka, GAJANIN Vesna, ZRNIC Bogdan

INTRODUCTION: In the bronchi on the place where the previous biopsy had been done, we noticed presence of regenerative changes, while in the bronchial glands we discovered changes with necrotizing sialometaplasia characteristic, which can be wrong diagnostic like mucoepidermoid or squamous cell carcinoma.
MATERIAL AND METHODS: Research includes 141 biopsy samples, which was get by repeated biopsy (rebiopsy). From 141 biopsy samples, changes in bronchial glands are noticed in 44 biopsy samples. The main goal of this research is discovered morphological changes in bronchial glands at the place of previous biopsy.
RESULT: Morphological changes which are discovered on the place of previous biopsy in bronchial glands are: lobular look of changes (59,09% all cases), lesion on the surface (or mucous membrane)(86,36%), fibrin (90,91%), granulations tissue (100%), squamous cells in fibrin (75%), reparative defect in the cartilage (66,67%), granulocytes in the epithelium (93,18%), cylindrical epithelial hyperplasia (93,02%), mucus in the interstitial tissue (77,27%), cystic formation (70,45%), dyskeratotic changes (70,45%), nuclear polymorphism (56,81%) and hyperchromatism (36,36%), multinuclear cells (15,91%), emphasized nucleolus (90,91%), mitosis (47,73%), necrosis (13,64%), 'capture' squamous cells in the granulation tissue (90,91%).
CONCLUSIONS: The characteristic changes in the bronchial glands on the place of previous biopsy are: lobular look of lesion with defect on the surface field up with fibrin or granulation tissue inside who accumulated islands squamous cells with cellular polymorphism, emphasized nuclei who are mitotic active, intraepithelial and stromal granulocytes, reparative defect in cartilage, goblet and cylindrical cells, mucus in the interstitium and cystic formation. The above facts could be wrong diagnostic like mucoepidermoid or squamous cell carcinoma.
KEY WORDS: bronchi, rebiopsy, bronchial glands, regeneration

INTERACTIVE TELEPATHOLOGY WITH THE COOLSCOPE, IN CONSULTATIVE DIAGNOSTICS OF THE DISPERSED LUNG LESIONS.
SLODKOWSKA Janina, *SIEMIATKOWSKA Krystyna, **WOJCIECHOWSKI Michal
National Tuberculosis and Lung Diseases Research Institute [NTB&LDRI], Warsaw. *Kujawsko-Pomorskie Center of Pulmonology [KPCP], Bydgoszcz; **Nikon, Warsaw. POLAND

The term „dispersed lung lesions" [DLL] is a common preliminary clinical diagnosis accompanying the lung biopsy specimen for the histological examination. Actually, DLL is a radiological term used for an undefined lung lesions, does not correlate with their extension nor anatomic distribution. The clinical interpretation of DLL includes: diffuse interstitial lung diseases [DILD], infections, neoplasms (primary or secondary), thrombembolic and cardiovascular diseases, ARDS. Many diseases (especially DILD) have various manners of manifestations and histologic patterns; need complex analysis of the patient data and create the diagnostic problems for the pathologist who will need the second opinion. As our previous studies showed the static telepathology has limited value in the teleconsultations of DILD.
The study was performed to assess the usability of a new generation of telemicroscopy - the coolscope system (NIKON, Japan) for the interactive teleconsultations of DLL.
40 cases of lung biopsy with the preliminary diagnosis "DLL" entered the interactive teleconsultations between KPCP and NTB&LDRI. The coolscope was installed at the workstation with 10 MB network transfer capacity; the viewing workstation used 2 MB transfer capacity (17 inches flat panel monitor with 1,3 mln pixles). For the voice Internet communication the Windows Messenger software was used. The telediagnoses were verified with the light microscope.
The viewing time of a complete microscopic slide ranged from 10 to 60 minutes/case and was depended on the case difficulty and time of image downloading (30' - 7'). The main diagnostic problems encompassed: classification of idiopathic interstitial pneumonias (usual v. non-specific interstitial pneumonia; mixed multilobular patterns; honeycomb stage) - 20 cases; granulomatous inflammatory pattern (extrinsic allergic alveolitis, sarcoidosis, aspergillosis) - 9; occupational diseases - 4; lymphoproliferative diseases - 2; infections - 2; thrombembolic disease - 2; bronchiolitis - 1. An overall diagnostic accuracy was 95% (38/40), 2 cases needed additional immunostaining.
The benefit from this technical development is a very high diagnostic accuracy in DLL teleconsultations combined with the high efficiency of the system (the standard Internet connection, free time access to the system, independent platforms, cheep and good quality of the service).

ISOLATED AMYLOIDOSIS OF THE TRACHEA
KORKOLOPOULOU Penelope 1, KAVANTZAS Nikolaos 1, THALASSINOS Nikolaos 2, ZACHILAS Dimitrios 2, PREZAS Loukas 2, LOUTRARIS Christos 1, ANASTASIOU Nikolaos 2, PATSOURIS Efstratios 1
1. Department of Pathology, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece.
2. Department of Thoracic Surgery, 1st IKA Hospital of Athens, Athens, Greece.

Introduction: Respiratory amyloidosis is a rare disease that occurs in three forms: tracheobronchial, nodular parenchymal and diffuse parenchymal involment. Tracheobronchial amyloidosis is characterized by focal or diffuse deposition of amyloid in the submucosa of the trachea and proximal bronchi.
Clinical and laboratory features: A female 55–year-old patient presented in the Department of Thoracic Surgery with symptoms of dyspnea on exertion the last 2 years. She reported previous hospitalization for sangeinous sputum and bronchiectasis. On physical examination she had rales and

prolongation of the expiratory phase. Her chest radiography was negative and the CT scan showed thickness of the posterior wall of trachea. On bronchoscopy, soft, whitish, sponteneously bleeding patches were discovered and biopsed. One of the lesions was obstructing the opening of the left main bronchus. Histological examination showed isolated amyloidosis of the trachea, without any involvement of the larynx or the bronchi. The diagnosis was confirmed by the Congo Red histochemical stain. The patient was initially treated with endoscopic laser surgery. Given that obstruction of the left main bronchus persists, the patient is a candidate for stent placement.
Conclusion: Primary isolated amyloidosis of trachea is a rare and probably recurrent disease. Airway compromise can be a persistent problem. Repetitive laser or cryotherapy interventions and use of stent is a palliative therapy for this disease with poor prognosis.

P 498
NON AMYLOÏDOTIC BRONCHOPULMONARY DEPOSITS OF IMMUNOGLOBULIN IN WALDENSTRÖM'S MACROGLOBULINEMIA
Alexandre VASILJEVIC (1), David MEYRONET (1), Lara CHALABREYSSE (1), GINDRE Dominique (1), Frédérique DIJOUD (2), Jean-François CORDIER (3), Françoise THIVOLET-BEJUI (1)
(1)Service d'anatomie et cytologie pathologiques , hôpital Louis Pradel , Lyon
(2)Service d'anatomie pathologique , hôpîtal Debrousse, Lyon
(3)Centre des maladies orphelines pulmonaires , hôpital Louis Pradel, Lyon

We report the case of a 49 years old woman, followed up since 2001 for Immunoglobulin M (IgM) kappa monoclonal gammopathy of undetermined significance and presenting for 4 years evolutive dyspnea with bronchorrhea.
Paraclinical evaluation has shown non-infectious proximal diffuse bronchiectasis associated with parenchymatous destruction by chest tomodensitometry ; a decrease of CO diffusion ; « candle stains » lesions of bronchi by endoscopy. A high rate of monoclonal IgM, previously undervalued because of a cryoglobulinic pattern, was found. There wasn't Bence Jones proteinuria. A bone marrow biopsy led to the diagnosis of Waldenström's macroglobulinemia.(WM)
MATERIAL AND METHODS :
The bronchic and pulmonary biopsies sampled by endoscopy and thoracotomy were fixed or frozen for optical microscopy , electronic microscopy and immunofluorescence.
RESULTS :
Under optical microscopy , bronchic submucosa exhibited deposits of a perivascular and intersitial amorphous eosinophilic material. Pulmonary tissue showed proximal acinar emphysema and bronchiolar dilatation. Congo red and T thioflavin stains showed these deposits to be non amyloïdotic. Immunofluorescence of the deposits were positive for anti kappa and anti mu immunoglobulin chains antibodies. They were granular under electronic microscopy. Similar but smaller deposits were found in alveolar wall.
DISCUSSION :
There are two classical types of lung involvement in WM : AL amylosis and primary lymphomatous invasion. The reported case is original because :
the bronchopulmonary presentation (proximal bronchiectasis) is exceptional
the nature of the deposits made of complete or fragmentary light chain and heavy chain of IgM is non amyloidotic
CONCLUSION :
This case represents an original anatomo-clinical syndrom. The pathological mechanism which explains that the monoclonal IgM kappa cryoglobulin forms deposits at bronchopulmonary level and leads to these clinical manifestations is still undetermined.

MUCORMYCOSIS MIMICING LUNG CANCER (CASE REPORT)
Fillinger J.,Soltesz I.,Udud K.,Csekeõ A.,Kludák I.

The authors introduce two cases, whose history includes diabetes mellitus.Either of them after ketoacidic coma were found to have unilateral pulmonary infiltration. Bronchoscopy showed cone shape stricture of the right main bronchus. the surface of the mucus membrain was rough and looked like a tumor. Histology did not find anything other than fungal infection.
In one case the regulary done investigation found a tumor, suspected,infiltration of the left lower lobe.The resected lobe has undergone histopathological investigation and showed infection of mucormycosis.
In the literature mucormycosis stands in forth place among opportunistic pulmonary fungal infection.Backround of the recent years recognised growing incidence of well known immundefficiency and increasing number of diabetes mellitus.

IMPROVED PCR-BASED DETECTION AND DIFFERENTIATION OF MYCOBACTERIUM TUBERCULOSIS COMPLEX IN PARAFFIN-EMBEDDED TISSUES BY APPLICATION OF THE HOPE*-TECHNIQUE
E. Vollmer1, D. Hillemann2§, T. Kubica1, G. Zissel3, J. Müller-Quernheim3, J. Galle1,
T. Goldmann1
1Clinical and Experimental Pathology, Research Center Borstel, Borstel, Germany.
2National Reference Center of Mycobacteria, Research Center Borstel, Borstel, Germany
3University Freiburg, Dept. for Pneumology, Freiburg, Germany

Introduction: Detection of mycobacterial DNA by PCR in formalin fixed, paraffin-embedded specimens may lack sensitivity due to degradation of nucleic acids.
Purpose of the study: To improve the results we set up an approach by application of the novel HOPE-fixative in PCR-detection of mycobacteria in paraffin-embedded tissues.
Methods used: PCR, Real time PCR, Spoligotyping.
Summary of the results: Comparison of PCR-results using DNA extracted either from HOPE- or formalin-fixed specimens in BCG-infected SCID-mice revealed a more than 100fold enhanced sensitivity for the HOPE-fixed material. Due to the preservation of DNA from degradation in HOPE-fixed tissues even differentiation within the M. tuberculosis complex was possible by spoligotyping.
Conclusions reached: We demonstrate that the HOPE-technique is a useful tool for molecular pathology, which enhances the sensitivity of PCR-based methods for detection of pathogens in paraffin embedded tissues compared to formalin-fixation. Due to the better preserved DNA improved differentiation of mycobacteria from archived materials is possible. These results promise new and substantially enlarged possibilities in the field of molecular pathology.

HISTOLOGICAL DIAGNOSIS OF LUNG BACTERIAL NECROTIZING INFECTION: A STUDY OF 4 FULMINANT CLINICAL CASES
LASSALLE Sandra (1, 2), HOFMAN Véronique (1, 2), BUTORI Catherine (1), HOFMAN Paul (1).
Laboratory of Clinical and Experimental Pathology, Pasteur' Hospital, University of Nice, Nice, France

We report the clinical and histological findings of four cases of pulmonary infection due to bacteria which were associated with a lung extensive necrosis. These infections were fulminant with a fatal course within a few hours. Histological findings were very similar in these 4 cases and were characteristics of these infections by associating an extensive hemorrhagic tissue necrosis, large layers of bacteria observed inside the alveola and/or in the connective tissue, and most often, a very weak or no inflammatory infiltrates. These infections were due to group A Streptococcus in two cases, Staphylococcus aureus in one case, and Haemophilus influenzae in one case. The histological features observed in these infections are due to the production of large amounts of different necrotizing toxins. These dramatic infections are extremely rare and can occur, both in immunodeficient and in immunocompetent patients without any apparent underlying disease. The differential diagnosis includes a viral infection which can be very difficult to be eliminate histologically. The precise diagnosis is always based on a correlation between the histological and the microbiological results. These data confirm the reappearance of some highly invasive strains, such as strain of group A streptococci, capable of producing a variety of fulminant diseases, including shock and diffuse pulmonary necrosis. The nonspecific presentation and fulminant progression require that the treating physician, the microbiologist, and the pathologist be both knowledgeable and vigilant.

P 502

LOH AT 9P21 (P16 LOCUS) AND 17Q13 (P53 LOCUS) CAN BE DETERMINED IN ORAL EXFOLIATIVE CYTOLOGY FROM NON-SMALL-CELL-LUNG-CANCER PATIENTS.

J Sanz-Ortega 1, J Sanz-Esponera 1, S Hernandez 2, M Saez 1, F Roig 3, L Callol 3 and A Munoz

Background: LOH at different loci is a frequent genetic alteration detected in non-small-cell lung cancer. Identical allelic deletions were found in most cases in normal bronchial cells adjacent to tumor Smoking exposure has been involved with these genetic changes in oral, larynx and lung tumorigenesis. Therefore, demonstration of LOH in any of these locations may detect patients with a higher risk of cancer. Design: Oral exfoliative cytology was obtained from 64 patients divided in 3 groups: 23 current smokers in which NSCLC was detected, 24 current smokers with no evidences of malignancies (3-5 years follow-up) , and 17 non-smokers control population.Results: We found LOH at 17q13 in 3/15 (20%) and LOH at 9p21 in 2/12 (16.6%) of the informative tumor cases. In total, 5 out of 18 (27,5%) patients that were informative for either alleles showed deletions. LOH was not found at any locus in oral mucosae from any non-tumoral case, smoker or non-smoker.
Conclusion: LOH at 9p21 (p16) and 17q13 (p53) can be determined not only in normal bronchial cells adjacent to NSCLC but also in oral exfoliative cytology. In our series these somatic genetic changes were unusual in patients with similar age and sex distribution with no evidences of malignancies. LOH assessment in oral exfoliative cytology may be useful in screening to detect smoker patients at a higher risk of malignant transformation.

P 503

THE POTENTIAL ROLE OF INCREASED CD68 POSITIVE MACROPHAGES AND MACROPHAGE MICROACCUMULATIONS PRESENCE, IN CASES OF CROHN'S COLITIS AND THEIR CONTRIBUTION IN ITS DISTINCTION FROM ULCERATIVE COLITIS

TSAMANDAS Athanassios, LIAVA Anna, ZOLOTA Vassiliki, SCOPA Chrisoula
Department of Pathology, University of Patras Greece.

Background: Previous studies have demonstrated that macrophage microaccumulations (MA) are present in gastric and small bowel mucosal biopsies from patients with Crohn's disease (CD). However, their presence in inflammatory diseases of the colon has not been fully elucidated. In this study we investigated whether CD68 immunostaining and MA can be used to distinguish CD from ulcerative colitis (UC).
Design: The study included 123 routinely processed colonic mucosal biopsies, including 72 specimens obtained from 30 patients with CD (mean age: 47 yrs, M/F: 10/20), 33 specimens from 20 patients with UC (mean age: 33 yrs, M/F: 5/15) and 18 specimens from 18 normal controls (mean age: 63 yrs, M/F: 8/10). On paraffin sections a standard streptavidin-biotin peroxidase method was applied using the anti-CD68 antibody. The total number of CD68(+)cells in 10 consecutive intercrypt regions (ICR) of the lamina propria was recorded in each biopsy specimen. The number of MA, defined as loose collections of at least 5 macrophages identifiable only by CD68 immunopositivity, and not by H&E staining, present in 10 consecutive ICRs was also recorded. Finally we employed statistical analysis in order to compare the results from the different patient groups.
Results: There were no significant differences in the number of subepithelial or basal lamina propria CD68(+)cells between the three patient groups. However, the mean number of CD68(+) macrophages in the mid lamina propria was higher in CD (29±4) than UC (19±8, $p<0.05$) and normal controls (23±3, $p>0.05$). MA were present in 24 biopsies from 19 (63%) CD patients, compared to 6 biopsies from 5 (25%) UC patients ($p<0.01$) and none (0%) of the normal controls ($p<0.0001$). Furthermore, only CD cases contained >1 MA (9 biopsies from 6 patients, $p<0.01$). None of the UC or control patients had >1 MA.
Conclusions: The study demonstrates that small aggregates of CD68(+)macrophages are more frequently present in CD than in UC and multiple MA are found exclusively in CD. Thus, the presence of multiple MA may contribute to the distinction of CD from UC in colonic biopsies.

AN ANALYSIS OF THE RELIABILITY OF DETECTION AND DIAGNOSTIC VALUE OF VARIOUS PATHOLOGICAL FEATURES IN CROHN'S DISEASE

Engin Cigerciogullarý*, Suha Goksel*, Gulen Bulbul Dogusoy*, Sibel Erdamar Cetin*, Aykut Ferhat Çelik**, Yusuf Erzin**, Ismail Hamzaoglu***
University of Istanbul, Cerrahpasa Medical Faculty, *Department of Pathology, ** Department of Gastroenterology, *** Department of General Surgery

Introduction. Due to the relatively high frequency of intestinal tuberculosis (IT) and intestinal involvement of Behçet's disease (BD) in Turkey, the differential diagnosis of Crohn's disease (CD) is difficult. This difficulty is valid for the pathologic investigation of both endoscopic and surgical GIT material. The aim of this study is to specify the pathological features of CD that will differentiate from the other conditions, and to analyze the reliability and diagnostic value of these features.
Material and Methods. In this study, 26 standardized patients, that have been diagnosed as CD through standard clinical, laboratory, radiological, endoscopic, microbiological procedures and further operated, have been investigated. The preoperative endoscopic biopsies, the surgical specimens and the immediate mucosal punch biopsies of the resected intestine have also been revised.
Results. In the resection specimens of 23 patients, fissure formation, transmural lymphoid follicle infiltration, submucosal fibrosis, neuronal hyperplasia, subserosal

fibrosis, which are the classical findings of CD were observed. The striking point in this regard was the infrequent presence of granuloma formation in these patients (30%). In the remaining 3 patients, even though some of the above findings exist, the classical Crohn's picture was not established. In the endoscopic biopsies the most presenting finding was antral metaplasia, and the most interesting finding was increase in eosinophils. In 2 of the patients the coexistence of BD and CD was observed.
Conclusion. Granuloma formation which a finding of CD is not observed too frequently among the patients in Turkey. The presence of antral metaplasia and increased eosinophils in the endoscopic biopsies of the chronic patients may be useful for diagnostic approach when combined with other histological findings. Due to the incidence of coexistence of BD and CD, the investigation of standardized BD and IT groups, are subjects of our ongoing studies.

A NEW SIMPLIFYED HISTOLOGICAL CLASSIFICATION OF COELIAC DISEASE
VILLANACCI Vincenzo * CORAZZA Gino Roberto
*2nd Department of Pathology - Spedali Civili di Brescia, Italy
First Department of Medicine IRCCS Policlinico S. Matteo University of Pavia, Italy

The diagnosis of Coeliac disease (CD) is still based on the biopsy-proven presence of duodenal-jejunal mucosal lesions which improve after gluten-free diet.
It is believed that the currently used criteria are often the source of disagreement between pathologists and clinicians.Marsh proposed a four stage grading: type1 infiltrative lesion, normal mucosal architecture with an increased number of intraepithelial lymphocytes (IELs), type 2 hyperplastic lesion, an increase in crypt depth without villous flattening, type 3 destructive lesion, villous atrophy .Oberhuber et al subsequently proposed a new standardized report scheme, based on the Marsh classification, in which stage 3 was split further into 3a, 3b and 3c, characterised respectively by mild villous flattening, marked villous flattening and completely flat mucosa. How can the Marsh-Oberhuber classification be simplified to improve its reproducibility without reducing its diagnostic accuracy with respect to CD? Obviously, type 1 infiltrative lesion – cannot be put aside. This lesion can in fact be the only evidence of a gluten-sensitive enteropathy in dermatitis herpetiformis and a sensitive, marker of latent CD. More recently, the upper limit of the normal range has been established as being 25 IELs/100 epithelial cells and we therefore feel that IELs counts above this figure allow the diagnosis of a type 1 infiltrative lesion. As regards type 2 hyperplastic lesion, we doubt its usefulness in the diagnosis of new patients – who would, in any case, already be identified by the increased IELs . As regards the substages 3a and 3b characterised by mild and marked villous flattening but not yet by flat mucosa, we suggest that these should be grouped in a single stage. Finally, as regards type 3c there is no doubt that this stage should be maintained. A simplification of the current histological classifications of CD is necessary in order to make the work of pathologists more uniform and to facilitate the relationship between pathologists and clinicians. We therefore propose that the lesions characterising celiac disease be divided into non-atrophic (grade A) and atrophic (grade B) and that the latter be further split into grade B1, in which the villus/crypt ratio is less than 3/1 with still detectable villi, and grade B2 in which the villi are no longer detectable.

ROLE OF OXYGEN FREE RADICALS ON THE MOTILITY OF RAT ILEUM:
NASTARAN EIZADI-MOOD(1) AND KAILASH PRASAD (2)
1 Assistant Professor of Isfahan University of Medical Sciences, Isfahan, Iran
2 Professor of department of Physiology, College of Medicine, University of Saskatchewan, Saskatoon, Saskatchewan S7N
OWO, Canada

ABSTRACT
The major objective of the present study was to characterize the effects of oxidants which generated by xanthine (X) plus xanthine oxidase (XO) on isolated rat ileum motility. The effects of three concentrations of X/XO on the basal tone of the rat ileum preparation were studied for 20 minutes. Developed tensions were measured in mg/mg tissues and then expressed as percentage of baseline tension. Also the effects of 2X concentration of X/XO in the presence and absence of Superoxide dismutase, catalase ,mannitol, histidine, and deferoxamine were evaluated.The result were expressed as mean +- SE. Xanthine plus xanthine oxidase produced relaxation of ileum. Superoxide dismutase (a superoxide anion metabolizer) and catalase (a hydrogen peroxide scavenger) did not protect ileum from effects of X/XO, suggesting that neither superoxide anion nor hydrogen peroxide involve in X/XO-induced relaxation of ileum. The results of this study suggest that hydrogen peroxide formed extracellularly by X/XO may enter the cells and interact with intracellular iron to form a highly reactive oxidant, hydroxyl radical. The finding that two powerful hydroxyl radical scavengers, dimethylthiourea (DMTU) and mannitol offered protection against X/XO-induced relaxation of ileum suggest formation of hydroxyl radical within the cells. Pretreatment with deferoxamine, a potent iron chelator, reduced the relaxation of ileum, indicating that hydroxyl radical plays an important role in mediating the X/XO-induced relaxation of ileum. In addition, the ability of exogenously administered histidine to reduce relaxation suggests that singlet oxygen is another oxygen derivatives which is responsible for relaxation of ileum-induced by X/XO.
Key Words: Ileum Strips; Xanthine; Xanthine oxidase; Hydroxyl radical; Singlet oxygen; Superoxide dismutase; Catalase; Dimethylthiourea; Manntiol; Histidine; Deferoxamine

THE EFFECT OF GINGER ON SMALL INTESTINE CHANGES INDUCED BY DIABETES IN RATS
ESKANDARI Mehdi *, SHIRPOOR Alireza **, GOL Ali **, ILKHANIZADE Behrooz ***
* Department of physiology & Pharmacology, Zanjan university of medical sciences
** Department of physiology & Pharmacology, Urmia university of medical sciences
*** Department of pathology, Urmia university of medical sciences

In the present study, we investigated the effect of ginger consumption on the morphological and histological changes in the small intestine of diabetized rats. Eighteen male wistar rats with average body weight 250 gr and 8 months old were chosen to do the study. They were divided into three equal groups (n= 6): the first group rats were nondiabetic; the second group rats were diabetized by streptozocine (60 mg/kg body weight) which received normal diet, and the third group rats were also diabetized which received normal diet and ginger (6 percent of daily diet weight). After 6 weeks abdominal cavity was opened and mesentery was separated carefully by using scissors. Then the small intestine was taken from pyloric sphincter and ileocecal sphincter. After weighing and measuring the length of small intestine, from three parts of small intestine including duodenum, jejunum and ileum 5

cm long samples were taken. After filling the lumen with 10% formalin buffer and ligature of it, they were put into formalin. After sectioning and staining, villi length, crypt depth and muscle thickness of samples was measured. The weight and length of small intestine, length of villi, depth of crypt and muscle thickness increased in non-treated rats comparing to those of nondiabetic rats. The mentioned parameters did not show any significant difference comparing to two groups of ginger-treated and healthy rats. The study showed that ginger as an antioxidant probably prevented changes caused by diabetes in small intestine.

MUCOSAL LYMPHATIC VESSELS IN IDIOPATHIC BOWEL DISEASE

STÖMMER Peter E.(1), BAYER Ingrid
(1) Gemeinschaftspraxis für Pathologie,Augsburg

Introduction
The lamina propria of normal colorectal mucosa contains only some small lymphatic vessels near the muscularis mucosae. New monoclonal antibodies (MoAbs) fascilitate their differentiation from blood capillaries.
Purpose of study
Chronic inflammations induce lymphatic angiogenesis in different organs. We investigated number and localisation of intramucosal lymphatic vessels in chronic idiopathic bowel disease (IBD), in respect of their contribution to the pathogenesis of colitis ulcerosa (C.u.) and Crohn's disease (CD)
Materials and Methods
MoAb D2-40 (reacting with lymphatic endothelium specific O-linked sialoglycoprotein MW 40K;DCS Hamburg; RTU) and LYVE (reacting with a lymphatic hyaluronanreceptor; DCS Hamburg; RTU) were used as markers for lymphatic vessels. Proliferation was quantified by nuclear Ki-67 (DCS Hamburg; Clone SP6).
Results
Colitis ulcerosa
In the interface of mucosa and muscularis mucosae, there are dense networks of thinwalled lymphatic vessels; they are oriented parallel to the circumference of the colon; their endothelial cells have activated nuclei, though they are negative for proliferation marker Ki-67.Numerous lymphatic vessels are found in the lower third of the mucosa; the middle third of the lamina propria contains less lymphatic channels; the upper third is free of lymphatics. Only rarely, there are perpendicularly oriented lymphatic vessels (mostly near lymphatic follicles).
The density of lymphatic vessels correlates well with the duration of C.u and the proliferative activity of crypt epithelia; the extension of inflammation and proliferative activity of lymphoid cells in the mucosa does not influence the density of lymphatic vessels.
Carcinoma in C.u. shows high density of lymphatic vessels in between of the neoplastic glands, correlating perhaps to its aggressive course.
Crohn's Disease
In contrast to C.u., the density of lymphatic vessels is augmented not only in the lower third of the lamina propria, but also in the middle and upper parts of the mucosa. High density is seen in fibrotic areas and in parts with enteral metaplasia. Their number correlates to the intensity of inflammation.
Conclusions and hypothesis
Proliferation of mucosal lymphatic vessels, consequence of elevated levels of VEGF in IBD, contributes to the differences in pathogenesis of late phases of C.u. and MC.

P 509

BCL-2 PROTO-ONCOGEN EXPRESSION IN ISCHEMIC MAMMALIAN SMALL BOWEL MUCOSA IN RELATION TO THE DURATION OF ISCHEMIA. (PRELIMINARY REPORT).

Grigoriou M*, Gerasimidou D**, Karayannopoulou G**, Atmatzides C*, Papadimitriou C.S**.
*2nd Surgical Department, Aristotle University Medical School, Thessaloniki, "G.Gennimatas" Hospital Greece.
**Department of Pathology, Aristotle University Medical School, Thessaloniki. Greece.

Introduction. Bcl-2 proto-oncogen is a key factor in the prevention of apoptosis in lymphoid and epithelial tissues. The aim of this study is to evaluate the role of Bcl-2 expression in ischemia-induced apoptosis of small intestinal mucosal cells.
We investigated the appearance of apoptosis at various time points of ischemia in comparison to the expression of the Bcl-2 protein.
Materials and methods. We examined samples obtained from mammalian small intestine (New Zealand White Rabbits) following ischemia induced by strangulation-obstruction of 5cm of jejunum. Samples were taken preoperatively and progressively at 30, 180 and 360 min from the onset of strangulation. Tissue sections were stained for H&E for the estimation of mucosal ischemic damage. Tissue sections taken from the same samples were stained immunohistochemically for Bcl-2 protein.
Observations from both H&E and Bcl-2 staining were compared to estimate the correlation of Bcl-2 expression with the severity of the ischemic injury.
Results. Histological changes were observed in the jejunum concerning the upper third, the upper two thirds and the whole length of the villi respectively at 30, 180 and 360 min from the onset of ischemia. Cytoplasmic expression (++++) of Bcl-2 protein was observed at villous epithelial cells, while it was barely obvious at the crypts at the onset of ischemia. Minimal reduction (++) of Bcl-2 expression at the apical third of the villi at 30 min and increased reduction concerning the two thirds of the villi at 180 min after the induction of ischemia was observed. Only scattered apoptotic epithelial cells were observed expressing the protein after 360 min of ischemia.
Discussion. Progressive suppression of the Bcl-2 proto-oncogen expression on ischemic injured small intestinal mucosal tissue suggests a key role of the Bcl-2 protein in the apoptotic pathway induced by ischemia. The correlation of this phenomenon to the severity of ischemic injury at consequent time intervals leads to the assumption that this is not a triggered effect but a dynamic process aggravated by the progression of ischemia.

INTESTINAL VASCULITIS MIMICKING A COLONIC NEOPLASM. REPORTING OF A CASE.

CASALOTS Alex, PARRA Tamara, ORELLANA Ruth, FERNANDEZ Sara, DINARES Carme, ESCODA Maria-Rosa, ANDREU Javier, REY Mercè.
Corporació Parc Taulí, Pathology Dept., UDIAT-CD, Sabadell, Barcelona. Spain.

INTRODUCCION
Vasculitis of the gastrointestinal (GI) tract is known to occur as a part of a systemic process such as Panarteriitis Nodosa, Churg-Strauss angiitis, Behcet's disease, giant-cell arteritis, Buerger's disease, systemic Eritematous Lupus, Henoch-Schölein purpura and rheumatoid arthritis. Systemic and isolated vasculitis classification is based on the predominant type and size of the vessel involvement. Polyangiitis overlap syndrome proposed by Leavitt and Fauci is defined as systemic vasculitis that does not fit precisly into a single category of classical vasculitis or overlaps several of the categories.
CASE REPORT

A 77-year-old woman presented with 2-days history of abdominal pain, bowel obstruction and abdominal distention. An abdominal computed tomography scan was performed and showed swelling and bowel wall thickening of the sigmoid colon. With the clinical diagnosis of a malignant tumor, the sigmoid colon was resected. Pathological examination of the resected colon segment revealed an stenotic pseudotumoral lesion (3-4 cm.), mucosal ulceration and severe obstruction that compromise 70% of the circumference. Microscope examination showed severe mucosal ischemic necrosis associated with necrotizing vasculitis involving medium and small-sized arteries and heavy infiltration of eosinophils. No granuloma formation was observed.

DISCUSSION

The main differential diagnosis has to be made within the group of vasculitis involving medium and small sized arteries. Wegener's granulomatosis is distinguished by its predilection to affect the upper and lower respiratory tract and kidneys, positive C-ANCA titer and GI involvement is uncommon.

Churg-Strauss syndrome is a disorder characterized by clinical features such as asthma, allergic rhinitis, hypereosinophilia and histological features of necrotizing vasculitis, eosinophilic infiltration and granulomas. GI involvement is about 50%.

PAN is a systemic disease that showed acute arteritis with fibrinoid necrosis of the vessel wall. GI involvement is relatively frequent (40-70%).

In our case, according to the clinical and pathological findings, we suggest the diagnosis of a polyangiitis overlap syndrome with some features of allergic granulomatous angiitis and Polyarteritis nodosa.

PRIMARY RHABDOID CARCINOMA OF THE ILEUM: REPORT OF THE SECOND CASE IN THE LITERATURE WITH EXTENSIVE IMMUNOHISTOCHEMICAL (IHC) WORK-UP AND OVERVIEW OF DIFFERENTIAL DIAGNOSIS.

TOTH Laszlo(1), NEMES Zoltan(1), GOMBA Szabolcs(1), ASZTALOS Laszlo(2), SZENTIRMAY Zoltan(3), MOLNAR Peter Pal(1).

University of Debrecen, Medical & Health Sciences Center (DE-OEC), Department of Pathology, (2)DE-OEC, 1st Department of Surgery, Debrecen, Hungary; (3)National Institute of Oncology, Institute of Pathology, Division of Molecular Pathology, Budapest, Hungary.

Introduction: Primary rhabdoid tumors of the small intestine are very rare but do occur as we demonstrate herewith.

Purpose: To describe the second case of primary rhabdoid carcinoma of the ileum with multiple recurrences.

Material and methods: The 81-y-old male patient had been treated for ischemic heart disease, arteriosclerosis and a benign papilloma of the urinary bladder. In November 2004 he was admitted and urgently operated on because of melena and progressive ileus. Abdominal examination revealed a firm, left parumbilical mass, easily palpable that was cca. 8 cm in diameter. A 20 cm long ileum-segment was removed. Its wall was widely infiltrated by a cauliflower-like, extensively hemorrhagic, ulcerated tumor. The invaded segment firmly adhered to the parietal peritoneum hence the resection included that part as well. Since the 1st operation the tumor has recurred twice (in 01/05 and in 03/05), each time breaking through the wall of the small intestine from the peritoneal surface and causing mucosal ulceration. These tumors were removed and re-excision of the surgical wound was also necessitated by local neoplastic re-growth. Presently tumorous infiltration along the surgical incision is evident again, but the patient refuses further surgery. The formol-fixed, paraffin embedded tumors comprised large necrotic-hemorrhagic areas and solid, highly cellular, solid sheets with focal loss of cellular cohesion. The round or polygonal cells were intermingled with bizarre, pleomorphic, often multinucleated forms. The nuclei were large, often polymorphic and eccentric with prominent nucleoli and numerous abnormal mitoses. The Mib-1 labeling index was 50-75%. Characteristic, pathognomonic, homogeneous eosinophilic cytoplasmic inclusions ("hyalin-globules") were seen. IHC revealed diffuse, strong vimentin, panCK and focal EMA positivity. CD30, Bcl-6, S100, HMB45, c-kit, CK7, CK20, p27-kip1, E-cadherin, SM actin, desmin, caldesmon and CD34 were negative. CD3, CD20 and LCA decorated the reactive lymphoid elements. Monoclonal p53 was diffuse positive. Some areas reacted with neu oncoprotein (++). All lymphnodes were reactive-hyperplastic but tumor-free. So far no distant metastases occurred.

Discussion: IHC and light microscopic morphology prove rhabdoid cancer excluding lymphoma, adenocarcinoma or leiomyosarcoma. EM and molecular tumor-analysis are in progress, the results will be presented. Literature-search disclosed only 1 earlier jejunal case by 04/05.

APPENDICEAL MUCINOUS NEOPLASMS: A ROLE IN PSEUDOMYXOMA PERITONEI

Kwang-Sun Suh, Moon-Il Park, Kyu-Sang Song, Wan-Hee Yoon*

Departments of Pathology and Surgery*, Chungnam National University School of Medicine

Mucinous neoplasms of the appendix are rare and associated with colonic or ovarian neoplasms, and pseudomyxoma peritonei (PMP). PMP is a rare form of dissecting gelatinous ascites associated with multifocal peritoneal and omental implants that secrete copious globules of extracellular mucin. Recent immunohistochemical and molecular genetic evidence suggests the appendix to be the primary site. We analyzed 30 cases of appendiceal mucinous tumors (22, mucinous cystadenoma; 4, borderline mucinous tumor; 4, malignant mucinous tumor), seven of which were accompanied by PMP. An immunohistochemical study for MUC2, MUC5AC, CK7, and CK20 was also performed to confirm the origin of PMP. Among 30 appendiceal mucinous tumor cases, four cases had right colon cancer, one case exhibited Peutz-Jeghers syndrome, one case endometriosis, and one diverculosis of the right colon. Seven PMP cases showed both appendicial and ovarian mucinous tumors. The appendiceal, peritoneal, and ovarian mucinous tumors showed the same immunoprofile (MUC2+/MUC5AC+/CK7-/CK20+). One case of appendiceal mucinous cystadenoma was associated with ovarian mucinous cystadenoma of borderline malignancy with no evidence of PMP. The appendiceal lesion was MUC2+/MUC5AC-/CK7-/CK20+. In contrast, the ovarian lesion was MUC2-/MUC5AC+/CK7+/CK20-. Therefore, these lesions are considered to be synchronous. In conclusion, the MUC2+/CK7-/CK20+ expression profile supports an appendiceal rather than ovarian origin for PMP.

ARE GOBLET CELL CARCINOIDS OF THE VERMIFORM APPENDIX CRYPT CELL CARCINOMAS?

Susanne van Eeden(1), G. Johan A. Offerhaus(1), Augustinus A.M. Hart(2), Lucy Boerrigter(3), Petra M. Nederlof(3), Marie-Louise F. van Velthuysen(3)

(1)Department of Pathology, Academic Medical Center, Amsterdam, The Netherlands

(2) Department of Radiotherapy, Het Nederlands Kanker Instituut/ Antoni van Leeuwenhoek Ziekenhuis, Amsterdam, The Netherlands

(3)Department of Pathology, Het Nederlands Kanker Instituut/ Antoni van Leeuwenhoek Ziekenhuis, Amsterdam, The Netherlands

Introduction and aim of the study:

Goblet cell carcinoids (GCC) of the vermiform appendix are rare neoplasms of uncertain histogenesis, with features reminiscent of both classical carcinoids (CC) and conventional colonic adenocarcinomas (CAC). This study was performed to investigate whether GCCs should be regarded as a separate entity or as a variant of CCs, of CACs or of other primary appendiceal tumors, i.e. mucinous cystadeno(carcino)mas (MCA).
Material and Methods:
The immunohistochemical expression pattern of 19 different markers in 16 GCCs was compared with the expression pattern in 14 CCs, 19 CACs and 10 MCAs. The mutation status of KRas codon 12 was determined in all tumors by a mutant-enriched PCR method. The results were subjected to a stepwise linear discriminant analysis.
Results:
GCCs could be distinguished from the control groups and were characterized by diffuse positivity for CAM5.2, CDX2 and CEA, frequent coexpression of Ck7 and Ck20, scattered positivity for endocrine markers in up to 50% of the cells and a proliferative activity (Ki67 positivity) intermediate between that of CCs and CACs. Alterations in KRas codon 12, TP53, DPC4 and in the Wnt-signaling pathway were rare or absent in GCCs. Histologically, GCCs showed a typical growth pattern and contained different cell types reminiscent of the neoplastic counterparts of normal crypt cells.
Conclusion:
The results suggest, that GCCs should be regarded as a separate entity, probably arising from a crypt progenitor cell as previously suggested. Therefore, the formerly used term 'crypt cell carcinoma' may be more appropriate than GCC and this diagnosis also better reflects the more aggressive clinical behaviour of these tumors.

P 514
TOXIC EFFECTS OF WATER EXTRACT OF TEUCRIUM POLIUM ON THE RAT INTESTINE
PANJEHSHAHIN Mohammad R., DEHGHANI Farzaneh, KARBALAEEDOOST Saeed
Department of Pharmacology, Faculty of Medicine, Shiraz University of Medical Sciences, Shiraz, Fars,Iran.

Teucrium Polium is traditionally used to lower blood sugar in diabetic patients in Iran and some other parts of the world. However, some gastro-intestinal side effects have been reported by the patients who have used this remedy. The aim of this investigation was to study of the effects of Teucrium Polium water extract on the structure of the small intestine in male rats . Fifty wistar rats were randomly divided to four experimental and one control groups. The experimental groups were fed different doses (4 g/kg, 3 g/kg, 2 g/kg,1 g/kg) of the Teucrium Polium extract by oral rout for 14 days. The rats were then scarified and histological sections were prepared. The result indicated that the extract could cause vascular delitation as well as lymphoid cell, macrophage and neutrophile infiltration in the intestinal tissues. Apoptosis was also observed in liver tissue. It seems that this extract may cause damage and changes to the small intestine, therefore, it is recommended that the extract of Teucrium Polium should be used cautiously. More investigation is needed to find its complications and mechanisms of damages induced by this extract.

LACK OF CLAUDIN 4 EXPRESSION AND HIGH EXPRESSION OF CLAUDIN 3 AND CLAUDIN 7 DIFFERENTIATE PANCREATIC ENDOCRINE TUMORS FORM PANCREATIC DUCTAL CARCINOMA
BORKA Katalin, KISS András, KALISZKY Péter*, KUPCSULIK Péter*, SCHAFF Zsuzsa
2nd Department of Pathology and *1st Department of Surgery, Semmelweis University, Budapest, Hungary

Introduction: A new family of tight junction (TJ) proteins called claudins was discovered in 1998. These transmembrane proteins are responsible for cell adhesion, polarity and paracellular permeability. Although changes in permeability of TJs were noted in several cancers, the role of claudins in carcinogenesis is controversial. Claudin 4 overexpression was reported in primary and metastatic pancreatic adenocarcinomas. These findings support use of claudin 4 as target for novel therapeutics of pancreatic cancers.
Purpose: To analyse different claudin expressions in human pancreatic endocrine tumors and ductal carcinomas using a panel of polyclonal (claudins 1, 3, 7) and monoclonal (claudins 2, 4) antibodies.
Methods: Twenty formalin fixed, paraffin embedded pancreatic endocrine tumors and ten pancreatic ductal carcinomas were studied, and immunohistochemical evaluation performed to analyse claudin 1, 2, 3, 4 and 7 expressions. Semiquantitative evaluation was used for the area of extension (0-5) and intensity (0-3) of reaction.
Results: Claudins 1, 2 proved negative in all endocrine tumors. The majority (7/10) of ductal carcinomas was positive for claudin 4, while endocrine tumors were negative. In contrast, claudin 7 showed high expression in all endocrine tumors, however, ductal carcinomas did not express the protein. Claudin 3 was detected in 80% (16/20) of endocrine tumors, while ductal carcinomas were negative. Claudin 7 expression was significantly higher in endocrine tumor cells, compared with claudin 3 ($p<0,0032$).
Conclusion: Our findings support that claudins 3 and 7 are specific marker for endocrine pancreatic tumors in contrast to ductal carcinomas. Further studies are necessary to assess the biological role of these proteins in pancreatic carcinogenesis.

GASTROENTEROPANCREATIC ENDOCRINE TUMORS: HISTOPATHOLOGIC FEATURES AND CATEGORIZATION ACCORDING TO WHO CLASSIFICATION
Deniz Peker, Gulen Bulbul Dogusoy, Sibel Erdamar Cetin, Suha Goksel
University of Istanbul, Cerrahpasa Medical Faculty, Department of Pathology

INTRODUCTION: Although gastrointestinal and pancreatic endocrine tumors (GEPs) are relatively rare they represent a complex tumor entity. The aim of this study was to determine the histopathological features and immunohistochemical profiles of GEPs diagnosed in our department.
METHODS: Of the 125 cases of GEP diagnosed between the years of 1995 and 2004, we reviewed cases based both on histologic patterns common to GEP and immunohistochemical results. Immune antibody panel included Chromogranin A, Synaptophysin, NSE, PGP 9.5 to all, Serotonin, Gastrin, Somatostatin, Glucagon, Insulin, VIP and some other peptides like ACTH, GRH to some sporadic cases. Ki67 expression was investigated to determine the proliferation index. Due to results of examination all cases were categorized according to new WHO classification.
RESULTS: 125 cases were collected from the archives of our department with a male to female ratio of 1.21 and a mean age of 61 years. The most common location was large intestine (43.2 %) followed by stomach, small intestine, pancreas and appendix (39%, 7.2%, 6.4%, 4.0% respectively). 64.8% of the cases were pure GEP whereas others were mixed endocrine- exocrine tumors. Among the pure GEP group, 11.1% were benign, 6.2% uncertain behavior tumors,

13.6% well differentiated and 69.1% poorly differentiated carcinomas. Synaptophysin was the most common immune marker observed and Ki67 indexes were correlated significantly with the biologic behavior categories ($p<0.05$)
CONCLUSIONS: The results of this study demonstrated that the distribution of our GEP cases in gut and the biologic behavior categories varied however malignancy –predictive factors including Ki67 index and immune profile were in accordance with previous reports.

IMMUNOHISTOCHEMICAL STUDY OF 29 SOLID PSEUDOPAPILLARY NEOPLASMS OF THE PANCREAS ON TISSUE MICROARRAYS

Virginie AUDARD (1), Hubert RICHA (2), Muriel INFANTE (1), Anne COUVELARD (3), Benoît TERRIS (4), François PAYE (2), Jean-François FLEJOU (1)Department of Pathology (1) and Digestive Surgery (2), Hôpital Saint Antoine, Paris; Department of Pathology, Hôpital Beaujon (3), Clichy; Department of Pathology, Hôpital Cochin (4), Paris, AP-HP France

Background : Solid pseudopapillary neoplasm of the pancreas is a rare tumour of uncertain histogenesis, that may raise difficult diagnostic issues.
Aim: To examine in a series of solid pseudopapillary neoplasm the expression of proteins of potential diagnostic and histogenetic interest by immunohistochemistry on tissue microarrays.
Methods : 29 solid pseudopapillary neoplasms of the pancreas were analysed. The expression of the following proteins was studied: CD10, oestrogen receptor, progesterone receptor, vimentin, cytokeratin (KL1), chromogranin A, synaptophysin, Mismatch Repair proteins (hMLH1, hMSH2, hMSH6), p53, b-catenin, E-cadherin.
Results : Tumours expressed the various antibodies with the following frequency: CD10 100%, progesterone receptor 100%, vimentin 93%, cytokeratin 72%, synaptophysin 46%, chromogranin A 0%, oestrogen receptor 0%. None of the cases presented a loss of expression of hMLH1, hMSH2 or hMSH6. There was no overexpression of p53 protein. In all cases a strong nuclear immunostaining of b-catenin was present in most tumour cells, with a “dot-like” cytoplasmic expression of E-cadherin that showed no membranous expression.
Conclusion: CD10, progesterone receptor, vimentin and b-catenin are expressed in solid pseudopapillary neoplasms of the pancreas, and are useful diagnostic markers for this rare tumour type. The pattern of b-catenin and E-cadherin expression that we observed suggests a major role for these proteins in the development of this tumour. The particular localisation of E-cadherin could be due to an abnormal trafficking of the protein to the membrane and/or to an endocytosis of this protein. Although solid pseudopapillary neoplasm develops in young patients and has a good prognosis, there is no immunohistochemical argument for the presence of microsatellite instability in these tumours.

P 518
SOLID AND CYSTIC PAPILLARY NEOPLASM OF THE PANCREAS

YILMAZ Banu, SAKIZ Damlanur,KABUKÇUOÐLU Fevziye, POLAT Nedim, KÖKSAL Hakan*
Þiþli Etfal Education and Research Hospital, Department of Pathology and Department of General Surgery*, Ýstanbul, Turkey

OBJECTIVE: Solid and papillary cystic neoplasm of the pancreas (SCPN) is a rare primary pancreatic neoplasm of unknown etiology, occurring most commonly in young women. Four patients with solid and cystic papillary tumor of the pancreas are evaluated to discuss the histopathological and immunohistochemical findings with the clinical course and surgical treatment.
PATIENTS AND METHODS: Three cases of SCPN located in the tail of the pancreas and one located in the head of the pancreas are presented. In two patients distal pancreatectomy with splenectomy were performed. Spleen was preserved in one of the patients. Whipple’s operation was performed for the patient with the tumor at the head of pancreas. The cases located in the tail of the pancreas were a 14 year old female, a 73-year-old female and 69-year-old male with the diameter of the masses as 6 cm, 2,5 cm and 6,5 cm respectively. The fourth case was a 17-year-old woman with a 5 cm mass in the head of the pancreas. In all patients the pancreatic lesions were shown by ultrasonography and a computed tomography scan. Histological diagnosis was made by performing haemotoxylene-eosin and PAS staining, immunohistochemical staining for progesteron receptors, vimentin, chromogranin A, EMA, NSE, cytokeratin, synaptophysin, CEA, Ki-67, CD10 and CD56.
RESULTS: The histological findings showed large encapsulated tumors with the section of the tumors surrounded by hemorrhagic and necrotic areas. The solid areas were composed of small and medium size tumor cells, which had no obvious atypia. Pseudopapillary structures were found in the cystic degeneration areas. Immunohistochemically,all of the tumors were positive for CD56,vimentin and progesterone receptor, negative for EMA, CEA.Two tumors stained for chromogranin or synapthophysin and one tumor stained for cytokeratin and synapthophysin. One tumor stained for CD10. Three tumors (Case 1,2,3) were, 1% nuclear positive and one of the tumors (Case 4) was, 5% nuclear positive for Ki-67.Case 4 showed an infiltrative growth into the surrounding pancreatic parenchyma.In the follow-up period (1-5 years) all patients are alive with no evidence of recurrence.
CONCLUSIONS: Solid and cystic papillary neoplasm of the pancreas (SCPN) is a neoplasm with a low malignancy and show favorable prognosis after surgical removal.In spite of the characteristic macroscopic and microscopic aspects, the immunohistochemical profile is nonspecific.

P 519
PANCREATIC SOLID AND CYSTIC HAMARTOMA IN ADULTS: CHARACTERIZATION OF A NEW TUMOROUS LESION

Ursula Pauser, M.D.1, Markus Kosmahl, M.D.1, Božo Krušlin, M.D. 2, Maria Teresa Simões da Silva, M.D. 3, Jörg Placke, M.D.4, David S. Klimstra, M.D.5, Günter Klöppel, M.D.1
Department of Pathology, 1University of Kiel, Germany, 2Sestre Milosrdnice University Hospital, Zagreb, Croatia, 3University of Coimbra, Portugal, 4Dinslaken, Germany, 5Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Introduction: Nonneoplastic tumor-forming lesions in the pancreas are uncommon. They include cystic and noncystic varieties that have to be clearly distinguished from malignancies.
Patients, Materials and Methods: We report on a solid and cystic tumor-like lesion of the pancreas that occurred in 4 adult patients. Because of the unclear nature of these lesions, resection was performed. Formalin-fixed, paraffin-embedded tissues from the specimens were investigated by means of immunohistochemistry.
Results: The four resection specimens each contained a firm, gray, well demarcated nodule with focal cystic changes. The size ranged from 2 to 7 cm in diameter. The surrounding pancreatic tissue was unaffected. Histologically, the tumors showed a disorderly arrangement of well differentiated endocrine and exocrine pancreatic tissue that was embedded in a fibrous stroma. The cystic structures were lined by duct-

like cells. Immunohistochemically CD34 and c-kit coexpression was seen in the spindle cell component in two cases. Scattered insulin-producing cells were detected between acinar and ductal cells. Islets were lacking.
Discussion: The four pancreatic tumors showed a histologic pattern compatible with that of a hamartoma of the pancreas.

P 520
ECHO ENDOSCOPIC ULTRASONOGRAPHY FINE NEEDLE ASPIRATION (EUS-FNA) IN PANCREATIC LESIONS. EXPERIENCE AT HOPITAL SAINT-JOSPEH.
DE PINIEUX Isabelle 1, HOMSI Toufik 1, , BALATON André 1, MARTY Olivier 2, MALLET Laurent 2,MOLINIE Vincent 1. Department of Pathology (1) and Gastroenterology (2), Hôpital Saint-Joseph, Paris, France.

Background: Endoscopic ultrasonograpghy (EUS) fine needle aspiration (FNA) is a new safe procedure used to explore non accessible pancreatic lesions.
Objectives: Evaluation of our early experience of EUS-FNA in pancreatic lesions.
Methods: The study was performed until 2003, by an experimented operator (OM), using a ultrasound transducer echoendoscope, with microbiopsy (FNA 22 G), without antibiotics prophylaxy (expected in cystic lesions). For each case 1 to 4 FNA was performed and pull in 1 or 2 AFA containers. For eache case the reporting data consisted in : clinical setting with echographic results, endocopic procedure (exact position of the trasducer, and transfixed organ) and site of biopsy. The pathological procedure consited in parrafin inclusion, after centrifugation. For histologic analysis a set of 5 slides were obtained with a single 3 HES staining sections, and 5 slides for histochemistry (PAS or Alcian Blue) or immunohistochemistry study.
Results: 50 EUS-FNA were performed in 30 patients (12 M/ 18 F) 62 years old mean (40 - 80). Echoendoscopic results were : 5 cystic lesions, 5 singl masses, 16 unresectable tumors. The maximal diameter was 26 mm (7-42), and 2 patients had a pancreatitis history.The site of biopsy was : body 3, head-isthmus 18, tail 9. The transfixed organ was stomach 52%, duodenum 48%. The number of biopsy studied was 1.8 (1-4).A non concluent diagnosis was performed in only 1 case (cystic lesion). The diagnosese were : malignant in 22 cases (Pancreatic carcinoma 16, Pancreatic endocrine tumor 5, lymphoproliferation 1) and benign in 7 cases (Abces 1, Tuberculosis 1, Normal pancreas 2, Pancreatitis 2, Mucinous cystadenoma 1).
Conclusion: The fiability of EUS-FNA in pancreatic lesion in our experience is 94%, similar to the fiability reported in the literature. In our experience, EUS-FNA is a vailable method even in small tumors, and specially in pancreatic adenocarcinoma. Cooperation between pathologist and gastro-enterologist is necessary to obtain the best organization for the best diagnosis.

P 521
ADENOCARCINOMAS OF THE AMPULLA OF VATER AND OF THE HEAD OF PANCREAS HAVE DIFFERENT EXPRESSION OF MUC1, MUC2, MUC5AC, AND MUC6 APOMUCINES
Fausto Sessa, Francesca Franzi, Clementina Zampatti, Carlo Capella
Department of Pathology, University of Insubria, Varese, and Ospedale di Circolo di Busto Arsizio, Varese, Italy

Background: Adenocarcinomas (AC) arising from the ampulla of Vater (AV) and the head of pancreas (HP) have similar morphologic features, clinical presentation and a common surgical treatment (Whipple procedure) but a different outcome. AV-AC are histologically classified as intestinal type (IT) and biliopancreatic type (BPT) ACs. The classification is based on the histological pattern, Cdx-2 expression and/or cytokeratin 20 positivity for IT ACs and cytokeratin 7 positivity for BPT ACs. Apomucines have different expression according to the site of the tumor or to the phenotypic differentiation. The de novo expression of MUC1 is indicated as a negative prognostic marker, while MUC2 seems to be involved in the tumor suppression of colorectal cancer.
The aim of this study was: a) to investigate the expression of MUC1, MUC2, MUC5AC and MUC6 and b) to explore the utility of apomucines in differentiating the HP ACs from the AV ACs.
Design: Forty four surgically resected invasive AV-ACs, previously classified as IT (28) and as BPT (16) by using Cdx2 immunoreactivity, were immunostained for MUC1, MUC2, MUC5AC and MUC6 using avidin-biotin-complex method, including positive and negative controls.
Results: Twenty-seven out 44 AC of AV (61%) were positive for MUC1. MUC5AC was present in 15/44 (34%), MUC6 in 13/44 (29%) and MUC2 in 11/44 (25%) cases. MUC1 was present in 14/28 (50%) IT AC and in 13/16 (81%) BPT AC. MUC2 was present in 8 AV AC classified as IT and in 3 cases classified as BPT. MUC5AC and MUC6 had no difference in their distribution in relationship to IT or BPT phenotype. In HP ACs we found 30/35 (86%) cases expressing MUC1, 25/35 (71%) MUC5AC, 7/35 (20%) MUC6 and 2/35 (6%) cases expressing MUC2. Follow up was available for 32 patients, 13 of which alive with a mean survival of 58 months and 19 dead of the disease after a mean survival of 20 months. Twelve of 13 alive patients express one or both intestinal markers.
Conclusions: The adenocarcinomas of AV and HP have different pattern of MUC expression. MUC1 and MUC5AC are much more expressed in HP ACs, in association with the poor prognosis of pancreatic cancer. AV-BPT adenocarcinomas show a pattern very similar to HP ACs. Only MUC2 is preferentially observed in AV-AC and it can be useful as marker of intestinal type differentiation of AV AC, related to a better prognosis of this type of cancers.

P 522
DIFFERENTIATION PATHWAYS IN AMPULLARY CARCINOMAS: COMPARATIVE STUDY ON MUCIN PEPTIDE CORE ANTIGENS (MUC1, MUC2, MUC5AC) AND CDX2 EXPRESSION, INCLUDING GASTRIC AND COLON CARCINOMAS.
Gursan N1, Gursan MS2,

A broad histomorphologic spectrum of ampullary carcinomas of Vater make a reproducible histologic classification difficult. The aims of this study were to determine histologic subtype of ampullary carcinomas kullanarak mucin peptide core antigens and CDX2 in comparison with gastric and colorectal carcinomas. We examined immunohistochemically for expression of MUC1, MUC2, MUC5AC, and CDX2 in ampullary carcinoma(30), gastric carcinomas (30) and colon carcinomas (30). sixty-four percent of the gastric carcinomas and sevety-five of the ampullary carcinoma expressed MUC1, whereas none of the colorectal carcinomas did. MUC2 mucin was highly expressed in colorectal carcinomas In ampullary carcinoma, gastric carcinomas expressed MUC2 89%, 83%, respectively. Immunohistochemically, MUC5AC were frequently expressed in gastric carcinoma. fifty-five of the ampullary carcinoma expressed MUC5A. The nuclear expression of CDX2 was closely associated with the expression of MUC2 in colon carcinomas . In ampullary carcinoma, gastric carcinomas expressed CDX2 75%, 62%, respectively. Moreover, the expression of MUC1. MUC2 MUC5A and CDX2 was a useful to determine histologic subtype of tumors derived from the ampulla of Vater.

P 523

HEP PAR 1 IMMUNOEXPRESSION IN THE TUMOURS OF PERIAMPULLARY REGION AND HEAD OF THE PANCREAS

GULLUOGLU Mine G.(*), KARAYÝGÝT Ebru(*), OZDEN Ilgin(**), KAPRAN Yersu(*), CEVÝKBAS Ugur(*), DÝZDAROGLU Ferhunde(*).
*Istanbul University, Istanbul Faculty of Medicine, Department of Pathology
**Istanbul University, Istanbul Faculty of Medicine, Department of General Surgery, Hepatopancreatobiliary Surgery Unit

Ampullary carcinomas may arise from two different types of mucosa and comprised of two different histologic types; intestinal and pancreatobiliary. It is important to distinguish them from each other since they have different therapeutic and prognostic implications. Monoclonal antibody Hep Par 1 which shows hepatocytic differentiation is generally used in the differential diagnosis of hepatocellular carcinomas. Some authors advocate that this antibody indirectly shows small intestinal differentiation. The aim of this study is to evaluate the Hep Par 1 immunoexpression in pancreatic, duodenal and extrahepatic biliary tract carcinomas including periampullary tumours and to explore the utility of this antibody in differentiating pancreatic ductal adenocarcinoma and ampullary adenocarcinoma of pancreatobiliary type from the intestinal type ampullary carcinoma.
We studied Hep Par 1 immunoexpression in 61 cases of periampullary (n=40), pancreatic (n=16), duodenal (n=4) and mid-choleductal (n=1) carcinomas. Twentytwo (55%) periampullary carcinomas, 14 (87.5%) of the tumours originating from head of the pancreas and two (50%) of the duodenal tumours were negative for Hep Par 1 ($p<0.05$). Fourteen of the 18 intestinal type periampullary tumours (77.7%) were positive for Hep Par 1 whereas only three of the 21 pancreatobiliary type tumours (14%) showed focal immunoreactivity ($p<0.0001$). There was no significant difference between the Hep Par 1 expressions of the pancreatic carcinomas and the ampullary carcinomas of pancreatobiliary origin.
In conclusion, we suggest that the ampullary tumours of intestinal origin can be seperated from the tumours of pancreatobiliary origin either ampullary or pancreatic by Hep Par 1 immunohistochemistry.

P 524

PROGNOSTIC SIGNIFICANCE OF EGFR AND HER2/NEU(C-ERB2) IN PANCREATIC CANCER

ZIZI-SERBETZOGLOU Adamantia,KATSAMAGOU Eleftheria,SPANOS Ilias,VASSILAKAKI Thivi,ELEMENOGLOU Ioannis
Department of pathology, Tzaneio General Hospital, Piraeus, Greece

Pancreatic duct carcinoma is a malignant tumor with an extremely poor prognosis. The mechanisms of the aggressive growth and metastasis are not completely understood.
Recent studies have shown that some growth factor receptors with tyrosine-kinase activity,e.g.,the epidermal growth factor receptor (EGFr) and the Her2/neu(c-erb2)oncoprotein,are associated with aggressive biologic behaviour in a variety of tumors.
The aim of this study was to detect the relation of EGFr and c-erb2 to the progression and metastasis of pancreatic duct carcinoma and analyze the correlation between EGFr and c-erb2 expression pattern
and clinicopathological factors.
MATERIAL and METHODS:We examined the immunohistochemical expression of c-erb2 and EGFr in formalin-fixed paraffin embedded tissue samples from 42 patients with pancreatic ductal adenocarcinoma,4 patients with carcinoma of Vater's ampulla and 10 patients with chronic pancreatitis.
RESULTS: 19 of 42(43.6%)samples of pancreatic cancer stained positive for EGFr and 23 of 42(53%) for c-erb2. 3 of 4 samples of carcinoma of Vater's ampulla expressed EGFr and 2 of 4 expressed c- erb2.1 of 10 samples with chronic pancreatitis expressed EGFr and 1 of 10 c-erb2. The coexpression rate of the two proteins was 28%(16/42).This coexpression in the pancreatic duct adenocarcinoma groups was correlated with histopathological grades and metastatic status of TNM classification ($p<0.01$).
CONCLUSSIONS: The immunohistochemical expression of EGFr and c-erb2 can be used as a marker of aggressive biological behaviour including recurrence and metastasis of pancreatic duct adenocarcinoma.

5- Rntech, France

Background: Ductal adenocarcinoma and its variants make up over 90% of all pancreatic tumours. Adenocarcinoma of the pancreas is characterized by local tumor growth that infiltrates vascular structures, nerves and lymphatics, and causes early hematogenous spread to the liver. Studies of pathologic characteristics of the primary or metastatic tumor have failed to define high-low risk subgroups of clinical significance, mainly because most patients experience rapid disease progression. Purpose: We conducted a study to identify histological quantitative and qualitative modifications in the region surounding exocrine pancreas carcinomas (peritumoral region) compared with normal parenchyma.Methods: We have studied 28 cases of ductal adenocarcinoma localized in the head, body, and tail of pancreas who underwent surgical resection. We defined the peritumoral region, as the portion of apparently not affected parenchyma in 1 centimeter surrounding the tumor. In this region we have been analyzed the inflammatory infiltrate (using an immunohistochemicaly technique with the antibody for CD 68)and angiogenesis (with antibody for CD 34)comparative within the tumor and to the parenchyma from distance . Results: In the studied cases, the inflammatory infiltrate was slight increased in the peritumoral region than the tumoral and normal, and there was a significant positive staining for CD68 (expressed on macrophages and monocytes). The expression of CD34 was not significant modified. Various pathological parameters have been evaluated (size, mitotic rate, vascular -perineural invasion, lymph node metastasis, necrosis, surgical margins, location).
Conclusion: Although the cell kinetics of the pancreas are not understood, it seems likely that there is a continuous slow turnover of cells, fed from a stem cells population in the ducts, and that the controls on the production rate of each cell type are local rather than systemic.The surounding inflammatory infiltrate(especialy macrophages)in the exocrine pancreas tumors is important in prognosis.This parameter can be important for tumoral behavior and therapeutic strategies.

P 526

MIXED DUCTAL ENDOCRINE CARCINOMA OF THE COMMON BILE DUCT

Authors and Affiliations:LIAPIS George, ALEXANDROU Paraskevi, TZIRAKIS Mixalis, ANDROULAKI Athina, KIRIAKOU Vasiliki.

DEPARTMENT OF PATHOLOGY LAIKO HOSPITAL, ATHENS

The mixed bile duct endocrine/ductal carcinoma is a rare neoplasm and only a few cases have been reported in the literature reviewed. We present a case of a carcinoma of the common bile duct with mixed histological features in a 71 years old man who presented with jaundice and a cholestatic biochemical profile. The carcinoma measuring 2,2 x 1 cm, arose in the wall of the common bile duct and invaded the gallbladder neck and the pancreas forming an intrapancreatic tumor mass of 3 cm in diameter. Histologically the tumor tissue consisted of a poorly differentiated endocrine carcinoma (small cell carcinoma) and a carcinomatous component with features of ductal adenocarcinoma. The two neoplastic elements showed a separate or merging growth pattern while biphasic structures exhibiting both cell types were also encountered. Interestingly, the pancreas was infiltrated exclusively by the small cell carcinoma. The endocrine immunophenotype was confirmed by the expression of chromogranin, NSE, synaptophysin and CD56 while the ductal adenocarcinoma showed a positive reaction to EMA, CEA, CD15 and cytokeratin 19. Regarding histogenesis the intimate topographical coexistence of the heterogeneous cell populations is very likely to represent their histogenetic association with a multipotential precursor cell.

P 527

IMMUNOHISTOCHEMICAL STUDY OF GENETIC ALTERATIONS, MUC1 AND MUC2 EXPRESSION IN INTRADUCTAL AND INVASIVE DUCTAL TUMORS OF THE PANCREAS

AYDIN Ovgu, GOKSEL Suha, ERDAMAR Sibel, GOCENER Selda, BULBUL Dogusoy Gulen

Pancreatic carcinoma is a highly malignant neoplasm that still carries a very poor prognosis. Majority of pancreatic carcinomas are malignant. So the classification has a clinical and prognostic significance. The ductal adenocarcinomas(DA) arising from Intraductal Papillary Mucinous Neoplasia (IPMN) are said to have a much beter prognosis than the classical adenocarcinoma.Also the pancreatic intraductal lesions, named as Pancreatic Intraepithelial Neoplasia (PanIN) have been classified by WHO. Multiple genetic alterations are involved in development of pancreatic neoplasm. In this study, pancreatic tissue obtained from 135 operations were examined for PanIN lesions. The frequency of PanIN in tumoral and nontumoral pancreata were compared and DA cases were evaluated for presence of IPMN.Then we investigated expression of p21, p53 and DPC4, the major apomucins (MUC1, MUC2)in PanIN lesions and tumors of the IPMN related carcinomas and the classical DA by immunohistochemical method. p21 and p53 expression increased progressively with the severity of the lesion. p21 expression was (-) in normal pancreatic tissue, PanIN1a, PanIN1b, PanIN2 lesions and was (+) in 2 PanIN3 lesions both of which were sampled from IPMN(-) DA (2/20) and 10 invasive carcinoma area most of which belonged to IPMN (-) DA. p53 expression was (-) in normal pancreata, PanIN1a, PanIN1b, PanIN2 lesions and was (+) in most of PanIN3 and invasive carcinoma samples. DPC4 was highly expressed in normal pancreata, PanIN1a, PanIN1b lesions and DPC4 expression decreased with the severity of lesions (PanIN2:%61, PanIN3:%57, TM: %43). IPMN(-) tumors highly express MUC1 and only 1 case was (+) for MUC2. On the other hand most of IPMN (+) cases were (+) for both MUC1 and MUC2. The most frequent PanIN lesion was PanIN3 in tumor cases. A positive correlation between PanIN1a, PanIN1b, PanIN2 and chronic pancreatitis was found. There was no correlation between chronic pancreatitis in DA and high grade PanIN lesions. Vascular invasion and lymph node metastasis were significantly less in IPMN(+) DA compared to IPMN (-) DA. This finding supports the hypothesis that IPMN(+) adenocarcinomas have a beter prognosis than a classical DA. DPC4 expression is especially present in low grade carcinomas in IPMN(-) tumors and loss of DPC4 expression increases with the grade of IPMN(+) tumors. p21 and p53 expression were both found to be late events in development of pancreatic neoplasia according to our results.

NON-INVASIVE INTRADUCTAL PAPILLARY MUCINOUS TUMORS OF THE PANCREAS. EXPERIENCE OF THE HOSPITAL CLINIC OF BARCELONA.

MIQUEL Rosa, GARRIDO Marta, PETIT Ana, BOMBÍ Josep-Antoni, COLOMO Lluís, SOLÉ Manel, SANCHEZ Marcelo, SORIANO Antonio, FERNANDEZ-ESPARRACH Gloria, NAVARRO Salvador and FERNANDEZ-CRUZ Laureano.
Departments of Pathology, Radiology, Gastroenterology and Surgery.
Hospital Clinic, IDIBAPS, University of Barcelona

Introduction. Intraductal Papillary Mucinous Neoplasms (IPMN) of the pancreas are intraductal tumors characterized by variable amount of mucin production, cystic dilatation and papillary growth, that have increased its frequency in the last past years. They display a wide spectrum of cytologic and architectural atypia, from benign adenomatous lesions to invasive carcinomas.
Objective. The purpose of these study was to report the clinicopathological features of non-invasive IPMN in our hospital.
Material and Methods. We reviewed the histologic material from surgical pancreatic resections performed between 1995 and April 2005 at the Hospital Clinic of Barcelona in wich the words mucinous, cystic or papillary formation were identified in the pathology reports, in order to identify and classify IPMN according the current WHO definition of these neoplasms. The clinical history and image studies of each patient were also reviewed.
Results. A total of 27 IPMN were identified of wich 14 (52%) were non-invasive. Ten of the 14 patients were man and 4 female, with a mean age of 72 years. In two patients the lesion was discovered because of abdominal pain and 1 for a constitutional sindrome. In 5 patients (36%) IPMN were discovered incidentally whereas a history of recurrent acute pancreatitis was found in 6 patients (43%). Most of the lesions were localized at the pancreatic head (10 71%) and 3 at the body/tail. The mean size was of 3 cm (1.3 to 5.8). In 9/14 cases USE-FNA was performed previous to surgery, obtaining mucin and ductal cells with or without atypia. Histologically, 10 cases displayed features of IPM adenoma, 2 moderate dysplasia and 2 high grade dysplasia/in situ carcinoma. Branch-type was the most frequent IPMN type found (11/14 79%) and in the other 3 cases the main pancreatic duct and its branches were affected. None of the patients had recurrence or died of the disease after a median follow-up of 22 months (from 1 to 88).
Conclusion. IPMN represents a group of pancreatic neoplasms that have increased its frequenty in the recent last past years, mostly due to their recognition in early phases as incidental lesions by the improvement and the most extended use of image techniques, specially in asymptomatic patients, as has been observed in 36% of the patients of our series of non-invasive IPMN.

2 Chair and Dept of Pathomorphology, Silesian Medical University, Zabrze
3 Dept. of Histopathology, Silesian Centre For Heart Diseases, Zabrze, Poland

Background: Chronic inflammation of gallbladder comprises simple form with mucosa with slight atrophy and rarely chronic hyperplastic form with arboriform hyperplasia of mucosa, suggesting neoplasia.
Aim: The aim of this study was the comparison of the morphology, proliferative activity and karyometry of mucosa cells in both types of cholecystitides.
Material and methods: 25 cases of simple chronic cholecystitis and 30 of chronic hyperplastic cholecystitis were collected. The morphological analysis of mucosa architecture was done using confocal laser scanning microscopy, proliferative activity was assessed with Ki-67 reaction, karyometric measurements included: nuclear area, length, breadth, perimeter, roundness, aspect and mean grey level.
Results: Simple chronic cholecystitis was characterized by monolayered glandular epithelium, in cases of hyperplastic chronic inflammation the multilayered epithelium was observed moreover, Ki-67 was positive in almost all epithelial cells, whereas in simple chronic inflammation only single cells were Ki-67-positive.
Conclusion: Chronic hyperplastic cholecystitis shows the different architecture of epithelium, increased proliferative activity and different karyometric characteristics, including rounding and widened nuclei with predominance of euchromatin.

Bucharest, Romania

The role of hepatitis B virus (HBV) and hepatitis C virus (HCV) infections in the etiopathogeny of the hepatocellular carcinoma (HCC) is well established.
Material and methods
We studied the presence of large cell changes (LCC) and small cell dysplasia (SCD) according to the etiology, age, necroinflammatory activity and fibrosis in a group of 1173 percutaneous liver biopsies from patients with chronic viral hepatitis B, C and D. The necroinflammatory activity and fibrosis were assessed based on Ishak semiquantitative score. A statistical analysis was performed using CHITEST (X 2) with a level of statistic significance (P) of 0.05.
Results
LCD was exclusively revealed in HBV+/-HDV infection (P=1x10-54); SCD was more frequent in HCV infection (P=9x10-6).
There were significant association between high necroinflammatory activity and LCC in HBV infection (P=2x10-27) and HBV+HDV infection (P=1x10-5); also, SCD and low necroinflammatory activity were associated with HCV infection (P=2x10-6) and HCV+HBV infection (P=6x10-6).
Advanced stages of fibrosis were associated with LCC and HBV infection (P=4x10-31), LCC and HBV+HDV infection (P=2x10-17), SCD and HBV infection (P=1x10-18), SCD and VHC infection (P=0.01) and SCD and VHC+VHB infection (P=1x10-212).
Conclusions
LCC appear in chronic hepatitis with high grades of necroinflammatory activity and advanced stages of fibrosis (they need a long time to develop – important fibrosis – but it seems they are elicited by the hepatocytic lesions – important activity). SCD also need advanced stages of fibrosis (long time to evolve) but low grades of necroinflammatory activity (SCD are caused by accumulations of genetic alterations in the hepatocytes)

USEFULNESS OF FINE NEEDLE ASPIRATION BIOPSY (FNA) AND THIN NEEDLE CORE BIOPSY (NB) FOR THE DIAGNOSIS OF HEPATIC NODULES LESS THAN 2 CM IN CIRRHOTIC PATIENTS

MOZOS Ana, SALA Margarita, VILANA Ramon, BIANCHI Lluis, BRUIX Jordi, SOLÉ, Manel
Departments of Pathology and Radiology, and Liver Unit. Hospital Clínic. IDIBAPS. University of Barcelona.

Introduction: Systematic screening of cirrhotic patients for the early diagnosis of hepatocellular carcinoma (HCC) results in the detection of nodules less than 2 cm that cannot be fully characterized by imaging techniques. The role of biopsy in this setting remains controversial, due to the risk of sampling error and to the assumed very well differentiated nature of the tumors.
Purpose: To evaluate the efficacy of a prospective diagnostic approach based on the combination of FNA and NB for the diagnosis of small (<2cm) nodules in cirrhotic patients.
Material and methods: 45 cirrhotic patients undergoing systematic ultrasonographic (US) screening in which a nodule less than 2 cm (17 out of them 1cm or less) was detected. FNA (45 cases) with cell block when enough sample was obtained (43 cases) and NB with a 20G cutting needle when allowed by the location of the lesion (16 cases) were performed. Both cytologic and histologic diagnoses were based on previously published criteria. Cases were classified in five categories: 1. Negative 2. Benign nodule (regenerative vs. low grade dysplastic) 3. Suspicious (high grade dysplastic vs well differentiated HCC) 4. Malignant 5. Insufficient. Cases in the 3 and 4 categories were treated accordingly. Nondiagnostic and benign cases were followed-up for a period ranging from 3 to 12 months and rebiopsied according to the same protocol when indicated by the imaging features (US-Sonovue, computed tomography and magnetic resonance) or nodule growth (21 rebiopsies in 17 patients).
Results: 22 patients were classified in the categories 3 or 4 after the first biopsy, and other 7 after a second (6 cases) or a third biopsy (sensitivity for the first biopsy 75,7%). 3 out of the 7 false negative cases were classified in category 5 in the first biopsy, and the other 4 in category 1. 7 cases diagnosed as category 3 or 4 measured 1cm or less; 6 were diagnosed at the first biopsy and the other in the second biopsy. FNA (cytology + cell block) failed to diagnose 4 out of 29 lesions classified as 3 or 4, whereas NB missed 4 out of 12 lesions in which this procedure was performed.
Conclusions: FNA combined with NB is an efficient method for the diagnosis of small nodules in cirrhotic patients. Failures in diagnoses seem to be related to sampling rather than to diagnostic difficulties by the pathologist. FNA comprising cytology and microhistology of cell blocks is more sensitive than NB, probably due to better sampling.

P 532
FINE NEEDLE ASPIRATION BIOPSY OF FOCAL LIVER LESIONS – THE EXPERIENCE OF 2111 CASES

Székely Eszter dr., Istók Roland dr., Székely Tamás,Járay Balázs dr
Semmelweis University, II. Department of Pathology, Budapest, Hungary

Introduction: Ultrasound (US)-guided fine needle aspiration biopsy (FNAB) of focal liver lesions is a cost effective diagnostic method, by which the nature of the lesion (benign / malignant, primary / metastatic) is easily diagnosed in most cases. Clinicians and pathologists of those centers, that lack an experienced team needed for these examinations usually deny the efficacy of cytological examinations, and prefer thick needle – core- biopsies.
Our purpose was to show our data, demonstrate the most relevant, most frequently occurring technical and diagnostic difficulties, and to show the role of FNAB in the diagnostic armory.
Method: In the past 20 years, 2111 US guided liver FNABs were performed in the neighbouring US laboratories, that were examined by our cytological team. The smears were wet fixed with ethanol, and stained with H&E.
The results are the following: Benign lesion (cyst, adenoma, FNH, etc) 405 cases. Malignant lesion:1046 - in this group 206 hepatocellular carcinomas (HCC) 719 metastatic diseases were found. In further 121 cases in this group malignant disease was diagnosed without comment, whether the lesion was primary or secondary. In the next category, „suspicious for malignancy"(122 cases). Malignancy could not be proven in 290 cases. In 145 cases, the smears were unsatisfactory for any diagnosis or opinion. In 60 % of these cases clinical follow up and/or histology or autopsy confirmed the nature of the hepatic lesion. No false positive case was found. In four cases metastatic disease was suspected, that turned out to be HCC, or mixed HCC-cholangiocarcinoma.
Conclusion: Our data may persuade those colleagues, who deny or haven't yet experienced the usefulness of liver FNAB-s, to use this easy method as a diagnostic modality, of which we do believe the patients benefit the most. We would like to share some of our „favourite cases" with the audience.

P 533
REGRESSION OF LIVER ADENOMATOSIS AFTER WITHDRAWAL OF ORAL HORMONAL CONTRACEPTIVE : A CASE REPORT

SVRCEK Magali (1), JEANNOT Emmanuelle (2), POUPON Raoul (3), ARRIVE Lionel (4), FLEJOU Jean-François (1), ZUCMAN-ROSSI Jessica (2), WENDUM Dominique (1).
(1) Department of Pathology, Saint-Antoine Hospital, AP-HP, Paris, (2) INSERM U434, CEPH-Fondation Jean Dausset, Paris (3) Department of Hepatology, Saint-Antoine Hospital, AP-HP, Paris, (4) Department of Radiology, Saint-Antoine hospital, AP-HP, Paris.

Liver adenomatosis (LA) is a rare disease characterized by the presence of multiple hepatocellular adenomas. Initially, LA was considered as a separate clinical entity from isolated hepatic adenoma by no relation with oral contraceptive use. However, recently, frequent biallelic inactivation of TCF1 gene encoding Hepatocyte Nuclear Factor -1*f*Ñ (HNF-1*f*Ñ) was identified in both hepatocellular adenomas and LA, suggesting a possible overlap of these two entities. Pathogenesis of LA is unclear. One case of LA regression is described in the literature after hormonal therapy withdrawal, but without any information concerning the TCF1 gene status. We report the second case of regressive LA after withdrawal of hormonal therapy. In this case, TCF1 was not inactivated.
A 48-year-old woman was admitted to our hospital in April 1990 because of a polynodular liver. Ultrasonography (US), computed tomography (CT) and magnetic resonance imaging showed at least eight masses in the liver: the largest one (6 cm) was located within segments VIII-VI. One of these masses, in the left lobe, was typical of angioma. Histological diagnosis of hepatocellular adenoma was made on laparoscopic liver biopsy performed on 2 nodules.
The patient had no diabetes and had been taking oral contraceptives for 10 years at the time of diagnosis. After withdrawal of hormonal therapy, she was examined regularly once a year by US and CT over a period of 10 years, and partial regression of the adenomas was documented. She died in June 2000 because of a pancreatic cancer. Necropsy showed a pancreatic cancer corresponding to an anaplastic carcinoma. Macroscopic and microscopic examination of the liver showed an hemangioma in the left lobe and revealed only one hepatocellular adenoma in the right lobe measuring 3 cm with large areas of ischemic necrosis, haemorrhage and fibrosis. A few microadenomas with steatotic hepatocytes were also present.
The immunohistochemical analysis for estrogen receptors and progesteron receptors performed on the partially regressive adenoma was negative. Neither somatic nor germline inactivation or mutation of TCF1 was found in the hepatocellular adenoma and the normal liver tissue.
With this case report, we demonstrate that LA, without inactivation of TCF1 gene, may almost completely regress after hormonal therapy withdrawal. Exogenous hormonal therapy probably has an important role in some cases of this disease and it seems indicated to avoid it in these patients.

ASSESSMENT OF IMMUNOHISTOCHEMICAL PROFILE IN HUMAN HEPATOCARCINOMAS

CEAUSU Mihai 1,2, BUTUR Georgeta 1, ARDELEANU Carmen 1,2, CEAUSU Maria 3, GRAMADA Zenaida Florea 1
1 – "Victor Babes" National Institute, Bucharest, Romania
2 – "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania
3 – "St. Andrew" County Hospital, Galati, Romania

The immunoprofile of human hepatocarcinoma (HCC) has a more or less diagnostic value, doing difficult the differential diagnosis with cholangiocarcinoma or metastasis of adenocarcinoma.
Our aim was to investigate and to test the efficiency of a selected panel of antibodies for assessing the immunohistochemical profile (IHC) of HCC for positive diagnosis.
We performed the indirect tristadial ABC method of IHC for 7 antibodies: CK 7, CK 8, CK 18, CK 19, AFP, CD 34, OCH1E5 on formalin fixed paraffin embedded tissues taken by biopsies from 33 cases with HCC.
Hepatocarcinomas were immunoreactive to CK 8 and 18 in 65% cases, the tumors being positive especially to CK 18; the immunoreaction intensity was higher to CK 18 than CK 8 in tumor and peritumoral hepatic tissue. Alpha fetoprotein was positive in 85% of cases, showing a great sensibility in all tumoral types. Well differentiated tumors stained strongly to CD34, with a perisinusoidal pattern of vessels; low differentiated tumors with compact pattern stained weekly to CD34 (with random distribution of vessels) or negative. OCH1E5 is a liver specific antibody (positive in over 75% of tumors, and in 100% of peritumoral hepatic tissue), but it is pretentious, requiring special technical pretreatments.
Despite of tumoral immunoreaction variability , this 7 antibodies panel proved to be a usefull tool with significant diagnostic value of human hepatocarcinomas.

Despite a variety of therapeutic strategies, HCC remains a significant cause of cancer death. Therefore ,to study the HCC pathogenesis is of the utmost importance for the prevention and treatment of this disease. In the present study markers known of regeneration(HGF/c -met system) and cell proliferation(c-myc oncogene) were studied in a series of 20 HCC cases. HGF concentration was estimated in serum by ELISA &in tumor tissues by immunohistochemistry, c-myc & c-met mRNA were detected by RT-PCR. HGF concentration in sera of HCC cases was higher than normal controls(mean value 52.2 versus 20.7 pg/ml). However it was not detected by immunohistochemistry in any of tumor tissues. The elevated levels of HGF had significant correlation with less differentiated and bigger size tumor tissue. c-met was detected in 45% of cases and c-myc in 30% of cases.There was a significant correlation between HGF&c-met &tumor size while no significant correlation between HGF/c-met system and c-myc.

P 536

THE POTENTIAL ROLE OF ACTIVATED CASPASE-3 EXPRESSION IN HEPATOCELLULAR CARCINOMA

TSAMANDAS Athanassios, PAGONI Niki*, PAPATHANASSIOU Zefi**, PETSAS Theodore**, KARATZA Chrisoula*, SCOPA Chrisoula. Departments of Pathology, *Internal Medicine and **Radiology, University of Patras, Greece

Background: Caspase 3 is a downstream effector cysteine protease in the apoptotic pathway. Previous studies have shown that caspase-3 is expressed in 52% of hepatocellular carcinoma (HCC) by immunohistochemistry. Nuclear survivin, present in 42% HCC, correlated with poor prognostic survival parameters. In this study we investigated caspase 3 expression in HCC and related it to survivin overexpression, prognostic parameters, and outcome.
Patients and Methods: Formalin-fixed, paraffin-embedded 4ìm sections obtained from 76 HCC hepatectomy specimens, were subjected to immunohistochemistry (streptavidin-biotin peroxidase) using polyclonal antibodies for activated caspase-3 and survivin (SantaCruz, USA). Human tonsils were used as positive controls. Immunostaining was evaluated in the cytoplasm and nucleus of hepatocytes and Kupffer cells. Results followed moprhometric analysis and were expressed as % of positive cells. Mean follow up time was 27.19 months (range 1.5-83 months).
Results: In HCC, activated caspase 3 was expressed within hepatocytes in 69/76 (90.7%) and within Kupffer cells in 52/76 (68,4%) cases. The stain was cytoplasmic and nuclear. Survivin was present in 34/76 (44.7%) and the stain was cytoplasmic and nuclear. Caspase expression was correlated with lower grade ($p<0.05$), higher disease free ($p<0.01$) and higher total survival ($p<0.01$). Caspase 3 expression was reversely correlated with cytoplasmic survivin expression ($p=0.024$).
Conclusions: Activated caspase 3 expression is correlated with higher disease free survival and higher total survival; in addition it displays a reversed correlation with survivin expression which is considered as a poor prognostic parameters given the fact that suppresses apoptosis. The higher caspase-3 expression probably reflects the fact that apoptosis is associated with good prognosis in cases of HCC.

GLUTATHIONE S- TRANSFERASE M1 (GSTM1) NULL GENOTYPE AND RISK OF HEPATOCELLULAR CARCINOMA IN HCV CIRRHOTIC PATIENTS.

Gabriela Perdomo Coral MD, PhD; Venâncio Avancini Ferreira Alves MD, PhD; Evandro Sobrosa de Mello MD, PhD; Gilka Jorge Figaro Gattás, PhD; Luiz Carlos da Costa Gayotto MD, PhD.
Department of Pathology/ LIM 14 & Oscar Freire Institute/ LIM 40, University of São Paulo School of Medicine, São Paulo, Brazil.

Glutathione S- transferase M1 (GSTM1) gene has a polymorphism and there are large differences in the prevalence of its null genotype among ethnic groups. Patients with GSTM1 null genotype are more susceptible to some cancers and other diseases. Although a few publications have assessed the link between GSTM1 null genotype and hepatocellular carcinoma (HCC), to our knowledge no one has assessed the impact of this polymorphism on cirrhosis due to HCV, the main etiological factor for HCC. The aim of this study was to investigate the modifying effect of GSTM1 null genotype on hepatocarcinogenesis in patients with cirrhosis secondary to HCV infection. Forty-three patients with cirrhosis secondary to hepatitis C virus infection were evaluated. Of these patients, 16 had HCCs (37.2%) and three had high-grade dysplastic nodules (HGDN). Age, gender, prior alcohol intake, grade of necroinflammatory activity and genetic polymorphism of GSTM1 were studied. DNA was extracted from paraffin blocks of explanted cirrhotic livers and their respective gallbladders. GSTM1 polymorphism was determined by PCR technique. The prevalence of GSTM1 null genotype was 13/43 (30.23%). Only GSTM1 null genotype was associated with HCC/HGDN in explanted HCV-related cirrhotic livers (RR: 4.49; 95% CI, 1.108-18.266; $P = 0.046$). In conclusion, this association of GSTM1 null genotype with HCC/HGDN in patients with cirrhosis secondary to HCV might represent the identification of a subgroup with a high risk of HCC development.

Activation of Wnt/ ß-catenin signalling is a frequent event in human hepatocellular carcinomas (HCC). We evaluated various ß-catenin target genes as molecular markers of aberrant activation of the ß-catenin pathway in ß-catenin and Axin1 mutated HCC. A collection of 45 HCC was characterized for activating ß-catenin and inactivating Axin1 mutations and analyzed for expression of the glutamine synthetase (GS), glutamate transporter (GLT-1), ornitho-aminotransferase (OAT), Gpr49, LECT2, c-myc and cyclinD1 genes by real-time RT-PCR. A subset of HCC was analyzed for ß-catenin and GS by immunohistochemistry. We found a significant correlation between ß-catenin mutations and over-abundance of mRNA for GS, GPR49 and GLT-1 ($p=0.0001$), but not for OAT, LECT2, c-myc or cyclin D1.

GS appears to have the best predictive value for ß-catenin activation and is a faithfull immunohistochemical marker of ß-catenin activation in human HCC. Interestingly, in Axin1-mutated tumors, none of the liver ß-catenin target genes validated in human HCC was overexpressed and accordingly, no aberrant accumulation of ß -catenin was observed. In conclusion, our results show that overexpression of each GS and GPR49 are reliable markers of HCC carrying an activated ß-catenin mutation. Surprisingly, HCC presenting inactivated Axin1 mutation do not show anomalous expression of the same genes.

P 539

THE VALUE OF IMMUNOHISTOCHEMICAL MARKERS (IMS) FOR THE DIAGNOSIS OF LIVER TUMORS IN CT-GUIDED LIVER BIOPSY

NOMIKOS Alexandros*, SAMARAS Vasilis*, TANOGLIDI Anna*, TSIKOU-PAPAFRAGOU Aikaterini*, KOKKINAKI Anna**, MYLONA Sofia**, THANOS Loukas**, BARBATIS Calypso*.
Departments of Pathology* and Radiology** Hellenic Red Cross Hospital. Athens, Greece.

Introduction: Guided and not blind liver biopsy is essential for diagnosing primary or metastatic liver tumors. Combination of IMs are useful for detection of specific antigens indicative of cell differentiation/maturation/function and their selective use is mandatory for a correct diagnosis.
Purpose of the study: To evaluate the usefulness of IM panels designed according to histological patterns and clinical history for the diagnosis of liver tumors.
Materials-Methods: 50 cases of CT-guided liver biopsies (Bs) were studied (43 males, 7 females). 10 patients had suffered from another primary malignancy, hepatocellular carcinoma was suspected in 9 cases of chronic hepatitis B and 40 were investigated for unknown primary tumor. Formalin fixed Bs were diagnosed with H+E, PAS, PAS-D, Masson Trichrome and Gordon's and Sweet's reticulin stain. The immunohistochemical method Envision-HRP was used for detection of mixed cytokeratins, CK7, 8,18,19, 20, CEA, Ca19-9, Ca125, c-erb-B2, TTF1, chromogranin A, oestrogen/progesterone receptors and the HepPar1 antibody which is normally expressed in hepatocytes.
Results: In 10/50 cases with another primary malignancy the selective use of IMs confirmed liver metastasis from the primary tumor. 9 hepatocellular carcinomas were diagnosed but attention sould be paid to the focal or absent expression of HepPar1 in high grade tumors. Primary site was suggested in 40 cases and confirmation of a correct liver biopsy diagnosis was available in 16/40 surgical specimens. 24 patients with proposed diagnosis were not traced as they were treated in other hospitals. Discordance was observed in two adenocarcinomas with immunophenotype (Ca19-9 +, CK7 +, CK20 -). The upper GI tract was proposed as primary site but colonic adenocarcinoma was diagnosed in another hospital. Comparison of liver and colonic tumors was unavailable.
Conclusion: CT-guided liver biopsy is a useful method for distinguishing primary from metastatic liver tumours and for the recognition of primary site. As the pool of IMs increases, a logical approach is needed for achieving high specificity and sensitivity

P 540

EVALUATION OF APOPTOTIC CELL TURNOVER AND P62 EXPRESSION IN THE PROCESS OF NEOPLASTIC TRANSFORMATION BEGINNING FROM CHRONIC HEPATITIS TO HEPATOCELLULAR CARCINOMA

Gülen Akyol, Özlem Erdem, Güldal Ýylmaz
Gazi University School of Medicine Department of Pathology

Background and Aim: It is well known that reduced apoptosis plays a significant role in hepatic carcinogenesis. Actin fragment, which is produced by caspase 3 during apoptosis, can be recognized by fractin and it has been demonstrated that fractin expression in tissues has a place in the evaluation of apoptosis. p62 is a tumor-related insulin-like growth factor which is shown that approximately one-third of hepatocellular carcinomas exhibited high expression of p62 protein immunohistochemically, whereas adjacent non-malignant parenchymal liver cells had no detectable staining. The aim of this study is to evaluate fractin and p62 expressions in cases of chronic viral hepatitis, cirrhosis and hepatocellular carcinoma to reveal out the possible impact of these proteins in hepatocellular carcinogenesis.
Material and Methods: Fractin expression has been evaluated in paraffin embedded sections by immunohistochemistry in cases of 13 mild, 11 moderates and 3 severe chronic hepatitis, 8 cirrhosis and 7hepatocellular carcinoma. Nuclear and cytoplasmic staining percentage was used for statistical comparisons
Results: Although fractin expression did not differ between groups of different degree of hepatitis, the difference was significant between cases of chronic hepatitis, cirrhosis and hepatocellular carcinomas. While the apoptotic rate was highest in chronic hepatitis, it was lower in hepatocellular carcinomas. In contrast to the literature, we could not detect p62 in hepatocellular carcinoma cases. However, it was found weakly positive in 1 hepatitis B and 1 cirrhosis case.
Conclusion: It has been suggested that apoptosis that evaluated by fractin antibody could be more helpful for defining preneoplastic lesions during hepatic carcinogenesis than p62 expression.

TGF-BETA PATHWAY CORRELATES WITH APOPTOTIC INDEX IN NEOPLASTIC HUMAN LIVERS

GIACOMETTI Cinzia, PONTISSO Patrizia, VALENTE Marialuisa, CALABRESE Fiorella
University of Padova Medical School, Padova, Italy

INTRODUCTION TGF-beta1 plays a central role in regulation of cell growth and differentiation. The signalling pathway is complex and its effect is dependent by the activation of specific transduction factors. PURPOSE OF THE STUDY The aim of the present study was to investigate the expression of TGF-beta pathway (TGF-beta1, SMAD 1-2 and TGF-beta type II receptor) in neoplastic human livers. METHODS 43 HCC tissue samples obtained form 12 liver biopsies and 31 surgical resections, 20 normal liver tissues, 6 cirrhotic and 20 viral hepatitis were investigated for the TGF-beta1 and its signalling pathway (TGF-beta1 type II receptor and SMAD) expression. Semi-quantitative RT-PCR for the detection of TGF-beta1 was performed on all frozen liver tissues. Apoptotic index was evaluated by TUNEL technique and proliferation index was analysed with MIB1 (Ki-67 antigen). Results TGF-beta expression (mRNA and protein) was higher in HCC compared with normal liver but it was significantly lower than cirrhosis and hepatitis. RESULTS A concordant expression of TGF-beta1 with RII and SMAD 1-2 was observed in the majority of cases ($p<0.05$). A positive correlation was observed between apoptotic index and TGF-beta pathway. No correlation was observed between TGF-beta pathway and other clinical and pathological parameters. CONCLUSIONS TGF-beta is markedly low expressed in HCC compared to inflammatory and degenerative processes. TGF-beta pathway plays an important role in the arrest of cell growth in HCC.

SCREENING OF SERUM BIOMARKERS IN HEPATOCELLULAR CARCINOMA BY SELDI TECHNIQUE

Jianzhong Zhang, Yanhua Zheng, Kai Feng
Department of Pathology and Laboratory Medicine
Beijing 306 Hospital
9 North Anxiang Road, Beijing 100101, China

Objective: Liver cancer is one of the diseases with higher incidence and mortality. New technologies for the earlier detection of liver cancer are urgently needed. The aim of this study was to screen serum biomarkers in patients with hepatocellular carcinoma by using surface-enhanced laser desorption and ionization time-of-flight mass spectrometry (SELDI-TOF-MS) Methods: Proteomic spectra were generated by mass spectroscopy in 88 cases, including 34 cases of hepatocellular carcinoma that had been pathologically confirmed with aged 45 to 94 years, and 34 cases of healthy control aged 20 to 78 years. 68 spectra obtained were used to train and develop a decision tree classification algorithm.
Results: A total of 17 distinguished proteomic peaks were detected, two of which were used to build a proteomic pattern. The results yielded a sensitivity of 91.18£¥ (33/34), specificity of 97.06£¥(32/34), and positive predictive value of 96.88£¥.
Conclusion: SELDI-TOF-MS offers a unique platform for the earlier detection of tumor. It also offers a noninvasive method to study the local microenvironment associated with the development and progression of liver cancer.

THE MESENCHYMAL HAMARTOMA OF THE LIVER IN ADULTHOOD: REPORT OF TWO CASES WITH IMMUNOHISTOCHEMICAL PROPHYLE, CLINICAL AND HISTOPATHOLOGICAL FEATURES

Gürbüz Y*, Turan G*, Utkan Z**, Alponat A**
*Kocaeli University Medical Faculty Pathology Department
**Kocaeli University Medical Faculty General Surgery Department

INTRODUCTION: Mesenchymal hamartoma is an uncommon cystic mass of the liver occur primarily in children. However there are a few reports of adulthood mesenchymal hamartoma of the liver (MHL).
CASE REPORTS: In this paper we present two cases of MHL in two female patiens 54 and 51 years old. In radiological examination of bouth of the cases the patiens had multiple cystic lesions in the liver accompanied a kidney cyst In microscopic examination a multilocular cyst lined by flattened epithelium surrounded by a mesencymmal component composed of mature connective tissue, arterial and venous vascular structures, peripheric nerve bundles, and ductal structures was observed. An immunohistochemical panel composed of desmin, smooth muscle actin, S-100, vimentin, CD34, CEA, Pan cytokeratin, cytokeratin 7 (CK7), CK8, CK17, and CK20 was applied to the paraffin sections. CK7 and CK19 immunoreactivity was observed in cystic epithelium and in ductal structures. Focal and patchy desmin immunoreactivity was observed in connecting tissue. S-100 was positive only in pheripheric nerve bundles.
CONLUSION: In conclusion MHL of aduthood is a localised tumoral abnormality that precedes birth which had delayed clinical presentation. These lesions seems to be in a maturation process just like the hosts carrying them. The stomal component consist of immature ebematous spindle cells stroma rich in mucopolicassatides convert to mature paucicellular hyalinised coonecting tissue. This maturation process may be also related with lost of precancerous potential of these tumors observed in juvenyl forms.

HIGH EXPRESSION OF CLAUDIN-4 IN BILIARY CARCINOMAS

LODI Csaba (1), SZABO Erzsebet (1), BATMUNKH Enkhjargal (1), HOLCZBAUER Agnes (1), PAKU Sandor (2), KISS Andras (1), KUPCSULIK Peter (3), ILLYES Gyorgy (1), SCHAFF Zsuzsa (1).
(1) 2nd Department of Pathology, Semmelweis University, Budapest, Hungary,
(2) First Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary,
(3) First Department of Surgery, Semmelweis University, Budapest, Hungary.

BACKGROUND/AIMS: Cell adhesion molecules play an important role in carcinogenesis, especially claudins, being part of tight junctions. It has been shown the importance of certain claudins in development of several tumors, and some of them even suggested as a future therapeutic target. For this reason, the aim of our study was to analyse the expression of claudins in biliary carcinomas (BCs).
METHODS: A tissue microarrays comprising 24 biliary carcinomas, arising from different localisations (gallbladder, common bile duct, hepatic ducts, intrahepatic bile ducts) were constructed to investigate claudin-1,2,3,4,7 expression by immunohistochemistry on formalin fixed, paraffin embedded slides. Claudin-4 was further investigated by Western blot analysis on 5 human surgically resected, snap frozen BC specimens. Subcellular localisation of claudin-4 was detected by confocal laser scanning microscopy.
RESULTS: Intensive membranous immunolabeling was found for claudin-4 in BCs of different origin. A single band of the expected size was detected on Western immunoblots and revealed a strong expression of claudin-4. Confocal microscopy confirmed the increased expression of claudin-4 on the membrane of BC cells.
CONCLUSIONS: Our data report the first time a significantly increased claudin-4 expression in BCs. The results represent a novel feature of BCs and claudin-4 protein could well become a potential diagnostic marker and therapeutic target for biliary carcinomas, as it has been suggested for pancreatic and ovarian cancers.
The project was supported by grants: NKFP-1/0023/2002, ETT- 077/2003, OTKA-T037838.

DETECTION OF RESPONSE-PREDICTING MUTATIONS IN THE KINASE DOMAIN OF THE EPIDERMAL GROWTH FACTOR RECEPTOR GENE IN CHOLANGIOCARCINOMAS

KIM Young-A1, PARK Jong-Moo2,GWAK Geum-youn3, AHN Young-Joon4, YOON Jung-Hwan3
1Department of Pathology, Seoul National University Boramae Hospital, 2Department of Neurology, Eulji University School of Medicine , 3Department of Internal Medicine, Seoul National University College of Medicine, 4Department of Surgery, Seoul National University Boramae Hospital

Purpose: Epidermal growth factor receptor (EGFR) signalings have recently been implicated in the genesis and progression of cholangiocarcinomas. Thus, the EGFR kinase inhibitor appears to be promising in the treatment of this cancer. The response-predicting mutations in the tyrosine kinase domain of EGFR gene have recently been detected in non-small cell lung cancers. This study was, therefore, to investigate if these mutations are also found in cholangiocarcinomas. Methods: Twenty-two consecutive cholangiocarcinoma patients who underwent surgical resection were enrolled. Their resected paraffin-embedded cholangiocarcinoma specimens were used for mutation analysis, which was performed by DNA sequencing of exons 18, 19 and 21 in the EGFR gene. Clinical characteristics were compared between each group

according to the presence or absence of mutations. Results: Three patients (13.6 %) harbored EGFR mutations. All the mutations found were deletions in exon 19. Mutations were more common in intra-hepatic or poorly differentiated tumors. Differences in age, sex, stage at diagnosis and survival were not observed between mutation-positive and -negative patients. Conclusions: This study, for the first time, demonstrates that a subset of cholangiocarcinoma patients has response-predicting EGFR mutations. Therefore, a highly selected application of the EGFR kinase inhibitor would be therapeutically effective in these patients.

HEREDITARY HEMOCROMATOSIS ASSOCIATED WITH A FULL SPECTRUM OF BILE DUCT LESIONS: CHOLANGIOCARCINOMAS, BILE DUCT ADENOMAS AND BILIARY MICROHAMARTOMAS.

GARCIA Adriana, MOYANO Susana, LANDOLFI Stefania, SANCHEZ Marcelo, GARCIA-VALDECASAS Juan-Carlos, BRUGUERA Miquel and MIQUEL Rosa.
Departments of Pathology, Radiology, Surgery and Liver Unit.
Hospital Clinic, IDIBAPS, University of Barcelona.

Genetic hemochromatosis (GH) is a relatively common inherited disorder associated with chronic liver damage and cirrhosis. Iron overload has been also associated with an increased risk for the development of primary liver tumours. Although hepatocellular carcinoma is the malignant tumor most frequently found in these patients, a wide spectrum of biliary lesions and cholangiocarcinoma have also been described. Von Meyenburg complexes and bile duct adenomas are two well known lesions associated with cholangiocarcinomas and considered putative precursor lesions.

We present a case report of a 64–years-old man with liver cirrhosis associated with GH, homozygotic for the C282Y mutation, and treated for the last 4 years with venesections. The patient was admitted to our hospital for the study of two hepatic focal lesions suspicious of metastasis. After the diagnosis of a well differentiated adenocarcinoma by a fine-needle aspiration of one of the nodules, and exclusion of a primary tumor in other localization, the patient was submitted for hepatic resection. A segmentectomy II-III, V and a percutaneous liver biosy of the left lobe were performed. Macroscopically five white nodules were observed, from 2.5 to 0.2 cm, in a micronodular background. The non-tumoral liver parenchyma showed cirrhosis with a moderate iron deposition. Microscopically the two largests nodules were cholangiocarcinomas. A total of 7 bile duct adenomas and numerous von Meyenburg complexes were also identified in the adjacent liver tissue of all the specimens. No morphological transition between benign and malignant lesions was observed. Immunohistochemical studies using citokeratin 7 and 20, EMA, CEA, p53, Mucins and Ki-67 antibodies were performed.

In GH individuals, primary liver tumors may present with a wide morphological spectrum, from hepatocyte-derived malignancies to cholangiocyte-derived lesions. A carcinogenic effect has been proposed for iron overload by both direct or indirect pathways. The unusual case we present shows a full spectrum of biliary lesions with biliary microhamartomas, bile duct adenomas and cholangiocarcinomas.

SOLITARY FIBROUS TUMOR OF THE LIVER: REPORT OF THREE CASES ONE OF THEM SHOWING MALIGNANT FEATURES

Peña C*, Rullier A*, Laurent C°, Le Bail B*, Bioulac-Sage P*.
*Department of Pathology and °Surgery CHU Pellegrin, Bordeaux, France.

Solitary fibrous tumors (SFT) are rare neoplasm arising from mesenchymal cells, which are difficult to diagnose. They have been reported in a wide range of anatomical sites usually benign, but malignant transformation has been described. SFT of the liver are exceptionally described and always benign.
We report three cases of SFT of the liver diagnosed during last ten years in our department. All were located in the right liver and surgically resected. Case 1 and case 2 were benign SFT diagnosed in 69 and 57 year-old women. The main clinical manifestation was abdominal pain with weight loss for case 1. Tumor size varied from 9 to 10.5 cm in diameter. The external surface was typically smooth, of firm consistency and well defined. The cut surface was light tan to gray-white with whorled texture with foci of cystic degeneration. Histologically, tumors showed alternating cellular and paucicellular areas. The former included spindle-shaped cells with finely disperse chromatin and uniform nuclei. The latter were made of abundant hyalinization and collagen deposits. The tumor vascular supply was well developed. Mitotic activity did not go beyond 4 mitoses/10 HPF. All tumor cells expressed CD34 and vimentin whereas cytokeratins, alpha smooth muscle actin, S100 protein and c-kit were negative. Proliferative index was low. The patients were alive without recurrence since 9 years and five months for cases 1 and 2 respectively .
Case 3 concerned a 70 year-old woman presenting with persistent abdominal pain. Tumor size was 16 cm with similar macroscopical characteristics as previous cases. Histologically the aspects were identical to previous tumor at one exception. An expansive and basophilic nodule was found in the cellular area with dense cellularity, fascicular pattern and, high mitotic activity (8 mitoses/10 HPF) and proliferative index. No necrosis nor lymph node metastasis were observed. The immunophenotype of tumor cells was identical as previous cases even in the atypical nodule. The patient is still alive without recurrence since three months.
Solitary fibrous tumor of the liver are exceptional. They are usually benign, but tumor with malignant features can occur with unknown prognosis.

P 548

SYNCHRONOUS PERIVASCULAR EPITHELIOID CELL TUMORS (PECOMA) INTRAHEPATIC, AND OF THE ROUND LIGAMENT OF THE LIVER.

ALFARO Luis, RAYÓN Miguel, FROUFE Agustín, SANJUÁN Fernando, MIR José.
Hospital La Fe. Valencia. Spain.

Perivascular Epithelioid tumors (PEComas) is a recently introduced concept to describe a family of lesions sharing peculiar features: co-expresion for muscular and melanocytic markers, spindle or epithelioid cell shapes, pale or clear cytoplasm, arrangement around blood vessels, melanosomes or premelanosomes in its ultrastructure, and absence of a normal precursor cell.
We present a case of double PEComa developed in left hepatic lobe, and round ligament, in a 24-year-old woman. She sufferered acne, in treatment with oral contraceptives, and came to the hospital with slight dyspepsia. On the echographic exploration two hepatic lesion were seen. Magnetic resonance confirmed a 8 cm lesion dependent of umbilical vein, and a second intrahepatic 3’5 cm lesion, located in segment IVb. No signs of tuberous sclerosis were found. Both lesions were resected, and showed on microscopical examination identical appearance. The tumors were composed of uniform spindle to round cells, with clear cytoplasm, and slightly pleomorphic nuclei. A prominent vascular component subdivided the cells in fascicles and nests. Mitotic activity was lower than 1/10 high power fields. Some areas had cells with prominent cytoplasmic melanic pigmentation.

Immunohistochemically the cells in both tumors strongly expressed HMB-45, smooth muscle actin and Melan-A. S-100 protein, keratin and desmin were all negative. C-kit, and CD99 were positive in more than 80% of tumor cells; and Ki-67 showed a proliferation index lesser than 1%. Electron microscopy study revealed oval cytoplasmic inclusions with dark staining granules, and some with cross striated structures, characteristic of melanosomes.
These kind of lesions had been suffering a controversy regarding its histogenesis and even its real existence a clinicopathological entity. Generally considered as benign lesions, some cases have been described with malignant evolution or sarcomatous transformation. Our case raised also the possibility of a metastatic intrahepatic lesion from and initial ligamentous tumor. However and, in spite of the exceptionality of these lesion and especially for multiples ones, they are usually considered as multicentric processes and not true metastatic lesions.

(2) Department of Surgery, CHU Pontchaillou, Rennes, France
(3) Department of Pathology, CHU Henri Mondor, Créteil, France

Hepatocellular carcinoma (HCC) and cholangiocarcinoma (CC) are reported as complications of genetic hemochromatosis (GH). We report two cases of GH with several benign and malignant lesions, including biliary adenofibroma (BAF).
For the first patient, of 68 years old, followed and treated by phlebotomy for 30 years, two hepatic nodules were found. Left hepatectomy was performed. Four nodules were macroscopically identified, mesuaring 0.5, 1.5, 1.5 and 5 cm. They corresponded, respectively, to bile duct adenoma, focal nodular hyperplasia, BAF and HCC. For the second patient, of 72 years old, GH and hepatic nodules were diagnosed at the same time. Abdominal imaging revealed four nodules in the right hepatic lobe. Histologically, 3 of them were HCCs and the fourth was BAF. In both patients, non neoplastic liver showed extensive fibrosis but no cirrhosis and multiple von Meyenburg complex (VMC). In the second case, the parenchyma showed severe siderosis with numeral iron free foci.
BAF is a rare benign neoplasm with only three previously reported cases in the litterature. It is characterized by a microcystic and tubuloglandular architecture composed of a biliary epithelium supported by a fibroblastic stroma scaffolding. Here we report the 2 first cases of BAF in GH patients. Existence of several biliary lesions, developped in a non cirrhotic liver in two patients with GH, suggest a relationship between iron overload and these lesions. BAF, as suggested Varnholt et al, could be an intermediate step in biliary carcinogenesis from VMC to CC. In this setting, occurrence of CC in GH have been already reported in association with VMC. Morcos et al, studying liver cancer in GH, have shown a wide histologic spectrum including VMC and CC.

HISTOLOGICAL CHANGES OF NON TUMORAL LIVER IN RIGHT HEPATECTOMY FOR METASTATIC COLORECTAL CANCERS. CORRELATIONS WITH PREOPERATIVE IMAGING.

A. Abbey-Toby (1), M. Ronot (2), D. Goere (3), P. Bedossa (1), J. Belgithi (3), V. Vilgrain (2), V. Paradis (1).
(1) Pathology Dpt, (2) Radiology Dpt, (3) Liver surgery Dpt, Beaujon hospital, Clichy France

BACKGROUND : Neo-adjuvant systemic chemotherapy is largely used in patients with liver metastastatic colorectal cancers. The impact of such treatment on non-tumoral liver tissue is still poorly investigated. The aim of this study was to (1) describe the morphological changes of non-tumoral liver tissue on surgical specimens, (2) correlate the microscopic findings with the preoperative radiological constatations in a prospective cohort of patients with right hepatectomy.
PATIENTS AND METHODS: From March 2002 to February 2004, 58 consecutive patients with liver metastases had a right hepatectomy. Among them, 43 had chemotherapy, associated with a right portal vein embolization in 8 patients. Liver specimens were reviewed by 2 pathologists and the following features were semi-quantified: steatosis (0: absent; 1 <30%, 2 > 30%), sinusoidal dilatation (0: absent; 1: few foci, 2: numerous foci involving 2/3 of the lobular surface, and 3: extensive areas associated with regenerative nodular hyperplasia), portal fibrosis (0: absent or mild: portal tracts normal or minimally enlarged, 1: extensive fibrosis). Preoperative imaging included CT and MRI in all patients. The following signs were analysed in consensus by 2 radiologists: morphologic changes of the liver, steatosis, abnormal enhancement patterns and signs of portal hypertension.
RESULTS: At pathology, 52 out of 58 (90%) post-chemotherapic liver specimens displayed significant liver changes. Steatosis was observed in 35 cases (60 %), mild and moderate in 29 and 6 cases, respectively. Vascular changes were present in 28 cases (48 %), mild and moderate in 18 and 4 cases, respectively. In 6 patients (10%), regenerative nodular hyperplasia was diagnosed. CT and MRI had a sensitivity to diagnose steatosis of > 30 % and between < 30% of 67% and 7%, respectively with a specificity of 100%. Among patients with microscopic vascular abnormalities, only 3 had abnormal enhancement at imaging (30 %).
CONCLUSION: This study shows that significant morphological changes are observed in the context of neo-adjuvant systemic chemotherapy given in most patients for liver metastastatic colorectal cancers, with steatosis and vascular changes the most prevalent lesions. Among them, regenerative nodular hyperplasia was frequent in this series and may have an important clinical impact on postoperative outcome. The accuracy of combined CT and MRI to detect steatosis was high whereas it was low for the detection of vascular lesions.

P 551
EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) EXPRESSION IN COLORRECTAL CANCER LIVER METASTASES

Alfredo Matilla1, Luis Vicioso1, Isabel Sevilla2, Elena Gallego3, Martina Álvarez3, Eduardo Marquez4, Isabel Hierro5.
Servicio de Anatomía Patológica1, Oncología2 and Cirugía4 del Hospital Clínico Universitario Virgen de la Victoria de Málaga, Unidad de Apoyo a la Investigación Oncopatológica de la Universidad de Málaga3 and Servicio de Anatomía Patológica del Hospital de Antequera/Málaga5.

EGFR represents a molecular binding for several antineoplastic agents. Results of treatment are not always related to the level of EGFR expression. This could be related to a different expression of EGFR in the primary tumor (PT) and in liver metastatic disease (LM).

Of the 48 cases 36 were EGFR positive in the PT and 12 were negative.Of the 36 positive patients in the PT 24 were also positive in the LM but in 12 LM EGFR were negative. From the 12 primary tumors EGFR negative 7 had EGFR negative LM and in 5 EGFR were positive in the LM. Besides the 48 cases 3 developed a second PT and in 2 of them EGFR expression of the second primary was the contrary of the first tumor. Seven of the 48 cases presented a second LM after a time (14.28 months), of these 4 presented a level of expression contrary to the first metastases.
In conclusion, EGFR expression in the colon PT and LM can be a prognostic factor for recurrence and response to anti-EGFR therapy.

METASTATIC RENAL CELL CARCINOMA IN THE SINONASAL TRACT-REPORT OF A CASE
Simona Mocan1, Simona Stolnicu2, Doinita Radulescu3
1Department of Pathology, County Clinical Hospital Targu Mures, Romania
2Department of Pathology, University of Medicine Targu Mures, Romania
3Department of Pathology, University of Medicine Iasi, Romania

Aim. Few sinonasal tumours can manifest, histologically, as clear cell neoplasia, the most frequent encountered being metastatic renal cell carcinoma.
Material and methods.We present a case of a 63 years old men presented with a six-month history of right-sided epistaxis associated with nasal obstruction. Previous medical history was significant for renal cell carcinoma. The clinical examination revealed a tumor mass localized in the anterior right nasal cavity. A craniofacial resection was performed for tumor extirpation. The tumor was fixed in formaline, embedded in paraffin and the sections were stained with H-E, PAS-ALCIAN blue. Immunohistochemical examinations were performed for Cytokeratin, Vimentin, S-100, EMA, CEA and HMB 45.
Results. Histologically, the tumor was represented nests and tubular structures of tumor cells and little stroma with prominent vascularity. The cells were large, with abundant clear cytoplasm and distinct cytoplasm membranes, the nuclei were rounded, centrally located with reduced nuclear pleomorfism. The tumor was ulcerated on the surface. Histochemistry confirmed the presence of tumor glycogen but no mucin. Immunohistochemistry confirmed strong expression for Cytokeratin, Vimentin and EMA.
Conclusions. Sinonasal tumors that can appear as clear cell malignancies include primary squamous cell carcinoma, salivary tumors (such as mucoepidermoid carcinoma, acinic cell carcinoma, clear cell carcinoma, epithelial myoepithelial carcinoma), metastatic tumors (from renal cell carcinoma and follicular thyroid carcinoma) and recently described entity as “sinonasal renal cell like carcinoma”. The differential diagnosis is made on histochemical, immunohistochemical and ultrastructural features.

THYROID METASTASIS FROM UNDIFFERENTIATED NASOPHARYNGEAL CARCINOMA: A CASE REPORT
ELLOUZE Sameh, GOUIAA Naourez, KHABIR Abdelmajid, CHTOUROU Imen, MAKNI Saloua, AYADI Lobna, GHORBEL Monem, BOUDAWARA SELLAMI Tahya

Introduction:
Metastatic lesions in the thyroid gland are rarely reported; they account less than 4% of malignant thyroid tumors ; but the number of cases seems to be increased in recent years, with routine use of fine-needle aspiration biopsy. The metastatic involvement of the thyroid gland does not appear to be dependent on age but is more common in females. The most common site of origin was the kidney closely followed by breast and lung. Thyroid metastasis from undifferentiated nasopharyngeal carcinoma (UCNT) has not been reported in the literature;
Objective:
The purpose of this work is to report the clinical and morphological characteristics of this unusual metastatic lesion in the thyroid gland.
Case report:
we report an original case of metastasis to the thyroid from UCNT occurring in a 47-year-old man, 8 years after the diagnosis of the original primary nasopharyngeal tumor treated by chemoradiotherapy. Clinical examination revealed a multinodular goiter. Thyroid gland was voluminous with intact capsule and showed many nodules of different size, witch were diagnosed as metastasis from UCNT. On immunohistochemistry study, the neoplastic cell showed a focally positive immunoreactivity for LMP1 and were negatives for thyroglobulin.
Conclusion:
The thyroid metastasis from UCNT are not always easily identified on routing stained sections and their diagnosis need clinical findings and even immunohistochemical analysis.

P 555
EXPRESSION OF MLH1, MSH2 AND EGFR IN 35 INTESTINAL-TYPE SINONASAL ADENOCARCINOMAS
Flora Poizat (1), Pierre Raynaud (1), Renaud Garrel (2), Valérie Rigau (1), Pierre Baldet (1), Valérie Costes (1).

Introduction : Intestinal-type sinonasal adenocarcinomas (ITAC) are malignant epithelial tumors that show histological, and immunochemical features reminiscent of colorectal adenocarcinomas. Unlike ITAC, colorectal adenocarcinoma is one of the most widely studied human malignancies. We have worked on the hypothesis that similarities between ITAC and colorectal adenocarcinoma might reflect equivalent genetic alterations and carcinogenesis.
Purpose of the study : The phenomenon of microsatellite instability (MSI) caused by mutation or methylation in the MLH1 and MSH2 mismatch repair (MMR) genes is a way of pathogenesis involved in 10-15% of sporadic colorectal adenocarcinoma. The aim of our study was to assess MSI status in ITAC by standardised immunochemistry in order to determine if the similarities between ITAC and colorectal adenocarcinoma extend beyond the light microscopic level to an eventual identical way of carcinogenesis.
Futhermore, overexpression of Epithelial Growth Factor Receptor (EGFR) is a common event in colorectal adenocarcinoma. We attempted to determine if such consistent expression of EGFR was also observed in ITAC.
Methods : MLH1, MSH2 and EGFR expression were

investigated in paraffine sections of resection specimens of 35 ITAC using standardised immunochemistry with antigen retrieval.
The expression of MLH1 and MSH2 was considered positive if there was definitive nuclear staining in any of the tumoral cells.
Membrane staining of EGFR was evaluated in the neoplastic cells and graded using a semiquantitative score (0-3+).
Results : All of the 35 carcinomas examined showed preserved nuclear expression of MLH1 and MSH2 with most cases showing strong nuclear staining.
There was no staining of neoplastic cells for EGFR in 8 cases (23%, score 0). Staining was weak in 9 cases (25%, score 1+), moderate in 10 (29%, score 2+), and strong in 8 (23%, score 3+).
Conclusions : First, these results suggest that defective DNA mismatch repair does not play an important role in the pathogenesis of ITAC and confirms the previous investigation of Perez and coll. in 10 patients.
Secondly, we show for the first time that most of the ITAC (77%) stained positively for EGFR with a frequency quite similar to colorectal adenocarcinoma (74 to 97%). On the basis of the already proven antitumoral effect of agents acting as EGFR inhibitors, it is suggested that patients with ITAC might benefit from these agents.

P 556
A MORPHOLOGIC AND IMMUNOHISTOCHEMICAL STUDY OF NASAL MUCOSA IN LEATHERWORKERS OF THE PROVINCE OF FLORENCE AND PISA, ITALY

PALOMBA Annarita*, BIANCALANI Mauro*, IAIA Tonina Enza†, CONTI Stefano?, BATTISTA Giuseppe‡, FRANCHI Alessandro**.
*Division of Anatomic Pathology, Department of Laboratory Medicine, “S. Giuseppe” Hospital, Empoli, †Department of Prevention, USL11, Empoli, ? Division of Otolaryngology Head and Neck Surgery, “S. Verdiana” Hospital, Castelfiorentino, ‡ Department of Prevention, University of Siena, **Department of Human Pathology and Oncology, University of Florence, Italy

Aims: An increased risk for developing sinonasal intestinal type adenocarcinoma has been ascertained in individuals occupationally exposed to leather manufacturing, but no conclusive data have been reported concerning the morphological precursors of these tumors. The purpose of this study is to investigate early histologic changes and modification in the phenotype of epithelial cells in nasal mucosa of leatherworkers, with specific reference to the presence of intestinal metaplasia.
Subjects and methods: 75 male subjects (age 38-75 years) who had a long-time exposure to leather manufacturing (range 7-48 years) underwent biopsy of the nasal mucosa of the lower turbinate. Samples were fixed in formalin and routine processed for histology. Serial sections were stained with haematoxylin and eosin, PAS diastase and immunostained for cytokeratin 20, CDX-2 and MUC-2.
Results: In the majority of the biopsies (66.6%) the normal ciliated epithelium showed areas of squamous metaplasia, which was associated with mild to moderate dysplasia in 24 cases (32%). Another frequent histopathologic finding was the presence of a chronic inflammatory infiltrate (90.6%). In 13 biopsies (17.3%) we observed an increased number of goblet cells, which showed an intense cytoplasmic positivity for MUC-2, while no immunostaining was observed for cytokeratin 20 and CDX-2 in any epithelial cell of surface or glandular epithelium.
Conclusions: As for woodworkers, the most common epithelial changes in the nasal mucosa of leatherworkers are squamous metaplasia (with or without dysplasia) and goblet cell hyperplasia. Intestinal metaplasia, with acquisition of CDX-2 and cytokeratin 20 expression, is not observed in nasal mucosa of leatherworkers, and may be a late event in the pathway leading to development of sinonasal intestinal type adenocarcinoma.

P 557
NASOPHARYNGEAL PAPILLARY ADENOCARCINOMAS. INCLUDING TWO CASE OF THYROID LIKE CARCINOMAS EXPRESSING TTF-1

LUNA Mario, PINEDA Keyla, NETO Antonio
Department of Pathology. M.D. Anderson Cancer Center

Introduction: Nasopharyngeal papillary adenocarcinomas (NPPAs) are uncommon neoplasms with different histogenesis and histomorphology.
Purpose: To characterize the behavior, and IHC of NPPAs.
Design: 19 neoplasms coded as NPPAs were identified in our files. Demographic data and histomorphology were reviewed. IHC for CKs 5/6 , 7 and 19 , S-100 protein, thyroglobulin (THYG) and TTF-1 were performed.
Results: 11 females and eight males ranged in age from 9 to 79 years(mean 47.5 yrs). NPPAs were reclassified as: 8 primay low grade nasopharyngeal adenocarcinomas (LGNPA),7 polymorhous low grade adenocarcinomas (PLGA), and two each thyroid-like papillary carcinomas and metastatic papillary thryoid carcinomas (MPTC).The only children in the study had TLPC. S-100 protein was expressed only in PLGA, CK 5/6 was postive only in LGNPA. TLPC and MPTC immnoreacted to CK 7, CK 19 and TTF-1, wheras only MPTC expressed THYG. All patinets were treated surgically, the pts with MPTC in addiiton received postoperative radiotherapy. All pts are alive without tumor. Pts with MPTC are alive with residual or recurrent tumor.
Conclusions:Differentiating these adenocacinomas has therapeutic and prognostic implications. Our findings document a strong correlation between histomorphology and IHC expression., allowing this distinction. Since THYG may not be express in metastatic papillary thyroid carcinomas,the diagnosis of TLPC is based in the absence of carcinoma in the thyroid gland

SEBASEOUS CARCINOMA OF THE NASAL VESTIBULE: A CASE REPORT

BIR Ferda, Pamukkale University, School of Medicine, Department of Pathology
AKBULUT MMetin, Pamukkale University, School of Medicine, Department of Pathology
SEN Nilay, Pamukkale University, School of Medicine, Department of Pathology
KELTEN Esra Canan, Pamukkale University, School of Medicine, Department of Pathology
TOPUZ Bulent, Pamukkale University, School of Medicine, Department of Otorhinolaryngology
DEMIRKAN Nese, Pamukkale University, School of Medicine, Department of Pathology

Abstract
Background: Sebaceous carcinomas are cutaneous appendageal tumors that may be extremely rare in the nasal vestibule. These lesions are relatively rare, but some have a predilection for the head and neck region and can easily be misdiagnosed as more common lesions. To our knowledge, only 19 examples of nasal sebaceous carcinomas have been reported in the literature.
Case report: Here the authors described a case of a 90-year-old man who presented with an ulcerated mass in the right nasal vestibule with a history of basal cell carcinoma of the same area. The patient stated that the lesion had been present for 18 months. The examination revealed a destructive, irregularly shaped mass measuring 1.5 cm in maximum diameter. At follow-up, 12 months later, a new lesion of 0.5

cm in diameter had appeared in the same area. Histologic examination of the mass was composed of small basaloid cells and large foamy cells. Sebaseous differentiation was evident in some tumor islands. The sebaseous cells were well defined and variably sized and contained minimally pleomorphic, centrally located, vesicular-shaped nuclei with prominent nucleoli, and had poorly defined cellular outlines. A lot of smaller, darkly staining, basaloid cells with oval shaped nuclei and prominent nucleoli are also frequently identified. The basaloid cells exhibited strong reactivity with 34beta12 and sebaseous cells in tumoral islands stained positive with CEA and EMA. No staining was observed with vimentin, actin and S-100. Mucicarmine stain and periodic acid Schiff stains with and without diastase were negative, confirming that the vacuolated clear cells were neither mucus cells nor glycogen-rich squamous cells. As a result histology revealed a sebaceous carcinoma.
Conclusion: Sebaseous carcinoma can be highly malignant, due to its histological differentiation. It is usually a slowly growing tumor, which is locally aggressive and capable of metastatic spread to regional lymph nodes and distant sides. Historical data indicate a nearly 30% local recurrence rate with standard surgical excision. Careful pathological examination with clinical correlation is essential in the diagnosis and the differential diagnosis of common tumors of the face should include this rare malignancy.

Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, California, USA; 6. Department of Microbiology and Immunology, Texas Tech University Health Science Center and Southwest Cancer Treatment and Research Center, Lubbock, Texas, USA.

Introduction. Esthesioneuroblastomas (ENBs) are rare malignant tumors of the nasal vault whose origin, diagnosis and management are still subjects of discussion. The fact that there is no related prognostic factor or generally recognized therapeutic regimen highlights the need for further analyses of its underlying biological features and investigations of new marker proteins that allow more reliable clinical testing. Purpose. To investigate whether Sperm protein 17 (Sp17) is expressed in ENBs and to compare whether Sp17 expression is correlated with other well characterized ENBs markers. Methods: The analyzed tissues came from 42 patients (23 males and 19 females with a median age of 54.5 years; range: 10-84) treated at the University of Erlangen-Nuremberg and the University of Southern California. Two-micrometer thick sections were cut and processed for immunohistochemistry. The immunohistochemical expression of the antibodies (Sp17, Ki-67, chromogranin, S100, synaptophisin, neurofilament) was evaluated by means of light microscopy of all of the available tissues for each patient at 20 x and 40x objective magnifications. Results. We here show that Sp17 is expressed in the ciliated cells of the normal olfactory epithelium and in a proportion of primary ENB lesions. We found an association between Sp17 expression and metastases at relapse ($p = 0.035$), cromogranin expression ($p = 0,014$), and female gender prevalence. A statistically non-significative relation was also found between Sp17 and S-100, synaptophisin, and neurofilament expression. No relation was also found between Sp17 expression and the proliferative capacity of the lesion that was evaluated with the Ki-67 immunohistochemistry. Conclusion. Our results extend previous findings showing that the ciliated cells of the respiratory system and male and female reproductive systems are immunopositive for Sp17, and suggest that Sp17 may be a useful new protein marker for distinguishing two subsets of ENB lesions. Furthermore, they may represent a first step towards the characterization of this histologically heterogeneous family of tumors going under the same name.

P 560
EXPRESSION AND DISTRIBUTION OF MASPIN PROTEIN IN POLYMORPHOUS LOW-GRADE ADENOCARCINOMA

MARTINS Marília, MACARENCO Cíntia, FONTES Alexandra, ARAÚJO Vera, SOUSA Suzana.
Oral Pathology Department, University of São Paulo, BRAZIL

Introduction. Polymorphous low-grade adenocarcinoma (PLGA) is a malignant neoplasm that affects almost exclusively minor salivary gland, representing, in these sites, the second or third most frequent malignant tumour, according to the published series. Despite the recognised clinical importance of the PLGA little is known about its biology. Maspin is a member of the serpin family of serine protease inhibitors with a peculiar role as tumour suppressor. It inhibits cell motility, invasion and metastasis and loss or reduction in maspin expression has been associated with tumoral progression. Maspin is mainly associated with myoepithelial cell and it was already demonstrated, by our group, to be present in a series of salivary gland tumours with myoepithelial cell participation. The aim of this study was to investigate the presence and distribution of the maspin protein among the different histological patterns of PLGA.
Material and methods: Immunohistochemistry for maspin was performed on archival formalin-fixed, paraffin-embedded samples of 19 cases of PLGA, using the labelled-polymer method.
Results: All cases studied were positive for maspin but the pattern and extent of staining varied among the histological patterns. Maspin was abundant in the lobular, more densely cellularized areas, while cribriform, tubular and trabecular showed part of the cells positive and papillary and single file pattern showed only occasional cells positive for maspin. It was also possible to notice, among the usually described medium-sized cell, with nuclei revealing fine chromatin and inconspicuous nucleoli, the scattered presence of a smaller cell, which showed hyperchromatic nucleus. This cell was always negative for maspin. When visible, the periphery of the lesions showed no positivity.
Conclusions: Maspin expression was more abundant in highly cellular areas suggesting that maspin needs cellular contact to be expressed. Although the well-recognized cytological uniformity it seems that there is possibly less differentiated cell in PLGA which does not express maspin. In salivary gland, maspin is not exclusive of cells with myoepithelial differentiation.

IN SITU HYBRIDIZATION SIGNALING OF HOXA7 AND TGIF TRANSCRIPTS IN ORAL SQUAMOUS CELL CARCINOMA.

MATIZONKAS-ANTONIO Luciana Fasanella*, ACQUAFREDA Thaís*, SILVA-VALENZUELA Maria das Graças*, LIBÓRIO Tatiana Nayara*, SPENER Roberta*, MICHALUARTE Pedro**, NUNES Fabio Daumas*.
* School of Dentistry, University of São Paulo, Brazil.

** Hospital das Clínicas of São Paulo, Brazil.

Oral cancer is one of the most frequent cancers worldwide. Although different types of cancers can affect the oral cavity, approximately 90% are squamous cell carcinoma (OSCC). The literature shows an extensive search for biomarkers which could predict OSCC behavior. Homeobox genes comprise a family of developmental regulators that are vital for several aspects of growth and differentiation. Recent studies demonstrated genetic alterations in homeobox genes or its expression in many cancers including homeobox HOXA7 and TGIF. HOXA7 may act as a repressor of transcription and down-regulates multiple differentiation specific genes during keratinocyte proliferation. HOXA7 was correlated with leukemia, epithelial ovarian tumors and mouse skin carcinoma. TGIF encodes a protein that is a transcription regulator. TGIF amplification and over-expression was observed in esophageal SCC. The involvement of HOXA7 and TGIF in OSCC has not been demonstrated yet. The purpose of this study was to verify the presence of HOXA7 and TGIF transcripts in OSCC and adjacent non-tumoral tissues (NT), and to see if there is a relation with the cells morphology. Biopsy specimens of OSCC were obtained from Hospital das Clínicas of São Paulo, Brazil. Samples of NT and OSCC tissues were collected and divided in two parts. One half was used for RNA extraction and transcripts amplification by RT-PCR. The other half was submitted to in situ hybridization (ISH) with sense and antisense digoxigenin labelled riboprobes on frozen tissues sections placed in silanized slides. Amplification of HOXA7 was seen in 72.73% of cases, 13.64% only in NT tissues, 40.91% only in OSCC samples and 18.18% in both tissues. TGIF was amplified in 81.81% of cases, 4.54% only in NT tissues, 18.18% only in OSCC samples and 59.09% in both tissues. ISH signal was similar for both transcripts, but more intense for TGIF. In NT tissues there was an intense expression in the epithelium, either in basal and suprabasal layers or disperse and more intense in the spinous layer. In OSCC transcripts were localized in all tumoral cells, but in poorly differentiated areas the signal was less intense and in a few cases it was negative. These results show that OSCC express HOXA7 and TGIF transcripts, mostly in well differentiated regions, suggesting a participation of these genes in OSCC development or progression.

ORAL SQUAMOUS CELL CARCINOMA: AN IMMUNOHISTOCHEMISTRY COMPARATIVE STUDY BETWEEN THE TUMOR AND THE PERILESIONAL MUCOSA

Lucinei Roberto de Oliveira
Alfredo Ribeiro-Silva
Leandra Náira Zambelli Ramalho
Sérgio Zucoloto
Department of Pathology, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Brazil

Oral squamous cell carcinoma (OSCC) is the most frequent malignant neoplasm of the head and neck region. Conversion of normal cells to cancer cells is achieved through a multi-step process that is closely associated with the accumulation of multiple gene changes including both oncogenes and tumour suppressor genes. This work aims to study the relationship between the immunoprofile of the OSCC and the corresponding perilesional normal tissue.
Immunohistochemistry with the antibodies p53, p63, p16, p21, p27, Ki-67, cyclin D1, BAG-1, matrix metalloproteinase 1 (MMP-1), MMP-2, CD34, vascular endothelial growth factor (VEGF), Checkpoint kinase 2 (CHK2), telomerase, epithelial growth factor receptor (EGFR), c-erbB-2, c-erbB-3, and Bcl-2 was performed in a formalin-fixed paraffin-embedded sample of human OSCC and the adjacent non tumoral mucosa. The immunostaining was evaluated as negative (-), weak to moderate/focal (+), or strong/diffuse (++). In the perilesional mucosa there was no reaction for CD34, EGFR, c-erbB-2, c-erbB-3, VEGF, Bcl-2, p21, p16, MMP-1 e MMP-2. The positivity for cyclin D1, BAG-1, p53 e CHK2 was graded as + while the positivity for Ki-67, p27, telomerase, and p63 was graded as ++. The carcinoma was negative for BAG-1, CD34, c-erbB-2, c-erbB-3, Bcl-2, p16, MMP-1, and MMP-2. None markers in carcinoma were classified as +. The positivity for Ki-67, cyclin D1, p21, p27, p53, p63, telomerase, EGFR, VEGF e CHK2 was graded as ++. These data indicate that the expression of p53, p21, EGF, VEGF, CHK2, BAG-1 e cyclin D1 changed from perilesional mucosa to the carcinoma. P21, p53 and CHK2 modulate multiple cellular functions, such as gene transcription, DNA synthesis and repair, cell cycle arrest, senescence and apoptosis. Mutations in these genes can abrogate their functions, leading to genetic instability and progression to cancer. Cyclin D1 overexpression plays a role in the carcinogenesis. BAG-1 has an anti-apoptotic effect, so its downexpression is a stimulus for the cellular proliferation. EGFR is a transmembrane protein, which is implicated in the progression of many epithelial cancer types. VEGF play a critical role in cancer progression by promoting new blood vessel formation. A better understanding of the molecular biology involved in the progression of OSSC is essential for new therapeutic approaches.

SQUAMOUS CELL CARCINOMA OF THE SUPRAGLOTTIC LARYNX.SURVIVAL RATE-FIVE YEAR STUDY

Slavisa A.Jancic,Milan Mijailovic,Ivana Lj.Maric,Snezana Jancic
Oncology Clinic,University Medical School-Nis,Serbia and Montenegro
Pathology Clinic,University Medical School-Kragujevac,Serbia and Montenegro
Radiology diagnostic Center-KC Kragujevac,Serbia and Montenegro

Having in mind dissimilarity of scientific reports regarding the survival rate the patients with squamous cell carcinoma of the supraglottic region,the aim of our research was to present our 5 year experiance in radiotherapy of this neoplasm.
Our study includes 171 patients with squamous cell carcinoma of the supraglottic larynx with various degree of the pathohistological differenciation and stage of illness(T1-T4).
Patients iradiated after surgical treatment from 1994-1998 have been analised at the Oncology Clinic University Medical School-Nis.Megavoltage therapy with x-rays of 10 MEV and electrontherapy of 6-14 MEV were utilized for the radiotherapy treatments.
In the group of patients iradiated after surgical treatment 3 years survival rate vary from 100%-12,5%,depending on the illness stage.In the same group of patients 5 years survival rate was recorded within 80%-12,5% cases.
Patients who were radicaly iradiated(iradiation alone)have had 3 years survival rate,recorded among 64%-8% and 5 years survival rate among 57%-4%.
The study discuss the influence of degree of tumor differentiation on the choise of the radiotherapy plan and the effects of side factors on radiotherapy (in)efficiency.

ABSTRACT
Purpose: Exploring the mechanisms of tumor lymphangiogenesis is necessary for understanding the metastatic behavior of epithelial neoplasms. The aim of this study was to investigate this phenomenon in head and neck squamous cell carcinoma (HNSCC) and address its possible clinical implications.
Methods: We examined 81 tissue specimens of patients with HNSCC using immunostaining for the specific lymphatic endothelium marker podoplanin. We assessed intratumoral lymphatic density (ILD) and peritumoral lymphatic density (PLD). We also quantified lymphatic invasion and examined the possible associations of all the above parameters with clinicopathological features and outcome. Finally, we used double staining with podoplanin and the cell proliferation marker ki-67 in order to evaluate intratumoral lymphangiogenesis.
Results: Both high ILD and high PLD were significantly associated with the presence of lymph node metastasis at the time of diagnosis ($p<0.001$ and $p=0.007$ respectively). We also noticed a significant correlation between ILD and lymphatic invasion. Patients with higher ILD exhibited shorter overall survival (OS, log rank $p<0.001$), whilst PLD had no influence on outcome. The correlation remained significant after multivariate analysis (Cox $p=0.04$) indicating that ILD is an independent prognostic factor for OS. Double staining revealed the existence of proliferating intratumoral lymphatics, in which tumor emboli were occasionally observed.
Conclusions: The above results indicate that lymphangiogenesis indeed occurs in HNSCC; that newly formed vessels are targets of invasion by cancer cells; and that ILD might be used as a criterion to separate patients at higher risk.

INTRODUCTION An alteration in the p53 tumor suppressor gene is the most frequent genetic abnormality in human cancers. The aim of the present study was to evaluate the overexpression of p53 protein, histological grade, stage of the disease and tobacco habit in oral squamous carcinomas in order to relate them with progression and prognosis of these tumors.
MATERIAL AND METHODS Primary tumors were studied on a series of 30 patients. Immunohistochemystry has been applied on paraffin sections of oral squamous carcinomas using DO7 antibody.
RESULTS Overexpression of the p53 protein has been found in 40% of patients. Overexpression of the p53 protein has been correlated with histological grade of the tumor (p¡Ü0,1) and lymph node metastases (p¡Ü0,05). Overexpression of p53 protein in well differentiated carcinomas (33,3%) was significantly higher than in poorly differentiated tumors (0%). Relaps of the disease and stage of the TNM has been correlated with prognosis in patients with this tumor. The higher TNM stage correlates with shorter survival of patients (p¡Ü0,05). No significant correlations were found between overexpression of p53 protein with stage of disease, tobacco habit and survival of patients.
CONCLUSIONS Study showed that immunohistochemical examination of p53 has no prognostic significance in oral squamous carcinomas. Overexpression of p53 protein correlates with histological grade and lymph node metastases.

INTRODUCTION: EGFR protein is expressed on membranes of squamous cells and it is overexpressed in HNSCC. The protein is coded by EGFR gene at 7p12. An antibody against the EGFR protein (cetuximab) may be used therapeutically in patients overexpressing the protein. PURPOSE OF THE STUDY: To introduce the treatment with cetuximab it may be important to establish the extent and type of the EGFR protein expression, and to find out whether the overexpression of the EGFR protein is caused by the EGFR gene amplification and/or by increased copy numbers of chromosome 7 or not. METHODS: We used tissue sections from 33 patients with HNSCC. The EGFR protein expression was tested immunohistochemically (IHC) using EGFR pharmDx (DakoCytomation). FISH to determine EGFR gene and chromosome 7 copy numbers (Abbott/Vysis) was applied. SUMMARY OF THE RESULTS: We found the EGFR protein expression in 31 of 33 patients. The EGFR protein expression had a variable pattern. In one case there were only scattered positive individual tumor cells. In 12 cases we found a variable intensity of the expression in the tumor cells (from 1+ to 3+). In 5 cases the tumor cells were 3+ positive at the periphery of the tumor nests. In 13 cases all tumor cells overexpressed the EGFR protein strongly (3+). The investigation of the EGFR gene revealed its amplification in 7 of 33 patients. The amplification was present in up to 50% of the tumor cells in an individual patient (median 33%). Increased numbers of chromosome 7 centromere signals were found in 23 of 33 patients. We did not find any correlation between the subtypes of the EGFR protein expression and amplification of the EGFR gene and/or increased copy numbers of chromosome 7. CONCLUSION: In patients with HNSCC the overexpression of the EGFR protein was found in a significant number of cases. This phenomenon is not caused by the EGFR gene amplification or by increased numbers of chromosome 7. Hence, the evaluation of the EGFR gene copy number and the number of chromosome 7 signals does not contribute to the decision whether to put these patients on cetuximab treatment or not. The evaluation of the EGFR protein expression by IHC testing appears satisfactory for this purpose. The type of the EGFR protein expression should be taken into consideration when evaluating the responsiveness of patients treated with cetuximab in future studies. Research Project FNM MZO 00064203

EXPRESSION OF C-ERBB-2 IN LARYNGEAL CARCINOMAS OF MALAYSIAN PATIENTS
HAFIZA A, SITI-AISHAH M.A, HARISFAZAL M.B, CLARENCE-KO C.H, JULIA M.I, EZANEE-AZLINA M.H,SHARIFAH N.A, ABDULLAH-SANI M.

Introduction: The c-erbB-2 (HER-2/neu)oncogene encodes for a 185-KD cell-membrane glycoprotein receptor sharing homologies with growth factor receptor. Overexpression of c-erbB-2 protein is a frequent and prognostically relevant event in a variety of human cancers. The aim of this study was to evaluate c-erbB-2 expression in laryngeal lesions and correlate the carcinomas with other available clinicopathological parameters.
Materials & Methods: We examined a total of 89 cases consisting of 47 cases of carcinomas (median 64.0; range 47-79 years), 10 papillomas, and 21 nodules or polyps diagnosed between 1995 and 2003 in Hospital Universiti Kebangsaan Malaysia. The specimens were obtained by laryngectomy or biopsies. Cases of the laryngeal carcinomas (44,[93.6%]males) included 45 squamous cell carcinomas (SCC), 1 sarcomatoid carcinoma and 1 spindle cell carcinoma. Immunohistochemistry was performed in 89 formalin-fixed, paraffin-embedded specimens using c-erbB-2 protein (DAKO A0485,1:300) by the streptavidin-biotin method. Membrane c-erbB-2 immunostaining was used and scoring was according to standard criteria, 0,1+,2+or3+. In addition, the 2+ case was evaluated using fluorescent in-situ hybridization (FISH) for HER-2 gene amplification. Clinical information was obtained from the medical records.
Results:Of the 89 patients, only 1(1.1%)case of SCC was c-erbB-2 protein-positive (2+) while the rest of the specimens were negative. This positive case showed gene amplification for HER-2. Clinical follow-up information was available for 35 patients, ranging from 2 months to 77 months (mean 31.2 months). Five (15.6%) of these patients died of the disease. There was no correlation between c-erbB-2 expression with histopathological grade of differentiation of laryngeal carcinoma, age, sex, lymph node metastases and stage of the patients.
Conclusion:c-erbB-2 protein is rarely expressed in laryngeal lesions and may not play a prominent role in laryngeal carcinomas.

LOCALIZATION OF PMX1 TRANSCRIPTS IN ORAL SQUAMOUS CELL CARCINOMA BY IN SITU HYBRIDIZATION.
ACQUAFREDA Thaís, MATIZONKAS-ANTONIO Luciana Fasanella, SILVA-VALENZUELA Maria das Graças, LIBÓRIO Tatiana Nayara, FERRAZ Alberto, NUNES Fabio Daumas

Oral squamous cell carcinoma (OSCC) is the most frequent cancer of the oral cavity being responsible for 95% of all oral malignancies and is the eighth most common cancer worldwide. Several studies have demonstrated that cancer and development share common features since both exhibit shifts between cell proliferation and differentiation. The homeobox gene family is responsible for encoding transcriptional factors during development bringing our attention for its potential role during carcinogenesis. Paired Mesoderm Homeobox 1 (PMX1, PRX1 or PHOX1) is a non-clustered homeobox gene and as all other members of this family has a homeodomain motif which is responsible for DNA binding. This gene has been related with mesenchyma throughout development such cardiovascular system and skeletal elements. The relation between PMX1 and tumor is not well established yet. The purpose of this study was to verify the presence of PMX1 transcripts in OSCC and adjacent non-tumoral tissues. For such study, tissues were obtained from Hospital das Clínicas (HCFMUSP), with patients' agreement, and divided in two halves. One was used for RNA extraction and transcripts amplification by RT-PCR. Sense and antisense probes were generated by in vitro transcription and labeled with non-radioactive digoxigenin. The other part was fixed in 4% paraformaldehyde, treated with 1X PBS and 30% sucrose before freezing. For in situ hybridization (ISH), serial sections were placed in silanized slides. In the adjacent non-tumoral tissues ISH signaling were detected at the basal and parabasal layers. In the OSCC the signaling was spread all over the tissue becoming more intense in areas with isolated carcinoma cells. Our findings suggest a participation of PMX1 in oral carcinogenesis and its expression in poorly differentiated carcinomas is being analyzed in detail. It is known that PMX1 is mainly expressed in mesenchyme and it is responsible for the maintenance of appropriate level of gene expression in the epithelium. For the first time PMX1 transcripts are detected in oral epithelium and in oral squamous cell carcinoma.

CORRELATION OF TSG101 AND E-CADHERIN EXPRESSIONS WITH TUMOR BEHAVIOR AMONG SUQAMOUS CELL CARCINOMA OF HEAD AND NECK
Chao-Cheng Huang, Chih-Yen Chien, Ching-Mei Chen, Chih-Ying Su, Chung-Feng Hwang, Jiin-Tsuey Cheng
Departments of Pathology and Otolaryngology, Chang Gung Memorial Hospital at Kaohsiung, Taiwan; Chang Gung University School of Medicine, Taiwan; Department of Biological Sciences, National Sun Yat-Sen University, Taiwan.

Tumor susceptibility gene TSG101 plays an important role to maintain genomic stability and cell cycle regulation. Aberrant expression of TSG101 has been associated with tumorigenesis in some carcinomas. Down regulation of E-cadherin has been known to be related to tumor invasion and metastasis. To study the clinical significance of TSG101 and E-cadherin expression among squamous cell carcinoma of head and neck, we retrospectively performed the immunohistochemical study on the surgical specimens of suqamous cell carcinoma among head and neck region from 65 patients who had received primary surgical treatment from 1986 to 1997. In the mean time, we used TSG101 antisense probe to study mRNA expression of these tumors by in situ hybridization. We found that TSG101 together with E-cadherin homogenously expressed over the suprabasal, granular and cornified layers but not the basal layer among the normal squamous epithelium and the well differentiated squamous cell carcinomas. The expression of TSG101 significantly correlated with that of E-cadherin ($p<0.001$). Besides, down regulation of either TSG101 or E-cadherin expression among tumor cells was significantly associated with poor differentiation of the tumor ($p<0.001$). Moreover, both TSG101 and E-cadherin expression significantly correlated with nodal status ($p<0.001$) but not tumor stage. The mRNA expression detected by in situ hybridization well correlated with protein expression by the immunohistochemical study. In conclusion, studies on TSG101 and E-cadherin expressions among squamous cell carcinoma of head and neck may be useful for the evaluation of the tumor differentiation and the risk of nodal metastasis. Further study on the close relationship between TSG101 and E-cadherin expressions in squamous cell carcinoma would be of interest and would potentially disclose their role to control cell differentiation and behavior.

P 570
B-CATENIN/CYCLIN D1 PATHWAY IS CRUCIAL FOR ORAL SQUAMOUS CELL CARCINOMA

GROWTH AND SUSCEPTIBLE TO WORTMANNIN ACTION

SALES Katiuchia Uzzun, ALVES Jr. Sergio Melo, SALLES Felipe Torquato, PINTO Jr. Decio Santos

B-catenin and cyclin D1 are crucial proteins related to tumor proliferation and progression. The complex composed by free cytoplasmic b-catenin and transcription factor LEF/TCF migrates to nucleus, activating several target genes such as cyclin D1. In order to evaluate possible correlations between b-catenin and cyclin D1 in oral squamous cell carcinoma (OSCC), the expression of these proteins was analyzed by immunohistochemistry on tissue sections and in OSCC cells lines treated with 2nM wortmannin for 10min. Protein expression was assessed in five cell lineages, HN6, HN19, HN30, HN31 and HaCat as control keratinocytes, analyzed by immunofluorescence and western-blot. Immunohistochemical results showed a strong correlation between cyclin D1 overexpression and b-catenin cytosolic and/or nuclear presence. No significant alterations in b-catenin expression in treated and control cells were observed by immunofluorescence. Wortmannin promoted cyclin D1 fast relocation to the cytosol. Western blot analysis confirmed the decrease of cyclin D1 levels after wortmannin treatment. This last molecule is able to simulate the PTEN pathway, blocking PI3K and consequent activation of proliferation pathways. Taken together, these results point out the crucial role that b-catenin/cyclin D1 and PTEN pathways might play together in OSCC, and may provide the development of more effective therapeutical approaches regarding this frequent neoplasm.

PSEUDOVASCULAR ADENOID SQUAMOUS CELL CARCINOMA OF THE ORAL CAVITY

ZIDAR Nina, GALE Nina
Institute of Pathology, Medical Faculty, University of Ljubljana, Ljubljana, Slovenia

Pseudovascular adenoid squamous cell carcinoma (PASCC) is an uncommon histopathologic variant of squamous cell carcinoma characterised by acantholysis of the tumour cells, creating anastomosing spaces and channels, thus mimicking an angiosarcoma. PASCC has been reported in the skin of the head and neck as well as in other organs, such as the breast, lungs, vulva, uterine cervix and urinary bladder. It has been suggested that PASCC has a more aggressive behaviour and a worse prognosis than conventional squamous cell carcinoma, but the number of patients reported so far is too small to draw firm conclusions.

We report two cases of PASCC in the oral cavity. One occurred on the buccal mucosa in a 59-year-old man who was a heavy smoker but denied alcohol abuse. The other occurred on the floor of the mouth in a 79-year-old woman who denied smoking and alcohol abuse. In both patients, radical tumour excision and neck dissection were performed. The bulk of both tumours was histologically consistent with PASCC, and contained foci of squamous cell carcinoma suggesting the correct diagnosis. In one patient, they consisted of conventional squamous cell carcinoma, and in the other, they consisted of a spindle cell carcinoma. Immunohistochemically, the tumour cells expressed keratin and vimentin; they did not express CD31 and the vast majority of the tumour cells did not express E-cadherin. Both patients had no metastases at the time of diagnosis, and are alive and well 2 years later.

Pathogenesis of PASCC is not completely understood. It has been suggested that acantholysis is the underlying pathogenetic mechanism. Consistent with this suggestion, we observed in our cases loss of immunohistochemical expression of E-cadherin, one of the major adhesion molecules of epithelial cells. E-cadherin was expressed only in areas of both tumours which exhibited the morphology of conventional squamous cell carcinoma or spindle cell carcinoma. We speculate that loss of E-cadherin expression might lead to the loss of the tumour cell-cell adhesion and acantholysis characteristic for this particular type of squamous cell carcinoma.

In conclusion, eventhough the prognostic significance of PASCC in the head and neck is at present unknown, its recognition is important because it may mimic angiosarcoma which may result in erroneous treatment. The study of our two cases suggest that PASCC might be pathogenetically related to the loss of E-cadherin expression.

LARYNGEAL SQUAMOUS CELL CARCINOMAS AND THEIR LYMPH NODES METASTASES COMPARED BY MULTIVARIATE STATISTICAL ANALYSIS OF DIFFERENT HISTOLOGICAL AND IMMUNOHISTOCHEMICAL PARAMETERS – RAISING THE QUESTION OF THEIR PRACTICAL VALUE.

GEORGIU Carmen*, GEORGIU A.**, OLINICI C.D.*
* Department of Pathology – University of Medicine and Pharmacy "Iuliu Hatieganu" Cluj Napoca, Romania
** Individual Medical Center 81, Cluj Napoca, Romania

Aims. Some of the histological and immunohistochemical parameters of laryngeal squamous cell carcinomas are frequently quantified for each patient but some of them raise more and more the question of their practical value in the prognostic and treatment of the patients.

Methods. A number of 40 primary tumors of squamous laryngeal carcinomas with and without lymph nodes metastases (20 cases of each one) were investigated by different histological and immunohistochemical parameters: grade of differentiation - G OMS, morphometric grade - MG (the percentage of suprabasal keratinocytic cells versus spinous and fully differentiated keratinocytes), type of tumor cells cohesion at the invasion front - IF, mitotic index corrected per volume - M/V (volume of tumor occupied by tumor cells and not connective tissue), MIB-1 proliferation index (percentage of MIB-1 positive tumor cells), p53 index, microvascular density index - MVD (the number of CD-31 positive microvascular endothelial cells) and the grade of peritumoral inflammatory infiltrate - ii. Results. The multivariate statistical analysis of these parameters suggests that the more elevated metastasizing potential have the tumors with the combination of high MIB-1, IF, M/V, MG, ii and G OMS. The most important indicators were the number of cells in cell cycle and the lack of cohesion between the tumors cells at the invasion front (both were three times higher than in the tumors without metastases). The MG was more important than G OMS suggesting that the differentiation pattern of tumor cells (number of spinous cells and the keratin production) may overshadow the real proliferating suprabasal keratinocytes. The p53 index did not affect the process of metastasis but the cells selected in this process were those with high p53 index (in the lymph nodes the p53 index was much higher than in the primary tumors). The high MVD influenced the metastasis, but MVD had much lower values in the lymph nodes than in the primary tumors. The metastasizing potential depends on the neoangiogenesis by the propensity of the tumor cells to create their minimal new ecosystem in the lymph nodes and not for other reasons.

MOLECULAR TARGETS FOR THERAPY IN PRENEOPLASTIC AND NEOPLASTIC LESIONS OF OROPHARYNX AND LARYNX

IOSIF Cristina Ileana 1, VASILESCU Florina 1, DOBREA Camelia 1, ANDREI Florin 1, BUTUR Georgeta 1, CEAUSU Mihai 1, MIHAI Mihaela 1, ARDELEANU Carmen 1, SARAFOLEANU Codrut 2.

1 Victor Babes National Institute of Pathology, Bucharest, Romania
2 "St Mary" Hospital, Bucharest, Romania

Introduction: EGFR, COX-2 and cerbB2 are known as molecular targets for antitumoral and antiangiogenic therapy. The aim of our study was to evaluate by immunohistochemical(IHC) method the expression of EGFR, COX2, and cerbB2 in preneoplastic and neoplastic lesions of larynx and oropharynx.
Materials and methods: We performed an IHC study on 30 biopsies from patients with preneoplastic and neoplastic lesions of the larynx and 20 squamous cell carcinomas of the oropharynx (ABC tristadial IHC method; EGFR from SIGMA-USA, COX-2 from Novocastra, cerbB2 from DAKO)
Results: In larynx neoplastic lesions we found EGFR expression in small vessels at the invasion front of the tumor, and lack of positivity in neoplastic cells; in premalignant lesions of the larynx EGFR expression decrease with the degree of dysplasia; the same expression we found for COX-2; for cerbB2 the positivity was inconstant; in neoplastic lesions of oropharynx we founded positive correlation between the expression of EGFR and COX-2; for cerbB2 the expression was focal and inconstant
We concluded that EGFR and COX-2 could be considered as valuable targets for antitumoral therapies in preneoplastic and neoplastic lesions of larynx and oropharynx; cerbB2 is expressed but require further investigation.

RETINOBLASTOMA GENE AND PROTEIN EXPRESSION IN EVALUATION OF LARYNGEAL SQUAMOUS CELL CARCINOMA*

PIETRUSZEWSKA Wioletta (1), KOBOS Jozef (2), GRYCZYNSKI Maciej (1)
(1) Department of Otolaryngology, Barlicki University Hospital, Medical University of Lodz
(2) Department of Pathology, Medical university of Lodz

The identification of possible genetic alternations in cancer involves inactivation of tumor suppressor genes or activation of proto-oncogenes. In cell cycle, most of the regulatory actions occur at the so-called restriction point (R) in the late G1 phase. Tumor suppressor genes; Rb, p53 and p21 are among the most important of the agents suppressing transition through R point. Changes in the expression of Rb (retinoblastoma) gene which is localizated in 13q14, correlate with the presence of Rb protein and they are believed to be an early event in carcinogenesis. This issue seems to be not plainly defined in laryngeal cancer. Our purpose was to investigate 13q14 LOH and expression of Rb protein and their possible prognostic value in laryngeal cancer. Surgical specimens were obtained from 41 patients with 5-year time observation who underwent surgical treatment at the Department of Otolaryngology Medical University of Lodz. Paraffin-embedded tissue sections were immunohistochemically stained with a monoclonal antibody raised against Rb protein. PCR-based techniques were used for investigating 13q14 LOH. The products of PCR reaction were fractionated on acrylamide gel. There were assessed correlation between the expression of Rb gene and Rb protein presence and clinical and histological implications (patients age, localisation of tumour origin, tumour size and nodal status based on TNM system, local and nodal recurrences, overall and disease free survival rate after surgical treatment and histological grading). Based on this findings it can be deduced that investigation of Rb gene expression and its protein product makes it easier to understand the process of cancerogenesis in laryngeal cancer and to establish its prognostic value further research and observations need to be attempted.

*This study was supported by grant No 502-11-132 from Medical University of Lodz

P 575
THE EXPRESSION OF P53 PROTEIN AND HUMAN PAPILLOMAVIRUS INFECTION IN CONJUNCTIVAL AND EYELID BENIGN AND MALIGNANT LESIONS

RESZEC Joanna, KODA Mariusz, SULKOWSKA Mariola, KANCZUGA-KODA Luiza,SULKOWSKI Stanislaw
Department of Pathology, Medical University of Bialystok, Waszyngtona 13, 15-269 Bialystok, Poland

Purpose: Squamous cell papillomas of eyelid and conjunctiva are common benign neoplasm of ophthalmological interest. Squamous cell and basal cell carcinomas are respectively the most common malignancy of conjunctiva and eyelid skin. Human Papillomavirus (HPV) infection as well as P53 protein function lost has been identified as frequent events in varies of human tumors.
The aim of our study was the evaluation of P53 protein expression and HPV infection in 45 benign (papillomas) and 38 malignant conjunctival and eyelid lesions (27 cases of basal cell carcinomas and 11 cases of squamous cell carcinomas).
Methods: Using monoclonal antibody for P53 protein (DAKO) performed the immunohistochemical reaction; LSAB technique and DAB detect the complex antigen-antibody. To detect HPV infection PCR-RFLP technique was performed, using specific set of primers (TaKaRa) and for identification of HPV types 16,18, 33 the PCR products were enzymatic digested at 37¢ªC.
Results: P53 protein expression was observed in 30 out of 45 (66,6%) squamous cell papillomas. In SCC and BCC groups P53 positivity was noticed in 31 out of 38 carcinomas and there was a statistically significant correlation between histological type of tumor and P53 protein expression. Malignant type HPV 16 and HPV 18 were detected in 3 squamous cell papillomas, 2 cases of BCC and 1 of SCC. However we observed P53 protein expression only in 2 HPV positive papillomas and 1 infiltrative type of BCC.
Conclusions: The results suggested P53 protein role in development of conjunctival and eyelid tumors, however the role of P53 protein in malignant transformation should be carefully investigated in the future. HPV seems to occur rarely, although in some cases it¡¯s role in pathogenesis of conjunctival and eyelid tumorigenesis should be considered.

P 576
STUDY OF KIT (CD 117) EXPRESSION IN PRIMARY UVEAL MELANOMAS AND METASTASES OF UVEAL MELANOMAS.

Lichvansceva V.G, Anurova O.A, Vereschagina M.V.

Nevertheless, uveal melanoma (UM) rate is about 1% of all human cancers, UM mortality rate is about 18% from dissemination. Comparison of these indexes let us think that UM is most malignant tumor. In the recent years with the help of immunohistochemistry it was achieved a great progress in investigation of tumor progression mechanisms. The KIT-gene encodes proto-oncogene c-kit, that has tyrosine kinase activity. Mutation in any exones of c-kit gene in tumor cells activates oncogene and stimulates production of mutant protein KIT in the lack of ligand. The result of all these mutatins is activation of mitotic activity of cells and tumor progression. Hyper expression of CD 117 detected in UM is the way of application of inhibitors of tyrosine kinases in the treatment of these tumors.

Purpose: To study CD 117expression in primary uveal melanomas and metastases of UM.

Materials and methods: Expression of c-kit was analysed in 39 paraffin-embedded sections of primary UM and 4 paraffin-embedded sections of UM metastases. Immunohistochemistry

was performed using the polyclonal anti-CD117 antibody from Dako.

Results: Immunohistochemistry for CD 117 was negative in 6 cases (15%), weakly positive in 11 cases (28%), moderately positive in 10 cases (26%) and strongly positive in 12 cases (31%) of primary UM. In 4 metastases (100%) of UM the reaction for CD 117 was strongly positive.

Conclusion: It appears justified to investigate the utility of imatinib mesylate in the treatment of these patients in clinical researches.

CENTRAL FACIAL DESTRUCTIVE GRANULOMA FOLLOWING COCAINE ABUSE

PAGLIARI Angelo Virgilio°,Klinger Francesco *, Klinger Marco *
° U.O.ORL Azienda Ospedaliera di Crema
* Istituto di Chirurgia Plastica e Ricostruttiva Università degli Studi di Milano-I.C.Humanintas

Introduction The use and consuption of cocaina by snorting and sniffing exploded into a full blown epidemic. The adverse effects of cocaine nasal passages have long been recognized. Only recently a cocaine complex mimicking the rare condition of massive facial midline necrosis is described.
Methods Four patients referred to us with extensive necrotizing lesions of naso-sinusal tract and midface are described. Diagnostic and treatment are discussed with a literature review.
Results On physiacal examination all patients had a severe crusting, granulation tissue, purulent discharge and necrosis of nasal septum, lateral cartilages and hard palate. None other medical conditions were associated. Biopsies of nasal tissue revealed chronic inflammation without evidence of vasculitis or granulomatosis. There were onion skin deposits of perivascular fibrosis with numerous eosinophils. Plasma cells and lymphocytes primary T cells were present.
Conclusion Massive facial midline necrosis continues to be a diagnostic challenge. The aetiology comprises autoimmune disorders and certain tropical diseases. We underlines as a possible cause the cocaine abuse. Ischemic necrosis due to vasoconstriction and prolonged anaesthesia may be factors causing tissue destruction.

A CASE OF : NASAL GLIAL HETEROTOPIA

JOSSELIN Nicolas(1), LACCOUREYE Laurent (2), DUBIN Jacques (2), TRIAU Stéphane (1), ROUSSELET Marie-Christine (1)
(1)Department of pathology
(2)Department of otorhinolaryngology
Hospital of Angers, 4 rue larrey- 49933 Angers

We observed a baby born at terms with an apgar of 10, presenting an inspiration dyspnea on its second day of life . Endoscopy discovered a tissular mass filling the right sinus. The imagery made favoured a teratoma.Under microscopy, areas of mature glial tissue of variable cellularity were embedded in the nasal mucous membrane. The cells of this cellularity, sometimes multi nucleic or of dystrophic aspect showed immunochemistry which varied depending on the areas of glial and neuron markers.There were not noticed numerous mitosis nor atypical cyto nuclears. The diagnosis of glial nose heterotopia was proposed.
Median congenital face malformations occur every 20000 to 40000 births. Among the most frequent, we note hemangioma, dermoid cysts, and encephaloceles. Nasal glial heterotopia is less frequent with only 250 cases observed. This pathology only concerns babies, mostly during the first month of life. After an asymptomatic period of time, the children had a weight loss which was due to alimentation problems because of nose obstruction. The location of 60 per cent of the lesions is extra nasal, 30 per cent of them is intra nasal and the remaining 10 per cent are mixed. They are probably due to confinement of an encephalocele during fœtal life which sometimes leaves a fibrous cord. Microscopically, these lesions are composed of glial tissue areas of variable cellularity made of non atypical and little proliferative astrocytes. A are association is that of a neuron component.
In presence of congenital median facial lesions, establishing diagnosis through biopsies is not indicated. Indeed in the case of encephaloceles this might open a (meningo) gap which could be responsible for a iatrogenic meningitis.
An MRA examining possible communication between intra cranial structures and lesions is compulsory before Therapeutic treatment. This consists presently of an endoscopy which avoids the complications of surgery needed by craniotomy.

P 579

CYTOGENETIC ANALYSIS OF ORAL LICHEN PLANUS

FARNEDI Anna, MAGRINI Elisabetta, PESSION Annalisa, **MONTEBUGNOLI Lucio, **MARCHETTI Claudio, FOSCHINI Maria P.
Department of Oncological Sciences, Section of Anatomic Pathology, University of Bologna.
** Department of Oral Sciences, University of Bologna.

Introduction: oral lichen planus (OL) is an inflammmatory lesion having controversial malignant potential, sometimes evolving to squamous cell carcinoma (SCC). SCC develops along a multistep pathway and thus accumulate genetic hits in functional targets relevant to tumour evolution. Recent studies suggest that chromosome instability increases with the degree of histologic changes from normal tissues to carcinomatous lesions. To date, there are no classic cytogenetic data on OL.
Purpose of the present study is to describe chromosomal alterations of a series of OL studied with classic cytogenetic technique.
Matherial and methods: fresh biopsies were divided in two specimens: one was formalin-fixed and paraffin embedded for histological and immunohistochemical analysis for p53 (DAKO, clone p53, diluted 1: 50) and Ki 67 (Dako, clone MIB-1, diluted 1:100) . The other was used for classic G-banding cytogenetic analysis on short term cultures.
20 cases having typical clinical and histological featuresof OL were obtained. No dysplasia was present in the lesions. Results were compared with 9 cases of normal gingival mucosa from tooth extraction.
On histology, all the cases showed OL typical inflammatory infiltration with basal membrane disruption, vacuolization and apoptosis of the basal cheratinocytes. Immunohistochemistry: p53 and Ki67 were expressed in 15 to 40% of basal and suprabasal cheratinocytes in OL, while they stained no more than 15% of basal cheratinocytes in normal gingival mucosa. Cytogenetic results: clonal alterations were found in 3/20 cases (gain of a chromosome 18 copy was present in two cases), while Non Clonal Alterations (NCA) were detected in14/20 cases. The most frequent NCA were: losses of chromosomes 21, 14, 9 and gains of chromosome 18. Alterations (i.e. gains and losses) involved also chromosomes 6 and 3. No clonal nor NCA alterations were found in cultures from normal gingival mucosa.
Discussion: present histological and immunohistochemical results show that, in cases of OL, oral mucosa shows a high proliferation activity. Cytogenetic analysis shows aneuploidy as the more frequent alteration, suggesting presence of chromosomal instability in these lesions. Althought we cannot identify, to date, the meaning of single gains or losses, we suggest that the chromosome instability in OL might indicate a risk of malignant transformation.

IMMUNOHISTOCHEMICAL ASSESMENT OF HEAT SHOCK PROTEIN 70 IN ADENOID TISSUE

AKTEPE Fatma*, SAHIN Onder*, DILEK Hüsniye.*, YILMAZ Deniz**, KAHVECI Orhan**, DEREKOY Sefa**
*Department of Pathology, **Department of Otolaryngology, University of Afyon Kocatepe, Faculty of Medicine, Afyon, Turkey.

Objectives: To evaluate the expression of heat shock protein 70 (HSP70) and its relation to histopathologic parameters in adenoid hyperthrophy. In addition, HSP70 expression in adenoid tissue was compared with in adult and childhood.
Materials and Methods: Parafin-embedded adenoid tissue sections were obtained from 17 childhood and 17 adult patients. Expression of HSP70 was evaluated by immunohistochemical staining using anti-HSP70 monoclonal antibody and correlated with histopathologic parameters.
Results: Positive HSP70 expression was observed mainly in the mucosal epithelium, lymphocytes in germinal centers, interfollicular lymphocytes, subepithelial plasma cells and vascular endothelium. HSP70 immunoreactivity in the metaplastic mucosal epithelium with severe intraepithelial lymphocytic infiltration was higher than in the respiratory epithelium. The decrease in plasma cells showing HSP70 positivity was corraleted with age.
Conclusions: These results suggest that intraepithelial lymphocytic infiltration is induce HSP70 expression in mucosal epithelium of adenoid.

P 581

SEVERITY OF EPITHELIAL DYSPLASIA IS ASSOCIATED WITH LOSS OF MASPIN EXPRESSION IN ACTINIC CHEILITIS

FONTES Alexandra, SOUSA Suzana, MARTINS Marília.

Introduction: Maspin is a member of the serpin superfamily of protease inhibitors and it is known to have tumour suppressor functions. It was demonstrated that maspin is expressed in normal cells, down-regulated in neoplastic cells and absent in metastatic cells. It was also inversely associated with increased dysplasia degree in mammary gland and gastric epithelium. Maspin is expressed in oral squamous cell carcinoma associated with a favourable prognosis. Actinic cheilitis is a potentially malignant lesion that is caused by long exposure to sunlight. Many authors consider that lip squamous cell carcinoma is always preceded by actinic cheilitis. Histologically this lesion is characterized by different degrees of epithelial dysplasia.
This study had the aim of evaluating the maspin expression in actinic cheilitis and comparing the findings to the degree of epithelial dysplasia.
Material and methods. Twenty nine cases histologically diagnosed as actinic cheilitis were retrieved from our files. The cases were represented by 13 cases with mild epithelial dysplasia, 9 moderate, and 7 intense dysplasia. The sections were submitted to the anti-maspin antibody (BD Pharmingen, 1:100) using the streptavidin-biotin method of immunohistochemistry. Immunostaining was semi-quantitatively evaluated and graduated: 0 (no staining), 1 (<5% of cells positive), 2 (5 to 50% of cells positive), 3 (<50% of cells positive).
Results: All the cases with mild dysplasia were graduated 3. In moderate dysplasia 2: 66.6% were graduated 2 and 33.3% received 3. All the cases with intense dysplasia were graduated 1. When the extent of staining was evaluated in the different epithelial layers, it was possible to notice that basal layer was abundantly stained only in 5 cases of mild epithelial dysplasia. In the other cases this layer showed scattered or no cells positive for maspin. In general, positivity in the layers decreased with the increase of atypias, from the basal to the surface.
Conclusions: Maspin expression was very abundant in actinic cheilitis with mild dysplasia and this expression decreased with the increase of the dysplasia degree. The first layer to lose maspin positivity was basal layer and successively upper layers lost positivity with the increased degree of dysplasia. In conclusion, this data suggests that in actinic cheilitis maspin expression is inversely related with progression of the lesion towards malignancy.

4-Endocrine Research Center, Shaheed Beheshti University of Medical Sciences
5-School of Medicine, Shiraz University of Medical Sciences

Study objective: To investigate whether iron supplementation can improve thyroid hormone function in iron-deficient adolescent girls.
Design: A double-blind intervention study.
Setting: The study was performed in 2002 through 2003 in a region in southern I.R.Iran.
Subjects: A total of 103 iron deficient subjects that fulfilled all of the inclusion criteria were chosen. In all 94 subjects successfully completed this study.
Interventions: Patients were randomly assigned to one of two groups and treated with a 300 mg ferrous sulfate 5 times/week (n=47) and placebo 5 times/week (n=47) for 12 weeks.
Main outcome measures: At the beginning and at the end of study blood samples were collected and assayed for hemoglobin, hematocrit, serum ferritin, iron, total iron binding capacity (TIBC), Thyroid stimulating hormone (TSH), total thyroxine (TT4), total triiodothyronine (TT3), free thyroid hormones (FT4 and FT3), triiodothyronine resin uptake (T3RU), reverse triiodothyronine (RT3), selenium and albumin concentrations.
Results: There was a significant increase in iron indices in iron treated group after intervention. Indices of thyroid at the end of study revealed a significant increase in TT4, TT3, T3RU, and a significant decrease in rT3 concentration in comparison to initial values in iron treated group, and a significant difference when compared to placebo group. Alterations in FT3 and TSH concentration were not significant, but concentration of FT4 revealed a significant difference between beginning and end of the study in iron treated group.
Conclusions: Our results indicate that improvement of iron status was accompanied with improve in some indices of thyroid hormones.

ANALYSIS OF PARAFOLLICULAR-C CELLS IN POLYNODOSE COLOID GOITRE OF THYROID GLAND

Ljiljana Vuckovic, Marija Havelka, Svetislav Tatic, Zivka Eri, Istvan Klem, Dragutin Savjak, Slavica Usaj Knezevic, Mileta Golubovic, Filip Vukmirovic, Tatjana Nenezic

INTRODUCTION: C cells of thyroid gland belong to a diffuse neuroendocrine system of the organism. There are different data in literature about usual normal number of C cells in thyorid gland. Colloid goitre is an after effect of an insufficient synthesis of thyorid hormones, and it results with assembling of great quantities of inactive colloid in follicules. Diameter of follicules becomes larger and due to the pressure, the height of follicular cells decreased. As the illnes progresses, the thyorid gland are enlarged at first diffusing and then due to the increase of connective tissue, a nodes is created.
PURPOSE: A connection between a number of C cells and height of follicular cells, size of follicules and quantity of colloid in polynodose colloid goitre of thyroid gland were analysed.
MATERIALS AND METHODS: There were analysed 96 polynodose colloid goitres, which were operated from year 2001 to 2004. The slides were fixed in formaldehyde and formed in paraffin blocks, and then they were colored with hematoxilin-eosin and immunohistochemical coloring on calcitonin.
RESULTES: The sample wes devided into groups, according to C cells and height of follicular cells, size of follicules and quantity of colloid, and all the resultes are semiquantitative. The results were statistically elaborated and they show high statistic significanse of C cells connection with height of follicular cells, although there is no significant connection between C cells and follicules size and quantity of colloid in observed sample.
DISCUSSION AND CONCLUSIONS: It is possible to conclude, according to the final data, there is a connection between C cells and height of follicular cells in polynodose colloid goitre of thyroid gland, but there is no connection with size of follicules and quantity of colloid.

CONCOMITANT USE OF FINE-NEEDLE BIOPSY AND LARGE-NEEDLE BIOPSY IN THE DIAGNOSIS OF THYROID NODULES
MIZUKAMI Yuji, *MICHIGISHI Takatoshi, TAKEMURA Akihiro, ONOGUCHI Masahisa, TAKAYAMA Teruhiko
Department of Radiological Technology, School of Health Sciences, *Department of Nuclear Medicine, Faculty of Medicine, Kanazawa University

Fine-needle asplration biopsy (FNA) and large-needle (cutting) biopsy (LNB) were performed on 109 patients with thyroid nodule or goiter who later underwent thyroidectomy. FNA alone provided a correct diagnosis in 84 (77%) of the 109 cases and LNB alone in 84 (77%) of the 109 cases, with the two methods yielding the same accuracy rate. Ninety-nine (91%) of the 109 cases were diagnosed correctly when both results were considered together. As to the causes for the discrepancies between the FNA or LNB results and the corresponding surglcal diagnoses, the most common one was cytologic interpretive errors and, in descending order, insufficient material and sampling errors in FNA. On the other hand, in LNB, histologic interpretive errors were less but sampling errors were more frequently found compared with FNA. The present study indicated a need to concomitantly perform FNA and LNB in the diagnosis of thyroid nodules. Careful attention is required to distinguish between the follicular variant of papillary carcinoma and follicular adenoma, between encapsulated follicular carcinoma and follicular adenoma, and between malignant lymphoma and chronic thyroiditis at FNA as well as LNB diagnosis.

COINCIDENCE OF HYPERPARATHYROIDISM AND THYROID CANCER FOUND AT THE TIME OF PARATHYROIDECTOMY
CEROVIC Snezana, IGNJATOVIC Mile*, BRAJUSKOVIC Goran, KNEZEVIC USAJ Slavica, HRVACEVIC Rajko**
Institute of Pathology, * Clinic of Surgery and ** Clinic of Nephrology, Military Medical Academy, Belgrade, Serbia and Montenegro

INTRODUCTION: A few reports have suggested an association between hyperparathyroidism (HPT) with thyroid cancer (TC) previous to surgery. Synchronous thyroid disease was found in 7% to 18% of primary HPT patients undergoing surgery, while 12% of thyroid lesions were found to be malignant. Association between non-medullary TC and primary HPT has been frequently reported. There is also some evidence for an association between secondary and tertiary HPT and thyroid cancer.
METHODS: This is a retrospective study of all cases of thyroid cancer in association with parathyroid disease treated surgically in our hospital from January 2000 to January 2004.
RESULTS: There were 280 surgical procedures for HPT in 274 patients. All patients had an elevated preoperative serum level of parathyroid hormone and serum calcium levels. Intraoperatively, 4 parathyroid adenomas and 270 parathyroid hyperplasia were diagnosed. In 50 patients (18.2%) thyroid resection was performed simultaneously. Three patients (1.1%) were found to have papillary thyroid cancer at the time of parathyroidectomy (PTX): one patients had primary HPT, one patients had secondary HPT, and one patient had tertiary HPT. Two cases were associated with metastatic spread to local lymph nodes. In those cases, total thyreodidectomy was performed, and frozen section revealed a small papillary microcarcinoma (diameter< 1cm in size). None of the patients with thyroid cancer had a prior history of head and neck irradiation .
CONCLUSION: These data suggest that the association between thyroid cancer and HPT is rare and coincidental. The association of simultaneous pathology in the two glands justifies preoperative thyroid imaging and fine-needle aspiration (FNA) biopsy to determine the best surgical approach for patients with HPT.

AN UNUSUAL NODULE OF THE THYROID: ECTOPIC MICROINVASIF THYROID THYMOMA OF AB TYPE(MIXTE)
Compérat Eva (1), Dinu Carmen (1), Menegaux Fabrice (2), Rouxel Agnes (3), Capron Frederique (1), Hoang Catherine(1).
(1) Service d'Anatomie et Cytologique Pathologique,
(2) Service de Chirurgie Générale Digestive et Endocrinienne
(3) Service de Médecine Nucléaire
CHU-Est La Pitié Salpetrière, Paris.

We report a rare case of ectopic thyroid thymoma of AB type. A 56 years old patient presented a left sided thyroid nodule discovered by palpation. Scintigraphic examination displayed a cold nodule, which measured 38 mm. Strong adhesion with the left loge was observed; the nodule predominated in the inferior pole of thyroid gland. Histologically the proliferation corresponded to a thymoma of AB type with neoplasic embols and extension to the adjacent adipous tissue. The jugulo-carotidic pick-up did not find any metastatic lymph nodes.
Ectopic cervical thymoma is a part of epithelial tumors with thymic differentiation of the neck. Incomplete descending or persistence of the cervical part of thymus is considered as the origin of ectopic thymus. These tumors are revealed by more or less compressive cervical masses without paraneoplasic syndromes. They present the same histological sub-types as their mediastinal homologue, but do not show any genetic anomaly. Differential diagnostic problems might be seen by extension of a mediastinal thymoma to cervical region, with an undifferentiated carcinoma, squamous cell carcinoma or

with lymphoma. Evolution remains local; relapses are never seen if surgery is complete. No prognostic factor is known nowadays.

P 587
CONNECTION OF THE LYMPHOCYTES PHENOTYPE AND PROTEIN OF APOPTOSIS IN LYMPHOCYTIC THYROIDITIS
Ljiljana Markovich MD PhD, Jelena SoptaMD PhD,Mirjana Atanackovich MD PhD,

In persons diseased on thyroiditis the number and function of CD8+ lymphocytes have been normal.It has been shown that iodide induces apoptosis of thyroid cells in culture and demonstrated that KI can do the same to rats with induced goiter. Impairment Bcl-2 and Bax genes on thyrocytes, have been detected as a direct consequence of administration of of iodine in potassium iodide-KI. Wistar rats having been receiving KI, KCl, NaI or NaCl. The Determinations of Peripheral Blood and Thymocyte Subpopulations of Rats have been done by FACScan.The double staining used FITC (CD8).and SA-PE(CD4). Immunohistochemical staining have been done with DAB on avidin-biotin and peroxidase using ARK, stained them with antibodies to:Bcl2 oncoprotein and Bax.We evaluated the intensity and distribution of positive DAB staining on a scale of 0 to 4.We perform statistic analisis by ANOVA and Student T-test.The histological analyses of thymus, spleen and thyroid have shown the changes in the thyroid as a diffuse mononuclear cell infiltration in the follicles and in the spaces between destruction of the acini, proliferation of connective tissue have been seen began between 5th and 10thday.So KI induced the symptomless LT in rats.Significant differences between individual groups ($p > 0.05$) nor in comparison to the non-treated controls ($p > 0.05$)has not been presented .Bcl-2 and Bax gene expression was significantly higher in rats with LT iodine induced and correlated with the extent of lymphocytic infiltratio. Bcl-2-expression was constantly seen in regular thyrocytes and in the mantle-zone of lymphofollicular infiltrates.Bcl-2 and Bax gene expression were not in conection with lymphocyte subgroups in peripheral blood. This work was partiali supported by MNS of Serbia, grant 1997

Hyalinizing trabecular tumor (HTT) of the thyroid is a rare tumor of follicular cell origin with a trabecular pattern of growth and marked intratrabecular hyalinization. The etiology of HTT is unknown but nuclear features, association with conventional papillary carcinoma, and RET/PTC rearrangements in some of these tumors suggest a relationship with papillary thyroid carcinoma. The majority of studies find that RET/PTC rearrangements and BRAF mutations are mutually exclusive in papillary carcinomas; however, one study considered that BRAF mutations may cooperate with RET/PTC rearrangements in the development of papillary carcinoma. RET/PTC rearrangements were detected previously in 28.6-75% of HTT. We examined six hyalinizing trabecular adenomas and two hyalinizing trabecular carcinomas for BRAF mutations All tumors showed positivity for thyroglobulin and TTF-1 and lacked immunoreactivity for calcitonin, chromogranin A, and synaptophysin. DNA was isolated from paraffin-embedded tumor tissues and the exon 15 of the BRAF gene was sequenced directly. No mutations were found in any tumor samples analyzed. Our results show that BRAF mutation do not seem to play, at variance with RET/PTC, a role in the etiopathogenesis of HTT (neither the typical V600E mutation nor the mutation associated to the follicular variant of PTC-K600E, was detected in any HTT). This work was supported by research grant (PGIDE 99PXI 90201B) sponsored by Xunta de Galicia, Spain.

THYROID FNA – QUALITY CONTROL
VILCHEZ JOse*, MANITA Isabel**, SARAIVA Catarina**, SANTOS Sofia*, PORTUGAL Jorge** and BRITO Maria-Jose*
Departments of Histopathology* and Endocrinology**
Hospital Garcia de Orta, Almada, Portugal

Introduction: Thyroid FNA is a widely available diagnostic method with different results according to different series.
Aim: To evaluate thyroid FNA diagnostic accuracy (DA), sensitivity (S), specificity (Sp), false negative (FN) and false positive (FP)values and predictive values, positive (PPV) and negative (NPV), in the present series.
Material and methods: All thyroid FNA performed between April 2000 and December 2004 (n=1044)were rewied and compared with histological diagnosis in 148 cases. Patients age varied between 11 and 85 years old, 87.74% were females.
Results: FNA were classified as diagnostic in 70.2%: 707 benign (goitre and thyroiditis) and 26 malignant (papillary carcinoma, medullar carcinoma and lymphoma); 29.79% were non diagnostic: 36 undetermined (follicular tumour and suspicious) and 12 insufficient. In 148 cases histological diagnosis was available: 83 corresponding to negative FNA, 17 to malignant FNA, 36 to undetermined FNA and 12 to insufficient FNA. FN (n=5) and FP (n=1) were 23.8% e 1.3%, respectively. The PPV was 94.1%, NPV was 93.9%, S was 76.2%, Sp was 98.7% and DA was 94.0%.
Conclusions: Our findings are in the range reported in literature. FNA is a good diagnostic tool in our hospital.

Institute of Pathology and Phisyology,Medical School,Kragujevac,Serbia and Montenegro
Clinic of Oncology,Medical Center Nis,Serbia and Montenegro

The mechanizm of the influence of lower level of thyreoid hormons on breast tissue is not enough explored.There is a suggestion in literature that the deficit of thyreiodea can predispose the development of the breast tumor.
The aim of our work is the influence of partial thyreidectomy on mammary glands of the rat.
We used for experiment virgo female albino Wistar rats,weight 120±10gr.,45 days old.The animals were treated with ethar narcosis during the partial thyreoidectomy.There were 18 rats as well as in the control group.The animals were sacrified after 70 days and there was used a tissue of the breast for PH analisys.
All specimens were fixed in Bouins solution.The tissue was embedded in paraffin wax,and sections were cut at 4-5 micrometar and stained with HE and immunocytochemical ABC-method with antibodies against beta TSH,EGF and PNA-lectin.

The significate hyperplasion of the acinus and ductulus was observed with PH analysis.until they looked kike microadenoma.In cytoplasma of the cell there are present a large number of vesiculas wich are often confluence,forming an macrodroped aspect.Mastocits,hypergranulated and polymorph,are present in the lipomatosa stroma around ductulus and acinus.
In comparision to normal mammary gland,in epithel of hyperplastical acinuses and ductuluses was found beta TSH,PNA-lectin and EGF.
Exept in epithel of the hyperplastical acinuses and ductuluses,EGF is found also in fibroblasts and fibrocites and in the epithel of the acinuses and ductuluses in mammary glands of control group of rats.
In this work we discuss about the mechanizm of the influence of the deficite of thyreoidal hormones on the mammary gland of the rats,as well as the influence of breast carcinogenesis.

OVEREXPRESSION OF EPIDERMAL GROWTH FACTOR RECEPTOR IN THE SOLID CELL NESTS OF THE THYROID AND THE CYSTIC TUMOR OF THE ATRIOVENTRICULAR NODE OF THE HEART

CAMESELLE-TEIJEIRO José1, ALFONSÍN-BARREIRO Natividad2, ABDULKADER Ihab1, PRETO Ana3, SOARES Paula3, REYES-SANTÍAS Rosa1, SOBRINHO-SIMÕES Manuel3
1Department of Pathology, Hospital Clínico Universitario, University of Santiago de Compostela, Santiago de Compostela, 2Department of Pathology, Hospital do Meixoeiro, Vigo, Spain; 3Institute of Molecular Pathology and Immunology, University of Porto, Porto, Portugal

Solid cell nests (SCNs) are a normal component of the human thyroid gland that play a putative stem cell role. The cystic tumor of the atrioventricular node (CTAVN) of the heart is a benign cystic mass located at the base of the atrial septum of the heart, in the region of the atrioventricular node. Recently, we proposed that CTAVN of the heart is the cardiac equivalent of the SCNs (ultimobranchial rests) of the thyroid. Both entities are identical and basically composed of solid and/or cystic nests of squamoid cells (main cells) with a minor population of neuroendocrine cells (C cells). Epidermal growth factor (EGF) has widespread growth effects, and overexpression of EGF and epidermal growth factor receptor (EGFR) were found in dyshormonogenetic goiters, follicular adenomas, and well differentiated and undifferentiated (anaplastic) carcinomas of the thyroid. For this reason we investigated a series of seven cases of SCNs and one of CTAVN immunohistochemically with a mouse monoclonal antibody directed against EGFR (EGFR pharmDX kit, DAKO). In all cases, the main cells of SCNs and CTAVN revealed a distinct membranous staining pattern with weak cytoplasmic reactivity. Normal follicular cells were totally negative for this staining. The overexpression of EGFR fits with our previous findings of a higher proliferative index in main cells and supports the idea of these structures having an active biological role. This work was supported by a research grant (PGIDE 99PXI 90201B) sponsored by Xunta de Galicia, Spain.

COX2 AND MULTIDRUG RESISTANCE PROTEIN 2 (MRP2) IN MEDULLARY THYROID CARCINOMAS (MTC).

RUGGERI Rosaria Maddalena1, SCIACCHITANO Salvatore2-3, VITARELLI Enrica4, TRIMARCHI Francesco1, BENVENGA Salvatore1, BARRESI Gaetano4, TROVATO Maria1-4.
1Sezione di Endocrinologia - Dipartimento Clinico Sperimentale di Medicina e Farmacologia, University of Messina, Messina, Italy;
2II Facoltà di Medicina e Chirurgia, Osp. S.Andrea, Università La Sapienza di Roma, Rome, Italy;
3Centro di Ricerca Osp.S.Pietro Fatebenefratelli, AfaR, Rome, Italy;
4 Dipartimento di Patologia Umana, University of Messina, Messina, Italy.

The characterization of the mechanisms regulating the expression of multidrug-resistance proteins (MRPs) is crucial to plan an adequate treatment of cancers that display different degrees of resistance to chemotherapic drugs. COX2, a key enzyme in the conversion of arachidonic acid to prostaglandins, is an up-regulator of a MRPs member, namely, MPRP-1. To determine whether COX2 is a potential regulator of MRP2 in MTC we evaluated the expression of MRP2 and COX2 in MTC.
We investigated the expression of MRP2 and COX2 in 12 MTC nodules, 10 colloid nodules and 6 normal thyroids by immunochemistry. The 22 nodules were studied paired with the adjacent non-nodular (normal) tissue.
Only MTC nodules showed immunoreaction: 9/12 (75%) were positive for MRP2 and 12/12 (100%) for COX2. The proportion of MRP2 positive cells (10% to 40%, mean 25%) was inversely related with the proportion of COX2 positive cells (10 to 100%, mean 54%); $r = 0.96$, $P < 0.05$. Both immunoreactions exhibited levels of intenstity from moderate to strong and were localized on the apical side pertaining to plasma membrane (MRP2) and to cytoplasm (COX2).
The results indicate that COX2 is a possible regulator of MRP2 expression in MTC and suggest its role in the limited response to chemotherapic agents.

P 593

THE SURVEY OF PATHOLOGICAL LESIONS IN THE AUTOPSY OF THYROID GLAND, ISFAHAN ,IRAN.

REISIFAR Malek, NAJAFI Farideh,NAJAFI Mohammad Reza

Background;thyroid gland autopsy is the suitable and exact way to consider the morphology of thyroid gland.
methods;this study is descriptive-analytic type.The thyroid gland were dissected carefully,weighthed and measured and fixed in %5 formalin for 72h and sliced for microscopic examination and histopathologic study by two pathologists.
Results;251 whole of thyroid glands were collected at autopsy who had no known cilnical history of thyroid disease(208 m;43 f,ratio4:84) and intend in anatomic study and 202 whole thyroid glands (159 m and43 f,ratio 3.7)were collected in pathologic study.normal histopathology in125case (4.85%) goiter 41cases (20.3%;nodular,diffuse) thyroididtis 22 ;neoplasia 15cases (12 papillary carcinoma and 3 follicular adenoma).
conclosion;normal thyroid gland can be lead cilnicaly to the great pathological finding in microscopic study in consideration of high malignant incidence and occult carcinoma.We should pay more attention to the smallest findings during clinical examinations in Isfahan city toward the other parts of the world such as Brazil.

PATTERN OF THYROID CARCINOMA AMONG UNITED ARAB EMIRATES NATIONALS A CLINICOPATHOLOGIC STUDY

* AL-SALAM Suhail , EL-TERAIFI Hassan **
* Pathology department, Faculty of medicine and health sciences, United Arab Emirates University, AlAin, UAE
** Pathology department, Twam Hospital, AlAin, UAE

Introduction

The United Arab Emirates (UAE) is a union of seven sovereign sheikhdoms of the Arabian Gulf, which was formed

in 1971. These sheikhdoms or emirates include Abu Dhabi (the largest), Ajman, Dubai, Fujairah, Ras AlKhaima, Sharjah and Um Al Quwain. Although the total population is estimated to be 4 millions, only about 600,000 people are 'nationals' or natives of the country, the rest representing an extensive expatriate population. The national or indigenous population is composed of Emirate Arabs who, historically, were registered into tribes that included pastoral nomads and small agricultural settlements .Thyroid cancer is the most common endocrine malignancy. In the UAE thyroid cancer is the sixth most common cancer among nationals and the second among females .

Objective:

The aim of this study is to analyze the distribution of various pathologic types of thyroid carcinomas in a native Arab population of the United Arab Emirates (UAE) at Twam hospital in AlAin.

Materials and methods:

Forty-nine patients with thyroid carcinoma diagnosed over a 14-year period (1991-2004) at Tawam Hospital ;the main oncology center in UAE were retrospectively studied clinically and morphologically and classified according to the World Health Organization (WHO) histologic classification .

Results

Forty-four patients (90%) were diagnosed before the age of 45 years with a mean age of 35.5 years. The overall peak incidence was in the 3rd decade. There was a high female to male ratio comprising 11:1.Of the 49 patients in the study, 86 % had papillary thyroid carcinoma (PTC), 12% had follicular thyroid carcinoma (FTC) and 2% had anaplastic thyroid carcinoma.

Conclusions

Thyroid carcinomas in the UAE are more common among females than males with a very high female to male ratio suggesting that female gender is a possible risk factor in their development. Since most of our cases were diagnosed before the age of 45 years; with expected good prognosis, the age before 45 years can be considered as an important prognostic factor as well as a possible risk factor. PTC predominates the histologic pattern of thyroid carcinoma in UAE, which is usually associated with iodide sufficient area.

P 595

ANAPLASTIC THYROID CARCINOMA IN A 14-YEAR-OLD CHILD. CASE REPORT.

Lange D, Wloch J, Szalecki M, Jarzab M, Nikiel B, Jarzab B.
Centre of Oncology, M.Curie-Sklodowska Institute, Gliwice, Poland

Anaplastic thyroid carcinoma is a highly malignant tumor with peak incidence during the sixth and seventh decade of life. The youngest patient described so far was 22 years old. A 14-year-old boy was admitted to the hospital in Kielce. Physical examination revealed in the right thyroid lobe a painless resilient tumor of 1.5 cm in diameter. A FNA biopsy was performed revealing the presence of atypical pleomorphic cells, arousing suspicion of medullary or papillary carcinoma. Chest X-ray showed numerous oval metastatic foci as well as enhanced stroma architecture. The patient had been referred to the Institute of Oncology in Gliwice. The patient underwent ADM+CDDP chemotherapy. Because of epilepsy onset, magnetic resonance was performed revealing numerous metastatic foci in the brain. Despite further chemotherapy the metastases in the central nervous system continuously progressed. The patient died on November 24, 2001, 17 months after initial diagnosis. Pathologic evaluation. In cross-sections of the right lobe a weakly separated tumor was found (2.0 cm in diameter). In microscopic assessment the majority of tumor texture was formed by anaplastic spindle-shaped cells with pleomorphic hyperchromatic nuclei. Numerous mitotic figures were seen. Foci of extensive necrosis and extravasated blood were noticeable in regions with anaplastic texture. Neoplastic texture fully occupied by anaplastic cancer with extensive necrosis was present in 4 lymph nodes measuring from 0.5 to 1.0 cm in diameter. Immunohistochemical study.In a few tumor cells showing features of papillary cancer thyroglobulin immunoassay was positive. The same tumor areas showed also expression of cytokeratin AE1/AE3 and cytokeratin 19. A weak reaction with cytokeratin was observed in some anaplastic cells both in the primary tumor and in node metastases. The majority of cancer cells present in metastases did not show, howeverthe presence of thyroglobulin. The fields of anaplastic, spindle-shaped cancer cells showed expression of p53 protein in ca. 50% of cell nuclei. Anaplastic histological features of the discussed neoplasm have been confirmed by the lack of reaction with TTF-1, a minimal reaction with thyroglobulin antibody and a very high, above 70% MIB-1 index in anaplastic fields of tumor. It appears symbolic that the birth date of a first child who died from anaplastic thyroid cancer is the same as the date of the Chernobyl disaster.

P 596

INSULAR CARCINOMA OF THE THYROID GLAND IN CHILDREN.

Rotin D.L., Pavlovskaya A.I., Savelov N.A., Smirnova E.A.
N.N. Blokhin Cancer Research Center RAMS, Moscow, Russia

INTRODUCTION: Insular carcinoma of the thyroid gland represents poorly differentiated tumors that are relatively infrequent. It is even rarer tumor in pediatric patients. It is written that this neoplasm occurs predominantly in patients elder than 50-60 years old. Currently, insular carcinoma is considered to be a tumor with very poor and unfavorable prognosis.

MATERIALS AND METHODS: We collected and investigated surgical thyroid specimens from 5 patients (age 9 to 15) with insular carcinoma. These specimens were routinely processed, stained with HE, PAS, van Gieson. Ultra structural and immunohistochemical investigations with monoclonal antibodies to vimentin, citokeratins, chromogranin A, thyroglobulin, calcitonin and Ki-67 were also performed. All case reports and follow-up were carefully evaluated.

RESULTS: The careful histological examination revealed the presence of insular pattern mixed with more differentiated (either papillary or follicular) thyroid carcinoma. We found no significant areas of necrosis in all cases, so peculiar and usual for this tumor. Ultrastructurely, all the features of follicular-cell differentiation were found. Immuhistochemically, all cases were positive for thyroglobulin, vimentin and citokeratins. In majority of tumors the activity of proliferation, evaluated by means of Ki-67 expression, was moderate to high. All these tumors were negative for calcitonin, chromogranin A. Clinically, no evidence either of distant metastasis or of local recurrence was seen in all 5 cases. Whole this group of patients is still alive, showing post-operative survivence from 2 to 5 years.

CONCLUSION: Insular carcinoma of the thyroid gland is very rare neoplasm in children and adolescence. In this age group it tends to have more favorable prognosis than it does in adults, where it often shows the evidence of distant metastasis and recurrence.In other words, the biological behavior of insular carcinoma in pediatric patients tends to have better than it seems by means of its histological appearance.

P 597

CYCLOOXYGENASE-2 IN NORMAL, HYPERPLASTIC, AND NEOPLASTIC FOLLICULAR CELLS OF THE HUMAN THYROID GLAND

GARCÍA-GONZÁLEZ Miguel, ABDULKADER Ihab, VÁZQUEZ BOQUETE Angel, LENS NEO Xosé Manuel, FORTEZA Jerónimo, and CAMESELLE-TEIJEIRO José
Departments of Nephrology and Pathology, Hospital Clínico Universitario de Santiago de Compostela

This study was undertaken to investigate cyclooxygenase-2 (COX-2) expression in follicular cells of the human thyroid. COX-2 expression was studied immunohistochemically in a total of 174 samples. COX-2 immunoreactivity was confined to the cell cytoplasm with the nuclei remaining unlabelled. COX-2 expression was observed in 5 cases (17.2%) of normal follicular cells and in one case (16.6%) of solid cell nests. Follicular carcinoma expressed COX-2 more frequently than follicular adenoma (93.4% vs. 21.1%) ($p<=0.001$). A higher percentage of cases of papillary microcarcinomas up-regulated COX-2 in comparison with all papillary carcinomas ($p<=0.05$). However, we could not establish any relationships between COX-2, patients' ages or lymph node metastases in papillary carcinomas. COX-2 expression was found in 12 (92.3%) poorly differentiated carcinomas and in 13 (92.8) undifferentiated carcinomas. We found that COX-2 is not always useful as a marker of malignancy. Our results suggests that COX-2 plays a role in progression of all thyroid carcinomas but, in papillary carcinomas, seems more important only in the early stages. COX-2 expression in the undifferentiated carcinoma deserves special consideration due to its prognosis and to the fact that selective COX-2 inhibitors were found to enhance tumour response to radiation in some studies. This work was supported by research grant (PGIDE 99PXI 90201B) sponsored by Xunta de Galicia, Spain.

CONCOMITANT GLOBAL DNA METHYLATION EVALUATION AND GALECTIN-3: POTENTIAL TOOL IN DIFFERENTIAL DIAGNOSIS OF THYROID NEOPLASIA

GALUSCA Bogdan 1,5, DUMOLLARD Jean Marc 2,4, VAUNOIS Brigitte 2, PRADES Jean Michel 3, ESTOUR Bruno 1, PEOC'H Michel 2,4
1 Endocrinology Department ; 2 Pathology Department ;3 ORL Department , CHU, Saint Etienne, France ; 4 EA6063, Inserm, Saint Etienne, France ; 5 Endocrinology, UMF Gr.T.Popa, Iasi, Romania

Introduction. The implications of global DNA hypomethylation were lately reported in several models of tumorigenesis. Little is known about this epigenetic event in thyroid neoplasia.
Over the last few years galectin-3 was promoted as an overall differentiating solution of thyroid nodules but it was also described limits of this marker regarding the follicular neoplasia differentiation.
This study aimed to evaluate concomitantely the status of global DNA methylation and galectin-3 in several types of thyroid tumors in order to define the diagnosis potential of this combination.
Materials and methods. 5-mc and galectin-3 immunostaining scores were evaluated by computerized image analysis in 17 papillary thyroid carcinomas (PTC), 6 follicular thyroid carcinomas (FTC), 16 follicular adenomas (FA), 19 nodular goiters (NG) and 10 Hürthle cells adenomas (HCA).
Results. We found a significant lower level of 5-mc immunostaining in thyroid carcinoma when compared with benign tumors or adjacent normal thyroid parenchyma ($p<0.0001$). Overall, 5-mc accuracy to distinguish malign from benign thyroid tumors was similar to that of galectin-3 (89% vs. 87%, $p>0.05$). The combination of 5-mc with galectin-3 lead to an excellent accuracy level of 96%. Among follicular neoplasia 5-mc accuracy to differentiate malign tumors trends to be higher than galectin-3 one (90% vs 66%, $p=0.06$).
Conclusions. These data stress out the necessity of epigenetic events evaluation among thyroid nodules and propose global DNA methylation assessment as a complementary diagnostic tool.

HBME - 1 MONOCLONAL ANTIBODY IN DIFFERENTIATION OF BENIGN AND MALIGNANT THYROID LESIONS

Mojgan Mokhtari , assistant professor of pathology Isfahan universisy.
Ardeshir Talebi, assistant professor of pathology Isfahan universisy.
Magid Sadeghi , Pathologist.

Abstract:
Introduction:
Monoclonal antibody HBME-1 was prepared using cells from an epithelial malignant mesothelioma as immunogen. It is an antimesothelial monoclonal antibody that recognized an unknown antigen on microvilli of mesothelial cells. The antibody is only relative specific for mesothelium and is helpful in the differential diagnosis between mesothelioma and adenocarcinoma, within the context of an appropriate immunohistochemical panel.Thyroid lesions have high incidence in human and distinction between benign and malignant lesions is very important for surgical approach.
In the past the only reliable method for diagnosis was H&E staining.
Purpose of the study:
The purpose of this study was to evaluate HBME1 monoclonal antibody staining for diagnosis of benign and malignat thyroid lesions.
Methods used:
This is an analytical descriptive study.90 formalin fixed and paraffin embedded thyriod lesions (45 benign and 45 malignant) were examined by immunostaining and light microscopy.Data were analysed with chi-square test and P value lower than 0.05 was determined significant.
Summary:
We found strong positive staining in the majority of papillary carcinoma (28/31), in some of follicular carcinoma (4/6), in a few follicular adenoma (2/17) and negative staining in oxiphilic cell adenoma (0/4), nodular goiter (0/13) and undifferentiated carcinoma(0/8)and thyroiditis(0/11).
Conclusion:
The results suggest that monoclonal antibody HBME-1 is useful in differentiating papillary and follicular carcinoma of the thyroid from benign lesions especially in more differentiated lesions. Strong and generalized immunoreactivity for HBME-1 in a follicular lesion should raise the suspicion of malignancy, but negative staining specially in poorly differentiated lesion does not rule out malignancy.

DIAGNOSTIC VALUE OF GALECTIN-3, HBME-1, P27, CYCLIN D1, CYTOKERATIN19, AND HIGH MOLECULAR WEIGHT CYTOKERATIN IN THE DIFFERENTIAL DIAGNOSIS OF THYROID TUMORS

Kyoung-Bun Lee, Hye Seung Lee, Jin Haeng Chung, Gheeyoung Choe, Seong Hoe Park, So Yeon Park.
Department of Pathology, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Gyeonggi, Korea

The distinction of benign and malignant thyroid tumor is critical for the management of patients with thyroid nodules. Immunohistochemical markers, such as galectin-3, HBME-1, p27, cyclin D1, cytokeratin19 (CK19) and high molecular weight cytokeratin (HMWCK) have been suggested to be helpful in the distinction of thyroid malignancy and papillary

thyroid carcinoma. We applied immunohistochemical staining in 262 surgically resected thyroid nodules including 181 papillary carcinomas (PC; 147 conventional papillary carcinomas [CPC] and 34 follicular variant of papillary carcinomas [FVPC]), 22 follicular carcinomas (FC), 25 follicular adenomas, and 34 nodular hyperplasias, to determine the diagnostic accuracy of these markers. The expression of all markers was significantly associated with thyroid malignancy. The sensitivity for the diagnosis of thyroid carcinoma was 97.0% for galectin-3, 90.6% for HBME-1, 82.8% for p27, 63.5% for cyclin D1, 90.6% for CK19. The specificity of these markers was 93.2%, 71.2%, 76.3%, 86.4% and 79.7%, respectively. Among the four benign nodules which showed focal galectin-3 positivity, none showed staining to HBME-1, cyclin D1 and CK19. In comparison of PC and FC, the expression of galectin-3, cyclin D1, CK19 and HMWCK was significantly higher in PC than in FC. When comparing FVPC with FC, the expression of CK19 and HMWCK was significantly higher in FVPC. However, CK19 showed focal positivity in 32% and diffuse positivity in 9% of FC. Although the expression of HMWCK was confined to PC, the sensitivity for the diagnosis of PC was only 58.6%. In comparison of CPC and FVPC, the expression of galectin-3, HMWCK, cyclin D1 was significantly higher in CPC than in FVPC. We concluded that although galectin-3 has limitation due to focal staining in benign lesion, it is a useful marker in the distinction of benign and malignant thyroid tumors, especially when used in combination with HBME-1, CK19 and cyclin D1. CK19 and HMWCK can be aided in the diagnosis of PC. However, the low sensitivity of HMWCK and low specificity of CK19 may limit its utility.

P 601

IMPACT OF ACTIVATING BRAF MUTATION ON AGGRESSIVENESS IN PAPILLARY THYROID CANCER

Jin-Man Kim1 ,Young-Suk Jo, Jun-Chul Lee, Ki-Hyun Kwon, So-young Rha, Hyo-Jin Lee, Bon Jeong Ku, Young-Kun Kim, Heung-kyu Ro,Minho Shong
Departments of Pathology1 and Internal Medicine, Chungnam National University College of Medicine, Daejeon, Korea

Activating mutations in the BRAF kinase gene have recently been reported in human papillary thyroid cancers. The aim of the present study was to determine the frequency of BRAF mutations in thyroid cancer and their correlation with clinicopathological parameters and various immunohistochemical markers including VEGF. We analyzed exon 15 of BRAF gene in 190 frozen or paraffin-embedded thyroid tumor tissues. A missense BRAF mutation was found in exon 15 in 105 of 166 papillary carcinomas(63.3%), 0 of 18 benign disease, 0 of 5 follicular carcinoma and 0 of 1 medullary carcinoma.

Mutation of BRAF and concomitant ERK activation may also influence the progression of papillary carcinomas. Examination of 166 patients with papillary thyroid cancer showed that BRAF mutation did not have correlation with clinical stage and distant metastasis, but BRAF mutation was more common in palpable thyroid cancer (p-value<0.05).

Angiogenesis is very important process during the development and progression of solid tumors. Vascular endothelial growth factor (VEGF) is a major regulator of angiogenesis and could be produced by papillary thyroid cancer. To investigate the relationship between BRAF mutation and VEGF expression in the tumorigenesis of human thyroid, immunohistochemical study was performed. VEGF expression did not correlate with various clinicopathological parameters but, clearly correlated with tumor size. Papillary thyroid cancer with BRAF mutation exhibited more intensive VEGF expression (p-value<0.05).

Our results suggest that activating mutation of BRAF gene closely related to VEGF expression and more common in palpable thyroid cancer.

P 602

ROLE OF CYTOKINES AND DENDRITIC CELLS ON FIBROSIS IN THYROID PAPILLARY CARCINOMA AND HASHIMOTO• FS DISEASE

KAWAKUBO Yasuaki 1), SATO Yuichi 2), JIANG Shi-Xu 3), OKAYASU Isao 3)
1) Department of Pathology, School of Nursing, Kitasato University, 2) Department of Molecular Diagnostics, School of Allied Health Sciences, Kitasato University,
3) Department of Pathology, School of Medicine, Kitasato University

Introduction: Significant fibrosis is observed in both Hashimoto• fs disease (HD) and thyroid papillary carcinoma (TPC). TPC is a particularly suitable model to study the role of tumor-associated macrophages (MfÓ) and/or dendritic cells (DC), because it is frequently associated with signs of immune reaction, including lymphocytic infiltration. On the other hand, interstitial cells such as fibroblast, DC and MfÓ are known to secrete various cytokines which have effects on connective tissue cells and endothelial cells in fibrotic lesions. Purpose: We tried to clarify whether the released cytokines from interstitial cells were related to development of fibrosis in the diseased thyroid. Materials and Methods: The role of cytokines such as TGFfÀ1, CTGF, GM-CSF and TNFf¿ in the development of fibrosis was examined with immunohistochemical staining (IHC) and in situ hybridization (ISH) using paraffin sections of the TPC and HD. The phenotype of the interstitial cells was examined by IHC. In addition, in vitro assays were performed using cultured fibroblasts (WI-38), thyroid carcinoma cells (HTC/C3) and differentiated U-937 cells including immature DC, and MfÓ, to determine how the released cytokines act on fibroblasts. The levels of cytokines, both in the cytoplasm and the culture medium, were examined using IHC, ELISA and RT-PCR. Results: In TPC, there was significant expression of TGFfÀ1, CTGF, GM-CSF and TNFf¿, not only in fibroblasts and/or MfÓin the stroma of the tumors, but also in the tumor cells and infiltrating DCs around the tumor cells. In the HD, mature DCs were seen mainly in lymph follicles, and immature DCs were focally observed around the degenerative or destructive thyroid follicles. Using in vitro assay, differentiated U-937 cells (mainly MfÓ and DC) were shown to significantly release GM-CSF and TNFf¿. When co-cultured with differentiated U-937 and/or HTC/C3 cells, respectively, WI-38 cells showed elongation of the cytoplasm and expressed cytokines. Conclusion: The results from both the in vivo and in vitro assays suggest that cytokines such as GM-CSF and TNFf¿ released by fibroblasts and MfÓ as well as CD1a+ cells, involve in the proliferation and differentiation of fibroblasts. This may contribute to the fibrosis development in TPC. However, in HD, the relationships between fibroblasts, DC, MfÓ and their released cytokines and fibrosis remain unclear.

P 603

GALECTIN 3, ONCOFETAL FIBRONECTIN, EMMPRIN, CYTOKERATIN 19, CITED1, AND TPO EXPRESSION IN THYROID TUMORS

WILT Marc, MILLON Régine, THEOBALD Serge, EBER Michel, RODIER Jean-François, JEANDIDIER Nathalie, SCHNEEGANS Olivier, GHNASSIA Jean-Pierre
Centre de Lutte contre le Cancer Paul Strauss, Strasbourg, France
Service d'Endocrinologie, Hôpitaux Universitaires, Strasbourg, France

Background: Fine needle aspiration (FNA) has become the keystone diagnostic tool in the management of thyroid nodules. However this method has some limitations, such as its lack of sensitivity for follicular neoplasm and may not be informative in 5 to 20% of FNA samples. The use of molecular markers of malignancies could improve the diagnostic performance of these inconclusive or non-informative FNA. The choice for the most relevant markers needs to be performed on tissue samples.
The aim of this study was to determine the expression of 6 genes that may be effective in diagnosing cancer: galectin 3, oncofetal fibronectin, emmprin, cytokeratin 19, CITED 1, and TPO by analysing surgical thyroid tissue samples.
Design: Eighty six tissue samples were analysed and divided into 5 types: 11 normal thyroid tissue, 21 adenoma, 40 papillary carcinoma, 8 follicular carcinoma and 6 anaplastic carcinoma. For each sample, the gene expression was assessed compared to an ubiquitary gene RPLP0 using quantitative real time RT-PCR. The ratio concentration of studied genes over RPLP0 represented the level of expression of the studied gene in each sample. For the 6 studied genes, means and medians of these ratios were calculated for each type of tissue sample. These ratios were compared using an ANOVA and Scheffe tests (proc GLM Sas Institute).
Results: The emmprin and cytokeratin 19 levels of expression were comparable in all 5 types of tissue studied (p=0.6 and p=0.4). Galectin 3, fibronectin and CITED 1 levels of expression were significantly increased only in papillary carcinoma compared to normal tissue. The mean value of galectin was 1.19 (IC 95%:0.94-1.44) vs 0.13(IC 95% : 0.08-0.18), mean value of fibronectin was 4.48 (IC 95%:2.5-6.06) vs 0.04 (IC 95% : 0.02-0.07) and mean value of CITED 1 was 6.94 (IC 95%:4.80-9.07) vs 0.20 (IC 95%:0.15-0.26). TPO was significantly underexpressed only in papillary carcinoma compared to normal tissue. The mean value of TPO was 0.6 (IC 95%:0.12-0.69) vs. 1.68 (IC 95%:1.15-2.22).
Conclusion: The emmprin and cytokeratin 19 gene did not seem effective in distinguishing different tissue types. The significantly increased levels of fibronectin, galectin 3 and CITED 1 and decreased levels of TPO found in papillary carcinoma compared to normal tissue may confirm the interest in these 4 genes as molecular markers of papillary cancer. An evaluation of these genes in cytology samples is now being conducted.

P 604
DIFFERENTIATED THYROID CARCINOMAS : IMMUNOHISTOCHEMISTRY IS USEFUL TO PREDICT THE OCCURRENCE AND THE CHRONOLOGY OF LYMPH NODES METASTASES

HOANG Catherine(1), JUST Pierre-Alexandre(1), MENEGAUX Fabrice(2), LEENHARDT Laurence(3), TRESSALET Christophe(2), AUBRIOT-LORTON Marie-Helene(1), CAPRON Frederique(1)
(1)Anatomie et cytologie pathologiques, (2)Chirurgie generale, digestive et endocrinienne, (3)Medecine nucleaire. Groupe hospitalier Pitie-Salpetriere, 47-83 boulevard de l¡¯Hopital, 75651 Paris Cedex 13, France.

Background : The poor outcome of differentiated thyroid carcinomas is difficult to predict, specially in pT1 (¡Ü2cm) carcinomas. The diagnostic interest of various immunohistochemical markers has often been demonstrated but their prognostic value still remains unclear.
Objective : Are immunohistochemical findings in differentiated thyroid carcinomas correlated to the occurrence and the chronology of their lymph nodes metastases?
Material and methods : HBME-1, Galectin-3, Thyroperoxydase(TPO), Cytokeratin-19(CK19) and c-erbB-2 expression was studied in 41 thyroid carcinomas : 10 (N0) limited to the thyroid gland during a 7 to 9 years follow-up and 31 (N+) with lymph nodes metastases (12 with synchronous, 10 with metachronous and 9 with synchronous and metachronous lymph nodes metastases).
Results : The tumors were 35 papillary carcinomas (PTC) and 6 follicular carcinomas (FTC), including one oncocytic variant. 31PTC/35 coexpressed HBME-1, Galectin-3 and CK19, 2/35 expressed c-erbB-2 and 32/35 had a loss of TPO-expression (TPO staining in less than 60% of tumor cells). 6/6 FTC were stained with CK19, 5/6 with Galectin-3, 4/6 with HBME-1, 0/6 with c-erbB-2 and 6/6 had a loss of TPO-expression. 10/10 carcinomas with exclusive metachronous lymph nodes metastases were totally negative for TPO versus 8/21 others N+-carcinomas (p=0.001).
7/8 N0-PTC had an intense (in more than 70% of the tumor cells) HBME-1 staining versus 5/27 N+-PTC (p<0.001). None N+-carcinomas was negative for Galectin-3 contrary to 4/10 N0-carcinomas (p=0.002). 9/9 N+-pT1-PTC associated an HBME-1/Galectin-3 coexpression and a loss of TPO-expression versus 1/5 N0-pT1-PTC (p=0.005).
Staining in tumors and their lymph nodes metastases was globally the same for each antibody except for galectin-3.
Conclusion : HBME-1, Galectin-3 and CK19 (alone or associated to each others) and the loss of TPO-expression are highly sensitive for the diagnosis of PTC. A strong HBME-1 staining is often found in N0-PTC whereas galectin-3 had a 100% sensitivity for N+-carcinomas. A galectin-3/HBME-1 coexpression with a loss of TPO-expression is correlated to the occurrence of lymph nodes metastasis in pT1-PTC. A completely negative TPO-staining seems to be related to the occurrence of metachronous lymph nodes metastases. These results should prompt to modulate the actual consensual surveillance of patients with thyroid carcinomas, according to immunohistochemistrical pattern.

P 605
BRAF T1799A MUTATION IN HUMAN THYROID PAPILLARY MICROCARCINOMA

LUSHNIKOV Eugeny, LANTSOV Dmitry, ABROSIMOV Aleksandr, SEDLIAROU Ilya, SAENKO Vladimir, ROGOUNOVITCH Tatiana, NAMBA Hiroyuki, NAKASHIMA Masahiro, MEIRMANOV Serik, YAMASHITA Shunichi
Clinical-Morphological Department, Medical Radiological Research Center RAMS, Obninsk, Russia
Departments of Molecular Medicine, International Health and Radiation Research, and Tissue and Histopathology Section, Atomic Bomb Disease Institute, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background. A hotspot mutation in exon 15 of BRAF gene, the T1799A transversion, has been shown to be a prevalent (28.8% - 68.6% in various series from different countries) and highly specific genetic alteration in human papillary thyroid cancer (PTC) in adult patients. BRAF mutation associates with certain histological variants of the tumor being found in a large proportion of PTC with classic papillary morphology and, vise versa, underrepresented in the tumors with follicular architecture. At the same time, little is known about the involvement of BRAF mutation in early stages of thyroid carcinogenesis such as papillary thyroid microcarcinoma (PMC) and its role in tumor progression.
Purpose of the study. Our investigation was set out i) to determine the prevalence of BRAF mutation in PMCs in patients from two geographically distinct groups, Japan and Russia; and ii) to evaluate a correlation between the presence of mutated BRAF and PMC morphology and biological behavior of the tumor.
Materials and methods. Tumor tissue was microdissected from serial sections of 15 PMCs from Japanese patients and 31 PMCs from Russian patients. DNA was extracted using Proteinase K/phenol-chloroform protocol. Fragment of BRAF exon 15 was PCR amplified and analyzed by direct sequencing.

Results. Mutated BRAF was detected in 13/46 (28.2%) of the tumors: 9/31 (29.0%) and 4/15 (26.6%) in Russian and Japanese individuals, respectively, displaying no signs of discrepancy in the mutational rates in patients with differing genetic background seen in PTCs. Occurrence of the BRAF mutation did not significantly correlate with patients' gender, age at presentation, metastatic indices as well as with papillary, mixed papillary and follicular, and solid/trabecular PMC histotype. On the contrary, tumors with follicular morphology significantly associated with the mutation-free genotype (P=0.018). In the mixed-type tumors characterized by co-occurrence of well-differentiated and less differentiated components, the BRAF mutational frequency was significantly elevated (P=0.020).
Conclusion. Results indicate that PMCs may have a spectrum of genetic events partly overlapping with that of PTCs. The BRAF T1796A mutation occurs in about one-third of PMCs irrespectively of the genetic background of patients and positively or negatively associates with particular tumor architecture whereas no correlation could be found with patients' demography and biological behavior of the tumor.

P 606
BRAF T1799A MUTATION IN VARIOUS THYROID DISEASES

ABAKUSHIN Dmitri N., ABROSIMOV Aleksandr Yu., KONOVA Marina V., PETUKHOVA Natalia S, LUSHNIKOV Eugeny F.
Clinical-Morphological Department, Medical Radiological Research Center RAMS, Obninsk, 4 Korolev str., 249036, Russia
E-mail: abakushin@mrrc.obninsk.ru

BACKGROUND: High prevalence of activating T1799A transversion in B Raf kinase-encoding gene (BRAF V600E) has been reported specifically in papillary thyroid cancer (PTC) varying 29-69% in series from different countries, but not in follicular thyroid cancer (FTC) and benign follicular thyroid adenomas (FA). With regard to other types of thyroid diseases information remains rather limited.
PURPOSE OF THE STUDY: In this investigation we determined BRAF mutational rate in medullary thyroid cancer (MTC), FTC, FA, nodular goiter (NG) and lymphocytic thyroiditis (LT) tissues along with that in PTCs in an attempt to elucidate the difference in BRAF alteration frequency among these entities.
MATERIALS AND METHODS: For the study we collected 2 MTCs, 5 FAs, 5 NGs, 2 LTs, 4 FTCs (1 case with lymph node metastasis) and 11 PTCs including 5 cases of follicular variant of PTC, 2 multi-focal PTCs with 2 lymph node metastases from adult patients (2 males and 27 females) aged 30-69 years at operation, residents of central region of Russia. We collected normal thyroid tissues for analyzing in all that cases also. The pathological diagnoses of all the tumors were made in accordance with WHO classification criteria (1988). Genomic DNA was isolated from fresh frozen surgical tissue samples using TRIzol reagent (Invitrogen, Carlsbad, CA) and analyzed for the BRAF mutation by mutant allele specific polymerase chain reaction. DNA extracted from PTC tissue previously determined to harbor mutant BRAF was used as a positive control.
RESULTS: In this series, we found no BRAF T1799A mutation in all eleven PTC cases as well as in any other type of tissue analyzed.
CONCLUSIONS: Our data demonstrate the absence of BRAF mutation in thyroid diseases such as medullary and follicular cancer, follicular adenoma, nodular goiter and lymphocytic thyroiditis. On the other hand, the fact that we were unable to detect BRAF T1799A transversion in 11 cases of PTC indicates that BRAF mutational rate is not too high in adult Russian patients suggestive that frequency of BRAF gene alteration in PTC may be substantially different in the individuals with distinct genetic background (i.e. it is markedly lower in Russian patients in comparison with e.g. Asian individuals). Greater comprehension is necessary to correctly evaluate BRAF mutation prevalence in Russian patients with PTC.

P 607
A NEW BRAF GENE MUTATION DETECTED IN A CASE OF SOLID VARIANT OF PAPILLARY THYROID CARCINOMA

Magalhães J1,2, Trovisco V3, Soares P3, Soares R3, Sá Couto P4, Sobrinho-Simões M1,2,3
1.Department of Pathology. Medical Faculty of University of Porto; 2.Department of Pathology, Hospital de São João, Porto, Portugal; 3.IPATIMUP (Institute of Molecular Pathology and Immunology of the University of Porto); 4.Department of Surgery, Hospital de São João, Porto, Portugal.

BRAF gene mutations have frequently been detected in papillary thyroid carcinoma (PTC).
Moreover, there is a close association between the type of mutation and the PTC histotype: BRAFV600E is associated with conventional PTC and with histological variants of PTC displaying a prominent papillary growth pattern, whereas BRAFK601E is associated to the follicular variant of PTC.
We report the detection of a novel BRAF triplet deletion in a case of solid variant of PTC. The deletion leads to the replacement of a valine and a lysine by a glutamate in the BRAF activation segment (BRAFVK600-1E) thus mimicking partially the two BRAF mutations previously described. Our study reinforces the existence of a close relationship between the occurrence of some types of BRAF mutation and some PTC histotypes. The genetic study of more cases of the solid variant of PTC is necessary to find whether or not there exists a significant association between the occurrence of BRAFVK600-1E and such PTC histotype.

P 608
PAX8-PPAR*f*× TRANSLOCATION: ANOTHER COMMON FEATURE TO FOLLICULAR THYROID CARCINOMA AND FOLLICULAR VARIANT OF PAPILLARY CARCINOMA

Magalhães J 1,2, Castro P3, Rebocho A3, Soares R3, Roque L4, Soares P1,3, Sobrinho-Simoes M1,2,3
1.Department of Pathology, Medical Faculty of University of Porto; 2.Department of Pathology, Hospital de São João – Alameda, Porto 3.IPATIMUP (Institute of Molecular Pathology and Immunology of the University of Porto); 4.IPO (Portuguese Institute of Oncology), CIPM, Lisbon, Portugal.

Thyroid tumours are among the few epithelial tumours harbouring chromosomal translocations. Papillary thyroid carcinomas (PTC) may display RET/PTC and TRK rearrangements and follicular tumours often have the PAX8-PPAR*f*× translocation.
The follicular variant of papillary thyroid carcinoma (FVPTC) is characterized by the cytologic nuclear features of PTC with a follicular pattern of growth. At variance with conventional PTC these tumours display a low frequency of RET/PTC rearrangements, low frequency of B-raf mutations (and of a distinct type from those found in conventional PTC) and a higher frequency of ras mutations.
In an attempt to further characterize the FVPTC we investigated the presence of PAX8-PPAR*f*× translocation in FVPTC using interphase FISH, RT-PCR and immunohistochemistry.
By FISH analysis we found that 41% (9/22) of FVPTC cases display the PAX8-PPAR*f*× translocation. All the cases which harboured the PAX8-PPAR*f*× translocation showed a strong immunoreactivity for PPAR*f*×, and the translocation was confirmed by RT-PCR in two of the cases.

The presence of PAX8-PPAR*f*× translocation was associated with the presence of invasion and/or metastasization (p=0.0034) and with the presence of multifocality (p=0.04).
We conclude that follicular carcinomas and FVPTC share the presence of PAX8-PPAR*f*× translocation at a very similar frequency. We also found three cases of FVPTC displaying both PAX8-PPAR*f*× translocation and Ras mutations. Finally, our data, together with the data already published, shows that FVPTC may be more closely related with FTC than with classical PTC.

P 609
THE EXPRESSION PROFILE OF DIFFERENTIATED THYROID CANCER: MULTI-GENE CLASSIFICATION APPROACH
D. Lange, E. Chmielik, B. Nikiel, J. W³och, A. Czarniecka, A. Kukulska, Z. Wygoda, K. Fujarewicz, K. Simek, M. Oczko, M. Jarz¹b, M. Kowalska, A. Swierniak, B. Jarz¹b
Centre of Oncology, M.Curie-Sk³odowska Institute, Gliwice, Poland

The diagnosis of thyroid cancer is still a field of many controversies, even among experienced pathologists. There is a paucity of efficient markers, both to differentiate benign and malignant cases and to recognize cancer subtypes. Thus, we apply the oligonucleotide microarray technology to study the expression profile of differentiated thyroid cancer and to select transcripts which differentiate between subclasses. We use state-of-the-art bioinformatic techiques, based on Support Vector Machines algorithms, to select not only the single "solitary" markers but rather the sets of genes which are taken into account cooperatively to enhance the diagnosis accuracy.
We start our analysis from the simplest model, the comparison between papillary thyroid cancer and normal thyroid tissue, mainly specimens from thyroid lobe contralateral to tumor.
In total, 82 thyroid samples were investigated by high density oligonucleotide microarrays (HG-U133A, Affymetrix): 48 PTC samples, 25 samples of macroscopically unchanged thyroid tissue and 9 benign thyroid lesions. We recently proposed (Jarzab et al., Cancer Res. 2005) a 20-gene classifier, trained on the initial group of 16 PTC and 16 normal samples, which took into account the interactions between genes and in our group outperformed any single-gene approach. It included DPP4, GJB3, ST14, SERPINA1, LRP4, MET, EVA1, SPUVE, LGALS3, HBB, MKRN2, MRC2, IGSF1, KIAA0830, RXRG, P4HA2, CDH3, IL13RA1, MTMR4. In the study we validate this classifier on the separate group of 50 samples and obtain 93% accuracy. The few misclassified tissues usually exhibit a low percentage of tumor cells in collected sample.
We further extend the analysis to the set of follicular neoplasms (10 follicular cancers and 10 follicular adenomas), where the specification of differentiating genes is much more difficult and it results in significantly lower accuracy.
Conclusion: The high diagnostic accuracy of the recently proposed own multigene PTC classifier has been confirmed.

IMMUNOHISTOCHEMISTRY IN THYROID TUMOUR PATHOLOGY
Louis THIENPONT(1),Paul VAN CROMBRUGGE(2) Beatrix COCHAND-PRIOLLET(3), Jan S. WILLEMS(1) and Jean-Pierre GILLARDIN(4)
Histo- and Cytopath. Lab(1) Dept. Internal Medicine-Endocrinology(2) Dept. General Surgery(4) Onze-Lieve-Vrouw Ziekenhuis B9300 AALST, Belgium; Department of Pathology (3) Lariboisière Hospital, F75475 Paris, France

Background and Aims:
Traditionally invasive growth is the only criterion of malignancy in follicular tumours of the thyroid, while nuclear characteristics are the major criterion for papillary tumours, both papillary and follicular variant.
Our aim was to investigate the immunohistochemical phenotype of follicular epithelium and to characterize in more refined way follicular lesions of various origin.
Material and Methods:
Thyroid lesions and nodules encountered in daily practice over the last eighteen months were stained for various antibodies. Antibodies were used to demonstrate follicular cells (thyroglobulin, TTF1), oxyphilic cells (thyroglobulin, TTF1 and CK14) and C-cells (calcitonin, CEA and chromogranin A).
Thyroid malignancy associated antibodies used were: CK19, HMW keratin, HBME1, Galectin 3, RET-PTC and PAX8-PPARgamma.
Preliminary Results :
HBME1 showed to be a most interesting valuable marker for follicular tumours, helping to distinguish follicular carcinoma from adenoma. Other useful stains in case of follicular carcinoma are Galectin3 (Gal3)and PAX-PPARgamma.
In our experience Cytokeratin 19 is a very good marker for papillary carcinoma; papillary as well as follicular variants. Most papillary cancers stain for HBME1 and Gal3 as well.
Conclusions:
1. Immunohistochemical staining of thyroid nodules in general is mostly a valuable adjunct to confirm equivocal histopathological diagnoses.
2. In encapsulated, non-invasive tumours with follicular growth pattern but with focal papillary carcinoma nuclear features, in our hands a definite correlation was noted with CK19 positivity.
3. Oxyphilic cells stain for CK14.
Gal3 and HBME1 markers, helpful in distinguishing benign from malignant follicular tumours, may be positive in both benign as well as in malignant oxyphilic tumours.
4. In cellular areas in thyroid nodules and goitres, the positivity of some malignancy-associated markers is at present not well understood, but might be due to clonal heterogeneity.

HER2/NEU STATUS IN THYROID TUMORS: A STUDY OF 92 THYROID CASES BY IMMUNOHISTOCHEMISTRY AND FLUORESCENCE IN SITU HYBRIDIZATION
DÝZBAY SAK Serpil*, ERGUN Dilhan*, PERCÝNEL Sibel*, ERDEN Esra*, KUZU Isinsu*, KURSUN Nazmiye**
Departments of Pathology* and Biostatistics**, Ankara University School of Medicine, Ankara, Turkey

Introduction: HER2/neu overexpression and amplification have been shown in a variety of carcinomas particularly breast carcinomas. However, a limited information is available concerning thyroid neoplasms in this regard.
Aims: The aim of this study was to determine HER2/neu status by immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) in benign and malignant thyroid neoplasms using low density manual tissue microarray.
Materials and Methods: For immunohistochemical study and FISH analysis, tissue cylinders of 4 mm diameter taken from

paraffin blocks of 92 thyroid tumors were arrayed in 8 recipient paraffin blocks. We analyzed HER2/neu status of 9 follicular adenomas, 50 papillary carcinomas, 19 medullary carcinomas, 10 anaplastic carcinomas and 4 follicular carcinomas by IHC (DAKO), using streptavidin biotin immunodetection system and by FISH (Q-biogene).
Results: A cytoplasmic staining with an intensity score changing between +1 and +3 was detected in various ratios in all groups except anaplastic carcinoma group immunohistochemically However, none of the tumors showed diffuse strong membraneous staining. Cytoplasmic and/or membraneous staining was observed in 88%, 68.4%, 66.6% and 100% of papillary carcinomas, medullary carcinomas, follicular adenomas and follicular carcinomas, respectively. There was no statistically significant difference between papillary carcinoma group and other tumor groups with respect to staining. No statistically significant difference regarding staining was detected between papillary microcarcinoma and papillary carcinoma group, either.
Although HER2/neu amplification was detected in single tumor cells in some cases, HER2/CEP17 ratio was found to be lower than 2 in all tumors.
Conclusion: Cytoplasmic and/or membranous HER2/neu expression by IHC can be seen in thyroid tumors but the staining is not as strong or widespread as observed in breast carcinomas. Immunohistochemical expression does not correspond to a high level of amplification by FISH. The mechanisms and clinical impact of immunohistochemical HER2/neu expression remains unknown.

P 612
DIFFERENTIAL EXPRESSION OF DYSADHERIN IN PAPILLARY THYROID CARCINOMA AND MICROCARCINOMA: CORRELATION WITH E-CADHERIN EXPRESSION

Scopa CD, Batistatou A*, Nakanishi Y**, Charalabopoulos K***, Hirohashi S**, Agnantis NJ*
Department of Pathology, University of Patras Medical School, Patras, Greece, *Department of Pathology, University of Ioannina, Medical School, Ioannina, Greece, **Pathology Division, National Cancer Center Research Institute, Tokyo, Japan and ***Department of Physiology, Clinical Unit, University of Ioannina, Medical School, Ioannina, Greece

Introduction: Papillary carcinoma is the most common type of thyroid cancers. Microcarcinomas are small tumors (<1cm) of the same histologic type, usually clinically silent and frequently detecting as incidental findings. E-cadherin is a cell adhesion molecule involved in the progression of several malignant neoplasms. Dysadherin is a recently described cell membrane glycoprotein, which has an anti-cell-cell adhesion function and downregulates E-cadherin.
Purpose: The purpose of the study was to examine the expression of dysadherin and E-cadherin in papillary thyroid carcinomas and microcarcinomas and investigate whether there are differences in their expression.
Methods: The expression of E-cadherin and dysadherin was detected immunohistochemically in 20 papillary carcinomas and 20 microcarcinomas of the thyroid gland. The method was applied on formalin-fixed, paraffin-embedded tissue sections using the EnVision System (DAKO) and the monoclonal antibodies: NCC-M53 against dysadherin and E-cadherin (CM170B, Biocare Medical). The intensity, the expression pattern and the percentage of neoplastic cell staining was recorded and correlated with the histologic type.
Results: Dysadherin was not expressed in normal thyroid follicular cells. In papillary carcinomas low membranous expression was detected in 40%(8/20) of the cases, intermediate expression in 20%(4/20) and high expression in 15%(3/20). In microcarcinomas low expression was detected in 40%(8/20) of the cases, intermediate expression in 10%(2/20) and high expression in 0%(0/20). Immunoreactivity for E-cadherin was detected in non-neoplastic follicular cells. In papillary carcinomas low expression was detected in 30%(6/20) of the cases, intermediate expression in 45%(9/20) and high expression in 20%(4/20). In microcarcinomas low expression was detected in 10%(2/20) of the cases, intermediate expression in 50%(10/20) and high expression in 40%(8/20). Increased dysadherin expression was correlated with aberrant (cytoplasmic) E-cadherin expression in most tumors.
Conclusion: Since dysadherin is not normally expressed in non-neoplastic thyroid follicular cells, it is conceivable that it plays a pivotal role in the neoplastic transformation of thyroid gland. Moreover its expression correlates with tumor size. In papillary thyroid tumors, dysadherin appears to downregulate E-cadherin expression, at least in part.

2Institute of Biology,NCSR Demokritos,Athens
3.Dana Farber Cancer Institute,Harvard Medical School, Boston

Introduction:
Fibrillin is an extracellular matrix glycoprotein ,a main component of microfibrills , with sites recognizable by integrin receptors, suggested to support cell attachment and to impact cell differentiation and migration. The aim of this study was to investigate and to compare the fibrillin expression in thyroid carcinomas at mRNA and protein level in cell lines, commercial available tissue microarrays and archival specimens,
since ECM proteins are suggested to be of great importance for the metastatic potential of carcinomas.
Material and Methods:
RNA was extracted from 13 thyroid cell lines (9 papillary Ca , 2 anaplastic Ca , 1 follicular Ca,and 1 medullary Ca) .RT-PCR analysis for Fibrillin- 1 mRNA was followed, using gene-specific primers.
Furthermore we investigated the fibrillin expression by immunohistochemistry in a commercial available tissue microarray (IMGENEX IMH 319) including 42 papillary Ca, 7 follicular Ca, 1 PDC and 9 benign thyroid tissues, as well as in archival tissue from the files of the Pathology Department of the Athens University, including 33 thyroid carcinomas(15 papillary, 4 follicular, 5 Huerthle cell-, 1 anaplastic and 8 medullary Ca).For immunohistochemistry an antibody against fibrillin 1 (Santa Cruz H-109) was used at dilution 1:100 (overnight) .The stain was evaluated semiquantatively (0 - +++)
Results:
RT-PCR analysis revealed Fbn-1 mRNA expression in all thyroid carcinoma cell lines, with highest expression in the follicular Ca cell line WRO, the papillary SW579 and the medullary TT, whereas lowest expression was found in the two anaplastic cell lines (ARO, FRO) and 1 papillary (BHP 18)
Fibrillin has been demonstrated immunohistochemically in cytoplasmic location in the tissue microarray as well as in the archival sections in almost all papillary (39-14), medullary(5), Huerthle cell-4) ,anaplastic(1) and poorly differentiated Ca (1), whereas it was absent in all follicular carcinomas.The most intense stain has been observed in papillary carcinomas, with a slight increased intensity in advanced stages.
Conclusions:

Our data indicate that,fibrillin 1 is strongly expressed by the neoplastic cells of thyroid carcinomas in different degree in the various histologic types and might be implicated in cell-stroma interaction in terms of signaling ,attachment and migration.

P 614

DIAGNOSIS OF METASTATIC CARCINOMA OF THE THYROID GLAND BY FINE NEEDLE ASPIRATION CYTOLOGY. A REPORT OF CLINICAL AND MORPHOLOGICAL FEATURES OF A CASE WITH THYROID METASTASES FROM COLON ADENOCARCINOMA.

IVANOVA Radina, KARANOVA Penka, KANEV Nikolai, KOVACHEVA Russana
Clinical Center of Endocrinology, Medical University, Sofia, Bulgaria

Clinically evident, diagnosed and surgically resected thyroid metastases are uncommon. In a series of 42 cases with nonthyroid carcinoma and thyroid nodules, thyroid metastases were found in 4 cases (2 – lung cancer, 1 – breast cancer, 1 – colon cancer) by ultrasound-guided fine needle aspiration cytology of the thyroid gland. We report the clinical and morphological features of a case of colon adenocarcinoma metastatic to the thyroid gland. The patient was a 56- year- old woman with progressively enlarging goiter and compression symptoms. A history of left hemicolectomy for colon adenocarcinoma with extracellular mucinous production - T3N0M0 (6 years ago), right lower lobectomy for lung metastasis (4 years ago) and chemotherapy was present. Thyroid ultrasound found a big tumor mass in the right lobe and a small one in the left lobe, and numerous enlarged neck lymph nodes. Fine-needle aspiration cytology of the thyroid showed atypical tall cells with an acinar pattern. Total thyroidectomy and lymph nodes' extirpation was done. Histological examination confirmed the presence of metastatic colon adenocarcinoma with moderate differentiation. Immunohistochemical staining of the thyroid tumor was negative for thyroglobulin but positive for CEA and cytokeratin 19. In conclusion ultrasound scan and FNA biopsy of the thyroid gland with cytology appear to be useful methods for the differential diagnosis of thyroid nodules in cancer patients, including colorectal carcinoma. The recognition of thyroid metastases is essential for the appropriate staging and therapy of primary carcinoma.

P 615

UTILITY OF HBME-1, CYTOKERATIN 19 AND GALECTIN-3 IMMUNOSTAINING IN THE DIAGNOSIS OF THYROID MALIGNANCY.

Matos PS , Ferreira AP, Facuri FO, Assumpção LVM, Ward LS, Metze K.
Department of Pathology and Division of Endocrinology, Department of Internal Medicine, Faculty of Medicine (FCM) - State University of Campinas (UNICAMP), São Paulo, Brazil

The aim of our study was to investigate the usefulness of immunohistochemical expression and immunolocalization of a panel of markers including HBME-1, CK-19 and galectin-3 in thyroid neoplasias and non-neoplastic lesions.
We evaluated 170 thyroid lesions including 148 neoplasias (84 papillary carcinomas, 38 follicular carcinomas, 18 follicular adenomas, 1 hyalinizing trabecular tumor, 5 medullary carcinomas, 2 anaplastic carcinomas) and 22 non-neoplastic lesions (12 adenomatous nodules and 10 Hashimoto´s thyroiditis). The percentage of positive cells as well the pattern of staining were analysed. The three markers were usually negative in normal thyroid tissue. This was helpful to differentiate lesions with follicular pattern, when there was doubt regarding the nuclear features of papillary carcinoma. HBME-1, galectin-3 and CK-19 were expressed in 94%, 72.6%, 72.6% of the papillary carcinomas and in 63%, 21% and 21% of the follicular carcinomas. Furthermore, the staining pattern of the three markers (diffuse, focal segmental of focal cellular) was useful to differentiate neoplastic from non-neoplastic nodules. Lesions could be differentiated by their staining pattern. Diffuse reactivity predominated among papillary carcinomas, specially in the follicular variant of papillary carcinoma, in contrast to the focal segmental and focal cellular pattern found in follicular adenomas or carcinomas and adenomatous nodules. Counting the percentage of galectin-3 and CK-19 positive cells was useful for the differentiation between cases of follicular variant of papillary carcinoma and follicular carcinoma or adenoma.
Therefore we conclude that immunohistochemical staining features may be useful for the differential diagnosis of thyroid lesions. Diffuse positivity is indicative of malignancy. We also suggest that HBME-1 is a very sensitive marker for thyroid malignancy, but the three markers together may be helpful in special cases. This panel of markers discriminates the lesions with a follicular pattern, with special reference to the follicular variant of papillary carcinoma .

P 616

IMMUNOHISTOCHEMICAL EXPRESSION OF GALECTIN-3 IN BENIGN, MALIGNANT AND THYROID TUMORS OF UNCERTAIN MALIGNANT POTENTIAL

ABROSIMOV Aleksandr, LUSHNIKOV Eugeny

Background. Well differentiated encapsulated thyroid tumors with a follicular architecture are sometimes quite difficult for pathologists to make differential diagnosis between a definite malignant or definite benign category. Pathologists are compelled to classify the tumors having questionable nuclear changes and questionable or absent capsular invasion as well differentiated tumors of uncertain malignant potential (WDT-UMP). In a series of recent reports it has been found that galectin-3 immunostaining may be useful to distinguish benign and malignant thyroid tumors. Immunohistochemical expression of galectin-3, a human lectin, has been shown to be highly associated with a malignant behaviour of thyroid tumors.
Purpose of the study. We studied galectin-3 expression in a spectrum of obvious benign, tumors of border-line or uncertain malignancy and obvious malignant thyroid tumors.
Materials and methods. Sixteen papillary carcinomas, two follicular carcinomas, five well differentiated thyroid carcinomas not otherwise specified (NOS), seventeen follicular adenomas and twelve thyroid tumors of uncertain malignant potential were examined. Monoclonal antibodies specific to galectin-3 (Novocastra Laboratories) and indirect streptavidin-biotin complex immuno-reaction were used for immunohistochemistry.
Results. Positive cytoplasmic immunostaining of tumor cells was seen in 14 papillary, 2 follicular carcinomas, 4 well differentiated carcinomas NOS, 2 follicular adenomas and 5 well differentiated thyroid tumors of uncertain malignant potential.
Conclusion. Galectin-3 is a reliable marker of well differentiated thyroid carcinoma. It can sometimes be expressed in benign tumors. Group of well differentiated thyroid tumors of uncertain malignant potential is seems to be a heterogeneous. The significance of positive immunostaining of tumor cells in obvious benign tumors and in some of the border-line group of tumors as well as negative immunostaining in some of the obvious malignant tumors needs to be further investigated.

IMMUNOHISTOCHEMICAL EXPRESSION OF FASCIN IN GASTROENTEROPANCREATIC ENDOCRINE TUMORS

BOBOS Mattheos, KARAYANNOPOULOU Georgia, GERASIMIDOU Domniki, TELEVANTOU Despoina, KOLETSA Triantafyllia, PAPADIMITRIOU S. Constantine
Department of Pathology, Aristotle University Medical School, Thessaloniki, 54006, Greece

Introduction. Fascin is a globular protein that organizes F-actin into well-ordered, tightly packed parallel bundles in vitro and in cells. Fascin is normally expressed by basal layer cells of the epidermis, neurons, glial cells, dedritic cells, endothelial cells and macrophages. Abnormal expression of fascin was reported in almost all cases of Hodgkin disease (in Reed-Sternberg cells), in T-cell lymphomas and in various types of carcinomas. In studies of non-small cell lung carcinoma and gastric adenocarcinoma high fascin expression is correlated with poor survival. Its immunoreactivity is variable in endocrine tumors (ETs). According to our knowledge, studies concerning the expression of fascin-1 in gastroenteropancreatic (GEP) ETs have not been reported.
The aim of the present study is to investigate the expression of fascin in GEP-ETs.
Material and Methods. A total 30 cases of GEP-ETs were included in this study. A panel of immunohistochemical markers was used for diagnosis. GEP-ETs were classified according to the latest WHO criteria in 13 cases of well differentiated ETs "carcinoids" and 17 cases of endocrine carcinomas (well or low differentiated). The primary tumors were located in the foregut (13-43,3%), midgut (14-46,7%), or hindgut (3-10%) respectively. All the cases were immunohistochemically tested using the monoclonal antibody that recognizes the C-terminal region of the fascin molecule. Twenty pancreatic and gastrointestinal tissue speciments with non-specific reactive changes were also tested for fascin expression.
Results. Diffuse cytoplasmic staining of fascin was found in neoplastic cells of 4/17 GEP endocrine carcinomas. These tumors had a high MIB-1 labeling index (over >50% of neoplastic cells). All the well differentiated ETs were non-reactive for fascin. The endocrine cells of Langerhans islands of pancreas and those of the GI tract were also negative.
Conclusion. High expression of fascin is reported in large-cell neuroendocrine carcinomas of the lung and in all cases of small-cell lung carcinoma. In typical or atypical carcinoids of the lung fascin is detected in a small number of cases. In our study only 4/17 cases of GEP endocrine carcinomas were positive for fascin. On the contrary all the well differentiated GEP-ETs were non-reactive. These results show that overexpression of fascin-1 in GEP-ET is not a common finding. Further extensive studies are essential to define the role of fascin expression in these neoplasms.

P 618

RELATIONSHIP BETWEEN IMMUNOHISTOCHEMICAL EXPRESSION AND PLASMA CONCENTRATION OF TOTAL GHRELIN IN PATIENTS WITH GASTRIC NEUROENDOCRINE TUMOURS.

TSOLAKIS Apostolos V. *, STRIDSBERG Mats **, PORTELA-GOMES Guida M. §, GRIMELIUS Lars #, TIENSUU-JANSON Eva *.
Dept. of Medical Sciences, Section of Endocrine Oncology *, Section of Clinical Chemistry **, Dept. of Genetics and Pathology #, Uppsala University Hospital, Uppsala, Sweden. Centre of Nutrition, Lisbon University, Lisbon, Portugal §.

Background: Ghrelin is a 28-amino acid growth hormone secretagogue occuring predominantly in the gastric mucosa. Ghrelin-immunoreactive (IR) cells in normal stomach also express vesicular monoamine transporter-2 (VMAT-2). Ghrelin has been reported in ECLomas type I and III and in regions with ECL cell hyperplasia.
Aim: To characterise neuroendocrine (NE) tumours of the human gastric corpus with respect to the occurrence of ghrelin-IR cells and relate the findings to plasma (P) total ghrelin concentration.
Material and Methods: The study included ECLomas type I (n=4), type III (n=5), one gastric NE carcinoma and one malignant gastric ghrelinoma. Antibodies against chromogranin A, synaptophysin, synaptic vesicle protein 2, VMAT-1, VMAT-2 and ghrelin were used for immunohistochemistry. P total ghrelin was measured using a commercial RIA kit (Linco Research, Mi, USA).
Results: Ghrelin immunoreactivity was found in varying frequency in neoplastic cells of ECLomas type I (VMAT-2-IR) and in virtually all cells of the ghrelinoma (VMAT-2 negative), but were not observed in type III ECLomas nor in the NE carcinoma. Immunoreactivity for ghrelin was detected among the ECL hyperplastic cells in the mucosa of ECLomas type I. In ECLomas type III and in the NE carcinoma slight diffuse hyperplasia of ghrelin-IR cells was also seen in the peritumoural mucosa. P total ghrelin levels were within the reference range (<5 ìg/L) in all ECLomas and in the NE carcinoma, despite the presence of neoplastic and/or hyperplastic ghrelin-IR cells. Increased P concentration of total ghrelin was only observed in the patient with the malignant gastric ghrelinoma, who had more than 400-fold increase (2100 ìg/L).
Conclusion: In spite of neoplastic and hyperplastic ghrelin-IR cells in ECLomas type I and ghrelin cell hyperplasia in the surrounding mucosa of the neoplastic tissue in type III and in the NE carcinoma no elevation of P total ghrelin concentration was detected. However, in the patient with the ghrelinoma the P total ghrelin was markedly elevated. Thus, expression of ghrelin in neoplastic (excluding the ghrelinoma case) and hyperplastic cells in the gastric mucosa does not seem to give rise to elevated circulating levels of ghrelin.

****Department of General and Visceral Surgery, University of Halle, Germany
*****Department of Molecular Neuroscience, Institute of Anatomy and Cell Biology, University of Marburg, Germany

Introduction: Microadenomatosis of the endocrine pancreas has been suggested to represent a hallmark of multiple endocrine neoplasia type 1 (MEN 1). Purpose of the study: On the basis of several observations we hypothesize that microadenomatosis may also occur independently of MEN 1 and that it may show features distinct from those in MEN 1.
Methods: Pancreatic tissue specimens from 40 patients were analyzed, using immunohistochemisty, confocal laser scanning microscopy and morphometric methods. The MEN 1 and Von-Hippel-Lindau (VHL) status were assessed clinically and by PCR based mutational analysis. Results: Twenty seven of the 31 MEN 1 patients were found to have microadenomatosis in addition to single macrotumors. Most microadenomas and macrotumors expressed glucagon, with pancreatic polypeptide and insulin following in frequency. In

nine of the 40 patients with pancreatic microadenomatosis neither MEN 1 nor VHL germline mutations could be found. Five of these nine patients suffered from hyperinsulinism caused by multiple microinsulinomas, while the four others had multiple clinically silent microglucagonomas. The nontumorous pancreatic tissue from both MEN 1 and nonMEN 1 patients contained proliferative endocrine cell lesions in the ducts and the islets. Conclusions: Microadenomatosis in MEN 1 is the basis for the development of single macrotumors, which may cause a hormonal syndrome. Microadenomatosis is not specific for MEN 1 or VHL, but may occur independently and cause a functional syndrome. In both conditions microadenomatosis is preceded by various preneoplastic proliferative changes of endocrine cells.

ARE PANCREATIC ENDOCRINE TUMORS A MANIFESTATION OF THE NF1 PHENOTYPE? MOLECULAR ANALYSIS OF A PATIENT WITH VON RECKLINGHAUSENS SYNDROME

PERREN Aurel, WIESLI Peter, SCHMID Sonja, MONTANI Matteo, SCHMITT Anja, MOCH Holger, KONNINOTH Paul
Institute for Clinical Pathology, Department of Pathology, University Hospital Zürich
Division of Endocrinology and Diabetes, University Hospital Zurich (W.P.)
Institut for Clinical Pathology, Kantonsspital Baden, AG, Switzerland (K.P.)

Introduction: Patients with a von Recklinghausen syndrome (NF1) carrying NF1 germline mutations are predisposed to endocrine tumors including pheochromocytomas and duodenal somatostatinomas. It is unclear whether the rarely reported occurrence of pancreatic insulinomas in NF-1 patients represents a coincident finding or whether insulinomas are a rare manifestation of the NF1 syndrome.
Aims: To determine the relationship between NF1 and insulinomas, we analyzed blood and tumor tissue of an insulinoma for NF1 mutation, allelic loss of the NF1 gene and its expression in a patient with von Recklinghausen syndrome.
Patient: The NF-1 patient presented with recurrent episodes with weakness, sweating, and occasional loss of consciousness. A MRI showed a 2.5 cm tumor in the body of the pancreas. A tumor enucleation was performed and histology revealed a well differentiated pancreatic endocrine carcinoma (WHO 2004) with a micrometastasis in a peripancreatic lymph node. Immunohistochemistry showed expression of insulin and proinsulin.
Methods: Mutation analysis was performed by direct sequencing of the peripheral blood and tumor tissue. Allelic loss (LOH) analysis of the NF1 gene was done using the intragenic microsatellite markers D17S1166, NF1.PCR3 and D17S1849 on 17q11.2. For expression analysis, a RT-PCR was designed spanning intron 3 of the NF1 gene including the mutated site in exon 4.
Results: Mutation analysis of peripheral blood leukocytes confirmed a 4 base pair deletion in exon 4 starting at codon 167 (499 del TGTT). LOH analysis of tumor tissue revealed retention of both NF1 alleles. While RT-PCR of peripheral blood showed biallelic expression of both the wild-type NF1 and the mutated form, RT-PCR of tumor extracts showed a sole expression of the mutated NF1 allele.
Conclusion: These results suggests that the transcription of the wild type NF1 allele is suppressed, probably by epigenetic mechanisms. This is a strong indication for a causal relationship between the insulinoma and the von Recklinghausen disease. It can be hypothesized that insulinomas are a rare manifestation of the NF1 pheonotype. Furthermore, the NF1 gene must be considered as a candidate tumor suppressor gene for insulinomas and other PET, since the second allele can be inactivated by other mechanisms than 17q LOH.

NESIDIOBLASTOSIS: A RARE CAUSE OF HYPERINSULINEMIC HYPOGLYSEMIA IN ADULTS.

Gürbüz Y*, Filinte D*, Erçin C*, Cantürk NZ**, Cantürk Z***, Türemen E***, Tarkýn I***, Çetinarslan B***
*KOCAELI UNIVERSITIY MEDICAL FACULTY PATHOLOGY DEPARTMENT
**KOCAELI UNIVERSITIY MEDICAL FACULTY GENERAL SURGERY DEPARTMENT
***KOCAELI UNIVERSITIY MEDICAL ENDOCRINOLOGY DEPARTMENT

INTRODUCTION: Nesidioblastosis is an uncommon cause of hyperinsulinemic hypoglisemia in adults. In this case report we will present an adulthood nesidioblastosis.
CASE REPORT: 73 years old man was admitted to the emergency service of Kocaeli University Medical Faculty with the complaint of senkop. During first examinations, the blood glucose levels were between 10-29 mg/dl. Although there was not any preoperative radiological findings of pancreatic mass, decision of surgical examination for the diagnosis and treatment of insulinoma was made. During surgery, 85% distal pancreatectomy was performed because of the lack of pancreatic mass during operative exproration.
The resection material was in 12X4X1,5 cm dimentions. All the pancreas was embedded in 24 blocks. Serial sections were applied to each block for three times and tumoral mass was not observed. In histopathological examination abnormal shaped Langerhans islands, ductulo-insular complexes, endocrin buddings from ductal structures, small clustures and single endocrine cells were observed in the pancreas parachyma. The insulin immunostaining was observed more than 80% in Langerhans islands, small clustures and single cells in the parancyhima. The typical peripheric alpha cell ring was not observed in some islands in glucagon immunostaining. The mean Langerhans island diameter was 270µ.
After the operation the patient's general condition deteriorated because of his respratory problems and sent to intensive care unit. The blood glucose levels were fluctuated between 90-110 mg/dl. The patient died because of the respratory problems in postoperative 48. day.
CONCLUSION: The diagnosis of adulthood nesidioblastosis was made according to clinical and histopathological features. Although insulinoma is the most common reason of deep hyperinsulinemic hypoglycemia the entity of nesidioblatozis must be in mind for differential diagnosis of this situation.

SUBTOTAL PANCREATECTOMY FOR PERSISTENT HYPERINSULINAEMIC HYPOGLYCAEMIA – CASE REPORT

BOGOEVA Biljana, KOCOVA Mirjana, PETROVSKI Pero, CVETKOVSKI Petar
Institute of Pathology, Pediatric Clinic, Pediatric Surgery clinic

The syndrome of persistent neonatal and infantile hyperinsulinaemic hypoglicaemia(PHHI) has long recognized, its pathogenesis remain to be eluciated.Two different forms, focal and diffuse, have been reported. The diffuse form corresponds to the lesion previosly described as " nesidioblstosis". Persistent hyperinsulinemic hypoglycemia (PHHI) rarely appears after infancy. We present a normally developed 4.5 year old boy with severe hypoglycemia resistant to medications.Treatment with glucose infusions did not keep his glycemia normal. He was hypoglycemic (initial glycemia 1.9 mmol/l) and no ketosis was detected. He

required 140 mg/min iv glucose for maintenance of glycemia within normal range. The insulinemia was 44 mu ;IU/ml at glycemia of 2.2 mmol/l (ratio 20:1). Hyperinsulinemia was persistent. Imaging of the pancreas by ultrasound and CT was normal. Diasoxide in a dose of up to 6 mg/kg showed a transitional effect. After two months the child became severely hypoglycemic again requiring permanent high doses of iv glucose. Glucagon and somatostatin did not correct the hypoglycemia as confirmed by continuous glucose monitoring. Subtotal pancreatectomy was performed. Metods and results: Intra-operative frosen section were performed on small pancreatic specimens taken from the different parts of the gland allows one to determine the type of lesion (focal or diffuse). The paraffin block obtained from subtotal pancreatectomies were sliced and stained with routine staining HE, reticulin, PAS and immunohistochemical stains: insulin, proinsulin, somatostatin, glukagon, pancreatic polipeptid, P57 and SUR-1. Hystology of the pancreas showed numerous normally configured islets that are quite numerous with variably sized.They are irregulary distributed in the acinar tissue and interlobular stroma.The structure was normal with insulin cells in the center and glucagon, somatostatin and pancreatic polypeptide cells at the periphery. The islets were not at rest. Labeling for P57 and SUR-1 was normal.There was no excessive release of insulin. The child is in good health 14 months after surgery and does not require any treatment. Continuous glucose monitoring showed normal values of glycemia. Last check up showed normal HbA1c (5.0%) and insulin level (10.4 uIU/ml). Histology and the clinical course are not typical for a diffuse form or a PHHI.

P 623

ANEUPLOIDY AND LOW P21/WAF1 EXPRESSION IN MALIGNANT PARAGANGLIOMAS

Fernando A. Candanedo-Gonzalez, Brenda Barraza-Ibarra, Arturo Cerbulo-Vazquez, Milena Saqui-Salces, Armando Gamboa-Domínguez.
Departments of Pathology from Oncology Hospital at Nacional Medical Center and National Institute of Medical Science and Nutrition, and Department of Citometry, INPer. Mexico City.

Background: Clinical and histopathological features do not reliably distinguish between benign and malignant paragangliomas. Additional markers that might be useful prognostic indicators in the pathological assessment of these tumors are sought. Aim: to determine if p21/WAF1, p27Kip1, p53 and Ki-67 expression, and DNA content correlates with clinical behaviour of the paragangliomas. Design: Patients submited to surgery for sporadic paraganglioma from sites anywhere with follow-up, were included in this retrospective case-control study. Gender, age, tumor size and metastases were obtained from medical records. Malignancy was defined as the presence of metastasis and/or extensive local invasion. IHQ detection of p21/WAF1, p27 Kip1, p53 and MIB-1 against Ki-67 antigen, was blindly performed. The reactivity was evaluated as percentage of positive nuclear immunoreactivity. For measurement of DNA content one block of each case was selected. Student t test was used. Results: The study group included 31 patients, 23 women and 8 men. Mean follow-up was 41 months (range, 0-123). Twenty-seven were benign and 4 malignant tumors. Three of the malignant tumors were present in men. Mean age of patients with benign and malignant tumors was 48 ± 11.3 years and 33 ± 12.3 years, respectively (p=0.031). The mean size for benign and malignant tumors was 4.5 cm ± 1.9 and 7.5 cm ± 8.3, respectively (p=0.093). Recurrences were observed in 2 patients (7%). p21/WAF1 expression was positive in 50% malignant versus 89% benign tumors. Only one benign case was positive for p53. p27Kip1 and Ki-67 expression no showed significant differences between groups. All malignant tumors were aneuploid versus only 23% of benign tumors. Conclusions: The present study showed that malignant paragangliomas were related to less age, higher tumor size, aneuploidy and less p21/WAF1 expression. This results suggest that p21/WAF1 can be inactivated in malignant paragangliomas inducing proliferation of neoplastic cells.

P 624

ADRENAL LIPOMAS: REPORT OF TWO CASES AS INCIDENTAL AUTOSY FINDING.

JM Suárez-Peñaranda, Alvarez-Iglesias MT, JI Muñoz, MS Rodríguez-Calvo, JA Ortiz-Rey*, L Concheiro.
Department of Pathology and Forensic Sciences. University of Santiago de Compostela.
* Department of Pathology . POVISA Medical Center. Vigo Spain.

INTRODUCTION

Adrenal lipomas are extremely rare, benign, non-functioning neoplasms, with very few cases recorded in the medical literature. Most cases have been incidental findings, usually during autopsy investigation of deaths from an unrelated cause. The size can be variable, ranging from one up to twelve centimetres. The follow up is limited to exceptional cases diagnosed during life and the outcome of these patients have been excellent.

CASE REPORTS

Case 1: A 70-year-old man is found dead in a beach. Medico-legal investigation and autopsy confirm that the death was due to drowning. A small tumour is noted in the right adrenal gland. It is a soft, rounded, yellow mass, with 1 cm in its largest dimension. Histopathological examination reveals a typical lipoma.

Case 2: A previously healthy 45-year-old man collapsed and dies while taken to the hospital. Autopsy examination shows that both adrenal glands are enlarged. The left weights 92 gr and a yellow-tan mass occupies most of the cut surface. Histopathologically corresponds to a pheocromocytoma, which was considered responsible for the death.

The right adrenal gland weights 18 gr. and has a 2 cm, soft, yellow mass. Histopathological examination reveals a lipoma.

COMMENTS

We report two cases of adrenal lipomas, one of them associated to pheocromocytoma in the contraleteral adrenal gland. To the best of our knowledge, this association has not been previously reported. Since lipomas are very unusual in this location, in both cases the whole mass was submitted for histopathological examination to rule out other possibilities such as myelolipoma or liposarcoma.

Histopathologically, adrenal lipomas are similar to conventional lipomas arising elsewhere in the body, a feature non contributive to asses its pathogenesis, which remains unknown. The relation between myelolipoma and lipoma has been discussed and a continuum spectrum between both neoplasms has been proposed, but never proved.

Our cases are typical, since they were asymptomatic and only discovered at autopsy. Although they present little difficulty in the histopathological diagnosis, their kwnowledge is merit because the incidental discovery of these neoplasms has increased during the last years.

HISTOPATHOLOGICAL STUDY OF PRENATAL STRESS ON ADRENAL GLAND TOTAL VOLUME AND ABSOLUTE VOLUME OF GLOMEROLUSA, FASCICULATE, RETICULARIS LAYERS AND MEDULLA IN 21 DAYS NEONATE RATS: A STEREOLOGICAL STUDY

Bahmanpour S, Noorafshan A, Karimpour M, Dehghani F
Shiraz University of Medical Sciences, Shiraz, Iran

Pregnant mothers may expose to various stresses and it may impact on their embryos. It affects the structural development of brain, gland and body weight. The detail of this histopathlogical changes have been little researched. The base of this study was the prenatal stress effects on adrenal gland stereological.
Sprague-Dawely rats were kept in standard condition for two weeks. The two female with one male were caged overnight. Vaginal pluge and sperm detection in vaginal smear confirmed the pregnancy. Then 30 pregnant rats were divided into two groups as control and experimental. The experimental group was exposed to stress from the first to the end of the pregnancy. The stress was induced three times a day, each time lasting 45 minutes. 21 days after birth one animal from each dam was selected and its adrenal gland was removed for tissue processing, and sterological study. 12 sections were selected by random systemic sampling and the Cavalier's method was used to calculate the gland volume. The statistical analysis revealed significant differences between the total and absolute volume of glomerolusa, fasciculate, reticularis layers ($P<0.001$) and medulla ($P<0.05$) in control and experimental animals.
It can be concluded that prenatal stress causes total adrenal gland and cortical layers hypertrophy and reduces the volume of adrenal medulla.

DGGE MUTATION ANALYSIS OF RET, VHL, SDHB AND SDHD IN A SERIES OF EXTRA-ADRENAL PHEOCHROMOCYTOMAS

1 E. Korpershoek, 1 B. Petri, 1 F. van Nederveen, 1 W.N.M. Dinjens, 2 A.A. Verhofstad, 2 J.W. Lenders, 3 S. Schmid, 3 A. Perren, 3 P. Komminoth, 1 R.R. de Krijger
1 Department of Pathology, Josephine Nefkens Institute, Erasmus MC, Rotterdam, the Netherlands, 2 Department of Pathology and Internal Medicine, Radboud University Nijmegen, the Netherlands, 3 Department of Pathology, University of Zürich, Switzerland.

Pheochromocytomas (PCC) are rare tumours that generally arise from the chromaffin tissue of the adrenal medulla, but approximately 10% may also develop from extra-adrenal tissues. Twenty-five to 30% of patients with adrenal PCC show germline mutations in either rearranged during transfection protoocogene (RET, associated with multiple endocrine neoplasia type 2), VHL (associated with von Hippel-Lindau disease), succinate dehydrogenase subunit B (SDHB) or succinate dehydrogenase subunit D (SDHD). So far, little is known about the occurrence of mutations in these susceptibility genes in extra-adrenal PCC, as only few studies have investigated these tumours in limited numbers of patients. Therefore we have investigated a large group of extra-adrenal PCC for the presence of mutations in RET, VHL, SDHB and SDHD. We have performed denaturating gradient gel electrophoresis (DGGE) mutation analysis on a series of 32 extra-adrenal PCC. Mutation analysis of SDHD showed two patients with previously described mutations D92Y and L95P in exon 3, whereas there were three patients with previously undiscribed SDHB mutations: S100F and S123P in exon 4, and C243S in exon 7. No mutations were found in RET and VHL. We conclude that SDHB and SDHD might be involved in the development of a small proportion (15%) of the extra-adrenal PCC, whereas it seems that VHL and RET play no role.

EVALUATION OF HISTIDINE DECARBOXYLASE EXPRESSION IN NEUROENDOCRINE TUMORS OF DIFFERENT SITES BY IMMUNOHISTOCHEMISTRY AND REAL-TIME RT-PCR.

UCCELLA Silvia, CERUTTI Roberta,FURLAN Daniela, OLDRINI Rita, CARNEVALI Ileana, LA ROSA Stefano, CAPELLA Carlo.
Dept. of Human Morphology, University of Insubria, Varese

Immunohistochemical (IHC) expression of HDC has been proposed as a marker for normal ECL-cell of the stomach and related neuroendocrine tumors (NETs). HDC immunoreactivity (IR) has been recently detected in NETs other than gastric ECL-cell tumors, such as intestinal, bronchial and pancreatic well differentated NETs (WDNETs) and in poorly differentiated neuroendocrine carcinomas (PDNECs) of the lung. To date, the only available anti-HDC antibody is a polyclonal directed against the whole recombinant protein. This raises the possibility of a cross reaction with DDC, which shares a large piridoxal-5'-phosphate-dependent domain with HDC.
Aim of this work was to study the HDC-IR in a series of 107 NETs and to validate the IHC results in a subset of cases by the analysis of HDC and DDC mRNA expression using quantitative real-time PCR technique.
We studied 51 WDNETs (8 gastric and 43 extragastric) and 56 PDNECs (11 of the lung and 45 extrapulmonary). Anti HDC antibody (Eurodiagnostica, Malmo, SW) was employed with standard immunoperoxydase technique on sections from formalin fixed and paraffin embedded tumor samples. Fluorescence-based real-time RT-PCR assay was performed on 37 cases (26 WDNETs- 7 gastric, 5 ileal, 7 pancreatic, 7 bronchial- and 11 PDNECs of the lung), using specific probes and primers for HDC and DDC.
HDC-IR was observed in 43/51 WDNETs (84%) with no significant differences among various sites. 32/56 PDNETs (57%) were HDC-positive, including all lung carcinomas and a fraction ranging from 33% to 55% from other sites. Quantitative real-time PCR showed an increased expression of HDC in HDC-IR gastric, ileal and pancreatic WDNETs, while DDC expression was absent or lower than in normal controls. By contrast, HDC mRNA levels were very low in HDC-IR bronchial carcinoids, while DDC was highly expressed in all cases. In addition, all lung PDNECs showed HDC mRNA levels below the normal control, whereas high levels of DDC mRNA were found in all cases.
This study shows that anti-HDC antibody against the whole recombinant protein cross-reacts with DDC. Therefore, HDC-IR in NETs should be critically evaluated and validated with a specific molecular approach. Our data demonstrate that HDC is expressed in ileal and pancreatic WDNETs, in addition to gastric ECL-cell tumors. On the other hand, HDC-IR in bronchial WDNETs and in lung PDNECs should be considered as a cross reaction with DDC.

*** "D. Bagdasar" Hospital, Neurosurgery Dept., Bucharest, Romania

Introduction
Angiogenesis is a dynamic process, essential for embryogenesis, morphogenesis, tumorigenesis and other biological processes, being the most important factor for growth and proliferation of tumors.
Aim

We proposed to evaluate angiogenic phenotype by quantified the vascular density for estimation the biological behavior and invasiveness to pituitary adenomas.
Materials and methods
For quantified the vascular density, we used histochemistry (Gomori stain) and immunohistochemistry analysis (for vascular endothelial markers CD31/CD34, FVIII and the most potent angiogenic molecule - VEGF).
Results
We have investigated 30 paraffin-embeded pituitary adenomas: 21 functioning and 9 non-functioning; 22 with local invasiveness, 16 invasive in cavernous sinus; 4 were recidives.
Immunohistochemical analyses of CD31/CD34, FVIII, demonstrate variable degrees of vascular density in different types of pituitary tumors. There were differences in the fields of the same tumor, and also in the different types of tumor, angiogenesis being more pronounced in the front of invasive than in the middle of tumor.
CD34 was expressed in 100% of cases, follow by FVIII in 83,3% of cases.
There is a good correlation between CD34 and FVIII expression.
We observed a positive correlation between vascular density and invasiveness, angiogenesis is more pronounced in invasive pituitary tumors.
VEGF expression is more prominent in certain adenoma subtypes; stronger in invasive pituitary adenomas.
Conclusions.
Analyses of vascular density may provide useful information regarding angiogenesis and their role in determining overall angiogenic phenotype and their tumor behavior.

P 629
ROLE OF NITRIC OXIDE IN THE MODULATORY EFFECTS OF OVARIAN HORMONES UPON BEHAVIORAL INDICES OF ANXIETY IN FEMALE RATS
SADEGHIPOUR RODSARI,Hamid Reza
Depte. of Physiology, Faculty of Medicine,Tehran University of Medical Sciences,Teharn, Iran

Nitric oxide, as neurotransmitter and neuromodulator is considered to be involved in several physiologic processes within the central nervous system. The objective of the present study is to determine the influence of this molecule on the indices of anxiety regulated by ovarian hormones.
The study was conducted on 150 sterilized female rats. Estradiol Benzoate (10 ìg/kg/SC), progesterone (25 mg/kg/SC), alone or both, were administered to the animals in different groups. Some groups received an additional dose of either L-name (60 mg/kg/IP) or L-arginine (100 mg/kg/IP) before the behavioral test. Then the anxiety indices based on open and closed arms exploration, were estimated in an elevated-plus maze test.
Finally, blood samples were obtained to measure serum nitrite-nitrate concentration (the metabolite of nitric oxide) using Griess reaction.
Our study showed an anxiolytic effect of progesterone and progesterone+L-name, along with a decrease in the nitrite-nitrate concentration. While the administration of estradiol alone or together with L-arginine showed an anxiogenic effect and a reduction in nitrite-nitrate concentration.
The findings suggest the possible involvement of nitric oxide in the process of anxiety induced by ovarian steroid hormones.

CHONDROMYXOÏD FIBROMA OF THE TIBIA. A CASE REPORT
AL ATAWNA Hind, EL BAKOURI Jalila, BENADRA Fatiha, RAIS Hanane, EL ATTAR Hicham, BELAABIDIA Badia
Pathology Department , Mohammed VI hospital , university of Marrakesh , Morocco

The chondromyxoïd fibroma (CMF) is a rare benign osseous tumour. It represents less than 1% of the primitive osseous tumours and 2% of the benign osseous tumours. Its radiological aspect is strongly evocative. Its histological aspect is misleading sometimes of a chondrosarcoma or a chondroblastoma. The diagnosis confirmation rests on anatomo-radiological confrontation.
A 28 years old man has consulted for metaphyso-epiphyseal tibial osseous pains . X-Rays demonstrated a metaphyso-epiphyseal lytic excentric limited tibial image without periosteal reaction nor invasion of the soft tissue.The anatomopathological exam for surgical curettage confirmed the diagnosis of CMF.
The CMF is a rare benign osseous tumour. It poses problems of differential diagnosis with a chondrosarcoma. The anatomo-clinical and radiological confrontation is needed for diagnosis confirmation. The prognosis of this entity is good.

P 631
ACTIVATION OF THE JAK1 – STAT3 SIGNAL TRANSDUCTION PATHWAY IS ASSOCIATED WITH PATHOGENESIS AND PROGRESSION OF HUMAN CHONDROSARCOMAS
D.J. Papachristou , O.A. Papaefthymiou , D. Strefanou, A. Batistatou and N.J. Agnantis
Department of Pathology, School of Medicine, University of Ioannina, Greece

Introduction: Chondrosarcomas represent the second most frequent primary bone malignancies. However, comprehension of the molecular mechanisms underlying their pathogenesis is far from thorough. The Signal Transducer and Activator of Transcription (STAT) family proteins are transcription factors pivotal in mediating cytokine signaling. Among them, STAT3 is frequently activated in human malignancies and transformed cell lines and is involved in tumorigenesis. Activation of STAT3 is regulated by JAK1, a member of the Janus Kinases family proteins. Recent studies have demonstrated that STAT3 interacts with the promoter of c-fos proto-oncogene, enhancing its transcription. In vitro and in vivo data suggest that the onco-protein c-Fos is overexpressed in human chondrosarcomas.
Purpose: To test the hypothesis that functional upregulation of the JAK1 – STAT3 pathway and induction of c-Fos, are implicated in the pathogenesis and progression of human chondrosarcomas.
Materials and method: We employed immunohistochemistry to assess the protein levels of JAK1, its substrate STAT3, the phosphorylated/activated form of STAT3, p-STAT3 and c-Fos, in 21 benign chondroblastic lesions (14 osteochondromas, 7 enchondromas), 36 chondrosarcomas (13 Grade 1, 15 Grade 2, 8 Grade 3) and in normal cartilage.
Results: Positive immunostaining for JAK1, STAT3, p-STAT3 and c-Fos was observed in 94.4%, 100%, 97.2% and 94.4% of the chondrosarcomas, and in 42.9%, 61.9%, 23.8% and 42.9% of the benign tumors, respectively. Normal cartilage was devoid of these immunoreactivities. The cellular levels of all proteins were significantly correlated to each other (Spearman's Rho 0.699-0.892, $p<0.001$ for each correlation). Significantly higher expression levels of all proteins were detected in grade 3 compared to grade 2/1 chondrosarcomas, and to benign chondroblastic lesions (Mann-Whitney U test, $p<0.001$ for each tumor grade pair, Kruscal Wallis $p<0.001$).
Conclusions: Our findings provide novel evidence that the JAK1/STAT3 signal transduction pathway and the onco-protein c-Fos are functionally operative in the neoplastic change of chondroblastic cells and the development and progression of human chondrosarcomas. Evaluation of the

expression levels of c-Fos and JAK1 - STAT3 signalling cascade components, may facilitate an improved prediction of the tumor's clinical behaviour and potentially be exploited in designing patient-tailored treatment regimens.

P 632
IMPLICATION OF JNK/ERK–AP-1/ –RUNX2 "CROSS-TALK" IN CARTILAGE LOAD-TRIGGERED CHONDROGENESIS

D.J. Papachristou (1,2), P. Pirttiniemi (3), T. Kantomaa (3), N.J. Agnantis (1), A.G. Papavassiliou (2), E.K. Basdra (4)
(1) Department of Pathology, School of Medicine, University of Ioannina, Ioannina, Greece
(2) Department of Biochemistry, School of Medicine, University of Patras, Patras, Greece
(3) Institutes of Dentistry, University of Oulu & University of Helsinki, Finland
(4) Department of Orthodontics, School of Dentistry, Aristïtle University of Thessaloniki, Thessaloniki, Greece

Introduction: Mechanical loads influence chondro-osteogenesis and thus skeletal morphology. However, the exact mechanisms by which mechanical stimuli are transduced in chondrocytes remain obscure. Recent data have documented the involvement of the JNK and ERK MAPK signaling pathways and the transcription complex AP-1 in chondroblastic differentiation, proliferation and maturation. Furthermore, in vitro studies have demonstrated the paramount importance of the transcriptional regulator Runx2 in chondroblast biology.
Purpose: To explore and characterize the mechanotransduction events occurring in chondroblasts under altered functional loading. To this end, the roles of JNK/ERK–AP-1 signaling cascades and Runx2 were investigated.
Materials and Method: Fourteen-day-old female Wistar rats were divided into 2 groups: the first group was fed whole pellets (simulating physiologic mastication), while the second group was fed soft diet (lowered temporomandibular joint (TMJ) loading). Animals were sacrificed at 6, 12, and 48 h post-experiment initiation and biopsy material was obtained from their TMJ condyles at each time point. Immunohistochemistry was performed to evaluate the expression levels of pc-Jun (c-Jun' s phosphorylated/active form), c-Fos (principal AP-1 partner of c-Jun), JNK2 (major c-Jun kinase), p-JNK (phosphorylated/active species of JNK2), p-ERK (ERK's phosphorylated/active counterpart) and Runx2, on each TMJ specimen.
Results: The protein levels of all the examined signaling mediators/effectors were markedly increased in animals fed with hard diet, throughout the experimental process (ANOVA, $p<0,001$ for all). Tukey post-hoc analysis revealed that protein expression levels were significantly higher in cartilage from the hard, compared to cartilage from the soft food group, at 48 and 12 h. The cellular levels of the proteins were positively and significantly correlated to each other (Kendall's tau = 0.601-0,812, $p<0.001$).
Conclusions: 1) Functional cartilage loading induces the MAPK cascades; 2) Coordinate targeting of AP-1 and Runx2 transcription factors by mechano-triggered JNK and ERK appears to "fine tune" chondroblastic differentiation/maturation; 3) Deciphering the molecular events underlying the mechanotransduction phenomena is important, in order to effectively combine mechanical therapy with pharmacological intervention to control cartilage growth, augment cartilage repair and prevent cartilage degeneration.

P 633
MESENCHYMAL CHONDROSARCOMA – MULTICENTRIC OR METASTATIC LESION

ATANCKOVIC Mirjana, SOPTA Jelena, NAGULIC Mirjana, TULIC Goran

We present a case of mesenchymal chondrosarcoma in a 25 year old man who had painless tumour of m.vastus lateris sinistri invented after trauma. Radiographic examination showed soft tissue mass with iregular calcification of femoral region.
Diagnostic evaluation disclosed a hematoma in obs., but MRI will show an aggressive soft tissue mass in the reg.femoris with areas of calcification.
One month later patient noticed a weal of eyelid inferior and sweling with protrusio bulbi oculi dextri. CT scans showed retrobulbar infiltrative mass soft tissue density. Tumor mass present at the right frontal sinus was 18-20 H.U.density.
Surgical resection was done at the same time of retrobulbar and reg.femoris tumors mass. Microscopically, tumours exhibited biphasic pattern, cellular and cartilage. The majority of the tumours were composed of sheets or aggregates of small round and spindl cells with hyperchromatic nuclei that resamble those of Ewing sarcoma. Somewhere cells were arranged in a manner suggestive of hemangioperycitoma. Poorly circumscribed cartilaginous areas are blend with the undifferentiated tumour cells. Rarely, the cartilaginous foci were well defined. The histological and imunohisthemical diagnosis was – mesenchimal chondrosarcoma.
Two months after operation it was marked on the skin small lesions of abdominal wall and reg. buccae. Pathohystological verification was done and diagnosis was – mesenchymal chondrosarcoma. At the same time on verthebral body of Th 2-4. Radiographic examination showed small osteolytic lesions, but those lesions didn't examinate pathohystologicali.
Chemotherapy (ADM) was apply 3,5 months after resection, but because of recurrens of retrobulbar tumour and its invasion at the cranium with simptoms of intracranial high pressure – patient died 8 months after diagnosis was made.
A critical step of presented case is to ascertain whether it is a multicentric soft tissue and bone mesenchymal chondrosarcoma or the first discovered localisation is primary tumour and the others - metastasis.

P 634
CONDROBLASTOMA, A RETROSPECTIVE STUDY OF 13 CASES OVER A PERIOD OF 6 YEARS.

POP Doina, POP Florinel

Condroblastoma is a rare benign tumor of the epiphysis encountered commonly in the 2nd decade benefiting exclusively from surgery.
Many histopathological pitfalls associated with this tumor make it a great mime of osseous tumors, especially of osteosarcoma, which is by far more frequent in this age interval and of giant cell tumor, sharing with it the same location. The extreme heterogeneity of this tumor coupled with its local aggressiveness, in long standing cases, awakes suspicion about malignancy. Because of extra compartmental involvement in 8 out of 13 cases, fine needle aspiration was the fist diagnostic procedure, which is a simple maneuver, sometimes in the range of the pathologist's competence and very often rewarding, if not with extreme precision of diagnosis at least as malignant/benign supposition.
Frequently our guess was giant cell tumor (5 out of 8 cases), and only in 1 case the condroblastoma diagnosis was carried out in this stage of diagnostic procedures. In two cases the aspirate was very cellular, mitoses were noticed as well as chondro and osteoid matrices, facts that arose suspicion of malignancy and urged for biopsy. As for the biopsy the pathologist task was not easy. histochemistry (Acid periodic-Schiff, Gordon-Sweet and Alcian Blau and immunohistochemistry(S-100 protein, neuron specific enolase, osteopontin, Ki-67 and PCNA) were performed and sometime contributory to the final right decision.

Those cases staged G1(Enneking), were submitted to surgical excision with thorough curetting after benign intraoperatory frozen sections .
The definitive paraffin diagnosis was carried out after scrupulous sampling and integration of all histopathological aspects some of which could be very intriguing if taken apart. Our presentation intends to show most of them which are related to the presence of condro-osteoid matrix, metaplastic areas and mitotic activity.

Immunohistochemisty was of little help in differential diagnosis so that one's experience and radiological correlation are essential.

Our study tries to catch the many faces of this tumor and establish an algorithm of diagnosis emphasizing on radiological-histopathological correlation.

PROTECTIVE EFFECTS OF VITAMIN D3 ON METHYLPREDNISOLONE ACETATE INDUCED LOSS OF BONE METABOLISM MARKERS AND BONE MINERAL DENSITY IN THE LUMBAR SPINE OF RAT.

Aligholi Sobhani Ph.D., Fatemeh Moradi, MSc., Parichehr Pasbakhsh Ph.D., Iraj Ragerdi Kashani, MSc.

Introduction: Although some vitamins have been shown to prevent glococorticoids induce osteoporosis in short time, the magnitude of this effect remains to be clarified. The aim of this prospective study is the evaluation of protective effect of vitamin D3 on methylprednisolone acetate induced osteoporosis in rats.

Methods and Materials: Total duration of the experiment was four weeks. Twenty-four male spargue Dawly rats (8 week old and 180 g weight) were randomly divided into four groups: Group A (n=6), was a base line control or normal animals. Group B (n=6), was treated only normal saline (0.9%), group C (n=6), was treated methylprednisolone acetate (0.2 mg/kg) subcutaneously for 4 weeks (3 times per a week) and finally group D (n=6) were administered methylprednisolone acetate resemble to group C and treated by Vitamin D3 (0.1 µg/kg dissolved in ethanol daily). For evaluation of biochemical agents changes in the serum, level of calcium, osteocalcine and acid phosphatase were measured before and after treatment. Also, bone mineral density (BMD) of lumber vertebrae was measured by dual energy x-ray absorptiometry (DEXA).

Results: The results showed that, the serum calcium level unaffected ($P>0.05$) by methylprednisolone acetate in all groups before and after treatment, but, the serum osteocalcine level and bone mineral density of lumbar vertebrae were significantly ($p=0.05$) decreased in group C compared with groups A and B. In group D serum osteocalcine level increased again significantly ($p<0.05$) but increasing of bone mineral density and bone mineral content were not significant ($P>0.05$). Also, the serum acid phosphatase level increasing in group C was treated by vitamin D3 (in Group D), but was not significantly ($p>0.05$).

Conclusions: The findings of present investigation indicate that by using of vitamin D3 in methylprednisolone acetate treated rats could increase bone formation and decrease bone resorption.

Key words: Methylprednisolone acetate, Vitamin D3, Osteoporosis, Bone Markers Metabolism, BMD and Rat.

FIBRONECTIN IN HUMAN BONE TISSUE REMODELLING

DAHSE Regine (1), ROSENHAHN Julia (2), KILIAN Olaf (3), KOSMEHL Hartwig (1)
(1) HELIOS Klinikum Erfurt; Institute of Pathology, Nordhäuser Str. 74, D-99089 Erfurt, Germany
(2) University of Jena, Institute of Human Genetics and Anthropology, Kollegiengasse 10, D-07740 Jena, Germany
(3) University of Giessen, Dept. of Trauma Surgery, Buchheimstr. 7, D-35392 Giessen, Germany

The extracellular matrix component fibronectin (fn) has fundamental functions in cell attachment, differentiation, proliferation and in cell migration. Embryonic forms of cellular fn, named EDA-fn and EDB-fn, are generated by alternative splicing. They are detected in proliferating tissue, wound healing and tumor invasion.
This study aimed to quantify fn and its splice variants in the most frequent highly malignant human bone tumor (osteosarcoma) in comparison to bone fracture healing tissue as a model for a physiological bone repair process.
Material and Methods: A real-time quantitative RT-PCR assay (LightCycler System, Roche) was developed to quantify levels of fn, EDA-fn and EDB-fn mRNA. Relative expression was correlated to cell proliferation and differentiation (detected immunohistochemically by Ki67 and CD31 marker) and to the level of osteoid formation.
Results: Both, osteosarcoma and bone fracture healing tissue, did express higher levels of the embryonic fn variants (EDA-fn, EDB-fn) compared to unspliced fn. No significant differences were found in the EDA-fn and EDB-fn mRNA expression comparing tissue remodelling in malignant or physiological repair processes. EDA-fn and EDB-fn expression in osteosarcoma did correlate to the osteoid formation.
Conclusions: Embryonic fn splice variants are a strong marker for active granulation and tissue remodelling processes in human bones comparable with wound healing processes. The stimulating effect of fn splice variants on reparative and proliferative processes can be found in physiological bone remodelling as well as in malignant transformation. EDA-fn and EDB-fn mRNA expression levels are a marker for the malignant differentiation in osteosarcoma.

P 637

TGF BETA 1 INFLUENCE ON OSTEOBLASTS IN PATIENTS WITH NONSYNDROMIC CRANIOSYNOSTOSIS

Severgina E, Leonova L, Severgina L, Lopatin A, Ovchinnikov S, Yassonov S.

Nonsyndromatic craniosynostosis (NC) is characterized by premature closure of cranial sutures in children. The aim of our investigation was to evaluate osteoblastic cell events that lead to NC. 10 children (from 8 months to 5 years old) incision biopsies were studied. All children had an isolated NC. Stenosed cranial sutures were removed during the cranioplastic operation, fixed, decalcified with the trilon B, paraffinized. Light microscopy, immunohistochemistry was performed with labeled, specific anti-TGF beta 1 and R1, Ki 67 antibodies.
We found mature osteons, fragments of the osteons, intermediate lamellas, osteon-like structures in the cranial biopsies. Osteoblastic cells lining the bone fronts were located on the inner side of sutures. We did not find in the biopsies the serrated margins of sutures in opposite to the control. We discovered the focuses of ossification as well as the areas of bone atrophy. Within affected sutures we revealed premature ossification, increased extent of subperiosteal bone formation and complete suture obliteration instead of connective tissue zone and osteogenic cells as seen in normal cranial sutures. The same criteria of the increased osteogenesis were seen about 3 cm from a closed suture. In conjunction with increased osteogenesis the morphological changes of the osteolysis were observed: the close situated serration resorption line, the dedifferentiation of the osteones,

the osteoclastic resorption, ”oncosis.” There were opened haversion canals and spaces in the inner plate of the bone.
The immunohistochemystry showed the expression of TGF beta 1 and R1 on the osteoblasts and overexpression of the same factor on the osteoblasts within the inner plate of the cranial bone. We found increased osteoblastic proliferation with deposition of Ki 67 in these areas. The TGF beta 1 is one of the factors regulating cell-to-cell and cell-to-matrix interactions, proliferation, differentiation and maturation of the osteoblasts. Also this factor stimulates osteogenic activity of osteoblasts and accelerates osteogenesis. The activated osteoblastic cells grew at a significantly increased rate and produced significantly more serum osteocalcin than the control (119,3 ng/ml vs. 31,5 ng/ml, $p<0,05$).
In general the morphological changes of the cranial bones were typical for cynostosis in all children, but the quantitative and qualitative features were different. Maximal TGF beta 1 expression in the cranial biopsies proposes a key role of this factor for NC due to stimulation of the osteoblast proliferation, differentiation and maturation. Our results indicate that an increased maturation of osteoblastic cells in the suture margins leads to the premature ossification in NC.

CLINICAL AND PATHOLOGICAL ASPECTS IN DISTAL FEMORAL PATHOLOGICAL FRACTURES DUE TO METASTASIS
P.Sirbu1, Doinita Radulescu2, Simona Stolnicu3, Simona Mocan3
1. Emergency Hospital, University of Medicine, Iasi, Romania
2. Department of Pathology, University of Medicine, Iasi, Romania
3. Department of Pathology, University of Medicine, Targu Mures, Romania

The present paper analyzed the clinical, pathological and therapeutic aspects in a group of 15 patients with surgically removed metastasis at the distal femur level. The mean age was of 52,5 years. 9 patients showed a history of malignancy (lung carcinoma- 5 cases, larynx carcinoma- 1 case, breast cancer- 2 cases and prostate cancer- 3 cases). All patients were operated fir the pathological fractures by tumor exeresis, cavity sealing with acrylic cement and internal fixation, with immediate mobilization. Histopathological examination showed similar differentiation degrees in metastasis and the primary tumor in 7 cases. 3 primary tumors were found while 3 metastasis remained with an unknown primary tumor. Even if the osteosynthesis was performed on pathological bone it insured the patient the required mobility that was balanced with the survival period.

P 639
THE FRA-1, FRA2 AND JUNB, JUND TRANSCRIPTION FACTORS ARE INVOLVED IN THE SIGNALING CASCADE TRANSDUCING MECHANICAL LOAD IN CONDYLAR CHONDROCYTES
Papachristou D.J. (1,3), Pirttiniemi P (2), Kantomaa T. (2), Agnantis N.J. (1), Papavassiliou A.G. (3), Basdra E.K. (4)
(1) Department of Pathology, School of Medicine, University of Ioannina, Ioannina, Greece

(4) Department of Orthodontics, School of Dentistry, Aristïtle University of Thessaloniki, Thessaloniki, Greece

Introduction: The chondrocytes of articular condylar cartilage proliferate, hypertrophy and finally undergo apoptosis, being replaced by osteoblasts. Mechanical loading influences the growth of the condylar cartilage, and the mechanical environment of the temporomandibular joint (TMJ) regulates the biological and histological features of the cartilage tissue via differentiation of proliferative cells into mature chondroblasts. Animal studies have shown that changes in the amount of chewing force and reduced masticatory function result in alteration of the overall growth of the mandible, hence decreased condylar cartilage growth activity. The Jun (c-Jun, JunB, JunD) and Fos (c-Fos, Fra-1, Fra-2) family of proteins are components of the dimeric transcription factor AP-1. They are activated by extracellular stress and play critical roles in bone remodeling and programmed cell death/apoptosis.
Purpose: The aim of this study was to examine the implication of the AP-1 constituents Fra-1, Fra-2, JunB and JunD in the signaling pathway of mechanical loading in the condylar cartilage. Furthermore, the association of mechanical load to cell differentiation and apoptosis through the involvement of the above factors was investigated.
Materials and Method: Fourteen-day-old female Wistar rats were divided into 2 groups: the first group was fed hard food (simulating physiologic mastication), while the second group was fed soft diet (resulting in lowered TMJ loading). Animals from both groups were sacrificed at 6, 12 and 48 h after the experiment initiation and histologic sections were obtained from their TMJ condyles at each time point. The condylar cartilage of both groups was immunostained against Fra-1, Fra-2, JunB and JunD.
Results: Our data revealed up-regulation of all the examined members of the AP-1 transcription factor family in all stages of differentiation of chondrocytes derived from mandibular condylar cartilage.
Conclusions: Mechanical loading of condylar chondrocytes results in early apoptotic phenomena of these cells and subsequent replacement by osteoblasts, most likely affecting the overall growth of the condylar head. Elucidating the signaling pathways of mechanical load in condylar cartilage cells may unravel new routes for innovative treatment approaches of patients suffering from dentofacial deformities.

P 640
CALCANEUS AS A LOCALIZATION OF SOLITARY UNICAMERAL BONE CYST
SOPTA Jelena, ATANACKOVIC Mirjana

The calcaneus is a skeletal site no so frequently affected by solitary unicameral bone cysts (SBC). In the period of 30 years at the Bone Biopsy Register of the Institute of Pathology, School of Medicine, Belgrade in calcaneus have been registered:3 chondroblastomas, 5 osteochondromas, 2 morbus exostosans, 4 chondrosarcomas, 1 osteoid osteoma, 1 osteosarcoma, 1 Ewing sarcoma, 1 giant cell tumor, 3 aneurysmal bone cysts and 17 solitary bone cysts. Calcaneal SBC accounts 3,25% of SBC of all localizations and 44,7% of all diagnosed tumors in calcaneus.
The diagnosis of calcaneal SBC based on radiographic features was possible in almost all cases. On CT scans and MRI scans the cysts were filled with fluid. A CT scan showed a central hypodense area of -120 Hounsfield units representing fat in the fluid-fluid cyst (differential diagnosis intraoseous lipoma).
After curettage cystic membrane was pathological observed. Histological features of SBC in calcaneus, are slight different from SBC of long tubular bones. The cyst membrane is usually thinner (in 2 cases absent), the zone of bleeding are more marked (9 cases), with cholesterol crystals (7 cases). Histologic proof of cementum-like substance (8 cases) showed that calcaneal cysts are true SBC and excluded intraoseous lipoma. Cementum-like substance was diagnosed more frequent in cancaneal (43%) than in long bone (10%) SBC. In 2 cases were presented histological characteristic of superposed aneurismal bone cyst.

In 80% of cases cysts were diagnosed on a characteristic and typical location- the trochlear processus, Ravelli's calcaneal triangle. The nature and clinical importance of calcaneal cysts is controversial and not clear. The risk of pathologic fracture is unpredictable and surgical treatment is not always necessary. SBC in caslcaneus is "self-limited" disease, and in significant percent of cases were described spontaneous filling of the defect.

P 641
HISTOPATHOLOGICAL CLASSIFICATION OF PERIPROSTHETIC LOOSENING MEMBRANES

Morawietz L (1), Schroeder J (2), Dynybil C (2), Kriegsmann J (3), Krenn V (1)
(1) Institute for Pathology, University Hospital Charite, Berlin
(2) Department for Orthopedic Surgery, University Hospital Charite, Berlin
(3) Group practice for pathology, Trier

Aims: To find a consensus on defined histopathological criteria for a standardized evaluation of the periprosthetic membrane from loose hip and knee endoprostheses.
Methods: Based on histomorphological criteria, four types of the periprosthetic membrane are defined: Wear particle type (detection of foreign body particles; macrophages and multinucleated giant cells occupy at least 20% of the area; type I); infectious type (granulation tissue with neutrophilic granulocytes, plasma cells and few if any wear particles; type II); combined type (aspects of type I and type II occur simultaneously; type III); indifferent type (neither criteria for type I nor type II are fulfilled; type IV).
Periprosthetic membranes from 370 patients (f=217, m=153, mean age 67.6 years, mean time to revision surgery 7.4 years) were analyzed according to the abovementioned criteria.
Results: Incidences of the histopathological membrane types: type I 54.3%, type II 19.7%, type III 5.4%, type IV 15.4%, not assessable 5.1%. The mean time between primary arthroplasty and revision surgery was: type I 10.1 years, type II 3.2 years, type III 4.5 years and type IV 5.4 years. The inter-observer reproducibility (three pathologists) was sufficient (87.1%, Cohen's kappa=0.805). The correlation between histopathological and microbiological diagnosis was high (89.7%).
Conclusion: Together with numerous co-workers, we propose a feasible classification system, enabling a standardized diagnostic evaluation of periprosthetic membrane samples. Furthermore, the importance of non-infectious, non-particle-induced prosthesis loosening (membrane type IV), which was observed in 15.4%, is highlighted.

P 642
ONCOGENIC OSTEOMALACIA (OO): REPORT OF TWO CASES

JOSSELIN Nicolas(1), CROUE Anne(1), KOFFI Emmanuel(1), AUDRAN Maurice(2), ROUSSELET Marie-Christine(1), SAINT-ANDRE Jean-Paul (1)
(1) Department of Pathology, University Hospital, 49933 ANGERS cedex 09, France
(2) Department of Rheumatology, University hospital, 49933 ANGERS cedex 09, FRANCE

Oncogenic osteomalacia (OO) is rare and characterized by vitamin D inefficiency, hypophosphatasia and loss of phosphate in urine. OO is mostly linked to benign mesenchymatous tumours. We report two cases.
The first concerned a woman of 67 who benefited from treatment for postmenopausal osteoporosis. The second one concerned a 52-year-old man who had an initial diagnosis of male osteoporosis. Both were treated by alendronate and vitamin D. Despite this treatment, these patients showed bone fractures and progressively increasing asthenia. New biological exams assessed dramatic hypophosphatemia and an abnormal phosphate tubular absorption. Calcic metabolism was normal. A bone biopsy was performed on the woman showing osteoporosis and rickets. For each case, biological results allowed to exclude a carential etiology. Tumours were located using CT-scan. For the woman, the tumour measured 15 mm beneath abdominal subcutaneous fat. For the man the tumour was located under the sole of the foot and measured at 30 mm. Both tumours showed the same histological aspect. They were composed of fusocellular cells. These cells were not atypical. They were surrounded by an often mineralized myxoid stroma. Vascularization showed a hemangiopericitic pattern. Bone pain, clinical signs and hypophosphatemia normalized a few months after removing of the tumour.
Oncogenic osteomalacia are most often linked to benign mesenchymatous tumours mostly located in bone or soft tissue. They have several histological aspects. They secrete ' Fibroblast Growth Factor' FGF23 which leads to loss of phosphate in urine by inhibiting phosphate tubular reabsorption.

P 643
QUANTITATIVE ANALYSIS OF PERIOSTEAL CIRCULATION IN LONG BONES

ANTABAK Anko, BRCIC Luka, BATELJA Lovorka, DAVILA Slavko, SEIWERTH Sven.
Dept. Of Surgery Clinical Center Zagreb; Institute of Pathology, Medical Faculty, Zagreb, Croatia.

The important role that periosteum plays in healing bone injury and its use as a potential source of osteoprogenitor cells is of high clinical interest. Periosteum is important for bone vascularization and osteogenesis. Periosteal tissue is divided into an outer fibrosis and an inner - active and proliferative layer with intrinsic periosteal blood system. So far few data are available about the quality of periosteal circulation especially regarding different bones and different bone segments. Aim of this study was to quantify microcirculation of inner layer of intact periosteum. We examined periosteum of radius and tibia, taken from 4 sheep 1 to 2 years old. Material for microscopic examination was fixed in 10% neutral buffered formalin, decalcinated in a mixture of formic and sulfuric acid, embedded in paraffin and stained immunohistochemically for CD34 and von Willenbrands factor according standard protocol (DAKO, Denmark). Two samples from each periosteum, 1 cm length respectively, were processed. From each sample 5 fields were analyzed microscopically using a x25 objective and computer-based image analysis system (ISSA, VAMSTECH, Zagreb, Croatia). Periosteal thickness and capillary count were accessed. Capillaries were counted in inner periosteal layer in a determined field of 10 000im2. Analysis of intact periosteal microcirculation yielded a mean capillary number of 5, and a mean periosteal thickness of 100um. Our quantification of the periosteal capillaries indicates no significant differences between periosteum taken from radius and those taken from tibia. From our data we concluded that they represent a basis for studying periosteal capillary circulation during the process of healing or its damage caused by osteosynthesis.

P 644
REPAIR OF BONE DEFECTS BY ANIONIC COLLAGEN MATRICES

(1) Department of Pathology, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Brazil, (2) Department of Pathology, Faculty of Medicine, (3) Institute of Computing, State University of Campinas, Brazil

The aim of this study was to evaluate the repair of critical-size bone defects by three anionic collagen matrices in rats. Samples of the collagen matrices with varying electric charge density were implanted in 4-mm cranial bone defects with empty defects as controls. Cranial bone was retrieved after 3,

7, 15, 30, 60 days and 1 year and submitted to radiological, histological, immunohistochemical and ultrastructural analysis. Texture analysis was done on digitalized microscopic images. Two of the matrices allowed a quick recovery of the bone structure. After two months, full recovery of the bone defects was seen. The collagen matrix with the highest electric charge density still had remnants at the periphery of the newly formed bone at the same period. The anionic collagen matrices were actively incorporated into the mineralized bone matrix, without signs of resorption prior to the mineralization process. At the beginning of the regeneration process insulin-like growth factor-I and bone morphogenetic proteins 2 and 4 were found in direct contact with anionic collagen matrices, revealing a possible mechanism of osteogenesis stimulation by the anionic collagen matrices. One year after implantation, all defects were fully recovered. Texture analysis showed decreasing values of entropy and the fractal dimension during the experiment. The changes of the fractal dimensions followed a power law for each matrix. Morphologically, the bone formed by the matrix with the highest charge density had a more mature aspect compared with the less electronegative matrices, which could also be demonstrated by comparison of the fractal dimensions. These results show that the anionic collagen matrices are effective osteoconductive biomaterials, showing a great potential for clinical application.

P 645
THE ROLE OF THE EXTRACELLULAR MATRIX IN THE BONE LAMELLA ARCHITECTURE
A. F. Vreju (1), G. S. Drãgoi (1,2), Trasca E.T. (1)
1. University of Medicine and Pharmacy- Craiova
2. Academic Hospital Filantropia -Craiova

Objective: The bone lamella participates to the formation of two components of the bone, compacta and the spongy part of the bone. The bone lamella, a constitutive part of the bone extracellular matrix was studied using a microanatomic study of the endochondral ortomorphogenesis; a study of the bone lamellar elements in trabecular bones, and a study of the bone lamellar system in bones with mixed osteogenesis.
Materials and methods: 53 bones from the axial skeleton (vertebra, sternum), 54 bones from the lower limb skeleton (femur, tibia, calcaneus). Stains: HE, Van Gieson, Gömöri.
Results: The research on the extracellular matrix from the cortex of the tibia diaphisis showed us a continuity of the interosteonal collagen lamella fascicles with those from the osteon's periphery. This doesn't concord with the classic images. The collagen lamella fascicles' stereotopography can be studied using mathematical methods – the parametric equation of a Moebius band. The collagen fibers from the bone lamella in the osteons from compacta of tibia diaphisis are birefringent and parallel with each other. Some fascicles are tangent to the oval spaces.
Conclusions: The stereodistribution of the collagen lamella fascicles is variable with the osteogenesis and the mechanic forces hereupon the bones are or will be submitted. The application of the mathematic methods of algebra topology and the finite element opens new ways in the modeling and the creation of abstractisation of the bone lamella system, on one way and in the evaluation of the hemato-pathological lesions on the bone biopsy on the other way.

P 646
EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) EXPRESSION IN CHORDOMA
PTASZYNSKI Konrad, PEKUL Monika, PIASCIK Agata, FALKOWSKI Slawomir.
MCS CANCER CENTER, INSTITUTE, WARSAW, POLAND

Epidermal Growth Factor Receptor (EGFR) overexpression has been found in various tumors with poor outcome. Chordoma is a neoplasm arising from the embryonal rest of the notochord. The most common locations are both ends of the spine, sacral bone and head and neck locations. Surgery and radiation therapy are the most commonly used treatment modalities. Purpose of the study was to evaluate an EGFR expression status in 21 cases of chordoma diagnosed at the MCS Cancer Center Institute between 2002 and 2004. Immunohistochemistry with anti EGFR antibody as well as Fluorescence In Situ Hybridisation (FISH) were utilised on the slides obtained from the paraffin blocks. Ten cases showed strong expression of EGFR receptor, eleven cases were negative. At the time of the evaluation, six cases with EGFR expression presented with metastatic disease. Four cases negative for EGFR expression showed metastatic disease. In many cases of chordoma surgical and radiotherapy treatment is not effective. New treatment modalities are needed. Anti EGFR (cetuximab) treatment approach might be a supplementary method.

P 647
GIANT CELL TUMORS OF THE BONE: A RETROSPECTIVE STUDY OF 33 CASES.
S Hannachi Sassi1, S karray2, F Laddeb2, M Douik2, K Ben Romdhane1.
1 Department of Pathology, Salah Azaiez Institute, Tunis, Tunisia.
2 Department of Orthopaedical Surgery, Mohamed Taïb Kassab Institute, Tunis, Tunisia.

Introduction: Giant cell tumors (G.C.T) of the bone are rare. They represent 5 to 10% of all primary bone tumors and 20% of benign lesions. They are often locally aggressive neoplasm characterized by large numbers of uniformly distributed, osteoclast-like giant cells and a more diagnostically pertinent background population of plump, epithelioid to spindle mononuclear cells.
Aims: To describe the epidemiological, clinical, radiological features and test the relationship between histological grading of Jaffe et al., established in 1940, and the prognosis.
Materials and methods: Thirty three cases of G.C.T of the bone were examined during 28-year period from 1970 to 1997. After studying the epidemiological, clinical and radiological features, the histological criteria of Jaffe et al. (1940) were performed for each case.
Results: Thirty three cases of G.C.T were retrieved with a range of age between 16 and 66 years with an average of 32.8 years. Female outnumbered male (23 vs. 10). Ninety-four (94%) were located in the long bones, the most frequent sites being the lower end of the femur (10 cases), the upper end of the tibia (6 cases) and the lower end of the radius (6 cases). Twenty cases (64%) occurred around the knee. Radiologically, 24 cases (77.4%) occupied the epiphysial and metaphysial regions. The tumor was centrally placed in 23 cases (69.7%) and eccentrically placed in 10 cases (30.3%). The tumor showed an expanded lytic lesion with fine to moderately coarse trabeculations in 26 cases (78.8%) and a pure lytic appearance in 7 cases (21.2%). Histological grading of Jaffe et al. resulted in 12 cases of grade I, 20 cases of grade II with 3 cases of grade II+ and 1 case of grade III. Statistical analysis revealed no significant correlation between all morphological parameters and prognosis.
Conclusion: Our epidemiological, clinical and radiological findings are in agreement with published data. Furthermore, there is no relationship between the histological grading and the prognosis.

P 648
A RETROSPECTIVE MULTIVARIATE ANALYSIS OF MYXOFIBROSARCOMAS: WITH A SPECIAL

EMPHASIS ON MARGIN STATUS AS A CRITICAL PROGNOSTICATOR

Chien-Feng LI^, Ching-Nan LIN^, Hsuan-Ying HUANG*
Department of Pathology, Chi-Mei foundation Medical Center^, Tainan, Taiwan
Department of Pathology, Chang Gung Memorial Hospital, Kaohsiung Medical Center*, Kaohsiung, Taiwan

Introduction: Myxofibrosarcomas (MFS) are characterized by tumor progression with increased metastases after relentless local recurrences (LR). It remains challenging to predict outcomes without a prudent survival analysis to assess parameters of primary lesions. Previous series suggested that LR could not be predicted by any factor, whereas few have uniformly examined prognostic factors by appropriate multivariate analyses. Purpose: The aim of this study was to identify critical clinicopathological variables related to outcome by Cox regression model. Methods: 70 primary MFS were retrospectively identified after review and graded by the FNCLCC scheme. Survival was compared by log-rank test with regard to recurrence-free survival (RFS), metastasis-free survival (MeFS), disease-specific survival (DSS), and overall survival (OS). Results: Follow-up (FU) was obtained in 61 cases with a median duration of 32 months (range: 2-201). Among them, there were 32 men and 29 women with a median age of 61 years. The size of primary tumors ranged from 1.5 to 24 cm (median, 5.5). The surgical margins were considered positive in 21 cases (34%). At last FU, 27 patients developed at least 1 LR, 14 patients experienced distant metastasis, 13 patients died of MFS, and 4 patients died of other causes. The cumulative 3-year rates of RFS, MeFS, DSS, and OS were 51%, 72%, 80%, and 74%, respectively. By univariate analysis, positive margins (p=0.0003) were the only significant factor for worse RFS. Mitoses¡Ù20/10HPF, high grade (grade 2,3), positive margins, tumor necrosis(¡Ù10%), prominent nuclear pleomorphism, and AJCC stage 3 were significantly correlated with MeFS, while factors associated with reduced DSS and OS included the former 3, together with tumor necrosis and nuclear pleomorphism found respectively significant for DSS and OS. By multivariate analysis, only high mitoses (p=0.0009 for DSS; p=0.0034 for OS) and positive margins (p=0.0203 for DSS; p=0.0034 for OS) remained independent for poorer patient survival. However, tumor necrosis (p=0.0053) was independently associated with MeFS, apart from high mitoses (p=0.0086) and positive margins (p=0.0142). Conclusions: Margin status is a critical prognostic determinant in MFS, not only proved as the single significant factor for reduced RFS but also independently predictive of metastatic propensity and patient survival as is high mitotic activity. However, tumor necrosis¡Ù10% independently predicts worse MeFS alone.

P 649

CALCIFYING APONEUROTIC FIBROMA. THE FIRST CASE REPORT COMPRISING COMPLETE HISTOLOGICAL, IMMUNOHISTOCHEMICAL, ULTRASTRUCTURAL AND CYTOGENETIC CHARACTERISTICS OF TUMOUR AND A REVIEW OF THE LITERATURE

RYS Janusz*, WASILEWSKA Anna*, KRUCZAK Anna*, ILISZKO Mariola**, MARKIEWICZ Dorota*, SZPOR Joanna*, WYSOCKA Joanna*, MOSKAL Julia*, DRABIK Grazyna***, MIERZYNSKI Wojciech***
*Cracow Center of Oncology, **Dept of Biology and Genetics Medical University of Gdansk ***Polish-American Children's Hospital, Jagiellonian University, Cracow, Poland

Introduction: Calcifying aponeurotic fibroma (CAF) is a rare soft tissue tumour that primarily occurs in children and adolescents and has a strong predilection for hands and feet. It has been described as locally invasive, recurring tumour without the ability to metastasize. Since initial report by Keasby, more than 100 cases have been documented in the literature. However, only a few reports presented histological, immunohistochemical and ultrastructural characteristics of the tumour.
Aims: The aim of the study is a presentation of CAF with morphological, and cytogenetic analysis of tumour. This is the first description of ultrastructural features of CAF in childhood, as well as the first note concerning cytogenetic study of the tumour.
Material and methods: A 2 year-old girl was operated on because of a nodule, 2.5 cm in diameter, localized in soft tissue of hypothenar of the left hand. Surgical exploration of the lesion revealed a rather dull-separated tumour attached to ulnar nerve and vessels. The mass was excised non-radically. Small fragments of tumour tissue were taken for cytogenetic and ultrastructural studies. Finally the material was fixed in 10% buffered formalin's solution, and embedded in paraffin blocks. Paraffin-embedded material was examined histologically and with immunohistochemistry, using the LSAB2+ kit.
Results: The lesion was characterized by a fibromatosis-like proliferation of fibroblastic cells, admixed with cartilage-like islands with areas of calcification. Spindled fibroblasts infiltrated striated muscles as well as nerves and vessels, and they were usually organized in well-orientated fascicle. Chondroid-like foci were built of swollen cells lodged in lacunae. Despite the focal cellularity of the lesion, mitotic figures were scarce, and did not exceed 2 per 50 high-power fields. MiB-1 index reached 9.6. Both spindle and chondroid tumour cells were stained with antibodies against vimentin, H-caldesmon, CD99, and S100 protein (diffuse reaction), as well as smooth- and muscle- specific actin (focal reaction). On the contrary, they lacked keratins, EMA, desmin, BCL-2, CD34, CD57, ER, PR and P53 expression. On ultrastructural examination a biphasic texture consisting of fibroblasts and cartilage cells could also be distinguished. The karyotype of tumour cells was normal.
Conclusion: Our findings favor the origin of CAF from fibroblastic cells which differentiate into fibrocartilage and/or hyaline cartilage.

Introduction: Extrapleural solitary fibrous tumours (SFTs) are uncommon mesenchymal neoplasm. Slightly more than 100 cases were reported. Most of them were localized in the upper respiratory system and the soft tissues of head and neck region. SFTs of the extremities are exceptionally rare. We found only eight such cases in the available literature. They pose problems in the differential diagnosis, especially from synovial sarcoma.
Aims: The object of the study is the clinico-morphological characteristics of 11 (including our two cases) described SFTs of the thigh and inguinal region and the estimation of prognostic significance of selected morphological and cytometric parameters of the tumour.
Material and methods: A 61-year-old woman and a 39-year-old man were admitted to the Centre of Oncology with the circumscribed, palpable masses localized in soft tissue of the thigh and inguinal region. The tumours were totally excised and both patients live with no evidence of tumour recurrence

49 and 12 months, respectively. Tumour tissues for light microscopy were fixed in 10% buffered formalin and embedded in paraffin. Representative paraffin blocks were chosen for immunohistochemical studies. Small fragments of fresh tumour tissue were taken for ultrastructural, cytometric and cytogenetic studies.
Results: Histological texture of tumours was characterized by a combination of hypocellular and hypercellular areas separated from each other by thick bands of hyalinized collagen and hemangiopericytoma-like vessels. The tumour cells of both cases were positively stained with antibodies against CD34, BCL2, CD99, and progesterone receptor. The first tumour showed additionally the small foci of necrosis. The proliferative activity of tumours was variable. The cellular areas of the first tumour presented up to 13 mitoses per 10HPF and 11.0% MIB-1 index. FCM study of these cells revealed 7.2% S-phase fraction (SPF) and aneuploidy (DI= 2.08). Conversely, the second tumour was diploid and characterized by low mitotic rate (6/10 HPF), MiB-1 index (7.2%) and SPF (0.3%). Cytogenetic analysis of this tumour showed 46,XX normal karyotype.
Conclusion: 1)High proliferative activity, aneuploidy, and focal necrosis do not have to indicate the malignant behaviour of SFT. 2)Lack of the (X,18) translocation facilitates the differentiation between SFT and synovial sarcoma.

P 651
ACRAL MYXOINFLAMMATORY FIBROBLASTIC SARCOMA
DERVISOGLU Sergulen, DEMIRKESEN Cuyan, OZTURK Kilicaslan Tulin, MIDI Ahmet
ISTANBUL UNIVERSITY CERRAHPASA MEDICAL FACULTY PATHOLOGY DEPARTMENT

INTRODUCTION:Acral myxoinflammatory fibroblastic sarcoma (AMIFS) was described as different entity in the larger group of myxomatous soft tissue tumors in 1997 and 1998 by three different authors. These tumors have quite characteristic clinical presentation and morphology. The lesion has morphologically myxoid or myxohyalen presentation and multinodular growth pattern. In this present study we report on three cases of AMIFS seen in our department to discuss their clinicopathological features and emphasize the rare occurrence of it's invasion to neighboring bone tissue.
MATERIALS and METHOD:We found 3 cases of AMIFS in our register in 1999 to 2004. We applied routine H&E sections and also immunohistochemical stains as vimentin, CD68, CD34, S100 protein, SMA and cytokeratin. Clinical features were obtained from archive records.
RESULTS and CONCLUSION: All of the cases were adult men of ages 29, 36, and 56. Lesions occurred in the 4.th and 5.th metacarpophalangeal joints of the right hand (first case), in the right elbow wrist (second case) and in the right toe thumb distal interphalangeal joint (third case). Tumors were composed of epithelioid to spindle cells containing myxoid zones and various inflammatory cells. In some foci, Reed-Stenberg like giant cells were seen. Immunohistochemically, tumors were diffusely positive for vimentin. Various numbers of cells were also positive for CD 68. Only one case was poorly positive for CD34 and SMA. All of the cases were negative for S-100. In contrast to the previous literature, we observed neighboring bone invasion in two cases. In follow up period, one case had regional lymph node metastasis. This newly described, both morphologically and clinically distinct tumor must be kept in mind when dealing with a tumor locating in distal extremities and must be in differential diagnosis with epithelioid sarcoma and myxoid or inflammatory type malignant fibrous histiocytoma.

P 652
A SINGLE-TEAM EXPERIENCE OF LIMB SPARING APPROACH TO ADULTS WITH HIGH-GRADE MALIGNANT FIBROUS HISTIOCYTOMA
ISSAKOV Josephine, KOLLENDER Yehuda, NIRKIN Alex, BICKELS Jacob , FLUSSER Gideon, MELLER Isaac ,LIFSCHITZ-MERCER Beatris ,MERIMSKY Ofer

Introduction: Malignant fibrous histiocytoma (MFH) is the most common subtype of soft-tissue sarcoma (STS). When located in a limb, MFH, as well as other STS, are currently treated with limb sparing surgery (LSS) followed by radiation therapy (RT).
Patients: From October 1994 through October 2002, 42 adult patients with high-grade limb MFH were approached by LSS followed by RT.
Results: Our results reflect a single-team experience with multi-disciplinary limb sparing approach towards adult patients with limb high-grade MFH, and point to several important conclusions. High grade MFH can be treated by surgery and postoperative radiation therapy, and controlled to yield a 10-year relapse free survival of 62% and a 10-year overall survival rate of more than 80%. Recurrences of MFH tend to occur during the first 2 years of follow-up, and become less frequent thereafter. Relapse free survival was affected mainly by location in the lower limb versus the upper limb, irrespective of the tumor size. Patients who had their diagnostic biopsies in another medical center had a greater tendency to local and systemic relapse probably due to compartmental and systemic contamination with tumor cells. This observation supports the need for early referral of patients with limb masses suspicious of sarcomas, to a specialized center for careful diagnosis and multidisciplinary therapy.
Conclusions: Our results are satisfactory and are within the accepted ranges. It seems that the most important key words for disease-free survival is the team experience, starting with biopsy, surgery, and post-operative radiation therapy. All other factors are tumor-biology dependent, and thus far are beyond our control.

*Laboratoire Central d'Anatomie et de Cytologie Pathologiques CHU Annaba-Algérie
**Service d'Orthopédie-traumatologie CHU Constantine-Algérie.

Primary hemangiopericytoma of the bone is a very rare vascular tumor. It can occur any where but the most common sites are pelvis, proximal femur, humerus, rachis, sacrum and mandible.
We report a case occurred in a patient aged 53 years who consulted in June 2004 for pain of the left knee evolving since 3 years and swelling.
Standard X-ray showed a lytic metaphyso- epiphysary tumor of the upper of the left tibia with cortical permeation and extension into surrounding soft tissues and fibula.
Giant cells tumor and chondrosarcoma were evoked. Biopsy concluded to a grade 2 hemangiopericytoma.
Immunohistochemical staining showed no expression of FVIII, actin and CK by tumoral cells.
The tumor was treated by en bloc resection followed by a chemotherapy.
The result was good. The patient presented neither recurrence nor metastasis 6 monthes after the treatment.

PECOMA OF ABDOMEN: A UNIQUE CASE

DEMONAKOU Maria, MACHERA Helen , MANOLIA Lora , RAPTIS Ioannis, TAMVAKIS Nikolaos, FINOKALIOTIS Nikolaos.
Department of Pathology and 2nd Department of Surgery Sismanoglion CH Marousi Athens Greece.
District General Hospital Attikis "KAT"

BACKGROUND: The World Health Organization recently recognized a family of neoplasms showing at least partial morphological or immunohistochemical evidence of a putative perivascular epithelioid cell (PEC) differentiation. These tumors include angiomyolipoma (AML), clear cell 'sugar' tumors of the lung (CCST), lymphangioleiomyomatosis (LAM), clear cell myomelanocytic tumors of the falciform ligament and distinctive clear cell tumors at various other sites. Pecomas are rare neoplams of pericytes, mainly affect young women. PCMs have been identified in uterus, lung,, vulva, breast, prostate, rectum, jejunum, liver, cardiac septum, falciform ligament soft tissue and in the abdomen with tuberous sclerosis.

CASE PRESENTATION: A 29 years old woman without previous history was admitted with a painless palpable mass in her abdomen. Laboratory tests were normal apart of ECHO revealing a mass up to 8c in her abdomen. The mass were easily identified and removed by laparoscopy. There were no sign of Tuberous Sclerosis.

The tumor was well circumscribed , encapsulated, measured 8x5x3cm.Cut surface was red, nodular, with visible blood vessels. Microscopy revealed a well developed vascular network in the vicinity of which a pleomorphic cellular component was recognised. Neoplastic cells at the immediate vascular location are epithelioid and spindled shaped whereas in areas away from vessels, resemble smooth muscle cells.

Epitheliod cells show variable morphology , some having clear cytoplasm and others eosinophilic with “ground glass “ configuration . Most display small, normochromatic round nuclei and other have large oval nuclei with prominent nucleoli. Immunostaining shows diffuse positivity in HMB-45 and SMA focal for S-100 , and negativity for cytokeratins and desmin.

Although most of these tumors have behaved in a benign fashion, they should be considered tumors of uncertain malignant potential given previous reports of recurrence and metastases. Our patient remains free of disease 36 months later.

P 655

LIPOMATOUS HEMANGIOPERICYTOMA (ADIPOCYTIC VARIANT OF SOLITARY FIBROUS TUMOR) OF THE ORBIT

FARAH-KLIBI Faten*, FERCHICHI Leila*, ZAIRI Issam**, ZERMANI Rachida*, RAMMEH Soumaya*, CHELBI Emna*,ADOUANI Ali**, BEN JILANI Sarrah*.

**: Departement of Maxillo-Facial Surgery of Charles Nicolle Hospital.Tunis.Tunisia.

Hemangiopericytoma (HPC) of the orbit is a rare tumor presenting with slowly progressive proptosis, ocular motility impairment and visual loss. In 1995, a newly variant of HPC termed lipomatous hemangiopericytoma (LHPC), was described. Only two cases arising in the orbit have been previously reported.

The authors describe a new case of orbital LHPC arising in a 64-year old woman who presented a 1-year history of pain in the right orbital region and a progressive right proptosis. Computed tomography scans revealed a well-delineated extraconal mass of 3x3x1,5cm affecting the superomedial area of the orbit. No signs of bony erosion or globe indentation were visible. Histological examination revealed an entirely encapsulated lesion composed of a haphazard proliferation of spindle, fibroblast-like cells alternating with hypocellular foci. The stroma was collagenous, with vascular spaces displaying a prominent hemangiopericytoma pattern (stag horn configuration) and lipomatous areas made of mature adipocytes was found. Mitotic figures were absent, and no cellular atypia, necrosis, or vascular invasion was observed. Immunohistochemical staining revealed an intense and diffuse positive reactivity to CD99, CD34 and bcl-2. The patient was free of recurrence when examined 9 months after surgery.

The aim of this study is to discuss the clinicopathologic features, including the immunohistochemical staining profile and ultrastructural appearance of this distinctive tumor, and briefly discuss the relationship between HPC and solitary fibrous tumor (SFT) of soft tissue, a neoplasm with many clinical and pathologic similarities.

ANGIOSARCOMA OF BONE

NIKOLAIDOU Anastasia1, PAPANIKOLAOU Athanasios2, KONSTANTINIDES Panagiotis3, MAKOS Christos4, TOPTSIS Konstantinos5
1 Registrar, Pathology Department, General Hospital of Kilkis, Kilkis, 61100 Greece
2 Registrar, Pathology Department, “Hippokratio” General Hospital of Thessaloniki, Thessaloniki, Greece
3 Orthopaedic Surgeon, Thessaloniki, Greece
4 Registrar, Oral and Maxillofacial Department, General Hospital of Kilkis, Kilkis, 61100 Greece
5Associate Director, Orthopaedic Department, “Hippokratio” General Hospital of Thessaloniki, Thessaloniki, Greece

The purpose of this work is to describe a rare case of an angiosarcoma of bone and to discuss about the low frequency and the variant behavior and histological appearance of the malignant vascular bone tumors.

Method and results: A male 47 years-old with a 4-year history of lower back pain was operated for a lumbar disk herniation, but during his transportation from the operation theater a pathological intertrochanteric fracture of the right hip was reordered.

The magnetic resonance imaging (MRI) showed a large soft tissue mass extending anteriorly with infiltration of the bone marrow to the cartilaginous level of the femur head. The histological examination revealed variable shapes of vascular anastomotic channels lined with large atypical endothelial cells with solid sheaths formations, pseudopapillary infolding arrangements and foci of necrosis. On immunohistochemical investigation many neoplastic cells were positive in factor-VIII and UEA-I endothelial markers. The treatment included a radiotherapy (300 rad/per day for 13 days) followed by an amputation and total hip replacement.

Conclusion: The malignant vascular bone tumors are very rare accounting less than 1% of the bone malignancies characterized by unknown etiology and variable biologic behavior and histological appearance.

P 657

MORPHOLOGICAL FEATURES OF 23 MALIGNANT VASCULAR TUMORS

KÖSEMEHMETOĐLU Kemal,MD and GEDÝKOĐLU Gökhan,MD,Professor

Introduction: Due to its rarety, information and experience about malignant vascular tumors are limited. Although many immunohistochemical techniques are available, determination of grade still requires a detailed morphological investigation.
Methods: We present histological features of 23 malignant vascular tumors, 8 of which had a prior diagnosis of angiosarcoma. Tumor size, mitotic index, pleomorphism, cellularity, presence of necrosis and grade are determined for

each case. Chi square test and linear regression analysis are used and $p<0.05$ is accepted as significant.
Results: Age at diagnosis was 6-77 years with a median of 35 years and male to female ratio was 1.5. Extremities(8) were most common primary site following head and neck(5); sacrum(3); parenchymal organs including colon (2), liver (1) and spleen(1); abdominal wall (1); inguinal (1) and breast (1). Tumor size, varied 1 cm up to 20 cm in diameter (median 5.5 cm), was >3 cm in 14 of cases, 9 of which were high grade lesions. Infiltrative pattern (15/23) and epitheloid cellular characteristic (15/23) were dominant. Majority of lesions were hemorrhagic (83%) and necrotic (70%). Mainly, pleomorphism and cellularity have contributed to grade of tumor. Decision giving for high grade tumor was directly associated with high pleomorphism ($p<0.00$) and tumor diameter (>3 cm, $p<0.02$). In cases of intermediate pleomorphism, cellularity has assisted on grading. After a total reexamination of all 23 vascular tumors 11 of them were categorised as high grade lesions. Follow up information were available for 7 of 23 patients: Five of them were alive for 5 years and 2 of them, both having high grade tumor, were dead of disease in 2 years.
Conclusion: Following an algorithm as consideration of pleomorphism, size and cellularity of malignant vascular tumors has a key role in determination of grade, thus the diagnosis of angiosarcoma. Still the need for more objective findings such as molecular studies is obvious on the way to specific diagnosis of malignant vascular tumors.

P 658
METASTATIC ANGIOSARCOMA ARISING IN AN EPITHELOID HEMANGIOENDOTHELIOMA OF AN LIGATED ARTERIOVENOUS FISTULA IN A IMMUNOSUPPRESSED PATIENT AFTER KIDNEY TRANSPLANTATION
Bodó K. 1, Liegl B. 1, S. Regauer 1, W. Weybora 1, E. Spuller 1
1: Institut of Pathology, Medical University, Graz, Austria

Introduction:
About one third of angiosarcomas develop in association with certain pre-existing conditions such as benign hemangiomas, synthetic vascular grafts or other foreign material. Immunosuppression in the setting of organ-transplantation is associated with the development of malignant tumors, most commonly carcinomas or lymphomas. Sarcomas are relatively infrequent. We report a male patient with chronic renal failure, who underwent kidney transplantation. The patient presented with an epitheloid hemangioendothelioma at the site of a ligated arteriovenous fistula constructed for haemodialysis at the left cubital region. Within 2 years a transformation into an angiosarcoma occurred. The patient died of multiple metastases.
Purpose of the study:
This is rare case of an epithelial hemangioendothelioma in an immunosuppressed patient at the site of an AV-fistula with malignant transformation into an angiosarcoma. It is important to keep in mind, that immunosuppressed patients can develop sarcomas in such circumstances.
Material and methods:
Formalin-fixed and paraffin-embedded archival material of biopsy and surgical specimen, as well as autopsy material of primary tumor and metastases were examined on HE-stained section and immunochemistry was evaluated using antibodies to CD31, CD34 and factor VII.
Results:
The initial biopsy and the surgical specimen showed a solid proliferation of a vascular tumor composed of short strands, cords and solid nests of rounded to slightly spindled eosinophilic endothelial cells, some of them with intracytoplasmic lumina containing erythrocytes. The autopsy specimens of the recurrent tumor at the primary site as well as the metastases (lungs, bone, axillary lymph nodes) showed classical features of an angiosarcoma with positive staining with antibodies against CD31, CD24 and factor VII.
Conclusion:
It is important to keep in mind, that immunosuppressed patients in addition to carcinomas or lymphomas may also develop sarcomas. Immunosuppressed patients with ligated AV-fistula do have an higher risk to develop a malignant tumor in the shunt. Especially we would like to draw attention, that angiosarcoma may arise in benign or intermediate vascular tumors under such circumstances.

P 659
EPITHELIOID HEMANGIOENDOTHELIOMA OF THE SOFT TISSUES IN A WOMAN'S ARM: A CASE REPORT AND REVIEW OF THE LITERATURE
I.Abbes, S.Sassi, R.Sallemi, K.Mrad, M.Driss, K.Ben Romdhane.
Department of Pathology, Salah Azaiez Institute, Tunis, Tunisia.

Introduction: Epithelioid hemangioendothelioma (EHE) is a rare vascular neoplasm arising in soft tissue, bone, lung and liver. This tumor is often considered to have an intermediately aggressive nature and a long clinical course depending on the sites involved.
Aims: To present the clinicopathologic and immunohistochemical features of a rare vascular tumor and to review differential diagnosis.
Material and methods: A 44-year-old woman presented with an expansive soft tissue mass of her left arm. Tumor resection was performed with light microscopic and immunohistochemical analysis.
Results: Macroscopic examination revealed a fusiform perivascular mass measuring 22 / 13 mm and infiltrating the surrounding adipocytic and skeletal muscle tissues. Histological examination revealed short strands, cords or solid nests of rounded to slightly spindled or epithelioïd eosinophilic cells. The stroma was hyalinized and focally calcified. Some tumor cells displayed endothelial differentiation as evidenced by intra-cytoplasmic lumina (vacuoles) containing erythrocytes. Mitotic activity was estimated as 1mitosis / 10 HPF. Immunohistochemical study revealed tumor cells immunoreactivity for CD 31, Ulex europeus and vimentin.
To date, neither recurrence nor metastases have been observed 10 months after initial diagnosis.
Conclusion: EHE of soft tissue is a rare borderline vascular tumor with unpredictable prognosis. This uncommon tumor should be considered in the differential diagnosis of other tumors such as carcinomas and malignant epithelioïd schwannoma. The role of immunohistochemistry is crucial.

P 660
VASCULAR MALFORMATIONS: CLINICOPATHOLOGIC CLASSIFICATION
WASSEF Michel (1-2), ENJOLRAS Odile (1-3), BISDORFF Annouk (1-3), MERLAND Jean-Jacques(3)
Consultation des Angiomes, (1) and Departments of Pathology (2)and Neuroradiology (3), Hôpital Lariboisière, 2 rue Ambroise Paré, 75475 Paris Cedex 10, France

Objectives:
The classification of vascular anomalies (vascular malformations and vascular tumours) has been a matter of debate. A first consensus was obtained at the International Society for the Study of Vascular Anomalies (ISSVA, Hamburg 1988) on separating infantile hemangiomas and other vascular tumours from vascular malformations. A common scheme of classification, based on the main vascular constituent was then adopted (Rome 1996). A more detailed classification of vascular malformations is still to be

achieved. We present the classification we have used for several years in our interdisciplinary group, based on clinical and pathological data.
Classification:
A - Troncular vascular malformations
Affecting arteries ,veins, or lymphatics
Anomalies of length, diameter, course, or number
Direct arteriovenous fistulas
B - Tissular (non troncular) vascular malformations
Capillary Malformations (Port Wine Stains and other telangectasias)
Venous Malformations (common, nodular, with glomus cells)
Lymphatic Malformations (capillary type, venous type, cystic type)
Arteriovenous Malformations
Soft Tissue Angiomatosis
C - Combined vascular malformations (associate 2 or more defined entities from A and/or B)
Hemo-lymphatic malformation
Arteriovenous-lymphatic malformation
…
D – Complex malformations
One or more from (A), (B) or (C) may be associated with non vascular anomalies of bone, soft tissues or viscera in eponymous syndromes.
Sturge-Weber syndrome, Klippel-Trenaunay syndrome, Parkes Weber syndrome, Bean syndrome, Proteus syndrome, etc.
Conclusion: This classification has proved to be convenient for our clinical, imaging, and pathological practice. The clinical and pathological features of the main types of vascular malformations will be illustrated.

P 661
CRANIAL FASCIITIS OF CHILDHOOD WITH UNDERLYING
Aneeta Jassar, VK Kumar, Ashok Kumar
Command Hospital (NC)
Udhampur J&K India

A ten-year old girl presented with a spontaneous, rapidly growing but painless subcutaneous mass over the left temporal region of the scalp. An initial biopsy of the
mass showed features of cranial fasciitis, a variant of nodular fasciitis first described by Lauer and Enzinger in 1980. Cranial fasciitis is considered a benign fibroblastic lesion of likely myofibroblastic origin but uncertain etiopathogenesis, though some authors have found an association with previous local trauma. Radiographically, there was a lytic skull lesion with destruction of both the inner and outer tables of left temporal bone. Computed tomography (CT) scan done to visualize extent of tumour showed intracranial extension and partial destruction of the greater wing of sphenoid but no midline shift. The tumour had destroyed the calvarial bone as well as part of the zygoma. Dura was pushed but not infiltrated. Peroperatively, there was a large, firm tumour of high vascularity. Cut section had a gritty feel and a 'honey-coombed' appearance. Histopathological examination showed cellular septae separating angiectoid cavernous spaces without endothelial lining. Multinucleated osteoclast-like giant cells and reactive bone formation were present. A
diagnosis of solid variant of aneurismal bone cyst was offered. Features of cranial fasciitis were restricted to the superficial part of the lesion which also showed
intercellular haemorrhages. The authors hypothesize that the cranial fasciitis in this child was a reactive response to intralesional haemorrhages from the aneurysmal bone cyst.
Thus cases of cranial fasciitis must be thoroughly worked up to rule out other underlying pathology. The child is well eight months post follow-up. This is the first such report in world literature.

P 662
ALTERATIONS OF THE ß-CATENIN PATHWAY IN SARCOMAS OF THE PULMONARY ARTERY(SPA)
Gaumann A1, Bode-Lesniewska B2, Zimmermann D2, Hofstädter F1, Dietmaier W1
1Institute of Pathology, University Regensburg, 2Institute of Pathology University of Zürich

Aims: The Wnt signaling pathway plays an important role in cell fate determination mediated by stabilization of the ß-catenin complex through APC. Thus, ß-catenin activation is an important step in the tumorigenesis through induction of transcription and proliferation via c-myc, cyclin A and cyclin D1. Since activation mutation of ß-catenin/APC has been shown to occur in a variety of tumors we investigated the expression and mutation of the involved molecules.
Methods: Expression of ß-catenin, cyclin A, cyclin D1 and mismatch repair proteins hMLH, hMSH2, hMSH6 were examined by immunohistochemistry in 18 SPA and microsatellite instability (MSI) using the recommended reference panel for colorectal cancer. In addition, sequencing of exon 3 of the ß-catenin gene was performed. Subsequently, survival analysis was performed for ß -catenin, cyclin A and cyclin D1.
Results: In 8 cases a membrane staining and in 3 cases additional cytoplasmic staining of ß-catenin was observed. 1 case showed some cells with nuclear staining and 3 cases were negative. Mutation analysis of ß-catenin revealed wildtype sequence of Exon 3 in all examined cases. Cyclin D1 was expressed in most cases while cyclin A was present in few tumors. MSI could only be detected in 2 cases of the SPA. Interestingly, this case also showed nuclear staining for ß-catenin. In addition, 4 cases revealed a LOH at the APC gene locus. Nuclear expression of hMLH1, hMSH2 and hMSH6 was detected in17cases. Survival analysis revealed a significant better survival for cyclin D1 positive tumors.
Discussion: LOH of APC was the prominent observation in our series supporting the view that misfunction of this tumor supressor gene may play a role in the tumorigenesis of some SPA. However, ß-catenin showed only nuclear translocation in 1 case, which was the only patient who had also MSI. Thus, alteration of the ß-catenin pathway and MSI seem to play a minor role in the proliferative activity of SPA in our series.

P 663
PREVALENCE AND SEVERITY OF AA AMYLOIDOSIS IN RHEUMATOID ARTHRITIS - A RETROSPECTIVE CLINICOPATHOLOGIC STUDY OF 161 AUTOPSY PATIENTS
Miklós Bély MD, PhD, DSc1 and Ágnes Apáthy MD2
1Department of Pathology,
Policlinic of the Hospitaller Brothers of St.John of God, Budapest, Hungary
2Department of Rheumatology,
National Institute of Rheumatology and Physiotherapy, Budapest, Hungary

Statement
AA amyloidosis (AAa) may exist in different stages of its development at the time of death.
AAa is a progressive cumulative process in each individual patient. The different stages of AAa found at death in a population of RA patients represent the progression of the pathological process of amyloid A protein deposition, i.e. the chronological development of AAa can be followed by studying its characteristics in individuals who died in various stages of the disease.
The aim of this study was to determine

(1) the prevalence of systemic AAa in RA, (2) the mortality due to AAa, (3) the clinically missed diagnosis of AAa, (4) the severity (extent) of amyloid A deposits in RA patients.
Patients and Methods
A randomized autopsy population of 161 in-patients with rheumatoid arthritis (RA) was studied.
AAa was diagnosed histologically.
The mortality and the clinically missed diagnosis of AAa were analyzed retrospectively by reviewing the clinical records and histological slides.
The degree of AAa was evaluated semi-quantitatively: the numerical values of amyloid A deposits were summarized in different tissue structures of the heart, kidneys, liver, and lungs of RA patients with AAa.
Results
(1) Systemic AA amyloidosis was observed in 34 (21.1%) of 161 cases. (2) Seventeen (50 rel%) of 34 patients died of uremia. (3) In 9 (26 rel%) of 17 amyloidosis was recognized clinically. (4) The severity of AAa distributed according to the curve of Gauss. Arranged according to increasing values the cases of 'severity' showed an exponential growth curve.
Discussion
Only about one quarter of existing amyloidosis was clinically recognized.
AAa was recognized clinically in end stage of the disease, characterized by severe amyloid deposits, and with clinical evidence of renal insufficiency and uremia.
Clinical signs of renal involvement (nephrotic syndrome) refer to an advanced stage of amyloidosis, with a worse prognosis.
Early clinical stages characterized by minimal, or small amounts of amyloid deposits remained clinically undetected.
In the autopsy population of this study minimal amyloid A deposits indicate the early stage of the pathological process; these patients died of other diseases before they developed massive deposits of AAa. In other words, by determining the extent and location of amyloid A protein deposition in different structures of various organs, one may estimate the stage of AAa in a given case. Staging has a prognostic value.

P 664
A VERY CURIOUS LESION OF THE SCALP
BOUILLOT-EIMER Sandrine (1), DAUTHERIBES Michel (2), LEPREUX Sébastien (1), COINDRE Jean-Michel (3)
Departments of Pathology (1,3), and Neurosurgery (2) – Pellegrin Hospital (1,2) and Bergonié Institute (3), Bordeaux – FRANCE

The presence of ectopic meningothelial tissue on the scalp can occur under different forms: typical or rudimentary meningocele, meningothelial hamartoma, primitive meningioma of the scalp, or extension of an internal or external skull meningioma on the scalp. Skin or subcutaneous hamartomas are extremely rare. A sixteen-month-old child presented with an hamartoma on the scalp with ectopic meningothelial elements. Since birth, this child had an occipital middle cyst, evoking a meningoencephalocele with associated lipoma. Clinically, this was a non evolutive unique lesion, measuring 1,4 cm, well-demarcated, rounded and soft, with no modification of the skin. The RMI scan showed a middle nodular tumor with liquid aspect looking like either a meningocele or an epidermal cyst. The lesion was removed, and the post-surgical course was uneventfull. Histologically, well-circumscribed mixture of vascular structures, conjonctive bundles and adipose cells was observed in the deep dermis, the entirety without specific architecture. The characteristic element was the presence of numerous epithelioïd cells, set up in irregular bundles or clusters, closely mixed with dermis. Some seemed to merge with the vessels, and sometimes seemed to form anastomotic structures which can mime a malignant vascular tumor. Immunostains witnessed the meningothelial origin of the epithelioid cells by the strong positivity of EMA and vimentin. Moreover, the negativity of CD34, CD31 and cytokeratin dismissed a vascular origin. The purpose of this case is to remind of the histological criteria of this rare entity. It also helps us to distinguish it from an atypical vascular proliferation and even from an angiosarcoma. Mix of meningothelial cells with conjonctive tissue and vessels, also allows to differenciate it from a cutaneous meningioma. On the histogenetic view, the presence of meningothelial component could be explained by ectopic meningothelial remnants on the scalp, and therefore must be considered as the part of an hamartomatous process.

P 665
RARE ASSOCIATION : OSTEOSARCOMA AND ANEURYSMAL BONE CYST
RAIS Hanane(1), BELAABIDIA Badia(1) MOUTCHOU Ahmed(2)
(1) Department Of Pathology, CHU Mohammed VI - Marrakech
(2) Department Of Pathology, Hospital HassanII -Agadir Morroco

The diagnosis of the lesions bony depends of the clinic, the radiology and the histology. However, the association of a malignant bony tumor and a pseudo tumor made this difficult diagnosis. The aneurysmal bone cyst is the result of a specific pathophysiologic change, which is probably the result of trauma or a tumor-induced anomalous vascular process. Osteosarcoma is rare preexisting lesion of aneurysmal bone cyst. A 38-year-old male presented with a painful progressive swelling in his right knee, without further complaints, which had been present for 5 weeks. Radiological examination was found to have a well-defined 5cm lytic lesion in the right tibial head and neck. The cortex was thinned. Surgical excision and histological exam showed a double tumorous proliferation:vascular and cellular. The diagnosis of aneurysmal bone cyst is the likeliest. However, an fibroblastic osteosarcoma cannot be eliminated. This rare association makes difficult to take therapeutic decision: curettage or amputation and chemotherapy. Bone tumors represent a group of tumors of various dignity. In spite of this, single tumor entities may display strong morphological resemblance to each other which can in turn result in deep difficulties in different diagnosis.

AKT INHIBITION ENHANCES APOPTOSIS AFTER TNF-ALPHA ADMINISTRATION IN PROSTATE CELL LINE LNCAP BUT NOT IN PC3.
RICOTE Mónica*, GARCÍA-TUÑON Ignacio*, FRAILE Benito*, FERNÁNDEZ Carlos#, ALLER Patricio#, PANIAGUA Ricardo* and ROYUELA Mar*
*Department of Cell Biology and Genetics, University of Alcalá. 28871 Alcalá de Henares. #Centro de Investigaciones Biológicas, Consejo Superior de Investigaciones Científicas. Madrid. Spain. E-mail: monica.ricote@uah.es

INTRODUCTION: Akt/PI3K play an important role in TNF-alpha resistance because has been reported like a survival factor in addition to NF-kappaB. Akt interferes with the apoptotic machinery by phosphorylating thus sequestering the

pro-apoptotic Bcl-2 family protein, caspase-9 and promoting NF-kappaB-dependent cytoprotection via transcriptional activation of a plethora of downstream target genes. In neutrophils, PI3-K/Akt inhibition prevents p38 and ERK1/2 activation.
PURPOSE: The aim of this study was investigate Akt/PI3K role (pro- or anti-apoptotic) after TNF-alpha administration in prostate cancer cell lines (LNCaP and PC3).
MATERIAL AND METHODS: Two establish human prostate cancer cell lines LnCap (CRL-1740) and PC3 (CRL-1435) were used. TNF-alpha treatments were carried out with TNF-alpha at several concentrations and selectively with specific pharmacological Akt/PI3K (LY294002). Apoptosis determination was evaluated by DAPI and flow cytometry. MAPKs activation was measured by Western blot.
RESULTS: TNF-alpha induces apoptosis in LNCaP when we increased TNF-alpha concentration (10, 20, 50, 75, 100 ng/ml) while this treatment has no significant effect on PC3 cells viability. Akt inhibition by LY294002 showed a significative apoptosis increment in LNCaP but not in PC3.
CONCLUSION: Constitutively activate PI3-K/Akt promotes cellular survival and resistance to chemotherapy and radiation in prostate cancer cells. Furthermore, showed that Akt is involved in the activation of NF-kappaB by tumour necrosis factor alpha (TNF-alpha). In our study PI3-K/Akt seems to be involved in TNF-alpha apoptosis regulation in LNCaP and may be through different survival factors as NF-kappaB.

CYCLOOXYGENASE-2 EXPRESSION CORRELATES WITH LOCAL CHRONIC INFLAMMATION AND MICROVESSEL DENSITY IN BENIGN PROSTATE HYPERPLASIA AND PROSTATE CANCER
Wanzhong Wang, Anders Bergh, and Jan-Erik Damber

BACKGROUND. Chronic inflammation has been suggested to be linked to the development and progression of prostate cancer. Up-regulated cyclooxygenase-2 (COX-2), which can be induced by elevated levels of proinflammatory cytokines, may play a role in influencing cell proliferation, differentiation, apoptosis, or angiogenesis. This study aimed to derive data from human BPH and prostate cancer tissues to investigate whether chronic inflammation and angiogenesis were correlated with the expression of COX-2. METHODS. Detection of COX-2 expression was performed on a total of 88 patients, including 45 BPH and 43 prostate cancers. Double-IHC technique were used with the combination of: COX-2/CD3, /CD68, /CD20, to investigate the COX-2 expression and the relationship with chronic inflammation; COX-2/Ki-67 and /Bcl-2, to determine the proliferation or apoptosis; COX-2/ CK34¦ÂE12 and /CK8, to detect the lay of epithelial cells; and COX-2/CD31, to show the microvessle density (MVD). RESULTS. A. In BPH, COX-2 expression was detected in prostate luminal epithelial cells in all 45 samples. The overall percentage of COX-2 positive glands was 7.5%, distributed as: 0.2% in normal prostate tissue, 25.7% in PAH, and 11.9% in simple atrophy. It was evidently that COX-2 expression was mainly found in atrophic glands, which commonly infiltrated with inflammatory cells. T-lymphocytes and macrophages were the predominant inflammatory cells related to the COX-2 expression. COX-2 expression was also associated with Bcl-2 immunostaining and the COX-2 positive epithelial cells had higher proliferation index. B, COX-2 positive staining was detected in 40/43 cancer samples with the very heterogeneous expression. Elevated COX-2 expression was associated with high Gleason score. COX-2-positive areas were noted with high T-lymphocyte and macrophage densities than COX-2 negative tumor areas. MVD were also found higher in COX-2-positive areas than in COX-2-negative tumor areas. CONCLUSIONS. This study demonstrates a novel relationship between COX-2 expression and the local chronic inflammation in situ. The data demonstrate that T lymphocytes and macrophages, by releasing pro-inflammatory cytokines, appeared to play an important role in the induction of COX-2 expression in prostate epithelium, both benign and malignant cells. It is likely that COX-2 may be an effective therapeutic target in prostate cancer treatment.

THE KI-67 EXPRESSION COULD BE USEFUL IN THE DIFFERENTIAL DIAGNOSIS OF PROSTATIC INTRAEPITHELMIAL NEOPLASIA AND DUCTAL ADENOCARCINOMA
N.Rioux-Leclercq, JJ. Patard, Emmanuelle Leray, Bernard Lobel, François Guillé, Florence Jouan, Pascale Bellaud, JI Epstein. Département d'Anatomie et de Cytologie Pathologiques, de Santé Publique et d'Urologie Faculté de Médecine,Rennes, France, and Departments of Pathology, Urology and Oncology, The Johns Hopkins Medical Institutions, Baltimore, Maryland, USA.

Background : Cribriform and /or papillary prostatic lesions observed on limited tissue, such as needle biopsy, can pose diagnostic dilemmas.One such area of difficulty is the distinction between papillary and/or cribriform prostatic high-grade intraepithelial neoplasia (HG-PIN) and ductal adenocarcinoma.
Design : Over 48 months, we identified 17 cases of ductal adenocarcinoma and 17 cases of HG-PIN from radical retropubic prostatectomy specimens. The HG-PIN lesions were in all cases associated with an acinar prostatic adenocarcinoma component. For each case, we evaluated the proliferative activity, assessed by Ki-67 immunohistochemistry. Results : The majority of ductal adenocarcinomas (82%) were composed of mixed papillary and cribriform patterns, with the remaining demonstrating pure papillary or cribriform patterns. The HG-PIN lesions showed a papillary, cribriform, or mixed papillary/cribriform architecture. The proliferative activity, defined as Ki-67 labeling index, was statistically higher in ductal adenocarcinoma (mean: 33%; range: 21%-66%) as compared to HG-PIN (mean 6%; range: 2%-15%), with no overlap in the Ki-67 indices (p,0.0001).
Conclusion : A combination of histologic features and measurements of cellular proliferation may be helpful to distinguish HG-PIN from ductal adenocarcinoma in limited prostatic tissue samples.

DOES AMACR/P63 ANTIBODY COCKTAIL DETECT NON SIGNIFICANT PROSTATIC CARCINOMA? A CORRELATIVE STUDY BETWEEN BIOPSIES AND RADICAL PROSTATECTOMIES.
Zahira Merabet (1), Alexandre de la Taille (1,2), Laurent Salomon (1,2), Eric Bonte (1), Sandy Azoulay(2), Hugo Faucon (2), Dimitri Vordos (1,2), René Yiou (1,2), András Hoznek (1,2), Dominique Chopin (1,2), Claude Abbou (1,2), Yves Allory (1,2).
1 CHU Henri Mondor, AP-HP, Créteil, France
2 EMI 0337, INSERM, Créteil, France

Introduction : AMACR/p63 antibody cocktail used in the context of atypical small acinar proliferations suspicious for malignancy provides an increased sensitivity in cancer diagnosis on prostate biopsies. However the risk to detect by this way non significant cancer is not estimated.
Aim of the study : to evaluate in radical prostatectomy the significance of prostate cancers that were diagnosed preoperatively using AMACR/p63 cocktail.

Methods : among the 525 prostate biopsies performed in year 2004, 37 cases were selected with cancer diagnosis made only after AMACR/p63 immunohistochemistry, 17 among these 37 cases were treated by radical prostatectomy and reviewed. Non significant cancer in radical prostatectomy was defined as an intraprostatic tumour with a Gleason score < 7 and a volume <0.5 cc.
Results : median number of biopsies was 21 (15-21) with tumour detected only in 1 biopsy (n=14), or 2 to 4 biopsies (n=3); Gleason score was 5 (n=1), 6 (n=15) or 7 (n=1), median total tumour length was 0.85 mm (0.4-4.6) with a median percentage involved of 0.3% (0.2-2.1). In radical prostatectomy, cancer was significant in 10 cases (Gleason score was 7 (n=9) or 8 (n=1), with a tumour volume above 0.5 cc in 5 cases (1.23-2.28), stage pT2 (n=8), pT3a (n=1) or pT4 (n=1) and positive margins in 3 cases). Cancer was not significant in other 7 cases but no stage pT0 was observed. Median PSA at diagnosis was 7.1 ng/mL in significant cancers (3.9-40) and 6.8 ng/mL in non significant cancers (5.2-14) without statistical difference.
Conclusion : the high rate of significant prostate cancer among those diagnosed preoperatively using AMACR/p63 immunohistochemistry confirms the strong interest of this ancillary technique in clinical practice.

P 671
ROLE OF TOUCH IMPRINT CYTOLOGY IN THE DIAGNOSIS OF PROSTATE CORE NEEDLE BIOPSIES
MANNWEILER Sebastian 1, PUMMER Karl 2, AUPRICH Marco 2, RATSCHEK Manfred 1, TSYBROVSKYY Olsksiy 1, MOINFAR Farid 1
1: Institute of Pathology, Medical University, Graz, Austria
2: Department of Urology, Medical University, Graz, Austria

Introduction: Patients at increased risk for prostate cancer with previously negative biopsies pose a diagnostic challenge.
Purpose: The aim of this study was to investigate the diagnostic accuracy of touch imprint cytology of core needle biopsies of the prostate.
Material and Methods: All patients were suspect for having prostate carcinoma. A total of 452 transrectal prostate needle biopsies were performed from 56 patients. The age ranged from 45 to 87 years, the median age was 68 years.
From each fresh biopsy cylinder two touch imprints were prepared which were stained with Diff-Quik and Papanicolaou methods. After formalin-fixation of the core biopsies a first histological diagnosis was made. The results of the touch imprints and the diagnosis of the first histological examinations were compared. Later on, up to 60 fine step serial sections from all biopsy cylinders, which were inconclusive or negative for carcinoma were prepared. The cytological and histological findings were evaluated by two pathologists.
Results: Needle biopsies: The routinely histologically examined slides of 352 biopsies and 259 touch imprints revealed no carcinoma. A carcinoma was diagnosed in 100 first histologically examined slides and in 193 touch imprints. In 93 touch imprints, a carcinoma was detected, which could not be identify in the first histological examination. While in the following serial sectioning in 336 slides no carcinoma was detected, 116 slides showed a carcinoma at deeper level. In 16 biopsy cylinders a carcinoma was diagnosed which was not identified in the first histological examination. In 77 imprints which were positive for carcinoma no carcinoma was detected even after serial sectioning.
Patients: While the routine histological examination of 27 patients revealed carcinoma, the touch imprint cytology showed carcinoma in 38 patients. In the following fine step serial sectioning of 29 histologically cancer-free patients, 26 patients remained to be negative. The fine step serial sectioning, however, displayed additional carcinomas in 3 patients who were initially negative in the first histological examination.
Conclusion: The additional use of touch imprint cytology of prostate core needle biopsies can improve the diagnostic accuracy. Touch imprint cytology of the prostate can particulary be useful as an adjunct in patients with repeated negative histology or in cases with previous inconclusive histological results.

EXPRESSION OF E-CADHERIN AND PROTEINS FROM THE CYCLINE-DEPENDENT KINASE INHIBITORS (CDKI) FAMILY IN PROSTATE ADENOCARCINOMA (PAC)
Ma³gorzata Janicka-Jedyñska, Aldona WoŸniak, Jakub ¯urawski, El¿bieta Kaczmarek, Joanna Bulak
Department of Clinical Pathology, Karol Marcinkowski University of Medical Sciences, Poznañ, Poland

INTRODUCTION: In the androgen-independent, metastatic PAC there is currently no successfull therapy. Therefore we need to improve our understanding of markers which can be helpfull in determining the metastasizing potential. It has been proposed that progression may be related to the presence of neuroendocrine differentiation, proteins from the CDKI family (p21, p27) and adhesion molecule E-cadherin. Decreased expression of this proteins may be associated with PAC invasion potential. The aim of our study was to evaluate if E-cadherin, p21 and p27 are valuable to identify individuals at risk for biologically active PAC.
MATERIAL AND METHODS: Archival tissues from 75 patients with PAC after total prostatectomy and 75 controls with BPH (and a 10-year PAC-free follow-up) were labeled for E-cadherin, p21 and p27. Analyzed neoplasms were subdivided into two groups: GL(5-6) (Gleason score 5-6) 48 cases (64%) and GL(7-9) 27 cases (36%). Immunoreactivity for E-cadherin was quantified using morphometric computer analysis. LM patterns were saved (mean 30 for case) and the percentage of cells with positive membranous reaction per 1000 cells was calculated. For p21 and p27 the percentage of positively stained nuclei was counted (per 1000). The results obtained were compared with the histological grade, Gleason score, staging system.
RESULTS: In BPH strong membranous reaction for E-cadherin was evident in all cases (in more than 80% of cells). Regions of PAC were less intensively stained. In the GL(5-6) the percentage of positive cells was above 80% in 34 cases (70.89%) when in the GL(7-9) group it was lower than 80% in 13 cases (48.74%) ($p<0.036$). Correlations between E-cadherin immunostaining pattern and histological malignancy were found. Decreased expression (less than 10% positively stained nuclei) for p27 was observed in 18 cases (66.71%) and 39 cases (81.25%) respectively in above mentioned groups ($p<0.032$). The percentage of positively stained nuclei was above 50% in all control cases. Loss of immunoreactivity was correlated with histological grading and staging. There were found no significant differences for p21.
CONCLUSIONS: The results obtained confirm the importance of E-cadherin and p27 as strong biomarkers for PAC. Decreased expression of this proteins is associated with aggressive phenotype in PAC and may provide additional information to decide which patients need more intensive monitoring or treatment (chemoprevention).

EXPRESSION OF MOLECULES OF INTERCELLULAR INTERACTION IN PROSTATE CANCER
MATSIONIS Alexander, MEDVEDEVA Larisa, MEDVEDEV Vladimir, RESNIKOVA Galina
Rostov Regional Bureau of Pathology, Rostov-on-Don, Russia

INTRODUCTION: It is known, that losses of an intercellular adhesion resulting in to disconnection of tumour cells, and also the changes of extracellular matrix can promote development of metastatic disease. It is doubtless, that the tumour cells at interaction, and also at construction of a stroma the same molecules use, as normal tissues, though the character expression of those or other factors in various phases of a cancerogenesis can be various. We investigated features expression of some adhesive molecules in prostate cancer.
MATERIALS & METHODS: Tissue samples were taken from 211 patients with prostate cancer, their age ranging between 51 and 82 years. Tissues sections were subjected to immunohistochemical study with a monoclonal antibody in to human ICAM-1 (clone My13), VCAM-1 (clone 1.4C3), CD31 (clone JC/70A), N-Cadherin (clone 3B9), P-Cadherin (clone NCC-CAD-299), E-Cadherin (clone HECD1), collagen 1Ó (clone C1Y 94), Laminin (clone 4C7), Tenascin (clone TN2) (Dako, Zymed). An EnVisionTM; +System (AES) complex staining kit (Dako) was used.
RESULTS: The obtained data allow revealing some differences of normal and tumour cells, and also nor-mal stroma and stroma shaped tumour. In particular, in samples of a normal tissue predominates expression of laminin, Ð- and Å-Cadherins in comparison with other molecules. We reveal ICAM-1 and tenascin rarely and absolutely misses VÑAM-1. At highly differentiated tumours reaction with laminin and collagen 1Ó increase reliable. At moderate differentiated tumours reliable decreases expression of Ð- and Å-Cadherins in comparison with a normal tissue and the expressiveness of reaction with CD31 and collagen 1Ó of increases. In poorly differentiated tumours cells demonstrate tenascin expression and absence or weak degree of reaction of remaining investigated molecules. It was founded that tumours demonstrating decreasing expression of cadherin (p=0,3) and laminin (p=0,3), and increasing expression of tenascin (p=0,05) are accompanied by the more frequent development of the biochemical relapse during three years after radical prostatectomy.
CONCLUSION. Thus, for the prostate cancer characterisation the most important are CD31, cadherin, laminin and tenascin. The changing of their expression is accompanied by the increasing of the frequency of the development of the biochemical relapse.

P 674
DIAGNOSIS OF LIMITED PROSTATE CANCER IN BIOPSY TISSUE: A BAYESIAN ANALYSIS.
DALTON Leslie
South Austin Hospital
Austin, TX USA

Background: Currently the threshold in the histologic diagnosis (dx) of prostate cancer (ca) from atypia/suspicious (A/S) is not fixed. Emphasis is now given to use as many methods as possible to increase sensitivity in the dx of ca. The question becomes whether or not continuing this approach has merit with respect to improving patient outcome (PO). A Bayesian approach was used to analyze the question.
Design: The existing relevant literature was searched for the numbers needed for input into the problem. Unlike prior considerations of this question, the initial point to begin calculating probabilities was where a single pathologist identifies a focus of A/S vs. ca. or even misses an A/S focus. From this point the logical progression of types of studies to review include: pathologist reproducibility (repro.) in the dx of prostate ca, use of immunohistochemistry (ihc) in dx, prostatectomy findings (pf) given a dx of limited ca, findings on repeat bx after dx of A/S or benign dx with persistent increase in PSA, disease progression (dp) based on pf, dp after biochemical failure, mortality/morbidity statistics, and watchful waiting (ww) as a tx.
Results: Studies of pathologist repro. in the dx of limited prostate ca are sparse. Repro. of the ihc methods currently being advocated to help in the decision of limited ca vs. A/S are virtually nonexistent. Possible coin flips therefore abound at the earliest phases of the problem. Then patients with a dx of A/S often show obvious ca after repeat bx., and conversely the dx of limited ca at bx often leads to insignificant ca found after prostatectomy. Ww in many clinical settings has not been proven to unfavorably compare with aggressive treatment. Pathologists rarely consider morbidity in their evaluation of patient outcome, and leave the input of this number as a blank.
Conclusions: At this juncture a defined threshold or set of specific criteria should be set before a dx of prostate ca should be given. Based on this study it appears that any questionable focus less than 0.5mm in a single bx core without Gleason grade 4 features could be regarded as A/S with ww recommended as tx. Diagnosis of ca in foci smaller than 0.5mm (GS <=6), despite many talented individuals feeling comfortable in doing so, should await better validation of technique.

P 675
THE ROLE OF LAMININ-5, VLA-6 AND TENASCIN IN PROSTATE ADENOCARCINOMA SPREADING
POPOVA-GLADSKIKH Olga, KUZNETSOVA Alla, DANILOVA Tamara, IVANOV Alexei, ANDREEVA Yulia*, SHEGAI Peter*, ALEXEEV Boris*, FRANK George*, PALTSEV Michael
Moscow Medical Academy, Moscow Research Institute of Oncology*, Moscow, Russia

Introduction. The process of tumor invasion is accompanied with the significant alterations in expression of different matrix components responsive for cell adhesion and cell migration and contribute to the carcinoma spreading. In prostate adenocarcinoma we investigated the expression of some matrix proteins and integrins have been reported to be highly expressed in many other cancers. The results were compared with respect to histological and clinical peculiarities.
Materials and methods. Cryostat sections and the primary cultures of prostate tissue from 20 patients were immunohistochemically examined using mAb against human tenascin, two forms of Fn, TSP-1, lam, lam-2, lam-5, VLA-2, VLA-6.
Results. Excepting laminin-5, VLA-6 and tenascin we didn't find any correlation with tumor characteristics and reveled variable patterns of expression of the other investigated antigens. All samples showed a complete loss of laminin-5 in focuses of invasion and in sharp contrast a strong positive staining of this antigen in adjacent hyperplastic benign areas. The loss or production of laminin-5 was exceptionally stable feature as it was confirmed in all primary cultures from histologically distinct zones. The immunostaining for VLA-6 was obviously positive in basal layer of all hyperplastic glands and generally negative or decreased in association with malignancy but it was newly observed and even further enhanced in only some cases at the invasive edge of tumor. Tenascin as well as VLA-6 showed positive staining in stroma of hyperlastic areas and it was highly prominent in a few samples, where it arose in epithelial carcinoma cells and partially increased in periglandular stroma of carcinoma foci. Analysis of the relationship of the VLA-6 and tenascin patterns with various clinicopathological characteristics and the patient state revealed that the tenascin presence in carcinoma cell cytoplasm and increased emergence of VLA-6 associated with lymph node metastasis and advanced clinical stage.

Conclusion. The complete loss of laminin-5 in prostate adenocarcinoma is a principal property of invasion and would suggest a less stable epithelial-stromal junction. Partial loss and later new reinforcing of VLA-6 and tenascin at the invasive margins of tumor could reflect a different stages of tumor growth or invasion and also indicate a contributive role of these antigens in migration of malignant cells and disruption of normal integrin signaling.

EZRIN EXPRESSION IN PROSTATE CANCER AND BENIGN PROSTATIC TISSUE

Alexander Valdman. Department of Urology, Karolinska Hospital, Stockholm, Sweden.
Xiaolei Fang. Department of Urology, Karolinska Hospital, Stockholm, Sweden.
See-Tong Pang. Division of Urology, Chang Gung Hospital, Tao-Yuan, Taiwan.
Bo Nilsson. Department of Biomedical Statistics, Karolinska Hospital, Stockholm, Sweden.
Peter Ekman. Department of Urology, Karolinska Hospital, Stockholm, Sweden.
Lars Egevad. Department of Pathology and Cytology, Karolinska Hospital, Stockholm, Sweden.

INTRODUCTION. The membrane-linking protein ezrin is highly expressed in several types of human cancers and correlations between its immunoreactivity and histopathological data as well as patient outcome have previously been shown. However, such studies have not yet been done on human prostate cancer.
PURPOSE. This study assesses ezrin protein expression in a series of clinical specimens.
METHODS. Immunohistochemical analysis was used to characterize patterns of ezrin expression in prostatic carcinoma and benign epithelium in 103 radical prostatectomy specimens. Ezrin immunoreactivity (IR) was scored 0 to 3 (absent, weak, moderate or strong staining). Agreement between three independent observers was calculated.
RESULTS. Ezrin IR in prostate cancers was moderate or strong in 70% of specimens while negative or only weakly positive in benign epithelium. Interobserver agreement of IR score was substantial (mean weighted kappa 0.70, range 0.67 - 0.73). Ezrin expression correlated with Gleason score ($p = 0.016$) and seminal vesicle invasion ($p = 0.006$) but not with extraprostatic extension or margin status. No correlation with biochemical recurrence after prostatectomy was found ($p = 0.19$). Urothelial and squamous metaplasia invariably showed moderate or strong ezrin expression. Epithelium of seminal vesicles and ejaculatory ducts was always intensely positive.
CONCLUSION. Ezrin was expressed in the majority of prostate cancers and correlated with adverse prognostic factors. Interestingly, high levels of ezrin IR were observed in benign metaplastic epithelium and in seminal vesicles.

CO-OPERATION BETWEEN THE ANDROGEN RECEPTOR AND THE ERBB FAMILY PROTEINS IN ANDROGEN-INDEPENDENT PROSTATE CANCER

Z. Kolar, V. Student, M. Hajduch, J. Bouchal, M. Svachova
Institute of Patology & Laboratory of Molecular Patology, Faculty of Medicine, Palacky University, CZ-77515 Olomouc, Czech Republic
Laboratory of Experimental Medicine, Faculty of Medicine, Palacky University, Olomouc
Department of Urology, Faculty of Medicine & Faculty Hospital, Palacky University, Olomouc

Introduction: The androgen receptor (AR) plays a crucial role in the development of androgen-independent prostate cancer (AIPC). There is also considerable evidence for significant activation of AR by growth factor receptors like the erbB family. Preliminary results have shown that the modulation of the AR function is mediated by the erbB-2/erbB-3 pathway and not by erbB-1 (EGFR).
Aim: To analyse the relationship between AR and erbB-1-4 expression in relation to AIPC development.
Material and methods: We used indirect immunohistochemistry for determination of the above mentioned expressions in prostate cancer samples obtained from 147 symptomatic AIPC patiens where prostatic biopsies were available both before the start of androgen deprivation and after AIPC development. Mild, moderate or strong membrane-specific staining was recorded semiquantitatively using H-score (intensity of staining 1-3 x % of positive cells). Relevant statistical methods were used to analyse the results.
Results: We found a statistically higher expression of erbB-1 and erbB-2 in cases with AIPC and a significantly shorter survival of patients with high expression of erbB-2 after AIPC development. The levels erbB-3 and erbB-4 proteins were unchanged. Expression of AR positively correlated with expression of erbB-2 in advanced cases with metastases.
Conclusions: These data suggest that the erbB family proteins pathway is a critical target in hormone-refractory prostate cancer and that pharmacological inhibition of these receptors may provide a powerful approach to treatment of advanced prostate cancers.
This work was supported by NC/7497-3.

IMMUNOHISTOCHEMICAL EXPRESION OF P21WAF1, P27KIP1, CYCLIN D1, P53 AND KI-67(MIB-1) IN PROSTATE INTRAEPITHELIAL NEOPLASIA AND ADENOCARCINOMA, WITH EMPHASIS ON PIN WITH MICROINVASION (PINMIC)

LUQUE Rafael J.(1), REGUEIRO Juan C.(2), LOPEZ-BELTRAN Antonio(2)
(1)Jaén and (2)"Reina Sofia" University Hospitals, Jaén and Cordoba, Spain.

INTRODUCTION: Prostate intraepithelial neoplasia (PIN) is the most likely precursor of adenocarcinoma (PCA) in the prostate, but the morphologic process in which PIN become PCA is poorly understood. Therefore, PIN with microinvasion (PINmic) could be the intermediate step in this morphologic continuum.
PURPOSE: The aim of this study is to present the differential expression of some G1-S modulators of the cell cycle in PINmic as compared with normal prostate (N), PIN, and PCA.
Thirty-seven formalin-fixed, paraffin-embedded samples from radical prostatectomies which contained foci of N (n=37), PIN (n=32), PINmic (n=22) and PCA (n=18) were used. Immunohistochemical expression of p21, p27, cyclin D1, p53 and MIB-1 was quantitated by the grid counting method and the corresponding labelling indices (LI) were determined. Statistical analysis included one-way ANOVA and Scheffe's test for post-hoc multiple comparisons.
RESULTS: We found an increase in the mean LI for all markers from N to PIN, PINmic and PCA. Significant differences between N and PIN, PINmic and PCA were characterized by down-regulation of p27 and up-regulation of the other markers investigated (ANOVA). Multiple group comparisons showed differences between all groups for cyclin D1 LI (N: 1.45±0.76, PIN: 2.49±0.99, PINmic: 3.68±1.02, PCA: 4.76±0.82) ($p<0.001$) and p53 LI (N: 1.55±1.09, PIN: 4.90±2.03, PINmic: 5.36±2.06, PCA: 9.02±4.02) ($p<0.001$), with PINmic showing values between PIN and PCA.
CONCLUSION: G1-S phase modulators of the cell cycle are frequently altered in a continuum from N to PIN, PINmic and PCA. PINmic should be considered an intermediate lesion from PIN to PCA and therefore it could be included as a morphologic variant of PIN.

(3) Service de Radiologie, CHU La Pitié-Salpêtrière, 75013 Paris
(4) Laboratoire TIMC, Faculté de Médecine Domaine de la Merci-38706 La Troche

Prostate cancer (PC) is the first cancer in terms of incidence and the second leading cause of death among men in France with 40309 new cases and 10004 deaths in 2000. Needle core biopsy is used for the diagnosis of prostate cancer by urologists worldwide. MRI has shown to be sensitive and specific for prostate imaging and is a useful diagnostic tool. It is critical to acquire that the best possible protocols for biopsy to improve PC treatment. The aim of this study was (i) : to compare retrospectively preoperative MRI images with histological data in order to improve pre-therapeutic disease staging, (ii): to evaluate feasibility and precision of a system of fusion of IRM and histopathological data and (iii) to collect data in order to constitute a 3D computerized prostate surface model with the major sites of prostate cancer, thus to improve biopsy, but also in order to perform medical interventions through the use of passive, semi-active, or active guiding systems.
This study has included 4 cadaver prostates and 8 specimen of radical prostatectomy. MRI imaging was available for all specimens. Cadaver prostates were examined by MRI after resection, patients who underwent prostatectomy had MRI examination before surgery.
Before examination of the prostates after the recommendations of the Stanford protocol, size, weight and volume were evaluated. To be able to reconstruct histology, parallel needles were inserted into the prostate from the apex to the base. These biopsy tunnels were labelled by ink. After staining of the histological sections, all slices were reconstructed and scanned. Contours of organ and tumor were defined. Using deformable modeling techniques, 3D computerized prostate surface models were reconstructed from prostatectomy specimens with localized prostate cancer. A 3D computer simulation system was developed to accurately depict the anatomy of the prostate and all individual tumor foci.
Registration accuracy determined on composite images was visually estimated to about 2-3mm. The composite image quality may be rather limited for MRI retrospective analysis
Composite images of histology/MRI have been defined, to improve the cancer detection. Histological/MRI fusion is still very promising to improve the pre-therapeutic staging of PC, to optimize the biopsy strategy by application of a computer aided system of reference, to increase positive biopsy rate
This may

P 680

NEW DATA ABOUT ETHNIC PECULIARITIES OF LATENT CANCER OF PROSTATE OF THE INHABITANTS AROUND FORMER NUCLEAR TEST SITE (SEMIPALATINSK, EAST KAZAKHSTAN)

WHEELER Thomas, BARAKAT Marina, AYALA Gustavo, PRUGLO Yuriy
Baylor College of Medicine, Houston, TX, USA; State Medical Academy, Semipalatinsk, Kazakhstan

Introduction: The study of prevalence pathogenesis and morphogenesis of prostate cancer (PC) is relatively restricted in countries of Asia. Ethnic variations in cancer incidence in the region are unknown.
Purpose of the study: Study of ethnic peculiarities of latent cancer of prostate of the inhabitants of Semipalatinsk.
Materials and Methods: Morphological analysis of prostates was performed on sequential gross autopsy material of histotopographic sections among 778 inhabitants of Semipalatinsk region in eastern Kazakhstan. The population in this area consists mainly of Europeans (68.1%, mean age at death: 55.3 yrs) and Asians (31.9%, mean age at death: 45.4 yrs).
Results: Cancer of prostate was discovered in 223 cases, PC occurred 2.5 times more often among the persons of Europeans origin, than among the Asians (35.5% vs. 14.1%, $P<0.05$). Of interest also is that in Europeans PC incidence increased with age, while among the Asians it decreased up to the 7th decades, and later ($P<0.05$). HGPIN was also more frequent in the Europeans population than Asians (35.5% vs. 16.1%, $P<0.01$). However Asians had more HGPIN in the 4th and 5th decades and Europeans in the older population. Low Gleason scores (GS) were more frequent in younger Asians. Also Europeans tend to have more foci of cancer than Asians.
Conclusions: Ethnic peculiarities were discovered among the inhabitants of Semipalatinsk region, Kazakhstan with latent cancer of prostate. Asian patients have a lower incidence of PC that happens earlier in life and is less aggressive biologically. This is further evidence of ethnic predisposition to the cancer of this origin.

NEUROENDOCRINE DIFFERENTIATION AND ANDROGEN EXPRESSION IN BENIGN AND NEOPLASTIC PROSTATE EPITHELIUM

GHIKONTI Ioanna (2), TSIGKA Alexia (2), MIHALOPOULOU Anna (2), BAIRAKTARI Georgia (2), TAMVAKOS George (1), GORANTONAKIS George (1), CHAMILOS Efthymios (1), THEODOSOPOULOS Nikolaos (2), SKOULIDAKIS George (2), THEODOROPOULOS Vasilios (1)
(1) Departments of Urology and (2) Pathology, Agia Olga General Hospital, Athens, Greece.

Introduction. A substantial proportion of primary prostatic adenocarcinomas contain a subpopulation of malignant cells expressing a neuroendocrine phenotype. Neuroendocrine cells (NEC) are considered important for regulating prostatic cell growth and differentiation. Androgen, acting via the androgen receptor (AR), is associated with the development and progression of prostate cancer. We determined the incidence and pattern of distribution of NEC and AR in prostate hyperplastic and cancer tissue and correlated their expression with tumor differentiation and invasiveness.
Material and Method. Antibodies to chromogranin A (CgA) and neuron specific enolase (NSE) were used for the immunohistochemical detection of NEC in formalin fixed, paraffin embedded prostate tissue. We immunohistochemically evaluated 70 prostate cancer (PCa)- 30 well, 20 moderately and 20 poorly differentiated-, 55 prostate intraepithelial neoplasia (PIN)- 30 PIN1, 10 PIN2, 15 PIN3- and 60 prostate adenosis (PA) specimens for CgA, NSE and AR expressing tumor cells. Neuropeptide immunoreactivity was scored as (-) no staining, (+) <2%, (++) 2-25% and (+++) >25% of isolated cells staining positive. AR expression was categorized according to the scoring of the estrogen receptor expression in breast cancer.
Results. Neuroendocrine differentiation (NED) (1% of tumor cells) was noted in 16% of well, 25% of moderately and 50% of poorly differentiated PCa specimens; in 16% of PIN1 and 66% of PIN3; and in 17% of PA cases. AR expression was

positive (weak-moderate) in 50% of well and 100% of moderately differentiated PCa, and moderate-strong in 75% of poorly differentiated PCa specimens.
Conclusions. NED is upregulated in prostatic carcinogenesis, with higher levels of expression in PIN and carcinoma compared with normal cells and hyperplastic tissue. In prostate cancer, NED was increased with PCa dedifferentiation; the same percentage was demonstrated in PIN, which in turn increased in high PIN grades. AR immunoreactivity was more pronounced in benign than malignant prostatic epithelium and became stronger as the tissue became increasingly neoplastic. No negative association between NED status and AR expression was noted in prostate carcinoma. The NEC may play a key role in the regulation of prostatic growth and differentiation.

BASAL CELL CARCINOMA OF THE PROSTATE: REPORT OF ONE CASE.
LÓPEZ José Carlos, PUÑAL Lidia, CARAMÉS Nuria and ABDULKADER Ihab.
Department of Pathology
Hospital Clínico Universitario
C- Choupana /SN 15706-Santiago de Compostela SPAIN.

INTRODUCTION
Basal cell carcinoma (BCC) is a very rare neoplasm, with only a few cases published in the literature.
CASE REPORT
A 51-year-old male presented with urinary obstruction and hematuria. Serum PSA was normal. The cystoscopic examination showed a nodule located in prostatic urethra that was biopsied and diagnosed as basal cell carcinoma of the prostate.
A radical prostatectomy was performed.
MATERIALS AND METHODS
Formalin-fixed and paraffin-embedded tissue was available from the biopsy and the radical prostatectomy specimen.
Immunohistochemical analysis was performed using a universal second antibody kit that used a peroxidase-conjugated labeled-dextran polymer (EnVision, Peroxidase/DAB; Dako-Cytomation Glostrup, Denmark).
RESULTS
Histologically, there was a proliferation of solid nests of uniform basophilic cells with scant cytoplasm and large nuclei with prominent nucleoli. Mitotic figures were inconspicuous.
The immunohistochemical study showed strong and diffuse positivity for BCL-2 and a high proliferation index (MIB-1).
Cytokeratin -34betaE12 was focally positive. Cytokeratin -7 and p53 were also positive.
Prostate-Specific Antigen (PSA), Prostatic Acid Phosphatase (PAP), Leukocyte Common Antigen (LCA), chromogranin, synaptophysin, Neuron-Specific Enolase (NSE), S-100 and p63 were all negative.
Microscopic examination of the radical prostatectomy specimen showed a predominance of a basal cell type solid pattern, but focally there were some cribriform areas. The neoplasm involved more than one-half of the right prostatic lobe (pT2b) and contacted with the inked surface, but periprostatic adipose tissue and striated muscle were free of tumor. Perineural invasion was present. No vascular invasion was identified.
DISCUSSION
Basal cell proliferative lesions of the prostate include lesions ranging from the common basal cell hyperplasia to the uncommon basal cell carcinoma.
Histological features that help to distinguish benign from malignant lesions are the presence of atypical cells with large nuclei and prominent nucleoli showing an infiltrative pattern , perineural invasion, extraprostatic extension or invasion of the bladder neck, necrosis and stromal desmoplasia.
In the case described herein necrosis was only focally seen and the stroma showed areas of myxoid change.
However, the strong and diffuse positivity for BCL-2 and the presence of a high proliferation index are extremely helpful in the diagnosis.

KI 67 AND P53 IMMUNOHISTOCHEMICAL EXPRESSION IN PROSTATE CANCER
Silvia Lacramioara Roznovan*, Doinita Radulescu **, Laurette Graziella Cozma ***, Simona Stolnicu****, Simona Mocanu******
*Clinical Hospital"C. I Parhon", Iasi, ** University of Medicine and Pharmacy , Iasi, *** Institute of Public Health, Iasi , **** University of Medicine and Pharmacy , Tg Mures, ***** Clinical Hospital, Tg Mures.

Prostate carcinoma is the most common male cancer and represents a serious health problem.
The aim of this study is to correlate P53 tumor suppresor protein , with tumor grade and proliferative activity. Clinical data were obtained from case notes.
Materials and methods:
Paraffin-embedded samples from 23 patients with prostate carcinoma the were assessed for pattern, Ki 67 and P53 expression. Biotinylated secondary antibodies and the streptavidin-biotin peroxidase complex were applied according to the manufacturer`s instructions (LSAB2 kit, DAKO, Denmark).
Immunohistochemical analise was performed for the expression of Ki 67and p53.Target retrieval solution was used .
Results and Conclusions:. All the carcinomas expressed Ki67, 12 having > 25% nuclear marking. Four patients who was strongly positive for p53 and had a high Ki67 score survived only one year after diagnosis. Survival ranged from 1 to 13 years after diagnosis.
This study confirms that the the expression of P53 correlates with Ki67.

PROLIFERATING CELL NUCLEAR ANTIGEN ANALYSIS IN PROSTATIC NEEDLE BIOPSY – CORRELATION WITH PSA
Silvia Lacramioara Roznovan*, Doinita Radulescu **, Laurette Graziella Cozma ***, Simona Stolnicu****, Simona Mocanu******
*Clinical Hospital"C. I Parhon", Iasi, ** University of Medicine and Pharmacy , Iasi, *** Institute of Public Health, Iasi , **** University of Medicine and Pharmacy , Tg Mures, ***** Clinical Hospital, Tg Mures.

Effective management of prostate cancer is dependent on adequate pathological reporting of the surgical specimen. Immunohistochemistry has become an important tool in surgical pathology and the evaluation of PCNA and PSA, specific immunohistochemical marker for tumors of prostatic origin, became now routine practice.
Aims: To evaluate the expression of PCNA and PSA in prostate needle byopsy specimens and transurethral resection of the prostate and corelation with tisular PSA and other prognostic indicators including age, Gleasson score and surviving period for some patients.
Materials and methods:
Biological markers (PSA, PCNA) were performed on 61 patients with prostate cancer. Biotinylated secondary antibodies and the streptavidin-biotin peroxidase complex were applied according to the manufacturer`s instructions (LSAB2 kit, DAKO, Denmark).
Diaminobenzidine was used as a chromogen for visualization. The slides were counterstained with light hematoxylin.
Results and Conclusions:

PSA immunoreactivity decreased in adenocarcinomas with higher Gleason score.
PCNA increases progresively from well differentiated through poorly differentiated cancer; correlation with canser stage is strong. In the less differentiated cases , the percent of positive nuclei is higher than the average. PCNA correlates with clinical stadialization and degree of tumor metastasis .

P 685
VIRTUAL SLIDES QUALITY ASSESSMENT TEST FOR EARLY PROSTATE CANCER ON A NATIONWIDE SCALE IN FRANCE
Nicole BERGER, Laurent BIENVENU, Eric BOUCHER, Marc de FROMONT, Alain FONDIMARE, Vincent MOLINIE, Eric PELTIER, Dominique PIRON, Mathilde SIBONY, Frédéric STAROZ, Marie TRILLER, Annick VIEILLEFOND. For Committee n°6 « Urinary tract », working on behalf of AFAQAP (French Association for Quality Assurance in Pathology).

Background: PSA screening increases the number of cancer cells detected at a low stage (pT1c), with only small foci found on biopsy specimens. In order to reduce the number of potential over- and under-diagnoses, a study was carried out through a quality assessment test on a nationwide scale in France on virtual microscopic slides.
Materials and methods: Twelve cases of prostatic specimens (biopsies, TRUP) displaying carcinoma and their mimics were selected: prostatic carcinoma (n=6), mimickers of cancer (n=5), high grade PIN (n=1). Among carcinoma there were Gleason score £ 6 (n=2), Gleason score > 6 (n=4), with small focus (n=5). Mimickers were atrophy (n=2), cribriform clear cell hyperplasia (n=1), basal cell hyperplasia (n=1), and sclerosing adenosis (n=1).
For each case an H&E slide was digitalized on a CD-ROM with the NAVIQAP® virtual slide system from Samba Technologies.
The CD-ROM was sent to 191 junior or senior pathologists scattered all over the country. The answer form included main items like benign lesion, prostatic carcinoma, need for new biopsy, and secondary items for the sub-classification of the lesions and the Gleason score in case of malignancy. After the deadline for the responses, each participant was given access to the results and comments on the CD-ROM.
Results: 130 answers were analyzed. Some mimic lesions were misinterpreted as carcinoma: sclerosing adenosis (37%), atrophy (2 -10%), basal cell hyperplasia and cribriform clear cell hyperplasia (2% of the participants). HGPIN was misinterpreted as a benign lesion by 13%, and over-diagnosed as carcinoma by 5% of the pathologists. Small foci of carcinoma were misinterpreted as benign lesions in respectively 6, 7 and 18% in Gleason score > 6, and in 40 and 48% in Gleason score £ 6. Ductal carcinoma was misinterpreted as a benign lesion by 5% of the participants.
Conclusion: This study demonstrated the ability to test on a large scale the pathologist accuracy on usual prostate lesions. Its results can be used to focus teaching efforts on obvious potential mistakes in a “the real life” setting.

P 686
HER-2/NEU ONCOGENE EXPRESSION IN PROSTATE CARCINOMA: EVALUATION OF GENE AMPLIFICATION BY FISH
SERTÇELÝK Ayþe, KANKAYA Duygu, PERÇÝNEL Sibel, KUZU Iþýnsu, BALTACI Sümer

Introduction: The variability in the clinical and biological behaviour of prostate cancer and the inadequacy of markers used for assessing prognosis leads to investigate for new prognostic parameters. There has been an increasing interest on Her-2/neu oncogene and studies which investigate its role in prostate carcinomas have given variable results.
Aim: The aim of the present study is to investigate whether Her-2/neu oncogene has a role in the initiation and progression of prostate carcinoma.
Methods: Radical prostatectomy specimens from 74 patients who have prostate carcinoma were included in the study. Tissue array blocks were constructed by taking 2-6 cores 4mm in diameter for each tumour specimen using punch biopsy needle. Overexpression of Her-2/neu protein was assessed in areas of carcinoma, low grade intraepithelial neoplasia (LGPIN), high grade intraepithelial neoplasia (HGPIN), and benign prostate hyperplasia (BPH) by immunohistochemistry (IHC). Flourescence in-situ hybridization (FISH) method was used to investigate Her-2/neu gene amplification in areas of carcinoma in 56 cases. The results of both methods were compared in correlation with gleason grade, stage of tumour and preoperative serum prostate spesific antigen levels.
Results: Her-2/neu protein was expressed in a cytoplasmic/membranous manner in the study cases. The expression of Her-2/neu oncoprotein significantly increased from areas of BPH to PIN and reached the highest degree in areas of carcinoma (p=0). Her-2/neu overexpression by IHC was observed in 66,21 % of prostate carcinomas while Her-2/neu gene amplification by FISH was present in 4,05 % of prostate carcinomas. There was no relationship between the ratio of Her-2/neu protein expression or gene amplification and gleason grade, stage of tumour and preoperative serum prostate spesific antigen levels.
Conclusion: The degree of expression of Her-2/neu oncoprotein increased from areas of BPH to PIN and reached the highest degree in areas of carcinoma by IHC though no correlation with gleason grade, stage of tumour and preoperative serum prostate spesific antigen was found. Her-2/neu gene amplification was observed in very few of the carcinoma cases, thereby making it difficult to comment on the significance of Her-2/neu protein expression in prostate carcinoma. Therefore, studies on larger series of prostate carcinoma representing different stages are necessary to clarify its significance.

THE SIGNIFICANCE OF THE IMMUNOEXPRESSION OF KI 67 AND P21 IN PROSTATE BIOPSY TISSUE
VLAHOVA Aleksandrina,CHRISTOVA Svetla, SLAVOV Chavdar
Chair of General and Clinical Pathology
*Department of General Urology
Alexandrovska University Hospital
Medical University, Sofia, Bulgaria

The diverse clinical outcome of patients with prostate cancer necessitates additional examination of biopsy tissue to achieve individual approach of treatment. Some clue can be provided by immunohistochemical establish abnormal expression of p21 or Ki 67. The aim of this study was to investigate the expression of Ki67 and p21 and to analyze their relationship in BPH and prostate cancer. METHODS: The expression of the Ki67 and p21 was examined by immunohistochemistry on paraffin embedded tissues sections from patients with BPH, PIN and prostatic carcinoma. RESULTS: A total of 52 patients, from 52 to 81 years old, were diagnosed: 9 benign prostatic hyperplasia, 11 prostatic intraepithelial neoplasia and 32 adenocarcinomas. The specimens were examined by immunohistochemistry for Ki67 and p21 . We found that BPH and PIN showed no or weak immunostaining for p21 and Ki 67, ranging from 0 to 3%, with one exception. Ki 67 was found positive mainly in prostates with PIN, revealing the premalignant nature of the lesion. In Gleason score 2-6 group Ki 67 showed equal percentage of cells in proliferation, and no p21 expression. The adenocarcinomas with high Gleason score revealed high proliferative index. The incidence of expression and the

percentage of Ki 67 positive cells increased with Gleason score. In the examined biopsies, different zones revealed different expression of Ki67, with tendency to increase in less differentiated areas. Overexpression of p21 was found only in four cases mainly in the areas with high Ki67 index.
CONCLUSION: Although the immunoexpression of Ki67 and p21 cannot help to differentiate between BPH, PIN and cancer, it provides additional information to find patients needing close clinical follow up. Their expression serves as independent prognostic factor after PSA, Gleason score and stage, and shows the effect of treatment and AIPC turn down. If the data are known from biopsy before the operation they can help to choose the most efficient treatment. The high proliferative index in biopsies of patients without cancer screens those needing close clinical and biochemical control.

COMPARISON OF NUCLEAR VOLUME IN PROSTATIC INTRAEPITHELIAL NEOPLASIA AND PROSTATE CARCINOMA

1S. Roznovanu, 2D. L. Frincu, 3D. Radulescu, 2D.L. Calin
1Division of Pathology, Parhon Hospital, Departments of 2Anatomy and 3Pathology, University of Medicine and Pharmacy „Gr. T. Popa", Iasi, Romania

Introduction. Prostatic intraepithelial neoplasia (PIN) is the most precancerous lesion of prostatic carcinoma, one of the most common malignant diagnosed tumor and there are no accurate technique for predicting their evolution. Gleason system has been shown to accurately predict prognosis for low and high grades PINs, but for prostate carcinoma is of limited prognostic use. We have been interested in using a computer-based quantitative measurement to determine a more accurate assessment of nuclear dimension.
Materials and methods. There were analyzed histologic sections from 82 biopsies and 40 transrectal rezections of prostate carcinoma. The biopsy tissue block and tumor fragments were paraffin included and quantitative analysis was performed on hematoxylin and eosin-stained histological sections with a computer-based program. All distinguishable nuclei in a microscopic measurement field were systematically selected for the standard measurement and for stereologic estimation of volume-weighted mean nuclear volume by the „point-sampled intercept" method. The lesion measured in each samples of primitive tumor was always the most severe and 40 nuclei were measured in each case.
Results. The stereologic results indicate a significant increase in nuclear volume from low grade PIN (301.0532 ± 68.1322) to high grade PIN (387.11563 ± 74.5381) and prostatic carcinoma (400.2371 ± 88.5272). It is a significant difference between the two grades of PINs, but the differences between high grade PIN and prostatic carcinoma was not significant.
Conclusion. Our study provides a more-objective differentiation of the two grades of PINs and demonstrates that stereologic nuclear volumetry adds significantly to the correct and objective clasification and prediction of these lesions and is of capital importance in patient management.
KEY WORDS: NUCLEAR VOLUME MEASUREMENT, PROSTATE CARCINOMA, PROSTATIC INTRAEPITHELIAL NEOPLASIA.

Prostate carcinoma (Pca), one of the most common cancer in men, is a major health problem, due to its morbidity and mortality in the growing elderly man population. New diagnostic and prognostic markers are needed, and the carcinogenesis of Pca remains to be clarified.
The disruption of the balance between cell proliferation and apoptosis in favor of apoptosis is responsible for the abnormal growth of the prostatic gland during neoplastic development. The chief effectors of the apoptotic pathway are the caspase family that induce cell death through activation ¡°in cascade¡± of different caspase members. Upstream, caspase 8, an initiator caspase, cleaves all other known caspases. Downstream, caspase 3, as executioner, is at the center of apoptotic process by cleaving cellular substrats and inducing DNA fragmentation.
The aim of this study was to evaluate the cleaved caspase 3 (Ccsp3) and 8 (Ccsp8) proteins expression in prostate cancers to better understand the role of the apoptotic pathway in these tumors.
Immunohistochemical study was performed on prostatic tumors (with tumoral and normal tissues in each case) from 30 patients. The cases were separated in low grade tumors (Gleason score ¡Ü6, n=12) and high grade tumors (Gleason score >6, n=18). For each case, paraffin sections was incubated with rabbit polyclonal antibodies raised against Ccsp3 or Ccsp8.
Ccsp 3 expression was significantly decreased (p= 0.0006) in cancers compared with normal tissues. Moreover, this expression was also decreased in tumoral tissues from low grade (p= 0.0025) and from high grade (p=0.0005) tumors, compared with normal tissues. By contrast, no significant changes (p>0.05) in Ccsp8 expression was detected in tumoral tissues from all the 30 cases or inside the subgroups (low or high grade) compared with normal tissues.
The loss of Ccsp3, -the key protein in the execution of apoptosis-, in prostate cancers compared with normal tissues suggests an inhibition of the apoptotic process in these tumors. Furthermore, the decrease in Ccsp 3 expression was observed even in low grade tumors, making of this activated protein a potential early marker of tumoral transformation. Nevertheless, how caspase 3 is inactivated in Pca remains unclear. It couldn¡¯t be accounted on the loss of activation of caspase 8 since its expression was not modified in Pca. A potential posttranscriptionnal deregulation of caspase 3 activation in Pca could be hypothesized.

INMUNOHISTOCHEMICAL CHARACTERIZATION OF LOCALIZED PROSTATE CANCER.

G.Olmedilla *, J.C. Tamayo**, P.Ramos *, A. Ruiz Villaespesa *, M. Sánchez Chapado **.
Departments of Pathology * and Urology **. Hospital Principe de Asturias. University of Alcalá de Henares. Alcalá de Henares, Madrid

Introduction: classical predictive factors for prostate cancer seem to be sometimes insufficient . Advances in molecular biology and inmunohistochemistry allow us to study molecules related with the cell cicle in prostatectomies with prostate cancer.
Aims: To define predictive value for prognosis of different molecules implicated in the biology of prostate cancer; using inmunohistochemistry for p-21, bcl-2 and ki-67 in radical protatectomies of localized prostate cancer in order to determine association with biochemical relapse.
Material and methods: We used inmunohistochemistry to analyze the expression of ki-67, p21 (waf1/cip1) and bcl2 protein in 96 radical prostatectomies with localized prostate cancer. The results were related with biochemical relapse (seric PSA more than 5ng/ml) using statistical analysis with Kaplan-Meyer curves and test log-rank. Gleason score and tumour stage were related.

RESULTS: Biochemical relapse was found in 22 cases (22%). Patients with overexpression of p21 and Bcl-2 were more prone to have biochemical relapse (36 months follow-up), but without statistical association. Patients with overexpression of Ki-67 had 3,15 more possibilities to have biochemical relapse, with statistical signification (p< 0,001).

CONCLUSIONS: Ki-67 overexpression seems to be a good prognostic predictive factor.

P 691

SINGLE-MINDED 2 HOMOLOG GENE (SIM2) IS OVEREXPRESSED IN PROSTATE CANCER

HALVORSEN Ole J., ROSTAD Kari, ØYAN Anne M., BØ Trond H., STORDRANGE Laila, OLSEN Sue, HAUKAAS Svein A., HOOD Leroy, JONASSEN Inge, KALLAND Karl-Henning, AKSLEN Lars A.
Section for Pathology and Sections for Microbiology and Immunology, The Gade Institute, Haukeland University Hospital, Department of Informatics, University of Bergen, Bergen, Norway, Institute for Systems Biology, Seattle.

The single-minded homolog 2 gene (SIM2) is present within the Down's syndrome critical region on chromosome 21 and encodes a transcription factor involved in development. A short (SIM2-s) and long (SIM2-l) isoform of the SIM2 transcript have been identified. In a recent study, we identified SIM2 among highly upregulated genes in 29 malignant prostate tumours (T), compared with 33 benign (B) prostate samples, using a 40k human cDNA microarray. SIM2 was identified as the second most consistently upregulated named gene in T versus B samples, only surpassed by AMACR. The purpose of our study was to validate the expression of the SIM2 gene and SIM2 isoforms, and examine the expression and prognostic impact of SIM2-s protein expression in prostate cancer. The upregulation of SIM2 was confirmed in a subset of samples using oligonucleotide microarrays. SIM2-s and SIM2-l specific and SIM2 total TaqMan Assays-by-design were employed for quantitative real time PCR (qRT-PCR) on an expanded material of 47 prostate T and 38 B total RNAs, including 31 T/B pairs. SIM2-s, -l and -total were significantly elevated in malignant vs. benign prostate tissues by 3.3, 6.3 and 3.8 fold (median), respectively. However, SIM2-s upregulation was paralleled by SIM2-l upregulation in tumours, contrasting previous studies. Low level expression of both SIM2 isoforms was also detected in benign prostate tissue. In order to examine a larger patient series, a tissue microarray consisting of paraffin embedded prostate cancers from 104 patients, treated by radical prostatectomy, was subjected to immunohistochemistry using an anti-SIM2-s specific antibody. A moderate/strong staining was noted in 44 of 103 carcinomas as opposed to a weak to negative staining in the remaining cases. Moderate/strong expression of SIM2-s was associated with adverse prognostic variables like high histological grade, extra-prostatic extension and elevated serum-PSA. The 13 year survival was 98.1 % vs. 72.8 % in patients with weak/negative vs. moderate/strong SIM2-s expression, respectively (P=0.008, log rank test). In conclusion, the SIM2 gene was upregulated in prostate cancer as validated by oligonucleotide microarrays and qRT-PCR, and SIM2-s protein expression was found to be associated with adverse prognostic variables and reduced patient survival. These findings may prove relevant as SIM2 has been proposed as a possible drug therapy target.

P 692

COMPARISON OF 34BE12 AND P63 IN VARIOUS LESIONS OF THE PROSTATE; ATYPICAL SMALL ACINAR PROLIFERATION (ASAP), LOW AND HIGH GRADE ADENOCARCINOMA AND HIGH GRADE PROSTATIC INTRAEPITHELIAL NEOPLASIA (PIN)

SAYGIN Tuzel, AKYILDIZ IGDEM Aysenur, SAHAN Elife, ERDOGAN Nusret
Department of Pathology, Taksim Training and Research Hospital, Istanbul, Turkey

Objective: The basal cell-specific cytokeratin antibody (34¥âE12) is widely used to aid diagnosis of prostate cancer. Recently p63, a nuclear protein, was identified as useful basal cell-specific marker.

In this study, specimens from prostate needle biopsies, transurethral resections of prostate (TURP), open enucleations and radical prostatectomies were examined. We compared staining patterns of 34¥âE12 and p63 on the lesions of atypical small acinar proliferation (ASAP), low and high grade adenocarcinoma and high grade prostatic intraepithelial neoplasia (PIN).

Results: It was a statistical significance in basal cell staining with 34¥âE12 and p63 in the foci of ASAP. In some cases, 34¥âE12 was stained basal cell layer as complet and strong, whereas p63 was stained fragmented and strong. In three cases, both stains did not stain basal cell layer.

In other lesions, ©¥t was not a statistical significance for staining of basal cell layer with 34¥âE12 and p63. However, some different features of both stains were observed.

Conclusion: ASAP is not a new tumor or precursor entity. Whereas the high predictive value of ©¥ts for subsequent adenocarcinoma warrants close follow-up and repeat biopsy.

The most commonly used ©¥mmunohistochemical marker in the diagnosis of prostate cancer is 34¥âE12. However, p63 is almost as sensitive and specific as 34¥âE12 in diagnosing prostate cancer in needle core biopsies. Both stains are usually equally effective in demostrating basal cells in benign glands. p63 is a basal cell- specific marker that could be used as a complemantary test for the traditionally used 34¥âE12 in diffucult cases. An important difference from 34¥âE12 is its consistent strong nuclear signal, which is easier to interpret.

P 693

CORRELATIONS OF SMALL (3MM OR LESS) FOCUS OF PROSTATE CARCINOMA ON NEEDLE BIOPSY WITH RADICAL PROSTATECTOMY SPECIMEN.

CAMPARO Philippe, DENOUX Yves, MOLINIE Vincent, HAUS Rachel, BARDIER Armelle, COMPERAT Eva, VIEILLEFOND Annick, SIBONY Mathilde.

Purpose of the study : In order to analyse the radical prostatectomy follow up of small foci of prostate cancer diagnosed on biopsies, we perfomed a multicentric retrospective study from1999 to2004.
Methods : We studied 107 consecutive patients, with a small focus of cancer (less or equal to (</=) 3 mm length) on only one biopsy core, a Gleason score </=7, and evaluated the pT stage and the tumour volume on subsequent radical prostatectomy specimen.
Results : Mean age of patients was 64,6 years (46-83 years). Mean PSA concentration was 9,12 (0,6-33) (no data available for 5 patients).
The average number of prostate cores per biopsy was 7,94 (5 – 21). Average total length biopsies was 83,69 mm (13-170). 45 patients had a focus </= 1mm, 30 between 1 and 2 mm and 32 between 2 and 3 mm. 15 patients had Gleason score </= 5, 73 of 6, and 19 of 7.
The whole prostate was embedded in paraffin ; cancer staging was reevaluated according to TNM 2002 classification. Volume of cancer was measured according to an elliptic model : length x width x heigth x 0.4. Average tumour volume at radical prostatectomy was 1,1cc (0,001 – 11,8).
pT Stages pT2a, pT2b, pT2c, pT3 (</= 1mm : 13, 3, 26, 3; 1-2 mm : 3,6, 13, 8; 2-3mm : 5, 4, 16, 7)

volumes </= 0,2 cc; 0,2-0,5cc;> 0,5cc (</= 1mm : 16, 6, 23; 1-2 mm : 7, 6, 17; 2-3 mm : 11, 6, 15)
A small focus </= 1 mm was statistically associated with an organ confined cancer (p=0,02), and associated with pT2a stage (p=0,04). Paradoxically, it was not associated with a small cancer volume (</= 0.5cc p=0.47 and </= 0.2cc p=0.77). PSA average value was correlated with cancer volume (p=0.02) and a volume </= 0.5cc was highly correlated with PSA<10ng/ml (p=0.001).
There was not a significant association between Gleason score and cancer volume (p= 0.47)
On multivariate analysis no association was found between cancer volume and length of cancer on biopsy, adjusted on PSA and gleason score (p>0.5).
Conclusion : This study demonstrates a strong association between small foci of tumour (</= 1 mm) on one prostate biopsie core and pT2a stage (but not with tumour volume) on prostatectomy. Those paradoxical results justify a prospective study on a series of patients with larger number of biopsies (i.e. 12 to 18) to determine wether length of tumour on biopsy can or not identify a subset of patients with good prognosis.

P 694
PATHOLOGICAL SECRETIONS IN PROSTATIC ADENOCARCINOMA
Lj Velickovic, B Djordjevic, V Katic, D Dimov, V Zivkovic

Introduction The presence of pathological intraluminal secretions in prostatic adenocarcinoma, ie. pink amorphous secretions, crystalloids, blue – tanged mucinous secretions, is always suspicious, but not diagnostic for prostate cancer. Between 10% and 23% of acinar – forming prostatic adenocarcinoma contain intraluminal crystal – like structures referred to as crystalloids, and are often associated with amorphous, intraglandular eosinophilic secretions. The aim of our study was to analysis the expression of these morphological signs in prostatic adenocarcinoma.
Methods Research was performed in 80 patients with prostatic adenocarcinoma, at the Institute of Pathology Clinical Centre Nis. The specimens were fixed in 10% formaldehyde and embedded in paraffin. The sections were stained with HE, PAS and HID-AB pH 2,5 methods.
Results The most common changes present in mucous secreting carcinomas were neoplastic glands lumen distension (43/80 – 53,75%), basophilic secretion (21/80 – 26,25%), presence of extracelular mucins (7/80 – 8,75%) and presence of crystalloids (22/80 – 27,5%). Presence of all morphological signs was recorded in carcinomas of Gleason grade 1-4A. Crystalloids were more often present in well differentiated and moderately differentiated neoplastic glands. Lumen distension was typical for Gleason grade 3 and 4A. The association of those morphological features with mucin secretion was confirmed with special methods for mucin detection (PAS and HID-AB).
Conclusions This study clearly showed that pathological intraluminal or extraluminal secretions are very often in prostatic adenocarcinoma and it can use as supportive features of prostatic cancer.

TUMOR MARKER DETECTION BY MEANS OF RT-PCR: ANALYSIS OF PARAFFIN-EMBEDDED SENTINEL LYMPH NODES OF PROSTATE CANCER PATIENTS
HAAS Christian J.*, CUBUKLUÖZ Figen*, WAGNER Benjamin*, WECKERMANN Dorothea**, ARNHOLDT Hans*, WAGNER Theo*
*Dept. of Pathology and **Dept. of Urology, Augsburg Central Hospital, Augsburg, Germany

Introduction: For the improvement of pathological diagnosis RT-PCR based expression analysis of tumor markers seems to be a highly promising method. However, the value of this technique for routine diagnosis has to be proven by application on paraffin-embedded tissue and direct correlation with immunohistochemical data.
Material and Methods: From 242 routinely paraffin-embedded SLNs obtained from 85 prostate cancer patients two immediately adjacent 8 µm sections were cut, one of which used for IHC and the other for RNA-extraction.
The obtained RNA was reverse transcribed and PCR for the detection of various tumor markers was performed. The specificity and sensitivity of these RT-PCRs was compared with the immunohistochemical results, as well as with the other pathological and clinical data of the respective patients.Moreover, for the RT-PCR positive specimen the tumor marker expression was quantified by real-time PCR and a correlation with the micromorphometric data was performed.
Results: For the tumor marker panel tested, the sensitivity of the RT-PCR as well as the negative predictive value was 99 % for detection of immunohistochemically identified tumor cells in the SLNs. All non-prostate cancer SLNs used as negative controls were RT-PCR negative. Of the 175 immunohistochemically negative prostate cancer SLNs 25 were RT-PCR positive. Of these 8 were from pN1(i+)(sn) patients and 14 from pN0(i-)(sn) patients with biochemical relapse. The real-time RT-PCR data corresponded well with the histopathological distinction between isolated tumor cells, micro- and macrometastases.
Conclusions: RT-PCR based techniques are feasible on single sections of paraffin material and thus can be used as a supportive methods in pathological diagnosis of prostate SLNs. This opens the possibility for extremely sensitive qualitative and even quantitative analysis of tumor marker expression. For prostate cancer patients RT-PCR analysis of appropriate tumor markers may be useful as an additional prognostic factor for the identification of patients with increased risk of biochemical relapse.

Signet-ring adenocarcinoma of the prostate is an unusual variant of prostatic carcinoma, with a high grade of malignancy. But with increasing use of needle biopsies as the primary mode of diagnosis, pathologists should be familiar with the full range of aspects of this tumor and its mimics. We report the cases of two male patients, with ages of 65 and 72 years, presented with urinary retention. Seric Prostatic specific antigen (PSA) level was increased in both cases. Fine needle biopsies were performed and fragments were fixed in formalin and embedded in paraffin. Histochemical reactions (mucicarmin, Alcian blue) and immunohistochemical methods (PSA) were applied. Over 90% of prostate samples were infiltrated by a poorly differentiated carcinoma with mucinous and signet ring patterns. The signet-ring cells presented abundant clear or vacuolated cytoplasms and ovalar, vesicular, eccentrically placed nuclei, with small nucleoli. The overall grade was assesed as Gleason grade 5 and immunohistochemical staining for PSA was positive in both cases. This aggressive tumor is an uncommon but distinct variant of primary prostatic carcinoma which should be distinguished from metastatic disease. The expression of prostate associated antigens such as PSA represents the diagnostic of prostatic origin.

***Department of Pathology, University of Medicine Targu-Mures, Romania

The aim of our study was to confirm the expression of prostate specific antigen (PSA) in ductal carcinoma of the prostate, and to analyse p53, and Ki-67 expression in these tumors. Paraffin-embedded samples from 12 patients with ductal carcinoma of the prostate were assessed for pattern, mitotic count and the presence of a microacinar carcinoma component. There were 6 pure ductal and 6 mixed microacinar and ductal carcinomas. Sections were stained immunohistochemically for the expression of PSA, p53 and Ki-67. Six of the ductal tumors had a papillary pattern whilst the others had a cribriform appearance. The mitotic rates in the ductal areas were high in the tumors from 8 of the 12 patients. PSA immunohistochemistry was positive in all cases. Two of the tumors were strongly positive for p53 protein. All the ductal carcinomas expressed Ki-67. This study confirms the expression of PSA in ductal carcinomas of the prostate. The percentage of tumors expressing p53 was similar to that published for high-grade microacinar carcinomas. The results for Ki-67 suggest that ductal tumors have higher scores than microacinar tumors, but further studies are necessary to ascertain this aspect. As half of the patients with ductal tumors had co-existent microacinar tumors, we advise transrectal prostatic biopsies in patients diagnosed with pure ductal carcinomas on transurethral resection specimens, to exclude high-grade microacinar carcinomas.

P 698

EXPRESSION OF CYCLIN A, CYCLIN B1, AND HIGH MOLECULAR WEIGHT CYTOKERATIN (34-BETA-E12) IN PROSTATIC CANCER

GOVEDAROVIC Vitomir*, RADOSAVLJEVIC Radosav**, MITROVIC Dragan*, BRASANAC Dimitrije*, ACIMOVIC Miodrag**, HADZI-DJOKIC Jovan**, MARKOVIC-LIPKOVSKI Jasmina*
*Institute of Pathology, Medical Faculty, University of Belgrade
**Clinical Centre of Serbia, Belgrade

Cytokeratin 34-beta-E12 staining is a useful tool in confirming and establishing of prostatic cancer diagnosis. Our aim was to investigate, whether cyclin A and B1, as a proliferative markers, have additional importance.
Forty three cases of patients with primary prostatic adenocarcinoma obtained from needle biopsy in Department of Urology, Clinical Centre of Serbia, Belgrade.
Cyclin A, cyclin B1 and cytokeratin 34-beta-E12 proteins expression were immunohistochemically assessed by semiquantitative evaluation using anti-human cyclin B1 monoclonal antibody (M 3530, DAKO) and anti-human cytokeratin 34-beta-E12 monoclonal antibody (N1553, DAKO). We examined relationship of this immunohistochemical markers with values of Gleason score, PSA and F/T PSA in serum.
Cytokeratin expression and Gleason score were in inversion correlation ($p<0.05$). Decreased cytokeratin expression was followed by increased expression of cyclin A ($p<0.05$), but without statistically significant increase of cyclin B1 expression ($p>0.05$). However, strong correlation between cyclin A and cyclin B1 expression were observed ($p<0.01$). PSA value and Gleason score were in very strong direct correlation ($p<0.001$). We could not found any significant relationship between F/T PSA and other analysed parameters. Increase of Gleason score which has prognostical significance, clinically has been followed by higher serum PSA levels and immunohistochemically by decreased expression of cytokeratin. Direct significant connection between Gleason score and cyclin A and B1 has not found.
We conclude that only 34-beta-E12 staining is still reliable immunohistochemical marker which improves prostatic carcinoma diagnosis on needle biopsies.
Key words: prostatic cancer, Gleason score, cyclin A, cyclin B1, cytokeratin 34-beta-E12, PSA, F/T PSA, needle biopsy

INTRAOPERATIVE FROZEN SECTIONS ANALYSIS OF THE POSTEROLATERAL MARGINS DURING NERVE SPARING LAPAROSCOPIC RADICAL PROSTATECTOMY: TECHNICAL ASPECTS

L. Doucet (1), N. Dreux (1), G. Fournier(2), A. Valeri (2), N. Lagarde(1), A. Volant (1).
(1) Department of Pathology, University Hospital of BREST, FRANCE
(2) Department of Urology, University Hospital of BREST, FRANCE

Introduction : nerve sparing procedure during laparoscopic radical prostatectomy need to perform a dissection closer to the posterolateral margins than without preservation of the neurovascular structures. Using intraoperative frozen sections (IFS) analysis on the posterolateral margins was unfrequently reported before during open or laparoscopic radical prostatectomy and could be an improvement of the technique allowing more patients to benefit from nerve sparing for preservation of potency in case of negative margins.
Purpose of the study: describe the technical aspects of the technique that we currently use in patients candidates to a nerve sparing procedure.
Methods: A total of 242 (uni or bilateral) IFS analysis were realised during nerve sparing laparoscopic prostatectomy between April 2002 and March 2005 for potent patients with clinically localized prostate cancer (T1&T2). After completion of the nerve sparing procedure and interfascial dissection the prostate is immediately remove. A specimen (2.5/4cm x 1cm) is cut by the surgeon from base to apex on one or both side of the prostate posterolaterally on the area of contact of the neurovascular bundles. The specimen including the capsule and 4 mm of the underlying prostatic parenchyma is immediately sent to the pathologist. After inking of capsular side 12ìm frozen sections are performed followed by toluidine blue staining and analyzed. Positive surgical margins are defined as tumor at the inked surface. In case of positive margins the ipsilateral neurovascular bundle is removed at the end of the procedure.
Conclusions: The usefulness of IFS during laparoscopic radical prostatectomy remains to be proven but seems to allow the surgeon to offer a nerve sparing procedure more frequently without compromising cancer control.

A MORPHOLOGICAL STUDY OF STARTING SITES OF INVASION FROM PROSTATIC INTRAEPITHELIAL NEOPLASIA (PIN) TO PROSTATIC ADENOCARCINOMA

Mareyuki Endoh, Tai-Yi Jin, Mika Watanabe, Takuya Moriya, and Hironobu Sasano

Introduction: High-grade prostatic inraepithelial neoplasia (PIN) has been considered as the most likely preinvesive stage of prostatic adenocarcinoma. However starting mechanisms of invasion from PIN has not been completely investigated not only from the view of genetics but also

morphology admittedly. Thus we examined a large number of complete serial sections so as to find out starting sites of invasion, and also we reconstructed 3D- images from the sections in order to visualize the sites and to examine them morphologically.
Materials and methods: Used were two prostatectomy specimens having extensive PIN with multiple invasive foci. After formalin fixed and paraffin embedded, five blocks were selected and sectioned serially in 3um thickeness completely. After HE stained and immunohistostained for high molecular weight cytokeratin (34bE12) in aid of searching for micro-invasion, invasive lesions connected with PINs were searched microscopically. Then, the lesions were reconstructed into 3D-images with computer-assisted 3D-reconstruction system.
Results: Total amount of the serial sections reached 824 sheets containing many invasive lesions, while only six sites were considered to be invasive lesions apparently connected with PIN. Furthermore, serial sections and 3-D images revealed the early invasive sites were distinctly diminutive compared from the surrounding invasive lesions.
Conclusion: The study confirmed morphologically that PIN was preinvasive lesion of prostatic adenocarcinoma. While starting sites of invasion were hardly discovered and the area were obviously smaller than the surrounded invasive lesions.

P 701
EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) EXPRESSION IN BASAL CELLS OF NORMAL, ATROPHIC, HYPERPLASTIC PROSTATIC GLANDS, AND PIN. A TISSUE MICROARRAY STUDY
R. Esgueva 1, M. Iglesias 1, M. Jimeno, V. Baena, N. Juanpere, M. Garcia, J. A. Lorente 2, S. Hernandez 5, L. A. Rioja 4, A. Gelabert 2,6, S. Serrano 1,6 and J. Lloreta 1,5.

Background: Epidermal growth factor receptor (EGFR) is involved in the autocrine regulation of basal and luminal cell growth in the prostate. Basal cells (BC) of the prostate act as reserve-regenerative compartment, and are important in the maintenance of normal glands and in the development of prostatic diseases. Expression of EGFR in BC has been documented, but modification of this expression under pathologic conditions has received relatively little attention. The present tissue microarray (TMA) study has focused on EGFR expression in BC of normal (N), atrophic (A), hyperplastic (H), and dysplastic (PIN) glands from patients with prostatic adenocarcinoma (PCa).
Design: 227 radical prostatectomies were reviewed and 4 TMAs were
constructed, with a total of 849 cores (3.7 cores/case). In addition to representative foci of PCa, the cores included 451 areas with benign or dysplastic lesions (N:57; A,168; H,146; PIN, 80). The slides were immunostained with a monoclonal EGFR antibody (H11, DakoCytomation), using the Envision system (DakoCytomation, Glostrup, Denmark). The results were scored in a four-tiered scale (0, 1+, 2+, 3+). The percentages of cores with EGFR-positive BC in N, A, H or PIN glands in each intensity category were compared using a Chi-square test.
Results: The distribution and relative percentages of positive cores for each category are summarized in the table. None of the observed differences was statistically significant.
Conclusion: 1.EGFR expression in BC is predominantly of low (1+) intensity. 2.The EGFR expression profile of BC in hyperplasia is similar to that of atrophic, and only slightly different from that of normal glands. 3. Strong positivity (3+) is observed more often in BC of glandular hyperplasia, but moderate and strong positivity are overall more extensively observed in BC of PIN. 4. EGFR expression in BC may be relevant in the pathogenesis both of hyperplasia and PIN.

P 702
BASAL CELL HYPERPLASIA OF THE PROSTATE
Sosa G, Álvarez M, Álves J, Picazo M. Department of Pathology. Universitary Hospital La Paz, Madrid, Spain.

Introduction: Prostatic basal cell proliferations is a benign condition in a background of nodular hyperplasia typically found in the transition zone and usually identified in transurethral resection or prostatectomy specimens. Some studies report an incidence of BCH in prostate between 8.9% and 10.2%. BCH show a wide spectrum of morphologic features, ranging from focal basal cell hyperplasia to florid adenoid basal cell hyperplasia. Unusual hystological patterns are rare and the distinction between benign and malignant lesions is difficult to establish. Morphologic evidence of malignancy include infiltrative growth, extraprostatic extension, perineural invasion, local recurrence or metastases, necrosis and stromal desmoplasia. When the lesion is well delineated, the term adenoma has been used (BCA). Hyperplastic lesions and adenoid cystic carcinomas have cytoplasmatic immunoreactivity to high molecular weight keratins, but the basaloid carcinoma does not have it. Purpose of study: The aim of this study is to remark this entidity because basal cell proliferations are uncommon lesions and sometimes can mimic prostatic intraepitelial neoplasia and carcinoma. Materials and methods: A 65-year-old white male underwent a retropubic simple prostatectomy. The serum prostate-specific antigen (PSA) was 2,8 ng/ml. We collected 18 cases with the diagnosis of BCH and BCA that were reported in this Department over a 35 year period (1970-2005). Results: Gross abnormalities were multinodular masses of variable size. Sectioning showed multiples nodules tan-white and uniformly firm. The largest one measuring 2.5 cm. Microscopic findings: in a background of benign nodular hyperplasia the largest nodule was well circumscribed and containing small nests of basal cells of two or more cell layers thick surrounded by a few concentric layers of compressed stroma. The basal cells were plump, with large and uniform nuclei, scant cytoplasm and inconspicuous nucleoli. Our diagnostic was basal cell hyperplasia with nodular pattern. Conclusion: BCH are uncommon lesions in the prostatic gland and can exhibit a morphologic ranging. Accounted for 18 cases reported in our files emphasizing the unusual of these diagnosis and the architectural and citology features of ordinary and unusual patterns of BCH that even more closely mimic prostatic intraepithelial neoplasia and carcinoma.

P 703
RETRACTION CLEFTING AND PROSTATIC INTRAEPITHELIAL NEOPLASIA IN NEEDLE CORE BIOPSIES
Krušlin B, Tomas D, Odak Lj, Cupic H, Kos M, Belicza M Ljudevit Jurak Department of Pathology, Sestre Milosrdnice University Hospital, Zagreb, Croatia

Introduction: In comparison to normal glands retraction clefting is more common and prominent around neoplastic acini and therefore represents an additional criterion for the diagnosis of prostatic adenocarcinoma. Prostatic intraepithelial neoplasia (PIN) composed of abnormal proliferation within the prostate ducts, ductules, and large acini, premalignant foci of cellular dysplasia and carcinoma in situ without stromal invasion is the most likely precursor of prostatic adenocarcinoma. However, in the literature, we were not able to find data on the relationship between clefts and prostatic intraepithelial neoplasia.
Purpose of the study: To determine the presence and extent of retraction clefting in glands with prostatic intraepithelial neoplasia (PIN) in needle core biopsies.
Methods: We analyzed needle core biopsies from 35 consecutive biopsies of patients with PIN diagnosed at the Department of Pathology, Sestre milosrdnice Universty Hospital. Specimens were fixed in 10% buffered formaldehyde, embedded in paraffin, cut at 4 μm and

routinely stained with hematoxylin and eosin. Glands with PIN were analyzed on high power field (400x) and classified in three groups: group I (no clefting), group II (clefting in up to 50% of gland circumference) and group III (clefts in more than 50% of gland circumference). Normal glands within the same biopsy served as a control.
Results: The age of the patients ranged from 53 to 84 years (median 67.8 years), with the PSA value from 4.2 to 121 ng/ml. In glands with PIN, clefts in more than 50% of gland circumference were not found. There were 8 PIN (22.8%) cases with clefting in less than 50% of circumference (group II) and 27 (78.2%) cases with no clefting.
Conclusion: Our results showing the lack of retraction clefting in PIN cases suggest the influence of stromal reaction in the development of clefts around neoplastic acini of prostatic adenocarcinoma and therefore clefting should not be considered as an aid in the differential diagnosis of PIN.

P 704

METABOLIC AND T2-RELAXATION TIME MAPPING OF PROSTATE USING 1H MRS

ROGOZHYN Vladimir, ROZHKOVA Zina, VOZIANOV Sergei
Radiological Center of the Academy of Medical Sciences of Ukraine, Kiev, Ukraine

PURPOSE: We propose quantitative description of metabolic and T2-relaxation time alteration of prostate tissue for differential diagnosis between prostatic carcinoma (PC) and benign changes such as hyperplasia (BPH) and inflammation.
MATERIALS AND METHODS: Two groups of patients are examined by 1.5 T Magnetom Vision System (SIEMENS). The 1-st group (PG) includes 10 patients (age range 34-76), the 2-nd group (VG) consists of 4 healthy asymptomatic volunteers (age range 32-48). For building of the metabolic map the 1H MR-spectra are recorded with 2D CSI sequence:TR/TE = 1500/60 ms. In T2-relaxation time measurement the 1H MR-spectra are recorded in two regions of the prostate (in the central zone (CZ) and in the peripheral zone (PZ)) with SVS STEAM sequence: TR/TE = 1500/60,80,100, 140,180 ms. All spectra are recorded with and without of water suppression. The water signal of prostate tissue as an internal standard for calculating of content of main metabolites is used.
RESULTS: Lesions identified on T2-weighted images were analyzed using the following criteria: low-signal nodule (well circumscribed, rounded low-signal area), low-signal zone (irregular, less circumscribed low-signal area), heterogeneous zone (mixed, high- and low-signal area), central gland asymmetry. From 1H MR spectra the peak areas of main metabolite signals: citrate (Cit, 2.6 ppm), creatine (Cr, 3.0 ppm) and choline (Cho, 3.2 ppm) and the mean peak height ratios of R = Cit/(Cr+Cho) are obtained. The values R>1.12 are indicative for PC, R>2.30 – for BHP, R>4.14 – for normal regions of prostate tissue. In the VG the mean values of T2 for water (Wat), and for Cit, Cr, and Cho are the following: T2 CZ (Wat)=(71.3+-0.56) ms, T 2 CZ (Cit)=(170.2+-0.23) ms, T 2 CZ (Cr)= (134.5+-0.3) ms, and T 2 CZ (Cho)=(254.13+-0.81) ms; T 2 PZ (Wat)=(123.5+-0.74) ms, T 2 PZ (Cit) =(216.8+-0.79) ms, T 2 PZ (Cr)=(241.2+-0.15) ms, T 2 PZ (Cho)=(323.7+-0.2) ms. In the PG the values of T 2 (from 56. 4 to 93.2 ms) are indicative for water signal in PC, and (from 98.7 to 117.4 ms) - for BHP.
CONCLUSION: Metabolic and T2-relaxation time mapping can be helpful for diagnosis and characterization of clinically localized PC and also for the estimation of efficiency of therapy.

P 705

IS P63 A RELIABLE MARKER FOR PROSTATE BASAL CELL EPITHELIUM? IMPLICATIONS FOR PROSTATE CANCER DIAGNOSIS

GHIKONTI Ioanna (2), TSIGKA Alexia (2), MIHALOPOULOU Anna (2), BAIRAKTARI Georgia (2), ALEKSANDRAKIS Konstantinos (1), GORANTONAKIS George (1), GERZELIS Ioannis (1), THEODOSOPOULOS Nikolaos (2), SKOULIDAKIS George (2), THEODOROPOULOS Vasilios (1)

Introduction. The diagnosis of prostate malignancy is often based on the absence of basal cells. Diagnostically reliable identification of prostatic basal cells has depended on staining for high molecular weight cytokeratin. The p63 gene, a member of the p53 gene family, has also been shown to be expressed in the basal epithelial cells of normal human prostatic epithelium. Additionally, irregularities in p63 expression in multiple organs have been associated with epithelial carcinogenesis; p63 may protect prostatic epithelial cells against neoplastic transformation, perhaps through a tumor suppressor function. We examined the differential expression of p63 protein and cytokeratin 903 in prostatic adenocarcinoma (PCa), intraepithelial neoplasia (PIN), atypical adenomatous hyperplasia (AAH) and benign prostatic hyperplasia (BPH).
Material and Method. We performed immunohistochemistry with monoclonal antibodies for p63 and cytokeratin 903 on specimens of PCa (70 cases: 30 well, 20 moderately and 20 poorly differentiated), PIN (55 cases: 30 PIN1, 10 PIN2, 15 PIN3) and AAH (60 cases).
Results. 100% of the PCa specimens were negative for p63 and cytokeratin 903 immunoreactivity. In PIN1-3, p63 expression was weak-moderate and focal in 100%, and cytokeratin 903 staining was weak and focal in 89% of the cases. Weak-moderate and focal expression of p63, as well as weak and focal expression of cytokeratin 903 were also observed in 85% and 70% of AAH cases, respectively. In BPH, p63 glandular expression was more extensive than cytokeratin 903.
Conclusions. In contrast to normal and preneoplastic prostatic tissue, prostate adenocarcinomas do not express p63. The latter seems to be a reliable marker for prostate basal epithelium, such as cytokeratin 903, and can potentially increase the specificity for discerning cancer from high grade PIN or atypical prostate lesions, thereby reducing diagnostic uncertainty. In prostate cancer (PCa), p63 can be considered a potential reliable method for facilitating its pathologic diagnosis.

P 706

ATYPICAL PROSTATIC BASAL CELL PROLIFERATIONS: MORPHOLOGIC AND IMMUNOHISTOCHEMICAL STUDY OF 4 CASES

VASILIU Viorel, CAMPARO Philippe, LIARD-MEILLON Marie-Elisabeth,
VIRE Olivier, TISSEAU Laurent, VIEILLEFOND Annick
1.Service d'Anatomie Pathologique - Hôpital Necker, Paris, 2.Service d'Anatomie Pathologique, Hôpital Val de Grace, Paris, 3.Cabinet d'Anatomie Pathologique, Brive, 4.Cabinet d'Anatomie Pathologique, St Raphael, 5.Cabinet d'Anatomie Pathologique, Saint Brieuc, 6.Service d'Anatomie Pathologique - Hôpital Cochin, Paris

Background: Besides usual basal cell hyperplasia commonly observed in prostatic adenoma, atypical basal cell proliferations are observed in less than 0,1% of samples provided from transurethral resection (TUR) or adenomectomy. Florid and/ or adenoid hyperplasia can be observed on repeated resections during years without aggravation, but a small subset of lesions displays a malignant evolution with extra prostatic invasion and /or distant metastases.

Design: Because of the rare occurrence of these lesions and the limited follow-up information available in elderly population, the histologic criteria of malignancy are not clearly established. We report 4 cases of florid basal cell hyperplasia and/ or carcinoma in attempt to precise these criteria.
Results: Patients were respectively 58, 73, 90 and 92 years old without previous prostatic surgery. An unusual basal cell proliferation was observed in almost the whole prostatic tissue obtained by TUR (1 patient) or adenomectomy (3 others). The lesions varied from small to large lobular sheets of basaloid cells with frequent cystic patterns to basaloid and/or comedo-like patterns with central necrosis. In 2 cases, adenoid cystic (AC) like pattern surrounded by dense hyaline stroma was predominant. In the 2 other cases there were large sheets of basal cells associated with infiltrative patterns suspect of malignancy. P63 was expressed by 50 to 100% of basal cells at the periphery of the lobules in AC like patterns and was negative in basaloid ones. Mib-1 expression was respectively 40% and 60% in the 2 cases suspect of malignancy and 10 and 30% in the 2 others. Bcl-2 was intensely expressed in 100% of cells of basaloid and/or comedo-like patterns, weakly and heterogeneously elsewhere. Without additional treatment the 4 patients are free of disease 2 years after surgery.
Conclusion: Morphological differences exist among these lesions in correlation with immunohistochemical profile. Basaloid proliferations displaying large cohesive pseudoinfiltrative and comedo-like patterns suspicious of malignancy are associated with a Mib 1 index > 30%, a strong bcl-2 expression and a lack of p63 expression. Considering the difficulty to assess extra prostatic or perineural extension in limited samples and the accurate infiltration except on total prostatectomy specimen, these morphologic and immunohistochemical features could be used to induce a more agressive therapeutic approach in patients with long life expectancy.

PROSTATIC MIXED EPITHELIAL-STROMAL (PHYLLODE) TUMORS: A REPORT OF 4 NEW CASES

PLES Raluca (1), DIMET Stéphanie (1), COPPOLA Sylvie (2), LE MARC'HADOUR François (3), DARREYE Ghislaine (4), VIEILLEFOND Annick (5), FERLICOT Sophie (1)
(1)Service d'Anatomie Pathologique, CHU de Bicêtre, Le Kremlin-Bicêtre,
(2)Centre de Pathologie, avenue Jean Jaurès,30900 Nîmes,
(3)Centre de Pathologie, rue Général Ferrié, 38100 Grenoble
(4)Cabinet de Pathologie, rue Deverrine, 87000 Limoges
(5)Service d'Anatomie Pathologique, Hôpital Cochin, Paris

We report 4 additional cases of mixed epithelial-stromal tumor (phyllode tumor of the prostate) arising in men aged 27 to 64 years. The presenting clinical symptoms included urinary retention (2 cases), hematuria (1 case), and hematospermia (2 cases). The tumors formed prostatic masses measuring from 6 to 12 cm in diameter.
The diagnosis was suggested in 2 cases based on needle biopsy. In all cases the whole tumor was resected and patients were well from 4 months to 5 years after surgery.
Histologically, tumors showed a non-neoplastic epithelial component with cystic glands, an elongated cleft-like space and stromal proliferation with occasional high cellularity and cellular atypia. There was no increased mitotic activity. The epithelial component was positive for cytokeratin and PSA. The stromal cells were positive for vimentin in all cases, smooth muscle actin in 2 cases, desmin in 2 cases, and occasionally CD34.
These tumors are of uncertain malignant potential and need to be distinguished from benign lesions (leiomyomas and stromal hyperplasia with bizarre nuclei), and from stromal sarcomas and leiomyosarcomas.
These four cases as well as most cases reported in the literature behave in an indolent fashion but recurrences and progression to sarcoma can occur. Thus, when the diagnosis is suggested based on needle biopsy, total resection of the lesion is required.

RECIPIENT DERIVED COLLAGEN TYPE III IN HUMAN TRANSPLANTED HEARTS

PICHLER Martin1, TESSARO Brigitte1, KNIEPEISS Daniela2, KLEINERT Reinhold1, HOEFLER Gerald1.
1 Institute of Pathology, Medical University Graz, Austria
2 Department of Surgery, Medical University Graz, Austria

Introduction: Transplantation of donor hearts is often associated with progressive development of interstitial myocardial fibrosis and alterations in composition and organisation of the extracellular matrix. Changes in cardiac interstitial collagen network are thought to contribute to abnormal stiffness and loss of function of the myocardium. Fibroblasts are the main producers of type I and type III collagens, the major interstitial collagens found in the heart. In transplanted hearts, intragraft fibroblasts consist of two cell populations. Donor-derived fibroblasts pre-exist in donor organs, whereas host-derived fibroblasts are progressively immigrating as mesenchymal progenitors from the circulation to the allograft.
Purpose of the study: To determine the contribution of these two distinct fibroblast populations to progression of myocardial fibrosis, we studied endomyocardial biopsies from eight male patients who had received hearts from female donors.
Methods: In these sex-mismatched patients two frequent genetic polymorphisms at the collagen III locus were determined by polymerase chain reaction-based restriction enzyme digestion, both in donor allografts and in the corresponding explanted recipient heart. Based on differences the of collagen-genotype in donor and recipient tissue, we selected 40 endomyocardial biopsies by hematoxylin eosin staining and determined population-specific collagen expression using single nucleotide polymorphisms.
Results: Total number of donor derived cells in biopsies determined by short tandem repeat analysis was up to 70%. Chromogene in situ hybridization with probes specific for Y-chromosomes and immunohistochemistry staining for CD68 demonstrates the majority of macrophages to be of donor origin. The amounts of interstitial collagen type I and type III increased in a time-dependent manner within cardiac allografts. Years after transplantation a substantial number of Y-chromosome-positive recipient-derived cells was non-inflammatory, non-endothelial spindle-shaped fibroblast-like cell types. A considerable quantity of collagen III mRNA can be attributed to recipient-derived fibroblasts in transplanted hearts.
Conclusion: Our data confirm the existence of a substantial number of fibrosis-mediating immigrated recipient-derived fibroblasts in cardiac allografts. Furthermore, this suggests an active, essential role for recipient-derived fibroblasts in the process of fibrosis in transplanted human hearts.

Centre Chirurgical Marie Lannelongue 133, avenue de la Résistance 92350 LE PLESSIS ROBINSON FRANCE

Acute pulmonary rejection is primarily cell-mediated and is characterized by perivascular mononuclear infiltrates. Acute vascular rejection with humoral component has only been suspected in few previously reported cases. Diagnostic criteria are not well established. We present a case of pulmonary vasculitis possibly related to such a rejection.
A 33-year-old female patient had an initially uneventful double lung transplantation for primary pulmonary hypertension. There were no panel-reactive anti-HLA antibodies. From day 19, she developed fever, progressive bilateral lung opacities with hilar lymphadenopathy and irregularities of the bronchial mucosa. Pulmonary function did not deteriorate. No was no sign of angiitis in other organs. No infection could be identified, beside the donor being HHV8+. Antineutrophil cytoplasmic antibodies were absent. Treatment with high doses of corticoids was started at day 58 and lead to rapid abatement of fever and progressive disappearance of lung opacities. The patient is well 6 months after her transplantation.
Bronchioloalveolar lavage at day 20 showed 90% of macrophages often containing nuclear debris and with important hemosiderosis. Transbronchial lung biopsy at day 20 was normal but bronchial and transbronchial biopsies at day 45 showed leukocytoclastic capillaritis. An open lung biopsy, performed at day 58 confirmed a widespread leukocytoclastic vasculitis involving capillaries, veins and arteries with foci of necrosis. A peribronchial lymph node was necrotic. Their was no usual criterion for acute resection. Special stains showed no micro-organism and there was no viral inclusion. Immunofluorescence on cryostat sections for C4d deposition was not conclusive. A second open lung biopsy, performed at day 109 during the treatment of a persisting pneumothorax, showed normal pulmonary parenchyma.
Acute humoral rejection is difficult to ascertain. However in rare cases similar to this one, clinical and pathologic data may suggest this diagnosis.

HUMAN HEART EXPLANT CONTAIN CELL POPULATION DIFFERENTIATING IN VITRO INTO MYOFIBROBLASTS
B.Wozniewicz, B.Cukrowska, E.Czarnowska, M.Pronicki, W.Grajkowska, T.Debinska-Szymanska, A Zajaczkowska .
Department of Pathology . CMHI Warsaw, Poland

Introduction. In human and experimental animal there is now incontrovertible evidence that new myocytes may be generated throughout life in responce to physiological and pathological stimuli.Adult heart stromal system has been proposed to consists of mesodermal stem cell that are capable of self -reneval into de novo cardiomyocytes. The rate of cell reneval is slow and low. Purpose. Sections from heart explants of patient endervent heart transplanation were cultured in vitro. This procedure was perform to obtain a population for future supporting failured heart with cultured 'stem cell' transplantation. Material.Multiple fragment from human heart explants were cultured in vitro.Method.Number of stainig procedures were performed to confirm phenotypes of growing cells (FGF, Titin, actin,myosin, vimentin, desmin, HLA class I and II, CD31, CD34, CD68 including electron microscopy. Results. The prolonged culture of heart fragments was the source of de novo growing cell population. Conclusion. It has been demonstraded that failured heart in contrast to normal has had precursor cells exchibits growth potentials to generate population of cells with immunocytochemical and ultrastructurel characters of myofibroblasts.

EXPRESSION OF PCNA GENE, NUCLEOLAR ORGANIZER REGION ACTIVITY AND NUCLEAR PLOIDY IN INTERVENTRICULAR SEPTUM CARDIOMYOCYTES FROM CHILDREN AND ADULTS WITH OHCMP
Rybakova M1, Gudkova A2, Borisov K3, Semernin E2., Selivanova G4, Vlasova T4, Parfenov V3, Bokeria L3 and Shlyakhto E2.
1 – Pathology Department, State Pavlov Medical University, St.Petersburg, Russia
2- Faculty Therapy department, State Pavlov Medical University, St.Petersburg, Russia
3 – Bakulev Reseach Center of Cardiovascular Surgery, Moscow, Russia
4 – Cytology Research Institute, St.Petersburg, Russia

Aim: to estimate PCNA expression, nucleolar organizer region activity and nuclear ploidy in interventricular septum cardiomyocytes from patients with obstructive hypertrophic cardiomyopathy (OHCMP).
Materials and methods: material from 61 patients with OHCMP was included into the study. Among those, 19 were below 21 y.o. and named as 'children'. The rest 41 patients were over 21 y.o. and named as 'adults'. The material was obtained upon the surgical interventions as well as upon express autopsies from the right side of the interventricular septum. The samples were stained with hematoxylin-eosin technique and by the method of nucleolar organizer regions silver staining. Expression of PCNA in cardiomyocyte nuclear was studied by immunohistochemistry. DNA content was estimated by Felgen method on dissociated cardiomyocyte nuclei and assessed by cytophotometry. One hundred tissue lymphocytes were used as a control for diploidal DNA content.
Clinical and echocardiographic data were obtained from case histories.
Results: the mean age in the children group was 14±1,1, ranging from 5 to 21 y.o. The mean age in the adult group was 46,4±1,9, ranging from 27 to 82 and being statistically different from the children group ($p<0,000$). The mean age of OHCMP diagnosis was 4,5±1,1 in children group, ranging from several days to 14 years. In the adult group this parameter was 38±2 and ranged from 2 to 69, being statistically different from children ($p<0,000$). There was no statistical difference between children and adults in LVMI (276,1±28,6±and 252,1±16g/m2) and IVS thickness in the outflow tract (2,89±0,14 and 2,54±0,08cm). In the children group compared to adult group there was a significant increase in AgNORs parameter (25,9±0,58 and 20,9±0,6, $p<0,000$), PCNA-positive cardiomyocytes (6,9% ±0,9 and 3,8%±0,4 $p<0,001$) and DNA content (15,2±2,2 and9,9 ±1,4 $p<0,017$). The mean number of maximal cardiomyocyte DNA content was higher in children group, then in adult group as well (53,5±7 and 30,7±2,2 $p<0,002$).
Conclusion: the children group with OHCMP is characterized by highest degree of myocardial hypertrophy, accompanied by increase in PCNA expression, increase in cardiomyocyte ploidy and increase in ribosomal biogenesis, estimated by AgNOR content in cardiomyocytes form right side of asymmetrically hypertrophied interventricular septum.

MORPHOLOGICAL CHANGES IN HIBERNATING MYOCARDIUM
Laky D., Parascan Liliana, Candea V.
Institute for Cardiovascular Diseases
Prof.Dr.C.C.Iliescu, Bucharest Romania.

Introduction:
Hibernating myocardium represent a prolonged but potentially reversible myocardium contractile dysfunction caused by chronic myocardial ischemia. The purpose of this study was to describe the morphological changes in diskinetical areas and their correlation with the functional investigations.

Material and methods:
In 48 patients with chronic ischemic heart diseases, areas of left ventricular hibernating myocardium were identified by angiography , thalium scintigraphy and dobutamine echography.On biopsies removed during by inter-ventions, ultrastructural and various histological and immunohistochemical investigation were effectuated.
Results:
The morphological changes are suggestive for embryofetals dedifferentiations and summarized as following: loss of the contractile structures, fragment glycogen granules, small mitochondria, absence of sarcoplasmic reticulum and T tubules, redistribution of chromatin, the presence of rough endoplasmic reticulum and a-smooth muscle actin , the decrease of cardiotonin, the expression of titin in puncted pattern. In the extracellular matrix were increased early matrix such for fibronectin, tenascin, collagen type I and III and fibroblasts. Also were observed stunned changes, cellular degeneration, apoptosis and reparative fibrosis.
Conclusions:
Hibernating myocardium is a transient incomplete adaptation to reduced coronary blood flow, an embryofetal dedifferentiation, that impose early revascularization.

EXPRESSION OF THE NUCLEOLAR ORGANIZER REGION'S ARGENTOPHYLLIC PROTEINS, TUMOR SUPPRESSOR GENE P53 AND CASPASE-3 IN CARDIAC SAMPLES FORM PATIENTS WITH IDIOPATHIC RESTRICTIVE CARDIOMYOPATHY.
Gudkova A1, Rybakova M2.
1 - Department of Faculty Therapy, St,Petersburg State Pavlov Medical University
2 – Department of Pathology, St.Petersburg Sate Pavlov Medical University

Aim
Our aim was to study the expression of argentophyllic proteins in the nucleolar organizer regions, tumor suppressor protein p53 and caspase-3 in cardiac samples from patients with idiopathic restrictive cardiomyopathy (IRCMP).
Material and methods
The express-autopsy cardiac samples from five patients with IRCMP were studied by hematoxylin-eosin, Van Gieson and Congo Red staining and well as by AgNOR staining. Immunostaining of p53 and caspase 3 were performed with DAKO monoclonal antibody. Cardiac samples from eight healthy people, died due an incidental cranial trauma were used as controls.
Results
In all study samples we found oxyphyllic amorphic protein depositions, which were positive for Congo Red staining only in two cases. Along with morphologically normal nucleoli in atrial and ventricular cardiomyocytes we identified micronucleolar, or atypical extranucleolar localization of argentophyllic proteins. The latter were more often seen in atria then in ventricles. The stromal cellularity was markedly increased, in some stromal cells 1-8 small, dot-like inactive nucleoli were observed. Positive staining for caspase-3 was present in cardiomyocyte cytoplasm and cardiomyocyte nuclei were positive for p53 staining. In the control samples, atipical extranucleolar localization of argentophyllic proteins were not present, as well as positive caspase-3 and p53 staining. Most of the stromal cells in the control cardiac tissue contain one dot-like nucleolus.
Conclusion
Cardiomyocyte nuclei from patients with IRCMP, complicated by terminal congestive heart failure, are characterized by increased p53 expression along with increased cytoplasmatic caspase-3 expression, which might illustrate p53-dependent apoptosis process. Atypical localization of argentophyllic proteins in cardiomyocyte and stromal cell nuclei as well as presence of micronucleoli might reflect the impairment of the protein synthesis. It is also important to note, that besides signs of structural and functional abnormality of the nucleoli in all study cases oxyphyllic amorphic protein depositions were found.

DISEASE GENETICAL SYNDROMS AND CONGENITAL HEART
LASTIC-MALETIC Sofija, KANJUH Vladimir, GLUMAC Sofija, POPOVIC Zoran, STOJSIC Zorica, RADOJEVIC-SKODRIC Sanja, VASILJEVIC D. Jovan
Institute of Pathology, Medical School, Belgrade, Serbia and Montenegro

INTRODUCTION: Congenital heart diseases (CHD) mainly develop as a consequence of multifactor influence, i.e. some develops as partially genetically induced anomalies. Therefore some CHD are often associated with different genetic syndromes.
PURPOSE: The aim of the study was to evaluate the incidence of CHD associated with genetic syndromes, as well as to analyze the types of CHD found in particular entity.
MATERIAL AND METHOD: At the Institute of Pathology, Medical School University of Belgrade, during the period from 1926-2004, a total number of 1399 cases of CHD were diagnosed. This investigation was made by analysis of data from standard autopsy protocols, and especially the designed forms for CHD cases. All autopsies were performed using standard or modified Rokitansky technique.
RESULTS: Our results showed that the most common association of CHD was with Down syndrome, found in 42 cases (3% of all CHD). Out of them, in 26 cases the atrio-ventricular septal defects (AVSD) was found; in 7 cases ventricular septal defect (VSD), in 6 cases atrial septal defect (ASD), and in 1 case there were trilogy of Fallot, aortic atresia and persistent ductus arteriosus. Besides Down syndrome, we found association of CHD with four cases of Edwards's syndrome, and one case of Turner syndrome. In three cases of Edwards's syndrome, isolated VSD was found, and in one case bivelar pulmonary valve with fibroelastosis of both ventricles was present. In only case of Turner syndrome, coarctacion of aorta and patent ductus arteriosus was found.
CONCLUSION: Our findings, made on very large autopsy series, indicate a relatively low percentage of CHD associated with different genetic syndromes. However these findings are in agreement with data from the literature, indicating that predominant influence in the development of CHD should be looked outside of genetic disorders.

P 715
ENDOMYOCARDIAL BIOPSY FINDINGS IN PATIENTS WITH MYOTONIC DYSTROPHY
VASILJEVIC D. Jovan, RAKOÈEVIC-STOJANOVIC Vidosava, GLUMAC Sofija, APOSTOLSKI Slobodan
Insitute of Pathology, Medical School, Belgrade, Serbia and Montenegro, ad Institute of Neurology, Clinical Center of Serbia, Belgrade

Introduction: Endomyocardial biopsies (EMB) are powerfull diagnostc tool in specific cardiomyopathies, including patients with different neuromuscular diseases and heart problems. Although among indications for EMB, usual non-pathognomonic findings in these entities are the reson for limmited series in the literature. In patients with myotonic dystrophy (MD) it has been shown changes such as myofibrillar degeneration, mitochondrial abnormalities, focal myocarditis, fibrosis and fatty infiltration of the myocardium, and especially changes in the conduction system.
Methods: This study presents the results of EMB findings in 10 patients with MD. The biopsies were carried out using King's bioptome, followed by routine histological procedure.

Results: In two patients with severe MD, biopsy specimens showed changes compatible with border-line myocarditis. In five patients with moderate to severe forms of MD, we found fibrosis and fatty infiltration of the myocardium, in addition to degenerative changes and hypertrophy of muscle fibers. Three patients with mild MD had non-specific degenerative and hypertrophic myocardial changes.
The histological changes described above were present in patients without cardiological symptoms and in those with normal ECG and echocardiographic findings. Only two of the 10 patients in whom EMB was performed complained of fatigue and occasional palpitations, while the rest of the patients were asymptomatic. One patient with focal myocarditis had ECG signs of left bundle branch block and echocardiographic evidence of reduced left ventricular contractility. Five patients with signs of endomyocardial fibrosis only had an abnormal Q-wave on ECG recordings. The remaining five patients with border-line myocarditis and/or with degenerative and hypertrophic myocardial changes had normal ECG and echocardiographic findings.
Conslusions: These results stress the significance of endomyocardial biopsy in detecting myocardial pathologic changes in patients with MD.

P 716
MYOCARDIAL FLUORESCENCE MEASUREMENTS AS MORPHOPATHOLOGICAL CRITERIA FOR DETERMINING THE DURATION OF MYOCARDIAL INFARCTION
ANESTIADI Vasile, TSIPLE Ilie
Centre for Pathobiology and Pathology, Academy of Sciences, Chisinau, Moldova

The study aimed towards finding new criteria for the determination of the duration in time of myocardial infarction (MI). 52 hearts from persons deceased from MI, in which MI beginning was documented clinically and by ECG, were selected. 30 hearts of persons deceased almost instantaneously from traumas served as controls. In each case we did 1000 measurements of myocardial primary fluorescence (MPF) at the wavelength of 360 nm, both in the necrotic (ischaemic) zone (NZ) and in extrainfarctic zones (EZ). During 8-12 hrs from MI beginning, the MPF decreased concordantly in both zones, being 89.6±2.3% of controls. At 24 hrs after MI onset MPF in NZ was 78.8±4.3%, in EZ 84.4±3.1% of controls. Minimal NZ MPF was at 4-5th and 9-10th days (66.3±2.5% and 62.6±2.1% of controls, $p<0.001$). EZ MPF at 4-5th days was 77.4±3.5%, at 9-10th days 82.3±2.2% and at 14-15th days 85.7±2.8%, remaining even up to 30-35th days of MI 7.3±0.8% below controls. MPF variations in time were approximated by splines. By solving a system of equations, which included formulae for EZ and NZ MPFs, it was possible to determine the time elapsed from the MI onset, with an accuracy of 9.6 hours.

P 717
APOPTOSIS IN ISCHEMIC CARDIOMYOCYTE INJURY
Rybakova MG, Kuznetsova IA (Dept. pathology, St Petersburg state medical university, St Petersburg, Russia)

It is believed that necrosis, apoptosis and reversible injury differentially contribute to cardiac functional loss in ischemia. Although apoptosis has been studied extensively as a pathogenic factor in cardiovascular pathology, its role in myocardial infarction remains not fully understood. THE AIM of the study was to evaluate apoptosis in ischemic myocardium and assess its pattern of distribution.
36 specimens of the myocardium were obtained during necropsy (performed within 6 h from death) from patients who died of acute cardiac failure within 24 h from the onset of the ischemic attack. M/F ratio was 1:1, median age – 62. Coronary arteries were 50-80% stenotic, with no signs of thrombosis. Myocardium from patients who died from brain hemorrhage was included for control purposes. Basing on clinical (ECG, enzyme assays) and morphologic data (basic fuchsin stain and polarized light microscopy). 5 groups were built with duration of ischemia from 0-1h, to over 24 h. Standard protocol was created for taking samples from the myocardium considering position towards ischemic region and heart anatomy. Bcl-2, caspase 3 and p53 were studied immunohistochemically (reagents from Dako Cytomation, Denmark).
Bcl-2 and caspase 3 were localized in peri-infarction zone, with increasing intensity from 6 to over 24 h of ischemia. Intranuclear positivity for p53 was demonstrated in isolated cardiomyocytes (CMs) and only in sudden cardiac death. TUNEL method was used to prove apoptotic DNA fragmentation. The distribution of TUNEL-positive CMs showed mosaic pattern in sudden cardiac death and was multifocal in peri-necrotic region in developed infarction. Marked chromatin clumping was seen in apoptotic cells. Strong statistical correlation between the apoptotic rate and contracture damaged cells in the myocardium was shown. By polarized light microscopy apoptotic CMs were localized in areas with marked contracture changes.
WE CONCLUDE that apoptosis contributes to the development of CM injury in ischemia. Apoptotic death of CMs may lead to electric instability of the myocardium in early ischemia and cause sudden cardiac death. Apoptosis of the peri-infarction CMs may precede extension of the necrotic area. Further studies of apoptotic death of CMs in ischemic heart disease may help to elaborate novel therapeutic strategies, aimed at regulation of apoptosis.

P 718
MORPHOLOGY OF CHOLINERGIC INNERVATION IN ISCHEMIC HEART DISEASE
Sorokina I.V., Yakovtsova A.F., Gargin V.V.

The sequence of changes in the vessels, cardiomyocytes and neurocytes in ischemic heart disease remains unsolved, but they are strategically important question for choice of pharmacological measures direction at the same time. The purpose of the present work was to study the morphological state of the parasympathetic innervation of the heart in ischemic heart disease.
The hearts of patients died with acute and chronic form of ischemic heart disease and hearts of persons who died due to cranial trauma were subjected to morphological study. The histological, histochemical, morphometric methods were used.
The results of the study have demonstrated that the parasympathetic plexuses had consistent topography with highest density near the heart hilum. The density of the ganglia was reduced in cardiosclerosis. Degenerative and sclerotic changes of all cholinergic elements were established. The number of the ganglia and density of the filaments did not correlate with level of coronary stenosis. The change of the form of perivascular neurocytes has been revealed with signs of perinuclear chromatolysis, edema, and augmentation of cell dimensions. Thus the vacuolization begins from periphery of the cells with the subsequent growth of vacuoles and movement of the nuclei to periphery. Study of cholinergic innervation revealed pronounced depression of acetyl cholinesterase activity.
The nervous fibers settle mainly along of vessels of microcirculatory bed. Both myelenic, and amyelenic nervous fibers are turgent, with signs of pronounced argyrophilia. Thus the fibers are impregnated irregularly with alternating of light and dark fields. The varicose thickenings, leakage of neuroplasm, microlocuses of destruction and fragmentation are marked; cytoplasm with signs of vacuolization.

So, deparasympathetization of myocardium could be one of the factors in pathogenesis of myocardial ischemia.

P 719
CARDIOMYOCYTE REMODELING, A NEW ASPECT OF ARRHYTHMOGENIC RIGHT VENTRICULAR CARDIOMYOPATHY
Czarnowska E.1, Pronicki M.1, Grajkowska W.1, Turska-Kmiec A. 2, Kawalec W. 2, WoŸniewicz B.1
1 Department of Pathology, and 2 Department of Cardiology, The Children's Memorial Health Institute, Warsaw, Poland

Background. Progressive deterioration of mainly right ventricular function due to fibro-fatty tissue infiltration and ongoing loss of myocytes is a characteristic feature of the arrhythmogenic right ventricular cardiomyopathy/dysplasia (ARVC/D). Histopathological investigations of endomyocardial biopsy samples have diagnostic value but till now were not dedicated to elucidate the cellular mechanisms underlying myocyte loss except apoptosis, and disease progression.
The study was aimed to show if structural cardiomyocytes remodeling might underlie the ARVC/D development and progression.
Methods. Endomyocardial biopsy specimens of the right ventricle wall were obtained from 7 paediatric pts. (4F, 3M, aged from 6 to 17 years) with ARVC/D established according to McKenna et al. (1994) criteria. Samples obtained from every heart were fixed in 4% buffered formaline and embedded in paraffin blocks, and in 2.5% glutaraldehyde in cacodylate buffer and embedded in Epon blocks. Serial paraffin sections stained hemotoxylin-eosin, AZAN, PAS and PAS with diastase, and immunohistochemically with antibodies anti-desmin, smooth muscle alpha-actin, vimentin were analysed. Ultrathin sections prepared from trimmed area bordering fibro-fatty tissue were routinely stained for EM examination.
Results. Some myocytes adjacent to fatty tissue showed vacuolisation, myolysis and accumulation of glycogen. Immunohistochemistry revealed that some of these cells exhibited abnormal pattern of desmin labelling at the level of Z-lines and positive staining for smooth muscle alpha-actin simultaneously. Electron microscopical studies showed in some cardiomyocytes lysis of contractile apparatus, accumulation of glycogen, loss of sarcoplasmic reticulum and T-tubules, polymorphic mitochondria and dispersion of nuclear chromatin. Both immunohistochemistry and electron microscopy presented related cell alterations probably.
Conclusions. Changes in ARVC/D in distribution and expression of proteins involved in contraction and excitation are probably phenotypic resemblance to fetal cardiomyocytes, what points the dedifferentiation of these cells. Dedifferentiation of cardiomyocytes might actually be considered survival states aimed to endure the altered conditions. Whether this state could be reversible needs further studies.
Acknowledgement. This work was supported by project QLG1-CT-2000-0191 financed by the UE.

QUANTITATIVE BASES OF COMPROMISED CARDIAC CONTRACTILITY DURING THE LATE STAGE OF SEPSIS
1L. L. Francu, 2A. Ciobanu, 1D. L. Calin,1 C. C. Ghibirsina
Departments of 1Anatomy and 2Infectious Disease, University of Medicine "Gr. T. Popa", Iasi, Romania

Introduction. Previously it is reported an association between sepsis and myocardial edema and histologic changes, but the anatomic base of sepsis-induced myocardial depression is incompletely understood. The objective of the present study was to determine whether are prerequisite morphometric myocardial parenchymal or microcirculatory changes for the development of contractile dysfunction in sepsis.
Material and methods. We have studied fourth-eight patients, who died of sepsis caused by abdominal infections and were been postmortem examination. The fragments from all cavities of the heart have been processed by paraffin technique and have been examined for qualitative diagnosis. The quantitative studies have been done with a video digital interactive program that utilized standard measurement of cardiac muscle fibers and stereology of percentual volumes of myocardial components.
Results. Our studies provide that histological changes are also a feature of myocardial injury in human sepsis. We noted alterations in the myocardium that consisted of interstitial miocarditis, interstitial edema, and muscle-fibers necrosis. We remarked differences between heart cavities, ventricles being more affected by myocytolisis and destruction of capillary wall. Morphometry relieved the increased of percentual volumes of interstitial space (22.1% vs. 13.5% in witness hearts) and myocardial capillaries occupied by leukocytes (16.8% vs. 4.1% in witness hearts).
Conclusion. We conclude that that objective myocardial structural changes and microcirculatory injuries may contribute to decreased ventricular contractility during sepsis.

3 Silesian Centre for Heart Diseases, Zabrze, Poland

Objective: Hemorrhagic myocardial infarction is one of the rarest kinds of myocardial necrosis. It is result from thrombolysis, hemorrhagic disturbances or mechanic trauma.
Aim: The aim of the work was the characterization of morphology of myocardial hemorrhagic infarction and its differences with ischemic myocardial necrosis (myocardial infarction).
Material and methods: The material consisted of 30 cases of macroscopically hemorrhagic myocardial infarction. Comparative group consisted of 20 cases of ischemic, pale myocardial infarction. The clinical history of disease was 48 hours. The studies were based upon histology and confocal laser scanning microscopy.
Results: Hemorrhagic myocardial infarction was characterized by the bulk of interstitial erythrorrhages, paucity of inflammatory infiltration, preserved continuity of cardiocytes hyperemia of coronary veins, compression of coronary arterioles and nerve trunks. In confocal laser microscopy the myocardial fibers shows no increased autofluorescence and fractures, but dominant feature was its thinning by interstitial hemorrhages.
Conclusion: Hemorrhagic myocardial infarction is a diverse morphological entity, closely resembled with hemorrhagic complications.

P 722
MYOFIBROBLASTS IN THE EVOLUTION OF HUMAN MYOCARDIAL INFARCTION
KOJC Nika, ZIDAR Nina

Recent studies have shown that cardiac fibroblasts and myofibroblasts play an important role in healing and remodeling processes after myocardial infarction (MI). Despite extensive research, the exact mechanisms are not

completely understood yet. The aim of our study was to analyze the distribution and immunophenotype of fibroblasts and myofibroblasts in the normal human heart and MI.
Methods. Autopsy samples of infarcted heart tissue from 15 patients with MI of different duration, and samples of heart tissue from 5 healthy persons who died in accidents, were included. Immunohistochemistry was performed by a sensitive peroxidase-streptavidin method on formalin fixed, paraffin-embedded tissue, using monoclonal antibodies against ¥á-smooth muscle actin (SMA), CD34, CD31, vimentin, desmin, activated caspase-3, Ki67, TGF©¬1 and TGF©¬1 receptors,.
Results. In normal hearts, there were scattered vimentin and CD34-positive fibroblasts in the subendocardial space and around intramyocardial blood vesssels. TGF©¬1 was focally expressed on capillary endothelial cells.
Myofibroblasts were found in MI which were at least 5 days old; they were vimentin and SMA positive and desmin negative ('VA' phenotype). Some were labeled with Ki67, and some with anti caspase-3. Myofibroblasts as well as most of inflammatory cells and endothelial cells also expressed TGF©¬1 and TGF©¬1 receptors.
In old scar, some myofibroblasts retained SMA and TGF©¬1 receptor expression.
Conclusions. 1. We found CD34-positive fibroblasts in the interstitium of the normal myocardium. These cells might be one of the origins of myofibroblasts, similarly to other tissues. 2. Myofibroblasts in MI were of the 'VA' phenotype. 3. Myofibroblasts, inflammatory cells and endothelial cells in MI also expressed TGF©¬1 and TGF©¬1 receptors suggesting that TGF©¬1 might be important in the healing process after MI as suggested by experimental studies 4. Some myofibroblasts were activated caspase-3 positive showing that apoptosis is an important mechanism in transformation of granulation tissue into a scar. 5. Some myofibroblasts in old scars after MI retained SMA expression, in contrast to dermal wound healing, where expression of SMA is transient. It has been suggested that this is due to the continuous mechanical stress caused by contraction and relaxation of the surrounding viable myocardium.

P 723
CLINICAL SPECTRUM OF CARDIAC LYMPHOMAS
Mary N Sheppard

Cardiac lymphmas are rare and there is often a delay in diagnosis. We present six cases where the clinical presentation varied from sudden death to infarction to pericardial effusion.
Two cases presented with large pericardial effusions in children. Both were T cell lymphomas. One child died suddenly after draining the effusion shortly after admission to hospital.
One T cell lymphoma presented as multiple areas of infarction due to vascular involvement with diagnosis only being made 6 months after presentation when a 29 year old male developed cutaneous lesions.
One large B cell lymphoma presented as a suspected bacterial endocarditis on an aortic homograft in a 57 year old male.
One case in an 81 year old presented with sudden death due to widespread infiltration by chronic lymphocytic leukaemia.
The final case presented as a sudden death in a 57 year old man ollowing cardiac transplantation six years previously. He had wiidespread microscopic involvement by a B cell lymphoma.
All these reflect the wide variation in cardiac involvement by lymphoma.

P 724
A NOVAL METHOD OF QUANTITATIVE FUNCTIONAL MORPHOLOGY ASSESSING CONTRACTILE RESERVES OF MYOCARDIUM USING HISTOLOGICAL SECTIONS
GHEVONDYAN Tigran.
Laboratory of Quantitative Functional Morphology,
Department of Pathological Anatomy of National Institute of Health, Yerevan, Republic of Armenia.

Introduction
The important information for cardiology and cardiosurgery obtained from morphological examination of heart muscle biopsies is the volume of the myocardial contractile potential. Currently this information can only be obtained by methods of quantitative functional morphology generally requiring electron microscopic examination (EME).
Aim
The aim of the study was to develop a method to determine the contractile reserve of the cardiac muscle using histological sections examined by light microscope (LM).
Materials and Methods
Cardiac muscle samples were collected and investigated as following: a) postmortem heart muscle from patients died of acute myocardial infarction and healthy people died in accidents, b) myocardium specimens from normal and physically exercised rats as well as animals with acute pancreatitis, c) the cardiac biopsy tissue from patients with valvular heart disease. We applied conventional histology, electron microscopy, stereology, micromechanography, statistics, mathematical modeling and quantitative functional morphology.
Results
A novel mathematical model was developed, which makes it possible to determine the contractile ability of cardiac muscle (fmyo) using quantitative morphological parameters obtained by LM. The parameters (Vv = volume density; Sv = surface density) take into account the most essential quantitative and qualitative changes of muscle fibres (mf), capillaries (cap) and interstitium (int). The following equation with a modular construction and an open architecture was derived:
fmyo=K•Vvmf•{ {
(1/Vvcap)+[1/(0,0064•Svcap)]+(Vvint/0,0073)+
[1/(0,0016•Svmf)]+
+(Vvmf/0,053) }•(1/v1)}-1,
The index (K) shows the relative level of myocytolysis. The ratio (1/v1) is considered the standard value for this model. The (-1) is the power for equation.
The statistically strongly correlated concordance of myocardial contractility data from the same hearts determined by using micromechanography from one side and by using EME, LM examination from the other side, supports the validity of the new mathematical model.
Conclusion
Our results demonstrated that the quantitative functional morphology using histological sections is a quick, reliable and easily applied method in assessing myocardial contractility. We suggest this noval method for routine evaluation of vital capacities of myocardium.

CARDIAC ANGIOSARCOMA
DOLENC - STRAZAR Zvezdana 1, GERSAK Borut 2, KOZELJ Mirta 3
1 Institute of Pathology, Medical Faculty, University of Ljubljana
2 Department of Cardiovascular Surgery, University Medical Center, Ljubljana, Slovenia
3 Department of Cardiology, University Medical Center, Ljubljana, Slovenia

Introduction:
Primary tumours of the heart are rare. 80-90% are benign. The most common malignant tumour is angiosarcoma, representing 40% of cardiac primary sarcomas. Patients are usually adult, more frequently men. We present a man with angiosarcoma of the right atrium.

Clinical history:
Otherwise healthy 22-year-old man was admitted to the hospital due to severe chest pain a day after a mild blunt chest trauma. ECG and chest x-ray were normal. Transthoracic echocardiogram demonstrated a moderate pericardial effusion and a mass measuring 3x3 cm, protruding into the right atrium above the tricuspid annulus, without obstruction of the orifice. The angiography showed abnormal vascularization originating from the right coronary artery. The tumour was excised but excision was not radical due to extension of the tumour. The patient refused urgent cardiac transplantation, which was performed six months later.
Macroscopically, the excised tumour was multilobular, dark, growing around right coronary artery. In explanted heart residual tumour measuring 6x4,5x3,5 cm infiltrating pericardium and a satellite tumour were found.
Microscopically, there were irregular vascular channels, papillary fronds lined by atypical endothelial cells, compressed capillary channels without recognizable lumina, sheets of anaplastic and spindle cells with extravascular erythrocytes. There were mitoses, some necrosis, invasion of blood vessels and nerves. Tumour extended to the resection margin in both samples.
Discussion:
Histologically, angiosarcoma of the heart has three major differential diagnostic possibilities, haemangioma with papilary endothelial hyperplasia, spindle cell and Kaposi sarcoma, which usually forms small nodules on pericardial surface with minimal infiltration of the heart. Most cases of cardiac angiosarcoma are diagnosed at the time of autopsy. Metastases, most often in lungs, are present at the time of presentation in 66-89% of patients. Prognosis is extremely poor, mean survival only 3 months, but survival up to 53 months has been reported. Complete resection is usually not possible, because of extensive local spread. Heart transplantation is the best option. Radiation therapy and chemotherapy may offer some temporary relief. Our patient is currently on radiation therapy, without any signs of disease, 11 months after presentation of the tumour.

P 726
METASTATIC SQUAMOUS CELL CARCINOMA MIMICKING CARDIAC MYXOMA
ELHAFEY Ahmed, PAPADIMITRIOU John C., BURKE Allen
Department of Pathology, University of maryland Medical School, USA

Introduction:
We report a case of squamous cell carcinoma of the uterine cervix, presenting with cardiac metastasis in a 42-year-old woman who had a radical hysterectomy for carcinoma of the cervix. The tumor was a poorly differentiated squamous cell carcinoma with extensive vascular invasion, involving the cervix, lower uterine segment, myometrium and parametrial soft tissue. The patient received radiotherapy and chemotherapy. Two years later the patient was admitted for symptomatic right atrial mass (clinical impression: Atrial myxoma).
Methods:
The original tumor and cardiac metastasis was analyzed for expression of low and high molecular weight cytokeratins, Ki-67, and p53.
Results:
The first intraoperative frozen sections exhibited prominent myxomatous stroma leading to an initial impression of myxoma. Subsequent intraoperative sections showed obvious squamous cell carcinoma.
Immunohistochemical study of the tumor showed expression of low and high molecular weight cytokeratins and high Ki-67 positivity. The original tumor and cardiac metastatic squamous cell carcinoma did not demonstrate any degree of p53 expression. Interestingly, the myxomatous stroma exhibited marked Ki-67 positivity.
Conclusion:
Patients with squamous cell carcinoma of the uterine cervix with extensive vascular invasion are at the risk of vascular invasion and hematogenous dissemination.
Metastatic squamous cell carcinoma to the right atrium can mimic atrial myxoma by CT and echocardiogram. Furthermore, a myxoid stromal reaction with high proliferative index can lead to an initial misdiagnosis of atrial myxoma.

P 727
PATHOLOGICAL FINDINGS IN SUDDEN CARDIAC DEATH
Burnley Hayley, Chase Deborah, Gallagher Patrick J, Roderick Paul. Southampton University Hospitals, Southampton SO16 6YD, UK

Sudden cardiac death results from an acute ischaemic evvent or a ventricular arrhythmia arising in an inflammed, scarred, hypertrophic or genetically abnormal heart. To determine the relative contributions of these causes we made a prospective study of all cases of sudden cardiac death in adults of any age over a one year period.
Three hundred and twenty one cases of out-of-hospital sudden cardiac death occuring within one hour of the onset of symptoms were studied. Each case was graded according to the certainity of the cause of death.Grade 1 cases were the certain result of ischaemia and had clear evidence of coronary artery thrombosis or myocardial infarction. Grade 2 cases had evidence of healed myocardial infarction and at least one coronary artery < 1mm in diameter. Grade 3 cases had coronary artery narrowing alone while Grade 4 had cardiac hypertrophy only. Grade 5 was unexplained cardiac death (SADS).In 107 cases (33%) there was coronary thrombosis or acute infarction. In 163 further cases there was coronary artery narrowing. 107(33%) had an associated myocardial scar (Grade 2) whilst 56 (17%) did not (Grade 3).In 45 cases (14%)non ischaemic heart dusease was present (Grade 4) and in 5 there was no obvious cardiac pathology (SADS).
The 33% incidence of acute ischaemia in sudden death is lower than in two studies from the 1990s (47% and 52%). Whether this is the result in changes in autopsy practice or a real change in the pattern of disease is uncertain. Our incidence of SADS is lower than in a recent UK study, but one that set an upper age of 65 years. Sudden death due to unexplained cardiac hypertrophy is important and has been underinvestigated.

P 728
SPONTANEOUS AORTIC DISSECTION. AN AUTOPSY STUDY OF 28 CASES.
ELD Mikkel(1), BANNER Jytte(2), KRISTENSEN Ingrid Bayer(2)
1) Institute of Pathology, Aarhus University Hospital, Aalborg Hospital, Denmark
2) Institute of Forensic Medicine, Aarhus University, Denmark

Background: Spontaneous aortic dissection is caused either by a tear in the intima or by an intramural haematoma preceded by rupture of the vasa vasorum. The dissection is caused by degeneration of the media, which is seen in different conditions like hypertension, heart valve diseases, pregnancy, cocaine abuse and certain syndromes.
Material and methods: In a 12-year period (1992 - 2003), 28 cases of sudden unexpected death were autopsied at the Institute of Forensic Medicine, University of Aarhus, and diagnosed as aortic dissection. The cases represent different clinical manifestations, diagnostic difficulties and different localizations of the dissection.

Results: Of the 28 cases 11 were females aged between 20-82 years (mean 47,2) and 17 were men aged between 31-80 years (mean 49,5).
In terms of De Bakey classification, 60 % were classified as Type I, 40 % as De Bakey Type II and none were classified as De Bakey Type III. Varying symptoms including, chest pain, nausea, dyspnoea, headache and sweating were reported in 68%, whereas 32% had been asymptomatic.60% had had medical contact and of these 21% had been hospitalized of which 50% had been misdiagnosed as coronary thrombosis, and two as gallstone and gastric ulcer. Aortic dissection was only diagnosed in one case by CAT-scan. The examinations done at admission were, electrocardiography (100 %), blood test (83 %), echocardiography (33 %), chest X-ray (16 %) and CAT-scan in the only pre-mortem correctly diagnosed case.
Conclusion: The diagnosis is difficult because the symptoms often mimic other conditions like gallstone, peptic ulcer and coronary thrombosis. With the symptoms in mind one should consider aortic dissection as a possibility, if the electrocardiography and blood tests are inconclusive for coronary thrombosis. The common used diagnostic procedures are CAT-scan, MR-scan, transoesophageal echocardiography and angiography, which have different accessibility, advantages and disadvantages.
The only chance of saving lives is to diagnose aortic dissection as early as possible, even though the prognosis is poor.
The only known treatment is surgery.

P 729
AUTOPSY FINDINGS IN CORRECTED TRANSPOSITION OF THE GREAT ARTERIES
LASTIC-MALETIC Sofija, GLUMAC Sofija, STOJSIC Zorica, POPOVIC Zoran, KANJUH Vladimir, VASILJEVIC D. Jovan
Institute of Pathology, Medical School, Belgrade, Serbia and Montenegro

Introduction: congenitally corrected transposition of the great arteries (C-TGA) represents the combination of atrio-ventricular and ventriculo-arterial discordance, with completely normal circulation, but with many associated cardiac anomalies.
Purpose: The aim of this study was to analyze the cases of C-TGA (sex, age and causes of death, atrial situs), and presence of associated cardiac and/or extra-cardiac anomalies.
Material and Methods: during the period from 1926-2004, a total number of 1.399 cases of congenital heart diseases (CHD) were diagnosed. All autopsies were performed using standard or modified Rokitansky technique. C-TGA was found in 24 cases (1.7 %).
Results: There were 15 males (62.5%) and 9 females (37.5%); in 20 cases the heart was in situs solitus (83.3%) and in 4 in situs inversus (16.7%). The viscera was always in situs solitus. Majority of the patients had 2 or more associated cardiac anomalies (20 ASD, 9 VSD, 3 AVSD, 2 PDA), and only 1 case had no communications between heart chambers; in 7 cases we found 1 communication, in 15 cases 2, and in 1 case 3. In addition, pulmonary atresia was present in 7 cases (29.2 %), and pulmonary stenosis in 4 (16.7%). Anomalous connection of pulmonary veins was found in 5 cases (20.8%), and anomalies of the coronary arteries too (hypoplasia in 3 and single coronary artery in 2). Majority of the patients died within the first month of life (13 or 54.2%), 6 within the first year (25%), 2 in the second year (8.3%), 1 in the third year (4.2%), and 2 lived over 20 years (8.3%). Extra-cardiac causes of death were predominant within the first year of life: bronchopneumonia (12 or 50%), athelectasis (4 or 16.7%), cerebral hemorrhage (3 or 12.5%), acute heart failure (2 or 8.3%), and myocarditis/endocarditis (1 or 4.2%).
Conclusion: Our results showed male predominance, situs solitus predominance, and the most often cause of death were extra-cardiac complications. Majority of patients died within the first year of life, and the most often associated cardiac anomalies were: ASD, VSD, pulmonary atresia or stenosis, and AVSD.

P 730
PECULIARITIES OF VULNERABLE PLAQUE FORMATION
PALTSEVA E.M., LYSENKO A.I., BELOV Iu.V., IVANOV A.A., PALTSEV M.A.

Vulnerable plaque formation exposed to rupture is the main cause of the acute coronary syndrome. The factors that promote the progression of atherosclerotic lesions instability are not clearly understood. In this study we showed the difference in extracellular matrix components and cellular distribution in vulnerable and stable plaques.
Methods and Results. Human carotid and coronary endarterectomy specimens (n=27) were obtained from patients with stenosis of >65%, as demonstrated by duplex ultrasonography and angiography. Plaques were histologically classified as either fibrous (stable), vulnerable (unstable) or plaques with features of instability – large lipid core, numerous inflammatory infiltrates and neovascularization but having thick fibrous cap. Immunohistochemical staining was used to analyze the expression of CD68, aSMA, collagen type III, fibronectin, laminin and thrombospondin-1. Macrophage (CD68 positive cells) infiltrates were greater in vulnerable plaques and plaques with features of instability. Laminin and thrombospondin-1 immunostaining was not detected in normal arteriers (n=5) and was larger in vulnerable plaques and plaques with features of instability than in stable plaques. The matrix components collagen type III and fibronectin showed variable distributions in all groups. There were no significant differences in aSMA immunostaining between different lesions also.
Conclusions. Our results suggest that laminin and thrombospondin-1 as well as CD-68 positive macrophages may be involved in the formation of vulnerable plaques and plaques with features of instability.

P 731
AORTIC DISSECTION, A LIFE THREATING DISEASE, TREATED BY USING „BIO-GLUE" SURGICAL ADHESIVE IN THE SURGICAL WALL REPAIR
Doina Butcovan, Cleopatra Borza - Department of Pathology Grigore Tinicã-Cardiology Center Iasi

Using Bio-Glue the cardiovascular surgery becomes a minimal invasive technique. Biologic glued anastomoses are obtained by applying a conventional technique of anastomosis indicated for severely altered aortic walls. We present a 55 years old man, without significant known history, having at presentation an anterior thoracic sudden violent pain, with duration of 1 hour and half. The patient was admitted at Cardiology Center Iasi with the suspicion of aortic dissection, which was confirmed after a complete cardiovascular evaluation. The histological examination of the surgical biopsic aortic specimens showed the morphological substrate of the disease represented by medial degenerative lesions that were evidentiated by using routine morphological techniques. The study revealed the importance of a complete cardiovascular evaluation and a rapid diagnostic for indicating an effective treatment and, in this way, for preventing an unpredictable complication. Concluding, we can appreciate that this biologic glue allows a good anastomosis, and a truly minimally invasive cardiovascular surgery may be possible.

P 732

CD44 IS LOCATED IN PLEXIFORM LESIONS OF IDIOPATHIC PULMONARY ARTERIAL HYPERTENSION

Keiko Ohta-Ogo, Hiroyuki Hao, Hatsue Ishibashi-Ueda

Introduction: The plexiform lesion in idiopathic pulmonary arterial hypertension (IPAH) is characterized by thin-walled microvessels with abnormal endothelial cells (ECs) proliferation. The pathogenesis of plexiform lesions has not been fully clarified. Recently, CD44 has been reported to regulate collateral artery formation via leukocyte trafficking and several growth factors. We hypothesized that CD44 is involved in formation of plexiform lesions of IPAH.
Methods: Expression of CD44 was examined on lung specimens including 46 plexiform lesions from 7 IPAH patients and normal lung tissues from 3 autopsy cases as control. To define localization of CD44, the following antibodies were used: CD31 for ECs, CD68 for macrophages, CD45Ro for T lymphocytes and alpha -smooth muscle actin for smooth muscle cells.
Results: ECs in 44 out of 46 plexiform lesions (96%) expressed CD44, while in patent muscular arteries from IPAH and muscular arteries from control lung tissue were negative for CD44. Intense expression of infiltrating leukocytes in plexiform lesions or perivascular accumulating leukocytes (mainly T lymphocytes) in lung tissue from IPAH was also observed.
Conclusion: CD44 expression was increased in ECs and leukocytes of plexiform lesions. The result indicates that CD44 might play an important role in the formation of plexiform lesions in IPAH.

P 733

CHAGAS´ DISEASE AND SUBSETS T CELL

Carmen E. Fuenmayor1 , Maria L. Higuchi2 , Hugo Carrasco1, Maryori García1 , Marcia M Reis2 , Julia Silvestre2 and Vera Aiello2 . Instituto de Investigaciones Cardiovasculares de la Universidad de los Andes, Mérida1, Venezuela. Instituto do CoraVão (InCor), São Paulo, Brasil2.

The present work reviewed endomyocardial biopsy specimens taken in the Instituto de Investigaciones Cardiovasculares de la Universidad de los Andes Mérida, Venezuela and Instituto do CoraVão, São Paulo, Brasil, from 1986 to 1998 and, looking for different CD4+/CD8+ T cell ratios in patients with chronic heart failure. For immunohistochemistry, T.cruzi antigens and CD4+ and CD8+ T cells in paraffin histological sections were quantified. The sections came from 4 groups of chagasic patients: A.- Acute phase (12 pts); B.- Indeterminate form (21 pts); C.- Cardiac form with arrhythmia (10 pts); and D.- Chronic heart failure (11 pts).
Groups A, B, C and D presented respectively: 100%, 10%, 40% and 45% of myocarditis; 58%, 0%, 10% and 0% with T.cruzi (+) antigens; with a mean CD4+/CD8+ T cell ratio of 0,75; 0,90; 1,17 y 0,79. The Pearson Correlation Test between mean numbers of CD4+ T and CD8+ T cells was high in groups A and B but not in groups C and D. Acute phase is characterized by myocardial inflammatory infiltrate with a balanced CD4+/CD8+ T cell immune response, associated with presence of parasite antigens. Indeterminate phase shows a lesser degree of myocarditis and balanced T cell immune response. Chronic cardiac forms are associated with myocarditis, but the quantity of T.cruzi antigens is much smaller and not detected by biopsy; an unbalanced immune response, with low CD4+/CD8+ T cell ratio, may be contributing to the persistence of active chronic myocarditis and injury of non-infected myocardial fibers.

P 734

PATHOLHISTOLOGICAL CHANGES IN AORTOCORONARY VENOUS GRAFTS

DUGANOVSKA Snezana, PETRUSEVSKA Gordana, BANEV Saso, FILIPOVSKI Vanja, TOLOVSKA Miljana, NIKOLOVSKI Momcilo
Institute of Pathology, Medical faculty, University "St Cyril and Methodius" Skopje, R. Macedonia

The aim of this paper is to present authopsy, histomorphological and immunohistochemical findings in aortocoronary saphenous vein bypass. Aortocoronary vein grafts removed at autopsy from 15 patients who died within one month up to 2 years after the bypass operation were examined. Histomorphological analysis was performed on paraffin sections stained with hemalaun eosin, Van Gieson elastica and Trichrome Masson. Immunohistochemical analysis for smooth cell actin, desmin, vimentin, CD 68, MAC 387, LCA, CD 20, and CD 43 (DACO products) was performed. A technique of LSAB+ immunoperoxidase (DAKO) was used with prior microwave antigen retrieval in citric acid buffer (pH 6,0). The main immunohistological finding were presence of intraluminal thrombotic masses, and endothelial damage with slight hyperplasia of tunica intima. Immunohistochemically we found a few smooth cell actin and vimentin positive cells in the intima. There were not found inflamatory cells, except at the anastomotic sites (CD68+, MAC 387+ and a few LCA+ cells). Positivity for the muscle cell actin in the intima suggests presence of adhesive molecules and cytokines that influence migration and hyperplasia of these cells, as well as in formation of atherosclerotic changes that occured in the wall of the vain grafts.

P 735

ULTRASTRUCTURAL ALTERATIONS OF THE PLACENTAL BARRIER UNDER HYPOXIA CONDITIONS

RESHETNIKOVA Olga, MILOVIDOVA Anna, MOROZOV Sergiy
Lugansk State Medical University,Ukraine

The electron microscopic investigation of placenta under hypoxia condition caused by maternal iron-deficiency anaemia and EPH-gestosis was carried.
Electronograms from 30 placentas, including 10 cases of EPH-gestosis, 10-maternal anaemia and 10-uncomplicated pregnancy (controls) were studied stereometrically by point count method at magnification X 5600.
Pathological ultrastructure's alterations of a placental barrier, including a damage of microvilli, thickening of basal membranes both of epithelium and endothelium, a stromal fibrosis were found. Compensatory proliferations of cytotrophoblast in cases of EPH-gestosis and in anaemia group; as well as hyperaemia of foetal vessels in EPH-gestosis group were seen too. The increase of the syncytiotrophoblast volume fraction (VF) in anaemia group (35,71±0,66 vs. 32,19± 0,26 % in controls), as well as cytotrophoblast, epithelium and endothelium basal membranes VF's both in anaemia (A) and gestosis(G) groups had registered
(correspondingly: A- 2,76± 0,04; 3,52±0,02; 0,57±0,06; G-1,05±0,03; 4,76±0,03; 0,74±0,04 vs. 0,76±0,04; 3,04±0,01; 0,38±0,12% in controls, $P<0,05$). The capillary lumen increased to 14,70±0,26% in gestosis group (13,5±0,21% VF in controls, $P<0,05$).
Pathological changes of a placental barrier could be a structural basis of a placental insufficiency. It was suggested that the process of ultrastructural remodelling of the placental membrane may compensate for different pathologies at the terminal parts of the villous chorion, which is essential base of the morphological correction of a placental insufficiency.

P 736

ULTRASTRUCTURAL STUDY OF THE EFFECT OF EXPERIMENTAL STAINING OF THE ANTERIOR LENS CAPSULE IN ALBINO RABBITS ON THE CORNEA AND ANGLE

Elham M. El-Shazli, M.D.
Ehsan El-Mehelmy, M.D.

Purpose: To study the value and safety of staining the anterior lens capsule in albino rabbits.
Methods: The experiment was divided into 3 stages. First, the capacity of different concentrations of crystal violet solution to stain the anterior lens capsule of postmortem albino rabbit eyes was tested. The toxicity of different concentrations of the dye (2% to 0.25%) was then tested to determine the highest concentration that was nontoxic to the cornea and trabecular meshwork. The third step was to detect possible toxicity of lower concentrations (0.1% to 0.05%). Different concentrations were injected into the anterior chamber of the rabbit eyes. The eyes were examined after 1 and 3 days, 1 week, and 1 month using light microscopy and scanning and transmission electron mcroscopy.
Results: Different concentrations of crystal violet stained the anterior lens capsule, allowing for easy capsulorhexis. The use of the 2% and 1% concentrations was accompanied with irreversible damage to all corneal layers. The use of the 0.5% concentration caused damage to stromal keratocytes and endothelium. The use of the 0.25% concentration did not damage any corneal layer of the trabecular meshwork. Lower concentrations of 0.1% and 0.05% also stained the capsule, providing good visibility for successful capsulorhexis, and were less toxic to the corneal endothelium.
Conclusion: Staining the anterior lens capsule with 0.25% ti 0.05% concentrations of crystal violet solution caused no injury to the cornea or trabecular meshwork in albino rabbit eyes.

P 737
LIVER INJURY IN HEAT STROKE: ELECTRON MICROSCOPY STUDY.

C.W. Hsueh, Y.Y. Tsai, N.H. Feng, T.M. Lee*
Depts. of Internal Medicine and Pathology*, Kaohsiung Armed Forces General Hospital, Kaohsiung, Taiwan.

It is common that thermal injury results in widespread injury of liver. The purpose of the study is to investigate the ultrastructural changes of liver in the patients with heat stroke.
Methods: A total 12 young soldiers with heat stroke, liver biopsy specimens were obtained within one week after the onset of heat stroke. Specimens were examined in electron microscope.
Results: Ultrastructural abnormalities of hepatic tissues were found in 11 cases. The changes of liver are as following: fat droplets in hepatocytes, increased autophagic vacuoles in cytoplasm, increased collagen fibers in space of Disse, dilated endoplasmic reticulum, cell debris and glycogen in sinusoid, and outer membrane disruption of hepatocytes. In one of the cases, the liver showed no remarkable change.
Conclusions: In this study, various degrees of liver injury were found in most of the patients with heat stroke. The histological changes of liver evidence that direct thermal injury and tissue hypoperfusion.

P 738
LET'S DO THE TWIST - A MODEL FOR THE ASSEMBLY OF CYTOPLASMIC AND NUCLEAR INTERMEDIATE FILAMENT PROTEINS

Bernd Sasse, Institute of Surgical Pathology, University Hospital Zurich, Switzerland
Ueli Aebi, Maurice E. Müller-Institute for Structural Biology, Biozentrum, University of Basel, Switzerland

Recently, intermediate filament (IF) proteins and especially the nuclear lamins have attracted wide attention as mutations in the lamin A-gene have been linked to various diseases such as lipodystrophy, dilative cardiomyopathy, muscular dystrophy, neurodegenerative disorders and progeria. Still the function of IF proteins is poorly understood. The ability of IF proteins to self-assemble into higher-order structures is conserved among species and thus seems to be key for protein function. Nuclear lamins and cytoplasmic intermediate filament proteins share the primary steps of assembly but ultimately form different structures in vivo.
Here we propose a model for the self assembly of nuclear lamins and cytoplasmic IF proteins which, on the basis of known interactions, explains the differences in assembly properties: IF proteins share a common tripartite architecture consisting of an alpha-helical central rod domain flanked by non-helical domains. The alpha-helices wind around each other resulting in dimeric coiled-coils. The dimers in a second step can interact basically in four different ways, one parallel and three anti-parallel, resulting in higher order structures such as unit-length filaments and ultimately filaments in case of the cytoplasic IF proteins and head-to-tail polymers and paracrystals in case of the nuclear lamins.
Nuclear lamins and cytoplasmic IF proteins are distinct in that nuclear lamins have a 42 amino acid insert in their rod domain. Our model explains, why this insert leads to a different behavior of assembly. We propose that IF filaments filaments are twisted structures emerging from surface lattices formed by dimetric IF proteins assembled via the known four basic dimer-dimer interactions and we extend this model onto the nuclear lamins, the geometry of which finally leads to other higher order structures.

P 739
THE ENDOMETRIAL PINOPODES INVESTIGATION IN WOMEN WITH UNEXPLAINED INFERTILITY.

ILYINA Olga, ZADOROZHNAYA Tamara, ILYIN Igor
Ukrainian Institute of Pediatrics,Obstetrics and Gynecology; Reproductive Genetics Institute; Kiev,Ukraine

Introduction The aim of the study was to evaluate the peculiarity of pinopodes formation in luminal uterine epithelial cells in women with unexplained infertility.
Materials and methods We have investigated the luminal epithelial cells morphology of endometrium in 16 patients with unexplained infertility and 10 healthy women from couples with male infertility. Double endometrium biopsy was taken on day LH+6/7 and LH+8/9. Specimens were examined with scanning electron microscopy for detection of pinopodes.
Results The SEM pictures of pinopodes were obtained in all the patients. Scanty pinopodes were present in 6 (37,5%) cases;the same stage of development in both biopsies or arrested pinopodes in 2 (12,5%) cases;high variability of the pinopodes shape and size in 8 (50%) cases;ciliated cells were absent in 4 (25%) cases.
In all the women from couples with male infertility were abundant or moderate pinopodes.
Conclusion We can consider,that the disturbances in pinopodes formation,maturation and ciliated cells quantity is one of the causes of implantation failure.

P 740
REVERSIBLE AND IRREVERSIBLE LUNG CHANGES AFTER EXOGENOUS SURFACTANT TREATMENT WITH IMMUNO-ELECTRON MICROSCOPY STUDIES

MARSZALEK Andrze, BICZYSKO Wieslawa

Exogenous surfactants are widely used in prevention and treatment of respiratory distress syndrome in newborns. There are also several attempts to use the same mode of therapy in

treatment of acute respiratory distress syndrome in adults but the results are still unsatisfactory.
The aim of the present study was evaluation of influence of exogenous surfactant on cells of air-blood barrier and the outcomes on its morphology in prolonged observations. The studies were conducted on animal model. The single dose of commercially available surfactant (Curosurf plus synthetic analogue of SP-B-HA) was introduced under anesthesia and intubation. Lung tissue samples were taken for morphologic evaluation after 1, 6, 24 hours and 5, 10, 21 and 42 days. Light and electron microscopic techniques as well as morphometric studies were used.
In the first periods of observation after administration of exogenous surfactant atelectasis, congestion, alveolar edema and erythrorrhagies were observed. After 5 days those changes started to decline and since the 10th day of observations first signs of alveolar fibrosis were recognized. Using the immuno-electron microscopic studies evidence of incorporation of exogenous surfactant into membrane systems of air-blood barrier cells was found.
In conclusion it should be stressed that exogenous surfactant internalize with cell membranes and cause lung injury. The injury of the lung parenchyma leads to alveolar fibrosis.

P 741
ULTRASTRUCTURE IN FAMILIAR HYPERTROPHIC CARDIOMYOPATHY WITH ARG723GLY MUTATION
BOMBÍ Josep Antoni, PETIT Ana, RAMÍREZ Josep, FRANCINO Antonio*, NAVARRO Francisco*.
Depts. of Pathology and Cardiology*. Hospital Clinic. University of Barcelona Medical School. Barcelona. Spain.

The Familiar Hypertrophic Cardiomyopathy is considered as the most prevalent (1/500) hereditary cardiomyopathy. At least ten genes are related to its appearance. In our hospital we have assessed a new mutation in three families over 30 carriers, that has demonstrated a worse prognosis. This is a Arg723Gly mutation in the gene that codifies for the heavy chain of beta-myosine. The carriers of this mutation show a non-obstructive form of the disease with evolution to clinical symptoms of cardiac failure that starts at the age of forty. The evolution of the patients is progressive heart failure leading to death at a mean age of 50 years, so they have to be treated with an implantable cardioverter-defibrilator or finally with heart transplant. Two of these patients needed a cardiac transplant, so we had the opportunity of studying these hearts histopathologically. Grossly they were within normal measurements, but a marked fibrosis was seen in the microscopical study. We performed electronic microscopy of both, that showed peculiar cytoplasmic granules, measuring 8-10 microns. These granules were dilated endoplasmic reticulum with granular material in dense areas.
As a conclusion this is the first time that a genetic based cardiomyopathy has been related to an abnormal morphological change. This contribution can be of help in order to make the diagnosis of these patients.

P 742
SOME EFFECTS OF ARTIFICIAL EXTRACELLULAR MATRIX ON FUNCTION AND MORPHOLOGY OF HUMAN ENDOMETRIAL EPITHELIAL CELLS IN VITRO.
NOURI Mohammad, GHAFFARI NOVIN Marefat
Infertility Center, Tabriz University of Medical Sciences, Tabriz, Iran
Department of Reproductive Endocrinology and Embryology, Reproductive Biology and Biotechnology, Avesina Research Center, Tehran, Iran

The importance of extracellular matrix (ECM) in development and function of different cells has been reported but little is known about its role in human endometrial epithelial cells. We have examined effects of artificial ECM (Matrigel) on the function and morphology of human endometrial epithelial cells using molecular techniques and electron microscopy. Endometrial samples were removed, with informed patient consent and Ethics Committee approval, from 17 previously fertile women undergoing total abdominal hysterectomy. The tissue was dissociated and centrifuged to provide an epithelial-rich suspension which was cultured either on plastic or seeded into Matrigel to produce polarized cells. Cells on plastic were undifferentiated, flattened and squamous but cells in polarized cultured were well-developed, tall, columnar and similar to secretory phase cells in vivo. The amount of total RNA in cells grown on Matrigel (23+1.5 pg/cell) was more than double that in cells grown on plastic (9.1+1.4 pg/cell). These results suggest that ECM plays an important role in function and morphology of human endometrial epithelial cells in vitro.

P 743
MULTIHORMONAL ADENOMAS OF PITUITARY. APPLICATION OF ELECTRON- AND IMMUNOELECTRON MICROSCOPY IN THE DIFFERENTIAL DIAGNOSIS
MAKSYMOWICZ Maria1, ZIELIÑSKI Grzegorz2, OLSZEWSKI W³odzimierz T.1, PODGÓRSKI Jan2
1- Institute of Oncology, 2 - Military Medical Institute, Warsaw, Poland

Pituitary adenomas are classified on the basis of hormones produced by the neoplastic cells detected by immunohistochemical stains. The pivotal part in pituitary tumors diagnosis is based on the electron microscopy investigation. Immunoelectron microscopy using single and double staining enables to identify cell types not detectable by routine methods. It is important to recognize some rare subtypes of pituitary tumors with specific biology and prognosis.
Aim. Evaluation of practical implementation of electron microscopic techniques in diagnosis of pituitary adenomas.
Material consists of 470 consecutive cases of surgically resected pituitary tumors. In pituitary adenomas were diagnosed (424 cases), clinically there were 147 patients with symptoms of acromegaly, 71 patients with hyperprolactinemia, 59 cases of Cushing's syndrome, 6 cases of Nelson syndrome, 3 cases of TSH hypersecretion and 138 clinically nonfunctioning adenomas. We selected 48 cases for current study.
Methods. All cases were diagnosed by routine histological examination and immunohistochemical identification of pituitary hormones (growth hormone, prolactin, ACTH, TSH, FSH, LH and alpha-subunit) and then examined with transmission electron microscope. Immunoelectron microscopy was done using a postembedding immunogold technique.
Results. Immunohistochemical analysis demonstrated the presence more than one pituitary hormone in the about 40% of pituitary adenomas. Immunopositivity was encountered in 27,5% of nonfunctioning tumors. Ultrastructural analysis provided proper diagnosis of selected cases (e.g. subtypes of silent corticotroph adenomas or mixed GH/TSH adenomas). Double immunogold labeling greatly facilitated the distinction among mixed growth hormone/prolactin, mammosomatotroph and acidophil stem cell adenomas.
Conclusions. Electron microscopy analysis was valuable to provide a useful informations regarding the diagnosis of rare multihormonal pituitary adenomas. At present, in the routine pathological diagnosis of pituitary tumors, immunoelectron microscopy (as well as molecular biologic methods) still are regarded as research tools. These methods has to be limited for cases in which they are necessary.

Objective: The aim of this study was to analyse the cervical cytological history of women with invasive cervical cancer.
Methods:Cases of invasive cervical cancer diagnosed between 2000-2003 were identified from six Pathology departments covering a Health Region in Catalonia (Spain). For each case we retrieve from the laboratories data base: age, histology, cervical smear histories in minimum 5 years preceding the diagnosis , time from last negative and time from last abnormal screen.
Results: During this period, we identified 104 patients with invasive cervical cancer. Seventy-five per cent of cases were squamous carcinoma and 26% adenocarcinomas. 81.8% (85/104) had not a cervical smear reported as negative one year before of the diagnosis of the cervical cancer. The average age of these patients was 57 years. Eleven patients (11%) had had an occasional normal cervical smear an average of four years before of the diagnosis. After review, we estimaded that 15% were reported as false negative
Conclusion: A majority of cases of invasive cervical cancer occur in women without evidence of cervical screening history. In a country with very low incidence rates of cervical cancer and opportunistic screening, specific actions to reinforce coverage among menopausic women may be justified.

P 745

NEW INSIGHT INTO THE EFFECT OF HIV ON HPV INFECTED CELLS

NYAGOL Joshua, LEUCCI Eleonora , CASTAGNINI Marta, COCCO Mario, ONNIS Anna, TILLI Chiara, DE FALCO Giulia, SANTOPIETRO Rosa, GIORDANO Antonio and LEONCINI Lorenzo
Department of Human Pathology and Oncology, University of Siena, Italy

The role of HPV in the carcinogenesis of intraepithelial and invasive anogenital lesions is currently well established. E6 and E7 oncoproteins of HPV 18/16 high risk genotype are known to inactivate p53 and pRb pathways. The role of HIV in cervical carcinomas associated with HIV infection is, however, less well known. Several studies have described an increased prevalence of both cervical HPV infection and invasive cervical cancer among HIV-positive women compared to HIV-negative ones. A high recurrence rate of invasive cervical cancer after standard treatment has been noted in HIV-positive women and the severity of these lesions seems to be inversely correlated to immune function. This combination of events typically results in a more aggressive phenotype. A primary means by which HIV infection may influence the pathogenesis of HPV-associated cervical pathology is by molecular interaction between HPV and HIV genes. Although not yet well defined, an upregulation of HPV E6 and E7 gene expression by HIV proteins such as Tat has been postulated by some authors. With this in mind, we investigated the role of HIV in cervical carcinomas both by transfecting HeLa cells, a cervical carcinoma cell line, with Tat and by analyzing HIV positive or negative cases.
Testing HIV negative cases by immunohistochemistry, we found a recurring pattern of pRb2/p130 expression. In precancerous lesions we found two distinct layers: a proliferating one, composed of Ki-67+/pRb2- cells, and a superficial one composed of Ki-67-/pRb2+ cells. In cancerous lesions all the cells showed staining for both markers, suggesting that the growth control exerted by pRb2/p130 may be lost due to the binding with HPV E6 and E7. We then tested the effect of the expression of the HIV-1 Tat protein in HeLa cells. After Tat over-expression in HeLa cells we observed a significant reduction of cell cycle inhibitor transcription and an increase in the levels of proliferating markers, such as Cyclin A, at the mRNA level.
These preliminary results seem to suggest that HIV may contribute to carcinogenesis by promoting cancer progression, because in HIV-positive women the disease may be aggressive and less responsive to treatment.

EXPRESSION OF CYCLIN-DEPENDENT KINASE INHIBITORS P16 INK4A IN PREMALIGNANT UTERINE CERVICAL LESIONS; ITS ASSOCIATION WITH DEGREE OF DYPLASIA, HUMAN PAPILLOMAVIRUS (HPV) STATUS AND COMPARISON WITH PROLIFERATION MARKERS LIKE KI67 AND AGNORS.

L. Baron, M. Postiglione, P. Beltotti , N. De Stefano, F. Quarto
U.O. di Anatomia ed Istologia Patologica e Citopatologia P.O. S.Leonardo, Castellammare di Stabia (NA), Italy

BACKGROUND:HPV is recognized as a casual agent for cervical carcinomas. Assimilation of HPV oncogenes E6 and E7 into the host DNA promotes upregolation of cyclin dipendent kinase inhibitor (CDKI) p16 detectable by monoclonal antibody in the developing cervical cancer cells.
STUDY DESIGN:The aim of this study is to examine the potential of p16 (INK4A) as a biomarker and to determine its utility as an HPV marker on a spectrum of cervical reactive and neoplastic lesions.
METHODS:A series of 172 cervical tissue samples (20 reactive, 88 CIN1, 54 CIN2, 10 CIN3) were analyzed by immunohistochemistry for expression of p16 (E6H4,CINtec™,DAKO) and Ki67 (Mib-1,DAKO) as well as by in situ hybridization for high risk HPV testing (INFORM® VENTANA) and by histochemical staining (Ploton) for AgNORs assessement. The distribuition of p16 staining was graded as patchy, diffuse basal and diffuse full thickness. Pearson's ÷2 test analyzed the relationship between p16, CIN, HPV, Ki67 and AgNORs expression.
RESULTS:In CIN1 p16 was positive in 48% ($p<0.001$) with 74% showing patchy, 21% diffuse basal and 5% diffuse full thickness; in CIN2 p16 was positive in 70% ($p<0.001$) with 3% showing patchy, 34% diffuse basal and 63% diffuse full thickness; in CIN3 p16 was positive in 100% ($p<0.001$) with 30% showing diffuse basal and 70% diffuse full thickness. The difference in the proportions of biopsies showing patchy p16 staining in CIN1 (LSIL) and diffuse full thickness staining in CIN2/3 (HSIL) was significant ($p<0.001$). High risk HPV increased from 52% in CIN1 to 94% in CIN2 and to 100% in CIN3 ($p<0.001$); in CIN1 39% of high-risk HPV positive biopsies were p16 positive ($p<0.001$) showing 61% patchy, 28% diffuse basal and 11% diffuse full thickness distribuition; in CIN2 69% were p16 positive (3% patchy, 29% diffuse basal and 68% diffuse full thickness) while all high-risk HPV positive CIN3 biopsies were p16 positive (30% basal and 70% diffuse full thickness).
Ki67 and AgNORs pattern of distribuition were similar: limited to basal layer in LSIL extending to middle and superficial layers in HSIL, correlated with degree of neoplasia, also if they were expressed in more reactive conditions than p16.

CONCLUSIONS:Diffuse full thickness p16 expression in lesion with high and intermediate-risk HPVs appears a good marker of persistent high risk HPV infection and might be useful to discriminate in equivocal cases HSIL from LSIL and to select LSIL with higher risk of neoplastic progression.

P 747

KI-67 EXPRESSION IN THE INVASION FRONT AS AN ADDITIONAL INDEPENDENT SIGNIFICANT PROGNOSTIC FACTOR INFLUENCING RECCURENCE IN EARLY STAGE CERVICAL CARCINOMAS

BASHESKA Neli, PRODANOVA Irina, KUBELKA-SABIT Katerina, YASHAR Genghis
Department of Histopathology and Clinical Cytology, Institute of Radiotherapy and Oncology, Medical Faculty, Skopje. Republic of Macedonia

INTRODUCTION: The attempts to determine the prognostic significance of biological markers and their relation to human papillomavirus (HPV) infection in cervical cancer have yielded controversial results.
AIMS: The aims of this retrospective study were to correlate alterations of cell proliferation, growth, differentiation and apoptosis regulatory proteins in early stage cervical carcinomas with HPV infection, histopathological and clinical parameters, and to estimate their prognostic significance.
METHODS: Expression of Ki-67, p53, mdm-2, bcl-2, c-erbB-2, EGFR protein, as well as estrogen and progesterone receptors was evaluated by immunohistochemistry in operative specimens of 83 patients with early stage cervical carcinoma. The results were assessed semiquantitatively in the surface area, center and invasion front of each tumor as a percentage of the immunostained cells and/or intensity of immunostaining for each protein. The presence of HPV was assessed by conventional in situ hybridization (ISH) technique and catalyzed reporter deposition signal amplification ISH using mixed biotinylated probes to identify types 6/11, 16/18 and 31/33 or 31/33/51.
RESULTS: In our case series 73 patients had a tumor limited to the uterine cervix less than 4 cm in diameter (pT1b1), while 10 patients had larger neoplasms belonging to pT1b2 category. Pelvic lymph node involvement was found in 20 patients. During the follow-up period (range, 65 -181, mean, 121 months) recurrences were observed in 9 patients. The 5, 10 and 15-year disease-free survival rate was 92.7%, 90.8% and 86.6%, respectively. Among the 18 variables pelvic lymph node involvement (P=0.0008), tumor diameter (P=0.035), depth of stromal invasion (P=0.029), histotype (P=0.0009), grade (P=0.056), HPV DNA presence (P=0.056), HPV type (P=0.043), as well as bcl-2 (P=0.035), mdm-2 (P=0.051), EGFR (P<0.0001), and Ki-67 (P=0.031) expression in the tumor's invasion front were identified as important predictive indicators of recurrence in the univariate analysis. Independent significant prognostic factors for disease-free survival in multivariate analysis were the histotype, HPV DNA presence and Ki-67 expression.
CONCLUSIONS: The invasive front of carcinomas proved to be the most important area for tumor prognosis. In addition to the detection of HPV presence and morphological parameters, Ki-67 evaluation could be used in selecting appropriate therapeutical approaches in patients with early stage cervical cancer.

HUMAN PAPILLOMA VIRUSES DO NOT PLAY AN AETIOLOGICAL ROLE IN ADENOSARCOMAS OF THE UTERINE CERVIX

GRAYSON Wayne, ALI Hasiena, TURTON Diane, MUMBA Everisto
Division of Anatomical Pathology, School of Pathology, University of the Witwatersrand and the National Health Laboratory Service, Johannesburg, South Africa

Primary adenosarcomas of the uterine cervix are exceedingly uncommon neoplasms. Although high-risk human papilloma virus (HPV) types have been linked to cervical carcinosarcomas, with demonstration of integrated virus in the nuclei of the malignant epithelial and sarcomatoid components, their role in the histogenesis of adenosarcomas is unclear. The aim of this study was to determine if HPVs play an aetiological role in cervical adenosarcomas. The HPV status of 7 adenosarcomas of the cervix was investigated by non-isotopic in situ hybridisation (NISH) and polymerase chain reaction (PCR). NISH was carried out using digoxigenin labelled probes to HPV types 6, 11, 16, 18, 31 and 33. PCR employed GP5+/GP6+ primers to the HPV L1 gene. Neither the benign epithelial components nor the malignant stromal components of the 7 neoplasms harboured nuclear NISH signals for the HPV types investigated. Amplimers of the HPV L1 gene could also not be detected by PCR in any of the tumours studied. HPVs do not appear to play an aetiological role in the pathogenesis of uterine cervical adenosarcomas. This suggests that a different histogenetic pathway for this rare tumour type must exist.

Objective: Hybrid Capture II (HC2) to detect high-risk HPV (hr-HPV) in our ongoing multi-centre trial was performed and compared to other optional testing screening tools [cytology (conventional and liquid-based {LBC}, screening colposcopy, Visual Inspection with acetic acid (VIA), Visual Inspection with Lugol's Iodine (VILI): conventional and self-sampling], for cervical cancer in Brazil and Argentina, in order to test the potential use of HC2 as a primary option for cervical screening. Purpose: A cohort of 12.107 women attending four clinics (Campinas, Sao Paulo, Porto Alegre, and Buenos Aires) are randomised into the 8 diagnostic arms. Women testing positive with any of the tests are referred for colposcopy, and cervical biopsies are used as the gold standard to assess performance characteristics (SE, SP, PPV, NPV, ROC) of the HC2 test. Methods: All cases with cytological abnormalities were referred to colposcopy and biopsies were taken according clinical evaluation. The HC2 protocol was performed according to the instructions of the manufacturer (Digene Co., Gaithersburg, MD, USA). In estimation of the viral load, samples with relative light units

(RLU) > 20 were considered to harbour a high viral load and, those with 5-19.9 were intermediate, and those with 1-4.99 were low. Only high risk HPV was tested. Chi-square test was used to analyze correlations between categorical data, with Pearson's correlation and Fisher's exact test, and calculating OR and their 95%CI where appropriate. In all statistical analysis, the p<0,05 were regarded as significant. Results: The sensitivity and specificity for CIN3 were 96.5 (95.1-97.9) and 66.1 (62.6-69.6), respectively. For CIN 2 the results were quite similar: 90.4 (88.2-92.6) and 69.0 (65.6-72.4). When we adjusted the results for Roc Curve (Receiver Operating Characteristics) the Sensitivity and Specificity were very robust: 82.5% and 82.3¨for CIN3, and 83% and 76.3% for CIN2. Conclusion: In our settings, positive hr-HPV-DNA showed an important agreement with high-grade lesions of the cervix. The Public Health authorities should seriously evaluate the potential use of HC2 as primary option in order to optimize the sensitivity of cervical cancer screening. Moreover, HC2 performance might be improved by the association of cytology (preferentially, LBC) performed either after HC2 or concomitantly.

P 750
CERVICAL INTRAEPITHELIAL NEOPLASIAS POSSESS ANGIOGENIC ACTIVITY. IMMUNOHISTOCHEMICAL AND MORFOMETRIC STUDY
MRÈELA Milanka, ILIÆ-FORKO Jadranka, BABIÆ Damir

Introduction. Angiogenesis is the fundamental process through which new blood vessels are made. Angiogenesis is necesary for growth of solid tumors. On the other hand, cervical intraepithelial neoplasias (CIN) represents the proliferational state of the epithelium with biological caracteristics of carcinoma.
Purpose. This research was performed to answer whether cervical intraepithelial neoplasias are able to provoke neovascularisation - angiogenesis.
Methodes. The blood vessel count along the basement membrane of the epithelium and the total number of blood vessels of given microscopic view field were compared between 30 specimens of CIN 1, 30 specimens of CIN 2, 30 specimens of CIN 3 and two control groups each of them containing 30 specimens of cervical tissue without pathohistological abnormality and differing from each other in the fact that specimens of control group K 1 were taken from patients who underwent hysterectomy for reasons unrelated to CIN and group K 2 of specimens taken from patients with CIN 3 lesions but from parts with no pathohistological abnormality. Samples were treated with immunohistochemical methods using anti-F-VIII and anti-CD 31 markers. Quantitative parameters were processed using quantitative morphometric analysis in program 'ISSA for windows', produced by VAMS, Zagreb. The results were statistically analysed by method testing analyisis of variance (ANOVA) based on Fischer's (F-test) as the criterion of significance.
Results. Statistically significant difference was found in the blood vessel count directly below or along the basement membrane between CIN 1, CIN 2, CIN 3 and the control group K1 using both immunohistochemical methods (P<0,05) and betwen CIN 3 and the control group K 2 (P<0,05). Statistically significant diference was found in the total number of blood vessels between control groups K 1, K 2 and CIN 3 only using method F-VIII (P<0,05). The blood vessel count close to the basement membrane of epithelium between CIN 1 and CIN 3, and CIN 2 and CIN 3 in both immunohistochemical methods was significantly different (P<0,05)
Conclusion. Since there is a significant difference in the blood vessel count along the basement membrane between normal and dysplastic epithelium, and that number increases with the rise of CIN grade, it was concluded that CIN lesions are angiogenic.

P 751
P16 PROTEIN EXPRESSION IN HISTOLOLOGICAL MATERIAL OF CERVIX AND ITS CORRELATION WITH HPV INFECTION
TRAUNER Antonija, ALINGER Beate, MUSTAFA Georg, MUSTAFA Lisa, GRAF Anton-Helmut, DIETZE Otto, HAUSER-KRONBERGER Cornelia
Department of Pathology, General Hospital Salzburg, Mustafa´s Laboratory Salzburg, Austria

Cervical carcinoma is a multistage process. It arises from defined precursor as low-grade intraepithelial lesions (LSIL), referred to as high-grade intraepithelial lesions (HSIL). An important factor in the pathogenesis is the high-risk HPV types (HR-HPV) infection. The HSIL may be initiated by deregulated expression of HR-HPV oncogenes E6, E7 in replicating epithelial stem cells. An indicator of active expression of viral oncogenes is the overexpression of the cyclin-dependent kinase inhibitor p16.
A total of 339 routinely processed cytological specimen were analyzed. The material was taken consecutively for Pap test and for HPV-DNA hybrid capture assay (HC™, Digene). The cytological reports were negative for intraepithelial lesion or malignancy, LSIL to HSIL and cells of undetermined significance (ASC-US). HR-HPV positive cases were used for further investigation. Amplification of ß-Globin was followed by subtyping of HPV 16-DNA with conventional PCR. A total of 73 cases of cervical carcinoma and its precursor lesion were diagnosed out of these 339 cases of routinely cytological cervical specimen. The histological report showed condylomatous atypia, cervicitis, mild dysplasia (CIN I), moderate dysplasia (CIN II), severe dysplasia (CIN III), carcinoma in situ (CIS) and invasive cancer (Ca). Formalin-fixed, paraffin-embedded tissue blocks were used for the immunocytochemical expression of p16 protein with CINtec™ p16INK4a histology kit (DakoCytomation, DN).
23 specimens with histological reports of condylomata acuminata, cervicitis and CIN I showed positivity for HR-HPV (HC™) in 79%, HPV 16-DNA (PCR) in 37% and p16INK4a in 26%.
63% of the Pap-test cases were diagnosed as LSIL or negative for intraepithelial lesion and malignancy.
50 specimens with histological results of CIN II to CIN III, CIS and Ca showed HR-HPV (HC™) positivity in 97% and for HPV 16-DNA (PCR) in 76% and in 87% for p16INK4a. 49% of the Pap-test cases were diagnosed as HSIL, CIS, Ca and 16% of the Pap-cases were reported as ASC-US.
Our results indicate that the cyclin-dependent kinase inhibitor p16 is strongly overexpressed in correlation with the transforming activity of the viral oncogenes of all HR-HPV types, but particular the HPV 16. The p16INK4a expression increases with the progression of dysplasia.

P 752
EXPRESSION OF MMP-1, -2 AND TIMP-1, -2 IN CERVICAL INTRAEPITHELIAL NEOPLASIA AND INVASIVE CERVICAL CANCER
MI SEON KANG, HYE KYOUNG YOON.

Destruction of extracellular matrix is one of the most important step for the metastasis and invasion of cancer cells. Matrix metalloproteinase-2(MMP-2) specifically cleaves collagen type IV and MMP-1 digests interstitial collagen type I and III. These proteolytic activities are regulated by stoichiometric binding of specific, locally produced tissue inhibitor of metalloproteinases(TIMPs). The aim of this study was to investigate the expression of MMP-1, MMP-2, TIMP-1 and TIMP-2 in cervical intraepithelial neoplasias(CINs) and

invasive squamous cell carcinomas. Paraffin-embedded tissue sections from 36 CINs (10 CIN I and 26 CIN II & III) and 60 invasive squamous cell carcinomas. We investigated the expression of MMP-1, MMP-2, TIMP-1 and TIMP-2 by using immunoperoxidase staining.MMP-1 expression rate in invasive carcinoma(66.7%) was higher than that of CIN I (10%) and CIN II & III (11.5% ($p<0.0001$). Expression rates of MMP-2 in CIN II & III and invasive carcinoma were 42.3% and 48.3%, but no MMP-2 expression was found in CIN I ($p=0.0162$). TIMP-1 expression rate in CIN I(60.0%) was higher than that of CIN II & III(34.6%) and invasive carcinoma(16.7%)($p=0.0078$). Expression rates of TIMP-2 in stromal cells of CIN II & III and invasive carcinoma were 30.8% and 46.7%, respectively. But no TIMP-2 expression was found in CIN I ($p=0.0114$). No significant correlations between MMP-1and TIMP-1, MMP-2 and TIMP-2 were found. The presence of MMP-1 in tumor cells may enhance the invasive ability, but MMP-2 expression is an early event during malignant transformation in cervical neoplasia. TIMP-1 have inhibitory activity in progression in cervical neoplasia, but TIMP-2 may enhance the progression of cervical neoplasia through activation of MMP-2.

P 753

EFFICIENCY OF IMMUNOHISTOCHEMICAL P16 EXPRESSION AND HPV TYPING IN CERVICAL SQUAMOUS INTRAEPITHELIAL LESION GRADING

YILDIZ Iþýl Z., USUBÜTÜN Alp, FIRAT Pýnar, AYHAN Ali, KÜÇÜKALÝ Türkan
Hacettepe University Medical School Departments of Pathology and Obstetrics and Gynecology

Diagnosing and grading cervical cancer precursors is challenging at some point.In search of a solution,this study detects presence of HPV and investigates the staining pattern of p16,a cyclin-dependent kinase inhibitor whose overexpression is reported to be typical for dysplastic and neoplastic epithelium of cervix,on the basis of distribution and intensity,immunohistochemically.
H&E stained slides from cervical loop excision materials formerly diagnosed as LSIL (15 cases) and HSIL (20 cases), were reviewed. An immunohistochemical panel consisting of p16,all HPV types (Viroactiv® HPV Screening Kit) and HR (high risk)-HPV types (16,18, 33, 35, 39, 45, 56, 58) (Viroactiv® HPV High Risk Kit) was applied. Nuclear staining was interpreted as positive for HPV evaluation. Both nuclear and cytoplasmic staining were accepted as positive for p16. Staining of p16 was evaluated as rare, basal and full thickness according to the distribution and the intensity was classified as weak, variable and strong. Chi-Square Test and Fisher's Exact Test were used for statistical analysis.
All HSIL cases (20/20) and % 80 of LSIL cases (12/15) were positive with p16. Of p16 (+) HSIL cases, epithelial distribution was % 50 full thickness, % 45 basal and % 5 rare. The staining intensity of the same cases were % 70 strong, % 20 variable and % 10 weak. Of p16 (+) LSIL cases, epithelial distribution was % 58.3 basal and % 41.7 rare. No cases of LSIL showed full thickness p16 positivity. The staining intensity of the same cases were , % 25 strong, % 16.7 variable and % 58.3 weak . % 48.6 of all cases (17/35) was positive with screening kit (all HPV types). % 31.4 of all cases (11/35) was positive with HR-HPV. The distribution of this positivity was as % 35 of HSIL and % 26.6 of LSIL cases. All HPV type positivity rate was % 48.6,the distribution being % 50 of HSIL and % 46.6 of LSIL cases.
P16 is a highly sensitive marker of cervical epithelial dysplasia. Strong and full thickness staining of p16 in the cervix epithelium is highly supportive of HSIL diagnosis, while weak and basal/rare staining is in the favor of LSIL.All HPV positive cases were also p16 positive but no statistically significant relationship between HPV positivity and the intensity and the distribution of p16 was found. Although HPV is very sensitive for the detection of the infection, it is not helpful in the grading of SIL since an unignorable rate of HR-HPV positivity (% 26.6) was detected in LSIL group.

P 754

THE ROLE OF CELL CYCLE REGULATORS IN THE MULTISTEP PROCESS OF HPV-ASSOCIATED CERVICAL CARCINOMA

1- Abeer A. Bahnassy: Ass. Prof. Pathology
2- Abdel-Rahman N.Zekri: Prof. Virology&Immunology
3- Hanaa M. Alam El-Din: Lecturer of virology&Immunology
4- Osama A. Shawki: Prof. Gynaecology&Obstetrics

High-risk HPV (HR-HPV) types have long been implicated in the pathogenesis of cervical carcinoma with a reported interaction between HR-HPV oncogenic proteins and cell cycle regulators. We investigated the involvement of aberrant expression and coexpression of some cell cycle related genes in the multistep process of HPV16/18- associated cervical carcinogenesis.
Forty-three invasive squamous cell carcinoma (ISCC), 38 carcinoma in situ (CIS), 11 high grade dysplasia (HGD), 18 low grade dysplasia (LGD) and 20 normal cervical tissues were evaluated for aberrations in p53, mdm2, Rb, cyclin D1, cyclin E, CDK4, p21waf, p27 KIP1, p16INK4A and SPF using immunohistochemistry, flowcytometry and molecular techniques.
There was a significant increase in the expression level of cyclin E, CDK4, Rb, SPF and a significant decrease in the expression of p27 KIP1 in the sequence from normal mucosa to ISCC. Aberration involving cyclin D1, p21waf, p53, mdm2 and p16INK4A were detected in CIS and ISCC cases only.
In conclusion, infection of normal cervical mucosa by HR-HPV types leads to dysregulation of the cell cycle control via altering the expression of some cell cycle related genes. Aberrations involving p27 KIP1, cyclin E, Rb and CDK4 are early events, whereas aberrations involving the p53f pathway, cyclin D1 and p16INK4A are late events in the genetic cascade of cervical carcinogenesis. Together, these alterations lead to acceleration of the cell cycle with an increased proliferation rate and acquisition of more genetic damage.

P 755

DETECTION OF HPV IN TISSUE BIOPSIES: A COMPARATIVE STUDY OF TWO VERSIONS OF INNO-LIPA SYSTEM AND MY09/11 PRIMERS

M.A. García-Cabezas, C. Perna, D.A. Hardisson, I. Briones, J. Jiménez-Heffernan and A. Suárez
Pathology Services from Guadalajara University Hospital and La Paz (Madrid) University Hospital, Spain

INTRODUCTION: we have detected the different HPV genital genotypes by PCR in paraffin-embedded biopsies since 1993 using the primers MY09/11, that amplify a 452-bp DNA fragment. Since 2003 we have used the INNO-LIPA system version 1 (IL-1). IL-1 amplifies a short 65-bp DNA fragment followed by reverse hybridization with type-specific probes of the 25 most relevant genotypes. Since 2004 we have used the second version of this system (IL-2).
METHODS: during 2003-4 we performed both MY and IL-1 tests in 56 biopsies. During 2004-5 we performed both MY and IL-2 tests in another 56 biopsies. All the biopsies showed pathologic findings of HPV related lesions. The presence of HPV DNA, the total number of viral genotypes and the presence of mixed infections were compared between MY and IL-1 (group 1) and MY and IL-2 (group 2).
RESULTS. GROUP 1: MY detected HPV DNA in 40 biopsies (71%) and IL-1 in 53 biopsies (94%). The total number of viral genotypes detected by MY was 42 and by IL-1 was 71. Mixed infections were detected by MY in 2

biopsies (5%) and IL-1 in 11 biopsies (20%). The viral genotypes detected by MY and IL-1 were the same in 25 biopsies. IL-1 detected more viral genotypes than MY in 20 biopsies and MY detected more than IL-1 in 2 biopsies. GROUP 2: MY detected HPV DNA in 46 biopsies (82%) and IL-2 in 49 biopsies (87%). The total number of viral genotypes detected by MY was 50 and by IL-2 was 58. Mixed infections were detected by MY in 4 biopsies (8%) and IL-2 in 7 biopsies (14%). The viral genotypes detected by MY and IL-2 were the same in 31 biopsies. IL-2 detected more viral genotypes than MY in 11 biopsies and MY detected more than IL-2 in 5 biopsies. IL-1 and 2 typified 4 cases of MY-unknown viral genotypes in both groups.
CONCLUSIONS: IL-1 was more sensible than MY in the detection of HPV DNA, several viral genotypes and mixed infections. IL-2 has reduced these differences in sensitivity. The material used in this study does not allow us to determine whether IL-1 is over-detecting HPV DNA (false positive results) or IL-2 is under-detecting HPV DNA (false negative results). However, IL-2 reveals no discordances compared with MY.

P 756
RETROSPECTIVE STUDY OF 68 PATIENTS WHO HAD COLPOSCOPY-GUIDED BIOPSY: COMPARISON OF THE CYTOLOGY RESULTS WITH HISTOLOGY

METE Ozgur (*), YAVUZ Ekrem (*), TUZLALI Sitki (*), ILHAN Ridvan (*), OZLUK Yasemin (*), TOPUZ Samet (**), IYIBOZKURT Cem (**) and IPLIKCI Altan (*)
(*) Istanbul University, Istanbul Faculty of Medicine, Department of Pathology
(**) Istanbul University, Istanbul Faculty of Medicine, Department of Obstetrics and Gynaecology

Reducing morbidity and mortality is the main aim of the health system in the world. The incidence of cervical cancer has been declining in the last decades due to the Papanicolau (PAP) smear which is the preferred screening test for cervical squamous cell carcinoma and its precursors. A zero error standard does not exist in cytopathology. The false negativity or positivity were determined by many factors. We aimed to examine the final histological findings in patients who had a cervical intraepithelial lesion (CIN/dysplasia), atypical squamous cells of undetermined significance (ASCUS) on PAP smears and underwent colposcopy-guided biopsy.
This study is a retrospective review of 68 smears obtained from patients who had colposcopy-guided biopsy between 2002 to 2004 in a single center where 10000 PAP smears have been screening annually. All cases were examined by experienced gynaecopathologists.
Of 17 patients who had CIN 1 on the PAP smear, 15 had CIN 1 or higher lesion and 2 had benign changes (inflammation, reparation) on the final histology. All of 11 patients who had CIN 2 on the PAP smear, had at least CIN 1 on the biopsy. Only in one of the 21 patients diagnosed as CIN 3 on the PAP smear, dysplasia can not be found on the final histology. We later found out that this patient has recently received chemotherapy for leukemia. Of 14 patients diagnosed as ASCUS, six had CIN 1, two had CIN 2, four had CIN 3 and two had benign changes such as reparation and inflammation. Five patients who had benign cytologic changes, had undergone colposcopic examination, which revealed CIN 1 in three and CIN 2 in two patients.
Based on the results of our study, we determined a 7.7% of false negativity rate and a 4.8% of false positivity rate for the PAP smear examination. The efficiency of the PAP smear was 88.2%.
After the reassessment of patients having benign cytologic features, we found that sampling errors, which were possibly related to small lesions or those exfoliating few cells, were practically the main reason of the false negativity in our study. It is well known that chemotherapy induces cellular atypia mimicking those of dysplasia or carcinoma, which was present in one of our cases. Even with optimal conditions, about 5-10 % of false negativity exist in cervical cytology.

STANDARDS FOR THE HISTOPATHOLOGICAL REPORTING OF UTERINE CERVICAL NEOPLASIA

PELLEGRIN de VILLENEUVE Michèle 1-2, d'ANJOU Joelle 1, MERINO Céline 1-2, MAC GROGAN Gaëtan 1-2, MERCIER Sylvaine 1-2, BELLEANNEE Geneviève 1-2, ETCHARRY Francine 1-2, MASSOT-BORDENAVE Mireille 1-2 , CARTIER Isalelle 1, PETITJEAN Alain 1, CIRILO-CASSAIGNE Isabelle 2, MATHOULIN Simone 2, VACHER-LAVENU Marie Cécile 1
1Groupe National du Compte Rendu Standardisé du Col Utérin, Service Central d'Anatomie et Cytologie Pathologiques, CHU Cochin-27 rue du Faubourg Saint Jacques-75679 Paris Cedex 14
2 Réseau de Cancérologie d'Aquitaine, 229 cours de l'Argonne - 33076 Bordeaux Cedex

Current practices in cancer pathologies has resulted in pathologists globally joining together in the elaboration of a standard histopathological report of samples for uterine cervical neoplasia. The accomplishment of this form was possible with the support of the INCa (Institut National du Cancer), the DGS (Direction Générale de la Santé), the DHOS (Direction de l'Hospitalisation et de l'Organisation des Soins) and the InVS (Institut National de Veille Sanitaire). This required the following stages. Firstly, the constitution of a multicentric work group. Secondly, the feasibility tests to use this form. Finally, its validity. A regular update is planned in accordance with the standard types of literature. This standardised report form and its handbook have been developed with the assistance of bibliographical references, actual standardised reports, publications, ANAES recommendations, WHO proposed classifications, UICC, and a consensus of experts. This document should replace the original and be part of the computerised medical records. Its intention is to be used as a shared document between the pathologists and the practioners. It will supply the practioner with appropriate datas for patient care. It takes into account or not organised screening tests. It allows a homogeneous procedure in the diagnosis of uterine cervical neoplasia. It supplies cancer registers with the necessary data for the epidemiological surveillance, and finally it facilitates the elaboration of computerised datas for the relevant pathologies.The proposed report will contain precise datas on the practioner, the pathologist, the patient and the samples. It will give the most complete macroscopic and microscopic diagnosis as possible. Thus providing the key elements to allow for an objective prognosis and a therapeutic follow up of the patient. It will be succinct, clear, homogenous and standardised. Therefore, facilitating a better understanding by all practioners and pathologists.

P 758
DETECTION OF HPV GENOTYPES IN CERVICAL LESIONS BY THE HPV DNA CHIP AND SEQUENCING

NAM Jong-Hee, CHOI Yoo-Duk, *CHOI Ho-Sun, PARK Chang-Soo
Department of Pathology, and *Obstetrics & Gynecology, Chonnam National University Medical School

Introduction: Cervical cancer is the second most common cancer in terms of both incidence and mortality worldwide. Recently, there is some agreement that the availability of high sensitive human papillomavirus (HPV) tests offers the potential for replacement of conventional cytologic screening

programs. In addition, the importance of HPV testing has been increasing because genetic typing is required to predict clinical progression. Digene hybrid-capture (HC-2) technology was widely used for it is highly sensitive, and if appropriately used, highly specific as well. A newly introduced HPV detection technique in cervical lesion, the HPV DNA chip test, contains 24 HPV probes and has the advantage of being able to detect 24 HPV types at once.
Objective: In this study, we evaluated the accuracy of HPV DNA Chip test for detection and typing of HPV in cervical lesions by comparing with result of HPV DNA sequencing of same samples. In addition, we desired to find out the types which were not detected in HPV DNA Chip test by HPV DNA sequencing of HPV-other types.
Methods: The HPV DNA sequencing was performed in samples of 282 patients, where specific HPV type had been shown in HPV DNA Chip test. The sixteen cases where multiple HPV types had been found in HPV DNA Chip test were included in 282 cases. The sequencing was also performed in HPV-other type samples of 95 patients, where positive in HPV-PCR, but specific HPV type had not been found.
Results: In 257 cases (91.1%) of 282 cases, the HPV types of the HPV DNA sequencing test was in agreement with types of the HPV DNA Chip. In 16 cases (5.7%), the sequencing types were different from the types of HPV DNA Chip. But, in nine of 16 cases, types in HPV DNA sequencing were absent types in HPV DNA Chip test. The interpretation of HPV DNA sequencing was impossible in nine cases (3.2%). The HPV DNA sequencing test of 95 cases of HPV-other type showed that the sequencing types from 94 cases (98.9%) were absent types in HPV DNA chip test. In sequencing test of HPV-other type, HPV-81 (20.0%), HPV-62 (14.7%), HPV-84 (13.7%), and HPV-61 (13.7%) were frequently detected.
Conclusion: HPV DNA chip is an accurate method for detecting the 24 HPV genotypes.

DNA VERSUS RNA BASED METHODS FOR HUMAN PAPILLOMAVIRUS DETECTION IN CERVICAL NEOPLASIA
Lie AK (1), Risberg B (1), Borge B (1), Sandstad B (2,3), Delabie J (1), Rimala R (4), Onsrud M (5), Thoresen S (6).

Background. Given the results summarized in the 2005 IARC monograph, HPV testing is likely to be implemented as the primary screening test within few years. HPV tests detecting either HPV DNA or HPV E6/E7 mRNA are now commercially available, and needs to be validated before inclusion in clinical practice. The aims of this study were to compare DNA-based and mRNA-based methods for detection of high-grade cervical neoplasia.
Methods. HPV prevalence was analyzed in 383 women with positive index cytology, selected from gynecology clinics. All patients were investigated by a new PAP smear, histology and two commercially available HPV tests: Hybrid Capture II (Digene Corporation) and the Pre Tect HPV-Proofer (NorChip AS). Cases with positive DNA test and negative mRNA test, and cases with high-grade histology and negative HPV tests were retested with PCR and sequencing. We regarded the infection as latent or transient if sequencing revealed a HPV type included in both assays.
Results. High-risk HPV was detected in 99.7% of the histological confirmed high-grade lesions (CIN2+) (290/291). The DNA test was positive in 95% (275/291), and the mRNA test was positive in 77% (225/291) of the histological confirmed high-grade lesions. All invasive carcinomas were mRNA positive. The DNA test was significantly more often positive in benign and low-grade lesions, some of which were found to be false positive due to cross-contamination with unrelated types. High-grade histology was detected in 83% of women with normal cytology and positive mRNA test. Latent or transient infections were detected in 11 low-grade and 12 high-grade preinvasive lesions. Sequencing revealed high-risk HPV types included only in the DNA test in 35 high-grade preinvasive lesions, HPV 52 and 58 were the most prevalent HPV types.
Conclusions. These HPV tests have potential to improve the detection rate of high-grade cervical neoplasia, with some limitations. The mRNA test seems to be more appropriate for risk-evaluation. Larger scale, population based studies are necessary to evaluate the predictive values of HPV testing in Norway. National monitoring of HPV testing should be obligate and incorporate cytology and histology results in order to give recommendations for follow-up.

P 760
SQUAMOUS CELL CARCINOMAS OF THE VULVA: ASSOCIATED EPITHELIAL LESIONS AND VALUE OF P16 AND P53 IMMUNOSTAINING.
S. Landolfi, M. Santos, L.M. Puig-Tintoré, B. Mellado, A. Torné, E. Campo, J. Ordi
Departments of Pathology, Oncology and Obstetrics and Gynecology, Hospital Clínic-Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), University of Barcelona, School of Medicine, Barcelona, Spain

Introduction and aim: Two types of vulvar squamous cell carcinomas (SCC) have been delineated: human papillomavirus related (HPV+) and unrelated (HPV-) SCC. HPV+ tumors are basaloid or warty (B/W), are considered to arise in relatively young women, are frequently associated to undifferentiated vulvar intraepithelial neoplasia (VIN) and over express p16. HPV-tumors are keratinizing (KER), arise in elderly patients, are frequently associated with differentiated VIN, lichen sclerosus (LS) and squamous cell hyperplasia (SCH), and show a high proportion of p53 mutations that result in p53 immunohistochemical positivity. However, some overlap between HPV+ and HPV- tumors exist. The aim of our study was to evaluate the correlation between the two major types of SCC and concurrent epithelial lesions and determine whether p16 immunostaining could be a good discriminator between these forms.
Methods: All patients diagnosed of vulvar SCC treated in our institution with radical vulvectomy or partial resection from 1995 to March 2005 were included. 84 patients were identified. 4 to 20 slides of every case (mean 8), including tumor and non-neoplastic tissue, were reviewed focusing on histological type of tumor and concurrent epithelial changes. Immunohistochemical analysis of p16 and p53 was performed.
Results: 70 (83,3%) were KER SCC, whereas 14 (16,6%) were B/W type (9 and 5 respectively). LS and SCH were present respectively in 36 and 60% of KER and in 7 and 21% of B/W SCC ($p<0.05$). VIN was detected in 47% of KER and in 43% of B/W SCC. p53 was positive in 50 cases (67% of KER, 7% of B/W) and p16 in 18 cases (7% KER, 93% B/W). p16 and p53 positivity were almost always mutually exclusive. Interestingly, 3 out of 5 keratinizing SCC positive for p16 showed undifferentiated VIN, suggesting a relationship with HPV, and the only basaloid SCC negative for p16 was intensely positive for p53 and showed differentiated VIN and LS in the non-neoplastic skin, indicating an HPV-unrelated pathway.
Conclusion: p16 and p53 immunostaining, seem to discriminate adequately between HPV-associated and HPV-unrelated vulvar squamous cell carcinomas. A small percentage of keratinizing SCC are probably related to HPV infection, whereas a few tumors not associated to HPV may have a basaloid or warty histology.

P 761
EXTRACELLULAR SIGNAL-REGULATED KINASE 2(ERK 2) EXPRESSION IN CERVICAL

INTRAEPITHELIAL NEOPLASIA AND CARCINOMA OF THE CERVIX.

Kouneli S, Arvaniti H, Kapetanios V, Bogris P, Stylianidi A, Lazaris a, Bairaktari-Kouri E

The HPV protein E5 seems to be weakly oncogenic and has been suggested to potentiate the transforming activity of E7.The molecular mechanisms of E5-induced cell proliferation are transmitted through the activation of potent transcription factors by the ERK/MAPK signaling pathway.The key event in E5 induced cell proliferation involves the activation if the mitogen-activated protein kinases(MAPK),which include a pair of protein kinases known as ERK1 and ERK2.
The aim of this study is to investigate the usefulness of ERK2 expression in predicting the grade of CIN lesions as well as to compare the expression with that of cervical carcinoma.
Immunohistochemistry was performed on paraffin embedded sections of 76 CIN lesions(20 CIN1, 20 CIN2 and 36 CIN3)and 30 cervical carcinomas(21 squamous,9 adenocarcinomas) using standard procedures with the application of the ERK2 monoclonal antibody(Santa Cruz Biotechnology, USA 1/300 dilution).A semiquantitative scoring into 3 categories was used as follows:1.slight staining equivalent to that of normal squamous epithelium 2.moderately increased staining cytoplasmic and/or nuclear 3.intense diffuse cytoplasmic and/or nuclear staining.
Results:The frequency of strong ERK2 expression increased from 0% for CIN1 lesions to 61% for CIN3 lesions.Specifically the majority of of CIN1 lesions(60%) showed a weak cytoplasmic expression in the basal and parabasal layers equivalent to that of the normal squamous epithelium while 40% showed a moderately increased staining.In CIN2 lesions 40% of the cases displayed either a weak equivalent to normal(20%) or intense(20%) expression while the majority(60%) showed a moderately increased expression.Finally in CIN3 lesions only 11% showed weak ERK2 expression while 28% and 61% of the cases expressed ERK2 moderately and strongly respectively.In cervical squamous carcinomas moderate and strong expression was found in 91% of the cases in approximately equal percentages(48% moderate,43% strong)while in cervical adenocarcinomas all the cases showed either strong(67%) or moderate(33%) expression.
Conclusions:According to our study a direct relationship between the increasing grade of the CIN lesion and the intensity of ERK2 staining was found.Moderate and strong ERK2 expression was related to high grade lesions(CIN3 or cancer).All cervical adenocarcinomas showed either moderate or intense ERK2 expression while in 10% of squamous cee carcinomas only weak equivalent tonormal staining was found.

HUMAN PAPILLOMAVIRUS TYPES IN SQUAMOUS CELL CARCINOMAS AND ADENOCARCINOMAS OF THE UTERINE CERVIX IN REGION OF RIJEKA, CROATIA

KRAŠEVIÆ Maja, ŠIMAT Marina, GRAHOVAC Blaženka
Department of Pathology,Medical Faculty University of Rijeka, Croatia

Introduction: The association between human papillomavirus (HPV) infection and cervical cancer have been well established. The different carcinoma-associated HPV types have been reported world wide. However in Croatian population, such data have not been reported to date.
Purpose of the study: To analyse the frequency and distribution in HPV types in two different histological forms of uterine cervical carcinoma among the patients in region of Rijeka, Croatia.
Material and Methods: A retrospective analysis was undertaken on formalin fixed paraffin embedded specimens of 54 squamous cell carcinoma (SCCs) and 40 adenocarcinomas (ACs), including 15 adenocarcinoma in situ, from patients treated in Clinical Hospital Rijeka. HPV genotyping was performed by consensus and type specific primers directed PCR. The results were correlated with clinicopathologic parameters i.e.age of the patients, FIGO stage, histological subtype and grade of the lesions.
Results: Of the 94 cases examined, 87(92.5) were HPV DNA positive; 50/54 (92.6%) of SCCs and 37/40 (92.5%) ACs. Eight different HPV genotypes were detected: 6/11, 16, 18, 31, 33, 52, 74 and undetermined type X. HPV types 6/11, detectable in 9.1 % of HPV positive cases, were observed as a part of coinfection, except in one case of AC. HPV 16 was the predominant type in SCCs, detectable in 26/50 (52.0%) of cases, whereas HPV 18 was the most common type in ACs 25/37 (67.5%). HPV 31 and 33 accounted for 16.0 % and 8.0 % of HPV positive SCCs and 8.1% and 5.4 % of HPV positive ACs, respectively. In addition, multiple HPV types were found in 21/87 (24.1 %) of carcinomas, without significant correlation to the histologic type, with 19.9 % in ACCs and 29.0 % in ACs. No relationship was found between viral type and any of the clinico-pathologic parameters analysed.
Conclusion: Our results indicate that cervical carcinomas are largerly associated with HPV types 16, 18, 31 and 33 in our study group in Rijeka region, with statistically significant predominance of HPV 16 in SCCs (52.0%) and HPV 18 in ACs (67.5%).

The transformation zone of the cervix is the place where most malignancies appear. The epithelial turn over seems to differ here from that of more stable structures in the vicinity. The occurrences of squamous metaplasia makes this zone more prone to malignancies but the reason why this happens remains a matter of debate. The extension of the stem cell theory to solid tumors has prompted new insight into tumor genesis. Classically it is admitted that a bipotent stem-like cell, the subcolumnar cell, is the origin of squamous metaplasia of the cervix. In this study we identified expression of p63 , a homologue of the tumor suppressor gene p53 and cytokeratin 17(CK17) in metaplastic and neoplastic cervical lesions. Cervical tissue from archival paraffin blocks was available from 30 pacients which had variable lesions:mature squamos metaplasia, moderate and severe dysplasia and squamos invasive carcinoma . We noted p63 expression consistently in the nuclei of reserve cells, hyperplasia of the basal layer of the dysplastic and neoplastic epithelium of ectocervix , while CK17 was sporadically found in the basal layer of ectocervical epithelium and always present in the basal cells of squamos metaplastic epithelium. Also, CK17 has increased expression during progression of CIN, and diffuse stained in squamos carcinoma. Our results concluded that a considerable number of premalignant and malignant lesions of the uterine cervix express CK17 and p63 which is also found in the progenitor reserve cells.

P 764

LARGE CELL NEUROENDOCRINE CARCINOMA OF THE UTERINE CERVIX: A CLINICOPATHOLOGIC STUDY OF FIVE CASES.

Chanona Vilchis JG, Vela Chavez TA, Dominguez Malagon HR, Cantu de Leon DF, Perez Montiel MD.

Background: Cervical carcinoma in not developed countries is the first cause of death for woman's cancer, in Mexico 9,913 new cases were reported on 2000 whit 4,620 deaths in the same year. The large cell neuroendocrine carcinoma (LCNC)of the uterine cervix is a rare entity and few cases have been reported in the international literature. The LCNC have been described as aggressive tumor with "organoid" growth patterns (trabecular, insular and solid). The neoplastic cells are large whit vesicular nuclei, prominent nucleoli, atypical mitosis (3-12 per high power field) and necrosis.
Design: All the cases identified as small cell neuroendocrine or undifferentiated cervical carcinoma from a period from 1991 to 2003 were revised separately by three pathologist using the criteria described in the background. Immunohistochemical staining with cromogranin and synaptophysin were done. Clinical information was obtained from patient's charts.
Results: Five patients were selected using the previous mentioned criteria from a pool of 103 cases; the tumors where no consensus in the diagnosis were obtained were excluded. Patients age ranged in 43-61 years. One patient was stage IIA and four patients were stage IIB. Maximal dimensions were 8 cm. Two patients were treated with surgery, chemotherapy and radiotherapy, two patients with chemotherapy and radiotherapy without surgery and one patient was lost, this patient was associated whit adenocarcinoma of the colon treated whit surgery and chemotherapy. Immunohistochemestry study was done, all the cases were positive for cromogranin and synaptophysin. Disease progression was documented in three patients; two with cerebral metastasis, one with node metastasis; one patient had persistent disease. Two patients are alive whit disease 17 and 18 months after diagnosis and two die with disease 6 and 8 months after diagnosis.
Conclusions: large cell neuroendocrine carcinoma is a rare neoplasia frequently confused with small cell neuroendocrine carcinoma or undifferentiated carcinoma. The patients had a high grade tumors whit advanced disease, and despite aggressive treatment, the patients have had progression and early recurrence.

P 765

SMALL AND LARGE CELL NEUROENDOCRINE CARCINOMAS OF THE UTERINE CERVIX. A REPORT OF 10 CASES

KUBELKA-SABIT Katerina1, PLASESKA-KARANFILSKA Dijana4, PRODANOVA Irina1, YASHAR Genghis1, HADZI-NICHEVA Biljana3, VELJANOSKA Slavica2, ZOGRAFSKI Georgi1, BASHESKA Neli 1

4Research Center for Biotechnologic Engineering and Genetics, Macedonian Academy of Science and Arts, Skopje, Republic of Macedonia

BACKGROUND: Small (SCC) and large cell (LCC) neuroendocrine carcinomas of the uterine cervix are rare and highly aggressive neoplasms. Their association with the integration of human papilloma virus (HPV) DNA of the types 16 or 18 has been documented in many studies.
AIMS: The purpose of this study is to present the clinical, histopathological, immunohistochemical characteristics and the presence of HPV DNA in ten cases of SCCs and LCCs of the uterine cervix.
METHODS: Seven patients with primary SCCs and three patients with LCCs of the uterine cervix were diagnosed at our department between 1989 and 2004. Clinical data were retrieved from the patients' files and included age, recurrence and survival. Routinely processed operative and/or biopsy specimens were used for immunohistochemical stains and hybridization procedures. Primary antibodies against several epithelial, neuroendocrine, mesenchimal and proliferative markers were included. The presence of HPV DNA was assessed by conventional in situ hybridization (ISH) using probes for HPV 16/18 and 31/33/51 and polymerase chain reaction (PCR), using three primers (MY09/11, GP5+/GP6+, E6). Six of the patients were surgically treated. Postoperatively, four received chemo and/or radiotherapy, two rejected further treatment and one patient was lost to follow-up. The other four patients underwent conservative treatment due to advanced disease.
RESULTS: The patients' age ranged from 25 to 71 years. Histologically, the tumors showed trabecular, nesting or a sheet-like pattern, with areas of necrosis and frequent mitoses. Their neuroendocrine nature was confirmed by diffuse positive immunostaining for neuron-specific enolase and low molecular weight cytokeratins. Focal positivity for chromogranin, synaptophysin and S100, together with pancytokeratin and EMA, was evident in the majority of the tumors. Their aggressive potential was confirmed by high Ki-67 proliferative index (50-90%). HPV types 16/18 were found in 4 tumors using ISH, and HPV 16 in additional 3, using PCR (type 16). 3 of the patients developed distant metastases and died 7-48 months after receiving partial or full treatment, while 6 are alive and without evidence of disease after 4-38 months.
CONCLUSIONS: SCCs and LCCs are highly aggressive neoplasms. However, early diagnosis and combined therapy may improve survival in some patients. Although mainly a morphologic diagnosis, immunohistochemistry may help in the diagnosis of SCC and LCC.

P 766

EVALUATION OF TUMOUR NECROSIS FACTOR (TNF ALPHA_) IN EUTOPIC &ECTOPIC ENDOMETRIA OF WOMEN WITH ENDOMETRIOSIS& ENDOMETRIUM OF HEALTHY WOMEN

PROF. DR.MAGDA HASSAN,PROF.DR.M.E.AZZAM ,PROF.DR.M.H.NASR EL DIN, DR.KHAED SAIID,DR. A. M. ABDEL AZIZ.
DEPT. OF PATHOLOGY,OBSTETRICS & GYNECOLOGY.AIN SHAMS UNIVERSITY.

To achieve a successful implantation, in addition to adequate embryonic quality,an appropriate endometrium is mandatory. Some alterations have been found in the eutopic endometrium of women with endometriosis that could be responsible, at least in part,for the subfertility in these women.
The aim of this study is to compare eutopic &ectopic endometrium of women with endometriosis with that of healthy controls , regarding expression of TNF alpha using immunohistochemical staining.Also, to gain more information about the possible role of cytokine TNF alpha in autocrine & paracrine growth regulation of endometriosis.
The study included 30 patients having endometriosis & endometriotic cysts in the ovary (study group) .Those patients were subjected to laparoscopy to confirm the diagnosis & obtain a biopsy of the endometriotic cyst , besides an endometrial biopsy. The control group included 30 healthy fertile women without endometriosis ,they did laparoscopy for tubal ligation followed by endometrial biopsy.For both groups the biopsies obtained were immunohistochemically stained & examined for TNF alpha expression.

.
The results revealed higher expression of TNFalpha in eutopic endometrium of patients having endometriosis than endometrium of healthy fertile female controls,with a highly statistically significant difference .Theses results have been confirmed by using image analyzer computer system which measured TNF alpha expressed in tissues quantitatively by measuring the optical density. Optical density was then expressed in the form of sum grey & mean grey.The sum grey of TNF alpha expression in eutopic endometrium of endometriosis patients was higher than that of healthy women (control group).
This study shows that increase TNF alpha expression in eutopic endometrium & ovarian endometriosis may explain why endometriosis develop in certain females, as TNF alpha was implicated as one of the factors related to the attachment & growth of the ectopic endometrium through its angiogenic & paracrine activities ..Besides high TNF alpha expression in the endometrium of patients having endometriosis may be a cause of endometriosis- associated infertility through affecting implantation.

THE EVALUTATION OF MALIGNANCY POTENTIAL IN ENDOMETRIAL HYPERPLASIA BY USING PROLIFERATION MARKERS (PCNA AN KI-67)
Itýr GERÇEKER MD, Sema ZERGEROĐLU MD, Tuðrul AYDOĐDU MD, Ümit BÝLGE MD, Leyla MOLLAMAHMUTOĐLU MD.

Introduction and objects : Endometrial hyperplasia can be described as proliferation of endometrial glands by disordered number and shape with an increase in gland/stroma ratio. The aim of the study is, to evaluate the malignancy potential of endometrial hyperplazia by using proliferating cell nuclear antigen (PCNA)and Ki-67. Which are known as proliferation markers.
Methods : We evaluated 62 pations (20 of them control group), ages between 25-62, whom are operated or taken specimen by D&C in Zekai Tahir Burak Womens Health and Education Hospital, between years 2002-2003. After routin procedures of preparation, pathologic specimens are labeled with PCNA and Ki-67 by using immunohystochemical methods. For statiscal analyses, Anowa and Post Hoc Tukey tests were used. ($p<0,05$)
Results : In complex atypic hyperplasia, both PCNA an Ki-67 expression was higher than in control group, with a statical significance.
Discussion : We suggest that, theese proliferation markers (PCNA and Ki-67) can bu useful specially to determine the malignancy potential of complex atypic hyperplasia of endometrium.

HISTOPATHOLOGIC CHANGES AFTER UTERINE ARTERIAL EMBOLIZATION WITH TRIS-ACRYL GELATIN MICROSPHERES
WEICHERT Wilko (1), DENKERT Carsten (1), GARUDER-BURMESTER Annett (2), KURZEJA Roberto (2), HAMM Bernd (3), DIETEL Manfred (1), KRÖNCKE Thomas (3)
(1) Institute of Pathology, (2) Department of Gynecology and Obstretics, (3) Department of Radiology, Charité University Hospital, Berlin, Germany

Introduction: Uterine artery embolization (UAE) as an alternative treatment of uterine fibroids and adenomyosis uteri becomes increasingly popular. Because there is considerable uncertainty with respect to the wanted and unwanted morphological changes induced by UAE we conducted a histopatholgic study on post UAE tissue specimen. Methods: A total of 173 women were treated with UAE using tris-acryl gelatin microspheres (TGMS) for either symptomatic adenomyosis or leiomyoma. Surgical specimen of 8 women who underwent subsequent myomectomy or hysterectomy were evaluated by conventional histology and immunohistochemistry.
Results: TGMS were readily apparent in both macroscopy and routine histology. In patients with fibroids, TGMS accumulated preferably in medium size vessels in the direct tumor vicinity. In patients with adenomyosis, a random distribution of TGMS was noted throughout the outer myometrium. A granulomatous foreign body reaction occurred in the vicinity of particles, eventually followed by formation of vascular pseudoaneurysms and complete vessel destruction. Leiomyoma treated with UAE showed either fibrinoid necrosis, coagulative necrosis or no change at all. Increased mitotic activity and tumor cell polymorphism was evident in some but not all treated smooth muscle tumors. Foci of adenomyosis remained unaltered.
Conclusions: In conclusion, after UAE with TGMS, particles were identified predominately but not exclusively at the periphery of fibroids. Pathologists must be aware of the morphologic changes induced by UAE in leiomyoma, to avoid misinterpretation of induced tissue alterations as signs of malignant tumor growth.

P 769
PTEN IMMUNEXPRESSION IN RANDOMLY SELECTED ENDOMETRIAL POLYPS
EREN Funda, ERBARUT Ipek
Marmara University School of Medicine, Deaprtment of Pathology, Istanbul, Turkey

Endometrial polyps are common in women over 40 and are thought to arise due to some type of hyperplastic process. Although most of them are benign, carcinoma developing in polyps is a rare but well-known condition especially in postmenopausal women. Recently, PTEN inactivation has been shown to be a common event in endometrial carcinogenesis. Also PTEN loss has been documented in some normal-appearing endometrial glands of 43% of premenopausal women suggesting that PTEN loss might be an early step in endometrial carcinogenesis. In order to search for the PTEN expression pattern in endometrial polyps we investigated the immunhistochemical expression of PTEN in 50 randomly selected endometrial polyps. The morphology of polyps were atrophic (n:21), functional (n:17), inactive (n:12) and hyperplastic (n: 1). PTEN was lost in more than 50% of the glands in 88% (n:17) of atrophic polyps. Also in the 2 of the 3 polyps with secretory epithelium there was diffuse PTEN loss. On the contrary there was diffuse PTEN expression in 75% of proliferative glands in functional polyps . None of the glands with PTEN loss showed atypical histological findings. In polyps containing both proliferative and inactive or atrophic glands, PTEN-null glands were restricted to atrophic or inactive glands. Expression of PTEN in stromal cells also was parallel to that of the epithelia. This data shows that in polyps PTEN is expressed strongly in proliferative epithelium but it is commonly decreased or lost in any kind of nonproliferative epithelium. Although it is strongly suggested that PTEN-inactivated glands could be 'latent precancers' care should be taken in evaluating the immunexpression in the absence of morphologic evidence of atypia. In conclusion, we think that finding PTEN inactivated glands in a polyp could be valuable in proliferative type glands but in normal-appearing nonproliferative epithelium it seems like a normal event.

(3)Departamento de Patologia da Faculdade de Medicina de Ribeirão Preto da Universidade de São Paulo.

Introduction: Endometrial polyps likely originate from basal layer but their biology underlying is not fully understood. Recently, p63, an important protein in regulating epithelial proliferation and differentiation, has been described as a marker of basal/ reserve cells in female genital tract.
Objective: Our objective was to verify if p63 is expressed differently in postmenopausal endometrial polyps and adjacent endometrium.
Design: In this study we evaluated the p63 expression in 36 specimens of postmenopausal endometrial polyps, obtained by hysteroscopic polipectomy realized in a tertiary care university hospital, using a monoclonal antibody clone 4A4 (1:200), which recognizes all p63 variants.
Results: The majority of endometrial polyps (94.4%) were p63-positive. Otherwise, only 5.6% of adjacent endometrium had presented rare nuclei immunostaining for p63 ($P < 0.0001$). Endometrial polyps had presented homogeneous pattern of distribution of p63 immunostaining.
Conclusions: Our results are an evidence of the maintenance of a basal cell immunophenotype in postmenopausal endometrial polyps. Furthermore, they suggest that P63 has a role in the pathogenesis of endometrial polyps and emphasize the necessity of more studies about P63 role and its different isoforms in the biological and clinical behavior of endometrial polyps.
Key-words: endometrial polyps, menopause, basal cells, P63.

P 771
HISTOPATHOLOGIC DIAGNOSES OF THE ENDOMETRIUM OBTAINED BY CONSECUTIVE BIOPSY PROCEDURES IN 1699 FRENCH AND 2887 ISRAELI WOMEN.

Czernobilsky, Bernard1, Lifschitz-Mercer Beatriz2,Bergeron Christine3
1PATHO-LAB Laboratories, Ness Ziona, Israel
2Institute of Pathology, Tel-Aviv Medical Center, Tel-Aviv, Israel
3Laboratoire Pasteur-Cerba, France

Introduction: Histologic examination of the endometrium is a common diagnostic procedure in peri and menopausal women with abnormal bleeding and/or thickened endometrium by ultrasound (US).
Purpose: This study, performed in France and Israel, was undertaken to compare frequency of histologic diagnoses in both populations and correlate the results with clinical information.
Methods: Hematoxylin-eosin stained slides of endometrial formalin fixed, paraffin embedded tissue from 1699 French and 2887 Israeli women aged 45 and above were examined independently by pathologists in each country.
Results: Proliferative endometrium was present in 22.3% of the French and 28.3% of the Israeli cases. Secretory endometrium including menstrual was seen in 10.1% of French and in 12% of Israeli patients. Atrophic endometrium, mostly in menopausal patients was diagnosed in 48.4% of the French and 32.2% of the Israeli population. No tissue was available for histologic evaluation in 5.5% of the French and in 10% of Israelis, most of them menopausal. Chronic endometritis was diagnosed in 0.2% of Israelis but none in French patients. Thus, in 86.3% of the French and in 82.5% of the Israeli women, the histology was within normal range of the age group studied. Endometrial polyps were found in 9.4% of the French and in 9.0% of Israelis. Endometrial adenocarcinoma was diagnosed in 2.1% of French and 2% of Israeli women. The only significant discrepancy between the French and Israeli series was simple hyperplasia without atypia diagnosed in 1.7% of the French and 6% of the Israelis. Complex hyperplasia was rare in both populations (0.1%). Atypical hyperplasia was also rare (0.4% in the French and none in the Israelis). Most likely these cases were classified as well differentiated endometriod carcinoma.
Conclusion: Histopathologic diagnoses of endometrium in French and Israeli populations showed with few exceptions remarkable similarities. Thickened endometrium (measured by US) and abnormal bleeding were not restricted to women with polyps, hyperplasia or carcinoma, but were present in the entire histopathologic spectrum including in atrophy.

P 772
EXPRESSION PATTERN OF OSTEOPONTIN (OPN) IN ENDOMETRIAL CARCINOMA – CORRELATION WITH EXPRESSION OF THE ADHESION MOLECULE CEACAM1

BRIESE Juliane, SCHULTE Heinrich M., LÖNING Thomas, BAMBERGER Ana-Maria

Introduction:
OPN and CEACAM1 have diverse biological functions in the uterus throughout the estrous cycle and have been shown to interact with integrin beta3. OPN is a glycoprotein of the extracellular matrix, which has been shown to mediate cellular migration and invasion and to contribute to tumorigenesis in several types of cancers. CEACAM1 is an adhesion molecule of the carcinoembryonic antigen family which we have recently found to be expressed in endometrial cancer and which has been shown to be down-regulated in colorectal and breast cancer.
Purpose:
Endometrial carcinoma is the most frequent invasive malignancy of the female genital tract in developed countries. The present study was designed to investigate the expression pattern of OPN in the normal human endometrium and in endometrial carcinomas and to correlate it with the expression of CEACAM1.
Material and methods:
In the present study, immunohistochemistry and immunofluorescence with specific antibodies were performed on a series of 20 normal endometrial samples and 40 endometrial carcinomas to investigate the expression pattern and cell-type specific localization of OPN and to correlate it with the expression of CEACAM1. In addition, western blot was performed on normal human endometrium and endometrial neoplasia.
Results:
Strong OPN expression with a consistent cytoplasmic localization in epithelial glandular cells was observed in the normal human endometrium in 80% of the samples of the proliferative and secretory phase (score 8-12). CEACAM1 showed similar results. Strong expression of OPN could be observed in 35 (87,5%) of the 40 analyzed endometrial carcinomas. Of the 40 analyzed tumors, 19 (47,5%) were in the high score (8-12) category with a strong OPN expression level, nine tumors of 40 (22,5%) showed a moderate score (4-7) category. With increasing malignancy grade, increasing areas with low OPN expression level or complete loss of OPN expression could be observed. CEACAM1 had shown similar results and was found to be co-expressed with OPN in normal human endometrium and in endometrial neoplasia.
Conclusion:
The expression pattern of osteopontin in endometrial tissue indicates that it might play a role in the pathogenesis of

endometrial cancer (possibly as a functional complex with CEACAM1) and to be useful as an additional diagnostic marker for such lesions. The correlation between pathological stage and OPN suggests a role for OPN in tumor prognosis.

P 773
MALIGNANT LYMPHOMA OF THE UTERUS: A CLINICOPATHOLOGIC ANALYSIS OF 14 CASES
HP Chien, SM Jung, S Hsueh, WY Chuang, TT Kuo.
Department of Pathology, Chang Gung Memorial Hospital, Tao Yuan, Taiwan

Introduction: Non-Hodgkin¡¦s lymphoma involving uterus is uncommon. Most tumors arise in the cervix while those of the uterine corpus are extremely rare. We evaluate the clinicopathologic features of 14 cases in Taiwan and reclassify them using new WHO classification.
Methods: Fourteen cases of Non-Hodgkin¡¦s lymphoma involving the uterus were retrieved from the pathology file of Chang Gung Memorial Hospital from 1987 to 2004 and reclassified by new WHO classification. Pathology slides, immunochemical study, and clinical information were reviewed.
Results: Patients ranged from 20 to 78 years (mean, 51.8 years). Of fourteen cases, eleven had primary tumor involving uterus at the presentation and three were secondary cases. The most common presenting symptoms were vaginal bleeding (43%). Histologically, nine tumors were diffuse large B-cell lymphoma (DLBCL) (5 centroblastic variant, 4 immunoblastic variant), three were follicular lymphoma and two were Burkitt¡¦s lymphoma. Six cases (43%) involved cervix (5 DLBCL, 1 Follicular) and were stage IE or IIE. Three cases (21%) involved corpus (all DLBCL) only and were all stage IVE. Five cases (36%) involved both cervix and corpus (2 Burkitt¡¦s, 2 Follicular, 1 DLBCL) and were stage IIIE or IVE. Follow-up information was available for 10 cases and ranged up to 75 months (mean, 26.9 months). Two follicular lymphomas relapsed in uterus transformed to diffuse large B-cell lymphoma 2 and 26 months after the diagnosis and were both stage IV cases. All low-stage (IE or IIE) cases received chemotherapy and were all alive without recurrence for 1-75 months (mean, 29.2months). Two stage IV cases died 0.5 and 2 months after the diagnosis.
Conclusion: Our study showed that malignant lymphomas involving cervix are all low stage irrespective of histological type. However, those involving uterine corpus (with or without cervical involvement) are of high-stage disease and more aggressive tumor type. Two cases of Follicular lymphoma showed transformation to diffuse large B-cell lymphoma.

P 774
AN UTERINE PECOMA : A CASE REPORT
IRVANLOO Gity, NOZARIAN Zohre
Cancer institute, Imam Khomeini Hospital, Tehran University of Medical Sciences

Epithelioid mesenchymal tumors of the uterus were previously considered to be either from smooth muscle or endometrial stromal lineage, but recently a new family of lesion have been described including HMB45 + epitheliod cells with clear to granular cytoplasm and perivascular distribution.
We described an uterine PECOMA in a 33 years old woman that tumor cells were positive for HMB45 but negative for epithelial and smooth muscle markers.

P 775
LOW GRADE ENDOMETRIAL STROMAL SARCOMA OF THE UTERUS WITH EXTENSIVE ENDOMETRIOID GLANDULAR DIFFERENTIATION
CC Wu, SM Jung, S Hsueh, CH Lai
Department of Pathology and Department of Obstetrics and Gynecology, Chang Gung Memorial Hospital, Taoyuan, Taiwan

Introduction: Low grade endometrial stromal sarcoma (LGESS) is a rare tumor of uterus. Occasional cases may cause problems in differential diagnosis because of variable patterns: epithelioid cells, sex-cord-like differentiation, benign or malignant endometrioid glands, smooth muscle metaplasia, and myxoid areas. We reported a rare case of LGESS with extensive glandular differentiation.
Case report: A 29-year-old woman presented with a painless palpable mass in the left lower abdomen for a month. She went to local hospital and a left ovarian mass with suspect of malignancy was noted under sonography and the CA-125 was elevated. She received left salpingo-oophorectomy, and hormone therapy after surgery for four months. Then she was transferred to our hospital for further management. Hysterectomy was performed. On gross examination, an ill-defined, tan to yellowish elastic multi-nodular mass measuring 8 cm in maximal diameter was in the myometrium. Histologically, the tumor diffusely penetrated the myometrium and lymphovascular space as irregular tongues or nests. It composed of oval or spindle tumor cells with rich network of delicate small arterioles and focal myxoid and fibrous stroma. The cells exhibited mild nuclear pleomorphism and a mitotic rate of 10/10 HPF. Most of the tumor also contained diffusely benign-appearing endometrioid glands. Immunohistochemical stains showed that the tumor cells were positive for ER, PR, smooth muscle actin, and CD10, and negative for desmin.
Conclusion: The differential diagnosis of LGESS with extensive glandular differentiation includes endometriosis, adenomyosis, endometrial stromal sarcomas arising in adenomyosis or endometriosis, and adenosarcomas. It is important that LGESS with extensive glandular differentiation in myometrium not to be mistaken for adenomyosis.

P 776
DEPICTION OF ANGIOGENIC AND LYMPHANGIOGENIC FACTORS INCLUDING VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF-C), PROLACTIN (C-17), PLATELET DERIVED GROWTH FACTOR (PDFG-A), FIBROBLASTS GROWTH FACTOR –1 (FGF-1), AND THEIR EXPRESSION IN 90 CASES OF ENDOMETRIOID AD
CATALANO Edison M.D., WEIDMANN James BSCT HTL (ASCP) Cooper University Hospital, Camden, NJ USA

Introduction: PDGF-A (N-30) is a mitogen for mesenchymal cells, which plays an important role in the angiogenesis and progression of tumor. The Vascular Endothelial Growth Factor C is a member of the family of growth factors, which is an important endothelial cell mitogen and is associated with an increase in angiogenesis and lymphangiogenesis. The increase in expression of Prolactin (C-17) protein has been related to a more aggressive tumor behavior.
The fibroblastic growth factor-1 (FGF-1) is a growth factor that stimulates the proliferation of mesenchymal, epithelial and neural ectodermal cells.
Purpose: This study was to investigate the relationship of the overexpression of VEGF-C, Prolactin (C-17), PDGF-A (N-30), and FGF-1 in 90 cases of invasive endometrioid adenocarcinoma, the effects of these factors over the angio and lymphangiogenesis. Also, through the survival tables we evaluate the prognostic significance of overexpression of these factors, as well as the relationship with the staging of the tumor and degree of differentiation.
Methods: Formalin fixed and paraffin embedded sections of the endometrial tumors were obtained from 90 cases. Immunohistochemical staining was obtained for VEGF,

Prolactin (C-17), PDGF-A (N-30) and FGF-1, and the measurement of the action of these factors, over the vascular proliferation evaluated with CD-34 and the microvascular density (MVD).
Summary of Results: In the 90 cases studied there was a perfect correlation in 50% of the cases between the VEGF-C and the increase in angiogenesis. Also, Prolactin and PDGF-A (N-30) showed an excellent correlation between the antibody staining (overexpression), in relationship to the tumor differentiation, staging and survival statistics.
In general the staining of this antibody, FGF-1 (C-19), was lighter in comparison with the previous and shows a diffuse cytoplasmic staining with no nuclear staining. There were more negative cases and the only positive cases were only 2+ or 3+. The correlation; however, with the survival was excellent, as well as with the staging and degree of tumor differentiation.
Conclusion: The overexpression of the factors VEGF-C, Prolactin (C-17), PDGF-A (N-30) and FGF-1 (C-19) demonstrated a cytoplasmic overexpression of these antibodies that activates the angio and lymphangiogenesis and leads to a more rapid tumor growth, higher stage of the disease and more aggressive clinical behavior demonstrated with the statistic analysis.

P 777
ABERRANT CDX-2 EXPRESSION IN SQUAMOUS MORULES IN ENDOMETRIOID ADENOCARCINOMA AND BENIGN ENDOMETRIAL LESIONS. –IMMUNOHISTOCHEMICAL ANALYSIS OF HOMEOBOX GENE TRANSCRIPTION FACTOR CDX2 AND PDX1-
WANI Yoji, NOTOHARA Kenji, TSUKAYAMA Choutatsu

Introduction: Cdx2 protein is a intestine-specific homeobox gene transcription factor that plays an important role in the regulation of differentiation of intestinal epithelium. Only a few data exist with Cdx2 expression of endometrial lesions. Pdx1 is also a homeobox gene that plays an essential role in the development or exocrine and endocrine of pancreas. Pdx1 expression is observed not only in the pancreas but also in Brunner's glands and pyloric glands. Little is known whether Pdx1 is expressed in the endometrium.
Purpose of Study: To investigate the potential role of Cdx-2 and Pdx-1 in endometrial lesions, we performed immunostaining for Cdx-2 and Pdx-1.
Methods: We selected 17 cases of normal or benign endometrial lesions(NBEs), 20 cases of Atypical endometrial hyperplasia(AEH)/endometrioid adenocarcinoma(EAC) with Squamous metaplasia(SqM), 24 cases of AEH/EAC without SqM. We defined that SqM is consisted of morules(MOs) and/or mature squamous cells(SCs). Cdx2 and Pdx1 expression was evaluated in formalin-fixed, paraffin-embedded materials. All cases were immunostained with the Envision+ method(DAKO), using a monoclonal anti-Cdx2 antibody(CDX2-88, 1:200 BioGenex), and a polyclonal rabbit anti-Pdx1 antibody(1:50 TransGenic Inc.). We used the following scoring system for Cdx2 and Pdx1 immnostaining: 0= negative; 1=1% to 10%; 2=11% to 50%, 3=51% to 100%.
Results: Four of 13 NBE cases contained foci of MO, where intense immunoreactivity for Cdx2 was seen. All AEH/EACs cases with SqM, except one (high-grade adenosquamous carcinoma), had variably Cdx2-expressed cells. In paticular, most foci of MOs in AEH/EACs are intensely positive, while sporadic immunoreactivity for Cdx2 was seen in foci of SCs. Neoplastic glandular cells in the backgrounds of SqM were variably Cdx2 positive in itself. Glandular cells were sporadically positive in six AEH/EACs without SqM. None of NBEs and AEH/EACs revealed positive for Pdx1.
Conclusion: We should note there are aberrant and distinct Cdx2 expressions for MO foci in NBEs. In four cases with MOs, Cdx2-positive cells are sporadicaly seen in glandular epithelium. In other words, morular formation itself seems to be made by intraluminal proliferation of Cdx2-positive glandular cells. Cdx2 expressions in MOs of NBEs and AEH/EACs tend to be very similar to that of nuclear beta-catenin(data not shown). Pdx1 does not seem to be related to NBEs and AEH/EACs.

P 778
CLINICO-MORPHOLOGICAL CHARACTERISTICS OF CANCER ARISING IN ENDOMETRIAL POLYPS
DERIZHANOVA Irina, VOLOSHIN Vladimir, VOLOSHINA Nina

Aims: to study morphogenesis of the carcinoma, arising in polyps of the uterus mucous membrane (EP).

The data of the clinical observations were analyzed. Endometrium scraps and the excised uterus and appendages from 16 patients with histological proved cancer in EP were subjected to common histological and histochemical examinations, the receptors of estrogen (ER) and progesterone (PR), as well as the markers of Ki67 (MIB-1) proliferation and p53, bcl-2 àpoptosis being simultaneously clearly seen.

Endometrioid adenocarcinoma (EA) was diagnosed in 13 of these patients. The patients age averaged 52,2 years, most of whom had their menstrual cycle still alive. 84,6 % of these patients suffered adiposity, 76,9 % - had hypertension, 61,5 % - diabetes. In all 13 patients ÅÀ was accompanied with àdenomyosis, uterus leiomyoma and hyperplasia of the ovarian theca. In 10 cases ÅÀ in Ò1à stage was well differentiated (G1). In 3 patients of Ò1b stage of EA it was of grade 2 (G2). ÅÀ was found to develop in polyps with diffuse (8) or focal adenomatosis (5), epithelium metaplasia and dysplasia I - III stage. Diffuse (5) or focal (5) simple (6) and complex (4) hyperplasia was seen in surrounding endometrium. The receptors of sexual hormones in prolipherating epithelium polyps and ÅÀ were exhibited in abundance. As epithelium àtypia grew, the ER content, PR in particular, was noted to decrease. The expression of Ki67, p53 was gradually intensifying.

Serous (SA) adenocarcinoma (G2) of T1c, Ò2 stages was found in 67-75-year - old women with the episodes of bleeding during menopausa (3 cases). The tumor was embedded in adeno-fibrous polyps accompanied by endometrium cyst atrophy. No attributes àdenomatosis and epithelium metaplasia were revealed. PR in the tumor was not revealed either. Poorly positive reaction to ER was demonstrated in some single epithelium cells, SA stroma and in the surrounding polyp. Expression Ki67 and p53 in cells was positively higher, compared to that of in the polyp surrounding epithelium and in àtrophic endometrium, with bcl-2 being reduced.

Conclusion: ÅÀ (81,3 %) developed in the polyps followed by àdenomatosis, metaplasia, epithelium àtypia and corresponded to estrogen-dependent neoplasia. SA (18,7%) embedded in adenî-fibrous polyps accompanied by the atrophy of glandular epithelium and were characterized by a high proliferation activity and corresponded to estrogen-independent carcinoma.

2) Department of Obsterics and Gynecology, Mito Kyodo General Hospital, Mito, Japan.
3) Hayakawa Clinic, Hitachinaka, Japan.

4) Department of pathology, The Institute of Chemotherapy, Ichikawa, Japan.

Introduction Endometriosis of the extraperitoneral part of the round ligament is very rare, from 0.4 to 0.6 % in the literature, mostly on the right side. Carcinoma arising from this endometriosis is an extremely rare event. Only a few cases have been reported. We present a case of endometrioid adenocarcinoma arising from endometriosis of the left round ligament.
Case report A 41-year-old woman, gravida III, para I, presented a left inguinal mass. Histerectomy with bilateral salpingo-oophorectomy and a tumorectomy ware performed under the clinical diagnosis of ovarian carcinoma and ltinguinal metastasis. The left inguinal tumor, a grey-whitish solid mass, arised from the extraperitoneal part of the round ligament. Frozen sections and imprint cytology suggested a epithelial malignant tumor. Macro- and microscopical examination revealed that uterus and bilateral adnexa were within normal limit. However the inguinal tumor was diagnosed as endometrioid adenocarcinoma(G3) associated with endometriosis. It was suggested that the tumor was arising from endometriosis of the extraperitoneal round ligament. Thereafter chemotherapy was performed. The patient is currently 2 years free of disease after operation.
Conclusion Extraperitoneal endometriosis is extremely rare moreover on the left side, malignancies arising from that should be considered in the differential diagnosis in women with an inguinal mass of reproductive age.

P 780
CELLULAR RETINOL BINDING PROTEIN-1 IS VARIABLY EXPRESSED IN ENDOMETRIAL CARCINOMA AND CORRELATES WITH HISTOLOGICAL GRADING

Augusto Orlandi1, Amedeo Ferlosio1, Arianna Francesconi1, Beatrice Lifschitz-Mercer2, Giulio Gabbiani3, Bernard Czernobilsky4, Luigi Giusto Spagnoli1

3Institute of Pathology and Immunology, University of Geneva, Switzerland
4Patho-Lab Laboratories, Ness-Ziona, Israel

Cellular retinol binding protein-1 (CRBP-1) contributes to maintain the differentiated state of the endometrium through regulation of retinol bioavailability of endometrial epithelial cells. Purpose of the study was the determination of CRBP-1 expression by immunohistochemistry in a consecutive series of 8 atypical hyperplasias and 42 endometrial carcinomas. Methods used: 40 endometrioid (well-differentiated =14; moderately differentiated =18; poorly differentiated n=8) and two serous adenocarcinomas were stained using a polyclonal antibody to CRBP-1. Staining was graded according to the percentage of tumor cells stained: intense (>75% positive), intermediate (25-75% positive) and weak or absent (<25% positive). The slides were examined independently by two pathologists, with an intervariability of less than 5%.
Summary of the results: CRBP-1 staining was mainly cytoplasmic. A high expression of CRBP-1 was observed in atypical hyperplasia and well-differentiated adenocarcinoma, with no significant differences between these two groups. The positivity was the highest in areas of squamous differentiation. A significant decrease of CRBP-1 immunostaining was detected with the progressive increase of histological grade of endometrial carcinomas. In fact, a comparison of CRBP-1 immunodetection and the degree of tumor differentiation revealed significant statistic differences (G1 vs G2: $P<0.005$, G1 vs G3: $P<0.005$ and G2 vs G3: $P<0.005$, respectively). The decrease of CRBP-1 expression in moderately and poorly differentiated carcinomas was parallel to that of estrogen and progesteron receptor positivity. In areas of different degree of differentiation in the same tumor, a variable CRBP-1 expression was maintained. Serous carcinomas were almost CRBP-1 negative. In 39.5% of cases (75% of them well-to moderately differentiated carcinomas), nuclear staining also observed. In contrast to cytoplasmic staining, nuclear CRBP-1 positivity was focal, and positive nuclei alternated with negative nuclei even in the same neoplastic glandular structure. Conclusions: Cytoplasmic staining for CRBP-1 can be considered a reliable method to support histological grading of endometrial carcinoma. Further studies are needed to define the biological role of these different patterns of CRBP-1 expression in endometrial neoplasms.

P 781
STRONG IMPACT OF VASCULAR PROLIFERATION, VASCULAR MATURATION AND LYMPHANGIOGENESIS ON PROGRESSION OF ENDOMETRIAL CANCER

STEFANSSON Ingunn, SALVESEN Helga B., AKSLEN Lars A.
The Gade Institute, Section for Pathology;
Department of Clinical Medicine, Section for Obstetrics and Gynecology, University of Bergen, Haukeland University Hospital, Bergen, Norway

Introduction:
In endometrial carcinoma, studies have reported reduced survival in tumors with high microvessel density.However, MVD might have limitations as a prognostic factor.The biological and clinical significance of lymphangiogenesis has not been much studied, predominantly due to the lack of specific lymphatic markers. Metastatic spread to regional lymph nodes is an important prognostic indicator, but lymphangiogenesis has not been previously studied in these tumors.
Purpose of the study:
To examine the significance of other angiogenic markers in endometrial cancer, especially vascular proliferation (by Ki-67/Factor-VIII staining) and vascular maturation (by á-SMA/Factor-VIII staining), as well as lymph vessel density (LVD) in a large and population-based series of endometrial carcinoma (n=281), with long and complete follow-up.
Methods used:
Paraffin-embedded tumor tissue was examined immunohistochemically by using double staining for Ki-67/F-VIII (vascular proliferation) and SMA/F-VIII (vascular maturation). To assess lymphatic vessel density (LVD), we used the LYVE-1 antibody. Tumor sections were scanned at low magnification to identify areas with the highest amount of vessels (“hot spots”), either stained by double-staining or LYVE-1. A panel of angiogenic factors (VEGF-A, VEGF-C, VEGF-D and bFGF) was also examined in this series, by Tissue Microarray analysis. The information was related to other molecular markers, clinico-pathologic data and patient prognosis.
Summary of the results:
Median vascular proliferation index (VPI) was 3.9%, and high VPI was associated with features of aggressive tumors like presence of necrosis, high FIGO stage, and decreased survival in multivariate analysis. The prognostic impact was superior to that of microvessel density. Median vascular maturation index (VMI) was 35%, and low VMI was significantly associated with vascular invasion and poor prognosis in univariate analysis. Peri-tumoral lymphatic vessels were found in 39.5% of the cases, and high LVD-pt was significantly associated with features of aggressive tumors and decreased survival.
Conclusion:
Other tissue-based angiogenic features than microvessel density, in particular vascular proliferation, should be evaluated as a part of the angiogenic profile of human

tumors. Peri-tumoral lymphatic vessel density also seems to play a significant role in the proggression and prognosis of endometrial carcinoma.

MICROSATELLITE INSTABILITY AT TETRANUCLEOTIDE REPEAT IN TYPE I ENDOMETRIAL CARCINOMA

*CHOI Jin, *CHOI Ho-Sun, KIM Hyun-Joong, NAM Jong-Hee, PARK Chang-Soo, JHUNG Sang-Woo
Department of *Obstetrics & Gynecology and Pathology, Chonnam National University Medical School, Gwangju, South Korea

Defects in the DNA mismatch repair (MMR) system results in a mutator phenotype, which is manifested as microsatellite instability (MSI). Colon cancers exhibiting MSI could be divided into 2 forms: MSI-high(MSI-H) and MSI-low(MSI-L), based on the observed frequency of genomic mutations. Noncolonic human cancers also show two types of MSI. One group shows a high frequency of MSI at mono- and di-nucleotide repeats similar to colon MSI-H type tumors. Another group rarely exhibits MSI in the mono- and dinucleotide repeats but does often exhibits MSI in the tri- or tetranucleotide repeats. This distinctive subtype of MSI is termed 'elevated microsatellite alterations at selected tetranucleotide repeat (EMAST)'. In contrast to MSI-H tumors, the underlying molecular mechanisms for MSI in MSI-L or noncolonic EMAST tumors have not been clarified.

In order to investigate the prevalence of MSI at tetranucleotide repeat in Type I endometrial carcinoma and the correlation between MSI staus and alterations of MMR gene, such as hMLH1 and hMSH2, we examined the 3 mono-, 3 di- and 6 tetra-nucleotide repeat markers by PCR and denaturation gel electrophoresis and the expression of hMLH1 and hMSH2 protein by immunohistochemistry in 39 Type I endometrial carcinomas.

The presence of at least one new allele, consistent with MSI, was observed in 9 (23.1%) at mononucleotide repeat, in 6 (15.4%) at dinucleotide repeats, and in 23 (59.0%) at tetranucleotide repeats of 39 endometrial carcinomas. MSI was divided into high frequency of MSI (MSI-H), single EMAST and multiple EMAST by the number of affected loci. MSI-H was detected in 9 (23.1%) of 39 patients, and single EMAST and multiple EMAST were noted in 10 (25.6%) and 4 (10.3%) of 39 carcinomas, respectively. MSI status was not associated with clinicopathologic features, such as FIGO stage, histologic grade and depth of invasion. Of 39 carcinomas, 12 (30.8%) showed an absence of hMLH1 expression, 8 (20.5%) revealed an absence of hMSH2 expression, and 16 (41.0%) tumors demonstrated the absence of either hMLH1 or hMSH2 expression. Seven (77.8%) of 9 MSI-H tumors, 2 (20.0%) of 10 single EMAST tumors, and 3 (75.0%) of 4 multiple EMAST tumors revealed the absence of either hMLH1 or hMSH2 expression.

These resulsts suggest that MSI-high and multiple EMAST endometrial carcinomas are highly associated with alterations of hMLH1 or hMSH2 and single EMAST tumors may be associated with another mechanism.

P 783
THE ASSESSMENT OF THE EPITHELIOSTROMAL MICRO ANATOMICAL RELATIONS IN THE UTERUS EPITHELIUM METAPLASIA

G.S Dragoi, Galbenu M., Patrascu M., P.R. Melinte, Rodica Silca, A.F. Vreju
Academic Hospital Filantropia Craiova Romania
University of Medicine and Pharmacy from Craiova

Objectives. The transformation and evolution sometimes abnormal of the endometrium and endocervix epithelium frequently become a dilemma for the pathologist. It draws the attention to the unknown problems of the metaplasia phenomena: the determined factors of the metaplasia genesis, the morph and functional epitheliostromal relations and finally its integration in neoplazia and displasia.
Purpose of the study. We proposed ourselves to identify and evaluate the potential of phenotype transformation of the epithelial cells and metaplasic epithelial structures inside uterus glands.
Materials and methods. We studied 400 cases of metaplasia of the uterus ephitelium, investigated by histologic and histochemic visualization methods for the epithelium cells, fiber elements of the extra cellular matrix and glicosaminoglicans.
Results and conclusions. The epithelial and stromal structures of the endometrium and endocervix suffer cycle transformations that we integrated inside “uterus epithelium remodeling cycle”. The extra cellular matrix integrates itself in this cycle but also in the processes of angiogenesis and apoptosis. Ortomeplasia imposes the evaluation of the epithelial transformations in ontogenesis and during normal and pathologic hormonal cycles. We discuss the integration of mataplasia in displasia and neoplasia pathomorphogenesis.
Key words: uterus, metaplasia, displasia, epithelium

Belfast, Northern Ireland

INTRODUCTION: Recently, a dualistic pathway of ovarian serous carcinogenesis has been proposed based on morphologic observations and molecular genetic analysis. In this scheme, low grade OSC arises in a stepwise fashion from a benign serous cystadenoma through a usual serous borderline tumour through a micropapillary variant of serous borderline tumour. In contrast, the more common high grade OSC arises de novo from the ovarian surface epithelium.
PURPOSE OF STUDY: Although the division of OSC into low and high grade variants is gaining greater acceptance, and although there is accumulating molecular genetic evidence for this, there is little published information regarding a comparison of protein expression between these two types of OSC. In this study, we have investigated the immunohistochemical expression of a wide range of proteins in cases of low grade (n=22) and high grade (n=47) OSC.
METHODS: Antibodies used were p53, MIB1, BCL2, WT1, HER-2/neu, C-KIT, osteopontin and survivin. For all antibodies, except MIB1, cases were scored as 0 (negative or occasional positive cells), 1+ (<10% cells positive), 2+ (10-25% cells positive), 3+ (26-50% cells positive), 4+ (51-75% cells positive) or 5+ (>75% cells positive). For MIB1, the percentage of positive nuclei was calculated. SUMMARY OF RESULTS: There was a statistically significant higher expression of p53, MIB1, BCL2, HER-2/neu and C-KIT in high grade compared to low grade OSC ($p < 0.05$). Thirty of 47 (64%) cases of high grade OSC exhibited 5+ staining with p53 compared to 4 of 22 (18%) low grade neoplasms. Twelve of 47 (26%) high grade OSC exhibited 5+ staining with BCL2 compared to one of 22 (5%) low grade OSC. The mean MIB1 proliferative index in high grade OSC was 55.4 % compared to 23.0 % in low grade OSC. Virtually all cases

of both low grade and high grade OSC exhibited diffuse nuclear positivity with WT1 and diffuse cytoplasmic positivity with survivin. Osteopontin expression was variable with no significant difference in expression between low grade and high grade OSC. CONCLUSION: The significant differences in protein expression between low grade and high grade OSC provides further support for a different underlying pathogenesis. In particular, the differences in p53 immunoreactivity are in keeping with the observation that p53 gene mutation is more common in high grade than low grade OSC.

OVARIAN ENDOMETRIOID TUMOR WITH YOLK SAC TUMOR COMPONENT.

Alejandro Pascual+, Enrique Poblet+ and Monica Romeu*
(+)Servicio de Anatomía Patológica.
(*)Servicio de Ginecología y Obstericia.
Hospital General Universitario de Albacete (Spain)

Case Report:
A 47 year old woman was admitted to our Hospital for abdominal pain. Physical examination showed, on palpation, a painful and firm Douglas sac. Transvaginal ecography revealed a 104 x 107 mm solid and cystic mass, located on the left ovary. The wall of the cysts appeared thick and irregular.
Histologically, the mass showed endometrioid carcinoma areas intimately admixed with yolk sac tumor areas. Reticulo-microcystic, enteroid-glandular, and solid histological patterns were readily identified on the endodermal sinus component.
FIGO stage of the tumor at this time was I-A.
Five months later a metastatic liver nodule was identified, with a significant rise of the serum alfa-fetoprotein. Histological examination of the liver nodule showed metastasis of the endodermal sinus tract component of the ovarian tumor.
Discussion:
Neoplasms that reproduce extraembrionary tissues (trophoblast or endodermal sinus tissue) not always have a germinal cell origin. These neoplasms may also be derived from somatic cells, usually from endoderm or mesoderm.
A differential diagnosis between an endometriod tumor associated with a endodermal sinus tumor, and the endometrioid variant of the endodermal sinus tumor, should be establish. Features that support the diagnosis of an endometrioid tumor associated with an endodermal sinus tumour are: the older age of the patient, the presence of endometriosic focus, and the presence of a biphasic immunohistochemical staining pattern. The biphasic immunohistochemical staining pattern is characterized by the presence of areas that are positive for EMA, estrogen and progesterone receptors (that represent the endometroid component of the tumor), and areas that are positive for alfa-fetoprotein, and negative for EMA (that represent the endodermal sinus tumor component).
The response of this tumours to chemotherapy is poor and they are usually cis-platinum resistant. Poor prognostic should be expected

P 786

IMMUNOHISTOCHEMICAL DISTRIBUTION OF AN USEFUL ANTIBODIES PANEL FOR OVARIAN NEOPLASMS

Camelia-Doina Vrabie1, Aura Mihalcea2, V. Muresan2, Cristina Bordea2, C. Copaescu2, Marieta Costache2, Elena Ionica3; 1National Institute of Pathology “V. Babes”; 2Department of Surgery, Hospital “Sf. Ioan”, 3Molecular Biology Center, University of Bucharest

Introduction. Cancer of the ovary represents about 30% of all cancers of the female genital organs (WHO, 2003). In developed countries it is about as common as cancer of the corpus uteri and invasive cancer of the cervix. About 70-75% of patients with ovarian cancer have tumor spread beyond the pelvis at the time of diagnosis.
Aim. Immunohistochemical study of the main epithelial tumors of the ovary-serous and mucinous adenocarcinomas-is a valuable adjunct the trorough histologic examination. Using a wide panel of antibodies, as ER (estrogen receptor), PGR (progesterone receptor), EGFR (epidermal growth factor receptor), cerbB2 (HER2NEU protooncogene), PCNA (proliferative cellular nucleolar antigen), CA125, Ki67 ,P53 (P53 oncoprotein) and CK7 (cytokeratin 7) we have tried to find a “happy combination” for an early and precisely diagnosis of ovarian epithelial cancers.
Matherial and methods. We investigated immunohistochemical a group of 60 patients with serous (n=45, 45.75%), mucinous (n=12, 20%) adenocarcinomas and borderline tumors (n=3; 5%). We used the tristadium methods of Hsu (1981) Avidin-Biotin-Peroxidase. A number of 19 patientshave had peritoneal implants (31,6%) and tumors were bilateral in 7 cases (11,66%).
Results. The method used revealed that the ER was positive in 70% cases, PGR in 60%, PCNA in 61,66% and p53 in 63,33%, CA125 in 81,66% and the perimembrane pattern of cerbB2 in 63,33%. The majority of cases were the serous carcinomas.
Conclusions. The relevance of CA125-an useful antibody in ovarian cancer, also for metastatic disease-is limited because it is positive in many conditions (mesothelial proliferations, metastatic carcinomas, etc).
The ovarian serous carcinomas are an homogenous group from the standpoint of pathogenesis. The panel of antibodies was positive in more than 50% of serous carcinomas.
None of the antibodies or combination has a clearly established role for staging and prognosis of the tumor.
Only the three-tiered grading system has important prognostic and therapeutic implications.

P 787

DIFFERENTIAL EXPRESSION OF CADHERINS AND CATENINS ASSOCIATES WITH DISTINCT OVARIAN CANCER HISTOLOGICAL TYPES

HARDISSON David (1), SARRIO David (2), HERNANDEZ-CORTES Gines (3), SANCHEZ-ESTEVEZ Carolina (2), MORENO-BUENO Gema (2), SUAREZ Asuncion (1), PALACIOS Jose (2)
(1) Dpto. Anatomia Patologica, Hospital Universitario La Paz, Madrid, Spain
(2) Laboratorio de Cancer Ginecologico y Mamario, Centro Nacional de Investigaciones Oncologicas, Madrid, Spain
(3) S. Obstetricia y Ginecologia, Hospital Universitario La Paz, Madrid, Spain

BACKGROUND: Ovarian carcinoma (OvC) is the leading cause of death among all gynecologic malignancies. In the last years, it has been demonstrated that alterations in the cadherin-catenin adhesion complexes are involved in tumor initiation, progression and metastasis. The aim of this study was to evaluate the immunoreactivity of the cadherins and the catenins in ovarian cancer and to correlate their expression with clinicopathological features.
DESIGN: Immunohistochemical staining was performed in 85 ovarian carcinomas: clear cell (CCs), n=31; serous (SCs), n=28; endometrioid (ECs), n=13; mucinous (MCs), n=13) using a tissue microarray. Monoclonal antibodies against E-cadherin (4A2C7, Zymed), P-cadherin, N-cadherin, cadherin-11, beta-catenin, gamma-catenin, and p120ctn (Transduction Labs) were applied using the LSAB method.
RESULTS: Overall, membranous expression of E-CD, N-CD, and P-CD was observed in 96%, 29.8%, and 8.4% of the OvCs analyzed, respectively. Cadherin-11 was rarely expressed in tumor cells but frequently in the stromal cells adjacent to the tumor nests. Each of the cadherins was

differentially expressed among the histological types of OvCs: E-CD preserved expression was frequent in MCs (61.5%) but very rare in SCs (3.6%). Serous tumors showed the higher incidence of N-CD (67.9%) and P-CD (21.4%) expression compared to the other histotypes. MCs and CCs rarely expressed N-CD or P-CD. With respect to catenins, significative differences were observed among the histological types: CC tumors and SCs showed more frequently reduced or absent expression of beta-catenin, gamma-catenin and p120 than other types. MCs were characterized by the frequent preservation of the three catenins. Abnormal nucleo-cytoplasmic beta-catenin expression was clearly associated with the EC histotype, since all cases showing this pattern (12%) were endometrioid tumors ($p<0.001$). Cytoplasmic localization of gamma-catenin and p120 was observed in 4.5% and 7% of OvCs respectively, but these expression patterns were not statistically associated to any histological type.
CONCLUSIONS: Our results suggest that each of the different histological types of OvC show a distinct and characteristic cadherin and catenin expression profile that could help in the differential diagnosis of these tumors and could explain differences in biological characteristics, such as the ability to dissemination.
GRANTS: FIS PI020342 and PI020355.

STAGE I OVARIAN CARCINOMA. A DIFFERENT DISTRIBUTION OF HISTOLOGIC PATTERN
L.Deligdisch,P.Schlosshauer,D.Fatemi, F.Nezhat
The Mount Sinai School of Medicine (MSSM), New York N.Y.USA

INTRODUCTION.Only a minority of ovarian carcinomas are diagnosed in StageI. The histologic subtypes of ovarian carcinomas,despite their common epithelial origin, arise in different histogenetic settings being associated with different clinical and diagnostic implications.
PURPOSE OF STUDY is to identify histopathologic patterns of ovarian carcinoma that are likely to have an impact on early stage diagnosis.
METHODS USED. Histologic slides and clinical charts from 27 consecutive patients diagnosed from 2000 to 2004 at the MSSM with Stage I non-mucinous ovarian carcinoma were reviewed. The tumors were classified into serous papillary (OSPC),endometrioid (OEC)and clear cell (OCCC) carcinomas. Associated pathologic findings including ovarian endometriosis (OE),endometrial carcinoma (EC),endometrial hyperplastic polyps (EP) and clinical data (age of patients, history of breast cancer,presenting symptoms)were correlated with the histologic subtypes of the ovarian tumors.
SUMMSRY OF RESULTS. The histologic subtypes of the ovarian carcinomas were: 15 OEC(55%),8 OSPC (29%) and 4 OCCC (15%). In 12 patients the OEC arose in OE (44%) and their clinical presentation was pelvic mass due to endometriotic cysts. Concomitant EC was diagnosed in 7 patients (26%) and EP in two(0.07%). Four of these patients presented with vaginal bleeding. Of the patients diagnosed with OSPC three had histories of breast cancer,presenting with pelvic masses,one had concomitant EC presenting with vaginal bleeding and one was BRCA1 mutation positive, her ovarian carcinoma being diagnosed incidentally in the prophylactically removed ovaries. The remaining three presented with pelvic masses, of which one due to cystic endometriosis. The four patients with OCCC presented with pelvic masses, three arose in cystic endometriosis and one had concomitant EC with vaginal bleeding. The average age of the patients with OEC was 49,4, with OSPC 58,9 and with OCCC 67 years.
CONCLUSION. OEC and OCCC are more commonly diagnosed in StageI because of their frequent association with symptomatic OC and OE. OSPC, the most prevalent ovarian carcinoma overall, is less commonly diagnosed in StageI, more often, however, in patients with breast cancer histories who are closely followed. Our findings suggest that screening of patients with OE, endometrial pathology and history of breast cancer can contribute to diagnose ovarian cancer in earlier stages.

P 789
RELATIONSHIP BETWEEN P53-ASSOCIATED PROTEINS AND ESTROGEN RECEPTOR (ER) STATUS IN OVARIAN SEROUS NEOPLASMS
Eun Yoon Cho(a), YoonLa Choi(a), Seoung Wan Chae(b), Jin Hee Sohn(b), Geung Hwan Ahn(a)
a Department of Pathology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea
b Department of pathology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea

Objective. This study was undertaken to evaluate the relationship between p53-associated proteins and ER status, and the methylation status of the ER CpG island in ovarian serous tumors.
Methods. We studied the immunoexpression of p14ARF, MDM2, and p53, and relationship between those protein expression and ERa in 158 cases of ovarian serous tumors, which comprised benign (n=23), borderline (n=41), and malignant tumors (n=94). We also investigated the methylation status of ER with correlation of ER status.
Results. The aberrant expression of p14ARF, MDM2, p53, and p53-associated proteins were observed in 19.6% (31/158), 47.5% (75/158), 39.9% (63/158), and 70.3% (111/158) of cases, respectively. The expression of MDM2 was significantly higher in borderline serous ovarian tumors than in benign ($P=0.04$) and malignant tumors ($P<0.01$). p53 expression in borderline tumors was not frequent and p14ARF expressional loss was mainly observed in carcinoma. Significant differences in the expressions of MDM2 ($P=0.01$), p14ARF ($P=0.04$), and p53-associated proteins ($P=0.02$) were observed between ER-positive and ER-negative cases. Methylation specific PCR for the ER CpG island revealed methylation bands in 48.3% (14/29) of borderline tumors, and in 36.4% (12/33) of malignant tumors. Methylation statuses of ER were not significantly related to ER status.
Conclusions. This study shows a significant association between ER status and p53-associated proteins, but no relationship between ER status and ER CpG island methylation. This study indicates that alteration of p53-associated proteins may affect tumor behavior in ovarian serous neoplasms, but ER methylation is probably not an important cause of ER loss.

P 790
AN IMMUNOHISTOCHEMICAL STUDY OF THE EXPRESSION OF ADHESION MOLECULES IN OVARIAN SEROUS NEOPLASMS
JiEun Kwon(1), Eun Yoon Cho(1), YoonLa Choi(1), Seoung Wan Chae(2), Jin Hee Sohn(2), Geung Hwan Ahn(1)
1Department of Pathology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea
2Department of Pathology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea

To clarify possible roles of adhesion molecules including E-cadherin, beta, gamma-catenin, CD44s, CD44v6, CD56, and CD99 in ovarian tumor development and progression, an immunohistochemical study was undertaken for 23 cases of benign, 41 cases of borderline, and 94 cases of malignant ovarian serous neoplasms using tissue microarray (TMA). Significantly reduced expression of E-cadherin, and overexpression of CD44s, CD56, and CD99 were more frequently observed in malignant tumors than benign and borderline tumors. Reduced expression of E-cadherin was

also correlated with high tumor grade (P=0.03), presence of peritoneal seeding (P=0.03), and low overall survival rate (P=0.02). Overexpression of CD44s was significantly associated with high tumor grade (P=0.04), advanced stage (P=0.03), and low overall survival rate (P=0.02). CD56 was increasingly expressed in the case of advanced stage (P=0.008) and peritoneal seeding (P=0.002). Among all clinicopathologic factors, E-cadherin expression, CD44s expression and stage were correlated with overall survival in univariate study. The results of immunohistochemical analysis suggest that E-cadherin, CD44s, and CD56 may be useful prognostic markers for serous neoplasm of the ovary.

P 791

EARLY STAGE EPITHELIAL OVARIAN CARCINOMAS: A STUDY OF MORPHOLOGIC PROGNOSTIC FACTORS

USUBÜTÜN Alp, YILDIZ Iþýl, GÜLTEKÝN Murat, AYHAN Ali, KÜÇÜKALÝ Türkan.

There is limited experience with the early stage ovarian carcinoma. We intented to evaluate the prognostic factors that are commonly used, and reavaluated the diagnosis in the light of new knowledge especially related with borderline neoplasia.

For this purpose we examined 111 patients' slides chosen from156 clinical early stage patients from the files of gynecologic oncology between 1984-2001, we eliminated the patients if we didn't have that patients' slides in our laboratory, if no absolute data and/or microscopic features concerning that it's a primary ovarian carcinoma was present and if patients' disease was reported as higher stage after the operation. We reviewed the slides, blinded to the clinical outcome, using current diagnostic criteria and graded the neoplasm according to the system suggested by Shimizu and noted the presence or absence of endometriosis. Statistical analysis for survival was done by Kaplan Meier Analysis and group comparisons were made with Log Rank test.

86 patients were stage 1 and 25 patients were stage 2. Distrubution of histologic subtypes were as follows; 16 serous papillary carcinoma (%14.4), 14 mucinous carcinoma (%12.6), 16 endometrioid carcinoma (%14.4), 9 clear cell carcinoma (%8.1), 2 mixed carcinoma, 1 transistional carcinoma, 1 indiferantiated carcinoma, 26 serous borderline (%26), 17 mucinous borderline (%17), 3 endometrioid borderline (% 2.7), 2 serous cystadenoma, 3 mucinous cystadenoma, and 1 brenner tumor. There was statistically significant difference in survival between stage 1 and stage 2 patients (p=0.0188) and endometrioid type had a better prognosis than clear cell (p=0.0105) and mucinous type (p=0.0321). In contrast there was no statistically significant difference in survival between mitotic scores, architecture scores, cytology scores and tumor grades. Endometriosis was present in 19 (%17.1) patients and endometriosis mostly related with endometrioid and clear cell type carcinoma (p< 0.05).

As a result pathologist must be familiar with the borderline tumor when dealing with early stage ovarian carcinoma, because borderline tumors can be diagnosed as carcinoma erroneously especially by non-gynecologic pathologist. Stage is the only significant prognostic factor in the early stage ovarian carcinoma. In contrast to wide spread knowledge, "clear cell carcinoma" histologic type is not a poor prognostic factor and tumor grade has no effect on survival for early stage carcinomas.

Introduction: Matrix metalloproteinase 7 (MMP-7) is a small member of MMP-family, which degrades various components of extracellular matrix. It has been shown that epithelial ovarian tumor cells produce MMP-7. Expression of MMP-7 has been shown to be regulated by beta-catenin.

Purpose of the study: To evaluate the prognostic significance of MMP-7 expression in human epithelial ovarian cancer. The relation between MMP-7 and beta-catenin expression was also studied.

Methods: Two hundred eighty four patients were diagnosed at Kuopio University Hospital and Jyväskylä Central Hospital, Finland, between 1976 and 1992. The median follow-up time was 29 months. The FIGO standards were used for staging. For histological typing and grading, the WHO classification was used. For immunohistochemical analyses, monoclonal antibodies for human MMP-7 and beta-catenin were used. Specimens were analysed by three independent observers and the intensity of staining and percentage area of positive tumor cells in the section were scored.

Results: Median percentage of MMP-7 expression was found to be 40%. A high percentage area (>40 %) of MMP-7 expression in tumor cells was significantly correlated with positive nuclear expression of beta-catenin (p=0.01). A low percentage area (< 40 %) of MMP-7 expression was correlated with high histologic grade of a tumor (p=0.003), advanced stage (p=0.002) and large primary residual tumor (p=0.005). A high percentage area of intense MMP-7 expression in tumor cells was found to be an prognostic factor predicting favorable disease related and recurrence free survival (p=0.0003 and 0.0052, respectively). Also in multivariate analysis a high percentage area of intense MMP-7 expression in tumor cells retained its prognostic power.

Conclusion: The low expression of MMP-7 in epithelial ovarian cancer cells is associated with high histologic grade, advanced stage and large residual tumor and the high MMP-7 expression with positive nuclear expression of beta-catenin. According to our results, the expression of MMP-7 seems to have prognostic significance in epithelial ovarian cancer.

CLINICOPATHOLOGICAL STUDY OF METALLOTHIONEIN IMMUNOHISTOCHEMICAL EXPRESSION, IN BENIGN, BORDERLINE AND MALIGNANT OVARIAN EPITHELIAL TUMORS.

N. Zagorianakou (1), P. Zagorianakou (1), G. Makrydimas (2), E. Briasoulis (3), V. Karavasilis (3), N J. Agnantis (1), Stefanou D. (1).

Departments of Pathology (1), Obstetrics and Gynecology (2) and Medical Oncology (3), Medical School, University of Ioannina, Greece.

Metallothioneins (MTs) are a family of cystein-rich metal-binding proteins, which are expressed in normal cells during fetal and postnatal life but also in a variety of human neoplasms. MT expression in human tumors has been linked to resistance to anticancer drugs and differentiation and progression in some types of tumors. This study examined the immunohistochemical expression of MTs in benign,

borderline and malignant tumors of ovarian surface epithelium and the possible correlations with clinicopathological parameters and survival. A total of 87 cases with diagnosis of ovarian surface epithelial tumors were included. Specifically, 21 cases of benign cystadenomas (11 serous and 10 mucinous), 14 borderline (low malignant potential tumors, 8 mucinous and 6 serous) and 52 cases of ovarian cancer were analysed.
Immunohistochemical expression of MT (cut-off level >10% of tumor cells) was clearly associated with malignancy. A statistically significant correlation was found between the expression of MT in cancer cases and benign tumors ($p<0.0001$) and cancer cases and borderline tumors $p= 0.003$. In cancer cases was observed a difference between grade I and III ($p=0.002$). There was no correlation of MT overexpression with survival in the small number of ovarian carcinoma patients where it was analysed. MT constitutes a marker that characterizes aggressiveness and a high malignant potential in ovarian epithelial tumors. In diagnostic problems MT may help distinguish between benign, borderline and malignant tumors.

P 794
INTRAOPERATIVE FROZEN SECTION DIAGNOSIS OF OVARIAN MASSES: HOW ACCURATE ARE WE?
TURAN Dilagah, YOLAC Evrim, MUEZZINOGLU Bahar
Kocaeli University Medical School Department of Pathology Kocaeli, TURKEY

In ovarian masses, intraoperative frozen section diagnosis is requested either to rule out malignancy or to verify the borderline or malignant tumor before proceeding with radical surgery.
A retrospectine study was conducted to determine the accuracy of frozen section diagnosis in ovarian masses.
We reviewed the frozen section diagnosis and permanent pathological diagnosis of 227 resected ovarian masses from May 1999 to December 2004. Frozen and permanent section diagnoses were divided into 3 groups: benign, borderline and malignant.
The accuracy, sensitivity,specificity, positive and negative predictive value of frozen section were studied.
Final histological diagnosis was benign in 173 (76.3%) cases, borderline in 8 (%3.5) cases and malignant in 46 (20.2%) cases. The sensitivity for malignant, borderline and benign cases were 93.4%, 87.5% and 99.4% respectively.There were one false positive and four false negative cases. The specificity for malignancy was 100%, for borderline 98.6% and 98% for the benign masses. The positive predictive value of a malignant frozen section diagnosis was 100%; the negative predictive value of a benign frozen section diagnosis was 98%.
Most of the false negative cases were belong to mucinous tumor group.Two mucinous adenocarcinomas were incorrectly diagnosed as borderline and a borderline mucinous tumor diagnosed as benign.False positive case was also a mucinous tumor having frozen section diagnosis of borderline mucinous tumor turned out to be a benign mucinous cystadenoma in permenant sections.
In conclusion, although we have limited number of borderline cases, the accuracy of frozen section diagnosis was high in benign, borderline and malignant cases.
Mucinous tumors constituted the main diagnostic problems in frozen section evaluation. Large masses with wide range of tissue types from benign to malignant underline the sampling errors leading to false frozen section diagnosis. Surgeons and the pathologists should be aware of the limitations of frozen section diagnosis particularly in mucinous tumors of the ovary.

P 795
OVARIAN WOLFFIAN TUMOUR: A CASE REPORT
R Sellami Dhouib, S Sassi, I Abbess, M Driss, K Mrad, K Ben Romdhane
Department of Pathology, Salah Azaiez Institute, Tunis, Tunisia.

Introduction: Ovarian wolffian tumors are defined according to OMS as tumor of presumtive wolffian origin characterized by a variety of epithelial patterns. This epithelial tumour may show diffuse solid tubular, hollow tubular and sieve-like patterns and a combination of the various patterns may occur. Altough more commun in the broad ligament, this tumour may occurs in the ovary.
Aims: To review clinical data, histologic features, immunohistochemical profile and to study the differencial of the ovarian wolffian tumor mainly from the endometroid carcinoma of the follopian tube.
Materials and methods: A 71-year-old woman presented with left ovarian tumour. Gross and microscopic finding were noted. Immunohistochemical stains for alpha inhibin was performed.
Results: Macroscopically, the tumour had 90x70x40 mm, lobulated, well circumscribed margins and was white and yellow. Histologic examination showed a well circumscribed islands or lobules of glandular and ductal epithelium in a back to back pattern. The lobules exhibited focal or extensive hyalinisation with obliteration of the epithelial component. The nuclei appeared moderately atypical and uniform. The central most part of the nodules appeared necrotic. The cells tumors were positive for alpha- inhibin.
Discussion and conclusion: The immunoreactivity of tumour cells with alpha inhibin and absence of squamous differenciation and destructive stromal invasion supported the wolffian nature of the neoplasm. Because of moderately nuclear atypia and striking mitotic activity, this tumor was considered as low grade malignancy.

P 796
THE RELATIVE FREQUENCY OF OVARIAN TUMORS AND THEIR AGE DISTRIBUTION OVER A 20 YEAR PERIOD IN SHARIATI TEACHING HOSPITAL, TEHRAN , IRAN .
- Maryam Kashanian, M.D, Assistant professor of Iran University of Medical Sciences. Department of Obstetrics and Gynecology , Tehran , Iran ,Tel : 0098217523487- Fax :0098217607016- Email : maryamkashanian@yahoo.com
- Naser Kamalian ,MD, Prof

Abstract:
Objective:
The evaluation of the relative frequency of ovarian tumors and their age distribution over a 20 year period in Shariati Teaching Hospital, Tehran, Iran.
Method:
A retrospective descriptive study was performed on all pathologic reports of ovarian tumors, from 1983 to 2003 in Shariati Teaching Hospital in Tehran, Iran. Then the relative frequency and their age distribution was evaluated .
Results:
493 ovarian neoplasia had been recruited. Surface epithelial tumors were the most frequent tumors with 283 cases (57.4%) followed by germ cell tumors with 152 cases (30.83%) and sex cord stromal tumors with 31 cases (6.28%). Metastatic tumors were present in 24 cases (4.86%) and the remaining 3 cases were 2 cases of luteoma and 1 case of chondroma. The most frequent benign neoplasia of the ovary was a dermoid cyst (mature cystic tratoma)(39.53%) followed by serocystadenoma (29.94 %) and mucinous cyst adenoma (14.82%) .
The most frequent ovarian malignancy was malignant serous tumors (53.69%) and then metastatic tumors (16.1%) and

mucinous cyst adeno carcinoma (14.09%). The most frequent age group was the 21-30 years old (111 cases).
Conclusion:
In this study the surface epithelial tumors were less than other studies, and the germ cell tumors were more so. It may have been due to the younger age of our patients or genetic factors. Metastatic tumors were more frequent probably due to the late diagnosis of malignancies.
Between sex-card stromal tumors, the most common tumor was fibrothecoma. Whereas in other studies granulosa – theca cell tumors were the most frequent. Genetic and racial factors may have played a role in this.
Key words:
Ovarian tumors, benign ovarian neoplasia, malignant ovarian neoplasia, Iran.

P 797

IMPORTANCE OF IMMUNOHISTOLOGICAL ER, PR EXPRESSION IN TUMOR FOR ENDOMETROID OVARIAN CARCINOMA HORMONOTHERAPY

E. Simonchuk, L. Zakhartseva, Y. Kokhanevich, M.Klevetenko

I. Introduction.
Endometroid ovarian carcinoma makes up 20% of ovarian carcinomas. Hormonotherapy of endometroid ovarian carcinoma equally with surgical treatment and chemotherapy improves patient's survivability and quality of their lives.
The aim of this investigation is to specify the hormonotherapeutic indications in patients with endometroid ovarian carcinoma taking into account the level of tumor's differentiation, receptors content to steroid hormones.
II. Materials and methods.
We examined 38 endometroid ovarian carcinoma patients. The immunohistochemical analysis for estrogen/progesterone receptors (ER/PR), was performed using formalin-fixed. The dependence between the level of tumor's differentiation and estrogen/progesterone receptors content in it was found.
III. Results.
Endometroid ovarian carcinoma is characterized by the high level of estrogen – 66.7% and progesterone – 98.8% in women in menopause (61-67 years old) with G I-II.
The absence of estrogen receptors expression , and the high level of progesterone receptors expression were noted in 32% of women in menopause with G I-II. The low estrogen/progesterone receptors content in women in menopause and their absence were noted in 86% of endometroid ovarian carcinoma women in childbearing age (27-42 years old) with G III-IV. Prescription of Depo-Provera 500mg once a day during 3 weeks together with single dosing of Carboplatin and Mitotaks resulted to the tumor decrease up to 2-3 sm, revealed after Second Look, comparatively with initial data of patients with III level of endometroid ovarian carcinoma with G I-II.
IV. Conclusion.
In complex treatment of endometroid ovarian carcinoma patients the hormonotherapy was used effectively in every case of finding out the high level of estrogen/progesterone receptors expression in tumor's cells.

Because the majority of ovarian cancer patients are diagnosed in an advanced stage of the disease, first-line therapy commonly consists of surgical resection, followed by platinum drug-based chemotherapeutic regiments. Unfortunately, second-line chemotherapeutic treatment merely achieve response rates of about 20%. These clinical observations indicate that long-term prognosis of ovarian carcinoma depends on intrinsic and acquired drug resistance. In vitro experiments demonstrated that multidrug resistance-associated protein-2 (ABCC2) overexpression can confer resistance to platinum-containing anticancer drugs like cisplatin and carboplatin to cancer cell lines including ovarian carcinoma cells
In the present study we analyzed the expression and cellular localization of ABCC2 in ovarian carcinoma-derived cell lines exhibiting different levels of resistance against cisplatin and in a group of post-surgically platinum-containing drug treated ovarian cancer specimens taken from first-look laparotomies and from secondary cytoreductions in the same group of patients. ABCC2 expression was correlated in dependence on cellular localization with sensitivity against cisplatin or clinical outcome.
The analyses were performed on samples of ovarian cancer originating from 73 laparotomies and on 11 ovarian cancer cell lines. To check specificities of antibodies by reproducing the cellular localization of ABCC2 described in other studies, immunohistochemical reactions were performed on two tissue microarrays (TMAs).
The performed immunohistochemical reactions on the level of light and electron microscope showed, that ABCC2 expression in nuclear envelopes of studied cells significantly correlates with cisplatin resistance. In tumor samples we have shown, that nuclear ABCC2 expression is specific for cases of shorter overall- and progression-free survival.
This study for the first time demonstrates, that ABCC2 can be expressed in nuclear envelope and this localization is specific for cisplatin-resistant ovarian carcinoma cases.

GRANULOSA CELL TUMORS FREQUENTLY EXPRESS EGFR (HER-1), HER-3, AND HER-4: POTENTIAL RELEVANCE TO NOVEL ANTI-HER THERAPIES

Sebastian Leibl 1, Farid Moinfar 1, Koppany Bodo 1, Margit Gogg-Kammerer 1, Andelko Hrzenjak 1, Edgar Petru 2, Raimund Winter 2, Helmut Denk 1 .
1 Department of Pathology, Medical University of Graz, Austria
2 Department of Obstetrics and Gynaecology, Medical University of Graz, Austria

Granulosa cell tumors (GCT) of the ovary are rare sex cord-stromal tumors. Up to 50% of patients develop recurrences which sometimes occur as late as 30 years following the initial surgical treatment. Although some recurrent tumors have been treated successfully by re-operation, radiation therapy and/or chemotherapy, the prognosis is usually poor.
The aim of this study was to analyze immunohistochemically the expressions of EGFR (Her-1), Her-2, Her-3, and Her-4 in 40 tumors comprising 38 adult type GCTs (AGCT) and 2 juvenile type GCT (JGCT). Thirty one cases (77,5%) were positive for at least one of the receptors EGFR (Her-1), Her-3, and Her-4. Twenty six out of 40 (65%) GCTs showed positive reaction for EGFR (Her-1). Eight tumors (20%) were exclusively positive for EGFR (Her-1). None of 40 cases

showed a positive reaction for Her-2. Positive reactions for Her-3 and Her-4 were observed in 18 (45%) and 23 (57,5%) tumors. Only one case (2.5%) was exclusively positive for Her-4. Four tumors (10%) showed positivity for Her-3 and Her-4 but were negative for EGFR (HER-1). While one of the two JGCTs was negative for all members of the Her-family, one showed reactivity for EGFR (Her-1), Her-3, and Her-4.
These findings may provide the basis for clinical trials using monoclonal antibodies against extracellular domain of EGFR (such as cetuximab) or small molecule inhibitors of EGFR (such as gefitinib). Furthermore, the expression of Her-4 in GCTs raises the intriguing possibility of treatment with Heregulin-beta2/PE40, a ligand toxin with known anti-proliferative effects on granulosa cell lines.

GRANULOSA-CELL TUMOURS OF THE OVARY: A STUDY OF 16 CASES
ELLOUZE Sameh, MAKNI Saloua, BAHRI Ibticem, GOUIAA Naourez, AYADI Lobna, GHARIANI Mekki, SELLAMI Ahmed, BOUDAWARA SELLAMI Tahya

Introduction:
The granulosa-cell tumors of ovary (TG) are the most known malignant tumours of the mésenchyme and sexual cords; they are rare, accounting for 2 to 5% of the whole of the malignant tumours of the ovary. These tumours are of two types; the adult type and the juvenile type.
Purpose: Through our results and after a review of the literature, we reported the epidemiological, anatomoclinical and therapeutical aspects of the TG of the ovary.
Methods used:
We made a retrospective study of 16 cases of TG that were examinated at the laboratory of pathological anatomy and cytology of the CHU Habib Bourguiba of Sfax, over 10 years period (1994-2003).
Resalts : The average age of our patients was 46 years for the adult type with extremes of age of 20 and 70 years and 35 years for the juvenile type; 19% of our patients were nulliparous, 31 % were menopausal women and an inductive treatment of ovulation was reported in 19 % of the cases; clinical symptomatology was dominated by the abdomino-pelvic mass and endometrial signs related to hyperoestrinism like disturbances of the menstrual cycle and post menopausic metrorragia. The tumour was unilateral in 94 % of the cases and bilateral in 6 % of the cases. Macroscopically, the tumor size was often important varying from 6 to 27 cm with a solido-cystic aspect in 50 % of the cases; histologically, the adult type was found in 94 % of the cases and the juvenile type in 6 % of the cases. The immunostaining was positive for the mesenchymatous markers (vimentine); variable positivity for the chromogranine, the NSE and the PS100 was observed. Association with endometrial lesions was noted in 44 % of the cases with simple hyperplasia without atypia in 25 % of the cases, polyp in 12,5 % of the cases and adenocarcinoma in 6 % of the cases. The treatment was surgical in all cases; only the patient with juvenile type was treated by chemotherapy. No relapse nor recurrence was noted after a follow up of 30 months for the adult type contrary to the juvenile type who developed multilocated metastasis.
Conclusion : granulosa-cell tumors are an interesting entity witch has several epidemiological and histological characteristics and a potential to aggressive behaviour.

P 801
ADULT TYPE GRANULOSA CELL TUMOR – MORPHOLOGICAL FEATURES
AMALINEI Cornelia*, BALAN Raluca*, PRICOP Florentina**, RADULESCU Doinita*, BUTUREANU Stefan**, DUMITRACHE Florentin**, COTUTIU Coriolan*
*Department of Pathology, University of Medicine and Pharmacy Iasi, Romania
**Department of Obstetrics and Gynecology, University of Medicine and Pharmacy Iasi, Romania

Granulosa cell tumors (GCT) account for about 5% of all ovarian tumors. They are usually unilateral and variable in size. Adult granulosa cell tumors (AGCT) account for approximately 1-2% of all ovarian tumors and 95% of all GCT. They occur more often in postmenopausal women, with a peak incidence between 50 and 55 years. 6 cases of AGCT were diagnosed in the Clinical Hospital of Obstetrics and Gynecology Iasi, in a 7 years period. The age of the patients ranged between 35 and 67 years, 4 of them (66.66%) being postmenopausal. The macroscopical appearance showed that all were unilateral tumors – 4 of them (66.66%) solid and 2 cystic (33.33%). After paraffin-embedding and usual stainings, we observed the granulosa cells as small, cuboidal to polygonal cells, arranged in anastomosing cords, and gland-like structures filled with an acidophilic material recalling immature follicles (Call-Exner bodies). Two tumors presented microfollicular and macrofollicular patterns. Three tumors (50%) presented also a thecoma component formed by sheets of cuboidal to polygonal cells (specifically called granulosa-theca cell tumors). In two of them both granulosa and theca cells presented aspects of luteinization (luteinized granulosa-theca cell tumors). Only one tumor (16.66%) was associated with simple hyperplasia of the endometrium (suggesting an active endocrine tumor). 4 of them (66.66%) presented areas of malignant transformation, 3 of them being associated with tumoral necrosis, 1 with calcifications, and 2 with vascular invasion. Although considered as benign tumors, only 5-25% of them being malignant, with an indolent course and only local recurrences, in the reported cases the tumors were mainly malignant (66.66%), two of them being highly aggressive, as vascular invasion was noted, and one of them was also advanced, with histologically confirmed implants of abdominal peritoneal surfaces.

P 802
SALPINGITIS WITH CHLAMYDIA TRACHOMATIS; POSSIBLE ROLE IN SECONDARY STERILITY
DAHI Fahed 1,2, HUDITA Decebal 1, CEAUSU Iuliana 1, HALALAU Florin 2, CEAUSU Mihai 2
1 – Department of Gynecological Pathology, Cantacuzino Hospital, Bucharest, Romania
2 – "Victor Babes" National Institute of Pathology, Bucharest, Romania

In etiopathogenesis of secondary sterility, salpingitis with various etiology plays an important role. The main infections of the tube in etiopathogensis of sterility, except gonorrhea, are Chlamydia Trachomatis, Mycoplasma Hominis and in post-partum streptococci and staphylococci.

This work is to demonstrate the role of Chlamydia Trachomatis infection in this matter.

A retrospective study was performed on 450 cases (women with age between 20 and 35 years) with secondary sterility, from which 160 cases (35,5%) had positive serology for IgM and 40 cases (9%) had positive cultures for C. Trachomatis from uterine cervix. Laparoscopic examination with prelevation of biopsies in 290 cases revealed in the majority of cases (280) chronic salpingitis with important sclerosis with obstruction of the tubal lumen and adhesions between fallopian tube and ovary and pelvic peritoneum. In five cases the histopathologic examination revealed the pattern of "salpingitis isthmica nodosa".

This high incidence of infection with important process of fibrosis demonstrates the main role of Chlamydia Trachomatis in the pathogenesis of sterility with tubal origin.

ANDROGENS AND PROGESTERONE IN PREECLAMPSIA

Dabirioskoei Atousa *,Golmohammadloo Sariyeh **,Nanbakhsh Fariba **
*Department of Obstetrics and Gynecology, Zanjan University of Medical Sciences, Zanjan, Iran
**Department of Obstetrics and Gynecology, Urmia University of Medical Sciences, Urmia, Iran

Hypertensive disorders of pregnancy are from the most common ones. As the pathogenesis of this disease is not clear yet and as there are so many reasons to prove the role of sex hormones in this disease, so this study tries to investigate the change of serum progesterone, total testosterone, free testosterone and dehydroepiandrosterone sulfate (DHEAS) levels in the patients with preeclampsia. Nineteen patients with preeclampsia who were referred to Kosar hospital of Urmia were compared gestational age and body mass index. All subjects were primigravid women. They were also compared considering those four mentioned hormones. T-test was used as statistical way of analysis. $P<0.05$ was considered as significant. Progesterone and free testosterone levels were significantly lower in patients with preeclampsia than in the control group ($p<0.05$). There were no significant differences in total testosterone and DHEAS. There were also no significant differences in maternal age, gestational age and body mass index. Sex hormone binding globulin can increases in preeclampsia, so that it can decrease the amount of free testosterone in serum. On the other hand progesterone can relax smooth muscle of vessels resulting decreasing of blood pressure. So it can be said that decreasing of progesterone in preeclampsia may indicate a role fore it in the pathogenesis of preeclampsia

P 804

THE ROLE OF P63 IN HYDROPIC ABORTION, PARTIAL HYDATIDIFORM MOLE, COMPLETE HYDATIDIFORM MOLE AND CHORIOCARCINOMA

Leandra Náira Zambelli Ramalho
Alfredo Ribeiro-Silva
Mariana Spigiorin Maggiori
Luiz Cesar Peres
Department of Pathology, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Brazil

Gestational trophoblastic diseases (GTD) are a group of interrelated diseases of trophoblastic tissue that include partial hydatidiform mole, complete hydatidiform mole, invasive mole, choriocarcinoma, and placental site trophoblastic tumor. Choriocarcinomas are clearly malignant neoplastic lesions but hydatidiform moles are just abnormal placental tissues with potential to malignant change. Thus, the identification of biological markers that allow differentiate these pathologies in doubtful cases are important in clinical practice. P63 is a p53 homologue that is associated to several malignancies. In normal placentas p63 is expressed in cytotrophoblast cells. The role of p63 in gestational trophoblastic diseases, however, merits further investigation. This work was carried out to study the expression of p63 in hydropic abortion (HA) and gestational trophoblastic diseases, including partial hydatidiform mole (PM), complete hydatidiform mole (CM), and choriocarcinoma (CC). Immunohistochemistry with the antibody p63 (clone 4A4) was performed in 40 formalin-fixed paraffin-embedded samples of placenta tissue. The cases were selected to represent HA (n=12), PM (n=11), CM (n=12), and CC (n=5). The distribution of p63 was quantitatively assessed in cytotrophoblast cells and recorded as: + (0-25% of cells stained by p63), ++ (26-50%), +++ (51-75%), and ++++ (75-100%). The intensity of immunostaining was also evaluated as weak, moderate, or strong. Statistical analysis was determined by the Fisher test. Contrary to the other diagnoses, none of the choriocarcinomas analyzed exhibited positive cells for p63 (CC x CM, P=0.0036; CC x PM, P=0.0002; and CC x HA, P=0.0104). There were no statistical relationship between CM x PM (P=0.5008); CM x HA (P=0.2825); and PM x HA (P=0.0444). Concerning the intensity of immunostaining, there was statistical difference only between PM and HA (P=0.0045). The lack of p63 expression in choriocarcinomas indicates that this protein may be helpful in distinguishing CC from other GTD in challenging cases. We also verified that the intensity of p63 expression was much stronger in PM than in HA. Since sometimes is difficult to differentiate an abortion from partial hydatidiform mole because villous blood vessels may be not easily identified within villous with exuberant edema, this find may have clinical importance.

P 805

EXPRESSION OF EGFR IN MOLE HYDATIDIFORMS, EXAGGARATED PLACENTAL SITES AND NORMAL PLACENTAS AND KI 67 IN MOLE HYDATIDIFORMS AND NORMAL PLACENTAS

KUPESIZ YILDIRIM Gokben*, PESTERELÝ Hadice Elif*, ERDOGAN Gulgun*, SIMSEK Mehmet**, KARAVELI Fatma Seyda*
Akdeniz University School of Medicine Departments of Pathology* and Obstetrics and Gyneacology

PURPOSE:The aim of this study is to find out differences between expression of EGFR in complete, incomplete mole hydatidiforms, exaggareted placental sites and Ki 67 labeling index (LI) in complete, incomplete mole hydatidiforms and normal placentas.
METHODS:Parafin embedded sections of 18 incomplete, 7 complete hydatidiform moles, 19 exaggareted placental sites and 10 placentas (control group) were studied immunohistochemically for EGFR and Ki 67. Statistical analysis of the results were made using student t or ANOVA with post huc Tukey test.
RESULTS:Ki 67 was detected immunohistochemically in villous cytotrophoblasts and extravillous intermediate trophoblast of complete , incomplete hydatidiform moles, and only in villous cytotrophoblasts of control group. Ki67 LI of villous cytotrophoblasts differed significantly between complete and incomplete hydatidiform moles ($p < 0.01$). Ki67 LIs of hydatidiform moles were significantly higher than control group ($p < 0.001$).
Immunostaining of Ki67 in extravillous intermediate trophoblasts were not different between complete and incomplete hydatidiform moles ($p = 0.58$).
EGFR was detected in syncytiotrophoblast and cytotrophoblasts of complete and incomplete hydatidiform moles, and control group. Staining of villous cytotrophoblasts differed significantly between complete hydatidiform moles and control group ($p < 0.001$) and incomplete hydatidiform moles and control group ($p < 0.001$) but staining of villous cytotrophoblasts was not differed significantly between complete and incomplete hydatidiform moles ($p=0.10$).
EGFR expression of syncytiotrophoblast differed significantly between complete,incomplete hydatidiform moles and control group ($p < 0.001$).However the difference of syncytotiotrophoblasts immunopositivity between complete and incomplete moles was not significant ($p > 0.05$).
EGFR immunostaining was not detected either in extravillous intermediate trophoblasts of mole hydatidiformes or exaggarated placental site.
CONCLUSION:Expression of EGFR in syncytiotrophoblast and cytotrophoblasts is important in the pathogenesis of complete and incomplete hydatidiform moles. Negative staining of EGFR in exaggareted placental sites may show us that EGFR-releated family of oncogens does not play a role in the pathogenesis of exaggarated placental site. Ki67 LI can be a useful marker in differentiating complete and incomplete moles.

P 806

EFFECT OF OBSTRUCTIVE CHOLESTASIS ON GONADOTROPINS AND GERM CELLS APOPTOSIS IN THE ADULT MALE RATS

NOORI Mugahi, Mohammad Hossein., NABAVI, Mohammad Bagher
Department of Marine Biology, Faculty of Marine Sciences, Khoramshahr University of Marine Sciences and Technology , Khoramshahr , Iran

Obstructive cholestasis is associated with overproduction of endogenous opioids (EOP) , nitric oxide (NO) and cytokins in the blood streams. These consequences can be affected sex hormones. Since proper fertility will be resulting of physiological balance of sex hormones so that we investigated the relationship between obstructive cholestasis and sex hormones and apoptotic germ cells in adult male rats.

To study this, we used three groups of animals: Control (No-surgery), Sham (surgerical control), and cholestatic (surgical ligation of the bile duct). After 3 weeks all animal were killed by ether, and serum concentrations of inhibin B , FSH and LH were determined by ELISA and Radioimmunoassay respectively, testicular germinal cells apoptosis was evaluated by DNA fragmentation detected by in situ terminal deoxynucloetidyl Transfrase-mediated dUTP nike end labeling (TUNEL).

Results: The findings of this study were shown that LH and FSH levels were significantly decreased in cholestatic compared to control and sham groups ($p<0.05$). However, inhibin B level was significantly higher in cholestasis than control and sham ($p<0.05$),On the other hand, we could not be shown any significant difference in germinal cells apoptotic index between cholestatic and other groups ($P>0.19$).

These findings have been shown which as obstructive cholestasis was although decreased the levels of serum gonadotropins but it has no significant effector testicular germinal cells apoptosis.We were speculated that testicular germinal cell apoptosis was not only dependent on gonadotropin hormones but also other factors may involved.

MULTICENTRIC FIBROADENOMA WITH FLAT EPITHELIAL ATYPIA

Simona Stolnicu1, Simona Mocan2, Florin Coros3, Doiniþa Rãdulescu4
1Department of Pathology, University of Medicine Targu Mures, Romania
2Department of Pathology, County Clinical Hospital Targu Mures, Romania
33 th Surgical Clinic, University of Medicine Targu Mures, Romania
4Department of Pathology, University of Medicine Iasi, Romania

Introduction: Fibroadenoma of the breast represents a benign biphasic tumour, wich occurs most frequently under 30 years old. The epithelial component may show a wide spectrum of typical hyperplasia but very rare, this hyperplasia presents atypia. We present the case of an 18 years old woman, with 5 fibroadenomas in the left breast, two of them presenting flat epithelial atypia.

Matherial and method: The five tumours (25, 35, 55, 40, 45 mm diameter) were evaluated on hematoxylin and eosin-stained sections. Immunohistochemical studies were performed on formalin-fixed, paraffin-embedded tissue, using Actin, p 53, ki 67, ER, PR.

Results: All the five tumours had classic fibroadenoma's pattern. Two of them presented the replacement of the normal epithelium by a single or stratified epithelium (up to 3-5 cell layers), columnar type.The epithelial cells showed mildly atypia. The acini and ducts were distended and contained an eosinophilic material. They were surrounded by myoepithelial cells, wich were Actin-positive. The epithelial cells were ki 67, p 53, ER and PR-positive.

Conclusions: The presence of multicentric fibroadenoma, two of them with flat epithelial atypia increases the risk of developing cancer in this patient. Clinical and mamographic follow-up of this patient is necessary in the future. Six month later the patient developed three more fibroadenoma in the same breast, one of them with flat epithelial atypia.

LOCALISING NYBR-1 - A LASER-CONFOCAL AND IMMUNO-ELECTRON MICROSCOPIC STUDY

B. Sasse, Institute of Clinical Pathology, University Hospital Zurich, Switzerland
C. Zuber, Division of Cellular and Molecular Pathology, University Hospital Zurich, Switzerland
J.-P. Theurillat, Institute of Clinical Pathology, University Hospital Zurich, Switzerland
Z. Varga, Institute of Clinical Pathology, University Hospital Zurich, Switzerland
D. Jäger, Department of Oncology, University Hospital Zurich, Switzerland
H. Moch, Institute of Clinical Pathology, University Hospital Zurich, Switzerland

Background: NY-BR-1 is a breast differentiation antigen recently discovered by SEREX technology in a breast cancer patient. Here we report on the localisation of this antigen in breast cancer cell lines as determined by confocal laser microscopy and immuno-electron microscopy. Methods: NY-BR-1 transfected breast cancer cell lines were cultured on glass cover slips, fixed, permeabilised and labelled with an anti-NY-BR-1 antibody. Further examinations involved confocal laser microscopy or transmission electron microscopy. Results: NY-BR-1 is associated to cytoplasmic vesicles preferentially close to the nucleus and follows the architecture of microtubules. In metaphase nuclei, NY-BR-1 co-localises with the chromosomes. Conclusions: NY-BR-1 is associated to microtubules, to vesicles and to chromatin. This suggests a function of the protein in cytoplasmic trafficking and/or chromosomal regulation in mitotic nuclei.

P 809

Introduction: Breast cancer is a significant public health problem worldwide. Plenty of mammographic screening programs resulted in the detection of breast carcinomas at early stage. The presence of microcalcifications in mammogram not only correlates with breast cancer in many cases, but also sometimes is the only early sign of this disease. Nowadays, Computer Aided Diagnosis (CAD) systems may help radiologists detecting and classifying clustered microcalcifications, which is vital for proper treatment.

Objectives: The objective of this work was to evaluate the performance of the computerized classification method for automatically detected clusters of microcalcifications.

Materials and Methods: In our research we used 106 images from Digital Database for Screening Mammography (DDSM), among which 67 presented malignant and 39 benign cases. Our experiments were carried out in two steps: automatic detection and automatic classification. For the detection, previously developed morphological method has been used. Before the classification task was conducted, the whole set of mammograms was divided into two groups: training and testing sets, including the same number of images. Only images from training set were used to train the Support Vector Machine (SVM) classifier. The performance of the classifier has been tested on images from testing set.

Results: Automatic classification of clustered microcalcifications in mammograms is a final stage of CAD

system which helps the radiologist in diagnosis. According to ROC analysis the presented algorithms yielded Az=95,23%. Conclusions: The SVM classifier used in experiments gave very good results and will be used in further research on complex CAD system.

PRODUCTION AND CHARACTERIZATION OF ANTIBODIES TO ESTROGEN RECEPTOR-BETA ISOFORMS EFFECTIVE FOR USE ON ROUTINELY-PROCESSED HUMAN TISSUES

DIMOLEA Eugene(1), TINIAKOS Dina(2), PECHTELIDOU Anastasia(1), FLORENTIN Ida(1), KITTAS Christos(2), SEKERIS Constantinos(1), ALEXIS Michail(1)
1. Molecular Endocrinology Programme, Institute of Biological Research and Biotechnology, National Hellenic Research Foundation, Athens, Greece,
2. Laboratory of Histology and Embryology, Medical School, National & Capodistrian University of Athens,Greece.

Introduction-aim: Estrogen receptor a (ERa) expression is a well established prognostic and predictive marker for breast cancer. Recent data indicate that ERß, a recently described estrogen receptor type mainly expressed through two isoforms, ERß1 and ERß2, may also play a role in human breast cancer progression. Clinical studies suggest that a correlation may exist between breast cancer responsiveness to tamoxifen and ERß1 or ERß2 expression. The lack of suitable antibodies has been a preventing factor for the elucidation of the role of ERß isoforms in breast cancer prognosis and treatment. We aimed to produce monoclonal antibodies (mAb) to ERß1 and polyclonal antisera (pAb) to ERß2 effective for the immunostaining of routinely processed human tissues.
Methods: An appropriately designed synthetic peptide (ERß1 aminoacids 517-530) and an appropriate GST-fusion protein were used as immunogens for the generation of mouse anti-ERß1 mAbs and rabbit anti-ERß2 pAbs, respectively. Following well established techniques, a number of specific ? Rß1 mAbs and ERß2 pAbs have been produced as determined by Western blotting.
Results: One anti-ERß1 mAb and one anti-ERß2 pAb proved to be effective for use on formalin-fixed, paraffin embedded human tissues. Both antibodies produced intense nuclear staining in the majority of epithelial cells in normal breast, while in archival breast carcinoma tissues the percentage of ERâ expressing neoplastic cells as well as the intensity of immunostaining varied considerably between tumours. Expression of ERß was also observed in lymphocytes, fibroblasts, endothelial cells as well as squamous cells of the nipple epidermis.
Conclusions: The newly produced anti ? Rß-antibodies may prove useful for studying the expression of ERß isoforms at the protein level in normal and malignant breast tissues in an effort to assess their significance in mammary carcinogenesis and their value as prognostic and predictive markers in human breast cancer.

FOUR SYNCHRONOUS FEMALE GENITAL MALIGNANCIES: THE OVARY, CERVIX, ENDOMETRIUM AND FALLOPIAN TUBE

SAÐLAM Arzu, BOZDAÐ Gürkan, USUBÜTÜN Alp, KUZEY Gamze Mocan, KÜÇÜKALÝ Türkan, GÜLTEKÝN Murat, AYHAN Ali
Hacettepe University Faculty of Medicine

The coexistence of multiple primary carcinomas in the female genital tract, and especially the common occurrence of synchronous ovarian and endometrial adenocarcinoma is well-known. While the etiology of this phenomenon remains unclear, it has been postulated that tissues of a common embryologic origin when simultaneously exposed to certain carcinogens may develop synchronous neoplasms.
We present the unique case of a 63 year-old woman with coexistent adenocarcinoma of the ovary, endometrium, cervix and fallopian tube; all of which we believe to be separate primaries, supported by the fact that that all four lesions are of low grade and stage and exist together with neighboring preinvasive lesions. To our knowledge, four synchronous primaries involving each aspect of the female genital tract has not previously been reported.

P 812
THE STUDY OF THE ULTRASTRUCTURE AND HORMONAL VARIATION OF CORPUS LUTEUM IN FEMALE RATS FED ANETHUM GRAVEOLENS EXTRACT

MONSEFI M, GHASEMI M, BAHAODDINI A
Biology department, School of Sciences, Shiraz university

Anethum graveolens L.(Dill) as a medicinal herb, used as a remedy for inducer of menstruation and increase mother's milk production. Using too much dill leads to sexual weaknesses and decrease spermatogenesis. This investigation was preformed on 54 Wistar female rats with regular estrous cycle divided into 6 groups: control, sham, low dose of aqueous extract (0.045 gr/kg), high dose of aqueous extract (.045 gr/kg), low dose of ethanol extract (0.5 gr/kg) and high dose of ethanol extract (5 gr/kg). The above mentioned doses of extracts were orally administrated by feeding needle for 10 days. Blood samples were taken at the following steps: 1- Blood sampling from tail vessels before the beginning of experiment, 2- Blood sampling from dorsal aorta after the end of experiment. Estrogen and progesterone hormones were measured by Elisa and RIA methods, respectively. In order to ultrastructural study of the corpus luteum , ovaries were dissected. The data was analyzed by the ANOVA test to determine the significant difference at $p<0.05$.
The results indicated no significant difference in serum estradiol concentration, but the serum concentration of progesterone hormone increased significantly in high dose of aqueous and ethanol extract groups. Ultrastructural studies showed the increase of mitochondria, SER, RER and polyribosome in granulosa lutein cells of the high dose of aqueous and ethanol extracts administrated rats.

It may be concluded that high dose of aqueous and ethanol extract of Anethum graveolens L. act as LH hormone, which induced modifications on structure and synthetic activity of the granulosa lutein cells and lead to prolongation of luteal phase and increase progesterone hormone concentrations.

ENDOMETRIAL AVB3 INTEGRIN AND OSTEOPONTIN EXPRESSION IN FERTILE WOMEN AND INFERTILE PATIENTS

Jaume Ordi, Gemma Casals, Helena Suárez, Cristina Guix, Montserrat Creus, Elias Campo and Juan Balasch
Department of Pathology, and Institut Clínic of Ginecologia, Obstetrícia and Neonatology, IDIBAPS-Hospital Clínic, University of Barcelona, School of Medicine, Barcelona, Spain

Background: Osteopontin (OPN) is a glycosilated protein originally identified as a constituent of bone matrix that mediates cell adhesion and cellular signaling by binding to integrin heterodimers. Osteopontin is the ligand of one of the putative embryo implantation factor, avb3 integrin, and recent evidence has suggested that osteopontin and its receptor avb3 integrin are coexpressed in the human endometrium around the time of the "implantation window". The aim of this study was to evaluate investigate the endometrial expression of OPN and avb3 integrin as well as its temporal relationship

throughout the luteal phase in both normal fertile women and infertile patients.
Design: We studied 10 fertile controls and 88 infertile patients. All women underwent two endometrial biopsies during a single menstrual cycle (a midluteal biopsy on postovulatory day +7 to +8 and another biopsy four days later). Biopsies were evaluated according to the criteria of Noyes et al. avb3 integrin was detected in frozen tissue and OPN in formalin-fixed, paraffin-embedded material using the EnVision system. Immunohistochemistry results were correlated with the histological dating, cause of infertility (endometriosis, unexplained infertility or male infertility) and fecundity.
Results: OPN and avb3 integrin endometrial expression followed a similar pattern, with glandular expression increasing from histological day +3, when 37.5% of endometria expressed OPN and 0% expressed avb3 integrin, to day 9, when 100% co-expressed both factors. Co-expression of OPN and avb3 integrin was less frequently observed in out-of-phase than in-phase endometria (7.4% vs. 56.5%, $p<0.05$). However, no differences in the co-expression of OPN and avb3 integrin were observed between fertile and infertile women or according to the different causes of infertility. No relationship was observed between endometrial expression of these factors and fecundity outcome for subsequently untreated infertile patients.
Conclusions: Integrin avb3 and osteopontin expression are markers of endometrial maturation but their significance in terms of endometrial receptivity for embryo implantation in the clinical setting remains to be shown.

ANALYSIS OF GENE EXPRESSION IN LIPOSARCOMA OF MIXED TYPE
Kyung Un Choi, Do Youn Park, Jee Yeon Kim, Chang Hun Lee, Mee Young Sol, Hyun Jeong Kang, and Dong Hun Shin.
Department of Pathology, Pusan University College of Medicine, Busan, Korea.

Abstract : Liposarcomas of mixed type are rare. We experienced a case of liposarcoma composed of pelomorphic and well differentiated components. To identify molecular alterations in this tumor, gene expression in pleomorphic liposarcoma (PL), well differentiated liposarcoma (WDL), and normal adipose tissue (NA) was examined using cDNA microarray representing 17,000 genes. The cDNA microarray analysis showed that 6 genes in WDL, not in PL, were upregulated more than 5-fold compared to NA, and 40 genes in PL, not in WD, were upregulated. Other 6 genes in both WDL and PL, were downregulated more than 5-fold compared to NA. The differentially expressed genes included those associated with signal transduction, transcription, cell cycle, enzyme, structural protein, immune system and others. Our experimental data domonstrated that multiple genes are differentially expressed in liposarcoma of mixed type. It is suggested that these genes are involved with the differences in morphological characteristics and carcinogenesis of liposarcoma.

CLINICO-MORPHOLOGICAL AND CYTOGENETIC STUDY OF SOFT TISSUE LEIOMYOSARCOMAS
WYSOCKA Joanna, ILISZKO Mariola*, WASILEWSKA Anna, LACKOWSKA Bozena, JASZCZ-GRUCHALA Agnieszka, MARKIEWICZ Dorota, KRUCZAK Anna, SZPOR Joanna, MOSKAL Julia, KOLODZIEJSKI Leszek, RYS Janusz
Cracow Center of Oncology, *Dept. Biology and Genetics Medical University of Gdansk, Poland

Introduction: Leiomyosarcomas of soft part (SPLsa) are relatively rare neoplasms which estimate less than 10% of all malignant soft tissue tumours. What is more they were a heterogeneous group of neoplasms divided according to their localization. Thus the pathologists' experience concerning these lesions is limited.
Purpose of the study: The aims of study are: morphological and cytogenetic characteristics of neoplasm and the estimation of prognostic parameters for patients treated because of separate groups of SPLsa.
Materials and methods: Clinical records of 37 patients treated for SPLsa were reviewed. Formalin-fixed, paraffin embedded material from 44 tumours was available for routine examination in light microscopy. In 7 cases we had at our disposal the primary tumours as well as recurrent or metastatic ones. Two pathologists independently analyzed the slides stained with hematoxylin-eosin, Masson's trichrome and/or stained immunohistochemically. Immuno-histochemical reactions were carried out using the avidin-biotin complex immunoperoxidase technique (LSAB2+ kit) or ultravision labeled polymer. Small fragments of fresh tumour tissue from 24 cases were taken for ultrastructural and flow cytometric studies. Additionally, in 12 cases, short- term in vitro cultures from tumour material were used to obtain metaphases for cytogenetic analysis.
Results: Patients included 21 female and 16 men. The tumours localized in soft tissues of extremities (31 cases), retroperitoneal space (4 cases), head and neck region, abdominal cavity and thoracic or abdominal wall (2 cases each) The metastatic tumours were situated in lungs and subcutaneous tissue. Histologically, all tumours consisted of long fascicles which were built of the spindle cells with cigar-shaped nuclei and deeply staining eosinophilic cytoplasm. Masson's trichrome dyed the cell cytoplasm red. In 18 cases the additional MFH-like component of tumour was observed (so-called pleomorphic leiomyosarcoma) The tumour cell were stained positively for smooth actin (29 cases), and H-caldesmon (35 cases). Additionally the positive reaction to S100-protein, CD57 and CD68 were noticed in 6, 1, and 7 cases, respectively. Mitotic activity varies from 4 to 150 figures per 10HPF. 24 patients live from 15 to 155 months after tumour resection. For 8 patients who died the mean survival reached 30 months.

SMALL ROUND CELL MYOEPITHELIOMA OF SOFT TISSUE: CLINICOPATHOLOGIC STUDY OF 3 CASES EXPANDING THE MORPHOLOGICAL SPECTRUM OF MALIGNANT MYOEPITHELIOMA.
SALGADO Roberto (1), GEBHART Michael (2), SEGERS Valérie (3), DELHOVE Olivier (4), LEEMPOEL Martine (5), DE SAINT AUBAIN SOMERHAUSEN Nicolas (1).

(5) Laboratoire d'Analyses Morphologiques, Brussels/Belgium

Background:
Myoepitheliomas and mixed tumors (« pleiomorphic adenomas ») are well-characterized in salivary glands but have only recently been recognized as primary soft tissue neoplasms. The plasticity of myoepithelial cells is responsible for a broad morphological spectrum. Tumors are usually composed of epithelioid, spindle or plasmacytoid cells,

arranged in nests or intersecting cords within an abundant chondromyxoid or hyalinized matrix.
Design:
We recently encountered a few cases of malignant myoepithelial tumors of soft tissue with an unusual small round cell component, mimicking other small round cell malignant neoplasms. We present the clinicopathologic features of 3 cases of this rare morphological variant.
Results:
There were 2 male and 1 female patients aged 4-21 years at the time of resection. Tumors were located in the mediastinum, elbow and leg (within a nerve). Histologically, 2 tumors had infiltrative margins; the intraneural tumor was well circumbscribed. All tumors were composed predominantly (60-95% of tumor tissue) of sheets of dyscohesive small round cells, with scant eosinophilic or clear cytoplasm and round hyperchromatic nuclei. All cases showed a high mitotic index (>10 mitoses / 10 high power fields). In all tumors, foci composed of epithelioid cells, arranged in a reticular growth pattern within a chondromyxoid or hyalinized matrix, were identified in the surgical resection specimen.
In all cases, tumor cells expressed at least focally cytokeratins (AE1-AE3), epithelial membran antigen, S-100 protein, smooth muscle actin, calponin, and GFAP.
Two tumors recurred locally and one metastasized in an inguinal lymph node, after 2 years.

Summary & Conclusion:
We present 3 cases of malignant myepithelioma of soft tissue showing a previously unreported small round cell appearance. All tumors affected young patients and the 2 cases with available follow-up behaved aggressively. The diagnosis was based on the identification of areas showing classical morphological features of myoepithelial differentiation, and on the co-expression of S-100, GFAP, myogenic and epithelial markers.
Our study expands the morphological spectrum of myoepithelial tumors. The differential diagnosis of small round cell myoepithelioma includes metastatic carcinoma, poorly differentiated synovial sarcoma, PNET/Ewing Sarcoma, mesenchymal chondrosarcoma and desmoplastic small round cell tumor.

MALIGNANT PERIPHERAL NEUROEPITHELIOMA 'PERIPHERAL NEUROBLASTOMA' A CASE REPORT
Al-IRHAYIM Bedoor, YOUSIF Amer A.
Departments of Pathology and Surgery
College of Medicine
Mosul, Iraq

Peripheral neuroepithelioma is a rare malignant tumour of primitive peripheral non autonomic nervous system. The tumour can occur at any age involving soft tissue mainly of lower extremities. Other sites of occurrence are the shoulder-thoracic region and the head and neck. It is a very aggressive tumour with early metastasis mainly to the lung.
We report a case of 16 years old female who was presented with rapidly enlarging soft mass of labia majora. Physical examination revealed a 15x10 cm oval lobulated firm mass covered by normal skin on the right side of labia majora. There was no lymphadenopathy. The remainder of the physical examination of the patient in general, was within normal, so were routine laboratory tests.
The mass was excised followed by administration of chemotherapy and radiotherapy. The tumour was very cellular with wide areas of necrosis and viability around vessels. The cells are small and rounded arranged all over in Homer-Wright rosettes. Vascular invasion was noticed at the periphery of the tumour with retained rosettes formation of the intravascular clumps. However, 3 months after excision, the patient developed secondaries in the lung, with pleural effusion, but no local recurrence.
This is a rare case of Peripheral neuroepithelioma. This tumour is classified under peripheral neuroectodermal tumours (PNET). Histologically, it is reminiscent to neuroblastoma, but the two tumours vary in clinical aspect, behaviour, prognosis, and response to treatment.

PLEXIFORM CELLULAR SCHWANNOMA: THE HISTOLOGICAL, IMMUNOHISTOCHEMICAL, ULTRASTRUCTURAL AND CYTOGENETIC STUDIES OF A RARE CASE WITH A LONG FOLLOW-UP.
MARKIEWICZ Dorota, DRABIK Gra¿yna*, KRUCZAK Anna, ILISZKO Mariola**, WASILEWSKA Anna, LACKOWSKA Bozena, SZPOR Joanna, WYSOCKA Joanna, MOSKAL Julia, KOLODZIEJSKI Leszek, MIERZYNSKI Wojciech*, RYS Janusz
Cracow Center of Oncology, *Polish-American Children's Hospital, Jagiellonian University, Cracow, **Dept. of Biology and Genetics Medical University of Gdansk, Poland

Introduction: Cellular variant of schwannoma is defined as the hypercellular tumor composed exclusively or predominantly of Antoni A tissue, and devoid of formed Verocay bodies. The cellular schwannomas growing in a plexiform or multinodular pattern are extremely rare and their diagnosis controversial. We found only 15 described cases of plexiform cellular schwannoma (PCS). The longest clinical observation in all those cases was about 13 years.
Aims: The aims of the study are: presentation of the case of a very rare neoplasm with very long follow-up and the analysis of criteria of malignancy in peripheral nerve tumours.
Case report: A 1-year-old girl underwent surgery in a case of a deeply localized lateral neck tumour. After 4, 18 and 20 years she developed 3 recurrences treated by incomplete excisions. Since the last one, she has been living for 3 years with loco regional, slowly growing tumour. No malignant transformation nor metastases was observed.
Materials and methods: Formalin-fixed, paraffin embedded material from primary and all recurrent tumours were available for routine examinations in light microscopy. Immunohistochemical (IHC), ultrastructural, flow cytometric and cytogenetic studies were made on the tissue samples from the third recurrent tumour.
Results: Gross examination showed tumor of 11cm in diameter, composed of multiple, variable in size nodules. The histological examination showed plexiform tumor infiltrating thyroid gland and soft tissue. At higher magnification the tumor was composed of uniform spindle cells, arranged in fascicles of high cellular density. Their nuclei were of low polymorphism. Mitotic activity was 2/10 HPF, neither atypical mitotic figures nor necrosis were found. IHC stainings for S100 and CD57 were strongly positive, and reaction to p53 was negative. MIB index reached 2.0. Evaluation in electron microscopy showed neoplasmatic well differentiated Schwann cells. The tumor cells were diploid and S phase fraction reached 2.2. The karyotype of tumour cells was normal.
Discussion: PCS is a entity that resemble MPNST. In our opinion multinodularity, infiltrative tumor borders and local tissue destruction are designative for local recurrence but not for capacity to metastases. Low or moderate polymorphism of cells, low mitotic activity and MiB-1-index, low S phase fraction, and negative reaction to p53 protein, as well as normal karyotype can prove against malignancy and metastatic potential of the tumor.

5Department of Gynecology, Oita-ken Saiseikai Hita Hospital, Hita, Japan

Myxopapillary ependymoma is a well recognized variant of ependymoma, which usually arises from the filum terminale. However, ectopic presentation in the pevis and around male and female genital tracts is extremely rare. We recently encountered a case arising in the pelvis of an elder Japanese female without any relationship to the spine, which was diagnosed as a myxopapillary ependymoma on basis of the histological appearance. The patient was a 69-year-old female, who was referred complaining of irregular genital bleeding in September 2003. Computed tomography and MR imaging revealed a mass lesion, which was measured approximately 8cm in the largest dimension and was located between the rectum and posterior wall of the vagina, but no relationship to the spine was confirmed. Two months later from initial presentation, transvaginal biopsy was performed along with resection of the uterus and left appendages, but failed to reach any specific diagnosis. In the middle of November 2003, the tumor was surgically removed. Microscopic examination revealed a lobulated mass lesion with dense fibrous septa, in which ovoid or polyhedral neoplastic cells were arranged in trabecular and reticular patterns against the background of loose myxoid stroma. In some areas, plump spindle cells showed solid growth with poorly organized fascicles. Intra- and extracellular hyaline globules were identified. Immunohistochemically, neoplastic cells showed diffuse positive reaction for vimentin and S100 protein, and focally positive for GFAP. Actins, desmin, CD34, cytokeratins, EMA, and Glut1 were completely negative. Follow-up observation detected a recurrent lesion three months later after surgical removal. But the lesion did not show aggressive growth and the patient is alive and well for a year. Myxopapillary ependymoma is not a highly lethal tumor and is designated as WHO grade I. Post-operative course in the present case would support the diagnosis. We present its histological features in detail and the literature is briefly reviewed.

BENIGN TRITON TUMOR: ABOUT ONE CASE

FATIHA BENADRA,HICHAM EL ATTAR,HANANE RAIS,BADIA BEELABIDIA

Benign Triton tumor of the hand: about one case
Introduction: The neuromuscular hamartoma or benign triton tumor is a developmental lesion composed of mature elements of both striated muscle and nerve.
Observation: A 22 years old woman presented a nodular mass of 1.5 cm in his finger; appeared since the birth. The excision was complete. Microscopic examination showed multiples nodules of fascicles striated muscles and nerves.
Discussion:
The benign triton tumor is rare. Large nerves are the most involved. Hand's location is unfrequent. The histological diagnosis has sometimes proved to be difficult. The differential diagnosis can be made with fibromatosis and rhabdomyoma. The pathogenesis still unclear and could be the result of incorporation of mesenchymal tissue into nerve sheaths during embryogenesis.

UNUSUAL PRESENTATION OF EWING SARCOMA IN A PATIENT WITH PLEXIFORM NEUROFIBROMA

METE Ozgur (*), BILGIC Bilge (*), DEMIRYONT Misten (*), OZGER Harzem (**), AYAN Inci (***)
(*) Istanbul University, Istanbul Faculty of Medicine, Department of Pathology
(**) Istanbul University, Istanbul Faculty of Medicine, Orthopedic Surgery
(***) Istanbul University, Institute of Oncology

Plexiform neurofibromas (PNF) are benign tumours of the peripheral nerves which mostly develop in patients with neurofibromatosis type 1 (NF1). Approximately in 10 % of NF1 patients, a malignant peripheral nerve sheath tumour (MPNST) emerges from a preexisting PNF. Ewing sarcoma, which is the second most common soft tissue malignancy in children has not been described in NF1 patients.
A 4-year-old female child presented with right thigh pain, swelling and with cafe au lait spots. MRI showed a large multilobulated mass. The plexiform tumour measured 50 cm. Immunohistochemical and architectural findings supported the diagnosis of PNF. Five years later, a mass measuring 16 cm in diameter occured in the soft tissue of left shoulder. Tru-cut biopsy revealed a high-grade, primitive small round cell malignancy. The neoplastic cells were diffusely immunoreactive for MIC-2. The cells were nonreactive for S100 protein, desmin, leukocyte common antigen, and keratin. The tumour was diagnosed as Ewing sarcoma. Initial treatment consisted of 3 cycles of chemotherapy (consisting of ifosfamide-etoposide alternating with vincristine, adriamycine, actinomycin-D and cyclophosphamide) (IE/VAC) every three weeks. Thorax computerised tomography revealed small lesions in both lungs, which were disappeared after 3 cycles of chemotherapy. After 3 cycles of chemotherapy the mass, which regressed radiologically more than 50%, was resected. The histopathological examination revealed 80 % of necrosis. Although the patient is now free of disease, she is going to have chemotherapy until 18 cycles will have finished.
Ewing sarcoma has not been described in NF1 patients. The immunohistochemical findings and response to chemotherapy justified our diagnosis. The t(11;22) (q24;q12) is the most detectable genetic changes in Ewing sarcoma, whereas the inactivation of the CDKN2A (9p21)is the second most common genetic alteration. It is noteworthy that the inactivation of CDKN2A is also responsible for the malignant transformation of PNF to MPNST. But there was no preexisting PNF in the left shoulder of our patient. Therefore, we can suggest that there may be a common genetic alteration on the gene regulating CDKN2A, which may be responsible for developing both tumour in our case.

HIGH NUCLEAR SURVIVIN EXPRESSION IS ASSOCIATED WITH METASTATIC DISEASE IN EWING SARCOMA

Aubert S*, Buob D*, Gonzales S*, Fron D°, Pichon F§, Leroy X*.
*Department of Pathology,CHRU Lille France
°Department of Pediatric Surgery, CHRU Lille France
§Departement of Oncology, Centre Oscar Lambret,Lille France

Introduction: Ewing's sarcoma (ES) is a small round blue cell tumour with a high incidence of metastasis and poor survival. Metastatic disease at diagnostic is the key adverse prognostic factor with a significant influence on relapse-free survival.

Recently, the overexpression of surviving, apoptotic inhibitor, has been shown to be correlated with unfavorable clinical outcome in several types of tumours.
Purpose: to assess the prognostic value of the immunohistochemical expression of survivin in ES of bone. This is the first study to evaluate the expression of survivin on ES.
Methods: Biopsy tissues of 24 consecutive patients with ES were assessed retrospectively for the immunohistochemical expression of survivin (monoclonal D-8, SantaCruz Biotechnology) by the streptavidin-biotin peroxydase procedure. For survivin, 1000 cells were counted and the percentage of positively stained nuclei was computed. A statistical analysis using the non-parametric Mann-Withney test was performed. Clinical data and follow-up were obtained by the patient charts.
Results: the series comprised 17 males for 7 females with a mean age of 17, 4 yrs (range 1-45 yrs). Metastases were present in 11 patients at diagnosis. Treatment consisted of chemotherapy, surgery and/or radiotherapy in all the patients. 8 patients developed metastasis and/or local recurrence after treatment. 5 patients died of the disease, 4 patients were alive with disease and 15 were alive without disease at last follow-up (mean follow-up : 26,8 months). Survivin immunostaining was only nuclear. The mean expression was statistically higher in ES with metastases (range : 0-26% ; mean 14,8 %) than in ES without metastasis at diagnosis (range : 0-23,7% ; mean 6,67 %) ($p=0,023$).
Comments: This preliminary retrospective study shows that a high level of nuclear survivin expression implied a more aggressive biological behaviour of ES of bone ($p<0,05$). So, survivin seems to be involved in the critical steps of cancer onset and may be associated with unfavorable clinical outcome.

ANALYSIS OF SEQUENTIAL SECONDARY CYTOGENETIC CHANGES IN EWING'S SARCOMA: A XENOTRANSPLANTATION MODEL
FERRER Jaime, NOGUERA Rosa, RUIZ Amparo, LOPEZ-GUERRERO Jose Antonio, BALLESTER Sandra, CARDA Carmen, PELLIN Antonio, LLOMBART-BOSCH Antonio.
Department of Pathology, University of Valencia, Valencia, Spain.

Background: Ewing's sarcoma (ES) is characterized by the specific cytogenetic event t(11;22)(q21;q24) and its variants, although minor cytogenetic aberrations have also been described, the most frequent being trisomy 8, trysomy 12 and the derivative chromosome der(1;16). Their prognostic relevance in ES is still unclear.
Purpose: Our aim was to evaluate the occurrence, frecuency and changes in the pattern of secondary numerical aberrations in a dynamic model of ES.
Methods: seven tumors were transplanted into athymic nude mice and sequentially maintained through serial passages, during a period of time ranging from 18 months to 6 years. Fresh samples from original tumors and their consecutive passages were cultured and karyotyped, and analyzed by means of comparative genomic hybridization (CGH), FISH, and image analysis (cytometry and morphometry). For CGH, tumor DNA and normal DNA from healthy donors were amplified, differentially labelled and cohybridized. FISH analysis with centromere-specific probes was carried out for chromosomes 8 and 12. Image analysis was performed with Isis 2.50 software (Metasytems, Germany).
Results: a good correlation between karyotypic changes and CGH and FISH results was found in all cases. All cases harbored the specific change t(11;22). The total mean number of numerical aberrations detected by CGH in the original tumors and their subsequent passages was low (1.9). Gain of chromosome 8, whether complete or restricted to the long arm, was the most frequent numerical aberration found by CGH (4 out of 7 tumors). Its appearance ranged from 0 to 26 months. In these cases, trisomy or tetrasomy of chromosome 8 was detected by FISH analysis. In two cell lines, gain of chromosome 8 was associated with gain of chromosome 12. Gain of 1q, loss of 16q (2/7 each) and other minor events were also detected by CGH.
Conclusion: gain of chromosome 8, whether associated or not with gain of chromosome 12, is the most frequent secondary change in ES. The cytogenetic heterogeneity in the pattern of occurrence of this numerical aberration could be related to the different proliferative advantage observed in these tumors.

1. "Victor Babes" National Institute of Pathology, Bucharest, Romania
2. Clinical Hospital, Craiova, Romania

CD117, the c-kit proto-oncogene product is a transmembrane receptor for stem cell factor, normally expressed by interstitial cells of Cajal of the gastrointestinal tract and by many others cells like: mast cells, melanocytes, germ cells, subsets of hematopoietic cells; it is expressed also by their malignant tumors. The positivity for CD117 in a tumor does not necessarily indicate a mutation of the gene. The problem to be solved is if a targeted therapy against CD117, may be useful only in GIST or equally in other CD117 positive tumors; for this reason it is necessary to assess a large number of such tumors.
We performed a tristadial indirect immunohistochemical method on formalin fixed, paraffin embedded sections for detecting CD 117 (Policlonal,DAKO,Denmark), CD34 (Monoclonal, BIOGENEX, USA) and Nestin (Monoclonal, Santa Cruz, USA).
We found a IHC positivity for CD117 in cases of : malignant melanomas (MM) (10), seminomas (6), disgerminomas (3), granulosa cell tumors (GCT) (2), phyllodes tumors of breast (BPT) (5), solitary malignant fibrous tumor (SMFT)(1), gastric glomic tumor (GGT) (1). The MM and the BPT presented also a positivity for Nestin; the SMFT and GGT were positive also for CD34.
We concluded that at least a part of various tumors expressing CD117 may be considered as extra GISTs. It remain to establish if all the CD 117 positive tumors could benefit a specific therapy.

Osteosarcoma (OS) is characterized by complex karyotype, high frequency of cytogenetic aberrations and gene amplification. Chromosomal instability (CIN) provides genetic diversity for OS tumour progression, but both the mechanisms that lead to CIN and the biological basis of the conferred selective advantage of genomic aberrations in this tumour are poorly understood. CGH studies have identified frequent amplification and rearrangement involving the central genomic region of 6p. A number of genes associated with oncogenesis such as RUNX2, TNFa and VEGF cluster to this region and their increased expression by amplification would be predicted to be associated with tumor progression. Moreover, the chromosomal domain hypothesis suggests that genes with a functional relationship may be closely linked within subchromosomal regions of the nucleus. Thus the location of a gene within a chromosomal territory is thought to influence access to the proliferative machinery responsible for specific nuclear functions, such as replication, transcription, splicing and repair. Segmental duplications within this region may facilitate amplification by homologous recombination. The aim of this study was to evaluate, by FISH technique, the frequency and distribution of 6p amplification in osteosarcoma. Fluorescence in situ hybridization (FISH) was performed on a 77 core tissue microrray of primary osteosarcoma using chromosome enumeration probe (CEP) for the centromeric region of chromosome 6 (SpectrumOrange, Vysis Inc., Downers Grove, IL). Hybridization signals were scored among 100 non-overlapping tumor cell nuclei using the following scoring criteria: disomy < or = 2 chromosome copies in > 90% of the cells, low trisomy 3 copies in > 10% but < 40% of the cells, high trisomy 3 copies in > or = 40% of the cells, low polysomy > or = 4 copies in > 10% but < 40% of the cells, high polysomy > or = 4 copies in > or = 40% of the cells. Numerical aberrations of chromosome 6 were observed in 7 out of 8 tumors. Low polysomy was detected in 4 cases, low trisomy in 3 and disomy in 1 case. An increase in the number of chromosome 6 may frequently occur in osteosarcoma. Further studies at molecular and clinical level must be carried out to identify the gene alterations reflected by polysomy 6 or amplification within 6p. Such studies may facilitate the detection of specific tumours subtypes and genes directly associated with OS-tumour progression and clinical response.

P 826

THE RESULTS OF PREOPERATIVE CHEMOTHERAPY AND/OR RADIOTHERAPY IN NONMETASTATIC HIGH-GRADE OSTEOSARCOMA OF THE EXTREMITIES

ONER Dincbas Fazilet*, DERVISOGLU Sergulen**,KOCA Sedat*, MANDEL Molinas Nil***,HIZ Murat****,KESMEZACAR Hayrettin****, OKSUZ Colpan Didem *,BICAKCI Ceylaner Beyhan* ,UZEL Burak***, KANBEROGLU Kaya*****Istanbul University, Cerrahpasa Medical Faculty, Departments of Radiation Oncology*, Pathology**, Medical Oncology***, Orthopedic Surgery****, Radiology*****

Purpose: To assess the role of neadjuvant chemotherapy and adding of radiotherapy to the chemotherapy in patients with nonmetastatic high-grade osteosarcoma of the extremities and to compare the response of therapies on local control, tumor necrosis rate and overall survival rate.

Methods and materials: Between 1990 and 2002, 61 extremity-localized nonmetastatic high grade osteosarcoma patients were treated with radiotherapy in our hospital. Thirty-eight patients were male and 23 patients were female. Median age was 17 years (11-66 years). All patients were treated with neoadjuvant chemotherapy. Chemotherapy schedule that was consisted of epirubicin, cisplatin and ifosfamide ¡À high dose methotraxate was given before surgery. In order to increase the chance of limb sparing surgery, preoperative radiotherapy was added to patients who refused amputation or whose limb-sparing surgery would have been difficult because of borderline respectability. Radiotherapy was applied usually between the second and the third cycle of chemotherapy. Radiotherapy was given 35 Gy in 10 fractions to 44 patients. Remaining 2 patients were treated with 46 Gy with 2 Gy/day. Chemotherapy was given 3-6 cycles after surgery. In the radiotherapy group tumor size was between 3-32 cm (median 10 cm). In the chemotherapy group tumor size was between 4-20 cm (median 10 cm).
Results: Fourty-four patients out of 46 patients who were treated with radiotherapy, had limb-sparing surgery. Thirteen patients out of 15 patients who were treated with only chemotherapy had limb-sparing surgery and 26 patients (56.5%) in radiotherapy group, 7 patients (46.7%) in the chemotherapy group had tumor necrosis rate ¡Ý90% (p=0.05). In the radiotherapy group the 5-year local control, disease-free and actuarial survival rates were 98, 38 and 52, respectively. In chemotherapy group the 5-year local control, disease-free and actuarial survival rates were 92, 41 and 31, respectively.
Conclusion: Preoperative radiotherapy helps to increase the tumor necrosis rate and the chance of extremity sparing surgery when combined with chemotherapy. Though local control and overall survival rates were higher in patients with treated radiotherapy and chemotherapy, this difference was not statistically significant. It is difficult to make definite conclusions, because this was a nonrandomized and retrospectively analyzed study and the quality and the quantity of the patients were not the same in two groups.

P 827

EXPRESSION OF E-CADERIN, P-CADERIN, BETA-CATENIN, APC AND C-ERBB-2 IN CONVENTIONAL OSTEOSARCOMAS OF EXTREMITIES

Guimarães APG, Cunha IW, Guimarães GC, Vilela RS, Soares FA. Research and Medical Center Hospital do Cancer, São Paulo, Brazil

Background: Several series of osteosarcomas (OS) have been reported in the literature, but debate still exists regarding the clinical prognostic factors for this disease. The WNT proteins form a large family of secreted signaling proteins implicated in the proliferation and morphology of several tumors. The prognostic importance of WNT pathway and c-erbB-2 expression in OS has not been totally clarified.
Methods: The present study included 97 extremities conventional OS cases (70 osteoblastic, 20 chondroblastic and 7 fibroblastic) retrieved from our files. Cases were stained immunohistochemically using antibodies against E-cadherin, P-cadherin, beta-catenin, APC and c-erbB-2. Expression of the markers was correlated with clinical data and local recurrence, distant metastasis, free-disease survival, and overall survival.
Results: Expression of E-cadherin was not observed in all cases of OS. However, expression of P-cadherin, could be observed in 94 cases (96.9%). All the three patients with loss of P-cadherin expression had overall survival less than 8 months. Positive APC staining was observed in 65 cases (67%). APC was more expressed in patients under 18yo (p=0.025). In patients treated with chemotherapy, positive immunoexpression of APC correlated with better survival. Patients APC positive had 69% of five year survival against

APC negative patients with 34% of five year survival. Only 3 cases showed immunoexpression of beta-catenin. Expression of c-erbB-2 was observed in 16 cases and did not show any correlation with clinical parameters and tumor outcome.
Conclusion: P-cadherin is the adhesion molecule expressed in extremities OS and loss of its expression is an indicative of worse prognosis. However it is a very infrequent event and further studies should be performed to validate this finding. Downregulation of APC was an important prognostic factor in patients treated with chemotherapy. Expression of beta-catenin and c-erbB-2 are infrequent events in OS, and did not correlate with clinical behaviour.

P 828
EVIDENCE OF GENETIC ALTERATIONS IN CHROMOSOME 11, 9, AND 2 IN EMBRYONAL AND ALVEOLAR RHABDOMYOSARCOMAS
KRSKOVÁ Lenka, KALINOVÁ Markéta, KOPECKÁ Pavla, HILSKÁ Irena, KODET Roman
Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University in Prague, Czech republic

Introduction: Rhabdomyosarcomas (RMS) are most common soft-tissue sarcomas of childhood. They are subclassified into two major subtypes - embryonal RMS (E-RMS) and alveolar RMS (A-RMS). Various chromosomal alterations have been described in both subtypes. Inactivation of tumor suppressor genes frequently occurs due to loss of heterozygosity (LOH). Mutations of one allele may be followed by a loss of the remaining wild-type allele.
Purpose: To study LOH in RMS in microsatellite loci at mismatch repair genes, at loci close to the genes coding p15 and p16, and at loci at 11p with three probable suppressor gene regions which may be involved in pathogenesis of RMS.
Methods: We used microsatellite polymorphic markers from the region 9p (tumor suppressor genes p15, p16), and from mismatch repair genes hPMS1, hMSH2 and hMLH1. The main attention was paid to telomeric region on 11p. We analyzed 11 patients with E-RMS and with 17 A-RMS. In all patients the presence of LOH was studied using frozen samples from tumor tissue taken at diagnosis. Each tumor sample was compared with constitutional DNA of the same patient obtained from peripheral blood or bone marrow aspirate.
Results: In the study 6/9 (67 %) informative E-RMS patients and 8/15 (53 %) informative A-RMS patients demonstrated LOH on at least one of the microsatellite loci in 11p region. The frequency of LOH for hMSH2 was 4/6 (67%) in E-RMS, and 2/11 (18 %) of informative A-RMS. For hPMS1 the result was 1/5 (20%) and 2/6 (33 %) of informative E-RMS and A-RMS, respectively. LOH in the region 9p was not detected in any of nine informative E-RMS and it was found in 5/14 (36%) A-RMS.
Conclusion: Our study demonstrates a frequent loss of heterozygosity on the short arm of chromosome 11 in both E-RMS and A-RMS and a relatively high frequency of LOH in 9p in A-RMS. High frequency of LOH in the locus D2S123 (hMSH2) in E-RMS may be caused by a relatively high portion of non-informative (homozygous) cases. At this stage of understanding it is impossible to speculate whether the described LOH are involved at early stages of the tumor development or whether they are secondary events of the tumor progression.
The study was supported by grants from Czech Ministry of Health 00064203, Czech Ministry of Education 0021620813 and Internal grant of FNM 9746.

RHABDOMYOSARCOMA OF THE SPINAL CORD: A CASE WITH IMMUNOHISTOCHEMICAL, ULTRASTRUCTURAL AND CYTOGENETIC STUDY
HEMMINGS Chris*, HALLAM Lavinia*, MAXWELL Lesley#, JAMMU Vapinder^
Departments of Anatomic Pathology*, Ultrastructural Pathology# and Cytogenetics^, ACT Pathology, The Canberra Hospital, ACT, Australia

INTRODUCTION
Although primary Central Nervous System (CNS) rhabdomyosarcoma has been described, it is very rare and is thought most often to arise from the meninges. We report a case of a spinal cord tumour showing rhabdomyoblastic differentiation on light microscopy, immunohistochemistry and electron microscopy. Cytogenetic analysis showed an unusual karyotype, which has not previously been reported in rhabdomyosarcoma.
METHODS
Case report
RESULTS
A 14 year old boy was found to have a contrast-enhancing spinal cord tumour at the level of the conus. At surgery the tumour appeared invasive and was not attached to the dura. Microscopy revealed a malignant tumour composed of rounded and spindled cells, with widespread rhabdomyosarcomatous differentiation, including strap cells. Although entrapped nerve fibres were identified within the infiltrative tumour, no evidence of a coexistant glial or other CNS neoplasm was found. Immunophenotyping confirmed positivity for vimentin, desmin and myoglobin.
Ultrastructural examination confirmed the presence of thick and thin cytoplasmic filaments, with clear evidence of sarcomere formation in places. Z bands were readily seen. Admixed myelinated neural cells were also seen, but there was no evidence of ependymal differentiation.
Cytogenetic analysis revealed an abnormal karyotype in 19 of 20 metaphases, containing a derivative chromosome 5 resulting from a t(5;18) translocation. The karyotype was: 45,XY,der(5)t(5;18)(p?15.3,p?11.2),-18 [19]/46,XY [1].
CONCLUSION
As only a small amount of tissue was available for study, we cannot entirely discount the possibility that this tumour represents myosarcomatous differentiation within a composite mixed or multiphasic malignant tumour. However, in the absence of any other evidence to the contrary, we present this as a case of apparent primary CNS rhabdomyosarcoma, with a novel cytogenetic aberration.

RHABDOMYOSARCOMA: CLINICOPATHOLOGIC REVIEW OF 36 CASES
DERVISOGLU Sergulen*,BAGCI Pelin*,OZTURK Kilicaslan Tulin*, CELKAN Tiraje**,MANDEL Molinas Nil***,ONER Dincbas Fazilet****
Istanbul University, Cerrahpasa Medical Faculty, Departments of
Pathology*, Pediatric Oncology**,Medical Oncology***, Radiation Oncology****

INTRODUCTION:Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma of childhood and adolescent periods and can seldomly be seen adults too. Despite all research, a single prognostic classification for modelling the treatment is still needed. The clinicopathological features of our recorded rhabdomyosarcoma cases are reviewed and the major prognostic factors are discussed.
MATERIALS AND METHOD: Thirtysix RMS cases diagnosed in our department between 2000 and 2005 were reevaluated with respect to age, sex, localization, histological type, immunohistochemical stains, therapy, recurrences, metastasis, survival time and correlations between these entities were studied.
RESULTS and CONCLUSION:Eleven Percent of our total malignant tumor material in this period was diagnosed as

sarcoma, among which 1,8% was RMS. The male / female ratio was almost equal and no significant difference was observed in survival between sexes (p>0,41). Cases below 10 years of age were 57%, between 10-20 were 23% and over 20 were 20% .Embriyonel RMS was the frequent histological type and had the best prognosis (p<0,002). Thirtyseven percent were located on head and neck region, 25% were intraabdominal. Desmin, HHF35, and Myogenin positivity of different intensities were observed in all cases . Fortyeight percent of the patients were at the stage of III or IV (IRS clinical classification) at the time of diagnosis. All of the cases were treated by chemotherapy (VAC) and radiotherapy whenever was needed. Some of the cases were inoperable , resection was done pre - or posttherapeutically in most of the cases. According to the clinical follow-ups ; 31% of the cases showed relapse or metastasis. The survival time was longer in early ages (p<0,02). Most of the chilhood cases were at the head and neck localization. If it was intracranial and parameningeal the survival time gets shorter and if there was spreading to serebrospinal fluid this time was too short . Histologic type may have an influence on prognosis and in the presence of alveolar component agressive course was expected, but it may be difficult to subclassify the tumor in a small biopsy specimen due to common use of FNAB or trucut biopsies because of the sample size and mixed nature of the tumor .

SPINDLE CELL RHABDOMYOSARCOMA IN ADULTS
BRACKO Matej, FRKOVIC GRAZIO Snjezana
Institute of Oncology Ljubljana, Slovenia

Spindle cell rhabdomyosarcoma (SCRMS), a rare variant of embryonal rhabdomyosarcoma, occurs mainly in the group of pediatric patients and is characterized by a predilection to male sex and paratesticular and head and neck location as well as very favourable prognosis which is superior to that of classical embryonal rhabdomyosarcoma. SCRMS is rare in adults and, to the best of our knowledge, only seven cases have been reported to date in patients older than 18 years.
To further elucidate the features of SCRMS occurring in adults we report additional three cases of this rare entity.
The tumours were identified in a 24-year-old woman, a 35-year-old man and a 39-year-old woman, and arose in the vulva, muscles of the calf and subcutaneous fatty tissue of the leg, respectively. They were all treated by surgery and chemotherapy. The first patient developed uncontrollable local recurrence in the pelvic soft tissues and died due to metastatic disease 22 months after the first surgery; the second patient developed inguinal lymph node metastases 24 months after surgery and was then lost to follow up; the third patient is alive with no evidence of disease 12 months after surgery.
Microscopically, the tumours were composed mainly of fascicles of relatively monomorphic spindle cells with eosinophilic cytoplasm and rare rounded or strap-shaped rhabdomyoblasts. Cross-striations could be identified in one case only. Immunohistochemically, all three tumors were positive for muscle specific actin (HHF35), desmin, myoglobin and MyoD1; two tumors were focally positive for alpha smooth-muscle specific actin, and none was reactive for S-100 protein.
The analysis of the data of the ten reported cases, including the three presented here, indicates that, as opposed to the pediatric group, SCRMS in adults shows no predilection to particular anatomic site or male sex, and is not associated with favourable outcome. In fact, its prognosis in adults seems to be equally poor as that of other histologic types of rhabdomyosarcoma.

HER-2 ONCOGENE AMPLIFICATION IN SYNOVIAL SARCOMA
Zoltán Sápi MD.Ph.D1, Zsuzsa Pápai MD.Ph.D2., Anett Hruska MD3, Imre Antal MD.Ph.D4, Miklós Bodó MD.DSc1, Zsolt Orosz MD.Ph.D5
1 Department of Pathology, St John's Hospital, Budapest, Hungary
2 Department of Oncology, National Helth Institute, Budapest,
3 Institute of Morphology and Physiology, Semmelweis University, Budapest
4 Department of Orthopedics, Semmelweis University, Budapest
5 Department of Pathology, National Institute of Oncology, Budapest

Background
The treatment regimens for synovial sarcoma (SS) is very limited, though this type of sarcoma seems to be more heterogeneous as it has been traditionally considered. The present study investigates the Her-2 oncogene status of 20 cases of SSs, whether the Her-2 amplification can be considered as an independent prognostic factor.
Materials and methods
Her-2 oncogene amplification was determined on smears (in each case frozen material was used from our tumor bank) using Fluorescence in Situ Hybridization technique (dual color FISH with centromeric probe of chromosome 17 and unique specific probe for Her-2 oncogene). Beside this, the DNA ploidy status was measured using image analysis. We had 5 biphasic and 15 monophasic SSs, patient age ranged from 13 to 68 years (mean, 39.8). Tumor size was larger than 5 cm in each case. Follow up ranged from 6 to 78 months (mean, 38.5 months). For statistical analysis the chi-squared-test was used.
Results
Her-2 oncogene amplification was found in three cases (15.0%) of 20 SSs, but so called massive amplification which is characteristic of some subset of breast carcinoma, was not observed. Her-2 oncogene amplification was significantly associated with a lower risk of developing metastasis (P<0.05) (none of 3 amplified cases had metastases), while no association was found concerning recurrences (P<0.5). 6 cases proved to be aneoploid and 14 were diploid but no association was found between Her-2 amplification status and ploidy and between ploidy status and metastases or recurrences.
Conclusions
Her-2 oncogene amplification is a rare event among SSs, but this small subset of SS has a better overall prognosis. Beside this, there may be a theoretically new treatment possibility with Trastusumab for Her-2 amplified cases of SSs.

P 833
A PULMONARY METASTASIS OF SYNOVIAL SARCOMA APPEARING 18 YEARS AFTER TREATMENT OF THE PRIMARY NEOPLASM
V. Janevska, S. Banev, L. Spasevska, V. Filipovski, M. Nikolovski
Institute of Pathology, faculty of Medicine, Skopje, FYRO Macedonia

A 57 years-old woman presented with weakness and coughing. Investigations revealed a mass in the left lower pulmonary lobe, which was resected. The histological examination suggested a diagnosis of synovial sarcoma. Anamnestic data found out a primary neoplasm treated 18 years ago, only by surgery. The patient is well doing a year after operation of the lung.
Methods: Tissue was examined by routine histological slides, stained by H.E. and immunohistochemically. A revision of the primary tumor was made.

Results: The bought tumors showed biphasic pattern. The pulmonary mass showed a presence of sheets and cords of polygonal epithelial cells with quite rare split like spaces. The epithelial component was intimately intermixed with a spindle-cell component, composed of uniform spindle cells with hyper chromatic nuclei. Immunohistochemical analysis showed widespread labeling for cytokeratins and local labeling for vimentin in the epithelial component, and positive labeling for epithelial membrane antigen in the epithelial and spindle-cell components.
Conclusion: This is a rare case of synovial sarcoma treated with surgery only, metastasing in the lung, after being indolent 18 years.

P 834
MYXOID MONOPHASIC SYNOVIAL SARCOMA OF THE FOOT: A CASE REPORT
R Sellami Dhouib, M Driss, S Sassi, I Abbess, K Mrad, K Ben Romdhane
Department of Pathology, Salah Azaiez Institute, Tunis, Tunisia.

Introduction and aims: Focal myxoid change is a well recognized feature of synovial sarcoma, but the presence of a predominatly myxoid stroma is rare. We described a case of myxoid monophasic synovial sarcoma in which marked myxoid change initially obscured the diagnosis, leading confusion principally with malignant peripheral nerve sheath tumor.
Case report: A 16-year-old adolescent presented with left foot tumour. Roentgenographic studies demonstrated tumor with irregular margin and evidence of bone destruction. Histologically, the tumour had an alternating hypercellular and hypocelllar foci. The areas of hypercellularity consisted of spindle cells arranged in fascicular growth. The cells had bland round or ovoid nuclei with a slightly wavy appearance. Because of nuclear hyperchromasia, the evaluation of mitotic activity is very difficult. Areas of hypocellularity contained individual spindle cells in a myxoid stroma. Neither calcifications nor foci of glandular differentiation were noted. Immunohistochemical stains for cytokeratin, S100 protein, desmin, myogenin and CD34 were negative, while a focal positivity for epithelial membrane antigen was noted. By reverse transcriptase polymerase chain reaction, a SSX1 transcript of synovial sarcoma was found.
Discussion and conclusion: Clinical differences between myxoid synovial sarcoma and conventional synovial sarcoma can't be evaluated because of too limited cases in the literature. Recognition of this rare histological variant of synovial sarcoma is important because it can be easily mistaken for other myxoid spindle cell neoplasms, potentially resulting in suboptimal therapy.

MORTALITY OF TUBERCULOSIS IN RHEUMATOID ARTHRITIS
Miklós Bély MD, PhD, DSc1 and Ágnes Apáthy MD2
1Department of Pathology,
Policlinic of the Hospitaller Brothers of St.John of God,
Budapest, Hungary
2Department of Rheumatology,
National Institute of Rheumatology and Physiotherapy,
Budapest, Hungary

The risk of tuberculosis is higher in RA, or other autoimmune diseases, than in a normal population.
The aim of this study was to determine
1. the mortality due to tuberculosis (Tb), or miliary disseminated tuberculosis (mTb) in RA,
2. the clinicllly missed diagnosis of Tb, or mTb in RA,
3. the main complications associated with Tb, or mTb in RA
4. the link between Tb, or mTb and coexistent major complications, such as systemic vasculitis (SV), or secondary AA amyloidosis (AAa), lethal septic infection (SI), or associated diseases like malignant tumours (mTu), diabetes mellitus (DM), and atherosclerosis (Ath) in RA.
Patients and Methods
A randomized (non-selected) autopsy population of 234 in-patients with RA was studied. RA was confirmed clinically according to the criteria of the ACR.
Post-primary tuberculosis, (with, or without miliary dissemination) and the major complications of rheumatoid arthritis (SV, AAa, SI) associated to Tb, or mTb, and accompanying diseases (mTu, DM, Ath) were confirmed histologically.
A possible link between tuberculosis, or disseminated miliary tuberculosis and coexistent complications, or associated diseases was determined statistically by Chi^2-tests.
Results
1. Post-primary fibrous, or fibrocaseous tuberculosis accompanied RA in 27 (11.54 %) of 234 cases.
Eight (3.4%, 29.6 rel%) of 27 post-primary fibrous, or fibrocaseous tuberculosis cases were complicated by disseminated miliary tuberculosis.
Three patients (1.28 %) died of circulatory failure due to Tb complicated by miliary dissemination.
2. Only one case of Tb with mTb and lethal outcome was clinically recognized.
3. There was a significant and positive correlation between vasculitis and tuberculosis ($Chi^2=4.16$ $p<0.04$), or mTb ($Chi^2=3.86$ $p<0.04$); furthermore between granulomatous type of vasculitis and mTb ($Chi^2=5.55$ $p<0.01$).
Conclusions
Coexisting complications modify the basic disease (RA) and present atypical clinical manifestations. The age of the patients, the autoimmune character of the underlying disease, the steroid and/or immunosuppressive treatment may also play a role in missing the clinical diagnosis of miliary tuberculosis.
The correlation between Tb, or mTb and vasculitis may represent statistically an influence of Tb, or mTb on vasculitis.
The diagnosis of vasculitis of the granulomatous type should alert the surgical pathologist to initiate clinical exclusion of existing tuberculosis with miliary dissemination.

P 836
CHRONOLOGIC SEQUENCE OF AA AMYLOIDOSIS IN RHEUMATOID ARTHRITIS - A RETROSPECTIVE CLINICOPATHOLOGIC STUDY OF 161 AUTOPSY PATIENTS
Miklós Bély MD, PhD, DSc1 and Ágnes Apáthy MD2
1Department of Pathology,
Policlinic of the Hospitaller Brothers of St.John of God,
Budapest, Hungary
2Department of Rheumatology,
National Institute of Rheumatology and Physiotherapy,
Budapest, Hungary

Statement
AA amyloidosis (AAa) is a progressive, cumulative process, involving in its early stages only a few structures in some organs, and increasingly more in the later stages of the disease.
During the progression of systemic secondary amyloidosis, amyloid A deposition begins in the organs and tissue structures that are frequently involved and later show marked deposition of amyloid. Where amyloid deposits are infrequent or less marked, deposition starts later (1).
The aim of this study was to determine
(1) the frequency and extent of amyloid A deposits in various tissue structures,
(2) the frequency and extent of AAa in different organs,

(3) the chronologic sequence of amyloid A deposition in various organs and tissue structures.
Patients and Methods
A randomized autopsy population of 161 in-patients.
Systemic AAa was observed in 34 (21.1%) of 161 cases (1).
AAa was diagnosed histologically.
Results
Amyloid deposits were frequent and massive in the wall of blood vessels, and along collagen and reticulin fibers (or, if present, on the basal lamina), mainly in the GI tract, heart, kidney, spleen, adrenal glands, and the liver.
Amyloid deposits were less frequent and in limited amount in skeletal muscles, synovial membranes, lymph nodes, peripheral nerves, bones, or skin.
The frequently involved structures and organs showed marked deposits of amyloid. In less frequently involved tissue structures and organs the amyloid deposits were less marked at death.
Discussion
The amyloid deposition starts in the wall of blood vessels (capillaries, arterioles, small arteries), followed by deposits on collagen fibers, basal membranes, and reticulin fibers (fat tissue). Deposition in the wall of medium size vessels starts later. The involvement of venules, small and medium size veins increases in case of stasis. Amyloidosis of peripheral nerves is a late, end- stage phenomenon.
The chronology of AA amyloid deposition in various organs is as follows: GI tract, heart, kidney, spleen, adrenal gland and liver. Other organs like pancreas, lung, thyroid gland, aorta, skeletal muscle, synovial membrane, lymph nodes, peripheral nerves, bones and skin are less frequently involved, and AA deposition starts later in them.

Focal myositis is a rare inflammatory disease of the skeletal muscle with histopathological features of interstitial myositis. Any skeletal muscle in the body can be affected. We present a 40-year-old female, previously in good health, with headache of one year duration and the three month history of a painful pseudotumor in the right temporal region. MRI pictures showed markedly thickened right temporal muscle with focally increased signal intensity on T2-weighted scan. Muscle biopsy revealed the characteristic histological findings of polymyositis. However, immunohistochemistry revealed the predominance of CD4 positive cells. In addition, immunofluorescence showed granular deposits of IgM and C3 in the walls of small endomysial and perimysial vessels. Therapy with nonsteroidal antiinflammatory drugs as well as with metilprednisolone was not effective, but responded to radiation therapy.

P 838
MULTIPLE MICROSCOPIC RENAL ANGIOMYOLIPOMA INDICATING TUBEROUS SCLEROSIS
Augros M.(1), Denis E.(2), Touraine R.(3), Cordier M.P(4)., Bouvier R.(5)
(1)Service d'Anatomie Pathologique, Laboratoire M. Mérieux, Lyon, (2) Service de Chirurgie, Centre Hospitalier St Joseph-St Luc, Lyon, (3) Service de génétique Faculté de Médecine de StEtienne , (4) Service de génétique et (5)Service d'Anatomie Pathologique, Hôpital Edouard Herriot, Lyon

Renal manifestations are present in one half of patients with tuberous sclerosis (TS). They include angiomyolipomas, cysts, combination of both and renal cell carcinomas. They are usually detected by imaging techniques. Pure microscopic diagnosis is rather rare.
We report the case of a 36 years old patient, treated surgically for ureteropelvic junction obstruction with calyceal and pelvic dilation and atrophic renal parenchyma.
The histological pictures were unusual. The obstructive lesions were rather moderate when compared to the severity of the renal atrophy. These were associated with chronic ischemic damages, low grade papillary tumor and medial angiodysplasia of arteries. In addition, small multi-focal nodules suggested smooth muscle-cells proliferation. Immunohistochemistry screening for these clusters show positive staining for HMB45. As such, diagnosis of multiple microscopic angiomyolipomas is confirmed.
These microscopic features led to conduct a genetic survey. No cutaneous ophthalmologic or neurological tumors were detected. However, one of his daughters presented neonatal achromatic spots and hypsarythmia when she was 5 months old. The study of the two known genes (TSC1 and TSC2) is in process.
Microscopic renal angiomyolipomas are often predominantly composed of epithelioid smooth muscle cells. These could be associated with vascular affection. They must be recognised as they are highly evocative of TS. Their presence must lead to a full clinical check, complementary imaging analysis, genetic investigation and screening for TS genes mutation.

P 839
A CASE OF PRIMARY RENAL MALIGNANT FIBROUS HISTIOCYTOMA AND ANGIOMYOLIPOMA
DEMIR Dilek(*), KILICASLAN Isin(*), NANE Ismet(**), DEMIRYONT Misten(*), UYSAL Veli(*)
(*) Istanbul University, Istanbul Faculty of Medicine, Department of Pathology
(**) Istanbul University, Istanbul Faculty of Medicine, Department of Urology

Primary renal malignant fibrous histiocytoma (RMFH) is a rare tumor of the kidney. Fiftytwo cases of RMFH have been reported in the literature. It is clinically and radiologically indistinguishable from a renal cell carcinoma.
We report a case of RMFH originating in the capsule of the upper pole of right kidney which was detected incidentally on routine physical examination of a 43-year-old man. The patient underwent right radical nephrectomy with a diagnosis of renal cell carcinoma clinically. The tumor was also seen peroperatively as a bulky mass around the vena cava and could not be resected totally. Gross examination of the specimen revealed two tumoral foci, one of which was a huge, yellowish white, rubbery, nodular mass measured 9x8.5x8.5 cm. Histologically, the tumor was mainly composed of inflammatory cells including lymphocytes, plazmocytes and histiocytes. There were also areas of plump spindle-epithelioid histiocytic cells densely arranged in whorl-like pattern. Because the differential diagnosis included inflammatory pseudotumor, sarcomatoid renal cell carcinoma and RMFH, immunohistochemical analyzes were performed for antibodies pancytokeratin, smooth muscle actin (SMA), desmin, CD31, CD34, CD68 and Ki67. Immunohistochemistry revealed diffuse positivity for CD68 and focal positivity for SMA. Ki67 proliferation index was detected to be 8-10%. The tumor cells were negative for other antibodies. Therefore, the tumor was diagnosed as RMFH.

The other tumor, 1 cm in diameter displaying similar macroscopical features to RMFH, was localised in the lower pole, diagnosed as angiomyolipoma histologically.

In conclusion, RMFH is a very rare tumor and it may lead to differential diagnostic difficulties in the reassesment of renal masses. To our knowledge this case is a unique example of RMFH because of its coexistence with angiomyolipoma.

P 840

COLLECTING DUCT CARCINOMA OF THE KIDNEY: A REPORT OF FIVE CASES AND REVIEW OF THE LITERATURE

Garrido Ruiz M, Meizoso T, Enguita AB, Saiz González A, Usera G

INTRODUCTION

Collecting duct carcinoma of the kidney is a rare neoplasm centered in the renal medulla; these tumors are aggresive, often metastatic and commonly result in death. The clinicopathological features of five cases are here presented to add to the approximately 100 cases reported so far in the literature.

CASES

Clinical presentation in the majoriry of cases has been hematuria, less frecuently loin or back pain, or urinary. Upper tract imaging often suggests urothelial carcinoma of the renal palvis. We report five illustrating cases.

PATHOLOGY

Macroscopic: CDC is usually located in the central region of the kidney and often involves hiliar structures. It ranges widely in size from 0,5 to12cm. The typical CDC is firm and gray-white with irregular infiltration borders; areas of necrosis, and rarely cystic elements may be present.

Microscopic: Typical CDC has a tubular or tubulo-papillary growth pattern. Irregular and disorganised tubules or ducts within a desmoplastic stroma infiltrate and expand the interstitial tissue of both the cortex and medulla, with scattered normal tubules and glomeruli within the malignant tissue.Vascular and lymphatic space invasion is common .Tumor cells are seen both infiltrating into stroma and evoking desmoplasia. Their cytoplasm appears granular and lightly eosinophilic; nuclear grade according to the grading system of Furhman et al. is typically grade 3 or 4. Cells with a hobnail pattern are often present.

Immunohistochemical studies on these carcinomas have been variable; the expected profile would be positive for low molecular weight keratin, for EMA, Ulex europaeus agglutinin and peanut lectin.

DISCUSSION

CDC shows a male predominance (ratio of about 2:1). There is a wide age range with a mean of 55 years, and it has been noted a strong family history of cancer. CDC are the most aggressive carcinomas of the renal tubular epithelium. Approximately 35% of patients have metastases at presentation. Approximately two thirds of patients with collecting duct carcinoma have died of the cancer within two years of diagnosis.

CDC are unlikely to be confused histologically with other renal cell carcinomas (including papillary renal cell carcinoma, urothelial carcinoma with glandular differentiation, adenocarcinoma arising from the urothelium of renal pelvis, and metastatic carcinomas). Accurate classification is important because CDC has a considerably worse prognosis than other renal neoplasms.

P 841

AN UNUSUAL CASE OF UNILATERAL PYELOURETERAL IDIOPATHIC RETROPERITONEAL FIBROSIS SIMULATING RENAL MALIGNANCY

Yolanda Rodriguez Gil
Murillo Lázaro Cristina
Segovia Blazquez Beatriz
Usera Sagarra Gabriel

INTRODUCTION

Idiopathic Retroperitoneal Fibrosis (IRF) or Ormond´s disease is a relatively uncommon disorder, with a reported incidence of 1 in 200000 inhabitants,with a male: female ratio of 2-3:1. It tipically presents insidiously, in the fifth and sixth decades of life and it is rare in children. It is most commonly localized around aorta and iliac vessels, it usually spreads laterally to involve the inferior vena cava and one or both ureters which are displaced medially. It can cause obstructive uropathy and renal failure.

CASE REPORT

A 85 year old man presented with fatigue, anorexia and weight loss, lasting about three months. History was significant for diabetes mellitus type 2 and hypertension. Computerized tomography (CT) showed a deformation of the right kidney due to a low density area which involved the renal hilum and was not clearly separated from the perirenal fat. On magnetic resonance imaging (MRI) the soft tissue mass appeared isointense with muscle on T1 weighted images and hyperintense on T2 weighted images. Excretory urography revealed proximal hydronephrosis and complete obstruction of the ureter. Radiological studies suggested a malignant tumor of the renal pelvis.

RESULTS

Lumbar incision revealed a dense hard grayish-white mass encasing the upper part of the ureter and extending to the hilum of the right kidney. Right nephrectomy was performed. Microscopic examination revealed a fibrous proliferation, broad anastomosing bands of hyalinized collagen and a prominent inflammatory infiltrate composed of mainly of lymphocytes and plasma cells often containing germinal centers, there were also some macrophages and eosinophils. Multiple histological sections were performed to rule out a malignant neoplasia with desmoplastic reaction. The diagnosis of IRF was made after secondary conditions both benignant and malignan were ruled out. The postoperative course was uneventful.

DISCUSSION AND CONCLUSIONS

IRF renal involvement is generally bilateral and tipically involves the middle third of both ureters. In our case renal pelvis and proximal part of right ureter were diffusely and deeply infiltrated by an inflammatory fibrous process. Originally sarcomatous or carcinomatous neoplasia were strongly considered in the clinical differential diagnosis and treated it with nephrectomy. The correct histologic diagnosis of IRF with multiple histological sections,allows urologist to choose less aggresive options of treatment.

P 842

NEPHROGENIC ADENOMA A PITFALL DIAGNOSIS WITH AMACR (P504S) STAINING

Eva Comperat (1), Marya Skrima (2), Isabelle de Pinieux (2), Annick
Vieillefond (3), Vincent Molinie (3).

Introduction : Nephrogenic adenoma is a rare distinctive benign lesion typically found in areas of urothelial mucosa after urinary injury. Microscopically, the lesion usually confined to the urothelial mucosa, exhibits a range of patterns with variable proportions of papillary, microcystic, solid nested, or tubular patterns. The cells lining the tubules, cysts, and papillae are predominantly cuboidal to low columnar with a small amount of cytoplasm, and with sometimes prominent nucleoli. In such cases when the tubular pattern is exclusive it could mimics prostatic carcinoma. Aim of the study : To characterise the morphology and immunoprofile of nephrogenic adenoma. Materials and methods : 23 cases of NA from surgical pathological files of two institution, were selected. Immunostaining was performed with Urinary and

prostate markers CK5/6 (Dako), CK7 (Dako), 34âE12 (Dako), PSA (Dako), PSAP (Dako), P63/p504s (PIN cocktail, Menarini Dg) antibodies.
Results : Histological features displayed a papillary pattern, associated with a tubular component in most cases. The tubes are lined by one layer of small cuboids cells with nucleolar nuclei, surrounded by an inflammatory stroma. In case of exclusive tubular pattern, infiltration could mimic a small acinar proliferation suspicious of prostatic cancer. No mitosis, necrosis or cytonuclear atypia was seen except in 1 case.immunostaining study revealed a 34âE12, CK 5/6 and CK7 positivity, with a diffuse cytoplasmic positivity with P504s. Furthermore only in urethral cases a weak and focal positivity for PSA and PSAP was observed. In all cases P63 was negative.
Discussion : One must be aware of the range of appearances of nephrogenic adenoma to avoid its misinterpretation. In exclusive tubular pattern with muscular involvement nephrogenic adenoma could mimic prostate carcinoma. In such cases one must remind that the over expression of AMACR (P504s) in such small glandular tubular structure may be misinterpreted as prostatic carcinoma. The presence of inflammatory stroma surrounding the small atypical tubes, and the positivity of CK 5/6, CK7 and 34âE12 positivity would restore the true diagnosis of such benign lesion.

INTERSTITIAL KIDNEY FIBROSIS IN AN EXPERIMENTAL MODEL OF UNILATERAL URETERAL OBSTRUCTION (UUO)

ARALICA Gorana, LJUBANOVIC Danica, RADOVIC Nikola*, RACAR Arijana, MÜLLER Danko, MANOJLOVIC Spomenka, KNOTEK Mladen**.
Department of Pathology, Clinical Hospital “Dubrava”, Zagreb, Croatia
*Department of Urology, Clinical Hospital “Dubrava”, Zagreb, Croatia
**Department of Internal Medicine, Clinical Hospital “Merkur”, Zagreb, Croatia

INTRODUCTION
Interstitial fibrosis is a final outcome of many chronic renal diseases, including obstructive nephropathy. Fibrosis considers fibroblast proliferation and intercellular matrix deposition, leading to characteristic tissue changes resulting in chronic renal failure. Angiotensin II is one of the most important factors in the progression of renal diseases.
OBJECTIVE
The objective of this study is to quantify the degree of interstitial fibrosis in rat kidney after experimental UUO and administration of an angiotensin converting enzyme (ACE) inhibitor – cilazapril.
MATERIAL AND METHODS
Male Wistar rats, weigh 210-300 g, were used in this experimental model. There were 4 experimental groups, 6 rats each: 1. sham-operated (sham-UUO); 2. UUO (left ureter was ligated); 3. sham-UUO+cilazapril 10 mg/kg oraly q.d. (Cilazil, Pliva, Zagreb, Croatia); 4. UUO+cilazapril 10 mg/kg oraly. Rats were sacrificed on the 10th day after the operation. The interstitial kidney fibrosis quantification was performed on Gomory stain slides using semiquantitative scale (0- no reticulin increase; 1- rare foci of reticulin multiplication; 2- fine reticulin net around tubuls; 3- dense reticulin net around tubuls; 4- reticulin foci in more then 50% of HPF; 5- diffuse fibrosis) and morphometric system ISSA (Vamstec, Zagreb, Croatia). Morphometric quantification was performed using computer grid (13x10 fields) by counting the number of grid fields containing interstitial fibrosis. Six, randomly selected, microscopic fields (400x) were reviewed for each case.
RESULTS
Interstitial fibrosis developed in all animals after UUO. Number of grid field containing fibrosis per HPF in UUO group was significantly higher than in sham-operated group ($p<0,05$) and in sham-operated+cilazapril group ($p<0,01$). Fibrosis level obtained by semiquantitative analysis did not showed statistically significant difference between experimental groups. However, there was significant corelation between semiquantitative and morphometric method (Pearson`s coefficient $r=0,71$, $p<0,0001$).
CONCLUSION
Interstitial kidney fibrosis developed after the UUO does not decrease after the ACE-inhibitor administration. The level of interstitial fibrosis can be determined using several methods, such as semiquantitative scale and morphometric quantification. The morphometric quantification is more sensitive method than semiquantitative scale.

LYMPHOEPITHELIOMA-LIKE CARCINOMA OF THE RENAL PELVIS: A CASE REPORT AND REVIEW OF THE LITERATURE

TSAI Chien-Chen(1), YANG Ching-Hua(2)
Department of Pathology(1) and Urology(2), Far Eastern Memorial Hospital, Taipei, Taiwan

[Introduction] Lymphoepithelioma-like carcinoma (LELC) shares the same morphologic features with undifferentiated nasopharyngeal carcinoma and is very rare in the urinary tract, especially the renal pelvis. We report the third documented case of LELC of the renal pelvis and review the literature to elucidate its clinicopathologic features.
[Case report] The tumor was found in a 58-year-old woman suffered from left flank pain and gross hematuria. The ultrasound study showed left hydronephrosis with a renal pelvic tumor; therefore, left nephroureterectomy was performed. Grossly, the tumor was fungating and fragile within the dilated renal pelvis. Microscopically, it was composed of sheets or ill-defined nests of syncytial undifferentiated cells exhibiting prominent nucleoli and mixed with extensive lymphoplasmacytic infiltrations. Immunohistochemically, the tumor cells were positive for cytokeratin, but negative for leukocyte common antigen and vimentin. No Epstein-Barr viral (EBV) transcripts were detected by in-situ hybridization for EBER-1. The tumor was limited within the pelvis with no renal parenchymal invasion. No evidence of conventional transitional cell carcinoma was seen after thorough sampling, although focal dysplasia was noted in the urothelium elsewhere. The patient remains well without malignancy 2 years after surgery.
[Conclusion] Reviewing the literature, all three cases of LELC of the renal pelvis occurred in the elderly with a good prognosis. They were not associated with EBV latent infection, unlike LELCs in salivary glands, lungs, or stomach. These clinicopathologic features were almost identical to those seen in the cases of LELC of the urinary bladder. Accordingly, urothelial LELCs should be separated from high-grade urothelial carcinoma and be classified as a distinct entity with a favorable outcome, although they were composed of undifferentiated tumor cells.

Introduction and aim:We present the case of an 60 year old man with no history of hormonal treatment and urological diseases except renal lithiasis. He was hospitalized for left lombar pain and intermittent hematuria. Echography and NMR revealed a kidney mass. A total left nephrectomy was performed The left kidney showed a polar tumor mass. Macroscopically examination of the tumour on cut section showed a solid white tissue with numerous cystic formations of several sizes.
Material and methods: Fragments of the tumor were fixed in formalin10%, embedded in paraffin and sections were stained with HE. Immunohistochemical tests have been done: ACT, CD 34,Progesterone receptors, Estrogen receptors, CD 117,CD 56,HMB 45,Androgen receptors, NK 1
Results:The tumor was composed of a mixture of a spindle cell proliferation intermingled epithelial elements that formed microcyst and macrocystic dilatation No hemorrhages areas, necrosis ,cytologic atypia or mitotic activity were present. Immunohistochemical analyses revealed: ACT, CD 34, Progesterone receptors expression in tumoral areas were positive and CD 117, HMB 45, Androgen receptors, Estrogen receptors, CD 56, NK 1 were negatives
Conclusions: The morphological appearance and immunohistochemical results enabled us to diagnose this case as a mixed epithelial and stromal tumour of the kidney. This is a rare entity in male (few cases previously reported) but our case present the particularity of no hormonal treatment and positive Progesterone expression.

MUCINOUS TUBULAR AND SPINDLE RENAL CELL CARCINOMA :

KOURDA Nadia, CHELBI Emna, , ZERMANI Rachida, RAMMEH Soumaya, FERCHICHI Leila, KACEM Olfa, FARAH Faten, AYED Mohsen, BALTAGI Sarrah.
Department of pathology. CHARLES NICOLLE Hospital, Tunis, Tunisia.

INTRODUCTION
The mucinous tubular and spindle renal cell carcinoma (MTSCC) is a very rare neoplasm, recently described as a distinct subtype of renal cell carcinoma (RCC). This low-grade polymorphic renal epithelial neoplasm with mucinous, tubular and spindle cell features may have striking morphologic similarities to the more common papillary RCC. Herein, we report an additional case of MTSCC with immunohistochemical study and summarise the present knowledge of this newly recognised entity.
CASE REPORT
A 52-years-old woman with uncontrolled hypertension underwent a renal ultrasonography that disclosed a 6.4-cm-sized mass involving the left kidney. A radical nephrectomy was performed. The gross pathology revealed a well-circumscribed whitish solid tumour. Microscopy showed a proliferation of regular cuboidal cells often arranged in long cords and tightly packed tubules and spindle cells component forming small sheets with low grade nuclear cytology. The stroma showed focally a mucinous materiel and clumps of foamy histiocytes. The mucinous material react strongly with alcian blue. The tumour's cells exhibit positive reactions for vimentin, epithelial membrane antigen (EMA), high-molecular-weight cytokeratin (CK), CK7 and CK18 the diagnosis of mucinous tubular and spindle renal cell carcinoma was made. The patient is free of disease since more than 12 months.
DISCUSSION
Clinically, female predominance is reported with a mean age of 53 years. MTSCC often presents as asymptomatic mass.
The MTSCC have a distinctive histologic appearance composed of cuboidal and spindle cells with mucinous extracellular matrix with some degree of morphologic variability. Some authors have reported small foci of clear cells. These pathologic features may be reminiscent of papillary RCC with sarcomatoid features or metanephric adenoma. Most MTSCC are immunoreactive for vimentin, EMA, CK cocktail, CK 7 and Ulex Europeus agglutinin-1 but usually not for CD10. Ultrastructurally, focal short microvilli are generally observed with sometimes junctional complexes and basal lamina. MTSCC exhibit multiple losses of chromosomes 1, 4, 6, 8, 9, 13, 14, 15, and 22 with no VHL deletions. The prognosis is commonly Favourable. However, few cases of local recurrence or metastasis are reported. Morphologic, immunohistochemical and ultrastructure features indicate differentiation toward distal nephron segments has been suggested as the MTSCC phenotype but this view is debatable.

BILATERAL RENAL ADENOMATOSIS AND ONCOCYTOSIS WITH MIXED ONCOCYTIC AND PAPILLARY TUMOURS

Tomas Tichy, Martin Dobias, Katerina Musilova, Patrik Flodr
Institute of Pathology, Faculty of Medicine, Palacky University and Faculty Hospital, Hnevotinska 3, 775 15 Olomouc, Czech Republic

Adenomatosis and oncocytosis are rarely described in the kidney. We report a case of 66-year-old man with bilateral renal adenomatosis and oncocytosis found at authopsy. Both kidneys were occupied by innumerable tumours, the majority of them fulfilled the criteria of renal papillary adenomas. Three tumours showed mixed solid alveolar and papillary patterns composed of oncocytic cells and small cells of papillary adenoma type. Transitional features between patterns were clearly visible. Moreover, apart from dysplastic tubules and microadenomas nearly all histological sections revealed multiple foci of oncocytic transformation of tubular epithelium and microoncocytomas. Oncocytic features of cells were confirmed ultrastructurally. Results of immunohistochemical examination showed that papillary adenomas might be of distal nephron origin.
To our knowledge this is the first case of bilateral renal adenomatosis and oncocytosis described. Mixed oncocytic and papillary tumours are not considered distinct entity. In this case they probably represent collision tumours but taking into account distal nephron origin of described papillary adenomas, oncocytic transformation of papillary tumour cells cannot be excluded.

COMPARISON OF HEP PAR 1 AND MITOCHONDRIAL ANTIGEN EXPRESSION IN RENAL ONCOCYTOMAS: IS IT MITOCHONDRIA WHICH HEP PAR 1 REACTS WITH?

G.GULLUOGLU Mine (*), METE Ozgur (*), KILICASLAN Isin (*), UYSAL Veli(*)
(*) Istanbul University, Istanbul Faculty of Medicine, Department of Pathology

Introduction: Monoclonal antibody, Hep Par 1 has been used to identify tissues of hepatocytic origin and those with hepatoid differentiation. The characteristic diffuse cytoplasmic granular immunostaining pattern suggests an organelle, possibly mitochondial localisation of the antigen. We investigated Hep Par 1 immunoreactivity in the renal oncocytomas which were proved to be rich in mitochondria and compared the mitochondrial antigen (Mab-2) expression of this tumor with Hep Par 1 expression.
Material and Methods: Thirty two cases of renal oncocytoma were included in this study. Staining intensity (+, ++, +++)

and staining area (0-25%, 25-50%, 50-75%, 75-100%) were noted for Hep Par 1 and Mab-2.
Results: We detected the mitochondrial antigen in 75-100% of tumoral areas with (++) to (+++) staining intensity whereas none of the tumors showed the coarse granular staining which is characteristic to Hep Par 1 immunohistochemistry. Only two oncocytomas displayed diffuse cytoplasmic immunoreactivity which is moderately intense while eleven showed faint cytoplasmic staining in <25% of the cells. Twenty tumors showed no immunoreactivity. We did not detect any correlation between the immunoexpression profiles of Hep Par 1 and Mab-2 in renal oncocytomas.
Conclusion: These findings suggest that there is no relationship between the mitochondria and the antigen which Hep Par 1 antibody reacts with.

IMMUNOHISTOCHEMICAL EVALUATION OF CATENINS IN RENAL CELL CARCINOMA

G. Basta-Jovanovic1, S. Radojevic-Skodric1, S. Djuricic2, D. Brasanac1, R. Bogdanovic2, S. Skodric11-Institute of pathology, Medical school,University of Belgrade
2-Mother and Child Health Institute of Serbia "Dr Vukan Cupic"

SUMMARY: Catenins have prognostic value in several human tumors.
AIMS: The aim of this study was to determine the expression of catenins in Renal cell carcinoma (RCC) and their relationship with tumor morphology and TNM status. METHODS: 28 cases of RCC, 2 metastasis and 2 samples of normal kidney tissue were studied using streptavidin-biotin-complex technique.Catenins expression levels were semiquantitatively scored. RESULTS: Alpha-, beta and gamma catenin were present in most cases of RCC (43%, 64% i 50%,respectively). Sarcomatid type of RCC and T3 RCCs displayed higher beta-catenin level than T1/T2 tumours. There is no correlation between cell type and level of alpha or gamma catenin expression($p>0.05$). Beta catenin is predominantly expressed in sarcomatoid type of RCC and this correlation showed statistical significance ($p<0.05$). Tumors of grade 1 more often showed alpha and beta catenin expression (84%;100%) then tumors of grade 2/3 (46%;50%), while there was no differences between gamma catenin distribution in this two groups of tumors (G1-65%;G2/3-41%). Alpha and gamma catenin were expressed more often in tumors of stage T3(57%;71%) then in T1/T2 tumors(38% for both catenins) and that difference has statistically significant association ($p< 0.05$). On the contrary, tumors of lower stage (T1/T2) showed beta catenin expression more often then tumors of higher stage (62%:57%), but this expression did not show significant correlation ($p>0.05$) with tumor stage.CONCLUSIONS: Our results indicate that there is different expression of cell adhesion molecules (alpha, beta and gamma catenin) in RCC, which depends on histological type, tumor stage and grade.

IMMUNOHISTOCHEMICAL EXPRESSION OF EPIDERMAL GROWTH FACTOR RECEPTOR AND MICROVESSEL DENSITY IN RENAL CELL CARCINOMA: PROGNOSTIC VALUE AND RELATION TO CLINICAPATHOLOGIC PARAMETERS.

Suheyla Uyar Bozkurt*, Arman Ozdemir**, Handan Kaya*
*Department of Pathology,** Department of Urology, Marmara University School of Medicine, Ýstanbul, Turkey

INTRODUCTION AND OBJECTIVE: Epidermal growth factor receptor and tumoral angiogenesis have been proposed as potential prognostic parameters in renal cell carcinoma.The aim of this study is to detect the immunohistochemical expression of epidermal growth factor receptor(EGFR) and microvessel density(MVD) and to relate to prognosis and clinicopathologic parameters.
METHODS: Immunohistochemical stains using EGFR and CD 34 monoclonal antibodies were used in 55 renal cell carcinomas diagnosed subsequent to radical nephrectomy or nephron sparing surgery between 1987 and 2001. The MVD was detected by counting the number of microvessels stained by CD 34 in the most vascularised area of tumor.
RESULTS:Univariate analysis showed only pathological stage of tumor has highly significant association with cancer specific survival($p<0.01$). EGFR immunostaining was present in 22 of 55 (40%) RCCs and mean number of counting vessel was 53,31.EGFR immunoexpression and MVD were not exhibited prognostic significance with respect to survival and clinicopathologic parameters such as stage and grade of tumors.
CONCLUSIONS: The expression of EGFR and MVD seems not to provide additional prognostic information in RCCs. Our results show that the best predictors of cancer spesific survival is pathologic stage of tumor in RCCs.

2: Department of Urology, Semmelweis University, Budapest, Hungary

Introduction: Claudins (CLDNs) are tight junctional (TJ) proteins expressed in epithelial and endothelial cells. They participate in the formation of barriers between different tissue compartments by regulating the efflux of molecules through TJ complexes.
Purpose: Our aim was to detect the difference between the expression of CLDNs in the embryonal and adult kidneys. Further, the expression of CLDNs in benign and malignant tumours of the kidney was also studied.
Method: CLDN 1,2,3,4,7 were studied by immunhistochemistry in formalin fixed, paraffin embedded samples of 11 normal embryonal and adult kidneys, and 18 kidney tumours [5 oncocytomas, 5 conventional renal cell carcinomas (CRCC), 5 papillary renal cell carcinomas (PRCC) and 3 chromophobe renal carcinomas (CRC)]. A semiquantitative evaluation was used.
Results: The expression of CLDNs was found to be similar in embryonal and adult kidneys. CLDN1 was expressed only in the Bowman's capsule, CLDN2 in the proximal tubules, CLDN3 in the distal tubules, CLDN4, 7 in the distal tubules, the collecting duct and the pyelon. In oncocytomas only CLDN7 showed a weak, focal, positive reaction, while the other CLDNs were negative. Similarly, CLDN7 was the only CLDN detected in CRC, though with much stronger reaction. In CRCCs intensive expression of CLDN4, 7, and a weak reaction for CLDN2 were observed, while CLDN1 and 3 were negative. In contrast, CLDN1 was expressed in PRCCs, while reaction for the other CLDNs was similar to that observed in CRCCs.
Conclusions: We described a characteristic CLDN pattern in the kidney, which is preserved through the embryonal development till the adult stage. Marked differences were noted among the tumors probably representing different cellular origin, which might be used in differential diagnosis too.

RELATIONSHIP BETWEEN VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) IMMUNOSTAINING PATTERN, VEGF PLASMA LEVELS, TUMOR NECROSIS AND USUAL PROGNOSTIC VARIABLES IN RENAL CELL CARCINOMAS

Nathalie Rioux-Leclercq, Patricia Fergelot, Emmanuelle Leray, Karim Bensalah, Francois Guille, Bernard Lobel, Jean-Jacques Patard.
Departement d'Anatomie et Cytologie Pathologique, Service de Santé Publique, Service d'Urologie, Groupe de Génétique et du Développement UMR-CNRS 6061, CHU, Faculté de Médecine, Rennes.

Objectives: VEGF has been proposed as an important prognostic marker in RCC. However no optimal method of VEGF measurement has been defined so far. The objective of this study was to compare different VEGF measurement modalities to usual clinical and pathological variables in order to better define links between tumor aggressiveness and VEGF blood release.
Methods. 50 clear cell carcinomas were prospectively analysed for VEGF levels by enzyme-linked immunosorbent assay in peripheral blood and in renal vein during nephrectomy (VEGFrv). In addition, detection of VEGF expression was performed in tumor tissue by immunohistochemistry (VEGFt) and three different types of VEGF immunostaining were defined: membranous (type 1), cytoplasmic (type 2) or both: (type 3) . The results were correlated together as well as to the following clinical and pathological variables: TNM stage, Fuhrman grade, tumor size, ECOG performance status, presence of tumor necrosis on pathological analysis, haemoglobin, platelet and leucocyte counts. Mann-Whitney and Kruskal-Wallis tests were used for comparison.
Results : VEGF immunostaining types and tumor necrosis were both correlated to T Stage (p:0.02) and Fuhrman grade (p:0.001 and 0.002 respectively). Tumor necrosis and VEGF immunostaining type were strongly correlated together: 5.3%, 62.2% and 80% of tumors with type 1, 2 and 3 VEGF immunostaining displayed necrotic lesions respectively ($p<0.0001$). VEGFpv (p:0.003), VEGFrv (p:0.03), VEGFt ($p<0.001$), platelet count (p:0.02) and haemoglobin (p:0.01) were correlated to VEGF immunostaining type. For example median VEGFpv was 99 (12-582), 144 (20-437) and 301pg/ml (230-1087) in type 1, 2 and 3 immunostaining type respectively. Similarly the presence of tumor necrosis was associated with increased VEGFpv (p:0.03), VEGFrv (p:0.0001), VEGFt (p:0.001), and platelet count (p:0.001) as well as with decreased haemoglobin level (p:0.02). Finally both VEGF immunostaining profile and tumor necrosis were associated with early cancer recurrence (p:0.003).
Conclusion. We presented here a particular VEGF tumor immunostaining pattern which is related to high levels of circulating VEGF and higher tumor stages. Moreover relationship between tumor necrosis and VEGF both in tissue and in peripheral blood is an additional evidence of the importance of the VHL/hypoxia inducible pathway in RCC.

P 853

CORRELATION BETWEEN RENAL ARTERY CHANGES AND TUMOR NECROSIS IN PATIENTS WITH RENAL CELL CARCINOMA

Tomi; K, Mladinov D, Tomas D, Tomi&; L, Belicza M, Krušlin B.
Department of pathology, Josip Benevi General Hospital Slavonski Brod, Croatia
Ljudevit Jurak Department of Pathology, Sestre milosrdnice University Hospital Zagreb, Croatia

INTRODUCTION: Different lesions might involve main renal artery such as arteriosclerosis, fibromuscular dysplasia (FMD) and some other conditions (arteritis, radiation injury and congenital malformations). Renal cell carcinoma (RCC) represents 2% of all human malignancies and over 90% of all malignancies of the kidney. Necrosis, cysts, hemorrhage and calcification are commonly present.
PURPOSE OF THE STUDY: Aim of the study was to correlate the presence and extent of necrosis in RCC and renal artery status.
METHODS: We analyzed a consecutive series of 112 patients (M: F=71:41) with RCC who underwent nephrectomy in the period from 2003 to 2004. Patients were aging from 35-82 years (mean 60.5) and the tumor size was 2-20 cm (mean 6.1). Necrosis was found in 88 (78.6%) cases of RCC of which 63 had less than 50% necrosis and 25 tumors contained more than 50% necrotic areas. Specimens were routinely fixed, embedded in paraffin, cut and stained with hematoxylin and eosin, Mallory trichrome method and orcein.
RESULTS: Renal arteries of 50 (44.6%) patients (M: F=36:14) showed no changes (Group I). These patients were in age from 38-78 years (mean 57.8) and tumors measured from 2.5-17 cm (mean 7.4). FMD (Group II) was found in 41 (36.6%) patients (M:F=17:24) ranging in age from 35-81 years (mean 59.1), and the tumor size was 2-19 cm (mean 8.2 cm). Atherosclerotic changes of renal arteries (Group III) were observed in 21 (18.8%) patients (M:F=18:3), aged from 42-82 years (mean 67.2) with tumors from 2-20 cm (mean 6.7).
In the first group necrosis was not found in 11 (22.0%) cases, 30 (60.0%) had less than 50% necrosis and 9 (18.0%) tumors were necrotic in more than 50%. In the second group, 7 (17.1%) cases were without tumor necrosis, 24 (58.5%) had less than 50% necrosis and 10 (24.4%) tumors were more than 50% necrotic. In the third group, 6 (28.6%) tumors did not show necrosis, 10 (47.6%) were less than 50% necrotic and 5 (23.8%) had more than 50% necrosis. Within the second group RCC of patients with FMD type I, 3 cases were less than 50% necrotic, while 4 cases were more than 50% necrotic, and only one was without necrosis. In the group of patients with FMD type IIb, 5 tumors were without necrosis, 21 had less than 50% necrosis and 4 were more than 50% necrotic.
CONCLUSION: Renal artery changes are very common in patients with RCC. Necrosis of the tumor was more common in patients with associated FMD and atherosclerotic changes of renal artery. However, t

SARCOMATOID RENAL CELL CARCINOMA. REPORT OF TWO CASES WITH IMMUNOCHISTOCHEMICAL STUDY

TSOBANIDOU Chrysoula1, NIKOLAIDOU Anastasia2, HASAKIOILIS Pantelis3, KLAMBATSAS Athanasios3, SACHINIS Konstantinos3
AMANATIDOU Simela, Technisian 2
1Department of Pathology, "Theagenio" Anticancer Institute, Thessaloniki, Greece
2Department of Pathology, General Hospital of Kilkis, Kilkis, Greece
3Department of Urology, General Hospital of Kilkis, Kilkis, Greece

Introduction: Sarcomatoid Renal Cell Carcinoma (SRCC) is an uncommon subtype of Renal Cell Carcinoma (RCC) with a poor prognosis. The origin of the sarcomatoid component is controversial: some authors consider it to be a dedifferentiation of the epithelial component while others believe that this tumor is a true carcinosarcoma.

Purpose-Method: In the present report two cases of this rare entity were studied using an extensive immunohistochemical panel of antibodies: cytokeratin 7, cytokeratin 20, cytokeratin 8, cytokeratin 18, cytokeratin 19,

P53, Bcl-2, Ki-67, AFP, PLAP, EMA, CEA, Vimentin Cyclin D1 and S-100.
The expression of these antibodies was evaluated in the sarcomatoid component.

Results: The first case showed no epithelial differentiation and in the second case the epithelial component was conventional RCC.
The two cases were intense and diffusely positive against vimentin. The second case did not show any positivity for any of the cytokeratin antibodies. The first case showed positivity for cytokeratin 8, cytokeratin 19, EMA, CEA, Cyclin D1, P53 overexpression and Ki-67 high labeling index.

Conclusion: Our results suggest that SRCC includes two different entities that should be separated: a sarcomatoid carcinoma and a mixed tumor with a true sarcomatous component.

CELL CYCLE REGLATORY FACTORS IN RENAL CELL CARCINOMA

PETRUSCA Daniela1, PETRESCU Amelia2, CONSTANTIN Claudia1, JINGA Viorel2, NICULESCU Liviu3, ROMAN Viviana1, HOTNOG Dan1, BRASOVEANU Lorelei1
1. Center of Immunology "St.S. Nicolau"Institute of Virology, Bucharest Roamnia 2."Prof.Dr.Th. Burghele" Hospital, Bucharest Romania 3.University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Introduction and aims: In this study we analysed the immunohistochemical expression of p53, Bcl-2, Rb and PCNA and the relation of this expression to apoptotic status, clinicopathological characteristics and prognosis in renal cell carcinoma specimens.
Material and methods: The expression of p53, Bcl-2, Rb and PCNA was studied by immunohistochemical methods in paraffin-embedded nephrectomy specimens from 22 patients with no history of chemotherapy, radiotherapy, or immunotherapy. The apoptotic status was determined by flow-cytometry following propidium iodide incorporation.
Results: The p53 protein expression was recognized with a very low intensity (1-8%) in most of the cases but not in those with sarcomatoid features where it was elevated (30%). The expression of Bcl-2 was recognized in only 17% of cases also with low intensity; it was associated with the high tumoral grade and medium apoptotic intensity. Half of the tumor specimens were Rb positive, it absences correlated with a high grade and a high mitotic index. PCNA was detected in 86% of cases and showed a heterogeneous expression and correlated with the high grade of tumor. In 2 cases PCNA expression was absent and was correlated with a very differentiated tumor tissue.
Conclusions: Our observations suggest that the high apoptotic intensity of these tumors seems to be not p53 dependent. Thus, the low p53 expression could sustain the high degree of resistance to chemotherapy and radiation of renal cell carcinomas. Also, our results emphasizes that high grade differentiated tumor cells induce Bcl-2 expression in order to stop apoptotic process. In renal cell carcinomas Rb protein seems to act like an antiproliferative factor but not like an antiapoptotic one. We observed that PCNA expression increase while apoptotic intensity decrease. In our study the expression of p53, bcl-2 had no independent prognostic value and suggests that they would play a minimal role in helping to further stratify patients at high risk for disease progression or recurrence. Rb and PCNA seem to be a good objective and quantitative marker of biological malignant potential in renal cell carcinoma.

°Department of Pathlogy, CHRU LILLE FRANCE
*Department of Urology, CHRU LILLE FRANCE
§Department of Radiology, CHRU LILLE FRANCE

Purposes: To correlate clinicopathological and imaging features of multilocular cystic renal cell carcinomas in order to propose preoperative criteria for therapeutic modalities.
Materials and Methods: Twenty four clear renal cell carcinomas with a chiefly cystic component were identified from 1993 to 2002. For each case, histological slides and available imaging studies were retrieved. Two tumor groups were defined: multilocular cystic renal cell carcinomas (MCRCC) and clear renal cell carcinomas with cystic change (CRCC) either by intrinsic growth or necrotic degeneration. Radiological correlation using CT scan and MRI studies was performed considering criteria such as mural nodule, cyst wall thickness, septa.
Results: On imaging study, MCRCC presented as a multilocular cystic mass lacking mural nodule, with regular thin cyst wall and septa. On pathologic study, MCRCC presented as complex, multilocular cystic carcinomas with septa covered by low nuclear grade clear renal tumor cells without grossly expansible nodule. They were all staged pT1 with a free clinical course. On the opposite, CRCC were described on imaging study with a mural nodule (5 mm or higher), thick, irregular cyst wall and irregular septa. On pathologic study, CRCC were characterized by a grossly expansible nodule within the septa and/or the cyst wall. Nuclear grade and TNM stage were higher in CRCC.
Conclusions: Preoperative recognition of MCRCC is possible when using strict CT and/or MRI criteria. The current study confirms the low malignant potential of MCRCC. A nephron sparing surgery should be proposed when MCRCC is suspected.

P 857
MORPHOMETRICAL ANALYSIS OF RENAL ARTERIES IN PATIENTS WITH RENAL CELL CARCINOMA

Batelja VuleticL, Mladinov D, TomicK, VucicM, Belicza M, Krušlin B
Dpt of Pathology, School of Medicine, Ljudevit Jurak Department of Pathology, Sestre Milosrdnice University Hospital, Zagreb, General Hospital Josip Bencevic, Slavonski Brod, Croatia

Introduction: The presence of tumor necrosis in renal cell carcinoma (RCC) is very common and was correlated with different features including tumor size, cell type, nuclear grade as well as microvessel density and the expression of different markers. However, there are no data about the relationship between renal artery changes including atherosclerosis and fibromuscular dysplasia (FMD) and the extent of necrosis in RCC.
Purpose of the study: to analyze renal arteries in patients with RCC especially regarding the thickness of medial layer and circumference of the artery using image analyzer.
Methods: We analyzed a consecutive series of 57 (35 male and 22 female) patients ranging in age from 35-79 years (mean 58.9 years) who underwent nephrectomy due to RCC in the year 2003. The patients had RCC measuring from 2-16 cm (mean 7.1 cm). Renal arteries were cut during nephrectomy up to 2 cm from renal hilus. Specimens were routinely fixed, embedded in paraffin, cut and stained with hematoxylin and eosin, Mallory trichrome method and orcein.
Results: The thickness of the media of 40 patients measured from 167.86-1177.21 μm (mean 571.35). Renal arteries of 17 patients (11 male, 6 female) were not measured due to

technical problems. The mean thickness of media in patients with FMD was 567.33 μm, those with arteriosclerosis 637.18 μm and with no renal artery changes 551.11. μm). There was a difference between the thicknesses of media in different types of FMD (FMD type I = 590.83 μm, FMD type IIA was 476.92 μm). Renal arteries of patients with arteriosclerosis were larger in comparison to arteries with no changes (4.2 mm: 3.5 mm), and control arteries obtained at autopsy, however this difference was not statistically significant.
Conclusion: Renal arteries of patients with RCC and atherosclerotic changes have thicker media and larger diameter in comparison with controls, and those with FMD.
The cause of such changes and their relationship to the degree of tumor necrosis and other changes in renal arteries should be further analyzed.

P 858
RENAL SINUS INVASION IN RENAL CELL CARCINOMAS.
Pasechnik D.

The renal sinus (RS) is the fatty region located near the renal cortex and not delineated from it by a fibrous capsule. The large quantity of vessels promotes a hematogenous and lymphogenous dissemination of the cancer cells at the tumor invasion to this zone. However, the present TNM staging system for renal cell carcinomas (RCC) does not take into the RS involvement.
The aim of research was to estimate the frequency of the RS invasion in RCC and its connection with tumor stage, grade and the histological form.
118 RCC were investigated (86 clear cell carcinomas, 13 papillary carcinomas, 11 chromophobe cell carcinomas, 8 oncocytomas). The tumor size of 51 renal carcinomas did not exceed 7cm; 67 RCC were over 7cm. The RS invasion was revealed in 81 cases RCC (68,6 %): 66 (76,7 %) clear cell carcinomas, 7 (53,8 %) papillary renal carcinomas, 8 (72,7%) chromophobe cell cancer. Oncocytomas did not invade into the RS. The RS involvement correlated with a nuclear grade of RCC. The RS invasion was 10 of 30 a low nuclear grade tumours (Fuhrman's grade 1-2) (33,3%), 55 of 71 a moderate nuclear grade tumours (Fuhrman's grade 2-3) (77,5%) and all of 17 a high nuclear grade tumours (Fuhrman's grade 3-4). However, the RS invasion did not depend on the tumor size. The RS involvement was marked at 39 (33,1 %) of patients at the tumor size up to 7 cm, and in 42 (35,6 %) cases at the tumor size over 7 cm. Tumour localization was the prior feature than tumour size. Among the RCC up to 7cm, the RS involvement was 19 (65,5%) of the 29 lateral location tumours, and 20 (90,9%) of the 22 medial location tumours. Besides fatty tissue, 44 (37,3 %) RCC invaded into the RS veins and lymphatic vessels. 11 (9,3 %) kidney cancer invaded into the lumen of the main renal vein. In 25 (21,2 %) RCC, the RS invasion combined with intrarenal dissemination of tumor. At the absence of the RS invasion, metastasizes were lacking.
The RS involvement should be regarded as a risk factor of the tumor dissemination. The prognostic value of the RS invasion in RCC is necessary to take into future revision of the TNM stading system for the tumors of this localization.

P 859
INCIDENTALLY DIAGNOSED RENAL CELL CARCINOMA: CLINICOPATHOLOGICAL FEATURES.
Pasechnik D., Gusev A., Kogan M., Derizhnova I.

In the last 20 years, with the increasing use of abdominal ultrasound and CT scans, many renal tumours are being diagnosed incidentally during examinations for other conditions.
Our study aimed to compare the clinicopathological features of renal cell carcinomas (RCC) discovered incidentally with those of symptomatic tumours. We retrospectively analyzed 149 patients subjected to radical nephrectomy.
61 tumours (40,93%) were diagnosed incidentally. No significant difference was detected between both groups in regards to middle age, sex, and histological type. A greater incidence of tumours in stage T1a was found in incidental RCC (59,21% vs 12,5%), while advanced forms (stage T3) were more frequent in symptomatic RCC (24,59% vs 67,04%). 33 (54,1)% incidental RCC were a low nuclear grade (Fuhrman's grade 1 or 2) and only 3 (5%) tumours were high grade. 2 (3,3)% incidental RCC were N1, and none were M1, whereas 15 (17%) symptomatic RCC were N1-2, and 9 (10,2%) were M1. Survival after 5 years was of 69,1% for symptomatic patients in comparison to 85,7% for the incidental group, which implies high statistical signification (log rank = 0.0018).
The patients with incidentally discovered RCC had a prognostically more favorable tumour size, stage and grade.

ASSOCIATION OF CXCR4 CHEMOKINE RECEPTOR EXPRESSION WITH MMP AND TIMP MRNA TRANSCRIPTION IN CLEAR-CELL RENAL CELL CARCINOMA
K. Struckmann 1, K. Mertz 1, P. Staller 2, W. Krek 2, P. Schraml 1, and H. Moch 1
1 Institute of Clinical Pathology; University Hospital Zurich
2 Institute of Cellbiology, ETH Zurich

Introduction: CXCR4 chemokine receptor mediated signalling is of importance for the metastatic process in a variety of human cancers. We have recently found increased CXCR4 expression levels in clear-cell renal cell carcinoma (ccRCC) compared with normal renal tissue. This study also revealed an association between strong CXCR4 expression and poor tumour-specific survival indicating the importance of this chemokine receptor in renal tumour biology (ccRCC; Nature, 425, 2003). Interestingly, it has been shown in vitro that ligand stimulation of CXCR4 leads to alterations in the expression levels of certain Matrix Metalloproteinases (MMPs) and Tissue Inhibitors of Matrix Metalloproteinases (TIMPs). Since deregulated expression of MMPs and TIMPs is one of the pre-requisites for tumour growth and tissue invasion in many human cancers including ccRCC one might consequently speculate that increased CXCR4 signalling contributes to tumour progression and metastatic dissemination by influencing the expression of MMPs and TIMPs.
Aims: In order to analyse the association of CXCR4 and MMP/TIMP expression in ccRCC we have correlated the mRNA abundance of certain MMPs and TIMPs with the CXCR4 expression status in primary tumour samples.
Methods: mRNA expression levels of MMP2, MMP9, TIMP1, and TIMP2 were determined in 29 primary ccRCC and 7 normal renal tissues with known CXCR4 expression levels by RT-PCR using the LightCycler system. The abundance of MMP/TIMP transcripts were correlated with the CXCR4 mRNA expression status of the given tissue samples.
Results: Twenty-six of 29 ccRCCs showed an increase of more than 2-fold in the expression level of CXCR4. The average increase in CXCR4 expression was 7.3-fold (range 2.3-18.8-fold). Expression of TIMP1 and TIMP2 did not correlate with CXCR4 expression levels. In contrast, mRNA expression of MMP2 and MMP9 was significantly higher in tumours with strong CXCR4 expression ($p=0.04$ and $p=0.01$, respectively).
Conclusions: CXCR4 up-regulation in ccRCC is associated with increased mRNA expression levels of MMP2 and MMP9. Our results provide first evidence for the involvement

of the CXCR4-MMP/TIMP pathway in renal cancer progression.

INTRODUCTION
Cigarette smoking is a known risk factor for renal cell carcinoma (RCC) with a modestly increased rate ratio (RR) and a positive dose-response relation. Cigarette smoke metabolites can cause mutations in human DNA.
Von Hippel-Lindau (VHL) gene mutations are considered a primary event in the carcinogenesis of RCC.
PURPOSE
We investigated whether smoking is associated with mutations in the VHL gene in sporadic RCC.
METHODS
The Netherlands Cohort Study on diet and cancer (NLCS) includes 120,852 persons, who completed a self-administered questionnaire on smoking habits and other factors. After 11.3 years of follow-up, 337 cases and a random sample of 5,000 persons (subcohort) were used in a case-cohort approach. Collected tumor DNA (N=235) was analyzed for VHL gene mutations. RRs and corresponding 95% confidence intervals (CI) were estimated using Cox proportional hazard models, adjusting for age, sex and body mass index.
RESULTS
For men, RRs for total RCC were 1.52 (95% CI: 0.89-2.59) and 2.07 (95% CI: 1.20-3.56) for ex- and current smokers compared to never smokers, respectively. Estimates for women equaled 0.95 (95% CI: 0.57-1.59) and 1.37 (95% CI: 0.87-2.16), respectively. For men, RRs for current smokers compared to never smokers were 2.34 (0.79-6.94) and 2.95 (0.65-13.28), for VHL gene mutated and VHL wildtype tumors, respectively. For women, these estimates were 0.82 (0.35-1.93) and 2.04 (0.94-4.45), respectively. Results have to be interpreted cautiously because of small numbers.
CONCLUSION
Smoking was associated with RCC risk of men, but not specifically with VHL gene mutations, irrespective of sex, suggesting that smoking may cause RCC independent of VHL gene mutations.

C-KIT EXPRESSION IN RENAL EPITHELIAL TUMORS

ÖZAÐARI Ayþim, KABUKÇUOÐLU Fevziye, SAKIZ Damlanur, ÇAÞKURLU Turhan, KÝREMÝT Murat Can, GÜMÜÞ Eyüp
Þiþli Etfal Education and Research Hospital, Department of Pathology and Department of Urology, Ýstanbul, TURKEY

C-kit encodes the membrane-bound tyrosine kinase KIT, whose expression has been identified in several types of human neoplasms. The overexpression of c-kit in chromophobe renal cell carcinoma and oncocytoma has been proposed as a possible specific hallmark of these neoplasms. The aim of this study is to establish immunohistochemical expression of KIT in a series of renal epithelial neoplasms and the normal renal tissues.
In this study we analysed KIT expression in 45 surgical specimens of clear cell, papillary, and chromophobe renal cell carcinomas and oncocytomas with the adjacent normal renal tissue. There were focal sarcomatoid differantiation in 6 cases. The extent of immunoreactivity was categorized as focal, moderate, and diffuse. Only membranous staining was considered positive.
All cases of chromophobe renal cell carcinomas (n=6) and two of 3 cases of oncocytomas showed diffuse membranous staining. Three of 33 cases of clear cell renal cell carcinomas were focally positive for KIT. One case with sarcomatoid differantiation showed focal positivity in the sarcomatoid areas. None of 3 papillary carcinomas were positive. In non-neoplastic kidney tissue adjacent to the tumor, strong KIT expression was detected in the cytoplasm of the renal tubules. The results suggest that KIT plays a role in the tumorigenesis of chromophobe renal cell carcinoma and oncocytoma, and could be a useful marker for differential diagnosis of different renal cell carcinomas. Overexpression of KIT in some subtypes of renal tumors indicates a potential therapeutic role for tyrosine kinase inhibitors in managing patients with these tumors.

EPITHELIAL CELL ADHESION MOLECULE (EPCAM) EXPRESSION IN RENAL CELL CARCINOMAS (RCC). A TISSUE MICROARRAY (TMA) STUDY

PANIZO Angel, SOLA Jesus Javier, TOLEDO Gemma, IDOATE Miguel Angel, LOZANO Maria Dolores, PARDO Javier.
Departamento de Anatomia Patologica. Clinica Universitaria de Navarra. Pamplona. Spain

Introduction: EpCam is a widely expressed adhesion molecule in normal epithelium of different organs and in epithelial neoplasms. Due to its membrane distribution, specific immunotherapies are now being used with promising results. Advances in the treatment of patients with RCC are utmost importance to improve the prognosis. The aim of this study was to study the expression of EpCam in RCC using TMA.
Methods: We studied retrospectively EpCam expression of renal tumors and matched normal renal tissue using a TMA. Different histologic subtypes of RCC were investigated, including 109 clear cell, 38 papillary RCC, 10 papillary adenomas, 50 chromophobe, 31 oncocytomas, 2 collecting duct carcinomas, and 2 mucinous tubular-spindle cell carcinomas. Primary clear RCC and corresponding metastases (n=32) were also studied. A mouse mAb anti-EpCam (clone VU-1D9, Novocastra, dilution 1:50) was applied after trypsin pretreatment. The immunoreactivity was correlated with clinicopathological data.
Results: EpCam is expressed in the distal nephron on normal renal tissue. EpCam overexpression was found in 17.4% of clear RCC (4.6% strong, 12.8% moderate). A total of 59 cases were negative. There was significant association between EpCam overexpression and distant metastases at diagnosis (pM stage) (p=0.03), and overall stage (p=0.039). Overall, 18.8% of metastases of clear RCC did show EpCam overexpression. EpCam overexpression was a significant univariate predictor of increased survival in clear RCC (p=0.035). Twelve (31.6%) of 38 papillary RCC showed EpCam overexpression. There was no different EpCam expression in type 1 and 2 papillary RCC. Three of 10 papillary adenomas showed EpCam overexpression. Fourty-

six (92%) chromophobe RCC showed EpCam overexpression (88% strong, 4% moderate), whereas only one (3.2%) oncocytoma revealed moderate EpCam in sparsely clustered cells ($p<0.05$). All cases of collecting duct and mucinous tubular-spindle cell carcinomas were negatives.
Conclusions: In clear RCCs, EpCam overexpression could be used as a prognostic marker (associated with improved survival). EpCam represents a potential target for immunotherapy (mAbs or vaccines) in the adjuvant and palliative treatment of RCCs. EpCam immunohistochemistry proves to be a useful tool in the differential diagnosis between chromophobe RCC and oncocytoma, because of the different staining patterns of these two entities.

P 864
GRANULOMATOUS REACTION IN PRIMARY ADULT RENAL NEOPLASMS: A CLINICOPATHOLOGICAL AND MOLECULAR STUDY OF 17 CASES
PANIZO Angel, SOLA Jesus Javier, TOLEDO Gemma, IDOATE Miguel Angel, LOZANO Maria Dolores, PARDO Javier.
Departamento de Anatomia Patologica. Clinica Universitaria de Navarra

Introduction: Granulomatous reactions (GR) within lymph nodes draining malignant neoplasms are well known. More rarely, GR may occur within the stroma of malignancies. The occurrence of GR in renal neoplasms appears to be much more rare (few cases reported).
Methods: Retrospective analysis of 488 renal cell carcinomas (RCC) and 25 renal angiomyolipomas (AML), diagnosed between 1994 and 2005, was performed. Clinicopathological data were reviewed. In selected cases, sections were stained with PAS, Grocott, and Ziehl-Neelsen. Immunohistochemical studies were performed using mAb againts CD20, CD3, CD4, CD8, and CD68. Paraffin sections and/or frozen tissue were subjected to molecular analysis: PCR method was used to detect the presence of M. tuberculosis complex DNA.
Results: Among 488 RCC studied, 16 cases (3.27%) with GR were detected. Thirteen patients were male (81.3%), and three were female, with a mean age of 60.4 yrs (range:34-77 yrs). No patient from our serie had any history of sarcoidosis or other granulomatous disease. The histological type of RCC were clear cell (n=12), papilary (n=1), chromophobe (n=1), and unclassifiable (n=2). Mean tumor size was 4.85 cm (range: 2.2-10 cm). Eleven of the 16 cases were TNM stage I or II. One case of GR was detected among 25 AML reviewed. GR was observed within the tumor stroma in all cases (focal: 7 cases, and diffuse 10 cases) and 3 cases had also GR within the normal kidney. One case demonstrated GR within lymph node metastasis. GR was characterized by groups of epithelioid cells and multinucleated giant cells (strongly positive for CD68), and small lymphocytes (predominantly CD3 althoug scattered CD20 positive were observed) without central necrosis in 14 cases (sarcoid-like). In 3 cases GR had central caseating necrosis: Mycobacteria were identified using Ziehl-Neelsen in 2 cases, and infection by M. tuberculosis complex were proved in 2 cases using PCR. Clinical follow-up was complete in 16 patients (median: 8.18 mos.; range: 1.83-109.13 mos): twelve patients were alive without clinically detectable tumor and granulomatous process.
Conclusions: The occurrence of granulomas within the stroma of renal neoplasms is extremly rare. Sarcoid-like GR in renal neoplasms could be an immunological response to tumor antigens. In patients with no previous diagnosis of tuberculosis, the discovery of caseating granulomas after nephrectomy for RCC is exceptional

STRONG COEXPRESSION OF OSTEOPONTIN AND VASCULAR ENDOTHELIAL GROWTH FACTOR CORRELATES WITH SURVIVAL IN CLEAR CELL RENAL-CELL CARCINOMA
MATUSAN Koviljka, DORDEVIC Gordana, MOZETIC Vladimir*, JONJIC Nives, LUCIN Ksenija
Department of Pathology, Rijeka University School of Medicine and Department of Urology*, Clinical Hospital Center Rijeka, Rijeka, Croatia

INTRODUCTION: Osteopontin (OPN) is a highly phosphorylated protein with numerous functions, including roles in bone remodelling, cell-adhesion, cell-mediated immunity, cell signalling, and angiogenesis. It has been recognized as a transformation-associated protein and as a potential prognostic factor for various human cancers. Several lines of experiments have implicated OPN in angiogenesis, and it has been shown that vascular endothelial growth factor may induce expression of OPN. Also, it has been shown that osteopontin overproduced by tumour cells acts as a potent angiogenic factor contributing to tumour growth.
PURPOSE OF THE STUDY: The aim of this study was to analyse the relationship between the OPN and vascular endothelial growth factor (VEGF) expression in clear cell renal-cell carcinoma. Also, we have analysed the association of VEGF and OPN coexpression with disease outcome.
METHODS: A total of 81 clear cell renal-cell carcinomas were immunohistochemically analyzed for the OPN and VEGF expression and scored in a semi-quantitative manner, by combining tumour epithelial proportion score and intensity score. Statistical analysis was performed by nonparametric Spearman's correlation coefficient method. Survival probabilities were estimated by the univariate Kaplan-Meier method and survival curves were compared by the log-rank test.
RESULTS: Renal-cell carcinomas showed heterogeneous staining pattern for both OPN and VEGF, ranging from focal expression of low intensity to strong and diffuse cytoplasmic staining of tumor cells. We found statistically significant correlation between OPN and VEGF expression at the level $p=0.0026$, ($rs=0.3304$). Also, the survival of patients with strong OPN and VEGF coexpression was significantly worse compared to those with either low or without OPN and VEGF coexpression ($p<0.003$).
CONCLUSION: Our results show the upregulation of OPN and VEGF in clear cell renal-cell carcinomas. The correlation between their expression and the association of their strong coexpression with poor disease outcome support the hypothesis that cooperation of OPN and VEGF may facilitate tumor progression in human cancer.

P 866
CD34 EXPRESSION IN RENAL CELL CARCINOMA IS EXCEPTIONAL BUT MAY BE FOUND IN HIGH GRADE TUMORS
N. Juanpere1, M. Jimeno 1, M. Iglesias 1, V. Baena1, M. Garcia1, R. Esgueva1, R. Jaramillo 1, , O. Bielsa 2, A. Gelabert 2, S. Serrano 1 and J. Lloreta 1. 1

Background:
CD34 is a transmembrane protein expressed by primitive hematopoietic and mesenchymal cells, endothelial cells, and a variety of other cell types. Its expression in epithelial cells and carcinomas is exceptional, and has never been reported in renal cell carcinoma (RCC). The observation of CD117 expression in some subtypes of RCC prompted us to investigate the expression of CD34, as both molecules are often coexpressed in other proliferations, most notably gastrointestinal stromal tumors.
Design:
A total of 138 renal epithelial tumors (104 clear cell, 17 chromophilic, and 2

chromophobe carcinomas; 1 collecting duct carcinoma; 14 oncocytomas) were used to construct two different TMA blocks with 200 cores each. Consecutive sections of both were stained with H E and with antibodies (Ab) for CD34 (QBEND, Biomeda, CA), and CD117 (DakoCytomation, Denmark). Representative sections of the positive tumors were stained with Ab for CD34, CD117, CD10, Cam 5.2, AE1-AE3, keratin 7, keratin 34 E12, vimentin, and HMB45. The immunohistochemical reaction was visualized with the Envision system (DakoCytomation, Denmark).
Results:
Only two out of 138 tumors showed intense and diffuse CD34 expression but were negative for the CD117 Ab. In standard sections, both tumors showed strong and diffuse membranous staining of epithelial cells with CD34 Ab, and were in addition positive with Ab for CD10, Cam 5.2, AE1-AE3, and vimentin. Keratins 7 and 34 E12, and HMB45 were negative. Both cases were morphologically and immunohistochemically classified as clear cell RCC. Case 1 is a 53 year-old man with a Fuhrman grade 4, stage T1 N0 M0 tumor, that subsequently developed lymph node metastases, and that is alive with residual disease 15 years after surgery. Case 2 is a 70 year-old woman with a grade 4, T3a N1 M0 tumor, and she is alive without disease 4 years after surgery.
Conclusion:
CD34, although exceptionally, may be expressed in clear cell RCC, without CD117 coexpression. The two cases in this series suggest that this feature may be observed in a subset of high grade tumors progressing to or presenting with high stage disease.

P 867
TISSUE MICROARRAY OVEREXPRESSION OF CYCLIN D1 IN RENAL EPITHELIAL TUMORS
N. Juanpere 1, M. Jimeno 1, M. Iglesias1, V. Baena1, M. Garcia1, R. Esgueva1, R. Jaramillo 1, O. Bielsa 2, S. Hernandez 3, A. Gelabert 2,4, S. Serrano 1,4 and J. Lloreta 1,3.

ABSTRACT
Background: Cyclins have an essential role in cell cycle control. Cyclin D is involved in the G1/S transition. The prevalence, biological meaning and prognostic impact of Cyclin D1 (CyD1) expression in renal cell carcinoma (RCC) are controversial. Some studies suggest a favorable role, but other series do not support this conclusion. This is a descriptive study of the immunohistochemical (IHC) overexpression of CyD1 in a RCC/oncocytoma tissue microarray (TMA), and its related clinicopathological variables in different tumor subtypes.
Design: A total of 138 renal epithelial tumors (104 clear cell (CCRCC), 17 papillary chromophilic (PCRCC), and 2 chromophobe carcinomas; 1 collecting duct carcinoma; 14 oncocytomas) were used to construct two different TMA blocks, 200 cores each. Consecutive sections were stained with an antibody for CyD1(DSC-6, DakoCytomation, Glostrup, Denmark). The IHC reaction was visualized with the Envision system (DakoCytomation, Glostrup, Denmark). CyD1 overexpression was defined as a 3+ intensity in more than 20% of the tumor cell nuclei.
Results: We found CyD1 overexpression in 9 (65%) of 14 oncocytomas, 23 (22%) of 104 CCRCCs, and 5 (30%) of 17 PCRCCs. From the 23 CyD1 overexpressing CCRCCs, 19 (82%) were low stage (T1-2), 17 (74%) were low grade (G1-2), and 18 (78%) were alive without disease. In the overall group of CCRCCs, 68% of the tumors were low stage, 57% were low grade, and 66% were alive without tumor. From the 5 CyD1 overexpressing PCRCCs, 4 were low stage, 1 was low grade, and all were alive without disease. In comparison, 65% of all the PCRCCs were low stage and low grade, and 70% were alive without disease.
Conclusion: 1.CyD1 is not uniformly overexpressed in all oncocytomas. 2.The proportion of CCRCCs overexpressing CyD1 is slightly lower than that of PCRCCs. 3.In both tumor types, this feature seems to be associated with more favorable prognostic variables than their respective overall groups. There is a paradoxically increased proportion of high grade cases in overexpressing PCRCC, that is not associated with higher stages or more adverse outcome. 4.CyD1 overexpression is relatively uncommon in RCC, and although it is associated with better outcome, it does not appear to be a useful tool in the prognosis of these tumors.
Supported in part by grant FIS 99/0736 (Fondo de Investigacion Sanitaria, Spain)

P 868
TISSUE MICROARRAY OVEREXPRESSION OF P53 AND PAB 240 IN RENAL CELL CARCINOMA
V. Baena1, M. Iglesias 1, M. Jimeno 1, N. Juanpere1, M. Garcia1, R. Esgueva1, R. Jaramillo 1, O. Bielsa 2, J. Santos 2, S. Hernandez 3, T. Baro 1,4, A. Gelabert 2,4, S. Serrano 1,4 and J. Lloreta 1,3

Background: The prognostic impact of p53 overexpression in renal cell carcinoma (RCC) is not fully understood. In different series, with diverse immunohistochemical (IHC) and evaluation protocols, variable p53 overexpression is reported, although association with poor outcome is usually suggested. We investigated the IHC overexpression of p53 in a RCC tissue microarray (TMA), using strictly standardized methods. We also studied expression of PAb-240, an antibody (Ab) that recognizes a p53 epitope exposed in many mutant forms of this protein. Expression of this Ab in RCC has not been previously reported.
Design: 138 renal epithelial tumors (104 clear cell (CRCC), 17 papillary chromophilic (PRCC), 2 chromophobe, and 1 collecting duct carcinoma; 14 oncocytomas) were used to construct two different TMA blocks (200 cores each). Ab for p53 (DO7, Novocastra, UK), and mutated p53 (PAb 240, DakoCytomation, Denmark) were used. A standardized IHC protocol included mutated cell lines as controls. p53 overexpression was defined as a 3+ intensity in >20% of the nuclei. PAb 240 was investigated in p53+ and - cases.
Results: p53 overexpression was observed in 12% (17 of 138 tumors): 30% (5 of 17) of PRCC and 12% (12 of 104) of CRCC. From those, 2 CRCC and 2 PRCC were positive with PAb 240, and the remaining cases in the TMA were negative. From all TMA cases, CRCC were high grade in 43%, high stage in 32% and progressed in 33% of cases. In contrast, 92% (11) of the p53 overexpressing CRCCs were high grade (3 G3 and 8 G4) and 75% (9) were high stage (6 T3 and 3 T4) and died with tumor. Similarly, p53 negative PRCCs were high grade in 20%, high stage in 30% and progressed in 20% of the cases, while 80% (4) of the overexpressing PRCCs were high grade (3 G3, 1 G4) and 40% (2) were high stage (T3,T4), progressing tumors.
Conclusion: 1. In both CRCC and PRCC, p53 overexpression is associated with a marked increase in grade, stage, and tumor progression. 3. Negativity of PAb 240 does not exclude non-productive mutations, but suggests that p53 overexpression is probably not associated with mutation. 3. p53 overexpression is uncommon in RCC, and is more often observed in PRCC than in CRCC. A large number of RCCs should be examined both by IHC and molecular methods to establish the prognostic and pathogenetic role of TP53 in renal cancer. TESTICULAR GERM CELL TUMOR PATHOLOGY REPORTING

Climent MJ, Vidal A, Lerin MA, Tascon R, Garcia del Muro X*, Germà-Lluch JR* and Condom E.
Department of Pathology. IDIBELL. Hospital Universitari de Bellvitge (HUB). *Department of Medical Oncology (ICO).IDIBELL. Institut Català d'Oncologia. L'Hospitalet de Llobregat. Spain.

Introduction.
Accurate pathology report is crucial in providing information regarding prognostic factors and possible further treatment.
Purpose of the study.
To compare the standard of pathology reporting for testicular tumors with the checklist provided by the College of American Pathologists (CAP) and to evaluate potential variation in reporting by hospital type.
Methods.
We reviewed 211 pathology reports for adherence to recommendations of the CAP and calculated the overall percentage of each item. We classified hospitals by teaching and non-teaching hospitals and used the chi-squared test to determine whether statistically significant difference existed by hospital type (teaching and non-teaching).
Results.
Adherence to CAP recommendations was 100% for description of histologic type, 87% for tumor size and 82% for laterality. All other criteria were reported in <80% of cases. Overall, teaching hospitals demonstrated greater adherence to CAP recommendations when compared with non-teaching hospitals ($p<0.05$).
Conclusions.
Pathology reports of testicular germ cell tumors omitted some critical items. The variability in reporting is based on hospital type.

P 870
MORPHOLOGICAL VARIANTS OF A V. TESTICULARIS SINISTRA FORMATION IN CHILDREN WITH VARICOCELE
Severgina E, Leonova L, Kondakov V, Godlevskyi D, Pykov M, Sporius R

There is no clear conception about the venous system, generated from pl. pampinifomis in a retroperitoneal space in patients with varicocele now. We evaluated the incision biopsies of vessels received during a high ligation from 20 boys from 8 to 15 years old. The biopsies were fixed and paraffinized. Light microscopy, immunohistochemistry was performed with labeled, specific anti-VEGF and CD 34 antibodies.
There were arterial vessels, surrounded with groups of muscular type veins and a plenty of engorged capillaries and postcapillar venules in biopsies. We found three morphological variants of the muscularis type veins. Type I was presented by veins of a large diameter with gaping lumens and thick walls composed of three layers. The most thin internal layer contained endothelial and longitudinal smooth muscle cells; a medium layer included circularly directed smooth muscle cells; and the thickest external layer was composed of smooth muscle cell bundles directed longitudinally and separated from each other by collagen fibers. This morphological variant of veins was considered as the basic trunk of v. testicularis.
Type II veins had a irregular configuration of a lumen. Their walls were thinner, than these of type I veins and were composed of three layers. The thick longitudinal external layer had fragments of collagen and elastic fibers. The flabby valves or fragments of the valves were found in some veins. Dilated vessels with fibrous walls were present.
Type III veins had a small diameter and thick walls with well defined three layers. The external muscular longitudinal layer was much thicker than the medium and internal layers both. The characteristic feature of these vessels was a present of small “pillows” generated from longitudinal smooth muscle cells of the internal layer. These “pillows” filled the lumens of some veins. This is considered to be an adaptive response to prevent a retrograde blood flow.
Engorged capillaries are most likely the newly formed vessels ensuring improved outflow of blood. This is confirmed by expression of the angiogenic factor VEGF and CD34 on endothelium cells.
The morphological analysis of vessels within the incision biopsies revealed multiple character of v. testiculatis sinistra formation in pediatric patients with varicocele, represented by three morphological variants of muscularis type veins. First of them is principal. We showed the possible variants of compensatory drainage of blood from the pl. pampinifomis system.

EXPRESSION OF KLF-6 TRANSCRIPTIONAL FACTOR IN CIS AND MALIGNANT TESTICULAR GERM CELL TUMORS.
Regadera J 1, Sanz-Rodriguez F 2, Botella ML 3, Serrano A 4, Nistal M 1,5, P. Gonzalez-Peramato 6.
1 Department of Anatomy, Histology and Neuroscience, Autonoma University of Madrid; 2 Department of Biology, Autonoma University of Madrid; 3 Centro de Investigaciones Biologicas, CSIC, Madrid; 4 Department of Urology, Guadalajara General Hospital, Guadalajara; 5 Department of Pathology, La Paz Hospital, Madrid; 6 Department of Pathology, Guadalajara General Hospital, Guadalajara and University of Alcalá, Madrid. Spain.

INTRODUCTION. KLF-6 (Kruppel-like factor 6) is a transcriptional factor that has been shown to be mutated in a significant number of prostate and colon carcinomas. KLF-6 is a candidate tumor suppressor gene.
PURPOSE OF THE STUDY. KLF-6 immunoexpression was explored in 21 seminomas, 12 embryonal carcinomas, 7 immature teratomas, 4 mature teratomas, 6 yolk sac tumors, and 27 combined tumors, including carcinoma in situ (CIS) as well as 4 normal adult testes.
METHODS. A polyclonal anti-KLF-6 antibody (Santa Cruz) was used at 1:400 dilution. Streptavidine peroxidase Zymed kit was employed. The immunoreaction was revelated with DAB. KLF-6 western blotting was done in 13 cases, including 2 normal testis.
RESULTS. Variable KLF-6 expression was observed in the cytoplasm of spermatogonia in human normal testis. However a significant increased expression was shown in the cytoplasm of CIS cells. This intense stain was constantly seen in intratubular and infiltrative seminoma. In mature teratoma, KLF-6 the expression of KLF-6 is higher in the epithelial component than in the mesenquimal tissues, although KLF-6 is always present in the immature neuroepithelial teratomatous differentiation. Interestingly, KLF-6 expression is lost in undifferentiated embryonal carcinoma, the most aggressive of the testicular cancers studied. No specific KLF-6 stain in the different patterns of yolk sac tumors was observed. KLF-6 expression is significantly higher by Western blotting and densitometric measuring in the cancer cases than in the normal cases.
CONCLUSION. The overexpression of KLF-6 in all types of testicular germ cells tumors and even in CIS cells suggests that KLF-6 is a transcriptional factor that may be implicated in the development and progression of testicular malignant tumors.

SEMINIFEROUS TUBULES WITH AN ABNORMAL CONFIGURATION: A NEW LESION OF THE TESTICULAR DYSGENESIS SYNDROME.
González-Peramato P.1, Nistal M.2,3, Regadera J.3, Jiménez-Heffernan JA 1, Serrano A 4.

1Department of Pathology, University Hospital of Guadalajara, Guadalajara and University of Alcalá, Madrid. 2 Department of Pathology, La Paz Hospital, Madrid; 3 Department of Anatomy, Histology and Neuroscience, Autonoma University of Madrid; 4 Department of Urology, University Hospital of Guadalajara; Spain.

INTRODUCTION. The entity of "Testicular dysgenesis syndrome" includes several heterogenic pathologies as undescended testis, hypospadias, testis cancer and infertility. Associations of different testicular histological lesions have been observed in the testicular dysgenesis syndrome including undifferenciated seminiferous tubules, partial Sertoli-cell-only tubules, testicular microliths, CIS cells and Leydig-cell micronodules.
MATERIAL AND METHODS. In a retrospective revision of 450 prepubertal and adult patients with infertility, crytorchidism, intersex and testicular cancer from the files of La Paz University Hospital, 15 cases with seminiferous tubules with abnormal configuration were observed.
RESULTS. In all 15 cases a spectrum of different patterns of malformative configuration of the seminiferous tubules abnormally were seen. The morphological anomalies of the seminiferous tubules included frequent ramifications, annular configuration, culde sac dichotomy ending and changes in diameter in different segments, with dilatations alternating with hypoplastic stenosed tubular segments. Different grades of impairment of the spermatogenesis was observed in this variants of abnormally configurated tubules. This new lesion was found in: 7 crytorchidic testis (5 with ambiguous external genitalia), 3 patients with descended testes that consulted on infertility, 2 patients with testicular microliths and 3 in the testicular biopsy contralateral to the testis excised by testicular cancer.
CONCLUSIONS. Seminiferous tubules with abnormal configuration was present both in infantile and adult testis which suggest a primary lesion. The lesion we describe should have been begin at that moment of the fetal development, because the abnormal tubules resemble the first stadies of the formation of sexual cords in normal fetus. However, the absence of remodelation of these sexual cords will cause the persistence of seminiferous tubules with an irregular caliber, frequent anatomosis and an irregular spermatogenesis varying from normal to completely absent. We suggest that the seminiferous tubules with abnormal configuration are characteristic lesions founded in testicular dysgenesis syndrome.

P 873
THE EFFECT OF CAFFEIC ACID PHENETHYL ESTER (CAPE) ON HISTOPATHOLOGICAL CHANGES IN TESTICULAR ISCHEMIA-REPERFUSION INJURY

* ATÝK Esin, **GÖRÜR Sadýk, **CANDAN Yaþar, **KÝPER Ahmet
(*)Department of Pathology, Mustafa Kemal University, Faculty of Medicine, Antakya-Hatay / Turkey
(**) Department of Urology, Mustafa Kemal University, Faculty of Medicine, Antakya-Hatay / Turkey

Purpose: Testicular torsion causes an enhanced formation of reactive oxygen species which contributes to the pathophysiology of ischemia-reperfusion injury in testis. We evaluated here the effect of caffeic acid phenethyl ester (CAPE), a new antioxidant and anti-inflammatory agent on histopathological changes in testicular ischemia-reperfusion injury.
Materials and Methods: Adult male Wistar rats were divided into 6 groups of 5 each: Control group1 (n=5), sham operation group2 (n=5), torsion/detorsion (T/D) group3 (n=5), T/D+Saline group4 (n=5), T/D+CAPE group5 (n=5) and T/D+CAPE group6 (n=5). One group served to determine baseline values of histopathological parameters, 1 that underwent sham operation served as a control, others were subjected to left unilateral torsion (2 h) and detorsion (4 h) periods. Rats were sacrified and unilateral orchiectomy was performed. Testis tissues were put into Bouin's solution. After routine tissue proccesing myeloperoxidase (MPO) and inducible nitric oxide synthase (iNOS) immunohistochemical methods were studied from paraffin embedded tissues.
Results: Treating rats with CAPE (applied at 10 µmol/kg, 30 min. prior to T/D) attenuated the testicular injury and as well as the tissue levels of MPO. At the same time testis tissue showed an increase in iNOS activity.
Conclusion: Our results suggest that CAPE treatment have a protective role on testicular T/D and this effect may be due to inhibiting the neutrophil mediated cellular injury.

P 874
CANCERS OF THE TESTIS: A RETROSPECTIVE STUDY OF 29 CASES

CHTOUROU Imen, GOUIAA Naourez, MAKNI Saloua, FAKHFAKH Ines, AYADI Lobna, SELLAMI Ahmed, BOUDAWARA SELLAMI Tahya

Intoduction:
Cancer of the testis (CT) is rare, accounting for about 1 % of all cancers in men; in Europe, the annual incidence rates range between 7,3 (West) and 4,6 (south) per 100.000; in Africa, the annual incidence rates are very low (less then 1 pour 100.000). It is the commenest cancer in men under 45 years old. Cryptorchidism is the only confirmed risk factor. The majority of CT are testicular germ cell tumours witch are divided into seminoma and non séminoma types for treatment planning because seminomatous testicular cancers are more sensitive to radiotherapy.
Objectives:
The purpose of this study is to discuss the clinic and pathologic characteristics, the course and the prognosis of CT.
Methods and materials:
We report a retrospective study of 29 cases of CT diagnosed in the department of pathology of the Habib Bourguiba hospital-Sfax-Tunisia over a five years period (2000-2004).
Resultats:
The mean age of our patients was 40 years (extremes 1 and 83 years). Indescended or maldescended testis are found in 80% of cases; all of CT are clinically detectable at initial presentation (diffuse pelvic mass 50%, inguinal swelling 30%; hardness scrotal mass: 20%).The chirurgical procedure to make the diagnosis was a radical orchidectomy in all cases. Pure seminoma was the most frequent histological type (30%) followed by mixed germ cell tumours (20%); 18% of patients have a testicular lymphoma and are old mens. Only four cases of paratesticular tumours are found and are a rabdomyosarcoma type in three cases. After testicular surgery, the management was depended on type and stage of disease.The mean fallow up was 47 months, 20% of patients with mixed germ cell tumours developed a pelvic recurrence versus any relapse for pure seminoma; a paratesticular rhabdomyosarcoma representthe most aggressive pathologic variant and early visceral metastases are observed in all cases.
Conclusion:
Cancer of the testis is a relatively rare disease; the majority are testicular germ cell tumours who occur most frequently in young men and have a good prognosis: it is highly treatable, often curable cancer; many germ cell tumours produce tumoral markers(AFP, HCG, LDH) who are useful in the diagnosis and staging of disease, to monitor the therapeutic reponse and to detect tumour recurrence.

CASE OF ABSOLUTE RELAPSE OF " BURNT-OUT" TESTICULAR TUMOR OF LECITHAL SAC

PAPANIKOLAOU Athanasios1,KAMPAS Lambros1,NIKOLAIDOU Anastasia2,FLARIS Nikolaos1,HATZIKALIAS Argirios1, PAPATHANASIOU Athanasios3
1Department of Pathology, Hippokration Hospital, Thessaloniki
2 Department of Pathology, General Hospital, Kilkis
3Department of Urology, Hippokration Hospital, Thessaloniki, Greece

We report the case of a 25-year- old man with testicular tumor of lecithal sac having as initial clinical indication a retroperitoneal tumor.
Macroscopically, the retroperitoneal tumor consisted of numerous grey, elastic- friable pieces of tissue. The maximum dimensions of the greatest piece were 6x4,5x3,5 cm.
Microscopically, the tumor was solid, dedifferentiated and metastatic. From the immunohistochemical examination performed with a great range of antibodies (CEA, EMA, LCA, UCHL1, CD 20, Vimentin, SMA, HMB-45, CD 56,HCG, PLAP, CD68, Ulex europaeus, CD 34, Desmin, S-100, MIC-2, pancytokeratin AE1/AE3, Synaptophysin) we concluded that the tumor cells were positive only for low grade molecular weight cytokeratin (AE1).
On ultrasonography numerous punctate ultrasonic lesions were found in the left testis. Later on, left testectomy was operated. The histological examination of the testis revealed a small scar with calcification and numerous testicular tubules with decations of intratubular neoplasia of germinal cells. Further estimation of the retroperitoneal tumor showed that the tumor cells were positive for AFP.
In conclusion, we can report that in case of a retroperitoneal metastatic tumor we should examine testis meticulously.

Malignant transformation in testicular teratomas has been reported very rarely in the literature. Although testicular teratomas in childhood are regarded as benign neoplasms, if these tumors are left untreated until advanced ages, the risk of malignant transformation may be in question.
We report a case of differentiated adenocarcinoma originated from colonic glands existing in primary testicular teratoma.

PURE SEMINOMA IN A MALE PHENOTYPE 46,XY TRUE HERMAPHRODITE

CHELBI Emna (1), RAMMEH Soumaya (1), ZERMANI Rachida (1), BEN MOUALLI Sami(2), FARAH Faten (1), KOURDA Nadia (1), FERCHICHI Leila (1), KACEM Olfa (1), ZEDDINI Abdelfateh (1), AYED Mohsen (2), BEN JILANI Sarrah (1)
(1) Departement of Pathology, Charles Nicolle Hospital, Tunis.
(2) Departement of Urology, Charles Nicolle Hospital, Tunis.

INTRODUCTION
True hermaphroditism (TH) is a rare cause of intersexuality characterized by the development of ovarian and testicular tissue in the same individual. The most frequent karyotype is 46,XX followed by various forms of mosaicism. The karyotype 46,XY is extremely rare, present in only 7% of cases. Gonadal tumours are reported in 4.6% of patients with TH, most of them are gonadoblastoma. Herein, we report a case of a pure seminoma occurring in a male phenotype 46,XY true hermaphrodite.
PATIENT AND METHODS
A 32-year-old man presented with pelvic pain, constipation and important weight loss. Physical examination revealed bilateral cryptorchidism and a firm pelvic mass, without gynecomastia. â-human chorionic gonadotropin, á-fetoprotein and carcinoembryonic antigen had normal levels in serum. The computerized tomography showed a large retrovesical tumor of unkown origin. The ultrasonography guided biopsies concluded to a pure seminoma. At surgery, an uterus, two tubes, two gonads, a prostate and two seminal vesicles were identified. The tumour (7 cm), adherent to the uterine cervix and to the prostate, was almost entirely excised.
RESULTS
The pathological examination confirmed the diagnosis of pure seminoma. The gonads were consistent with two ovotestis one of them was massively unfiltered. Cytogenetic evaluation of peripheral leukocytes revealed a 46,XY karyotype with a sex-determining region of the Y chromosome (SRY gene) detected by PCR. The patient received a complement of radiotherapy (35 Gy). He was free of disease six months later.
CONCLUSION
TH is a complex and heterogeneous condition. SRY gene seems to play a major role. Further studies are needed to better characterize its pathogenesis. Few cases of tumours occurring in the gonads of true hermaphrodites have been reported. Our report is peculiar by the arising of a pure seminoma in the ovotestis of a male phenotype 46,XY true hermaphrodite.

P 878

HISTOLOGICAL INHOMOGENEITY IN MULTIPLE TESTICULAR BIOPSIES

MAGYAR Éva, ERDEI Edit*, LELLEI Ilona
National Medical Centre, Department of Pathology and Andrology*, Budapest, Hungary

Introduction:
Histological evaluation of testicular biopsy is an important method in management of male infertility.
Materials and methods: Multiple testicular biopsies of 143 infertile men were taken using atraumatic microsurgical method. Samples were fixed for 24 hours in Bouin's fixative or buffered formaline. After paraffin embedding 3-4 um slides were cut and stained by HE. Data of histological reports were examined concerning inhomogeneity using three different methods.
Results:
1. Etiological inhomogeneity: 43 of the 86 azoospermic, 22 of the 29 OATS and 21 of the 28 oligozoospermic patient showed different etiology int he biopsies.
2. Spermatogenetic activity: 24 of the azoospermic individuals presented mature spermatozoa only in some of the samples. 13 men int he OATS group showed spermatogenesis only in some of the biopsies. 10 of the oligozoospermic patients was proven inhomogenous concerning spermatogenetic activity.
3. Statistical inhomogeneity: The number of mature spermatozoa counted in 10 round shaped tubules was evaluated. In the azoospermic group an average of 59,4 +/- 92,3 was found. Int he OATS an oligozoospermic group it was 122 +/-120,4 and 152,7 +/-130,5, respectively.
Discussion:

Our data proved that function of testicular tissue shows marked local differences in etiology and spermatogenetic activity either. Taking of single biopsy might give a false impression of spermatozoa content and alterations. Histological evaluation of multiple biopsies helps andrologist to plan further therapy.

Anargiri" Cancer Hospital, Athens, Greece, 4. Dept of Medical Oncology, Papageorgiou Hospital, Aristotle University of Thessaloniki, School of Medicine, 5. Dept of Pathology, Tzaneio Hospital, Piraeus, Greece, 6. Department of Pathology, "Ag. Anargiri" Cancer Hospital, Athens, Greece

BACKGROUND AND OBJECTIVE : Testicular germ cell tumors consist 95% of all malignant tumors arising in the testis and most of them are sensitive to chemotherapy. However 10-20% of those develop resistance to chemotherapy. Recently, targeted therapy drugs are in use for the management of chemoresistant malignancies. Imatinib (STI571) is one of them and targets c-Kit among other molecules. Overexpression or constitutive activation of c-Kit by mutations have been associated with the development and progression of various malignancies. In this context we investigated the expression of c-Kit in testicular germ cell tumors in order to evaluate the incidence of its expression in various tumor types along with the possible use of c-Kit inhibitors as a tool for therapeutic intervention.
MATERIALS AND METHODS: In this study, 169 archival tumor samples were analyzed immunohistochemically, using a polyclonal rabbit anti-human antibody against c-Kit (DAKO). From them 61 were seminomatous (49 pure, 11 anaplastic, 1 spermocytic) and 108 non-seminomatous tumors (36 malignant teratoma undifferentiated , 15 malignant teratoma trophoblastic , 21 malignant teratoma intermediate , 32 malignant teratoma combined , 5 other). c-Kit expression was considered as positive, if >10% of tumor cells displayed membranous staining.
RESULTS: 77.5% (n=38) of pure seminoma exhibited a positive immunostaining for c-Kit, while only 18.2% (n=2) of anaplastic were identified as positive ($p<0.001$). Out of 32 cases with a combined tumor, 17 showed a positive c-Kit reactivity and 15 a negative one, while only 2 non-seminomatous tumors had a positive staining. Although c-Kit expression is strongly correlated with seminomatous histological features ($p<0.001$), there is no correlation with stage ($p=0.19$) or chemotherapy treatment response ($p=0.11$). Overall, 4 (1 seminoma, 3 combined tumors) out of 22 chemoresistant cases revealed a positive expression for c-Kit and one of them had a positive response to Imatinib treatment in combination with chemotherapy.
CONCLUSIONS: c-Kit is expressed in the majority of seminomas and in seminomatous components of the combined tumors, in a minority of anaplastic seminomas and rarely in non-seminomatous tumors. The recent development of c-Kit inhibitors may offer a possibility of cure in chemoresistant testicular germ cell tumors overexpressing this transmembrane receptor.

P 880

BLOOD VESSELS IN TESTICULAR BIOPSIES OF INFERTILE MEN

JEZEK Davor, BILIC Ernest, GRAHOVAC Gordan, KNEZEVIC Nikola
University of Zagreb, Medical School, Zagreb,Croatia

INTRODUCTION
Infertile men were shown to have reduced lumen of the testicular blood vessels. The reduced lumen is mostly due to the process called "hyalinization", pathological accumulation of glycoprotein substance within the blood vessel wall. Hyalinization could be found in the case of cryptorchidism, immune orchitis, Klinefelter's syndrome and in the significant number of patients with idiopathic infertility. Microangiographic data on the testicular arterioles in severe cases of male infertility demonstrated irregular blood flow, damage of the blood vessel wall and reduced spermatogeneis within the seminiferous tubules.
AIM
There is a lack of electron microscopic, immunohistochemical and morphometric studies dealing with the structure of testicular blood vessels in patients with the non-obstructive azoospermia. Therefore, the aim of our study was: a) to identify the most frequent blood vessel type affected in this group of infertile patients; b) to describe blood vessels changes both at light and electron microscopic level; c) to perform an immunohistochemical and morphometric (stereological) analysis of small blood vessels of the testicular biopsies of infertile men.
MATERIALS & METHODS
48 couples that consulted andrologist at the Urology Clinic (University of Zagreb, Medical School) for infertility in the period 1997-2003 were included in the current study. The infertility problem was due to the male factor. In 40 infertile men, a non-obstructive azoospermia could be diagnosed. 8 patients had obstructive azoospermia with completely preserved testicular tissue and served as controls. Whenever possible, a bilateral biopsy was performed. Testicular biopsies were examined by light and electron microscopy, immunohistochemistry (IHC) and stereology.
RESULTS
Interstitial blood vessels in the control group displayed regular architecture. In infertile group, there was a change in the morphology of some arterioles and venules. In the subendothelial layer of these vessels, an accumulation of a hyaline could be observed. Observed by the transmission electron microscope, the thickened subendothelial layer had an accumulated material of a moderate electron density. IHC and stereological analysis pointed out a significantly increased number, volume, length and curvature of capillary network in the infertile group of patients.
CONCLUSION
In the testis of infertile men, there is a pathological change of arterioles, venules and capillaries.

P 881

PRIMARY MALIGNANT LYMPHOMA OF THE TESTIS

PETRESCU Amelia 1, DOBREA Camelia 2, NICULESCU Liviu 3,.GÃLEªEANU Mihai 1, VASILICÃ Mariana 4 ANDREI Florin 2
1.Prof. Dr.Th.Burghele Hospital Bucharest, Romania 2.V Babes Institute of Pathology, Bucharest, Romania 3. Carol Davila University of Medicine and Pharmacy Bucharest Romania 4. Department of Hematology, Fundeni Clinical Institute, Bucharest Romania

Introduction and aim: Primary testicular lymphomas are rare entities representing 1-2% of non –Hodgkin lymphoma (NHML) and 1-7% of malignant testicular tumors and they are the most common testicular tumor in men older than 50 years of age. This study included 8 cases of inpatients

diagnosed by echography and NMR) with testicular tumors. The age of patients was between 46 and 81 (with a mean of 52). The tumors were unilateral, with disease limited to testicle and accompanied by pain. Orchectomy was performed as first therapeutic and diagnostic purpose. All patients were clinically staged according to the Ann Arbor criteria and received a doxorubicin based chemotherapy regimen (CHOP, MTX, CVP, and Leukeran).. A standard chemotherapy protocol has not been used because of reduced number of patients.
Material and method: Tumor fragments were fixed in 10% formallin, paraffin embedded, sectioned and standard H.E. stained. Immunohistochemistry for L26, Alphafetoprotein, NK1, CD30, and CLA was performed.
Results: Microscopy revealed in all cases a stromal proliferation with medium size cells, monomorphic shape and prominent nucleoli. Alphafetoprotein was positive in seminal tubes and negative in tumor, NK1 in small lymphocyte and negative in tumor and L26 diffuse positive in tumor. We were able to follow up only four patients.
Conclusions: The diagnosis was of NHML in 6 cases and for 2 secondary involvement of hematopoietic malignancy (myeloid sarcoma and leukemia). Lymphoma cases were typed using REAL classification as small and large B cell lymphoma. Unfavorable evolution with 6 months relapse and one death prove a more aggressive evolution of primitive testicular lymphoma.

P 882
SEMINOMA WITH A MICROCYSTIC AND TUBULAR GROWTH PATTERN
H.L. Barrett, M. Redmond, M. Leader
Royal College of Surgeons in Ireland.

A 63year old gentleman presented with a large right testicular mass, which was subsequently resected. On macroscopic examination, the testis was extensively replaced by a cream coloured tumour, which focally had a nodular appearance. On histological examination, the tumour was composed of polygonal cells with clear cytoplasm and a stippled chromatin pattern. Much of the tumour had a solid growth pattern but, in large areas, showed florid microcystic change and tubule formation. The spaces were generally small and closely packed. Granulomata were present and there was a mild lymphocytic inflammatory infiltrate. There was no evidence of intra-tubular germ cell neoplasia in the residual tubules. On immunohistochemical staining, the tumour cells were negative for PLAP. The tumour cells were immunoreactive for CD117 (c-kit).
Seminomas with microcystic and tubular growth patterns are unusual and should not be confused with a yolk sac tumour, but the cytological features are helpful in distinguishing these two entities. It is not yet known if these tumours are associated with an adverse prognosis compared to the classical seminoma.

P 883
ISOLATED POLYARTERITIS OF THE MALE REPRODUCTIVE SYSTEM COINCIDING/ASSOCIATED WITH A MALIGNANT GERM CELL TUMOUR OF THE TESTIS: A CASE REPORT
Achim Fleischmann[1], Urs E. Studer[2]
Departments of Pathology[1] and Urology[2], University of Bern, Switzerland

Polyarteritis nodosa (PAN) is a necrotizing vasculitis affecting primarily small and medium-sized arteries. PAN presents mostly as a systemic disease with poor prognosis, rarely in an isolated form with a usually favorable outcome. Both forms may affect the male reproductive system. The etiology of this inflammatory disease is still unclear. However, PAN has been described in the contexture of various diseases such as systemic lupus erythematodes, rheumatoid arthritis, hepatitis B and C, human immunodeficiency virus (HIV) infections and neoplasms. Therefore it has been speculated that triggering events may be identified in most cases in the future. We report for the first time a localized PAN of the reproductive system coinciding/associated with a mixed germ cell tumour of the testis in a 21-year-old man. One year after surgery he is without evidence of recurrence of either the tumour or PAN.

P 884
SURVEYING 177 TESTIS BIOPSIES OF INFERTILE MALES AND COMPARING THE RESULTS WITH OTHER DIAGNOSTIC MODALITIES
Mozaffari Reza*, Ensani Fereshteh** , Saremi Aboutaleb**
* Department of Pathology, Islamic Azad University, Tehran Medical Unit
** Department of Pathology, Tehran University of Medical Sciences

Background : Recently infertility becomes more common. In half of the infertile couples, men are completely or relatively responsible. Therapeutic approaches to infertile males impose great expenses on the family. Present study deals with sensitive clinical or paraclinical methods, other than testis biopsy, that could provide informative data regarding the absence or presence of sperms.
Material and Methods : Medical files of 177 infertile men were reviewed. Then findings of physical examination, hormonal studies, past medical history and testis aspiration were compared with hystopathological findings of testis biopsies. All these patients underwent testis biopsy following the initial studies. Spermatid count per tubule was considered to be the major criteria of fertility in patiants' biopsies.
Result : of 177 patients, 95 (53.5%) had no chance of fertility due to the absence of mature spermatid or spermatozoa in their biopsies. Testis aspiration has a sensitivity of 86%, specificity of 85% and positive predictive value of 93% to detect sperm.
Conclusion : Our result revealed that physical examination, serum hormone assay and testis needle aspiration can not substitute hystopathological studies of the testis biopsy to prove infertility.

P 885
CANCER OF THE PENIS.PATHOLOGICAL ASPECTS OF SEVEN CASES OBSERVED IN CAMEROON(CENTRAL AFRICA)
NKEGOUM Blaise,SOW Mamadou,FOUDA Pierre,SASTRE-GARAU Xavier,DECREMOUX Patricia,BOSMAN Fred, ESSAME OYONO J L.

BACKGROUND:Cancer of the penis is an ucommon malignancy in developed countries,but the incidence is as high as 17% of all male cancers in some undeveloped countries. The most important etiologic factor is the presence of an intact foreskin but this is still unknown.
METHODS/ We described the pathological aspects of seven cases of penile cancers observed in Cameroon, an underdeveloped country of 15000000 inhabitants situated in Central Africa, within a period of twenty years (1984-2004). Human Papilloma Virus(HPV) DNA detection and typing were carried out on paraffin-embedded specimens of our cases by Polymerase Chain Reaction.
RESULTS
The patients aged 43 to 75 years and were circumcised. Four of the seven cases were observed in 2004 an one of this four patient was HIV(Hman immunodeficient Virus) positive and another was diabetic. All patients consulted late with

metastatic disease.The pathological aspect was squamous cell carcinoma. HPV DNA was detected in four cases.
CONCLUSION/ Penile cancer is still rare in Cameroon were only 10%of cancers are confirmed histologically.The etiology is unclear. The HIV should be investigated as an etiologic cofactor.

***** Individual Medical Center 81, Cluj Napoca, Romania

A case of primary localized multinodular amyloid tumor of the retroperitoneum is reported. A previously healthy 40 year old man presented with non specific symptoms of lower abdominal pain and a tumour mass in the inguinal region. The clinical diagnosis (based mainly on echography and computed tomography, the serology being normal) was that of a very large tumor mass, of 20/8/6 cm, occupying the right retroperitoneal space, from the kidney to the inguinal region. The surgical excision revealed a multilobular tumor mass with an osseous consistency, apparently well circumscribed but infiltrating the adipose tissue and pressing the ureter. The patient needed an ureterostoma. Subsequent histology showed nodular amyloid deposits associated with osseous metaplasia, giant cell reaction and an apparently normal lymphocyte and plasma cell infiltrate. Further standard tinctorial tests, like a positive dimethyl benzaldehide method for triptophan and permanganate-resistant congophilia, revealed the lesion to be a primary AL type immunoamyloid. Immunohistochemical investigations did not reveal any immunoglobulin light chain restriction, being ê and ë intense positive, at the site of plasma cells but also of the amyloid deposits. These observations indicate that the amyloid nodules are produced by the plasma cells, which are of polyclonal rather than monoclonal origin, implying an inflammatory process rather than a solitary extramedullary plasmacytoma. The patient is well two years after the surgical excision, without recurrences.

2. I. Dept. of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary
3. II. Dept. of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary

Introduction Several publications reported that RNA recovered from paraffin embedded tissue could be used as a substrate for PCR. Formalin fixed, paraffin embedded histopathology archives contain an inestimable collection, which could be analyzed to investigate changes in mRNA expression in pathological processes. It would be also reasonable to decide for future tissue conservation of pathology samples which fixative to use to satisfy both histological and molecular biological needs.
Aim Three different fixation methods were compared by histology, immunohistochemistry and Real-Time RT-PCR.
Materials and Methods 24 hours' fixation with RNAlaterTM, acetone and formalin, followed by paraffin embedding, were compared on human endometrium samples. Hematoxylin-eosin staining and immunohistochemistry with mono- and polyclonal antibodies were performed. RNA was extracted and the transcription of different size amplicons (121, 225, 406 bp for GAPDH; 166, 310, 536 bp for beta globin) were compared by Real-Time RT-PCR.
Results The most adequate tissue preservation was found with formalin fixation, while there were no significant differences in the 3 fixative's yields for various size amplicons with Real-Time PCR (GAPDH 121 bp threshold cycle number for RNA later 28,4±3,3, acetone 26,9±2,7, formalin 27,8±3,0). PCR product quantity decreased with length regularly, longer than 225 bp amplicons gave poorer results.
Conclusion Acetone and formalin fixatives followed by paraffin embedding can also be used for RNA studies besides histological and immunohistochemical use, with the limitation of using short amplicons for paraffin embedded material. Longer amplicons gave less reliable results because of RNA fragmentation, while shorter amplicons can represent better real tissue composition. Our findings confirmed the importance of suitably designed primers' on the success of RNA recovery. Further investigations are necessary to define the correct use and validity of paraffin RNA for gene expression studies.

MOLECULAR ANALYSIS OF GENOMIC LOW COPY NUMBER DNA EXTRACTED FROM LASER-MICRODISSECTED CELLS
G. Giuffrè, L. Saravo*, D. Di Martino*, N. Staiti*, A. Simone, G. Sippelli, G. Tuccari.
Department of Human Pathology, University of Messina, and *Laboratory of Molecular Biology – Raggruppamento Carabinieri Investigazioni Scientifiche, Messina, Italy

INTRODUCTION. Tissue microdissection techniques, allowing a correlation between the topologic organization of the cells and the molecular analysis of nucleic acid extracted, represent a key technique in molecular pathology. In fact, the presence of a wide spectrum of cell types in tissue samples may complicate the analysis of a particular cellular population. Laser-assisted microdissection is an advanced procedure to cut small tissue fragments as well as single cells by an ultraviolet laser beam in order to select a specific cell population of interest from a heterogeneous sample, under direct microscopic visualization. In the present report we evaluate the sensitivity of this method in order to perform genomic analysis from low copy number DNA.
METHODS. Laser-microdissection was performed using a Leica AS LMD system (Leica Microsystems, Germany) on smears of aploid (spermatozoa) and diploid (lymphocytes) cells, on sections of tissues routinely formalin-fixed and paraffin-embedded, on cryostatic sections obtained at surgery and post-fixed with cold methanol. The samples were stained with specific procedures (Haematoxilin-Eosin, Giemsa, Papanicolau, Picroindigocarmine-Nuclear fast red). For each sample, an increasing number of cells from 1 to 100 was harvested in different PCR tubes. DNA extraction was performed by Chelex™ 100 (Biorad), QIAmp DNA Micro Kit (Qiagen) and DNA IQ™ System (Promega Corp.). The DNA extracted from each sample was amplified to identify a specific genetic profile by the most common microsatellite loci (BAT25, BAT26, BAT40, D2S123, D5S346, D17S250) as well as multiple Short Tandem Repeat (STR) typing

(AmpFLSTR Identifiler, PE Biosystems) of forensic interest. PCR products were separated by capillary electrophoresis with 3100 AB Prism Genetic Analyzer; and analyzed by the Genescan and Genotyper Softwares v 3.7.
RESULTS. We have obtained sufficient DNA for amplification and STR typing starting from 10 aploid cells while amplification for microsatellite loci was achieved with 5 diploid cells obtained from routinely processed tissue samples. Moreover, some differences in relation to the integrity of the extracted DNA was found with the specified staining procedures.
CONCLUSIONS. The documented possibility to perform a genomic analysis of low copy number DNA from few cells harvested by laser microdissection represents a valid aid in order to solve diagnostic and forensic problems in the medical practice.

P 889
ASPECTS OF DIGITAL MICROSCOPY IN HUNGARY
GOMBÁS Péter, MOLNÁR Béla*
MI Central Hospital, Department of Pathology;
Cellanalysis Laboratory, 2nd Department of Medicine, Semmelweis University, Budapest, Hungary

AIMS: Although telepathology techniques have been accepted as global method, there are serious doubts to implement cyber age tools in professional practice. Traditional static telepathology has proven biased due to the low explicit/implicit ratio of transmitted information; dynamic telepathology can not be automated using remote controlled conventional microscopes. Our aim is to present concept and realizations of digital
microscopy in Hungary.
METHODS: Selected histopathological samples were captured with a bright field transmitted light microscope and in house developed slide scanner. Images of biopsies have been joined in order to create digital slides using different scanning methods. Electric slides have been stored on slide server, then diagnosed at remote stations via Internet.
RESULTS: The value of bias of transferred digital information can be reduced to zero digitizing series of histopathology slides. We tested the following systems:
1. Manual digitizing of the specimen via x and y axes using RGB microscopic camera and frame grabber is extremely laborious and inappropriate in the routine practice.
2. Automatic scanning of slides applying traditional microscope, which is equipped with motorized stage digitizes the entirety of selected slides but not able for fully automated capturing of large slide series.
3. Histological slide scanner without conventional microscope but with network connected slide server, containing software controlled stage and auto-focus, enable creation and storage digital slide series and remote diagnostics on routine way.
CONCLUSION: Basic questions of digital slide's application in the routine practice are the way of slide scanning, the speed of archive's access and image quality of digital slides. Application of slide scanner, slide server accessed via TCP/IP protocol dissolves bias experienced in telepathology practice and enables a new agenda for expert discussions, consultations, archiving, education and quality assurance.

THE ADVANCES IN SCANNING FLUORESCENT MICROSCOPY, (AUTOMATED SLIDE HANDLING, METAL-HALIDE ILLUMINATION, SOFTWARE FEATURES) MEANS SIGNIFICANT ADVANTAGE FOR ROUTINE APPLICATIONS
MOLNAR Bela, VARGA Viktor, CSENDES Gabor, VIRAG Tibor *, TULASSAY Zsolt
Cell Analysis Lab, II.Dept. of Medicine, Semmelweis University
3DHISTECH ltd, Budapest, Hungary

Background: we reported recently about the application of single slide fluorescent scanning technology on a routine motorised microscopy. Several technical limitations became known as scanning speed, slide identification, scanning area determination., Internet access to fluorescent digital slides, application on histological sections.
Aims: Development and evaluation of an automated new fluorescent slide scanner (HI-Scope, 3DHISTECH Ltd, Budapest) and software enhancements for supporting high volume automated analysis.
Materials and methods: For automated slide handling slides, coverslips and slide boxes(50 slides) were developed. Hi-Scope (3DHISTECH Ltd, Budapest Hungary) features a vertical fluorescent illumination pathyway of a commercial microscope, automated slide box movement (upto 6), slide loading and barcoded identification, edge fluorescent labelled coverslip localication and laser triangulometry based focus point determination. Automated scanning software features multichannel slide digitisation depiding on the staining intensity upto 1 sec for three channels. Coverslips are fixed using Pro-long media (MolecularProbes, USA). Illumination was enhanced using a metal-halide fluorescent light source. Cytometric calibration and standardisation was done using beads Coulter beads.
Results: The Hi-scope system"s slide box and slide loading safety was proven in a three month tests. Mechanical slide loading errors were found occasionally after loading 300-400 slides. Focus determination worked without error. CV of the densitiy measurements on the calibration beads were 3.9 %. The determination of area of interest using prelabelled coverslips was automatically perforemd without failures. Resolution of the system is 0.3 um2
/ pixel. Digitisation of a field of view took upto 0.1 sec in FITC, 0.1 sec in DAPI, upto 0 sec in the Rhodamine channel. This way a cytospin area could be scanned in three channels in less then 4 minutes.
Conclusions: Hi-Scope can contribute to high volume fluorescent slide scanning. The produced image quality is acceptable for routine use. Based on these results development of routine applications can be started.

WORKING EXPERIENCE WITH DIGITAL SLIDE AND VIRTUAL MICROSCOPY-BASED ROUTINE AND TELEPATHOLOGY EVALUATION OF BIOPSY SPECIMENS
ZALATNAI Attila, SZENDE Béla, BERCZI Lajos, FÓNYAD László, KOPPER László
Semmelweis University, 1st Department of Pathology and Exp. Oncology

INTRODUCTION
Automated scanning of histological sections and visualisation of the histological image by virtual microscopy is becoming increasingly important in routine diagnostic pathology.
PURPOSE OF THE STUDY
The aim of present study is to test Zeiss Mirax slide scanner solution (Carl Zeiss, Jena) as virtual microscope system about its usability in routine diagnosis of biopsy specimens as well as in telepathology.
METHODS
Altogether 1500 biopsy sections were scanned and examined on screen until the submission of this abstract. The established diagnoses were compared to those which were given after light microscopic examination. The study was carried out by four experienced pathologists, both on site and at a remote workstation equipped with the software including the facility of remote access for digital slides.
RESULTS
Accurate diagnosis could be established in all cases using the virtual microscope, if the sections and the staining were of

good quality and 8 u thin or less, both on site and from the remote workstation. The images taken by use of 20x objective were suitable for routine diagnosis. The scanning of an average sized section took 5-7 minutes at this magnification. Three hundred sections/day can be scanned without difficulty. Further digital magnification of the images did not improve the quality of structures. A period of 3-4 weeks is needed even for experienced pathologists to get used to microscopic images on the screen. The system enables the establishment of collections and the storage of histological images, first of all for gradual and postgradual education.
CONCLUSION
The Mirax virtual microscope system is valid for use in diagnostic histopathology and telepathology.

P 892
THE EFFECT OF DIFFERENT THICKNESS OF THE SAME TISSUE SECTIONS ON THE COLORIMETRIC DETERMINATION OF COLLAGEN CONTENT
GEDIK Nursal[1],TARCIN Orhan[2]
[1]Istanbul Naval Hospital, Division of Clinical Biochemistry,
[2]Gumussuyu Military Hospital, Division of Gastroenterology, Istanbul, TURKEY

In clinical and experimental studies, it is important to measure the collagen content quantitatively in tissues for study in the development of fibrotic changes. Fibrosis has been estimated by histomorphometric or qualitative methods. Histomorphometric methods are time consuming and qualitative analysis inaccurate. A simple and reproducible method has been reported by López-de-León and Rojkind routinely to estimate collagen content in formalin-fixed paraffin-embedded sections. The method is based on the selective binding of Sirius Red and Fast Green FCF to collagen and noncollagenous proteins, respectively.In this method 15 µm thick- sections are frequently used. But studying with 15 µm thick- sections have some difficulties in process. The aim of this study is to evaluate the reliability of the colorimetric collagen measurement method with different tissue sections and staining procedures.
40 bile duct ligated-female Wistar Albino rats (200 ±30 gr) were used in this study. 3, 6, 9 and 15 µm-thick double sections were obtained for each liver section.
Collagen content was measured 320 liver-tissue sections for using two different staining procedures. First staining procedure was based on the method published by Lopez-de León and Rojkind.After the liver sections were deparaffinized, all of them covered with saturated solution of picric acid in distilled water that contained 0,1% Sirius Red and 0,1% Fast Green FCF and incubated 30 minutes in a rotary shaker. Sections were rinsed several times with distilled water until the fluid was colourless. 1 ml of 0,1 N NaOH in absolute methanol was then added and mixed until all the colour was eluted from the section. Eluted colour was read immediately in Jasco V 50 UV-VIS spectrophotometer at 540 and 605 nm, i.e.Second staining procedure was based on Gascon Barrë and et al. In this procedure, sections were first stained with 0,04% Fast Green FCF and with both dyes. Different from Lopez-de León and Rojkind's procedure 1 ml of 0,05 N NaOH in 50% aqueous methanol was added for obtaining eluted colour. Eluted colour was read immediately in Jasco V 50 UV-VIS spectrophotometer at 530 and 605 nm.
Collagen contents of four different thickness of the same tissues showed a high correlation with each other (r mean= 0, 9896, $p<0.01$). The results of the different staining procedures are highly correlated (r mean= 0, 9638, $p<0.01$).
This method is not affected by tissue thickness and different staining procedures.

Whole histological slide digitization, allowing "virtual slide" examination and analysis, has several potential applications for pathologists.
It may be useful first for teaching purposes, using web-based interactive self-instructive methods. It is expected to provide, in the near future, adequate solutions for telepathology exchanges. It also potentially offers the best response to the difficult problem of tissue heterogeneity for quantification of prognostic markers in oncology.
Nowadays, virtual slides are obtained using costly and more or less rapid devices, yielding to images which can barely be manipulated and which cannot be automatically processed, due to their huge size. The issue of disk storage capacity will probably be solved in the near future, but the development of efficient, rapid and economic methods, for fully automatic analysis of images of more than 10 Gigabytes, will not be achieved before several years.
Purpose : In this context, we propose an inexpensive, swift and multipurpose approach, using 4,000 dpi scanned images of the whole histological slide, ranging from 15 to 70 Megabytes, which can be either stored in a database or automatically processed for tissue marker quantification.
Methods : Thanks to a simple calibrated professional slide scanner, we were able to build a user-friendly website dedicated to breast pathology, including around 250 cases (scanner image associated to relevant microscopical details). Furthermore, dedicated image analysis routines have been developed, one allowing automatic quantification of tissue markers on whole slides (cytoplasmic or nuclear immunostaining, immunolabeled blood vessels or stroma), the other performing automatic labeling and analysis of Tissue Micro Arrays. Superimposition and image matching of serial immunostained sections, as well as analysis of staining heterogeneity, are also available.
Conclusion : We herein propose to take advantage of an inexpensive and swift image acquisition device, affordable by each pathology, biology or research department, for low resolution virtual slide production, examination and analysis.

P 894
TOWARDS COHORT BASED FROZEN TISSUE BIOBANKS: LOGISTICS AND RNA QUALITY
BOTLING Johan, PONTEN Fredrik, MICKE Patrick
Department of Pathology
Uppsala University Hospital
SE-751 85 Sweden

New sophisticated tools for molecular profiling generally require collection of fresh frozen tissue as a source of high quality DNA and RNA. Unfortunately, most frozen tissue biobanks represent a selected fraction of surgically removed cancer cases. There is usually an over-representation of large, well-demarcated tumors while sampling of small, diffuse tumors is avoided due an appropriate concern about diagnostic safety. To address this issue, we have implemented a prospective biobank allowing for "clinical cohort-based" collection of cancer tissues.

Novel logistics for managing non-fixed specimens has been established. Resected tumors and biopsies are sent on ice to the Department of Pathology. Selected pieces of representative diseased and normal tissue are cut out, blocked in cryogel, and snap frozen. High quality "tape-transfer" frozen sections are produced from each case and the sections are included in the routine histopathological examination. In our experience safe evaluation of small lesions and even resection margins can be done on these slides. In this way a non-selected collection of cases can be obtained from a treated patient cohort. Digital images of the frozen sections are linked to the biobank register. Thus, the cellular composition of the tissue can be assessed before profiling experiments and microdissection.
Difficulties associated with the fragile nature of RNA prompted us to examine the effects of transport time and transport conditions. Structural RNA integrity was checked by microchip electrophoresis in a Bioanalyzer, and gene expression patterns were analysed using real-time PCR. In an experimental set-up, tonsil tissue was cut into cubes and some pieces were snap frozen immediately after surgery. The remaining pieces were left at room temperature, kept on wet ice, in normal saline or in a commercial RNA-stabilising buffer. Surprisingly, the RNA remained quite stable in the tonsil specimens under all conditions and time points tested. Even after 16 h at room temperature only slight RNA degradation was revealed by the electropherograms. However, gene expression levels at different transport time points were most stable during transport on ice.
Our study shows that non-fixed tissue from most tumors can be collected safely in a routine pathology setting and that RNA degradation is a minor problem during handling of fresh tissue before biobanking.

SOFTWARE DEVELOPMENT FOR FRACTAL ANALYSIS OF HISTOPATHOLOGIC IMAGES

PAVLOPOULOS Petros (1), KAVANTZAS Nikolaos (2), AGAPITOS Emmanouel (2), PATSOURIS Efstrastios(2).
(1) Urologic Clinic, 1st Social Security Hospital, Athens, Greece.
(2) Department of Pathology, Medical School, National University of Athens, Greece.

Aim: Considering the multiple applications of fractal analysis in the field of histopathology, we developed "Fractalyser", a specialized fractal analysis software program for Windows operating system.
Material and Methods: The application was developed in Visual Basic 6.0 (SP5) (Microsoft Corp.) environment. For user friendliness the program was designed with multiple document interface and Windows XP compatibility. "Fractalyser" can open, edit and analyze the most common image file types (bmp, jpg, gif). Images and graphs created by the program can be saved as bmp files, while numerical results can be saved in a text file. The program has some basic image processing functions such as invert, horizontal and vertical flip, grayscale conversion and crop. The user can precisely select the area of interest applying parameterized threshold or edge detection algorithms in the color image, while getting real time graphical feedback on the process. The produced binary image, which is projected as a red layer on the original image for user facilitation, can be further optimized before fractal analysis with 'dilation', 'erosion' or several noise reduction filters. The estimation of the fractal dimension of the image is carried out by using the "box-counting" algorithm. The box size range as well as the number of grid offsets are specified by the user. The program provides detailed numerical results, as well as a graphic presentation of the data and the least-squares linear regression results. The correlation coefficient and the coefficient of determination are also estimated.
Results: The accuracy of the application was assessed by analyzing images with theoretically known fractal dimension. The errors ranged from 0.0 to 5.8%, being conversely proportional to the number of grid offsets. Repeated comparisons of the statistical results of the program with the corresponding data of a commercially available statistical package (Statistica v.6.0, StatSoft Inc.) confirmed their validity and precision.
Conclusion: As it has been observed in thorough testing, the application presented here constitutes a stable, relatively fast, reliable and easy to use tool for fractal analysis. "Fractalyser" is provided as freeware to researchers after request via e-mail to pavlopoulos@medscape.com.

P 896
THE PATHOLOGIST AND THE ELECTRONIC HEALTH RECORD.THE ROLE OF THE IHE (INTEGRATING THE HEALTHCARE ENTERPRISE) INITIATIVE.

Daniel-Le Bozec Christel1, Henin D2, Hemet J3, Martin A3
1 Georges Pompidou Hospital, INSERM U729, 2 Bichat Hospital, 3 ADICAP, France

The challenging aim of the Electronic Health Record (EHR) is to gather current and previous medical data, including images, coming from several experts. In pathology, the necessary technology for digital imaging is available allowing pathologists to enrich the EHR. The challenge now is to define specific healthcare needs and workflows and to agree on technical protocols and file formats for "virtual slides" and reports exchange. The goal of the Integrating the Healthcare Enterprise (IHE) initiative is precisely to stimulate integration of healthcare information resources to improve clinical care. IHE promotes implementation and use of established data standards. Although the ADICAP (Association for the Development of Informatics in Cytology and Pathology) proposed a European de facto standard for image folders in pathology, the most used standards in medical imaging are HL7 and DICOM standards.
The objective of the presented work, done in the framework of a national IHE initiative promoted by ADICAP, consisted identifying the main integration profiles that could be addressed in pathology, taking advantage of the work done in radiology and biology, and to define the main requirements for virtual slides and reports communication according to both the principles of the ADICAP and the DICOM modes.
ADICAP, with the collaboration of the GMSIH (Group promoting the Modernization of Hospital Information Systems in France), recruited national IHE initiative participants to work on the Pathology Technical Framework: 7 pathologists and haematologists, 4 IT professionals, 2 professional associations and 12 vendors. Three working sessions were organized to define the pathologists' needs and to propose Integration Profiles. Furthermore, a DICOM module was developed to produce DICOM Visible Light objects and DICOM Structured Reports and tested at the Georges Pompidou Hospital.
The integration profiles for pathology were defined and presented at the 2005 IHE-Europe workshop in Noordwijkkerhout (Netherland). The images and reports produced by the DICOM module were stored into the Picture Archiving and Communicating System (PACS) of the Georges Pompidou Hospital and available within the EHR.
In conclusion, the national IHE initiative in pathology produced a first definition of useful integration profiles in pathology. On that basis, a first version of the Pathology Technical Framework could be proposed at an European level. Next steps are to support testing, demonstration and educational activities to promote the deployment of this framework by vendors and users.

P 897

QUALITY ASSURANCE IN PATHOLOGY : AUDITS ON LABORATORY WORKFLOW AND INDIVIDUAL PRACTICE

HENIN* Dominique, MICHIELS** Jean-François, RIOLACCI-DHOYEN*** Nathalie and the members of the Committee n°4 "Organisation et Structures", on behalf of the AFAQAP (French Association of Quality Assurance in Pathology).
*Pathology department, Bichat-Claude Bernard hospital, Paris, France; ** Pathology departmentPasteur hospital, Nice, France; ***HAS, Saint-Denis, France.

In 1998, on behalf of the AFAQAP, standards and guidelines of quality management for individual Pathologists or in Pathology department were published. AFAQAP Committees have elaborated and conducted numerous voluntary audits, mainly on diagnostic performance or technical quality in the past 10 years. In 2002 and 2004 clinical governance was introduced in France, as in other countries, to ensure that each doctor was involved in a continuing professional development (CPD) program. The pathologists always had a duty to patients but that duty now becomes a legal obligation. Clinical audit are performed against standards is the process by which pathologists can gather the evidence to improve patient care. ANAES (National Healthcare Accreditation and Evaluation Agency) /HAS (Main Healthcare Authority) has developed a strict methodology for the certification of clinical audit. To ensure high quality of clinical audit, it has to fit in the audit cycle : choose a frequent topic, identify agreed relevant standards, collect data, compare to standards, plan changes, re-evaluate. The AFAQAP intends to help pathologists (either individual or in pathology department) to meet their duty of quality by providing a selection of audits. To ensure high quality for pathologists 2 kinds of clinical audit are necessary, based either on laboratory work organization (preanalytic, analytic or postanalytic processes, risks assessment …) or on individual professional performance (applying evidence-based practice, clinical standards). In 2004, Committee 4 in relation with HAS developed 2 audits,

? "laboratory work" testing the pre-analytic process of the specimen (collection, transport, reception and registration). Are procedures written, available knowledgeable to persons involved in those activities? Is the personal safety appropriate (adequate space? formadehyde vapor …) ? Are the patient and specimen identification satisfactory?…

? "individual practice" testing histopathological reports on tissue samples. Is every specimen identity maintained at all times? Are gross examination performed in accordance with guidelines? Do gross and microscopic findings support pathological diagnosis or hypothesis? Are standards systems of grading and staging used in cancer cases?…

More than 90 voluntary pathologists underwent those 2 self auto-evaluations. Statistical analysis in on progress.

Many other countries, such as Great Britain or US, are involved in CPD program. Quality programs should be maintained under pathologists responsibility. Europe is an opportunity to exchange experiences.

THE NEW FIXATIVE RCL2, A NON TOXIC ALTERNATIVE TO CRYOPRESERVATION.

ROCHAIX Philippe*, LACROIX-TRIKI Magali*, LAMANT Laurence**, DECHA Audrey***, VOIGT Jean-Jacques*.
*Pathology department, Institut Claudius REGAUD ; ** Pathology department, CHU PURPAN ; *** Oncogenetic Laboratory Institut Claudius REGAUD, TOULOUSE, FRANCE

Introduction

Fixed specimens are suitable for most of diagnosis and immunostainings. However, identifying tumour determinants of drug efficacy looks like a new Holy Grail quest and the conservation of the cellular components becomes a key step in the specimen management.

Purpose

We present a new fixative fluid developed in our laboratory that allows extraction of RNA, DNA and proteins from paraffin embedded specimens.

Methods

The quality of tissue samples fixed and paraffin embedded according to our technique was evaluated on:

- the tissue morphology (H&E staining)
- the immunostaining results of more than 20 antibodies
- the FISH (PathVysion Vysis™) results
- the mRNA quality using a 2100 bioanalyzer (Agilent™), and quantity using RQ-PCR
- the DNA size and quality using agarose gel electrophoresis and three different long range PCR of 600bp , 800bp and 2600bp followed by DNA sequencing
- the protein quality using the bioanalyzer and by Western blotting of a nuclear protein (estrogen receptor), a cytoplasmic protein (actin F) and a mitochondrial protein (Bcl-2).

Results

The tissue morphology was very good, close to that obtained using AFA or Bouin's fluids. The immunostaining results were similar to those obtained on formalin fixed specimens. We succeeded in FISH technique (PathVysion Vysis ™) without modification of the procedure designed for formalin fixed specimens. The mRNA quality was very good with 28S/18S ratio rising above 1.5. The results of RQ-PCR were always similar to those of the frozen samples of the same specimen. The DNA extracted was of very large size (>> 10 kbp) and all the long range PCR worked without modification of the procedures designed for frozen samples. The sequencing of the amplification products was also performed easily without procedure modification. While the protein profiles were slightly different from those observed in the frozen samples of the same specimen, the Western blotting results were similar for the proteins tested.

Conclusion

This new fixative fluid allows the extraction of high quality mRNA, DNA and good quality proteins from paraffin embedded tissue samples. Furthermore, the tissue morphology and immunoreactivity are very well preserved. It can be a good alternative for tissue preservation when freezing is difficult such as for small biopsy or in private laboratory.

Moreover, it is worthy of note that this fixative fluid does not contain any toxic product.

P 899

EUROPEAN TISSUE ARRAY : A USEFUL TOOL FOR QUALITY CONTROL OF IMMUNOHISTOCHEMISTRY. A PROGRAM OF THE EORTC GI GROUP

JULIÉ Catherine, AUST Daniela, BELLUCO Claudio, NORDLINGER Bernard, KÖHNE Claus, VAN CUTSEM Eric, BRÜNNER Niels, LUTZ Manfred P., EORTC GI and RB Groups; CHU Ambroise Paré, Boulogne, France; University of Dresden, Dresden, Germany; University of Padova, Padova, Italy; Klinikum Oldenburg, Oldenburg, Germany; University Hospital Gasthuisberg, Leuven, Belgium; Royal Veterinary and Agriculture University, Frederiksberg, Denmark; Caritasklinik St. Theresia, Saarbrucken, Germany

Background: Numerous studies are based on immunohistochemistry (IHC) results, but IHC is not standardized and quality control is not yet widely established. In addition, important variability may be due to fixation time

and tissue heterogeneity. Therefore, the EORTC GI group designed a quality control tissue array (TA), in order to evaluate the suitability of a given antigen/antibody test before use in clinical trials. Here we report testing of the TA with routine antibodies.
Methods: A 216-spot-TA was designed using paraffin-embedded tissue from 14 colorectal cancers coming from 4 european centers. Immediately after surgery, specimen from tumor rim or tumor center were formalin-fixed individually overnight, for >24 h, or for >48 h, respectively. After evaluation by H&E staining, 3 cores from each specimen were assembled in a tissue array, i.e. 18 cores per tumor. Sections were distributed to 3 pathology departments for IHC, each using one or more of nuclear (p53, Ki67) or cytoplasmic antibodies (CEA, CK20, Cox2) in routine staining protocols. Blinded reading of immunoreaction was performed manually using a visual grading system based on the percentage of positively stained malignant cells.
Results: IHC was successful in the 3 laboratories. The staining pattern varied considerably between cores from individual specimen (e.g. Ki67: from 10-90% pos. nuclei; CEA: 50-100% pos. cells, CK20: 10-60% pos. cells) with moderate differences for staining intensity (variation from weak to moderate or moderate to strong). If average staining intensity or staining pattern for the 3 cores per location were calculated, there was no difference between tumor center and rim ($p = 0.62$ in paired t-tests for all comparisons). Most importantly, fixation time had no impact on the expression levels of the five antigens (p values from 0.12 to 0.93).
Conclusions: We observed a high heterogeneity in the staining from core to core for each tumor. However, we couldn't demonstrate an impact of location (rim or center) or fixation time on the expression levels for the five tested antibodies. This quality control TA is a useful tool to ensure the reliability of a given antibody and staining procedure before its use in translational research in multicenter clinical trials.

THE HOPE TECHNIQUE OFFERS A COMPLETE PANEL OF MOLECULAR APPLICATIONS IN PARAFFIN-EMBEDDED MATERIALS
T. Goldmann, D. Drömann, J. Gerdes, S. Uhlig, U. Uhlig, S. Loeschke, A Flohr, J. Bullerdiek, P. Zabel, D. Branscheid, E. Vollmer.
Research Center Borstel, Borstel, Germany
Inst. of Human Genetics, Univ. Bremen, Bremen, Germany
Hospital Großhansdorf, Großhansdorf, Germany

Introduction: Asservation of materials for pathologic diagnostics is mostly achieved by formalin-fixation and paraffin embedding. This results in good preservation of histologic details, but to a large degree prevents the application of modern molecular techniques due to the bad condition of nucleic acids and proteins if compared to fresh or frozen specimens, which show a comparably low preservation of histomorhologic details.
Purpose of the study: To establish an alternative fixation technique to overcome with these problems.
Methods used: We have shown that the novel HOPE-technique allows for both, well preserved 'formalin-like' morphology and excellent preservation of nucleic acids and proteins. In this study we present protocols for In situ hybridization, Immunohistochemistry, Western-blot, Northern-blot and Transcription-microarrays.
Summary of the results: All of these methods can be unambiguously performed with HOPE-fixed materials.
Conclusions reached: These results open up new perspectives for molecular approaches in paraffin-embedded probes providing a novel powerful tool for modern pathology.

ICON-TMA® FOR QUALITY CONTROL OF IMMUNOHISTOCHEMISTRY
IVER PETERSEN, AXEL KOEPENIK*, MANFRED DIETEL, VEIT KRENN
Institute of pathology, Charité Campus Mitte, Berlin, FRG
*Oligene GmbH, Charité Campus Mitte, Berlin, FRG

Immunohistochemistry (IHC) has become an essential adjunct in daily histopathological diagnosis. However, quality control is difficult and becoming critically important considering the need for standardization and quantification of immunoreactivity.
To help solving these problems we developed small size tissue microarrays (TMAs) with 2 to 4 punch biopsies from well characterized specimens of sizes between 0.6 and 2 mm diameter. In its simple variant these internal control (iCon) TMAs consist of 2 tissue cylinders, one being clearly positive and the other clearly negative for a specific immunohistochemical marker, e.g. cytokeratins or hormone receptors. In its more elaborate format, the iCon-TMAs carry additional tissue spots providing a scale for quantitatively assessable markers, e.g. providing examples of immunoreactivity scores 0, 1+, 2+, 3+. The specimen with the yet unknown immunoreactivity is then applied to the iCon-TMA section and both are simultaneously analyzed.
A successful IHC analysis could almost be judged by the macroscopical inspection of the two +/- spots representing the positive and negative sample of the iCon TMA. While the spot with positive control provided an internal standard for strong immunoreactivity, the negative one provided an estimate to differentiate weak positivity from unspecific background staining. The technique proved to be particularly useful for markers that were not necessarily present in the uncharacterized specimen.
iCon-TMAs provided a convenient measure for internal quality control and may become an indispensable tool for standardization and quantification of gene expression by immunohistochemistry or related techniques like mRNA in-situ hybridization.

The peritoneal mesothelium acts as a bioactive cellular membrane regulating serosal responses to injury, infection and neoplastic diseases. Inflammation of the serosal surfaces induces an "activated" mesothelial cell phenotype. In the present study we simulated activation of cultured human peritoneal mesothelial cells (HPMC, isolated from human omentum majus) by treatment with the pro-inflammatory cytokine interleukin-1beta (IL-1beta). Respiratory activity of suspended cells was analysed by high-resolution respirometry to assess changes in respiratory capacity and coupling of oxidative phosphorylation in activated HPMC. Citrate synthase (CS) and lactate dehydrogenase (LDH) activites

were determined by spectrophotometry. IL-1beta activation for 48 hours resulted in a significant decline of respiratory capacity ($P < 0.05$), without affecting integrity of the inner mitochondrial membrane or cell viability. Treatment of HPMC with IL-1beta resulted in a decrease of CS activity ($P < 0.05$) and an increase of LDH activity ($P < 0.05$). The present data indicate that activation of peritoneal mesothelial cells with IL-1beta is associated with a decrease of oxidative phosphorylation and mitochondrial content that appears to be compensated by an increase in glycolytic capacity.

THE IMPORTANCE OF HISTOPATHOLOGICAL/ NECROPTIC EXAMINATION IN COWDEN'S DISEASE

ZURAC Sabina*, LAVRIC Luciana*, VRABIE Alexandra*, MICU Gianina*, GRAMADA Eliza*, ZAHARIA Anca*, ANDREI Razvan*, OPRISAN Alexandra*, STANICEANU Florica*, NICA Sanda**

Bucharest, Romania

Cowden's disease (CD) is a rare autosomal dominant inherited disease characterized by multiple hamartomas with ectodermal, mesodermal and endodermal origin, the most constant features being the mucocutaneous lesions (almost pathognomonic). It associates an increased risk of malignancies (especially breast and thyroid) and, sometimes, due to the presence of multiple tumors in different organs, an overestimation of the stage is possible ("metastatic cancer")
We present the case of a 82-years-old female recently investigated for progressive alteration of the general status and loss of weight; a supposition of possible metastatic malignant melanoma was made – based on the presence of innumerable pigmented cutaneous lesions (with diffuse distribution including face and palmoplantar localization) and CT findings (many tumors in the skull, meninges, lungs and liver).
The current episode consisted in hemyplegia in right limbs; during admission, an acute ischemia of the left leg developed; considering the neurological status and the "terminal malignant disease" no surgical treatment was considered. Autopsy revealed recent left sylvian infarct, recent thrombotic occlusion of the left external iliac artery and numerous tumors (oncocytic meningioma, intraosseous cranial, pulmonary and hepatic hemangioma, pulmonary hamartoma, bilateral adrenal adenomas, gastric leiomyoma, ovarian serous papilifer cystadenofibroma, pigmented seborrheic keratosis); previous hysterectomy for leiomyomas. CD was concluded (1996 International CD Consortium criteria).
Despite the simplicity of the case, we want to emphasize the risks of clinically misinterpretation of CD as metastatic cancer (without histopathologically proven malignancy) and a subsequent therapeutical redrawn. Only histopathologic/autopsy examination establishes the correct nature of these tumors and a precise diagnosis.

PATHOGENIC CONSEQUENCES OF ALV INFECTION IN CHICKENS INOCULATED IN MID EMBRYOGENESIS

VERNEROVA Zdenka, PRUKOVA Dana, STEPANETS Volodymir, GERYK Josef, SVOBODA Jan
Department of Pathology, 3rd Faculty of Medicine, Charles University Prague, Czech Republic, Institute of Molecular Genetics, Academy of Sciences of the Czech Republic

Introduction: Avian leukosis viruses (ALV) in addition to their oncogenic potential are responsible for induction of a syndrome called wasting disease (WD). Clinical signs of WD are progressive weight loss, anaemia and occassionally diarrhoea as well. Histopathological findings include depletion of lymphoid tissue and immunosupression.
The aim of this study was to determine the rate and severity of WD induced in chickens by various ALV strains and to evaluate pathological and immunological consequences of the disease.
Material and Methods: For the experiments outbred Brown–Leghorn chickens (genotype C/E) were used. Virus was inoculated in mid embryogenesis into the chorioallantoic vein. ALV viruses of subgroups A–D were tested. Signs of the wasting were monitored during the first 2 weeks after hatching. Lymphatic organs were thoroughly examined immunohistochemically.
Results: When comparing ALVs of different subgroups for their ability to induce WD, viruses of subgroup C (namely td B77-C) were found to cause the most prominent changes. Chickens infected with viruses of subgroup A did not differ significantly from the control birds. WD can be induced only by intraembryonic inoculation of the virus and in a mild form also when inoculated on the 1st day after hatching. The lowest limit for WD induction was determined as 102 infectious units of the virus. In diseased chickens, severe B cell depletion in primary and secondary lymphatic organs was found. Thymus atrophy seems to be partially compensated by a moderate increase of the T lymphocyte number in T-dependent regions. Lymphocyte depletion is accompanied by prominent activation of the a monocyte-macrophage system. While defects of both humoral and cellular immunity were found in chickens infected by ALV-C, only the second one was injured by viruses of subgroup A. A significant increase of peripheral CD8+ T lymphocytes was produced by viruses of subgroup C.
Conclusion: These results indicate that inoculation of chicken embryos by ALVs provides a suitable experimental model for study of retroviruses-induced impairment of immunity.
This work was supported by grant No. 523/04/0489 from the Grant Agency of the Czech Republic.

Biodegradable polylactide/polyglycolide copolymers are applied widely in medicine for joining broken bones. Their disadvantage is a small mechanical endurance. It can be increased by creating copolymer and carbon fire composite. The aim of the study was morphological evaluation of the healing process of mandibular bone defects in rabbits filled with a composite made of polylactide/polyglycolide copolymer and carbon fibers [P(LLA/GLA)+CF].
The study was performed on 30 New Zealand rabbits. After the soft tissue was prepared, the mandibular bone was exposed. The hole here a composite implant was inserted, had been drilled with a 3.2 mm bur. The wound was suture. Moreover, the composite cylinders were inserted into

subcutaneous and intramuscular pockets. The animals were divided into 7 groups, 4 rabbits in each group. The groups were euthanazied after 1, 2, 3, 6, 12, 24 and 52 weeks and bones were fixed in 10% solution of neutralized formalin. Bone tissue was decalcified in Romeis fluid with decalcifying agent PW23. After the typical procedure, the samples were emerged in paraplast. The blocks were sliced in a microtome. The 6 microtone slices were deparaffinizied and dyed routinely wit hematoxylin and eosin. The obtained preparations were evaluated in a light microscope wit magnifications from 40 to 400x. After 1 week, clearly formed canal around the implant was visible in the mandible. The features of active band of bone tissue in the form of numerous young, immature bone trabeculas surrounded by osteoblasts. Numerous, immature and mature bone trabeculas covered with osteoblasts were present after two weeks. Three weeks later and in the following periods, mature bone trabeculas without osteoblastic activity were observed. A connective tissue capsule was formed around the implant in the subcutaneous tissue. Mature, cicatrizing, fibrous connective tissue, growing among the injured bundle of muscle fibers was visible in the muscle tissue around the implant. The study showed good tolerance of the applied P(LLA/GLA)+CF composite implants in the animal body, no inflammatory reactions and an increased time of bone tissue regeneration around implants.

Rapid progress of medicine connected with reconstructive surgery leads us to searching for the new materials which would substitute, temporarily or permanently, harmed tissues.

The TiNiCo alloy with the shape-memory effect was taken upon the study and implanted to rats of Sprague-Dawley breed. After the implantation period lasting 12, 24 or 52 weeks the implants were removed and the surrounding tissues subjected to histopathological examination.

The morphologic features of inflammation (lymphocytic, granulocytic, eosinophilic, plasmocytic infiltrations), necrosis, fibrosis (fibrous capsulae formation), degeneration, giant cells and granulomas presence in the tissue samples were evaluated. The vascular proliferation and nuclear changes were estimated as well. The TiNiCo alloy and Titanium placed in the tissues accordingly to the ASTM F 981-99 standards cause low biologic tissue activity.

The investigated materials do not trigger any tissue response that could suggest their cytotoxicity or carcinogenic properties. The achieved results indicate high biocompatibility of TiNiCo alloys.

Key words: tissue response, rat, shape-memory effect alloy, TiNiCo implant, biocompatibility, Titanium

P 907

A HIGH AUTOPSY RATE IN A TEACHING HOSPITAL IN BRAZIL

Alfredo Ribeiro-Silva, MD, PhD
Luiz Cesar Peres, MD, PhD
Department of Pathology, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Brazil

Autopsy is an invaluable diagnostic tool in medical practice since postmortem studies provide relevant information in patients with complex pathologies. In academic hospitals, autopsy also contributes to research and teaching by supplying a rich material to these purposes. In our Institution, autopsy is performed in 85% of patients that die during hospitalization (75% among adults and 90% among fetal and pediatric patients). A high autopsy rate allows accurate epidemiological studies and quality control. As a teaching Hospital, it is also important to know if death of patients varies along the year, days and months in an attempt to identify if there are medical and non-medical factors such as the activity of less trained residents and undergraduate students influencing it. We analyzed all autopsies performed in a University Teaching Hospital in Brazil during 52 consecutive weeks. The following data were retrieved from individual autopsy records: gender, age, time of death (hour of the day, day of the week and month) and the main cause of death. There were 1419 autopsies (79% adults and 21% pediatrics, 60% male and 40% female). Those performed during working days summed up to 67.5%, the remainder 32.5% were performed during weekends or holydays. They were more frequent during the nocturne than diurnal period (52.6% and 47.4%, respectively). The causes of death distributed among the ICD-10 categories were: cardiovascular diseases 21.3%, infectious diseases 19.2%, neoplasms 12.8%, perinatal conditions 10.8%, respiratory diseases 6.6%, gastrointestinal diseases 6%, congenital anomalies 4.7%, CNS diseases 3.8%, genito-urinary diseases 1.8%, and others 13%. In our Hospital a high autopsy rate is maintained due to readiness of results, performance of autopsy during the 24 hours of the day, very short interval between death and autopsy and a team composed by an experienced pathologist, a resident and a mortuary assistant. There was coexistence of diseases typical of both industrialized and developing countries, indicating the epidemiological transition in our country. The regular distribution of deaths along the day, weeks and months indicate that it is not affected by the inexperience of training students and residents probably due to adequate supervision.

P 908

UNUSUAL SITES OF FUNGAL INFECTION

Barboza-Quintana Oralia MD FIAC,Mendez-Olvera Nora MD, Ancer-Rodriguez Jesús MD, Garza-Guajardo Raquel MD FIAC Anatomic Pathology and Cytopathology Service, Universitary Hospital “Dr. José E. González”, UANL, Monterrey, México

Aspergillus is a filamentous fungus commonly isolated from soil, plant debris, and indoor air environment, includes over 185 species, and Aspergillus fumigatus is the most commonly isolated. Immunosupression is the major factor predisposing to development of opportunistic infections. There are several reported cases that describe female genital tract infections with opportunistic fungi, Candida and Aspergillus are most commonly found in fungal endometritis and are generally requering some type of predisposing condition like a use of Intrauterine Device

Coccidioidomycosis is a systemic infection caused by Coccidioides immitis, a dimorphic fungus endemic in the south of the USA and in the north of Mexico. The disease usually affects the lungs. Primary cutaneous infection is extremely rare.

Blastomycosis is a disease caused by the dimorphic fungi Blastomyces dermatitidis, and is acquired via inhalation of the conidia, which transform into the yeast form once in the lungs, however at least 50% of primary infections are

asymptomatic and most of the cases become manifest during a chronic phase that may affect the lungs, skin, bones, genitourinary tract and other reticuloendothelial organs. Involvement of genitourinary tract is seen in 10% of cases and affects the prostate and epididymis.
We present 5 cases of non-usual sites infections with this 3 fungi: 2 cases of aspergiliosis in a curettage secondary to spontaneous abortion, 2 cases of primarious cutaneous coccidioidomycosis localized in the nose and ear, and a case of blastomycosis localized on the prostate, in the 5 cases the patients did not reveal the presence of a primary infection in any other system. It is important to have in mind this unusual sites of primary infection by fungi because we can mislead the opportunity to bring the patient an opportune treatment with anti-fungal drugs.

UNKNOWN PRIMARY CANCER: IMMUNOHISTOCHEMICAL ALGORITHMIC APPROACH FOR EPITHELIAL NEOPLASMS WITH MULTIPLE METASTASES.

SAVELOV Nikita*, SHAPOVALOV Dmitry**, KOMAROV Igor** and PETROVICHEV Nikolay*.
*Department of Pathology, N.N.Blokhin Cancer Research Center, Moscow, Russia.
**Department of Diagnostic Oncology, N.N.Blokhin Cancer Research Center, Moscow, Russia.

Introduction: The exact diagnosis of unknown primary cancer (UPC) is a common problem for the surgical pathologist especially in cases with multiple metastases at different sites. The typical feature of a UPC with > 2 metastatic sites at the initial clinical presentation is a rapid progression of the disease, often less than three months. This requires rapid diagnosis in these patients. The aim of this study was to develop an optimal algorithm of immunohistochemical investigation of UPC with multiple metastatic sites.
Materials and methods: Histopathological and immunohistochemical investigations were performed in thirty two cases with UPC with > 2 metastatic sites, mainly in lymph nodes. A broad immunohistochemical panel and high sensitivity polymer detection system were performed on formalin fixed paraffin embedded tissues from each case.
Results: Because the metastatic tumors were mainly poorly differentiated carcinomas or poorly differentiated adenocarcinomas, the initial step of immunohistochemical investigation was to determine lines of cell differentiation. For this purpose we used the panel consisting of p63, CK8, HMW, CD56 (N-CAM) and calretinin. For adenocarcinomas (CK8+, HMW+/-, p63-, CD56-, calretinin-) the second step was to identify a primary site. To perform this we investigated expression of CK7 and CK20, and 'tissue specific' transcription factors - TTF1, Cdx2, WT1, ER and PR. In addition we investigated expression of some specific cell products, such as CA-125, PSA, GCDFP-15. Approximately in thirty percent of performed cases the results of histopathological and immunohistochemical investigations were the same. In seventy percent of cases the results of immunohistochemical investigations gave important additional information for further management of the patients or radically changed the interpretation of histopathological date.
Conclusion: Although the morphological examinations is the basis of diagnosis in surgical pathology, immunohistochemistry is a powerful ancillary method, particularly in cases with multiple metastases of unknown primary site.

POLY(ADP-RIBOSYLATION) MODULATES THE EXPRESSION OF TUMOR-RELATED GENES DURING CARCINOGENESIS

MARTIN-OLIVA David,MUÑOZ-GAMEZ Jose Antonio, AGUILAR-QUESADA Rocio, O'VALLE Francisco, GARCIA del MORAL Raimundo,RUIZ de ALMODOVAR Mariano, PIRIS Miguel Angel, OLIVER F Javier.
University Hospital, San Cecilio, Granada; Institute of Parasitology and Biomedicine, CSIC, Granada, Spain. Department of Pathology, University of Granada;Department of Radiology and Physical Medicine, University of Granada; Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid, Spain.

PARP-1, an enzyme that catalyzes the attachment of ADP ribose units to target proteins, acts as a component of enhancer/promoter regulatory complexes. In a previous study we have shown that parp-1 knockout mice exhibit resistance to chemical carcinogenesis and this was related to a decreased NF-kB activation. Objetive: Our aim was evaluated the effect of parp-1 inhibitor on skin carcinogenesis in a model of parp-1 knockout mice. Material and Methods: We used cDNA expression arrays analyis, Real-Time PCR, image analysis and morphological conventional techniques in this study.
Results: We show that pharmacological inhibition of PARP-1 with DPQ (3,4-dihydro-5-[4-(1-piperidinyl)butoxyl]-1(2H)-isoquinolinone) results in a strong delay in tumor formation and in a dramatic reduction in tumor size and in skin morphological changes and multiplicity during DMBA+TPA-induced skin carcinogenesis. PARP inhibition also affected AP-1 activation but not NF-kB. Using cDNA expression arrays analysis, a substantial difference in key tumor-related gene expression was found between chemically-induced mice untreated or not with PARP inhibitor and also between wild type and parp-1 knockout mice. Most important differences were found in gene expression, mainly for nfkbiz, s100a9, hif1alfa and other genes all of them involved in carcinogenesis and inflammation. These results were corroborated by Real-Time PCR. In summary, this study shows that inhibition of PARP on itself is able to control tumor growth and PARP inhibition or genetic deletion of PARP-1 modulates tumor promotion through their ability to cooperate with the activation AP-1 and/or NF-kB and to regulate the expression of genes related with tumor promotion/progression.

ABSENCE OF MYCOBACTERIUM TUBERCULOSIS PCR DETECTION FROM LYMPH NODES'SARCOIDOSIS GRANULOMAS ISOLATED BY LASER CAPTURE MICRODISSECTION.

LASSALLE Sandra (1), SELVA Eric (1), HOFMAN Véronique (1), VENISSAC Nicolas (2), MOUROUX Jérome (2), DELLAMONICA Pierre (3), HOFMAN Paul (1).
(1) Laboratory of Clinical and Experimental Pathology, (2) Department of Thoracic Surgery, and (3) Department of Infectious Diseases, University of Nice, Nice, France

Previous recent works have shown the usefulness of polymerase chain reaction (PCR) performed in granulomas isolated by laser capture microdissection (LCM) for improving the detection of M. tuberculosis in formalin-fixed paraffin-embedded tissues. Some studies have demonstrated that mycobacterial DNA can been sporadically detected by means of PCR amplification performed on formalin-fixed paraffin-embedded tissues in granulomatous diseases other than tuberculosis, such as sarcoidosis and Crohn'disease. The aim of the present work was to investigate if mycobacterial DNA could be detected by PCR in granulomas isolated by LCM from lymph nodes'sarcoidosis. The PCR DNA amplification method was used to detect M. tuberculosis in granulomas microdissected from one section stained by haematoxylin and eosin from a formalin-fixed paraffin-embedded specimen. The results were compared to those obtained from PCR performed from tuberculosis granulomas

with positive Ziehl staining. Twenty-nine formalin-fixed and paraffin-embedded samples from 29 patients with sarcoidosis and 24 similar conditionned samples obtained from 24 lymph nodes'tuberculosis were investigated by this combined method. After staining with hematoxylin and eosin, granulomas were microdissected using a LCM microscope (PixCell II, Arcturus Engineering). For the PCR reaction, we used specific sequences of the 16S ribosomal RNA gene to M. tuberculosis. Results: PCR from microdissected sarcoidosis granulomas procured from one 5 mm section of each specimen was negative in the 29 studied cases, whereas PCR from microdissected tuberculosis granulomas was positve in the 24 studied cases. In conclusion, our work showed that mycobacterial DNA is not detected in lymph nodes'sarcoidosis when using PCR on laser microdissected granulomas from formalin-fixed paraffin-embedded specimen.

DCPC, National Cancer Institute, Bethesda, MD 20852, USA, 4 Department of Surgery, University of Alabama at Birmingham, Birmingham AL 35294,USA, 5 Current address: Comprehensive Cancer Center, Ohio State University, Columbus, Ohio,43210 USA.

DNA hypermethylation is associated with decreased gene expression of tumor suppressor genes. In a previous study we observed decreased Fhit expression and Fhit promoter region methylation in rodent tumors induced by various carcinogens and noted differential methylation patterns in DNA from tissues of different organs; i.e., the 5' regulatory regions in the promoter, exon 1 and intron 1 were differentially methylated, depending on the tissue of organ. Because different carcinogens were used for induction of tumors of the different organs, we could not conclude that the methylation patterns were tissue-specific. In order to determine if 1) rat Fhit methylation status is related with expression levels and 2) rat Fhit methylation patterns were tissue or carcinogen-specific, by examining Fhit methylation status and expression levels in DMBA and MNU-induced benign and malignant mammary tumors. Fhit intron 1 was methylated in 3/9 DMBA and all (5/5) MNU-induced benign mammary tumors in association with reduced Fhit expression levels; Fhit promoter and intron 1 were methylated in all DMBA and MNU-induced tumors in association with highly reduced Fhit expression levels. Treatment of rat cancer cells in vitro with the DNA methyltransferase inhibitor, 5'-Aza-2'deoxycytidine, for 4 days, increased Fhit expression and altered the methylation status. Before treatment both promoter and intron 1 regions were methylated; after treatment only intron 1 remained methylated. Thus there is an overall association of rat Fhit regulatory region methylation with its expression and hypermethylation patterns were tissue and not carcinogen-specific.

P 913

HIGH MOBILITY GROUP (HMG) PROTEINS IN MALIGNANT TUMOURS - FROM DIAGNOSTIC MARKER TO INDEPENDENT PROGNOSTIC FACTOR?

IIntroduction: High mobility group proteins are structural transcription factors with further involvement in enhancosomes and hormone-receptors. Because of their ability to boost proliferation, infiltration and metastasis of tumour-cells, they are sometimes referred to as kinases. In the normal adult tissue they are either not or only very weak expressed.
Purpose: In previous publications it was shown that HMGA1 and A2 are expressed in many neoplastic tissues and mark either malignancy or bad prognosis. Because there were no data concerning Breast- and Non-Small-Cell-Lung-Carcinoma (NSCLC) we started investigations concerning these frequent tumours.
Methods: Breast- and NSCLC tissue were investigated concerning HMG expression on RNA-Level (using Real-Time PCR) and Protein level (using Immunohistochemistry). First data are compared concerning immunohistological and Real-Time PCR results. Furthermore, first data of HMGA1 and HMGA2 expression in these frequent tumours are shown.
Results and Conclusions: In breast-carcinoma HMGA1 expression is significiantly correlated with Grading, Hormone-Receptors and HER-2.
In NSCLC HMGA2 is highly expressed in appr. 50% of squamous cell carcinoma and 20% of adenocarcinoma. There seems to be no correlation with any other morphological marker, but, as first data suggest, with disease free and over-all-survival.

PILOMATRIX CARCINOMA: A CHALLENGING DIAGNOSIS OF BASALOID CELL TUMORS

Dr Homayon Moslehi, Assistant professor of dermatology Tehran university of medical science
Dr Monsour Nasiri Kashani, Assistant professor of dermatology Tehran university of medical science
Dr masoud Asgari, assistant professor of pathology Tehran university of medical science

Pilomatrix carcinoma (PC) is a rare locally aggressive tumor of hair matrix that has a predilection for head and neck. There is male to female ratio of 2:1. The mean age of affected patients is 48 with a reported range from age 2 to 88. We report a case of PC treated by Mohs surgery that initially diagnosed as basal cell carcinoma (BCC) which is the main and most challenging differential diagnosis.

A 35-years old man was evaluated of a solitary, slow growing nodule on his dorsum of the nose. The nodule has been present for a few years without any pain and tenderness. The nodule was ulcerated by patient manipulation. On physical examination a 2cm firm nodule with telangiectasia and central depression on surface was noted on the dorsum of the nose. From initial biopsy specimens, It has been reported lobulated island of basaloid cells connected to the epidermis with a final diagnosis of BCC that involve surgical margins and depth. Mohs surgery carried out for an incomplete excised and recurrent BCC of the nose. Frozen section revealed island of tumors in deep dermis without connection to epidermis. Permanent slides showed sheets and nests of neoplastic basaloid cells in deep dermis, hypodermis and between muscles with varing degree of central necrosis. The neoplastic cells had hyper chromatic nuclei, moderate pleomorphism and numerous mitosis, some of which were atypical. The mitotic rate was 75 per 10 high power fields (35/mm2). The basaloid nest went abrupt transition to central necrotic areas with pycnotic and shadow cells. Using immunohistochemical techniques, Ki-67 showed proliferation rate of 50%. Bcl-2 was expressed in 3% and P53 in 36% of the tumor cells. A large portion of neoplastic cells expressed Low molecular cytokeratin (CK19). S100 and CEA were negative, all findings confirming the diagnosis of PC.

In summery, although the histopathological diagnosis of PC is simple, in the presence of epidermal connection as our case

in first biopsies, it will be problematic. However with more careful study, numerous mitosis and central necrosis can be seen which are rare in BCC.

ROLE OF NON-HISTONE PROTEINS IN EARLY DIAGNOSIS OF NORMAL AND SKIN LESIONS

Monsef Ar, MD*- Hosseinipanah SM, Ph.D- Ebrahimi M, MD – Mahjob H, Ph.D – Eghbalian F, MD.
*Dept. of Pathology, Faculty of Medicine, Hamadan University of Medical Siences,
Hamadan, IRAN.
e-mail: monsef_ar2001@yahoo.com

Abstract:
Objective: Evaluation of the diagnostic value of silver nucleolar organizer Region assessment in skin diseases is important. According to this reason we want to study the Argyrophilic Nucleolar Organizer Region (Ag-NOR) count and Subjective Ag-NOR Pattern Assessment (SAPA) score in normal skin, Squamous Cell Carcinoma (SCC), Basal Cell Carcinoma (BCC) and Solar Keratosis (SK).
Method: The study groups considered of 69 cases (18 SCC, 18 SK, 17 BCC and 16 Normal skin) was studied by H&E staining and silver staining for Ag-NOR.
Results: The mean count was in SCC 2.92, in SK 2.29 in BCC 1.59 and 0.93 in normal skin (p value <0.001).
The SAPA score was in SCC 7.94 in SK 7.61 in BCC 6.35 and in normal skin 5.00 (p value <0.001).
Conclusion: Ag-NOR count and SAPA score in normal and pathological state of skin has positive results.
Key Words: Ag-NOR, SCC, BCC, SK, Skin.

HISTOPATHOLOGIC STUDY OF ROSACEA

A.R.Monsef Esfahani. F.Eghbalian
Dermatopathology dept. Sina Hospital. Hamedan university of medical sciences Hamedan, Iran

Bakground :
Rosacea is a common but ill-defined disease and Demodex follicularum has been reported in rosacea in a number of clinical studies. As the Demodex mite is also present in many healthy individuals, the mite may have a pathogenic role only when it is present in high densities.
In this study the possible role of demodex follicularum and the importance of mite density had investigated using an elliptical incisional skin biopsy technique.
Methods :
Thirty-nine patients with rocacea, twenty-five female, 14 male, and 41age and sex matched healthy persons entered the study. With the incisional skin biopsy of face we studied six section of each sample. We studied the number of follicles, mite dencity in them, epidermal changes, solar elastosis, inflammatory cells in the dermis and their pattern , granuloma formation and vascular changes.
Result :
Varing degree of vasodilatation, solar elastosis and in flammatory infiltrate were found in all patients. The infiltrate were lympho-histiocytic in 29 cases, lympho-plasmacytic in 6 cases and neuropilic, specially around hair follicles in 2 cases, and eosinophilic infiltration mixed with mononuclear cells in 2 cases. The number of D. follicularum was statistically significant. Between male and female there was not important difference, 0.929 to 1.200, P value 0.81; .
There was important difference in the number of mite in rosacea related to age , it was 0.545 in under 40 year group and 1.308 over 40 year age, P value 0.047. But it was not meaningful in non rosacea group 0.118 mite per follicle under 40 and 0.509 mite per follicle over 40 year, P value 0.53.
There was granuloma to appendages in 3 of cases and granuluma around hair folicole in 2 of cases. One of the later group revealed degenerated demodex demodex cuticle.
Conclusion :
Rosacea is a multifactorial disease, and high densities of demodex is important, in the form of hypersensitivity reaction to antigens or granuloma formation in response to its cuticle or destructed hair follicles. The individual properties may modify the severity of inflammatory response to demodex.

P 917

ANALYSIS OF CYCLOOXYGENASE-2 EXPRESSION AS A POSSIBLE MARKER OF VITALITY IN CUTANEOUS WOUNDS

ORTIZ-REY José Antonio, SUÁREZ-PEÑARANDA José Manuel* ,SAN MIGUEL Pilar , ÁLVAREZ Carlos, MUÑOZ José Ignacio* ,RODRÍGUEZ-CALVO María Soledad*, CONCHEIRO Luís*
Servicio de Anatomía Patológica, Hospital POVISA, Vigo.
*Instituto de Medicina Legal, Universidad de Santiago. Spain.

Introduction
The histologic differential diagnosis between vital and postmortem cutaneous wounds is difficult when the injury is inflicted close to the time of death. Ancillary techniques such as immunohistochemistry may aid to the diagnosis of vitality through the analysis of molecules implied in the initial inflammatory reaction.Cyclooxygenase-2 (COX-2), an enzyme rapidly synthesized in response to different insults to the skin, is essential for prostaglandin biosynthesis, which is an important process for cutaneous wound healing.
Purpose
Our objective has been to investigate COX-2 expression in vital and postmortem cutaneous wounds to check its possible application as a marker of vitality.
Materials and methods
41 samples from human incised cutaneous wounds were investigated comprising: 16 vital injuries aged 3 minutes to 8 hours (mean:125 minutes), 14 inflicted postmortem (collected after a period of 1-3 hours), and 11 scars from sutured surgical incisions whose age was 0.5 to 11 months. Formalin-fixed paraffin-embedded sections were immunostained through the labelled streptavidin-biotin technique using a monoclonal antibody anti COX-2 (DakoCytomation).
Results
All of the samples showed normal immunoreactivity for COX-2 in eccrine glands with faint staining in sebaceous glands and the basal layer of the epidermis. Differences in staining were not observed when comparing the injury edge with the opposite margin in every specimen, nor between vital and postmortem wounds. Scars with inflammatory reaction in the dermis (aged 0.5 to 3 months) showed overexpression of COX-2 in histiocytes and mononuclear cells.
Conclusions
Immunohistochemical analysis of COX-2 has not been useful to differentiate vital and postmortem injuries. Overexpression of COX-2 could only be detected in the histiocytic inflammatory phase of wound healing. For these reasons it is not a good marker to diagnose vitality in difficult injuries, aged just a few hours.

EXPRESSION OF E-CADHERIN AND CATENINS IN VITAL AND POSTMORTEM CUTANEOUS WOUNDS

ORTIZ-REY José Antonio, SUÁREZ-PEÑARANDA José Manuel* ,SAN MIGUEL Pilar , IGLESIAS Begoña , MUÑOZ José Ignacio* ,RODRÍGUEZ-CALVO María Soledad*, CONCHEIRO Luís*
Servicio de Anatomía Patológica, Hospital POVISA, Vigo.
*Instituto de Medicina Legal, Universidad de Santiago. Spain.

Introduction
The differential diagnosis between vital and postmortem wounds is often difficult for the pathologist, specially when the injury is produced close to time of death. Immunohistochemical detection of different molecules involved in inflammatory reaction and healing process have been proposed to aid to the diagnosis. Re-epithelialization is a key process in the wound healing and it begins early after the injury. E-cadherin and catenins, critical for adhesion between keratinocytes, play an important role in the process. The diagnostic value of their expression as markers of vitality has not been well established.
Purpose
Our objective was to analyse the expression of E-cadherin and catenins (alpha, beta and gamma) in vital and postmortem wounds as possible markers of vitality.
Materials and methods
The study comprised 42 human incised wounds (32 vital and 10 postmortem) and 3 cutaneous scars. The vital wounds were obtained from abdominal surgical incisions with post infliction intervals between 55 minutes and 8 hours. Two of the scars were 2 months old and the other was 5 months old. The postmortem specimens were obtained from autopsy abdominal incisions and were collected after a mean period of 105 minutes (range 15-180).
Formalin-fixed paraffin-embedded sections were immunostained following the labelled streptavidin-biotin technique with monoclonal antibodies against E-cadherin (BioGenex) and alpha, beta and gamma catenins (Transduction Laboratories). Staining of the wound edge was compared to that of the opposite margin of the sample.
Results
Differences in the staining between the two margins of the specimen were noted in 11 cases (9 vital and 2 postmortem). The staining was increased in the wound edge in 7 cases and in the control edge in 4. The differences corresponded to E-cadherin in 5 cases, alpha-catenin and gamma-catenin in 3. No differences were appreciated for beta-catenin.
Conclusions
Immunohistochemical analyses of E-cadherin, alpha, beta and gamma catenins are not useful for the differential diagnosis between vital and postmortem wounds. This could be related to a low sensitivity of immunohistochemical techniques to detect the subtle changes of levels of these proteins at the beginning of the inflammatory reaction.

GENERALIZED LICHEN AMYLOIDOSIS: A CASE REPORT
* ATÝK Esin, **SERARSLAN Gamze
(*)Department of Pathology, Mustafa Kemal University, Faculty of Medicine, Antakya-
Hatay / Turkey
(**)Department of Dermatology, Mustafa Kemal University, Faculty of Medicine, Antakya-Hatay / Turkey

Lichen amyloidosis is a type of cutaneous amyloidosis, caused by the extracellular deposition of amyloid composed primarily of degenerated keratin filaments. Generalized lichen amyloidosis is a rare form of the disease and characterized by pruritic discrete hyperkeratotic scaly papules. We report a case of lichen amyloidosis with extensive distribution in a 33-year-old female.

Introduction : Radiodermatitis is a rare cutaneous disorder induced by radiation used in diagnostic and interventional procedures. The histologic characteristics of this entity have been poorly described.
Case report : A 74-year-old man with a history of coronary disease presented with a 10-centimeters, pruritic, fixed, well demarked erythematous patch of the back, which had begun four weeks after a coronary artery stenting. A skin biopsy was performed showing interface dermatitis. Given the history of radiation exposure and the clinical course of the lesion, the histological findings were felt to be consistent with subacute radiodermatitis.
Discussion : Skin damages in subacute radiodermatitis involve epidermis and dermis. The main histological findings are : interface dermatitis with keratinocyte necrosis, clefting along the dermal-epidermal junction and variable perivascular lympho-histiocytic infiltrate with no eosinophils. Key differentiating factors from graft-versus-host disease and fixed drug reaction include history, clinical morphology, type and distribution of cutaneous infiltrate.
Conclusion : With the increased use of radiation for diagnostic and interventional technique, this entity should be known and discussed by both clinicians and pathologists, when an interface dermatitis is observed.

IMMUNOHISTOCHEMICAL STUDY OF SKIN LESIONS AFTER THERAPEUTIC IRRADIATION
Monica Banita, Cătălina Pisoschi, Gh. Drăgoi
University of Medicine and Pharmacy Craiova, Romania

Introduction. We focused on skin alterations after cobalto-therapy knowing that exposure to overdoses of radiation could induce cancerous lesions.
Purpose of the study. We studied the expression of S100 protein in order to assess melanoblastic cells, dendritic cells and nervs, Vascular Endothelial Growth Factor (VEGF) for its mitogenic effects on endothelial cells and that of cytochrome c to evaluate apoptosis as a phenomenon involved in regulation of cell number using immunohistochemistry.
Materials and methods. Samples of breast integument irradiated for therapeutic reasons and control non-irradiated ones were collected after tumor excision and than processed for paraffin embedding. Serial sections were rehydrated and incubated with each required primary antibodies and then the immunoreaction was amplified using avidin – biotin or PAP (peroxidase - antiperoxidase) technique.
Results. After irradiation we noted an increased number of melanoblastic cells in the epidermal basal layer and also in the deep intermediate one revealed by the S100 immunolabeling. The same antibody marked also an increased number of Langerhans cells with the same distribution. The latest were also increased in the papillary dermis with a pericapillary disposition from the irradiated skin compared to control samples.
VEGF were found positive in few stromal cells and negative in endothelial cells from normal integument. In the irradiated dermis the number of VEGF positive fibroblast cells was increased and same the endothelial cells of capillaries from the papillary dermis. Vessel walls of arterioles and venules were entirely negative.
Epidermal germinative layer displayed few cytochrome c positive cells disposed with an insular pattern. Some cells from vessel walls were also positive for the apoptotic marker.
Conclusions. Irradiated skin has a non specific cellular reaction similar to that from the inflammatory process. The most obvious changes were found in the upper dermis layer

where mitotic effect and increase of permeability induced by VEGF seem to imbalance apoptotic post irradiated response.

CD 30 EXPRESSION IN TWO CASES OF NODULAR SCABIES
POTIER Alexandra(1), LECLECH Christian(2), VERRET Jean-Luc(2), CROUE Anne(1)
(1) Department of Pathology, University Hospital, 4 rue Larrey, 49933 Angers Cedex 09, France.
(2)Department of Dermatology , University Hospital, 4 rue Larrey, 49933 Angers Cedex 09, France.

CD30 antigen, protein of the tumor necrosis factor receptor family is a marker of lymphocyte activation. Its expression in large atypical cells has been observed in non neoplastic cutaneous inflammatory infiltrates. We report two cases of nodular scabies with CD30-positive large cells.

A 74-year-old woman presented with a nine-month history of generalized pruritus. On examination there were well demarcated papuloerythematous prurigo-like lesions on the back and the buttocks. The second patient, a-30-year old man, presented with a persistant pruritus after scabies treated six months before. Clinically, papulonodules of the external genitalia and the buttocks suggested nodular scabies. Histopathological examination of the two cutaneous biopsies revealed a prominent perivascular inflammatory infiltrate in the papillary and reticular dermis. It contained lymphocytes, histiocytes, few eosinophils and many large lymphoid cells with cleaved nuclei and one or more large nucleoli resembling Reed-Sternberg cells. Many mitoses were found in one case. Immunohistochemichal analysis revealed that most cells of the infiltrate including large cells were CD3 positive. The large cells expressed CD30 in a membranous pattern with accentuation of the Golgi apparatus. We suspected a primary cutaneous CD30-positive lymphoproliferation. Nevertheless the demonstration of Sarcoptes Scabiei after skin scraping and the improvement of cutaneous lesions with treatment for scabies led us to the diagnosis of nodular scabies.

The presence of large CD30-positive atypical cells has been reported in cutaneous inflammatory infiltrates of scabies with long standing lesions. No CD30 expression has been found in early lesions (less than two months). Atypical CD30-positive lymphoid cells have also been observed in activated lymphocytes in a variety of inflammatory reactions rich in neutrophils and eosinophils especially in insect bites, infectious conditions including bacterial, viral (herpes virus and molluscum contagiosum) and fungal, hidradenitis suppurativa, Sweet syndrome, drug eruptions…

CD30 expression in cutaneous infiltrates is not uncommon in non neoplastic inflammatory conditions and doesn't imply a diagnosis of primary cutaneous CD30-positive lymphoproliferative disorder, particularly lymphomatoid papulosis: others parameters (clinical feature, evolution) are required to establish this definitive diagnosis.

P 923
MERKEL CELL CARCINOMA – CASE REPORT
Dimov D, Mihailoviæ D, Katiæ V, Petroviæ A, Kostadinov V.
Medical faculty of Niš, University of Niš, Serbia

Introduction: Merkel cell carcinoma (MCC), first described by Tang and Toker in 1972., is a rare highly malignant skin tumour of neuroendocrine origin. Pathognomonic immunohistochemical markers for the diagnosis are epithelial (CK20), as well as neuroendocrine (chromogranine) markers.
Case report: A 69 years old woman, showed dark-red nodules, located in the lateral side of the her right leg. Although the mass was large measuring 28 cm, there was no evidence of nodal involvement. It consisted of small epithelial cells (small cell type) which formed solid cell complexes, arranged in characteristic trabecular patterns. The tumour cells were monomorphic, with oval nucleus, numerous mitotic figures, and massive necrosis. These cells infiltrated subcutaneous fat. The diagnosis MCC was confirmed through the histological and immunohistochemical analysis: Merkel cell tumour expressed epithelial (CK20) as well as neuroendocrine (chromogranine) markers.
Conclusion: In addition to histological/immunohistochemical characteristics for MCC diagnosis, the clinical data that indicate on primary skin tumour, provide a great help to pathologist in establishing the diagnosis of Merkel cell carcinoma.

P 924
ASSOCIATION OF MERKEL CELL CARCINOMA AND BOWEN´S DISEASE
Suárez-Peñaranda JM, Delgado-Gonzáles V(1), Casas Fernández L(2), Vieites B, Ortiz-Rey JA(3), Varela Durán J.
Department of Pathology. University of Santiago de Compostela Hospital and Medical School. Santiago de Compostela. Spain.
(1) Department of Surgical Pathology. Hospital Guillermo Almenara. Lima. Perú.
(2) Department of Dermatology. Fundación Hospital Barbanza. Ribeira. Spain.
(3) Department of Pathology. Centro Médico POVISA. Vigo. Spain

Introduction
Merkel cell carcinoma (MCC) is an uncommon neuroendocrine malignant neoplasm whose origin has not been well established. Little is known about its association with other malignant skin diseases, although there have been some reports associating it with basal cell carcinoma in-situ or infiltrating squamous cell carcinoma and malignan tmelanoma.
Case report
An 86-year-old woman was referred to the hospital complaining of a 10-cm tumour located in her left forearm. The tumour was completely excised.
Histopathological examination showed dermal nests of small and medium-sized, round, basophilic cells arranged in a trabecular or diffuse pattern, extending deeply through the dermis to the subcutaneous fat tissue. In some sections, the keratinocytes located in the overlying epidermis were atypical and immature in appearance, exhibiting hyperchromatic nuclei and pleomorphism. Occasionally, dyskeratotic cells and areas of pagetoid appearance were also observed.
Dermal tumour cells were positive for neuron-specific enolase, synaptophysin, chromogranin A, CK 20 and CK AE1-AE3. The neoplastic epidermal cells were negative for neuron-specific enolase, synaptophysin, chromogranin A and CK20, but strongly positive for CKAE1-3. The diagnosis of Merkel cell carcinoma associated with Bowen's disease was established. The patient died two years later of an unrelated disease.
Comments
Histopathological examination and immunohistochemistry clearly demonstrate that this patient has two different but synchronous neoplasms arising in the same place. The reason for the association of both neoplasms remains unknown. Although the induction of a second neoplasm by the first tumour cannot be excluded, the most probable explanation is that we are dealing with a collision tumour, well casual or because they share some common etiopathogenic agents or risk factors that have not yet been identified.

CYCLO-OXYGENASE 2 EXPRESSION IN MERKEL CELL CARCINOMA
JOACHIMS Zohar, FEINMESSER Raphael, PURIM Ofer, HAlPERN Marisa, BRENNER Baruch, FENIG Eyal, ROIZMAN Pepy, SULKES Jaqueline, FEINMESSER Meora.

Departments of Otolaryngology, Pathology, Oncology and Epidemiology, Rabin Medical Center and Sackler School of Medicine, Tel Aviv University

Introduction: Merkel cell carcinoma (MCC) is an aggressive neuroendocrine tumor of the skin associated with a high rate of recurrence and metastasis and only partial response to current radio- and chemotherapy regimens. The cyclo-oxygenase 2 (COX2) enzyme is involved in the development and progression of many tumors, including large bowel, breast and lung cancers. COX2 inhibitors have been shown to block tumor growth. The aim of this study was to examine COX2 expression in 26 primary MCCs and 5 of their lymph node metastases.
Materials and methods: Formalin-fixed paraffin-embedded tissues were stained immunohistochemically with monoclonal antibody directed against COX2. The percentage and intensity of staining were analyzed semiquantitatively using a three-tiered system.
Results: Immunopositivity for COX2 was found in 20 out of the 26 primary tumors (76%), including 16 (80%) with widespread positivity. Staining intensity was mostly weak (9 tumors-45%) or moderate (6 tumors-30%). Three of the 5 metastases (71%) showed similar staining. Tumors with prominent mitotic activity were associated with more widespread COX2 immunopositivity. No association was found between COX2 expression and outcome.
Conclusions: Most MCCs express COX2. Expression is related to one parameter of aggressive behavior- a high mitotic rate- but not to any others. Owing to the large number of MCCs that express COX2, the possibility of treating patients with COX2 inhibitors should be considered.

MYXOID NEUROTHEKEOMA: IMMUNOHISTOCHEMICAL ANALYSIS OF A CASE
Zioga A, Batistatou A, Bonitsis N, Agnantis NJ
Department of Pathology, University of Ioannina Medical School, Ioannina, Greece

Introduction: The myxoid variant of neurothekeoma is a benign, myxomatous neoplasm, that most probably originates from the peripheral nerve sheath. Recently it has been proposed that the so-called cellular and mixed (intermediate) variants of neurothekeomas warrant a separate classification, since they show no evidence of neurosustentacular differentiation.
Method: Herein, we describe the clinical, histopathologic and immunohistochemical features of a case of myxoid neurothekeoma, in a 53-year-old woman.
Results: The patient presented with a subcutaneous tumor, measuring 1.5 cm in maximal dimention at her lower back (sacrococcygeal area). The preoperative diagnosis was a lipoma. On macroscopic examination, a circumscribed mass with a rubbery to hard consistency and gray-white cut surface was noted. On microscopic examination, the tumor was centered to the dermis, and extended to the subcutaneous fat, without extending to the epidermis. At low-power magnification it had a multinodular architecture, with varying-sized nodules of moderate cellularity, separated by dense bands of collagen. The neoplastic cells were small, stellate- or oval-shaped, with bland nucleus, pale eosinophilic cytoplasm and very rare mitoses. They were loosely arranged within Alcian blue-positive myxomatous stroma. Upon immunohistochemical examination, the neoplastic cells showed strong nuclear and cytoplasmic staining for S100 protein. In addition they exhibited weak immunoreactivity for NSE (Neuron Specific Enolase) and CD57 (Leu-7). Based on the morphologic and immunohistochemical features the diagnosis of myxoid neurothekeoma was made. The tumor had been excised completely. The patient is well 1 year after excision, without evidence of local recurrence.
Conclusion: Myxoid neurothekeoma is a benign neoplasm of probable Schwannian origin. Dermatologists should be aware of this neoplasm, whose complete surgical excision appears to be curative.

INTRAPARENCHYMAL MELANOCYTIC NEVUS IN AXILLARY LYMPH NODE
SAN MILLÁN Beatriz1, FACHAL Carmen1, RIVAS Eloy1, TARDÍO Antoni1, ALLEGUE Francisco2
1Department of Pathology, Vigo University Hospital Trust (Meixoeiro Hospital),SPAIN
2Departament of Dermatology, Vigo University Hospital Trust (Meixoeiro Hospital),SPAIN

INTRODUCTION
Benign melanocytic cells within lymph nodes is a well-documented but unusual finding. Stewart and Copeland firstly reported it in 1931. Focal aggregates of nevocytes are occasionally found in the fibrous capsule and trabeculae of lymph nodes, whereas an intraparenchymal location is exceptional. Only 20 cases have previously been reported. Non-malignant cellular inclusions can be misinterpreted as metastases from a melanoma or carcinoma.
We report here an intraparenchymal nodal nevus within an axillary node removed from a patient with breast cancer and nodal metastases.

CASE REPORT
A 64-year-old woman underwent a left radical modified mastectomy with axillary lymphadenectomy for a 6cm breast carcinoma in the external quadrants. Tissue specimens removed were fixed in 10% buffered formalin and routinely processed for light microscopy. Histopathological examination showed a multicentric infiltrating pleomorphic lobular carcinoma with histological grade 3 and an associated in situ component. Metastases were found in 5 out of the 24 nodes identified.
Clusters of medium size cells were detected within the nodal parenchyma, as well as in the capsule and trabeculae of one of the metastases-free lymph nodes. This cells showed a pale citoplasm, with little or no melanin pigment and indistinct cell borders. Nuclei with diffuse chromatin pattern were centrally placed. Cytological atypia, mitosis, and prominent nucleoli were not observed. When we compared this aggregates with the primary carcinoma cells they showed morphological differences. The query cells were positive for S-100 but negative for CEA, Keratins, HMB-45, Ki-67 and hormone receptors.
CONCLUSION
Melanocytic nevi within lymph node parenchyma is a very unusual finding.
Nevus cell aggregates could be easily mistaken for metastatic melanoma or carcinoma. A differential diagnosis between nodal nevi and metastases requires a careful morphological examination and supportive immunohistochemical studies, mainly in patients with a primary tumor without obvious features of malignancy.
This case highlights the rarity of nevus cell aggregates within the parenchyma of lymph nodes, and alerts the pathologist to avoid a misdiagnosis of malignancy.

P 928
EZH2 EXPRESSION IS ASSOCIATED WITH INCREASED PROLIFERATION RATE AND AGGRESSIVE TUMOR SUBGROUPS IN MELANOMA AND CANCER OF THE ENDOMETRIUM, PROSTATE, AND BREAST
BACHMANN Ingeborg M .1, HALVORSEN Ole J. 1, COLLETT Karin 1, STEFANSSON Ingunn M. 1, STRAUME Oddbjørn 1, HAUKAAS Svein A. 3,

SALVESEN Helga B. 1,2, OTTE Arie P. 4, and AKSLEN Lars A. 1

Introduction:
The Enhancer of Zeste Homolog 2 (EZH2) is a member of the polycomb group of genes (PcG), which are important for transcriptional regulation through nucleosome modification, chromatin remodelling and interaction with other transcription factors. EZH2 serves as a histone methyl transferase (HMT), and disruption of EZH2 expression may lead to dysregulation of genes critical for the G2/M transition. Further, EZH2 is controlled by E2F transcription factors, which is downstream of the retinoblastoma protein (Rb), and is also involved in p53 regulated œll cycle control. EZH2 is previously shown to be overexpressed in prostate, and breast cancer, and increased expression evaluated by in situ mRNA was found in 34% of human cancers in a recent study.
Purpose:
The aim of our study was to evaluate the expression of EZH2 in a broader range of human cancers, with special attention to key features such as tumor cell proliferation, tumor extent, and patient outcome. This is especially relevant since the polycomb group proteins have recently been suggested as candidates for targeted therapy.
Patients and methods:
In our study of 696 patients, we examined EZH2 expression by immunohistochemistry using high-throughput Tissue Microarray (TMA), and its association with clinical features and other tumor markers in malignant melanoma and cancers of the endometrium, prostate and breast.
Results:
Strong EZH2 expression was significantly associated with increased tumor cell proliferation in all four cancer types. Associations were also found between EZH2 and important clinico-pathological variables, such as tumor thickness and level of invasion, histologic grade, locally invasive growth, and extent of the disease. Further, EZH2 expression showed significant prognostic impact in melanomas, prostate and endometrial carcinomas in univariate survival analyses, and revealed independent prognostic importance in carcinomas of the endometrium and prostate.
Conclusion:
Our present findings point at EZH2 as a novel prognostic marker in malignant melanoma and endometrial cancer, and extend previous findings on prostate and breast cancer. The fact that EZH2 might identify aggressive subgroups in several cancers may be of significant practical interest, since the polycomb group proteins have recently been suggested as candidates for targeted therapy.

TMA: CADHERINS & CATENINS STUDY IN DIFFERENT STAGES PROGRESSION OF CUTANEOUS MALIGNANT MELANOMA

RODRIGUEZ PERALTO Jose Luis, SAIZ Ana, ALONSO Soledad, CARRILLO Rosario*.
Staff of Pathology Hospital Universitario 12 de Octubre de Madrid.
*Staff of Pathology Hospital Universitario Ramón y Cajal de Madrid.

INTRODUCTION
Cutaneous malignant melanoma, the most agressive common skin tumor, is characterized by a multifactorial etiology. The incidence and mortality of this tumor have increased over the last several decades.
Cadherins comprise a growing family of surface membrane glycoproteins that mediate cell-cell adhesion. The extracellular domains of cadherins serve as zippers conecting neighboring cells, whereas the citoplasmic tails are linked noncovalenty to the actin cytoskeleton via catenins.
PURPOSE OF STUDY
The aim of our study is to determine the protein expression patterns of some catenins and cadherins using tissue microarrays (TMA), in 191 malignant melanomas samples from 162 patients in different histological progression phases. The study tries to identify a set of stage-specific markers, and allows a predictor model to be developed that identifies groups of patients with increased risk of death.
METHODS USED
Primary radial and vertical phases, and metastatic malignant melanoma were used to construct a TMA´s from a series of 162 patients diagnosed at Ramon y Cajal University Hospital, Madrid, between 1978 and 2002. There was no history of familial incidence. We also included normal tissues as internal controls, with a 1.5mm diameter needle.
Antibodies used for these study were E-Cadherin, N-Cadherin, Cadherin 11, ?catenin, ßcatenin and p120.
RESULTS
The serie compriseS 162 patients diagnosed of cutaneous malignant melanoma. Fourty (20.7%) radial growth phase malignant melanomas, 128 vertical ones (66.3%), and 24 (12.4%) cutaneous or ganglionar metastases. Patients with radial growth phase malignant melanomas never had metastases, and vertical growth phase malignant melanomas had metastases in 42.9% of cases.
In general, all immunostaining showed a membranous pattern, except for ßcatenin which also expressed on the nucleous. E-cadherin and ? catenin expression showed notably decreasement with melanoma progression. The expression pattern of ß;- catenin was very similar to p-120 expression. Both proteins showed moderate decreasement with tumor progression. The expression pattern of Cadherin11 was absent.
CONCLUSIONS
The current study demonstrates the suitability analysis of TMA technique in the study of a classical model of human tumor progression. This study also demonstrates qualitative changes in the expression of some catenins and cadherins in different stages of malignant melanoma progression.

P 930

THE CORRELATION OF ANGIOGENESIS WITH METASTASIS IN PRIMARY CUTANEOUS MELANOMA: A COMPARATIVE ANALYSIS OF MICROVESSEL DENSITY, EXPRESSION OF VASCULAR ENDOTHELIAL GROWTH FACTOR AND BASIC FIBROBLASTIC GROWTH FACTOR

RAMAZANOGLU Rana*,DEMIRKESEN Cuyan*,BUYUKPINARBASILI Nur*, OGUZ Oya**, MANDEL Molinas Nil***, KANER Gultekin*
*Department of Pathology,**Department of Dermatology, ***Department of Oncology, Cerrahpaþa Medical Faculty, University of Istanbul

Tumor cells supply oxygen and nutrients necessary for growth by the recruitment of new blood vessels.Angiogenesis is not only a must in tumor growth but in metastasis as well. However, the prognostic significance of angiogenesis in malignant melanoma is controversial. In order to find out the correlation of angiogenesis with metastasis in primary cutaneous melanoma (PCMM), we studied the microvessel density, the expression of vascular endothelial growth factor (VEGF) and basic fibroblastic growth factor (bFGF) in 22 cases of PCMM with metastasis at presentation (metastatic group) and 28 cases of PCMM without any metastasis for 24 months or more (nonmetastatic group). Microvessels were stained with CD31/PECAM-1 antibody and counted. Besides the proportion of VEGF expression in tumor cells, lymphocytes infiltrating the tumor (TIL) and lymphocytes at the periphery of the tumor, as well as, the proportion of bFGF expression in tumor cell cytoplasms, nuclei and intra- and peritumoral vessels were assessed. An increased microvessel density was detected in the metastatic group [15-33

(24.09±5.55) vs. 2-24 (12.96±6.02)]. Moreover, enhanced expression of VEGF in tumor cells and peritumoral lymphocytes (Chi-square p=0.038 and p=0.018) and bFGF in peritumoral vessels (Chi-square p=0.013) correlated with the simultaneous presence of melanoma metastasis in PCMM.
In conclusion microvessel density, as well as, the expression of both VEGF and bFGF might be informative concerning the progression of melanoma.

P 931
THE MITOCHONDRIAL SIGNATURE OF MELANOMAS PROVIDES A MARKER OF PROGNOSIS
CAMARASA Natalia1 ,CARRILLO Rosario1 , MARTINEZ-DIEZ Marta2, MOYA Laura3, CUEZVA Jose M2.
1Departamento de Anatomia Patologica y 3Dermatologia, Hospital Universitario Ramon y Cajal, 28034 Madrid and 2Departamento de Biologia Molecular, Centro de Biologia Molecular Severo Ochoa, Universidad Autonoma de Madrid, 28049 Madrid, Spain.

Introduction: A large body of clinical data documents that most human carcinomas contain reduced levels of the catalytic subunit of the mitochondrial H+ATP synthase (B-F1-ATPase). In colon and lung cancer this alteration correlates with a poor patient prognosis.
Purpose of the study: In this study we have investigated the mitochondrial phenotype of melanomas as a prognostic marker of disease progression.
Material and methods: A set of twenty-one nevi, forty-one melanomas and thirteen metastases were examined for quantitative differences in protein expression of the mitochondrial B-F1-ATPase and Hsp60 markers by immunohistochemical techniques. Quantification of the expression level of the markers was carried out in digital images acquired at 20x magnification with a Leica DC100 camera and processed with the Leica QWin software. Correlations of the expression level of the protein markers were established with the clinicopathological information of the melanomas and the follow-up data of the patients.
Results: The expression B-F1-ATPase and Hsp60 was significantly higher in melanomas and metastases than in nevocellular nevi. However, with advanced disease, the expression of both mitochondrial markers was significantly diminished in the melanomas. Cluster analysis by the expression level of the mitochondrial markers allowed the identification of a group of melanomas that predicted a worse prognosis for the patients. The good prognosis group had an expression level of B-F1-ATPase that was 50% higher (P<0.001) than that found in melanomas of worse prognosis. Kaplan-Meier survival analysis showed that the expression level of B-F1-ATPase significantly correlated (P=0.024) with overall survival of the patients.
Conclusion: The alteration of the mitochondrial proteome of melanomas provides a relevant marker to add in the prognosis of these patients.

P 932
IMMUNOHISTOCHEMICAL EXPRESSION OF MSH-2 AND MLH-1 EN MALIGNANT MELANOMAS:CORRELATION WITH TUMOR STAGE AND PROGNOSIS
SAN MIGUEL Pilar, ORTIZ-REY Jose Antonio, MONTEAGUDO Benigno, ALMANZA Concepción, BARBOSA Mª jose, IGLESIAS Begoña, ÁLVAREZ Carlos, ANTÓN Iosu.

Introduction: Defects in DNA mismatch-repair genes MLH-1 and MSH-2 first described in hereditary nonpolyposis colon cancer, have been postulated to be responsible for malignant transformation in many types of tumors, including malignant melanomas.
Purpose of the study: The main aim of this study was to investigate the expression of these genes in malignant melanomas in relation to tumor stage and prognosis.
Methods: We examined the protein expression pattern of MLH-1 and MSH-2 by immunohistochemistry in 20 cutaneous melanomas. Formalin-fixed paraffin-embedded sections were immunostained following the labelled streptavidin-biotin technique (LSAB2Ò, DAKO) using monoclonal antibodies against MLH-1 (1:10, clone G168-15, BD Biosciences) and MSH2 (1:200, cloneG219-1129, BD Biosciences). For epitope retrieval slides were pretreated with citrate buffer for 5 minutes in a pressure cooker.
Association of expression of MSH-2 and MLH-1 with clinical stage (pT1, pT2, pT3 and pT4) and prognosis (alive or died) was evaluated.
Results: The study cohort comprised 12 females and 8 males ranging in age from 17 to 74 years (average 55 years). The 20 patients in the study cohort had malignant melanomas with the following pT distribution: pT1:35%, pT2:20%; pT3:10% and pT4:35%.
Relation between tumor stage and detection of MLH-1 was: pT1:50%, pT2:42%, pT3:37% and pT4:48%.
Relation beween tumor stage and presence of MSH-2 was: pT1:81%, pT2: 82%, pT3: 75% and pT4:44%.
Relation between prognosis and positivity for MLH-1 was: alive: 46.6%; died:46.4%.
Relation between prognosis and detection of MSH-2 was: alive: 80%; died:45.7%.
The immunohistochemical expression of MSH-2 was significantly correlated with tumor stage (p=0.01) and prognosis (p=0.002).
Conclusions: The analysis of mismatch-repair genes MLH1 and MSH-2 can be studied by immunohistochemistry. Our study demonstrates that expression of MSH-2 has statistical correlation with tumor stage and prognosis. Further studies with larger series should be performed in order to confirm our results.

P 933
VEGF AND VEGF-C IMMUNOHISTOCHEMISTRY IN HUMAN CUTANEOUS NEVI AND MALIGNANT MELANOMAS
Michala Fiuraskova, Svetlana Brychtova, Alice Hlobilkova, Martin Tichy*, Eva Sedlakova, Tomas Brychta**
Institute of Pathology & Laboratory of Molecular Pathology, Faculty of Medicine, Palacky University and Faculty Hospital, Hnevotinska 3, 775 15 Olomouc, Czech Republic, *Department of Dermatology and Venerology, Faculty of Medicine, Palacky University and Faculty Hospital, I.P. Pavlova 6, 775 20 Olomouc, Czech Republic
**SPEA Olomouc, s.r.o., nam. Hrdinu 2, 772 00 Olomouc, Czech Republic

Vascular endothelial growth factors (VEGFs) are a family of secreted endothelial cell-specific cytokines that act as endothelial cell mitogens. They play a hierarchical role in regulating physiologic and pathologic angiogenesis. These factors are involved in vasculogenesis and vasculogenic sprouting which are crucial for tumour development and metastasis. VEGFs also act as vascular permeability factors. VEGFs are overexpressed in many skin disorders characterized by angiogenesis and increased vascular permeability. In order to determine their possible role in melanocytic tumour progression, VEGF (immunoreactive for VEGF-A and VEGF-C) immunohistochemical expression were evaluated in 107 biopsy specimens of human skin including 28 superficial spreading melanomas (SSM), 40 nodular melanomas (NM) and 39 common nevi. Primary mouse monoclonal antibody VEGF (Santa Cruz Biotechnology, clone C-1, diluted 1:50) and goat polyclonal antibody VEFG-C (Santa Cruz Biotechnology, clone N-19, diluted 1:50) were used for the analysis. VEGF was expressed

markedly not only in malignant melanoma cells but also in half the cases of common nevi. In malignant lesions staining of stromal cells - fibrocytes, endothelial and inflammatory cells predominated. VEGF-C staining was found mainly in malignant lesions but less frequently in cells of common nevi. Stromal staining in malignant lesions was significantly higher in comparison with the stroma microenvironment surrounding moles. Our results indicate that VEGFs expression may regulate skin vessel function under benign as well malignant conditions and therefore cannot be used to discriminate between malignant melanoma and benign melanocytic lesions. Nevertheless strong up-regulation of the above mentioned factors may contribute to the progression of melanoma.

INTRODUCTION: The clinical behaviour of melanoma is often unpredictable using clinical and histological criteria. Differentiation between naevi, especially dysplastic naevi and melanomas, can sometimes be difficult to assess by conventional histopathological analysis. Malignant transformation of melanocytes is a multistep process characterized by distinct histopathological stages.
AIM: To analyse the differences in proliferative activity and apoptosis between intradermal naevi (IN), dysplastic naevi (DN) and cutaneous melanoma (CM).
MATERIALS AND METHODS: 45 IN, 45 DN and 45 CM (thickness less than 1.5 mm) were immunohistochemically stained for Ki-67, which was used as a proliferative marker, p53 as an apoptotic and bcl-2 as an antiapoptotic marker. The number of positive cells was counted on 200 melanocytes.
RESULTS: The median values of Ki-67 positive cells in IN, DN and CM were 2.5, 6.0 and 12.16, respectively. Statistical analysis showed a significant difference in proliferative activity comparing IN, DN and CM group ($p=0.000$) with a significant positive correlation ($r=0.659$, $p=0.000$) between the proliferative activity and lesion malignancy. The p53 overexpression was present in 3.3 IN, 50.0 DN and 22.6 CM cells. Statistical analysis showed that the observed difference in p53 overexpression comparing IN with both DN and CM is statistically significant ($p=0.000$), but showed no significant difference between DN and CM. The median values of bcl-2 in IN, DN and CM were 49.2, 42.3 and 26.7. Statistical analysis showed a significant difference between IN and DN comparing to CM ($p=0.000$).
CONCLUSION: Our preliminary results show a progressive growth of proliferative activity from benign to malignant melanocytic lesions. The strongest expression of p53 in DN suggests that its overexpression could be the first step in the loss of cell cycle regulation and possible malignant transformation of melanocytes. Lack of bcl-2 expression correlates with progression of malignant melanoma and it could be related with poor prognosis.

Dr.y.Sedaghat Resident of dermatology
Tehran university of medical science

Primary cutaneous B-cell lymphoma (PCBCL) is an uncommon neoplasm of skin giving rise to anywhere between 4.5 to 20 percent of all primary cutaneous non-Hodgkin's lymphomas (Zackheim HS, et al. J Am Acad Dermatol 2000; 43:793-96). Although this type of lymphoma was primarily reported in older individuals, the occurrence of this neoplasm has also been observed in children. We would like to report a unique case study performed on an 11-year old Iranian female suffering from a slowly expanding round tumour on her left lower leg.

The 11-year old Iranian girl was seen in our clinic with a 2-year history of asymptomatic tumours on her left lower leg. Physical examination revealed two firm tumoral masses on her lower leg, the larger measuring 8 cm x 8 cm. No hepatosplenomegaly or lymphadenopathy was detected. The patient otherwise felt well and a review of systems was negative. Laboratory studies, X-ray of leg, CT scan of chest, abdomen and pelvic and sonography were all normal. Smear for leishmaniosis, culture for deep mycosis and atypical mycobacterium were all negative. Histopathologic examination of multiple ellipse biopsy specimens from the larger lesion demonstrated dense diffuse infiltration of small blue round cells in superficial and deep dermis in 'botton heavy' pattern with destruction of hair follicles and eccrine glands. The neoplastic cells have round hyper chromatic atypical nuclei and scant cytoplasm of small to intermediate size without any rosette formation. No differentiation is observed. Mitosis is inconspicuous. No well-formed germinal centers were evident and tingible body macrophages were not seen. Using immunohistochemical techniques, a large portion of neoplastic cells expressed common leukocyte antigen confirming the lymphoid origin of the tumour with demonstrated lambda light chain restriction. Stains with CD19 were invariably positive. Stain with HMB45, S100, cytokeratin20, CD5, CD3 were all negative; the latter excluded any T-cell lymphoma.

In summary, PCBCL is an entity that can be suspected clinically, detected and confirmed pathologically. To the best of our knowledge this is amongst the first rare reports of PCBCL without dissemination in a very young girl.

HISTOPATOLOGICAL, IMMUNOHISTOCHEMICAL AND CLINICAL CORELATIONS IN CUTANEOUS LEIOMYOSARCOMAS (CLMS)

Mariana Costache 1 , Ana Maria Ene2, Maria Sajin3, Olga Simionescu2
1-Department of Pathology , ¨Victor Babes ¨ National Institute Bucharest , Romania
2-Department of Dermathology, ¨Carol Davila ¨University of Medicine, Bucharest, Romania
3- University of Bucharest, Biology Faculty, Romania

Introduction: Cutaneous leiomyosarcomas (CLMS) is a malignant tumour who may be derived from arrector pili muscles or subcutaneous blood vessel walls and is more common in a deep location.
Materials and methods: The authors make a retrospective study of 10 parafin - embedded cases diagnosticated histopathologycal like leiomyosarcomas and confirmated by immunohistochemical reactions. The immunohistochemical tests are : Actin, Desmin, Mioglobulin, Caldesmon, Vimentin, S-100 protein, citokeratin. IHC study was carried on formalin

fixed, parafin - embedded tissue using the avidin-biotin peroxidase complex.
Discussion and conclusion: Histopathologycal (with hematoxylin and eosin stain), CLMS is composed by numerous interlacing bundles of smooth muscle cells with eosinophilic cytoplasm and large , sometimes monstruous , hyperchromatic , blunt-ended nucleus.
Their pleomorphism and presence of mitotic activity , particulary abnormal and greater , constituting an important criteria for malignancy. Sometimes areas of myxoid degenerescensy may occur.
Usually CLMS can occurs at any age but in childhood are rare ; both sexes are affected , with a slight prediction for males ; is present tendency to local recurence . Most of the tumors appear solitary (nodules ulcerated or not) and the usual site is the limbs
(especially the legs).

MALIGNANT ECCRINE SPIRADENOMA (SPIRADENOCARCINOMA) : A CASE REPORT

FERCHICHI Leila*, RAMMEH-ROMMANI Soumaya*, ZERMANI Rachida*, FAZAA Becima**, FAREH-KLIBI Faten*, KOURDA Nadia*, CHELBI Emna*, BALTAGI BEN JILANI Sarrah*
* Departement of Pathology, Charles Nicolle Hospital, Tunis Tunisia.
**Departement of Dermatology, Charles Nicolle Hospital, Tunis, Tunisia.

Introduction : Eccrine spiradenocarcinoma is a rare dermal appendage carcinoma believed to arise from transformation of a long-standing benign spiradenoma. This tumor demonstrates highly malignant biologic behavior with a high recurrence rate, frequent lymph node metastases, and overall poor survival.
Observation: We report the clinicopathologic and immunohistochemical features of a spiradenocarcinoma occurring in the forehead of a 73-year-old man. The lesion had been present for 10 years; recently, it had increased in size and had bleeded occasionally. Cervical lymph nodes were inconspicuous on palpation and full body examination was within normal ranges. Sections cut from excision specimen revealed a lobulated tumor with illdefined borders and cavity-like structures. The proliferation, located in the dermis without obvious continuity with the epidermis, consisted of multiple lobules of epithelial cells surrounded by connective tissue and contained ducts and cystic spaces. The tumor cells were polygonal in shape with scant pale cytoplasm and round slightly hyperchromatic nuclei. Mitoses were up to four per high-power field. Areas of necrosis were seen. In certain foci, especially at the periphery of lobules, sheets, nests and glandular structures were surrounded by abundant stroma and infiltrated skeletal muscle infiltration and perineural tissue. Immunohistochemical studies for markers of proliferation (Ki-67, Mib1, proliferating cell nuclear antigen: PCNA) revealed 80% of tumor cells staining positive for PCNA and 20% for Ki-67. One year after the excision of the nodule, the patient is free of signs and symptoms of recurrence or metastasis. No complementary treatment had been administered.
Conclusion: Spiradenocarcinoma is an exceedingly rare malignant neoplasm with ductal differentiation. Many authors consider it to be an eccrine neoplasm, and others favor apocrine differentiation. It originate from previous spiradenoma that remained unaltered for many years, but de novo spiradenocarcinomas had already been reported.
The authors report a new case and review the literature about spiradenocarcinoma, and discuss briefly some histogenetic concepts relevant to this neoplasm.

P 938

IMMUNOHISTOCHEMICAL STUDY OF MUC1, MUC2, AND MUC5AC EXPRESSION IN MALIGNANT SWEAT GLAND NEOPLASMS

JUNG shih-ming, CHU po-hsien, KUO tseng-tong
Department of Pathology and Department of Internal Medicine, Chang Gung Memorial Hospital and Chang Gung University, Taoyuan, Taiwan

Introduction: Malignant sweat gland neoplasms are rare skin tumors. MUCs are glycoproteins associated with carcinogenesis and cell adhesion. MUC1 is suggestive to inhibit cell to cell adhesion. In the present study, we examine the immunohistochemical expression of MUC1, MUC2, and MUC5AC in malignant sweat gland neoplasms.
Materials and Methods: Formalin fixed, paraffin embedded tissues of nineteen cases of malignant sweat gland neoplasms were immunohistochemically studied. Intensity and percentage of staining were evaluated.
Results: Patients included eleven females and eight males, mean age 60 yrs (age range: 24-84 yrs). Three cases had extramammary Paget¡¦s disease. The head and neck was involved in 6 cases, the trunk in 5 cases, the genital regions in 4 cases, the thigh in 3 cases. The histologic feature showed sweat gland adenocarcinomas (n=9), sweat duct carcinoma (n=4), porocarcinoma (n=2), microcystic adnexal carcinoma (n=3). 18 cases were immunopositive for MUC1. One porocarcinoma case was negative for MUC1. All 19 cases of malignant sweat gland neoplasms were immunonegative for MUC2 and MUC5AC. The intraepidermal component of extrammary Paget¡¦s diseases in 3 cases was positive for MUC5AC. Follow up data was available in 12 cases.
Conclusion: Malignant sweat gland neoplasms are associated with expression of MUC1 and not associated with MUC2 and MUC5AC expression. These observations suggest that MUC1 may play a role in cancer cell invasion malignant sweat gland neoplasms.

HYALINE-CELL RICH MALIGNANT CHONDROID SYRINGOMA WITH OVERT MORPHOLOCIGAL FEATURES OF MALIGNANCY. A CASE REPORT

STOJŠIÆ Zorica1, BACETIÆ Dragoljub1, JANKOVIÆ Radmila1, DRNDAREVIÆ Neda2
1Institute of Pathology Medical School, Belgrade, 2Institute for Medical Research, Belgrade

Malignant chondroid syringoma (MCS) is malignant mixed tumor of the skin. It is extremely rare neoplasm. We describe a case of MCS which was characterized by predominant hyaline-cell population and distinctive morphological signs of malignancy. A 62-year-old female presented with subcutaneous mass 5 cm in diameter on the lateral side of the left forearm. After a 15-year period of slow growth, the lump suddenly increased in size. The surgically excised neoplasm was evaluated by routine histology and immunohistochemistry. Histopathologically, the tumour consisted mainly of broad sheets of pleomorphic plasmacytoid-hyaline cells with rare mitoses. A part of the tumor showed the features of benign mixed tumor, where uniform slightly eosinophilic cells formed irregular small nests, partly with tubular and cystic lumina, in the myxoid and hyaline matrix. Large areas of necrosis were surrounded with small undifferentiated cells with high mitotic rate: 7/10HPF. Invasion of the capsule and satellite nodules in subcutaneous adipose tissue were found. The hyaline cells were strongly and diffusely immunopositive for CK, EMA, CAM 5.2, CEA, and partialy for GFAP antibody. S-100, aSMA, desmin, calponin and bcl-2 immunostaining was negative. In areas with high mitotic activity mean p53 protein index was 21%. Although the ductal differentiation was vague, we favour the diagnosis of MCS over myoepithelial

carcinoma due to the lack of immunoexpression of myogenic markers and S-100 protein.

P 940
SYRINGOID ECCRINE CARCINOMA
Alfaro Luis, Roca Mª José, Froufe Agustín, Rayón Miguel, Baena Pablo.
Hospital 9 de Octubre. Valencia. Spain

Syringoid eccrine carcinoma is a rare variant of adnexal carcinoma thought to derive from eccrine sweat glands. It's often clinically underestimate which lead to local recurrences. We received a lesion developed on the forehead of a 27 year old woman. Clinically a lipoma was suspected. The lesion measured 1'1 x 0'7 cm and was excised reaching focally the muscular layer. On microscopic examination the epidermis was unremarkable, and a proliferation of small, low density, glandular structures was seen all over the dermis. A few of them configured small keratinous cysts especially in superficial areas. The lumina were lined by two layers of cuboidal cells, and contained a granular eosinophilic material. There was a slight pleomorfism in nuclei, mainly in the inner layer, with small single nucleoli. Mitotic activity was very scant, lower than 1 per 10 high power fields. Some of the glands had a thin projection, giving a comma shaped appearance. The stroma had a fibrous configuration, with dense collagenous pseudonodular disposition centred by the glands. Perineural invasion was occasionally seen, and deep dermic infiltration, although not reaching the muscular layer.
Immunohistochemical study showed in the glandular cells expression for keratin (AE1-AE3); epithelial membrane antigen, carcinoembryonic antigen (CEA), and S-100 protein. Cytokeratin 7 was focally positive, and Cytokeratin 20 negative.
This neoplasm shares certain similitude with the more common eccrine microcystic carcinoma. In fact many reports use those terms as synonyms, but syringoid carcinoma lacks the basaloid nest differentiation of microcystic carcinoma, has the typical comma shaped tubules, and has a less prominent perineural invasion. Confusion extends when using the other synonymous term, sclerosing duct carcinoma, generally referred to microcystic carcinoma, but present also in our case with a prominent concentrically peritubular stromal reaction.

P 941
THE INTERPRETATION OF BENIGN BIOLOGIC BEHAVIOR FOR KERATOACANTHOMA VERSUS CUTANEOUS SQUAMOUS CELL CARCINOMA, USING A PANEL OF ANTIBODIES AGAINST:CYCLIND1,P53,P21RAS,EGFR
AL- SHAWAF A. Zahi MD
Prof. of Pathology
Department of pathology
Al-BAATH University

Introduction:

The keratoacanthoma (KA) is a relatively common tumor which most often occurs on the sun – exposed areas of light skinned individuals of middle age and older.

This tumor is regressing spontaneously ,so the recognition of the true nature of this tumor is of considerable practical and biological important

Its etiology is unlcear, although ultraviolet light, viruses, oncogenic chemicals, and epidermal growth factor have been considered.

- EGFR : is membrane growth factor receptor encoded by the Cerb 1 gene
- P21 ras: is a signal transducing (cytoplasmic) oncoprotein with GTP as activity. Ras mutative abolishes GTP as activity and results in constitutive stimulation of the way.
- P 53 Nuclear protein playing an important protective role in the response to DNA damage induced by ionizing radiation chemical carcinogens and viruses.
- Cyclin D 1: CDK Complex regulates the RB protein (PRB) . Mutational gene causes hyperphosphory lat of RB

protein .with consultative stimulation of the pathway

Material and methods :

- 24 cases of Keratoacanthoma
- 26 cases of SCC
- Immunostainning of EGFR, P21 ras, P53, Cyclin D 1 oncoprotein
- Scores of Positive staining : diffuse basal and suprabasal staining. Focal basal and suprabasal staining

Results

- The expression of P53 (mutant gene) showed a great difference between SCC and Keratoacanthoma (20/26 – 80% in SCC versus 4/24 – 16% in KA) (P<0.01) -2/4 of KA . Cases were reevaluated as SCC (KA –like SCC) .
- The expression of P21 ras was more evident in KA versus SCC (14/24 -58 % in KA versus 5/26- 19% in SCC (P < 0.05).
- EGFR was negative in both all cases of KA and SCC.
- Cyclin D1 showed more evident (focal expression) in SCC (10/26 -38% in SCC versus 4/24 – 16 % in KA)

Conclusions:

- - Our results refer to the decisive role of P53 mutation in the development of SCC and Its invaluable role in setting down a convincing diagnosis of SCC.
- - P21 ras was more definitive in KA
- - EGFR : is expressed more in reactive and benign epidermal growths , and has no role in both KA and SCC.
- – P53 mutation is critical and decisive in the development of cutaneous malignancy.

APOPTOSIS AND PROLIFERATION IN SQUAMOUS CELL CARCINOMA AND KERATOACANTHOMA
Batinac Tanja1, Zamolo Gordana2, Stemberger Christophe2, Zauhar Gordana3, Simat Marina2, Grahovac Blazenka2
1 Department of Dermatovenerology, Clinical Hospital Center Rijeka, Rijeka, Croatia
2 Department of Pathology, University of Rijeka, Rijeka, Croatia
3 Department of Physics, University of Rijeka, Rijeka, Croatia

BACKGROUND: The controversy of distinguishing keratoacanthomas (KAs) from a well-differentiated squamous cell carcinoma (wdSCCs) is still present. Model of cutaneous carcinogenesis focus on the regulation of keratinocyte proliferation, differentiation, apoptosis and/or inability to undergo growth arrest.
OBJECTIVE: We investigated the expression of proliferation and apoptosis markers in wdSCC, poorly differentiated squamous cell carcinoma (pdSCC), proliferating keratoacanthoma (pKA) and regressing keratoacanthoma (rKA) in order to distinguish a factors important in the progression of SCC and the regression of KA.
METHODS: 120 tumors (30 of each group) were analyzed for p53 protein, Bcl-2, Bak and Ki-67.
RESULTS: The percentage of p53 positive tumor cells was 73.20% in pKA, 46.62% in rKA, 69.32% in wdSCC and 78.96% in pdSCC. Ki67 was found in 35.13% in pKA, 30.11% in rKA, 48.57% in wdSCC, and 65,68% in pdSCC. Bcl-2 protein was found in 3.07% of cells in pKA, 13.43% in rKA, 14.97% in wdSCC, and 4.69% in pdSCC. Pro-apopotic protein Bak was expressed in 96.23% in pKA, 41.63% in rKA, 93.04% in wdSCC, and 54.69% in pdSCC.
CONCLUSION: Relatively slow proliferation rate, as compared to SCC, coupled with an intensive apoptosis seen in

pKA could lead to regression of this tumors. Growth and malignancy of pdSCC could be a result of intensive proliferation of tumor cells. Proliferation in pdSCC is mainly controlled by an intensive but still not sufficient apoptosis. This preliminary study suggest that balance in expression of proliferation and apoptosis related proteins could be important factor in determining a tumor progression or regression.

P 943

AN INCIDENTAL FINDING OF COEXISTENT, CUTANEOUS KAPOSI'S SARCOMA AND LEISHMANIASIS IN AN HIV-INFECTED PATIENT.

FFOLKES Lorrette, BHAGANI Sanjay, PATALAY Rakesh, DEROIDE Florence
Royal Free Hospital NHS Trust, Royal Free Hospital, London, UK

Cutaneous lesions in Mediterranean visceral leishmaniasis are very unusual, except for the presence of Leishmania organisms in cutaneous Kaposi's sarcoma in patients infected by the Human Immunodeficiency Virus (HIV). A 40 year old male with a 15 year history of HIV presented with a one month history of multiple purple asymptomatic papules on his left forearm, feet, penile tip, buccal mucosa and splenomegaly. His current CD4 count was 39 cells/mm3 and viral load, 10411. The patient lived in Southern Spain and had recently adopted a dog. Histological examination of one of the biopsied lesions on his forearm showed a dermal vascular proliferation suggestive of kaposi's sarcoma, with positive immunostaining for Human Herpes Virus 8 (HHV8). There was an associated peripheral infiltrate of plasma cells and histiocytes, the cytoplasm of which contained many small round Leishmania amastigotes. A large number of these Giemsa positive, PAS negative organisms were also seen extracellularly. The features of the skin biopsy were those of coexistent cutaneous leishmaniasis and Kaposi's sarcoma. The patient's splenomegaly was attributed to visceral leishmaniasis. Canines are the natural host of Leishmania donovani. Most cases of leishmaniasis in HIV-positive patients appear in the advanced stages of the disease (CD4<200mm3). Leishmania organisms are thought to reach the skin by dissemination during visceral disease, either after external infection or by reactivation of latent leishmaniasis. Kaposi's sarcoma is now classified as a low-grade malignancy but is regarded by many authours as a non-tumoural, reactive, entity. DNA sequences from HHV8 have been found in all types of Kaposi's sarcoma. The role of Leishmania in Kaposi's sarcoma remains a subject of discussion. The fact that the vascular tumour usually regresses after treatment of the parasitic infection, strengthens the proposal that it is a reactive process.

The study of lymphatic vessels and lymphatic tumours has been hampered with difficulty, due to the overlapping morphological features between blood and lymphatic endothelial cells, as well as to the lack of specific lymphatic endothelial markers. Over the last few years, lymphatic vessels and lymphangiogenesis have received great attention owing to their putative implications in terms of metastatic dissemination and the promise of targets for lymphangiogenic therapy. Prox-1 is a nuclear transcription factor that plays a major role during embryonic lymphangiogenesis and is deemed to be a useful marker for differentiating lymphatic endothelial cells from the other blood vessels endothelial cells. Here we describe a double-immunostaining strategy for formalin-fixed paraffin-embedded tissues aiming to evaluate the distribution of Prox-1 and CD 31 - a cytoplasmic pan-endothelial marker - in a series of twenty eight mucousae, cutaneous and soft tissue vascular lesions and tumours (haemangiomas, n=12; spindle cell haemangioma, n=1; lymphangiomas, n=10; lymphangiectasia, n=1; Kaposi's sarcoma, n=4). Our results showed that in non lesional mucousae and skin, Prox-1 decorated exclusively the nuclei of endothelial cells in vascular structures with bona fide morphological features of lymphatic vessels. CD 31 stained endothelial cells of blood vessels of superficial and deep dermal plexuses and also lymphatics. Prox-1 stained almost all the benign lymphatic vascular lesions/tumours (93%) and was absent or only focally positive in 75% of blood vascular tumours. CD 31 showed positive staining in all blood vascular lesions/tumours, being focal in two lymphatic lesions/tumours. Kaposi's sarcomas were all positive for both CD 31 and Prox-1 markers. In conclusion, whilst not utterly specific in the tumoral setting, Prox-1 may be employed as an adjunct marker of lymphatic endothelial cells in routinely processed formalin-fixed paraffin-embedded samples, namely of non-tumoral vessels.

P 945

EXPRESSION OF CYTOKERATIN SUBTYPES IN INTRAEPIDERMAL MALIGNANCIES: A GUIDE FOR DIFFERENTIATION

DEMIRKESEN Cuyan, ASLAN Figen, TUZUNER Nukhet
Department of Pathology, Cerrahpaþa Medical Faculty, University of Istanbul

Among intraepidermal malignancies of epithelial origin, Bowen's disease, bowenoid actinic keratosis (BAK), intraepidermal malignant eccrine poroma (MEP) and Paget's disease may pose diagnostic difficulties. Considering these difficulties, the localization, histologic features, and immunohistochemical profiles of 24 cases of Bowen's disease, 21 cases of BAK, 18 cases of intraepidermal MEP and 11 cases of Paget's disease were analyzed. Using multivariate logistic regression test, multinuclear giant cells and solar degeneration were found to be the only histologic parameters of diagnostic help. On the other hand, bivariate tests, performed for each pair of diseases revealed that an immunohistochemical panel composed of four different cytokeratin (CK) subtypes could be of benefit in the differential diagnosis. A widespread positive reaction for CK 5/8, CK 7, CK 19,and negative reaction for CK 10, was a helpful feature in differentiation of Paget's disease from Bowen's disease and BAK. CK 10 expression could be considered in favor of Bowen's disease, when compared to BAK. The widespread expression of CK 5/8 and CK 7 and negative reaction for CK 10, was in favor of Paget's disease, compared to intraepidermal MEP. On the other hand, widespread expression of CK 19 was a common finding in inraepidermal MEP, in contrast to Bowen's disease. In conclusion, our findings suggest that an immunohistochemical panel including certain cytokeratin subtypes such as CK 5/8, CK 7, CK 10 and CK 19, can

provide significant hints in the differentiation of common intraepidermal malignancies, Bowen's disease, BAK, MEP and Paget's disease, especially in problematic cases.

P 946

LOCALIZED AMYLOIDOSIS IN BASAL CELL CARCINOMA

CINGIL Hakan. Istanbul Naval Hospital, Istanbul, Turkey

Introduction: Amyloid can be found in some disease localized on lesion regions. One of these diseases is Basal Cell Carcinoma(BCC). The existence of amyloid deposits in basal cell carcinomas of the skin has been an established fact since 1930. Purpose: In my study I purposed to investigate the presence of amyloid in 60 BCC tissue specimen and the amyloid's relationship between BCC's histopathologic types, mitotic rate, solar elastosis, degree of apoptosis and the age of the patients.
Material and Methods: Their ages ranged from 24 years to 92 years with a mean age of 56 years. The male to female ratio was 1.14. Excisional biopsy specimens were obtained from 60 patients were fixed in 10% buffered formalin and embedded in paraffin. Five micrometer thick sections were stained with hematoxylin and eosin and Congo Red. Results: The histologic distribution of the amyloid deposits was fairly consistent. They were found in the fibrous stroma between clumps of tumor cells and in the connective tissue abutting the advancing front of the carcinoma. Amyloid was identified as amorphous, eosinophilic extracellular material which stained rose-pink with Congo Red. Conclusion: Amyloid is found on the 55% of the BCC patients. The presence of amyloid didn't change with the age of the the patients, the tumours histopathologic types and apoptosis. A relationship between solar elastosis and mitotic rate quantity and the presence of amyloid is detected.

P 947

MEASUREMENT OF TELOMERE LENGTHS IN SQUAMOUS CELL CARCINOMAS FROM BOTH RENAL TRANSPLANT RECIPIENTS AND NON-TRANSPLANT INDIVIDUALS USING AN ESTABLISHED FLUORESCENT IN SITU HYBRIDISATION METHOD FOR ARCHIVAL TUMOUR MATERIAL.

LYNCH Ailish, CONNEELY Maura, PERREM Kilian, LEADER Mary, KAY Elaine
Department of Pathology, The Royal College of Surgeons in Ireland, Beaumont Hospital, Dublin 9, Ireland.

Telomeres are specialised repeats at the extreme ends of chromosomes that prevent chromosomal instability and that shorten in most normal somatic cells at each round of cell division. This is due to the inability of the replication machinery to fully maintain the ends of linear DNA molecules. Critically shortened telomeres cause cessation of cellular proliferation and it is significant that most human cancers have reactivated the ribonucleoprotein enzyme telomerase, which compensates for telomere shortening and maintains the telomere lengths.
We have performed telomere length measurements in formalin fixed paraffin embedded tissue sections of both normal skin and squamous cell carcinoma from renal transplant recipients (SCCRTR) and non-transplant individuals (SCCN). These analyses were undertaken to determine whether telomere length maintenance via telomerase plays a role in the almost 100-fold increased incidence and more biologically aggressive nature of the SCCs that develop in immunocompromised renal transplant patients, compared with the non-transplant population. Telomere lengths were determined using a modified TELomere Fluorescence In-Situ Hybridisation (TEL-FISH) technique recently developed for archival material. We examined TEL-FISH signals in 21 SCCRTR tumours, 25 SCCN lesions and in 10 normal skin specimens from both renal transplant and non-transplant patient groups. We then established a telomere length standard curve using FISH and Southern analysis of telomere lengths from three different human cell lines. Statistical analysis subsequently revealed that both SCCRTR and SCCN tumours have shorter telomeres than their respective normal skin controls, which is consistent with the telomere length profiles of many types of carcinoma. Furthermore, there is a statistically significant trend towards longer telomeres in the SCCRTR than in the SCCN tumours. This may be indicative of a central role for telomere lengthening and maintenance in the increased incidence and aggressiveness of SCC in renal transplant recipients.

P 948

BASAL CELL CARCINOMAS OF THE SCROTUM

CINGIL H. Istanbul Naval Hospital, Istanbul, Turkey

Introduction: Basal Cell Carcinoma(BCC) is the most common human tumor. However, its appearance on scrotal skin is rare with an estimated incidence of 0.1/100.000 cases per year. These tumors must be differentiated from the more common Squamous Cell Carcinoma(SCC).
Purpose: Their etiology remains unclear compared to the occupational predisposing factors reported in the literature for SCC in the same area. Wide surgical excision is recommended and prognosis is usually good. I report the clinical and histologic features of scrotal BCC and review the literature. Methods: A 88-year-old man presented with a 6-month history of asymptomatic scrotal plaque. Physical examination lesion was 1.2cm. indiameter, erythematous and had irregular, ill defined borders. No adenopathy was present and the remainder of the skin examination was unremarkable. In case, it was no history of trauma, radiation therapy, or exposure to chemicals, or arsenic. Results: Tissue from the incisional and then excisional biopsy were fixed in formalin and embedded in paraffin. Samples were stained with hematoxylin and eosin. Biopsy specimen showed superficial BCC. The lesion was excised with a margin of 1.8cm. of normal skin. Examination of the surgical specimen revealed a superficial BCC, which was completely excised. The patient has been free of disease for 24 months. Conclusion: Scrotal carcinomas are uncommon, with an estimated annual incidence of 0.1/100.000. The majority are squamous lesions and cases of BCC of the scrotum have been documented in the world literature. In contrast to SCC, BCC is usually of low malignancy. Thorough clinical evaluation, followed by wide local excision may be most appropriate initial therapeutic approach to these lesions.

P 949

EXPRESSION PROFILES OF P53 AND KI67 IN PREINVASIVE AND INVASIVE LESIONS OF BURN SCAR

SAKIZ Damlanur, TASKIN Tugba, LIVAOGLU Ayten, KARASOY Aysin, KABUKCUOGLU Fevziye
Departments of Pathology, Plastic and Reconstructive Surgery Sisli Etfal Education and Research Hospital, Department of Pathology Erzurum State Hospital

Introduction: Burn scars with the reconstruction difficulties and developing tumor are still the lesions that cause problems. In the background of burn scars usually squamous cell carcinoma, basal cell carcinoma, malignant melanoma, skin adnexial tumors and soft tissue sarcomas can develop. In this study we investigated the presence of reactive atipia, dysplasia, melanocytic hyperplasia, melanocytic atypia in the

epidermis and the tumors that develop from burn scars and evaluated the relation of these findings with p53 and Ki67 immunohistochemically.
Materials Methods: The study subjects were 35 cases of burn scar from 1999 to 2005. Parafin blocks of all specimens were examined immunohistochemically with monoclonal antibodies p53 and Ki67.
Results: 21 cases were male and 14 female. Their ages varied from 9 to 80 years, with a mean age of 44.6 years. The causes of the initial burn injury were flame, 20; hot water, 4; lightning, 3; electrical, 1; chemical , 1; and hot milk,1. The duration of burn ranged from 10 months to 57 years with a mean of 27,3 years. The lesions were located on the limbs in 22 cases, 8 on the head and neck, and 5 on the trunk.
On the histopathological examination we described squamous cell carcinoma in 10 cases, malignant melanoma acral lentiginous type in 1 case, basosquamous cell carcinoma in 1 case and pseudosarcomatous fasciitis in 1 case. In the cases that had no tumor, showed the following changes in the epidermis: low grade and high grade dysplasia in 2 cases, low grade dysplasia in 11 cases, melanocytic hyperplasia in 10 cases, atypical melanocytic proliferation in 3 cases, reactive atypia in 5 cases, and changes indefinite for dysplasia in 2 cases. In 2 cases there were no pathological finding in the epidermis. With Ki67 proliferation marker, in the cases with dysplasia, there was a continuous nuclear staining at the basal layer of the epidermis. The tumors showed high staining ratio with Ki67. In the cases with dysplasia or tumor, we established varying staining ratios with p53.
Conclusion: In this report we found out that Ki67 proliferation marker can be helpful in the differential diagnosis of the dysplasia in burn scars. We also suggest that p53 gene mutation can play a role in some of the tumors that arise in burn scars.

P 950
MULTIPLE CONDYLOMATOUS CARCINOMA (WARTY CARCINOMA): A CASE REPORT
SAKIZ Damlanur, TASKIN Tugba, KABUKCUOGLU Fevziye, KARSIDAG HACIKERIM Semra
Departments of Pathology, Plastic and Reconstructive Surgery Sisli Etfal Education and Research Hospital

Introduction: Condylomatous carcinoma is a variant of squamous cell carcinoma that has marked condylomatous features. Unlike verrucous carcinoma, condylomatous carcinoma demonstrate features of cytoplasmic vacuolization and nuclear changes resembling koilocytic atypia. It is frequently associated with HPV infection. This tumor has been reported in various sites, such as anogenital region, oral cavity, vagina, cervix and bladder. Two condylomatous carcinomas which arise in condyloma acuminata in the same patient are introduced.
Case Report: The patient was a 66 year old, male. He referred with genital and right axillary lesions, present for 15 years. The diameters of the tumors were 15cm and 2,7cm in the genital and axillar regions respectively. On histopathological examination, there were typical features of condyloma acuminatum at the periphery of each lesion. Each tumor has multiple papillary projections with a keratinized epithelial surface. Most of the tumor cells have cytoplasmic perinuclear clearing similar to koilocytosis.
Conclusion: To our knowledge, this is the first case of multiple condylomatous carcinoma on the skin. Light microscopic, immunohistochemical features and differential diagnosis of condylomatous carcinoma are presented here.

P 951
THE FIRST REPORT ON SARCOID OCCURRENCE IN CASPIAN PONY IN IRAN
Abavisani,Abbas
Maleki,Mohsen
Adibnishabouri

INTRODUCTION:
Sarcoid as the most common skin tumor,take place in different breeds,colors,and both genders of perisodactyla(horse,donkey,mule).The most common areas of such an occurrence are those area with thin skin and less hair.Diffrent forms of sarcoi consist occult,warty,fibroblastic, and mixed types. Treatment approaches are different,but recurrent state is the most important problem in this regard.
Methods and materials:
A five-year-old Caspian pony was observed with a warty mass in axillary site and around its prepuce in rakhsh equestrian section of khorasan Jihad-e-agriculture educational complex and was examined. To confirm the diagnosis,the biopsy of the mass was conducted .
Results and conclusions:
Given the examination of the mass under study,the sarcoid warty type was identified. The histopathological examinations proved the sarcoid tumor.They include acantotic hyperplasia,prolifration of sattelite and fusiform fibroblasts,vast ground substance with collagen fibers and mitotic form of cells.
Although sarcoid has been frequently reported in horse so far,the recent article is the first report of sarcoid occurrence in Caspian pony.
Key words: sarcoid, caspian pony.

THE NATURAL COMPOUND BUTYLIDENEPHTHALIDE STRONGLY SUPPRESSES HUMAN MALIGNANT BRAIN TUMOR GROWTH IN VITRO AND IN VIVO
Nu-Man Tsai. Shinn-Zong Lin, Chau-Chin Leec, Hsuan-Chi Su, Wen-Liang Chang, Horng-Jyh Harn
Institute of Medical Sciences, Buddhist Tzu-Chi University, Hualien, Taiwan, ROCa;
Neuro-Medical Scientific Centerb and Departments of Radiologyc and Pathologyd, Buddhist Tzu Chi General Hospital, Hualien, Taiwan, R.O.C., and School of Pharmacy, National Defense Medical Center ,Taipei, Taiwan

Brain tumors are the third leading cause of cancer-related death in those aged 15-34 years old. In particular, glioblastoma multiforme (GBM) and malignant gliomas present the lowest one-year survival rates. Current anti-tumor drugs are not effective against GBM. The naturally occurring compound butylidenephthalide (BP) isolated from the chloroform extract of Angelica sinensis (AS-C) has been studied in treatment of angina. Presently, we report on the potency of BP in the growth suppression of malignant brain tumor cells without coincident fibroblast cytotocixity. BP up-regulated the expression of CKI including p16 and p21 and down-regulated the expressions of cell cycle regulators. The result was a decrease of phosphorylated Rb proteins and the cell arrest at G0/G1 phase. The expression of p53 protein was increased by BP and correlated with the activation of apoptosis-associated proteins. In vivo, BP not only suppressed growth of subcutaneous rat and human brain tumors, but also shrank the volume of GBM tumors in situ. The post-BP survival period of the rats was significantly prolonged. These in vitro and in vivo anticancer effects indicates that BP has the potential as a new anti-brain tumor drug.

AN ANALYSIS OF CENTRAL NERVOUS SYTSEM TUMORS IN RASOOL AKRAM HOSPITAL IN IRAN
SADEGHIPOOR Alireza,SABZEVARY Saeedeh
Departement of neurosurgery, Rasool Akram Hospital, Tehran, Iran

Neoplasm of the nervous system and its adjacent structures are diverse group of lesions.They can be primary neoplasm in all degrees of differentiation derived from any of the many normal cellular constituents of this organ or secondary neoplasm metastatic from a variety of primary sites.
A series of 240 pathologically verified brain and spinal cord tumors from the neurosurgical department of Rasool Akram Hospital in Tehran, Iran were analyzed for the relative incidence as well as the distribution of the age and sex.
These data were compared with series from another countries.The male/female ratio was 119/121 and the age distribution was:<4 years old(y/o)(3.7%), 4-11 y/o(8.1%), 12-18 y/o(3.6%), 19-44 y/o(45%), 45-54 y/o(16%), 55-64 y/o(12%), 65-74 y/o(9.9%) and >75 y/o(1.3%).Percentage of representative tumors were meningioma(26.25%), glioma(25.4%), pituitary adenoma(11.6%), and neurinoma(13.7%).The incidence of glioma was lower and that of neurinoma was higher in Rasool Akram Hospital than those in other reports.

P 954
PATHOLOGIC CHARACTERISTICS OF CONVENTIONAL AND ANAPLASTIC PLEOMORPHIC XANTHOASTROCYTOMAS
Takanori Hirose, MD
Department of Pathology, Saitama Medical School
Moroyama, Irumagun, Saitama 350-0495, JAPAN

Introduction: Pleomorphic xanthoastrocytoma (PXA) is an uncommon CNS tumor characterized by a relatively favorable prognosis despite of ominous pathologic features. However, PXA may occasionally undergo anaplastic transformation. The aim of this study is to clarify pathologic characteristics of conventional and anaplastic PXAs.
Cases: According to the WHO classification, 8 PXAs were divided into conventional (5) and anaplastic (3) types. The age of 8 patients (7 females and 1 male) ranged from 16 to 79 years (median 45.5, mean 42.6). All tumors were located in supratentorial regions: frontal (3), occipital (2), parietal (1), frontotemporal (1), and sellar (1). Radiologic images, available in 5 patients, exhibited contrast-enhancement in 5 and cystic changes in 3.
Results: All tumors showed typical microscopic features of PXA, that is, pleomorphic tumor cells with xanthic changes, intranuclear pseudoinclusion, marked desmoplasia, perivascular lymphoid cuff, numerous eosinophilic granular bodies, and occasional calcification. In anaplastic PXA, monotonous proliferation of atypical cells was noted and mitotic counts were 10, 11, and 15/10 HPF, respectively. Two also showed necrosis and microvascular proliferation. One was a combined tumor of conventional PXA and glioblastoma. Another PXA underwent anaplastic changes through two recurrences. PXA showed immunoreactivity for GFAP (100%), S-100 protein (100%), neurofilament proteins (88%), and synaptophysin (33%).
Conclusions: Anaplastic transformation may occur de novo or through recurrences in PXA probably more frequently than previously postulated. This anaplastic variant should be distinguished from glioblastoma by identifying areas showing conventional microscopic features. PXA often shows neuronal immunophenotype, which may arouse some controversies about its classification and histogenesis.

P 955
THE RHABDOID TUMOURS OF THE NERVE CENTRE : SEVEN CASE STUDIES
CHTOUROU Imen, MAKNI Saloua, KHABIR Abdelmajid, BAHRI Ibticem, MNIF Hela, SELLAMI Ahmed, BOUDAWARA SELLAMI Tahya

Introduction :
The rhabdoid cerebral tumours were first identified by Beckwith and Palmer in 1978.Their frequence was estimated to be 2,1% of those affecting children under eighteen. Such tumours are equally characterised by a critically and speedy mortal development. Their historical genesis is still a controversial issue.
Purpose statement:
The aim of the present study is to discuss the various anatomically clinical aspects and examine the prognosis of this rare tumours.
Methods and materials:
In the course of this study, we will observe, examine and compare seven cases hospitalised in a period of eight years (1994-1997) in the sfax laboratory of anatomy and pathological cytology.
Results:
The average age of hospitalised patients is 22 years old among whom four being under fourteen and five males. The clinical symptomatology showed a predominance of the intracranial hypertension syndrom. Radiography through magnetic resonance revelat a heterogenous tumours processus localised respectively at the level of the spine (two cases), the insula (1 case) the temporal front (three cases) and the medulla (one case). The histological examination of those tumours has also showed a proliferation of giant cells whose cytoplasmic inclusion is hyalin based. These inclusion were rather positive for the vimentine and the keratin.
A tumours rhabdoid diagnosis was made and an adjuvant X-ray treatment was prescribed for five patients. The evolution was equally marked by a recurrence of rhabdoid tumoursamong three cases. Five patients were pronounced dead with a delay range between a week to eighteen months.
Conclusion:
The cerebral rhabdoid malignant tumour constitutes one of the most aggressive intracranial tumours. Still, there is hardly any efficient therapeutic protocol.

P 956
EXPRESSION OF TTF-1, CK7, AND CK20 IN BRAIN METASTASES
JUNG shih-ming, CHU po-hsien
Department of Pathology and Internal Medicine, Chang Gung Memorial Hospital and Chang Gung University, Taoyuan, Taiwan

Introduction: Metastatic carcinoma to the brain is a common problem but complicated by the histologic similarity to determine the primary origin. Thyroid transcription factor (TTF-1) is a tissue specific transcription expressed in the thyroid cancer and lung neoplasms. In the present study, we evaluate the role of TTF-1, CK7, and CK20 in identifying the primary source.
Materials and Methods: Forty-eight consecutive cases of histological proven brain metastases cases were retrieved from a four-year period. Formalin-fixed, paraffin-embedded sections of metastatic carcinoma to the brain were immunostained with TTF-1, CK7, and CK20.
Results: There were 24 females and 24 males ranging in age from 35 to 78 years (mean 59 years). 22 cases were immunopositive for TTF-1. TTF-1 staining was present in 20 (71%) of the 28 metastatic lung carcinomas. 26 cases were negative for TTF-1 and the sites of origin included: lung (n=8), colon (n=7), breast (n=3), liver (n=2), esophagus (n=1), nasopharynx (n=1), kidney (n=1), prostate (n=1), and unknown primary (n=2). CK7 staining was present in 26 (93%) of the 28 metastatic lung carcinomas. CK20 staining was negative in 24 (86%) of the 28 metastatic lung carcinomas. 28 metastatic lung carcinomas showed CK7(+)/TTF-1(+)/CK20(-) (n=17), CK7(+)/TTF-1(+)/CK20(+) (n=3), CK7(+)/TTF-1(-)/CK20(-) (n=5), CK7(+)/TTF-1(-)/CK20(+) (n=1), CK7(-)/TTF-1(-)/CK20(-) (n=2).

Conclusion: CK 7 and TTF-1 are helpful aid in brain metastases with lung origin. Positive staining is suggestive of lung primary. However, in our study, about 30% of metastatic lung carcinomas to the brain are negative staining for TTF-1.

P 957

HAEMANGIOBLASTOMA : REPORT OF 5 CASES AND REVIEW OF THE LITERATURE

BENADRA Fatiha(1),RAIS Hanane(1), ELATTAR Hicham(1), AITBENALI Said(2),BELAABIDIA Badia(1)
(1) anatomie pathologie, (2)Neurochirurgie

Central nervous system haemangioblastoma is a histologically benign tumor that usually occurs in the cerebellum and represents 1,1 % to 2,4 % of all tumors of the central nervous system. Haemangioblastoma can present as sporadic lesions or as manifestations of Von Hippel-Lindau syndrome (VHL).
Five patients with haemangioblastoma are presented. They were 4 men and 1 woman . The age of patients at diagnosis ranged from 36 to 60 years. In 4 cases, the tumors were located in the cerebellum. One patient had intramedullary tumor. The younger patient had VHL syndrome. Histologically, the tumors were composed of small blood vessels and large vacuolated stromal cells. No deaths associated with surgery occurred.
Haemangioblastoma is a rare tumor, affects mostly young adults and has a favorable prognosis after surgery. However, patients with VHL syndrome are at risk of developing new lesions. They require lifelong follow-up

P 958

LARGE CELL/ANAPLASTIC MEDULLOBLASTOMA WITH LONG SURVIVAL - A CASE REPORT

CVETKOVIC-DOZIC Dubravka*, GOLUBICIC Ivana**, DOZIC Slobodan*, SKENDER-GAZIBARA Milica*, DOZIC Branko*
Institute of Pathology, School of Medicine* and Institute of Oncology and Radiology of Serbia**, University of Belgrade, Serbia and Montenegro

Medulloblastomas (MBs) are malignant small cell embryonal tumors of the cerebellum found predominantly in children. Modern diagnostic methods, classification and treatment of MBs contribute to the progress in five-year survival. However, the clinical outcome and response to therapy is sometimes difficult to predict although, there are some increasing evidence that clinical outcome may depend on histological type of MB. Besides the histologically “classic” MBs there are two extremes of the histological spectrum that could correlate to their survival: MBs with extensive nodularity versus large cell/anaplastic (LC/A) MBs which are associated with better and worse clinical outcome, respectively.
We present a case of LC/A MB with unusual long survival. Our patient 26 years-old male was operated on for the first time at the age of 11-years because of cerebellar tumor without CSF dissemination. The tumor was totally resected and diagnosed as MB. The combined radiation and chemotherapy for pediatric MB was performed and the patient was free of disease without cognitive and hormonal disturbances almost fifteen years. He was followed-up with serial brain CT scans and MRI. In the meantime he graduated Secondary School and University School for Agriculture. At the age of 26-years because of recurrent cerebellar tumor the patient underwent to the second operation. However he died three months later due to CSF metastases.
We analyzed histologically and immunohistochemically surgical specimens of the first and recurrent tumor. Both tumors were similar and showed the features of LC/A MB. Histologically, they were predominantly composed of large highly pleomorphic cells that wrapped around one another. Their nuclei were also large, markedly atypical with irregular shapes, often without prominent nucleoli. The mitotic and apoptotic rate were increased. There were zones of necrosis and vascular proliferation. In the vicinity of highly severe anaplastic foci of LC/A MB small zones of “classic” MB were present. Immunohistochemically, the cells expressed synaptophysin, NF and focally GFAP. The EMA, LCA, CK and SMA were negative.

The poor survival should be expected in our case with LC/A MB. However, patient age, absence of CSF metastases and total tumor resection may contribute to long survival of fifteen years. We concluded that determination of histological subtype of MBs is not sufficient for clinical outcome and that the correlation with clinical data is mandatory.

INTRACRANIAL LOW GRADE FIBROMYXOID SARCOMA (A CASE REPORT)

Mahzooni Parvin MD *, Sanei Mohammad Hossein MD *, Masih Saboori MD†
*Department of pathology, Isfahan university school of Medicin, Isfahan
†Department of neurosurgery, Isfahan university school of Medicin, Isfahan

Intracranial low grade fibromyxoid sarcoma (A case report)
We report Low grade fibromyxoid sarcoma of brain(LGFS) a very rare tumor in the twelve's years old boy with history of temporal bulging from two months ago.MRI study was shown a large extra-axial mass with wide dural base at left frontal region with compress effect on brain tissue and subfalcian herniation and thinning of bone.Resected tumor was 10*9*5 cm with firm gray cut surface.In microscopic examination ,proliferation of bland spindle cell in background of fibromyxoid stroma was seen.cellularity varied from low to high.we considered all primary or metastatic spindle cell tumor ,include: neurofibroma, schwannoma, perineurioma, fibromatosis, solitary fibrous tumor, , myxofibrosarcoma , chordoma,and mono phasic synovial sarcoma .The tumor cells were negative for pancytokeratin ,epithelial membrane antigen,S100, CD34, actin , GFAP and were reactive only for vimentin.Therfore, we have excluded all suggestive differential diagnosis and have established LGFS.In pub med we have found only one case of intracranial LGFS which was reported by paulus and colleage in1991.
Key words:Intracranial sarcoma, Low grade fibromyxoid sarcoma

P 960

EFFICACY OF NEUROENDOSCOPIC BIOPSIES IN OBTAINING MATERIAL FOR HISTOPATHOLOGICAL EXAMINATIONS OF BRAIN TUMORS IN PEDIATRIC PATIENTS.

Grajkowska W.1, Barszcz S.2, Roszkowski M.2, Daszkiewicz P.2, Gadaj P.2
1. Department of Pathology, 2. Department of Neurosurgery, Children’s Memorial Health Institute, Warsaw, Poland

Introduction
Neuroendoscopic biopsies seem to be valuable method in obtaining material for pathological examination in cases of intra- and periventricular brain tumors. The procedure is usually performed in patients in whom total microneurosurgical tumor resection is impossible or is to be delayed. In some cases neuroendoscopic technique facilitates removal of small intraventricular lesions.
Aims of the study were: 1. to evaluate the efficacy of endoscopy in obtaining representative tissue samples according to particular tumor locations; 2. to estimate the accuracy of pathological diagnosis in a subgroup of patients in whom pathology was verified by open or stereotactic

biopsies; 3. to define locations and growth characteristics of tumors where endoscopic biopsies were ineffective.
Material and methods
Between years 1996 and 2003 we performed 93 neuroendoscopic biopsies of brain tumors in children. The material was analysed according to the following locations of the lesions: tumors of the lateral ventricles, suprasellar tumors, pineal region and posterior third ventricle tumors, thalamic tumors (focal and diffuse), posterior fossa tumors and others.
Results
In 65/93 cases representative samples were obtained. In the remaining 28/93 patients the biopsies were not informative, the samples were too small or the tissue specimens were removed from the tumor margins. In 55 out of 93 patients open and/or stereotactic biopsies were also performed, moreover in 42 children we could compare the diagnoses established on the basis of neuroendoscopic biopsies with the diagnoses after open/stereotactic procedures. In 38/42 cases the diagnoses were the same. The biopsies of thalamic tumors were less reliable. Ineffective procedures in 3/8 lesions of lateral ventricles were caused by thin ependymal tumor spread, marked tissue necrosis or calcifications.
Conclusions
This study proved that neuroendoscopic biopsies were most effective in cases of suprasellar, pineal region and posterior third ventricle tumors as well as in patients with posterior fossa lesions. The biopsies of thalamic tumors were less reliable.
Stereotactic or open biopsy seem to be better method for thalamic lesions. Indications for neuroendoscopic procedures should be established on the basis of careful evaluation of neuroradiologic examinations to avoid false results.

P 961
MALIGNANT PERIPHERAL NERVE SHEATH TUMOR (MPNST) WITH GIANT ROSETTES: THE FIRST CASE ASSOCIATED WITH SPINAL NERVES IN NEUROFIBROMATOSIS (NF1).
MOLNÁR Péter Pál(1), SZILÁGYI László(2), NÉMETH Tamás(1), LAJGUT Attila(3), DOBAI József(3)
(1)University of Debrecen, Medical and Health Sciences Center, Department of Pathology; (2)Regional Hospital, Department of Pathology, Berettyóújfalu; (3)County Medical Center, Department of Neurosurgery, Miskolc, Hungary

Introduction: MPNST associated with NF1 and characterized by giant rosettes, complex immunohistochemical (IHC) profile, arising from spinal nerve-roots has not as yet been reported.
Purpose: To present the results of thorough analysis of the first case of MPNST with giant rosettes arising from spinal nerves and associated with NF1, and to discuss differential diagnostic aspects of the case.
Methods: conventional histological, IHC and electron microscopic (TEM) methods were used on formalin-fixed, paraffin embedded tissue.
Findings: The 24-y-old woman had had café-au-lait spots, several subcutaneous and one subpleural, indolent, slowly growing nodules, that did not cause clinical or cosmetic problems. She was admitted and urgently operated on because of subtotal „cauda-syndrome'. Partial resection of a necrotic, hemorrhagic, grossly encapsulated tumor, attached to a nerve root, located at the level of vertebrae ThXII-LII was accomplished. Severe, progressive caudal syndrome developed 4 months later and the patient died of ARDS. None of the neurofibromata were malignant. The caudal 18 cm long portion of the myelon was almost completely destroyed by a firm, hemorrhagic-necrotic, grayish-white neoplasm ensheathing nerve roots and the filum terminale without distant metastases. The spindle-celled tumor displyed focal regimentation and whorls. Antoni A or B areas and Verocay bodies were absent. The mitotic activity was marked (Mib-1 LI: 35-55%.) Rich vascularity with endothelial cells which strongly reacted with CD31, CD34 and FVIII was present. The vascular smooth muscle cells were SM actin positive. None of these antibodies reacted with the neoplastic elements. The latter were intensively decorated by vimentin and S100, were focally positive with NSE, NF, GFAP. Desmin, panCK, FXIIIa, CK14, CAM5.2, synaptophysin and CD57 did not react with the tumor cells. The most striking feature was the high number of S100 and NSE positive giant rosettes (diameter = 100-350 μm). Homer-Wright- or ependymal rosettes and perivascular pseudorosettes were absent. EM showed schwannian differentiation, broad processes, incomplete basal lamina plus long spacing collagen and broad amianthoid fibers in the matrix.
Differential diagnosis: giant rosettes were described in one case of „neuroblastoma-like neurilemmoma' and rarely in fibromyxoid fibrosarcoma, but our results excluded these entities. A thorough search of PubMed and Google Scholar failed to disclose a similar case.

P 962
CORRELATION OF THE HISTOLOGICAL FEATURES AND CLINICAL PICTURE IN VESTIBULAR SCHWANNOMAS
BIERZYNSKA-MACYSZYN Grazyna *, KWIEK Stanislaw J. **, WLASZCZUK Pawel *, GOLKA Dariusz *, LUSZAWSK Jerzy I**, BAZOWSKI Piotr **, WOJCIKIEWICZ Tomasz **
*Department of Pathology, and **Department of Neurosurgery in Katowice,
Medical University of Silesia, Katowice, Poland

The objective of the study was to evaluate relationships between histological features of vestibular Schwannomas and onset of early clinical symptoms.

The 125 patients, who had their first surgery for vestibular Schwannoma in the years 1988-2004, were analyzed retrospectively.

Conventional Schwannoma (including the “ancient” variety) and Cellular Schwannoma variant, according to the WHO 2000 classification, were diagnosed. The relationships of facial nerve paresis before the surgery and the histology of the tumour (including 15 morphological criteria), the tumour size and historical classification into Antoni A, B and mixed types, were statistically analysed.

· The early onset of facial nerve paresis was most frequent (50%) in patients suffering from Cellular Schwannoma variant, less frequent in connection with Conventional (ancient) Schwannoma (37%), and the least frequent in Conventional Schwannoma (26%).

· In the group of “small” tumours (up to 20mm), the incidence of facial nerve paresis was lower (25%) than in “medium sized” lesions (20-40mm), and in “large” tumours (larger than 40mm). In these two groups, the incidence of facial nerve paresis was nearly equal (36% and 38% respectively).

· Facial nerve paresis before the surgery was observed with similar frequency (33% and 38%) in cases classified as Antoni A and A/B or as in Antoni B and B/A. These relationships were representative for tumours of different diameters.

· Analysis of relationship between early onset of the facial nerve paresis and histological picture of vestibular Schwannomas revealed statistically significant correlation ($chi2=6,56$; $p<0,05$) of this symptom with low cellularity of the tumour. The paresis appeared sooner in lesions with low number of cells, rich in blood vessels, with effusions, oedema, other degenerative changes, necrosis in large tumours.

· We observed as well statistically significant coexistence ($chi2=6,63$; $p<0,05$) of early onset of the facial nerve paresis and numerous Verocay’s bodies, plexiform

structures, coiled structures and nuclear palisades in small tumours.

· Correlations of other morphological features and early onset of facial nerve paresis were not statistically significant.

P 963

P 53, KI-67 AND BAX EXPRESSION AND THEIR RELATION WITH SURVIVAL IN GRADE II AND GRADE IV ASTROCYTOMAS

GÜRER Ýnanç Elif MD., UÇAR Tanju* MD., BAÞSORGUN Ýbrahim MD., KORKMAZ Emre* MD., GÖKHAN Güzide MD. Departments of Pathology and Neurosurgery* of the University Hospital of Akdeniz, ANTALYA, TURKEY

Introduction: Diffusely infiltrating astrocytomas are the most frequent intracranial neoplasms. Patient factors influencing patient survival includes the age and the general condition, tumor location and the adequacy of the surgical resection performed prior to conditional radiotherapy and/ or chemotherapy. Mutation of tumor supressor genes, expression apopitosis related genes and Ki-67 labeling index are the markers used to predict the patient survival.

Purpose of the study: In this study, we investigated immunohistochemical expression and the correlation between proapopitotic gene bax, Ki-67 labeling index and mutant p53 in glioblastoma multiforme (GBM) and grade II astrocytoma specimens with the patients' survival.

Material and methods: The immunohistochemical expression of p53,Ki-67 and bax, in the specimens of the 9 grade II, and 40 in GBM specimens who underwent resection for glial tumors in the Department of Neurosurgery were evaluated. Histological parameters were based on WHO criteria. Grade II and IV tumors were compared by Mann-Whitney U tests. Spearmans's rho test was used to analyse the correlation between parameters.Karnovsky performance scale was used for the survival.

Results: 9 patients with grade II and 40 patients with grade IV tumors were evaluated. Median ages were 39 in grade II, 50 in grade IV tumors (p= 0.009). Median Ki-67 values were 4 in grade II and , 14.5 in grade IV tumors (p=0.001). No difference for bax, p53 or Karnovsky score was observed between groups. Correlation analysis showed no statistically significant relation between age, Karnovsky score and immunostaining parameters.

Conclusion: Value of the largely used immunohistochemical markers related with apopitosis or cell proliferation in prediction of the patient survival is controversial.It seems that adequate surgical resection is the gold standart for the patients with glial tumors. In this study we conclude that utilisation of these markers is not cost effective since we did not obtain statistically significant results.

ANALYSIS OF PROTEIN EXPRESSION REGULATING THE PI3-K/PKB/AKT SIGNALING PATHWAY IN RELATION TO ASTROCYTOMA PATHOGENESIS

HLOBILKOVA Alice, MALIKOVA Jana, SEDLAKOVA Eva, EHRMANN Jiri, SVACHOVA Michaela, STRAKOVA Nicol, FIURASKOVA Michala, BRYCHTOVA Svetlana, and KOLAR Zdenek

Laboratory of Molecular Pathology and Institute of Pathology, Faculty of Medicine, Palacky University, Hnevotinska 3, Olomouc, CZ-775 15, Czech Republic, hlob@hotmail.com

Introduction: The most frequent alterations in astrocytomas are mutations and deletions of the tumour suppressor genes PTEN, p53 and amplification of epidermal growth factor receptor (EGFR) and platelet derived growth factor receptor (PDGFR). Growth factor receptors activate phosphatidyl-inositol-3-kinase (PI3-K) in the PI3-K/protein kinase B/Akt (PI3-K/PKB/Akt) pathway. PTEN dephosporylates phosphatidyl-inositol-3 phosphate and inactivates its downstream target, PKB/Akt.

Aim: The aim of our study was to detect changes in: PTEN, the phosphorylated form of PKB/Akt and EGFR protein expression in astrocytoma tissue samples.

Material and methods: We used paraffin embedded astrocytoma tissue samples from 71 patients which were divided into low grade astrocytomas (grade I-II) 34 samples and high grade astrocytomas (grade III IV) 37 samples. Mouse monoclonal antibodies against PTEN (26H9, Cell Signaling), PKB/Akt phosphorylated on serin 473 (587F11, Cell Signalig) and EGFR (31G7, Zymed) were used, followed by standard indirect immunohistochemical method with Envision plus kit (DakoCytomation).

Results: EGFR was expressed mainly in membranes. EGFR protein expression was detected in 25 % of low grade and in 65 % of high grade astrocytomas with stronger intensity of staining in high grade compare to low grade tumours. The phosphorylated form of PKB/Akt was localised in both nucleus and cytoplasm. Protein expression of phosphorylated PKB/Akt was found in about 85 % in both groups of astrocytomas with similar intensity of staining. In the group of high grade tumours a slight increase in PKB/Akt phosphorylation in the nucleus was observed. PTEN was detected mainly in the cell cytoplasm but in a few cases it was seen in the nucleus. Generally, PTEN protein expression was lower compared to EGFR and the phosphorylated form of PKB/Akt expression. PTEN was detected in 30 % of all astrocytomas, in 20 % of high grade, and in 40 % of low grade tumours.

Conclusion: Protein expression of EGFR increases with astrocytoma grading. This may subsequently lead to activation of PI3 K/PKB/Akt survival pathway. A rather suprising finding was no difference in phoshorylation of PKB/Akt in either group of tumours. We expected high level of PKB/Akt phosphorylation in high grade astrocytomas. PTEN expression was alterated in more than half the analysed astrocytomas, more frequently in high grade tumours.

GRANULAR CELL ASTROCYTOMA: A RARE MORPHOLOGIC VARIANT OF DIFFUSE ASTROCYTOMAS

YILDIRIM S, KURTKAYA YAPICIER O*, HAHOLU A, YILMAZ I, CERMÝK H, BERBER U, BALOGLU H

GATA HEH Pathology Department and *Marmara University Neurologic Sciences Instýtute ISTANBUL,TR

Aim: To present a rare morphologic variant of diffuse astrocytoma, namely granular cell asstrocytoma and to define the diagnostic criteria of this tumor.

Introduction: Granular cell astrocytoma is an infiltrative glioma consisting of astrocytes with prominent granular cytoplasm due to lyzozomal accumulation. Morphologically may be confused with demyenilating disorders, infarctus and other granular cell tumors. Although it has not been set in the recent WHO classification, it is known a granular cell variant of diffuse astrocytoma.

CASE REPORT

58 years old male aplied to our emergency room with a strong headache lasting for a month in lower stringency. In addition, tendency to sleep and walking disability were seen. Physical examination revealed only a left-sit paresis prominently. A 6x4.5X3 cm-contrast enhancing mass with an oedomatous halo was located in the cerebral right frontoparietal lob with a striking shift on his CT scans. The cerebral mass was totally removed under urgent surgical circumstances. On histologic examination of the sample submitted during the operation

were seen numerous macrophage-like cells as well as hemoragic and ischemic changes. Owing to atypical cells observed, low grade neuroglial tumors were included in the differentiel diagnosis. The microscopic examination of the permanent sections revealed the cells with abundant granular and polygonal cytoplasm, round and peripheral nuclei. Morphologically fibrilar formations were also seen in scarcely seperated spindle cells. Mitosis was observed, but there was no necrosis. The MIB-1 index was moderately high. Cytoplasms of the tumor cells showed strong PAS staining. Tumor cells were reactive for GFAP, S100, CD68 proteins immunohistochemically. The tumor was diagnosed as granular cell astrocytoma.
Conclusion: Because of the rarity and the morphologic similarity to some non-tumoral lesions of the cerebrum, practicing surgical pathologists should keep in mind this morphologic variant of diffuse astrocytoma.

EVALUATION OF HTERT IMMUNOPOSITIVITY IN THE BRAIN AND ASTROCYTIC TUMORS.
KOTOULA Vassiliki, CHEVA Angeliki, PAPADIMITRIOU Constantine, KARKAVELAS George
Dept. of Pathology, Medical School, Aristotle University, Thessaloniki, Greece

Assessing the histological grade of astrocytic tumors can be problematic because these tumors are often quite heterogeneous in terms of histology and biomarker distribution. This problem becomes more pronounced in stereotactic biopsies where limited material needs to be evaluated. In this study, we asked whether hTERT expression, which has been reported to correlate with the histological grade of astrocytic tumors, could serve as a diagnostic aid when evaluating stereotactic biopsies. For this purpose, we used 45 astrocytic tumor specimens, 31 of these from stereotactic biopsies (16 low-grade [I and II], 29 high- grade [III and IV]) and 12 normal brain specimens, 6 from patients without cancer. hTERT expression was assessed by immunohistochemistry (IHC) with the NCL-TERT antibody, in situ hybridization (ISH) and relative quantification (RQ) with real time PCR on paraffin embedded tissues. With ISH and IHC, hTERT was identified in the majority of neoplastic cells in high-grade tumors, but also in single neurons and endothelial cells. IHC further showed focal hTERT positivity in neoplastic cells of low-grade tumors that were negative with ISH. These findings corresponded to the RQ values obtained from hTERT positive microdissected specimen areas ($p < 0,001$) but not from respective whole tumor extracts. hTERT protein was specifically localized in the nucleus, in a lacy pattern with prominent nucleolar positivity (pattern A), or as dense granular staining throughout the nuclear area with or without recognizable nucleoli (pattern B). When positive, normal and neoplastic cells of all grades exhibited pattern A of hTERT protein distribution. Pattern B was observed rarely in neurons, focally in low-grade, and focally or diffuse in high-grade tumors. Rarely, cytoplasmic staining was observed. According to these data, IHC but not PCR seems to be a valuable tool for the investigation of hTERT in the brain, since astrocytic tumors heterogeneously express this protein. It will be interesting to evaluate the patterns of hTERT positivity in larger series of these tumors in order to determine the respective clinical impact. The limited but specific positivity observed in low-grade astrocytic tumors should be taken into account when assessing stereotactic biopsies with this marker. hTERT is expressed in normal neurons, a finding of potential important biological significance in the context of neuronal progenitor research.

CHONDROID METAPLASIA IN GLIOMAS - AN IMMUNOHISTOCHEMICAL STUDY
KODETOVA Daniela, ZAMECNIK Josef, SKAPA Petr, KODET Roman
Department of Pathology and Molecular Medicine, Charles University, 2nd Medical Faculty, Prague, Czech Republic

The presence of cartilage in neuroepithelial brain tumors was rarely reported in the literature and there are many controversies concerning its origin. We present an immunohistochemical study of four cases of gliomas (two ependymomas and two astrocytomas) in which foci of hyaline cartilage with a formation of metaplastic bone were found. No other tissues suggesting diagnosis of teratoma were identified. Immunohistochemistry for extracellular matrix (ECM) components (tenascin, vitronectin, fibronectin, laminin, collagen types II, IV and VI) revealed that the type II collagen, which represents one of the major structural components of a cartilage, was present in these tumors in the wall of the blood vessels as well as in the intercellular spaces. Investigation of other ECM glycoproteins, tenascin and type VI collagen, which were also reported to be structural components of human cartilage revealed a similar observation. The abundant ECM production was in these particular tumors accompanied by areas of dystrophic calcifications. The anti-GFAP immunohistochemical reaction revealed the cartilage to be GFAP-positive in the astrocytomas and in one case of ependymoma. We interpret the cartilaginous islands as having their origin from neoplastic glial cells. A rare coexistence of the specific local conditions such as calcifications and a capacity for production of cartilaginous ECM might lead in such gliomas to the formation of chondroid areas even with metaplastic ossification.

Glioblastoma multiforme (GBM) are the most frequent and malignant tumors of the human central nervous system. Within these tumors primary glioblastomas develop rapidly, with a short clinical history de novo, a mean age at diagnosis of 55 years, and with a genetic pathway showing EGFR gene amplification/overexpression, and only in exceptional cases TP53 mutations.
EGFR, a tyrosine kinase receptor, has been implicated in tumorigenesis and neoplastic progression in many tumors. EGFR has been reported to activate NFkB, a transcription factor that regulates genes involved in cell survival and oncogenesis.

We present 16 newly diagnosed GBM with initial symptoms detected between 7 days to 4 months before diagnosis. The mean age was 58 years old (ranging from 45 to 77 years). CT scans of the brain showed mass tumors in supratentorial localization, with a size from 2,5 to 4,5 cm large. Histopathological study revealed cellular heterogeneity, anaplasia and glial astrocytic differentiation. Hyperplastic and irregular vascularization, and necrosis have been observed. Evaluation of proliferation showed a mean of 6,5 mitosis per 10 HPF (ranging from 3 to 12) and a mean of 26,6% Ki-67 (MIB-1) labelling index. Neoplastic cells were GFAP

immunoreactive. Inmunohistochemical expression of EGFR was also detected.

All cases showed trisomy/polysomy of chromosome 7 by FISH analysis. EGFR gene amplification and no mutations in TP53 gene (exons 5 to 8) were demonstrated in all cases.

Overexpresion of NFKB was detected with EMSA (electrophoretic mobility shift assay) in 11 cases of these primary glioblastomas. Neoplastic cells showed positive expression of NFkB in all cases by immunohistochemistry.

These data suggest a relationship between EGFR activation and the NFkB transduction pathway during the neoplastic progression of primary glioblastomas.

HYPOXIA-INDUCIBLE FACTOR 1ALPHA (HIF-1) AND CARBONIC ANHYDRASE IX (CA 9) EXPRESSIONS IN GLIOBLASTOMA MULTIFORM ARE PREDICTIVE OF RESPONSE TO RADIATION THERAPY.

MOKHTARI Karima, SIMON J.Marc, BISSERY Anne, CAPRON Frederique, HAUW J.Jacques, JAILLON Patrice, GENESTIE Catherine.

Pitié-Salpêtrière and Saint-Antoine Hospitals, AP-HP, Paris, France.

Background: Tumor hypoxia is known to be associated with resistance to radiotherapy. Hypoxia induces the expression of hypoxia-inducible factor-1alpha (HIF-1), allowing up-regulation of the expression of downstream genes such as carbonic anhydrase IX (CA 9).

Methods: We examined the expression of HIF-1 and CA 9 by immunohistochemistry in glioblastoma multiform (GBM) biopsies, and investigated their relationship with response to radiation therapy. The response to irradiation was assessed by comparing contrast-enhanced magnetic resonance images obtained before and six weeks after the completion of radiotherapy. Assessment of odds ratio were based on the logistic regression model with stepwise adjustment. The multivariate model included HIF-1 and CA 9 coded on a semi quantitative scale according to the positive tumor cell percentage (0 = no expression; + = 1-10%; ++ = 11-50%; +++ = 51-100%), and age.

Results: Fifty six consecutive patients with inoperable glioblastoma treated with radiotherapy (59.4 Gy in 1.8 Gy/fraction) at the Pitié-Salpêtrière hospital between 1995 and 2002, were included in this study (median age: 56 years, range, 30 to 67 years). HIF-1 was expressed in 33 of 56 (59%), and CA 9 in 38 of 52 (73%) of glioblastomas. Tumor HIF-1 expression correlated significantly with that of CA 9 (Kappa = 0.23, p = 0.003). The response rate to radiotherapy for the entire population was 29%. The expressions of HIF-1 and CA 9 were correlated inversely with the rate of response to radiotherapy (univariate analysis: HIF-1 +: odds ratio 0.21, 95% CI [0.06, 0.71], p = 0.012; CA 9 +: odds ratio 0.15, 95% CI [0.04, 0.59], p = 0.0063). The multivariate analysis showed that HIF-1 + (odds ratio 0.13, 95% CI [0.03, 0.65], p = 0.013), CA 9 +++ (odds ratio 0.21, 95% CI [0.04, 0.98], p = 0.047) and age (odds ratio 0.91, 95% CI [0.82, 0.99], p = 0.046) were independent predictors of response to radiotherapy.

Conclusions: Glioblastomas with a hypoxic profile (expression of HIF-1 and/or CA 9) were associated with a significantly worse response to radiotherapy, independently of known prognostic factors.

According to the classical model of carcinogenesis in glioblastoma multiforme (GM) the primary (de novo) GM is related mainly to the amplification or overexpression of EGFR and MDM2, LOH 10p and 10q, p16 deletion, PTEN mutation. The secondary GM, occurring after the progression of low-grade astrocytomas is related to the p53 mutation and loss of heterozygisity (LOH) on chromosome 17.

The aim of our study was identification of molecular markers in GM in 32 tumor tissue with GM and peripheral blood from patients. We examinated the LOH on chromosome 9, 10, 13, 17, EGFR amplification. Mutations of p53 were examinated in patients with EGFR amplification or/and LOH 10. Additionally, the immunohistochemical study was performed using antibodies against p53, Rb, EGFR, p21 and p27, Ki67.

LOH 10 was detected in 25% (8/32) cases, in one case a deletion on chromosome 10 was detected; LOH 9 in 15,5% (5/32); LOH 17 in 12,5% (4/32); LOH 13 in 9,3% (3/32); EGFR amplification was identified in 21,8% (7/32) cases.

In one of cases, p53 mutation was detected together with LOH 9,10, 13. In other unusual case, the genetic alterations were more complex, consisted in p53 mutation, LOH 10, LOH 17, and EGFR amplification.

Our study reveals, that molecular changes in GM may be complex and indicates overlapping of two main genetic pathways of primary and secondary GM.

P 971

PROGNOSTIC SIGNIFICANCE OF CELL CYCLE PROTEINS P53, P21, P27, P14, P16 AND MDM2 IN GLIOMAS.

ZOLOTA Vassiliki, TSAMANDAS Athanassios, AROUKATOS Panagiotis, FRATZOGLOY Akis*, PANAGIOTOPOULOS Vassilios*, SCOPA Chrisoula.Department of Pathology and *Neurosurgery, University of Patras, Medical School, Rion, Patras, Greece.

Background: Gliomas are among the most aggressive and treatment refractory of all human tumors and molecular pathogenesis has been under intense investigation as a part of the effort to develop more effective therapeutic strategies for these tumors. Cell cycle regulatory genes and especially CDK inhibitors have been found commonly affected in gliomas. This study investigates the immunohistochemical expression of 6 essential cell cycle proteins (p53, p21, p27, p14, p16 and mdm2) in astrocytomas and their correlation with tumor grade, proliferating index (Ki67 positivity) and patients' survival.

Material and Methods: Paraffin-embedded sections of 63 brain biopsies from equal number of patients with astrocytomas of the central nervous system divided in low grade (I and II, N=15) and high grade (III and IV, N=48) tumors, were analyzed immunohistochemically using polyclonal and monoclonal antibodies. Follow up data were available for all patients (follow-up time: 2-70 months, mean 22.2). Cases containing >5% immunostained tumor cells were

considered as positive. Tumors with high proliferating index were considered those with >10% immunostained tumor cells. Results: The number of cases in which the expression of p53, p14, p16, p21 p27 and mdm2 were detected was: 54%(34/63), 76%(48/63), 63%(40/63), 45%(28/63), 87%(55/63) and 100%(63/63) respectively. The mean index for Ki67 was 14.58. A highly significant relationship was observed between tumor grade and survival ($p<0.001$) as well as between proliferating index and survival ($p<0.001$). P53 and p21 were more frequently expressed in high grade tumors ($p<0.05$ respectively). P53 expression was associated with lower survival only in p21(+) tumors ($p<0.05$). Neither p14 nor p16 expression were associated with grade, Ki67 index or overall survival. Cox regression analysis revealed that only tumor grade and Ki67 index were independent prognostic factors (CI: 0.032-0.502, p=0.03 and CI:1.167-5.408, p=0.019).
Conclusions: The study confirms that in cases of gliomas, tumor grade and proliferating index, predict the outcome of the patients. P53 was associated with poor prognosis only in tumors overexpressing p21; that means high levels of p21 in tumor cells associated with aberrant p53 protein expression, may result in a state refractory to therapy.

P 972

ANTI-INVASIC AND ANTI-ANGIOGENIC EFFECTS OF MMI166 ON GLIOMA CELLS

Nakabayashi H, Park KC, Yamada SM, Toyonaga S, *Maki H, Shimizu K
Department of Neurosurgery, Kochi University, Medical School, Kochi, Japan and *SHIONOGI & CO., LTD., Osaka, Japan

Constitutive overexpression of matrix metallo-proteinases (MMPs) is frequently observed in malignant tumors. In particular, MMP-2 and MMP-9 are reported to be closely associated with invasion and angiogenesis in malignant gliomas. The aim of our study was to evaluate the anti-tumor effects of MMI-166, a new MMP inhibitor in three human glioma cell lines (T98G, U87MG, KNS2). The gene expression of MMP-2 and MMP-9 were analyzed by semi-quantative RT-PCR. The anti-invasive effect of MMI-166 was analyzed by in vitro invasion assay. The cytotoxicity of MMI-166 was determined by MTT assay. The gelatinase activity was analyzed by gelatin zymography. In vitro angiogenesis assay was also performed. Glioma cell lines, which produced both MMP-2 and MMP-9, showed invasive capacity in invasion assay. The invasion of glioma cells was suppressed by MMI-166. No remarkable suppression of the proliferation by MMI-166 was observed in the MTT assay. Gelatin zymography revealed complete suppression of MMP-2 and MMP-9 activity by MMI-166. Angiogenesis assay showed the suppressive effect of MMI-166 on angiogenesis induced by glioma cells. These results suggest that MMI-166 has potential suppresive effects on invasion and angiogenesis of glioma.

ESTROGEN RECEPTOR BETA (ERÂ) PROTEIN EXPRESSION CORRELATES WITH BAG-1 AND PROGNOSIS IN BRAIN GLIAL TUMOURS

Batistatou A1, Kyzas PA1, Goussia A1, Arkoumani E1, Voulgaris S2, Polyzoidis K2, Agnantis NJ1, Stefanou D2
1Department of Pathology and 2Department of Neurosurgery, University of Ioannina, Medical School, Ioannina, Greece

Introduction: Estrogen receptor â (ERâ) is an important mediator of estrogen function in a variety of tissues. Its expression declines in breast, ovarian, prostatic and colon carcinomas as well as in astrocytic tumours. BAG-1 is a multifunctional protein with anti-apoptotic action that may have an important role in neoplasia and is possibly regulated by estrogen receptors. One of the direct targets of BAG-1 is HSP70.
Aim: The purpose of this study was to analyse the expression pattern of ERâ, BAG-1 and HSP70 proteins in two distinct types of glial neoplasms (astrocytic and oligodendroglial), to investigate their possible correlation and probe their impact in prognosis.
Patients-Methods: ERâ, BAG-1 and HSP70 protein expression was monitored immunohistochemically in 66 cases of astrocytomas of all Grades (I-IV) and 20 oligodendrogliomas. Grading was performed according to the WHO grading system. Protein expression was detected by immunohistochemistry using the EnVision System (DAKO, Carpinteria, CA, USA) and the following antibodies: monospecific polyclonal antibody to Estrogen Receptor â protein (Ab No. 385P, Biogenex, San Ramon, CA, USA/ MENARINI diagnostics, Greece), monoclonal mouse antibody to BAG-1 (Mob 335, DBS, Pleasanton, CA, USA/MENARINI diagnostics, Greece) and monoclonal mouse antibody to HSP70 (clone 8B11, NOVOCASTRA Lab Ltd, Newcastle Upon Tyne, UK).
Results: In astrocytic tumours low ERâ expression correlated significantly with high grade ($p<0.001$), higher expression of cytoplasmic BAG-1 ($p<0.001$) and worse survival (log rank p=0.02). ERâ expression had an independent prognostic value for overall survival in this cohort of patients (Cox p=0.03). There was also statistically significant association of BAG-1 nuclear expression with HSP70 cytoplasmic expression. This last association was noted in oligodendrogliomas as well.
Conclusion: Our results strengthen the hypothesis that ERâ, BAG-1 and HSP70 play an important role in the pathogenesis and progression of glial neoplasms, particularly those of astrocytic origin. Moreover, ERâ expression in astrocytic tumors appears to be an important, independent prognostic factor for survival, and a possible target in therapeutic strategies.

P 974

EXPRESSION OF HISTONE GENES IN ASTROCYTIC BRAIN TUMOURS AND ITS PROGNOSTIC SIGNIFICANCE IN PATIENTS AFTER SURGICAL TREATMENT

SLOWINSKI Jerzy *, MAZUREK Urszula **, BIERZYNSKA-MACYSZYN Grazyna ***, ORCHEL Joanna **, GLOGOWSKA-LIGUS Joanna **, STOMAL Monika *, MROWKA Ryszard *
* Department of Neurosurgery and Neurotraumatology in Bytom, **Department of Molecular Biology and Genetics in Sosnowiec, ***Department of Pathology in Katowice, Medical University of Silesia, Poland

Introduction:
Expression of histone genes is known to reflect proliferative activity of normal and neoplastic cells. It is hypothesised that expression of histone genes also characterizes biological aggressiveness of astrocytic tumours (AT) and can be useful in the prediction of clinical course in patients after surgical treatment.
Purpose of the study: 1) To assess the correlation between expression of histone genes H1, H2A, H2B, H3 and H4 and histological grade as well as other proliferative indices in AT. 2) To validate the usefulness of histone genes expression in prognostication in patients with AT.
Methods:
Eighty four patients (52 men and 32 women, mean age: 50.5 years), with supratentorial astrocytic tumour grade II (n = 13), III (n = 19) and grade IV (n = 52) were studied. The expression of histone genes was analyzed semi-quantitatively by in situ hybridization (ISH) in paraffin sections and defined as histone labeling index (HLI). In 52 patients the histone genes expression was analyzed with quantitative reverse-transcriptase polymerase chain reaction (QRT-PCR). The

RNA extract served as a matrix in the QRT-PCR reaction for quantitative analysis of histone H1, H2A, H2B, H3 and H4 mRNAs, with application of sequence detector ABI Prism 7700 (TaqMan). The results of QRT-PCR reaction were calculated as a target gene mRNA copy number to the reference gene (beta-actin) mRNA copy number ratio. For ISH study a cocktail of fluorescent-labeled oligonucleotide probes, labeling histone H2B, H3 and H4 mRNAs was used. The Ki-67 labeling index was studied after immunostaining performed in paraffin sections with use of avidin-biotin complex.

Results:

The global expression of histone genes increased significantly with increasing grade of the tumour. Expression of histone H3 gene showed the highest correlation with histological grade (R=0.55), HLI (R=0.33) and Ki-67 (R=0.37) proliferative indices. Multivariate analysis using the Cox proportional hazard model showed that patient age, tumour grade, postoperative performance score and the expression of histone H3 gene are independent prognostic factors. Significantly shorter survival times were observed in patients with histone H3 mRNA levels higher than 1.26.

Conclusion:

Our results support value of the histone genes expression as a marker of biological malignancy, tumour progression and cellular proliferative activity in AT. The level of H3 mRNA is an independent molecular prognostic factor in patients

The difficulties connected with diagnosing and treating of gliomas are a reason to develop new methods of precise determination of these tumours biology. The determination of the gliomas malignancy was supplemented with molecular analysis of transcriptinal activity of some proliferation and apoptosis markers in stereotactic biopsy samples of these tumours.

The objective of our study was to determine the expression profiles of genes taking part in proliferation and apoptosis in diffuse brain astrocytomas and to search for correlation between mRNA concentration profiles of these genes,the findings of the morphological examinations, the course of the disease and the response to the implemented treatment.

The biopsy samples of 232 patients who had undergone stereotactic biopsy in the last 6 years in the Department of Neurosurgery in Sosnowiec, Poland, were investigated. In most patients, radiotherapy was the only treatment or it was adjuvant to surgery. The morphological and molecular analyses were carried out on 85 gliomas (30 cases of G2 WHO diffuse astrocytomas of low malignancy and 55 cases of G3 WHO anaplastic astrocytomas), 62 of these patients underwent radiotherapy.

An analysis of full clinical data, cytological examination, routine histopathological examination, determination of malignancy grade according to the WHO criteria and immunohistochemical proliferative responses (Ki-67) and investigation of apoptosis markers (p53, BCL2, BAX, FAS, FAS-L) were performed. A pattern of material processing for the molecular analysis was developed - the markers were determined by the RT-QPCR method (Taq-Man) with application of an ABI PRISM 7700 sequence detector. The response to brachytherapy was assessed with imaging techniques (CT, MRI).

We found that fixed in pure alcohol, dry and not-stained cytological smears are enough to obtain the amounts of mRNA sufficient to carry out molecular analyses. Analysing clinical data, histological findings, and number of the mRNA molecules coding H3, p53, BCL2, BAX and FAS proteins in the investigated material, we found that molecular investigations are better correlated with the course of the disease and the response to implemented treatment than morphological examinations. Our findings enable us to claim that assessment of the genes' expression may be considered as a valuable additional marker in the diagnosis and prognosis of diffused astrocytomas.

PROGNOSTIC SIGNIFICANCE OF STEROID HORMONE RECEPTORS AND DNA CONTENT IN MENINGIOMAS

Marwa A. El-Shaer
Sonia L. El-Sharkawy
Naglaa F. Abbas
Nabila S. Hassan

The possibility that meningioma growth may be related to female sex hormone levels is suggested by several lines of evidence. Meningiomas are twice as common in women as in men, have been observed to wax and wane with pregnancy, and are positively associated with breast cancer. However, unlike breast cancer, meningiomas are much more commonly positive for progesterone receptor than for estrogen receptors. Overall, 70% of meningioma specimens have been found positive for progesterone receptor while only 30% were positive for estrogen receptor. Therefore, clinically and biologically more interesting are the unexpectedly aggressive clinical course of some meningioma, is a diagnostic dilemma for routine histopathology. Comparison between hormone levels was mostly significant. Also the relationship between expression of progesterone with the ploidy determined by image cytometric measurement (Leica Quin 500 DNA Cytometry Software) has been interpreted as signs of aggressive in the tumor tissue support the possibility of their application as a test for grading and for adequate treatment choice.

Key words: Meningioma-Steroid receptors-DNA ploidy.

MULTIPLE SPINAL MENINGIOMAS WITH POSITIVE PR – CASE REPORT

MILENKOVIC Sanja,Department of Pathology Clinical Hospital Center Zemun, Zemun
BERISAVAC Iva,Department of Neurosurgery,Clinical Hospital Center Zemun, Zemun
BOJOVIC Vladimir,Department of Neurology, Clinical Hospital Center Zemun, Zemun
CVETKOVIC-DOZIC Dubravka,Institute of Pathology, Medical Faculty, University of Belgrade

SKENDER - GAZIBARA Milica,Institute of Pathology, Medical Faculty, University of Belgrade
MARKOVIC Marko,Department of Neurosurgery, Clinical Hospital Center Zemun, Zemun

Short introduction
Multiple spinal meningiomas are relatively rare neoplasma and accounting only about 3% of all spinal meningiomas. They are defined as at least two spatially separated meningiomas occurring at the same time or more than two meningiomas arising sequentially from two clearly distinct regions. We report a case of the 52-year-old woman who was admitted to Department of Neurosurgery because of a progressive motor weakness with spastic paraparesis and sensation disturbance which gradually developed in the in both legs for last 3 years. Computed tomography (CT) scan revealed clearly defined three intradural extramedullary lessions at the Th6, Th10 and Th12. After operation in which the total resected tumors were performed histopathological examination showed two psammomatous meningiomas and one menigothelial meningiomas which was progestereone receptors (PR) positive. Proliferative potential which were measured by Ki67 antibodies were lower than 1%.
Purpose of the study:
In the present case rare multiple spinal meningiomas were investigated by the presence and distribution of the PR and proliferative potential with Ki 67 antibody with aim to predict eventually recurrence.
Methods used
Tumor samples after the third operation was analyzed by standard pathohostological technics, histochemical staining and immunohistochemical methods for PR,Vimentin, EMA and Ki 67 antibodies.
Summary of the results
The two tumors specimens from the Th10 and Th 12 showed a psammomatous meningiomas with large numbers of psammoma bodies (round calcified bodies). One tumor specimen from the Th 6 showed classic meningothelial meningiomas with cellular whorls and pseudonuclear inclusion.
Samples of the meningothelial meningiomas showed exclusively nuclear PR stain in a 15% of the tumor cells. In contrast, PR was negative in other two psammomatous meningiomas. Proliferative index were measured by Ki67 antibodies and in all tumors samples was lower than 1%.
Conclusion reached
To our knowledge, this is the first report of an association between multiple (three) spinal meningiomas (three) and PR.

P 979
CASPASE-3 EXPRESSION IS AN INDEPENDENT PREDICTOR OF RECURRENCE IN PATIENTS WITH INTRACRANIAL MENINGIOMAS

KONSTANTINIDOU Anastasia Evangelia1, GIVALOS Nikolaos1, NONNI Aphrodite1, GAKIOPOULOU Hariklia1, THYMARA Irene1, KOTSIAKIS Xenophon2, PATSOURIS Efstratios1
1Department of Pathology, Medical School ,University of Athens, Greece,
2Division of Neurosurgery, General Hospital of Hania,Greece.

Caspase-3 is the ultimate executioner caspase that is essential for the nuclear changes associated with apoptosis. In this study, we investigated caspase-3 expression in relation to baseline apoptosis, in order to assess the prognostic impact of an apoptotic mode of cell death in meningiomas' recurrence.
The expression of caspase-3 was evaluated immunohistochemically in a consecutive series of 56 patients with primary intracranial, totally resected meningiomas. Caspase-3 expression was investigated in relation to baseline apoptosis -as illustrated by the expression of the ssDNA-, the apoptosis suppressor protein bcl-2, proliferation indices (Ki-67, PCNA, Topoisomerase IIa and Mitosin C), and hormonal status as expressed by estrogen, progesterone and androgen receptors. Furthermore, caspase-3 expression was correlated to standard clinicopathological parameters and patients' disease-free survival.
Immunostaining for caspase-3 was observed in 60.7% of cases demonstrating a cytoplasmic granular pattern of expression. Caspase-3 labeling index was significantly associated with ss-DNA expression (p=0.03). Moreover, significant positive correlations emerged between caspase-3 labeling index and mitotic index (p=0.002), PCNA labeling index (p=0.004), while a suggestive association was observed between caspase-3 and the proliferation associated molecule mitocinC. As far as the conventional parameters are concerned, a significant correlation was established between caspase-3 expression and histological grade of meningiomas,in that grade II and III meningiomas (atypical and malignant respectively) demonstrated a significantly increased caspase-3 labeling index ($p<0.0001$). In univariate and multivariate survival analyses caspase-3 predicted meningiomas' recurrence affecting independently disease-free survival (p=0.0297 and p=0.047 respectively).
In conclusion, caspase-3 may prove to be a useful marker of recurrence in a group of neoplasms characterized by the frequent discordance between histology and clinical behavior.

INTRACRANIAL LESIONS MIMICKING MENINGIOMAS: REPORT OF 18 CASES.

(BOUHAJEB Youssef, MIGUEL SALAS María teresa, ANEIROS FERNANDEZ José, RUÍZ BARNÉS Pedro*, SARASA CORRAL Jose luis,). Department of pathology, *Department of Neurosurgery, Hospital "Fundación Jiménez Díaz", Madrid.

OBJECTIVE:
To analize the neurosurgical cases in which both the clinical and neuroimaging features suggested intracranial meningioma but resulted in different entities from a neuropathological point of view.
PATIENTS AND METHODS:
The clinical history and histopathological reports of patients with intracranial mass lesions mimicking meningioma and operated in our hospital, were reviewed.
RESULTS:
Our analysis revealed 18 cases with different neuropathological diagnosis. They were distributed as follows: 8 cases of hemangiopericytoma, 2 cases of Rosai-Dorfman´s disease, and one case of each of the following entities: solitary fibrous tumor, medulloblastoma, cerebral lymphoma, histiocytosis X, metastasis of adenocarcinoma,oligodendroglioma, pleomorphic xanthoastrocytoma and fibrous pseudotumor.
CONCLUSIONS:
The clinical and neuroimaging features of meningiomas are mimicked by different neoplastic and nonneoplastic entities. Because these lesions can resemble a meningioma during intraoperative biopsy, they must be considered in the differential diagnosis and kept in mind by the pathologist at this moment.

P 981
PARTICULAR FORMS OF MENINGIOMA: ABOUT FOUR CASES

HICHAM ELATTAR,HIND ATAWNA,FATIHA BENADRA,HANANE RAIS,BADIA BELAABIDIA
HOPITAL IBN TOFAIL-MARRKESH-MOROCCO

Meningothelial tumors or meningioma represent between 13 and 26 % of all nervous tumors in adult. The intracerebral meningotheliomatous form is the most frequent. We report

four cases which have a particular clinical presentation and particular microscopic patterns.
The first case occurred in 39-years-old women who developed a multifocal cystic tumour. The CT scan proposed the diagnosis of glioma. Microscopic pattern and immunochemistry made the diagnosis of multifocal meningioma. The second case is about another parietal cystic tumour occurring in a 60 years old woman. The diagnosis was a microcystic meningioma.
The third case is about a sixty years old woman who developing an intraventricular atypical meningioma.
The last case is about a 40 years old woman who developing an intramedullary papillary meningioma.
Consequences of Particular clinical and histological forms of meningiomas can be their misdiagnosis. The knowledge of this entities is important for a successful therapy

CORRELATION BETWEEN VITAMIN E AND FOLIC ACID LEVELS AND THE DEVELOPMENT OF ALZHEIMERS DISEASE IN A MOUSE MODEL OF AD
NEGAR OMIDI;PARICHEHR PASBAKHSH;

Alzheimers disease(ad)is the most common type of dementia(75%),manifesting as a severe deterioration of mental functions.the brains of people with alzheimer disease exhibit deposition of amyloid beta peptid and progressive degeneration of nerve cells.scientist are studying ways that may help decrease or prevent neurodegeneration and may help injured neurons to regrow.we determined whether the antioxidant vitamin e+folic acid affected the presence of amyloid plaques in brain of aged pdapp transgenic mice.beta-amyloid precursor protein (app).is important for the pathogenesis of alzheimers disease(ad),which is characterized by progressive decline of cognitive functions,formation of a beta plaques,and neurofibrillary tangles,and loss of neurons.in the present study we have examined that treatment by vitamin e+folic acid in pdapp aged mice compare with control groups is able to decrease 20% in ab plaques levels of cerebral amyloidosis in neocortex.more over ,our results suggest that treatment by vitamins is able to prevent the disruption of basal cholinergic forebrain system and prevent of loss of cholinergic basal forebrain neurons(ms+hdb,vdb)

AN AMINO ACID MOTIF COMMON TO BETA AMYLOID PROTEIN AND TO NEURODEGENERATIVE VIRUSES MAY TRIGGER NEURONAL DESTRUCTION.
Parvaneh Rahimi-Moghaddam MD. Ph.D.
Razi Institute for Drug Research, Iran University of Medical Sciences, Tehran, Iran

Research in the field of neuroscience has provided a better understanding of the cascade of biochemical events in neurodegenerative diseases. Most neurodegenerative conditions are marked by the presence of protein aggregations, and, in many cases, increased levels of oxidative damage in post-mortem tissues. The proteins associated with the neurodegenerative conditions may cause the over-production of free radicals in the neuronal tissues of the patients. We discovered that a 5-amino-acid sequence, Gly-Ala-Ile-Ile-Gly, residues 29-to-33 of the b-amyloid protein from Alzheimer's disease, is also found in proteins from three neurodegenerative viruses: HIV-1, Newcastle disease virus, and Japanese encephalitis virus. We used PC12 cells and SH-SY5Y cells to study the toxicity of this pentapeptide, using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium (MTT) assay and the measurement of caspase-3 activity. b-Amyloid 29-to-33 produces a concentration-dependent cytotoxicity to PC12 cells and to differentiate SH-SY5Y cells, but the reverse sequence (b-amyloid 33-to-29) is not toxic. Also, b-amyloid 29-to-33, but not b-amyloid 33-to-29, increases the caspase-3 activity in PC12 cells in a dose-dependent manner, which is blocked by U-83836E, U-101033E and vitamin E. These results emphasize role of free radicals in the pathogenesis of neurodegeneration.

1H MRS COMPARATIVE STUDY OF CEREBRAL METABOLISM IN PATIENTS WITH MILD COGNITIVE IMPAIRMENT (MCI), VASCULAR DEMENTIA (VD) AND IN NORMAL ELDERLY SUBJECTS (N)
ROZHKOVA Zina, ROGOZHYN Vladimir, Bachinskaya Nataliya
Radiological Center of the Academy of Medical Sciences of Ukraine, Kiev, Ukraine

Purpose: The aim of our study is to characterize the metabolic changes in the brain of patients with MCI, VD, and normal elderly subjects on the basis of analysis of 1H MRS data.
Materials and Methods: Three groups of patients are studied by MRI and 1H MRS with 1.5T Magnetom Vision (SIEMENS). The 1st group includes 25 patients (56-84y) with MCI. The 2nd group consists of 9 patients with VD (52-73 y). The 3rd group (N) consists of 30 healthy volunteers (60-75 y). 1H spectra are recorded in hippocampus (H), amygdala (A), frontal lobes (FL) and in entothinal cortex (EC) with the SVS STEAM method: TR/TE=1500/135,30 ms, VOI = 8cm3, NS = 128.
RESULTS: In the 1H spectra the following signals are identified: N-acetylaspartic acid (NAA)-2.02 ppm, total creatine (Cr)-3.03 ppm, choline (Cho)-3.24 ppm, and myo-Inositol (mIns)-3.56 ppm. From the spectra in all sampled regions of the brain the peak areas of main metabolites: NAA, Cr, Cho and mIns, and also the metabolite ratios are obtained. For the patients of the 1st verse the 3rd group the significant decrease of NAA and Cr and the increase of Cho peak areas in all regions and also significant decrease of NAA/Cr, and Cho/Cr in H and FL are observed. In the 1st group (NAA/Cr=1.01; mIns/Cr=0.82; Cho/NAA=0.96), in the 2nd group (NAA/Cr=1.14; mIns/Cr=0.58; Cho/NAA=0.86), and in the 3rd group (NAA/Cr=1.25; mIns/Cr=0.62; Cho/NAA=0.53) are obtained. There is the significant increasing in mIns/Cr (0.69) ratios in the patients of the 1st group compared with the patients of the 2nd group (0.52). Comparison 1H data in the right and left FL and EC for the patients of the all groups a significant reduction of NAA/Cr in the left hemisphere and non-significant reduction of NAA/Cr in the right hemisphere are found. The ratios of Cho/NAA, mIns/NAA in H, FL and EC are the most accurate values for differentiation MCI, VD and N.
CONCLUSION: 1H MRS data are useful in predicting the progression of MCI and VD and also for identification of cognitively normal subjects at risk for developing MCI.

INTRODUCTION: Whether the alteration of blood-brain permeability plays a role in the pathophysiology of Alzheimer disease (AD) has long been debated and recently white matter

disturbance was implicated in AD's pathogenesis. We have recently shown, that mutations in TP present in patients with MNGIE result in loss of expression of thymidine phosphorylase in the white matter, which correlates with white matter hypointensity on MRI and albumin positive cells in the white matter suggesting increased BBB permeability. Furthermore its embryological expression reveals a maturation pattern, which coincides with the temporal and spatial maturation of the BBB.
PURPOSE: The aim of the pilot study is to test whether TP expression is altered in AD and this alteration correlate with increased BBB permeability
METHODS: We completed a pilot study on post mortem brain tissue from patients with definite AD and age and sex matched controls. Immunohistochemical stains for TP and intracellular albumin were performed and quantified by counting positive cells per 10 high-power fields.
RESULTS: The number of TP positive cells was 5.36 and 14.15 ($p<0.01$) in the parietal lobe, 5.97 and 16.22 ($p<0.01$) in the frontal lobe of Alzheimer and control brains, respectively and inversely correlated with the number of albumin positive cells (29.99 and 16.08 ($p<0.01$) in the parietal lobe, 25.94 and 12.06 ($p<0.01$) in the frontal lobe of Alzheimer and control brains, respectively). The number of TP positive cells was independent of age. Although patients with MNGIE do not develop AD, they succumb at a young age usually. Formal neuropsychological testing has not been performed on patients with MNGIE or their heterozygote family members to detect subtle cognitive impairment.
CONCLUSION: Whether loss of TP expression contributes to the pathogenesis of AD or it is a secondary phenomenon , needs further elucidation.

RETROSPECTIVE STUDY OF SKIN NEUROFIBROMATOSIS (SN) OF TWENTY YEARS PERIOD (1991 -2000) IN 4 IRANIAN PATHOLOGY CENTERS
NOORI Mugahi Seyed Mohammad Hossein,NABAVI Seyed Mohammad Bagher
Khoramshahr University of Marine Sciences and Technology

The present study was designed to assess the frequency and stage of Skin Neurofibroma in the samples of patients with age, gender and biopsy locations.
Data obtained from annual record files of four different pathology centers with considering factors of Diagnosis, Age, and Gender and Biopsy location, examined for statistical difference. Each diagnosis has been coded by ICD method. Statistical examination has been done in 4186 samples of skin related to 52907 cases. The results of this experiment showed that
1) SN distributed in 52.9% of male cases and 47.1% of female cases.
2) Among all cases, trunk was the most common site of biopsy with 691 cases (24.7%). 632 cases (22.6%) were in face & 438 cases (15.8%) were in head & neck. Three samples (5.3%) were taken from the eyelids, 9 (15.8%) were taken from the faces, 11(19.3%) were taken from the heads and necks, 9 (15.8%) were taken from the trunks, 9 (15.8%) were taken from the upper limbs, and 19 samples (28.1%) were taken from the lower limbs showed Neurofibroma.
3) Among all cases, the third decades of life was the most common time of SN appearance with 860 cases (21.7%). 648 cases (16.4%) were in 4th decade & 592 cases (14.9%) were in 5th decade. This results may indicated that we should work more about (SN) and its effects on our life story.

P 987
INTERACTION OF VESICULAR MONOAMINE TRANSPORTER2 (VMAT2)AND NEUROMELANIN PIGMENT AMONG THE MIDBRAIN DOPAMINERGIC NEURONS ,IN MAN
P.PASBAKHSH(Ph.D);D.C.GERMAN(Ph.D);N.OMIDI(M)
Neuromelanin(nm)pigment accumulates with age in catecholaminergic neurons in man,and the ventral substantia nigra dopaminergic neurons that are the most vulnerable to degeneration in parkinsons disease(pd)contain the greatest amount of this pigment.in vitro data indicate that nm pigment is formed from the excess cytosolic catecholamine that is not accumulated into synaptic vesicles via the vesicular monoamine transporter2(vmat2).using semi-quantitative immunohistochemical methods in human postmortem brain,we sought to examine the relationship between the cotents of vmat2 and nm pigment.the immunostaining intensity(isi)was measured for vmat2 in two regions of the midbrain dopaminergic cell complex. The isi of the cells was related to the density of nm pigment within the cells.we also measured the isi for tyrosine hydroxylase(th)and examined the noradrenergic neurons in the locus coeruleus(lc).in brains 22-65 years of age:1)ventral substantia nigra neurons had the lowest vmat2 isi of all neurons in the midbrain cell complex,whereas over 2-fold higher levels are found in most ventral tegmental area neurons :2)there was an inverse relationship between vmat2 isi and neuromelanin pigment in the midbrain dopaminergic neurons:3)neurons with the highest vmat2 isi resided in lc:4)neurons with high vmat2 isi also had high th isi:and 5)inthe newborn brain,which has not yet accumulated neuromelanin pigment in the aminergic neurons,the regional distribution of vmat2 and th-isi was similar to that found in the adult brain.these data support the hypothesis that among the midbrain dopaminergic neurons,the ventral substantia nigra dopamine neurons accumulate the highest levels of nm pigment because they have the lowest levels of vmat2,which thereby renders them especially vulnerable to degeneration in pd.

The changes in density of inhibitory parvalbumin-immunoreactive (PV-ir) interneurons were quantitatively studied by immunohistochemistry in series of human neocortical samples comprising a whole spectrum of malformations of cortical development (MCD) and the non-malformed epileptic temporal neocortex in patients with temporal lobe epilepsy (NET). The highest counts of PV-ir cells were obtained in the control samples ($n = 21$). The number of PV-ir neurons was significantly decreased in NET ($n = 73$, 80.5 % of control values). In a proportion of pacients with NET as well as in two control samples we observed patchy regions of absence of PV staining. The total count of PV-ir cells in categories of MCD was further decreased, representing 72.4%, 55.0% and 12.2% of control values in groups of 'mild MCD' ($n = 25$), focal cortical dysplasia (FCD) type I ($n = 16$) and type II ($n = 15$), respectively. Significantly different PV-ir cell densities were demonstrated between the FCD types IIA and IIB. In MCD, we observed the decrease of

PV-ir cells to be more pronounced in infragranular layers. No significant differences were revealed between the temporal and extratemporal examples of MCD. This study provides evidence for reduction of inhibitory PV-ir interneurons in the epileptic neocortex affected by MCD as well as in morphologically unaffected temporal neocortex representing thus a possible mechanism for their epileptogenicity.

1H MRS STUDY OF METABOLIC ALTERATIONS IN PATIENTS AFTER ISCHEMIC STROKE IN ACUTE AND REHABILITATION PERIODS

ROGOZHYN Vladimir, ROZHKOVA Zina, SHCHEGLOV Viktor, SHCHEGLOV Dmitrii, KUZNETSOVA Svetlana, KUZNETSOV Viktor
Radiological Center of the Academy of Medical Sciences of Ukraine, Kiev, Ukraine

Purpose: We propose the quantitative indicators for the characteristics of regional multivoxel distributions of the brain metabolites (Cho, Cr, NAA) in patients after ischemic stroke in acute and rehabilitation periods.
Materials and Methods: Two groups of subjects are examined by 1H MRS using 1.5T Magnetom Vision (SIEMENS). The 1st group (VG) consists of 75 volunteers (in the age from 18 to 73 years). The 2nd group (SG) includes 80 (60 females and 20 males) patients (in the age from 46 to 87 years) in the acute (<12 hours), subacute (<10 days) and chronic (from 10 days to 12 months) stages of ischemic stroke. In all patients 12x12 spectral matrixes in supraventricular region parallel to the canthomeatal line are obtained. 2DCSI 1H spectra are recorded with: TR/TE=1500/135 ms, VOI=8x8x2cm.
Results: In each voxel of the spectral matrix we introduce two indicators: the metabolite content AM as the peak area and the metabolite concentration CM as the ratio of the peak area to the sum of all the peak areas S: CM=AM/S. We describe the metabolic state in each voxel by the triad T* = {ACho, ACr, ANAA}, where ACho, ACr, and ANAA are the peak areas of the signals from Cho, Cr and NAA. For each of the areas we assign three values: 1, 2 and 3, to obtain six symbolic spectral configurations: 1* ={1,2,3}, 2* = {2,1,3}, 3* = {1,3,2}, 4* = {3,2,1}, 5* = {3,1,2} and 6* = {2,3,1}. We analyzed the temporal alterations of the triad distributions after ischemic stroke. In the VG triads 1* and 2* dominate in all voxels of VOI. The most frequent configurations in the acute period are 5* and 6*. The triad regional variability decreased during rehabilitation period. Triads 3* and 4* are more often in elderly subjects.
Conclusion: The triad distributions give us a quantitative way for the estimation of efficiency of stroke therapy.

P 990

REGIONAL ALTERATIONS OF CONTENT AND VALUES OF T2 RELAXATION TIME OF THE MAIN CEREBRAL METABOLITES IN PATIENTS WITH PARKINSON'S DISEASE (PD): IN VIVO 1H MRS STUDY

KARABAN' Irina, KARABAN' Nikolay, ROGOZHYN Vladimir, ROZHKOVA Zina
Radiological Center of the Academy of Madical Sciences of Ukraine, Kiev, Ukraine

PURPOSE:From the analysis of ¹H MRS data and their echo-time dependence we propose the quantitative indicators for the characteristics of the brain state in patients with PD.
MATERIALS AND METHODS:Two groups of patients are studied by ¹H MRS with 1.5T Magnetom Vision (SIEMENS). The 1st group (PG) includes 40 patients with PD (48-70 y). The 2nd group (VG) consists of 15 healthy volunteers (50-73 y). Spectra are recorded in the temporoparietal cortex (TC), lentiform nucleus (LN), putamen (P) and substantia nigra (SN) with STEAM method:TR/TE=1500/135,155,175,200,270 ms.
RESULTS:We introduce two indicators: the metabolite content A^M as the peak area and the concentration C^M=A^M/S. We describe the metabolic state in VOI by the triad T*={A^{Cho}, A^{Cr}, A^{NAA}}, where A^{Cho}, A^{Cr}, and A^{NAA} are the peak areas of the signals of metabolites. For each of the areas we assign three values:1,2,3, to obtain six symbolic spectral configurations:1* ={1,2,3}, 2* = {2,1,3}, 3* = {1,3,2}, 4* = {3,2,1}, 5* = {3,1,2}, 6* = {2,3,1}. In the VG triads 1* and 2* dominate in all VOI, 3* and 4* are often in elderly subjects. In the PG the most frequent configurations in TC are 2* and 5* and in LN, P and SN are 5* and 6*. From comparison of T₂^M values in P, LN and SN in the both groups the shortening of T₂^M in the PG are obtained. In the TC the T₂^M values are similar in PG and VG.
CONCLUSION:This study gives a new insight into brain biochemistry in patients with PD.

PERONEAL NERVE REGENERATION THROUGH A HEALTHY TIBIAL NERVE: A DETAILED MORPHOMETRIC ANALYSIS

SAKELLARIOU A1, BATISTATOU A2, LYKISSAS M3, BAI M2, BERIS A3, AGNANTIS NJ2

University of Ioannina Medical School, Ioannina, Greece

INTRODUCTION: End-to-end nerve reconstruction is considered to be the treatment of choice, in the repair of peripheral nerve injuries. However, in cases of long nerve defects, the optimal surgical procedure has not yet been established, but the gold standard continues to be the use of autologous nerve grafts. For short nerve defects, a lot of different conduits have been studied, as well as the end-to-side nerve suture.
PURPOSE: The purpose of this study was to evaluate the regeneration of the transected peroneal nerve utilizing the tibial nerve as a conduit, with the use of proximal and distal neurorraphy.
METHODS: Forty male Wistar rats, weighing 230-300g, were included in this study. The peroneal nerve was transected and the animals were divided in five groups. Group I: End-to-end neurorraphy. Group II: The proximal stump of the peroneal nerve was sutured in an end-to-side fashion to the tibial nerve. The distal stump was sutured end-to-side 1.0 cm distally, along the tibial nerve. All coaptations were performed with epineurotomy of the tibial nerve. Group III:The proximal and distal stumps were left in situ. Group IV: Double end-to-side neurorraphy with intraperitoneal injection of valproic acid. Group V: Double end-to-side neurorraphy, plus subcutaneous injection of erythropoietin. During the waiting period, walking track analysis was performed in all animals. After 16 weeks, all rats were sacrifised. Specimens including sciatic, tibial and peroneal nerves from both sides were dissected and fixed in 2.5% Glutaraldehyde in 0.1M Cacodylate. Representative samples were taken, embedded in a resin mixture and semi-thin sections (1im) were stained with a modified solution of Toluidin blue and evaluated. A semiquantitative morphometric analysis using an image analyzer, was performed. The tibialis anterior muscle weight was recorded.
RESULTS: Axonal counting, the mean axonal diameter and area and the mean myelin thickness were estimated in all

groups, and compared to the contralateral unoperated side. The morphometric parameters of the Group II were comparable to Group I, while the preliminary data regarding Group V, suggest a further slight improvement.
CONCLUSIONS: The morphometric data presented in this study support the use of the tibial nerve as a conduit for the regeneration of the peroneal nerve, when the immediate repair is not possible

COMPARATIVE STUDY OF THE ABNORMALITIES OF CENTRAL NERVOUS SYSTEM IN CHILDREN AND ADULTS AUTOPSIED AFTER BONE MARROW TRANSPLANTATION
BENITES FILHO Paulo Roberto, TAFAREL Jean R., ZANIS NETO José, DE MEDEIROS Carlos R., PASQUINI Ricardo, BLEGGI-TORRES Luiz F.
Department of Pathology, Hospital de Clinicas, UFPR, Curitiba, Brazil
Bone Marrow Transplantation Unit, Hospital de Clinicas, UFPR, Curitiba, Brazil

Background: We compare the neuropathological abnormalities found in children and adults after bone marrow transplantation (BMT) who were autopsied in the Department of Pathology, University of Paraná, Brazil.
Methods: The autopsy reports of 180 patients were reviewed. They were divided in two groups: patients under 15 years old and those with 15 or more. Age, gender, clinical diagnosis at time of BMT, survival time, neuropathological abnormalities and cause of death were analyzed.
Results: In children (26,6% of total) and in the adult group (73.4% of total), the main clinical diagnosis prior to BMT were respectively: severe aplastic anemia (31.2%) and chronic myeloid leukemia (36.3%). The mean survival time for children was 102.6 days and for adults 185.9 days after BMT. The brain lesions were considered cause of death in 20.8% of paediatric cases and 11.3% of the adult group. The neuropathological abnormalities were morphologically similar in children and adults with the following respectively prevalence: cerebrovascular diseases in 58.3 and 56% (p=0.8655), neurotoxoplasmosis in 6.2% and 3% (p=0.3856) and infections in 27 and 25.7% (p=0.8489).
Conclusions: The paediatric patients had a shorter survival than adults with increasing prevalence of neurotoxoplasmosis and the brain lesions were considered cause of death in twice as many as compared to adult patients.

PATHOGENESIS OF HETEROTOPIC ECTOPIC GRAY MATTER IN THE BRAIN OF MOUSE PRENATALLY EXPOSED TO IRRADIATION
X.Z. SUN, S. TAKAHASHI, Y. KUBOTA, *R. ZHANG, *C. CUI, H. *Y. FUKUI, S. YOSHIDA
Environmental and Toxicological Sciences Research Group, National Institute of Radiological Sciences, Japan;
*Department of Anatomy and Developmental Neurobiology, School of Medicine, Tokushima University, Japan

The developing brain is one of the fetal structures most susceptible to irradiation. Studies of survivors exposed to atomic bombing in Hiroshima and Nagasaki or to x-rays during medical procedures indicated that mental retardation and microcephaly with heterotopic gray matter are prominent findings after in utero radiation exposure. The heterotopic gray matter could be caused by cell death and abnormal neuronal migration during a critical gestational stage of sensitivity to irradiation. However, the possible cellular and molecular mechanisms involved in the abnormal neuronal migration caused by irradiation are unknown. We have examined the pattern of brain malformations in 8-week-old mice prenatally exposed to doses of rradiation ranging from 0.5 to 2.0 Gy at different embryonic days. Brain malformations, identical to radiation-related small-sized heads with heterotopic gray matter, were reproduced in mice exposed to 1.5 Gy on embryonic day 13 (E13). In the present experiment, pathogenesis of such brain malformation was studied with immunohistochemical detection methods. Pregnant females were exposed to irradiation at a dose of 1.5 Gy on E13. Brains from fetuses and pups were obtained every day from 6 hrs after exposure to different postnatal days. Six hrs after exposure extensive dead cells appeared throughout the brain mantle. On E16 some cells came together to form rosettes. On E18 a high proportion of BrdU-labeled cells reached the superficial layers of the cortical plate with the remaining cells located in the heterotopic neuronal masses. The quantitative study showed that labeled-cells in layers II-III were fewer and those in layers IV-VI more numerous in the adult mice prenatally irradiated than controls. These results indicated the disruption of normal cell migration in the irradiated brain. The anti-GFAP immunostaining revealed that radial glial fibers were markedly straight and perpendicular to the pial surface in the controls, but disorganized after the irradiation exposure. Migration of young neurons along radial glial fibers is the prevalent mode of neuronal cell movement in the developing mammalian brain. The crumpled fibers might have presented unpassable, only partially passable, or disoriented pathway for neuronal migration. These findings suggested that the heterotopic gray matter in the brain of mice prenatally exposed to irradiation resulted from interrupted neuronal cell migration and migratory pathway.

P 994
EXPRESSION AND CELLULAR DISTRIBUTION OF MULTIDRUG RESISTANCE PROTEINS (MRP-1 AND MDR-1) IN FOCAL CORTICAL DYSPLASIA CASES
Oz Büge, AY Bahadýr, UZAN Mustafa, ÖZKARA Ciðdem, AK Halil, SAR Mehmet

PURPOSE:
Focal cortical dysplasia (FCD) is a congenital cortical developmental abnormality, which is generally characterized by drug resistant epilepsy. We aimed to investigate, multidrug resistance-associated protein 1 (MRP-1) and multidrug resistance gene-1 P glycoprotein (MDR-1) in the resection material of patients with FCD who underwent surgery.
METHODS:
Formalin-fixed parafin-embedded human brain tissues obtained from 20 patients and 10 age-match autopsy controls were studied ,. Sections of 5 µm were cut and the sections were stained with HE, Bielschowsky and Luxol-Fast-Blue. The resection materials were evaluated according to Palmini's Focal Cortical Dysplasia classification. Different type neurons, reactive astrocytes, endothelial cells within the dispastic cortex were examined for the expression MDR-1 and MRP-1 by immunocytochemistry. Immunreactivity in the cells was scored as -, - / +, + and ++.
RESULTS:
The Disstribution of cases were 2 type IA, 4 Type IB, 8 Type IIA (40%) and Type IIB (30%) FCD.
Evaluation of immunreactivity::
Neuron: MDR-1 and/or MRP1 was strogly positive in 16 cases (80%) of patients whereas in control cases MDR-1 was none or MRP-1 weakly positive in 50% of cases. Astrocytes: 10 % (2 cases) with MRD-1 ,and 55% (11 cases) with MRP-1 positivity were observed in FCD patients whereas MDR-1 was none and MRP-1 was 22% weakly positive for controls. Capillary endothelial cell: MDR-1 in 90% of controls, 50% of patients, whereas MRP-1 50% of patients, 10% of control were positive. In type IIA and type IIB FCD cases, MRP-1 positivity was detected 70 % (10/14 cases)in dysmorphic neurons and 20% (3/14 cases) giant neurons whereas MDR-1 positivity were seen only 15 % in dysmorphic neurons (2/14

cases) and 7% in giant neurons (1/14 cases). Immunreactivity for MDR-1 and MRP-1 in the balon cells of Type IIB FKD cases was observed in 4 cases (33%).

CONCLUSIONS:
The distribution of MRP-1 was more strong than MDR-1 in FCD cases.
MDR-1 and MRP-1 expression were prominent in neuronal cell were than the other cells. The overt expression of MDR proteins within the dysplastic tissue may be an evidence for the drug resistant seizures in patients with FCD comparing the control cases.

NEUROCYSTICERCOSIS: BIOPSY ANALYSIS OF FIVE YEARS PERIOD
SKENDER GAZIBARA Milica, CVETKOVIC DOZIC Dubravka, GAZIBARA Tatjana, MILENKOVIC Sanja, DOZIC Slobodan

Introduction. Neurocysticercosis (NC) is caused by larval stage of the pork tapeworm, Taenia solium. It is the most common parasitic cerebral infection encountered in worldwide neurosurgical practice. In some geographic regions it is the leading cause of space-occupying intracranial lesions.
Purpose of this study was neuropathological analyses of NC in surgical material of patients with space-occupying intracranial lesions, operated on during five years period (2000-2004).
Methods. Surgical biopsy specimens of NC were examined using standard histological and histochemical staining procedures.
Results. Of 4987 patients with intracranial lesions, NC was diagnosed in 18 cases (0,37%). The most frequent clinical manifestations included: hydrocephalus, epileptic seizures and chronic psychoorganic syndrome. The mean age of the patients was 51,66 (ranged from 40 to 68) years. Female to male ratio was 1:1. The great majority (16/18) of cases had solitary cystic lesion. In other two cases there were two parenchymal cystic lesions associated in one of them with third, solid, partly calcified suprasellar nodus. Cysticercus was located more frequently in the ventricular system (13 cases - 72%) than in brain parenchyma (5 cases – 28%). Inside of ventricular system, left lateral ventricle was the most frequently involved (7 cases).
Grossly, majority of cystic lesions were approximately 2 cm in diameter with thin, translucent membrane and water-clear fluid. Three ventricular cysts had a grapelike appearance (racemose form of cysticerci). Occasionally, single small (2-4 mm) whitish nodule was attached to the luminal surface of the wall. Microscopically, typical three-layered vesicular membrane was consisted of external wavy eosinophilic lamina, cellular layer and interior to this loose connective tissue. Rudimentary parasitic body and scolex showed different stages of involution. In some sections of viable scolex there were muscular suckers and hooklets. Around degenerated and dead parasite there was so called reactive membrane, composed of histiocytes, multinuclear giant cells, collagen fibers, prominent inflammatory cells (lymphocytes, plasmocytes and eosinophils) and layer of reactive astrogliosis.
Conclusions. According to our series of neurosurgical biopsy material, NC accounts for only 0,37% of surgically treated space-occupying intracranial lesions. This percent is significantly less than in series of NC from well known endemic regions in the world

*Department of Surgery University of Pisa (Italy)
Department of Morphological Sciences University of Modena (Italy)

Autism is a severe developmental disorder characterized by impairments in reciprocal social interaction and communication, restricted and stereotyped patterns of behaviour and interests, and an onset before 3 years of age (World Health Organization, 1992). Many regions of the brain have been implicated in the genesis of autism, but the neurobiological basis of the disorder remains unknown. Autism is a rare disorder which was described relatively recently and there are only a few post-mortem studies. Few data are available about molecular mechanisms of this pathology. A neuropathological study of autism was established and post-mortem brain tissue examined from one male individual.
It is known that RhoA, a small GTPase, inhibits axonal growth during early neuronal differentiation and axonal regeneration, while promotes the axonal growth during late neuronal differentiation. Infact RhoA controls a wide variety of cellular processes such as actin cytoskeleton rearrangement, microtubule dinamics, cell adhesion and polarity.
The cerebellar cortex was fixed in 10% formaldehyde, embedded in paraffin and sectioned.
Immunohistochemistry for glial fibrillary acid protein (GFAP), neurofilaments and RhoA was performed using the avidin-biotin complex method with diaminobenzidine as the chromogen.
The sections were acquired on digital support. Studied antigens distribution and expression analysis were evaluated by image analysis software Quantimet 500 plus.
Our results showed a reduced Purkinje cells number in the autistic cerebellum compared to the control one. RhoA expression was greater in Purkinje cells than other cells. GFAP and RhoA expression were reduced, while neurofilaments production was increased in the autistic cerebellum compared to the control one.
GFAP expression is mainly localized in granular layer cells both in control and autistic specimens. These data, together with the literature, suggest that an abnormal behaviour of cerebellar cells can occur, as shown by GFAP and neurofilament expression, also because of an alteration of RhoA expression.

STRUCTURAL CHANGES OF THE HUMAN PINEAL GLAND IN RELATION TO HYPOXY DURATION.
Manevska B., V. Dokov, W. Dokov?
Department of Pathology, *Department of Forensic Medicine, Medical University of Varna, Bulgaria

Introduction: Morphological data of the relation of hypoxy to the structure of the human pineal gland (PG) are very few.
The aim of this study was to investigate the morphological changes of PG in relation to acute and chronic hypoxy.
Methods: Seventy three PG's were observed – 56 male and 17 female. Length, width, weight and density of the glands were measured. To determine the duration of hypoxia, the cases were separated in three groups: 1st – 26 died of mechanical asfixia of hanging (MAH), mean age 57.24 ± 11.34; 2nd – 28 died of acute respiratory insufficience (ARI), mean age 51.5 ± 10.93; 3rd – 19 died of chronic respiratory insufficience with exacerbation (CRIE), mean age 52.33 ±13.06. Paraffin slides were stained with hematoxylin–eosine and Azan.
Results: PG's of the 1st group were significantly (t=7,3, P<0,05) heavier (168.15±42.15 mg) than 2nd (111.67±42.94 mg) and 3rd (115.61±50.58 mg). In the cases of ARI the density is significantly higher than those of MAH (2.6±1.77

kg/m3) and CRIE (3.45±1.97 kg/m3). In the cases of CRIE the stroma increases and the pseudolobs are atrophic. The frequency of well shaped pseudolobs is significantly higher in the 3rd (58.92%) than in the 1st (26.92%) and 2nd group (25%). The frequency of glial prolifration in MAH (46.15%) and ARI (64.29%) is significantly lower (t=2,39, P<0,05) than CRIE(76.47%).
Conclusions: Continuous hypoxia in the cases of CRIE developes gliosis and increases the relative share of well shaped pseudolobs of PG and proliferation of stroma and different stages of pseudolobar atrophy. The acute hypoxia of MAH and ARI does not develope structural changes of the PG.

PATHOGENESIS OF HETEROTOPIC ECTOPIC GRAY MATTER IN THE BRAIN OF MOUSE PRENATALLY EXPOSED TO IRRADIATION

X.Z. SUN, S. TAKAHASHI, Y. KUBOTA, *R. ZHANG, *C. CUI, H. *Y. FUKUI, S. YOSHIDA
Environmental and Toxicological Sciences Research Group, National Institute of Radiological Sciences, Japan;
*Department of Anatomy and Developmental Neurobiology, School of Medicine, Tokushima University, Japan

The developing brain is one of the fetal structures most susceptible to irradiation. Studies of survivors exposed to atomic bombing in Hiroshima and Nagasaki or to x-rays during medical procedures indicated that mental retardation and microcephaly with heterotopic gray matter are prominent findings after in utero radiation exposure. The heterotopic gray matter could be caused by cell death and abnormal neuronal migration during a critical gestational stage of sensitivity to irradiation. However, the possible cellular and molecular mechanisms involved in the abnormal neuronal migration caused by irradiation are unknown. We have examined the pattern of brain malformations in 8-week-old mice prenatally exposed to doses of rradiation ranging from 0.5 to 2.0 Gy at different embryonic days. Brain malformations, identical to radiation-related small-sized heads with heterotopic gray matter, were reproduced in mice exposed to 1.5 Gy on embryonic day 13 (E13). In the present experiment, pathogenesis of such brain malformation was studied with immunohistochemical detection methods. Pregnant females were exposed to irradiation at a dose of 1.5 Gy on E13. Brains from fetuses and pups were obtained every day from 6 hrs after exposure to different postnatal days. Six hrs after exposure extensive dead cells appeared throughout the brain mantle. On E16 some cells came together to form rosettes. On E18 a high proportion of BrdU-labeled cells reached the superficial layers of the cortical plate with the remaining cells located in the heterotopic neuronal masses. The quantitative study showed that labeled-cells in layers II-III were fewer and those in layers IV-VI more numerous in the adult mice prenatally irradiated than controls. These results indicated the disruption of normal cell migration in the irradiated brain. The anti-GFAP immunostaining revealed that radial glial fibers were markedly straight and perpendicular to the pial surface in the controls, but disorganized after the irradiation exposure. Migration of young neurons along radial glial fibers is the prevalent mode of neuronal cell movement in the developing mammalian brain. The crumpled fibers might have presented unpassable, only partially passable, or disoriented pathway for neuronal migration. These findings suggested that the heterotopic gray matter in the brain of mice prenatally exposed to irradiation resulted from interrupted neuronal cell migration and migratory pathway.

Inter-laboratory validation of PCR-based detection of *Mycobacterium tuberculosis* in formalin-fixed, paraffin-embedded tissues

Received: 1 November 2004 / Accepted: 15 February 2005 / Published online: 21 June 2005
© Springer-Verlag 2005

Abstract The present study is based on the initiative for quality assurance in pathology of the German Society of Pathology and the Professional Association of German Pathologists. Four panel laboratories with experience and expertise in polymerase chain reaction (PCR) detection of *Mycobacterium tuberculosis* were selected to establish the prerequisites for continuous external laboratory trials, in particular, by providing pre-tested specimens and evaluation criteria for participating institutes. In the first step, the four panel laboratories performed an internal trial to test their own reliability and reproducibility. Paraffin sections and DNA preparations from 34 tissues (25 clinical specimens and 9 controls) totalling to 66 samples were evaluated by each panel institute according to their own protocols. The methodologies differed and are described in detail. Despite these differences, a high degree of inter-laboratory reliability was achieved. In this report, we summarise our results including the correlation with the histology and provide recommendations for applying PCR-based methodology for the detection of mycobacterial DNA in surgical specimens. Supplementary data are available online at http://www.charite.de/ch/patho (rubric "Forschung"). Pre-tested specimens are now available for the external trial and can be ordered from the steering institute via Oligene (http://www.oligene.com/). All molecular pathology laboratories are invited to participate in this quality assurance initiative.

Introduction

Polymerase chain reaction (PCR)-based analytical technologies have developed to a standard methodology in nearly all disciplines of biosciences. Among others, this approach provides the option to look at targeted gene sequences and to amplify them, thus, enormously increasing sensitivity for detection. Detection and identification of disease-related genes in surgical pathology specimens, i.e. in biopsies, cytology samples, surgical resections and specimens from autopsies, have gained increasing importance in recent years and have created the discipline of molecular pathology [19]. The use of formalin fixation and paraffin embedding (FFPE) in pathology, however, implies several methodological obstacles, which need to be accounted for and cleared appropriately [13, 40, 48]. The commonly used fixation agent formalin is known to cause damage to DNA via fragmentation and/or cross-linkage. For this reason, the primer sets should be selected in such a way that specific and small, preferably multi-copy or repetitive, sequences are amplified. Additionally, reaction periods of the PCR cycles need to be sufficiently long.

In the literature, a large number of successfully applied set-ups are recommended for this purpose [2, 8, 17, 20, 26, 30, 39]. However, their reliability and reproducibility have only rarely been validated by comparative inter-laboratory trials [3, 28].

PCR-based investigation for mycobacterial DNA is an important application of molecular pathology, because granulomatous tissue responses are frequently, although not exclusively, attributed to mycobacterial infections. Detection of mycobacterial DNA is mandatory in tissues affected by granulomatous disorders, because the Ziehl–Neelsen (ZN) staining for acid-fast bacteria often fails to yield conclusive results [18, 24, 43].

Similarly, other approaches such as auramine staining or immunohistochemical identification using polyclonal antibodies against mycobacteria proved to be not sensitive enough for this purpose [29, 41]. Moreover, none of these classical techniques enables the distinction among *Mycobacterium tuberculosis*, atypical mycobacteria [also called mycobacteria other than tuberculosis complex (MOTT), or non-tuberculous mycobacteria (NTM)] and their subtyping [9, 35]. With FFPE, this task can only be solved by PCR-based methodology to date.

In addition to FFPE-related problems, mycobacteria carry a further methodological obstacle because of their thick mycolate-rich outer cell wall, which requires special measures of cell disintegration without causing further damage to DNA [14]. Thus, detection of mycobacteria in pathology samples is particularly critical and needs validation.

As part of a joint initiative of the German Society of Pathology (Deutsche Gesellschaft für Pathologie, http://www.mh-hannover.de/institute/pathologie/dgp/) and the Professional Association of German Pathologists (Berufsverband Deutscher Pathologen, http://www.bv-pathologie.de/) for quality control in pathology (QuIP), we performed an internal comparative inter-laboratory trial in the field of PCR-based detection of *M. tuberculosis*. Four institutes were selected by both societies because of their expertise and experience in this area [13, 16, 40, 47]. Our aim was to compare and to validate methodological variants employed by the four panel laboratories in order to draw general conclusions how to achieve high-level standards for PCR-based diagnostics of mycobacteria, but also to provide recommendations for nucleic acid amplification technology of surgical pathology specimens in general. This study followed the general guidelines in molecular pathology [19] and is similar to another multi-centre trial on Ki-67 labelling index [27]. General minimal demands for employing PCR and its terminology have been defined by the German Industrial Standard [7].

Despite a number of methodological variations, PCR-based diagnostics of mycobacteria proved to be reliable and reproducible. The specimens tested constitute the stock of a sample collection that is available for external molecular pathology laboratories in order to test their methodology and to increase quality assurance.

Materials and methods

Design of study

Each of the four panel groups (A–D) supplied eight cases for examination of *M. tuberculosis* by PCR including *M. tuberculosis*-positive and *M. tuberculosis*-negative samples (see below). Both DNA stock solution and the corresponding paraffin block were provided.

These materials were collected by the steering institute in Berlin, encoded and sent to the single panel laboratories. Each laboratory received a set of 66 samples consisting of 30 cases from clinical material and two experimentally infected human lung tissues for which paraffin sections and DNA stock solutions were provided as well as two paraffin samples from *M. tuberculosis*-infected mice.

The samples were provided in an anonymous fashion so that the respective investigators of the laboratories were blinded concerning the expected results.

Tissue samples

Of the 32 human samples, 25 were clinical cases that were previously investigated by one of the panel laboratories for *M. tuberculosis* because of clinical or histopathological suspicion for infection.

Negative controls consisted of three foetal lung tissues as well as two adult lung samples, one with lipoid pneumonia around a squamous cell carcinoma and one with little unspecific inflammatory reaction. Two cases of freshly operated human lung samples that were infected in tissue culture with *M. tuberculosis* BCG similarly as recently described for *Chlamydia pneumoniae* [37] acted as positive controls. Furthermore, lungs of *M. tuberculosis*-infected mice adjusted to defined colony forming units (0.7–0.8 CFU/lung) served as positive controls. These specimens originated from the Max Planck Institute for Infection Biology, Berlin [41]. Two positive and one negative control was submitted to HOPE (Hepes Glutamic Acid Buffer Mediated Organic Solvent Protection Effect) fixation instead of formalin followed by paraffin embedding [42].

For the 32 human tissues, one tube with 5 to 10 paraffin slices of 3-μm thickness as well as one tube containing 30–50 μl of DNA stock solution were assessed. For the two experimental mouse specimens, tubes with five paraffin slices of 3-μm thickness were sent to the panel laboratories. A survey of the tested specimens is provided in Table 5.

Histological evaluation

The paraffin blocks used for PCR analysis were histologically reassessed. Tissue sections were stained by hematoxylin and eosin (H&E), ZN, auramine–rhodamine and immunohistochemistry (DAKO, rabbit anti-*Mycobacteri-*

um bovis BCG), and semi-quantitatively evaluated in the following way:

- Necrosis. Extent: 0, negative; 1, minimal/punctuate; 2, low; 3, medium/confluent; 4, strong/greater than 50%. Type (predominant): 0, negative; 1, mainly caseous; 2, cellular; 3, fibrinoid
- Perinecrotic reaction. Intensity of inflammation: 0, negative; 1, little; 2, medium; 3, strong. Fibrosis: 0, negative; 1, little/focal granulation; 2, medium; 3, strong/circular sclerosis
- Granulomas. Each of the three granuloma types (caseous, pseudotuberculoid and sarcoidosis-like) were assessed as 0, absent; 1, present; 2, abundant
- Giant cells. Samples were searched for Langhans type or other (generally foreign body) types of giant cells and scored as 0, absent; 1, present; 2, abundant
- General inflammation intensity: 0, none; 1, little; 2, medium; 3, strong
- ZN, auramine and the immunohistochemical stainings were each scored as 0, negative; 1, weakly; 2, medium; 3, strongly positive

The histological parameters were statistically correlated with the PCR results using the SPSS software package (version 11.5). The detailed histological evaluation and representative microscopic images of each case are available as supplementary data at the abovementioned Charité web site.

Preparation of DNA from paraffin-embedded tissue

A survey on the experimental strategy is shown in Fig. 1. The methods for tissue preparation and DNA extraction differed slightly and are specified in Table 1.

In general, sections were cut from each tissue block and collected in 1.5 ml of Eppendorf vials. After each block, the microtome was cleaned and the knife changed. Paraffin was removed by extraction with xylene and centrifugation. This procedure was carried out either once, twice or three times; the pellet was then washed one to three times with ethanol (see Table 1). The supernatant was removed and the pellet air-dried. In parallel, blank extraction controls (dummies) containing no mycobacterial material were processed. These controls consisted of extractions containing all of the reagents without tissue and extractions of tissues ascertained to be negative for mycobacterial DNA.

All panel laboratories applied proteinase K digestion to disrupt the tissue, but the procedures to obtain the mycobacterial DNA as well as extraction and enrichment methods differed. Details of the respective protocols of the four laboratories are specified in the following.

Laboratory A

Air-dried tissue pellets were processed using the QIAamp DNA Mini tissue kit (http://www.qiagen.com/). Briefly, the pellets were suspended in lysis buffer and heated for 15–20 min at 95°C. After cooling to room temperature, the following steps were carried out according to the manufacturer's instructions with the exception that elution of DNA was performed with 50–80 µl of buffer.

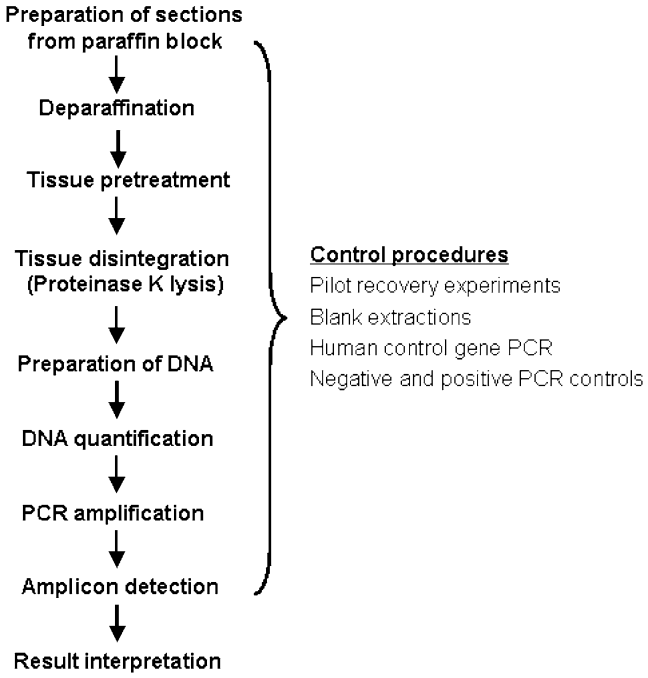

Fig. 1 Experimental steps in PCR-based detection of *M. tuberculosis* from paraffin-embedded tissue

Laboratory B

DNA preparation was performed according to the protocol by Ghossein et al. [12] and Popper et al. [31]. For digestion, the pellet was suspended in 100 µl of TEN-buffer (0.04 M Tris–HCl, 0.2 M NaCl, pH 8.0, 1 mM EDTA), 5 µl of proteinase K (Merck, Darmstadt, Germany, 20 mg/ml) and 5.25 µl of sodium dodecyl sulphate [final concentration 1% (w/w)] at 55°C for 3–4 h. To inactivate proteinase K, the solution was boiled for 10 min and centrifuged, and the DNA was precipitated with 96% ethanol (two volumes) in the presence of NaCl (final concentration 0.2 M) at room temperature for 30 min, recentrifuged at 13,000 rpm for 30 min and dissolved in 30–50 µl of ultrapure water (HPLC grade, Merck).

Laboratory C

DNA was extracted by the use of the Gen-ial First-DNA Kit (Fa. Gen-ial, Troisdorf, Germany, http://www.gen-ial.de/). Briefly, after removal of xylene, 500 µl of lysis buffer 1, 50 µl of lysis buffer 2 and 10 µl of proteinase K were added and incubated at 37°C overnight. To get access to mycobacterial DNA, the solution was heated to 90°C for 4 min and then shock-frozen in liquid nitrogen five times. After this step, 375 µl of lysis buffer 3 were added, vortexed and

Table 1 Methodological variants for tissue preparation and DNA extraction

Laboratory[a]	Sections	Deparaffinization	Tissue pre-treatment	Proteinase K lysis	Preparation of DNA	DNA amount[b] (µl, ~µg/PCR)	PCR volume (µl)
A	5–10 (3 µm)	1×xylene, 1×ethanol, air drying	Heating in lysis buffer for 15–20 min at 95°C	2–3 h at 55°C	QIAamp DNA Mini Kit	1–5 µl, 0.2–0.5 µg	25
B	5 (10 µm)	3×xylene, 3×ethanol, air drying	Nothing	3–4 h at 55°C	Precipitation with 96% ethanol	1–10 µl	50
C	2–5 (5 µm)	1×xylene	5×heating to 90°C followed by shock freezing with liquid nitrogen after proteolysis	at 37°C over-night	Gen-ial First-DNA Kit, precipitation with 96% ethanol	1–3 µl according to intensity after agarose (2%) gel electrophoresis	20
D	5 (2 µm)	2×xylene, 2×ethanol, air drying	Freeze-thawing before and after proteolysis	16 h at 55°C	QIAamp DNA Micro Kit	1–10 µl, 0.4 µg	50

[a]Laboratories: A, Berlin; B, Dresden; C, Munich; D, Borstel
[b]Extraction volume/DNA mass per reaction

cooled down for 5 min at −20°C. The samples were centrifuged at 13,000 rpm for 20 min, and the supernatant was transferred into new sterile tubes. At last, the DNA was precipitated with ethanol, and the pellet was diluted with sterile H_2O to a final volume of 50 µl.

Laboratory D

Extraction of DNA was performed by the use of QIAamp DNA Micro Kit (QIAGEN) with the following modifications: Two temperature treatments were included before and after the proteinase K incubation step (16 h at 55°C). Each of these treatments consisted of three cycles of 2-min incubation of the samples at 37°C, 30-s vortexing and 2-min incubation at −80°C in a dry ice/ethanol bath.

DNA quantification

To standardise the conditions and to estimate the amount of extracted DNA, the concentration of DNA was measured spectrophotometrically (laboratories A, B and D). In addition, the OD ratio (260 nm/280 nm) was measured to obtain information about the purity of the template DNA (laboratories B and D). The integrity and the quantity of the DNA was assessed semi-quantitatively via gel electrophoresis by laboratory C. DNA amounts and PCR reaction volumes of each laboratory are specified in Table 1. To examine whether amplifiable DNA was present in the samples, all panel laboratories assessed the quality of the prepared DNA by different control PCR to amplify an appropriate segment of a human gene (Table 2).

PCR amplification and amplicon detection

PCR of mycobacterial DNA sequences was performed employing different primer sequences for the amplification of distinct target genes of *M. tuberculosis* (Table 3). The genus-specific 16*S* rDNA and 65-kDa antigen genes harbour consensus sequences of mycobacterial organisms and thus cover the broadest detection range. The IS*6110* gene from the *M. tuberculosis* complex is suitable to detect

[a]Method numbering corresponds to that of Tables 5 and 6

M. tuberculosis, *M. bovis*, *M. bovis* BCG, *M. africanum* and *M. microti*.

The PCR protocols, i.e. reaction conditions, cycle programmes and detection method also differed and are compiled in Tables 1 and 4. Further details are as follows.

Laboratory A

For detection of *M. tuberculosis*, the oligonucleotide primers described by Eisenach et al. [8] were used to amplify a 123-bp fragment of the IS*6110* insertion sequence. The PCR reagents were commercially available (Reddy Mix, *AB* gene, http://www.abgene.com/). The final reaction volume of 25 µl contained 75 mM Tris–HCl (pH 8.8 at 25°C), 20 mM ammonium sulphate, 1.5 mM $MgCl_2$, 0.2 mM of each deoxynucleotide trisphosphate, 0.01% (v/v) Tween 20, 1.25 units Thermoprime DNA polymerase, as well as loading buffer and dyes for electrophoresis. The twofold concentrated kit reagents were complemented by a PCR DIG labelling mix (DIG detection, Roche, http://www.roche.com/), with a final concentration of 120 µM to render possible PCR-ELISA detection. The primer concentration was adjusted to 0.1 µM. The cycle conditions are specified in Table 4. A 10-µl aliquot of the reaction mix was subjected to 3.3% agarose gel electrophoresis and ethidium bromide staining. A second 2.5-µl aliquot containing the digoxigenin-labelled PCR products was hybridised with the biotinylated probe (Table 3), immobilised onto a streptavidin-coated microtiter plate and detected as described in the instruction manual (Roche, see above).

The amplification of the consensus 65-kDa antigen gene was similarly performed by the use of Reddy Mix (*AB* gene) without labelling using a 0.125-µM primer concentration.

The nested PCR was performed according to Cook et al. [4] by the use of PCR Master Mix (Promega, http://www.promega.com/) without restriction enzyme analysis of PCR product. One microliter of the first round product was amplified in the second PCR. Again, the PCR products were detected by 3.3% agarose gel electrophoresis.

Table 4 PCR conditions and amplicon detection

Laboratory	PCR reaction mixtures	Final Concentrations	Thermocycler profile	Detection procedure
A	Reddy Mix: Thermoprime DNA polymerase (*AB* gene) PCR, Dig-labelling mix (Roche)	0.65 units enzyme, 1.5 mM $MgCl_2$, 0.1 µM primer, 0.2 mM dNTPs, 120 µM dNTPs and 6 µM DIG-dUTP	I*6110*: 94°C 5 min, 40× (94°C 1 min, 68°C 2 min, 72°C 1.5 min), 72°C 7 min	*DIG PCR/ELISA*: 2,5 µl digoxigenin labelled PCR products were hybridised with biotinylated probe, immobilised and detected on microtiter plates (Roche)
	Reddy Mix: Thermoprime DNA polymerase (*AB* gene)	0.65 units enzyme, 1.5 mM $MgCl_2$, 0.125 µM primer, 0.2 mM dNTPs	65 kDa Ag: 94°C 5 min, 40× (94°C 1 min, 60°C 1 min, 72°C 1 min), 72°C 5 min	Electrophoresis: 3.3% agarose gel, ethidium bromide staining and UV visualisation
	Promega PCR Master Mix (2×)	0.65 units enzyme, 1.5 mM $MgCl_2$, 0.3 µM primer, 0.2 mM dNTPs	Nested PCR 65 kDa Ag: 94°C 5 min, 40× [94°C 1 min, 57°C 1 min (first round), 52°C (second round), 72°C 1 min], 72°C 5 min	
B	Ampli Taq Gold (Perkin Elmer Applied Biosystems)	1 unit enzyme, 1.5 mM $MgCl_2$, 0.1 µM primer, 0.2 mM dNTPs	IS*6110*: 94°C 9 min, 35× (94°C 1 min, 68°C 1 min, 72°C 1 min), 72°C 7 min	Electrophoresis: 6% polyacrylamide gel
	Ampli Taq Gold (Perkin Elmer Applied Biosystems)	1 unit enzyme, 1.5 mM $MgCl_2$, 0.1 µM primer, 0.2 mM dNTPs	M. tub. 16S rDNA: 94°C 9 min, 40× (94°C 1 min, 57°C 1 min, 72°C 1.5 min), 72°C 15 min	
C	Ampli Taq Gold (Perkin Elmer Applied Biosystems) Nucleotides (Amersham Pharmacia)	0.025 units enzyme, 1.5 mM $MgCl_2$, 1 µM primer, 0.2 mM dNTPs	IS*6110*: 95 °C 10 min, 45× (94 °C 1 min, 66°C 1 min, 72°C 1 min) 72°C 8 min.	Electrophoresis: 4% polyacrylamide gel
D	Invitrogen	5 units enzyme, 5 mM $MgCl_2$, 0.8 µM primer, 0.2 mM dNTPs	M. tub. 16S rDNA: 94°C 5 min, 40× (94°C 1 min, 57°C 1 min, 72°C 1,5 min) 72°C 15 min	Electrophoresis: 2% agarose-gels stained with ethidium-bromide and UV visualisation. Sequencing: according (Richter 1995)

Laboratory B

For detection of *M. tuberculosis*, the IS*6110* and the 16*S* rDNA genes were amplified. All reactions were throughout performed in a volume of 50 µl using Ampli Taq Gold DNA polymerase (1U PE Applied Biosystems, http://www.appliedbiosystems.com/) and reagents according to the manufacturer's instructions. Further details are given in Tables 3 and 4. PCR products were run on 6% polyacrylamide gel and visualised by staining with SYBR Green I (Biozym FMC) and UV transillumination.

Laboratory C

Similar to laboratories A and B, the detection of *M. tuberculosis* complex DNA was performed by amplification of the IS*6110* sequence. The cycler profile is given in Table 4. The detection was performed by gel electrophoresis after cleaving the PCR product by a specific restriction endonuclease digestion with *Hae*III (Roche Diagnostics, Mannheim, Germany, http://www.roche.com/) [2]. The PCR products were separated on a 4% agarose gel and visualised on a UV screen after staining with ethidium bromide. All samples with positive amplification of IS*6110* were subjected to further analysis by spoligotyping. The method was performed as described previously [22, 32, 44]. We used a commercial Spoligotyping Kit (Isogen, Maarsen, The Netherlands, http://www.isogen.nl/). Due to differences in the presence of non-repetitive DNA spacers, the hybridisation patterns vary among *M. tuberculosis* complex strains. Due to the absence of spacers 39 to 43 in all known *M. bovis* isolates, this approach allows a clear differentiation between *M. tuberculosis* and *M. bovis* strains, as well as the identification of sub-species or defined genetically related families.

Laboratory D

Amplifications were performed by the use of oligonucleotide primer sets for a 590-bp genus-specific fragment of mycobacterial 16*S* rDNA and a 193-bp fragment of the 16*S* rDNA of *M. tuberculosis* complex, respectively (Table 3), as described previously [34]. For amplification, 400 ng DNA, 20 mM Tris–HCl (pH 8.4), 50 mM KCl, 1.5 mM

$MgCl_2$, 200 μM of each deoxynucleotide trisphosphate (Invitrogen), 5 units Taq-Polymerase (Invitrogen) and 0.8 μM of each primer were added to a final volume of 50 μl. PCR was performed in a Biometra Uno-II thermocycler with cycle conditions as specified in Table 4. The amplicons were detected by 2% agarose gel electrophoresis.

When the outcome of the 193 bp PCR was negative and the 590 bp PCR was positive, the long PCR products were subjected to sequencing by the use of primer 9 as previously described by Richter et al. [34]. Sequence analysis was carried out using an automated fluorescent DNA-sequencer (AbiPrism 377, Applied Biosystems) to determine the respective (atypical) mycobacterial species. Database comparison was done with the aid of GenBank at the NCBI applying the BLAST tool (http://www.ncbi.nlm.nih.gov/BLAST/). Because this analysis was performed only in single selected cases, it was not included in the sensitivity and specificity analysis.

Control procedures

Two different types of negative controls were included in the study to rule out contaminations: In the first one, sterilised water was used instead of the sample to check the PCR. In the second one, material from 'blank extractions' (dummies, see above) was used in order to exclude any contamination in the extraction system [14]. To examine the reliability of both reaction mixtures and reaction conditions, each analysis was combined with a positive control of mycobacterial DNA obtained from highly diluted suspensions of *M. tuberculosis* DNA or *M. szulgai* (genus PCR, laboratory D).

Results

Of the 34 cases, 25 were clinical samples that were previously investigated by one of the panel laboratories for tuberculosis because of clinical or histopathological suspicion for infection. In addition, five negative human control samples and four positive, two human and two mice, tissues were included (Table 5).

Amplification of control genes

DNA stock solutions (n=32) and paraffin sections (n=34) were sent to the four panel laboratories for PCR, thus, totalling to 264 control reactions. Only a small share of them did not supply the expected results. Thirteen were negative and six displayed only a weakly positive outcome. A higher share of negativity occurred when large target sequences were amplified (16/19, laboratories B, D) compared to small target sequences (3/19, laboratories A, C). A somewhat higher abundance of negative outcomes was observed with the DNA stock solutions (8× negative, 3× weakly positive) compared to DNA that was extracted from the paraffin sections by each laboratory (5× negative, 3× weakly positive).

PCR detection of *M. tuberculosis*

The results for PCR detection of *M. tuberculosis* genes are shown in detail in Table 5. It represents the analysis of each case using DNA solutions and DNA from paraffin sections by all four laboratories using five different detection methods. Each laboratory provided a definite final assignment (positive or negative) of the 34 specimens that was based on the investigation of the different DNA preparations and PCR approaches for detection of mycobacterial DNA (column 'laboratory score', 0 = negative, 1 = positive). These were added for the calculation of a total score ranging from 0 to 4.

For 29 out of 34 sample sets, all four laboratories achieved identical assessments. The specimens from mouse tissues with defined CFU (samples 33 and 34) were evaluated consistently positive. From these samples, it could be calculated that 5–10 copies of the bacterium per set-up were reliably detected.

In five cases, conflicting data were obtained by one of the four laboratories, i.e. three aberrant positive results (samples 7, 21, 31) and two aberrant negative ones (samples 12 and 28). Case 7 was positive with the paraffin sample, but not with the DNA solution, which was interpreted as final positive result by the panel laboratory C. Both sample types also gave a positive result in the nested PCR of laboratory A; however, it was finally interpreted as negative because the IS*6110 M. tub*. complex PCR was negative. Similarly, case 21 gave positive results in the IS*6110* complex PCR and spoligotyping analysis in both sample types. This case was consistently negative in all analyses of the other laboratories. The third case (31) was positive in the DNA preparation from the paraffin sections, but not in the conveyed solution in laboratory D. In the same case, laboratory B detected mycobacterial DNA in the IS*6110* region, which, however, was not confirmed by the 16*S* rDNA analysis (A/tb primers) leading to a final negative evaluation. In one of two cases that were aberrantly evaluated as negative (case 28), amplification of the 193 bp sequence of 16SrDNA yielded no amplicon; however, the PCR for IS*6110* was positive. In the second case (sample 12), an amplicon of wrong size was seen with the A/tb primers thus leading to the negative final interpretation.

Three aberrant results, two aberrant positive and one aberrant negative, were obtained in the two laboratories that used freeze-thawing for DNA extraction as compared to one aberrant negative result in the two laboratories that did not employ this technique.

The results of the majority of the panel laboratories were defined as PCR consensus and served for the comparison of the applied methodologies regarding sensitivity and specificity (Table 6). The highest sensitivity was achieved for the amplification of the IS*6110* gene followed by the

16*S* rDNA of *M. tuberculosis* complex, whereas regarding specificity, the latter was superior to the IS*6110* detection.

Correlation with microscopic findings

During the course of this study, all samples were microscopically reassessed and semi-quantitatively scored for the parameters necrosis, granuloma, giant cells, inflammation/fibrosis and acid-fast bacilli. The data were statistically correlated with the PCR consensus results. The extent of necrosis was highly significantly associated with the positive PCR result (P=0.006 by Fisher's exact test). Furthermore, there was also a positive correlation with immunohistochemical detection of acid-fast bacilli (P=0.027). For the other parameters, there were no statistically significant correlations. Details of the histological evaluation together with representative histological images of each case are available as supplementary data at http://www.charite.de/ch/patho under the rubric "Forschung".

Discussion

Detection of pathogen-specific DNA or RNA by using methodology of molecular pathology is implicated in diagnostics and characterisation of infections. This task includes the choice of the suitable methodological approach, its correct handling by an expert and experienced staff as well as critical interpretation of results and their impact in the final diagnosis.

PCR is a highly sensitive procedure, which is extremely susceptible to interference by contamination [23, 36]. Moreover, particular requirements are needed as to disintegration of sample material and quality of nucleic acid preparation. Therefore, a number of preconditions should be fulfilled to prevent both false-positive and false-negative results. Some essential general preconditions for PCR analysis are provided as supplementary data to the manuscript (http://www.charite.de/ch/patho, rubric Forschung).

The present inter-laboratory trial indicated a high degree of inter-laboratory reliability of the PCR-based detection of *M. tuberculosis* genes. Importantly, all positive and negative controls were evaluated consistently. Positive controls originated from experimentally *M. tuberculosis*-infected mice and human lung tissue cultured in the presence of *M. bovis* BCG. Negative samples were from foetal and adult human lung that had no clinical or histological evidence of infection and were previously PCR negative. The majority of the samples consisted of clinical material that harboured characteristic morphological signs suggestive for mycobacterial infection, i.e. caseous necrosis, granulomas and/or giant cells. Interestingly, the extent of necrosis carried the most significant association with the detection of *M. tuberculosis* DNA. In contrast, neither the presence and type of giant cells, granuloma type, nor the staining results for ZN and auramine showed a significant correlation. The insufficient association with the conventional stainings is probably due to

Table 6 Sensitivity and specificity of the *M. tuberculosis* detection methods

No.	Method	Sensitivity[a]			Specificity[b]		
		All	*P*	DNA	All	*P*	DNA
1	*M. tub.* complex (16S rDNA)	0.87, *n*=76	0.91, *n*=40	0.84, *n*=36	0.95, *n*=39	0.95, *n*=20	0.95, *n*=19
2	*M. tub.* complex (IS*6110*)	0.95, *n*=114	0.94, *n*=60	0.96, *n*=54	0.88, *n*=84	0.89, *n*=42	0.86, *n*=42
3	*M.* genus		0.83, *n*=20			1.0, *n*=14	
4	*M.* genus nested	0.92, *n*=12			0.84, *n*=26		
5	Spoligotyping	0.88, *n*=38	0.83, *n*=20	0.95, *n*=18	0.82, *n*=28	0.88, *n*=14	0.78, *n*=14

Samples with score 0 or 1 are defined as true negative, samples with score 3 and 4 are defined as true positive. This agreement is important for the estimation of sensitivity and specificity

[1–4]Method numbering corresponds to that of Table 3

[a]Sensitivity [true positive results/(true positive plus false negative results)]

[b]Specificity [true negative results/(true negative plus false positive results)]

the preselection of cases, because generally, only the ZN-negative cases are further analysed by PCR. Auramine revealed more positive cases that, however, by PCR, turned out to be related to unspecific staining. Only immunohistochemical detection correlated significantly with the PCR results and may thus increase the armamentarium of morphology-based methods.

Except for the positive controls, no microbiological data were available. Although this may be a limitation of our study, it is representative for the inherent problem of tuberculosis detection in pathology specimens. On the one hand, clinicians and surgeons do not always pay attention to the possibility of an infection, and therefore, do not send adequate material to the microbiology department. On the other hand, the suspicion of such an infection is frequently raised only by histomorphological analysis. Thus, the available specimen is already formalin-fixed and cannot be further analysed microbiologically.

The molecular pathological analysis needs to be considered in the context of the histopathological and clinical setting. On the one hand, it may strongly enhance the sensitivity and considerably shorten the time period for achieving the specific diagnosis of an infection. On the other hand, the PCR methodology itself with all the pre-amplification, amplification and detection procedures implicates multiple obstacles that may hinder the detection of the pathogen unless appropriate conditions are maintained.

Sectioning of paraffin blocks

Paraffin blocks, usually generated after formalin fixation of the tissue, are the fundamental working material in pathological institutes. These blocks need to be cut to gain paraffin sections that are suitable for DNA extraction. To our knowledge, there are so far no general rules for tissue sectioning in molecular pathology analysis.

The panel laboratories took the following measures for paraffin block sectioning:

- Cleaning of the microtome after each tissue block from unused paraffin material by aspirator
- Cleaning of knives after each block to remove paraffin and tissue remnants
- Change of knives between each block (in particular if the same microorganism is detected)
- Precautions for contaminations during transfer of tissue sections into the tubes

Within the panel laboratories, the section thickness varied between 2 and 10 μm, the number of sections was between 2 and 10, thus giving a range of tissue thickness between 10 and 50 μm. This variation is mainly due to the area of tissue within the paraffin block and its cellular composition. The optimal amount depends largely on the experience of each laboratory and should be tested. Interestingly, one report recently described a higher sensitivity for the detection of mycobacterial DNA using thin tissue sections [25].

For this investigation, the sections were provided by one laboratory for the in-house preparations by each panel member (P). The additionally distributed DNA preparation (DNA) originated from all four laboratories that contributed DNA solutions and paraffin blocks.

DNA extraction

The use of formalin-fixed and paraffin-embedded tissue is hampered by a high degree of cross-linking, which renders its disintegration difficult. This difficulty is reinforced by the presence of a thick mycolate-rich outer cell wall in mycobacteria. Therefore, additional and even drastic methods of cell rupture were applied by the laboratories. The aim is to keep a balance between DNA recovery from the bacteria and tissue and DNA integrity for later amplification. Although the influence of the DNA extraction method was not systematically tested, our experience suggests that tissue pretreatment enhances the amount of recovered DNA whereas higher number of cycles in tissue pretreatment does not necessarily increase the sensitivity of detection. It was observed in the present study that heating prior to proteinase K digestion promotes tissue disintegration and may thus increase DNA recovery. Additional

cycles of freeze thawing were applied by two laboratories and resulted in two additional (aberrant) positive results. Whether this reflects contamination or an increase in sensitivity needs to be clarified by future studies. The optimal conditions should be examined in pilot recovery experiments by each laboratory independently.

DNA quantification

The variation of amount and composition of a tissue will greatly influence DNA recovery and purity. Differences in the preparation procedures like extraction volume, addition of proteinase K, duration of digestion, procedures for DNA concentration and others may also contribute to this variation. In daily practice, this variability is firstly accounted for by the tissue amount entering the extraction procedure and secondly by measurement and standardisation of the DNA amount for PCR. In addition to quantification, photometric measurement of the OD ratio at 260/280 nm may also provide an indication for sufficient DNA purity and is thus highly recommended.

Each laboratory should find out the optimal DNA concentration for its PCR set-up. The few discrepancies of the PCR results between the P and DNA preparations within the panel laboratories may be attributed to differences in DNA preparation and partitioning for amplification. In our experience, amounts of 100 ng for the control gene and up to 400 ng for the detection of mycobacteria, respectively, yielded best results.

PCR amplification

Formalin fixation results in cross-linking and degradation of the DNA, thus, limiting its use as template for amplification. The impact of the fragment size for the detection of the pathogen and the control gene was clearly evident from our inter-laboratory trial. Small target sequences should be applied in order to minimise the risk of false-negative results. We observed the highest frequency of positive control gene amplification for β-globin (268 bp fragment, 1 dropout) followed by β-actin (202 bp fragment, 2 dropouts).

Similarly, the 123-bp fragment of the IS*6110* gene of *M. tuberculosis* complex showed the highest sensitivity, which is additionally owed to the fact that it constitutes a repetitive genomic sequence of the bacterium. To achieve high yields of PCR products, cycle numbers between 35 and 45 as well as prolonged reaction times between 60 and 90 s were applied.

Nested PCR being additionally performed by one laboratory for amplification of the 65-kDa antigen harbours the potential of an even higher sensitivity. However, in our experience, this method should only be applied in the context of further tests due to the relatively low specificity (Table 6).

Recently, it has been shown that application of the novel *HOPE* fixation boosts the sensitivity of PCR to detect mycobacteria in paraffin-embedded samples at least 100-fold along with a well-preserved morphology [42]. The HOPE-fixed samples (code no. 17, 18, 20), including two positive and one negative control, gave highly reproducible results. The morphology was similar to the conventionally fixed specimens and can be checked on the supplementary data web site. Formalin, however, is and probably will remain for some time the standard fixative in most hospitals and pathological institutes, thus requiring accordingly optimised procedures in molecular pathology.

Amplicon detection

The most common and convenient way to confirm a successful amplification is agarose or polyacrylamide gel electrophoresis. However, an amplicon of the correct size does not necessarily represent the specific target. Therefore, further confirmative analysis is recommended. This is one reason why all panel laboratories applied different primer sets for PCR to detect mycobacterial DNA. For additional confirmation, restriction enzyme digestion, hybridisation to a specific internal probe followed by ELISA detection, DNA sequencing and spoligotyping were performed. Hybridisation techniques and restriction enzyme digestion are easier and faster than DNA sequencing followed by database comparison. Therefore, the latter approach is often restricted to the detection and subtyping of atypical mycobacteria.

Extremely high sensitivity can be achieved by the spoligotyping technique [22]. In the present study, as compared to conventional PCR, the typing was successful, providing additional information on distinct strains of the *M. tuberculosis* complex. Most of the samples exhibited a *M. tuberculosis*-specific signature. In two lung samples, *M. bovis* BCG strains were detected. A number of the *M. tuberculosis* strains revealed spoligotyping patterns, which are listed in an international database [11] and resemble common and well-characterised signatures. However, two samples provided aberrant positive spoligotyping results, which were found out by PCR to be negative as to the presence of *M. tuberculosis* DNA. Interestingly, these cases yielded only incomplete, patchy spoligotyping patterns. Further studies are needed to clarify whether these findings are due to non-specific amplification or hybridisation products or whether they indicate an extremely low level of *M. tuberculosis* DNA, whose clinical relevance has to be established. At present, this approach is not mandatory and generally recommended for diagnostic purposes, but may be used to address alternative issues, such as evolution and spread of the *M. tuberculosis* complex.

Interpretation of PCR results

The final plus/minus assignment of the PCR results for *M. tuberculosis* genes (Table 5, laboratory score) stands for a summing up of all analyses that were performed by each laboratory. Similar to the amplification of the control genes,

there were also discrepancies in single cases between the multiple approaches for *M. tuberculosis* detection (DNA solution vs new extractions from paraffin section, different PCR methods). The specifications in Table 5 may thus reflect complex considerations. The criteria that were applied by the laboratories will be discussed in the following:

Generally, a case was scored positive when the PCR and the following detection yielded a definite outcome in one of the preparations. As an exception of this rule, laboratory B required two positive parameters, i.e. either positive outcome in the PCR for IS*6110* and A/tb or positive outcome in both DNA preparations (D+P) for a definitive assessment. The backgrounds for these more stringent criteria are reports from the literature indicating that the use of the primer set for IS*6110* by Eisenach et al. [8] may identify *M. tuberculosis* in cases of sarcoidosis [6, 10, 21, 38]. Thus, the positive detection of the A/tb was scored with a higher priority than the IS*6110* fragments. From the experience of the other panel laboratories, positive outcome for IS*6110* in cases of sarcoidosis is not or only occasionally observed. However, this phenomenon was not systematically investigated in this inter-laboratory trial and merits further investigation. In general, this issue highlights the need to apply multiple approaches for the detection of mycobacterial DNA, in particular, in case of suspicion of sarcoidosis.

Similarly, the nested PCR performed by laboratory A was scored only when both preparations showed equal results in repetitive analyses, thus, considering the high frequency of false-positive results.

Discrepancies within and between the laboratories can also be due to low-copy infection and unequal distribution of the mycobacteria in the tissue. Considering the multiple difficulties in the *M. tuberculosis* detection as mentioned here, we achieved a high rate of consistent results.

Conclusions

The present inter-laboratory trial has clearly demonstrated reliability and reproducibility of PCR-based detection of *M. tuberculosis*, provided that appropriate conditions are kept. Moreover, the prerequisites are now established for a subsequent external inter-laboratory trial in which other molecular pathology laboratories are invited to participate.

Standardised fluorescence in situ hybridisation in cytological and histological specimens

Received: 29 November 2004 / Accepted: 7 January 2005 / Published online: 10 June 2005
© Springer-Verlag 2005

Abstract Fluorescence in situ hybridisation (FISH) has gained major impact in the detection of chromosomal aberrations. The application of FISH, however, is hampered due to complicated protocols. We therefore designed a FISH protocol that allows the fast and reliable application on cytological and histological specimens. Cytological and histological specimens of bone marrow, lymph nodes, liver and breast were analysed with 14 sets of centromere or locus-specific probes. A pretreatment of enzymatic digestion and microwave heating with the same incubation times for all specimens and probes used was performed. Hybridisation efficiency was proved by calculating the thresholds for monosomy, trisomy and translocations. Values in cytological specimens reached 9.0, 3.9 and 4.6%, respectively. In histological sections, values of 6.4% were seen for aneusomy and 3.1% for translocations. However, values for monosomy reached 20.5% in bone marrow and 61.8% in liver tissues due to cutting artifacts. In bone marrow with acute myeloid leukaemias, lymph nodes with follicular and mantle cell lymphomas, breast carcinomas and liver cell carcinomas, FISH confirmed aberrations already found using conventional cytogenetics. The protocol shown here is easy to perform and can be used with cytological and histological specimens. Moreover, with "hands on" time of less than 2 h, FISH can also be used for daily routine purposes.

Introduction

Chromosomal imbalances are characteristically found in most solid and haematological neoplasias [12]. For some leukaemias, such as chronic myeloid leukaemia (CML), acute myeloid leukaemia (AML) M3 and AML M4Eo, translocations t(9;22), t(15;17) and inv(16), respectively, have already been defined as specific [2, 14, 17]. Also, in solid tumours, characteristic imbalances have been found to be associated with carcinomas of the urinary tract, the lung and the liver [8, 16, 22]. Moreover, new treatment regimens focus on important genetic changes such as amplification of Her2/neu in breast carcinoma [5].

However, detection of aberrations by conventional cytogenetics, in particular in solid tumours, is impaired due to low proliferative activity and metaphase number in vitro [1, 18]. As an alternative approach, fluorescence in situ hybridisation (FISH) has been developed. FISH is based on the hybridisation of hapten or fluorescent labelled probes complementary to target DNA or RNA sequences in the nucleus and cytoplasm [15]. A major drawback of FISH, however, is the complicated and time-consuming protocols that have to be adapted to the cytological and histological specimens analysed. The effort required for these procedures seems to be high even for larger institutional laboratories.

Therefore, the aim of this study was to establish an easy-to-perform FISH protocol suitable for both cytological and histological specimens. Based on our previous experience in this field, this protocol was tested on normal and neoplastic specimens with a variety of commercially available probe sets, to ensure high quality of results.

Materials and methods

Cytological and histological specimens

Non-neoplastic bone marrow aspirates as well as trephine core biopsies were available from five different patients. Smears and bare nuclei were prepared as described else-

where [7]. Smear preparations were air dried. Bare nuclei were fixed and stored until use in a mixture of methanol and acetic acid (3:1). Trephine core biopsies were fixed for 24 h in a mixture of buffered formalin and methanol (3,200 ml methanol, 1,667 ml 37% formaldehyde, 133 ml buffer (150 ml 802.97 g $NaH_2PO_4 \cdot H_2O$ and 1,000 ml dH_2O and 650 ml 10.67 g Na_2HPO_4 and 1,000 ml dH_2O) and 6.65 g glucose adjusted to pH 7.4. Biopsies were then decalcified in a solution of 200 g Tetriplex 3 and 66 g Tris(hydroxymethyl)-aminomethane (both Merck, Darmstadt, Germany) and 2,000 ml dH_2O adjusted to pH 7.4 and paraffin embedded. Fine-needle aspirates (FNA) of livers with reactive changes of five patients were analysed as well as non-neoplastic tissues of the liver of five other patients as histological specimens.

For detection of chromosomal changes, cytological and histological samples of patients with haematological disorders were included; cytogenetic analysis of these patients was performed in parallel. This included a case of myelodysplastic syndrome (MDS) with del(5)(q14q31), an myelodysplastic syndrome (MDS) with monosomy 7, an AML with trisomy 8, and AML with a translocation t(8;21).

Additionally cytological and histological samples of neoplasms were analysed for which typical aberrations are known, but conventional cytogenetics was not performed due to the problems mentioned above and/or to the fact that only paraffin-embedded tissue was available. This group included a breast carcinoma with amplification of Her2/neu, a follicular centre lymphoma (FCL) with t(14;18), a mantle cell lymphoma with t(11;14) and hepatocellular carcinoma (HCC) with aneuploidy of chromosomes 1 and 8, and gains of 8q24.

Probes

Fourteen different probes and/or probe combinations were used. These were specific for the centromeric regions of chromosomes 1, 7, 8 and 17, for 5q31, 8q24, 13q14, 17q21, tel19q, 20q12 and 21q22, and for the detection of translocations t(8;21), t(11;14) and t(14;18) (Table 1). Probes were commercially available and supplied by Abbott Corp. (Wiesbaden, Germany).

Table 1 Fluorescence in situ hybridisation (FISH) probes used for the experiments performed in this study (all probes supplied by Abbott, Wiesbaden, Germany)

D20S108	20q12
ETO	21q22
AML/ETO	t(8;21)(q22;q22)
IgH/CCND1	t(11;14)(q13;q32)
IgH/BCL2	t(14;18)(q32;q21)

Pretreatment

Pretreatment of bare nuclei and cytological smears started with incubation for 3 min at room temperature in 50 ml of a pepsin solution in a coplin jar. The pepsin solution was prepared from 99 ml dH_2O, 1 ml HCl 1 N and 5 mg pepsin (Sigma, Taufkirchen, Germany), and was made freshly every day. Slides were then washed for 1 min in dH_20 followed by washing for 10 min in paraformaldehyde [1.5% (v/v), Merck, Darmstadt, Germany]. A new solution was prepared every 7 days and stored at 4°C until use. After washing for 1 min in dH_2O, slides were air dried at room temperature.

Paraffin-embedded tissues (4-μm sections) were mounted on Super Frost Plus slides (Menzel, Braunschweig, Germany), dried overnight at 56°C and subsequently passed through xylol and a series of 95, 80 and 70% ethanol. To minimise the amount of probe needed to cover the tissue, the specimens were downsized with a microtome blade to a size of 0.2×0.2 cm. For this purpose, the area of interest was marked on the H&E or Giemsa-stained sections and scratched away with a scalpel on the parallel sections used for FISH. The specimens were then boiled in a microwave oven for 30 min in 6 M Na-citrate buffer (pH 6.0), cooled to room temperature and rinsed in distilled water. This was followed by incubation with the pepsin solution described above for 5 min at room temperature, washing for 1 min in dH_20, incubation for 10 min in paraformaldehyde (1.5%) and again washing for 1 min in dH_2O. The slides were then air dried.

Hybridisation and washings

Hybridisation of both cytological and histological sections was started by adding 0.5 μl of centromere or locus-specific probes to 4 μl hybridisation buffer (Abbott, Wiesbaden, Germany) and 1 μl H_2O pipetted onto the slide. A glass coverslip (Menzel, Braunschweig, Germany) was placed onto the slides and sealed with rubber cement (Fixogum, Marabu, Tamm, Germany). Specimens were heated to 80°C for 10 min to denature probe and specimen DNA and incubated overnight at 37°C in a humidified dark chamber. Afterwards, the rubber cement was stripped off and the coverslip was removed by gently washing the slides twice in 0.4×SSC/0.3% Igepal (Abbott, Wiesbaden, Germany) at 75°C for 2 min. Slides were then counterstained in a light-protected coplin jar filled with 50 ml DAPI (40 ng/ml, Qiagen, Heidelberg, Germany). Finally, a drop of Vectashield antifade (Vector, USA) was added and the slide was covered with a coverslip. Excessive fluid was removed with a Kim wipe and a drying block (Schleicher & Schuell, Dassel, Germany). The "hands-on" time for the experimen-

tal steps before hybridisation was less than 90 min and after hybridisation less than 30 min.

Evaluation of signals was carried out using an epifluorescence microscope (Axioskop 2, Zeiss, Oberkochen, Germany) equipped with a fluorescein, Cy3 and DAPI filter set and a 100-W mercury lamp. In each tumour, 50 nuclei were evaluated and documented with the ISIS software package (Metasystems, Altlußheim, Germany).

Results

Non-neoplastic samples

Bare nuclei bone marrow aspirates

The mean percentages of nuclei with one signal only for cen7, 13q14 and 20q12 were 2.90, 1.6 and 2.6%, respectively, with standard deviations (SDs) of 1.40, 1.1 and 1.5% (Table 2). According to Ward et al. [21], the thresholds were calculated by adding three SDs to the mean obtained for the particular probe. Thus, thresholds were 7.1, 4.9 and 7.10%, respectively. For defining aneusomy of cen8, tel19q and 21q22, mean values were 0.30, 1.40 and 1.2% (SD 0.33, 0.8 and 1.30%), and the depending thresholds 1.28, 3.80 and 5.10%. For the translocation probe t(8;21), the mean, SD and threshold were 1.00, 1.20 and 4.60, respectively.

Table 2 Mean values, standard deviations (SDs) and thresholds for defining monosomy, aneusomy and translocations based on the evaluation of normal specimens of bare nuclei of leucocytes, smears of bone marrow aspirates, bone marrow trephines, fine needle aspirates (FNAs) of the liver and core biopsies of the liver

Threshold	61.81	56.35	47.00	6.24	6.09	6.40

Smear preparations of bone marrow aspirates

Monosomy for cen7, 13q14 and 20q12 was seen with mean values of 1.78, 2.4 and 1.21% (SD 0.45, 1.90, 1.1%). Thresholds were set at 3.13, 8.10 and 3.31%. Aneusomy was seen for cen8, tel19q and 21q22 in 2.2, 2.33 and 2.26% (SD 2.0, 0.52, 0.43%) with thresholds at 8.2, 3.89 and 3.55%. For t(8;21), values were 0.6, 0.43 and 1.89%, respectively.

Histological specimens of bone marrow

The percentage values of cells bearing one signal only for cen7, 13q14 and 20q12 were 12.78, 11.2 and 13.66% (SD 1.96, 3.1 and 2.0). Accordingly, thresholds had values of 17.74, 17.30 and 18.66%. For aneusomic count, values for cen8, tel19q and 21q22 were 1.66, 0.93 and 2.21% of cells (SD 0.9, 0.68 and 1.1.4). Thresholds were set at 4.36, 2.97 and 5.63. For t(8;21), values were 0.8, 0.78 and 3.14%, respectively.

FNA of the liver

The analysis of the cytological specimens of the liver revealed mean values of one signal/cell for cen1, cen8 and 8q24 in 2.65, 3.2 and 4.8% (SD 0.86, 1.55 and 1.40%). Thresholds were set at 5.23, 7.84 and 9.00%. For aneusomic counts of these probes, mean values were 0.65, 0.50 and 1.20% (SD 0.14, 0.18 and 0.80%). Thresholds were 1.06, 1.03 and 3.60%, respectively.

Core biopsies of the liver

For these histological samples, the values for one signal/cell for cen1, cen8 and 8q24 were 39.6, 36.0 and 35.0% (SD 7.4, 6.78 4.0%), respectively. Therefore, thresholds for these probes were 61.81, 56.35 and 47.0%. For aneusomic counts, mean values were 2.00, 2.80 and 1.6% (SD 1.41, 1.1 and 1.6%). Thresholds were 6.24, 6.09 and 6.4%, respectively.

Neoplastic samples

MDS with del5q and −7

For these cases of histologically proven MDS, conventional cytogenetics revealed del(5)(q14q34) in 20 of 20

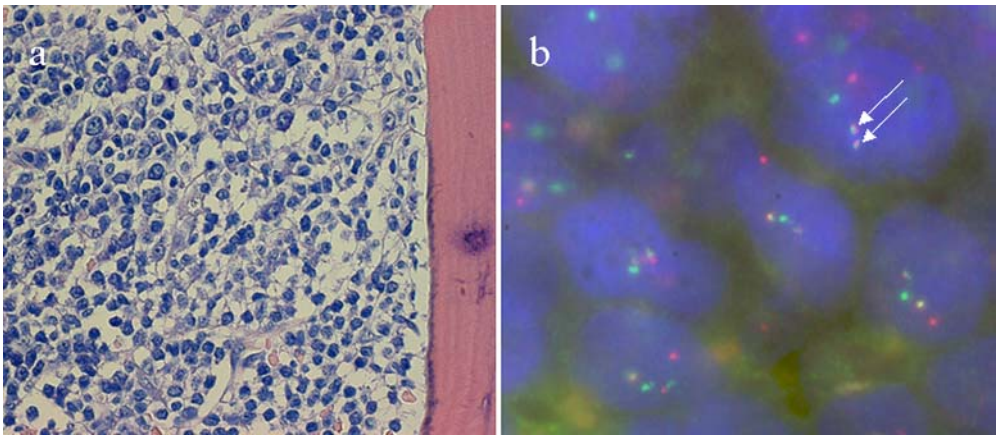

Fig. 1 Histological section of bone marrow infiltrates of a follicular cell lymphoma (**a** original magnification ×400). Fluorescence in situ hybridisation (FISH) was performed with a probe set giving two yellow fusion signals for the translocated chromosomes and one green and one red signal for the normal chromosomes. Fusion signals in the neoplastic cells are indicated by *arrows* in a cell example (**b** original magnification ×1,000). Due to cutting artifacts, not all signals expected are detectable in the nuclei

metaphases and −7 in 18 of 20 metaphases. Using FISH with the combined probes for cen5/5q31, one signal for 5q31 occurred in 78% of bare interphase nuclei. In the cytological specimens, this value was 61.5%; whereas in the bone marrow core, the percentage was 31%. In the case with monosomy 7, 78% of the bare nuclei revealed only one signal. In the cytological specimens, 60% of cells were affected, and in the trephine biopsy this value was 65.5%.

AML with trisomy 8

Again, this aberration was seen in all metaphases (15 of 15). The percentages of aberrant cells in the bare interphase nuclei, in the cytological specimens and in the core biopsy were 87, 74.5 and 68%, respectively.

AML with t(8;21)

A translocation t(8;21) was detectable in 22 of 22 metaphases. The number of aberrant bare interphase nuclei was 97%. In the cytological specimens, 88% and, in the core biopsy, 91% of the cells had the signal constellation typical for t(8;21).

Lymphomas

In a core biopsy, histological examination raised the differential diagnosis of splenic marginal zone and FCL. Using a probe set specific for t(14;18), fusion signals were detected in the neoplastic tumour cell population in 70% of the nuclei analysed, arguing the case for a FCL (Fig. 1). In a lymph node of another patient, a mantle cell lymphoma was seen. This diagnosis was confirmed using FISH with fusion signals in 80% of the lymphoma cells (Fig. 2).

Breast carcinoma

In the histological specimen of this sample, a ductal carcinoma in situ and an invasive ductal carcinoma of the breast were detected. The relationship between signals of Her2/neu and cen17, calculated from signals of 60 nuclei as recommended, was 6.7 in the DCIS, whereas this ratio was 1.4 in the invasive breast carcinoma (Fig. 3).

FNA of the liver

In a sample of low differentiated HCC, means of 4.90 signals per nucleus for #1 and 14.66 signals per nucleus for

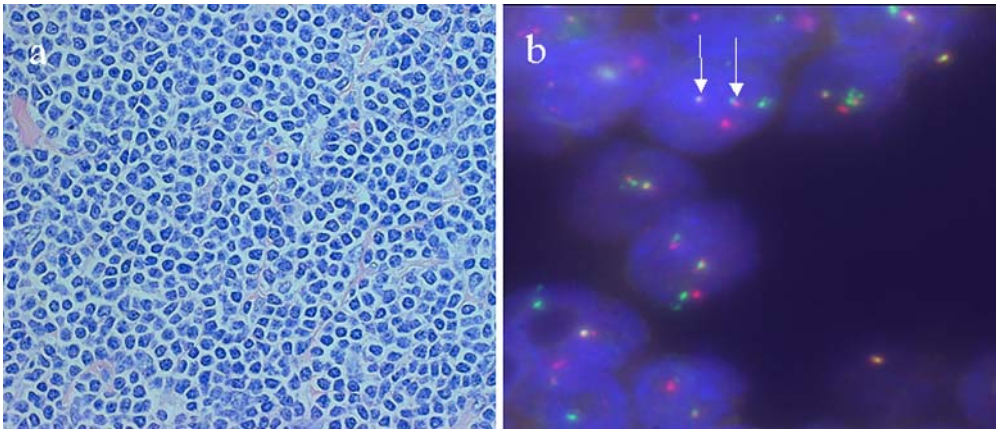

Fig. 2 Histological section of a mantle cell lymphoma in a lymph node (**a** original magnification ×400). For detection of the t(11;14), a probe set was used giving two yellow fusion signals besides the normal green and red signals of unaltered chromosomes 11 and 14, respectively (**b** original magnification ×1,000). These two fusion signals are indicated by *arrows* in a given cell

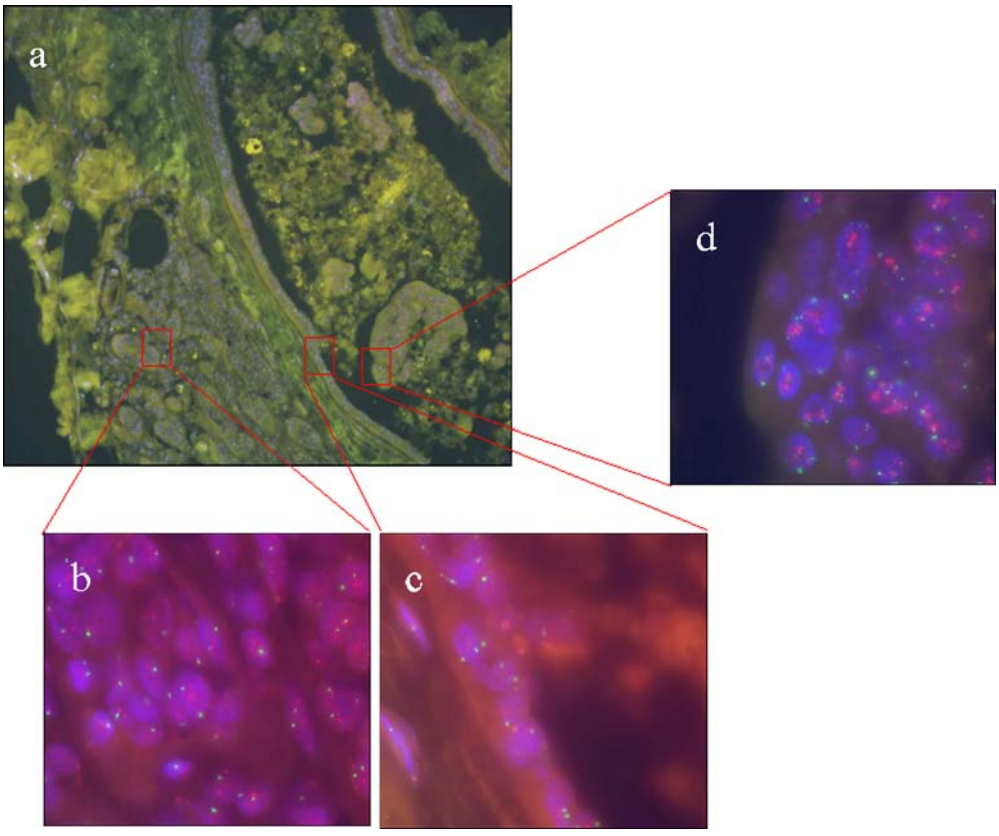

Fig. 3 **a** Fluorescence in situ hybridisation (FISH) using specific probes for Her2/neu (*red*) and cen17 (*green*) in a case of a breast carcinoma with an invasive component (**b**) and an intraductal carcinoma (DCIS) (**d**). In the invasive carcinoma and the epithelial cells covering the inner layer of the duct (**c**), an amplification of Her2/neu was not detectable, although a high amplification occurred for the DCIS (×100, ×630)

#8 with 41 different signal combinations, indicating a high chromosomal instability in this sample, were found.

Application in daily routine work

To determine the applicability of the FISH protocol for daily routine work, FISH analyses of bare nuclei, cytological specimens and histological sections were evaluated for sufficient hybridisation efficiency, i.e. more than 90% of nuclei bearing signals. By counting at least 100 nuclei, 100 cases each were analysed. The percentages of cases with sufficient hybridisation efficiency were 95% for specimens of bare nuclei, 93% for cytological specimens and 87% for histological sections.

Discussion

The definition of diagnostically and prognostically important genetic markers in neoplastic diseases implicates an increasing impact of FISH. The main advantage of this technique is found in the combination of the detection of cytogenetic aberrations in interphase nuclei with preserved morphology. This ensures that the neoplastic cells are analysed even when mixed with non-neoplastic cell populations. Here, FISH is clearly superior to other techniques such as conventional cytogenetics or polymerase chain reaction. In this study, we aimed to find an easy and fast-to-perform protocol. It is applicable to both cytological and histological specimens by standardised pretreatment and hybridisation steps. This allows a distinct analysis, not only of numerical changes but also of structural alterations of particular importance in leukaemias and lymphomas [6, 12].

The main step in the successful application of the protocol was the pretreatment of the specimens. First, enzymatic digestion was carried out by incubation of cells with a pepsin solution. In comparison with proteinase K, it was not necessary to adapt the time of digestion with regard to the type of cells treated. Three minutes of pepsin digestion allowed FISH analysis of all specimens used to be carried out with high hybridisation efficiency and well-preserved morphology. This is of particular interest when only one sample is available.

However, the single use of pepsin was not sufficient for histological sections. Microwave pretreatment was mandatory in these cases. Microwave pretreatment is a well-known technique to enhance staining intensity in immunohistochemistry [3, 19, 20]. Cross-links between proteins caused by formalin fixation and their break-up by microwave irradiation have been described as the underlying effect of staining enhancement in immunohistochemistry [19, 20]. Those cross-links can also occur after formalin fixation in nucleic acids [11]. Accordingly, a positive effect of this technique in the detection of DNA and RNA sequences has been described previously [13, 23]. Leers et al. [10] proposed that heating dewaxed tissue sections leads to a diminishing of nucleic proteins, allowing propidium iodide to get into the nuclei. This effect could

also be helpful for diffusion of probes in the nuclei. As seen for pepsin digestion in cytological specimens, an adaptation of incubation time for the different tissues is not necessary. Heating reaches a maximum effect after breaking up all proteins affectable by this harsh procedure with no further improvement by additional incubation. In our study, a standardised time of 30 min was sufficient to obtain clearly detectable signals against a low background.

In this point, our results differ from those of Chin et al. [4] who also reported a combination of microwave pretreatment and enzymatic digestion. In their study, an incubation time of 60 min was found necessary to detect both kinds of probes. This probably is due to the different temperatures during the heating process. Chin et al. [4] used 80°C whereas, in our study, the temperature was raised to the boiling point above 100°C. Moreover, our protocol also worked acceptably in liver specimens reported to give high autofluorescence by Chin et al. [4]. The protocol also gave highly adequate results in bone marrow biopsies despite decalcification steps before paraffin embedding. A further advantage of our protocol was seen in the decreased number of washing steps performed, bringing down the total "hands-on" time needed for the whole procedure to less than 2 h.

A decreased number of incubation steps is also seen in comparison with the protocol of Haralambieva et al. [9] using RNAse treatment not necessary in our protocol.

As a drawback of FISH, it has to be mentioned that assessing losses of chromosomes in histological sections is hampered by high thresholds of 20% in bone marrow sections and 60% in liver sections. This problem is due to the cutting artifacts that have an increasing influence in larger cells, as seen for the smaller cells of the bone marrow in comparison with the larger cells of the liver. As shown for the detection of chromosome gains and structural imbalances, this problem seems to be of lower impact.

A further point to be mentioned is the time of tissue fixation. Since 24 h of fixation is normally taken as a standard for routine purposes, we focused on this time here. Nevertheless, based on our own experience with tissues taken from surgical specimens of the liver after 4 days or more of fixation, FISH can be impaired (data not shown). Therefore, overfixation should be avoided.

In conclusion, the new protocol is easy and fast to perform and can be applied to both cytological and histological specimens. With this protocol, the advantages of FISH can be used not only for research but also for daily routine purposes even in smaller laboratories.

Characteristics of Epstein-Barr virus associated childhood non-Hodgkin's lymphoma in the Republic of Korea

Received: 15 February 2005 / Accepted: 21 April 2005 / Published online: 1 July 2005
© Springer-Verlag 2005

Abstract To analyze the clinicopathologic characteristics of childhood non-Hodgkin's lymphoma (NHL) associated with Epstein-Barr virus (EBV), EBER in situ hybridization was performed in 80 cases of NHLs. EBER-positive lymphomas account for 25% (20/80) and include NK/T-cell lymphoma (6/6), aggressive NK-cell leukemia (1/1), peripheral T cell lymphoma (5/11), diffuse large B-cell lymphoma (5/14), hydroa-like T-cell lymphoma (1/1), marginal zone B-cell lymphoma (1/2), and post-transplantation lymphoproliferative disorder (1/1). Other types including 19 cases of Burkitt's lymphoma were negative. For 9 EBER-positive cases, immunohistochemical staining for LMP-1, and EBNA-2 was performed to determine the EBV latency pattern. Two of nine EBER-positive cases expressed both LMP-1 and EBNA-2. Clinically, patients with EBV-positive B-cell lymphomas were cured with chemotherapy, whereas EBV-associated NK- and T cell lymphomas pursued fatal clinical course. In conclusion, EBVs infected in childhood NHLs are frequently associated not only with NK- and T- cell lymphomas but also large B-cell lymphomas.

Introduction

Epstein–Barr virus (EBV) is a well known oncogenic virus associated with various lymphoproliferative disorders. EBV is identified in endemic Burkitt's lymphoma, peripheral T-cell lymphoma, T/NK (natural killer) cell lymphoma, aggressive B cell lymphoma, human immunodeficiency virus (HIV) -associated lymphoproliferative disorder, and Hodgkin's lymphoma. In Hodgkin's lymphoma, the highest frequency (approximately 75%) is found in mixed cellularity HL, and the lowest incidence (10–40%) in nodular sclerosis Hodgkin's lymphoma [5]. According to several studies, the EBV association in T/NK cell lymphoma approaches 50–60%, while that of B cell lymphoma is only between 5–10% [11, 12, 15].

Malignant lymphomas arising in children differ in the frequency of subtype and response to chemotherapy from those of adult patients. In adult patients, EBV is strongly associated with T or NK cell lymphoma such as nasal-type NK/T cell lymphoma which commonly occurs in Far East Asia, especially Hong Kong, Japan, and Korea, suggesting racial or environmental influence. In pediatric patients, there have been few studies regarding EBV-infected non-Hodgkin's lymphomas (NHLs). Recently, Chabay et al. reported high association of EBV in NHLs in children with immune deficiency such as HIV infection or primary immune deficiency [2]. On the other hand, pediatric patients analyzed by Peh et al. showed that EBV was more strongly associated with B-lineage lymphomas than T-lineage lymphoma [12]. Korea is one of the endemic area of EBV infection. At preschool age, more than 80% of children show positive serology for EBV antigen. Considering the common occurrence of EBV-associated NK/T cell lymphoma in adult patients, high prevalence of EBV in pediatric NHLs is strongly suspected. In this study, we analyzed the distribution of EBV in NHLs of children.

Materials and methods

Cases

NHLs diagnosed in patients under the age of 18 years were retrieved from the surgical pathology files. A total of 99 cases were diagnosed in Samsung Medical Center (43 cases) from 1995 to 2003 and Asan Medical Center (56 cases) from 1991 to 2003. Among these, 80 cases for which information for EBER in situ hybridization or paraffin block for the study was available were further analyzed. Clinical information including age, sex, site of involvement, and outcome was obtained from the medical records.

EBV in situ hybridization

Paraffin-embedded tissue sections (5 μm) containing lymphoma were prepared on glass slides. The tissues were digested with proteinase K, dehydrated in 95% ethanol and dried. Hybridization was performed using FITC-labeled EBER-1 and -2 oligonuclotide probes (Novocastra). Following the incubation with anti-FITC antibody tagged with alkaline phosphatase, slides were covered with 5-bromo-4-chloro-3-indolyl phosphatase (BCIP), nitroblue-tetrazolium (NBT), and 1M levamisole. Positive reaction was regarded as such when the majority of tumor cells show nuclear signal.

Immunohistochemical staining

To determine the type of EBV latency, immunohistochemical stain for LMP-1 (Dako, 1:20) and EBNA-2 (Dako, 1:20) was performed in nine EBER-positive cases. A standard three-step immunoperoxidase staining was performed using automated stainer (Dakochemate, Dakocytomation). All cases underwent antigen retrieval with microwave treatment in citrate buffer at pH 6.0.

Results

The 99 patients comprised 30 females, and 69 males, aged 10 months to 18 years (median age 9.5 years) at diagnosis. Histologic subtypes include lymphoblastic lymphoma (13), marginal zone B-cell lymphoma (2), diffuse large B-cell lymphoma (16), mediastinal large B-cell lymphoma (1), Burkitt's lymphoma (32), anaplastic large cell lymphoma (14), NK/T-cell lymphoma (8), peripheral T-cell lymphoma, unspecified (11), hydroa-like T-cell lymphoma (1), and post-transplantation lymphoproliferative disorder (1).

Distribution of EBV in non-Hodgkin's lymphoma (Table 1)

Among 80 cases analyzed by in situ hybridization, 20 cases (25%) were EBER-positive.

Table 1 EBER positivity according to histologic subtype

Subtypes	Positive case/no. of cases examined
Marginal zone B-cell lymphoma	1/2
Diffuse large B-cell lymphoma	5/14
Peripheral T-cell lymphoma	5/11
NK/T-cell lymphoma	6/6
Aggressive NK cell leukemia	1/1
Hydroa-like T-cell lymphoma	1/1
Post-transplantation lymphoproliferative disorder	1/1
Lymphoblastic lymphoma	0/10
Mediastinal large B-cell lymphoma	0/1
Burkitt's lymphoma	0/19
Blastic NK-cell lymphoma	0/1
Anaplastic large cell lymphoma	0/13

EBV positive rate was lower in male patients (9/53) than in female patients (11/26). There was no discernible difference according to age. Five of 19 patients younger than 7 years of age were positive for EBV, four of 24 patients between 7 and 12 years, and 11 of 36 patients between 13 and 18 years. According to histologic subtypes, EBER was negative in all cases of anaplastic large cell lymphoma (0/13), Burkitt's lymphoma (0/19), lymphoblastic lymphoma (0/10), mediastinal large B-cell lymphoma (0/1) and blastic NK-cell lymphoma (0/1). EBER was positive in marginal zone B-cell lymphoma (1/2), diffuse large B-cell lymphoma (5/14), peripheral T-cell lymphoma (5/11), NK/T-cell lymphoma (6/6), aggressive NK cell leukemia (1/1), hydroa-like T-cell lymphoma (1/1), and post-transplantation lymphoproliferative disorder (1/1) (Table 1).

Determination of EBV latency (Table 2 and Fig. 1)

By immunohistochemistry, LMP-1 was detected in two of nine EBER-positive cases. Both were diffuse large B-cell lymphoma and expressed EBNA-2 as well. Clinically, those two patients had no obvious immune deficiency. The remaining seven cases were negative for both LMP-1 and EBNA-2 (Table 2 and Fig. 1).

Discussion

The predominant histologic subtypes of cases enrolled for the study were Burkitt's lymphoma (32 cases, 32%) followed by diffuse large B-cell lymphoma (16 cases, 16%) and anaplastic large cell lymphoma (14 cases, 14%). The distribution of common subtypes is similar to that of previous studies for pediatric non-Hodgkin's lymphoma [1, 12, 14]. On the other hand, the frequency of lymphoblastic lymphoma (13 cases, 13%) was relatively low. The frequency of NK/T-cell lymphoma (8 cases, 8%), and peripheral T-cell lymphoma (11 cases, 11%) was higher than

that from different geographic location showing that peripheral T-cell lymphoma accounts for 1–10% [1, 14].

EBV is one of DNA viruses belonging to the herpes virus family, which consists of 172 kilobase double-stranded DNA [4]. Since EBV was discovered in tumor cells of Burkitt's lymphoma in 1964, the spectrum of EBV-associated human disease has been expanded and includes infectious mononucleosis, nasopharyngeal carcinoma, gastric lymphoepithelioma-like carcinoma, gastric adenocarcinoma, leiomyosarcoma, leiomyoma, and lymphoproliferative disorder of various type [10].

Regarding EBV-related pediatric lymphoid malignancy, there have been three reports so far, from Argentina, Malaysia, and Western Europe [2, 7, 12]. Overall frequency of EBER expression in the present study was similar to that from Argentina group [2], which reported EBER expression in eight out of 32 cases (25%) of pediatric non-Hodgkin's lymphoma. However, since five out of eight EBER positive patients in the study from Argentina were immunocompromised, actual EBV positivity in patients without immunodeficiency was much lower than that in the present study [2]. Compared with the result from Malaysia which showed EBV association in 21% of non-Hodgkin's lymphoma, EBV positive rate in the present series was slightly higher, which might be due to the higher number of EBV-associated malignancies such as NK/T cell lymphoma and peripheral T cell lymphoma, unspecified type, enrolled in the present study. Otherwise EBER-positive rates of each subtype, including NK/T-cell lymphoma, anaplastic large cell lymphoma, peripheral T-cell lymphoma, unspecified type, and diffuse large B-cell lymphoma, were similar [12].

All 19 Burkitt's lymphomas in this study were EBER-negative. This frequency is the lowest among those of previous studies from Pakistan (80%: 8/10), Israel (34%: 11/32), Taiwan (80%: 8/10), Malaysia (38%: 3/8), and Western Europe (11.3%: 25/222) [3, 7, 9, 12, 13]. Although sporadic Burkitt's lymphoma, which is the type of Korean Burkitt's lymphoma, generally has a low frequency of EBV infection, negativity of EBV in Burkitt's lymphoma was unexpected. It may be postulated that pathogenetic association of EBV with sporadic Burkitt's lymphoma differs

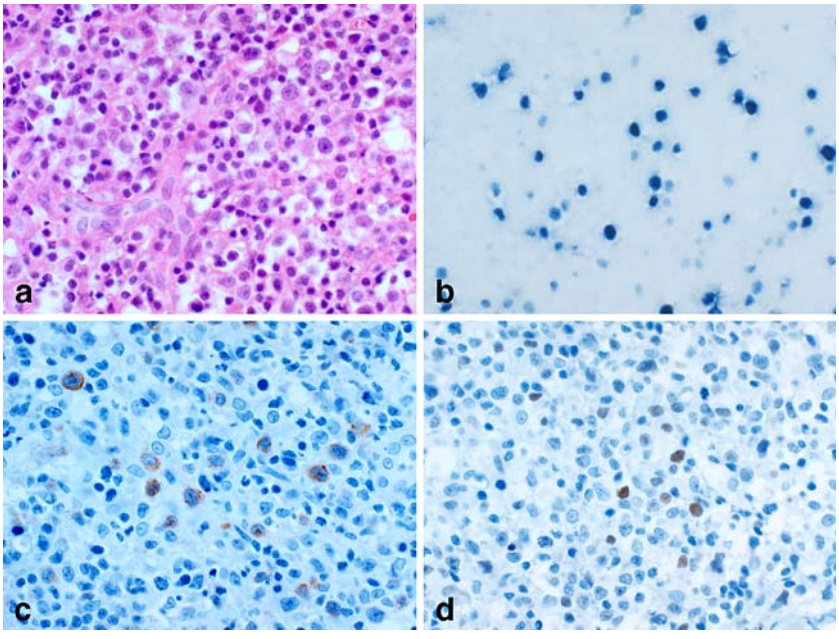

Fig. 1 Diffuse large B-cell lymphoma with expression of LMP-1 and EBNA-2 (Table 2, case 6) (**a**) Histologic finding. (**b**) EBER in situ hybridization. (**c**) Immunostain for LMP-1 protein. Some tumor cells express LMP-1. (**d**) Immunostain for EBNA-2 protein. Some tumor cells express EBNA-2

according to the ethnic group; however, further study with larger numbers of cases is required to verify this finding.

Three types of latency, types I, II, and III, have been identified in different EBV-associated malignancy. Latency I expressing EBNA-1 in the absence of other proteins such as EBNA-2, LP, LMP-1, LMP-2 is observed in Burkitt's lymphoma; latency II, coexpressing EBNA-1 and LMPs in the absence of other EBNA proteins is found in Hodgkin's lymphoma or nasopharyngeal carcinoma. Latency III, which is characterized by expression of all latent viral proteins, is found in B-lymphoblastoid cell lines and HIV-associated lymphomas [6]. The present study is limited in its ability to evaluate the latency type of EBV because the antibody panel for immunostain in this study did not include EBNA-1 and other latent infection-associated protein, except EBNA-2 and LMP-1. However, the seven cases which did not express LMP-1 gene and EBNA-2 seem to represent type I latency. Interestingly, the other two cases showed type III latency, which is usually identified in immuno-compromised patients. Clinically, those two patients had diffuse large B cell lymphoma in the nasopharynx, without obvious immune deficiency.

Generally, patients with EBV-positive T and NK cell lymphomas pursued an aggressive clinical course. In particular, patients with NK/T-cell lymphoma have a poor prognosis. Five patients with NK cell leukemia/lymphoma, peripheral T-cell lymphoma, or hydroa-like T-cell lymphoma died within 13 months after diagnosis. Three of these patients had hemophagocytic syndrome. In contrast to T and NK cell lymphoma, three patients with EBER-positive diffuse large B-cell lymphomas and one patient with marginal zone B-cell lymphoma were cured with chemotherapy and still alive. A large previous series for diffuse large B-cell lymphoma reported no significantly different clinical features between EBV-positive and EBV-negative cases [8].

In conclusion, EBV infected in pediatric non-Hodgkin's lymphomas are frequently associated with not only NK- and T- cell lymphomas but also large B-cell lymphomas.

Tracing origin of serrated adenomas with *BRAF* and *KRAS* mutations

Received: 14 December 2004 / Accepted: 6 February 2005 / Published online: 1 July 2005
© Springer-Verlag 2005

Abstract Serrated neoplasm of the colorectum raised many as-yet unanswered issues. To characterize serrated neoplasia pathway, we investigated *BRAF* and *KRAS* mutations in 35 traditional serrated adenomas. *BRAF* exons 11 and 15, and *KRAS* exon 2 were amplified by polymerase chain reaction and directly sequenced. *BRAF* V599E mutation was found in 27 serrated adenomas (77.1%), and *KRAS* mutations were found in 3 (8.6%) of 35 traditional serrated adenomas. In 13 cases, mixed polyps composed of traditional serrated adenomas and hyperplastic (serrated) polyps were observed, and seven of them showed the same *BRAF* mutations in both components. Somatic mutations of *BRAF* and *KRAS* genes were mutually exclusive. These findings suggest that *BRAF* mutations are early and a critical event in the serrated adenomas, and most serrated adenomas in both sides of colon may progress from microvesicular hyperplastic polyps via *BRAF* mutations, and some left-sided serrated adenomas develop via *KRAS* mutations.

Keywords Serrated adenomas · *BRAF* · *KRAS* · Mutations

Introduction

The serrated neoplasia pathway suggests that dysplasia can arise within hyperplastic colonic polyps, resulting in the formation of a traditional serrated adenoma and potentially the development of colorectal carcinoma [7, 9–13]. Although the concept of a "serrated pathway" for colorectal neoplasia is very exciting from a scientific point of view, from a practical perspective, it raised many as-yet unanswered issues (K.P. Batts, unpublished material). The consistent morphological identification of serrated adenomas is prerequisite to gaining a clearer understanding of the serrated neoplasia pathway [2]. The polyps of this pathway differ morphologically and genetically from those of traditional adenoma–carcinoma sequence. Genetically, serrated adenomas are characterized by a high frequency of low mutator phenotype, *p53* mutations, *KRAS* mutations, *BRAF* mutations, and low frequency of *APC* gene mutation than in sporadic tubular adenomas [5]. However, activation of the *RAF*/*RAS* signal transduction cascade by *RAS* mutations in serrated neoplasia is mainly concentrated on hyperplastic (serrated) polyps, and their occurrence in traditional type SA is limited to small numbers of cases, and their relation to histogenesis is not described [3, 14, 26, 27]. To explore the clinicopathological and genetic characteristics of traditional serrated adenomas during the serrated neoplasia pathway, well-recognized and reproducible pathological diagnostic criteria of serrated adenomas were adopted, and this is the first large-scale study on *BRAF* and *KRAS* mutations using traditional serrated adenomas.

Material and methods

Material

Thirty-five traditional serrated adenomas and five hyperplastic polyps were included in this study for detection of mutations in *BRAF* and *KRAS*. Four retention polyps and 15 cases of colonic mucosa from histologically normal portion of the polypectomy specimens were selected as negative controls. All the samples were obtained from Our Lady of Mercy Hospital and Samsung Medical Center from 1998 to 2004 by computer search and review of the slides. The 35 patients included 12 women and 23 men with a

mean age of 54.2 years (range 32–73). In the present study, serrated polyps were reviewed according to the provisional classification proposed by Torlakovic et al. [24], and only traditional type serrated adenomas with pseudostratification, micropapillations of the surface epithelium with eosinophilic cytoplasm, were selected. According to the presence of hyperplastic (serrated) polyp components and epithelial dysplasia based on histological and cytological criteria, the tumors were divided into 13 mixed serrated adenomas with hyperplastic (serrated) polyp, 21 serrated adenomas with low-grade dysplasia, and one serrated adenoma with high-grade dysplasia.

Mutation of *BRAF* and *KRAS*

DNA was extracted from 0.1% methylene blue-stained 10-μm sections under microscopy using 20 gauge needles and proteinase K solution as previously described [5]. In 7 of the 13 mixed polyps composed of serrated adenomas and hyperplastic (serrated) polyps, DNAs from both serrated adenomas and hyperplastic areas were obtained by manual microdissection and examined for mutations of *BRAF* and *KRAS*. Primer pairs were used to amplify the complete coding sequences of *BRAF* exon 11 (forward TTC TGT TTG GCT TGA CTT GAC TT, reverse ACT TGT CAC AAT GTC ACC TT) and exon 15 (forward TGC TTG CTC TGA TAG GAA AAT G, reverse AGC ATC TCA GGG CCA AAA AT), and of *KRAS* exon 2 (forward CTG AAA ATG ACT GAA TAT AAA CTT GT, reverse ATA TGC ATA TTA AAA CAA GAT TTA CC). Polymerase chain reaction (PCR) was performed in a 20-μl volume containing 100 ng of template DNA, 10×PCR buffer; 0.25 mM deoxynucleoside triphosphate (dNTP), 20 pmol primers, and 1.5 U *Taq* DNA polymerase (Takara Shuzo, Kyoto, Japan). PCR products were electrophoresed on 2% agarose gels, purified, and both strands were directly sequenced using the BigDye Terminator v3.1 cycle sequencing kit, followed by analysis with an Applied Biosystems 3700 automated sequencer (Applied Biosystems, Foster City, CA, USA).

Statistics

A statistical analysis comparing clinical, histological, and mutation results was performed using χ^2 test and two-tailed Pearson correlation analysis with the statistical software SPSS (version 10.0, Chicago, IL, USA).

Results

Clinicopathological findings of traditional serrated adenomas

Of the serrated adenomas, 8 (22.9%) occurred in the right colon and 27 (77.1%) occurred in the left colon. Every traditional serrated adenoma in this study was endoscopically and grossly protruded, polypoid, and nodular in shape with a size ranging from 0.3 to 2.2 cm (mean 1.0 cm). All the serrated adenomas had serrations more than 50% of the lesion, frequent pseudostratification, nuclear atypia, and micropapillations of the surface epithelium with eosinophilic cytoplasm. In one case, high-grade dysplasia was noted in the head portion of the polyp (Fig. 1a–c). Thirteen cases of serrated adenomas showed hyperplastic (serrated) polyp areas featuring microvesicular type hyperplastic polyp described by Torlakovic et al. [24]. These hyperplastic areas were noted in the neck or mid-portion of the polyps (Fig. 2a–c).

BRAF mutations in traditional serrated adenomas

BRAF mutation was found in 27 (77.1%) serrated adenomas and in 1 (20%) hyperplastic polyp, whereas 15 normal colon tissue and 4 retention polyps had wild-type *BRAF*. Mutations found in this study were a single missense mutation in codon 599 of exon 15 (V599E), an activation segment of *BRAF* (Fig. 3a,b). All 13 mixed polyps with serrated adenomas and hyperplastic areas had *BRAF* mutations. Using seven mixed polyps, DNAs from both serrated adenomas and hyperplastic (serrated) polyp areas were examined for *BRAF* mutations. Surprisingly, both of these areas in all examined cases had the same V599E mutations. In serrated adenomas displaying low-grade dysplasia (21 cases), 14 cases (66.7%) exhibited *BRAF* mutation. One serrated adenoma displaying high-grade dysplasia harbored no *BRAF* mutations. When we scrutinized the histology, all serrated adenomas without *BRAF*

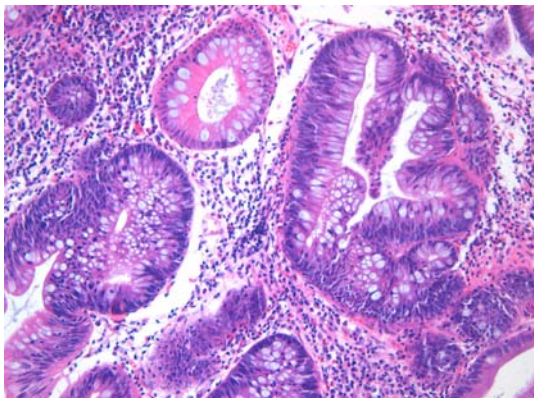

Fig. 4 Abnormal proliferations with increased dysplasia and pseudostratification, abundant dystrophic, and mature goblet cells were noted focally in traditional serrated adenomas without *BRAF* mutations

mutations had areas of abnormal proliferations, increased dysplasia, pseudostratification, and abundant dystrophic and mature goblet cells along with traditional eosinophilic cells (Fig. 4), and five of them showed tubular adenomas focally (Fig. 5). One hundred percent of serrated adenomas from the right colon had mutations of *BRAF*, whereas 70.4% of left-sided serrated adenomas had *BRAF* mutations although statistically not significant (p=0.08). The incidence of *BRAF* and *KRAS* mutations and their relationship to clinicopathological findings are depicted in Table 1.

KRAS mutation in serrated adenomas

KRAS G12D (G35A) mutations were found in 3 of 35 (8.6%) traditional serrated adenomas (Fig. 3c,d). One high-grade serrated adenoma had *KRAS* mutation. Of the seven mixed polyps with serrated adenomas and hyperplastic areas, both serrated adenomas and hyperplastic areas harbored no *KRAS* mutations. All three serrated adenomas with *KRAS* mutations occurred in the left colon and showed focal area of tubular adenoma and shared the histological features of serrated adenomas without *BRAF* mutations.

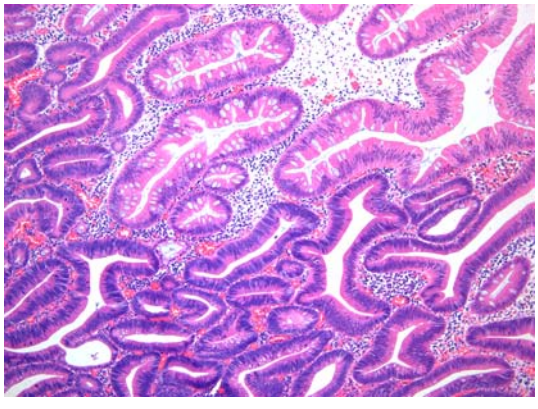

Fig. 5 Focal tubular adenoma areas were observed in serrated adenomas with *KRAS* or without *BRAF* mutations

Table 1 Mutations of *BRAF* and *KRAS* and their relationship to clinical findings of traditional serrated adenomas

Five hyperplastic polyps, 15 normal colon tissue, and 4 retention polyps showed no *KRAS* mutations.

Discussion

The *BRAF* gene is mutated in about 70% of malignant melanomas, 10 to 22% of colon cancers, and a smaller proportion of other cancer types. *BRAF* mutation in the active segment, a conversion of valine 599 to glutamic acid (V599E), is a hotspot for *BRAF* mutation in human cancers. All mutations identified to date are within the kinase domain, with a single missense mutation (V599E) accounting for 80% [4]. In this study, all *BRAF* mutations were found in this hotspot of *BRAF*, and we could confirm that V599E is the most common mutation found in traditional serrated adenomas. Moreover, no *BRAF* mutations in exon 15, other than the common hotspot mutation, were identified in our large series, and furthermore, we could demonstrate no mutations at all in exon 11. Previous mutation analysis of *BRAF* using colonic carcinoma samples has shown that *BRAF* mutations are more common in the earlier stages, and the subjects had long-term survival without recurrence. This suggests less invasive biological behavior for those cancers harboring *BRAF* mutations [27]. In our study, mutation of *BRAF* was frequent in traditional serrated adenomas with low histological grades. Chan et al. [3] reported a 100% frequency of *BRAF* mutations for 10 cases of serrated adenomas and 30% for 50 cases of hyperplastic polyps. We could demonstrate *BRAF* mutations in 77.1% of traditional serrated adenomas and in 20% of hyperplastic polyps, respectively, in this large-scale study. It is very interesting that *BRAF* mutations go with traditional serrated adenomas with hyperplastic (serrated) polyp components (mixed polyps). These results suggest that mutation of *BRAF* is a critical event in traditional serrated adenomas that arise from or differentiate into hyperplastic (serrated) polyps of microvesicular type during

the serrated neoplasia pathway. We found that traditional serrated adenomas with frequent serration and surface micropapillations with eosinophilic cytoplasm had a high frequency of *BRAF* mutations. All the *BRAF* mutation-negative and *KRAS* mutation-positive serrated adenomas were left-sided and showed frequent immaturity of epithelium with increased dysplasia and abundant dystrophic or mature goblet cells among eosinophilic cells, featuring the serrated polyp with abnormal proliferation or goblet cell type hyperplastic polyps. In a previous report, goblet cell type hyperplastic polyps seem to have frequent *KRAS* mutation and to be left-sided [16]. Therefore, this would explain the lack of *BRAF* mutation given the possible origin of some serrated adenomas in this variant. Along with colonic villous adenomas [27], papillary thyroid carcinomas [6], and serous papillary ovarian tumors [20–22], these findings suggest that the *BRAF* mutations may be related to the specific histological morphology of epithelial cells, i.e., the formation of papillary projections. All traditional serrated adenomas derived from the right colon had *BRAF* mutations. Right side serrated adenomas had a higher frequency of *BRAF* mutations than did the left one. *BRAF* was previously reported to be mutated in 11 to 22% of colonic carcinomas, with a strong association with the epigenetic alteration of *hMLH1* [15, 17, 25], although *BRAF* mutation was not caused by a mismatch repair deficiency [25]. Our right side predilection of *BRAF* mutation is consistent with these previous observations. A negative correlation between mutations in the *BRAF* and *KRAS* genes is also evident, which supports earlier studies that found that somatic mutations in these genes are mutually exclusive [22, 23]. *KRAS* mutations were found in three left serrated adenoma cases. In previous studies, *KRAS* mutations in serrated adenomas are heterogeneous ranging from 0 to 40.4% [1, 8, 18, 19]. In this study, *KRAS* mutations were found in 8.6% of traditional serrated adenomas in the left colon. Although *BRAF* mutations occurred in both younger and older ages (Table 1), *KRAS* mutations were exclusively found in older age. All three serrated adenomas with *KRAS* mutations occurred in the left colon, showed focal area of tubular adenoma, abnormal proliferations, and increased dysplasia with more pseudostratification. These results suggest that *KRAS* mutations involve some left-sided serrated adenomas with high-grade dysplasia occurring in older age.

Although our data on the natural history of traditional serrated adenomas need more supporting evidences, we propose that *BRAF* mutations are early and a critical event in serrated adenomas. The occurrence of the same *BRAF* mutations found in both serrated adenomas and hyperplastic areas observed in mixed polyps suggests that some of traditional serrated adenomas may progress from hyperplastic (serrated) polyps via *BRAF* mutations and some left serrated adenomas originate via *KRAS* mutations.

Gonadoblastoma: evidence for a stepwise progression to dysgerminoma in a dysgenetic ovary

Received: 9 February 2005 / Accepted: 12 April 2005 / Published online: 21 June 2005
© Springer-Verlag 2005

Abstract Gonadoblastomas are neoplasms of dysgenetic gonads which may undergo regression or become overgrown by malignant germ cell tumors (mGCTs). Since little is known about their relationship to normal gonadal development and mGCTs, we studied the phenotype and antigenic profile of gonadoblastomas in comparison with adjacent dysgerminomas and fetal gonads. Three cases of gonadoblastomas and fetal gonads of both sexes were analyzed using oncofetal markers to M2A-antigen (M2A), germ cell alkaline phosphatase (PLAP/GCAP), receptor tyrosine kinase c-kit (c-kit), and somatic angiotensin converting enzyme (sACE) as well as the proliferation marker MIB-1. Morphologically, microfollicular pattern of gonadoblastomas showed a fetal germ cell organization reminiscent of oocytic clusters of fetal ovaries. They contained both cell types, similar to oocytes (M2A-, GCAP-, c-kit+/−, sACE-) and oogonia (M2A+, GCAP+, c-kit+, sACE+). The percentage of germ cells immunoreactive for oncofetal markers and the proliferation index increased from microfollicular over coronary patterns to adjacent dysgerminomas. Supportive cells of gonadoblastomas showed a uniform phenotype (CK18+, vimentin+, sACE+, alpha-inhibin+, M2A-) but in contrast to fetal germ cells lacked a clear equivalence to fetal tissues. Our results show that gonadoblastomas mimic female fetal ovary and exhibit a stepwise progression from follicular pattern to coronary pattern and finally to dysgerminomas.

Introduction

Gonadoblastoma is a rare tumor which may occur in gonadal streaks, ovaries, or abdominal testes. It is composed of sex-cord derivatives and germ cells, intimately arranged in nests of two different forms, the microfollicular and coronary patterns. These peculiar nests of uncertain origin and significance are generally surrounded by dense connective tissue, similar to the ovarian cortex [18, 20, 22].

Most gonadoblastomas arise in dysgenetic gonads of XY sex-reversed individuals, who are phenotypically females due to mutations of the single sex determining region gene of the Y chromosome (*SRY*) or few other genes involved in the early sex determining pathway [1, 4, 5]. Mutation and dysfunction of *SRY* lead to impairment or absence of fetal testes, dysgenetic gonads, and partial or complete female sex development [3, 9]. Very rarely, gonadoblastomas may also occur in fertile females and in Turner patients [28]. However, probably all gonadoblastomas need fragments or still functioning genes of the Y chromosome to develop. Only Turner patients with a 45, X/46,XY mosaicism in their dysgenetic gonads are at risk to develop these lesions, in contrast to those with a pure 45,X karyotype [25].

In 50–60% of cases, gonadoblastomas are associated with malignant germ cell tumors (mGCTs), mostly presenting as a pure dysgerminoma or, less frequently, as immature teratoma, yolk sac tumor, embryonal carcinoma or choriocarcinoma. Other gonadoblastomas do not progress to invasive malignancies but regress to calcifying masses, referred to as “burned out gonadoblastoma [20]”. In general, the stromal component of gonadoblastomas is

thought to be benign, although in few cases associated Sertoli cell-like tumors have been reported [13].

In the absence of comparative studies, various practical and theoretical issues remain a matter of debate. It is still unclear whether gonadoblastomas are true neoplasms with initial characteristics of in situ-germinomas [11, 20] or rather hamartomatous lesions [6, 11, 17], what is the meaning of its two growth patterns and to what extent these patterns match with the supposed "recapitulation of gonadal development" [20]. To address these issues, we performed this study on typical gonadoblastomas using well known oncofetal antigens germ cell alkaline phosphatase (GCAP), c-kit receptor (c-kit), M2A, and sACE. Additionally, markers to ovarian stroma cells, cytokeratin 18 (CK18), vimentin and alpha-inhibin, were also studied. Histological patterns and antigenic profiles of gonadoblastomas were compared to adjacent dysgerminomas and normally developed fetal gonads of both sexes.

Materials and methods

Tissues

Tissues of gonadoblastomas in three adult patients were selected from the files of the Departments of Pathology, Universities of Bonn and Giessen. Two patients had a unilateral, one a bilateral gonadoblastoma. Two phenotypically female patients, one 19 (patient 1) and the other 18 (patient 2) years old, underwent preventive adnexectomy because of a history of XY-pure gonadal dysgenesis and high risk of developing mGCTs. The third patient, a 52-year-old, had a female phenotype and XY-genotype and underwent bilateral adnexectomy because of acute small bowel obstruction and adhesive ileus and a 9 cm sized tumor of the right ovary. The clinical data of all patients are summarized in Table 2.

Specimens of ten fetal ovaries and 16 fetal testes from fetuses of various weeks of gestation (weeks 15, 16, 19, 20, 22, 24, 25, 33 and 35) were collected during the period 1999–2004 from the tissue archives of the Department of Pathology, University of Bonn. All fetal tissues were obtained for diagnostic or documentary reasons because of legal interruptions or fetal deaths (amnion infection or premature rupture, congenital heart failure). Normal ovaries from six mature newborns removed for enlarged benign cystic lesions were also included in this study.

Tissue preparation and immunohistochemistry

Tissues were fixed by immersion in phosphate-buffered formalin (pH 7.0) and embedded in paraffin using standard techniques. Gonadal tissues from adult patients were embedded completely and 4–15 paraffin blocks were prepared. Consecutive tissue sections were mounted on superfrost slides (Menzel-Gläser, Braunschweig, Germany), dried for 12 h at 37°C, and the first section of each series was stained by hematoxylin and eosin (HE). Immunohistochemistry was performed using alkaline phosphatase anti-alkaline phosphatase (APAAP) or avidin-biotin peroxidase complex (ABC) techniques, as published before [14, 26]. Prior to incubation with the primary antibodies, the dewaxed tissue sections were microwave-pretreated for antigen retrieval. The antibodies and their working dilutions are summarized in Table 1.

Results

Clinical data and histomorphological findings

Histological examination of right ovaries of patients 1 and 2 revealed partially calcified gonadoblastoma with numerous vital gonadoblastoma nests next to a small dysgerminoma. In addition, calcified masses in the left ovary were found in patient 1, corresponding to a burned out gonadoblastoma. In the third patient, the 9 cm sized tumor of the right ovary was mainly composed of pure dysgerminoma with a minor gonadoblastoma part. In patients 2 and 3 the left ovary contained fibrous stroma without germ cells or gonadoblastoma (Table 2).

Histologically, all vital parts of the analyzed gonadoblastomas showed the arrangement of germinal structures in both microfollicular (Fig. 1a) and coronary growth patterns (Fig. 1b). In microfollicular pattern, the supportive cells were predominant and surrounded individual germ cells or laminated hyaline material. In gonadoblastoma nests of the coronary pattern, an increased number of germ cells displaced the supportive cells to the periphery. Next to coronary pattern, invasive dysgerminomas were found in all three vital gonadoblastomas, presenting either as small invasive tumor cords within the ovarian stroma or as large solid tumor masses.

[a]DG: Dysgerminoma

Immunohistochemical findings

In all vital gonadoblastoma nests, germ cells were found to be selectively labeled by GCAP (with identical pattern of the two antibodies used), c-kit, and M2A, while sACE labeled both, germ cells and stromal cells. In general, percentage of germ cells positive for GCAP, c-kit and M2A was higher in the coronary than in microfollicular nests of each gonadoblastoma (Figs. 1c,d and 2). This increase could not be statistically calculated because of the small number of cases included in this study. However, the highest number of positive germ cells was counted for c-kit, which ranged from 50 to 70% in the microfollicular and from 80 to 95% in the coronary pattern of patients 2 and 1, respectively (Fig. 2). In contrast, M2A, GCAP, and sACE labeled only a small germ cell fraction within the microfollicular gonadoblastoma nests of patient 1, but showed also a marked increase of immunopositive germ cells in coronary nests and adjacent dysgerminoma (Fig. 2). The clear difference in immunoreactive germ cells among

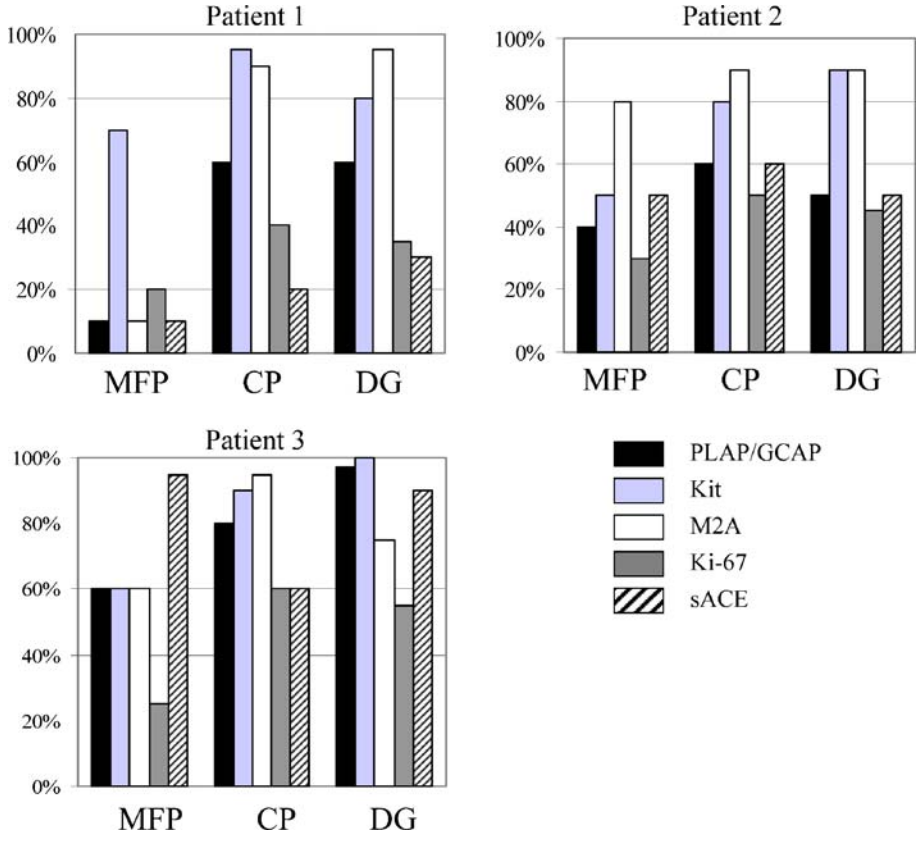

Fig. 2 Relative distribution of oncofetal markers PLAP, Kit, M2A and sACE and Ki-67 staining in gonadoblastomas of three patients (1–3), evaluated separately in follicular pattern (*MFP*), coronal pattern (*CP*), and in invasive dysgerminoma (*DG*)

the growth patterns of gonadoblastomas was also paralleled by changes in germ cell proliferation index. Similar to germ cell markers, the highest proliferation index (estimated with Mib-1 antibody) was found in the coronary pattern and in adjacent dysgerminomas (Fig. 2). Generally, germ cells in microfollicular pattern showed a lower proliferation index than in the coronary pattern. Interestingly, nest-forming clonal expansion of germ cell within microfollicular nests showed the same proliferating activity as in coronary pattern and in invasive dysgerminoma (Fig. 1e and 2). Independent of histological pattern, the supportive cells of all gonadoblastomas showed uniform immunoreactivity for CK18, vimentin, alpha-inhibin, and sACE. M2A was negative and the number of MIB-1 positive stromal cells was low and less than 5%.

Histological and immunohistochemical comparison with fetal gonads

In none of the analyzed fetal testes were any complex structures found that were morphologically identical to that of gonadoblastoma. Fetal seminiferous tubules were clearly distinguishable from the intestitial space and contained numerous c-KIT positive gonocytes (not shown). In contrast, in all ovaries obtained from mature newborns and fetuses (from weeks 15 to 35) nests similar to microfollicular pattern of gonadoblastoma were observed within the ovarian stroma (Fig. 3a–c). In all fetuses, the majority of oogonia were found in the cortical region of the ovary and were positive for M2A, GCAP, c-kit, and sACE (Fig. 4a). In the medullar region of ovaries, oocytes were closely assembled in the nest-like clusters and were negative for M2A, GCAP, and sACE but positive for c-kit (Fig. 4b). Primordial follicles in the medullary region of the ovaries were also negative for M2A, GCAP, sACE and positive for c-kit (Fig. 4c and d). Taken together, the germ cell population of microfollicular gonadoblastoma nests matched the antigenic profiles of oogonia and oocytes in fetal ovaries.

Supportive cells and surrounding stroma of gonadoblastoma diverged morphologically and immunohistochemically from their fetal counterparts. As demonstrated in Table 3, the immunophenotype of stromal sex cord of gonadoblastomas did not match with fetal testicular and ovarian counterparts at any stage (Table 3). No structural or cytological similarities have been found between gonadoblastoma and the forming seminiferous tubules of fetal male gonads including pre-Sertoli cells.

Discussion

Gonadoblastomas are tumors that are linked to gonadal development, and are reported to contain immature germ and stromal cells. Our study confirms that gonadoblastomas are populated by germ cells at a fetal stage of differentiation [11]. This is shown by the uniform expression of oncofetal markers similar to those produced by their fetal ovarian analogues, namely proliferating oogonia (M2A+, GCAP+, c-kit+, sACE+) and oocytes (M2A−, GCAP−,

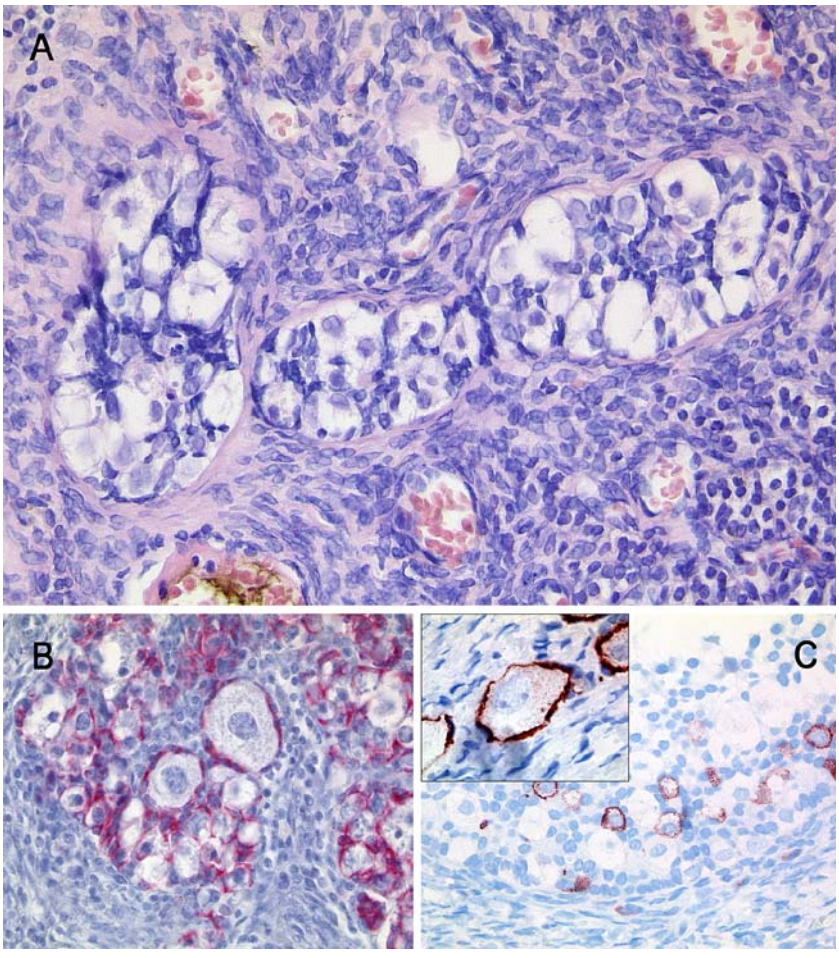

Fig. 3 Fetal organization of germ cells in oocytic clusters within the normal ovary of newborns (**a**, H&E) and in fetal ovaries (week 22 of pregnancy) (**b**, vimentin) resembling the microfollicular pattern of gonadoblastoma. Germ cells inside of oocytic clusters are partially surrounded by fetal stromal cells, which are positive for vimentin (**b**). **c** C-kit is expressed in a portion of oocytes (insert indicate membraneous staining pattern). Original magnification ×20 **a**, **c**, ×40 **b**

c-kit+/−, sACE−). We also found histological similarities between the microfollicular pattern of gonadoblastoma and the fetal ovarian organization of oocytes in nest-like structures, the so-called oocytic clusters [24]. These represent groups of germ cells entering the prophase of meiosis until primordial follicles are formed and subsequently separated

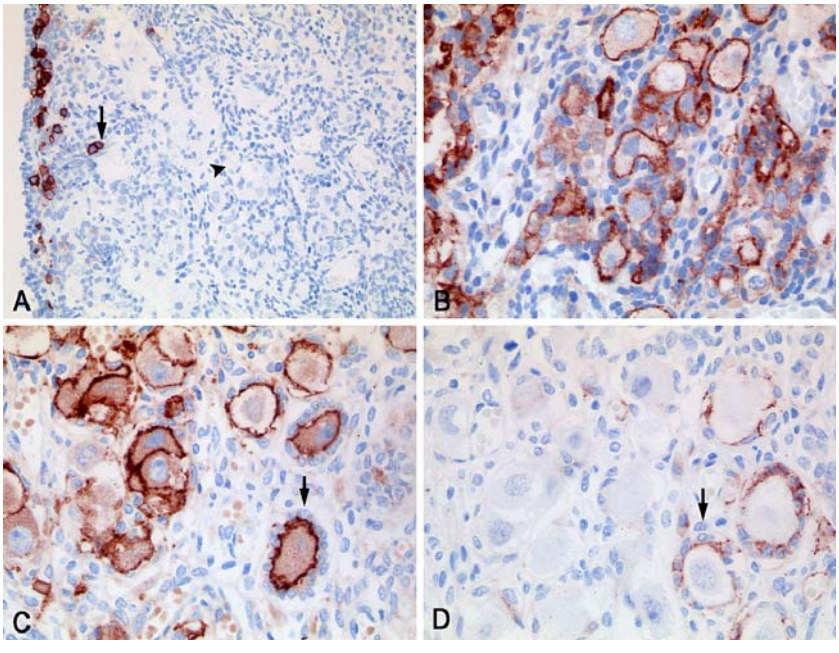

Fig. 4 Immunophenotype of fetal female germ cells. Oogonia in the cortical region of fetal ovary of 15th week of pregnancy are positive for GCAP/PLAP (**a**, arrow), whereas oocytes in the medullar region are PLAP-negative (**a**, arrowhead). Germ cells in oocytic clusters express c-kit (**b**) (week 22 of pregnancy). In week 25 of pregnancy, germ cells at the stage of primordial follicles are still c-kit positive (**c**, arrow) and are surrounded by fetal sACE-positive pre-granulosa cells (**d**, arrow; immunohistochemistry with mAb to sACE)

Table 3 Markers of sex-cord cells in gonadoblastomas (*GB*) and fetal gonads

	Stromal cells in GB	Fetal testicular pre-Sertoli cells		Fetal ovarian pre-granulosa cells	
		Mid fetal	Late fetal	Mid fetal	Late fetal
CK18	+	(+)	−	+	+

M2A	−	(+)	+	−	(+)

into the late-fetal ovarian stroma [24]. We believe that the microfollicular pattern of gonadoblastoma reflect early female germ cell differentiation blocked at the developmental cluster stage of pachytene oocytes prior to their stromal integration.

This view is in agreement with the fact that patients with loss or mutations of the single Y-chromosomal gene *SRY* or its regulatory sequences develop a female phenotype and dysgenetic gonads, and carry a high risk of developing gonadoblastomas [3, 19]. Without proper function of *SRY* or several other genes involved in the early sex-determining pathway, Sertoli-cells and testicular structures cannot be formed [2, 3]. Moreover, a recent report showed that an XY female human fetus, deficient in *SRY*, developed ovaries and a regular appearing female germ cell population, including oocytes, at least until the 14th gestational week [1]. This is definitely later than the structural sex determination in human gonads when formation of testicular cords and pre-Sertoli cells can be recognized (between the 5th and 6th gestational week) [27].

In dysgenetic ovaries, failure in meiotic pairing of different chromosomes may be followed by loss or absence of oocytes in animals and humans [5, 12, 23]. This is well documented in Turner patients, who show degeneration of meiotic oocytes, and loss of almost all oocytes in early childhood [21]. In contrast, the germ cells in dysgenetic gonads of XY females or XY mosaicisms may survive, leading to the frequent occurrence of gonadoblastoma. Since we found the phenotypes of oogonia and oocytes still present in gonadoblastoma of a 52-year-old patient (patient 3), oogonia probably gained a survival advantage similar to that of spermatogonia which are able to persist in a pre-meiotic stage during the male life-span [10]. This advantage is most likely provided by genes from the Y chromosome or its fragments *TSPY* [14, 29].

In gonadoblastomas, supportive cells appear more differentiated compared with fetal ovaries and testis. They showed a distribution still reminiscent of oocytic clusters, whereas their cytological and molecular features differed from any definable fetal stage and often resembled activated granulosa cells [6, 7, 16]. Furthermore, in this and different previous studies, fetal testes from the 8th gestational week onwards never showed structures comparable with that of gonadoblastoma [8]. The fact that Sertoli cells cannot be formed without proper function of *SRY* supports the granulosa origin of these cells [2, 3]. However, it cannot be ruled out that these granulosa-like cells imitate few morphologic and ultrastructural features of adult Sertoli-cells [17]. This may be due to Y-derived gene products from the residual Y chromosome.

Most gonadoblastomas are found incidentally during the investigation of amenorrhea and sometimes beneath a surgically removed mGCT or in the contralateral ovary of adult tumor patients [18, 20, 22]. Therefore, the reported frequencies of associated mGCTs and in situ germinomas may be biased by some selection routine, neglecting small and non-apparent lesions. In this study, we show that the percentage of proliferating germ cells with oogonial features (M2A+, GCAP+, c-kit+, sACE+) increased from the microfollicular to the coronary pattern (Figs. 1 and 2). In parallel, the number of supportive cells decreased from microfollicular to coronary patterns, where they were displaced to the periphery of the gonablastoma nests. Proliferation index and marker expression of germ cells found in the coronary nests of gonadoblastomas were almost the same as in the neighboring dysgerminomas. This suggests that particularly the coronary pattern bear a neoplastic population of oogonia-like cells, the in situ germinoma. Thus, coronary pattern obviously represents an important step in the progression of gonadoblastoma to invasive dysgerminoma. Furthermore, invasion of neoplastic germ cells into the stroma was demarked by loss of supportive cells as shown in our study.

In conclusion, our results indicate that gonadoblastoma is a true in situ neoplasm with two different histological pattern. The microfollicular pattern represents an early stage of gonadoblastoma development and recapitulates the fetal female gonadal development. Proliferation of neoplastic germ cells inside microfollicular nests give rise to the coronary pattern of gonadoblastoma. The latter results from expansion of highly proliferating neoplastic germ cells and represents an advanced stage of gonadoblastoma.

This suggests that every gonadoblastoma, especially if a coronary pattern is present, should be examined completely and carefully in order to exclude an invasive dysgerminoma component. Because early invasion may be difficult to recognize by routine histology, serial immunohistochemical examinations using antibodies to neoplastic germ cells and to sex-cord stromal cells as presented in our study may help to identify an invasive tumor.

Acknowledgements The skillful technical assistance of Barbara Reddeman, Susanne Steiner, Christiane Esch and Gerrit Klemm is gratefully acknowledged. We would like to thank Dr. Irina Fenic for a critical review of the manuscript. This study was supported from a BONFOR research grant of the Medical Faculty, University of Bonn.

Microinvasive germ cell tumor of the testis

Received: 20 December 2004 / Accepted: 7 March 2005 / Published online: 21 June 2005
© Springer-Verlag 2005

Abstract Microinvasive germ cell tumor (MGCT) consists of a limited number of malignant germ cells in the intertubular tissue of the testis. The cells have large nuclei, prominent nucleoli, abundant clear cytoplasm, and distinct cellular borders in hematoxylin and eosin staining. MGCT can be the first stage of malignancy in the development of testicular germ cell tumor (TGCT). Biopsies from men with maldescended testes have been reported to contain intratubular germ cell neoplasia, unclassified (IGCN) and MGCT in 1.8% of the examined cases (95% CI 0.5–4.6%). MGCT has also been found in testes of subfertile men and in the contralateral testis of patients with TGCT. MGCT is a frequent finding (19%) in the testicular tissue adjacent to an overt TGCT. Men with a high risk of TGCT may gain from screening for precursor lesions of TGCT with ultrasonography of the testes followed by a testicular biopsy if suspicious abnormalities are found: Treatment is high-voltage radiotherapy for intratubular germ cell neoplasia (IGCN), and orchidectomy for MGCT and germ cell tumor in situ, either intratubular seminoma or intratubular embryonal carcinoma. After local treatment, patients with precursor lesions can be followed with a surveillance program. The mRNA levels of invasion-related genes were evaluated based on a DNA microarray data set, and we found two gene abnormalities most relevant for the invasion of malignant germ cells: matrix metalloproteinase 9 (MMP9) and plasminogen activator, urokinase (PLAU) genes were up-regulated in a study comparing tissue samples of TGCT and IGCN.

Introduction

Macroscopically overt testicular germ cell tumors (TGCT) for adult men develop through a preclinical phase with at least one of three precursor neoplastic lesions: intratubular germ cell neoplasia non-otherwise specified (IGCN) [20, 71, 80, 99, 149], microinvasive germ cell tumor (MGCT) [180], and intratubular germ cell tumor in situ (Fig. 1) (GCTIS) [12]. The only exception is spermatocytic seminoma. Langhans described IGCN in 1887 [91], and in 1896, Wilms reported that the testicular tissue adjacent to a TGCT could have atrophic tubules containing neoplastic seminoma-like germ cells [194]. In 1972, Skakkebaek reported that untreated IGCN, denoted carcinoma in situ of the testis, could progress to MGCT or TGCT during follow-up [148].

MGCT is a secondary precursor stage of TGCT with extratubular invasion of neoplastic germ cells in the interstitial tissue of the testis. Therefore MGCT is by definition malignant. In 1977, Schulze and Holstein described MGCT as a step in the development from IGCN to seminoma [141]. Supporting MGCT as a separate precursor stage for TGCT, von Eyben and coworkers reported three patients with MGCT, but without overt TGCT, diagnosed within a decade in a limited region of Sweden [180]. Recently, Henley et al. reported 12 additional patients evaluated at two institutions in the USA [61]. Another secondary precursor lesion is GCTIS with either seminoma or embryonal carcinoma, found only intratubularly [12, 116].

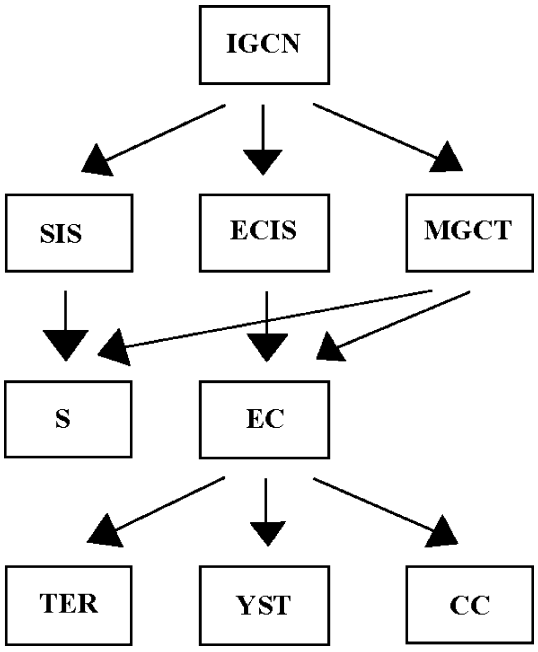

Fig. 1 Progression from IGCN through secondary precursor stages to TGCT. *EC* denotes embryonal carcinoma, *TER* teratoma, *YST* yolk sac tumor, and *CC* choriocarcinoma

Despite the expanding literature on the precursor lesions, there is no consensus about the role of MGCT in the development of TGCT or of its relevance for staging and management of patients. Authors have used 33 different terms for MGCT [4, 6, 20, 21, 24, 38, 39, 53, 61, 62, 78, 80, 94, 101, 104, 105, 109, 111, 116, 117, 125, 128, 143, 149, 171, 180, 196, 198], but most terms are questionable. A term such as "invasive carcinoma" [104, 109] does not separate MGCT from cancers of non-germ cell origin. Furthermore, IGCN and MGCT may progress to both embryonal carcinoma and TGCT with other histologic patterns. The cells of the precursor lesions have morphologic similarities with the cells of seminoma and not with the cells of embryonal carcinoma. The precursor lesions develop from germ cells and do not show epithelial features — the main criteria for carcinoma [70, 111, 141, 142]. The terms "early seminoma" [127], "interstitial seminoma" [143, 196], "intertubular seminoma" [61], and "microinvasive seminoma" [24] imply that MGCT is a small seminoma despite that fact that MGCT are found also in testes with non-seminomatous TGCT without a seminoma component. Tumor is a general term for both benign and malignant swellings, but the World Health Organization (WHO) classification of tumors of the male genital system uses the term "testicular germ cell tumors" to denote testicular germ cell malignancies [40]. The present review applies the term "microinvasive germ cell tumor" as it describes the lesion best. Men with MGCT can have germ cell tumor metastases, but the metastatic potential does not militate against MGCT being applied as the term for the primary testicular lesion.

This review summarizes the present knowledge regarding clinical aspects of MGCT such as incidence, etiology, detection, histopathology, immunohistochemistry, ultrastructure, differential diagnosis, clinical course, and treatment. For comparison, similar aspects are reported regarding IGCN, GCTIS, and TGCT. Moreover, the review describes cytogenetics, genetics, and pathogenesis of TGCT in the perspective of factors contributing to the invasion of malignant germ cells, and the development from IGCN to TGCT.

Clinical studies

Incidence

TGCT is the most frequent malignancy in young men, whereas this group have a very low incidence of precursor lesions of TGCT [48, 50]. Several subgroups of men have a high risk of TGCT. Men with intersex, gonadal dysgenesis, androgen insensitivity, and testicular feminization have a very high incidence of IGCN [130, 131, 137].

The incidence of IGCN is also increased (0.5–7%) in other groups of men [37, 134, 150]. Patients with maldescended testis have a lifetime risk of TGCT of 4%, which is 4–35 times the risk for men in general [48, 103, 191, 192], and the risk is higher for the affected testis than for the contralateral testis. Correspondingly, men with maldescended testes undergoing testicular biopsies have a 1–3% incidence of IGCN [25, 48, 90, 107, 119, 120, 134, 151]. The incidence is lower before than after puberty [41, 107], and a hypoplastic testis increases the incidence [48, 90, 107, 119]. Adult men with intra-abdominal testis, abnormal external genitalia, or abnormal constitutive karyotype have an especially increased risk of germ cell neoplasia [25]. Men treated for maldescended testis had an incidence of MGCT of 1.8% (Table 1) [120, 190, 198].

Table 1 Prevalence of IGCN and MGCT in men treated for maldescended testes. The table details three studies of men with maldescended testes that reported the prevalence of IGCN, MGCT, and TGCT

[b]All cases with MGCT also had IGCN in the testis. There was a trend towards a higher incidence of precursor lesions than of TGCT in connection with the screening

Men who are subfertile due to oligospermia or azoospermia have a 0.3% incidence of IGCN [14, 28, 112, 146] and a lower incidence of MGCT (Table 2) [125, 143]. For such men, only hypoplastic testes with a Johnson score lower than 4 contained IGCN [14]. For patients with TGCT, the contralateral testis has a 4–11% incidence of IGCN [32, 33, 57, 110, 174]. The incidence of IGCN is especially increased for those less than 30 years of age, and for those with hypoplastic testes [57]. In addition, MGCT was reported in the contralateral testis in a series of patients with TGCT (Table 3) [68]. Testes with a macroscopically overt TGCT have an especially high incidence of IGCN and MGCT in the surrounding testicular tissue [78, 87, 142, 185]. Testes of patients with metastatic germ cell tumor may contain precursor lesions in the absence of an overt testicular tumor. A study described autopsy findings for 17 men without a primary TGCT who died of widespread metastases of non-seminomatous germ cell tumor, of whom 13 men had testes with IGCN, and 4 had testes that also contained MGCT [6].

IGCN can also be found in men with extragonadal germ cell tumors [27, 43]. The incidence of IGCN is not significantly associated with the site of the extragonadal germ cell tumor. Eighteen of 53 patients with retroperitoneal germ cell tumors had IGCN as had 3 of 12 patients with mediastinal germ cell tumors (P=0.36, Fisher's exact test). Testes with a macroscopically overt TGCT have a high incidence of IGCN (77%) in the tissue adjacent to the tumor [78, 87, 99, 142, 185].

[a]Without MGCT and TGCT. CI denotes the 95% confidence interval
[b]All cases with MGCT also had IGCN in the testis

Two cases have been reported with an intratubular embryonal carcinoma without TGCT [129]. The frequency of GCTIS adjacent to TGCT remains to be determined. GCTIS was found in 0.7% and 1.0% of the patients with TGCT stage I in two series by the Danish Testis Cancer (DATECA) Study group [185], and in 36% of the patients in two other studies [12, 116].

In contrast, the testes of men with spermatocytic seminoma, and testes of prepubertal boys with TGCT seldom contained IGCN [158]. Therefore these tumors may not be associated with the secondary precursor lesions [54, 145, 152].

Most patients with testicular germ cell neoplasia are diagnosed with TGCT and only a few patients are diagnosed with precursor lesions. Nevertheless, the two types of germ cell neoplasia had the inverse pattern for the predominance in prospective screening studies of high-risk men (Table 1, 2, 3).

Etiology

Several observations suggest that an initial damage inducing a neoplastic transformation of testicular germ cells may occur during intrauterine, fetal life [84, 123, 190]. Brothers to patients with TGCT have an increased risk of TGCT in contrast to the relatively low risk for their fathers [190]. Smoking of the pregnant mother may cause an initial damage to the testis of the male fetus [84, 123] but some studies showed inconsistent results [103]. TGCT has an association with the childhood residence but not with the geographical site at diagnosis [102]. Smoking of men increased the risk of TGCT whereas smoking cessation did not mitigate the risk [160].

Detection

Precursor lesions for these high-risk men can be detected with a testicular biopsy. Therefore, it is important that physicians consider the possibility of IGCN and MGCT and offer screening in the management of these men. The precursor lesions do not cause testicular enlargement and rarely causes clinical symptoms [98, 177]. Nevertheless, screening studies of high-risk men have regularly detected the precursor lesions.

The initial screening procedure for testicular germ cell malignancy is ultrasonography (Fig. 2), because 11 of 15 testes with testicular germ cell neoplasia examined with ultrasound, contained microlithiasis [7, 28]. It is calcium deposits in the seminiferous tubules and is seen on ultrasonography as multiple, dispersed, punctuate, uniform, non-shadowing hyperechogenic foci. The examination may also reveal a very irregular pattern suggestive of IGCN, or a focal lesion [92]. A homogenous hypoechoic lesion indicates a subclinical seminoma, while a heterogeneous lesion with poorly defined margins and cystic areas indicates a subclinical non-seminomatous TGCT [54, 145]. Men may accept an ultrasonographic examination more

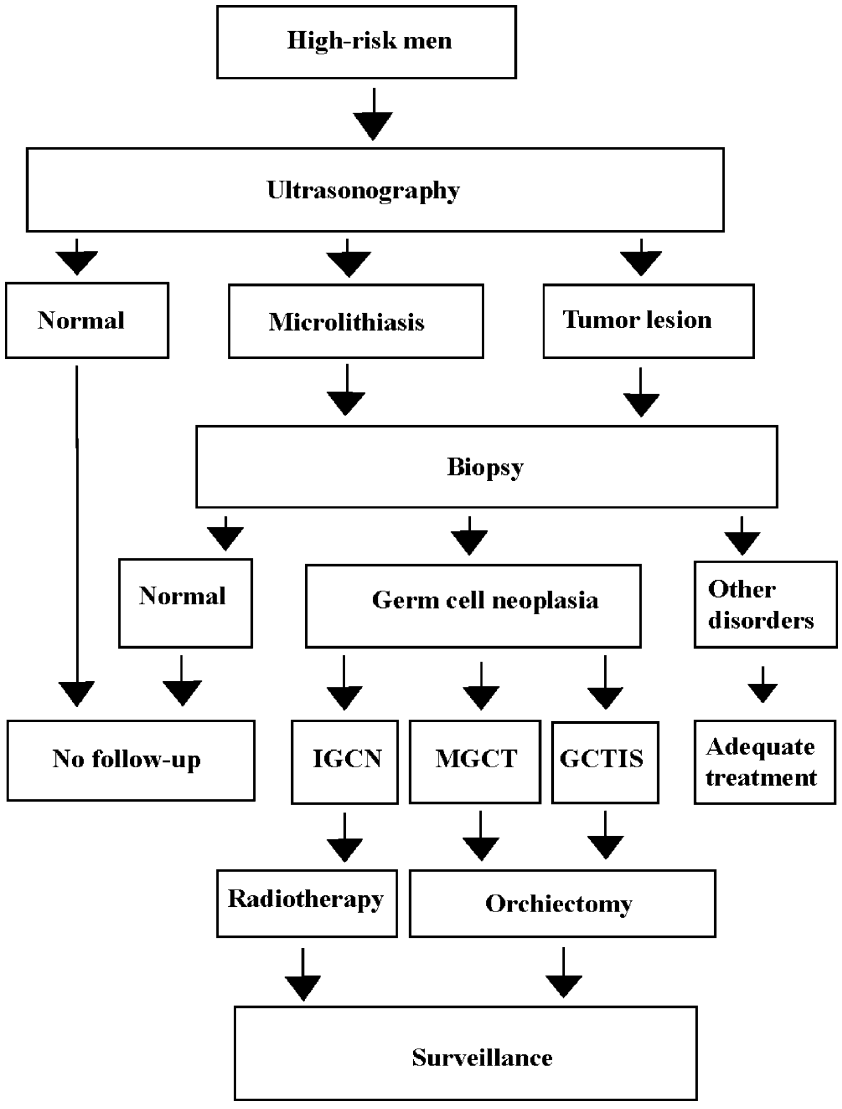

Fig. 2 Screening for testicular germ cell neoplasia and management following the examination of high-risk men without palpable testicular tumors

often than a surgical biopsy [90]. Testicular microlithiasis is found in 1% to 9% of men. In three series of high-risk men, 85 of 483 (17%) men had microlithiasis, and 18 of the 85 (21%) men with microlithiasis had testicular germ cell neoplasia [7, 28, 68].

If the testes contain testicular microlithiasis or a focal lesion, the next diagnostic step is a surgical biopsy (Fig. 2). A testicular biopsy can be obtained on an outpatient basis, and while the biopsy caused minor complications for half the examined men, none had persistent sequelae [19]. One to three tissue samples of the testis, 3 mm in diameter, are sufficient for detection of most IGCN [13, 36, 86]. Tissue specimens can be obtained from most parts of the testis. In a study of the contralateral testis for men with TGCT, one biopsy detected IGCN in 18 of 295 (6%) testes, and additional two biopsies detected IGCN in a further six testes (2%) [86]. A surgical testicular biopsy is efficient in the search for germ cell neoplasia, and adult men with a biopsy that did not reveal IGCN, have a very small risk of later developing TGCT [14, 33, 51, 112, 119]. The biopsies do not cause scrotal seeding of neoplastic germ cells [151].

A fine needle aspiration biopsy has also been used in detection of IGCN [17, 188]. A fine needle biopsy has occasionally been used in connection with surgical exploration for impalpable focal lesions demonstrated by ultrasonography [18]. The findings show good agreement with the histologic findings after orchiectomy for TGCT [10]. The fine needle biopsy may be as sensitive for detection of IGCN as a surgical biopsy [56]. Genetic analyses of ejaculates can detect genetic abnormalities in spermatozoa suggestive of IGCT [17, 76].

The European Association of Pathologists has published guidelines for the handling of testicular specimens [195]. Tissue samples must not be mechanically compressed, and the fixative should be adequate, for example, Stieve's fluid, Bouin's solution, Cleland's solution or formalin [33]. Tissue specimens should be cut and stained according to routine procedures, including staining with hematoxylin and eosin (H & E) and periodic acid-Schiff. Immunohis-

tochemical staining for placental alkaline phosphatase (PLAP) is helpful in diagnosing IGCN and MGCT.

Histopathology

The diagnosis of all precursor lesions, IGCN, MGCT, and GCTIS, depends on examination of a testicular specimen in a microscope and should be based on characteristic histologic criteria.

The first precursor lesion, IGCN, is composed of atypical germ cells in the seminiferous tubules of the testes [72, 80]. The lesion may be present widely or focally in the tubules of a testis. The cells are characteristically located side-to-side, mostly in one, or slightly more than one, layer, in the basal part of germinative cell layer, beneath or between the Sertoli cells (Fig. 3a). Tubules with IGCN rarely contain spermatocytes, spermatides, and spermatozoa. The wall of the tubules is thickened and often multilayered. IGCN may be infiltrated with lymphocytes and plasma cells [15]. Neoplastic germ cells are rather uniform, polygonal and large (20 μm in diameter) [111, 189]. The nucleus is large (10–12 μm in diameter) and rounded, with a coarse chromatin pattern and one or more large and irregular nucleoli. Mitoses are often seen and some are abnormal. The cytoplasm is abundant and usually contains large amounts of glycogen. In H & E staining, the cytoplasm appears clear, and it stains positive with periodic acid-Schiff. The cellular borders are distinct. Syncytiotrophoblastic giant cells may be found in IGCN. Many studies, reviews, and textbooks have described IGCN [40, 71, 106, 134, 171]. The sixth edition of the TNM (T for primary tumor, N for metastases in regional lymph nodes, and M for distant metastases) classification by the International Union against Cancer (UICC) from 2002 included IGCN as a precursor stage for TGCT [157], as did the WHO classification of testicular tumors from 2004 [40]. The Danish version of SNOMED includes IGCN as a separate tumor lesion.

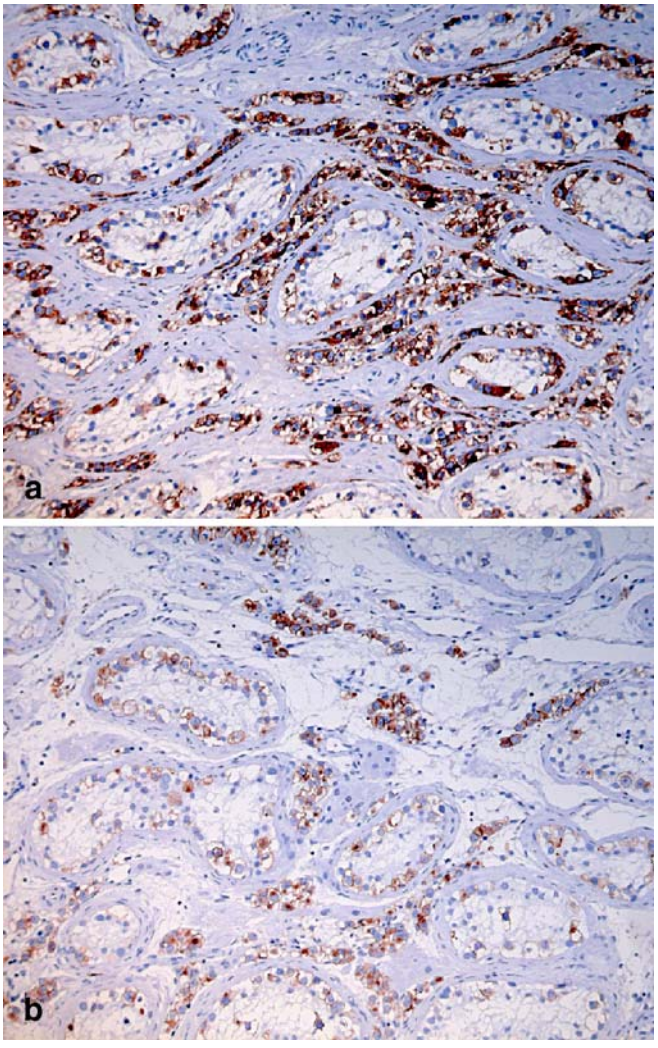

Fig. 3 Microinvasive germ cell tumor from a testis with TGCT stained for placental alkaline phosphatase (**a**), and stained for c-kit receptor (CD-117) (**b**)

MGCT is a secondary precursor stage characterized by extratubular malignant germ cells without a macroscopically overt TGCT. Testis with MGCT may exhibit gross features such as an ill-defined firm area with a pale to brown discoloration [61]. MGCT may appear as single cells or as one or more small groups of rather uniform malignant germ cells (<1 mm^3) in the testicular interstitium (Fig. 2a and b). MGCT is focally distributed in the testicular parenchyma. Tubules near MGCT have thickened and multilayered walls. Otherwise, the tubular structures and the overall architecture of the testis are preserved. MGCT can be associated with infiltration of lymphocytes [82]. Histopathologic tumor classifications by WHO mentioned MGCT [41, 109]. The Danish version of SNOMED includes MGCT as a separate tumor lesion.

GCTIS is another secondary precursor stage with intratubular differentiation of neoplastic germ cells into a seminoma or an embryonal carcinoma without extratubular invasion of the cells. The malignant germ cells fill and distend the affected tubules, and typically eradicate the Sertoli cells [12, 116]. The intratubular malignant cells of these lesions and the cells of overt seminoma and embryonal carcinoma have similar morphology. GCTIS is usually found at the margin of an overt TGCT, in contrast to MGCT [12]. Intratubular embryonal carcinoma is often very necrotic [116].

TGCT is a mass of malignant germ cells (>1 mm^3) that is immediately visible. TGCT destroys the tubules and the architecture of the interstitial tissue [40]. The tumors comprise two main groups, seminoma and non-seminomatous TGCT. Non-seminomatous TGCT consists of embryonal carcinoma and histological subtypes that are differentiated toward embryonal and extra-embryonal cellular patterns and tissues, such as teratoma, yolk sac tumor, and choriocarcinoma.

In adult testes with TGCT, IGCN, MGCT, and GCTIS may be present in the adjacent testicular tissue [5, 59, 78, 87, 99, 142, 185]. IGCN and MGCT may be found distant and separate from the TGCT, indicating that IGCN and

Table 4 Criteria for relevance of secondary precursor lesions in development of TGCT

Lesion separate from TGCT in a testis	+	(+)	Berney [12]; Oosterhuis [116]; von Eyben [185]

MGCT are not extensions of TGCT (Table 4) [101]. IGCN is not found in the adjacent part of the testis in children with TGCT [55].

Immunohistochemistry

The cells of IGCN show a positive staining for PLAP (Fig. 3a), whereas normal germ cells have negatively staining [21, 79, 98, 128]. IGCN also stain positive for the stem cell factor receptor (*KIT*, v-kit Hardy Zuckerman 4 feline sarcoma viral oncogene homolog, CD-117, c-kit receptor) (Fig. 3b) [126], ferritin [77], and lactate dehydrogenase (LD) subunit B [22]. IGCN stained positive with a monoclonal anti-seminoma antibody M2A [8, 49]. Cancer/testis antigen 1B and the melanoma antigen family A4, MAGEA4, have also been demonstrated immunohistochemically in IGCN [5, 143]. Most neoplastic germ cells of IGCN expressed junction plakoglobin, alias γ-catenin, whereas it is rarely expressed in normal germ cells (12%) [154]. IGCN expressed growth factor receptor-bound protein 7 more often than normal germ cells. The antigens HB5, HE11, HF2, and 43-9F [49, 64], and proteinases like cathepsin D (lysosomal aspartyl protease) were also demonstrated in IGCN [59, 60]. Embryonal carcinoma expresses tumor necrosis factor receptor super family, member 8, CD30, and in testes with embryonal carcinoma, CD30 is also present in half of the IGCN [12]. IGCN adjacent to embryonal carcinoma often have positive staining with a monoclonal antibody against an embryonal carcinoma antigen, TRA-1-60, in contrast to IGCN appearing alone or adjacent to seminoma [128]. Syncytiotrophoblastic giant cells present in IGCN show a positive staining for human chorionic gonadotropin (hCG) [87].

IGCN stain negative for alpha-fetoprotein (AFP), hCG, lactate dehydrogenase subunit C (LDHC), actin, cytokeratin 18, integrin α6, laminin, and vimentin, with few exceptions [22, 38, 80, 87, 147, 158]. IGCN stain negative for protein tyrosine phosphatase, receptor type, C (CD45, leucocyte-common-antigen) and other markers of lymphoma [171].

MGCT stain positive for PLAP, cathepsin D, c-kit receptor, and LD subunit B, and stain negative for LDHC [22, 59, 60, 185]. MGCT is partly surrounded by basement membrane material showing immunoreactivity for actin, integrin α6, and laminin, like the basement membrane of seminiferous tubules [38]. MGCT and seminoma are often infiltrated by reactive, mainly T, lymphocytes that stain positive for integrin, alpha L (antigen CD11A (p180), lymphocyte function-associated antigen 1; alpha polypeptide, LFA).

Intratubular embryonal carcinoma is CD30 positive, and immunohistochemical examination for CD30 may reveal lesions of malignant germ cells in tubules not recognized in H & E staining [12]. Intratubular embryonal carcinoma may also stain positive for AE1/AE3 and p53, and stain negative for cytokeratin 20, cyclin dependent kinase inhibitor 1A, alias p21, and AFP [129].

TGCT showed a reduced expression of p21 compared with IGCN, and an increased expression of mouse double minute 2 homolog, mdm2, transformed 3T3 cell double minute 2, p53 binding protein (mouse) [26]. TGCT also had a downreglation of cyclin-dependent, kinase inhibitor 2A, $p16^{INK4A}$ [11]. TGCT did not express the NK3 transcription factor related, locus 1 (Drosophila), NKX3-1 while it was expressed in normal germ cells and IGCN [155]. The same difference was found for the expression of cancer/testis antigen 1B [140]. TGCT had an up-regulated expression of cyclin D2 gene compared with normal testicular germ cells and IGCN, whereas the fragile histidine triad gene and 0-6-methylguanine-DNA methyltransferase gene were down-regulated [154]. TGCT stain negative for epithelial membrane antigen (EMA). Seminoma stain positive for PLAP, and negative77 for CD30 and inhibin. In contrast, embryonal carcinoma stain positive for CD30. Yolk sac tumor stain positive for AFP, and choriocarcinoma stain positive for hCG.

Electron microscopy

The cells of IGCN adhere broadly to the basement membrane of the tubules [52, 69, 72, 111]. The walls of the involved tubules are 1–20 μm thick. The nuclei of the neoplastic germ cells have a homogenous and finely granular chromatin and may be eccentrically placed [52]. Nucleoli are usually placed centrally in the nuclei, and have a reticular pattern. The cytoplasm contains large mitochondria that are often clustered regionally in the cytoplasm of some cells, and may contain abundant glycogen. The cell membranes are smooth and regular, and do not have intercellular bridges [52, 72].

The cells of IGCN, MGCT and of seminoma share many ultrastructural features [52, 83, 124, 144, 161] whereas the cells of IGCN and MGCT also differ in some aspects [72, 111]. Extratubular malignant germ cells are partly surrounded by a thin layer of basement membrane material [72], and might be slightly larger than the intratubular neoplastic germ cells, and might have a higher nucleocytoplasmic ratio [111].

Seminoma cells may also be surrounded by basement membrane material [38]. Spermatocytic seminoma has a different ultrastructural pattern [135, 166]. Cells of embryonal carcinoma have mature desmosomes, junctional complexes, and prominent microvilli, and have only little glycogen in the cytoplasm [124].

Differential diagnosis

Gynecomastia can be due to endocrine disorders, but may also be due to precursor lesions in testis or TGCT.

Impalpable small, focal, centrally located lesions in the testis detected by ultrasonography may be due to fibrosis, Leydig cell tumors, Sertoli cell tumors, adenomatoid tumors, malignant lymphomas, and metastatic tumors or germ cell neoplasia [62, 156, 165]. In ultrasonograms, the benign tumors present generally as homogenous and hyperechoic lesions.

The cells of IGCN, MGCT and of seminoma have similar morphologies [4, 70, 141, 180]. In contrast, seminoma is organized in a large cluster or large masses of malignant germ cells that destroy the architecture of the interstitium and the tubules.

Malignant cells of malignant lymphomas and metastatic tumors can also be found in the interstitial testicular tissue, and these malignancies may later invade the tubules, eradicate the normal intratubular cells, and cause thickening of the tubular walls. However, malignant testicular lymphomas and metastatic lesions are diagnosed at a higher age (in men more than 50 years old) than MGCT and TGCT [42, 80]. The cells of malignant lymphomas are smaller than malignant germ cells, have scant cytoplasm without glycogen, are more irregularly shaped, have nuclei with irregular chromatin, and stain positive for various markers for lymphomas. Plasmacytoma of the testis has a positive staining for immunoglobulin. Testicular metastases of high-grade prostatic adenocarcinoma have a positive staining for prostata specific antigen (PSA) and EMA.

Serum tumor markers

The sixth edition of the TNM classification recommends that three serum tumor markers are used routinely in the staging of TGCT [157]: serum concentrations of AFP and hCG, and serum activity of LD. Patients with IGCN or MGCT have normal levels of the three serum tumor markers [24, 61, 62, 120, 167, 179, 182]. If a patient with a precursor lesion has raised levels of the serum tumor markers, a search should be undertaken for an overt TGCT [184].

Clinical findings

Most cases of IGCN without a concomitant TGCT are diagnosed in men 20–50 years old. The clinical course for men with IGCN is known from studies where treatment was postponed until tumor invasion was diagnosed [113, 149]. Up to 98% of untreated IGCN in adult men progresses to MGCT and TGCT [14, 33, 36, 146, 149, 171], whereas only 0.05% of the examined testes of adult men with a biopsy negative for IGCN developed MGCT or TGCT during follow-up. Detected in prepubertal men, IGCN rarely develop into TGCT [41, 109]. IGCN may be found in the testes of patients with extragonadal germ cell tumors, suggesting that these tumors may be metastases from IGCN [27, 110].

Previously reported patients with MGCT without concomitant TGCT were often 30 to 34 years old at diagnosis (Fig. 4a) and had often hypoplastic testes (Fig. 4b). Regarding the patients with TGCT stage I examined by the DATECA Study group, those who had both seminoma and MGCT were significantly younger at diagnosis than those who had only seminoma [185], whereas the two groups of patients had similar size of the seminoma. In patients with nonseminoma, the presence or absence of MGCT was not associated with the age at diagnosis and the size of the tumor [185]. The progression of MGCT into TGCT has been described in a few case reports [111, 113]. Patients with MGCT without an overt TGCT can have germ cell tumor metastases [4, 61].

Clinical studies of TGCT stage I followed with surveillance revealed characteristics that predict a later relapse, such as the size of the primary tumor for seminomas, and

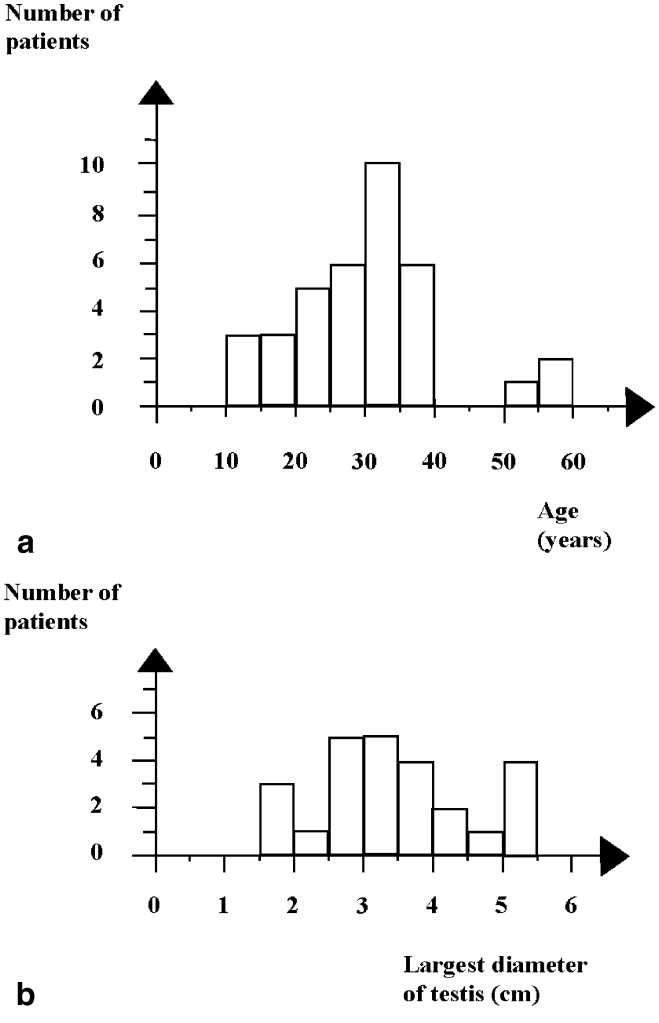

Fig. 4 Findings in previously reported patients with MGCT. Age at diagnosis (**a**), and size of largest diameter of the testis with MGCT (**b**). Smallest size for the largest diameter of the normal testis is 4 cm

presence of embryonal carcinoma for nonseminomas [81, 82, 177]. The two precursor stages, IGCN and MGCT, did not predict relapse for these patients [185].

Treatment

Patients with precursor lesions of the testis have localized disease, with few exceptions, and should be treated accordingly. Local treatment of patients with precursor lesions depends on the histologic findings (Fig. 2). IGCN is treated with radiotherapy of the testis to a total dose of 18 to 20 Gy delivered as nine to ten fractions of 2 Gy each (one fraction per day, 5 days per week) using 16 to 18 MeV electrons [23]. Radiotherapy is curative with few exceptions [35], whereas modern chemotherapy is less efficient [176]. High-voltage radiotherapy of the testis impairs the testosterone production only moderately [34, 122, 175].

Treatment of MGCT is sparsely documented. A few patients with MGCT were treated with orchiectomy and adjuvant radiotherapy [101, 180], but orchiectomy and follow-up with surveillance without adjuvant radiotherapy can be sufficient to secure long-term cure, provided that the patients adhere to a 5-year surveillance follow-up program [181, 185].

Treatment of GCTIS is not documented. If GCTIS is diagnosed without TGCT, adequate local treatment will be orchiectomy. It remains to be shown whether local irradiation of the testis can cure SIS without causing extensive damage of the normal testicular tissue.

After adequate local treatment, the follow-up for patients with precursor lesions of the testis is similar. Follow-up with surveillance is a safe and effective monitoring of the patients with precursor lesions according to the two DATECA studies of surveillance for patients with TGCT stage I (Fig. 1) [133, 177, 185].

Biological studies

Cytogenetics and genetics

IGCN is mainly hypertriploid to hypotetraploid [17, 29, 108, 115]. Two cytogenetic studies showed that IGCN adjacent to TGCT had an increased copy number of 12p material [172, 186], whereas studies of microdissected IGCN cells and investigations using comparative genomic hybridization showed a more complex, sometimes polyclonal, pattern [95, 99, 117, 118, 136, 163].

Studies using differential display polymerase chain reaction and microarrays showed that IGCN was associated with abnormal expression of genes and expressed sequence tags [3, 66, 156]. IGCN consistently expressed NANOG and POU5F1, alias OCT3/4, two transcription factors that were also expressed in the early blastocyst [3, 46, 156]. Microarray studies and a study of array comparative genomic hybridization described gene expressions associated with IGCN and TGCT [3, 100, 114, 132, 153, 156, 159, 193, 197]. These studies added valuable information to that of the previous genetic studies. One study gave information as to AP-2gamma as a biomarker of IGCN [67].

Progression from IGCN to MGCT and TGCT is associated with cytogenetic and genetic abnormalities [178]. A microspectrophotometric study of a testis with IGCN and MGCT showed that the malignant germ cells of MGCT had a higher DNA index than the neoplastic germ cells of IGCN [183]. TGCTs characteristically have an increased copy number of the short arm of chromosome 12, 12p, in part due to one, or more than one, isochromosome i (12p) [30, 31], and the increase may be associated with the extratubular invasion of malignant germ cells [97, 136]. MGCT has not been examined in studies using microarrays.

Seminoma and nonseminoma differ in abnormalities in cytogenetics compared with IGCN [29]. TGCT is associated with abnormal expressions of many genes [178]. Some abnormalities are associated with the stage of the localized TGCT, and other abnormalities are associated with differentiation into either seminoma or embryonal carcinoma [114]. TGCT may have mutations and polymorphisms of *KIT* that can contribute to the development of bilateral TGCT [85, 96, 139]. A few microarray studies described how IGCN and TGCT differ in gene expression [3, 153, 156].

Pathogenesis

Morphologic and genetic studies point to germ cells of the testis as the origin for TGCT. The tumor development in adult men reflects many histological and histochemical similarities between prepubertal prespermatogonia and cells of IGCN and MGCT [52, 73, 111, 127]. According to Gondos, neoplastic germ cells derive from prespermatogonia that remain after puberty, continue to proliferate and differentiate, and finally undergo malignant transformation [52]. Otherwise, Holstein argued that TGCT initiate from post-pubertal spermatogonia A that dedifferentiate as part of the malignant transformation and revert structurally and functionally to a fetal or pre-pubertal pattern of germ cells [69]. The neoplastic germ cells of IGCN have similarities in gene expression with gonocytes but not with spermatogonia [11, 74].

MGCT have caused two controversies. IGCN can progress through MGCT to seminoma in adult men [141], and correspondingly Mikulowski and Oldbring argued that MGCT is the first definitely malignant stage in the progression, and a starting point for differentiation into seminoma and non-seminoma [101]. Alternatively, Oosterhuis and coworkers argued that IGCN could be the starting point for the differentiation. According to this concept, IGCN differentiates intratubularly into GCTIS, either seminoma or non-seminoma, prior to the invasion into the extratubular tissue [116]. Perhaps both secondary precursor stages contribute to the development of TGCT (Fig. 1). Several criteria may be applied in judgement of the relevance of these precursor stages (Table 4). One study indicated that malignant germ cells emigrate passively out of the testicular tubules as consequence of an extensive

intratubular proliferation and accumulation of neoplastic germ cells [38]. Alternatively, the extratubular invasion of the malignant germ cells can be an active process.

Malignant cells break down extracellular matrix and move in the interstitial tissue as part of an active invasion. Several groups of proteins contribute to these processes, and the proteins have been studied in IGCN and TGCT. Cell adhesion molecules may inhibit movements of the cells. Among these proteins, cadherin type 1, E cadherin (epithelial) was not expressed in normal germ cells whereas 18% of seminomas and 62% of nonseminomas expressed the protein [59]. Catenin (cadherin-associated protein) alpha-1, 102 kDa, was not expressed in seminomas but was expressed in a quarter of nonseminomas [138]. Three quarters of seminomas and non-seminomas expressed catenin (cadherin-associated protein) beta-1, 88 kDa. The Ig supergene family of the cell adhesion molecules might also be involved in the invasion of malignant germ cells. However, seven of ten seminomas expressed low levels of intercellular adhesion molecule-1 (CD54), human rhinovirus receptor, and the expression was not associated with clinical aspects [170]. In addition, integrins may contribute to the invasiveness of the malignant cells. Integrin alpha 3 was expressed in IGCN, but not in seminoma [169]. Integrin alpha 5 (fibronectin receptor, alpha polypeptide) was not found in IGCN [159], whereas embryonal carcinoma cells expressed integrin alpha V (vitronectin receptor alpha polypeptide, CD 51) [121]. Another cell adhesion molecule, trophinin, was expressed in TGCT, and the stage correlated with the expression of the protein [58].

Proteinases that destroy basement membranes and extracellular matrix contribute to the invasion of malignant cells. Matrix metalloproteinases (zinc-dependent endopeptidases, MMPs) may interact with tissue inhibitors of matrix metalloproteinases (TIMPs) and cleave type IV collagen, the predominant protein of the basement membranes. MMP-14 forms a complex with TIMP-2 and MMP-2, and the complex activates MMP-14 and stimulates the enzymatic activity of MMP-2. Activated MMP-2 and MMP-9 cleave type IV collagen, elastin, and laminin-1.

A microarray study of seminomas showed that MMP-9 was up-regulated, and MMP-19 and TIMP-2 were down-regulated [114]. In a tumor xenograft model, MMP-2, MMP-16, vascular endothelial growth factor, VEGF, and plasminogen activator inhibitor-2 (PAI-2) were associated with development of seminoma metastases in lymph nodes [88]. Retinoic acid can induce embryonal carcinoma cells to differentiate into teratoma, and the differentiation was associated with an increased expression of MMP-2 while the expression of TIMP-1 and TIMP-2 remained unchanged [168]. Analyses of data from a recent oligo DNA microarray study allowed a comparison of the gene expression in normal germ cells, IGCN, seminoma, embryonal carcinoma, choriocarcinoma, yolk sac tumor, and teratoma [156]. The expression levels of invasion-related genes differed significantly between the various histological subgroups of TGCT (Fig. 5 and Table 5). Compared with normal germ cells, TIMP2 was down-regulated in TGCT apart from teratoma (median expression levels relative to that in normal testes 0.60, range 0.19 to 1.2 versus 0.97, range 0.81 to 1.01, P=0.018, Fisher's exact test). TIMP2 was up-regulated in teratoma compared with other testicular germ cell neoplasia (median 1.28, range 0.70–2.71, versus median 0.53, range 0.19–1.2, P=0.004, Fisher's exact test). TIMP3 was up-regulated in IGCN, yolk sac tumor, choriocarcinoma and teratoma compared with normal germ cells (median 1.80, range 0.63–15.1 versus 1.00,

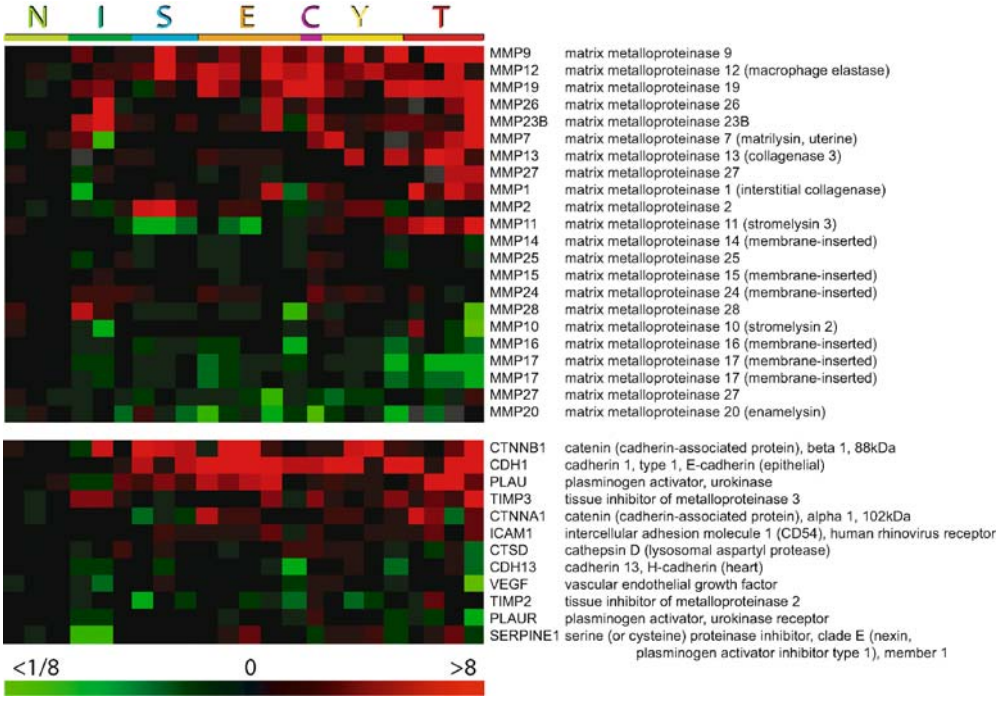

Fig. 5 Gene transcript levels of MMPs, TIMPs, and other genes encoding invasion relevant products from a recent microarray study [156]. *N* denotes normal testis, *I* IGCN, *S* seminoma, *E* embryonic carcinoma, *C* choriocarcinoma, *Y* yolk sac tumor, and *T* teratoma. Approved gene symbols and names are used

Table 5 Matrix metalloproteinases and plasminogen activator, urokinase in 1GCN and histological subgroups of TGCT

Gene symbol	Expression level of gene for histologic subgroups							*P*-value
	IGCN (*n*=3)	TGCT (*n*=17)	IGCN and NS (*n*=17)	S (*n*=3)	NS (*n*=14)	IGCN and non-Ter (*n*=16)	Ter (*n*=4)	
MMP9	1.31 (0.87–2.23)	2.58 (1.08–8.23)	-	-	-	-	-	0.046
MMP12	1.64 (1.08–1.64)	3.22 (1.09–24.52)	-	-	-	-	-	0.014
PLAU	0.63 (0.52–2.66)	1.87 (0.96–7.35)	-	-	-	-	-	0.016
SERPINE1	0.16 (0.146–0.96)	1.32 (0.37–2.78)	-	-	-	-	-	0.16

MMP11	-	-	-	0.38 (0.35–0.50)	1.32 (0.38–13.99)	-	-	0.014
	-	-	-			0.90 (0.35–2.01)	4.3 (2.11–13.99)	<0.0005
MMP7						1.04 (0.29–4.8)	2.61 (1.55–27.69)	0.006
MMP17	-	-	-		-	0.67 (0.38–1.05)	0.36 (0.33–0.53)	0.007

The findings derive from a recent microarray study [156]. Each row compares gene expression in two histological groups of testicular germ cell neoplasia (e.g. IGCN versus TGCT) using Fisher's exact test, without correction for multiple testing. The values indicate the genes' RNA levels relative to the median level among the normal testes samples. *S* denotes seminoma, *NS* non-seminomam, *Ter* teratoma, and *non-Ter* TGCT apart from teratoma. Approved gene symbols are used

range 0.55–1.01, *P*=0.009, Fisher's exact test). TIMP3 was also up-regulated in testicular germ cell neoplasia apart from seminoma and embryonal carcinoma compared with seminoma and embryonal carcinoma (median 3.0, range 0.64–15.1 versus 0.86, range 0.53–4.0, *P*=0.001, Fisher's exact test). Most histologic types of TGCT had a distinct pattern of expression of the MMPs, as shown in Fig. 6.

Serine proteinases form another group that can contribute to the invasiveness of malignant germ cells. The active form for plasminogen activator, urokinase, PLAU, can modify plasminogen into plasmin that activates MMPs. *PLAU* was up-regulated in TGCT compared with IGCN, while the plasminogen activator, urokinase receptor, *PLAUR*, did not change similarly. Expression of serine proteinase inhibitor, clade E, member 1 (SERINE1, alias plasminogen activator inhibitor-1, PAI-1), was downregulated in IGCN but not in TGCT (Figs. 5 and 6). Thus the proteinase may have a role in the migration of malignant germ cells (Fig. 5). Another serine protease, testitin, was shown in IGCN but not in TGCT [75]. A third group of proteinases is cysteine proteinases. Of these, cathepsin D has been demonstrated in IGCN and was up-regulated in MGCT [59].

Inducers of angiogenesis also facilitate the growth of invasive malignant germ cells. Vascular endothelial growth factor (VEGF) was up-regulated in TGCT, and the up-regulation was associated with presence of microvessels [45, 88, 89, 173]. Also the protooncogene v-ets avian erythroblastosis virus E26 oncogene like, ETS1, differed significantly between metastatic and non-metastatic TGCT [2]. Abnormalities in angiogenetic factors may be useful for the treatment of TGCT. An experimental study showed that angiostatic factors like thrombospondin or endostatin, and low dose carboplatin acted synergistically to inhibit a nonseminoma from developing metastases [1].

According to cytogenetic studies, IGCN may develop into embryonal carcinoma through a cytogenetic seminoma-like stage [30, 31]. It is likely that the morphologic equivalent to this stage in the tumor development is MGCT whereas it is unlikely that the morphologic equivalent is ECIS. The precursor lesions of TGCT progress through a seminomatous and a non-seminomatous line [44]. In the non-seminomatous line, embryonal carcinoma may be an intermediate step in the development of teratoma, yolk sac tumor, and choriocarcinoma [44, 113]. Gene abnormalities shared by seminoma and nonseminoma, but not found in precursor lesions, can be associated with invasion, whereas other gene abnormalities specific for either seminoma or embryonal carcinoma can be associated with differentiation of TGCT [63, 156, 162, 164, 178]. The genes DPPA3, DPPA4, GDF3, and POU5F1 contribute to the pluripotency of embryonal carcinoma cells [3, 9, 16, 156]. External stimuli may induce embryonal carcinoma to differentiate into teratoma, and the stimuli may be mediated by signal

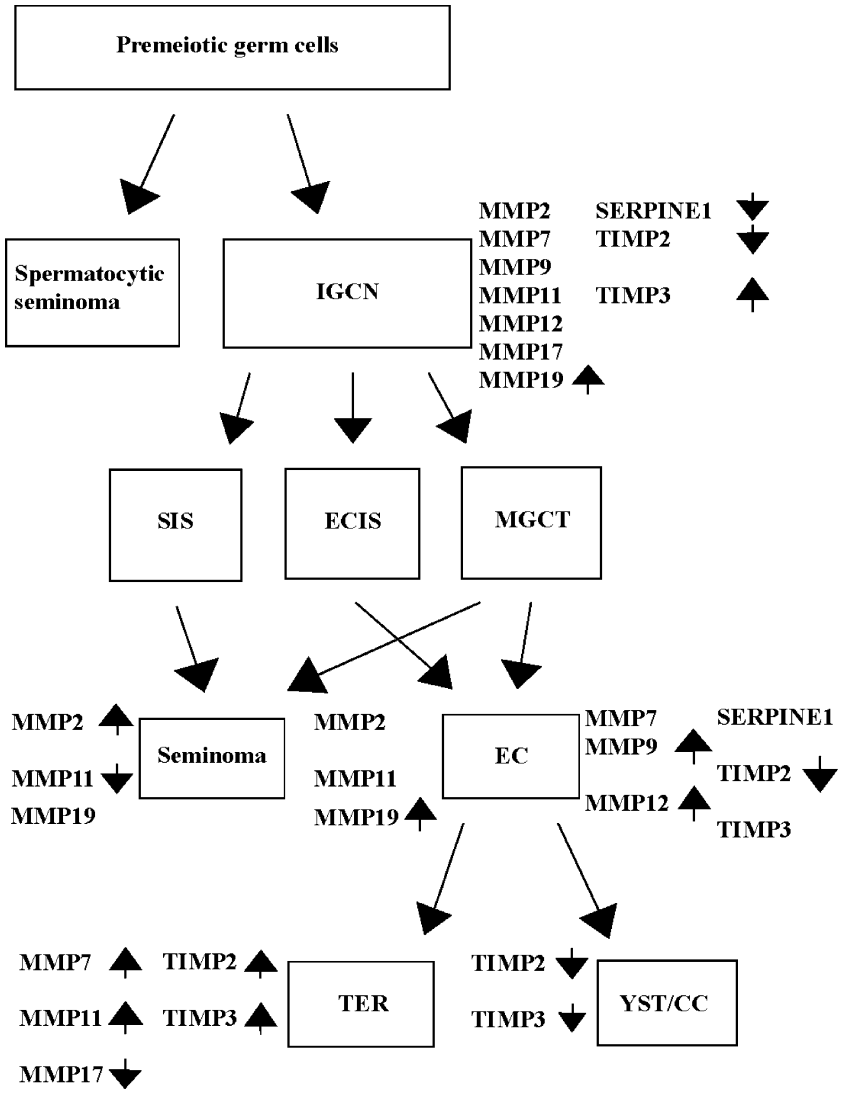

Fig. 6 Significant MMPs and TIMPs in relation to a model for development of TGCT. Abbreviations for histology as in Fig. 1, and use of approved gene symbols. The arrows besides the gene symbol denote a significant change in regulation of the biologic analytes, either up-regulation or down-regulation. Absence of an arrow besides a gene symbol indicates that the gene had no significant deviation in expression from normal testicular tissue. Gene symbols to the right of the boxes indicate gene abnormalities associated with stage of the germ cell neoplasia, and gene symbols to the left of the boxes indicate genes related to differentiation

transduction through the wingless–type MMTV integration site family, WNT, and NOTCH pathways [187, 193].

The concomitantly presence of primary and secondary precursor lesions and TGCT in a testis supports that these lesions are closely related in the tumor development. Such testes provide a platform for new studies that may evaluate the gene abnormalities associated with tumor invasion and with tumor differentiation.

Perspectives

We recommend a strict definition of MGCT and use of a single term for MGCT. If men with high-risk of testicular malignancy are adequately examined, testicular germ cell neoplasia can be detected while it is in a precursor stage such as IGCN, MGCT, or GCTIS. TGCT is associated with up-regulated MMP-9 and PLAU genes compared with IGCN. The up-regulated genes may facilitate the invasion process, and the details in the up-regulation should be studied further in relation to the development of TGCT. It remains to be shown whether the upregulation is associated with the transition from IGCN to MGCT. The abnormalities may also inspire to new forms for treatment of TGCT.

Detection of precursor lesions in the testis has implications for the management of men with high-risk for TGCT. Screening for precursor lesions should be undertaken in two steps where ultrasonography of the testes is followed by a testicular biopsy for men with findings associated with germ cell neoplasia. Local treatment for IGCN is high-voltage irradiation of the affected testis, whereas it is orchiectomy for MGCT and GCTIS. Patients with precursor lesions should be followed-up with surveillance. Thus, it is advantageous to detect precursor stages of testicular germ cell neoplasia because patients with these lesions can be cured with a less extensive and toxic treatment than that used for most TGCT. Urologists, radiologists, pathologists, and oncologists should be aware of the precursor lesions of TGCT so that they can provide an adequate counselling and management for men in whom the lesions are suspected or diagnosed.

Augmented expression of metallothionein and glutathione S-transferase pi as unfavourable prognostic factors in cisplatin-treated ovarian cancer patients

Received: 10 December 2004 / Accepted: 9 February 2005 / Published online: 21 June 2005
© Springer-Verlag 2005

Abstract Resistance to cis- or carboplatin represents the principal cause of therapeutic failures in ovarian carcinoma. The phenomenon of resistance to platinum-based drugs is partly related to expression of metallothionein (MT) and of glutathione S-transferase pi (GST-pi), but opinion on the subject is discordant. Documentation of a negative predictive effect of MT and GST-pi expression for the therapy employing platinum-based drugs would permit to select resistant cases in which other therapeutic approaches could be employed. The present study aimed at examining the relation between intensities of MT and GST-pi expressions in ovarian carcinomas and dynamics of the clinical course in the neoplastic disease in a group of cisplatin-treated patients. The analyses were performed on samples of ovarian carcinoma originating from 43 first-look laparotomies (FLLs) and, in 30 cases, from second-look laparotomies (SLL) from the same patients. Immunohistochemical reactions were performed on paraffin sections of studied tumors, using monoclonal antibodies to MT and GST-pi. The calculations showed that in cases with augmented expression of MT, mortality was higher. On the other hand, augmented expression of GST-pi predisposed to more frequent relapses, deaths and progression of the tumor. Kaplan–Meier analysis showed that a significantly shorter survival time was linked to cases of higher expression of MT at FLL and of higher expression of GST-pi at FLL, whereas a shorter progression-free time was manifested by cases with higher expression of GST-pi at FLL. The performed investigations indicate that augmented expressions of MT at FLL and GST-pi at FLL in ovarian cancer represent an unfavourable predictive factor in cisplatin-treated patients.

Introduction

In Western and Northern Europe, as well as in the United States, ovarian carcinoma represents the third leading cause of incidence of malignant tumors in female genital organs and the fifth leading malignancy in women. It represents also the fifth most common cause of death due to malignant tumors, next to breast carcinoma, colorectal carcinoma, lung carcinoma and gastric carcinoma. In the European Union, the incidence is appraised at 12–17 new cases per 100,000 inhabitants per year. This corresponds to 27,000–30,000 new cases per year [9]. The rising incidence of the tumor is observed worldwide. According to the data of the National Cancer Data Base in the United States, duration of 5-year survival in respective FIGO stages amounted to I (74%), II (58%), III (30%) and IV (19%) [1].

Due to their location, ovarian cancers are frequently diagnosed at an advanced stage of the disease. Therefore,

surgical procedures are accompanied by chemotherapy in a significant proportion of the cases. Most schemes of the treatment in the disease are based on cis- or carboplatin [1]. Thus, resistance of tumor cells to the platinum-based drugs involves the principal reason of therapeutic failures of the disease.

Metallothioneins (MTs) are low molecular weight proteins (6–7 kDa), whose chains are composed of 61 or 62 amino acids. Typically, they contain multiple cysteine residues and few aromatic amino acids. MTs are thought to mediate several functions, including, i.a. control of indispensable trace element levels (e.g. zinc and copper), alleviation of toxic effects of cadmium and mercury or protection of cells from oxidative stress [6, 11]. Numerous reports document MT presence in cells of various tumors, including ovarian cancer [3, 7, 17, 28].

Studies in vitro documented the strict relationship between expression of MT and resistance to cisplatin [12]. A single molecule of MT was found to be capable of binding ten molecules of cisplatin [5]. However, no relation has been discovered until now between intensity of MT expression in ovarian carcinomas and clinical response of patients treated with cisplatin [11].

Glutathione S-transferases (GSTs) catalyse conjugation of reduced glutathione with a variety of electrophilic xenobiotics and also play a role in degradation of lipid peroxidation products. A relationship has been suggested between expression of GST-pi isoform and resistance to cisplatin, adriamycin, cyclophosphamide and etoposide [23]. However, the data on relations between expression of GST-pi and clinical response to cisplatin therapy are divergent: in several studies, expression of GST-pi has been noted to correlate with less favourable response to cisplatin [2, 16], whereas no such a relationship can be detected in other investigations [10, 15, 31].

Previous studies failed to demonstrate unequivocal links between expression of MT and GST-pi, and clinical course in ovarian cancer patients treated with platinum-based drugs. On the other hand, in vitro studies suggested participation of the proteins in detoxication of the tumor cells from platinum-containing compounds [5, 12, 32]. Moreover, expression of MT and GST-pi has not been analyzed in ovarian cancer samples originating from first-look laparotomies (FLLs) and second-look laparotomies (SLLs) in the same patients. Demonstration of a link between expression of MT and GST-pi, and poor clinical response of ovarian cancer patients to therapy with the discussed compounds would facilitate prospective selection of resistant cases in whom other therapeutic approaches could be employed. Examination of the resistance to platinum-based compounds in detail is also highly significant for studies on novel therapeutic strategies.

In the present study, the expression levels of MT and GST-pi were determined by immunohistochemistry in platinum-based drug-treated ovarian cancer specimens from FLL and from second-look procedures in the same group of patients, and the expression levels were correlated with histopathological criteria and clinical outcome.

Materials and methods

Patients

Immunohistochemical examination was performed retrospectively on tissue samples taken for routine diagnostic purposes. Forty-three patients who underwent surgery in 1999–2002 due to ovarian carcinoma in the Department of Gynaecology and Obstetrics, University Medical School in Poznań, Poland, were qualified for the studies. The cases were selected based on availability of tissue and were not stratified for known preoperative or pathological prognostic factors. The study was approved by an Institutional Review Board (IRB) and the patients gave their informed consent before their inclusion into the study. Following the first surgery, all the patients were subjected to chemotherapy using cisplatin-based schemes (Table 1). Thirty-six patients from the same group were subjected also to the second-look operation. In seven cases, no second-look procedure was performed due to advancement of the disease. In six cases, no tumor cells were detected in the material originating from the second-look procedure (Table 1). The patients were monitored by periodic medical checkups, CA-125 serum levels, ultrasonographic and radiological examinations. During the follow-up period, 22 patients (51%) had a recurrent disease and 13 patients (30%) died of the disease. The mean (median) progression-free survival time was 16.9 months (range 0–52 months), whereas the mean (median) overall-free survival time was 24.6 months (range 6–52 months).

Fragments sampled from studied tumors were fixed in 10% buffered formalin and embedded in paraffin. In each case, haematoxylin-and-eosin-stained preparations were subjected to histopathological evaluation by two pathologists. The stage of the tumors was assessed according to the International Federation of Gynaecology and Obstetrics [30]. Tumors were graded according to the Silverberg grading system [24].

Immunohistochemistry

Formalin-fixed paraffin-embedded tissue was freshly cut (4 μm). The sections were mounted on Superfrost slides (Menzel Gläser, Germany), dewaxed with xylene and gradually rehydrated. Activity of endogenous peroxidase was blocked by 30-min incubation in 1% H_2O_2. Immunohistochemical reactions were performed using the monoclonal mouse antibodies (clone E9) detecting isoforms 1 and 2 of MT (DakoCytomation, Denmark) at dilution 1:100, and monoclonal mouse antibodies (clone 353-10) to GST-pi (DakoCytomation) at dilution 1:100. The antibodies were diluted in the Antibody Diluent, Background Reducing (DakoCytomation). Tested sections were incubated with the antibodies for 1 h at room temperature. Subsequently, incubations were performed with biotinylated antibodies (15 min, room temperature) and with streptavidin-biotinylated peroxidase complex (15 min, room

temperature) (LSAB+, HRP, DakoCytomation). NovaRed (Vector Laboratories, UK) was used as a chromogen (10 min at room temperature). All the sections were counterstained with Meyer's haematoxylin. In every case, controls were included in which the specific antibody was substituted by the Primary Mouse Negative Control (DakoCytomation).

Intensity of the immunohistochemical reactions was appraised using the semi-quantitative ImmunoReactive Score (IRS) scale, in which intensity of the reaction and percentage of positive cells were scored (Table 2). The final result represented a product of scores given for individual traits and ranged between 0 and 12 [22]. Intensity of immunohistochemical reactions was evaluated independently by two pathologists. In cases of divergencies, the evaluation was repeated using double-headed microscope.

Statistical analysis

Statistical analysis of the results took advantage of Statistica 98 PL software (Statsoft, Poland). The employed tests included Mann–Whitney *U* test and ANOVA rank test of Kruskal–Wallis. Kaplan–Meier statistics and log-rank tests were performed using SPSS software (release 10.0; SPSS, Chicago, IL, USA) to estimate significance of differences in survival times. The length of progression-free survival was defined as the time between the primary surgical treatment and diagnosis of a recurrent tumor or death. Because univariate analysis revealed no significant relationships between studied clinicopathological parameters (age, histology, grade, CA-125 at FLL level) and overall survival and progression-free time of studied patients ($P>0.05$), we have not performed a multivariate analysis. Because 95% of the studied patients were in stage FIGO III, we have not investigated relationships between stage and survival data.

Table 2 Evaluation criteria of MT and GST-pi expression using IRS score [19]

Percentage of positive cells	Points	Intensity of reaction	Points
No positive cells	0	No reaction	0
<10% positive cells	1	Weak colour reaction	1
10–50% positive cells	2	Moderate intensity	2
51–80% positive cells	3	Intense reaction	3
>80% positive cells	4		

Results

The data obtained by clinical observation of the studied patients are included in Table 1. In the case of MT, reactions of a nuclear and a cytoplasmic localization of various intensity in individual cases were obtained (Fig. 1a). In preparations originating from the first operation (FLL), mean intensity of the reaction was 5.44±0.58 (min. 0, max. 12), whereas in the material obtained upon the second-look procedure (SLL), it amounted to 7.07±3.28 (min. 1, max. 12). In the case of GST-pi, a cytoplasmic reaction of a variable intensity in individual cases was obtained (Fig. 1b). Mean intensity of GST-pi reaction at FLL was 4.28±3.83 (min. 0, max. 12), whereas mean intensity of GST-pi reaction at SLL amounted to 5.1±3.81 (min. 0, max. 12).

At the first stage of statistical analysis, Mann–Whitney *U* test was used to compare intensity of MT expression at FLL and SLL, and intensity of GST-pi expression at FLL and SLL. Expression of MT at FLL was found to be lower compared to the expression of MT at SLL (at the verge of significance, $P=0.058$). In the case of GST-pi, the differences were far from being significant ($P=0.31$).

Using the ANOVA rank test of Kruskal–Wallis, relations were examined between intensities of MT and GST-pi expression on the one hand, and relapses, patient death, grade and response to therapy on the other. We have shown that cases with relapse of the neoplastic disease demonstrated higher expression of GST-pi at FLL ($P=0.004$) and at SLL ($P=0.02$), compared to the cases with no relapse (Table 4). No such relationship was detected in the case of MT at FLL or SLL (Table 3). In the cases terminated by death of the patient, expression of MT at FLL (Table 3), of GST-pi at FLL and at SLL (Table 4) was significantly higher ($P=0.003$, $P=0.0006$, $P=0.03$, respectively) than those in surviving patients. No such relationship could be

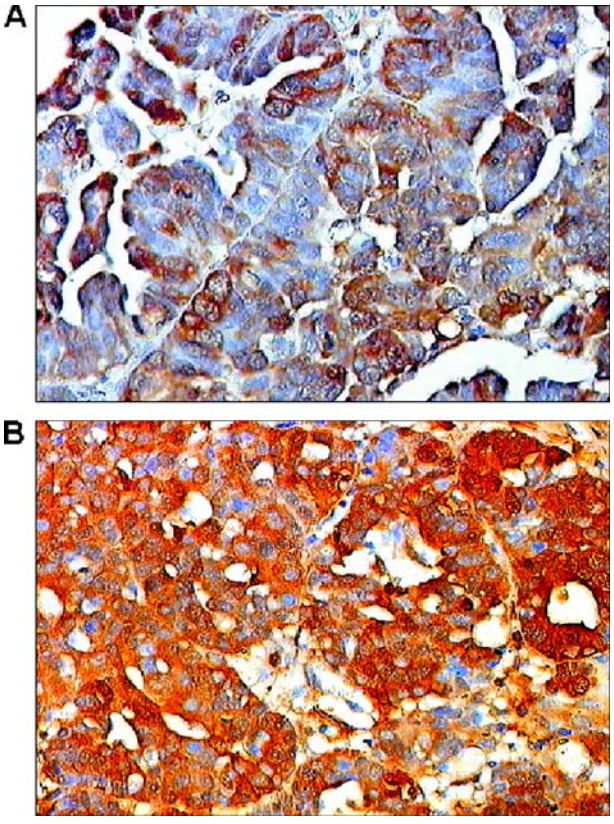

Fig. 1 Immunohistochemical localization of **a** metallothionein (MT) (×400, haematoxylin counterstaining) and **b** glutathione S-transferase pi (GST-pi) (haematoxylin counterstaining, ×200) in ovarian carcinoma. The red reaction product is located in the cytoplasm (in the case of MT, also in cell nuclei) of neoplastic cells

disclosed in the case of MT at SLL (Table 3). In the case of MT, clinical response to the therapy manifested no relationship to intensity of the protein expression (Table 3), but expression of GST-pi at FLL was the highest in cases of progressive disease (PD) (P=0.009). A similar tendency was seen in the case of GST-pi at SLL (P=0.06) (Table 4).

None of the examined variables was related to the grade of the tumor (Tables 3 and 4).

Spearman's rank correlation demonstrated a positive correlation between intensities of MT expression at FLL and GST-pi expression at FLL (P=0.008) (Fig. 2).

In the analysis of Kaplan–Meier, the cut-off value of 4 was accepted for MT at FLL, MT at SLL, GST-pi at FLL and for GST-pi at SLL to make calculations uniform in all studied groups. Accordingly, the overall survival time and the progression-free time were examined for groups manifesting expression of 0–4 (no or lower expression intensity) and those manifesting expression of 5–12 (the higher expression intensity). The calculations demonstrated that (1) cases of no/lower MT expression at FLL showed a significantly longer overall survival time (P=0.009) (Fig. 3) and (2) cases of no/lower GST-pi expression at FLL showed a significantly longer overall survival time (P=0.003) and progression-free time (P=0.002). For GST-pi expression at SLL, a marginally significant relationship was detected for the progression-free time (P=0.0500) (Fig. 4).

Discussion

Cisplatin displays clinical activity against a wide variety of solid tumors. In advanced ovarian carcinoma, cisplatin-based combination chemotherapy including paclitaxel (PC scheme) and topotecan (PT scheme) represents the main treatment option, along with debulking surgery [1]. Its cytotoxic mode of action is mediated by its interaction with DNA to form DNA adducts, primarily intrastrand cross-link adducts, which activate several signal transduction pathways, and culminate in activation of apoptosis [25]. There are several mechanisms responsible for cisplatin resistance, and they include reduced intracellular drug accumulation, increased inactivation by thiol-containing molecules (MTs and GSTs), modulation of DNA damage repair pathways, dysfunction of tumor-suppressor p53 and overexpression of apoptosis inhibitors [13].

FLL First-look laparotomy, *SLL* second-look laparotomy, *GST-pi* glutathione S-transferase pi

In this study, we describe the expression of MT and GST-pi proteins detected by immunohistochemistry in the group of 43 primarily isolated samples and in the group of 36 samples originating from the second-look procedure performed in the same patients. The studied group was uniform: 95% of the patients were in FIGO stage III, 86% of the studied cases involved serous carcinoma, 98% of the patients were treated with cisplatin-based schemes and 2% or one patient with a carboplatin-based scheme. We confirm that the studied proteins are expressed in ovarian carcinomas [2, 17]. We have found that intensity of MT expression is higher in sections from second-look procedures (after chemotherapy) and that there is no difference in expression intensity of GST-pi between sections from primary laparotomies and second-look procedures. There are also no relationships between MT and GST-pi expression, and grade of studied tumors.

The data on the relationship between MT expression and resistance to cisplatin are divergent. Studies in vitro showed that cells transfected with *MT* gene demonstrated a significantly lower sensitivity to cisplatin compared to the non-transfected cells [29]. In immunohistochemical studies, cases of squamous cell carcinoma of the esophagus [8], bladder carcinoma [26] or urothelial transitional cell carcinoma [27] showing a higher MT expression reacted less favourably to treatment with cisplatin. In the case of head and neck squamous cell carcinoma, expression of MT in samples isolated following treatment with cisplatin was significantly higher than that in untreated tumors [20]. In the cases of germ cell tumors and testicular germ cell tumors, no relationship could be demonstrated between expression of MT and response to cisplatin therapy [16, 18]. Wrigley et al. [32] studied a group of 80 cases of ovarian cancer of a variable grade, stage and histology (59 cases involved primary laparotomies and 21 samples originated from second-look procedures, but not from the same patients). Forty-four patients were treated with cisplatin, and MT expression was measured by radioimmunoassay. The studies disclosed no relationships between MT expression and clinical response to cisplatin therapy. We have found that cases with relapse of the disease and cases that have been terminated by death of the patient have been characterised by a significantly higher expression of MT at FLL. The Kaplan–Meier analysis has shown that cases with higher MT expression at FLL have manifested a shorter overall survival time. Thus, we have shown that ovarian cancer cases treated with platinum-based drugs and manifesting augmented expression of MT at FLL carry less favourable prognosis, suggesting that MT participates in the mechanisms of resistance to the drugs. No such significant relationships could be noted for MT at SLL. The absence of relationship between MT expression at SLL and clinical course of the disease explains the fact that following SLL, the patients no longer received any chemotherapy. The phenomenon suggests that MT expression in ovarian cancer represents an exponent of resistance to platinum-based drugs, and not of a more dynamic course of the disease, as suggested for other tumors [3, 7]. To our knowledge, this study demonstrates for the first time significant unfavourable predictive value of MT expres-

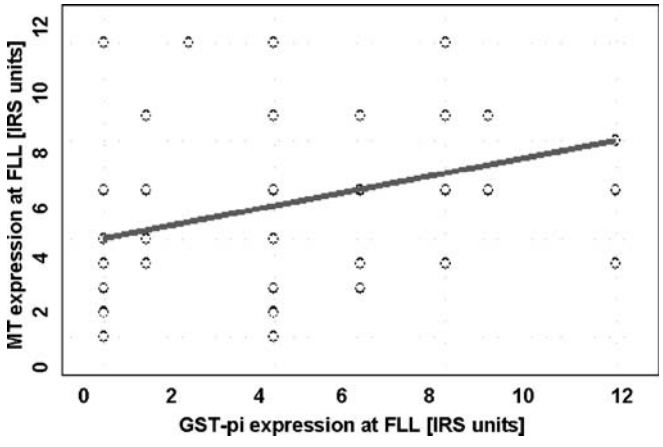

Fig. 2 Positive correlation between MT at FLL and GST-pi at FLL expression (Spearman's rank correlation, *P*=0.008). ImmunoReactive Score (IRS) (see Table 2) was used for immunohistochemical reaction evaluation

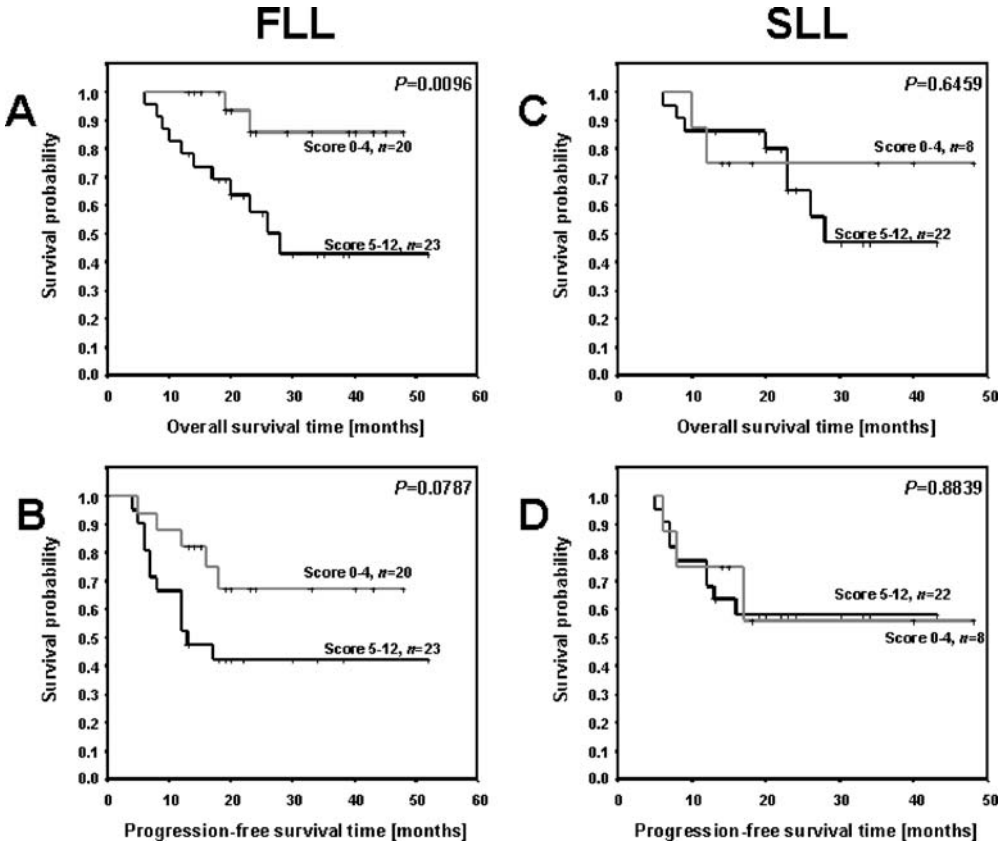

Fig. 3 Kaplan–Meier curves for survival and expression of GST-pi in the studied group of 43 ovarian cancer patients: **a** patients with lower MT at FLL expression have an increased overall survival time; **b** no significant differences in progression-free time between patients with lower and higher MT at FLL expression; **c** no significant differences in overall survival time between patients with lower and higher MT at SLL expression; **d** no significant differences in progression-free time between patients with lower and higher MT at SLL expression. Analyzed tissues were obtained during the first- and second-look operations (FLL and SLL, respectively). IRS (see Table 2) was used for dividing patients in groups with no/lower or higher expression of MT determined by immunohistochemistry. *n* number of patients

sion on platinum-based drugs therapies in human ovarian carcinomas.

The relationship between GST-pi expression and resistance to cisplatin was demonstrated in cell lines (colon adenocarcinoma, lung adenocarcinoma and glioblastoma cell lines) [4] and in clinical cases of head and neck cancers [21]. In contrast, no relationship could be documented in cases of cervical carcinoma [14] and non-small cell lung cancer [19]. In the case of ovarian carcinoma, similarly equivocal data were documented on the relationship between GST-pi and clinical response to cisplatin therapy. Mayr et al. [16] and Satoh et al. [23] documented relationship between elevated expression of GST-pi and a less favourable response to treatment with cisplatin in the heterogenous group of 213 cases and in the heterogenous group of 117 cases. On the other hand, Ikeda et al. [10] and Van der Zee et al. [31] were unable to document any dependence between expression of GST-pi in ovarian carcinomas and a resistance to cisplatin in the heterogenous group of 93 cases and in the equally heterogenous group of 127 cases, respectively. Our studies have shown that cases with relapse of the disease, terminated by death of the patient or in which progression of the disease has been noted by clinical observations, have been characterised by more pronounced expression of GST-pi at FLL and at SLL. Moreover, Kaplan–Meier analysis has shown that the cases with higher expression of GST-pi at FLL and SLL showed shorter overall survival and progression-free time. In our study, we have shown that augmented expression of GST-pi is typical for cases with less favourable response to chemotherapy with platinum-based drugs. Poor prognosis in patients manifesting augmented expression of GST-pi at SLL suggests that the protein displays a more intense expression in cases of a more aggressive clinical course.

We have also demonstrated a positive correlation between MT expression at FLL and GST-pi expression at FLL. The correlation suggests that cases resistant to cisplatin manifest higher expression of the two proteins, and therefore, MT and GST-pi have to be taken into account in the search of approaches aimed to overcome resistance to platinum-based drugs.

In summary, we found that augmented expression of MT and GST-pi in ovarian cancers characterises cases that are resistant to platinum-based drugs. In such patients, application of other therapeutic modalities should be considered.

Concomitant deregulation of HIF1α and cell cycle proteins in *VHL*-mutated renal cell carcinomas

Received: 18 January 2005 / Accepted: 21 March 2005 / Published online: 1 July 2005
© Springer-Verlag 2005

Abstract Renal cell carcinomas (RCCs) of the clear cell type are associated with alteration of the von Hippel-Lindau (VHL) tumour suppressor gene as well as subsequent stabilization and over-expression of hypoxia inducible factor (HIF), which causes up-regulation of cyclin D1. On the basis of their ability to interact with cyclin D1 we investigated a number of cell cycle proteins to shed further light on the downstream effects of HIF dysregulation. Expression of HIF1α, cyclin D1, cyclin-dependent kinase 4 and cyclin-dependent kinase inhibitors p16, p21 and p27 was studied by immunohistochemistry. Since NFκB1/RelA have been shown to bind to the cyclin D1 promoter, mRNA expression of these transcription factors was further analysed by quantitative PCR. In RCCs harbouring VHL mutations/hypermethylation, over-expression of HIF1α was paralleled by up-regulation of cyclin D1 and CDK4 and down-regulation of p21 and p27. Moreover, p27 expression was inversely correlated with tumour cell differentiation. Comparison of non-tumorous autologous kidney tissues revealed a significant down-regulation of NFκB1 mRNA expression in patients harbouring RCC with *VHL* mutations/hypermethyation. Our data support the notion of a link between VHL deficiency/HIF dysfunction and disturbances of cell cycle control in the tumorigenesis of VHL-negative RCC.

Introduction

At least 50% of renal cell carcinomas (RCCs) develop upon bi-allelic inactivation of the von Hippel-Lindau (VHL) tumour suppressor gene [3, 6, 16, 32]. The *VHL* gene product (pVHL) represents the substrate recognition site of an E3–ubiquitin–ligase complex, thereby targeting proteins for proteasomal degradation [13]. pVHL is involved in many celular processes, including cell cycle control, extracellular matrix formation and regulation of microtubule stability [2, 7, 12, 20]. Known pVHL targets are α-subunits of the hypoxia-inducible factors (HIF) 1 and HIF2 [18]. Under normoxic conditions HIFα undergoes ubiquitylation by the pVHL-E3-ligase complex for subsequent degradation [18, 24]. However, under hypoxic conditions HIF1α is stabilized and forms a dimer with the constitutive subunit HIF1β (aryl hydrocarbon nuclear translocator, ARNT) to form HIF1, which, in turn, causes the transcription of a number of hypoxia-inducible genes, including glucose transporter 1, vascular endothelial growth factor (VEGF), transforming growth factor alpha (TGFα), erythropoietin and others [9, 15, 17, 24, 30]. Loss of pVHL function interrupts the hypoxia response pathway thus mimicking hypoxic conditions. Accordingly, loss of pVHL leads to the accumulation of HIF, resulting in excessive transcription of HIF target genes [30]. This mechanism might explain why VHL-negative tumours, such as RCCs of the clear cell type, overexpress VEGF and are highly vascularized [22].

Studies on murine and human cell lines suggested that HIFα subunits might be also involved in the regulation and control of the cell cycle machinery [1, 5, 8, 21, 31]. Cyclin

D1 and cyclin-dependent kinases (CDKs) CDK4/CDK6 are important cell cycle regulators that promote G1/S progression, at least in part, by phosphorylating the retinoblastoma protein (pRb) and thereby inactivating its ability to bind to proteins of the E2F transcription factor family and to suppress their transcriptional activity [19, 25]. Relaxed control of cell cycle regulation is considered a hallmark of malignant transformation, and *Rb* has been shown to be frequently altered in human malignancies [19]. However, in RCC, mutational inactivation of *Rb* is rare [11, 29].

Thus, there is a possibility that, in RCC, the Rb pathway might be disrupted due to disturbances of crosstalk with the HIF pathway triggered by VHL deficiency. This view is supported by recent observations of cyclin D1 up-regulation in *VHL*-deficient RCC, both in cell line and sporadic tumours [1, 2]. To establish the role of *VHL* deficiency and HIF dysfunction in cell cycle regulation it is important to further explore known cell cycle regulators in *VHL*-mutated/hypermethylated and non-mutated [*VHL* wild type (wt)] clear cell RCC. Since the hypoxia-responsive transcription factors NFκB1/RelA transactivate cell cycle regulator genes such as cyclin D1, we further tested whether these factors are up-regulated in RCC with and without *VHL* alterations, using quantitative PCR. Here we report comparative analyses of cyclin D1, CDK4 and cyclin-dependant kinase inhibitors (CDKIs) p16, p21 and p27, as well as transcription factors NFκB1 and Rel A, and discuss the findings with respect to their potential meaning in the tumorigenesis of clear cell RCC.

Material and methods

Patients and tissue samples

Formalin-fixed, paraffin-embedded tissue samples and snap-frozen tissues from 56 clear cell RCCs and the autologous normal kidney tissues were obtained from patients (male to female=2:1; median age 62.5 years, range 39–83 years) who had undergone radical nephrectomy. Of these patients, 22 had somatic *VHL* mutations/hypermethylations and/or 3 p LOH as recently described by Brauch et al. (Table 1) [3]. Histopathological classification of each tumour was performed according to the criteria proposed by Thoenes and co-workers, which are in line with the recent classification of the World Health Organization [26, 28]. Tumour grading was performed according to the grading scheme of Störkel et al. [27]. After paraffin embedding, tumour specimens were cut into 5 µm sections and stained routinely with H&E to define representative tumour regions. For the preparation of tissue micro-arrays (TMAs) at least two tissue cylinders (3 mm in diameter) from each tumour and the corresponding normal kidney were punched from these regions of the donor blocks, placed on 25 mm×35 mm paraffin blocks and H&E stained for control purposes.

Monoclonal and polyclonal antibodies

Immunohistochemical (IHC) staining was performed with monoclonal mouse antibodies (mAbs) or polyclonal rabbit antibodies (rAbs) to the following antigens: cyclin D1

(1:25, mAb; Novo Castra Laboratories, Newcastle upon Tyne, UK); CDK4 (1:80, rAb; Santa Cruz Biotechnology, Heidelberg, Germany); $p16^{INK4A}$ (1:20, rAb) and HIF1α (1:800, mAb; both Abcam, Cambridge, UK); $p21^{WAF1/cip1}$ (1:20, mAb; Calbiochem, San Diego, Calif., USA), $p27^{Kip1}$ (1:50, mAb; DAKO, Glostrup, Denmark). The secondary biotinylated rabbit anti-mouse and goat anti-rabbit immunoglobulin antibodies (IgGs) were purchased from DAKO (Hamburg, Germany).

Immunohistochemistry

TMA blocks were serially cut into 5 μm sections. In brief, after deparaffinization, sections were microwaved for 2–7 min in citrate buffer at 750 W. Following a washing procedure with Tris-buffered saline (TBS; pH 7.4) blocking of endogenous peroxidase was done with 3% H_2O_2 for 15 min. The tissue sections were then incubated for 10 min at room temperature with normal swine serum diluted 1:10. Primary antibodies were applied and allowed to react for 1 h at room temperature. After being rinsed twice in buffer the sections were incubated with the secondary biotinylated anti-mouse/anti-rabbit antibodies. Tissue staining was detected with the Vectastain ABC-kit (Vector Laboratories, Burlingham, Calif., USA) and DAB substrate chromogen solution. Slides were counterstained with haematoxylin, dehydrated and mounted.

All slides were independently reviewed by two investigators (D.A., C.G). Only tumour cells or mesangial/epithelial cells of the normal kidney tissues displaying nuclear reactivity were considered positive. We evaluated the number of positive cells by counting at least 200 cells in randomly chosen high-power fields (HPFs; magnification ×400) and calculating the mean from the results of both investigators.

RNA isolation and real-time PCR

Total RNA from the 56 clear cell RCCs and the autologous normal kidney tissues was extracted from snap-frozen fresh material using the Rneasy Kit as described by the manufacturer (Qiagen, Hilden, Germany). The RNA was randomly primed by hexanucleotide primers and reverse transcribed with a first-strand cDNA synthesis kit (MBI Fermentas, Lithuania). RNA expression of the transcription factors NFκB1 and RelA was quantitated by real-time PCR (RT-PCR) relative to the expression level of the house-keeping gene β-actin using the ABI Prism 7,700 Sequence Detection System (Applied Biosystems, Foster City, Calif., USA). Sequences of PCR primers and the 3′-Fam/5′-BHQ probes were as follows:

NFκB1: 5′-GCACTGGAAGTACAGGTCCA-3′/5′-GTCATCACTTTTGTCACAA CCT-3′ with probe 5′-CCTGGAACTACTAAATCTAATGCTGGGATGAAGC-3′ and RelA:5′-GAAGAGTCCTTTCAGCGGAC-3′/5′-ACACCATGGTGGGAAACTCAT-3′ with probe 5′-CCAAGCCAGCACCCCAGCCC-3′.

Primer and probe for β-actin (Human ACTB Endogenous Control, cat. no. 4326315E), as well as probes for NFκB1 and RelA, were purchased from Applied Biosystems. Primers for NFκB1 and RelA were synthesized by Roth (Karlsruhe, Germany).

RT-PCR reactions were carried out in a final volume of 25 μl. The final concentration of reagents in the RT-PCR mix for NFκB1 and RelA were 1×TaqMan Universal PCR Master Mix (cat. no. 4304437, Applied Biosystems), 300 nM forward primer, 300 nM reverse primer, and 200 nM probe. RT-PCR for β-actin was performed according to the manufacturer's instructions. PCR conditions were 50°C for 2 min followed by 95°C for 10 min, followed by 45 cycles of 15 s at 92°C and 1 min at 60°C. The RT-PCR data are given in Ct values.

Statistical analysis

IHC staining results, *VHL* mutation/hypermethylation status and RT-PCR data were statistically analysed according to their scale level: data description was based on absolute and relative frequencies for binary endpoints and on medians and quartiles for continuous endpoints. Univariate significance analysis was based on the Mann–Whitney U-test for binary parameters and on the two-sample Wilcoxon's test for continuous parameters. The Kendall's tau-b correlation coefficient was used to assess the associations. Local significance was assumed for two-sided P values <0.05. All computations were performed with SPSS release 11.0 for Windows.

Table 2 Expression of cell cycle proteins in RCCs and corresponding autologous non-tumorous kidney tissues (*NK*)

**Differences are statistically significant (P<0.05)

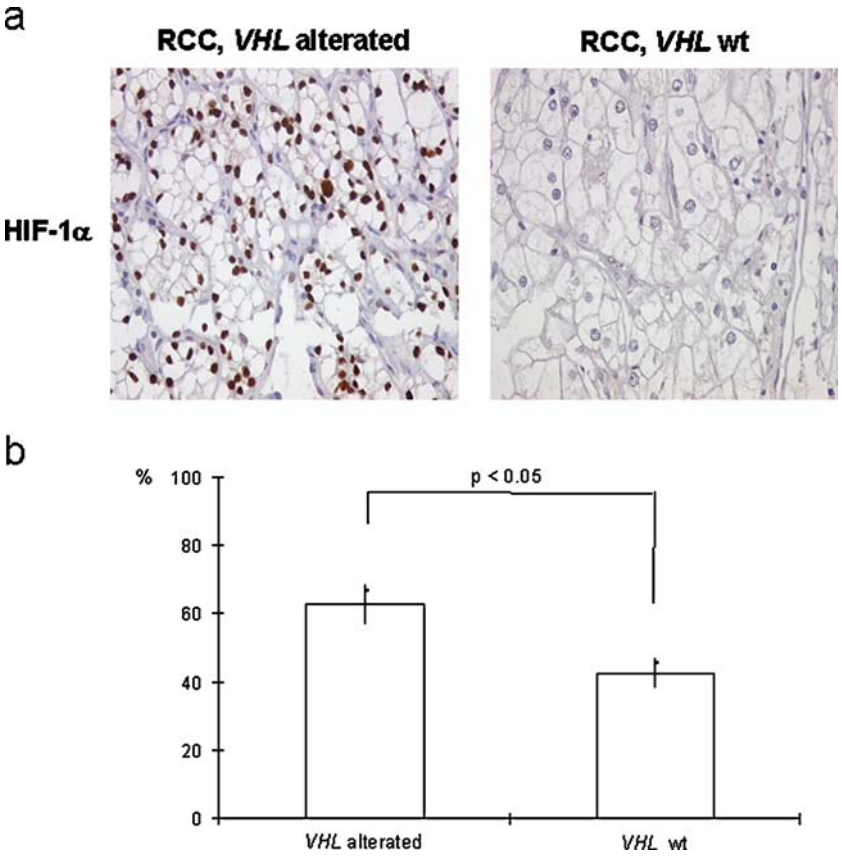

Fig. 1 **a** Immunohistochemical detection of HIF-1α protein in RCCs of the clear cell type demonstrating positive nuclear staining in a RCC bearing *VHL* alterations and mainly negative staining in a *VHL* wt RCC (×400). **b** HIF1α nuclear staining is significantly greater in RCCs harbouring *VHL* alterations than in *VHL* wt RCCs

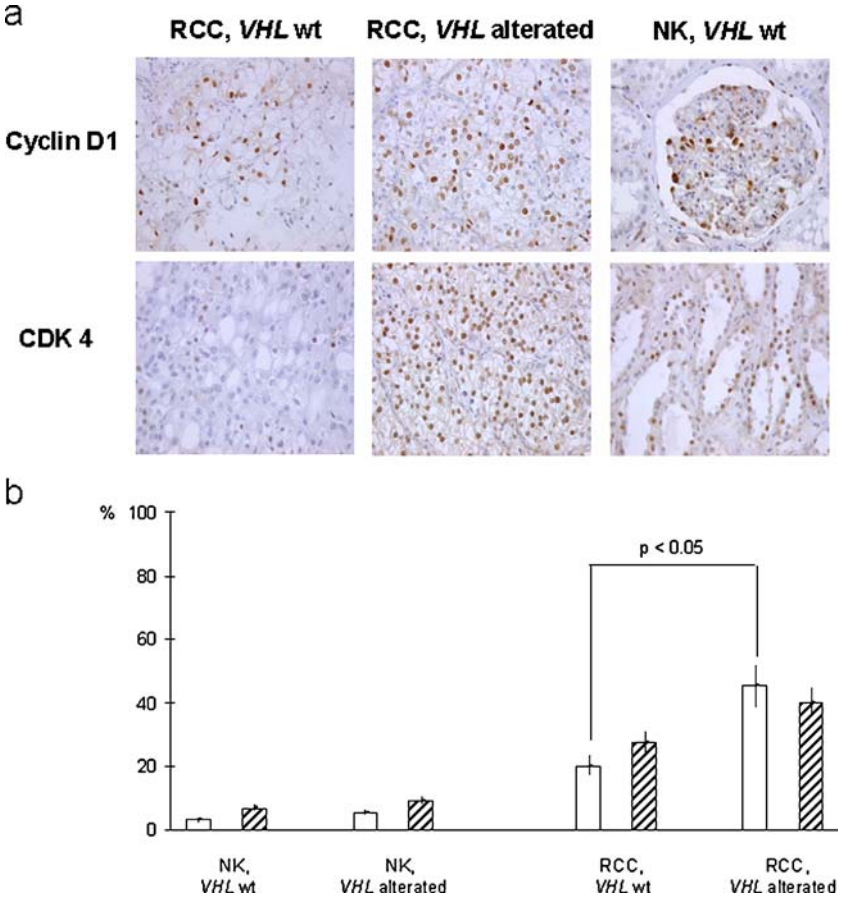

Fig. 2 **a** Immunohistochemical detection of expression levels of cyclin D1 and CDK4 in clear cell RCCs and autologous non-tumorous tissues (×400). *From left to right* RCC *VHL* wt, RCC *VHL* mutated/hypermethylated (*VHL* altered), autologous normal kidney tissue (*NK*, *VHL* wt). Nuclear staining positive for both antigens was seen in approximately 30% of all tumour cells. In contrast, less than 10% of the epithelial and mesangial cells stained positive for cyclin D1 and CDK4 in non-tumorous kidney tissue. Both antigens revealed a higher percentage of positively stained tumour cells in *VHL*-altered RCCs than in *VHL* wt RCCs. **b** Comparison of nuclear staining frequencies of cyclin D1 (*open columns*) and CDK4 (*hatched columns*) of NKs and RCCs with and without *VHL* mutations/hypermethylation. Expression of cyclin D1 and CDK4 is higher in RCCs harbouring *VHL* alterations, a difference which is significant for cyclin D1 ($P<0.05$)

Results

Up-regulation of HIF1α in RCCs bearing *VHL* alterations

RCCs were stratified according to the presence or absence of *VHL* mutations/hypermethylation and tested for differential HIF1α protein expression [3]. As expected for *VHL*-mutated/hypermethylated RCCs, IHC staining for HIF1α showed a significant up-regulation, as shown by positive nuclear staining of tumour cells. More than 60% of *VHL*-mutated/hypermethylated tumour cells, but only 42% of the *VHL* wt tumour cells, displayed staining positive for HIF1α ($P<0.05$; Table 2, Fig. 1). In contrast, nuclear staining positive for HIF1α was not detectable in epithelial or mesangial cells of non-tumorous kidney tissues (not shown).

Differential expression of cell-cycle proteins in RCCs and autologous non-tumorous kidney tissues

We determined the differential expression of the various cell cycle proteins, including cyclin D1, CDK4, p16, p21, and p27, in RCCs and matched autologous non-tumorous kidney tissues (Table 2). IHC results showed up-regulation of cyclin D1 and CDK4 in RCCs when compared with non-tumourous autologous tissues (Fig. 2). Only 4% and 7% of the epithelial and mesangial cells in non-tumorous kidney tissues expressed cyclin D1 and CDK4, respectively. In contrast, RCC cells showed nuclear staining positive for cyclin D1 and CDK4 in 30% and 32%, respectively (Table 2). The differences between RCC cells and autologous non-tumorous kidney tissues were significant for both cell cycle proteins ($P<0.001$). Moreover, the expression of both antigens was significantly correlated to each other ($P<0.05$).

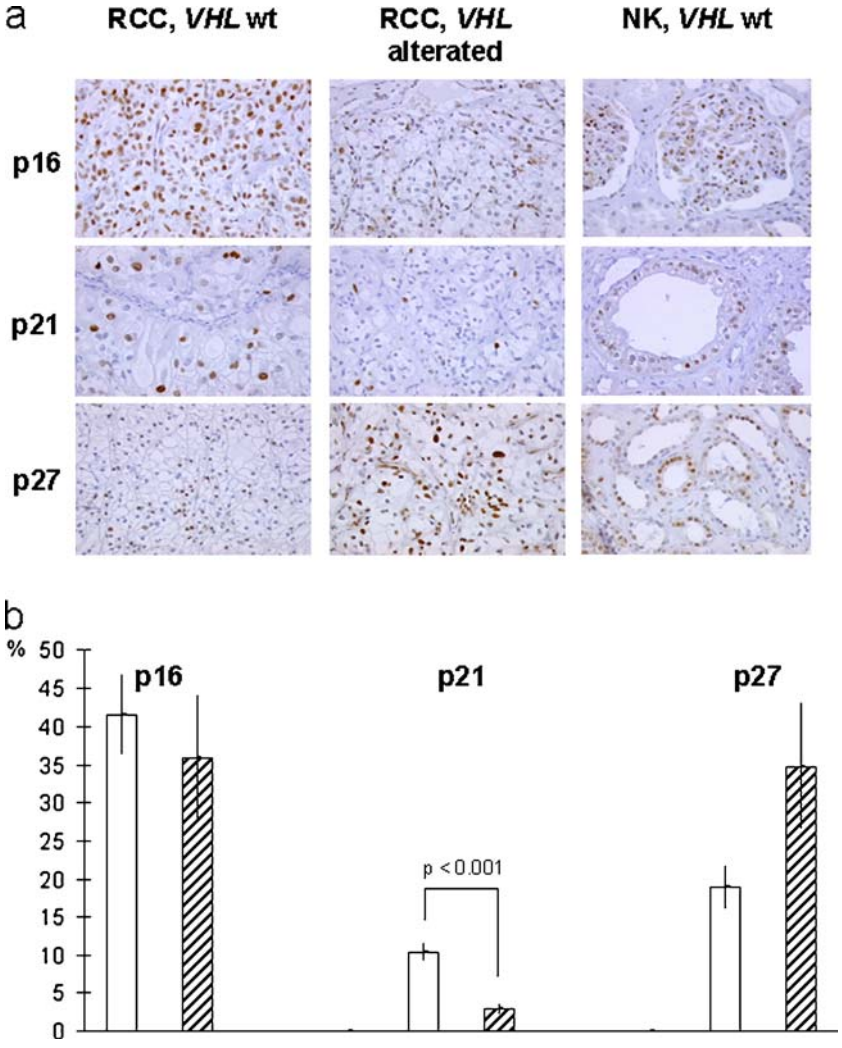

Fig. 3 **a** Immunohistochemical detection of CDKIs p16, p21 and p27 in *VHL* wt and *VHL*-altered RCCs and non-tumorous kidney tissues (NKs). (400×) p16: Only 39 % of all tumour cells (RCC, *VHL* wt and RCC, *VHL* altered), but more than 50% of normal epithelial and mesangial cells (NK, *VHL* wt), show positive staining for p16. p21: Although overall expression of p21 was low in both RCCs and matched non-tumorous kidney tissues, *VHL* wt RCCs displayed a higher percentage of stained tumour nuclei than did RCCs bearing *VHL* mutations/hypermethylation. p27: More than 30% of *VHL*-mutated/hypermethylated tumour cells, but less than 20% of *VHL* wt tumour cells, showed nuclear p27 expression. **b** Comparison of nuclear staining frequencies showed a significant difference between *VHL* wt RCCs (*open columns*) and *VHL*-mutated/hypermethylated RCCs for p21 (*hatched columns*) but not for p16 and p27

In contrast, expression levels of CDKI were lower in tumour cells than in corresponding normal epithelial and mesangial cells. In particular, p16 and p27 expression levels were 39% and 25% in tumour cells and 54% and 62% in epithelial and mesangial cells of non-tumorous kidney tissues ($P<0.02$, Table 2). Approximately 7% of the tumour cells, but only 5% of the non-tumorous epithelial and mesangial cells, displayed nuclear staining positive for p21 ($P=0.137$).

Differential expression of cell cycle proteins in RCCs with and without *VHL* alterations

Comparison of cyclin D1 expression and CDK4 expression in RCCs with and without *VHL* alterations revealed a statistically significant increase of cyclin D1 expression in *VHL*-mutated/hypermethylated tumours ($P<0.05$; Table 2, Fig. 2). In parallel, expression of CDK4 was increased in *VHL*-mutated/hypermethylated RCCs, but the difference between *VHL*-mutated/hypermethylated and *VHL* wt tumours did not reach statistical significance.

Since expression of cyclin D1 and CDK4 appears to be more frequent in RCCs harbouring *VHL* alterations (Fig. 2), we further analysed whether this was also the case for CDK inhibitors. As shown in Fig. 3, there is a differential expression of p21 and p27, but not of p16, in *VHL*-mutated/hypermethylated versus *VHL* wt RCCs. In detail, only 3% of *VHL*-mutated/hypermethylated tumour cells but 10% of the tumour cells without *VHL* alterations stained positive when the anti-p21 mAbs were used ($P<0.001$). In contrast, 35% of the *VHL*-mutated/hypermethylated tumour cells, but only 19% of the *VHL* wt tumour cells, displayed nuclear staining positive for p27. However, the difference between RCCs with and without *VHL* alterations did not reach statistical significance for p27 expression.

Correlation of VHL-deficiency, tumour grade, and expression of cyclin D1 and p27

In order to assess a possible correlation between *VHL* mutations/hypermethylation and tumour cell differentiation we grouped RCCs according to their *VHL* status and tumour grading (G1 versus G2/G3). Analysis of the IHC results revealed an inverse correlation for cyclin D1, p27 and tumour grading only in RCCs bearing *VHL* alterations. Among the latter, ten tumours were well-differentiated (G1) and 12 tumours displayed intermediate (G2; $n=10$) or low (G3; $n=2$) differentiation. Expression of cyclin D1 and p27 was detectable in 73% and 59% of well-differentiated tumour cells but only in 22% and 15% of intermediate or low differentiated tumour cells, respectively ($P<0.05$; Fig. 4). In contrast, among RCCs without *VHL* alterations, only 23% and 25% of well-differentiated tumour cells (G1; $n=17$) displayed nuclear staining positive for cyclin D1 and p27, respectively, whereas 17% and 13% of intermediate (G2; $n=15$) or low (G3; $n=2$) differentiated tumour cells stained positive for both antibodies, respectively (Fig. 4). These differences were not significant.

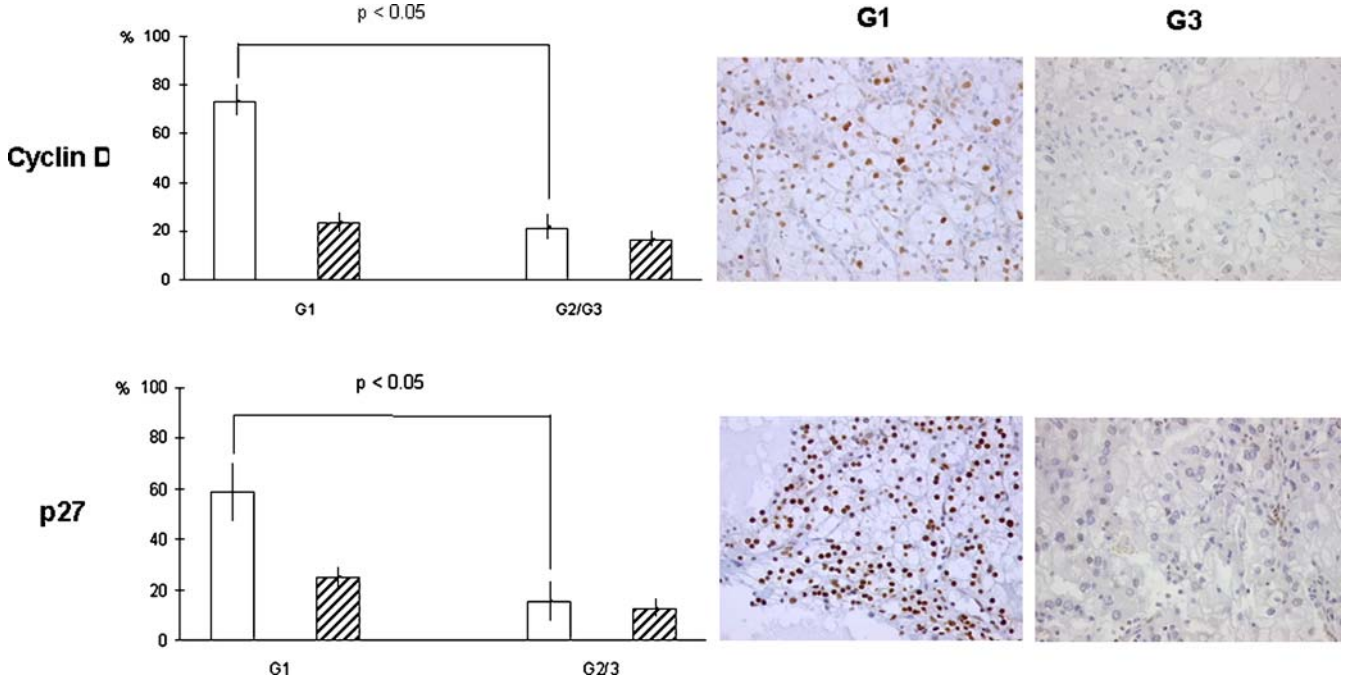

Fig. 4 Inverse correlation between cyclin D1/p27 expression and tumour grading in *VHL*-mutated/hypermethylated RCCs (×400). IHC staining for cyclin D1 and p27 demonstrated that both antigens are highly expressed in well-differentiated tumour cells (G1), whereas the majority of intermediate (G2) or low (G3) differentiated tumour cells stained negative. *Open columns* RCC, *VHL* mutated/hypermethylated, *hatched columns* RCC, *VHL* wt

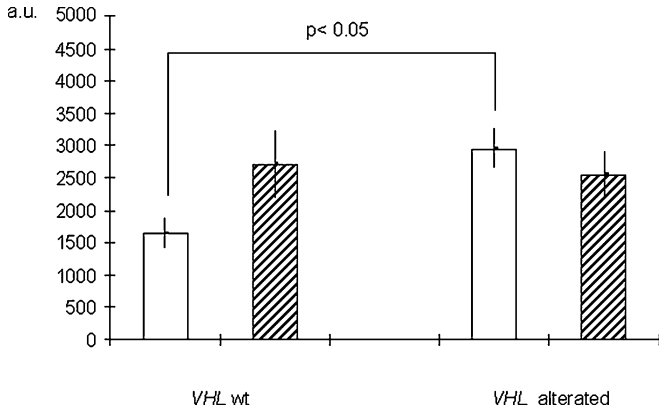

Fig. 5 mRNA expression of NFκB1 assessed by quantitative RT-PCR, which does not show significant differences in the amount of NFκB1 mRNA between matched normal kidney tissues (*open columns*) and RCCs (*hatched columns*), or between RCCs with or without *VHL* alterations. However, mRNA expression significantly differed between normal kidney tissues, depending on the *VHL* status of the corresponding tumour. Data represent means from two independent experiments

Transcriptional up-regulation of NFκB1 in RCCs bearing *VHL* alterations

Besides HIF1 there are several other well-characterized transcription factors, such as NFκB1 and RelA, that are known to regulate genes coding for cell cycle proteins. In order to assess a possible role of these transcription factors in the context of RCCs bearing *VHL* alterations, we quantified RNA expression levels by RT-PCR and correlated them with the IHC data. Comparison of *VHL* wt RCCs with RCCs bearing *VHL* alterations showed no statistically significant difference with respect to the RNA expression levels of both transcription factors. However, there was an obvious difference in the expression of NFκB1 in the corresponding non-tumorous kidney tissues, indicating that NFκB1 is up-regulated during the tumorigenic process of RCCs that acquire *VHL* mutation/hypermethylation. The different NFκB1 expression in autologous normal kidney tissues was significant ($P<0.05$; Fig. 5).

Discussion

The results from this study show that factors involved in cell cycle regulation are differentially expressed in clinical samples of clear cell RCCs and that these differences might be related to VHL deficiency and HIF pathway dysfunction. These findings are based on comparisons of protein or mRNA expression levels between normal and tumorous tissues and on comparisons between RCCs with and without *VHL* alterations.

Firstly, we stratified clear cell RCCs according to diagnostic and molecular characteristics such as grading and *VHL* mutation status previously established [3]. To explore a possible relationship between *VHL* alterations and cell cycle dysregulation we assessed protein expression of HIF1α by IHC. The rationale behind this is that VHL negativity due to *VHL* mutation/hypermethylation may interrupt the HIF pathway, which, in turn, may affect cell cycle control. As expected from previous reports, we observed a significant correlation of HIF1α up-regulation with *VHL* alterations [9, 30].

In a next step we showed that expression of cell cycle regulators cyclin D1 and CDK4 was significantly increased in RCCs when compared with normal renal epithelial and mesangial cells. These data suggest that nearly one-third of tumours were in G1/S transition. When we further stratified RCCs into *VHL* wt and *VHL*-mutated/hypermethylated tumours it became evident that cyclin D1 and CDK4 levels were more increased in RCCs with *VHL* alterations, particularly those with increased HIF1α expression. Thus, our data obtained from clinical clear cell RCCs support the notion of a regulatory role of HIF1α in the transcription of cyclin D1 and CDK4. In particular, over-expression of cyclin D1, resulting from pVHL deficiency and HIF1α dysregulation, might point to a mechanism by which the Rb pathway is deregulated in clear cell RCC, a notion that has been previously suggested on the basis of in vitro experiments [2]. A possible link between VHL deficiency, HIF dysregulation and subsequent overexpression of cyclin D1 seems plausible, since the cyclin D1 promoter contains at least two HIF-binding consensus sites (hypoxia-responsive elements, HREs) at positions -552 and -390 [23]. Thus, our data suggesting HIFα-dependent up-regulation of cyclin D1 and CDK4 expression are in line with an HIFα-mediated dysfunction of cell cycle control in clear cell RCCs harbouring *VHL* mutations/hypermethylation.

When we further extended our investigations to inhibitors of the cyclin D1/CDK4 complex we observed significant expression between autologous non-tumorous tissues and RCCs, with respect to CDKIs p16 and p27 but not p21. However, in contrast to cyclin D1 and CDK4, variation of CDKI expression resulted in a decrease rather than an increase. Further comparison of CDKI protein expression levels between RCCs with and without *VHL* alterations showed that, for p27, this decrease was less pronounced in tumours with *VHL* alterations than in VHL wt tumours. Although, there was no significant variation of p21 expression levels between non-tumorous tissues and RCCs, already mentioned above, we observed a significant difference between *VHL* wt and *VHL*-mutated/hypermethylated RCCs in that expression levels of p21 were decreased in RCCs with VHL mutations/hypermethylation but increased in *VHL* wt RCCs (Fig. 3). Interestingly, a concomitant increase of cyclin D1 expression and p27 expression in RCCs bearing *VHL* alterations was correlated with more favourable tumour cell differentiation (Fig. 4).

Cyclin D1 abundance varies with the cell cycle. In short-lived cells cyclin D1 is subject to rapid ubiquitination and proteasomal degradation [14, 25]. Since cyclin D1 abundance is largely controlled by the rate of gene transcription, we also included transcription factors NFκB1 and RelA, which are able to bind to the cyclin D1 promoter, for analysis [10, 14]. Interestingly, a significant difference in NFκB1 mRNA expression was found in autologous non-tumorous renal epithelial tissue that corresponded to tu-

mours harbouring *VHL* alterations. This raises the possibility that the tumorigenic process of clear cell RCCs harbouring *VHL* alterations might require substantial upregulation of NFκB1 prior to the initiating tumorigenic event. This interpretation is in line with recent findings of Figueroa et al., who linked NFκB with HIF-target gene expression by blocking HIF1α protein expression and subsequent erythropoietin gene expression through inhibition of NFκB under hypoxic conditions [4].

Altogether, our observations obtained from clinical RCC samples support a possible role of cell cycle proteins in the tumorigenesis of RCCs bearing *VHL* mutations/hypermethylation. In particular, CDKIs of the CIP/Kip family of proteins (p21 and p27), but not of the Ink4 family (p16), seem to be associated with the tumorigenic process of RCCs harbouring *VHL* mutations/hypermethylation. Accordingly, cell cycle dysregulation might require pVHL deficiency and HIF1α dysfunction to mediate the disruption of the control of G1/S transition on the level of cyclin–CDK complex inhibition. Although the precise mechanisms of interaction of cell cycle proteins in *VHL*-altered tumorigenesis remains elusive, our results acknowledge the prominent role of cyclin D1 and its regulatory factors within the CDK/CDKI system of cell cycle regulation.

Rb1cc1 is critical for myoblast differentiation through Rb1 regulation

Received: 18 November 2004 / Accepted: 19 November 2004 / Published online: 21 June 2005
© Springer-Verlag 2005

Abstract Rb1-inducible coiled-coil 1 (Rb1cc1) expressed at high levels is associated with the maturation of human embryonic musculoskeletal cells. To clarify the molecular role of Rb1cc1 in muscular differentiation, we investigated the expression of Rb1cc1 and other genes that regulate differentiation in murine embryonic tissues and in C2C12 myoblasts. We also evaluated the effects of RNA interference (RNAi)-mediated *Rb1cc1* knockdown on C2C12 myoblast differentiation. After Rb1cc1, Rb1 and myosin heavy chain (Myhc) were expressed in mouse embryonic muscles. The synchronous expression of *Rb1cc1* and *Rb1* predicted *Myhc* expression during C2C12 myoblast differentiation. RNAi-mediated knockdown of *Rb1cc1* led to *Rb1* suppression, and C2C12 myoblasts failed to differentiate. These results indicated that Rb1cc1 is a potent regulator of the Rb1 pathway and a novel mediator that plays a crucial role in muscular differentiation. Rb1cc1 expression is, thus, a prerequisite for myogenic differentiation.

Introduction

During differentiation, skeletal muscle undergoes terminal withdrawal from the cell cycle, the activation of coordinated gene expression, and the fusion of myoblasts into multinucleated myotubes. These events are largely dependent on muscle-specific transcription factors and the retinoblastoma 1 (Rb1) tumor suppressor. The MyoD family includes MyoD, myf5, myogenin, and MRF4 [3, 11, 22], among which MyoD plays particularly pivotal roles in the activation of muscle-specific gene expression and cell-cycle arrest [7, 19]. However, the roles of these myogenic factors apparently depend on Rb1, which might mediate both terminal withdrawal from cell cycle and the upregulation of tissue-specific genes associated with terminal differentiation [12, 23]. Myotubes deficient in *Rb1* do not differentiate and, in fact, re-enter the cell cycle in response to mitogens [21]. Moreover, introducing MyoD into *Rb1*-deficient mouse embryonic fibroblasts cannot induce late markers of myogenic differentiation and cell-cycle arrest, indicating that Rb1 is required for MyoD-mediated myogenic function [8, 18]. Although Rb1 is important to muscular differentiation, the precise mechanisms remain obscure.

We recently identified a novel molecule, Rb1-inducible coiled-coil 1 (Rb1cc1), which is expressed at high levels in human embryonic musculoskeletal and cultured osteosarcoma cells. Rb1cc1 induces Rb1 expression in a variety of cultured cells [5, 6], and the expression of both molecules is synchronous [5]. We also demonstrated that Rb1cc1 contributes to the maturation of human embryonic musculoskeletal cells [6]. These findings implied that Rb1cc1 is involved in muscular differentiation.

To define the relationship between Rb1cc1 function and muscle differentiation, we used the murine C2C12 myoblast model, which has been widely studied as an in vitro model to understand the regulation of myogenic differentiation [10, 13]. Switching C2C12 cell lines to low-serum medium induces their differentiation. This process closely resembles myogenic differentiation in vivo. The expression of both *Rb1cc1* and *Rb1* is similarly upregulated in the model. Furthermore, *Rb1cc1* knockdown led to the downregulation of *Rb1* expression, and late markers of myogenic differentiation were not expressed. The present study showed that Rb1cc1 is vitally involved in skeletal muscle differentiation.

Materials and methods

Northern blots

Mouse embryo full stage blots (Seegene, Seoul, Korea) were hybridized with gene-specific probe nucleotides (nt) 1536–3500 of *Rb1cc1* (GenBank accession number, AB070619), 336–675 of *Rb1* (GenBank accession number, NM000321), and 2695–2719 of *myosin heavy chain* (*Myhc*) (GenBank accession number, NM144961). The probes were labeled with [α-^{32}P] dCTP (3000 Ci/mmol; Amersham, Piscataway, NJ) using random priming and hybridized with the blot membrane at 42°C overnight in 50% formamide containing 1% sodium dodecyl sulfate (SDS), 1 mol/l NaCl, 200 mg/ml sonicated herring sperm DNA, and 10% dextran sulfate. The blots were then washed twice at 42°C in 2×standard saline citrate (SSC) containing 1% SDS and once with 0.2×SSC containing 1% SDS for 5 min at 65°C. Blots were visualized using autoradiography with a Kodak BioMax and intensifying screens (Kodak, New Haven, CT).

Histology and immunohistochemistry

Pregnant female C57BL6 mice were sacrificed by cervical dislocation, and embryos were transferred to 10% buffered formalin and fixed overnight. The embryos were washed several times in 70% ethanol, embedded in paraffin, and serially sliced into 4-μm sections. Deparaffinized sections were immersed in 0.3% H_20_2, autoclaved at 120°C for 1 min, and rinsed with 1×Tris-buffered saline (TBS) prior to incubation overnight at 4°C with the following primary antibodies: anti-Rb1cc1 rabbit antiserum (α-Rb1cc1–1104) [2, 5], anti-Rb1 monoclonal antibody (G3–245; PharMingen, San Diego, CA), and anti-Myhc monoclonal antibody (RNMy2/9D2; Novo Castra, Newcastle, UK). The sections were rinsed with 1×TBS and incubated with secondary antibody (Simple Stain MAX-PO; Nichirei, Japan) at room temperature for 1 h. The sections were then stained with 3,3′-diaminobenzidine tetrahydrochloride and counterstained with hematoxylin.

Cell culture

C2C12 mouse skeletal myoblasts were cultured in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum (growth medium). To induce muscular differentiation, the cells were rendered quiescent by serum withdrawal for 48 h and stimulated to differentiate by adding 2% horse serum [differentiation medium (DM)].

RNAi and transfection

Three kinds of small interfering RNA (siRNA) plasmid vectors (608, 1993 and 4525) corresponding to different targeting sites (nt.608–626, nt. 1993–2013 and nt. 4525–4545, respectively) of *Rb1cc1* mRNA (GenBank accession number, AB070619) were synthesized in vitro by inserting artificial oligonucleotides into pRNAT-H1.1/Hygro (GenScript, Piscataway, NJ). We introduced each siRNA or control vector into C2C12 cells using FuGENE6 according to the supplier's recommendations (Roche Applied Science).

Reverse-transcription polymerase chain reaction

Total RNA was isolated from C2C12 cells using TRIzol (Gibco-BRL), and first-strand cDNA was synthesized using Superscript III reverse transcriptase and Oligo d(T)$_{12–18}$ primer (Gibco-BRL). The gene primer sequences were as follows: murine *Rb1cc1*: forward, 5′- TGCTGCACAA GACTCTCACA and reverse, 5′- CAGCATTTCCTTCTG CTGTG; *Rb1*: forward, 5′- CACGTGTAAATTCTGCTG CAA and reverse, 5′- CCTGG TGGAGGCATACTGTAA; *Gapdh*: forward, 5′- CATGACAACTTTGGCATTGTG and reverse, 5′- GTTGAAGTCGCAGGAGACAAC; *Myhc*: forward, 5′- AAGG AACTTGAAGAAAAGATGGTG and reverse, 5′- TCAAGTTTTCTCTTG GCTCTTTCT; *cyclin D3*: forward, 5′- TAGGCGCCTGCTCTATGTCT and reverse, 5′-ATCTGTGGGAGTGCTGGTCT; *p21*: forward 5′-GTCCAATCCTGGTGATGT CC and reverse, 5′- CAG GGCAGAGGAAGTACTGG. The PCR protocols consisted of 26 cycles for *Rb1cc1*, *Rb1* and *p21*, 21 for *Gapdh*, 38 for *Myhc*, and 36 cycles for *cyclin D3* of a 20-s denaturation at 95 C, 20-s annealing at 55 C, and 30-s extension at 72°C.

Immunocytochemical analysis of C2C12 cells

The above-mentioned primary antibodies were labeled with Alexa Fluor 555 (Molecular Probes, Eugene, OR) accord-

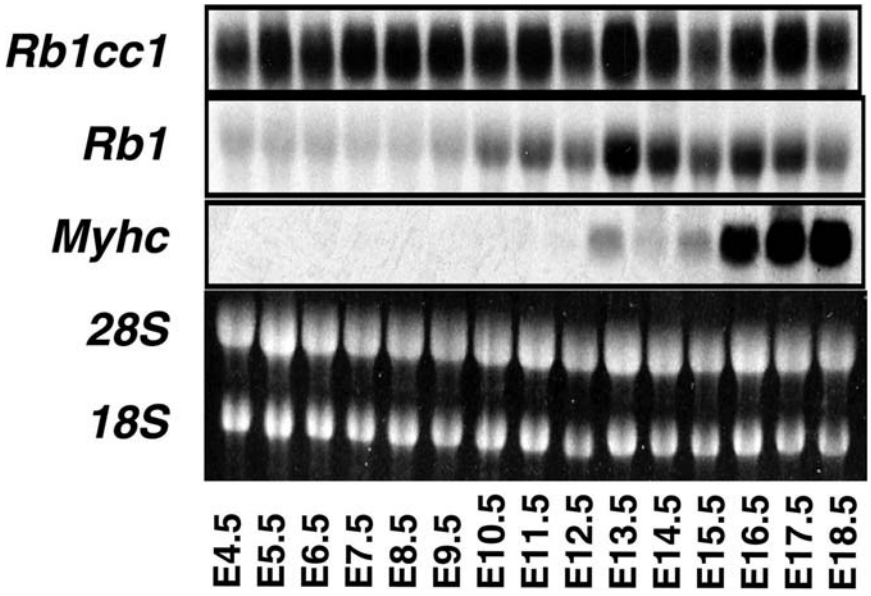

Fig. 1 Expression of mRNA during mouse embryogenesis. Membranes were hybridized with specific probes for *Rb1cc1*, *Rb1*, and myosin heavy chain (*Myhc*). Equal sample loading was conformed by ethidium bromide staining of RNAs. Rb1cc1 mRNA was constitutively expressed in embryos and predicted Rb1 and Myhc

ing to the supplier's protocol. The C2C12 cells treated with siRNA were fixed, incubated with the appropriate labeled antibody, and evaluated using fluorescent microscopy.

Results

Rb1cc1 predicts Rb1 and Myhc

To determine the importance of Rb1cc1 in muscular differentiation, we analyzed Rb1cc1 expression in murine embryos. Northern blotting showed that *Rb1cc1* mRNA was constitutively expressed in the embryos and predicted *Rb1* and *Myhc*. *Rb1* mRNA was obviously induced in E10.5 embryos and upregulated at E13.5–14.5 and E16.5–17.5. Following *Rb1cc1* and *Rb1* expression, *Myhc*, a late marker of myogenic differentiation, was expressed in E13.5 embryos and obviously induced at E16.5 (Fig. 1).

Immunohistochemical staining with Rb1cc1, Rb1, and Myhc in murine embryos also showed Rb1cc1, Rb1, and Myhc expression in developing murine muscular tissues (Fig. 2). Rb1cc1 was expressed predominantly in the cytoplasm, and Rb1 was located in the nucleus. Myhc was expressed throughout 18 dpc mouse muscles.

Expression of *Rb1cc1* and *Rb1* is associated with muscular differentiation

To investigate the Rb1cc1-mediated molecular mechanism in muscle differentiation, we used the murine C2C12 myoblast system. *Rb1cc1* and *Rb1* gene expression was induced

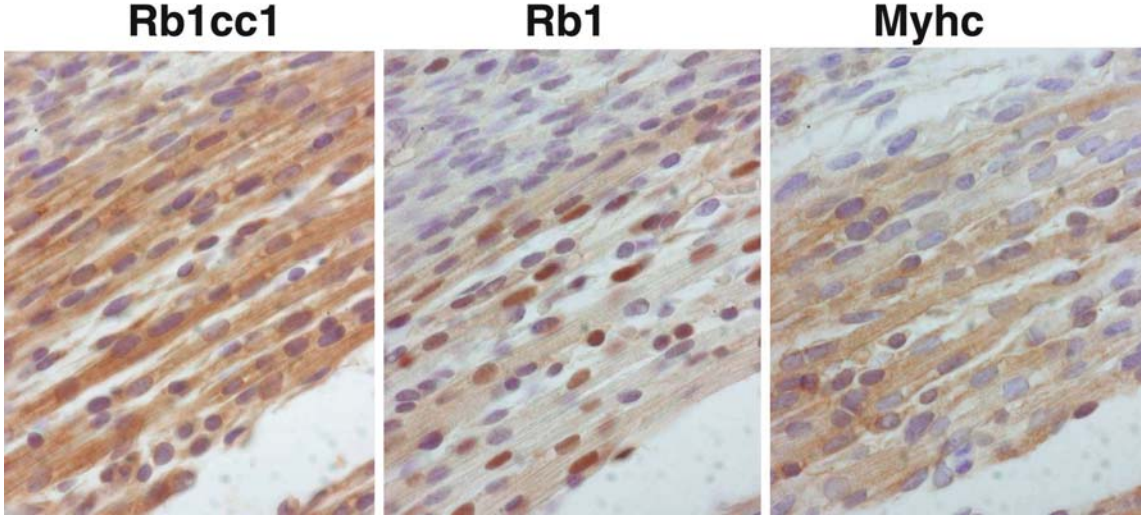

Fig. 2 Expression of Rb1cc1, Rb1, and Myhc in mouse embryos. Immunohistochemical analysis demonstrated predominant Rb1cc1 expression in cytoplasm and Rb1 in nuclei. Myhc expression is scattered throughout 18.5 days post-conception (dpc) mouse muscles

in C2C12 cells by DM. Thereafter, differentiated C2C12 cells also expressed high levels of *Myhc*, a late marker of myogenic differentiation, compared with proliferating C2C12 cells. More *p21* expression was induced in differentiating than in proliferating C2C12 cells (Fig. 3).

Rb1cc1-specific knockdown disturbs myoblast differentiation

To study the functions of endogenous Rb1cc1 during the differentiation of C2C12 myoblasts, we knocked down *Rb1cc1* expression using siRNAs. This process led to *Rb1* repression, as well as failed *Myhc* expression and myoblast differentiation. The expression of a series of genes, including *p21* and *cyclin D3*, was similar during the experimental process for the differentiation (Fig. 4). Immunocytochemically, C2C12 cells with siRNA vectors failed to synthesize Rb1cc1 and expressed low levels of Rb1 and Myhc (Fig. 5). Exposure to several siRNAs corresponding to different regions of *Rb1cc1* mRNA similarly caused C2C12 myoblast differentiation to fail (data not shown).

Discussion

Rb1cc1 is a novel gene that is associated with multidrug resistance to anti-cancer agents. The expression of both *Rb1cc1* and *Rb1* is synchronized in various cancer cell lines and in normal human tissues. Moreover, the introduction of wild-type *Rb1cc1* induces *Rb1* expression in human leukemic cells [5]. Rb1cc1 expressed at high levels contributes to the maturation of human embryonic musculoskeletal cells [6]. To our knowledge, Rb1cc1 might interact with Stathmin [17], the Listeria monocytogenesis surface protein ActA [20], or with focal adhesion kinase

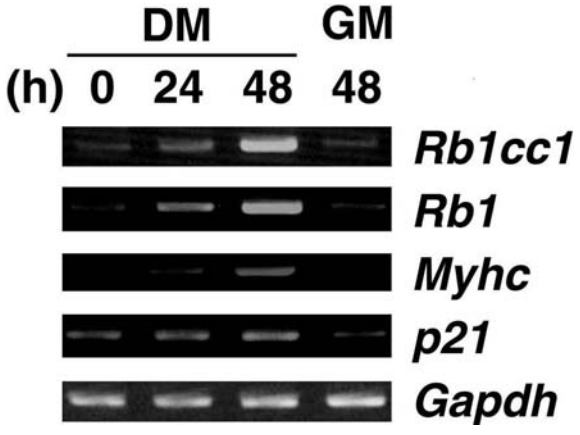

Fig. 3 Serial expressional analysis of genes regulating muscle differentiation. Expression levels of *Rb1cc1*, *Rb1*, *Myhc*, *p21*, and *Gapdh* in C2C12 cells incubated in differentiation medium (DM) for indicated periods, or maintained in growth medium (GM) were determined by semi-quantitative reverse-transcription polymerase chain reaction. More *Rb1cc1* and *Rb1* genes were induced by DM. Following expression of these genes, *Myhc* was obviously inducted in differentiated C2C12 cells

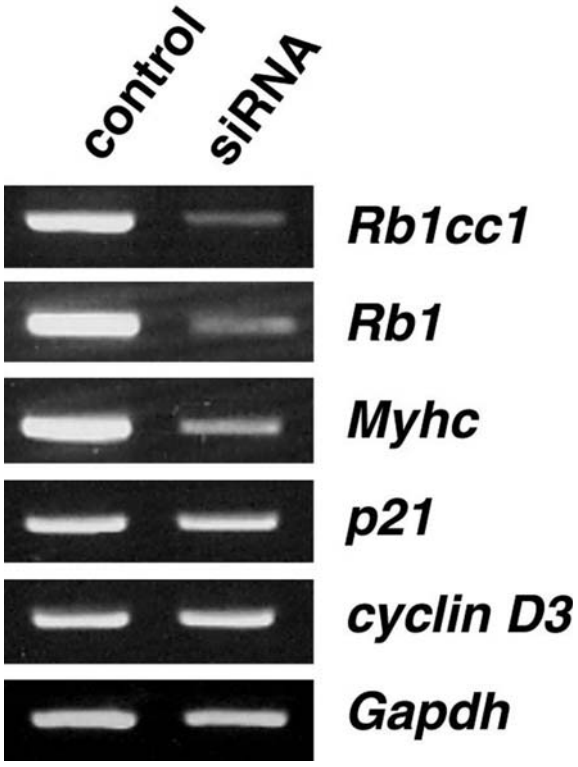

Fig. 4 Effects of *Rb1cc1* knockdown in C2C12 cells. C2C12 cells treated with siRNA vector (4525) were incubated in differentiation medium (DM). Expression levels of *Rb1cc1*, *Rb1*, *Myhc*, *p21*, *cyclin D3* and *Gapdh* were determined using semi-quantitative reverse-transcription polymerase chain reaction. *Rb1cc1* siRNA inhibited *Rb1* expression and resulted in failed *Myhc* expression. Expression of *p21* and *cyclin D3* was not affected

[1]. However, other molecules that associate with Rb1cc1 remain unknown, and the molecular mechanisms of Rb1cc1-mediated cellular functions are obscure.

To determine the function of Rb1cc1, the present study investigated the roles of Rb1cc1 on skeletal muscle differentiation. Northern and immunohistochemical analyses of mouse embryos showed that *Rb1cc1* expression predicted that of *Rb1* and *Myhc*. Although we demonstrated that the expression of Rb1cc1 and Rb1 is synchronized in musculoskeletal tissues of human embryos [6], Rb1cc1 was expressed more ubiquitously and earlier in mouse than in human embryos. Further, the intracellular localization of Rb1cc1 could change according to the developing status, and Rb1cc1 is involved in the murine developmental process [2]. More importantly, *Rb1cc1* and *Rb1* expression closely correlated and led to *Myhc* expression during C2C12 myoblast differentiation. These results suggest that Rb1cc1 is intimately involved in muscle differentiation in vivo and in vitro. Rb1 protein plays crucial roles in the induction of late markers during myogenic differentiation [8, 18]. Rb1cc1 predicted Rb1 during mouse myogenic differentiation and might play an important role in the expression of Rb1 and subsequent Myhc, a late marker of this process.

The RNAi-mediated knockdown of *Rb1cc1* reduced Rb1 expression at the transcriptional level, and Myhc was

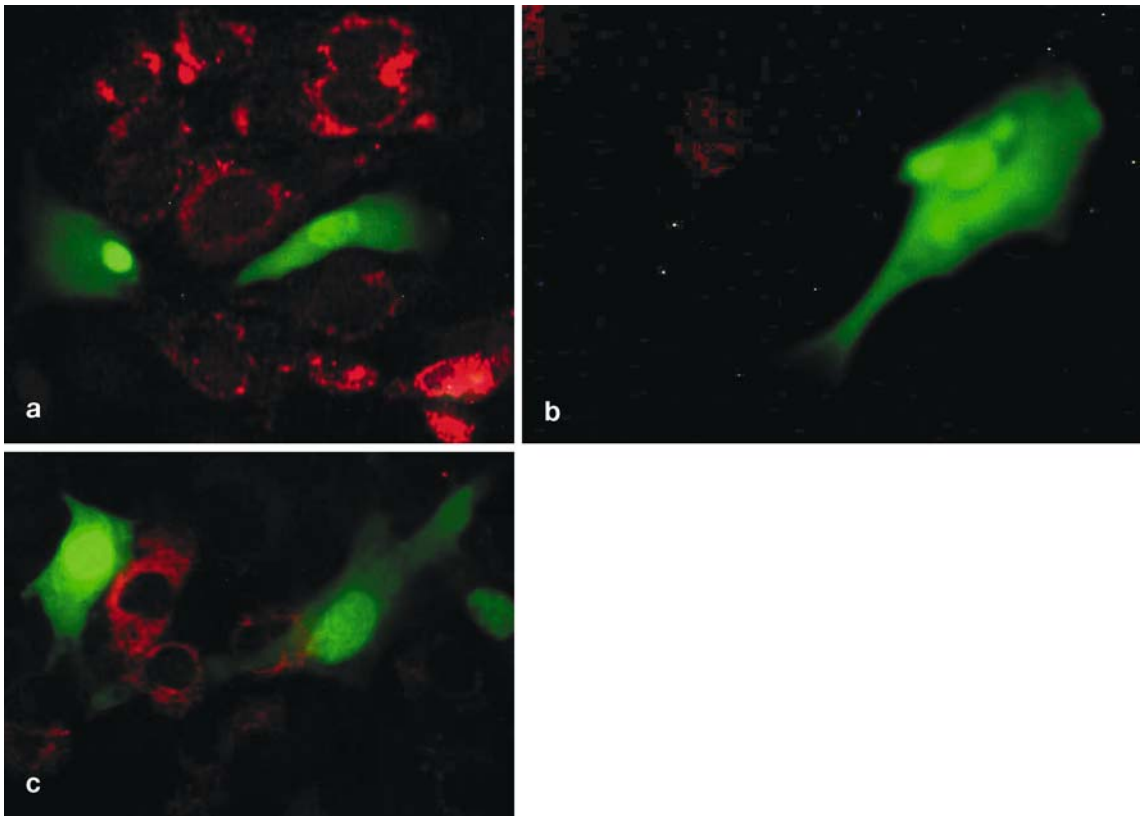

Fig. 5 Effects of Rb1cc1 knockdown on C2C12 myoblasts differentiation. C2C12 cells treated with siRNA vector (4525) were incubated in differentiation medium (DM). Fluorescent immunocytochemistry of Rb1cc1, Rb1, and Myhc demonstrated that the C2C12 cells treated with Rb1cc1 siRNA (green: GFP) failed to synthesize Rb1cc1 (Red, Alexa Fluor 555; A) in the cytoplasm, and they expressed neither Rb1 (Red, Alexa Fluor 555; B) nor Myhc (Red, Alexa Fluor 555; C)

not induced during C2C12 myoblast differentiation. The findings suggest that Rb1cc1 acts in the same pathway as Rb1 and plays a crucial role in myoblast differentiation upstream of Rb1 rather than downstream.

Although many proteins are implicated as critical modulators of myogenic differentiation, the complexity of this process suggests that more remain to be discovered. Here, we postulate that Rb1cc1 is a novel modulator of myogenic differentiation. We found that Rb1cc1 appears to be primarily required for muscular differentiation and that its suppression causes failed maturation of myoblasts largely due to the loss of Rb1 expression. Rb1cc1 is thought to induce Rb1 expression [5]. Rb1cc1 regulated Rb1 expression at the transcriptional level, although many proteins are involved in Rb1 regulation by affecting its phosphorylation status [9, 14, 21, 23]. Rb1cc1 might directly bind the *Rb1* gene promoter and induce its expression. Although Rb1cc1 predicted Rb1, such concordance was incomplete during mouse embryonic development. These findings indicate that Rb1cc1 indirectly rather than directly regulates Rb1 expression. Otherwise, Rb1cc1 might associate with Rb1. The Rb1cc1 protein contains a consensus nuclear localization signal (KPRK) [5], and the protein was localized in both the nucleus and cytoplasm. In addition, intracellular sublocalization of Rb1cc1 changes in accordance with developmental status [2]. Rb1cc1 may play functional roles by altering its intracellular sublocalization. Thus, Rb1cc1 might cooperate in nuclear Rb1 expression.

The present study demonstrated that *Rb1cc1*-siRNAs decreased the expression of *Rb1* and subsequently *Myhc* but not that of *p21* and *cyclin D3*. MyoD, a pivotal factor for myogenic differentiation, can activate muscle-specific gene expression and induce cell-cycle arrest through Rb1-dependent pathways [18, 21]. At the onset of myogenic differentiation, MyoD activates the expression of *Rb1*, *p21*, *cyclin D3* and induces cell cycle arrest, a process that is referred to as early events [4, 15, 16]. MyoD also co-operates with Rb1 to promote the expression of late markers of muscular differentiation, such as Myhc, which is referred to as a late myogenic event [4]. Therefore, the failed differentiation of myoblasts due to *Rb1cc1*-specific knockdown was largely dependent on Rb1 repression with no change in *p21* and *cyclin D3*, suggesting that Rb1cc1 is a crucial regulator of late, rather than early myogenic events.

Here, we reported that Rb1cc1 is a novel modulator of myogenic differentiation. The Rb1cc1-Rb1 pathway is primarily required for myogenic differentiation, and elucidating the components and precise mechanisms of the pathway during this process will help to clarify how Rb1cc1 functions under physiological conditions.

Granular cell tumor of the neurohypophysis: report of a case with unusual age presentation

Received: 12 July 2004 / Accepted: 9 February 2005 / Published online: 18 August 2005
© Springer-Verlag 2005

Abstract Granular cell tumor (GCT) usually occurs as a solitary, small, nodular tumor and rarely grows to a sufficient size to present symptoms. The tumor is more prevalent in female adults. The authors report a case of an 8-year-old boy with GCT of the neurohypophysis presenting with central precocious puberty. Few cases of symptomatic GCT have been reported in the literature, none of them in a patient in the first decade of life. Clinical picture, histopathological features, and histogenesis of GCT of neurohypophysis are discussed.

Keywords Granular cell tumor · Neurohypophysis · Central precocious puberty

Introduction

Granular cell tumor (GCT) is a neoplasm commonly found in the head and neck; however, it may occur in different locations such as tongue, skin, gastrointestinal tract, and central nervous system [1, 7, 18, 21]. It usually occurs as a solitary, nodular, and asymptomatic mass and is most frequently diagnosed as an incidental finding at autopsy [1, 2, 6, 16, 20, 27]. The tumor is more prevalent in female adults [1, 2, 27]. Since the initial description by Boyce and Beadles in 1893, GCTs have been described under many names such as choristoma, granular cell myoblastoma, granular cell pituicytoma, and granular cell schwannoma, reflecting the ongoing controversy concerning the cells of origin of these tumors [1, 7–9, 19–23].

We report the clinical, radiological, and pathological findings of a case of GCT affecting the neurohypophysis of an 8-year-old boy.

Clinical history

An 8-year-old boy suffering from obesity since he was 3 years old (weight 20.8 kg, height 90 cm) presented with a 2-month history of pubarche. The penis and testes were enlarged, and he also showed acne, dizziness, frontal headache, decreased visual acuity, and occasional vomiting.

Hormonal evaluation revealed a normal thyroid function. A provocative test with insulin-induced hypoglycemia was also normal for growth hormone (GH) and adrenocorticotropic hormone. A test with intravenous infusion of gonadotropin-releasing hormone rendered pubertal ranges of gonadotropic hormones, thus supporting the clinical suspicions of central precocious puberty.

Computed tomography scans revealed a round, well-delineated suprasellar mass. The tumor was solid, with calcifications, and was enhanced homogeneously after administration of contrast.

Materials and methods

The surgically resected specimen was fixed in 10% buffered formalin, embedded in paraffin, cut in 4-μm-thick sections, and stained with hematoxylin and eosin (H & E) as well as periodic acid-Schiff (PAS) stain. Immunohistochemical studies using the biotin–streptavidin peroxidase technique were performed using antibodies against cytokeratin (1:400; Dako, CA, USA), neuron-specific enolase (1:2,500; Dako), S-100 protein (1:1,500; Dako), chromo-

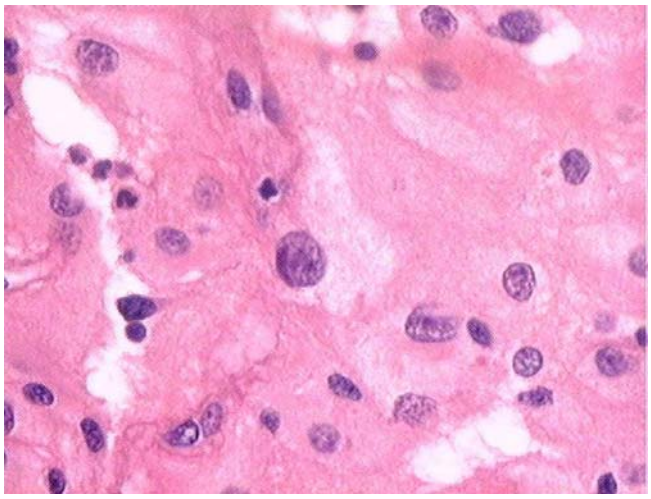

Fig. 1 Photomicrographs displaying large polygonal cells arranged in lobules separated by thin septa of tumorous cells presenting abundant eosinophilic, granular cytoplasm and nuclear polymorphism (H & E, ×100)

granin A (prediluted; Zymet, CA, USA), synaptophysin (1:200; Dako), desmin (1:800; Dako), muscle-specific actin (HHF-35) (1:500; Dako), and glial fibrillary acidic protein (GFAP) (1:500; Dako).

Results

Histological sections revealed a hypercellular tumor with large and polygonal cells arranged in lobules separated by thin septa of tumors cells presenting abundant eosinophilic and granular cytoplasm and nuclear polymorphism (Figs. 1 and 2). Cytoplasmic granules were PAS-positive and resistant to diastase digestion (Fig. 3).

Immunohistochemical analysis revealed strong positivity for neuron-specific enolase, but negative for S-100

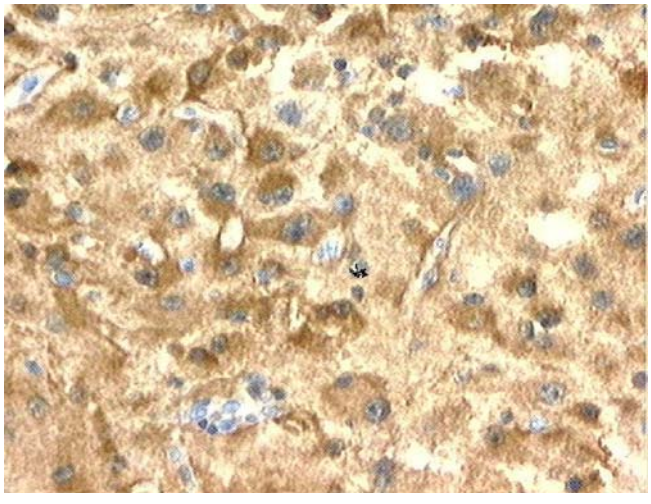

Fig. 2 Photomicrographs displaying large polygonal cells arranged in lobules separated by thin septa of tumorous cells presenting abundant eosinophilic, granular cytoplasm and nuclear polymorphism (H & E, ×400)

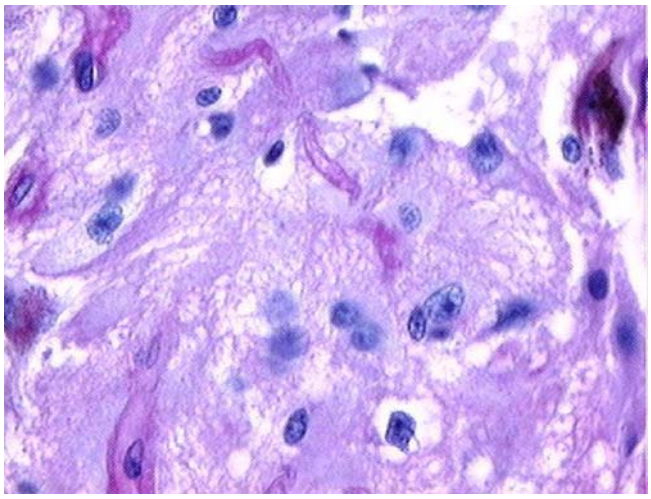

Fig. 3 Cytoplasmic granules displaying PAS-positivity resistant to diastase digestion

protein, cytokeratins, chromogranin A, synaptophysin, desmin, actin, and GFAP (Fig. 4). The histopathological diagnosis was GCT of the neurohypophysis.

Discussion

Granular cell tumors may occur in virtually any anatomic site, but they have a prediction for the head and neck. Intracranial GCTs are usually found in the posterior hypophysis and rarely in the cerebral hemispheres or leptomeninges. They are more often encountered as incidental autopsy findings in up to 17% of unselected adult autopsy cases as clusters of granular cell "tumorettes" [16, 20]. There is a 2:1 predominance in females, and despite the wide range of age distribution (30–60 years old) [1, 18], we could not find any case diagnosed in the first decade of life, like the present report. It usually occurs as a solitary, small, nodular tumor and rarely grows to a sufficient size to present symptoms [2, 3, 15, 20, 27]. To date, only 50 clinically

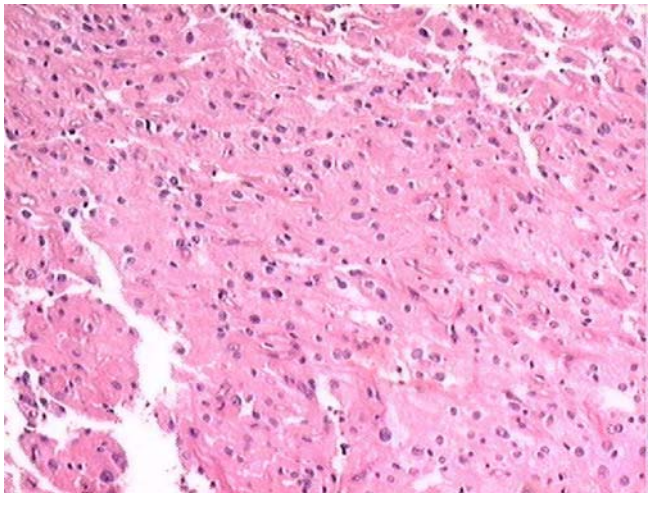

Fig. 4 Immunohistochemical staining displaying neuron-specific enolase positivity (×400)

symptomatic cases of GCT have been reported in the literature.

Symptomatic GCTs of the neurohypophysis present usually with ophthalmologic abnormalities in up to 90% of patients, which include bilateral temporal field deficit, optic nerve atrophy, and decreased visual acuity resulting from compression of the optic chiasm. Hormonal disturbance is described in 50% of patients and includes secondary amenorrhea, galactorrhea, decreased libido, infertility, and weight gain or loss. Diabetes insipidus, as well as multiple endocrine neoplasia type 1, was described in one case each [1]. Persistent headache, repeated vomiting, memory loss, and behavior disorder are rarely seen [2, 7–9, 10, 21].

In our case, ophthalmological and hormonal disturbances were found probably due to a compressive process. Hamartomas, optic nerve gliomas, and astrocytomas are frequently associated with the development of central precocious puberty, whereas craniopharyngioma, Rathke's cysts, germinomas, and Langerhans cell histiocytosis are not. One explanation would be coexistence with a pituitary adenoma, a well-known cause of precocious puberty [5, 24]. Tomita and Gates [25] studied 100 pituitary glands examined at autopsy and found that 9% harbored a GCT, and of these, a coexisting pituitary adenoma was observed in three cases. Despite that, we did not find any tumor in the adenohypophysis.

Another possible mechanism for central precocious puberty would be the secretion of a luteinizing hormone (LH)/follicle-stimulating hormone (FSH) precursor or FSH/LH per se. A similar picture was reported by Losa et al. [10] regarding GH. These authors suggested that a GCT could secrete a GH precursor, thus explaining the acromegaly presentation of their patient. However, as in our case, it was not possible to establish a scientifically proven pathogenetic pathway.

GCTs of the sellar region are morphologically similar to those tumors occurring outside the nervous system. The tumors are composed of densely packed polygonal cells with eosinophilic, granular, PAS-positive, diastase-resistant cytoplasm. Sometimes, small areas of foamy cells can be observed, as well as cytoplasm and round nuclei with delicate chromatin and uniform nucleoli. Perivascular lymphocytic aggregates are a common feature [1, 7, 9]. Despite absent mitotic activity, Kasashima et al. [7], in their literature review of GCT with histologically atypical features, found lesions that were characterized by remarkable cellular and nuclear polymorphism, nuclear hyperchromatism, large nucleoli, mitosis, and necrosis.

Although the histological appearance is remarkably characteristic, the histogenesis of GCTs is unknown [1]. The numerous denominations attributed to the tumor reflect this uncertainty [7, 17, 18, 20]. These tumors were initially believed to be an aberrant growth of embryological tissue and were called "choristomas" [11]. Later, the term "granular myoblastoma" was suggested because of the similarity to the GCTs of the tongue originally considered to be derived from embryonic muscle cells [4, 12, 13]. There is, however, no evidence that these neurohypophysial tumors originate from muscle cells [14], due to their negativity for immunoperoxidase staining for desmin and smooth muscle actin. Currently, their histogenesis is disputed to be between Schwann cell and the modified glial cell of the pituitary, the pituicyte [1, 7, 16]. Becker and Wilson [3] described strong GFAP immunoreactivity in neurohypophysial GCT. However, several other investigators have reported negative staining for GFAP in the tumor, which constitutes evidence against a pituicyte origin [9, 15, 17, 21]. A third hypothesis, which is endorsed by some authors, including us, believes that, due to the variable immunoreactivity, these tumors are biologically heterogeneous in spite of histological homogeneity [4, 26].

In summary, we have reported an additional case of symptomatic GCT, a rare condition. However, the most astonishing feature in our case is the early presenting age of a tumor, which, to the best of our knowledge, has not previously been reported to occur in the first decade. Furthermore, the present report documents the possibility of a GCT present with central precocious puberty.

Lymphoepithelioma-like carcinoma of the breast. Report of a case with the first electron microscopic study and review of the literature

Received: 26 April 2004 / Accepted: 6 December 2004 / Published online: 10 June 2005
© Springer-Verlag 2005

Abstract Lymphoepithelioma-like carcinoma (LELC) is a tumor which occurs outside the nasopharynx and has morphological features identical to nasopharyngeal lymphoepithelioma. LELC of the breast (LELC-B) is uncommon, and its resemblance to medullary carcinoma of the breast (MC-B) obscures distinction between these two tumors. We report a case of LELC-B occurring in a 47-year-old woman. The tumor consisted of multinodules without circumscription. The tumor cells mainly exhibited loose clusters being permeated by numerous lymphocytes. The tumor cell clusters showed inconspicuous margins, which were far from syncytial patterns. The epithelial nature of the tumor cells was demonstrated by positivity for epithelial membrane antigen, AE1/AE3 and CAM5.2. Furthermore, glandular differentiation of the tumor cells was confirmed using electron microscopy for the first time. Epstein–Barr virus (EBV) was not detected using either in situ hybridization or polymerase chain reaction. These findings, together with former reports of LELC-B, suggest that the distinction between LELC-B and MC-B depends on whether circumscription and syncytial growth patterns exist. The other findings, including absence of EBV and immunohistochemical aspects of the tumor cells, are not considered different thus far. Although the prognosis of LELC-B is thought to be favorable, which is also similar to MC-B, distant metastasis was detected in the present case. To confirm the clinicopathological entity of these two tumors, it is important to recognize the difference between LELC-B and MC-B.

Introduction

Lymphoepithelioma is a distinctive neoplasm of the nasopharynx, composed of undifferentiated malignant epithelial cells in a background of lymphocytes. The counterpart of the other sites is diagnosed lymphoepithelioma-like carcinoma (LELC), which has been seen in the major and minor salivary glands [10, 13, 17, 19, 30, 31], larynx [3], thyroid [32], thymus [21, 38], lungs [5, 12, 27], stomach [4, 16, 23, 26, 33, 39], uterine cervix [22, 35, 37], prostate [28], urinary bladder [2, 9] and skin [6, 34, 35, 36]. Including the first description of LELC of the breast (LELC-B) by Kumar et al. [18] in 1994, there have been four reports and nine cases of LELC-B. Morphological similarity of LELC-B to medullary carcinoma of the breast (MC-B) seems to make the clinicopathological entity of LELC-B obscure. It might be one reason for the rarity of LELC-B. Although the role of Epstein–Barr virus (EBV) in the pathogenesis of nasopharyngeal lymphoepithelioma is now well established, EBV has not been detected in LELCs, except for those of the lung, stomach, salivary gland and thymus [15]. All reported cases of LELC-B were negative for EBV [7, 8, 18, 24], as has been the case in MC-B. Thus far, the most conspicuous difference between LELC-B and MC-B that has been indicated in most reports [7, 8, 24] is the absence of cir-

cumscription and syncytial growth patterns of tumor cells in LELC-B. Cristina et al. emphasized that hormone and adhesion molecule status was different between LELC-B and MC-B [7], but no obvious difference except circumscription and syncytial growth patterns has been detected. Our present report, which includes the first electron microscopic study of LELC-B, must be meaningful in considering the clinicopathological entity of LELC-B.

Clinical history

A 47-year-old female noticed a palpable mass of 40 mm in diameter located between the upper outer and inner quadrants of her left breast. Since fine needle aspiration cytology proved it to be malignant, a total mastectomy with axillary node dissection and anti-estrogen therapy with tamoxifen citrate were performed. After 4 months, a parasternal mass thought to be lymph-node metastasis, detected using computed tomography scan, was confirmed to be malignant using aspiration cytology. Radiation (total 40 Gy) and CEF (cyclophosphamide, epirubicin hydrochloride and 5FU) therapy (for 2 months) was performed. Metastasis to the parasternal lymph node and the lung was detected 19 months after the therapy.

Materials and methods

The removed breast was fixed in 10% buffered formalin and routinely processed for microscopic examination. The paraffin-embedded tissues were investigated by means of histopathology using hematoxylin and eosin stain, immunohistochemistry, in situ hybridization (ISH) and polymerase chain reaction (PCR) for the EBV genome.

Immunohistochemistry

Immunohistochemical studies were performed on formalin-fixed and paraffin-embedded tissues after microwave antigen retrieval with an avidin-biotin-peroxidase complex method using monoclonal antibodies: AE1/AE3 (Nichirei, Tokyo, Japan; dilution 1:4), KL-1 (Immunotech, Marseille, France; 1:100), CAM 5.2 (BD Immunocytometry Systems, San Jose, CA, USA; 1:3), epithelial membrane antigen (EMA) (Dako, Glostrup, Denmark; 1:100), MPO (Dako; 1:3200), p80 (Dako; 1:100), CD1a (Immunotech; 1:2), CD3 (Dako; 1:800), CD4 (Novocastra, Newcastle, UK; 1:50), CD5 (Novocastra; 1:400), CD8 (Nichirei; 1:2), CD10 (Novocastra; 1:80), CD20 (Dako; 1:200), CD30 (Dako; 1:80), CD45 (Dako; 1:100), CD56 (Novocastra; 1:100), CD68 (Dako; 1:1100), CD79a (Dako; 1:100), e-cadherin (BD Pharmingen, San Jose, CA, USA; 1:100), estrogen and progesterone receptors (Dako; prediluted), c-erb-B2 (Dako; prediluted), bcl-2 (Dako; 1:50), MIB-1 (Dako; 1:50), latent membrane protein-1 (LMP-1) (Dako; 1:25) and EBV-encoded nuclear antigen-2 (EBNA2) (Dako; 1:25).

Electron microscopy

An electron microscopic study was carried out using tumor tissues from the specimen fixed in 10% buffered formalin.

In situ hybridization

ISH with EBV-encoded RNAs (EBERs) was performed on 5-μm-thick paraffin sections using Rembrandt ISH and detection kit (Pan Path, Amsterdam, Netherlands) following the manufacturer's recommendation.

PCR amplification of EBV genome

DNA was extracted from formalin-fixed, paraffin-embedded tissues using chelating resin as described previously [25]. Briefly, two 10-μm sections were transferred into sterile distilled water containing 20% (w/v) chelating resin Chelex 100 (Bio-Rad Labs, Hercules, CA) and boiled for 15 min. After centrifugation (12,000 *g* for 10 min), the supernatant was used as a DNA sample. The recovery of amplifiable DNA was verified using PCR amplification of

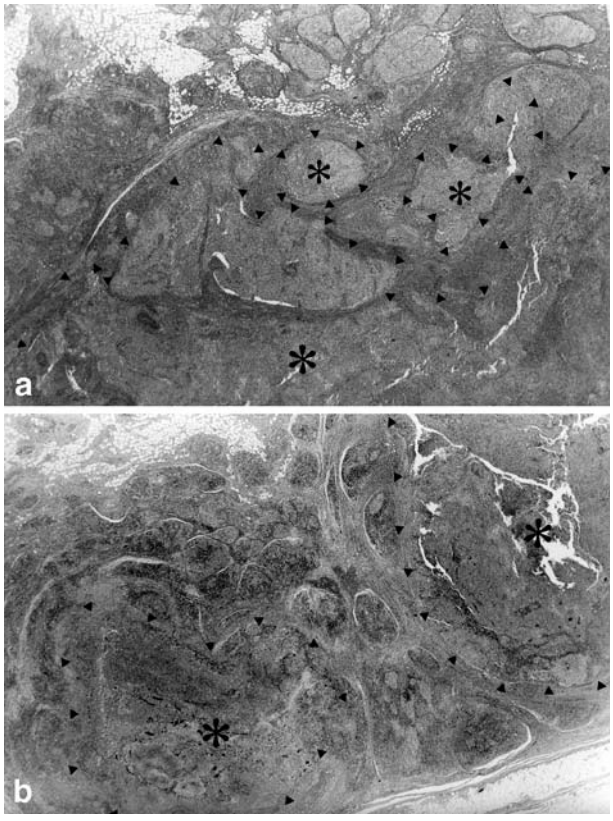

Fig. 1 The tumor shows irregular borders without circumscription. **A** Small tumorous nodules exist on the periphery of the tumor. **B** At one end of the tumor, it separates into two tumorous nodules. The breast tissue surrounding the tumor shows lobulocentric lymphocytic infiltration. *Asterisks* and *arrowheads* indicate tumor nodules and borders of them, respectively. Hematoxylin and eosin stain (**A** ×1.6, **B** ×1.4)

beta-globin gene, which produced a 123-bp fragment. A 5-μl aliquot of the DNA sample was diluted into 25 μl containing 0.2 mM dNTP, 1.5 mM $MgCl_2$, 500 nM of each primer, 0.6 U of AmpliTaq Gold DNA polymerase (Applied Biosystems, Foster City, CA) and 1× PCR reaction buffer provided by the manufacturer. Primer sequences for EBV BamHI-W fragments were 5′-CGGTCGCCCAGTC CTACCAG-3′ and 5′-CCTGGAGAGGTCAGGTTACT-3′, amplifying a 126-bp segment of EBV genome. PCR was performed (35 cycles at 95 C for 30 s, 58 C for 30 s and 72 C for 30 s), and amplified products were electrophoresed and examined in ethidium bromide-stained 3% agarose gels on an ultraviolet transilluminator.

Results

The tumor, of which the size was 28×23 mm in the greatest dimension, showed irregular borders. The cut surface had a gray-white appearance and was soft and of uniform consistency. No hemorrhagic foci existed.

Microscopically, at low magnification, the tumor existed in the breast tissue and was composed of multinodular tumorous lesions without encapsulation (Fig. 1A, B). The surrounding breast tissue showed a mild degree of fibrous proliferation. The tumor was composed of tumor cells and dense infiltrates of predominantly small lymphocytes. Occasional aggregates of plasma cells and histiocytes were also present. The tumor cells had pale eosinophilic cytoplasm with inconspicuous cell boundaries (Fig. 2A). The nuclei were round or oval in shape with single prominent nucleoli. These tumor cells formed vague small or large clusters (Fig. 2B) or were scattered in the numerous lymphoplasmacytic background (Fig. 2C). In part, sheet-like growth patterns were seen (Fig. 2D). Most of the clusters showed unclear margins because they were permeated by the lymphocytes as seen in nasopharyngeal lymphoepithelioma with the Schmincke pattern. These findings were distinct from syncytial patterns of growth observed in MC-B and lymphoepithelioma with the Regaud pattern and were hardly recognized as the epithelial nature of the tumor cells. Mitotic figures were 15 per 10 high-power fields. Small areas of necrosis were identified.

Although the breast tissue surrounding the tumor displayed marked lobulocentric lymphocytic infiltration, disruption of the lobular or duct structure by lymphocytes was not significant. Lymphoepithelial lesions were indistinct. The distant part of the breast from the tumor did not show conspicuous infiltration of lymphocytes. Neither ductal nor lobular carcinoma in situ was found in multiple sections of both tumorous and non-tumorous breast tissue. No metastases were found in the 33 isolated axillary lymph nodes.

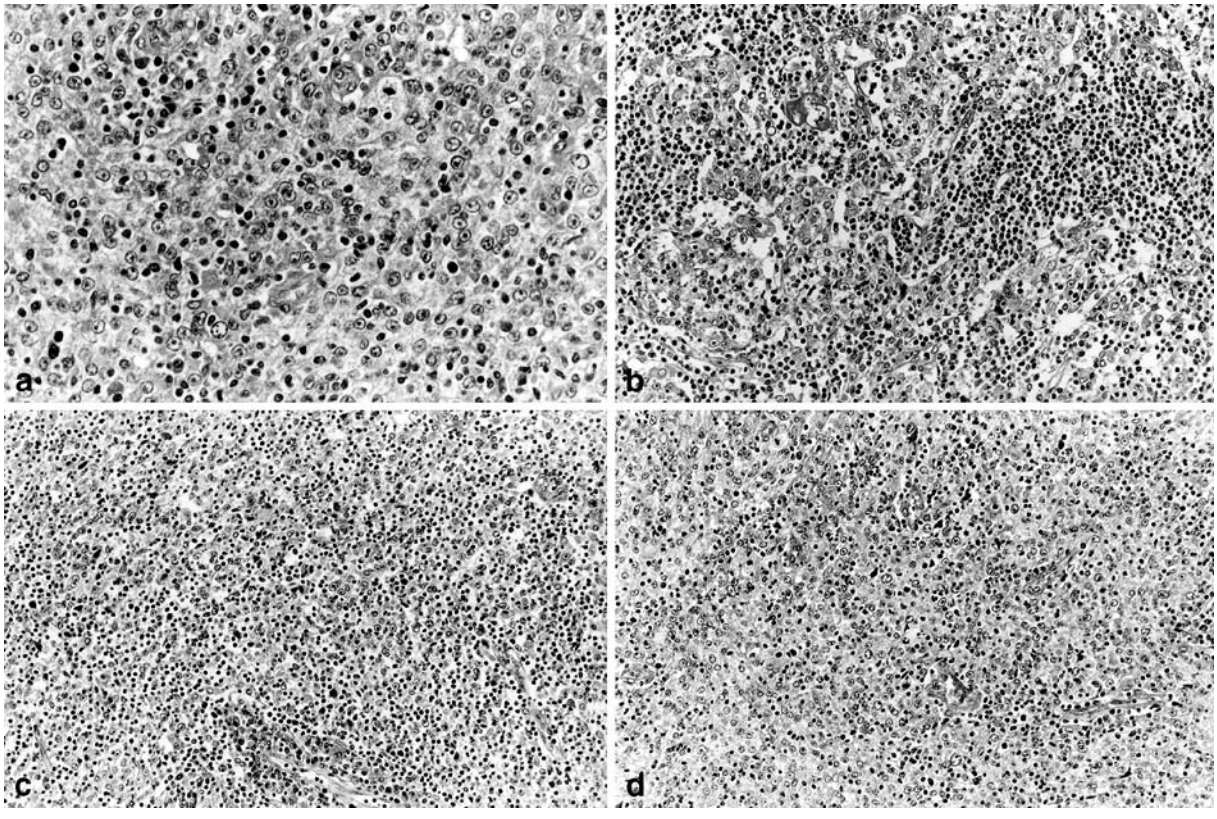

Fig. 2 **A** The tumor cells have round or oval nuclei with single prominent nucleoli. The cell boundaries are inconspicuous. **B** Although the tumor cells have a tendency to aggregate, the clusters are loose and vague. **C** In large areas, the tumor cells are scattered in the lymphoplasmacytic background without forming clusters. **D** In part, sheet-like growth patterns are present, but margins of the clusters are unclear. Fig. 3 **A** Most tumor cells show strong positivity for epithelial membrane antigen. **B** Approximately 70% of the tumor cells are positive for AE1/AE3. Immunoperoxidase stain, hematoxylin counterstain (**A** and **B** ×40)

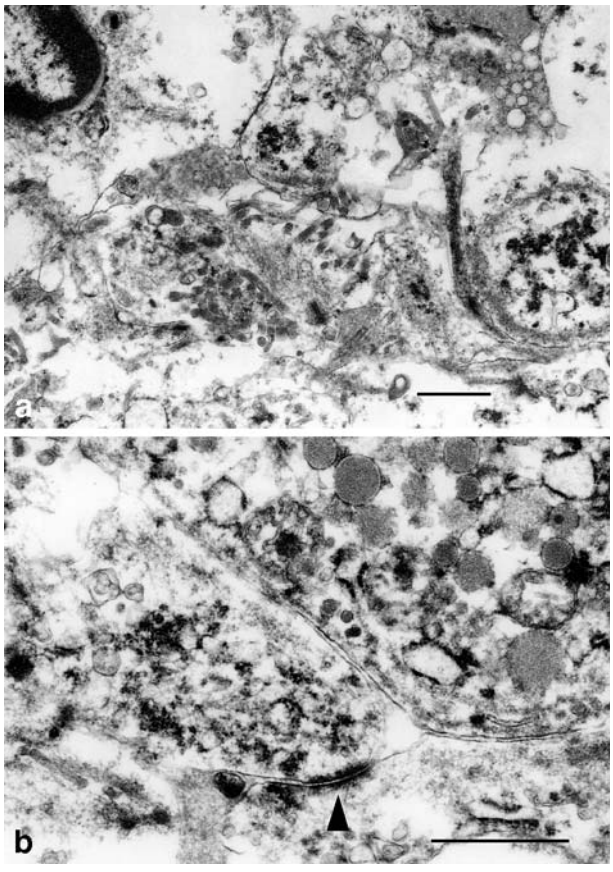

Fig. 4 An electron microscopic study. **A** Some tumor cells possess microvilli with irregular projections. *Bar*=1 μm. **B** Tumor cells having secretory granules (*right upper portion*) and a desmosome (*arrowhead*). *Bar*=1 μm

On immunostaining, nearly all of the tumor cells were strongly positive for EMA (Fig. 3A). Approximately 70% and nearly half of the tumor cells were positive for AE1/AE3 (Fig. 3B) and CAM 5.2, respectively. However, no tumor cells reacted with KL-1. Other than the epithelial markers, the tumor cells were positive for e-cadherin and c-erb-B2 and negative for MPO, p80, CD3, CD4, CD5, CD8, CD20, CD30, CD45, CD56, CD68, CD79a, p53, bcl-2 and estrogen and progesterone receptors. About half of the tumor cells were positive for CD10. Neither LMP-1 nor EBNA2 was present. The MIB-1 staining index was approximately 80%. Most lymphocytes permeating in the tumor cells were positive for CD3 and negative for CD1a, whereas lymphocytes in the surrounding breast tissue consisted of both B and T cells; the distribution of lymphocytes was the same as that seen in reactive hyperplasia of lymphatic tissues.

An electron microscope revealed aggregation of microvilli with irregular projections (Fig. 4A) and secretory granules in some tumor cells (Fig. 4B). In part, desmosomes existed between tumor cells (Fig. 4B).

ISH for detection of the EBV genome was negative in both neoplastic cells and lymphocytes. We extracted DNA from two paraffin blocks of the tumor and examined the presence of EBV genome using PCR. The 35-cycle amplification of BamHI-W fragment of EBV genome did not show any clear bands (results not shown).

Discussion

LELC describes tumors occurring outside the nasopharynx, which show similar morphological features to those of nasopharyngeal lymphoepithelioma, consisting of malignant epithelial cells and diffusely infiltrating lymphocytes. This is the tenth reported case of LELC-B.

Because of the undifferentiated appearance of neoplastic cells and presence of intensely infiltrating lymphocytes, LELC and lymphoepithelioma of the nasopharynx with the Schmincke pattern could be confused with lymphoma. The present case should also be differentiated from lymphoma, particularly anaplastic large cell lymphoma. However, neoplastic cells were positive for EMA and specific types of cytokeratin and lacked any lymphocytic markers analyzed except CD10, which is also detected on some types of epithelial cells. These immunohistochemical findings were consistent with the epithelial nature of the tumor cells. Dadmanesh et al. reported that tumor cells reacted only with low-molecular-weight cytokeratin [8]. Since tu-mor cell reactivity to cytokeratin depended on one type, caution is required when using cytokeratin as an epithelial marker.

Moreover, an electron microscopic study, which was first carried out on LELC-B, showed differentiation toward glandular epithelium as well as epithelial origin of the

neoplastic cells. This is the first case of LELC-B with glandular differentiation. The phenotype of permeating lymphocytes in the tumor, positive for CD3 and negative for CD1a, excluded involvement of type-B2 thymoma (cortical thymoma).

All the reports stated that LELC-B seemed to behave favorably, although the follow-up period was not long [7, 8, 18, 24] (Table 1). However, prognosis of LELC-B may not be necessarily good, because distant metastasis to the lung was detected 19 months after the therapy in the present case.

The evidence of EBV infection was not detected, even using PCR, as well as ISH and immunohistochemistry, similar to reported cases of LELC-B [7, 8, 18, 24] (Table 1, Table 2).

In the discussion as to a clinicopathological entity of LELC-B, distinction from MC-B is most important. The tumor margins of MC-B are characteristically well circumscribed, with smooth round edges, and tend to push against the surrounding breast tissue without invasion. The tumor cells are sharply demarcated from the adjacent stroma, with a various amount of lymphoplasmacytic infiltrate, and form irregular interconnecting islands, resulting in a syncytial mass. Definitive histopathological features of MC-B include a prominent lymphoplasmacytic reaction, circumscription, a syncytial growth pattern, poorly differentiated nuclear grade and high mitotic rate [29]. The present case did not fulfill this criteria with respect to circumscription and a syncytial growth pattern because the tumor consisted of multinodular lesions, and there was no circumscription. Furthermore, tumor cells formed small clusters, nests or sheet-like growth patterns with unclear margins because they were permeated by numerous lymphocytes. These findings did not correspond to the syncytial growth patterns seen in MC-B. Atypical MC-B also requires a syncytial growth pattern in its pathological diagnosis. Therefore, our tumor should be distinguished from MC-B from the morphological standpoints of dissociation of tumor cells with infiltrating lymphocytes and the poorly described outer margins.

Cristina et al. described LELC-B as different from MC-B in immunoreactivity as well as the growth patterns stated above [7]. They reported that LELC-B was positive for estrogen receptor and negative for e-cadherin. However, not all reported cases demonstrated a constant result (Table 2). In our case, both estrogen and progesterone receptors were negative, and e-cadherin was positive. As far as we know, no significant differences have been recognized between LELC-B and MC-B, except for growth patterns. Glandular differentiation of tumor cells first observed by our electron microscopic study in LELC-B is also reported in MC-B [14], but ultrastructural study has not yielded consistent findings, even in MC-B [1, 14].

Iezzoni et al. summarized that EBV was associated with LELCs only in the stomach, salivary gland, lung and thymus [15]. The evidence that EBV is involved in the pathogenesis of MC-B also has not been shown [11, 20].

LELC-B and MC-B share many clinicopathological findings, including admixture of tumor cells and lymphocytes, favorable prognosis and absence of EBV. Thus far, although the difference between LELC-B and MC-B has been limited to growth patterns, i.e., whether circumscription and a syncytial growth pattern exist, these might be the significant characters that define each tumor. Therefore, LELC-B should be recognized as a distinct entity, and acquiring more cases for study is important.

Acknowledgment We thank Yuji Shibata for his excellent technical assistance.

Inflammatory pseudotumor of the liver associated with malignant disease: report of two cases and a review of the literature

Received: 2 November 2004 / Accepted: 20 December 2004 / Published online: 21 June 2005
© Springer-Verlag 2005

Abstract Two cases of inflammatory pseudotumor (IPT) of the liver associated with gastrointestinal tract cancer are reported. In addition, the etiological correlation between IPT and abscesses of the liver in cancer patients is discussed. The first patient was a 63-year-old woman who underwent distal gastrectomy and partial hepatectomy under a diagnosis of stomach cancer with liver metastasis. The second patient was a 66-year-old man who had undergone surgery for rectal cancer 6 years previously and underwent partial hepatectomy under a diagnosis of metastasis of rectal cancer to the liver. The gastric cancer was a papillary adenocarcinoma limited to the mucosa, and the rectal cancer was a moderately differentiated adenocarcinoma limited to the subserosa. The resected liver tumor in the first case measured 5.5×5.0×4.0 cm and was 2.5×1.9×1.6 cm in the second. The cut surface showed that both masses were well circumscribed and divided into lobules by fibrous tissue. They were yellowish white in color and there was no evidence of necrosis or hemorrhage. Histologically the masses consisted of fibrous areas and cellular areas, and the cellular areas consisted of fascicles of plump spindle cells mingled with varying numbers of plasma cells, lymphocytes, and histiocytes. The masses were diagnosed as IPTs. Obliterating phlebitis suggesting infection via the portal vein was seen in the adjacent liver tissue in both cases. According to previous cases reported in the literature, there are three types of cancers associated with hepatic IPT: gastrointestinal tract cancer, biliary tract cancer, and cancers that need strong systemic chemotherapy. The underlying cancer types of IPT of the liver are almost similar to those associated with pyogenic liver abscesses suggesting the etiological correlation between IPT and abscesses of the liver.

Introduction

The inflammatory pseudotumor (IPT) of the liver is a rare, benign tumor-like lesion [6, 15], and about 60 cases have been reported in the English-language literature [17]. Some cases of IPT of the liver have been associated with malignant tumors [1, 7–9, 11, 13, 16]. Six such cases have been reported in the English-language literature [1, 7, 8, 11, 13, 16] and four cases in Japanese-language literature [9], but the etiological correlation between hepatic IPT and liver abscess in cancer patients has never been mentioned. In this paper, we report two cases of IPT of the liver with gastrointestinal tract cancer and discuss the etiological correlation between IPT and abscess of the liver in cancer patients.

Clinical history

Case A

A 63-year-old Japanese woman was admitted to our hospital because of epigastralgia, nausea and progressive appetite loss over 3 months. Laboratory tests on admission including serology tests for HBsAg and HBcAb were all normal except for an elevated blood glucose level. Early

gastric cancer of the protruding type was detected by gastroscopy. A post-contrast computed tomographic (CT) scan showed a large irregular-shaped mass in the left lobe of the liver. The mass showed peripheral rim-like or septal enhancement and an internal low density area. Gastric cancer and liver metastasis were diagnosed, and a distal gastrectomy and partial hepatectomy were performed. The patient is currently well, 25 months after surgery.

Case B

A 66-year-old Japanese man was referred to our hospital because of a small hepatic mass detected on a follow-up CT scan 6 years after surgery for rectal cancer at another hospital. Laboratory tests on admission, including serology tests for HBsAg and HBcAb, were all normal. No local recurrence was detected at the site of resection. A post-contrast CT scan showed a 2.5-cm mass in the right lobe of the liver. The mass showed contrast enhancement at the peripheral rim on the delayed-phase image. Rectal cancer metastasis to the liver was diagnosed, and a partial hepatectomy was performed. The patient is currently well, 25 months after the operation.

Pathological findings

Case A

The resected stomach contained a protruding tumor that was histologically diagnosed as papillary adenocarcinoma limited to the mucosa. The resected liver measured 13.0×11.0×5.0 cm in size and contained a tumor that measured 5.5×5.0×4.0 cm. The cut surface showed that the tumor was well-circumscribed and was divided into lobules by fibrous tissue. It was yellowish white in color, and there was no evidence of necrosis or hemorrhage (Fig. 1). Histologically, the mass showed lobulation into the fibrous area and cellular areas (Fig. 2a), and the cellular areas consisted of fascicles of plump spindle cells mingled with varying numbers of plasma cells, lymphocytes, and histiocytes. Residual bile ducts and hepatocytes were seen in the tumor (Fig. 2b). Immunohistochemical stains were performed on formalin-fixed, paraffin-embedded tissue. Antibodies to both kappa and lambda light chains were positive on plasma cells in normal proportions, revealing the polyclonal nature of the plasma cells. Spindle cells were all positive for vimentin, and some were weakly positive for muscle actin, but negative for CD21 and CD35. Thus, these results suggest that spindle cells are differentiated into myofibroblastic cells not into follicular dendritic reticulum cells (FDCs). Epstein–Barr virus (EBV), latent membrane protein (LMP-1) and anaplastic lymphoma kinase (ALK) protein were not expressed in spindle cells and inflammatory cells. No EBV RNA (EBER-1) transcripts were detected using in situ hybridization (ISH). No bacteria or fungi were found on histological sections. No bacterial cultures of the tumor were performed. The

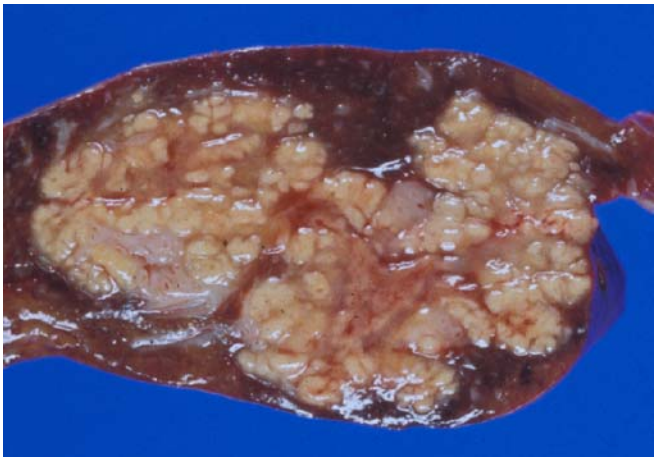

Fig. 1 Gross appearance of the hepatic tumor in case A. The size of the tumor was 5.5×5.0×4.0 cm. The mass was divided into lobules by fibrous tissue. It was *yellowish white* in color and there was no evidence of necrosis or hemorrhage

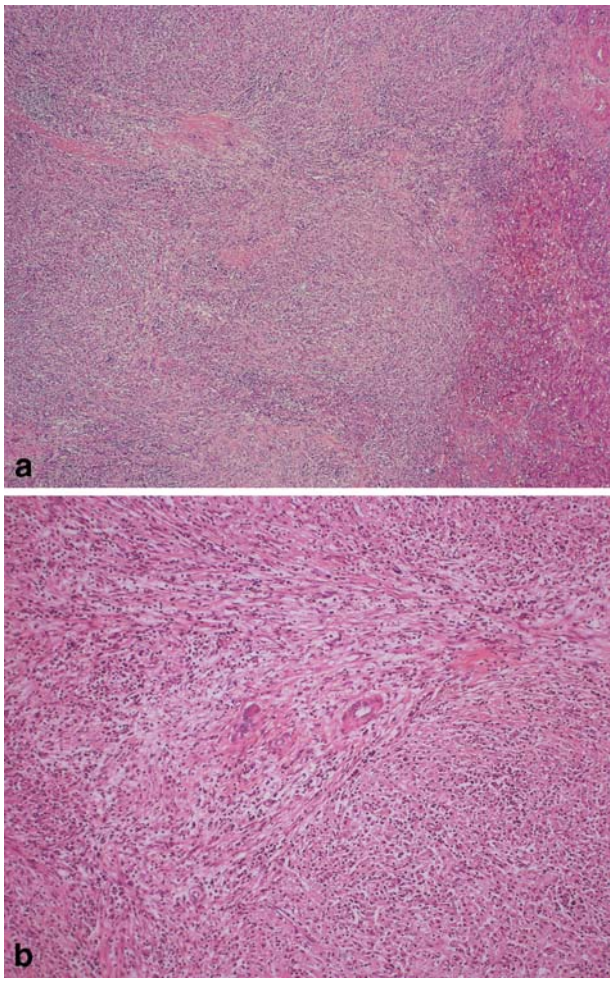

Fig. 2 Histological appearance of the hepatic tumor in case A. **a** The mass showed lobulation into fibrous areas and cellular areas (hematoxylin and eosin; H&E). **b** The cellular areas consisted of fascicles of plump spindle cells intermixed with varying numbers of plasma cells, lymphocytes, and histiocytes. Residual bile ducts were seen in the tumor (H&E)

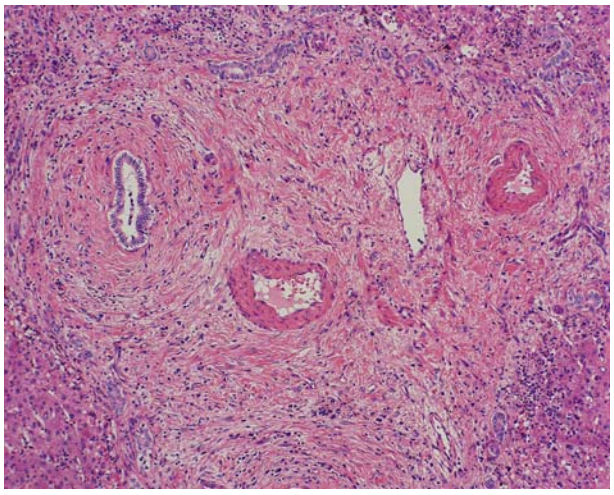

Fig. 3 Histological appearance of obliterating phlebitis in the adjacent liver in case A. A medium size portal vein was thickened by fibrosis (hematoxylin and eosin)

histological appearance of the hepatic tumor was consistent with a diagnosis of IPT. The hepatic tissue outside the tumor was non-cirrhotic. The portal veins penetrating and surrounding the tumor were thickened with fibrosis, suggesting obliterating phlebitis (Fig. 3).

Case B

The rectal cancer was ulcerated, and a review of the slides showed a histologically moderately differentiated adenocarcinoma limited to the subserosa. The hepatic tumor measured 2.5×1.9×1.6 cm. Its gross appearance, histological appearance, and the immunohistochemical and ISH results were almost the same as in case A. The non-tumorous liver tissue was non-cirrhotic, and the small portal veins surrounding the tumor were thickened by fibrosis, suggesting obliterating phlebitis.

Discussion

IPT is a relatively benign tumor-like lesion mostly occurring in the lung [12]. The liver is the second most common site of IPT, reported in about 60 cases to date [17], but the etiology of hepatic IPT in cancer patients has never been discussed.

Some IPT of the liver have been associated with malignant tumors. In the English-language literature, 6 such cases have been reported [1, 7, 8, 11, 13, 16] and 4 such cases in the Japanese-language literature [9]. The clinical findings of 10 reported cases and the present 2 cases are summarized in Table 1; 11 cases were reported from Japan and 1 from the United Kingdom. The patient population consisted of nine men and three women, ranging in age from 3 years to 66 years (average 52 years). The most common symptom was upper abdominal pain. The clinical diagnosis was metastatic liver cancer (seven cases), liver abscess (two cases) and cystadenocarcinoma (one case). Therefore, we should need a systemic liver biopsy to avoid unnecessary surgical resection, because laboratory data and imaging findings do not discriminate between metastasis and IPT. In our case A, if we had taken notice of an unusual association of early gastric cancer and a huge hepatic mass, we could have performed systemic biopsy and diagnosed the hepatic tumor as IPT before the operation. The tumor was located on the right in seven cases, on the left in four cases and bilaterally in one. The tumor was single in eight cases and multiple in four cases. The size of the tumor ranged from 1.5 cm to 12 cm (average 3.9 cm). The primary malignancy was colorectal carcinoma in four cases; leukemia in two cases; and gastric carcinoma, gallbladder carcinoma, ampula Vater carcinoma, ovarian carcinoma, breast carcinoma, and nephroblastoma in one case each. In six patients, the hepatic IPT was detected at the time of diagnosis of the malignancy, and in another six patients the hepatic IPT was detected after or during the therapy for malignant disease. The stage of the cancer was advanced in seven cases and early in two. The hepatic tumor was resected in ten cases, and followed and shrunken in two cases. The patient outcome was excellent in all cases, which the authors described in their papers.

There are three types of cancer patients associated with IPT of the liver: one is gastrointestinal tract cancer patients, the second is biliary tract cancer patients, and the third is the patients who might be receiving strong systemic chemotherapy, e.g., leukemia, nephroblastoma, ovarian, and breast cancer patients. The correlation between pyogenic liver abscesses and cancer has been reported previously, and the type of cancer in which pyogenic liver abscess and liver IPT have been reported to develop is almost similar [10, 19]. Common types of cancer associated with pyogenic liver abscesses are hematological malignancies, hepatobiliary tract cancers, and gastrointestinal tract cancers [10, 19]. Systemic chemotherapy with resultant neutropenia may be a cause of liver abscess in leukemia or lymphoma patients [10]. Hepatic artery seeding with uncertain infectious organisms following systemic chemotherapy is suggested [19]. The pathogenesis of liver abscesses in hepatobiliary tract cancer patients is mainly malignant biliary obstruction and spontaneous or iatrogenic necrosis of primary hepatic neoplasms with superimposed bacterial infection [19]. The pathogenesis of liver abscesses in gastrointestinal tract cancer patients includes portal venous suppuration secondary to colorectal cancer, and postgastrectomy for gastric cancer [19]. Obliterating phlebitis is seen in five of nine hepatic IPT patients reported by Horiuchi et al. [6]. They suggest that infection through the portal vein is one of the causal participants in hepatic IPT. In addition, some reports indicate that cholangitis may also be responsible for the development of hepatic IPT [6, 12, 15, 17]. In Table 1, there are two cases (cases 6 and 10) [1, 8] that suggest the etiological correlation between liver abscesses and liver IPT. In cases 6 and 10, a cystic space was detected in the lesions of the liver, and *Staphylococcus aureus* was cultured from the cystic fluid in both cases. Obliterating phlebitis was found

[a]Cancer stage is classified using TNM Classification of Malignant Tumors (Sixth Edition) from the International Union Against Cancer

in case 3 [9] and our present cases (cases 1 and 2). Therefore, the etiology of hepatic IPT may be similar to that of the pyogenic liver abscess because of the similarity of associated cancer types and the etiological correlation of clinical course in some patients.

Recent studies suggest that a proportion of so-called hepatic IPT represents EBV-associated FDC proliferations [3, 14]. Therefore, these tumors are thought to become a different entity from IPT and the name IPT-like FDC tumor is recommended [3]. Hepatic tumors of both our cases did not express FDC markers, and neither contained EBV. Some cases of hepatic IPT, especially in young age, show ALK expression [2], and IPT-like FDC tumors never express ALK [3]. Neither of our cases expressed ALK in immunohistochemical study.

In cancer patients, Japanese patients were predominant even in the English-language literature [1, 7, 8, 13, 16]. It has been reported that all hepatic IPT patients are predominantly Japanese: 17 of 51 patients (33%) are Japanese [15]. Furthermore, there are some reasons why Japanese people may more prone to develop IPT of the liver than patients in other populations. EBV may be related to the development of some so-called hepatic IPTs: now they should be called IPT-like FDC tumors [3, 14] and Japan is an EBV endemic area [3]. An autoimmune reaction has also been suggested as a cause of IPT of the liver [18]. Immunological disturbances and staphylococcal infection may have been the cause of hepatic IPT in a Papillon–Lefevre syndrome patient [4]. Therefore, viral infection or the body's autoimmunity may be another basic cause for the development of IPT of the liver. It is thought to be possible that the Japanese population may have some inherent physiological factors that make them prone to develop IPT.

In summary, we have reported two cases in which IPT of the liver was associated with gastrointestinal tract cancer and discussed the etiology of hepatic IPT in cancer patients. Populations at particular risk of developing hepatic IPT may be those with cancer—especially of the gastrointestinal and hepatobiliary tracts, and patients who are undergoing strong systemic chemotherapy.

Acknowledgements We thank Professor Tadashi Yoshino of the Department of Pathology, Okayama University Graduate School of Medicine and Dentistry for detection of the Epstein–Barr virus and immunohistochemical stainings against CD21, CD35, and ALK. This study was partially supported by Grants-in-Aid for Cancer Research from the Ministry of Health, Labour and Welfare of Japan.

Note added in proof. Case A has been published recently in Japanese Journal of Clinical Oncology (2005) 35:218–220. That is a case report focussing on CT and histopathological correlation, and its discussing point is completely different from this report.

Secondary glioblastoma with advanced neuronal immunophenotype

Received: 5 January 2005 / Accepted: 21 March 2005 / Published online: 21 June 2005
© Springer-Verlag 2005

Abstract We describe an unusual progression of astrocytoma into secondary glioblastoma exhibiting advanced neuronal immunophenotype. A tumor of the left frontal lobe of a 35-year-old man was diagnosed as astrocytoma. The tumor was treated by partial removal with postoperative chemoradiotherapy, followed by extensive removal of the residual regrowing tumor 5 month later. A secondary tumor was discovered and partially resected 8 years later, but the patient died 11 months following the operation due to extensive tumor progression showing subarachnoidal and intraventricular dissemination. The secondary tumor was small cell-predominant, highly proliferative tumor with an extremely high MIB-1 labeling index (80%). Unexpectedly, most of the tumor cells were positive for neuronal markers (synaptophysin and NeuN), but not for glial fibrillary acidic protein (GFAP). Retrospective examination of the original tumor revealed not only diffuse GFAP expression, but also neuronal marker expressions in small numbers of tumor cells that were hard to discriminate from the other cells on hematoxylin-eosin (HE) stain. This way of malignant progression of astrocytoma was quite unusual. Although the secondary tumor was classified as glioblastoma according to World Health Organization (WHO) classification (2000), it might be categorized into new variants of malignant glioneuronal tumors proposed recently.

Introduction

Glioblastoma, the most common malignant neuroectodermal tumor of the central nervous system (CNS), can be divided into two major categories, primary and secondary [8]. These are not only clinically but also genetically distinct subsets. Primary glioblastoma is a de novo malignancy and characterized by epidermal growth factor receptor (EGFR) gene ampflication or overexpression, mouse double minute 2 homolog (MDM2) gene ampflication or overexpression, p16 deletion, or phosphatase and tensin homolog (PTEN) gene mutation. Secondary glioblastoma develops from diffuse astrocytoma (WHO grade II) or anaplastic astrocytoma (WHO grade III). Secondary glioblastoma usually retains an astrocytic nature, as evidenced by immunoreactivity to glial fibrillary acidic protein (GFAP), but its reactivity tends to be reduced, especially in undifferentiated types. Genetically, secondary glioblastoma often shows TP53 mutation, an alteration also present in the precursor lower grade tumor in most cases [11]. No histological feature precisely discriminates primary and secondary glioblastoma, but small cell architecture is implicated as a hallmark of the former [3]. We describe here an unusual progression of astrocytoma into secondary glioblastoma exhibiting an undifferentiated, small cell-predominant morphology and advanced neuronal immunophenotype.

Clinical history

A 35-year-old male presented with general tonic convulsion. Computed tomography (CT) scan revealed a mass in the left frontal lobe. The patient underwent partial removal of the tumor with postoperative irradiation (60 Gy) and chemotherapy with nimustine (ACNU), followed by extensive removal of the residual regrowing tumor 5 months later. A small enhanced nodule remained on CT, but additional interferon (IFN) therapy was discontinued because of the patient's leukocytopenia.

Eight years following the last operation, the patient presented with a headache and nausea. A huge destructive mass involving the left lateral ventricle was noted in the left frontal lobe on CT. The patient underwent 70% removal of the tumor, but died from extensive tumor progression 11 months later. Autopsy examination was performed.

Materials and methods

The tumor tissues resected in each operation and the whole brain at autopsy were fixed in 10% formalin. All the surgical materials and sufficient portions of the autopsy material were embedded in paraffin. Routine hematoxylin-eosin (HE)-stained sections were generated from 5 μm-thick sections.

All immunohistochemical examinations, including the retrospective study of the original tumor, were performed on the paraffin sections by the avidin-biotinylated immunoperoxidase method. To enhance the staining, heat-induced epitope retrieval was performed. The following antibody reagents were applied: GFAP (polyclonal, 1:100; Dako Corporation, Santa Barbara, Calif., USA), S-100 protein (polyclonal, 1:250; Dako), synaptophysin (monoclonal, 1:100; Dako), NeuN (monoclonal, 1:1000; Chemicon, Tamecula, Calif., USA), neurofilament protein (NFP) (monoclonal, 1:100; Dako), p53 (monoclonal, 1:100; Novocastra, Newcastle, UK), EGFR (monoclonal, 1:20; Zymed Laboratories, South San Francisco, Calif., USA), and MIB-1(monoclonal, 1:200; Immunotech, Marseilles, France).

Results

Findings on the original tumor

The original tumor was diffuse astrocytoma [World Health Organization (WHO) grade II]. The tumor consisted of an admixture of fibrillary, protoplasmic, and gemistocytic cells, exhibiting a relatively low cellularity and frequent microcystic change with a pooling of mucoid material (Fig. 1a,b). In accordance with the astrocytic character, an immunohistochemical examination of the tumor cells performed retrospectively indicated diffuse immunoreactivity to GFAP (Fig. 1c) and S-100 protein. Some of the tumor cells were also immunoreactive for synaptophysin with perinuclear and punctate staining pattern. In addition, occasional cells were positive for a more specific neuronal marker, NeuN (Fig. 1d). NFP-positive tumor cells were not identified. The tumor cells showing the neuronal immunophenotype were difficult to discriminate from the other tumor cells on HE stain. These cells were not considered as entrapped neurons because of the morphology and their location (deep white matter). Immunoreactivity to p53 was observed in a small number of the cells. Growth fraction was low, as estimated by an MIB-1 labeling index of 2%. At the second operation 5 months later, gemistocytic tumor cells predominated, and very few neuronal cells were recognized.

Findings on the secondary tumor

The resected specimen of the secondary tumor exhibited an extremely high cellularity that gave it the appearance of a blue cell tumor (Fig. 2a). Most of the tumor cells had small

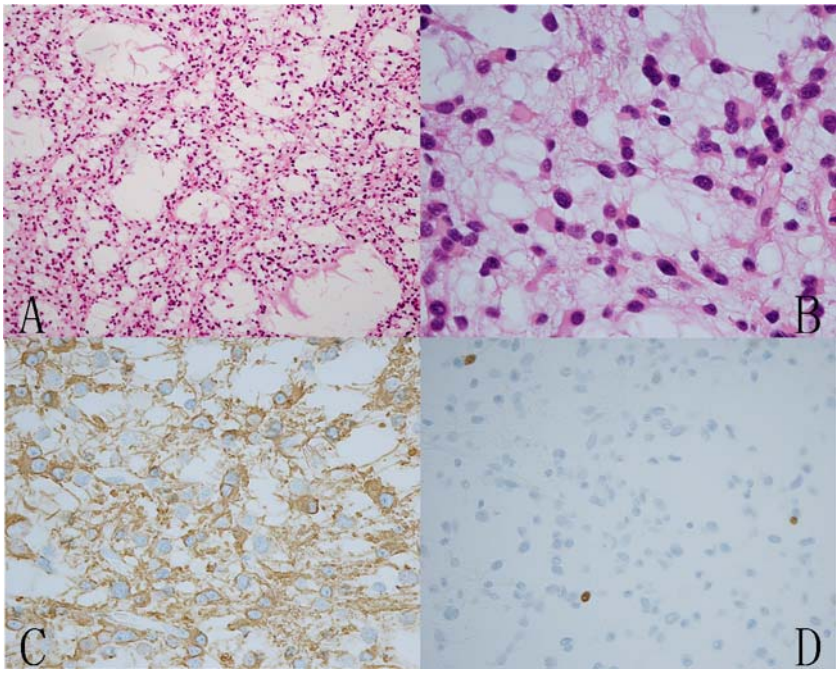

Fig. 1 (**a**) The original tumor was diffuse astrocytoma (WHO grade II), showing frequent microcystic change (hematoxylin-eosin stain; ×100). (**b**) A higher magnification view of the tumor (×400). (**c**) The tumor cells are diffusely immunoreactive for GFAP (×400). (**d**) Occasional cells are immunoreactive for NeuN (×400)

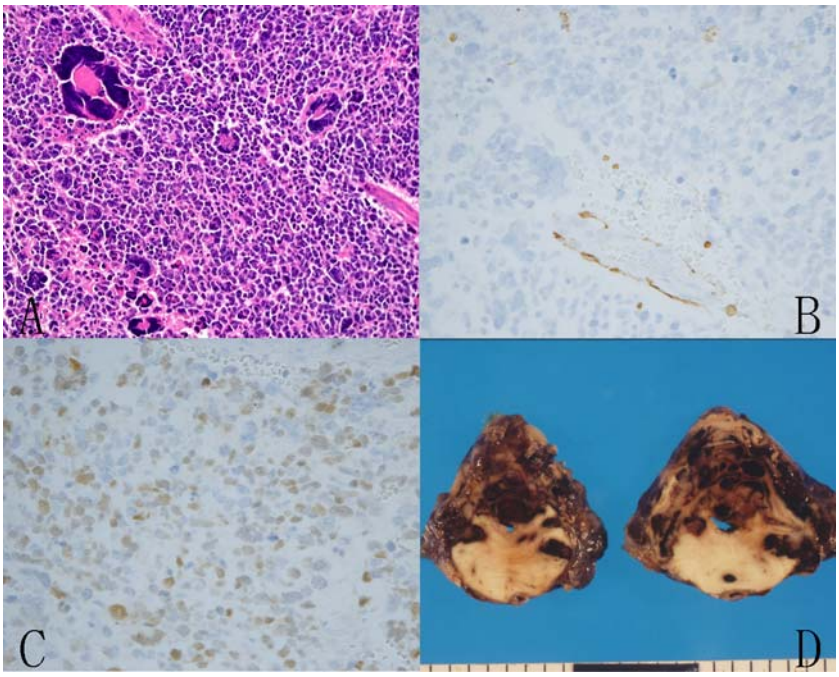

Fig. 2 (**a**) The secondary tumor was small cell-predominant glioblastoma with scattered large pleomorphic or multinucleated giant cell (hematoxylin-eosin stain; ×100). (**b**) Immunoreactivity to GFAP is obvious around the vessel, whereas tumor cells were almost non-reactive (×400). (**c**) In contrast, more than half of the tumor cells show immunoreactivity to NeuN (×400). (**d**) The tumor showed extensive subarachnoidal dissemination at autopsy

angular nuclei containing coarse, granular chromatin and scant cytoplasm without notable fibrillary process. Large pleomorphic cells bearing bizarre nuclei and multinucleated giant cells were scattered individually or in clusters. Other malignant features included frequent mitoses or atypical mitoses, high densities of microvessels with endothelial cell proliferation and geographic necrosis accompanying nuclear palisadings. This morphological appearance was consistent with undifferentiated, small cell-predominant glioblastoma. As is usually the case with this type of glioblastoma, few tumor cells were reactive to GFAP or S-100 protein on immunohistochemical examination (Fig. 2b). Unexpectedly, however, the tumor cells, including the large pleomorphic or multinucleated giant cells, were diffusely immunoreactive to synaptophysin and more than half of the cells were positive for NeuN (Fig. 2c). Expression of NFP was not detected. Immunoreactivity to p53 was observed in about 20% of the tumor cells, whereas EGFR expression was completely absent. The MIB-1 labeling index was about 80%.

At autopsy, the brain weighed 1360 g. On gross examination, local recurrence surrounding a large defect after surgical treatment was noted in the left frontal lobe as a poorly circumscribed infiltrating mass with encasement of the left lateral ventricle. In addition, subarachnoidal and intraventricular dissemination was extensive, forming numerous hemorrhagic tumor nodules in the cerebrum, cerebellum, brain stem (Fig. 2d), and spinal cord. On microscopic examination, the tumor showed almost the same histology as the last surgical specimen, namely, small cell-predominant glioblastoma showing prominent neuronal immunophenotype and a high MIB-1 labeling index. Exceptionally, part of the local recurrent lesion in the left frontal lobe contained relatively small numbers of apparently astrocytic tumor cells that exhibited immunoreactivity to GFAP and S-100 protein. The MIB-1 labeling index of these astrocytic cells was somewhat lower than that of the small cells.

Discussion

The clinical course of the present case was a typical malignant progression of diffuse astrocytoma into secondary glioblastoma. Histologically, the secondary tumor exhibited a small cell-predominant architecture with scattered large pleomorphic cells and multinucleated giant cells. Glioblastoma often contains small cell constituents as minor or predominant components, and these “undifferentiated” or “embryonal” cells often lack immunoreactivity to GFAP. In a recent report, Burger et al. concluded that the small cell-predominant glioblastoma is an important component of primary glioblastomas through observation of EGFR gene amplification at a high frequency in this type of glioblastoma [3]. The present case was inconsistent with this finding, as the small cell-predominant glioblastoma of the case was obviously a secondary tumor.

The most unusual finding was advanced neuronal immunophenotype of the secondary tumor. A considerable number of the tumor cells other than apparently astrocytic cells in the local recurrent region were positive for neuronal markers, synaptophysin and NeuN. Retrospective examination revealed that the original tumor also contained a small number of NeuN-positive neuronal cells which were hard to discriminate from the other tumor cells based on morphological appearance. The tumor was ordinal diffuse astrocytoma, except that it contained such neuronal cells, and there was no finding indicating that it was a specific

type of glioneuronal tumor such as papillary glioneruonal tumor, glioneuronal tumor with neuropil-like islands and several other new entities [4].

Recently, Varlet et al. proposed new variants of malignant glioneuronal tumors (MGNTs) [10]. The tumors had histopathological features indistinguishable from conventional malignant gliomas, but all coexpressed GFAP and NFP by definition. Other neuronal markers (NeuN, synaptophysin and chromogranin A) were expressed inconstantly. Neuronal phenotype of malignant glioma was not a new finding, as was described in earlier literatures that showed NFP-positive tumor cells in 20–33% of malignant glioma [5, 7]. In their series, however, MGNTs had a marked tendency to metastasis, an infrequent event in malignant glioma [2], and that gross total resection was curative in some cases. The latter finding indicated that distinction of MGNT from malignant glioma is of clinical importance. Two cases in the series were secondary MGNT. The retrospective examination of the initial tumors, which had been diagnosed as pleomorphic xanthoastrocytoma and pilocytic astrocytoma respectively, revealed NFP-positive tumor cells in both cases. As for the present case, we could not detect NFP expression in either the initial or secondary tumor even with epitope retrieval procedure. However, we consider that expression of synaptophysin and NeuN is sufficient evidence for the neuronal phenotype and NFP expression is not requisite, as central neurocytoma, a representative neuronal tumor, generally lacks NFP expression [6]. Extensive subarachnoidal and intraventricular dissemination of the secondary tumor is consistent with the characteristic feature of MGNTs by Varlet et al. Thus, this unusual secondary tumor might be classified into the similar category.

Advances in embryology have revealed that both the neuronal and glial cells of CNS develop from the common multipotential stem cell previously referred to as the radial glia [1]. Moreover, Singh et al. recently isolated brain tumor stem cell expressing the neural stem cell surface marker CD133 and nestin from several human gliomas [9]. These findings form a basis to explain the possibility that CNS neuroectodermal tumors could contain both neuronal and glial neoplastic cells originating from the common precursor.

At present, we do not know the meanings or significance of neuronal cells in an otherwise ordinary astrocytoma. Their presence might indicate possible progression into the unusual glioblastoma (or MGNT) characterized by diffuse neuronal immunophenotype as well as a highly proliferative state and extensive dissemination. Accumulation of similar cases will be required before we can resolve this issue and clarify the genetic alterations in this type of glioma progression.

Mixed epithelial and stromal tumor of the kidney with cervical and intestinal differentiation

Received: 20 February 2005 / Accepted: 3 April 2005 / Published online: 16 July 2005
© Springer-Verlag 2005

Dear Editors:
Mixed epithelial and stromal tumor of the kidney (MESTK) has only recently been recognized as a rare benign tumor of the kidney which has distinct clinical and morphological characteristics. The name MESTK was first used by Michal and Syrucek in 1998 [1], and was newly recognized in the recent WHO classification of the urinary system as a distinct entity [2].

We report a unique case of MESTK which showed cervical and intestinal epithelial differentiation. To the best of our knowledge, no such differentiation within MESTK has ever been described in the literature [3, 4]. A 50-year-old woman presented with hematuria associated with pain in the left flank. The patient had a 20-year history of taking oral contraceptives. Computed tomography revealed a 7 cm solid and cystic mass at the upper poles of the left kidney. On thorough clinical check-up, no other tumor was found in the patient. Under the diagnosis of renal tumor, the patient underwent total nephrectomy and adrenalectomy. After surgery, no additional treatment was given. Seven months after excision of the tumor, the patient is without signs of recurrence and metastasis. Macroscopically, the tumor was localized in the upper part of the kidney. The tumor was 7 cm in diameter, well-circumscribed, and composed of irregular mixtures of solid and cystic areas. The solid areas of the tumor were firm and gray-white on gross section. The cysts varied in size ranging from 0.5 to 2 cm in diameter. There were no signs of infiltrative growth into the surrounding renal parenchyma and the adjacent calyceal system.

Histologically, the tumor was composed of a mixture of epithelial elements that formed glands and cysts and stromal component formed mainly by spindle cells. The epithelial component had a characteristic appearance both

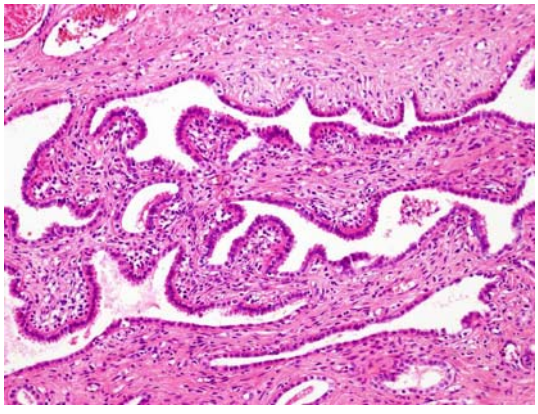

Fig. 1 Glandular epithelium formed serous tubules and multilocular cysts lined by cells with ciliated brush border and peg cells typical of Fallopian tubes. The stroma has bland looking spindle cell appearance, typical of MESTKs

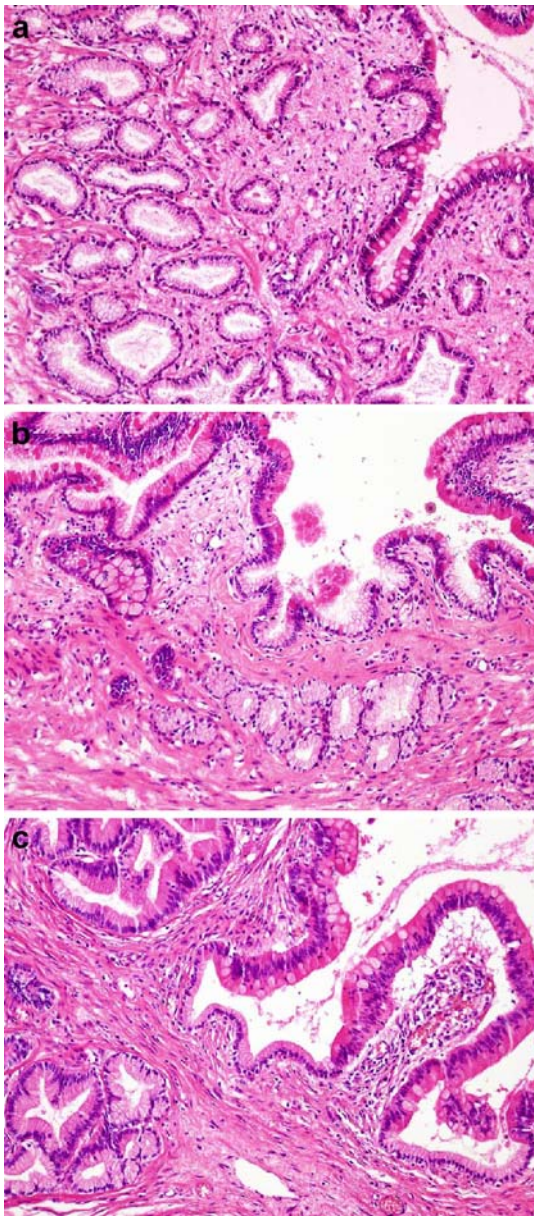

Fig. 2 In some places, the adenomatous structures had the appearance of cervical glands (left side) and intestinal (right side) (**a**). Focally Paneth cell differentiation was seen in the epithelium of the MESTK (**b**). The border between the intestinal and pyloric epithelium was often sharp (**c**)

in architecture and cell type. In some places, glandular epithelium formed serous tubules and multilocular cysts lined by ciliated brush border and peg cells typical of Fallopian tubes (Fig. 1). In other places, the adenomatous structures had the appearance of cervical glands (Fig. 2a) and still other areas revealed typical intestinal epithelium (Fig. 2a) containing Paneth (Fig. 2b) and goblet cells. The border between the intestinal and cervical epithelium was often sharp (Fig. 2c). No cytological atypia or mitotic figures were observed in the epithelial component. The excised adrenal gland was normal without signs of tumor. Immunohistochemically, the epithelial elements expressed cytokeratin (dilution 1:50; Dako, Denmark) and were immunonegative for ER (dilution 1:50; Dako), PR (dilution 1:50; Dako). The stromal elements were focally ER (Fig. 3) , PR and smooth muscle actin (SMA) (dilution 1:50; Dako) positive. Both the epithelial and stromal elements failed to react with S-100 (dilution 1:50; Dako, Denmark), CD34 (dilution 1:50; Dako), HMB-45 (dilution 1:50; Dako) antibodies. Considering the clinicopathological features, a diagnosis of MESTK was easily established in our case [3, 4].

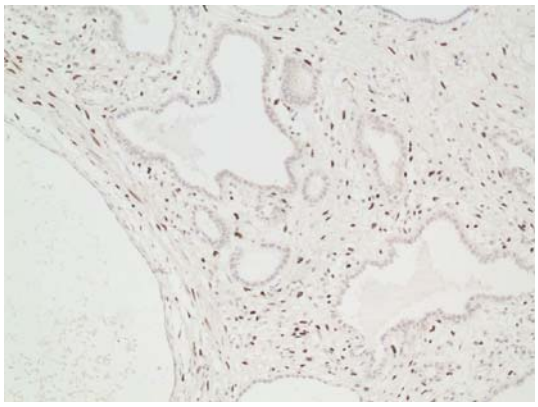

Fig. 3 The stromal elements were immunoreactive to ER

While our case demonstrated morphological features typical for MESTKs, it also showed unique glandular structures represented by cervical and intestinal mucinous epithelium containing goblet and Paneth cells, which is a hitherto undescribed differentiation in MESTK. The presence of cervical and intestinal mucinous epithelia in MESTK is a hitherto undescribed feature of MESTK. The cervical and intestinal mucinous cystic tumors belong to the most common types of epithelial neoplasms occurring in the ovary. In addition, transition between cervical and intestinal epithelium containing goblet cells within single glandular structures is a well known phenomenon described in ovarian tumors [5]. Since MESKT is a tumor displaying a wide range of epithelia and the stroma are often indistinguishable from that of the ovary, it is not surprising that the same transitions between cervical and intestinal epithelium containing goblet cells within single glandular structures were observed in our case. The description of intestinal epithelium in MSTK is important, because it must be differentiated from metastatic mucinous well-differentiated cystadenocarcinomas originating in intestinal tract, gallbladder and pancreas to kidney. This differentiation is easy, because metastatic adenocarcinomas with intestinal differentiation do not reveal other types of epithelium as cervical or that of Fallopian tubes and spindle cell stroma as seen in our case.

Splenic tumors in an adult with tuberous sclerosis: the giant "histiocytoid" cells are dysplastic histiocytes

Received: 15 December 2004 / Accepted: 11 February 2005 / Published online: 25 August 2005
© Springer-Verlag 2005

Dear Editor,

Tuberous sclerosis (TS) patients suffer from a wide constellation of lesions, including hamartomatous tumors affecting virtually every major organ system and renal carcinomas [5]. A recently developed set of criteria has facilitated and standardized the diagnostic process in the setting of the individually variable disease phenotype [2]. Splenic lesions are rare in TS and, by these criteria, are not considered diagnostic. A few reports summarized by Bender and Yunis [1] described three cases of large-cell nodular lesions in neonates. These authors added five additional neonate autopsy cases of diffuse splenic lesions composed of very large cells with eosinophilic cytoplasm. On the basis of morphological features and the presence of lysosome-like ultrastructures, they called these cells "histiocytoid." No such lesions have been reported in adults.

In our case, a 21-year-old female underwent splenectomy due to remittent anemia of unknown origin since the age of 16 years (hemoglobin ranging from 6 to 11.4 g/dL, red blood cell packed volume 19–35.5%) and the presence of several splenic tumors. The splenic tumors were hypoechogenic on the ultrasound. Their sizes ranged from 11 to 57 mm on the computerized tomography scan. The patient had a documented personal and familial history of TS. At the age of 3 months, she started to suffer from seizures, which were later associated with the presence of numerous subependymal calcifying tumors in close proximity to the lateral ventricles and/or a large tumor at the frontal horn of her right lateral ventricle. An unspecified retinal tumor was photocoagulated in her childhood. She manifests subungual fibromas and facial angiofibromas. Her kidneys are currently extremely enlarged (beyond the ultrasound measurement capacity), with their appearance consisting of numerous angiomyolipomas in the computerized tomography. Psychological evaluation done at the age of 20 years demonstrated mild mental retardation. The patient's father died at the age of 34 shortly after emergency surgery due to massive intra-abdominal bleeding from his "polycystic" kidneys (an autopsy was not performed). His charts did not mention splenomegaly.

Grossly, the formaldehyde-fixed spleen measured 18×11×5.5 cm and weighed 420 g. Cross sections revealed several rather sharply circumscribed, lobulated gray-brown tumors measuring up to 37 mm [Fig 1]. One small tumor was reddish and was microscopically proven to be necrotic. The remaining tumors consisted of fibrovascular proliferations containing locally variable numbers of very large cells. The large cells displayed ample cytoplasm with individually varying characteristics: deeply or faintly uniformly eosinophilic, clear, delicately granular, or even foamy, but with transitional forms indicating that they all belong to the same population [Fig 2]. The cytoplasm was faintly periodic acid-Schiff stain (PAS) positive and bluish in the Giemsa stain. Some cells contained a granular yellow-brown birefringent pigment consistent with hemosiderin. The nuclei of the large cells were usually oval and regular, sporadically double, and occasionally with prominent nucleoli. The most spectacular nucleoli were reminiscent of viral inclusions or even imparted some similarity to the RS cells. Immunohistochemically, most of the large cells were positive for CD68–KP1, and some for CD68–PGM1 [Fig 3], S100, CD4, and vimentin. There was no correlation between the immunopositivity of the markers and the nuances of the morphologic features in the large

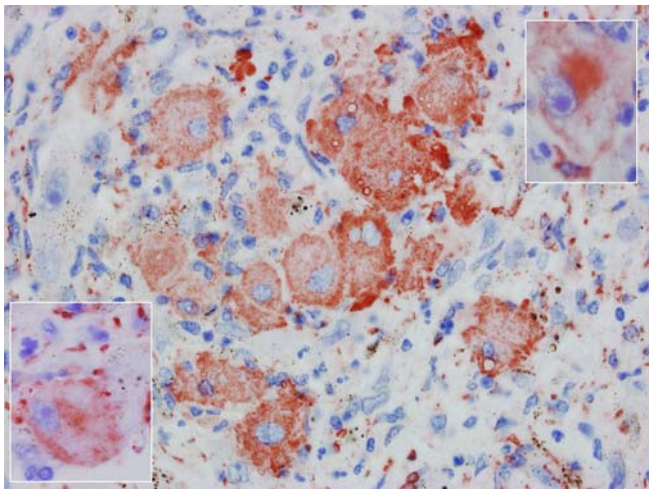

Fig. 3 Strong expression of CD68–PGM1 in a cluster of large cells. A cell with a prominent inclusion-like nucleolus to the *left* of the cluster is immunonegative. The *insets* show various cytoplasmic patterns of CD68–PGM1 expression in similar cells (APAAP technique, lens ×60)

cells, although CD68–PGM1- and S100-positive cells tended to cluster, the latter ones close to fibrous bands, partially delineating the tumors. Clustering was also observed for most CD4-positive large cells. The large cells were negative for other immunomarkers: desmin; smooth muscle actin (SMA); muscle-specific actin (MSA); CD31; CD34; FVIIIR; epithelium membrane antigen (EMA); polyclonal cytokeratins; CK7; CK19; CK20; CD45-leukocyte common antigen (LCA); CD20; CD79a; CD138; CD43; CD3; CD45RO; CD1a; CD35; CD23; placental alkaline phosphatase (PLAP); mast cell tryptase; CD117; myeloperoxidase; lysozyme; CD30; glial fibrillary acidic protein (GFAP); neurofilaments; chromogranin; synaptophysin; HMB45; cytomegalovirus (CMV); and p53. Remarkably, they did not show any mitotic activity nor Ki67 expression. The tumor background contained numerous typical histiocytes, frequently interspersed between the large cells, some granulocytes, and small regular lymphocytes, almost exclusively of the T lineage. The number of interspersed mast cells was striking (up to 30/high-power field), which contrasted with their rare occurrence in the adjacent unaffected spleen. The mast cells were dispersed and cytologically typical, oval in shape, and with no signs of degranulation. Several clusters of disorganized vessels were located at the tumor periphery, usually close to the hyaline fibrous bands partially ramifying the lesions [Fig 4]. These bands contained few smooth muscle cells as documented by immunohistochemistry (SMA, MSA, and desmin).

Aside from the tumors and small accessory spleen, the spleen histology was unremarkable. Two small hilar lymph nodes presented with nonspecific reactive changes, including sinus histiocytosis, but without an accumulation of the characteristic large cells. A trephine bone marrow biopsy

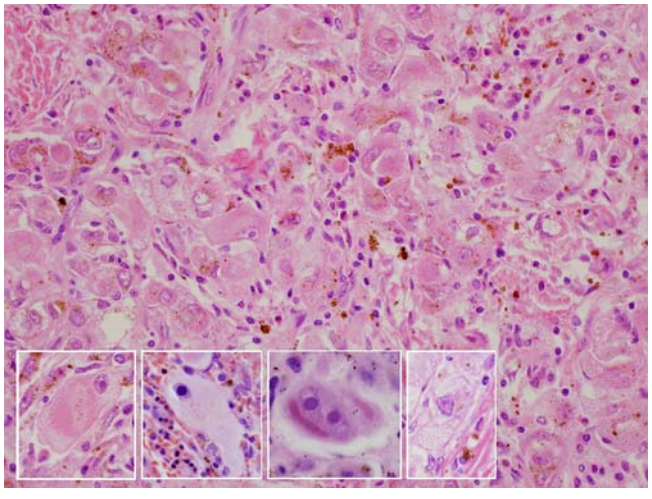

Fig. 2 Large cells composing the nodules show eosinophilic cytoplasm, hemosiderin pigment, and, occasionally, prominent nucleoli (H & E, lens ×40). *Inset*: morphological variability of the giant cells (lens ×60)

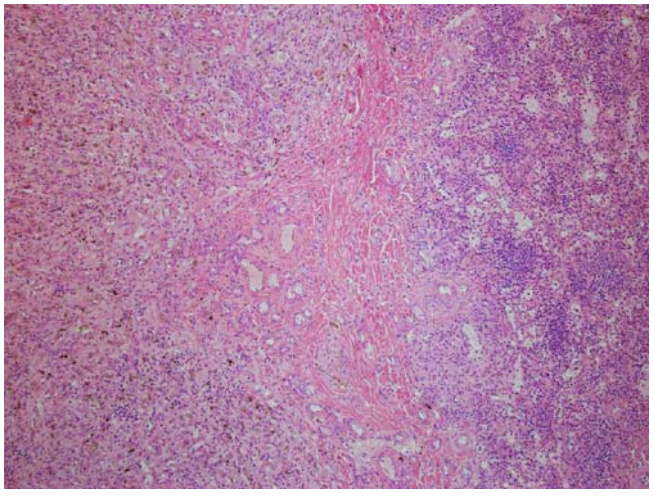

Fig. 4 Fibrous connective tissue strand containing an angiomatoid structure which separates the tumor (*left*) from the normal spleen (*right*) (H & E, lens ×10)

submitted shortly prior to the splenectomy specimen also demonstrated mild reactive changes and lacked the large cells.

The features of the large cells in our case are comparable to the histiocytoid cells reported by Bender and Yunis [1]. Inferring from the apparent lack of analogous lesions in adults, these authors supposed that the presence of histiocytoid cells could have been a transient phenomenon limited to the neonatal period. Our case clearly shows that the tumors composed of histiocytoid cells may belong to the permanent clinicopathologic spectrum of TS, although these probably constitute a great rarity.

Medline-indexed literature contains only nine papers on TS-associated splenic pathology, with one report of a neonatal histiocytoid cell lesion, and the remaining reports describing splenic hemorrhages or vascular tumors, including angiosarcomas in a rat model of TS.

The vascular origin of the histiocytoid cells may be excluded by our immunomarker panel (CD31, CD34, FVIIIR). Emerging from our study, the most likely phenotype of the histiocytoid cells is actually the true histiocyte, with the strongest argument being the positivity for the PGM1 epitope of CD68, a very sensitive and specific marker of histiocytes [4]. Positive immunoreaction with CD68–PGM1 can only be found in synovial cells, neoplastic mast cells, and occasionally in specialized antigen-presenting cells [3, 4]. The synovial origin of the large cells can be excluded on the basis of the histological and topographic context of the lesions. Other features of immunophenotype (negativity for CD1a, CD23, CD35, CD117, and mast cell tryptase) are inconsistent with the antigen-presenting cell or mast cell origin. Expression of CD4 in the absence of other T-cell markers is typical for histiocytes [4]. A nearly "null" phenotype, with only a focal expression of CD68–PGM1, S100, and CD4, and a notable absence of LCA, is a perplexing phenomenon for which we have no explanation. We can only speculate that the silencing of some genes may contribute to the functional inertia of the large histiocytes, possibly resulting in their accumulation. A lack of lysozyme and no Ki67 expression indirectly corroborate this hypothesis.

Most probably, the splenic tumors containing dysplastic histiocytes have little or no direct clinical significance. They grow very slowly, as they were present in our patient 3 years ago, and on the computerized tomography scans, their size seemed to be stable. The large cells and other tumor components showed no appreciable proliferative activity. Upon splenectomy, the patient's anemia did not improve, so it seems highly unlikely that these tumors contribute to the increased erythrocyte consumption. However, in TS patients with a proven or suspected renal carcinoma, these tumors can pose a significant problem in differential diagnosis with splenic metastases. We did not have an occasion to examine the cytological specimen of such a tumor, so we may only speculate that fine-needle aspiration could be helpful in solving this dilemma.

The fibrovascular tumors with large dysplastic histiocytes were confined to the spleen. Their absence in other histiocyte-rich organs, like the accessory spleen, perisplenic lymph nodes, and bone marrow, argues against any fundamental defect in histiocytic maturation or the sequel of storage of unknown substance and supports the hypothesis of the hamartomatous origin of these lesions. It is likely that the dysplastic histiocytes are responsible for the abnormal local milieu attracting the reactive T cells and mast cells, whereas the pathogenetic relation of histiocytes to adjacent fibromuscular and vascular hamartomatous structures remains enigmatic.

To summarize, the fibrovascular tumors with giant dysplastic histiocytes may occur in adult patients with TS. Most probably, they are clinically irrelevant and belong to the spectrum of the hamartomatous lesions of TS.

Reticular and plexiform perineurioma: clinicopathological and immunohistochemical analysis of two cases and review of perineurial neoplasms of skin and soft tissues

Received: 24 May 2005 / Accepted: 31 July 2005 / Published online: 27 August 2005
© Springer-Verlag 2005

Abstract Perineurioma represents a recently described and relatively rare neoplasm in the spectrum of benign peripheral nerve sheath tumours composed of perineurial cells staining immunohistochemically positive for epithelial membrane antigen (EMA). In addition to intraneural, extraneural and sclerosing perineurioma, rare variants of perineurioma may occur, and their knowledge is important in the differential diagnosis of mesenchymal tumours of different lines of differentiation and clinically more aggressive neoplasms. We present a case of deep-seated reticular perineurioma arising on the upper arm of a 34-year-old female and a case of a dermal plexiform perineurioma arising on the lower lip of a 60-year-old female. The diagnosis was confirmed in both cases immunohistochemically; neoplastic cells stained positively for EMA and for the newly described perineurial markers, claudin-1 and glut-1. The morphological spectrum and the differential diagnosis of perineurial neoplasms of skin and soft tissues are discussed.

Keywords Nerve sheath neoplasms · Perineurioma · Epithelial membrane antigen · Claudin-1 · Human erythrocyte glucose transporter (glut-1)

Introduction

Peripheral nerve sheath tumours, both benign and malignant, are composed of one or several cellular components including S-100-positive Schwann cells, CD34-positive or negative fibroblasts and perineurial cells in varying proportions. In addition to neurofibromas, schwannomas, different forms of neuromas and malignant peripheral nerve sheath tumours, neoplasms consisting predominantly or exclusively of perineurial cells, have been described and characterised as perineuriomas in the last years. Perineuriomas arise in dermal, subcutaneous and deep soft tissues and only rarely in visceral location [12, 17, 29]. Although perineurioma has been first described in 1978 [19], it still represents a poorly recognised neoplasm in the spectrum of peripheral nerve sheath tumours [25], and, especially, examples of unusual histological variants cause considerable diagnostic problems and may be mistaken for different or more aggressive soft tissue tumours. Interestingly, rare examples of benign peripheral nerve sheath tumours showing a combination of perineurioma and schwannoma as well as of perineurioma and neurofibroma have been reported most recently [18, 23]. In this review one case each of reticular and plexiform perineurioma is reported, and a review of perineurial neoplasms of skin and soft tissues is given.

Materials and methods

The cases were retrieved from the routine files of the Dermatopathologische Gemeinschaftspraxis in Friedrichshafen, Germany, and from the consultation files of one of the authors (T.M.; see acknowledgment). The specimens were obtained by surgical excision, fixed in 10% buffered formalin and processed routinely for paraffin embedding. Four micrometer-thick sections were stained with haematoxylin and eosin. In addition, sections were stained immunohistochemically by the labelled Streptavidin Biotin (LSAB) technique using commercially available antibodies; appropriate positive and negative controls were used in each case. The used antibodies, their sources and dilutions are summarised in Table 1. The clinical and follow-up informations were obtained from the referring clinicians and pathologists.

Table 1 Immunohistochemical reagents used

Antibody	Clone	Dilution	Source
EMA	Mc5	1:400	Biogenex, CA, USA
Glut-1	Polyklonal	1:200	DAKO, Glostrup, Denmark
Claudin-1	Polyklonal	1:600	Zymed, CA, USA
Pancytokeratin	MNF116	1:100	DAKO
Desmin	D33	1:200	DAKO
ASMA	1A4	1:300	DAKO
S-100 protein	Polyklonal	1:4000	DAKO

Results

Case 1

A 34-year-old lady developed a deep-seated soft tissue neoplasm on her right upper arm. The patient complained about a slowly growing mass that was not painful, and, clinically, a lipoma was suspected. The intramuscular neoplasm was completely excised and measured 8×5×3 cm. There is no sign of recurrence at 18 months. Grossly, a circumscribed mass with soft and yellow-white cut surfaces was described, areas of haemorrhage or tumour necrosis were not evident. Microscopically, the paucicellular neoplasm was partly circumscribed but unencapsulated. Focally, a superficial infiltration into the skeletal muscle was noted. On low-power view, the neoplasm was characterised by a reticular pattern of anastomosing spindled cells set in a prominent myxoid matrix with microcystic changes (Fig. 1). Cytologically, the neoplastic cells contained a pale eosinophilic cytoplasm and ovoid to fusiform nuclei with mild nuclear pleomorphism, nucleoli were not seen or inconspicuous and no increased proliferative activity was noted. Characteristically, neoplastic cells had elongated and very thin cytoplasmic processes, which appeared to interconnect in many areas (Fig. 2). Focally, a slightly increased cellularity with a rather lamellar growth pattern of elongated tumour cells was identified (Fig. 3). The intercellular matrix contained abundant myxoid/mucoid material, and numerous capillary sized blood vessels with focal hyalinisations of their walls were present. Immunohistochemically, neoplastic cells stained strongly and homogenously positive for claudin and glut-1, whereas epithelial membrane antigen (EMA) was expressed only focally (Fig. 4). The remaining immunohistochemical markers (S-100 protein, CD34, alpha-smooth muscle actin, desmin, CD31 and pancytokeratin) were all negative.

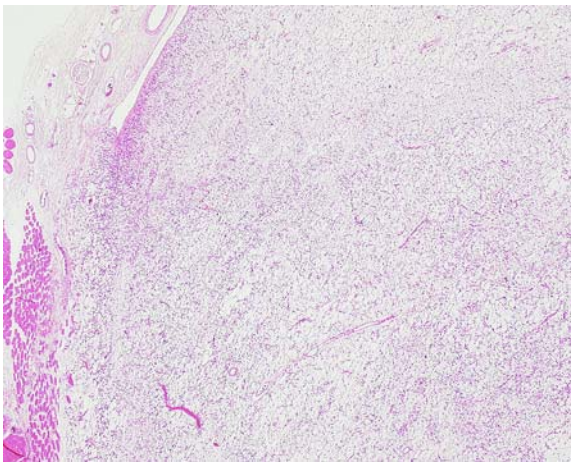

Fig. 1 Low-power view of case 1 shows a deep-seated, well-circumscribed, but focally infiltrating hypocellular neoplasm

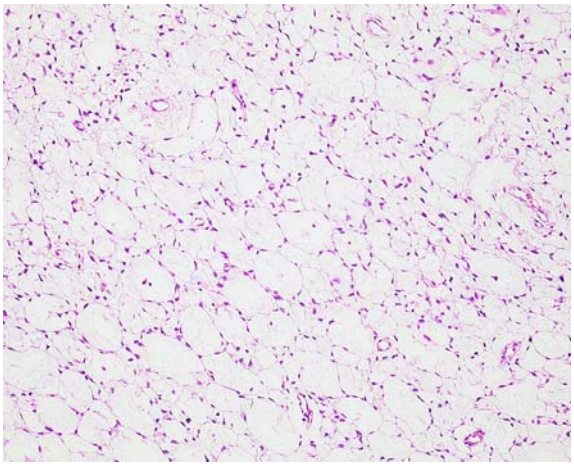

Fig. 2 The neoplasm is composed of spindle-shaped cells containing elongated cell processes, anastomosing in a lace-like pattern. Note slightly enlarged hyperchromatic nuclei

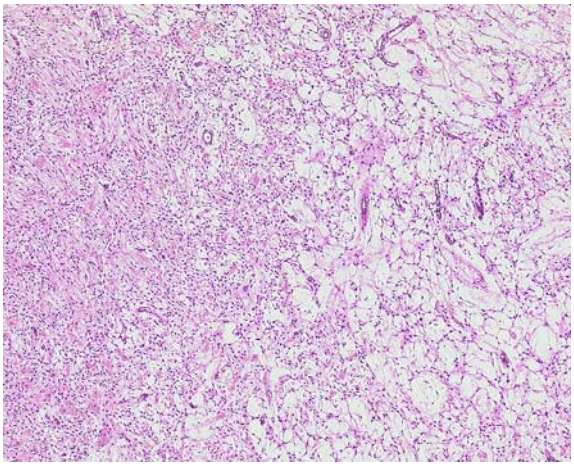

Fig. 3 Focally, a transition to more cellular tumour areas was present

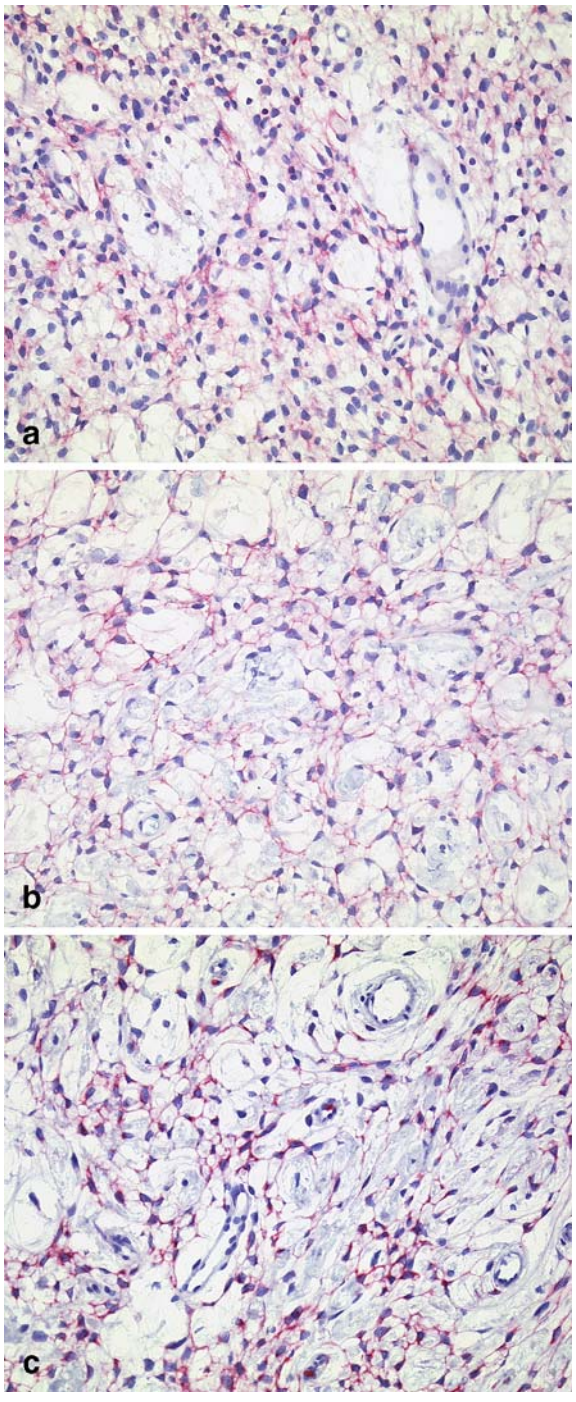

Fig. 4 Immunohistochemically, tumour cells stained positively for EMA (**a**), claudin-1 (**b**) and glut-1 (**c**)

Case 2

A 60-year-old female patient complained about a papular lesion on the lower lip present since childhood. Clinically, a soft and yellowish lesion was described. The neoplasm was marginally excised, and there was no sign of recurrence at 21 months. Grossly, a spindled skin specimen with an indurated dermal nodule measuring 0.4 cm in largest diameter was described. Histologically, a plexiform mesenchymal neoplasm composed of plump spindle-shaped tumour

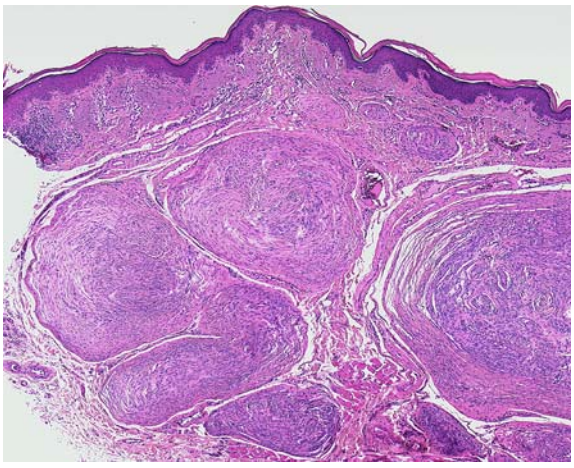

Fig. 5 In case 2 a plexiform, dermal neoplasm is seen

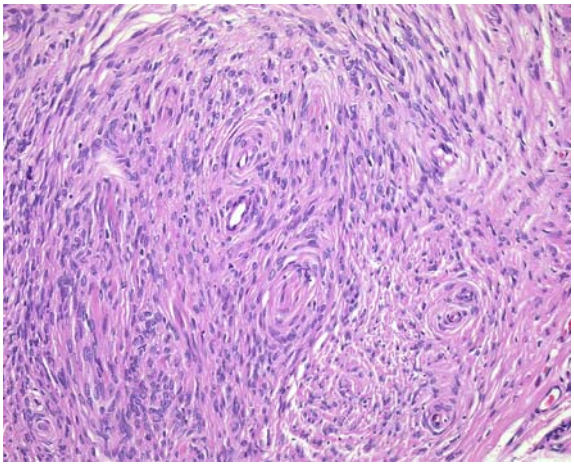

Fig. 6 The neoplasm is composed of plump spindled tumour cells set in a collagenous stroma with thin-walled blood vessels

cells with an ill-defined, pale eosinophilic cytoplasm and spindled or round nuclei was noted (Fig. 5). Neoplastic cells were arranged in nodular formations of different size and set in a collagenous matrix with thin-walled blood vessels (Fig. 6). Tumour cells stained positively for EMA, claudin and glut-1 (Fig. 7), whereas S-100 protein and CD34 were negative.

Discussion

Perineurial cells, both non-neoplastic and neoplastic, are usually spindle-shaped with bipolar, palely eosinophilic cytoplasm and fusiform nuclei with a finely distributed chromatin, which are variably tapering or plump; typically long and very thin cell processes are evident. Ultrastructurally, these bipolar cell processes are surrounded incompletely by an external lamina, and numerous pinocytic vesicles as well as well-formed tight junctions are noted [8, 19]. Immunohistochemically, perineurial cells stain positively for EMA [27, 28]. Whereas CD34 is expressed in

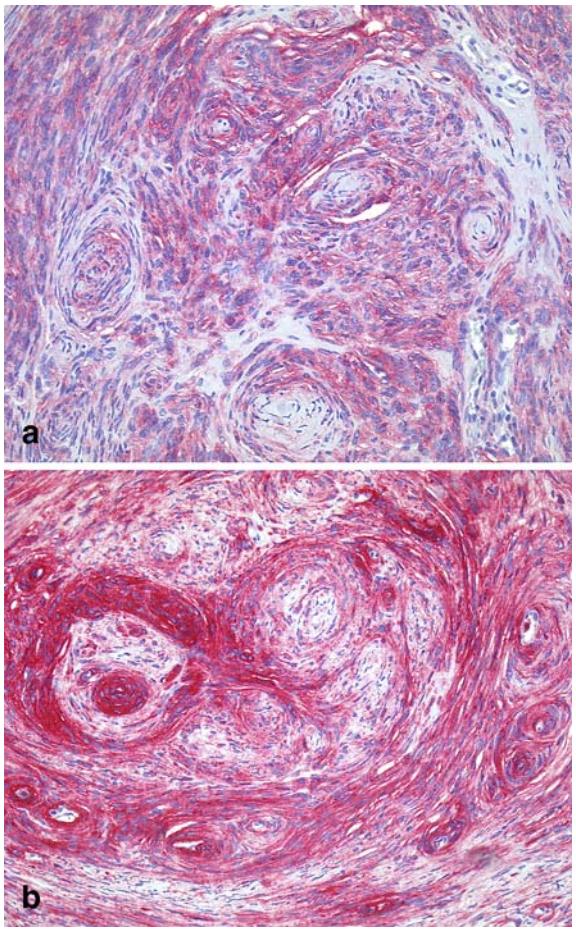

Fig. 7 Neoplastic cells stained positively for EMA (**a**) and glut-1 (**b**)

several perineuriomas [13, 16], S-100 protein and myogenic markers are negative by definition. Unfortunately, there are as well limitations in the use of EMA as a perineurial marker. Firstly, EMA is expressed in several spindled mesenchymal neoplasms showing a fibroblastic line of differentiation (i.e. solitary fibrous tumour). In addition, EMA expression in classical cases of perineurioma may be only focal and weak, given the presence of elongated and very thin cell processes with a small amount of cytoplasm. In the last years, claudin-1 [10] and glut-1 [30] have been described as new perineurial markers. Claudin-1 belongs to a family of integral transmembrane proteins with structural and functional role in tight junctions and has been found in non-neoplastic and neoplastic perineurial cells, whereas tested fibro- and myofibroblastic neoplasms did not show an expression of this marker [10]. Human erythrocyte glucose transporter glut-1 is normally expressed in erythrocytes, perineurial cells, renal tubules, germinal centres of lymphoid tissue and in several carcinomas [31]. Whereas cases of schwannoma and neurofibroma are negative for glut-1, this marker is strongly expressed in cases of perineurioma [30]. In addition, it has been mentioned that soft tissue meningioma, which resembles perineurioma histologically and immunohistochemically [21], is consistently negative for glut-1 [30]. Although not specific, claudin-1 and glut-1 are quite sensitive perineurial markers and should be included in the immunohistochemical panel for the diagnosis of perineurial neoplasms.

Perineurial-differentiated neoplasms of skin and soft tissues composed predominantly of neoplastic perineurial cells are rare and represent less than 1% of nerve sheath and soft tissue neoplasms, respectively [26]. After the delineation of perineurioma in 1978 [19], several clinical and morphological variants have been described in the last years, and their knowledge is important to avoid misdiagnosis of different or more aggressive mesenchymal neoplasms.

Intraneural perineurioma, also known formerly as localised hypertrophic neuropathy of the limbs [3, 7], is characterised clinically by a fusiform swelling with progressive muscle weakness and/or sensory disturbances. Histologically, residual S-100-positive nerve fibres are surrounded concentrically by EMA-positive perineurial cells forming concentric layers around nerve fibres and characteristic pseudo-onion bulbs. No prominent atypia and no increased proliferative activity of neoplastic perineurial cells are seen. Although some authors still regard this condition not as a form of perineurioma, cytogenetic findings add strong support to the interpretation of these lesions as an intraneural form of perineurioma [7].

Extraneural spindle cell perineurioma arises often on the trunk and the extremities of middle-aged adults and is not associated with neurofibromatosis; only rarely perineurioma occurs in children [2]. These neoplasms are seen frequently in subcutaneous tissue, whereas deep soft tissues and the dermis are more rarely affected. Perineuriomas of soft tissues are usually well circumscribed but unencapsulated; however, rarely and focally an infiltration into surrounding structures may be present [16]. Histologically, extraneural perineurioma is characterised by a variable cellularity and different growth patterns (storiform, whorled, lamellar, fascicular) of spindled tumour cells showing features as described above. The collagenous stroma often shows focal hyalinisations. It has been shown convincingly that the presence of focal infiltration and of cytological atypia does not affect the benign biological behaviour of perineurioma [16]. Cytological features and the immunophenotype of neoplastic perineurial cells allow distinction from benign and malignant spindle cell neoplasms of skin and soft tissues (i.e. dermatofibroma, superficial acral fibromyxoma, dermatofibrosarcoma protuberans, neurofibroma, schwannoma, solitary fibrous tumour, low-grade fibromyxoid sarcoma). The evidence of identical cytogenetic changes in intra- and extraneural perineuriomas, monosomy of chromosome 22, supports the view that both forms are part of a clinicopathological spectrum of a single entity [7, 11].

Sclerosing perineurioma tends to occur in superficial tissue of the hands of young adults and is composed of plump spindled and epithelioid tumour cells set in a hyalinised stroma containing numerous thin-walled blood vessels. Often a perivascular and lace-like arrangement of neoplastic cells is noted [9]. The differential diagnosis of

sclerosing perineurioma comprises epithelioid dermatofibroma, sclerosing dermal fibroma in acral location, superfical epithelioid haemangioendothelioma and sclerosing melanocytic and epithelial neoplasms; however, the characteristic immunoprofile of sclerosing perineurioma is of help in the distinction of these entities. Interestingly, in superficial location, neoplasms showing a combination of features of spindle extraneural cell perineurioma and sclerosing perineurioma have been reported [25].

Reticular perineurioma, first reported as retiform perineurioma [22], represents a recently described rare subset of perineurioma that is easily admixed with several mesenchymal neoplasms [13]. Most cases of reticular perineurioma occurred in soft tissues, whereas a single case of intraneural reticular perineurioma has been reported [5]. Reticular perineurioma is characterised by the presence of prominent degenerative myxoid or edematous stromal changes sometimes with the formation of pseudocystic spaces. The neoplastic cells contain very thin and elongated cell processes anastomosing in a lace-like, reticular pattern. Occasionally, degenerative nuclear atypia is noted [13]. Especially in deep-seated, intramuscular examples of reticular perineurioma, intramuscular myxoma represents the most important differential diagnosis. Tumour cells in intramuscular myxoma do not contain very thin and elongated cell processes anastomosing in a lace-like pattern and are usually negative for perineurial markers. However, as said before, a focal staining for EMA may be seen in intramuscular myxoma as well, but claudin and glut-1 are not expressed. Myxoid solitary fibrous tumour is composed of plumper fibroblastic cells staining positively for CD34 and often for CD99 and bcl-2, whereas EMA is negative or only focally positive. Myxoid monophasic fibrous synovial sarcoma may also closely resemble reticular perineurioma; however, tumour cells in synovial sarcoma are plumper and stain only focally positive for EMA. In addition, often pancytokeratin is focally expressed, and frequently, positivity of CD99 and bcl-2 is observed. Rare myxoid dermatofibrosarcoma protuberans is composed of CD34-positive, EMA-negative tumour cells arranged predominantly in a storiform pattern and characterised by a diffuse infiltration of subcutaneous tissue. Myoepithelioma of soft tissues may show a reticular growth pattern, but neoplastic cells are variably positive for S-100 protein, pancytokeratin, actins, glial fibrillary acidic protein, desmin and p63 [15]. In several cases of extraskeletal myxoid chondrosarcoma, a focal expression of EMA has been reported [20], but tumour cells in extraskeletal myxoid chondrosarcoma tend to be larger and contain more eosinophilic cytoplasm with PAS-positive material.

Plexiform perineurioma seems an extremely rare variant of perineurioma with only one case reported so far [34], and several neoplasms showing a plexiform architecture have to be distinguished. Plexiform neurofibroma, plexiform schwannoma and rare plexiform (solitary) circumscribed neuroma [1] are predominantly composed of S-100-positive Schwann cells, and in neurofibromas, scattered EMA-positive perineurial cells are noted only. Plexiform fibrohistiocytic tumour is composed of spindled fibro- and myofibroblasts associated with CD68-positive histiocytoid cells including osteoclast-like giant cells, whereas EMA-positive perineurial cells are not present.

Rare sclerosing pacinian-like perineurioma, lipomatous perineurioma, perineurioma with granular cells and ossifying perineurioma have been reported in the last years [4, 6, 24, 33].

Malignant perineuriomas, also known as malignant peripheral nerve sheath neoplasms showing a perineurial differentiation, represent exceedingly rare malignant neoplasms, and are characterised morphologically by an infiltrative growth, prominent cytological atypia and increased proliferative activity [14]. So-called atypical cellular perineurioma may be regarded as a lesion intermediate between benign and obvious malignant perineurioma, and among four lesions reported so far, two neoplasms recurred locally, but none metastasized [32].

In summary, perineurial neoplasms of skin and soft tissues represent a heterogeneous group of mesenchymal neoplasms composed of spindle shaped and/or epithelioid tumour cells showing histological, immunohistochemical, ultrastructural and molecular features of perineurial-differentiated cells. Reticular and plexiform perineurioma represent rare and recently delineated morphological variants of benign perineurioma of skin and soft tissues. Although not specific, claudin-1 and glut-1 are quite sensitive perineurial markers and should be included in the immunohistochemical panel for the diagnosis of perineurial neoplasms.

Acknowledgements The authors are grateful to Dr. Outrata, Stuttgart, Germany, for kindly providing case material and clinical follow-up for case 1.
