Background: Gastric adenocarcinoma and squamous cell lung carcinoma are quite common entities. The purpose of this study is to present an unusual case of synchronous gastric adenocarcinoma and squamous cell lung carcinoma of the left lower lobe. The gastric adenocarcinoma showed metastasis to the paraesophageal and gastric lymph nodes, to one peribronchial lymph node and lymph nodes of the carina, as well as liver metastasis. The lung carcinoma showed metastasis to peribronchial lymph nodes. Method: The patient was male, 63 years old. Endoscopic examination revealed a gastric adenocarcinoma while CT scanning revealed tumors in the liver and the lower lobe of the left lung, as well as enlargement of the peribronchial lymph nodes and lymph nodes of the carina. Results: The patient underwent gastrectomy, lobectomy and limited hepatectomy including the tumor. Also subcarinal lymph nodes were excised. Microscopic evaluation revealed a moderately differentiated gastric adenocarcinoma of intestinal type according to Lauren classification, which infiltrated the whole gastric wall, with metastases to the paraesophageal and gastric lymph nodes. The hepatic nodule was a metastatic nodule of the adenocarcinoma. The lung tumor was a moderately differentiated squamous cell carcinoma with metastases to the peribronchial lymph nodes. Curiously, one of them showed metastasis of the gastric adenocarcinoma. Moreover, the subcarinal lymph nodes had metastases of the adenocarcinoma. Conclusion: Synchronous appearence of two carcinomas is unusual. The fact of lymph node metastasis to a peribronchial lymph node and to the subcarinal lymph nodes from the gastric adenocarcinoma while the others showed metastases from the lung carcinoma is quite curious. Eitherway, the prognosis is poor.

PP2-109
EFFECTS OF NIMODIPINE ADMINISTRATION ON SMALL BOWEL MUCOSA FOLLOWING LAPAROTOMY AND CONSEQUENT 48-HOUR STARVATION IN A RAT MODEL

Harilaos Kantsos[1], Andreas Lazaris[2], George Agrogiannis[2], Stefanos Papadopoulos[3], Despina Perrea[1], Theodoros Xanthos[1], Ioannis Vlachos[1], Alkistis Pantopoulou[1], Sofia Tseleni[2], John Bramis[3], Efstratios Patsouris[2]
[1] Laboratory For Experimental Surgery And Surgical Research, School of Medicine, University of Athens, Athens Greece
[2] National And Kapodistrian University of Athens, School of Medicine, 1st Department of Pathology
[3] University of Athens, Medical School, First Department of Propedeutic Surgery, Hippokration Hospital, Athens Greece

Background The combination of starvation and surgical trauma induces disturbances to the intestinal mucosal structure and function, as well as changes in mucosal barrier function in the rat small bowel. The aim of the present study was to evaluate the effects of nimodipine administration, on intestinal mucosal structural changes and enterocyte apoptosis, following laparotomy and subsequent postsurgical starvation (PSS) in the rat. Method Thirty Wistar rats were divided into two experimental groups: A: Control group (n=15), where the animal models underwent laparotomy and consequent 48-hours PSS and B: Nimodipine group (n=15), where the rats underwent

laparotomy, followed by intraperitoneal nimodipine administration and consequent 48-hour (h) PSS. Small bowel mucosal structural changes and enterocyte epithelial apoptosis were determined 48 h following laparotomy. Results Nimodipine rats (group B) demonstrated a significant decrease in small bowel villous height in jejunum (p=0.016) and ileum (p=0.002). Similarly, crypt depth decreased in jejunum (p<0.001) and ileum (p<0.001). Nimodipine group exhibited significantly higher apoptotic index in ileum compared to control rats (p=0.006). Conclusion Nimodipine did not protect the intestinal mucosa from damage caused by surgery and consequent PSS and had obvious damaging effects on intestinal mucosa with derangements to its structure and subsequent mucosal atrophy.

PP2-110
TUMOR BUDDING IN COLORECTAL CARCINOMAS

Sevda Sert, Gulsun Inan, Ibrahim Metin Ciris,
Kemal Kursat Bozkurt, Fatma Nilgun Kapucuoglu
Suleyman Demirel University, Faculty of Medicine, Department of Pathology, Isparta, Turkey

Background: In colorectal carcinomas, tumor budding has been defined as the presence of isolated single cells or small cell clusters in the stroma at the invasive tumor margin. There are reports which determine tumor budding along the invasive margin is associated with tumor behavior. In this study the relation of tumor budding at the invasive margin with pathologic parameters is investigated. Materials and Methods: Retrospectively H&E slides of 73 of colorectal carcinoma specimens were evaluated for tumor budding. Of 73 case, 37 (%50.6) were well differentieted, 28 (%38.3) were moderately differentieted and 8 (%10.9) were poorly differentieted. There was lymph node involvement in 41 (%56.1) cases and no lymph node involvement in 32 (%43.8) cases. Vascular invasion was present in 27 (%36.9) cases and no vascular invasion was detected in 46 (%63) case. The intensity of tumor budding at the invasive margin was evaluated by 2 observers. After the specimens were assessed in general, the highest density of tumor budding area was counted within a microscopic field of x200. Tumor budding density of cases were separated into 2 groups as < 10 (low grade) and ≥ 10 (high grade) .The relation of these groups with histologic grade, vascular invasion and lymph node involvement were investigated. Results: Of the 73 colorectal carcinomas, 33 (%45.2) cases had low and 40 (%54.8) cases had high grade tumor budding density, respectively. Of 33 low grade group, 21 (%63.6) were well differentieted, 10 (%30.3) were moderately differentieted and 2 (%6.1) were poorly differentieted. Of 40 high grade case, 16 (%40) were well differentieted, 18 (%45) were moderately differentieted and 6 (%15) were poorly differentieted. Of the 33 low grade cases, there was no lymph node involvement in 23 (%69.6) cases, but there was lymph node involvement in 10 (%30.4) cases. Of the 40 high grade cases, there was no lymph node involvement in 9 (%22.5) cases but there was lymph node involvement in 31 (%77.5) cases. In the low grade group, no vascular invasion was detected in 27 (%81.8) cases and vascular invasion was present in 6 (%18.2) cases; in the high grade group no vascular invasion was detected in 19 (%47.5) cases and vascular invasion was present in 21 (%52.5) cases. Histologic grade (p= 0.042), lymph node involvement (p= 0.0001) and vascular invasion (p= 0.0034) were significantly associated with high grade tumor budding density. Conclusion: High grade tumor budding density is associated with aggressive phenotypical features in colorectal carcinoma.

PP2-111
PRIMARY GASTROINTESTINAL STROMAL TUMORS IN THE OMENTUM AND MESENTERY: REPORT OF THREE CASES

Savelina Popovska[1], T. Betova[1], N. Ivanova[2]
[1] Dept of General and Clinical Pathology Medical University – Pleven, Bulgaria
[2] Dept of Oncology Medical University – Pleven, Bulgaria

Introduction: Gastrointestinal Stromal Tumors (GISTs) are the most common tumors of mesenchymal origin in the gut. Less than 1% of GISTs occur in the mesentery, omentum or retroperitoneum. Methods: We report three cases of GIST- two mesenteric with malignant potential and one of the omentum and their diagnosing with imaging and immunohistochemical methods. Results: The patients had been complaining of pain and oppression in the epigastric and abdominal area. Abdominal Ultrasound showed tumor formation with heterogeneous tissue. CT scan of the abdomen showed large round masses in the upper abdomen. The patients underwent an operation with biopsy. The macroscopical and histologic findings of the tumors were described. The mesenteric and omental tumors showed histologic features similar to GISTs with elongated spindle cells and moderate to high cellularity. Immunohistochemically, all tumors were positive for both KIT and CD34. Conclusion: The use of contemporary diagnostic technologies – ultrasound, CT and immunohistochemical methods are important factors for the diagnosis and staging of GISTs.

PP2-112
HISTOLOGICAL TUMOR REGRESSION PATTERNS OF PREOPERATIVE NEOADJUVAN CHEMO-RADIOTHERAPY APPLIED COLORECTAL CARCINOMA AND THE IMPORTANCE OF THE IDENTIFICATION OF ASSOCIATED RADIATION INDUCED BOWEL CHANGES FOR LIFE QUALITY

Nuray Kepil[1], Suha Goksel[1], Sabri Erguney[2], Sibel Erdamar Cetin[1], Tayfun Karahasanoglu[2], Gulen Dogusoy[1]
[1] Department of Pathology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey
[2] Department of General Surgery, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Background. Several grading and staging systems have been proposed for the histological quantification of the tumor regression of colorectal cancer after chemo-radiotherapy. Radiation induced colitis and vasculopathy are also well established entities. We had observed different regressional changes during the histopathological investigation of these tumors and presented our group composed of 10 cases in Turkish National Pathology Symp. in 2006. The aim of this ongoing study is the assessment of the effects of different histological tumor regression patterns on the tumor regression biology, prognosis and the life quality of the patients. Method. Between 97-06, 18 patients who received preoperative neo-adjuvant chemo-radiotherapy followed by surgery for colorectal carcinoma were enrolled in the study. Two of them had mucinous adenocarcinoma. Histological regression patterns(HRP) have been described and subclassified as follows: Type-I-massive necrosis; Type-II-massive fibrosis (successor to tumor); Type-III-cystic degeneration with central necrosis of the tumor parenchyma with fibroplasia; Type-IV-massive microcalcification of tumor parenchyma with fibroplasia. In addition to common histological prognostic parameters of colorectal carcinoma, xantogranulomatous reaction and the changes of adjacent bowel wall and vessels were recorded. Results. The distribution of HRP in non-mucinous group were Type-I in 3 cases, Type-II in 5 cases, Type-III in 3 cases and Type-IV in 4 cases. There was not any regression in 1 case in this subgroup due to early developing generalized bowel infarction and died soon after. One of the patients had mucinous adenocarcinoma fully resistant to therapy, and after the local

recurrence she died in the 5th year. In another case with mucinous carcinoma, persistence of the acellular mucin pools were observed. Overall, complete regression was seen in 5 patients. The features of the chronic ischemic colitis and occlusive radiation vasculopathy were observed in all patients. Conclusion. For the evaluation of the co-efficiency of preoperative neo-adjuvant chemo-radiotherapy, there is a necessity for a worldwide consensus including grading, staging of the tumor regression, and histological regression pattern. However, the whole effort should not focus on the tumor. It is the responsibility of the pathologist to define and report the intensity and spread of the mesenteric ischemic properties of the resected specimen. Another point of study should be the standardization of the long term effects of ischemic parameters on the quality of life.

PP2-113

CYCLOOXYGENASE EXPRESSION IN THE COLON ADENOCARCINOMAS AND ITS RELATIONSHIP WITH OTHER PROGNOSTIC PARAMETERS

Mehmet Bilgic[1], Nagehan Ozdemir Barisik[1], Medine Murtazaoglu[2], Sezer Gezgin[1], Nimet Karadayi[1], Sevinc Keser[1], Dilek Yavuzer[1], Mahmut Gumus[3]
[1] Dr. Lutfi Kirdar Kartal Education and Research Hospital, Pathology Department, Istanbul, Turkey
[2] Hakkari State Hospital, Pathology Department, Hakkari, Turkey
[3] Dr. Lutfi Kirdar Kartal Education and Research Hospital, Medical Oncology Department, Istanbul, Turkey

Background: There are two isoforms of cyclooxygenase (cox) which takes place in the synthesis of thromboxanes and prostoglandines from arachidonic acid. Inducible form is cyclooxygenase-2 (cox-2) and its role in the pathophysiologic processes is well known. In this study immunohistochemical expression of cox-2 in the colon adenocarcinomas and its relationship with other prognostic parameters are investigated. Method: Paraffin embedded blocks of 59 cases of colon adenocarcinomas which diagnosed at the Dr.Lutfi Kirdar Kartal Education and Research Hospital, Pathology Department, were investigated for expression of cox-2 by immunohistochemistry. According to the extent of expression, cases are graded as score 0 for no expression and score 1, score 2, score 3 score 4 for the 1-9%, 10-29%, 30-60%, 61% and above, respectively. For the intensity of the staining, cases were graded as score 0 for no staining and score 1, score 2, score 3 for the weak, moderate and strong cytoplasmic staining, respectively. Extent and intensity of the immunostaining compared with the prognostic parameters as age, sex, tumor grade, stage, vascular invasion, perineural invasion, inflammatory response and lymph node metastasis. Results: According to histologic differentiation, our cases were 15.6% grade I, 59.3% grade II, 27.1% grade III. Intensity and extent of the cox-2 expression was significantly higher in the vascular invasion positive cases (p: 0.0218, p: 0.035, respectively) and lymphocytic response was weak (p:0.035). We also found reverse relationship with the lymphocytic response and the histologic grade (p: 0.069). Conclusion: In this study we found statistically significant relationship with cox-2 expression and vascular invasion which is an important prognostic parameter.

PP2-114

ADENOMYOMA OF THE GASTROINTESTINAL TRACT. REPORT OF THREE CASES AND REVIEW OF THE LITERATURE

Miljan Krstic[1], Aleksandar Petrovic[2], Vesna Zivkovic[1], Boban Stamenkovic[1], Ljubinka Velickovic[1], Marija Andjelkovic[1], Vuka Katic[1]
[1] Institute of Pathology, Medical Faculty Nis, Serbia
[2] Institute of Histology, Medical Faculty Nis, Serbia

Adenomyoma of the gastrointestinal tract is a rare benign tumor-like condition characterized histologically by a mixture of glandular structures lined by tall columnar epithelium with intervening bundles of smooth muscle. The pathogenesis of adenomyoma is considered to be either a form of myoepithelial hamartoma or a pancreatic heterotopia. We describe three cases of adenomyoma. One was the jejunal adenomyoma that presented with intussusception occuring in a 48-year-old man. The other was gastric antral adenomyoma found incidentally in a 62-year-old man, during cholecistectomy. It had intra-abdominal localisation, origining from the antral subserous region. The third was the papilla of Vater adenoma, discovered during the autopsy if a 54-year-old woman. Clinical diagnosis was dysfunction of the papilla Vateri, associated with severe obstructive jaundice induced by its carcer. Formaldehyde fixed, paraffin sections were stained with H&E,Van Gieson, PAS and HID-AN pH=2,5 methods. Immunohistochemical LSAB2 immunohistochemical method was used for verification of epithelial, smooth muscles tissues and, nuclear proliferative activity (DacoCytomation). On histological examination, the lesions consisted of hyperplastic glandular lobules of the pylorus, exocrine pancreas and jejunum, covered by single-layer epithelium of cuboidal and columnar cell type. The cells showed no atypia; some ducts shoved cystic changes. The hyperplastic glandular lobules were surrounded by hyperplastic mesenchymal tissue, composed of bundles of smooth muscle. Immunohistochemically, intense expression of panCytokeratin (epithelial marker), as well as desmin (smooth muscle marker) was found. Ki-67 activity (proliferative activity marker) was negative. In conclusion, adenomyoma of the gastrointestinal tube is a rare benign lesion. The differential diagnosis from adenocarcinoma, especially in a frosen section, might be difficult. The main features are the absence of cytological abnormalities, the absence of desmoplastic stroma and the presence of smooth muscle bundles encircling the cysts.

PP2-115

FIBROMUSCULAR DYSPLASIA OF THE MESENTERIC VASCULATURE RESULTING CROHN LIKE AND ULCERATIVE COLITIS LIKE CHRONIC ISCHEAMIC BOWEL DISEASE IN YOUNG ADULTS

Suha Goksel[1], Ilker Ersozlu[2], Hasan Kalafat[3], Ahu Senem Demiroz[1], Serap Aslan[1], Engin Cigerciogullari[1], Zerrin Calay[1], Ugur Korman[4], Yilmaz Ersan[5], Ismail Hamzaoglu[5]

[4] Department of Radiology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey
[5] Department of General Surgery, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Fibromuscular dysplasia (FMD) is described as a no inflammatory segmental disease of the arteries of unknown origin. FMD may affect arteries of all sizes and is commonest in middle-aged women, but it can occur in both sex and in all ages, including children. FMD of the mesenteric vessels is too rare and we couldn't find involvement of veins together with arteries in the literature. We report four cases with mesenteric FMD that cause to chronic ischemic bowel disease mimicking Crohn's disease in three cases and ulcerative colitis in the fourth case. Case 1. 38 years old female followed up as Crohn's disease since 1996, in addition to esophageal leiomyom. Case 2. 30 years old female followed up as Crohn's disease since 1994. Case 3. 36 years old male followed up as Crohn's disease since 1999. Case 4. 40 years old male followed up as Ulcerative Colitis since 2001, in addition to classical seminoma in the testis. Pathologic investigation of surgical resection specimens of all patients revealed that FMD involved extramural intestinal arteries and veins. The whole histologic spectrum (intimal, medial,

periarterial and also petal-like periadventitial patterns) of FMD was seen in the several vessel samples in all patients. Unexpectedly, venous involvement was equivalent or same degree with arterial involvement. Periadventitial hyperplastic smooth muscles, in bundle form, surrounding the artery/vein couple was recorded in these cases as an undescribed feature of FMD. The appearance of the whole thickness of the walls of the affected vessels and periadventitial petal like smooth muscles hyperplasia were very well organized and hamartomatous in nature. In first three cases the affected area was small bowel, in the fourth case it was large bowel. Affected small bowel expressed Crohn's like morphological changes radiologically, macroscopically and microscopically. Similarly, the affected large bowel expressed ulcerative colitis like changes. In conclusion, mesenteric involvement by FMD may cause chronic ischemia, not only acute ischemia. Chronic ischemic bowel disease may mimic idiopathic inflammatory bowel disease also in young adults, and not only elderly. FMD may involve veins. Further investigation is necessary for congenital etiology of the FMD characterized by whole thickness and periadventitial involvement of the couple of artery and vein.

PP2-116

ALTERED EXPRESSION OF MONOCARBOXYLATE TRANSPORTERS 1, 2 AND 4 IN COLORECTAL CARCINOMAS

Celine Pinheiro[1], Adhemar Longatto-Filho[1], Luisa Ferreira[1], Cristovam Scapulatempo[2], Venâncio Af Alves[2], Luc Pellerin[3], Fernando Schmitt[4], Fátima Baltazar[1]
[1] Life and Health Sciences Research Institute, School of Health Sciences, University of Minho, Braga, Portugal
[2] University of São Paulo School of Medicine, Brazil
[3] Faculty of Biology and Medicine, University of Lausanne, Switzerland
[4] IPATIMUP, Porto, Portugal; Medical Faculty of the University of Porto, Portugal

Background: In order to prevent apoptosis by cellular acidosis, tumour cells increase proton efflux through pH regulators, such as proton pumps, sodium-proton exchangers, bicarbonate transporters and monocarboxylate transporters (MCT). Since in ColoRectal Adenocarcinomas (CRC), data concerning expression of MCTs are scarce and controversial, present study was aimed at the assessment of the role of MCTs in CRC, by studying the immunohistochemical expression of the MCT isoforms 1, 2 and 4 in a well characterized series of CRC and searching for its correlations with clinico-pathological parameters Casuistic and Methods: Formalin-fixed, paraffin-embedded samples from 126 CRC were analyzed for MCT1, MCT2 and MCT4 amplified by avidin-biotin-peroxidase system. Consolidating a semi-quantitative assessment, cases were further subdividing as positive or negative for each MCT, yielding further comparison with 15 clinico-pathological variables. Results: Immunoexpression of all MCTs in tumour cells was significantly superior to the findings in adjacent normal epithelium (81.7 % vs 19.8% for MCT1,$p < 0.001$), 93.7% vs 45.8% for MCT2,$p < 0.001$, 95.2% vs 41.6% for MCT4, $p < 0.001$). Remarkably, there was a significant loss of plasma membrane staining in the transition to malignancy (118/126 cases, 93.7% vs 38/83 , 45.8% ($p < 0.001$). Such difference was not finding in plasma membrane immunoexpressions of MCT1 nor of MCT4. As regards clinico-pathological variables, MCT1 expression in plasma membranes pattern was found in a lower percentage of positive cases in adenotubulo-papilar carcinomas ($p = 0.023$). On the other hand, plasma membrane expression of MCT1 was directly related to the presence of vascular invasion ($p = 0.001$). Regarding histological differentiation, both MCT2 ($p < 0.001$) and MCT4 ($p < 0.001$) were significantly more frequently expressed in low grade tumors , whereas just a trend was found for MCT1 ($p=0.095$). Conclusions: The significantly higher expression of MCT 1, 2 and 4 in CRC as compared to corresponding non-tmoral areas found herein may serve as preliminary evidence for a pottentially important role of these MCTs in colorectal carcinoma . Further studies should be performed to assess whether this aberrant expression might justify the use of these proteins as targets in colorectal carcinoma drug therapy.

PP2-117

EXPRESSION OF bcl-2, P53, MDM-2 PROTEINS AND APOPTOSIS IN COLORECTAL ADENOMAS AND CARCINOMAS

Maria Tzouvala[1], Chariklia Kouvidou[2], Georgios V Papatheodoridis[3], Andreas Lazaris[4], Nikolaos Kavantzas[4], Thomas Papathomas[4], Nikiforos Kapranos[5], Ioannis Elemenoglou[6], Emanuel Agapitos[4], Dimitrios Karamanolis[7]

[3] 2nd Department of Internal Medicine, Med School of Athens University, Hippokration Hospital, Athens, Greece
[4] 1st Department of Pathology, Med School, University of Athens, Greece
[5] Department of Pathology, Mitera Hospital, Athens, Greece
[6] Department of Pathology, Tzaneion Hospital, Piraeus, Greece
[7] 2nd Department of Gastroenterology, Evangelismos Hospital, Athens, Greece

Background: Bcl-2, p53 and mdm-2 are genes implicated in the regulation of apoptosis. The aim of this study was to investigate the expression of bcl-2, p53, mdm-2 proteins and apoptosis in colorectal adenomas and carcinomas and to correlate them with clinicopathological parameters and patient's survival. Materials and Methods: Formalin-fixed paraffin- embedded tissue from 121 cases of colon adenomas and 46 colorectal carcinomas was stained by immunohistochemistry for bcl-2, p53 and mdm-2 protein. Apoptosis was measured by TUNEL method. The number of the positive stained cells was counted by using image analysis technique. Results: Bcl-2 cytoplasmic staining was found in 114/121 (96%) adenomas and in 18/46 (39%) colorectal carcinomas. P53 nuclear staining was found in 97/121 (80%) adenomas and in 19/46 (41%) colorectal carcinomas. Mdm-2 nuclear staining was found in 78/121 (78%) adenomas and in 25/46 (57%) colorectal carcinomas. Apoptotic index was higher in adenomas ($p=0.012$) in relation to carcinomas ($p=0.006$). P53 and bcl-2 protein expression was higher in tubulovillous-villous adenomas ($p=0.03$ and $p=0.02$, respectively) and in adenomas with size> 1 cm ($p=0.006$ and $p=0.03$, respectively). A statistically significant relationship between bcl-2 expression and the degree of dysplasia was observed ($p=0.009$). In carcinomas an inverse relationship between p53 and bcl-2 was found ($p=0.035$). In Cox regression analysis, Dukes' stage was the most significant independent prognostic indicator of a worse survival ($p=0.019$), whereas when stage was eliminated, bcl-2 expression was also a potential predictor for poor prognosis ($p=0.02$). Conclusions: Bcl-2 and mdm-2 expression seems to occur in the early stage of colorectal carcinogenesis. In large adenomas bcl-2 overexpression, in adittion to increased p53 expression, reduces apoptosis and give them a potential malignant phenotype. In carcinomas, apart from Dukes' stage, the bcl-2 expression seems to be an independent prognostic factor associated with an unfavourable outcome.

PP2-118

INTESTINAL BEHCET'S DISEASE: A CASE REPORT

Basak Doganavsargil[1], Gokhan Keser[2], Gulsen Kandiloglu[2], Cemil Caliskan[3], Muge Tuncyurek[1], Eker Doganavsargil[2]
[1] Ege University Faculty of Medicine Department of Pathology, Izmir, Turkey
[2] Ege University Faculty of Medicine Department of Rheumatology, Izmir, Turkey
[3] Ege University Faculty of Medicine Department of General Surgery, Izmir, Turkey

Behçet's disease (BD) is a multisystemic inflammatory disorder characterized by recurrent aphthous ulcers, genital ulcers, ocular and skin lesions. Hulusi Behçet, a Turkish Dermatologist first defined it in 1937 as a triad. Since its initial description involvement of many other organs has been reported. Gastrointestinal tract disease has been reported to occur in 3–60% of patients with BD. It is most frequent in patients from Japan (50-60%), followed by those from the UK and is least common in Turkish patients (2.8%). Any part of the intestine may be affected, but the ileocaecum is the most predominant site. We report on a 33-year-old male patient who was admitted to the hospital because of fever, abdominal pain, nausea, vomiting following a haemorrhoid operation. He has been diagnosed as BD 12 years ago, and received "colchicine" for 7 months. The treatment was quitted for its side effects as diarrhea, the patient remained untreated for 11 years. Although mucocutaneous lesions recurred meanwhile, ocular controls revealed any progression. He has been suffering from hematochezia related with hemorrhoids for 6 years. Following the haemorrhoid operation, massive hematochezia was developed. Due to previous history of BD he has taken puls steroid therapy that resulted in healing of symptoms. Abdominal ultrasound detected oedema in the walls of right colon and ileum. He underwent a colonoscopy which showed multiple ulcers in the right colon, with areas of closed perforation. A right hemicolectomy with distal ileal resection was performed. The resected specimen showed fibrinous exudate, congestion and serosal adhesions as well as closed perforations and mucosal ulcers. Histologic examination revealed superficial or penetrating ulcers with perforation, leading to peritonitis. There was a nonspecific inflammatory infiltrate in the neighbourhood of ulcers and focal areas of ischemic necrosis. The most striking feature was "Lymphocytic vasculit" observed in small to medium sized venules. The small and medium sized arteria and venules of serosa also showed thrombus, thrombosis and recanalization. Neutrophylic phylebitis was observed in small vessels. But no granulom formation or fibrinoid necrosis was present. The underlying pathology was consistent with vasculitis that affects both small and large vessels. With the aid of the clinical history, the case was considered to be an intestinal reflection of Behçet's disease and responded well to high dose steroid therapy and cyclophosphamid. The case was presented for its demonstrative histopathologic findings.

PP2-119

SOLID PSEUDOPAPILLARY TUMOR OF PANCREAS: IS IT REALLY RARE?

Ovgu Aydin, Gulen Dogusoy, Sibel Erdamar, Suha Goksel
Department of Pathology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Background: Solid pseudopapillary tumor is an uncommon neoplasia of pancreas presenting mostly at young age in women. These tumors show acinar, ductal and endocrine cell differentiation mostly with predominance of exocrine features. They are usually found incidentally at physical examination or they sometimes cause abdominal discomfort. The neoplasms present as large, round encapsulated and well demarcated masses. The cut surface is lobulated with necrotic and hemorrhagic areas. The microscopic examination revaeals solid monomorphic pattern with pseuopapillary component located more centrally which is the most distinctive feature of this tumor. The neoplastic cells occasionally contain diastase-resistant PAS positive globules. The most consistent positive immunohistochemical markers for this tumor are alpha-1- antitrypsin, alpha-1-antichemotrypsin, progesterone receptors (PR) and CD10. The citeria for malignancy are perineural invasion, angioinvasion or deep invasion to sorrounding tissue. Method and Results: In our study, we reviewed 13 cases of solid pseudopapillary tumor which accounted for about 14% of all exocrine tumors, diagnosed during 15-year period (1992-2007) and analyzed for clinicopathological features, expression of several markers including alpha-1- antitrypsin, neuron specific enolase (NSE), vimentin, PR, chromogranin and synaptopyhsin. The malignancy citeria were reviewed for each case. The mean age was 34,4 (range: 19-73) and all the patients were women except one. Two cases that had been diagnosed as cystic papillary neoplasia in the past had the same histology and the immunohistochemical properties as solid pseudopapillary tumor.. Positive immunohistochemical staining for endocrine markers was seen in some of the cases. Conclusion: Solid pseudopapillary tumor which are included in less common neoplasms of pancreas are probaby being diagnosed more frequently as the number and sensitivity of diagnostic imaging studies increase. Number of the solid papillary tumors diagnosed at our center during the last 4 years was 10 which constitutes the majority (the other 3 cases diagnosed within 11 years). So the pathologist should be alert when dealing with a large cystic tumor composed of a solid monomorphic morphology and pseudopapillary areas and should make a detailed workup including immunohistochemical panel for the diagnosis and malignancy potential.

PP2-120

CORRELATION BETWEEN TELOMERASE ACTIVITY, TUMOR BUDDING AND SEVERAL IMMUNOHISTOCHEMICAL MARKERS WITH THE STAGE INFLUENCING PARAMETERS IN COLORECTAL ADENOCARCINOMAS

Liljana Spasevska[1], Vesna Janevska[1], Rubens Jovanovic[1], Slavica Kostadinova-Kunovska[1], Gordana Petrusevska[1], Nikola Jankulovski[2], Toni Josifovski[2], Vlado Janevski[2], Aleksandar Sumkovski[2], Aleksandar Karagjozov[2]
[1] Institute of Pathology, Faculty of Medicine, Skopje, R. Macedonia
[2] Clinic for Digestive Surgery, Clinical Center, Skopje, R. Macedonia

Background: Although may be out of date, evaluation of telomerase activity in human cancer and it's importance in tumor progression is still intriguing. Hoping to get some data about the correlation of telomerase activity to other, more widely evaluated parameters in colorectal adenocarcinoma (CA), including macro- and microscopic features influencing the disease stage, we performed the following study. Methods: We analyzed 52 specimens of resected CA with different AJCC stages, sent from the Clinic for Digestive Surgery. All of them were formaline fixed, and tissue samples for standard pathohistologic analysis were embedded in paraffin. Sections were stained with H.E and immunohistochemicaly (ICH) for p53, Bcl-2 and Ki-67 (DAKO Cytomation EnVision+ HRP system). Besides the analysis of standard macro- and microscopic parameters for staging, we analysed the tumor budding (TB) according to Moradomi's criteria. ICH stainings were evaluated semiquantitatively. From 22 specimens accepted at the Institute of Pathology as unfixed, samples from tumor tissue and control samples from the resection margins were frosen for telomerase activity analysis (RTA) using ''TeloTAGGG PCR-ELISA'' kit from Roche. Results: RTA was significantly increased (2,5 fold) in tumor samples compared to controls ($p<0,05$). Significantly lower RTA was detected in CA with 2+ Bcl-2 expression (1,8 fold increase, compared to controls), compared to Bcl-2 negative CA (2,4 fold higher,

compared to controls) (p<0,05). We found similar difference in RTA between tumors that haven't pnetrated the bowel wall, compared to those that have (p<0,05). RTA showed positive correlation to the extramural tumor spread (SpearmanR 0,517; p<0,05) and negative correlation to Bcl-2 expression (SpearmanR -0,60;p<0,01) and Ki-67 (SpearmanR -0,48;p<0,05). Our data showed significant differences between CA without distant metastases and CA that have metastasized concerning following parameters: TB, number of positive lymphnodes and extramural venous invasion (p<0,01). TB showed strong positive correlation to the following parameters: extramural spread, infiltrative growth pattern, number of involved lymph nodes, extramural venous invasion, and distant metastases (p<0,05), having the strongest impact on the number of lymph nodes affected (b=0,69;p=0,015). Conclusion: RTA is significantly increased in CA with extramural spread and Bcl-2 negative ICH staining. However, TB is cheaper and simplier to evaluate and is associated to more significant parameters such as lymph node and distant metastases.

PP2-121
GASTRIC CANCER-APPROPRIATE RESECTION WITH LYMPH NODE DISSECTION

Małgorzata Malinowska[1], Anna Nasierowska-Guttmejer[2]
[1] Oncology Center-Institute Warsaw, Poland
[2] Clinical Hospital MSWiA Warsaw, Poland

BACKGROUND: The extend of lympadenectomy and gastric resection remain controversial issues in management of early gastric cancer (EGC). The latest study was performed to appropriate gastric resection with lymph node dissection for early gastric cancer. AIM: We analyze the extension of gastric resection and lymphadenectomy in EGC and advanced gastric cancer. METHODS: 104 patients; 50 patients with early gastric cancer and 54 with advanced gastric cancer were operated in Oncology Center-Institute in Warsaw, from 1999 to 2005. 93 patients underwent total gastrectomy; 44 patients with early gastric cancer and 49 with advanced gastric cancer. 10 patients underwent subtotal gastric resection (5 cases with early gastric cancer and 5 cases with advanced gastric cancer). Endoscopic mucosal resection was performed in 1 cases with early gastric cancer. Lymphadenctomy was performed in 103 cases. RESULTS: In cases with EGC mucosal invasion was observed in 21 patients and submucosal invasion in 29 patients. From 2 to 48 lymph nodes were obtained in patients with early EGC and from 6 to 55 in patients with advanced gastric cancer). Lymph node metastases were found in 5 cases with EGC (4 cases with submucosal invasion) and 36 cases with advanced gastric cancer. CONCLUSION: Our study confirms that the depth of invasion and lymph node involvement is an extremely important prognostic factor. For the reason, D2 gastrectomy is the standard treatment even in EGC.

PP2-122
SERRATED POLYPS OF THE LARGE INTESTINE: CLINICOPATHOLOGICAL FEATURES OF SESSILE SERRATED ADENOMAS

Ozben Yalcin[1], Cigdem Ataizi Celikel[1], Neşe Imeryuz[2], Erol Avsar[2]
[1]Marmara University School of Medicine, Department of Pathology, Istanbul, Turkey
[2]Marmara University School of Medicine, Department of Internal Medicine, Istanbul, Turkey

AIM: Serrated polyps of the large intestine, including traditional hyperplastic polyps (HP), traditional serrated adenomas TSA), and more recently described sessile serrated adenomas (SSA), have gained increased recognition in recent years because of growing evidence that one of these lesions, SSA, might be the precursor lesion for some cases of microsatellite unstable colorectal carcinoma. However, for many practicing pathologist, numerous diagnostic challenges exist to diagnose SSA. METHODS: A total of 236 colonic polyps from over a three-year period (2005-2007) were retrieved from the archives of pathology department. Endoscopic polypectomy biopsies diagnosed as tubular adenoma with low grade dysplasia (TA) (n=42), HP(n=54), TSA (n=18), SSA(n=5), abberrant crypt foci (ACF)(n=8) and normal mucosa (NM) (n=15)were retrospectively examined. "Architectural dysplasia" and "cytologic dysplasia" were evaluated. Among architectural findings; branching and dilatation of the base of the crypts, inverted T- and L- shaped crypts, the presence of mature cells with goblet cell or gastric foveoler phenotype at the base of the crypts replacing the proliferative zone, serration at the base of the crypts, foci of pseudostratification of the surface epithelium, eosinophilic change of the surface epithelium, subtle nuclear alterations were noted. All polyps were re-classified according to Snover et al. as HP, SSA, TSA, mixed serrated polyp (SSA+TA) and sessile serrated polyp (SSA+HP). RESULTS: Seven cases were re-classified as SSA (1 TA, 2 HP, 2 ACF, 3 NM), 5 cases as mixed serrated polyp (4 TA) and 3 cases as sessile serrated polyp (3 HP). The age range was 32-75 years (average 54 years). Twelve patients were females and 8 were males. The sites of SSAs were as follows: 6 in ascending colon, 5 in hepatic flexura, 4 in transverse colon, 5 in rectosigmoid colon. The diameter of the SSA ranged from 5 to 12 mm. Irregular shapes of the crypts with branching and dilatations in the basal parts and mature cells in the basal crypts were the two easily applied morphologic criteria in the diagnosis of SSA. In 2 patients with SSA there was synchronous adenocarcinoma of the colon. CONCLUSIONS: There is histologic overlap among the features of HP, TSA, SSA, and ACF which creates diagnostic difficulty. Accurate diagnosis requires the examination of the base of the crypts in well-oriented sections. Approximately 20% of SSA cases have areas of tubular adenoma which shows that the progression to a more aggressive form is not uncommon.

PP2-123
APOPTOSIS AND CELL PROLIFERATION IN GASTROINTESTINAL STROMAL TUMORS (GISTS)

Vera Todorovic[1], Marjan Micev[2], Predrag Pesko[3], Neda Drndarevic[1], Marija Drajic[1], Sanja Vignjevic[1]
[1] University of Belgrade - Institute for Medical Research, Department of Immunohistochemistry and Electron Microscopy, Belgrade, Serbia
[2] Institute of Digestive Diseases, Clinical Center of Serbia; University of Belgrade - Institute for Medical Research, Department of Immunohistochemistry and Electron Microscopy; Belgrade, Serbia
[3] Institute of Digestive Diseases, Clinical Center of Serbia, Belgrade, Serbia

Background: Although GIST has been extensively investigated in an attempt to identify factors predictive to aggressive behavior, there are few molecular investigations directed towards determining importance of apoptosis in these tumors. In addition, relatively little is known about the mechanisms by which tumor cells growth and proliferate. In this study, the authors present the results of relation of apoptosis and cell proliferation in GIST, in correlation with tumor site and disease grade. Method: Eighty two cases (40 male and 42 female patients, age range 31-73 years) with surgically resected GIST were admitted into the study. The site of the lesion was the gaster in 35, small intestine in 28, colon/rectum in 7 and extraintestinal site in 12 cases. GISTs were reclassified into low-, intermediate-, and high risk group regarding their estimated potential for aggressive clinical behavior as proposed by NIH. Apoptosis was assessed using the TUNEL detection system (TdT-FragEL kit, Oncogene, San Diego, CA). Immunohistochemistry for Ki67 was performed using avidin-biotin-peroxidase complex technique (LSAB+/HRP kit; Dako, Denmark). Apoptotic index (AI) was calculated from the number of positive-staining cells in at least 1,000 tumor cells.

Ki67 labeling index (Ki67 LI) was determined by the quotient of Ki67+ cells and the total number of cells, and at least 300 cells were counted in 3 representative tumor areas. Results: Our analysis revealed that apoptotic index is associated with histopathological grade of tumors, and was significantly higher in intermediate- compared with low risk group (6.9±2.1 v.s. 4.97±0.74; $p<0.05$). Also, in intermediate and high risk groups was found that apoptosis is in correlation with proliferation ($p<0.01$). Refer to tumor localization, significant increase in apoptotic activity was found in extraintestinal tumors compared to lesions in colon/rectum (7.23±0.78 v.s. 6.64±1.82; $p<0.01$), while both proliferation (11.7±3.05 v.s. 6.92±1.39; $p<0.01$) and apoptosis (7.02±1.36 v.s. 5.67±0.69; $p<0.05$) was significantly increased in small intestine lesions compared to gaster. Contrary, in low risk group of tumors apoptotic index was found significantly increased in gaster compared to small intestine lesions (5.84±0.84 v.s. 3.41±0.84; $p<0.01$). Conclusion: Our results suggest that not only cell cycle regulatory proteins, but those who regulate apoptosis might reflect tumor grade and patients prognosis of gastrointestinal stromal tumor. Also, it seems that site of the lesions may be a contributing factor to the pathogenesis of GISTs.

PP2-124

SOLITARY LIPOMATOUS POLYP OR LIPOMA OF GASTROINTESTINAL TRACT: 3 CASE REPORTS

Fahri Yilmaz[1], Yasemin H Balaban[2], Neriman Şengul[3], Cetin Boran[1]

[1] Abant Izzet Baysal University, Izzet Baysal of Medical Faculty, Pathology Department, Bolu, Turkey

[2] Abant Izzet Baysal University, Izzet Baysal of Medical Faculty, Gastroenterology Department, Bolu, Turkey

[3] Abant Izzet Baysal University, Izzet Baysal of Medical Faculty, General Surgery Department, Bolu, Turkey

Backgrounds: Lipomas are most common, benign, mesenchymal neoplasm consisting of mature adipous tissue in their stroma. Most of the lipomas are located superficially or deeply in the skin, although, they also can be seen in gastrointestinal tract and are usally insidental findings in the submucosa or serosa of the small and large intestine. The solitary lipomas of colon have been reported to have a tendency to occur in the vicinity of ileocaecal valve or the ascending colon. Lipomatous poliposis is a rare "non-inherited gastrointestinal polyposis syndrome" associated with diffuse lipomatous polips of colon. Here we reported 2 cases of solitary colonic lipomatous polips at distal colon and a case of duodenal lipoma in order to emphasize the confusion in the terminology of lipoma and lipomatous polip. Case 1: Sixty nine year's old, female complained of hematochesia for 3 weeks. She had the history of hypertension and hyperlipidemia. The physical examination, blood tests were within normal range. Colonoscopic examination revealed pancolitis associated with patch hemorrhagic areas and 1 cm sesile polyp in the rectum. The stroma of polyp was composed of mature fat tissue and fibrocollagen which were surrounded by normal rectal epithelium. Case 2: Seventy six year's old, female patient with hypertension and hyperlipidemia was investigated for constipation of one year duration which was recently accompanied by hematochesia. Her father and sister had the history of larynx and colon cancers, repectively. Her physical examination, blood tests were within normal range. There was a large tumor and 2 cm sesile polyp in the rectum. Pathologic examination revealed normal rectal epithelium lining the stroma of mature adipocytes and blood vessels at different sizes. Case 3: Fifty nine year's old female had been previously operated for breast cancer. On routine check up, all the laboratory tests were normal except for elevated erithrocyte sedimentation rate. A 3 cm sesile polyp had been detected at second portion of duodenum and polypectomy was applied to it. There was a thin fibrous capsule beneath duodenal epithelium and surrounding mature adipose tissue. Conclusion: We though that solitary lipomatous polips are much more rare than lipomas in the gastrointestinal tract. The differentiation of submucosal gastrointestinal lipomas from lipomatous polips can be based on the presence of a prominant capsule in a unpedinculated polyp. Although most of the colonic polyps are adenomatous, the differential diagnosis from lipoma or lipomatous polyps is necessary.

PP2-125

EXPRESSION OF EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) IN GASTRO-INTESTINAL STROMAL TUMORS

Khadija Bellil[1], Selma Bellil[2], Amina Mekni[2], Ines Chelly[2], Nidhameddine Kchir[2], Moncef Zitouna[2], Slim Haouet[2]

[1] La Rrabta Hospital, Pathology, Tunisia

[2] La Eabta Hospital, Tunisia

Epidermal Growth Factor receptor (EGFR)is a member of the ErbB family of receptors existing on the cell surface and activated by binding of its specific ligands, wich include epidermal growth factor and transformaing growth factor. Activation of EGFR is associated with cell growth and transformation. It is overexpressed in many types of cancers, especially colorectal cancer and seems to reflect more aggressive histological and clinical behaviors. Material and method: The aim of this study was to evaluate EGFR immunohistochemical reactivity in 20 gastrointestinal stromal tumours (GISTs) of the stomach (n = 12), small intestine (n = 7) and colon (n=1) using standard immunostaining techniques in paraffin-embedded sections. Result: 9 cases of GISTs (45%) expressed EGFR. EGFR(-)tumors(11 cases) measured 11±5.8 cm of size, were extragastric in 5 cases (45.5%), with high risk of malignancy in 7 cases. Mitotic index was 2.6±2.3 mitosis /50 HPF in GISTs EGFR (+) and 17.2±15.7 /50 HPF in GISTs EGFR (-) with significant difference ($p=0.012$). Proliferative index was estimated by MIB-1 expression and was evaluated to 1 ± 1.3 in GISTs EGFR (+) and 8.3±9.6 in GISTs EGFR (-) ($p=0.051$). Conclusion: These preliminary results suggest that loss expression of EGFR in GIST is correlating with aggressive biological tumors.

PP2-126

TRANSMURAL BACTERIAL AND FUNGAL INVASION AND MYCOTIC THROMBOSIS OF THE MESENTERIC VESSELS IN PATIENTS WITH ACUTE MESENTERIC INFARCTION. A BRIEF REPORT OF A PRELIMINARY STUDY

Hacer Ece Arslan[1], Suha Goksel[1], Gokhan Aygun[2]

[1] Department of Pathology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

[2] Department of Microbiology and Clinical Microbiology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Background: The translocation of commensal bacteria in patients with ischemic bowel, and development of septic and toxic shocks are well known incidents in practice. During our routine pathological examination, we have identified candida strains and some pleomorphic filamentous microorganisms invading necrotic bowel wall. The aim of this study is to determine the prevalence of the invasive fungi infestation of the infarctoid bowel and to specify the invasive filamentous microorganisms that cause mycotic thrombosis. Method: Seventy five consecutive patients in whom acute intestinal ischemia was diagnosed between 2005 and 2006 were retrospectively reviewed. Tissue Gram, PAS, Gridley, and Masson thrichrome stains were applied on the paraffin section of tissue samples that contain microorganisms. Results: There were 41 men and 34 women. Ages ranged from 24 to 87 years (mean 55,5 years). Only small bowel resection, only large bowel resection, both small and large bowel resections were applied in 55, 8, and 12 patients respectively. 4 patients had superior mesenteric vein thrombosis, 7 patients had superior

mesenteric artery occlusion, 5 patients had external herniation, 3 patients had internal herniation, 7 patients had bride ileus, 5 patients had previous abdominal radiation therapy, and 12 patients had previous abdominal surgery. The others had unknown etiology. Pathological examination revealed transmural infarction in 28, mural infarction in 12, mucosal infarction in 19 cases. Subacute ischemic enteritis with acute exacerbation was observed in 16 cases. In patients with transmural infarction, cocci and rods were invading the necrotic wall and the subserosal mesenteric fat tissue. Colonization of the candida strains were observed on the luminal aspect of the necrotic wall, under the denudated necrotic membrane. Candida colonization was also seen on the serosal surface in some patients with transmural infarction. In addition to these findings, some pleomorphic filamentous microorganisms were invading the whole thickness of necrotic and semiviable bowel wall, and subserous space. The lumen of the extramural arteries and veins were obliterated with these microorganisms that were PAS (-), and Gridley (-). Conclusion: Acute mesenteric infarction is still a disease with a consistently high mortality rate. If surgery is performed in an early stage, the survival rate increases regardless of age. One of the most important prognostic factors is the time interval between the onset of symptoms and surgery. We suspected that candidiasis and invasive filamentous microorganisms were probably seen in the patients that delayed diagnosis. The presence and identification of these microorganisms in the surgical specimens may be important in the post-operative management of the patients, especially in prophylactic therapy of the infections.

PP2-127

THE RELATIONSHIP OF K-ras MUTATION AND MUCINOUS DIFFERENTIATION OF COLORECTAL CARCINOMAS

Sibel Erdamar[1], Esra Ucaryilmaz[1], Nuray Kepil[1], Ugur Ozbek[2], Ece Arslan[1], Ahmet Dirican[3], Gulen Dogusoy[1], Suha Goksel[1]
[1] Cerrahpasa Medical College Pathology Department, Istanbul, Turkey
[2] Istanbul University Experimental and Research Center, Istanbul, Turkey
[3] Cerrahpasa Medical College Biostatistics Department, Istanbul, Turkey

BACKGROUND: Accumulation of molecular alterations, including K-ras mutations are believed to be critical events in carcinogenesis. Mucinous adenocarcinomas of colon need to be more investigated for their different behaviour.We aimed that at clarifying the role of k-ras mutation related to mucinous differantiation in Colorectal Carcinomas (CRC). DESIGN: This retrospective study was composed of 33 sporadic colorectal cancer cases which had undergone radical surgery and diagnosed in Cerrahpasa Medical College. The cases were subdivided according to presence of extracellular mucinous secretions. K-ras mutations in codon 12 were examined in tumor tissues using PCR-RFLP analysis. RESULTS: Twenty one (66%) of the cases had either focally or no extracellular mucin secretion (M-). Other 12 cases showed extracellular mucin (M+) in different percent ranging 10-90% of all tumors. K-ras mutation was found in 15 (45,3%) of all cases and 8 (66,6%) of M(+) cases. Mucin secretion showed statistically significant correlation with k-ras mutation and depth of invasion ($p<0.05$. There was not found significant correlation between mucinous diferentiation and sex of the patients, age and tumor grade. CONCLUSIONS: Our data indicate that the presence of mucinous secretion in colorectal carcinomas is associated with presence of k-ras mutation. This finding is important to understand for distinct behaviour pattern of CRC with mucinous differentiation.

PP2-128

MOLECULAR ANALYSIS OF SERRATED POLYPS AND SYNCHRONOUS CANCERS THAT ARISE IN THE SETTING OF HYPERPLASTIC POLYPOSIS SYNDROME

Berna Savas[1], Arzu Ensari[1], Astrid Hirschmann[2], Andreas Jung[2], Thomas Kirchner[2]
[1] Ankara University, Medical Faculty, Department of Pathology, Turkey
[2] Munich Ludwig Maximilians University, Institute of Pathology, Germany

Background: Hyperplastic polyposis syndrome (HPS) is an uncommon condition, characterized by the presence of multiple, large hyperplastic polyps (HP), the majority of which is mainly located in the right colon. Though, the true risk is not known, HPS is associated with an increased risk for colorectal cancer (CRC) through alternative morphologic and molecular pathways. Molecular analysis of the carcinomas and representative premalignant lesions was performed in order to understand the morphologic and genetic changes that lead to the development of carcinoma in this syndrome. Method: Two cases of HPS comprising two male patients of 51 (case 1) and 75 (case 2) years old underwent rectosigmoidectomy and total colectomy, respectively, for CRC. Case 1 had 20 in the descending colon while case 2 showed 25 hyperplastic polyps (HP) and/or sessile serrated adenomas (SSA) in transvers and rectosigmoid colon. DNA extraction was performed from carcinomas, three representative polyps, and from normal mucosa in each case. Mutation analysis was performed using PCR and sequencing exon 2 and exon 3 of KRAS gene. Microsatellite instability status was determined using primers for BAT25, BAT26, D5S346, Mfd15 and D2S123. MSI-high (MSI-H) cases showed mutation in two of five markers whereas in MSI-low (MSI-L) phenotype only one of five markers was unstable and in microsatellite stable (MSS) cases none was mutated. Immunohistochemical detection of mismatch repair gene proteins was performed using antibodies to hMLH1, hMSH2, hMSH6 and PMS2. Tumour cells without nuclear staining, in the presence of positively stained stromal cells were considered to have an abnormal pattern of expression. Results: Both tumours were moderately differentiated adenocarcinomas. KRAS mutation was found on exon2, codon12 (glycine to aspartat) in the tumor sample of case 2. There was no evidence of microsatellite instability at any of the five loci examined, in either of the carcinomas and both tumours were positively stained with mismatch repair gene proteins. HPs or SSAs did not show KRAS mutations or MSI in the representative samples. Conclusion: The molecular analysis of HPS showed no evidence of MSI in either the carcinomas or any of the precursor lesions examined, including HPs and SSAs. The neoplastic progression in HPS seems to follow the classical genetic pathway rather than the “serrated pathway” of colorectal carcinoma which occurred synchronously with mutation of KRAS in one of the tumours studied.

PP2-129

THE CORRELATION BETWEEN SERUM VEGF LEVELS AND TUMOR-ASSOCIATED MACROPHAGES IN COLORECTAL CANCER

Alfredo Matilla[1], Luis Vicioso[1], Martina Alvarez[1], Elena Gallego[2], Francisco J Gonzalez[3], Isabel Sevilla[3], Eduardo Marques[4], Lorenzo Alonso[3], Emilio Alba[3]
[1] Department Of Pathology. University Of Malaga, Malaga, Spain
[2] Department Of Pathology, Virgen De La Victoria University Hospital, Malaga, Spain
[3] Medical Oncology Service, Virgen De La Victoria University Hospital, Malaga, Spain
[4] Colorectal Surgery Unit, Virgen De La Victoria University Hospital, Malaga, Spain

Background: The angiogenesis process is stimulated by angiogenic factors released by tumoral cells, but other cells as

such tumor-associated macrophages (TAM) can also contribute to increase angiogenic proccess in colorectal cancer (CRC) producing the proangiogenic molecule vascular endothelial growth factor (VEGF). Aims: To determine in primary CRC patients the contribution of VEGF expression of TAMs and tumor cells in circulating VEGF levels, and their relation to p53 expression. Methods: Immunohistochemistry was used to identify TAMs, p53 protein, and to evaluate the VEGF expression by TAMs and tumor cells in 110 primary CRC patients. Serum VEGF levels were determined before and after surgery using an enzyme immune assay (ELISA). Results: VEGF expression in tumor cells was significantly greater in stage III carcinomas than in stage II and also correlated with lymph node metastases. There was a greater expression de VEGF in tumours with p53 positive immunohistochemical stain than in p53 negative. Macrophage index was not related to tumor VEGF secretion. We observed no significant association between serum VEGF values and VEGF tumor expression, node status, histological grade or p53. However, patients had high number of TAM expressing VEGF showed higher presurgery serum VEGF levels than those patients with median or low number of VEGF positive TAM (378 vs 246 or 251 pg/ml). Surgery produced an increased of serum VEGF levels at 6-8 hour after tumor removal (354 vs 285 pg/ml). Conclusions: Our data suggest that in primary CRC, presurgery circulating VEGF levels are mainly related to VEGF secreted by TAM instead of VEGF secreted by tumor cells. Abbreviations: microvessel density (MVD), vascular endothelial growth factor (VEGF), tumor-associated macrophages (TAM), enzyme-linked immunosorbent assay (ELISA).

PP2-130
SERRATED ADENOMAS AND SESSILE SERRATED POLYPS

Merva Soluk[1], Gulen Bulbul Dogusoy[2], Sibel Erdamar[2], Suha Goksel[2]
[1] University of Istanbul Institute of Oncology, Department of Tumor Pathology, Istanbul, Turkey
[2] University of Istanbul Cerrahpaşa Medical Faculty, Department of Pathology, Istanbul, Turkey

Background: Serrated adenoma (SA) is characterized by having combined architectural features of hyperplastic polyps and classical adenomas.A recently recognized lesion is a variant of polyps characterized by relatively large size, atypical histology and proximal location in the colorectum. Because this lesion lacks the traditional cytology of colorectal adenoma and in order to avoid confusion with SA, it is referred to in this review as sessile serrated polyp (SSP). In this study, the incidence and clinicopathologic features of SAs and SSPs previously diagnosed were investigated. Design: Between 2002 and April 2007, archives of Cerrahpaşa Medical Faculty, Department of Pathology were reviewed in both resection materials and endoscopic biopsies, all the cases diagnosed as SAs, adenomas with SA components and SSPs were collected. Their slides were reexamined and clinicopathologic features were discussed. Results: 173 polyps were reexamined in 165 cases. 84 cases were diagnosed as SAs, 58 cases as adenomas with serrated components (Mixed polyps) and 4 cases were SSPs. 26 of them were in resection materials whereas 139 cases were in endoscopic biopsies. Female/male ratio was nearly 1/2 and the mean age was 62,58. The most common location of SAs was rectosigmoid, however 2 cases of SA were seen in stomach, 2 cases in ampulla Vateri and small bowel, 3 cases in appendix, 9 cases in transvers colon, 14 cases in descending colon,25 cases in caecum and ascending colon,76 cases in rectosigmoid and 42 cases at specifically unknown location. SSPs were located mostly in caecum and ascending colon (3 cases). The diameter of SAs and SSPs ranged between 1,5cm. and 0,2 cm., 1,3 cm. and 0,1cm., respectively. In 7 of SAs and 9 mixed polyps development of carcinoma was observed. 9 SAs and 2 mixed polyps were found in the distant sites of colon in cases of colorectal carcinoma.40 cases were include high grade dysplasia pattern,29 cases were include moderate grade dysplasia pattern,56 cases were include low grade dysplasia pattern and 46 cases had no dysplasia pattern. Conclusion: This study showed that SAs are characterized by a heterogeneous group of changes at the clinicopathologic changes. SSPs are distinct variants located in the proximal colon. Our future project is to detect the molecular changes of these lesions.

PP2-131
CORRELATION OF HISTOPATHOLOGICAL CRITERIA WITH CLINICAL PRESENTATION IN INFLAMMATORY BOWEL DISEASE (IBD): IS IT USEFUL IN DETERMINING THERAPY?

Berna Savas[1], Arzu Ensari[1], Mehmet Bektas[2], Ali Tuzun[3], Sibel Percinel[1], Hulya Cetinkaya[2]
[1] Ankara University Medical School, Department of Pathology, Ankara, Turkey
[2] Ankara University Medical School, Department of Gastroenterology, Ankara, Turkey
[3] Ankara University Medical School, Department of Biostatistics, Ankara, Turkey

Background: Patients with ulcerative colitis (UC) and Crohn's disease (CD) share many similarities, but there are also many significant differences that make a distinction necessary. Since different surgical approaches are being used for their treatment pathologic decision making can become very stressful. In order to overcome the difficulty in the diagnosis of IBD and also to predict patients who might need additional therapy it might be useful to assess the value of histologic parameters and colitis pattern in distinguishing UC from CD. Method: A total of 70 patients biopsied for suspected IBD were included in the study. Their demographic findings as well as clinical symptoms (diarrhoea, blood in stool, abdominal pain, resistance to therapy) were noted. Histologically the presence of ulcer, villiform surface, cryptitis, crypt abscesses and distortion, mucin depletion, lamina propria inflammation, basal lymphoplasmacytosis, granulomas, lymphoid and ganglion hyperplasia, submucosal extension of inflammation, dysplasia was evaluated and graded as mild, moderate and severe. Statistical analysis was performed using Fisher's exact, chi square and Mann-Whitney tests. Results: There were 53 UC and 17 CD cases comprising 30 males and 40 females with an age range of 17-70. The most commonly observed histologic finding was LP inflammation seen in 66 (94,3%) patients followed by crypt distortion (n=62; 88.6%), cryptitis and mucus depletion (n=58; 82.9%). No statistical difference was observed between UC and CD patients in terms of histologic parameters except LP inflammation ($p<0.05$) which was more common in UC compared to CD. Patients who had rectal bleeding showed significantly increased cryptitis ($p<0.05$), basal lymphoplasmacytosis ($p<0.05$) in their biopsies. In patients with abdominal pain ($p<0.05$) and tenderness ($p<0.05$), cryptitis and crypt abscesses were significantly increased. Crypt abscesses were significantly ($p<0.05$) less common in patients who had the sense of well being. Patients with frequent diarrhoea showed significantly ($p<0.05$) more common ulcer formation and crypt abscesses in their biopsies. No correlation was observed between resistance to therapy and histologic parameters. Conclusion: Our results suggest that histological changes in IBD may be grouped under clinically relevant categories that provide a framework for their interpretation. Histological criteria of disease activity seem to correlate with clinical presentation of the patients with IBD and, thus could be used to design appropriate therapy.

PP2-132
ISOLATED ICC HYPERPLASIA: PRECURSOR OR UNUSUAL FORM OF GIST?
Hatice Ozer[1], D. Sema Arici[1], Arzu Ensari[2], Sahande Elagoz[1], Omer Topcu[3]
[1] Cumhuriyet University Medical School Department of Pathology, Sivas, Turkey
[2] Ankara University Medical School Department of Pathology, Ankara, Turkey
[3] Cumhuriyet University Medical School Department of General Surgery, Sivas, Turkey

Background: The most common primary mesenchymal neoplasms of the gastrointestinal tract are gastrointestinal stromal tumors (GISTs). The vast majority of GISTs occur in the stomach and small intestine. Colorectal GISTs are rare, comprising less than 10%. Precursor lesions for sporadic GISTs have not been well defined. Hyperplasia of interstitial cells of Cajal (ICCs) may represent facultative precursor lesion for sporadic GISTs in a hyperplasia–neoplasia sequence. ICCs are intestinal pacemaker cells that initiate peristalsis in the stomach and intestine, and are considered to be cell of origin for GISTs. Diminutive lesions consisting of KIT-positive spindle cells have been recognized in rare cases of familial GISTs and in von Recklinghausen's disease and very rarely in the vicinity of sporadic GISTs. Isolated cases of ICC hyperplasia not related to any other clinical condition or GIST has not previously been reported. Case report: A 56-year-old woman suffering from constipation and abdominal pain was attended to emergency room. A diagnosis of intestinal obstruction was made and she underwent an abdominal surgery. No mass lesion was observed except for serosal thinning in the sigmoid colon and adherence of omentum to abdominal wall. Serosa of the sigmoid together with the bowel wall was resected and histopathology revealed a diffuse lateral hyperplasia of spindle cells located between the layers of the muscularis propria throughout sigmoid colon. Spindle cells were positive for c-kit and CD34 but negative for myogenic or neurogenic markers, supporting that they are ICCs. No mitoses or cellular atypia were seen. There was no other tumour in the resection specimen. Thus the case was considered as (isolated hyperplasia of ICC) microscopic c-kit positive stromal nodul (GIST?). On further clinical evaluation the patient did not have any related clinical condition such as von Recklinghausen's disease, Carney's triad or GIST elsewhere. Conclusion: Since no association with GIST or any other condition related to GIST was present in our patient, the case was considered as an isolated hyperplasia of ICC. Interestingly the lesion was located in the colon which is not the typical site for GISTs. Whether this condition is a precursor of GIST or an unusual form of GIST needs to be further evaluated.
Key Words: Cajal cell hyperplasia, GIST

PP2-133
SERRATED POLYPS: COUNTING OR NOT COUNTING THE HISTOPATHOLOGICAL CRITERIA?
Berna Savas[1], Arzu Ensari[1], Mehmet Bektas[2], Ali Tuzun[2], Evrim Kahramanoglu[2], Hulya Cetinkaya[2]
[1] Ankara University Medical School, Department of Pathology, Ankara, Turkey
[2] Ankara University Medical School, Department of Gastroenterology, Ankara, Turkey

Background: The concept of "serrated neoplasia" pathway in colorectal carcinogenesis has introduced new precursor lesions with a generic name "serrated" polyps among which are hyperplastic polyps (HPs), sessile serrated adenomas (SSAs), serrated adenomas (SAs) and mixed polyps (MPs). SSAs are histologically similar to HPs but biologically comparable to adenomas. Though many histologic criteria have been proposed in the differential diagnosis of HPs and SSAs a consensus has not been reached yet. Therefore, we have decided to apply the proposed criteria to a series of serrated polyps in order to assess their discriminatory diagnostic value. Method: A total of 84 serrated polyps (38 HPs, 37 SSAs, 4 SAs, and 5MPs) were included in the study. There were 9 criteria comprising of exaggerated serration, papillary surface configuration, increased crypt branching, horizontally arranged crypts, basal crypt dilation, increased epithelium/stroma, mitosis and cytological atypia in the upper crypt zone, inverted crypts, and irregular distribution of goblet cells, used in the diagnosis. Each case was re-examined for the presence of these criteria and scored accordingly. Number of positive criteria and frequency of each criterion in each polyp group were evaluated in order to assess their diagnostic value. Results: In HPs, 78.94% of which had less than 3 criteria, the number of positive criteria ranged from 0 to 5 while 83.78% of SSAs had 4 or more positive criteria ranging from 3-7. Only 10.52% of HPs showed 4 or 5 criteria whereas 16.22% of SSAs had 3 criteria. MPs and SAs, all showed more than 4 criteria ranging from 4 to 7. Papillary surface configuration (50%) and crypt dilation (34.21%) were the most frequently observed criteria in HPs whereas SSAs showed irregular distribution of goblet cells (94.59%) and mitosis and cytological atypia in the upper crypt zone (89.19%) in a majority of the cases. Of the 5 SSAs with only three criteria, all showed mitosis and cytological atypia in the upper crypt zone and all but one had irregular distribution of goblet cells while HPs with more than 4 criteria did not demonstrate either of the latter two. Conclusion: Some overlap was observed between HPs and SSAa in terms of the number of diagnostic criteria found in both lesions. However, both mitosis and cytological atypia in the upper crypt zone, inverted crypts, and irregular distribution of goblet cells prove to be more suggestive of SSAs than HPs. Therefore, a qualitative approach rather than quantitation of criteria would aid in the diagnosis of serrated polyps.

PP2-134
PATHOLOGY TRAINEES: CAN THEY DIAGNOSE GASTROINTESTINAL EPITHELIAL DYSPLASIA AS WELL AS WE DO?
Duygu Enneli Kankaya[1], Cevriye Cansiz[1], Hatice Germen[1], Gulsah Kaygusuz[1], Ayse Ozgun[1], Sibel Percinel[1], Berna Savas[1], Guldal Yilmaz[1], Arzu Ensari[1], Yasemin Genc[2]
[1] Ankara University, School of Medicine, Department of Pathology, Ankara, Turkey
[2] Ankara University, School of Medicine, Department of Biostatistics, Ankara, Turkey

Background: Diagnosis and grading of dysplasia in one of the most difficult tasks of a pathologist, mainly due to lack of objective criteria and a worldwide consensus among pathologists. Despite consensus meetings and classification systems, interpretation of biopsies showing dysplasia is still difficult even for experienced gastrointestinal pathologists as well as pathology trainees. We therefore decided to assess the diagnostic difficulties that pathology trainees experience in dysplasia interpretation in gastrointestinal specimens and also to evaluate interobserver aggreement. Method: Eight training pathologists and one expert gastrointestinal pathologist reviewed 20 gastric and 8 colonic lesions (11 endoscopic biopsies, 6 polypectomy, and 10 operation specimens). The specimens were evaluated according to a simplified classification scheme of five categories: i. regenerative changes, ii. low grade dysplasia, iii. high grade dysplasia, iv. intramucosal carcinoma, and v. carcinoma with submucosal invasion using both cytologic and architectural criteria reviewed elsewhere by each trainee separately. The trainees were further divided into three groups according to their level of experience in pathology as group 1: 2nd year trainees (n=3), group 2: 5th year trainees (n=2), and group 3: 8th year trainees (n=3). Kappa statistics and McNemar test were performed for statistical analysis. Results: According to the expert pathologist there were 1 regenerative change, 4 low grade, 5 high grade dysplasias, 17 intramucosal carcinoma and 1 invasive carcinoma diagnosis among the study cases. The agreement of the trainees on the

diagnoses of gastrointestinal specimens showed great variation with a kappa value of 0.250 to 1.000 while kappa value of agreement between expert and trainees ranged from 0.339 to 0.600. The trainees diagnosed all regenerative lesions and invasive carcinomas (100% agreement) whereas only 15.625% of cases with low grade dysplasia and 45% of high grade dysplasia were in agreement with the expert pathologist. Conclusion: Our results suggest that experience in pathology seems to be a major determinant of diagnostic accuracy even in the training period and also that gastrointestinal dysplasia remains to be the cause of diagnostic difficulty for both young and experienced pathologists. However, there is still much to be done to improve the diagnostic skills of pathology trainees and to standardize the criteria of gastrointestinal epithelial dysplasia.

PP2-135
AN UNUSUAL CASE OF GASTRIC ADENOCARCINOMA, LEIOMYOMA AND SIMULTANEOUS OCCURRENCE OF B-CELL SMALL LYMPHOCYTIC LYMPHOMA INVOLVING THE PERIGASTRIC LYMPH NODES AND SPLEEN

Hatice Germen[1], Gulsah Kaygusuz[2], Isinsu Kuzu[1], Eda Akpinar[1], Cevriye Cansiz[1]
[1] Ankara University, School of Medicine, Department of Pathology, Ankara, Turkey
[2] Ankara University, School of Medicine, Department of Pathology Ankara, Turkey

Background: Chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) is a low grade indolent systemic neoplasm involves bone narrow and lymph nodes. Since it has a longstanding clinical presentation, it is expected having an higher risk of secondary cancers. We present here a rare case of a simultaneous occurrence of adenocarcinoma of the gastric cardia, submucosal leiomyoma and CLL/SLL involving the perigastric lymph nodes and spleen. Case: A 78 year old man underwent total gastrectomy, omentectomy and splenectomy because of the advanced cardia tumor. Macroscopically, the cardiac tumor was 2,7 cm in greatest dimension. There were multipl tumoral nodules in the omentum and hilar region of the spleen. Microscopically, the tumor composed of mucin producing atypical glandular and cribriform structures infiltrating the cardiac serosa. Non-tumoral antral mucosa showed hyperplastic polyp plus minute submucosal spindle cell tumor that was 5 mm in diameter. Six perigastric lymph nodes and splenic hilar lymph nodes revealed metastasis of adenocarcinoma whereas other nodes and white pulp of the spleen were diffusely infiltrated by uniform, small atypical lymphoid cells. Immunohistochemically, atypical lymphoid cells were strongly positive for CD20, CD5, CD23, and Bcl-2. Submucosal spindle cell tumor showed SMA, h-caldesmon and desmin positivity consistent with leiomyoma. Conclusion: This is the first case of unrelated simultaneously presented cardiac adenocarcinoma and leiomyoma in association with CLL/SLL infiltration in the perigastric lymph nodes and spleen in the literature.

PP2-136
GANGLIOCYTIC PARAGANGLIOMA OF THE DUODENUM: A CASE REPORT

Eda Akpinar[1], Gulsah Kaygusuz[2], Hatice Germen[1], Esra Erden[1], Cevriye Cansiz[1]
[1] Ankara University, School of Medicine, Department of Pathology, Ankara, Turkey
[2] Ankara University, School of Medicine, Department of Pathology Ankara, Turkey

Background: Duodenal gangliocytic paraganglioma (GPG) is a rare tumor that characteristically occurs in the second portion of the duodenum and typically presents with gastrointestinal bleeding. Duodenal GPGs have an excellent prognosis after surgical resection but metastatic spread to regional lymph nodes and recurrence may rarely occur. We present here a rare case of duodenal GPG in view of the literature. Case: A 41 year old man underwent pancreaticoduodenectomy for carcinoma of the ampulla vater. Macroscopically, the tumor, 2,7cm in greatest dimension, located in the ampulla without infiltration of the pancreas. Histologically, the tumor composed of epitheloid cells, ganglion-like cells with abundant cytoplasm and vesicular nuclei, and spindle cells arranged in broad fascicles. Immunohistochemically, tumor cells were strongly positive for S100, pancytokeratin, chromogranin A and synaptophysin. There was no metastasis in the regional lymph nodes. Conclusion: Paragangliomas of the ampulla vater have malignant potential. We review the differential diagnosis of this infrequent tumor.

SMALL VESSEL CHANGES IN POSTTRAUMATIC ULCERS

Radmila Stevanovic[1], Zorica Stojsic[1], Slobodan N. Savic[2], Aleksandar Stanojevic[2], Sofija Glumac[1], Jovan D. Vasiljevic[1]
[1] Institute of Pathology, Medical School, Belgrade, Serbia
[2] Institute of Forensic Medicine, Medical School, Belgrade, Serbia

Background: There are many different risk factors for developing stress ulcers after sever trauma. Different investigations showed that stress ulcers are more often in older age. Some authors consider that pathological changes on small vessels involve in developing stress ulcers after severe trauma and may have main role. Method: Material for this study was collected in the Institute of Forensic medicine in Belgrade. All cases with trauma who had risk for stress ulcers (period of survival at least 24 hours) are observed. They were divided in experimental (with stress ulcers) and control group (no stress ulcers). Histological analyses of abdominal organs were done with special focus on small arteries and arterioles. We analyzed data obtained from autopsy protocols, heteroanamnestic data from deceased's family and medical documentation about treatment, too. The samples were statistically prepared (χ2-test, Fisher's test). Used staining were H&E and elastica van Gieson. Results: The vast majority of all analyzed cases were male (71,43% in the experimental and 85,71% in the control group). Age average was 59,00 (SD=21,64) in the experimental and 52,86 (SD=21,48) in the control group. Regarding age, stress ulcers were most frequently diagnosed among individuals in eight decade of life (6 or 28,57%). There is no significant statistical difference between experimental and control group when we compared age (χ2=0,268, p>0,05). The mean outliving period was 14,65 days (SD=12,94) in the experimental group and 8,76 days (SD=8,70) in the control group. Analyses was also performed in relation to the manner of death. The vast majority of persons in both group were injured in accidents (17 or 80,89% in both group), predominantly traffic acidents (13 or 61,90% in the experimental and 10 or 47,62% in the control group). The most freqently couse of death in both groups, was demage of vital brain centers with/or without complications. Atherosclerosis of abdominal aorta in the experimental group in 52% cases were difficult. There is no significant differences between experimental and control group when compare frequency of changes on small vessels (X2=0,102, p>0,05). Histological changes on small vessels of gaster are not significantly different in experimental and control group (P=0,232, p>0,05). In some cases without ulcers spasm of small arteries was found. Conclusion: Morphological changes of small vessels do not have main role in appearing posttraumatic stress ulcers.

IMMUNOHISTOCHEMICAL ANALYSIS OF GALEKTIN-3 EXPRESSION AND PROGNOSTIC FACTORS IN INVASIVE GASTRIC CARCINOMA

Melin Ozgun Gecer[1], Osman Huten[2], Nevra Dursun[2], Nilsen Yildirim Erdogan[2], Erol Rustu Bozkurt[2], Nimet Karadayi[1]
[1] The Ministry of Health Dr Lutfi Kirdar Kartal Training and Research Hospital, Turkey
[2] The Ministry of Health Istanbul Training and Research Hospital, Turkey

Background: Gastric carcinoma is a common disease with different incidences in the countries.Nowadays gastric carcinoma is one of the most common neoplasm of all cancers. In gastric carcinoma, many studies has conducted for finding out the prognostic factors and various factor like the type of the tumor and its deepness, stage, metastas to lymph nodes, distant metastas were linked in the period survival. Galectin-3, a multifunctional B-galactocide binding lectin possibly participates in a variety of biological events including cell proliferation ,differentiation and apoptozis.The implication of galectin-3 during malignancy progression has been suggested in several cancers ,including colon ,prostate, thyroid and breast cancer,however ,scarce data are available in gastric cancer. Method: In our study, we investigated the expression of galectin -3 in gastric cancer progression and metastasis, 60 invasive gastric carcinoma cases were examined for galectin -3 expression by using immunostaining. Results: We found that cases with high grade gastric cancer expressed galectin-3 were slightly more than low grades. But we found the different galectin-3 expressions according to type of tumor. This was statistically significant. In conclusion: Our results seem to be irrelevant with current literature on the gastric cancers, but there are generally differences between galectin expressions in all organ cancer. The importance of galectin-3 in prognostic markers will be determined with many case series.

UP-REGULATION OF FIBROBLAST AND EPIDERMAL GROWTH FACTOR RECEPTORS, IN URINARY BLADDER CARCINOGENESIS IN HUMANS AFTER THE CHERNOBYL ACCIDENT

Alexander Vozianov[1], Alina Romanenko[1], Anna Iemelianova[2], Shoji Fukushima[3]
[1] Institute of Urology AMS of Ukraine
[2] National Medical University, Kiev, Ukraine
[3] Osaka University Medical School, Japan

Background. The morbidity of urinary bladder cancer in the Ukraine increased from 6.7 to 10.0 per 100 000 population between 1986-2006 after the Chernobyl accident. The present study was carried out in order to examine the molecular status of selected growth factor receptors (GFRs) in the urinary bladder lesions, recently described by our group as “Chernobyl cystitis”. Material and Methods. Fibroblast growth factor receptor 3 (FGFR3), epidermal growth factor receptor 1 (EGFR1), the member of the same family EGFR2neu, and Raf-1 serine/threonine kinase expression were immunohistochemically (IHC) evaluated in urinary bladder biopsies from 22 males with benign prostate hyperplasia (BPH) – group 1. For comparison, 16 analog males with BPH and 5 females with chronic cystitis living in non-radio-contaminated areas of the country were also investigated as controls (group 2). Additionally, 23 patients with primary urothelial carcinomas (UC), living in the radio-contaminated areas were included for carcinomas group. The current study was approved by the Institute of Urology Ethics Committee, Kiev, Ukraine. Results. Chronic proliferative atypical cystitis (“Chernobyl cystitis”) was observed in group 1 patients. Foci of dysplasia and carcinoma in situ (CIS) were found in 22 (100%) and 19 (86%) of the 22 cases, respectively; moreover, two pTa grade 1 Ucs were also incidentally detected. Greatly elevated levels of FGFR3, EGFR2neu, and to a lesser extent EGFR1 and Raf-1 expression in the urothelial dysplasia and CIS were evident for patients with BPH of group 1. Statistically significant differences in IHC scores for FGFR3, EGFR1 and Raf-1 were observed between groups 1 and 2 ($p < 0.0001$; 0.001; 0.005, respectively) and between groups 1 and carcinomas group ($p < 0.0001$; 0.005; 0.0001, respectively), including EGFR2neu ($p<0.005$). Conclusion. Our findings suggest that FGFR and EGFR signaling pathways, associated with Raf-1 activation, may contribute to multi-stage urothelial carcinogenesis, through autocrine or paracrine growth stimulation.

PP2-139

NON-TUMORAL PARENCHYMA IN LEYDIG CELL TUMORS: PATHOGENETIC CONSIDERATIONS

Mariana Cajaiba[1], Miguel Reyes-MúGica[2], Juan Carlos Rios[1], Manuel Nistal[1]
[1] Department of Pathology, Hospital La Paz, Universidad Autónoma de Madrid - Madrid, Spain
[2] Department of Pathology, Hospital La Paz, Universidad Autónoma de Madrid - Madrid, Spain; Departments of Pathology and of Pediatrics, Yale University School of Medicine - New Haven, CT, USA

BACKGROUND: Little is known about the pathogenesis of Leydig cell tumors (LCTs) of the testis. Interest has grown in studying male reproductive tract disorders based on a new concept on this field: the testicular dysgenesis syndrome, which comprises a variable spectrum of clinical manifestations, such as cryptorchidism, hypospadias, impaired spermatogenesis and testicular germ cell neoplasms. The observation of several associated dysgenetic features in the non-tumoral parenchyma and in the contralateral testes of men with testicular germ cell neoplasms has served as the basis to propose that there may be a common mechanism for different male reproductive disorders.

However, the possible relationship between LCTs and other testicular lesions has not been explored. Here we describe the presence of primary lesions in the non-tumoral parenchyma of testes with LCT, from which we try to establish possible pathogenetic associations. METHOD: We studied the non-tumoral parenchyma adjacent to 16 LCT specimens. Parameters as Leydig cell hyperplasia (LCHY), qualitative evaluation of the germinal epithelium and spermatogenesis, presence of Sertoli cell-only tubules (SCOT), and Sertoli cell nuclear morphology were consistently assessed in all cases. RESULTS: SCOT associated with Sertoli cell dysgenetic morphology was the most frequent finding, present in 50% of cases. Another interesting finding was the presence of LCHY in 4 cases (25%). Abnormal spermatogenesis was found in 81.25% of cases, and it consisted of lesions in the adluminal or basal compartments of seminiferous tubules. CONCLUSION: Although the pathogenesis of LCTs is unknown, their association with other primary testicular abnormalities may be relevant to improve our understanding of their development. The present work delineates the spectrum of morphological findings in the adjacent parenchyma of LCTs. The occurrence of either dysgenetic Sertoli cells and/or LCHY adjacent to LCTs could represent primary anomalies resulting from a common insult, also involved in tumorigenesis. However, the abnormalities in spermatogenesis observed here are likely to represent consequences of either tumor compression or abnormal hormonal production. The significance of these associations merits further investigation regarding a common pathogenesis.

PP2-140

THE ROLE OF DNA PLOIDY AND PROLIFERATION MARKERS (MIB-1 AND "S-PHASE) AS PREDICTIVE FACTORS OF TUMOR VOLUME, STAGE OF TUMOR AND PRESENSE OF POSITIVE MARGINS AFTER RADICAL PROSTATECTOMY

Marta Kovylina[1], Dmitry Pushkar[1], Tomas Sebo[2]
[1] Moscow State Medical Dentistry University, Russia
[2] Mayo Clinic, Rochester Minnesota, USA

Backgrounds: DNA ploidy has consistently been found to be a correlate of prostate cancer patient outcome. However, a minority of studies have used pretreatment diagnostic material. The aim of this retrospective study was to evaluate correlations between DNA ploidy, proliferation markers (MIB-1, S-phase), Gleason score, presence of perineural invasion, volume of tumor on biopsy and Gleason score, volume of tumor, stage, presence of positive margins, extraprostatic extension and seminal vesicle invasion after radical retropubic prostatectomy (RRP). Patients and Methods: 212 patients undergoing needle biopsies were diagnosed with cancer between January 2005 and April 2006. All patients were treated with RRP without preoperative adjuvant hormonal therapy. Based on the needle biopsies, DNA ploidy, S-phase and MIB-I immunostaining were measured. These data were combined with the Gleason score, percent cores and percent surface area positive for carcinoma, and status of perineural invasion in multivariate models using tumor volume and risk of extraprostatic extension at radical retropubic prostatectomy. Results: On the basis of DNA content measurement, 145 patients were classified as diploid, 67 patients were classified as non diploid. In non diploid group the mean volume of tumor after radical prostatectomy was 5.04 cm3, percentage of cases with positive margins was 30.9% versus 2.23 cm3 and 12.0% in diploid group. Predictors of tumor volume, presence of positive margins and extraprostatic extension were DNA ploidy (P, 0.0001), MIB-1 positivity (P, 0009), the percent nuclei classified by DNA quantification to be in the "S-phase" category (P 0.04), the percent surface area positive for carcinoma (P, 0.0001). Predictors of coincidence of Gleason score on biopsy and radical prostatectomy was DNA ploidy (P, 0.0001). Conclusions: DNA ploidy and proliferation markers appear to be an interesting feature at diagnosis. DNA ploidy and MIB-1 makes it possible to predict a T3-T4 stage disease and confined tumor.

PP2-141

PRIMARY COMBINED TUMOR OF BLADDER: SQUAMOUS CELL CARCINOMA AND ADENOCARCINOMA COLONIC TYPE.

Marta Kovylina, Pavel Rasner, Dmitry Pushkar
Moscow State Moscow Dentistry University, Russia

Introduction. The most common histological type of bladder cancer is urothelial carcinoma which comprises 90-95% of bladder cancer. Squamous cell carcinoma (SCC) of the bladder is much less frequent. Worldwide it constitutes about 1,3% of bladder tumors in males and 3,4% in females. Primary adenocarcinoma (AK) of bladder account for less than 1% of all bladder malignancies. Of these 20-30% are urachal in origin. The most important risk factors for SCC and AK of non urachal origin are tobacco smoking, occupational exposures and schistosomiasis. Prognosis: these tumors are almost radioresistant and the treatment is primarily surgical with extended partial or total cystectomy, in case of urachal AK excision of the urachal mass, urachal tract and umbilicus advocated. Clinical case. A 53-years old man chronic tobacco smoking and with occupational exposure presented macroscopic hematuria. Ultrasound examination, cystoscopy and CT scan showed a solid mall with wide basement on the right bladder wall in the greatest dimension 5x4 sm. The TUR biopsy of tumor was done. Histological examination of the tumor indicated two differentiations of malignant cells: well differentiated AK colonic type and well differentiated SCC. In order to exclude metastases from GI rectoscopy, colonoscopy, gastroscopy were done/ No malignancy in GI found. Diagnosis of primary combined SCC and AK of bladder was performed. The partial cystectomy, lymphadenectomy were done. The was no connection between urachus and tumor. Nevertheless excision of urachus was performed. Macroscopically tumor was presented by solid bulky mass with necrotic masses. Histologic examination of the tumor indicated from well to moderate differentiation SCC and from well to poor differentiation AK of colonic type. Metastases were found in 3 lymphatic nodes. One metestases was presented with poor differentiated AK, and two with moderately differentiated SCC. Conclusion. We report one case of a very rare combined tumor of bladder with considered a highly aggressive behavior. Prognosis in this case is not clear due to the absent of such cases in the literature.

PP2-142

ROLE OF ULTRASOUND-GUIDED CORE BIOPSY IN THE DIAGNOSIS OF RENAL MASSES

Ayman Gaafar, Francisco José Bilbao,
Aitor Fernandez De Larrinoa, José Luis Del Cura, Rosa Zabala,
Laura Oleaga, José Ignacio López
Hospital de Basurto, Basque Country University, Bilbao, Spain

Background: Ultrasound-guided core biopsy has being increasingly used in the last years in the diagnosis of renal masses, but its performance has not still reached a generalised acceptance among radiologists and pathologists. The purpose of this study is to investigate its diagnostic usefulness in a series of renal masses. Material & Methods: Over a 7-year period (2000-2006), a total of 64 renal masses in 63 patients were biopsied under ultrasound control with 18G BioPince® needles. The cases specifically selected for puncture belonged at least to one of the following groups: a) patients with complicated clinical situations that contraindicated surgery, b) tumours with atypical radiological presentation, and c) evaluation of renal involvement in systemic diseases. Surgery confirmed the diagnosis of carcinoma in 8 cases. The clinical context and previous history served as diagnostic controls in the remaining patients. Results: Males predominated in the series (46M/17F), and the average age was 58.14 (range 1-92). Right kidney was slightly more affected (34R/30L). One patient showed bilateral masses. Ablation with radiofrequency was performed in 22 cases. 49 cases (76.56%)

were neoplastic. Diagnostic categories included renal cell carcinoma (34 cases), oncocytoma (6 cases), malignant lymphoma (3 cases), Wilms tumour (2 cases), carcinoid tumour (1 case), cystic nephroma (1 case), spindle cell sarcoma (1 case), and metastatic squamous cell carcinoma (1 case). Five cases (7.8%) were pseudotumours (3 renal cysts and 2 chronic pyelonephritides). Finally, normal renal tissue (6 cases) and fibroadipous tissue (3 cases) were also diagnosed. There were no major diagnostic discrepancies in the series, and only minor changes in assigning the histological variant of renal cell carcinoma were detected in 2 cases. No major complications related to the technique were detected Conclusions: Ultrasound-guided core biopsy is a very useful and reliable method in the diagnosis of renal masses and should be included within the first-line tools in its initial management.

PP2-143
HOW OFTEN ARE CK 5/6, 34βE12, P63 AND P504S USEFUL IN SUPPORTING THE DIAGNOSIS OF MINIMAL CANCER IN PROSTATE BIOPSIES?
Ayman Gaafar, Francisco José Bilbao, Carmen Etxezarraga, Cosme Ereño, Maddi Garmendia, José Ignacio López
Hospital de Basurto, Basque Country University (EHU/UPV), Bilbao, Spain

Background: Prostate pathology is quite heterogeneous and the diagnosis of cancer in core biopsies is not always easy. Main difficulties are related to the identification of minimal cancer and its distinction from cancer mimickers. Immunohistochemistry appears as a highly recommended tool to resolve these diagnostic dilemmas. The aim of this study is to critically evaluate the usefulness of this diagnostic method in a large homogeneous series. Methods: A series of 46 minute prostate carcinomas (unique focus of cancer of 0.5 mm or less) have been tested retrospectively with CK5/6 (Dako, 1:100), 34βE12 (Dako, 1:100), p63 (Dako, 1:100) and p504S (Dako, 1:100) antibodies to evaluate the reliability of these markers in supporting the diagnosis of cancer vs. benign lesion. Results: Gleason index (GI) distribution in the series was as follows: <7 (39 cases, 84.8%), 3+4 (3 cases, 6.52%), 4+3 (1 case, 2.17%), and >7 (3 cases, 6.52%). Cancer remained minute in 22 cases (47.8%) when additional cuts were done for immunohistochemistry and grew to become non-minute in 7 cases (15.3%). Interestingly, the minute focus of cancer utterly disappeared in 17 cases (36.9%) making impossible the immunohistochemical evaluation. Basal cells indicative of benignity were better identified with CK 5/6, who showed intense immunostaining in 40 cases (87%) and moderate in 6. On the other hand, 34βE12 displayed intense reaction only in 11 cases (24%), being moderate in 14 and mild in 19. Nuclear staining with p63 offered even poorer results, with only 26 cases (56.5%) being positive in unequivocal basal cells. p504S showed positive immunostaining in the minute cancer of 25 cases (54.3%), but was also positive in benign foci of 4 cases. Conclusions: The diagnosis of minute prostate cancer relies mainly on H&E sections by recognizing the classical morphologic criteria. Serial section intended for immunohistochemistry may loose a significant number of cases. CK 5/6 shows the more intense immunostaining of basal cells. p504S confirm the diagnosis of malignancy in half of the cases and may show false positive results. Immunohistochemistry must be interpreted in the particular context of every patient.

PP2-144
BILATERAL LEYDIG CELL TUMOR AND MALE INFERTILITY: A CASE REPORT
Behrouz Ilkhanizadeh
Imam Komini Hospital, Pathology Department, Urmia, Iran

Background: Leydig cell tumor is a rare form of testicular neoplasm which comprises 1-3% of all testicular tumors and only about 3% of these tumors are bilateral. A few Leydig all tumor have been described in patients with klinefelter's syndrome so far. Case: The patient described in this case report was a 24 year-old man with chief complaint of infertility for one year. Physical examination, semen analysis, testes sonography and hormonal assay were done for him. Right side simple orchiectomy was performed for patient. Conclusion: This tumor is always benign in children and approximately 90% are benign in adults. Clinical presentation is testicular enlargement, gynecomastia, sexual activity disturbances such as decreased libido, infertility and azoospermia. We recommend complete exam and karyotype in patients with infertility and azoospermia. Key words: Leydig cell tumor, Infertility, Azoospermia.

PP2-145
EXTRAGONADAL GERM CELL TUMOR AND MALE INFERTILITY
Behrouz Ilkhanizadeh
Imam Komini Hospital, Pathology Department, Urmia, Iran

Background: Over recent decades a possible decrease in sperm quality and an increase in the incidence of testicular cancer have been reported in many populations. Some recent findings, as cohort studies, showed an increased risk of testicular cancer in men with abnormal semen analysis. Case: A 30 years old man referred to our clinic with chief compliant of infertility for 3 years. Spermogram revealed azoospermia and right extratesticular intrascrotal mass was detected by ultrasound examination. Right inguinal surgical approach showed intact small sized atrophic right testis and an intrascrotal mass. In microscopic examination of the mass mixed germ cell tumor with teratoma, yolk sac and embryonal components were reported. Conclusion: Extragonadal germ cell tumors, like their testicular counterparts are associated with primary germ cell defects. The higher incidence of antecedent infertility suggests that either congenital or acquired primary germ cell defect contributes to defective spermatogenesis and therefore, there is higher risk of cancer development in incompletely migrated germ cells. We recommend complete evaluation of cancer in patients with infertility and azoospermia. Key words: Germ cell tumor, Extragonadal, Azoospermia

PP2-146
CAN CELL CYCLE REGULATORY PROTEINS p53, Ki67 AND bcl-2 PREDICT BIOCHEMICAL RELAPSE AFTER RADICAL PROSTATECTOMY: A TISSUE MICROARRAY STUDY
Dilek Ertoy Baydar, Barbaros Baseskioglu, Haluk Ozen
Hacettepe University Hospital, Ankara, Turkey

Background: Prognostic value of cell cycle regulatory proteins in prostatic adenocarcinoma has been under intense investigation. To analyze p53, Ki67 and bcl-2 expression in our series and their predictive role in biochemical recurrence after surgery, we performed an immunohistochemical study in malignant and non-neoplastic prostate tissue. Methods: 71 patients who had undergone radical prostatectomy between 1992 and 2001 with follow-up data available were selected. Tissue microarrays were constructed from their radical prostatectomy specimens. They contained four cores from neoplastic and additional four cores from corresponding non-neoplastic regions. Gleason score ranged from 6-9, and pathological stage ranged from T2N0Mx to T3BN1. Staining for bcl-2 was scored visually taking percent negative, weak, moderate and strong positivity into consideration. Strong immunoreactivity was considered positive for p53. Ki-67 index was measured as the percentage of positive nuclei among tumor cells. Results: Age of the patients ranged between 48 and 75 (median 62). Follow-up period extended from 4 to145 months, except four males who were lost to follow-up immediately after the surgery. %56 had no evidence of disease, %44 were alive with disease. Tissue microarrays contained normal epithelium in 63, PIN in 3 and tumor in 69 cases. The expression of p53, Ki67

and bcl-2 in tumors were 39%, 76%, 5% respectively. While the secretory layer showed negative or weak bcl-2 staining in most cases, expression in basal cells was often stronger. Pairwise analysis revealed differences in staining between normal and carcinoma for all 3 markers. There was no correlation between stainings and the presence of or time to biochemical relaps. On the other hand, cases with higher Gleason sum showed the tendency for overexpression of p53, Ki-67 and bcl-2 although the differences were not statistically different. Conclusion: The proteins bcl-2, p53 and Ki-67 were expressed at a different rate in normal and neoplastic prostate tissue. Bcl-2 was mainly expressed by basal cells in normal glands. p53 and Ki-67 expression were increased in most prostate carcinomas. But overall expression levels did not correlate with biochemical recurrence in this study.

PP2-147

PLASMACYTOID UROTHELIAL CARCINOMA: PATHOLOGICAL AND IMMUNOHISTOCHEMICAL PROFILE OF FOUR CASES

Ayman Gaafar, Francisco José Bilbao, Maddi Garmendia, José Ignacio López
Hospital de Basurto, Basque Country University (EHU/UPV), Bilbao, Spain

Background: plasmacytoid urothelial carcinoma (PUC) is a very rare variant of Transitional cell carcinoma (TCC). The few previously reported cases were aggressive, high grade neoplasms, with a high stage at initial diagnosis and a poor prognosis. Its clinical presentation is frequently late due to the frequent absence of haematuria and indurated mucosal surface at cystoscopy. Materials and Methods: All cases of high grade urinary bladder TCC were reviewed for a period of 8 years in our hospital between years 1999 and 2006, to identify tumours with plasmacytoid differentiation. Clinical data were obtained from the clinical records, and representative sections from each case which was reported as TCC with plasmacytoid differentiation were examined, and tested with AE1/3, S-100, CD45, EMA, CAM5.2, CK7, CK20, CEA, CA19-9, beta-HCG, Ki-67 antibodies. RESULTS: There were a total of 4 cases of PUC out of 720 cases of high grade TCC (0.55%). The average age was 73 years (range 70-75). Haematuria was the main clinical presentation. Three cases showed distant metastases at time of diagnosis, two of them with peritoneal carcinomatosis, and the third one with soft tissue metastasis in left thigh. Radiological and cystoscopic examination revealed diffuse thickening in the urinary bladder. All cases showed local recurrence after a complete course of chemotherapy. Histopathological examination of bladder biopsies showed common papillary high-grade TCC with invasive areas of PUC in three cases, one of them showed areas of micropapillary TCC. One case showed pure plasmacytoid differentiation. The PUC component showed loose myxoid stroma infiltrated by non-cohesive tumour cells with round borders, abundant deeply eosinophilic cytoplasm, and small, hyperchromatic, eccentrically placed nuclei that closely mimicked plasma cells. Mitotic figures were frequent in the invasive component. Some typical signet ring cells were also present. Immunohistochemical profile of the plasmacytoid areas showed positivity for AE1/3, EMA, CK7 in all cases, with variable Ki-67 positivity (range 40% - 90%). CK20 was positive in 2 cases, CAM5.2 in 3 cases, CEA in one case, CA19-9 in two cases. All cases were negative for CD54, S-100, and Beta-HCG. CONCLUSIONS: PUC resembles plasma cell myeloma and is often confused with haemopoietic malignancies secondarily involving the urinary bladder. When plasmacytoid features are observed in TCC, it should be confirmed by immunohistochemical techniques, and should be reported to aid correlation with prognosis and distant metastasis.

PP2-148

PRIMARY MEDIASTINAL SEMINOMA: A COMPREHENSIVE ASSESSMENT INTEGRATED WITH HISTOLOGY, IMMUNOHISTOMISTRY, AND FLUORESCENCE IN SITU HYBRIDIZATION FOR CHROMOSOME 12P ABNORMALITIES IN 23 CASES

Ming-Tse Sung[1], Gregory T. Maclennan[2], Antonio Lopez-Beltran[3], Shaobo Zhang[4], Rodolfo Montironi[5], Liang Cheng[6]

[6] Departments of Pathology and Laboratory Medicine, Urology, Indiana University School of Medicine, Indianapolis, IN, USA

BACKGROUND: Accurate diagnosis of mediastinal seminoma is critical because of its favorable response to radiation therapy and/or cisplatin-based chemotherapy. However, discrepancies between the genetic alterations and immunoprofiles of mediastinal and testicular seminomas have been reported, raising the question of whether techniques that are useful in the diagnosis of gonadal seminoma are applicable to its mediastinal counterpart. METHODS: The present study was conducted to evaluate the morphological and immunohistochemical characteristics and chromosomal abnormalities of 12p in 23 primary mediastinal seminomas and to compare their applicability as diagnostic tools. RESULTS: Lymphocytic infiltration was found in all 23 cases (100%). The incidence of other histological characteristics were as follows: fibrous septa/stroma (21 cases, 91%), prominent tumor cell nucleoli (21 cases, 91%), clear tumor cell cytoplasm (20 cases, 87%), distinct tumor cell borders (20 cases, 87%), granulomatous inflammation (17 cases, 74%), necrosis (8 cases, 35%), cellular pleomorphism (8 cases, 35%), prominent cystic change (2 cases, 8%), intercellular edema (1 case, 4%) and syncytiotrophoblasts (1 case, 4%). Moderate to strong nuclear OCT4 staining were identified in all 23 cases (100%). 17 tumors (74%) showed membranous expression of c-kit. Weak to moderate staining intensity staining for PLAP was identified in 10 cases (43%) with occasional background staining artifact. The incidences of positive staining were 43% for AE1/3, 39% for HMWCK, 48% for Cam 5.2, 39% for CK7 and 9% for EMA respectively. In most cases these epithelial markers highlighted only a small proportion of tumor cells. CD30 and CK20 immunostaining was completely negative in all seminomas. 22 seminomas (96%) revealed chromosome 12p abnormalities, including 12p amplification in 20 cases (87%) or i(12p) in 15 cases (65%). CONCLUSIONS: Lymphocytic infiltratis the most common histological feature observed in primary mediastinal seminoma and both OCT4 immunostain and FISH for 12p abnormalities can be very helpful in diagnosing mediastinal seminoma. The intense staining pattern of OCT4 and the high sensitivity of FISH make them superior to other auxiliary diagnostic utilities for detecting seminoma. In addition, the incidences of cytokeratin expression of primary mediastinal seminoma are similar to those of its gonadal counterpart and pathologists must exercise caution in the interpretation of epithelial markers in mediastinal neoplasms.

PP2-149

PURE LEIOMYOMA OF THE PROSTATE GLAND

Sadeq Al-Dandan, Sate Hamza
University of Manitoba, Health Sciences center, Department of Pathology, 820 Sherbrook Street, MS471, Thorlakson Building, Winnipeg, Manitoba, R3A 1R9, Canada

BACKGROUND: Spindle cell tumors and tumor-like lesions of the prostate gland are never-ending challenge with regard to the differential diagnosis. Although minute leiomyomatous sromal nodules are common in the setting of benign nodular hyperplasia, pure leiomyomas of the prostate are rare entities. METHOD: A 75-year-old man presented with acute renal insufficiency due to bladder outlet obstruction and urinary retention. The patient had a history of prostatism and few urinary tract infections. Digital rectal examination revealed extremely large prostate, certainly greater than 100 mL and it was of benign consistency. Computed tomography scan of the abdomen and pelvis showed bilateral hydronephrosis secondary to considerable prostatic enlargement. The patient underwent an open prostatectomy. RESULTS: Grossly, there was a sharply circumscribed and round nodule measuring 5 cm in greatest dimension with fine trabecular pattern on cut section. On microscopy, the nodule was composed of fascicles of spindle cells. There was no cytological or nuclear atypia and mitotic figures were absent. Immunohistochemical staining showed positivity for vimentin, desmin, smooth muscle actin and h-caldesmon. CONCLUSION: Because leiomyomatous stromal nodules of the prostate are frequent lesions in the background of benign nodular hyperplasia, certain critertia have to be met before a diagnosis of pure leiomyoma of the prostate is established. Other spindle cell tumors and tumor-like lesions must be considered in the differential diagnosis. Moreover, smooth muscle tumors of low or uncertain malignant potential have to be excluded on histopathological evaluation.

Bladder cancer complicating schistosomiasis ranks first among the reported malignancies in Egypt. Recently, it was correlated to viral infection with Epstein-Barr virus (EBV) and Cytomegalovirus (CMV). The present study was undertaken to determine the role of EBV and CMV in the etiopathogenesis of cancer bladder associated with urinary schistosomiasis and to study the correlation of viral genomic sequences in bladder tissue biopsies, serum and urine samples with serologic responses, electron microscopic studies (EMS) of the buffy coat cells and bladder tissue Cytokeratins (CK). Sixty inpatients in Urosurgery Department, TBRI with cancer bladder, 35 with schistosomiasis (group I) and 25 without (group II) and 20 clinically and pathologically proven non-cancer bladder controls (groupIII) were enrolled in this study. Midstream urine, blood and bladder biopsies were collected from all subjects. The following assays were performed; detection of EBV and CMV genomic sequences in bladder tissue biopsies, serum and urine specimens by the polymerase chain reaction (PCR), CMV Antigenemia test for detection of pp65 antigen in polymorphonuclear leucocytes (PMNLs), Enzyme Immunoassays (EIA) for detection of CMV IgG and IgM, EBV nuclear antigen (EBNA) IgG and IgM and EBV early antigen (EBEA) IgG in serum, EMS of the buffy coat cells of 10 patients of each group and Immunohistochemical (IHC) examination for detection of CK–5,6,8,17,19 in bladder tissue biopsies. Our results showed that viral sequences were detected in an overall of 33% of bladder tissue biopsies. From which both CMV and EBV sequences were detected in 80%. Significant values were found overall for viral infection in male (90%) patients with transitional cell carcinoma (TCC) (80%) of grade II (90%), with schistosomal affection (65%), with recurrence tendency (60%) with mixed infection with both CMV and EBV (80%). The results of all assays for detection of CMV or EBV in serum and urine were analysed against PCR on bladder tissue biopsies. Their diagnostic values were found to be unreliable. Cytokeratins were found to be significant.

PP2-151

TISSUE MICROARRAY ANALYSIS OF THE PROGNOSTIC VALUE OF RON AND MET AND HISTOPROGNOSTIC FACTORS IN UPPER URINARY TRACT TRANSITIONAL CELL CARCINOMA

Eva Maria Comperat[1], Morgan Roupret[2], Emmanuel Chartier-Kastler[2], Francois Richard[2], Frederique Capron[1], Olivier Cussenot[3]
[1] Hopital La Pitie, Service d'Anatomie Pathologique, France
[2] Hopital La Pitie, Service d'Urologie, France
[3] Hopital Tenon, Service d'Urologie, France

Objectives: RON and MET are members of the MET proto-ocogene family. RON (Recepteur d'Origine Nantais) is known to play a role in cell transformation and epithelial tumorigenesis. MET (c-met) encodes a receptor tyrosin kinase and intervenes in oncogenesis. Overexpressions of both genes have been demonstrated in human bladder cancer. As urothelium covers the whole urinary tract, we wanted to explore whether overexpression of both molecules plays a role in tumorogenesis in the upper urinary tract transitional cell carcinoma. We also wanted to define histoprognostic factors of these tumors, known to be of poor clinical outcome. Materials and Methods: 42 patients with upper urinary tract urothelial carcinoma have been explored. 24 had localisation in the renal pelvis, 18 ureteral localisation. (14 pTa low grade tumors and 2 pTa high grade tumors; 8 pT1, 6 pT2, 10 pT3 and 2 pT4). Immunohistochemistry for RON and MET was performed on tissue micro arrays taken from surgical specimen of all these patients. Results: Patients were aged from 46 to 100 years (mean 70.6 years). 23 (54%) patients died of disease. Eleven displayed association with carcinoma in situ. Overexpression of MET antigene was associated with higher risk to develop embols ($p=0.0002$), on the opposite, RON was not statistically significant ($p=0.5$). Univariante analysis showed that relapse was statistically significantly associated with ureteral localisation ($p= 0.02$), the presence of vascular invasion ($p=0.003$), high grade ($p=0.04$) and high stade urothelial carcinomas (0.02). The presence of vascular invasion, high grade and high stade urothelial carcinomas ($p<0.0001$ respectively) was also statistically significant. Superficial tumors displayed important relapse rate ($p=0.003$). Conclusion: Independent prognostic factors of relapse in urothelial carcinomas of the upper urinary tract are ureteral localisation, the presence of vascular invasion, high grade and high stade urothelial carcinomas. MET seems to influence one of theses prognostic factors, the development of vascular invasion via a mechanism, which is not exactly known yet. Nevertheless

association of MET overexpression and aggressive clinical behaviour in upper urinary tract carcinomas has not be shown before. In the opposite of bladder carcinomas, RON does not seem to have prognostic value in this kind of malignancies.

PP2-152
MICROVESSEL DENSITY IN PROSTATE CARCINOMA

Yasemin Ozkan Unuvar[1], Serife Basaran[2], Sebnem Batur[3]
[1] Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Department of Pathology Istanbul, Turkey
[2] Haseki Training and Research Hospital, Department of Pathology Istanbul, Turkey
[3] Avrasya Hospital, Department of Pathology Istanbul, Turkey

OBJECTIVES: Angiogenesis is believed to play an important role in tumor progression and metastasis. Previous studies have suggested that tumor angiogenesis (microvessel density [MVD]) may be of prognostic significance in patients with prostate carcinoma. The aim of this study was to assess MVD in patients with prostate carcinoma and its possible correlation with Gleason score and perineural invasion. MATERIALS AND METHODS: MVD was evaluated using the CD34 monoclonal antibody in archival paraffin embedded TURP (n=28) and radical prostatectomy (n=17) specimens from 45 patients. MVD was counted in areas with the greatest microvessel immunostaining which were designated “hot spots”. RESULTS: The microvessel density count in the tumor area significantly increased with increasing Gleason score (p=0,031) but it did not increase significantly with perineural invasion (p=0,068). CONCLUSION: Although problems exist in methods of counting, MVD, using CD34 monoclonal antibody may provide prognostic information for prostate carcinoma.

PP2-153
A CARCINOSARCOMA ARISING IN AN URINARY BLADDER DIVERTICULUM WITH BREAST METASTASIS IN 45-YEAR OLD MALE: A CASE REPORT

Kristijan Peros[1], Tomislav Bozek[1], Ingrid Prkacin[2], Slavko Gasparov[2], Mirjana Sabljar Matovinovic[2]
[1] University Clinic Vuk Vrhovac, Zagreb, Croatia
[2] Clinical Hospital Merkur, Zagreb, Croatia

A 45-year-old man with no previous history of genitourinary disease presented with dysuria and pain in the left groin. The urinalysis showed significant microhematuria, and urinary system ultrasound revealed a large urinary bladder diverticulum (UBD) in the left upper segment. An intravenous pyelogram showed UBD and significant medioposition of the left urether, but without signs of obstruction and secondary hydronephrosis. A cystoscopy examination revealed a large UBD, containing a tumor mass. Diverticulectomy and pelvic lymphadenectomy were performed. Microscopic examination revealed areas containing malignant neoplastic cells with an epithelial component of the transitional and squamous epithelium. Also, some neoplastic cells had morphologic characteristics of the mesenchymal component. Immunohistochemically, the reactions with antibodies against cytokeratin 8, cytokeratin HMV, neuron-specific enolasis and sarcomeric actin were positive, while negative results were obtained in reactions with antibodies against cytokeratin 20, PSA, PSAP, alpha-actin, S-100, CEA, PLAP and synaptophysin. The histopathological diagnosis was carcinosarcoma. Perineural invasion, invasion of the great vessel walls and infiltration of the fat and muscular tissue was observed. Lymph nodes were negative. Three weeks after the surgical procedure CT scan revealed thickness of the urinary bladder wall in the area of the resected diverticulum and one enlarged lymph node in the adipose tissue next to the urinary bladder. Irradiation therapy was started. Five months later the patient discovered palpabile node in the right breast. A fine-needle aspiration was performed and it revealed neoplastic cells with different grades of differentiation with some cells and clusters of cells showing the differentiation towards squamous epithelium. Systemic chemotherapy according to the M-VAC protocole and paliative radiotherapy of the right breast were started. The patient died twelve months after the diagnosis has been established. To our knowledge, we report the first case of UBD carcinosarcoma with breast metastasis.

PP2-154
ADENOMATOUS HYPERPLASIA OF THE RETE TESTIS. REPORT OF A NEW CASE

Petrescu Amelia Nicoleta[1], Berdan Gabriela[1], Mihai Mihaela[2], Ambert Valentin[1], Hulea Ionela[1], Gaitanidis Raluca[1], Niculescu Liviu[3]
[1] Prof. Dr. Th. Burghele Hospital, Bucharest, Romania
[2] Victor Babes National Institut of Pathology, Bucharest,Romania
[3] University of Medicine and Pharmacy “Carol Davila”, Bucharest,Romania

Introduction: The great majority of the testicular neoplasms are germ cell tumors but pseudotumors of various types are also encountered and are often diagnostically challenging. Thus, adenomatous hyperplasia of the rete testis is an uncommon benign lesion. Here, we present the clinicopathological features and immunohistochemical findings occurring in a 45 year old man presenting with a grossly and echographical identifiable solid, hilar testicular area. Left orchiectomy was performed under the diagnosis of carcinomas of the rete testis. Macroscopically examination revealed a 5/4/ 3,5 cm testicule presenting on the cut surface a gray white translucide and firm hilar area. Material and methods: Many fragments of the tumor were fixed in formaldehyde 10%, included in paraffin and the sections were stained with HE, VG; immunohistochemically and histochemically : PLAP, CD117,PAS, Red Congo. Results: Microscopic examination revealed a diffuse rete testis tubulopapillary epithelial pattern with cystic dilation and the continuity with non-hyperplastic rete. The lining cells were cuboidal without mitotic figures. The seminiferous tubules surrounded showed atrophic changes. Immunohistochemical and histochemical tests done showed: PLAP and CD117 negative reaction, PAS and Red Congo negative reaction. Conclusions: These findings plead for the diagnosis of rete testis hyperplasia and differential diagnosis must be made with primary adenocarcinoma of the rete testis and metastatic adenocarcinoma of prostate.

PP2-155
ACTIVATED AKT EXPRESSION AND PROGNOSIS IN RENAL CELL CARCINOMAS

Martina Hager[1], Haufe Heike[1], Ralf Kemmerling[1], Gregor Mikuz[2], Christian Kolbitsch[3], Patrizia Moser[2]
[1] Paracelsus Medical University, Salzburg, Department of Pathology, Austria

[3] Medical University Innsbruck, Department of Anaesthesia and Intensive Care Medicine, Austria

Abstract Purpose: The phosphatidylinositide 3-kinase-protein kinase B (Akt) is involved in the control of apoptosis and cell proliferation therefore overexpression may contribute to tumour development and progression. In detail, a-AKT inhibits the pro-apoptotic activity of BAD, caspase-9 and the forkhead family, and activates several anti-apoptotic substrates. A mechanism of increased Akt activation has been shown to be frequent inactivation of the PTEN. Promising anti-cancer therapies increasingly focus on pathways involving phosphatidylinositide 3-kinase inhibitors as adjuncts to conventional chemotherapy in advanced renal cell carcinomas (RCC). Overexpression of a-AKT has a negative impact on prognosis in various types of malignancies. So the present study investigated the frequency of Akt activation and association with clinicopathological features and prognosis in renal cancer. Material and Methods:

Immunohistochemical analysis (p-Akt and PTEN) was performed on 386 tissue microarrayed specimens with renal cell carcinoma (clear cell n = 305, chromophobe n = 20, papillary n = 40, sarcomatoid n = 17) and tumor-negative renal tissue. Results: Increased a-Akt expression was seen in 158 (40.9%) of 386 RCC with strongest overexpression in the papillary (82.5%) and lowest overexpression in the chromophobe (10%) subtype. Clear cell carcinomas showed increased expression in 39 %. High stage and high grade carcinomas showed increased a-Akt in 45% which was more frequently expressed when compared with low stage and low grade carcinomas. Increased a-Akt expression was significantly associated with shortener survival in univariate and multivariate analysis. Conclusions: Increased expression of activated Akt is a prognostic marker in renal cell carcinomas and the overexpression in a considerable number of high grade and high stage tumors may provide a novel therapeutic option for advanced renal cell carcinomas which are often unresponsive to conventional treatment strategies.

PP2-156
MULTIPLE CARCINOMA OF THE URINARY TRACT

Petrescu Amelia[1], Berdan Gabriela[1], Hulea Ionela[1], Gaitanidis Raluca[1], Ambert Valentin[1], Jinga Viorel[1], Niculescu Liviu[2]
[1] Prof. Dr. Th. Burghele Hospital, Bucharest, Romania
[2] University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Introduction: We present the case of a 69 year old man, smoker, hospitalized in the "Prof. Dr. Th. Burghele" Hospital in 2002 accusing right lumbar pains and intermittent haematuria accentuated one month before the event. Ultrasonography and the MRI performed for establishing the diagnosis have shown the presence of a tumoral mass placed at the upper pole of the right kidney. The complete nephrectomy was made. The macroscopic exam of the nephrectomy piece has shown a mass with tumoral aspect, 7/6,5/5 cm in size, yellowish with gray-white zones, hemorrhage and necrosis, apparently delimitated from the rest of the parenchyma, lying at the upper pole of the right kidney. Two years later the patient came back to the Hospital accusing disuria and hematuria. Ultrasonography and cystoscopic exam had show at the urinary bladder a tumoral mass with a cauliflower-like aspect, sessile, 2,5/2 cm. Transuretral resection of the tumoral mass was made and tissulary fragments were sent to the Pathology Laboratory for establishing the hystologic type, the tumor degree and invasion. Material and methods: Fragments of the tumors were fixed in formaldehyde 10%, included in paraffin and the sections were stained with HE and VG. Results: The microscopic exam (Nikon Eclipse 600) of the kidney mass revealed a proliferation composed of nest cell with clear cytoplasm and conspicuous membrane or eosinophylic cytoplasm with round central regular and irregular nuclei, increased size and macronucleoli. The nests were separated by a fine network with thin-walled vases, these features suggesting a clear cell renal carcinoma grade 2 Fürhman. The urinary bladder fragments presented an aspect of papillary urotelial carcinoma high-grade, infiltrating the muscular wall. Conclusions: The frequency of the synchronic neoplasms increase with the hope of life and the investigation methods improvement. The most frequent association of the multiple carcinoma of the urinary tract was urinary bladder and prostate carcinoma (in the radical prostatectomy pieces). Our association is rare but the clinicians must allow for the possibility of multiple synchronic and methachronic carcinoma with this location.

PP2-157
PROSTATE CANCER IN PATIENTS YOUNGER THAN 50 YEARS: COMPARISON WITH OLDER AGE GROUPS IN A CONTEMPORARY SERIES BASED ON 10-CORE BIOPSY

Kiril Trpkov[1], Asli Yilmaz[1], Melissa Chan[1], Leanne Kmet[2], Bryan Donnelly[3]
[1] Anatomical Pathology, University of Calgary, Canada
[2] Centre for Advancement of Health, Calgary Health Region,Canada
[3] Urology, University of Calgary, Canada

Background: Prostate cancer is increasingly diagnosed in younger patients due to public awareness, prostate-specific antigen (PSA) testing, and practice of extended biopsies. We explored the clinical and the pathology findings in patients of different age groups in a larger contemporary study. Design: We retrieved clinical, biopsy, and radical prostatectomy (RP) data from our institutional database for patients who had biopsy and RP between 07/2000 and 06/2006. All men had 10-core biopsy and all RP were completely sampled. We compared the data of 1441 men in <50, 50-59, 60-69, >70 years age groups. Statistical analyses were performed using chi-square test for categorical variables and medians were compared for continuous variables with a nonparametric test for trend. Results: Age groups <50, 50-59, 60-69, >70, consisted of 141 (9.8%), 557 (38.6%), 645 (44.8%), and 98 (6.8%) men, respectively. Men <50 had median PSA of 4.1 ng/ml (range 0.5-17.6), which was lower than 5.3, 6.3, and 7.9 in age groups 50-59, 60-69, and >70, respectively (all medians, p<0.001). In 48.2% of men <50 PSA was [LTEQ]4. Patients <50 had median gland volume of 26.9 cc (range 7-75.1), vs. 32.6, 41.6, and 40.4, in men 50-59, 60-69, and >70, respectively (all medians, p<0.001). Ultrasound abnormalities were less common in men <50 (12.8%), than in older age groups (21.2%, 20.9%, 27.6% in 50-59, 60-69, >70, respectively; p=0.033). PSA density and abnormal rectal exam were not significantly different between the groups. On biopsy and RP, Gleason score (GS) 7 and GS [LTEQ]8 were less common in men <50. The proportions of Gleason score 3+4 on biopsy (91%, 79%, 79%, 89%) and RP (84%, 82%, 82%, 80%) were similar across the groups. Cancer extent on biopsy (core %) and tumor (TU) volume on RP did not differ significantly between the groups. Only 5% of men <50 had pT3 disease (vs 7%, 13.5% and 18.4% in men 50-59, 60-69, >70, respectively; p<0.001). Margin positive rate of 22.7% in men <50 was lower than 25%, 28.4%, and 41.8% in men 50-59, 60-69, >70, respectively (p=0.003). Seminal vesicle invasion, node positivity, and lymphatic/vascular invasion were not significantly different in all age groups. Conclusions: Men with prostate cancer <50 currently present with lower PSA, have smaller gland volumes, and lower GS on biopsy and RP, but TU volumes on biopsy and RP are similar as in older men. We document the lowest incidence of pT3 disease on RP in men <50, and a low incidence of adverse findings on RP in all age groups, which further documents the stage-shift of the disease.

PP2-158
ASAP IN NEEDLE CORE PROSTATE BIOPSIES IN MIGUEL SERVET UNIVERSITY HOSPITAL BETWEEN 2002 AND 2006

Isabel Marquina[1], Francesc Felipo[1], Ana Marco[2], Mar Pascual[1], Ana Fuertes[1], Guillermo Muñoz[1], Celia Del Agua[3], Luis Plaza[1], Angel Borque[2]
[1] Pathology Department, Miguel Servet University Hospital, Zaragoza, Spain
[2] Urology Department, Miguel Servet University Hospital, Zaragoza, Spain
[3] Pathology Department, Alcañiz Hospital, Alcañiz (Teruel), Spain

Background: The term atypical small acinar proliferation (ASAP) comprises a broad group of lesions such as high grade PIN,

mimickers of cancer and reactive atypia. It also includes situations in which, after a review, it was seen that they were focal carcinoma, but lacked enough cytological and/or architectural atypia to establish a definitive diagnosis of cancer. Method: We will review needle core prostate biopsies performed in Miguel Servet University Hospital of Zaragoza (Spain) between 2002 and 2006. We will determine the incidence of ASAP among these biopsies, the average number of cores per patient, the number of patients with a diagnosis of ASAP who underwent repeated biopsies, and the time elapsed between the first and the following biopsies. We will also determine the percentage of carcinomas diagnosed in the first repeated biopsy. Results: Some provisional results of the study show an incidence of ASAP of 1,9% among 3600 needle core prostate biopsies performed in five years. All patients with ASAP were re-biopsied, 42% of them had a diagnosis of prostate adenocarcinoma in the first repeated biopsy, the predominant Gleason score being 6 (75%). Conclusion: An ASAP does not have defined morphological features, but reflects that a given acinar proliferation lacks definitive diagnostic criteria of carcinoma. Urologists must be aware that ASAP is not the same as high grade PIN, as the risk of diagnosing cancer in re-biopsies is much higher in ASAP, with an average of 40,2%. It has been described that around 90% of carcinomas following a diagnosis of ASAP are detected in the first repeated biopsy. All patients with a diagnosis of atypia suspicious for carcinoma or ASAP should undergo re-biopsy within 3-6 months. Some studies affirm that only 56% of patients with a diagnosis of ASAP are re-biopsied. We believe in the importance of performing repeated needle core prostate biopsies in patients with diagnosis of ASAP, since a high percentage of these cases are actually carcinoma.

PP2-159
URACHAL ADENOCARCINOMA CLINICAL PATHOLOGICAL CHARACTERISTICS: 20 YEAR EXPERIENCE AT THE HGM AND INCMNSZ

Mercedes Hernandez[1], Daniel Montante[1], Braulio Martinez[2], Monica Romero[1]
[1] National Autonomous University of Mexico, Hospital General de México, Facultad de Medicina, Mexico
[2] Instituto Nacional de Ciencias Médicas y de la Nutrición "Salvador Zubirán", Mexico

Aim: To know the epidemiological, clinical and pathological characteristics of urachal malignant neoplasms Material and Methods: Cases diagnosed as urachal carcinomas, seen in the last 20 years were selected from the archives at the General Hospital of Mexico Pathology Unit and Pathology Department at the INCMNSZ. The macroscopic descriptions, photographs and histological slides were assessed in each case. Clinical information was gathered from each patient's chart. Results: Seven cases were found based on surgical samples and diagnosed as urachal adenocarcinoma. Average age of tumor presentation was 50.2 years. Five cases were in males and the remaining two in females. The most frequent symptom was hematuria, reported in six cases (85.7%) followed by mucous urination in 3 cases (42.8%), dysuria (42.8%), tenesm (28.5%) and a mucous discharge from the umbilical wound in only one case. Six cases had urachal remnants, 4 were of cystic appearance. Two cases had diffuse invasion of the bladder wall, while in two cases there was infiltration of the prostate. One case had regional lymph nodes metastases. The most frequent histological types were the mucinous type in three cases, two were colonic and two others were of the "ring stamp" variety. The last two were the most clinically advanced stages. Conclusions: Urachal adenocarcinoma is a rare neoplasm. Its incidence ranges between 0.34 and 0.7% of all bladder tumors. It is estimated that overall survival is 5 years, independent of surgical treatment, ranging from 43 to 50%. Due to its low frequency, prognostic factors have not been determined for this type of neoplasm.

PP2-160
EXPRESSION OF VARIOUS CELLULAR MARKERS IN GENITOURINARY RHABDOMYOSARCOMA: IMMUNOHISTOCHEMICAL STUDY USING TMA METHODOLOGY

Eddie Fridman[1], C Reinus[2], Boris Chertin[2], Yoram Mor[1]
[1] Sheba Medical Center, Israel
[2] Shaare Zedek Medical Center, Israel

Background: Rhabdomyosarcoma (RMS) is the most common sarcoma in the pediatric age group, with 20% of the cases involving the genitourinary tract. These tumors are often characterized by rapid growth, local extension as well as by early metastatic spread. Multimodal therapy has therefore been introduced with ongoing efforts to improve characterization of various prognostic factors, in order to diminish the therapeutic burden and minimize side effects. In accordance, the use of immunohistochemical analysis of the expression of various cellular markers in tumoral cells may enable to better design the therapeutic schedule according to individualized risk-based data and may even define specific therapeutic targets in RMS. The aim of this study was to evaluate the extent of expression of various cellular markers in RMS, using tissue microarray (TMA) technique. Methods: TMA paraffin embedded block was constructed of 8 samples of RMS from different patients operated between 1995-2005. Each tumoral sample was presented in the block by several cores, 2 mm in diameter, containing tumoral tissue with adjacent transitional epithelium and normal detrusor which served as positive and negative controls. After serial slicing of 4 μm thickness, the histological slides were stained with hematoxylin&eosin (H&E) and immunostained with antibodies against Erb-B2, p53, c-kit, Ki 67, Caspase 3, EGFR, N-CAM, TOPO-II and BCL-10. The immunostaining was graded semiquantitatively by the percent of positive cells and the intensity of stain. Results: Four cellular markers were expressed in RMS including Erb-B2, Ki 67, EGFR and N-CAM. Significant positive staining (grades 2-3) for at least one of these markers were noted in 5 of the cases. Conclusions: The expression of Erb-B2, Ki 67, EGFR and N-CAM in genitourinary RMS may have potential therapeutic implications. Our preliminary results may promote further studies to assess the potential role of these markers to serve as therapeutic targets for specific therapeutic agents and thus decrease the overall treatment burden in children suffering from genitourinary RMS.

PP2-161
EXPRESSION OF VARIOUS DRUG RESISTANCE PROTEINS IN WILMS' TUMOR: IMMUNOHISTOCHEMICAL STUDY USING TMA METHODOLOGY

Eddie Fridman[1], Joseph Skarda[2], Jehonathan Pinthus[3], Yoram Mor[3]
[1] Department of Pathology, Sheba Medical Center, Israel
[2] Dept. of Pathology, LF UP Olomouc, Czech Republic
[3] Department of Urology, Sheba Medical Center, Israel

Background: The multidrug resistance-related protein (MRP-1), lung resistance-related protein (LRP) and topoisomerase-II (TOPO-II) are associated with drug resistance against various chemotherapeutics and protect cells against toxic compounds. Their expression in cancer cells may result in altered membrane transport (MRP-1, LRP) and altered enzymatic activity (TOPO-II). The aim of this study was to evaluate the extent of MDR-related protein expression in Wilms' tumor (WT) using tissue microarray (TMA) technique. Methods: TMA paraffin embedded block was constructed from normal renal tissue, 14 samples of WT from different patients, and from xenografts derived thereof. Each tumoral sample was presented in the block by several cores, 0.06 mm in diameter. After serial slicing, of 4 μm thickness, the histological slides were stained with hematoxylin & eosin (H&E) and immunostained with antibodies against MRP-1, LRP and

TOPO-II. The immunostaining was graded semi-quantitatively by the percentage of the stained cells and the intensity of stain. Results: All the normal kidney tissue samples expressed MRP-1 and were weakly stained or negative for LRP and TOPO-II. Samples of WT were universally stained for MRP-1 (only in the tubular component of the tumor), no expression of LRP was detected and various distribution of TOPO-II was observed. The xenografts varied regarding MRP-1 and TOPO-II expression and exhibited weak or negative staining of LRP. Conclusions: Our study presents the expression of various multidrug resistance proteins in WT, indicating that only MRP-1 might have a potential clinical role. The differences between the expressions of those proteins in the authentic tumors and in their related xenografts might explain differences in response to chemotherapy comparing original tumors and related animal models.

SYSTEMATIC, STANDARDIZED PATHOLOGICAL EXAMINATION OF THE PROSTATE IN RADICAL CYSTECTOMY SPECIMENS RAISES THE DETECTION RATE OF PROSTATIC CARCINOMA IN THESE SPECIMENS

Eddie Fridman[1], Ignat Schwartz[1], Yoram Mor[2], Menachem Laufer[2], Jackob Ramon[2]
[1] Department of Pathology, Sheba Medical Center, Tel-Hashomer, Israel
[2] Department of Urology, Sheba Medical Center, Tel-Hashomer, Israel

INTRODUCTION The accepted treatment for patients suffering from urinary bladder cancer is radical cystectomy. Since the majority of these patients are males above 60 years of age, a high rate of coincidental prostatic carcinoma would be expected. Surprisingly, the normal pathological examination of these specimens, using random sampling, results in a lower than expected incidence of prostatic carcinoma. Revised, standardized protocols for sampling and microscopic examination of prostate specimens have recently been implemented in our institution. We here examine the effect of these new methods on the detection rate of prostatic carcinoma in radical cystectomy specimens. METHODS Pathological reports of radical cystectomy procedures in males conducted at the Sheba Medical Center between the years 1994-2004 were reviewed. Specimens examined during the years 1994 and 1998 were processed using a random sampling method; all but 5 of the cases examined between 2000-2001 were also processed using random sampling; and cases examined between 2003-2004 were all processed using the new standardized sampling protocol. The data collected on each case included: the patient's age, total amount of paraffin blocks per case, and amount of paraffin blocks for prostate samples per case. RESULTS 62 pathological reports were reviewed. In comparison with random sampling method, used previously, the detection of prostatic carcinoma increased drastically using systematic standartized pathological examination: 64,7% in 2003-2004 years and 22.2% in 2000-2001 yearsversus 5.6% in 1994 and 1998 y.y. Simultaneously the total number of paraffin blocks from prostate per case was increased from 4.4 blocks per case in 1994 and 1998 years to 13.8 blocks in 2003-2004. The data collected is presented in the table. CONCLUSIONS The results indicate a direct correlation between sampling methods and the detection rate of prostatic carcinoma found in male radical cystectomy specimens. The use of systematic, standardized sampling protocols when processing the prostate in these cases raised the rate of detection of prostatic carcinoma from 5.5% to 64.7% - a rate similar to that reported in the medical literature for the general population

[2] Department of Pathology, Egirdir Bone Joint Diseases Treatment and Rehabilitation Hospital, Burdur, Turkey
[3] Department of Urology, Suleyman Demirel University School of Medicine, Isparta, Turkey
[4] Department of Pathology, Aydin State Hospital, Aydin, Turkey

Background: CD24 recently identified novel prognostic marker gene that consists of 27 amino acids and is attached to cell membrane by a phosphoatidylinositol anchor. It functions as an alternative ligand of P-selectin, an adhesion receptor expressed on activated endothelial cells and platelets, and could thus enhance the metastatic potential of CD24 expressing tumor cells. It has been implicated in metastatic tumor progression of various solid tumors. We aimed to investigate CD24 expression in prostate adenocarcinomas, low and high grade PIN's and benign prostate hyperplasias, and to evaluate its relationship with histopathological parameters, and serum PSA level. Method: We examined immunohistochemically the expression of CD24 protein in 76 prostate adenocarcinomas, 16 low grade PIN, 16 high grade PIN, and 14 benign prostate hyperplasias and correlated our findings with histopathological parameters, and serum PSA level. Results: While we detected CD24 expression in prostat adenocarcinomas and PIN specimens, there was no expression in benign prostate tissues. CD24 immunoreactivity was detected in 48 (63.2%) out of 76 prostate adenocarcinomas. In prostate adenocarcinomas cytoplasmic CD24 expression was significantly positively correlated with Gleason score ($p=0.000$, $r= 0.465$) and PSA level ($p=0.022$, $r=0.263$). Conclusion: Our findings demonstrated that positive CD24 expression occurs in prostate adenocarcinomas with high Gleason score, and high PSA level. We suggest that CD24 might constitute an important moleculer marker for prostate cancer biology. Key words: Prostate adenocarcinoma, PIN, CD24, immunohistochemistry

PP2-164
p53, Ki-67 AND CYCLOOXYGENASE-2 (COX-2) CORRELATION BETWEEN PAPILLARY UROTHELIAL CARCINOMAS OF LOW MALIGNANT POTENTIAL AND NONINVASIVE LOW GRADE UROTHELIAL CARCINOMAS

Alpay Cetin, Aysenur A Igdem, Nusret Erdogan
Department of Pathology, Taksim Training and Research Hospital, Istanbul-Turkey

Introduction : Difficulties can be seen at the histomorfological diagnosis of the low grade noninvasive papillary urothelial carcinomas (LG-PUC) and the papillary urothelial neoplasms of low malignant potential of the bladder (LMP-PUN) that have different prognosis. We studied p53, Ki-67 and cycloxygenase-2 (cox-2) markers for detecting the possibility of getting benefit at the differential diagnosis of these two subgroups. Materials and methods : We reviewed the cases diagnosed as urothelial neoplasias at the Urology Clinic of Taksim Eğitim ve Araştırma Hospital and applied transuretral resection (TUR) or biopsy. We re-evaluated the cases diagnosed as papilllary urothelial neoplasia of low malignant potential and low grade noninvasive papillary urothelial carcinomas by using WHO classification 2004. From the primary tumors we applied p53, Ki-67 and cox-2 immunohisttochemically to 22 LMP-PUN and 23 LG-PUC, totally 45 cases. Results : While statistically significant difference was observed between LMP-PUN and LG-PUC cases with p53 and Ki-67(lower at LMP-PUN), cox-2 was found to be oppositely related(higher at LMP-PUN). Commonly(both basal and

superficially) staining pattern found to remind LG-PUC with all the three antibodies. Cox-2 staining percentiles were significantly different between LMP-PUN and LG-PUC. Cox-2 is more, commonly stained at LMP-PUN then LG-PUC cases. Discussion : At our study we came to conclusion that immunohistochemical p53 and Ki-67 antibodies can be used to get benefitt of diagnosing the cases histomorfologically similiar to both LMP-PUN and LG-PUC. Moreover we decided that cox-2 inhibitors can be experienced at treatment and at preventing the progression of early stage bladder tumors. Key words : Bladder, LG-PUC, LMP-PUN, p53, Ki-67, Cox-2

PP2-165
IMMUNHISTOCHEMICAL STAINING WITH AMACR/ P63/HMWCK TRIPLE ANTIBODIES BY DOUBLE STAINING METHOD IN RADICAL PROSTATECTOMY SPECIMENS

Saynur I Beser, Gulistan G Yilmaz, Onder Peker
Pathology Department, Haydarpasa Numune Hospital, Istanbul-Turkey

Introduction : Our study aims to find the staining percentage , staining density , sensitivity and spesifity of immunohistochemical markers for prostate carcinomas in one slide with three antibodies (AMACR/P504S, P63, HMWCK) together by double staining method . Materials and Methods : We search for 59 radical prostatectomy and 1 TURP materials from January 2002 to December 2005 in Istanbul Haydarpaşa Numune Hospital retrospectively. In our study we especially select low grade prostate carcinomas including wide HGPIN areas. In these cases , we get one slide that include both HGPIN and tumor areas and stain these with triple antibodies (AMACR/P504S, HMWCK, P63) by double staining method . Then we look for their staining intensities and percentages. Results: In our study AMACR expression in malign and HGPIN areas with 100 % specifity, sensitivity values for carcinoma areas as 65-85 %, for HGPIN areas as 98.2 %. In benign areas we don't see any AMACR expression. And also we find positive relationship between Gleason combined score of tumor, the carcinoma area and AMACR expression in the same slide. We see no staining in carcinoma areas with HMWCK and p63 antibodies so find HMWCK, P63 spesifity as % 100. HMWCK sensitivity in benign areas around carcinoma is 85.0 ± 10.33 and also in this area p63 sensitivty is 86.0 ± 9.6. HMWCK and p63 sensitivity and spesifity in HGPIN areas around carcinoma are % 100 for both. Conclusion : AMACR / P504S biomarker helps us to diagnose prostate carcinoma with high sensitivity and spesifity. Although today we look for values of PSA in serology for diagnose of prostate carcinoma, AMACR /P504S may be more spesific biomarker than PSA. We recommend new researches about this biomarker, AMACR / P504S.

PP2-166
IMMUNOHISTOCHEMICAL ANALYSIS OF TISSUE FACTOR EXPRESSION IN HUMAN BLADDER CARCINOMA: CORRELATION WITH ANGIOGENESIS, CLINICOPATHOLOGICAL ASPECTS AND SURVIVAL

Vinicius Duval Da Silva, Eurico Dornelles, Gustavo Franco Carvalhal, Carlos Fay, Eduardo Franco Carvalhal, Guilherme Rosa, Henrique Sarmento Barata, Carlos Luiz Reichel
Pontificia Universidade Catolica do Rio Grande do Sul, Porto Alegre, Brazil

BACKGROUND: Recent studies have shown that tissue factor (TF), a primary physiologic initiator of coagulation cascade, may be involved in tumor angiogenesis and metastasis. This study was designed to assess whether TF expression correlates with microvessel density (MVD), clinical presentation, TNM and prognosis in bladder carcinoma. METHOD: Tissue samples were obtained from 67 specimens of transurethral resected bladder carcinoma. Clinicopathologic and follow-up data of patients were prospectively collected. Expression of TF was examined by immunohistochemical methods. Tumor MVD was evaluated using anti-CD34 as the endothelial marker. Statistical analysis comparing the TF expression with MVD, TNM and overall survival was performed. RESULTS: Forty-one (61.2%) patients had Ta tumors, six (9%) had T1 tumors and 20 (29.9%) presented T2 tumors. Thirty tumors (44.8%) were classified as Grade 1, 15 (22.4%) as Grade 2, and 22 (32.8 %) as Grade 3. Twenty-six specimens had less than 12 microvessels per high power field, and 41 had 12 or more. TF expression ranging from 0 to 25% of the tumor area were observed in 16 specimens (22.5%), 26 to 50% in 11 (16.4%), 51 to 75% in 33 (49.3%) and 76 to 100% in 7 (10.4%). Neither MVD nor TF correlated with tumor stage or grade. There was not a significant correlation between TF expression and MVD However, patients with lower TF expression had better overall survival than groups with TF expression ranging from 26 to 100%. CONCLUSIONS: Most bladder tumors from expressed TF and were highly vascularized. There was not significant correlation between TF and MDV. However, the group with less TF expression had better overall survival when compared with cases expressing an intensity of 26 to 100% of tumor area.

[2] Department Of Urology, Hippokration General Hospital Thessaloniki, Greece

Splenogonadal fusion is a rare congenital malformation, in which the spleen is abnormally connected to the gonads or mesonephric derivaties. Approximately 150 cases have been reported so far in the literature since the condition was first described by Bostroem in 1883. We report a case of a 23-year-old man who was admitted to the urology department of our hospital for evaluation of left cryptorchidism. CT scan revealed three abdominal nodules on the left and right solitary kidney. During the exploratory laparotomy, the left testis was found in the pelvis and was connected to the spleen with a reddish cord-like structure, which contained two nodules with diameter 0,9 cm and 2,7 cm. Gross examination identified that the testis had a diameter of 3,7 cm. Histological examination revealed that the testis was atrophic with small, thick-walled seminiferous tubules, germinal cell aplasia and mild hyperplasia of Leydig cells. A few seminiferous tubules contained psammoma bodies. The morphological and immunohistochemical findings (negative stain for PLAP-Placental alkaline phosphatase) ruled out in situ carcinoma. The other two nodules consisted of splenic tissue. The histological findings suggested the diagnosis of splenogonadal fusion. We present this case because of its rarity and we review the findings in the literature.

A NEW CASE OF TESTICULAR UNCLASSIFIED MIXED GERM CELL SEX CORD-STROMAL TUMOR

Berdan Gabriela[1], Petrescu Amelia[1], Mihai Mihaela[2], Popescu Mircea[1], Hulea Ionela[1], Gaitanidis Raluca[1], Niculescu Liviu[3]
[1] Prof. Dr. Th. Burghele Hospital, Bucharest, Romania
[2] Victor Babes National Institute of Pathology, Bucharest,Romania
[3] University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Introduction: We present the morphological and immunohistochemical features of one case of testicular unclassified mixed germ cell sex cord-stromal tumor (MGSCST) of a 36 years old man hospitalized with a painful left testicular

mass, which appeared 3 months before. Ultrasound exam revealed a 30/20 mm testis with a hipoechogen parenchymal nodule, 8 mm in diameter, without vascularity. A radical left orhidectomy was performed. Macroscopic examination showed a parenchymal nodule, 10/10 mm, near the albuginea, partially circumscribed, grey-whitish coloured. Material and methods: Fragments from the tumor, testicular parenchyma, epididimys and spermatic cord were fixed in formaldehyde 10 %, then included in paraffin, stained with HE, VG and processed for immunohistochemical markers. Results: Microscopically examination revealed a tumoral proliferation of 2 components: epithelial and stromal. The epithelial cells were diffusely disposed in the center of the tumor and they formed tubular structures at the periphery of the tumor. They had abundant vacuolar, here and there eosinophylic cytoplasm; there were also scattered germinal-like cells, with round small nuclei, inconspicuous nucleoli and clear cytoplasm. The stroma was mainly fibrous. There was slightly nuclear pleomorphism, but no atypical mitosis. Some of the tumoral cells seemed to penetrate into the surrounding normal parenchyma. The other testicular structures were free of tumor. The immunohistochemical markers: VIM, S100 positive diffusely in the tumor, PLAP positive in some scattered cells of the tumor (dot-like pattern); inhibin , cromogranina and EMA negative, sinaptophisine weakly positive in tumoral cells. Conclusions: The pathological diagnosis was unclassified MGSCST. Testicular sex cord-stromal tumors are interesting neoplasms because they lead to many issues in differential diagnosis. Despite the negativity for inhibin in our case, this result is not an argument against the diagnosis of sex cord-stromal tumor. The positivity of PLAP favoured the diagnosis of MGSCST, excluding the other sex cord-stromal tumor with entrapped germ cells. Because of the small size of the tumor and the absence of atypical mitosis, we think that our case carry out a favorable prognosis.

PP2-169

RELATIONSHIP BETWEEN RENAL ARTERY CHANGES AND EXPRESSION OF VACULAR ENDOTHELIAL GROWTH FACTOR AND CD31 IN RENAL CELL CARCINOMA

Davor Tomas[1], Karla Tomic[2], Tanja Lenicek[1], Alma Demirovic[1], Majda Vucic[1], Hrvoje Cupic[1], B. Kruslin[1]
[1] Ljudevit Jurak Department of Pathology, Sestre Milosrdnice University Hospital, Zagreb, Croatia
[2] Department of Pathology, Dr Josip Bencevic General Hospital, Slavonski Brod, Croatia

Background: Renal cell carcinoma (RCC) represents more than 90% of all malignancies of the kidney in adults. Main renal artery may show different lesions such as atherosclerosis or fibromuscular dysplasia (FMD). The aim of this investigation is to correlate expression of vascular endothelial growth factor (VEGF) and CD31 (microvessels density) with renal artery changes in RCC. Patients and methods: We analyzed consecutive series of 55 patients (M:F=35:20) with RCC who underwent nephrectomy. Patients were aging from 35 to 79 years (mean 59.8) and the tumor size was 2.5 to 16 cm (mean 7.1). Specimens were routinely processed and stained with hematoxylin and eosin, Mallory trichrome method and orcein. Immunohistochemical analysis was performed using primary antibodies to VEGF and CD31 (DAKO). Immunohistochemical reaction on VEGF was assessed as: 0–no positive tumor cells; 1–up to 10% positive tumor cells; 2- >10-50% positive tumor cells; 3- >50% positive tumor cells. Microvessels density was immunohistochemically highlighted with antibodies to CD31. The area of tumor that contains the maximum numbers of discrete microvessels and two adjacent areas which were counted have been identified by scanning entire tumor at low power field (X40). Microvessels were counted under high power field (X400) and cut off value was set at 40 microvessels per HPF. Statistical analysis was performed using $\chi 2$ test. The level of significance was set at $p < 0.05$. Results: Renal arteries of 23 (41.8%) patients showed no changes, FMD was found in 25 (45.5%) and atherosclerosis was observed in 7 (12.7%). VEGF expression was negative in 14 (25.5%) cases, 19 (34.5%) cases had less than 10% positive tumor cells, 13 (23.6%) cases had 10-50% positive tumor cells and 9 (16.4%) tumors expressed VGF in more that 50% tumor cells. Twenty (36.4%) tumors had microvessels density over cut off value and 35 (63.6%) had lower number of microvessels. Statistical analysis showed no connection between VEGF expression and microvessels density with T-stage, tumor grade, and renal artery changes ($p>0.05$) but showed correlation between VEGF expression and microvessels density ($p<0.05$). Conclusion: Renal artery changes, especially FMD, are very common in patients with RCC. Expressions of VEGF by tumor cells and microvessel density did not correlate with renal artery changes. Microvessels density correlated with VEGF expression despite of renal artery status. The cause of renal artery changes and their relationship to the tumor neoangiogenesis should be further analyzed.

PP2-170

EXPRESSION OF MAGE-A3/4 AND NY-ESO1 IN RENAL ONCOCYTOMA AND CHROMOPHOBE RENAL CELL CARCINOMA

Božo Kruslin[1], Tatjana Bujas[2], Ivana Pavic[1], Alma Demirovic[1], Tvrtko Hudolin[3], Michael Heberer[4], Giulio Cesare Spagnoli[4], Davor Tomas[1], Mladen Belicza[1]
[1] Ljudevit Jurak Department of Pathology, Sestre milosrdnice University Hospital Zagreb, Croatia
[2] Department of Pathology, General Hospital Karlovac, Croatia
[3] Dept of Urology, Clinical Hospital Centre, Zagreb, Croatia
[4] Dept of Surgery, Division of Research, University of Basel, Basel, Switzerland

Background: The human genes MAGE-A3/4 encode tumor-specific peptide antigens, which are recognized by cytotoxic T lymphocytes. The antigens coded by those genes may be useful target for cancer immunotherapy. There is, however, little information on the expression of these genes and their proteins in renal tumors, especially renal oncocytoma (RO) and chromophobe renal cell carcinoma (CRCC). The aim of the study was to investigate the expression of MAGE –A3/4 and NY-ESO1 in RO and CRCC detected by immunohistochemistry. Methods: We randomly selected 20 consecutive tumors: 10 CRCC and 10 RO. Monoclonal antibodies MAGE-A3/4 and NY-ESO1 were used for immunohistochemical staining. Immunohistochemical staining results were expressed as follows: negative (-), (+) positive in up to 10% of tumor cells, (++) >10-50 % of tumor cells and (+++) >50% tumor cells. Results: Male/ female ratio for RO and CRCC was 3:7 and 2:8, respectively. The average age of patients with RO was 66,5 years (range 57 to 77). The size of tumor was from 0,9 to 8 cm (mean 3,6 cm). Strong cytoplasmic expression of MAGE-A3/4 was observed in RO in 4 cases (40%), moderately positive in 3 (30%) and slightly in 3 cases (30%). Positive cytoplasmic staining was also observed in adjacent kidney tissue. Strong NY-ESO1 expression was observed in 5 RO cases (50%), moderately positive in 2 (20%) and slightly positive in 3 cases (30%). The reaction in adjacent renal tissue was negative or slightly positive. The average age of patients with CRCC was 55,6 years (range 47 to 71). The size of tumor ranged from 2,7 to 17 cm (mean 5,4 cm). The expression of MAGE-A3/4 protein was negative (-) in 3 cases of CRCC, slightly positive (+) in 5 cases and in 2 cases moderately positive (++). Similar reaction was found in surrounding renal parenchyma. NY-ESO1 protein expression was not seen in 5 cases, slightly positive in 3, moderately and strongly positive in one case each. The expression found in surrounding renal parenchyma was stronger than in tumor tissue. Conclusions: This study documents strong immunostaining of MAGE-A3/4 and NY-ESO1 in RO, while staining of CRCC was weak and present in minority of cases. Positive staining for both antigens was

found in adjacent renal tissue. It seems that antigens may not be used as potential therapeutic target. Further studies are needed to explore potential value of MAGE - A3/4 and NY-ESO1 in the differential diagnosis between RO and CRCC.

BILATERAL GONADOBLASTOMA ADMIXED WITH COMPOSED MALIGNANT GERM CELL TUMOR ARISING IN CRYPTORCHID TESTIS: A CASE REPORT

Ben Abdelkader Atef, Yacoubi Mohamed Tahar, Trabelsi Amel, Abid Lilia, Belaid Leila, Korbi Sadok
Department of Pathology, F Hached Hospital Sousse 4000 Tunisia

Gonadoblastoma is a tumor composed by germ cells associated to sex cord component. It usually arise in gonads in patient with chromosomal anomalies. The development of malignant germ cell tumors in gonadoblastoma impose a severe prognosis. We report a new case of patient with 16 year-old who consult for abdominal pain. Physical examination showed abdominal mass. Surgical investigation found 2 hypogastric masses with bowel malrotation. At gross, these masses were well circumscribed with 1200 and 800 g in weight and yellow at cutting with calcifications. Histologically, they shared the same feature of typical gonadoblastoma, associate to seminoma in the once and to seminoma and choriocarcinoma in the second. Adjacent testis tissue was found. The patient died in a context of lung metastasis a day after the surgery. We describe than, the histogenesis of gonadoblastoma, the criteria of diagnosis and the genotype context.

PP2-172
EPITHELIAL TO MESENCHYMAL TRANSITION IS OF STRONG PROGNOSTIC IMPORTANCE IN PROSTATE CANCER

Karsten Gravdal[1], Ole Johan Halvorsen[1], Svein Andreas Haukaas[2], Lars Andreas Akslen[3]
[1] Section for Pathology, The Gade Institute, Haukeland University Hospital, Norway
[2] Dept. of Surgical Sciences, Haukeland University Hospital, University of Bergen, Norway
[3] Section for Pathology, The Gade Institute, Haukeland University Hospital, University of Bergen, Norway

Cell adhesion molecules are of crucial importance in cancer invasion and metastasis. Epithelial to mesenchymal transition (EMT), characterized by reduced E-cadherin and increased N-cadherin expression, has been recognized as a feature of aggressive tumors, but the importance of this phenotype has not been settled in human prostate cancer. A consecutive series of 104 radical prostatectomies with detailed and long clinical follow-up was studied immunohistochemically for classical cadherins and catenins. In univariate survival analyses, cadherin switching (high N-cadherin and low E-cadherin) showed strong and significant associations with multiple end-points of progression and cancer specific death. In multivariate analysis of time to clinical recurrence, the EN-switch (HR 4.3; $P<0.0005$), had strong and independent prognostic impact, together with Gleason score. These novel data unravel the importance of EMT for prostate cancer progression, and a switch from E-cadherin to N-cadherin expression could have significant impact on the care of prostate cancer patients.

PP2-173
INVESTIGATION OF EPSTEIN-BARR VIRUS INFECTION IN PROSTATE CANCER IN TUNISIAN PATIENTS

Mounir Trimeche, Sonia Ziadi, Mohamed Hachana, Khaled Amara, Moncef Mokni, Badreddine Sriha, Sadok Korbi
Laboratory of Pathology, CHU Farhat Hached, Sousse, Tunisia

Background: Epstein-Barr virus (EBV) infection has been linked with several malignancies of lymphoid and epithelial cell origin. North Africa is considered as a high-risk area for two EBV-associated tumors: pediatric Hodgkin's lymphoma and nasopharyngeal carcinomas. It has been recently suggested that EBV may be involved in the pathogenesis of some cases of prostate carcinomas. The purpose of this study was to evaluate the prevalence of EBV infection in prostate carcinomas in Tunisia. Methods: Sixty-three consecutive adenocarcinomas of the prostate were tested for the presence of EBV on formalin-fixed and paraffin-embedded tissue specimens. Detection of EBV genomic DNA was performed by polymerase chain reaction (PCR) using primers flanking a 122-bp sequence in the BamHIW repetitive sequence. The presence of EBV in prostatic cells was investigated by EBER1/2-in-situ hybridization and by immunohistochemistry for the detection of EBV latent membrane protein-1 (LMP-1) and Epstein-Barr-replication activator protein (ZEBRA). Results: PCR for the detection of a 268-bp sequence in the β-globin gene indicated the presence of amplifiable DNA in all cases. EBV-DNA-sequences were detected by PCR in 7 cases (11%). By in-situ hybridization, EBER1/2 expression was not detected in neoplastic cells in any of the 63 cases, but in 3 cases, scattered non-neoplastic lymphocytes were EBV-positive. Immunohistochemical study of LMP-1 and ZEBRA was negative in all cases. Conclusion: Given the sensitivity of the technique used, theses results do not support a relationship between EBV and prostate carcinomas in Tunisia.

PP2-174
ANALYSIS OF HUMAN PAPILLOMAVIRUS INFECTION IN BLADDER CARCINOMAS IN TUNISIA

Mounir Trimeche, Sonia Ziadi, Walid Ben Selma, Khaled Amara, Mohamed Hachana, Moncef Mokni, Sadok Korbi
Laboratoire d'Anatomie Pathologique, CHU Farhat Hached, Sousse, Tunisia

Background: Human papillomavirus (HPV) infection has been associated with a variety of benign and malignant epithelial lesions. The association of HPV with a subset of bladder carcinomas has been reported but remains controversial. The aim of this study was to evaluate the frequency of HPV infection in bladder carcinomas in Tunisia. Methods: 125 consecutive bladder carcinomas (119 urothelial carcinomas, 5 squamous cells carcinomas and 1 adenocarcinoma) were investigated for the presence of HPV DNA sequences by polymerase chain reaction (PCR). DNA was extracted from formalin-fixed paraffin-embedded tumor tissues. HPV sequences were amplified by three different methods; these included the E1350L/E1547 primers amplifying a 180-bp sequence in a highly conserved region of a wide spectrum of anogenital HPV, the pU-1M/PU-2R primers specific for the oncogenic HPV types 16, 18, 31, 33, 52, 58, and the PU-31B/PU-2R primers for low-risk HPV types 6, 11. Results: PCR for the detection of a 268-bp sequence in the β-globin gene demonstrated the presence of amplifiable DNA in all cases. No HPV-related DNA sequences were identified by PCR in any case of bladder carcinomas tested. Conclusion: This study indicate that bladder carcinomas are not etiologically related to the anogenital HPV tested in patients from Tunisia, however the possibility that other types of HPV contribute in the bladder carcinogenesis can not be excluded and remain to be clarified.

PP2-175
INVESTIGATION OF HUMAN POLYOMAVIRUS INFECTION IN PROSTATE CANCER IN TUNISIAN PATIENTS

Mounir Trimeche, Sonia Ziadi, Khaled Amara, Mohamed Hachana, Badreddine Sriha, Moncef Mokni, Sadok Korbi
Laboratory of Pathology, CHU Farhat Hached, Sousse, Tunisia

Background: Several investigations have suggested that infectious agents can be potential cofactors in prostate cancer development. Human polyomaviruses JCV and BKV represent viruses with proven linkage to different human cancers. To determine whether these viruses contribute to prostate tumorigenesis in Tunisian patients, we have carried out a polymerase chain reaction (PCR) screening in archival samples obtained during transurethral resection of the prostate. Methods: A group of 63 patients affected by primary prostate cancer randomly selected has been analyzed in comparison with a control group of 24 benign prostatic hyperplasia samples. The DNA of the polyomaviruses BKV and JCV has been searched on formalin-fixed paraffin-embedded prostate tissue specimens by PCR using specific primers. Results: PCR for the detection of a 268-bp sequence in the human β-globin gene demonstrated the presence of amplifiable DNA in all specimens. These samples were considered to have sufficient DNA quality and were therefore used for subsequent analysis. JCV was not detected in any of the 63 prostate cancer cases; whereas 4 benign prostatic hyperplasia cases (16%) have shown positive signals. BKV investigation was negative in all prostatic cancers and benign prostatic hyperplasia specimens. Conclusion: Given the sensitivity of the technique used, theses results do not support a relationship between polyomaviruses BKV and JCV and the pathogenesis of prostate cancer

[3] Departments of Pathology, Chang Gung Memorial Hospital-Kaohsiung Medical Center, Chang Gung University College of Medicine, Kaohsiung, Taiwan
[4] Department of Pathology, Chi-Mei Foundation Hospital, Liouying Campus, Tainan, Taiwan

Background: Urothelial carcinoma (UC) of the upper urinary tract (UUT) is relatively uncommon. It usually pursues aggressive clinical course and shows high frequency of urinary bladder (UB) recurrence and some with metastases even after radical surgery. Only few series on UUT-UC had prudently addressed what parameters could affect final outcomes and urinary bladder recurrence by using large-scaled survival analyses. Methods: Two hundred and ninety-six primary localized UUT-UC surgically treated through a 14-year span were retrospectively analyzed. Patients with preceding UB tumors or metastatic disease and presented as pT4 tumors were excluded. The clinical endpoints evaluated were disease-specific survival (DSS) and UB recurrence-free survival (UBRFS). Follow-up was obtained in all cases which ranged from 1 to 140 months. Results: There were 142 males and 154 females. There were 119, 135, and 42 tumors involved renal pelvis, ureter, and both sits, respectively. Concomitant UB tumors were observed in 52 cases. The primary tumors were non-invasive in 97, T1, T2, and T3 in 72, 48, and 78, respectively. Thirteen cases were of well-differentiated, 136 and 147 were of moderately and poorly differentiated, respectively. For DSS, tumor involving both ureter and renal pelvis ($p=0.0018$), high pT status ($P<0.0001$), a predominant papillary configuration ($p<0.0001$), marked nuclear pleomorphism ($p=0.0006$), high mitotic count (>=5/10 HPFs) ($p=0.0006$), perinurial invasion ($p<0.0001$), the presence of vascular invasion ($p<0.0001$), as well as squamous differentiation ($p=0.0013$), high histological grade ($p<0.0001$) and presence of tumor necrosis ($p<0.0001$) were significant survival predictors. For UBRFS, only the presence of concomitant urinary bladder tumor was significant predictor ($p=0.0045$). Conclusions: Among the clinicaopathologic parameters, high pT status, predominantly papillary growth pattern, perineurial and vascular invasion, accompanied by high histological grade and presence of tumor necrosis are strongest survival determinates for DSS in primary localized UUT-UC. While UBRFS is very difficult to predict and is only associated with the presence of concomitant UB tumor.

PP2-177
PROTEIN EXPRESSION AND MUTATIONAL ANALYSIS OF EPIDERMAL GROWTH FACTOR RECEPTOR IN RENAL ANGIOMYOLIPOMAS

So Dug Lim[1], Wanseop Kim[2], Geunghwan Ahn[3], Ghee Young Kwon[3]
[1] Department of Pathology, Konkuk University School of Medicine and Center for Geriatric Neuroscience Research of Biomedical Science and Technology, Konkuk University, Seoul, Republic of Korea
[2] Department of Pathology, Konkuk University School of Medicine, Seoul, Republic of Korea
[3] Department of Pathology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Renal angiomyolipoma (AML) is a benign but progressive tumor which occasionally requires nonsurgical therapy and there appears to be a possibility that epidermal growth factor (EGF) is associated with pathogenesis of renal AML. The response to gefitinib, anti- epidermal growth factor receptor (EGFR) agent and a prime example of target therapy, reportedly has been correlated with the presence of mutations within the tyrosine kinase (TK) domain of EGFR or the expression of its truncated form, EGFR variant III. Therefore we investigated EGFR protein expression and gene mutations in exons 18, 19 and 21 in 40 renal AMLs. No EGFR gene mutations of TK domain were detected in any of the 40 cases studied and strong immunostaining was found in 5% of the renal AML cases. Our findings indicate that in renal AML, anti-EGFR treatment may not be promising but that there is a possibility that EGFR is associated with renal AML pathogenesis.

PP2-178
INCIDENCE OF FOCAL CARCINOMAS AND ATYPICAL GLANDULAR PROLIFERATIONS (AGP) IN 1000 NEEDLE PROSTATIC BIOPSIES

Angel Fomperoza-Torres, Alfredo Valero, Jose Miguel Gonzalez-Berjon, Julian Arista-Nasr
Instituto Nacional de Nutricion Salvador Zubiran. Mexico

Introduction: with the routine use of prostatic specific antigen blood determination, sextant biopsies and immunohistochemical studies, focal carcinomas and atypical glandular proliferations (AGP), limited to isolated histologic fields are being detected more frequently. The recognition of these lesions is important since many of them correspond to potentially curable cancers or to benign lesions that mimic carcinoma. Materials and Methods: 1000 consecutive prostatic biopsies performed during the period of 2000-2007 were reviewed. 42 focal prostatic lesions were retrieved. We reassessed the original HE slides. Additional histologic sections and immunohistochemical studies were performed in those cases with uncertain diagnoses in order to clarify the nature of the lesions. Results: Thirteen (1.3%) lesions corresponded to focal carcinomas and 29 (2.9%) to AGP. Immunohistochemical studies and the analysis of additional histologic sections allowed the classification of 17 cases of AGP into specific categories (prostatic adenosis, atrophy, atypical basal cell hyperplasia and seminiferous ducts). Only three of the 13 patients diagnosed with focal carcinomas were subjected to radical prostatectomy in our institution; all of them had disease limited to the prostatic gland. Of the 29 AGP, additional biopsies

were taken in four cases and in one of them prostatic carcinoma was the final diagnosis. Conclusions: A significant number of AGP biopsies could be sub classified in to specific diagnostic categories with the use of immunohistochemical studies and additional HE levels. The frequency of focal carcinoma and AGP in our material was similar to other series; however in many of the AGP cases additional biopsies were not performed despite its high predictive value for carcinoma. Increase use of follow-up biopsy procedures is needed in order to detect early potentially curable lesions.

PP2-179
LIPOSARCOMA OF SPERMATIC CORD

Berdan Gabriela[1], Petrescu Amelia[1], Terzea Dana[2], Badescu Dan[1], Hulea Ionela[1], Gaitanidis Raluca[1], Niculescu Liviu[3]
[1] Prof. Dr. Th. Burghele Hospital, Bucharest, Romania
[2] Victor Babes National Institute of Pathology, Bucharest, Romania
[3] University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Introduction: We present the case of a 57 years old man admitted to our hospital for the presence of a posttraumatic right scrotal mass. Ultrasound exam showed a large solid, inhomogeneous scrotal tumor which pushed downward the testis and epididym. The MRI exam revealed no inguinal and abdominal adenopatic masses. A radical right orhidectomy was performed. Macroscopic examination showed a normal testis and epididym; the spermatic cord presented in the distal portion a large multinodular tumor (12 cm maxim diameter), with gray-whitish, yellow and gelatinous areas. Material and methods: Fragments from the tumor, spermatic cord, testicular parenchyma, epididimys were fixed in formaldehyde 10 %, then included in paraffin, stained with HE, VG and processed for immunohistochemical markers. Results: Microscopic examination revealed a tumoral proliferation composed of myxoid areas with fine arborizing vascular pattern, signet-ring lipoblasts, small cells with uniform nuclei, mature fatty tissue areas, colagenic areas. There were slightly cellular pleomorphism and rare mitosis. No necrosis was found. The parenchymal testis and the epididym were not involved by the tumor. Immunohistochemical markers: VIM, S100 diffusely positive in the tumor, ACT, CD34 positive in blood vessels, PCNA 10-15% positive in the tumor. Conclusion: The morphologic and immunohistochemical diagnosis was liposarcoma with areas of myxoid and well differentiated liposarcoma. Liposarcomas of spermatic cord are rare, comprising approximately 5-7% of all spermatic cord sarcomas. Due to the fact we hadn't any data about the resection margins, local radical excision seems to be insufficient because local recurrence is a major problem, occurring in up to 50% of the patients.

PP2-180
INTRATUBULAR GERM CELL NEOPLASIA IN ADULTS: RETROSPECTIVE EVALUATION OF 446 ORCHIECTOMY CASES.

Huseyin Baloglu, Hasan Aktug Simsek, Nuri Yigit, Aptullah Haholu, Ozgur Ekinci, Ufuk Berber
GATA Haydarpasa Training Hospital, Department of Pathology. Istanbul, Turkey

Background: Intratubular germ cell neoplasia (ITGCN) is a precursor lesion for certain types of invasive germ cell tumors (IGCT) in testes. We present a demographic profile of 61 ITGCN cases. Method: Data of 544 orchiectomy cases were retrieved from the archive of GATA Haydarpaşa Training Hospital between 1989 and 2006. Orchiectomies were performed because of maldescent testes in 284 cases, germ cell tumors (GCT) in 152 cases, trauma in 21 cases, and prostate cancer in 87 cases. ITGCN diagnosis was confirmed on second views. Microscopic diagnosis of ITGCN was based on H&E, PAS and PLAP staining results. ITGCN rate was calculated for each group. Age range of was 16 to 74 in maldescent group (average: 26,7 median: 23), 16 to 68 in GCT group (average: 20,3 median: 20), 54 to 89 in 87 prostate cancer group (average: 66,5 median: 65), and 16 to 74 in maldescent group (average: 26,7 median: 23). Results: Of 284 maldescent testes, 13 revealed ITGCN (4,5 %). Associated ITGCN was found in peritumoral testicular parenchyma in 93 of 152 GCT cases (61,1 %). In none of the prostate cancer group testes and trauma group testes were ITGCN found. Conclusion: ITGCN rate in our series is found similar to the previously reported incidence ranging between 2-4% for maldescent testes, and 63-99% for association with GCT. This study supports the high ratio coincidence of ITGCN and GCT in the same testes. In addition, recent studies also denote shared molecular alterations supporting the continuity between ITGCN and GCT. ITCGN is considered to be the preinvasive phase of testicular GCT with the exceptions of spermatocytic seminoma, pure yolk sac tumor, and mature teratoma.

COMPARISON OF IMMUNOREACTIVITIES OF P53, E-CADHERIN AND PTEN IN PATTERNS OF ACINAR PROSTATIC ADENOCARCINOMA

Ufuk Berber[1], Huseyin Baloglu[1], Aptullah Haholu[1], Ismail Yilmaz[2], Aktug Simsek[1], Nuri Yigit[1]
[1] Gulhane Medical Academy Haydarpasa Training Hospital Department of Pathology, Turkey
[2] Corlu Military Hospital, Turkey

BACKGROUND: Prostate cancer is the most common invasive malignancy in men. Despite many studies, etiology of prostate cancer remains unclear. Lots of genetic alterations have been reported but any specific genetic alterations or an alteration that is seen in most of the patients have not been identified yet. Prostate cancer differs from other epithelial tumors by its intratumoral heterogeneity and multifocality. METHOD: In this study, p53, PTEN, and e-cadherin immunoreactivities were examined in different histological patterns of the prostate cancer that are known to have prognostic significance. With this aim, 40 prostatic adenocarcinoma specimens having different Gleason patterns were selected from the paraffin-embedded archival blocks from patients that had underwent radical retropubic prostatectomy in GATA Haydarpaşa Training Hospital between 1997 and 2006. In all of the patients, p53, PTEN, and e-cadherin expressions were evaluated by immunohistochemistry in areas of different Gleason patterns. Also the relationships between these 3 markers and well known prognostic parameters of prostate cancer including extraprostatic involvement, lymph node metastasis, seminal vesicle infiltration, positive surgical margins, and tumor volume were examined. RESULTS: Between areas with Gleason grades 3 and 4, there was not any difference in p53 immunoreactivity, but loss of PTEN and e-cadherin expressions were found to be more common in grade 4 areas. In clinicopathologic variables, an association was observed between tumor volume and p53 immunoreactivity, also loss of PTEN expression was associated with seminal vesicle infiltration and positive surgical margins. We have not seen a relationship between loss of e-cadherin expression and chlinicopathological variables that we have investigated. Interestingly, loss of e-cadherin expression in patients that showed p53 immunoreactivity tends to be associated with positive prognostic parameters. CONCLUSION: These results show that alterations in p53 gene occur at an early stage but alterations of the PTEN and e-cadherin genes appear with the progression of the disease. We have not seen a case that shows abnormal expression of any of the three markers in low grade areas without abnormal expression in high grade areas. This finding suggests that the multifocality of prostate cancer results from the intraprostatic spreading of a monoclonal lesion rather than different primary tumors. As number of cases in our study were limited, for this purpose new studies with larger series are required.

PP2-182
MOLECULAR ALTERATIONS OF EGFR IN PROSTATE TUMOURS

Silvia De Muga[1], Silvia Hernandez[2], Laia Agell[1], Jose Antonio Lorente[1], Sergi Mojal[3], Sergi Serrano[1], Antoni Gelabert[1], Josep Lloreta[2]

[2] Hospital del Mar-UPF, Spain
[3] Hospital del Mar-IMIM, Spain

Background: The epidermal growth factor receptor (EGFR) is involved in a high variety of processes, mainly proliferation and apoptosis modulation. Recently, point mutations, small deletions, and amplification of this gene have been reported in lung, colo-rectal, head and neck, and many other tumours. These genetic changes seem to correlate with response to kinase inhibitor drugs. Most studies in prostate cancer have dealt with immunohistochemical overexpression of the protein but little is known about EGFR mutations in this tumor. The purpose of this study is to investigate EGFR gene alterations in prostate adenocarcinoma. Material and Methods: 69 prostate tumours and 2 cell lines (DU145 and PC3) have been studied. The tumours were 47 clinically significant (biopsy or prostatectomy) cases, 14 autopsy tumours, one lymph node and 7 bone metastases (42 Gleason ≤7 y 27 >7). DNA was extracted by manual microdissection from formalin-fixed, paraffin-embedded tissue. Exons 18 to 21 were studied by DNA amplification (PCR) with intronic primers and direct sequencing. Protein expression was studied by immunohistochemistry (Clone H11, Dako, Glostrup, Denmark) in a subset of 28 cases. Results: 9/69 (13%) tumours showed EGFR mutations: in 7 cases, all of them Gleason >7, mutations involved exon 21, while in the remaining 2 cases, with Gleason 6, mutations were identified in exon 20. The number of mutations was significantly different between low and high Gleason grade tumours, the latter including metastases (Exact Fisher's test, p=0,026). No mutations were found in the cell lines. The mutations resulted in 5 different protein sequence changes, the most frequent being V834A, in 4 tumours, and I821T, in 2 tumours. 7/28 tumours showed immunohistochemical expression of EGFR; 2/7 (28%) positive and 3/21 (14%) negative cases had mutations in the gene. Conclusions: EGFR gene mutations are found in 13% of prostate tumours, most of them with Gleason grade >7. There is a statistically significant trend towards higher mutation rates in high grade, high stage tumours. The mutation frequency is higher in tumours showing protein expression but the number of cases is low. These results must be compared with gene amplification analysis by FISH. This study has been funded by grants FIS/ISCIII 06/1411 and Asociación Española Contra el Cáncer-Barcelona-2006.

PP2-183
C-ERB-B2, AURORA-A, MIB-1 AND P53 HAVE PREDICTIVE VALUE FOR VASCULAR INVASION AND RELAPSE IN UPPER URINARY TRACT TRANSITIONAL CELL CARCINOMAS

Eva Comperat[1], Philippe Camparo[2], Morgan Roupret[3], Emmanuel Chartier-Kastler[3], Francois Richard[3], Frederique Capron[1], Olivier Cussenot[4]
[1] Service d'Anatomie Pathologique, Hôpital La Pitié, Faculté PMC Paris VI, France
[2] Service d'Anatomie Pathologique Val de Grace Paris, France
[3] Service d'Urologie, Hôpital La Pitié, Faculté PMC Paris VI, France
[4] Service d'Urologie, Hopital Tenon; Faculté PMC Paris VI, France

Objectives: Upper urinary tract transitional cell carcinomas (UUT-TCC) are rare but aggressive. Today's main prognostic factors are tumor stage and grade. Vascular invasion, a factor for predicting relapse and metastatic disease is not always seen on surgical paraffin embedded samples, although they might be present. We wanted to evaluate an immunohistochemical profile to be able to predict vascular invasion and relapse in UUT-TCC. Materials and Methods: 41 patients with UUT-TCC have been explored. 18 had ureteral localisation, 23 in the renal pelvis. (13 pTa low grade tumors and 2 pTa high grade tumors, 8 pT1, 6 pT2, 10 pT3 and 2 pT4). Immunohistochemistry for c-erb-b2, Aurora-A, p53 and MIB-1 was performed on tissue micro arrays taken from surgical specimen of all these patients. Fluorescence in situ hybridization (FISH) was made on samples with immunohistochemical overexpression. Results: Patients were aged from 46 to 100 years (mean 70.6 a). Eleven patients (27%) showed association with carcinoma in situ, 14 (34%) of patients displayed vascular invasion in surgical specimen, 25 (61%) developed relapse, 23 (54%) died of disease. Vascular invasion was associated with overexpression of c-erb-b2 ($p<0.001$), Aurora-A ($p= 0.0034$), p53 (0.0082) and MIB-1 (0.0017). Relapse was associated with high expression of c-erb-b2 ($p= 0.019$), Aurora-A ($p= 0.17$), MIB-1 (0.067) and p53 (0.047). c-erb-b2 results have been confirmed by FISH. Conclusion: Independent prognostic factors of vascular invasion and relapse in UUT-TCC are important to be established. Immunohistochemistry is easily available in pathologists daily routine, and it is important to find profiles on protein level to predict bad clinical outcome for a better patient's follow-up. c-erb-2 is an important prognostic factor and its overexpression has been observed in high grade and high stade bladder tumors. Few data are available on UUT-TCC, our study demonstrates clearly implication of this molecule. Aurora-A plays a role in cell division and in maintaining genomic integrity. It is linked to clinical aggressiveness and poor overall survival of the patients in bladder cancer. Our study is the first to show implication in UCC-TCC. Major implication p53 and MIB-1 in UCC-TCC are known to be prognostic factors of bad clinical outcome. Our data confirm these findings of the literature. We propose an immunoprofile of c-erb-b2, Aurora-A, p53 and MIB-1 to predict vascular invasion and relapse in UCC-TCC, considering that each marker has predictive power.

PP2-184
KLF6 AND P53 MUTATION IN PROSTATE CANCER

Laia Agell[1], Silvia Hernandez[2], Silvia De Muga[2], José Antonio Lorente[3], Sergi Serrano[4], Josep Lloreta[2], Antoni Gelabert[5]
[1] Department of Pathology and Urology, Hospital del Mar
[2] Department of Pathology, Hospital del Mar and University Pompeu Fabra, Barcelona, Spain
[3] Department of Urology, Hospital del Mar and Autonomous University of Barcelona, Spain
[4] Department of Pathology, Hospital del Mar and Autonomous University of Barcelona, Spain
[5] Department of Urology and Autonomous University of Barcelona, Spain

Background: KLF6 is a zing finger transcription factor that reduces cell proliferation through up-regulation of p21 in a p53-independent manner. Different studies have proposed a high variability in the frequency of mutations (form 55% to 0%). The frequency of mutation of TP53 is also controversial ranging from 3% to 42%. The aim of our study is to investigate the role of the tumour supressor genes KLF6 and TP53 in a well-defined group of prostate tumours with different stages and Gleason scores. Design: The study is based on 78 cases of prostate cancer (Gleason 28 ≤6; 24 Gleason =7 y 26 ≥8), plus 16 from autopsy (8 Gleason ≤ 6; 3 Gleason=7 and 5 Gleason ≥ 8), 8 bone and 2 lymph node metastases and 2 cell lines (PC3 and DU145). DNA was extracted from formalin-fixed, paraffin-embedded tissue and manually microdissected. For KLF6 and TP53 exons 1-4 and 4-9 were amplified, respectively. All the changes found in a first round were confirmed or rejected by a second round of amplification and sequencing of the same DNA. Results: Only 1/102 (1%) mutation in KLF6 was identified. This was a

missense mutation (E227G, exon 3, Gleason 7). This was the only change of a total of 38 (3%) confirmed by a second amplification, the remaining 37 being fixation-induced artifacts. 5/102 cases (5%) showed mutations in TP53. They were located in exon 5 (L130H, 2 cases with Gleason 7-8 and one organ metastasis), in exon 6 (H214R, in a Gleason 9 tumour) and in exon 7 (Y234C, in a Gleason 6 tumour). For TP53, these 5 confirmed mutations represented 19% of the 27 changes found in the first amplification. Two previously reported mutations were found (P223L and V274F) in exon 6 and 8, in the DU145 cell line. Conclusions: Our findings indicate that KLF6 mutations are extremely uncommon in prostate cancer. TP53 mutations are also a rare event. The differences in the number of changes found in a first analysis and those confirmed in a second amplification can be explained by Taq polymerase artefacts in formalin-fixed material. Interestingly, if discarded changes are included, the figure approaches the mutation percentages reported by some authors that do not confirm their findings in a second amplification nor in a second DNA extraction. In conclusion, mutations must always be confirmed by a second test, to avoid misinterpreting artefactual changes as true, pathogenic sequence abnormalities. Supported by FIS 06/1411.

ESTROGEN AND PROGESTERONE RECEPTORS EXPRESSION IN PROSTATIC ADENOCARCINOMA – CORRELATION WITH C-ERB2 STATUS

Maria Chorti[1], Christina Tsakona[1], Nikoletta Maounis[1], Nikolaos Trakas[1], Anna Emmanouilidou[1], Nikolaos Tamvakis[1], Stamatis Theocharis[2], Charalambos Deliveliotis[1]
[1] Sismanoglio General Hospital, Greece
[2] Medical University of Athens, Greece

Background: The carcinogenesis in Prostate results as an imbalance between cell hyperplasia and apoptosis. This process can be influenced by age, diet, hormones and EGFR signaling. The exact role of estrogens in the development of prostate cancer remains unclear. Immunohistochemical expression of estrogen receptor alpha (ER-a) in prostatic cancer revealed conflicting results ranging from loss of up to increased receptor expression. Additionally, the potential implication of the progesterone receptor (PR) in prostatic carcinogenesis has been reported. The expression of c-erb2, a transmembrane glycoprotein similar to the EGF, has also been reported and has conflicting results. Method: In the present study, the expression of ER, PR and c-erb2 was examined immunohistochemically in 70 cases of prostatic adenocarcinoma and was correlated with Gleason's score and TNM stage. Results: ER-a and PR proteins were immunodetected in the nuclei of stromal cells, whereas c-erb2 expression was demonstrated in the cytoplasm of epithelial prostatic cells. The only statistically significant relationships found, in our group of patients, were between c-erb2 and PR expression ($p<0.012$) and between Gleason score and stage ($p<0.004$). Conclusion:Our data suggest that the estimation of hormonal receptor status on prostatic adenocarcinoma histopathological material could be used in order to apprehend the model of prostatic carcinogenesis and can be possibly used for a more effective therapy.

LATE METASTASES OF RENAL CELL CARCINOMA: THREE CASES

Gulcin Kamali, Tulay Sayilgan, Deniz Ozcan
Okmeydani Training Hospital, Pathology Department, Istanbul, Turkey

Renal cell carcinomas (RCC) account for approximately 85 % of all malignant renal tumors. It has a high propensity for early metastasis. Most common sites for RCC metastasis are the lung (50 %), bone (33 %), liver, brain and skin. Approximately a third (4-50 %) of patients have metastatic disease at the time of diagnosis. Of these patients 1,6-3,6 % have solitary metastases. Metastases to the head and neck region include 8-14 % of all cases. Solitary soft tissue metastasis is extremely rare. We report three cases of late RCC metastatic to oral mucosa, cervical and gluteal soft tissue and larynx. Case 1: 60-year-old male patient underwent radical nephrectomy for grade III, stage III left RCC in 1997. He presented with right inferior gingival buccal RCC metastasis in 2004. He was treated with chemotherapy postoperatively. Case 2: 65-year-old male patient has been followed up for grade III, stage III left RCC since 2003. In 2005 cervical left soft tissue mass biopsy and in 2007 trucut biopsy of right gluteal soft tissue mass revealed RCC metastasis 4 years after radical nephrectomy operation. He underwent chemotherapy postoperatively. Case 3: 62 year-old male patient. He presented with left cruris mass in 2003. The incisional biopsy revealed RCC metastasis. On urologic and radiologic examination inoperable stage IV left renal mass and multiple bone metastases were diagnosed. He received both chemotherapy and radiotherapy after the diagnosis. In 2005 laryngeal mass biopsy showed RCC metastasis. Multiple hepatic metastases were radiologically demonstrated in 2007. All of the three cases were male. Metastases were seen in 4-10 years after the diagnosis of the primary tumor. All cases are alive at the present without further complications, the third case having tracheostomy. Histopathologic appearances of the metastases were consistent with clear cell carcinoma and identical to those of the primary tumors. Immunohistochemical studies demonstrated diffuse strong EMA and vimentin positivity. HMWC, CEA, S-100, CK 7 were negative. We present these three cases because RCC metastases to these regions are rare and also because of their late occurence. We discuss their histopathological and immunohistochemical findings.

PP2-187
ATYPICAL SMALL ACINAR PROLIFERATION IN THE PROSTATE: REVIEW OF A SERIES OF 64 PATIENTS

Luisa Morell-Quadreny, Francisco Clar-Blanch, Maria Navarro-Hervas, Laia Bernet-Vegué, Antonio Cremades-Mira, Rafael Cano-Munoz
Hospital de la Ribera, Spain

Background: Since the initial pathologic diagnosis of atypical small acinar proliferation of the prostate (ASAP) not always ends in prostate carcinoma, we evaluate clinical and histopathologic factors in order to detect risk of cancer in patients with atypical small acinar proliferation (ASAP) on initial prostate biopsy. Method: From 2002 to December 2006, 51 out of 64 patients with a diagnosis of ASAP were rebiopsied, with a mean time between second and third biopsy of 6 months. In all cases we collected clinical urologyc data and serum prostate-specific antigen (PSA) level. Results and Conclusion: The mean age of patients were 67 years. All but two patients had elevated PSA levels (60.9% of them, between 4.1-10 ng/ml). ASAP was diagnosed in all patients: 53 in the initial biopsy,6 in the second one and 5 in the third one. After ASAP diagnosis, 51 patients were rebiopsied: Of these,5 again showed, 18 benign prostatic tissue and 28 had prostate cancer. We are not seen relations between age or clinical and laboratory data and final diagnosis of cancer.Radical prostatectomy was applied to 20 patients and their pTNM and Gleason grades was as varied as in with others radical prostatectomy specimens in our files. Since ASAP was associated with a definitive diagnosis of prostate cancer in 55% of cases, identification of ASAP warrants repeat biopsy to rule out concurrent invasive carcinoma

PP2-188
THE INCIDENCE OF PELVIC LYMPH NODE METASTASES IN PROSTATE CANCER PATIENTS WITH INTERMEDIATE VALUES OF PROSTATE SPECIFIC ANTIGEN

Snezana Cerovic[1], Goran Brajuskovic[1], Nebojsa Jeremic[2], Novak Milovic[1], Vinka Maletic Vukotic[3]
[1] Military Medical Academy, Belgrade, Serbia
[2] CHC Zvezdara, Belgrade, Serbia
[3] CHC Dragisa Misovic, Belgrade, Serbia

INTRODUCTION: Feasibility of radical prostatectomy (RP) in patients with locally invasive prostate cancer (PC) is assessed according to standard parameters such as stage of the disease, serum Prostate Specific Antigen (PSA) and bioptic Gleason grade (GG). In PC the presence of metastases to the pelvic lymph nodes (PLN) is recognized widely as an unfavorable prognostic factor. Intermediate values of PSA are important in predicting the local confines of the tumor but can be detected in more than 30% of patients with locally advanced PC. AIM of this study was to find out the incidence of PLN metastases in PC patients with intermediate serum PSA in clinically localised stages of PC in whom RP was performed. MATERIAL AND METHODS: We used the biopsy cores and the tissue obtained after RP from 46 patients who had intermidiate PSA values which were defined as PSA from 2,6 to 10 ng/ml. In all patient clasical regional lymphadenectomy was performed. In all patients, preoperative stage was determined according to Partin tables (PT) from 2001. RESULTS: In 52,17% patients biopsy GG was ≤6, while it was 7 in 47,83%of patients. Clinically localised disease (cT2b) was found in 86,96 % of patients; other 13,04% of patients had locally advanced PC. After RP, the incidence of localised PC was 47,83%, while advanced disease was found in 52,17%. Metastasis in one or two regional lymph nodes (N1) were found in 10,87% patients with advanced PC. According to PT, expected incidence of positive PLN should have been 8% for pT3 stage. Positive correlation between assumed N1 stage according PT and N1 stage in our RP was statistically significant (p=0.012). CONCLUSION: In more than 50% of patients with intermediate values of PSA, locally advanced disease can be expected after RP. The use of Partin tables have important predictive value in assesing the local confines of the cancer and metastasis in regional lymph nodes. Recent RP series indicate PLN metastases to be less than 10%. We demonstrated detection of LN metastases (10.87%) in our RP series. Our results suggest that PLN should be performed even in patients with low-risk PC.

PP2-189
EXPRESSION OF PPAR GAMMA, KI-67 AND DNA PLOIDY IN UROTHELIAL CARCINOMAS AND CORRELATION WITH PROGNOSIS OF PATIENTS.

Kalliopi Diamantopoulou[1], Panagiotis Bakarakos[2], Ioanna Giannopoulou[2], Alexandros Nomikos[2], Christina Magkou[2], Irene Nikolaou[3], Euphemia Thoma-Tsagli[1], Lydia Nakopoulou[2]

[3] 2nd Department of Pathology, Attikon University Hospital, Athens, Greece

BACKGROUND: Peroxisome Proliferator Activated Receptor gamma (PPAR gamma) is member of the Nuclear Hormone Receptor superfamily (NHR) of ligand activated transcription factors. Recent studies reported that PPAR gamma affects various pathways, important in tumorigenesis and tumor development in several types of cancer and revealed its potential antineoplasmatic role through regulation of the apoptotic mechanism and cell differentiation and inhibition of cell proliferation and angiogenesis. PPAR gamma was also studied in various organs and was correlated with the outcome of patients, although the results were controversial. The purpose of this study was to examine the expression of PPAR gamma protein, Ki-67, DNA ploidy, clinicopathological parameters and patients survival in urothelial carcinomas. METHOD: An immunohistochemical method was applied on paraffin-embedded tissue specimens from 117 urothelial carcinomas, 68 superficial (Ta-T1) and 49 invasive (T2-T4), in order to detect the PPAR gamma protein, Ki-67, mismatch repair genes (MSH6) and DNA ploidy. The above markers were assessed in combination with clinicopathological parameters. The results were statistically processed using chi-square test and overall survival distribution curve was assessed by Kaplan-Meier test. RESULTS: PPAR gamma protein was expressed in cytoplasm of cancer cells in 78.6% (92/117) of total cases. PPAR gamma was expressed in 91.2% (62/68 cases) and 61.2% (30/49 cases) of superficial and invasive carcinomas respectively. PPAR gamma was positively correlated with DNA ploidy (p=0.034) and MSH6 (p=0.036) and was inversely correlated with grade (p=0.002), invasive tumors (T2-T4) (p<0.001) and Ki-67 (p=0.042). Regarding survival, PPAR gamma was associated with improved overall survival (p=0,01), as shown by univariate analysis. CONCLUSION: Our study provides evidence that the expression of PPAR gamma is correlated with urothelial carcinomas of low grade of malignancy and low stage and also exerts favorable impact in the prognosis. These results are further supported by our findings regarding DNA ploidy and the inverse relation between PPAR gamma and Ki-67 and its own possible favorable role in overall survival.

PP2-190
INCIDENTALLY DETECTED PROSTATE CANCER IN CYSTOPROSTATECTOMY SPECIMENS

Sanja Nikolajevic, Snezana Cerovic, Goran Brajuskovic, Novak Milovic
Military Medical Academy Belgrade, Serbia

OBJECTIVES: Bladder urothelial cancer and prostate cancers occur with increasing prevalence in the ageing population. To determine the incidence of adenocarcinoma of the prostate for patients undergoing radical cystoprostatectomy for bladder cancer.
METHODS AND MATERIALS: We retrospectively reviewed the pathology reports of 57 men who underwent cystoprostatectomy for bladder cancer. All patients had no evidence of prostate cancer on preoperative clinical assessment. The bladder was adequately sampled and the entire prostate sectioned at 5-mm intervals and examined histologically, in order to identify unsuspected prostatic cancer.
RESULTS: Nine patients (15.8%) were found to have incidental prostate cancer. All except one of incidental prostate cancers were organ confined and moderately differentiated. Prostate cancer was organ confined in 8 (88.88%). Capsular invasion was evident in 1 patient (11.11%). No patients exhibited nodal or distance metastases by the prostate cancer.
CONCLUSION: The incidence of prostate cancer in cystoprostatectomy specimens is high. We recommend digital rectal examination and Prostate Specific Antigen evaluation as part of the bladder cancer workup, and complete removal of the prostate at cystoprostatectomy to detect prostate cancer.

PP2-191
PROGNOSTIC SIGNIFICANCE OF MICROSATELLITE INSTABILITY DETERMINED BY IMMUNOHISTOCHEMICAL STAINING OF MSH2 AND MSH6 IN UROTHELIAL CARCINOMA

Eleni Mylona[1], Evanthia Karamitopoulou[2], Aristides Zarogiannos[3], Alexandros Nomikos[1], Ioanna Giannopoulou[1], Irene Theohari[1], Anastasios Zervas[3], Lydia Nakopoulou[1]
[1] 1st Department of Pathology, Medical School, University of Athens, Greece
[2] 2nd Department of Pathology, Attikon University Hospital, Athens, Greece
[3] Department of Urology, Laikon University Hospital, Athens, Greece

BACKGROUND: Mismatch repair (MMR) genes (hMLH1, hMSH2, PMS1, PMS2, hMSH6) are involved in the recognition and repair of certain types of acquired DNA damage, arising during cell division, playing thus an essential role in preserving genetic stability. METHOD: An immunohistochemical method was applied on 130 bladder urothelial carcinomas (BUCs) specimens to detect hMSH2 and hMSH6 in order to investigate their clinocopathological and prognostic value as well as their relation to markers indicative of the tumor phenotype. Nonparametric statistics were performed to evaluate the association between hMSH2 and hMSH6 and the various parameters of interest. Survival distribution were assessed by both univariate and multivariate analysis. RESULTS: hMSH2 and hMSH6 proteins expression was absolutely detected in the nuclei of the malignant cells. Of the BUCs studied, 25,9% were negative for hMSH2 and 49,2% were negative for hMSH6, considered to depict microsatellite instability (MSI). The expression of hMSH2 protein was found to correlate with that of hMSH6 (p=0,028) and both proteins expression to correlate with the age of the patients (p=0,003 and p=0,041 respectively), whereas no association was found with patients' sex. Nuclear hMSH2 values were statistically lower in non-invasive UCs (Ta-T1) (p=0,013) as well as in carcinomas characterized by decreased p53 staining (p=0,04) and high Bax immunoreactivity (p=0,003). Furthermore, lower hMSH6 values were more often observed in well differentiated tumors (p<0,0001) and in tumors with low expression of the protein p53 (p=0,016). As far as the survival is concerned, both hMSH2 and hMSH6 negative immunoreactions were found to exert favorable impact on patient overall survival (p=0,041 and p=0,034 respectively), a finding further verified in the multivariate analysis, only for the hMSH2 protein expression (p=0,026). CONCLUSION: This is the first study to show that lack (and not reduction designated according to various cut points) of hMSH2 and hMSH6 proteins expression is of favorable prognostic significance and to correlate it with wild type p53 and increased Bax expression and therefore a possibly functional apoptotic pathway.

PP2-192
CD10 EXPRESSION IN UROTHELIAL BLADDER CARCINOMAS AND RELATIONSHIP WITH CLINICOPATHOLOGIC PARAMETERS: PRELIMINARY STUDY

Nilufer Onak Kandemir[1], Burak Bahadir[1], Banu Dogan Gun[1], Gamze Yurdakan[1], Nimet Karadayi[2], Şukru Oguz Ozdamar[1]
[1] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Dr. Lutfi Kirdar Kartal Research and Training Hospital, Department of Pathology Istanbul, Turkey

Background: CD10 is a cell surface metalloprotease that inactivates various bioactive neuropeptides such as inflammatory mediators and vasoactive peptides. It is expressed by hematopoietic cells and their neoplasms and in variety of nonhematopoietic tissue and neoplasms. In colorectal and breast carcinomas, it was reported that CD10 positivity was associated with invasion and metastases. CD10 has been suggested as a useful marker for urothelial carcinoma, but the few studies of CD10 in urothelial tumors have shown varying results. The aims of this study were to investigate the expression of CD10 in urothelial bladder carcinomas and to clarify its association with clinicopathologic parameters. Materials and Methods: A total of 50 urothelial bladder carcinomas were selected from archival material. All cases were reevaluated histopathologically and graded according to the WHO/ISUP 1998 systems. The TNM system was used for their pathological staging CD 10 immunohistochemical staining was performed in selected slides. Results: The age of the patients ranged from 23 to 89 (mean± SD 67.2±12.1) years. The cases consisted of 46 men (92%) and 4 women (8%). According to the histological grade, 23(46%) cases had a low grade and 27(%54) cases had a high grade. 35 of the 50 patients (70%) showed positive CD10 immunostaining: +1, +2 and +3 reactivity in 8(16%), 21(42%) and 6(12%) patients, respectively. The remaining 15 cases (30%) were negative for CD10. We observed a cytoplasmic diffuse or granular immunostaining pattern in tumor cells. In addition, rare stromal cells were also positive for CD10 in only a few cases.There was a statistically significant positive correlation between low grade and high grade tumors in the relation to the CD10 expression (P=0.0001). No association was detected between CD10 expression and pathological stage and other clinicopathologic parameters. Conclusions: According to our findings, the CD10 expression in high grade carcinomas showed a higher level than that in low grade carcinomas, and it is positive correlated with the histological grade. CD10 may play an important role in the progression and differentiation of bladder urothelial carcinomas. We believe that further studies will clarify the significance of CD10 expression in bladder urothelial carcinomas.

PP2-193
CORRELATION OF GLEASON SCORES BETWEEN NEEDLE BIOPSY AND RADICAL PROSTATECTOMY SPECIMENS IN PROSTATIC ADENOCARCINOMA

Arsenal Sezgin, Hakan Postaci, Nuket Eliyatkin
Izmir Training and Searching Hospital, Department of Pathology, Izmir, Turkey

BACKGROUND: The Gleason histologic grade of prostatic adenocarcinoma is one of the most powerful predictors of prognosis and plays an important role in the treatment decision. The objective of this study was to compare the Gleason scores of prostate needle biopsies with subsequent radical prostatectomy specimens. Possible factors affecting the accuracy of needle biopsy diagnosis and Gleason score (GS) were investigated.
METHOD: The case records of 51 patients with localized prostate cancer who underwent radical prostatectomy between 1998 and 2003 were reviewed, comparing the primary, secondary grade and Gleason score of needle biopsy and radical prostatectomy specimens. The concordance between the biopsy and the prostatectomy Gleason score was then established according to 4 groups as well-differentiated (GS 2-4), moderately differentiated (GS 5-6), moderately to poorly differentiated (GS 7) and poorly differentiated group (GS 8-10). The correlation of Gleason scores between needle biopsy and radical prostatectomy specimens was evaluated by analyzing parameters such as the patient age, preoperative PSA level, biopsy-core number, percent of biopsy tissue containing cancer and tumour heterogeneity.
RESULTS: Mean patient age was 63.9±4.87 years and mean PSA level was 13.94±12.04 ng/ml. Tumors in needle biopsies were mostly in the moderately differentiated (GS 5-6) group and in prostatectomy specimens in the moderately to poorly differentiated (GS 7) group. Comparing the Gleason scores, there was agreement between the biopsy and the prostatectomy specimens in 15 (%29.4) patients. The biopsy Gleason score was lower in 16 (%31.3) and higher than prostatectomy specimens in 20 (%39.2) cases. The difference between the Gleason scores was

±1 for 24 patients, ±2 for 9 patients and ±3 for 3 patients. By classifying patients into 4 groups, the concordance increased from % 29.4 to %49. Statistically, the strength of agreement was considered to be fair and no significant corelation was found between grading discrepancies and the patient age, preoperative PSA level, biopsy-core number, percent of biopsy tissue containing cancer and tumour heterogeneity.
CONCLUSION: The classification of patients into 4 distinct groups increases the concordance between the biopsy and the subsequent prostatectomy Gleason score. Although prostatic needle biopsies may be associated with significant grading errors, they provide valuable information about the histologic pattern reflecting the biologic behavior of the tumor and, help predicting prognosis.

PP2-194
EVALUATION OF MVD IN BIOPSY SPECIMENS OF ATL PATIENTS AND COMPARISON WITH NORMAL CASES BY IMMUNOHISTOCHEMISTRY METHOD

Nourieh Sharifi
Mashhad Medical University, Ghaem Hospital Department of Pathology, Iran

Abstract Background : adult T-cell leukemia-lymphoma (ATLL)is a rapidly progressive systemic illness with the causative agent ,the human T-cell lymphotropic virus type -1. It is endemic in the japan , Africa ,Brazil and recently north east of Iran ,particulary the region of mashhad. The role of angiogenesis is appreciated in development and prognosis of many malignancies. To examine a possible association between tumor angiogenesis and ethiopathogenic and prognostic role of it in ATL patients this study is performed. Material and methods: This study included 20 ATL patients between 2000-2006. Micro vessel density (MVD) were identified immunohistochemically , using monoclonal CD34 antibody .the MVD of tumoral tissues was defined by counting the number of microvesseles in three hot spots , and the mean values indicated the Micro vessel density (MVD). Normal tissues as control group are noticed. Results: There was statistically significantly increased MVD in tumoral tissue of ATL patients (Mean =17,78)comparison to normal tissues(M =3,54).[p=0,000] Conclusion : Intratumoral Microvessel density quantification in histologic specimens of ATL patients reflects the biologic malignant potential and may be valuable in stratifying patients in planning appropriate adjuvant and antiangiogenesis therapy.

PP2-195
CASTLEMAN'S DISEASE AFFECTING FOCALLY THE CERVICAL REGION. APROPOS OF AN UNUSUAL CASE

C. Hadjileontis[1], K. Zervas[2], E. Panousi[3], V. Kaloutsi[3]
[1] Pathology Dept, Medical School, Aristotle University of Thessaloniki, Hellas; Pathology Dept, "Achillopouleion" General Hospital, Volos, Greece
[2] Haematology Clinic, "Theagenion" Cancer Hospital, Thessaloniki, Greece
[3] Pathology Dept, Medical School, Aristotle University of Thessaloniki, Greece

BACKGROUND: Castleman's disease is an unusual lymphoproliferative disease presenting with two different clinical forms, the localized and the multicentric. In the localized form which is curable, 70% of the cases concern the mediastinum and 14% the retroperitoneal space. The multicentric form on the other hand, progresses aggressively and complete remission is achieved only with prednisone or chemotherapy, provided that they are given at the time of diagnosis. CASE REPORT: We present the case of a 43 year old male who presented with an asymptomatic cervical mass measuring 4 cm in diameter, reporting a rapid increase of its volume during the last month. His physical examination and biochemical tests were unremarkable for pathological findings. Chest X-ray and thoracic computed tomography scan showed no significant lesions. The mass was surgically excised and three years after surgery, no sign of recurrence has been recorded. RESULTS: Macroscopy revealed the presence of a swollen lymph node with lobular shape, dishomogeneous texture and whitish cut surface. Histological examination showed a severe lymphadenitis with significant angiofollicular hyperplasia. The latest consisted of nodular masses with proliferating vascular spaces, prominent endothelia and a mixed lymphoid population with histiocytic involvement, infiltrating in a hyalinized stroma. Plasma cells were immunohisochemically identified as polyclonal, exhibiting though an IgG predominance. Lymphoid cells of T-cell origin showed no, or minimal cytological atypia, and were also polyclonal. No vessel distraction or angiocentricity were noted,

nor any viral infection was detected. CONCLUSIONS: Based on the above findings and despite the unusual location of involvement, we diagnosed this case as Castleman's disease, with histological features more compatible to the hyalino-vascular type. Although the disease remains of unknown aetiology, an inflammatory theory with reactional hyperplasia of the beta-lymphocytes has been proposed, being some of the times a result of viral infection. Angioimmunoblastic lymphadenopathy however should always be included in differential diagnosis, especially in cases of multicentric involvement.

PP2-196

QUANTITIVE MICROSCOPIC MEASUREMENTS IN BONE MARROW BIOPSIES. A PROPOSAL FOR A NEW MORPHOMETRIC METHOD

C. Hadjileontis[1], K. Zervas[2], V. Kaloutsi[3]
[1] 1st Pathology Dept, Medical School, Aristotle University of Thessaloniki, Hellas; Pathology Dept, Achillopoulleion General Hospital, Volos, Greece
[2] 3rd Haematology Clinic, Theagenion Cancer Hospital, Thessaloniki, Greece
[3] 2nd Pathology Dept, Achillopoulleion General Hospital, Greece

BACKGROUND: Morhometry in bone marrow biopsies is a field of increasing interest in Haematopathology. It usually focuses on the cellular or angiogenic bone marrow quantity in several diseases, as follow-up or for prognostic evaluation of patients. Based on the Weinder's method for angiogenic estimation and taking in consideration the special characteristics of bone marrow, we developed a new morphometric technique for such measurements. METHOD: The technique is based on the adjustment of an ocular millimetric grid so as to screen the marrow surface and measure within it the studied cells or structures. The grid also provides the potential of simultaneous evaluation of the actual dimensions of cells or vessels, as well as their density in the marrow surface. Measurements are performed at 400X magnification, in whole the cellular marrow, while soft tissues and bone cartilage are excluded. The number of cells or vessels found for each case is finally divided to the number of the high power fields used for screening the whole marrow surface. This division erases the differences of uneven marrow distribution that cells or vessels might manifest. Furthermore, since every parameter of interest is studied both comparatively and statistically, with the findings in normal bone marrow biopsies, the final division outcome, represents the marrow quantity in mean values for every parameter studied. The results are finally expressed as density of cells or vessels per square millimeters. RESULTS: We have so far used this method for measuring the microvascular and mast cell density in the bone marrow of patients with Waldenstrom's disease and multiple myeloma, as well as the density of blasts in patients with myelodysplastic syndromes ranging from RAEB to MDS/AML. The results from applying this method are discussed through a comparative study of relevant references in literature. CONCLUSIONS: This we believe is a reliable method, cost effective and easily accessible for routine work, since it requires no special equipment or training skills.

PP2-197

IGM MYELOMA: REPORT OF A RARE CASE AND REVIEW OF THE LITERATURE

C. Hadjileontis[1], K. Zervas[2], V. Kaloutsi[3]
[1] Pathology Dept, Medical School, Aristotle University of Thessaloniki, Hellas; Pathology Dept, "Achillopouleion" General Hospital, Volos, Greece
[2] Haematology Clinic, "Theagenion" Cancer Hospital, Thessaloniki, Greece
[3] Pathology Dept, Medical School, Aristotle University of Thessaloniki, Greece

BACKGROUND: IgM myeloma is a rare plasma cell neoplasm, with an estimated incidence of 0.5% in patients with multiple myeloma. It is estimated that 2 to 3.3% of IgM monoclonal gammopathies are IgM myelomas. Furthermore both IgM myeloma and Waldenstrom's macroglobulinemia may display similar clinical and histological features that make differential diagnosis very difficult. CASE REPORT: We present the case of a 65 year old female patient, who came up with multiple bone lesions and general deterioration. Hepatomegaly, splenomegaly, lymphadenopathy, hemorrhagic diathesis or neurologic involvement were not noted. Laboratory investigation revealed anemia, hypercalceaemia, as well as elevated IgM serum levels (33 g/l). RESULTS: The histological examination of the bone marrow biopsy performed, showed an extensive infiltration of the marrow spaces, reaching up to 75% of the cellular marrow, by neoplastic plasma cells with minimal cytological atypia. Neoplastic cells infiltrated the marrow spaces in an interstitial and diffuse pattern and were immunohistochemically positive for CD45, CD45RA, CD20, plasma cell and cyclin D1 antigens. The investigation for heavy and light immunoglobulin chains revealed IgMκappa clonality. The patient was treated with VAD/thalidomide and eight months later developed bacterial pneumonia and deceased. CONCLUSIONS: Since cases of IgM myelomas are very rare and sporadically reported in literature, no consensus has been achieved so far, regarding the criteria for considering this malignancy as a distinct clinical entity in the spectrum of B-cell neoplasias. Within this concept, we discuss the clinical, histological and immunohistochemical findings of the present case, in contrast with relevant bibliographic references.

PP2-198

MYELOID SARCOMA OF THE SMALL INTESTINE IN AN ALEUKEMIC PATIENT PRESENTING AS SMALL BOWEL OBSTRUCTION

Ioannis Venizelos, Zoi Tatsiou, Alexandra Moulla, Charalambos Charalambidis
Department of Pathology, Hippokration Hospital, Thessaloniki, Greece

Myeloid sarcoma (MS) is a rare localized extramedullary tumor composed of immature cells with myelogenous differentiation. It usually develops either concurrently with acute myeloid leukemia (AML) or after remission. On rare occasions, it may be the initial manifestation of AML, occurring most commonly in bone, soft tissue, lymph node and skin. Primary gastrointestinal localization is very rare. A review of the literature revealed that only 15 cases of MS in the small intestine have previously been reported in aleukemic patients. We report the case of a 60-year-old woman who was admitted in our hospital with acute abdominal pain, vomiting and distention, symptoms suggestive of small bowel obstruction. On physical examination, there was no hepatoslenomegaly, peripheral lymphadenopathy, gingival hypertrophy or skin lesions. Her complete blood count was normal. A CT-scan of the abdomen and pelvis revealed a large solid mass in the terminal ileum. She underwent an exploratory laparotomy with complete resection of the tumor. Macroscopically, the tumor had maximum diameter 4 cm and on cut sections it was whitish and elastic. Microscopically, there was a dense and diffuse infiltration of the small intestinal mucosa, submucosa, muscularis propria, serosa and the adjoining adipose tissue, by medium or large neoplastic cells, having a small rim of cytoplasm and enlarged atypical nuclei with fine chromatine and small nucleoli. Immunohistochemically, the neoplastic cells were positive for myeloperoxidase, lysozyme, CD15, CD34, CD43 and CD68 whereas, they were negative for CD20, CD79a, CD3, CD45RO, CD30, CD99, CD117, pancytokeratin and HMB45. So, the diagnosis of MS, blastic type was made according to the WHO classification. The patient received systemic chemotherapy and 6 months later she is in a good condition without evidence of hematological disorders. In the absence of any initial hematological abnormality, the diagnosis of MS remains very difficult. In the present study we report an extremely rare case of

isolated MS of the small intestine in an aleukemic patient presenting as small bowel obstruction. Recognition of this rare entity is important, because early, aggressive induction chemotherapy can improve prognosis.

PP2-199

INCIDENTAL FINDING OF MYELOID SARCOMA IN AN ABDOMINAL LYMPH NODE DUE TO ACUTE APPENDICITIS

Ioannis Venizelos[1], Zoi Tatsiou[1], Apostolos Triantafillou[2], Alexandra Moulla[1], Anastasios Chatzitolios[1]
[1] Department of Pathology, Hippokration Hospital, Thessaloniki, Greece
[2] B' Prop. Department of Surgery, Hippokration Hospital, Thessaloniki, Greece

Myeloid sarcoma (MS) is a neoplasm of immature myeloid cells involving an extramedullary anatomic site, that is usually associated with acute myeloid leukemia (AML). Any extramedullary site can be involved by myeloid sarcoma, although most commonly occurs in bone, soft tissue, lymph node and skin. We report the case of a 64-year-old man who was admitted in our hospital due to abdominal pain in the right lower quadrant and fever of approximately 24 hours duration. From his past medical history he was receiving treatment for hypertension, heart insufficiency and type 2 diabetes. All previous hematological tests were normal. On physical examination there was rebound tenderness of the right lower quadrant and rigidity on palpation. There was no hepatoslenomegaly or peripheral lymphadenopathy. His white blood count was 23.000/μL with 46% neutrophils, 4% eosinophils, 9% lymphocytes, 40% monocytes and 1% basophils. Haemoglobin measured 13 g/dL, and the platelet count was 150.000/μL. The peripheral blood film revealed 30% myeloblasts and AML was diagnosed. An abdominal and pelvic ultrasound identified an enlarged appendix with features of gangrenous appendicitis. Because the clinical examination was highly suggestive of acute appendicitis, an appendectomy was performed. During the operation enlarged mesenteric lymph nodes were noted and one of them was excised. Histological examination of the appendix showed a gangrenous appendicitis. The lymph node biopsy revealed effaced lymph node architecture due to diffuse infiltration by a relatively uniform population of medium-sized and large neoplastic cells with a small rim of cytoplasm and enlarged atypical nuclei. Moderate numbers of mitoses were present. Immunohistochemically, the neoplastic cells were positive for myeloperoxidase, lysozyme, CD15, CD34, and CD68 whereas, they were negative for CD20, CD3, CD99, pancytokeratin and HMB45. So, the diagnosis of MS, blastic type was made. The patient died 3 days after the operation due to heart failure. In the present study we report an extremely rare case of MS in an abdominal lymph node, developed concurrently with AML, as an incidental finding due to acute appendicitis.

PP2-200

PRIMARY BILATERAL ADRENAL NON-HODGKIN'S LYMPHOMA PRESENTING AS ADDISON'S DISEASE

Ioannis Venizelos[1], Zoi Tatsiou[1], Anastasios Chatzitolios[1], Ioannis Amplianitis[1], Eudokia Mandala[2]
[1] Department of Pathology, Hippokration Hospital, Thessaloniki, Greece
[2] Department of Internal Medicine, Hippokration Hospital, Thessaloniki, Greece

Adrenal masses are usually metastases from malignant tumors, most often from bronchial carcinomas. Non-Hodgkin's lymphoma (NHL) affecting the adrenal glands is usually secondary, associated with other sites of disease, most usually the retroperitoneal lymph nodes and ipsilateral kidney. Adrenal involvement in widespread NHL occurs in 4% of cases. Bilateral primary adrenal NHL is even rarer with only a few previous cases reported. Adrenal insufficiency is a common manifestation in bilateral primary adrenal NHL, occurring in half of the reported cases. We report the case of a 78-years-old woman presented with a 4 month history of nausea, anorexia, weight loss, weakness, night sweats and hyperpigmentation of the skin and the buccal mucosa. Addison's disease was diagnosed based on the clinical presentation and laboratory findings of low cortisol and high adrenocorticotropin levels. Computerized tomography (CT) of chest and abdomen revealed solid, large, bilateral adrenal masses. There was no enlarged lymph nodes or hepatosplenomegaly. A needle biopsy of the left adrenal mass revealed diffuse infiltration by large neoplastic cells characterized by enlarged atypical nuclei with prominent nucleoli and scant cytoplasm. The mitoses were numerous. Immunohistochemically the neoplastic cells were positive for CD20, CD79a, LCA and Vimentine whereas they were negative for NSE, Synaptophysin, Chromogranin, pancytokeratin, UCHL-1 and CD30. So, the diagnosis of diffuse large B-cell lymphoma was made according to the WHO classification. A metastatic work-up, including body CT-scan and bone marrow aspiration and biopsy revealed no evidence of disease, suggesting a stage I NHL. After corticosteroid replacement therapy, the patient received 7 courses of systemic chemotherapy with CHOP and rituximab and 14 months later, both adrenal masses decreased dramatically and the patient is in an excellent condition. Primary adrenal NHL is a rare entity and must be included in the differential diagnosis of bilateral adrenal masses. Histological examination with needle biopsy is very important in order to reach the correct diagnosis, avoid an unnecessary operation, apply the appropriate treatment and improve the survival.

DIAGNOSTIC VALUE OF COMBINING IMMUNOSTAINING FOR CD3 AND NUCLEAR MORPHOMETRY IN MYCOSIS FUNGOIDES

Mariana Lira[1], André Schenka[1], Luis Alberto Magna[1], Ana Cotta[1], Maria L. Cintra[1], Elemir Macedo De Souza[1], Pierre Brousset[2], José Vassallo
[1] Faculty of Medical Sciences, State University of Campinas, Unicamp, Brazil
[2] University of Toulouse, France

Background: Mycosis fungoides (MF) represents the most common skin lymphoid neoplasm. In initial stages, differential diagnosis of MF with other benign dermal lymphoid infiltrates (BDLI) may be impossible on morphological basis alone. In previous studies by our group, only deletion of CD7 in MF proved to be of diagnostic help, but not the ratio between immunoexpression of CD4 and CD8. In the present study, 30 cases of MF and 11 cases of BDLI were analyzed, in order to compare morphometric parameters, which could be of diagnostic aid. Methods: Immunohistochemical detection of T-cells was made using an antibody to CD3, on paraffin-embedded tissue from all 41 patients (30 MF and 11 BDLI). Images of 100 positive cells per case in both groups were captured and analyzed using a simple computer program (Imagelab®) for nuclear perimeter (P), area (A), diameters (D) and nuclear contour index (NCI). Results: All parameters showed statistically significant higher values for MF. Area was the variable with the strongest discriminating power between the two groups of patients. Even if morphologic evaluation is not accurate to distinguish benign versus malignant dermal lymphoid infiltrates, due to the variability of size and shape of these cells, a more sensitive method promptly shows this difference. Conclusion: Our results suggest that morphometry of CD3-positive lymphoid cells may add valuable information in the differential diagnosis of MF and benign dermatoses. DETERMINATION OF ABSOLUTE CD4 LYMPHOCYTE COUNTS IN HIV/AIDS PATIENTS

Bahrom Aliev, Erkin Musabaev, Malika Nizamhodjaeva, Ludmila Kalugina
Institute of Virology, Tashkent, Uzbekistan

Introduction: Human immunodeficiency virus (HIV) infection is increasing at an alarming rate worldwide. The HIV affecting CD4 lymphocytes, finally leads to sharp weakening of immunity (AIDS) and an organism destructions. The CD4 lymphocyte count remains the strongest short-term predictor of risk of AIDS. Obtaining accurate, reliable and affordable CD4 lymphocyte counts is essential in determining disease stage, progression and when to start or change antiretroviral therapy (ARVT) and whole monitoring ARVT. Aim and methods: The objective of this study was to study of CD4 lymphocyte count at early stages of HIV type 1 infection, using the manual magnetic bead method (Dynabead). Blood samples were collected in EDTA Vacutainer containers from each of 200 HIV-positive patients (disease stage I and II). This method requires a three-step technique: depletion of monocytes, isolation of CD4 cells and CD4 lymphocytes counting. After isolation, the CD4 cells were lysed and the liberated nuclei counted in a conventional light microscope after staining with Sternheimer-Malbin solution. Nuclei stained with this staining solution appear blue under white light microscope. The number of cells counted in the haemocytometer is converted to the concentration of CD4 lymphocytes in whole blood by the special formula. Results: Our investigation showed differences in total CD4 lymphocyte counts by stage of the HIV infection. In the patients with HIV infection (stage I) CD4 cells count were about 320-1185 cells/mm^3. In HIV infection, stage II patients CD4 lymphocytes count ranged from 200 - 600 cells/mm^3. Conclusion: The results of this study demonstrated tendency to progressive loss of CD4 lymphocytes at early stages of HIV infection. (This work is supported by Grant A-9-154 RUz).

[4] Spanish National Cancer Research Center (CNIO), Madrid, Spain

BACKGROUND: Cutaneous lymphomas (CL) represent a unique group of lymphomas and are the second most frequent extranodal lymphomas. CL probably are the result of a multifactorial and multistep process. Firstly an inflammatory reactive process is developing secondary to various chronic stimuli that may be genetic, environmental, infectious and immunologic. Consequences are the negative effects in cell regulation and deregulation of oncogenes and/or suppressor genes that later promote transition from pre-neoplastic conditions to neoplasia. Detailed molecular expression analysis of cutaneous T-cell lymphoma is not available. Some oncogenic alterations have been demonstrated, such as functional inactivation of the Fas receptor, constitutive activity of STAT 3, or the inactivation of the p16 gene via deletion or promoter hypermethylation. Objective: To study the expression of p16, c-myc, Ki67, bcl-2, CD1a, CD123, TCL1, CD68, STAT 3, STAT 4 and MAL1 in an homogeneous group of CL diagnosed in a terciary Hospital in order to know more about the characteristics of this neoplastic process. METHODS: We have studied 30 CL diagnosed consecutively as Mycosis Fungoides (14 early and 16 advanced stages) between January 2005 and December 2006. By macrotissue array techniques and immunohistochemistry protocol with p16, c-myc, Ki67, bcl-2, CD1a, CD123, TCL1, CD68, STAT 3, STAT 4 y MAL1 was applied in all paraffined histological samples. RESULTS: In 28 samples (92%) we have observed p16 positive overexpression, the two negative samples corresponding to early affectation. In 14 samples from early stages (48%) c-myc was negative. In 29 samples (96%) CD1a was positive in dermal and epidermal layer. CD123 (interleukine 3 receptor) was negative in 16 samples (52%) and TCL1 was positive in 12 cases (39%) in small cells with oval and cleaved nucleus and scarce cytoplasm. Overexpression of MAL1 was observed in advanced patients with aggressive CL. CONCLUSIONS: In our study, overexpression of p16 is observed in the majority of cases and high c-myc expression is seen in advanced stages. Probably dendritic plasmacytic cells are involved in the pathogenesis of skin lymphoproliferative disorders with cutaneous T cell infiltration. MAL1 could be a predictor of aggressive CL, but more studies and more cases are necessary in order to confirm it.

PP2-204
EXPRESSION OF BCL-2 PROTEIN AND AMPLIFICATION OF C-MYC GENE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Milica Strnad[1], Goran Brajuskovic[1], Biljana Todoric Zivanovic[1], Natasa Strelic[2], Dragana Stamatovic[3], Zvonko Magic[2]
[1] Institute of Pathology, Military Medical Academy, Belgrade, Serbia
[2] Institute for Medical Research, Military Medical Academy, Belgrade, Serbia
[3] Clinic of Haematology, Military Medical Academy, Belgrade, Serbia

BACKGROUND: Chronic myeloid leukemia (CML) represents the malignant myeloproliferative disease developed out of pluripotent hematopoietic stem cell that contains fusion bcr-abl gene. The mechanisms that lead to these changes at molecular level are still unknown as well as the mechanisms that increase proliferative capacity of these cells. Disorders that occur in the process of apoptosis represent one of the possible molecular mechanisms that bring about disease progress. Within our study we carried out the analysis of the presence the amplification of C-MYC oncogene as well as the analysis of the changes in expression of Bcl-2 in patients with CML. METHODS: Our study included 30 patients with CML (23 in chronic phase, 7 in blast transformation). Using immunohistochemical APAAP method we analyzed the expression of Bcl-2 protein in mononuclear bone marrow cells of 30 CML patients. By differential PCR method we followed the presence of amplified C-MYC gene in mononuclear peripheral blood cells. RESULTS: The level of expression of Bcl-2 protein is considerably higher in bone marrow samples of patients undergoing blast transformation of disease. The amplification of c-myc gene has been detected in 30% patients in blast transformation of disease. CONCLUSION: The results of this work have shown that expression of Bcl-2 protein and amplification of C-MYC gene are in correlation with disease progression.

PP2-205
HISTOLOGICAL AND IMMUNOHISTOCHEMICAL CHARACTERISTICS OF THE PLASMA CELL DYSCRASIAS

Snezana Duganovska[1], Gordana Petrusevska[1], Lolita Andonovska[1], Slavica Kostadinova Kunovska[1], Vanja Filipovski[1], Maja Vasileva[2]
[1] Institute of Pathology, Medical Faculty, University "St. Cyril and Methodius" Skopje, Macedonia
[2] Clinic for Infectious Diseases, Clinical Centre, Skopje, Macedonia

Aim: The aim of this paper is to show the role of the immunohistochemical technique in differentiation of the reactive from malignant lymphoproliferative processes. 3 cases of a plasma cell dyscrasias from the autopsy material at the Institute of pathology in Skopje, differentiated with the usage of the histological (HeEo, Giemsa) and immunohistochemical analysis are shown. Material and Methods: The method of Streptavidin Biotin Peroxidase Technique using a panel of monoclonal antibodies: kappa, lambda, and antibodies for IgA, IgG, IgM, plasma cell IgG (PC), LCA, CD20, and Ki67 were performed. The patients were 2 males and a female at the age of 65, 50 and 57 respectively. Standard autopsy technique and vigorous histological and immunohistochemical analysis were used. In all cases the basic pathological finding was proved to be plasma cell dyscrasia: immunocytoma (case No I), plasmacytoma (case No II) and myeloma multiplex (case No III). Results: The diagnosis was confirmed with immunohistochemical analysis where atypical lympho-plasma cell infiltrates in the tissue specimens taken from the visceral organs were with monoclonal nature: kappa -, lambda + (case No I, and case No III), and kappa +, lambda - (case No II). Besides, the staining for the other markers showed the following results: IgG+, CD10+, CD56+, and PC+. Conclusion: Immunohistochemical technique is important for differentiation of the monoclonal from polyclonal lympho-plasma cell dyscrasias, since they may appear in chronic inflammatory processes, too. The confirmation of the monoclonal characteristics of the same implies the neoplastic proliferation in these 3 cases.

PP2-206
CYCLIN D1 EXPRESSION IN NODULAR LYMPHOCYTE PREDOMINANT HODGKIN'S LYMPHOMA
Kemal Kosemehmetoglu, Aysegul Uner
Hacettepe University Faculty of Medicine, Department of Pathology, Ankara, Turkey

BACKGROUND: Hodgkin's lymphomas are divided into two main groups: Classical Hodgkin's lymphomas (cHL) and nodular lymphocyte predominant Hodgkin's lymphomas (NLPHL). Although these two diseases share morphological properties, it has been shown that these two entities have distinct origins. The differential diagnosis of Hodgkin's lymphoma (HL) from various types of non-Hodgkin lymphoma including T-cell rich B cell lymphoma (TCRBCL) can be challenging. Cyclin D1, a member of G1 cyclins, is a cell cycle regulator protein which has a major role at the G1 and S checkpoint, thus overexpression may result in the disturbance of cell-cycle regulation and apoptosis. Expression of cyclin D1 in HL has not been well characterized. In a few series overexpression of cyclin D1 in only 2-19 % of cHL has been reported. In contrast, expression in NLPHL has not been well characterized systematically. METHODS: Eleven NLPHL, 9 TCRBCL and 12 cHL (6 mixed cellular and 6 nodular sclerosing type) cases were culled from the archives of Hacettepe University Faculty of Medicine, Department of Pathology. Cyclin D1 expression was evaluated immunohistochemically (monoclonal antibody; clone SP4, Neomarkers). RESULTS: Strong cyclin D1 expression was seen in 6 (50%) of 12 NLPHL, in contrast to 3 (25%) of 12 cHL, in which few neoplastic cells expressed Cyclin D1. In TCRBCL group, only 1 case showed cyclin D1 expression. Interestingly, this case was a monomorphic posttransplant lymphoproliferative disorder with EBV positivity. CONCLUSION: Cyclin D1 can play a role in the pathogenesis of NLPHL and could be used as an additional marker in the differential diagnosis of LPHL.

PP2-207
BCL-1 POSITIVITY IN NON-MANTLE CELL LYMPHOMAS- REPORT OF TWO CASES
Nazan Bozdogan, Emine Benzer, Gulay Bilir, Isin Pak, Gozde Muhafiz
Ankara Oncology Hospital, Ankara, Turkey

Bcl-1/PRAD gene rearrangement involving the cyclin D1 gene is a feature of mantle cell lymphomas, virtually all of which show this rearrangement by flourescein in situ hybridisation and immunohistochemistry. Bcl-1 gene disregulation can also rarely be found in other B-cell neoplasias. We report two cases of Bcl-1 positivity in non-mantle B-cell lymphomas: CASE 1: Axillary lymph node excision was performed on a 58 year-old male patient. Macroscopic examination revealed a conglomerate lymph node of 6.5x4.5x3 cm with a multinodular cut section. Microscopic examination revealed a lesion which showed alternate follicular patterns and diffuse infiltration. The tumor was composed of two types of cells: The small to medium sized with cleaved nuclei, and the other having small nucleoli and pale cytoplasm. Immunohistochemically, the tumor cells expressed Bcl-1, Bcl-2, CD20 and CD10. Based on these morphologic and immunohistochemical features, the lesion was diagnosed as "Follicular Lymphoma". CASE 2: A 24-year-old male patient was presented with a pelvic mass. The macroscopic examination revealed a conglomerate lymph node with the greatest diameter of 6 cm. In the microscopic examination, the lymph node structure was replaced by diffuse neoplastic infiltration. The tumor was composed of large cells with pleomorphic, hyperchromatic, vesicular nuclei and conspicuous nucleoli. Immunohistochemically; the tumor cells expressed LCA, CD20, CD43, CD10, CD79a and Bcl-1. Based on these features the lesion was diagnosed as "Diffuse Large B-Cell Lymphoma".

PP2-208
INCIDENCE OF TRANSLOCATIONS INVOLVING THE T-CELL RECEPTOR AND TCL1 GENES IN PERIPHERAL T-CELL LYMPHOMA USING FLUORESCENCE IN SITU HYBRIDIZATION SCREENING OF TISSUE MICROARRAYS
Andrew Feldman, Mark Law, Karen Grogg, Eric Thorland, Stephanie Fink, Paul Kurtin, William Macon, Ellen Remstein, Ahmet Dogan
Mayo Clinic, Rochester, Minnesota, USA

Background. The genetics of peripheral T-cell lymphoma (PTCL) remain poorly understood. Translocations involving the T-cell receptor (TCR) and TCL1 genes have been described in T-cell lymphoblastic and prolymphocytic lymphomas, respectively, but their incidence in other types of T-cell lymphomas is not well defined. Methods. Tissue microarrays (TMAs) were constructed using triplicate cores from paraffin-embedded tissue blocks in 104 cases of PTCL seen at Mayo Clinic between 1987 and 2006. Diagnoses were classified according to current WHO criteria, and included 19 angioimmunoblastic, 12 anaplastic large-cell (ALCL), 57 unspecified-type (PTCL-U), and 16 other T-cell lymphomas. Home-brew, two-color breakapart fluorescence in situ hybridization (FISH) probes that flanked the gene loci of the T-cell receptor (TCR) alpha, beta, and gamma genes (14q11, 7q35, and 7p15, respectively) and the TCL1 gene (14q32) were used to screen TMAs for abnormalities involving these gene loci. Results. We detected translocations involving TCR-alpha in 2 of 94 informative cases (2.12%), and involving TCR-beta in 1 of 66 (1.52%). No translocations involving TCR-gamma or TCL1 were detected (87 and 72 cases, respectively). One patient with PTCL-U had translocations involving both TCR-alpha and TCR-beta. One patient with ALK-negative ALCL had a translocation of TCR-alpha; further studies suggest the partner gene resides on chromosome 5q. Conclusions. Though rare, translocations involving TCR loci occur in peripheral T-cell lymphomas and can be detected by FISH. These findings may shed light on the genetics and pathogenesis of some cases of PTCL, including a potentially novel translocation involving TCR-alpha and chromosome 5q in a patient with ALK-negative ALCL.

PP2-209
P53 AND P27 EXPRESSION IN DIFFUSE LARGE B CELL LYMPHOMA AND SMALL LYMPHOCYTIC LYMPHOMA: IMMUNOHISTOLOGY WITH PROGNOSTIC SIGNIFICANCE?

Tugba Dogruluk[1], Aylin Orgen Calli[1], Sadi Bener[1], Betul Bolat Kucukzeybek[1], Gozde Evcim[1], Bahriye Payzin[2]
[1] Izmir Ataturk Training and Research Hospital, Department of Pathology
[2] Izmir Ataturk Training and Research Hospital, Department of Hematology

OBJECTIVE: The heterogeneity of non-Hodgkin lymphoma is highlighted by the variable expression of a variety of molecular aberrations, some of which have been shown to be predictive of outcome. The p27/Kipl gene inhibits a variety of cyclin-cyclin-dependent kinase complexes and regulates cell growth. The p53 gene acts as a tumor suppressor gene, controlling entry into the S-phase of the cell cycle. The purpose of the present study was to investigate alterations of cell cycle-related molecules, including p27,and p53, in diffuse large B cell lymphoma and small lymphocytic lymphoma, and their relation to conventional clinical prognostic parameters. METHODS: The expression levels of p27 and mutant p53 proteins in 39 diffuse large B cell lymphomas and 26 small lymphocytic lymphomas were analyzed by immunohistochemistry. The clinicopathological variables, recurrence and disease-free interval were assessed. Meanwhile, the clinical significance of them was analyzed combining with the clinicopathological factors and followup data. RESULTS: In diffuse large B cell lymphoma cases, p53 and p27 nuclear reactivity was seen in 30 (%76.9) of 39 and 7 (%18.4) of 39 cases, respectively. In small lymphocytic lymphoma cases, p53 and p27 were seen in 20 (%76.8) of 26 and 17 (%65.4) of 26 cases, respectively. There were statistically significant differences in p27 expression between the two lymphoma groups. The p27, and p53 protein expression in diffuse large B cell lymphoma were not associated with age, stages, lymph node localization, B symptoms, extranodal extension, relaps, drug resistance, and mitosis. p53 protein expression in small lymphocytic lymphoma was also not associated with age, stages, lymph node localization, B symptoms, extranodal extension, relaps, drug resistance, but p53 protein expression was associated with mitosis ($p=0.039$). No significant association was found between p27 status and clinicopathological parameters. p53, and p27 expression was not associated significantly with overall survival rate ($p>0.05$). CONCLUSION: The authors concluded that p53, and p27 protein expression was not related to the clinicopathologic parameters, and survival in two lymphoma groups. Further studies are needed to evaluate the predictors of outcome in non-Hodgkin lymphoma, considering a variety of prognosticators.

PP2-210
HUMAN IMMUNODEFICIENCY VIRUS-NEGATIVE PATIENT WITH COEXISTENT INTESTINAL KAPOSI'S SARCOMA AND ANAPLASTIC LARGE CELL LYMPHOMA

Işil Yildiz, Aysegul Uner, Gokhan Gedikoglu
Hacettepe University, Faculty of Medicine, Department of Pathology, Ankara, Turkey

BACKGROUND: Classical form of Kaposi's sarcoma is known to mainly affect elderly and visceral involvement is not often in HIV-negative patients. Here, we present a case of multifocal intestinal Kaposi's sarcoma in a patient who also had a coexistent anaplastic large cell lymphoma. CASE REPORT: A 41-year-old woman with no prior medical history was admitted to the emergency department with abdominal distention and pain. A preliminary diagnosis of mesenteric vascular occlusion was made and the patient underwent laparatomy. Segmentary small intestinal resection was performed. The patient deteriorated and died two weeks after the operation. No mass lesion was noted on the resection specimen, however the serosa and mucosa was brown, fragile and edematous. The mucosa was randomly sampled and mesenteric lymph nodes measuring upto 1 cm were dissected from the mesocolon. Microscopically, infiltration of lamina propria with multifocal spindle cell proliferation positive for CD31, CD34, factor 8 and thrombomoduline and negative for c-kit, S100, HMB45 and melan-A were seen. Additionally, on the serosal surface of the intestine and in mesocolonic lymph nodes, an infiltration by a different group of large, pleomorphic neoplastic cells positive for LCA, CD30, EMA, ALK, granzyme B and negative for CD3, CD20, CD79a and CD138 were noted. The patient was proven to be HIV-negative both by PCR and serologically. To further support the diagnosis of visceral Kaposi's sarcoma in an HIV-negative patient, immunohistochemical detection of HHV-8 infection was done by the use of antibody directed against LANA (latent nuclear antigen). Neoplastic lymphoid cells were found to be negative while nuclear positivity was detected in the neoplastic spindle cell proliferation. CONCLUSION: It was concluded that, this was a rare case of multifocal intestinal Kaposi's sarcoma with coincidental ALK- positive anaplastic large cell lymphoma in an HIV-negative patient. Although HHV-8 associated lymphomas have been reported to take anaplastic large cell morphology, association between these two entities could not be presented in this case as HHV-8 could not be detected in the latter.

PP2-211
B-CELL LYMPHOMAS WITH TRANSLOCATIONS INVOLVING THE CDK6 GENE LOCUS REPRESENT A DISTINCT CLINICOPATHOLOGICAL ENTITY.

Ellen D. Remstein, Dong Chen, Mark Law, Ahmet Dogan
Mayo Clinic, Rochester, MN, USA

Reentry and progression through the G1 phase of the cell cycle is driven by cyclin-dependent kinases (CDK) in cooperation with cyclins, and alteration of this pathway is an important mechanism in oncogenesis. In lymphoid neoplasms, this pathway has been best studied in mantle cell lymphoma, in which CDK/Cyclin interaction is deregulated by translocations involving cyclins, most commonly cyclin D1. In this study, we describe clinicopathological and genetic features of lymphomas with genetic alterations affecting the CDK arm of this pathway. Four cases of B-cell lymphoma showing cytogenetic abnormalities of the 7q22 region where CDK6 gene is located were identified in the Mayo Clinic Cytogenetic database. Clinical and pathological data were reviewed. The karyotypes were studied by G-banding, and breakapart and dual-fusion fluorescent in situ hybridization (FISH) strategies using probes targeting CDK6, IGH , IGK and IGL loci were applied on metaphase spreads and paraffin embedded tissue. Three patients were male (age: 56, 66, 77) and one was female (age 68). All patients presented with peripheral lymphocytosis and three had systemic lymphadenopathy and splenomegaly. Peripheral blood morphology showed small to intermediate cells with atypical nuclear features. The bone marrow contained nodular and interstitial infiltrates of small lymphocytes. The spleen histology was available in two cases and showed features most consistent with a splenic marginal zone lymphoma. Immunophenotypically the neoplastic cells expressed CD20 and weak/partial CD5 but not CD23, CD10 or cyclin D1. Genetic analysis revealed that three cases had fusion of the CDK6 and IGK gene loci. The fourth case had a translocation involving CDK6 and an unknown partner gene on chromosome 21. Limited clinical follow-up data implied an indolent clinical course. Our findings suggest that B-cell neoplasms with CDK6 abnormalities have unique clinicopathological features overlapping with mantle cell lymphoma and splenic marginal zone lymphoma and may represent a distinct entity.

PP2-212

EPIDEMIOLOGIC, DEMOGRAPHIC DATA OF 212 NON-HODGKIN MALIGNANT LYMPHOMA AND MORPHOLOGICAL / IMMUNOHISTOCHEMICAL STUDY ACCORDING TO WHO CLASSIFICATION

Muzaffer Yildirim, Suleyman Demir, Isin Pak,
Eda Yilmaz Akcay, Emine Benzer
Ankara Oncology Hospital, Pathology Department, Ankara, Turkey

Aim: According to 2001 WHO- REAL classification; distribution of the subtypes of malign lymphoma differs all around the world. The frequency of B cell lymphomas is higher in western countries whereas T cell lymphomas are more common in asian countries. Our aims are; 1. To examine the morphology and immunohistochemical profile of non-hodgkin lymphoma cases (NHL), subclassify them according to WHO classification and to obtain demographical and epidemiological data by evaluating the diagnoses with clinical features. 2. To compare our data with the others reported in different parts of the world and improve epidemiological studies. Material-methods: Retrospectively, we examined 212 non-hodgkin lymphoma cases presenting between january 2003- december 2004 in Ankara Oncology Hospital, Pathology Department. The cases have been evaluated immunohistochemically (ALK, BCL-1, BCL-2, BCL-6, CD3, CD4, CD5, CD8, CD10, CD15, CD20, CD23, CD30, CD43, CD45, CD45RO, CD56, CD79a, EMA, Tdt, Granzym-B and EBV), clinical and morphological and than classified as B and T cell neoplasms according to 2001 WHO classification. Results: Of 212 non hodgkin lenfoma cases 195 (%92) are B cell, 17 (% 8) are of T cell origin. Most common subtype is Diffuse large B cell lymphoma (DLBCL)(125 cases, % 59). Other subtypes are respectively; Follicular lymphoma(%10,4), Small lymphocytic lymphoma (% 9.9), Mucosa associated lymphoid tissue-lymphoma (% 4.2), Mantle cell lymphoma (% 2.8). Uncommon subtypes are; lymphoplasmacytic lymphoma (% 2.4), nodal marginal zone lymphoma (% 1.4), Burkitt lymphoma (% 0.9), precurser B lymphoblastic lymphoma (0.5), intravascular large B cell lymphoma (% 0.5). The most common T cell lymphoma subtypes are respectively; peripheral T cell lymphoma (% 2.8) and anaplastic large cell lymphoma (% 1.9). Precursor T lymphoblastic lymphoma is more common than precursor B lymphoblastic lymphoma (% 1.4 and % 0.5). In our series there is small number of Mycosis fungoides, NK/T cell and primary cutaneous anaplastic large cell lymphoma cases. Gastrointestinal localisation is the most common extranodal lymphoma, following in order; head and neck, skin, extradural. Most common extranodal lymphoma subtype is DLBCL but skin lymphomas are of T cell origin. Conclusion: In our series immunophenotypic results of NHL subtypes are compatible with other reports in literature. When diagnosing and subtyping NHL cases, clinical, morphological and immmunohistochemical results should be evaluated together

PP2-213

FOCAL ADHESION KINASE (FAK) IN NORMAL AND NEOPLASTIC LYMPHOID TISSUES

Sermin Ozkal[1], Sara Tedoldi[1], Jennifer Paterson[1],
Martin L Hansmann[2], Aydanur Kargi[3], Sanjiv Manek[4],
Teresa Marafioti[1]
[1] Leukaemia Research Fund Immunodiagnostics Unit, Nuffield Department of ClinicalLaboratory Sciences, University of Oxford, Oxford, UK
[2] Senckenberg Pathology Institute, Johann Wolfgang Goethe-University Clinic Frankfurt am Main, Frankfurt am Main, Germany
[3] Department of Pathology, School of Medicine, Dokuz Eylul University, Izmir, Turkey
[4] Department of Cellular Pathology, John Radcliffe Hospital, University of Oxford, Oxford, UK

Background: Focal adhesion kinase (FAK) is a protein tyrosine kinase that plays a major role in the focal adhesion complex. FAK is essential for intracellular regulatory events such as cell growth, differentiation, cell migration and tumor metastasis. FAK expression has been reported to correlate with clinical behavior in several types of solid tumors such as neoplasia of brain, breast, thyroid, prostate, and colon. The aim of this study was to analyse the expression of FAK protein in a series of normal and neoplastic lymphoid tissues. Method: A polyclonal anti-FAK antibody was used to study by immunohistochemistry the protein expression in paraffin-embedded sections of normal haemato and (reactive lymph node, tonsil, thymus, spleen, bone marrow and lymph node with Toxoplasmosis infection), non haematolymphoid (skin, muscle, breast, thyroid, gallbladder, liver, stomach, pancreas, kidney, adrenal, endometrium, placenta, ovary, prostate, testis) tissues as well as in neoplastic non-haematolymphoid (fibroadenoma, breast carcinoma, thyroid carcinoma, adenocarcinoma of the colon, prostate, cervix, endometrium, ovary) neoplasias, and in a total of 453 lymphomas (including B, T cell non-Hodgkin lymphomas, Hodgkin's lymphomas and myelomas). Results: In normal lymphoid tissue, the strongest expression of FAK was detected in germinal centre and marginal zone B cells, positive staining was also found in mantle zone B cells and plasma cells. In human lymphomas, FAK was expressed mostly in B cell lymphomas. T cell lymphomas were predominantly negative with the exception of two cases of peripheral T cell lymphomas. In Hodgkin's lymphomas (HL), FAK was found only in the neoplastic cells of lymphocyte predominant Hodgkin lymphoma whereas the tumour cells of the classical form were FAK-negative. FAK that was expressed in normal plasma cells was negative in 9 out of 10 cases of myeloma. Conclusion: We demonstrate for the first time the expression of FAK in paraffin-embedded lymphoid tissue sections. FAK was expressed in many B-cell lymphomas whereas in T cell lymphomas FAK was negative in almost all instances. In HL, the highest expression of FAK was seen in the tumour cells of lymphocyte predominant, whereas in all cases of classical Hodgkin, the neoplastic cells were FAK-negative. Its differential expression may be of relevance for some B cell lymphomas e.g. it can be used as an additional marker to distinguish B from T lymphoblastic lymphoma/leukemia, or to distinguish lymphocyte predominant from classical Hodgkin lymphoma and normal from neoplastic plasma cells.

[4] Cerrahpasa Medical Faculty Department of Hematology, Istanbul, Turkey
[5] Cerrahpasa Medical Faculty Department of Oncology, Istanbul, Turkey
[6] Cerrahpasa Medical Faculty Department of Pathology, Istanbul, Turkey

Angiogenesis and angiogenic growth factors have a major role in the pathogenesis of malignancies. Studies related to non Hodgkin lymphomas and angiogenesis are relatively limited and have conflicting results. We investigated the role of angiogenesis in diffuse large B cell lymphomas (DLBCL) and its relation with clinical prognostic indicators. In this respect, We assessed microvessel density (MVD) in pretreatment lymph node biopsies of 54 previously untreated patients with DLBCL using anti CD34 immunohistochemical staining. All patients were treated with CHOP or R-CHOP. Mean age was 50,9 and median survival time was 83 months. The interobserver reproducability of microvessel

assesment was high. MVD was compared with age, gender, Ann-Arbor stage, WHO performance,IPI-score,bulky disease,bone marrow involvement, extra-nodal involvement, LDH level, type of the treatment, respons to first-line treatment and overal survival. We did not find a significant relationship between MVD and patient characteristics and response to treatment. In univariate analysis, survival correlated with Ann-Arbor stage, presence of B-symptoms and IPI-score. Response to treatment correlated with age, Ann-Arbor stage and the numbers of extranodal involvement. Larger series of patients are needed to determine the prognostic value of angiogenesis in NHL.

PP2-215
T-CELL LYMPHOMA WITH STRONG CD20 EXPRESSION ACQUIRED IN A RELAPSE: A CASE REPORT

Vit Campr[1], Marketa Kalinova[1], Eliska Axmannova[1], Zuzana Gattnarova[2], David Starostka[3]
[1] Department of Pathology and Molecular Medicine, Charles University in Prague, 2nd Medical Faculty, Czech Republic
[2] Department of Pathology, Hospital Havirov, Czech Republic
[3] Department of Clinical Haematology, Hospital Havirov, Czech Republic

Background: Immunophenotypical lineage infidelity in mature non-Hodgkin lymphoma is a well-known phenomenon. The expression of T-cell marker CD5 in B-cell lymphoma is notoriously known and is regularly used in a diagnosis of CLL and MCL. On the contrary, a subset of T-cell lymphomas with the expression of some panB-cell markers (either CD20 or CD79a, usually not both at the same time) is also described. Such cases are explained by the origin of tumor cells from a subset of bone marrow CD20-positive T-lymphocytes. Another possibility may be an aberrant inconsistent expression on neoplastic cells. We describe a case of T-cell lymphoma, which acquired a CD20 positivity during the course of the disease. Case report: 70 year old female presented with peripheral lymphadenopathy and systemic symptoms. Peripheral T-cell lymphoma of angioimmunoblastic type (AILT) was diagnosed. The tumor cells were CD45+ CD45R0+ CD3- CD4+ CD8- CD10-/+ CD56- CD30- Ki67+ (approx. 50 %). The patient with aaIPI 1, stage IV B disease received 5 cycles of PACEBO chemotherapy. The treatment was well tolerated and complete remission was reached according to a PET/CT scan. The disease recurred after ten months. The tumor cells were CD45+ CD45R0+ CD3- CD4-/+ CD8- CD10-/+ CD56- CD30+ Ki67+ (more than 80 %). A surprising finding was a strong membrane expression of CD20; CD79a and BSAP (PAX5) were negative. No such aberrant expression in a primary tumor was present. The PCR examination using BIOMED-2 primers in both tumors revealed oligoclonal population with TCR gamma rearrangements of the same size. IgH or IgL were not clonally rearranged. Conclusion: There are cases of diffuse large B-cell lymphoma evolution in an AILT described in the literature. This possibility was excluded by PCR results. We conclude that the expression of panB-cell marker CD20 on T-cell lymphoma in the presented case is an example of an aberrant immunophenotype in therapeutically influenced tumor cells. Because the finding of CD20+ CD3- tumor cells may be a source of a misdiagnosis, our case stresses the importance of using the broad panel of antibodies rather than single lineage-specific markers. In cases with aberrant immunophenotype it is necessary to apply molecular methods to disclose clonality. The diagnosis of a lymphoma even in a relapse is a complex and multidisciplinary process which can bring surprising results. This study was supported by Research Project FNM MZO 00064203 n. 6704.

PP2-216
DIAGNOSTIC ROLE OF RET, PGP 9.5, PPAR GAMMA, CK19, HBME-1, GALECTIN-3, AND KI-67 EXPRESSIONS IN THE ONCOCYTIC THYROID NEOPLASMS

Cenk Sokmensuer, Gaye Guler Tezel
Hacettepe University Faculty of Medicine Department of Pathology, Ankara, Turkey

Background: Thyroid carcinoma with oncocytic changes may sometimes cause diagnostic difficulties. The purpose of the current study was to investigate the expression and diagnostic role of RET, PGP 9.5, PPAR gamma, cytokeratin 19, HBME-1, Galectin-3, and Ki-67 expressions in oncocytic thyroid neoplasms. Methods: We investigated the expression of RET, PGP 9.5, PPAR gamma, cytokeratin 19 (CK19), HBME-1, Galectin-3, and Ki-67 using immunohistochemistry in 30 cases with oncocytic variant of thyroid carcinoma. The study group comprised of 18 cases of oncocytic variant papillary carcinoma and 12 cases of oncocytic variant follicular carcinoma. Expression score and correlation between immunohistochemical markers were analysed. Results: The expression of HBME-1, Galectin-3 and CK19 were found statistically significant in oncocytic papillary carcinoma group compared to oncocytic follicular carcinoma. RET oncoprotein staining was present merely in three cases of papillary carcinomas, whereas PPARγ synthetase positivity had an equal distrubution in both types of tumours. PGP 9.5 had no different staining patern in both of the groups. Oncocytic variant follicular carcinomas had lower Ki 67 proliferation indices compared to those of papillary carcinomas. Conclusion: Although oncocytic change creates morphological diagnostic problems, this study shows that oncocytic transformation does not indicate a spesific immunohistochemical expression profile. A panel of HBME-1, Galectin-3 and CK19 antigens is still useful to differentiate the oncocytic variant of papillary carcinomas from follicular neoplasms similar to their conventional counterparts.

PP2-217
GALECTIN-3 AND CD44V6 EXPRESSION IN THYROID LESIONS

Helen Kourea[1], Anna Liava[1], Constantinos Vagianos[2], Chrisoula Scopa[1]
[1] University Of Patras Medical School, Department Of Pathology, Greece
[2] University Of Patras Medical School, Department Of Surgery, Greece

Background: Diagnostic difficulties are at times encountered with follicular thyroid lesions, usually attributed to the presence of variably developed nuclear features of papillary thyroid carcinoma (PTC). Such observations led to the introduction of the term “well differentiated tumor of uncertain malignant potential” (WDT-UMP). Galectin-3, a protein involved in numerous biological pathways and affecting cell apoptosis, proliferation, adhesion and neoplastic transformation, has been proposed as a useful marker for the diagnosis of PTC. CD44 variant domain 6 protein (CD44v6), a type 1 transmembrane glycoprotein involved in cell-cell and cell-matrix interactions, has been implicated in tumorigenesis, tumor invasion and metastasis and has been a target for antibody-guided therapy in various epithelial malignancies. CD44v6 has been reported to differentiate benign from malignant epithelial thyroid lesions in both cytologic and histologic specimens. The purpose of this study was to examine the usefulness of galectin-3 and CD44v6 in distinguishing follicular thyroid lesions. Method: Seventy nine thyroid lesions, including 15 nodular goiters (NGs), 25 PTCs, 20 follicular adenomas (FAs), 11 follicular carcinomas (FCs) and 8 WDTs-UMP, were studied. Immunohistochemistry was performed using commercially available monoclonal antibodies against galectin-3

(clone 9C4) and CD44v6 (clone VVF-7). Galectin-3 positive cases were considered those that displayed nuclear and cytoplasmic staining of any intensity in ≥25% of cells while membranous immunostaining for CD44v6 in ≥1% of cells was interpreted as positive. Results: Nuclear and cytoplasmic expression of galectin-3 was observed in 1/15 (7%) NGs, 22/25 (88%) PTCs, 2/20 (10%) FAs and 1/8 (12%) WDTs-UMP. FCs were negative for galectin. The sensitivity, specificity and predictive value of positive and negative test were 88%, 93%, 85% and 94%, respectively. Membranous expression of CD44v6 was observed in 2/15 (13%) NGs, 1/25 (4%) PTCs, 1/20 (5%) FAs, 2/11 (18%) FCs and 5/8 (63%) WDTs-UMP. CD44v6 was mainly observed in neoplastic cells entrapped within sclerotic foci of PTC. Conclusion: The results of the present study show that galectin-3 is highly expressed in PTCs, representing a useful marker in differentiating follicular variant of PTC from FA. CD44v6 highlights WDT-UMP, although this association needs to be further investigated in larger numbers of WDT-UMP.

THYROID MALIGNANCIES AND RENAL FAILURE.

Serap Toru[1], Muge Unlukaplan[1], Banu Bilezikci[1], Zubeyde Arat[2], Beyhan Demirhan[1], Mehmet Haberal[3]
[1] Baskent University Pathology Department, Ankara, Turkey
[2] Baskent University Medical School, Ankara, Turkey
[3] Baskent University General Surgery, Ankara, Turkey

Introduction: Findings suggest that the incidence of nearly all malignant tumors is increased in immunosuppressed organ transplant recipients. Parathyroid and thyroid dysfunctions are detected in some of patients with chronic renal failure undergoing hemodialysis. Thyroidectomy and parathyroidectomy may become necessary in some of these patients. The aim of this study is to investigate the relative incidence of thyroid nodules in patients with on dialysis or renal transplant in comparison with the general population. Material and Methods: In 41 renal transplant recipients with thyroid dysfunction, thyroid FNAB findings, primary renal disease and the period of immunosuppression were evaluated retrospectively. Thyroidectomy specimens were also examined when available. These findings were compared with those of 230 cases in heamodialysis programme and with 221 patients without renal failure. Results: In transplant group the immunosupression period was about 5.5 years. Only one case had papillary carcinoma and one case had follicular neoplasia. Fifty of the 230 patients (21.7%) on hemodialysis who had thyroid FNAB underwent thyroidectomy. Papillary thyroid carcinoma was seen 4.3% of patients on hemodialysis. Conclusions: The most common abnormalities in transplant recipients' thyroid FNAB were amyloidosis (9.7%), and papillary thyroid carcinoma (2.4 %). The carcinoma rate between three goups were not significantly different (Transplant: %2.4, dialysis: %2.2, control: %1.4) ($p>0.05$). The frequency of amyloidosis was significantly higher in the transplant group (%9.8) in comparison to both the hemodialysis group (%3.5) and the control group (%0.9) ($p=0.005$). Our findings do not suggest on increase in the incidence of thyroid malignancies after renal transplantation. This may conceivably be due to closer examination of patients on dialysis resulting in detection and removal of nodules in thyroid and parathyroid.

PP2-219

HISTOPATHOLOGICAL ASSESSMENT AND DIAGNOSTIC IMAGING APPROACH TO GASTRO-ENTERO-PANCREATIC CARCINOMAS OF NEUROENDOCRINE ORIGINE - SINGLE NET CENTER EXPERIENCE IN POLAND

Jaroslaw Krzysztof, Anna Nasierowska-Guttmejer, Cwikla Jeziorski
Clinical Hospital Ministry of Internal Affairs and Administration, Warsaw, Poland

Background The recent WHO classification confirmed GEP/NETs into four categories according to gross and histopathological features. The microscopic type of tumor and a multimodality approach in imaging for detection the primary tumor and metastases decide of a treatment. The aim of the study was to review the current diagnostic approach, based on the experience of one center in Poland performed during a 4-year period. Methods All of 134 patients with histologically confirmed GEP were subjected to clinical, biochemical and imaging examinations performed as routine clinical work-up. The imaging techniques consisted of anatomical (CT, EUS) and functional approaches (SRS, mIBG and FDG PET). Results The clinical classification divided the primary origin of the tumor as follows: 49% -foregut tumors, 44%- midgut, and 7% of tumors of unknown origin. All of patients had malignant advanced disease. Group of patients with WHO 2, diagnosed as well differentiated endocrine carcinoma, consisted of 98 (73%) subjects. CT and SRS imaging were used in each case, and additionally EUS in foregut tumors, to localize the primary tumor, and assess tumor extent. Overall sensitivity of CT considering the active disease amounted to 96%, while specificity-75%. Sensitivity of SRS was 97%, while specificity- 85%. Second group of patients diagnosed as WHO 3, poorly differentiated endocrine carcinoma, included 29 patients, 17 foregut and 9 midgut tumors, and 3 of unknown origin. Diagnostic imaging examinations consisted of CT. Standard SRS (sst2) was negative in most of cases. The aggressive behavior of this type of tumors was detected by means of FDG-PET. Sensitivity of CT amounted to 100%, and that of SRS- 44%. Specificity of CT amounted to 67% and that of SRS-100%. Third group of patients diagnosed as WHO 4, mixed tumor, consist 7 patients, 4 foregut and 3 midgut neoplasms. The imaging approach consisted of CT/MR and in 5 cases FDG-PET. Sensitivity of CT amounted to 100%. Only one patient presented with a SRS positive study. FDG- PET sensitivity amounted to 100%. Conclusion: A microscopic type of GEP-NET correlates with imaging methods. A new histological WHO classification to be very helpful in order to select patients towards the best treatment modality and further follow-up. Diagnostic imaging of GEP-NET, consider anatomical and functional techniques, which should be read together.

PP2-220

METASTATIC BREAST CARCINOMA INVOLVING THE THYROID GLAND AFFECTED WITH PRIMARY PAPILLARY CARCINOMA DIAGNOSED BY IMMUNOHISTOCHEMISTRY. CASE REPORT

E. Moroz, D. Rotin, A. Pavlovskaya, V. Ermilova
N Blokhin Russia Cancer Research Center, Russia

Background: Metastatic involvement of the thyroid is occurred to be uncommon (in 2, 2 % of female cases) and having poor prognosis. Thyroid affection in the patients with breast cancer is diagnosed many years after mastectomy. The combination of both the primary and secondary malignant tumours in the same thyroid gland is a great diagnostic problem hardly solved not only clinically but also microscopically. Design (Case report): The patient, female, white 45-year-old, underwent radical mastectomy (1991), histologically - invasive ductal carcinoma. 5 years later (1996) she underwent left semi-thyroidectomy because of the nodes in her thyroid; histologically the thyroid gland tumor was corresponding with metastasis of breast invasive ductal carcinoma. After 9 years (2005) she underwent right semi-thyroidectomy for the same reason. Histologically, in tumor nests there were area of different appearance; solid, cribriform and alveolar patterns were intermitted with foci of tubular-follicular pattern. Nuclear characteristics and features in these different types of tumor areas were also distinguished. To produce more accurate diagnostic definition immunohistochemical investigation with the wide panel of markers including ER, PR, GCDFP-15, TPO, TTF-1 was performed. Results: Tumor cells in solid, cribriform and alveolar patterns were strongly positive for ER,

PR, GCDFP -15, being negative for TPO and TTF-1. In contrary, the structures of follicular pattern were strongly positive for TPO, TTF-1 and negative for breast cancer IHC markers that confirmed the presence of concomitant thyroid papillary carcinoma (diffuse follicular variant). Conclusion: We presented the case report of the coincidence thyroid papillary carcinoma and its metastatic affection by breast cancer. IHC method afforded to demonstrate difference between the primary and the metastatic origin in the very uncommon combination of neoplasms.

PP2-221
TWO CASE REPORTS: MIXED MEDULLARY-FOLLICULAR CARCINOMA AND MIXED MEDULLARY-PAPILLARY CARCINOMA OF THYROID

Feray Gunver, Tugce Guzel Cay, Zuhal Gulcin, Esra Pasaoglu, Erol R. Bozkurt
Istanbul Training and Research Hospital, Department of Pathology, Istanbul, Turkey

Mixed medullary and follicular carcinomas and mixed medullary and papillary carcinomas are tumors showing the morphological features of both medullary carcinoma and follicular carcinoma or papillary carcinoma, respectively. These tumors are also called composite carcinoma, biphasic carcinoma or compound carcinoma. These are very rare tumors and most have been described in single case reports. In mixed medullary-follicular carcinoma, the morphologic features of medullary carcinoma together with immunoreactivity for calcitonin co-exist with those of a follicular neoplasm together with immunoreactivity for thyroglobulin. Mixed medullary-papillary carcinoma contains intimately admixed populations of cells with the characteristic clear nuclei of papillary carcinoma and medullary carcinomas component. Our first patient was a 44 year old woman, who had a mass in her right thyroid lobe and clinically had hoarseness and dysphagia. In her ultrasound, she had a 1 cm solid nodule on the right side of the thyroid. Right complete thyroidectomy and left nearly complete throidectomy had been performed and 1,3 cm nodule on the right lobe of the thyroid was diagnosed as Mixed Medullary-Follicular Carcinoma after performing calcitonin and thyroglobulin immunohistochemistry and follicles showing neoplastic features. Non-tumoral areas and left lobe were diagnosed as Adenomatous Hyperplasia and Lymphocytic Thyroiditis. Our second patient was a 23 year old man who had a painless mass in his right thyroid lobe. In his ultrasound, he had a 1 cm solid nodule which was a cold nodule on scintigraphy. Right complete thyroidectomy and right modified neck dissection had been performed. 1,2 cm nodule on the right lobe of the thyroid was diagnosed as Mixed Medullary-Papillary Carcinoma after performing calcitonin and throglobulin immunohistochemistry and classical histopathological features of papillary carcinoma. There were three metastatic lymph nodes in his right modified neck dissection and they were diagnosed as Medullary Carcinoma metastases. As mixed medullary-follicular (or papillary) carcinomas of thyroid are very rare neoplasms, every diagnosed case should be reported, in order to increase the data in the literature.

PP2-222
HASHIMOTO'S THYROIDITIS WITH PAPILLARY THYROID CARCINOMA LIKE NUCLEAR ALTERATIONS AND THE ROLE OF IMMUNHISTOCHEMISTRY IN DIFFERANTIAL DIAGNOSIS OF TRUE PAPILLARY THYROID CARCINOMA

Fazilet Kayaselcuk, Tarik Nursal, Emrah Kocer, Tuba Canbolat, Kenan Caliskan, Ilhan Tuncer
Baskent University, Turkey

Hashimoto's thyroiditis (HT) is an autoimmune disease with widespread lymphocyte infiltration, fibrosis, and parenchymal atrophy in thyroid glands. In hemotoxyline-eosin slides; focal and incomplete papillary thyroid carcinoma (PTC)- like nuclear alternations – nuclear enlargement, overlapping, chromatin clearing, grooves and intranuclear inclusions- in thyrocytes may be described almost one-third of HT on routine microscopic examination. The incidence of carcinoma in HT has been reported wide range ratio between 0.5% and 30%. Although there is a high incidence of PTC in HT and common morphological features between these entities, the carcinogenetic steps between PTC and HT is not well understood. The aim of present study was to determine similar or different molecular expression patterns between PTC and HT. We selected four PTC-associated proteins and examined the expression of cytokeratin (CK)-19, fibronectin 1(FN1), galaktin 3, HBME1 and one proliferative activity marker-Ki-67- proteins by immunohistochemistry in PTC, HT, HT+ papillary carcinoma, HT+ follicular neoplasia cases. Fourty-one cases of HT, 15 HT+PTC, 7 HT + follicular neoplasia, 20 PTC, and 10 nodular goiters were selected from the archives of the department of pathology. Immunohistochemical staining was performed manually using the standard avidin-biotin peroxidase complex technique with DAKO (LSAB kit, DAKO, Denmark). The expressions of the proteins in malignant tumors were diffuse. There was no expression or focal staining in nonneoplastic thyroid tissue. Focal expression of galaktin 3, CK19, HBME1, FN1, and Ki-67 were seen in thyrocytes showing PTC-like nuclear alternations in HT. We could not demonstrate the expression of these five proteins in thyrocytes with no PTC-like nuclear alternations in HT. There was a high expression of both Galactin 3 and CK19 in true papillary carcinoma and PTC-like nuclear alternations in HT. In summary, PTC associated proteins are focally expressed in HT, especially in thyrocytes with PTC-like nuclear alternations. Similar molecular and morphological features between PTC and these thyrocytes suggest a common pathway for carcinogenesis.

PP2-223
IMMUNOHISTOCHEMICAL DETECTION OF P53 AND P63 IN THE CHRONIC LYMHOCYTIC THYROIDITIS WITH PAPILLARY THYROID CARCINOMA

Nagihan Yalcin, Yasemin Utku, Sermin Coban, Ender Duzcan
Department of Pathology, Pamukkale University School of Medicine, Denizli, Turkey

BACKGROUND: The pathologic mechanisms underlying papillary thyroid carcinoma are incompletely understood. Most models suggest that the origin of papillary carcinoma is the mature thyroid follicular epithelial cell. In recent reports, p63 was detected in papillary carcinoma, hashimoto's thyroiditis, in squamoid aggregates and solid nests. The aim of the study was immunohistochemical detection of p53 and p63 in chronic lymhocytic thyroiditis with papillary thyroid carcinoma. METHODS: Immunoperoxidase staining was performed in 10 slides that were prepared from archival blocks with the diagnosis of chronic lymhocytic thyroiditis with papillary thyroid carcinoma. p53 and p63 staining patterns in and around the tumor areas evaluated. RESULTS: Nine of the cases were female. The ages ranged from 20 to 60. P53 staining in tumoral areas was positive in 6(60%) cases with the ratio of 0 -80 %. Staining was also positive in thyroiditis areas in 6(60%) cases with the ratio of 0-40%. P63 staining in tumoral areas was positive in 5(55.5%) cases with the ratio of 0 -80 %. Staining was also positive in thyroiditis areas in 7 (77.8%) cases with the ratio of 0-20%. Both p53 and p63 staining were observed in squamous metaplasic focuses in tumoral areas. CONCLUSION: p53 and p63 expressions are parallel in the areas of papillary thyroid carcinoma and chronic lymhocytic thyroiditis. These finding suggests that papillary thyroid carcinoma and chronic lymhocytic thyroiditis may be associated in etiology.

PP2-224

HETEROTOPIC THYROID TISSUE PRESENTING AS A PORTA HEPATIS MASS

Nilufer Onak Kandemir[1] Burak Bahadir[1], Aylin Ege Gul[2] Nimet Karadayi[2]
[1] Departments of Pathology, Zonguldak Karaelmas University School of Medicine, Zonguldak, Turkey
[2] Departments of Pathology, Dr. Lutfi Kirdar Kartal Research and Training Hospital, Istanbul, Turkey

BACKGROUND: Heterotopic thyroid along the course of thyroglossal duct or close to midline is a well known entity and particularly involves the base of tongue, submandibular region, larynx, trachea, mediastinum, and heart. It is extremely uncommon in the subdiaphramic area except those seen as a component of ovarian teratomas. In the literature, only five such cases have been reported in porta hepatis to date; the current case represents the sixth. CASE REPORT: A 60 year-old woman with a history of bilateral subtotal thyroidectomy due to multinodular guatr presented with acute cholecystitis underwent total cholecystectomy. Throughout operation a 5 cm mass at porta hepatis was detected and subsequently excised. RESULTS: On gross examination the mass was 5x3x3 cm with gelatinous cut surface and focal areas of calcification. Microscopically, follicles rich in colloid, arranged in nodular fashion some of which displayed cystic dilatation lined by oval to cuboidal epithelium were observed. No atypia or any other features suggesting neoplastic transformation including papillary structures and psammoma bodies were noted. Neither lymph node architecture nor teratomatous tissue elements were detected. The possibility of a metastatic origin from an occult thyroid carcinoma was excluded by the clinical and histopathological findings. Immunohistochemically, epithelium together with colloid was reactive for thyroglobulin. Accordingly, the lesion was diagnosed as an ectopic thyroid tissue with nodular goiter and hyperplastic changes. Both grossly and microscopically, cholecystectomy specimen was an ordinary one exhibiting acute inflammation with gall stones. CONCLUSION: Possible causes of accessory thyroid tissue include a component of teratoma; epithelial metaplasia; abnormal migration in embryogenesis; implantation due to trauma or operation; and metastasis from thyroid carcinoma with minimal atypia. Considering the current case, the heterotopic tissue appeared to be an individual nodule; no finding consistent with metastasis or a direct epithelial connection suggestive of metaplasia was revealed. Moreover, neither any other processes suggestive of implantation nor components of teratoma was perceived. Consequently, intra-abdominal heterotopic thyroid including those in porta hepatis as seen in the present case may be developmental in origin, and thus it might have developed during early embryonic stage before the complete development of diaphragm.

PP2-225

THE CHANGES IN THE INCIDENCE OF THYROID GLAND DISEASES: DATA FROM CUKUROVA REGION OF TURKEY

Naciye Ozeren, Bermal Hasbay, Aysun Uguz, Canan Ersoz
Cukurova University Medicine School Pathology Department, Adana, Turkey

BACKGROUND: The incidence of thyroid diseases differ in various geographical regions and it is effected by environmental conditions. The only established risk factor for differentiated thyroid cancer is ionizing radiation. The most dramatic effect of exposure to fallout from the Chernobyl accident on physical health has been the increase in thyroid cancer.The aim of this paper is to analyse changes in thyroid disease incidence trends in Cukurova region during the period of 1986-2006. MATERIAL - METHODS: All thyroidectomy cases were retrieved from the archives of Cukurova University, School of Medicine, Department of Pathology and classified according to the final diagnoses and other available information, retrospectively. The cases were evaluated in 3 periods: 1986-1990, 1991-1996 and 1997-2006. RESULTS: From 1986 to 1990, 21320 cases were registered to the Pathology Department. Hundred and seventy six (0.8 %) of them were thyroidectomy specimens. Overall histopathological diagnoses were nodular goiter (79%), adenoma (3.4%), fethal nodul (3.4%), papillary carcinoma (P.C) (8.9%), follicular carcinoma (F.C) (2.8%), and metastatic carcinoma (1.7%). Female/male ratio was 1.12 in all cases. A malignant tumor was seen in 13.4% of the thyroidectomy specimens. The average age was 42. From 1991 to 1996, 46120 cases were registered. Five hundred and eleven (1.1 %) of them were thyroidectomy specimens. Overall histopathological diagnoses were nodular goiter (79.5%), adenoma (3%), fethal nodul (1%), lymphocytic thyroiditis (0.4%), P.C (5.6%), F.C (2.2%), medullary carcinoma (0.8%). Female/male ratio was 1.58 in all cases. A malignant tumor was seen in 13.6% of the cases. Average age was 45. From 1997 to 2006, 220180 cases were registered. One thousand five hundred and twelve (0.6 %) of them were thyroidectomy specimens. Overall histopathological diagnoses were nodular goiter (66%), adenoma (12%), lymphocytic thyroiditis (3.5%), P.C (13%), F.C (2.7%), medullary carcinoma (1.4%), well differentiated papillary – folicular thyroid carcinoma (0.07%) and papillary + follicular carcinoma (0.007%). Female/male ratio was 1.163 in all cases. A malignant tumor was seen in 17.8% of the cases. Average age was 44. CONCLUSION: The mean ages and female /male ratio of the patients did not differ in three periods.The incidences of nodular goiter and follicular carcinoma were also similar. However FA, PC and lymphositic thyroiditis incidences seemed to increase from 1986 to 2006. Further and detailed investigations based on the population in Cukurova region are needed to explain these changes in the incidences.

PP2-226

CLINICAL AND PATHOLOGICAL FEATURES AND PROGNOSTIC FACTORS FOR PAPILLARY THYROID CARCINOMAS: A REVIEW OF 753 CASES.

Tulin Ozturk[1], Esra Ucaryilmaz[1], Pelin Bagci[1], Ahmet Korkut Belli[2], Figen Aksoy[1]
[1] Istanbul University Cerrahpasa Faculty of Medicine Department of Pathology, Istanbul, Turkey
[2] Istanbul University Cerrahpasa Faculty of Medicine Department of Surgery, Istanbul, Turkey

OBJECTIVES: The aim of this study was to present a descriptive frequency of papillary thyroid carcinomas in our department, using our registry data. From 2000 to 2006, Intraoperative and postoperative pathologic samples of 753 individuals were diagnosed papillary thyroid carcinoma at the Istanbul University Cerrahpasa Faculty of Medicine Department of Pathology. Pathologic samples of 414 of these 753 patients who underwent surgery and examined pathologically at the other hospitals were consulted for second opinion at our department. RESULTS: Of the patients evaluated, 81% were female and 19% male, with an average age of 48 (minimum 10- maximum 89). Of all the cases, 74,1 %(n=559) were of the usual type, whereas 25,9 % (n=194) showed complex histological features with different components present and 18% represented specific subtypes. Pathologic analysis revealed 753 papillary thyroid carcinomas, including 326 classic variant of papillary thyroid carcinomas (PTCs) (43.3%) and 250 follicular variant of PTCs (33.2%) and 127 sclerosing variant of PTCs (16.8%) and 9 cystic variant of PTCs (1,2%) and 8 tall cell variant of PTCs (1,1%) and 7 hurtle and oncocytic cell variant of PTCs (0.9%) and 7 low differentiated variant of PTCs (0.9%) and 6 classic variant of PTCs with Warthin type areas (0.8%) and 3 classic variant of PTCs (0.9%) with oncocytic cells and 2 follicular variant of PTCs with oncocytic cells (0.3%), 2 Warthin like follicular variant of PTCs (0.3%) and 2 trabecular variant of PTCs (0.3%) and 2 clear cell variant of PTCs (0.3%) and 2 dedifferentiated variant of PTCs (0.3%). Of the

surrounding non-tumor tissue, 6.0% (n=45) had hyperfunction signs; 2%(n=15) Hashimato thyroiditis; 4,2% (n=32) follicular adenoma; 1,2%(n=9) Hürthle cell adenoma; 2,8%(n=21) Hürthle cell metaplasia and 26% (n=198) non-specific lymphocytic thyroiditis. 72,6% (n=541) adenomatous hyperplasia. We found multicentricity 27,5% (n=207) of all cases. CONCLUSION: Histological assessment is the gold standard for detecting invasive thyroid cancer. Thyroidectomy is effectively a staging procedure by which the presence and extent of invasive disease can be established and subsequent management determined.

PP2-227
CLINICAL AND PATHOLOGICAL FEATURES AND PROGNOSTIC FACTORS FOR FOLLICULAR THYROID CARCINOMAS: A REVIEW OF 153 CASES

Tulin Ozturk[1], Hacer Ece Arslan[1], Serap Arslan[1], Ahmet Korkut Belli[2], Figen Aksoy[1]
[1] Istanbul University Cerrahpasa Faculty of Medicine Department of Pathology, Istanbul, Turkey
[2] Istanbul University Cerrahpasa Faculty of Medicine Department of Surgery, Istanbul, Turkey

OBJECTIVES: The aim of this study was to present a descriptive frequency of follicular thyroid carcinomas in our department, using our registry data. From 2000 to 2006, Intraoperative and postoperative pathologic samples of 153 individuals were diagnosed follicular thyroid carcinoma at the Istanbul University Cerrahpasa Faculty of Medicine Department of Pathology. Pathologic samples of 64 of these 153 patients who underwent surgery and examined pathologically at the other hospitals were consulted for second opinion at our department. RESULTS: Of the patients evaluated, 83% were female and 17% male, with an average age of 47 (minimum 14- maximum 83). Pathologic analysis revealed 153 follicular thyroid carcinomas, 10.4% (n=16) had 1 cm sized tumor or less; 89,6% (n=137) had larger than 1 cm tumor. Of all the cases, 81 %(n=124) were of minimally invasive type, whereas 19 % (n=32) showed widely invasive histological features. Vascular invasion was found 11,7% (n=18) of the patients. Of the surrounding non-tumor tissue, 3,9% (n=6) had hyperfunction signs; 11,7% (n=18) adenomas and 12,4% (n=19) non-specific lymphocytic thyroiditis. 56,8% (n=87) adenomatous and/or diffuse hyperplasia. Accompanying other thyroid carcinomas were also seen in 6,5% (n=10) of the patients. CONCLUSION: Histological assessment is the gold standard for detecting invasive thyroid cancer. Thyroidectomy is effectively a staging procedure by which the presence and extent of invasive disease can be established and subsequent management determined.

PP2-228
DNA PLOIDY ANALYSIS IN BENIGN AND MALIGNANT THYROID LESIONS

Mehmet Dogan, Aylar Poyraz
Gazi University Department of Pathology, Ankara, Turkey

In this study we investigated 112 benign and malignant thyroid lesions with image analyzer in order to identify the frequency and diagnostic importance of aneuploidy. All specimens were sent for intraoperative diagnosis and at that time touch imprints of the identified lesions were done. Slides were stained with the feulgen method for DNA ploidy analysis. Ploidy software of Samba image analyzer (Grenoble, France) was used for examination of slides in cytometric method. Of the 112 patients, two were diffuse goiter, sixty eight were nodular goiter, eleven were follicular adenoma, five were minimally invasive follicular carcinoma, twenty-four were papillary carcinoma and two were poorly differentiated carcinoma. DNA ploidy analysis revealed that the 112 cases 93 (83%) were diploid, 4 were (3.5%) tetraploid and 15 (13.4%) were aneuploid. Frequency of aneuploidy was 13.6 % in benign lesions and 12.9 % in malignant tumors. There was no statistically significant difference between benign and malignant lesions. The highest frequency of aneuploidy was observed in cases of nodular goiter with adenomatous hyperplasia (25%) followed by cases of follicular adenoma (18.2%), nodular goiter without adenomatous hyperplasia (11.7 %) and papillary carcinoma (16.7 %). These results were supported by the literature. But we did not find aneuploidy in 2 poorly differentiated and 5 minimally invasive follicular carcinomas in contrast to the literature. This may be explained by the fact that we did not have enough carcinoma cases for analysis. In conclusion, our results showed that aneuploidy is not helpful in differentiating benign and malignant lesions. However, in larger series, DNA ploidy analysis along with genetic and cytogenetic investigations may contribute to understanding the etiology and pathogenesis of thyroid lesions.

PP2-229
THE FOLLICULAR VARIANT OF PAPILLARY CARCINOMA – THE ANALYSIS OF CYTOLOGIC FEATURES

Ewa Stobiecka, Ewa Chmielik, Dariusz Lange, Magdalena Jaworska, Krystyna Woloszynska, Bogna Szczesniak-Klusek
Department of Tumor Pathology, Centre of Oncology, M. Sklodowska-Curie Memorial Institute, Gliwice, Poland

Background:The follicular variant of papillary carcinoma (FVPC) is the second encountered form of papillary carcinoma (PC). Cytological findings in FVPC are variable and can be mistaken for follicular lesions (FL). Methods: 28 cases of FNA's from histologically confirmed FVPC were analysed. Several cytologic features of FVPC were evaluated in comparison with 9 PC and 10 benign FL. Results: Cellularity of FVPC was variable, in 11 cases (39%) was high. Follicle structures were present in all cases (100%), monolayered sheets in 13 cases (46%), papillary structures in 5 cases (18%). Nuclear grooves and powdery chromatin were present in all cases (100%), intranuclear inclusions in 20 cases (71%), predominant nucleoli in 9 cases (32%), in 5 cases (18%) psammoma bodies were present. There were similar cytologic features excluding large number of follicular structures in FNA of PC. There were no papillary structures, inclusions and abundant nuclear grooves in FNA of FL. Conclusions: The combination of cytologic features such as follicular structures, nuclear enlargement, intranuclear inclusions and grooves are significant for the follicular variant of papillary carcinoma diagnosis.

PP2-230
IDENTIFICATION OF DIFFERENTIALLY REGULATED GENES IN PAPILLARY THYROID CANCERS

Song Mei Huang[1], Ki Young Lee[2], Shengjin Li[1], Jin-Man Kim[1]
[1] Department of Pathology, Chungnam National University College of Medicine, Korea
[2] Department of Anesthesiology, Yonsei University College of Medicine, Korea

Background: Techniques designed to identify differentially expressed genes (DEGs) in tumors have become pivotal in modern pathology. Genefishing techniqueTM using the annealing control primer (ACP) system was recently developed by Hwang et al to screen for DEG transcripts in low concentrations. The technique that uses primers that anneal specifically to the template and allows only genuine products to be amplified, a process that eliminates false-positive results. Design: We have utilized a new differential display method, designated with ACP system, to analyze differentially expressed genes (DEGs) in seven cases of normal thyroid tissues and papillary thyroid carcinomas. The genes identified in this study should provide an insight into the carcinogenesis and progression mechanisms of papillary thyroid carcinomas. Results: With this method we detected 21 genes that are differentially expressed in PTCs and performed cloning with sequencing in 14 genes. We confirmed

the expression patterns of 2 DEGs by RT-PCR assay and identified same results in 7 PTCs. The two DEGs overexpressed in PTCs are confirmed for a DC-stamp and type I collagen A1. They are novel genes firstly identified in PTCs. Conclusion: These results suggest that this new PCR-based technique is a very useful tool for the identification of novel genes differentially expressed in PTC. This study was undertaken as a step toward identifying previously unrecognized molecular genetic mechanisms in PTC. Although the detailed functions of these two genes and their products remain to be determined, the genes identified here will provide insights into mechanisms of carcinogenesis or tumor progression in PTCs.

PP2-231
MULTIFOCALITY IN THYROID CARCINOMAS
Aylar Poyraz[1], Hayriye Dogan[1], Ferit Taneri[2]
[1] Gazi University Department of Pathology, Ankara, Turkey
[2] Gazi University Department of Surgery, Ankara, Turkey

Histopathologic type, tumour size, extrathyroidal spread, metastasis and multifocality are risk factors that should be considered for therapeutic approach in thyroid carcinomas. The aim of this study is to investigate frequency of multifocality of thyroid carcinomas in thyroidectomy specimens. 140 patients who underwent thyroidectomy and diagnosed as malignant neoplasms were included in this study. A retrospective pathology report review was performed for all patients. Of the 140 thyroid carcinomas, 118 (84.2 %) were papillary carcinomas, 16 (11.4 %) were follicular carcinomas, 5 (3.5 %) were medullary carcinomas, and 1 was poorly differentiated thyroid carcinoma. 44 out of 118 papillary carcinomas were papillary microcarcinomas. Multifocality was observed in 29 cases (24.5 %). Malignancy was noticed out of nodule in 42 biopsies. Gross examination and frozen section of the thyroidectomy may be helpful identification of multifocality and some malignant lesions that were not defined before the surgery. This will prevent patients from the second operations.

BACKGROUND: Parathyroid adenomas are unusual neoplasms, three times more frequent in women and occur at any age. In terms of location, 10% occur in anomalous positions and 70% of them are in the mediastinum. CASE/PATIENT: We report a case of a 56 year-old woman with metastatic malignant melanoma. PET-Scan (Positron Emission Tomography) was performed for staging the neoplasm and revealed an upper mediastinal mass suspicious for lung and pericardial invasion. A metastasis was suspected. No abnormalities were detected in blood chemical analysis, including calcium and phosphate levels. Thoracothomy and resection of the mass were done. RESULTS: The tumor was well circumscribed, envolved by a delicate capsule, weights 210g and measures 10,5 x 9,0 x 5,0 cm, it was solid, grayish brown with hemorrhagic areas. Microscopically the patterns of growth were diffuse, acinar and follicular, composed predominantly for oxiphylic cells with minimal nuclear atypia. Immunohistochemistry was performed and there was diffuse positivity for parathormone and positivity for chromogranin and Neuron-specific enolase; ki-67 labeling index was less than 1%. CONCLUSIONS: Considering the variety of aberrant locations in which ectopic parathyroid adenomas may be found, these neoplasms can be difficult to identify and treat surgically. They can rarely growth to a larger size. In the present case another difficulty is that the patient had already a diagnosis of malignant melanoma. Virtually all parathyroid neoplasms, including the rare parathyroid carcinoma, are functional. Despite the large size of this neoplasia, the patient hadn't symptoms of hyperparathyroidism or hypercalcaemia. To our knowledge this is the greatest parathyroid adenoma reported in the literature.

PP2-233
DIAGNOSTIC UTILITY OF TTF-2 (FOX-E1) AND PAX-8 IN THYROID EPITHELIAL NEOPLASMS
Yunjia Tang[1], Ronald Ghossein[2], Luis Chiriboga[1],
Daisuke Nonaka[1]
[1] New York University School of Medicine, USA
[2] Memorial Sloan-Kettering Cancer Center, USA

Background: Thyroid-specific transcription factors, TTF-1, TTF-2 and Pax-8, are crucial for thyroid organogenesis and differentiation. Compared with TTF-1, the other two markers have not been extensively investigated in surgical pathology. The goal of this study is to evaluate the expression of these markers in thyroid tumors of the full spectrum of differentiation. Their sensitivity and specificity to thyroid tumors are studied by observing the expression in other tissues including lung carcinomas. Design: A total of 69 cases of thyroid neoplasms were studied: 16 papillary carcinomas (PCAs); 18 follicular adenomas (FAs); 16 follicular carcinomas (FCAs); 8 insular carcinomas (ICAs); 3 anaplastic carcinomas (ACAs); and 8 medullary carcinomas (MCAs). Immunostains for TTF-1, TTF-2, Pax-8 and thyroglobin were performed using tissue microarrays. In addition, TTF-2 and Pax-8 were applied on 77 cases of lung carcinomas, comprised of 73 adenocarcinomas and 4 squamous cell carcinomas, as well as normal tissue and malignant tumors from 16 other organs/sites. The extent of staining was graded as focal (<50%) and diffuse (>50%). Results: TTF-1 nuclear expression was seen in all PCAs, FAs, FCAs and ICAs in a diffuse fashion, whereas its expression in MCAs was variable. Two of the three ACAs demonstrated only a few positive cells. TTF-2 expression was diffuse in a majority of the PCAs, FAs, FCAs, and ICAs in a predominantly nuclear staining, and one ACA showed focal nuclear staining. TTF-2 reaction, however, was predominantly cytoplasmic in all MCAs. Pax-8 was diffusely expressed in a predominantly nuclear staining in all PCAs, FAs, FCAs, ICAs and ACAs except for a focal staining in one PCA and ACA, whereas the expression was predominantly cytoplasmic in all MCAs. Thyroglobin was diffusely expressed in FAs, and variably in PCAs, FCAs and ICAs, but it was negative in ACAs and MCAs. TTF-2 was negative in all other neoplastic and non-neoplastic tissue including those of the lung. Pax-8 was expressed in renal tubules as well as clear cell renal carcinoma, nephroblastoma, seminoma, ovarian serous carcinoma and diffuse large B cell lymphoma, but not in lung tissue/carcinomas. Conclusion: Pax-8 is a sensitive marker for thyroid lesions, but its specificity is compromised by the expression in lesions of metanephric and gonadal derivation, and B-lymphocytes. TTF-2 is a sensitive and specific marker for thyroid lesions. Both markers can be useful to differentiate between thyroid and lung carcinoma.

PP2-234
SURGICAL THYROID PATHOLOGY. PROTOCOL APPLIED IN THE INTERDISCIPLINARY THYROID PATHOLOGY STUDY GROUP IN THE LAST 20 YEARS
Ana Puras[1], A Echegoyen[1], C De Miguel[1], MV Zelaya[1],
P Salvador[2], E Menéndez[3], Y Ruiz de Azúa[1]
[1] Hospital Virgen del Camino. Pamplona, Department of Pathology, Spain
[2] Hospital Virgen del Camino. Pamplona, Department of Surgery, Spain
[3] Hospital Virgen del Camino. Pamplona, Department of Endocrinology, Spain

Introduction: The sampling in well differentiated thyroid tumors and the nomenclature used in the thyroid tumors are in general matter of discussion in the literature. The Thyroid pathology study group of our hospital has made a pursuit of both parameters with the aim to classify them. Material and Methods**:** We have compiled the surgical thyroid pathology in the last 20 years (2431 studies). The standardized protocol and terminology established by consensus in the Thyroid Pathology Study Group, has been applied in our hospital during the last 20 years. Results: The results are the followings: Adenoma: 353; Papillary Carcinoma: 358; Follicular Carcinoma: 110; Poorly Differentiated Carcinoma: 21; Anaplastic Carcinoma: 2; Medullary Carcinoma: 21; Lymphoma: 7; The remaining ones were Hyperplasias and Thyroiditis. Conclusions: 1. In the interdisciplinary thiroid pathology study group meeting, after revision of this great number of cases, we have proved that it is necessary to follow a standardized protocol with the aim of diminishing diagnostic difficulties. 2. In the interest of adequate management of thyroid patients, the nomenclature must be consensuated with the work group. 3. When in frozen sections the diagnosis is delayed, it is necessary to issue the definitive diagnosis quickly (24 hours-4 days) to avoid surgical complications. 4. In our Hospital we have detected: a) great number of well differentiated carcinoma; b) many problems are made by a quick diagnosis of some bordeline tumors.

PP2-235
COX-2 AND INOS EXPRESSIONS IN THYROID NEOPLASMS

Aysun Uguz[1], Canan Ersoz[1], Ferhat Yildirim[1], Gulsah Seydaoglu[2]
[1] Cukurova University, Medical Faculty, Department of Pathology, Adana, Turkey
[2] Cukurova University, Medical Faculty, Department of Bioistatistics, Adana, Turkey

Background: The aim of this study is to evaluate the differences in the immunohistochemical expressions of the Cox-2 and INOS proteins in papillary carcinoma (PC), follicular carcinoma (FC) and follicular adenoma (FA) cases of the thyroid. Cox-2 is highly inducible at inflammation sites and is associated with various types of human tumors. Cox-2 expression is also upregulated during increased proliferation of tumor cells, inhibition of apoptosis and neovasculogenesis. However INOS overexpression is related with chronic inflammatory diseases as well as human tumors. INOS plays a crucial role in tumorigenesis as a mediator of carcinogenic nitrosamine formation. Materials and Methods: Hundred and two cases were selected from the archieves of the Department of Pathology, Cukurova University Hospital. Of the total 102 cases; 63 were papillary carcinoma, 18 were folicular carcinoma and 21 were folicular adenoma. Histopathologic diagnoses were reviewed by two pathologists. Cox-2 and INOS expressions were examined by using immunohistochemical methods. Results: INOS expressions were detected weakly in 9 (14.3%), moderately in 9 (14.3%) and severe in 45 (71,4%) of the PC cases. In FC cases; weak, moderate, and severe stainings were observed in 9 (50,0%), 3(16,7%) and 6(33,3%, and in FA cases 8(38,1%), 6(28,6%) and 7(33,3%), respectively (p=0.002). Of the PC cases, 8(12,7) stained weakly, 12(19,0)stained moderately and 43(68,3)stained severe according to Cox-2 expressions. These results were 5(27,8), 4(22,2) and 9(50,0) in FC, and 10(47,6), 4(19,0) and 7(33,3) in FA groups, respectively (p=0.01). There were no significant differences between two carcinoma groups according to ratio of severe staining in Cox-2 but the ratio of severe expression is significantly higher in PC than FC according to INOS. A significant difference was observed between carcinoma and adenoma groups in Cox-2 expressions, but no difference was determined in INOS expressions. Conclusion: The present study showed that Cox-2 expression may serve as an useful marker to distinguish carcinoma cases from adenoma cases. These results are compatible with literature and suggest that Cox-2 expressions could be an important molecular event for the thyroid tumor progression. However, INOS expressions did not show any differences between these two groups. In addition, 1/3 of the FA cases were stained severe with INOS. In PC cases INOS expressions were detected higher than FC cases. For this reason INOS could be an important agent for devoloping papillary tumors of the thyroid.

PP2-236
CHRONIC THYROIDITIS AS A RISK FACTOR FOR MULTIFOCAL PAPILLARY THYROID CARCINOMA

Ibrahim Mansoor, Idris Ocal
Yale University, School of Medicine, New Haven, CT, USA

Background: Weather Chronic Thyroiditis (CT), particularly Chronic Lymphocytic Thyroiditis is associated with increased risk for the development of Papillary Thyroid Carcinoma (PTC) is controversial. Aim of this study is to explore any association of CT with PTC in our patient population, with special emphasis on multifocal PTC (MF-PTC). Methods: All thyroid resections performed at our institution from 01/2000 to 10/2006 were reviewed. Along with the primary surgical diagnosis any morphological changes in the non-lesional thyroid parenchyma were also collected and categorized into CT, Hyperplasia (including Graves Disease) and Normal. Multifocality was defined as 2 or more separate foci of same type of tumor. Clinical significance of this lymphocytic infiltration was beyond the focus of our study. Results: A total of 626 thyroid resections (512 females and 114 males) with 385 total/near-total thyroidectomies, 207 lobectomies and 30 lobe+isthmusectomies were identified in our database. Our study group consisted of 483 cases (77% of total), where background information was reported for non-lesional thyroid tissue. In this group, primary surgical diagnosis was PTC in 210 cases (43%), follicular/Hurthle cell adenoma in 90 (19%), follicular/Hurthle cell carcinoma in 15 (3%), other malignancies (medullary, poorly differentiated or anaplastic carcinomas, lymphomas, metastases, etc.) in 18 (3%) and benign (other than adenomas) in 150 (31%) cases. Overall, CT was reported in the background thyroid in 153 cases (32%), Hyperplasia in 172 (36%), and it was reported to be normal in 158 cases (33%). Of 210 patients with PTC, 118 were unifocal and 92 were multifocal. In unifocal PTC, the background showed CT in 37 (31%) cases, hyperplasia in 32 (26%), and unremarkable histology in 49 cases (42%). In multifocal PTC, the background showed CT in 46 (50%), hyperplasia in 14 (15%), normal in 32 (35%) cases. Conclusion: CT was reported in overall 153 (32%) of 483 thyroid resections as the background morphology and 40% of all PTCs. However, when PTCs are divided into unifocal and multifocal cases, UF-PTC (n=118) was associated with background CT in 31% of cases, patients with MF- PTC showed a markedly higher incidence of CT (50%) in the non-neoplastic thyroid as compared to other primary diagnoses ($p<0.05$). Any causal relationship between the chronic lymphocytic inflammation and PTCs or a common etiologic mechanism in pathogenesis of these two disorders should be considered.

PP2-237
HBME-1, CYTOKERATIN 19 AND GALECTIN 3 EXPRESSION IN THYROID CARCINOMAS

Banu Yilmaz Ozguven, Emine Mataraci, Fevziye Kabukcuoglu
Sisli Etfal Training and Research Hospital, Pathology Laboratory, Istanbul, Turkey

AIM: The existence of HBME1, cytokeratin19 and galectin 3 expressions were investigated in different malignant tumors of thyroid in this study. MATERIAL AND METHOD: : 51 tissues of thyroid operation materials diagnosed as malignant thyroid tumors in our laboratory between 2003-2005 were selected and examined retrospectively. Immunohistochemistry was performed

for HBME-1 , cytokeratin 19, and galectin 3. RESULTS: 51 malignant thyroid tumors were examined. The diagnoses were as follows: 38 papillary carcinoma, 7 follicular carcinoma, 3 medullary carcinoma, and 3 poorly differentiated thyroid carcinoma. 33 cases of papillary carcinomas stained for HBME-1 diffusely, and 5 of them focally. Two of the follicular carcinomas expressed HBME-1 diffusely, 3 of them focally, and 2 of the cases did not stain. Two of the medullary carcinomas were stained focally, and one of them diffusely. One of the poorly differentiated thyroid carcinomas stained focally, one stained diffusely, and one case did not stain. 33 of the papillary carcinomas stained for cytokeratin 19 diffusely, and 5 of them stained focally. Three of the follicular carcinomas stained diffusely and 4 of them stained focally. Two of the medullary carcinomas stained diffusely and one of them stained focally. One of the poorly differentiated thyroid carcinomas stained diffusely, two of them stained focally. 29 of the papillary carcinomas stained for galectin 3 diffusely and 9 of them stained focally. Two of the follicular carcinomas stained diffusely and 5 of them stained focally. All three of the medullary carcinomas stained diffusely, one poorly differentiated thyroid carcinomas stained diffusely, and two of them stained focally. For staining of HBME-1, 31 cases of papillary carcinomas, showed membranous pattern, 6 cases showed both membranous and cytoplasmic pattern, and one case showed cytoplasmic pattern. CHI square test was performed statistically in the study. A considerable difference was observed in distribution and pattern of expression of HBME-1 in papillary carcinoma. CONCLUSION: There are immunohistochemically different markers supporting the diagnosis of thyroid cancers. Among them are HBME-1, cytokeratin 19, and galectin 3. Expressions of HBME-1, cytokeratin 19, galectin 3 and membranous staining pattern for HBME-1 were found significant for papillary carcinomas in this study.

PP2-238

SOLITARY FIBROUS TUMOR OF THE THYROID GLAND

Aysim Ozagari[1], Canan Uzel[2], Huseyin Bircan[2], Kamil R. Peker[3], M. Kemal Sarman[3], Fevziye Kabukcuoglu[1]
[1] Sisli Etfal Education and Research Hospital, Department of Pathology, Istanbul, Turkey
[2] VKV American Hospital, Department of General Surgery, Istanbul, Turkey
[3] Istanbul Pathology Group, Istanbul, Turkey

Introduction: Solitary fibrous tumor is an uncommon mesenchymal neoplasm that arises primarily from the pleura, but recognized also in other tissues. The clinical behaviour is usually benign, but the existence of aggressive cases has been documented both in the pleura and in extrapleural sites. Solitary fibrous tumors of the thyroid gland are rare; only nineteen cases have been reported in the literature. Case Report: A 65-year-old woman was admitted to hospital with a slow-growing thyroid mass. Ultrasonography revealed a solid intrathyroid nodule in the left lobe. The tumor was evaluated as a spindle cell neoplasm at intraoperative consultation. Bilateral total thyroidectomy was performed. Grossly, the tumor measured 6 cm in diameter and occupied almost the whole left thyroid lobe. The cut surface was white-tan and had a whorled appearance with occasional small cystic areas. Microscopically the tumor was well-circumscribed and was composed of a patternless proliferation of bland spindle cells, collagen bundles and entrapped thyroid follicles. Immunohistochemically tumor cells were positive for vimentin, bcl-2 and CD34. Discussion: Although solitary fibrous tumor was first described as a primary spindle cell tumor of the pleura, it may occur in a wide variety of sites, including the orbit, mediastinum, abdomen, retroperitoneum, extremities, and in almost any organ. With regard to the thyroid gland, 19 cases have been reported to date. Intrathyroid solitary fibrous tumor should be differentiated from similar cases located in the perithyroid soft tissue. The differential diagnosis of solitary fibrous tumor includes other benign and malignant mesenchymal tumors of the thyroid, spindle cell follicular adenoma, Riedel's thyroiditis, the spindle cell, and paucicellular variants of anaplastic carcinoma, and papillary thyroid carcinoma with nodular fasciitis-like stroma. Recurrence and metastasis has not been described in any reported cases, but the clinical behaviour of solitary fibrous tumor is unpredictable and requires long-term follow-up.

PP2-239

SCLEROSING PARAGANGLIOMA OF THE CAROTID BODY WITH CERVICAL LYMPH NODE METASTASIS: A CASE REPORT AND REVIEW OF THE LITERATURE

Ozlem Yapicier[1], Saime Sezgin Ramadan[1], Tayfun Gurbuz[2], Kutlay Karaman[3]
[1] Department of Pathology, Anadolu Health Care Center, Kocaeli, Turkey
[2] Department of Cardiovascular Surgery, Anadolu Health Care Center, Kocaeli, Turkey
[3] Department of Radiology, Anadolu Health Care Center, Kocaeli, Turkey

Background: Carotid body paragangliomas have an unpredictable history with no correlation between histology and clinical behavior. Recently a distinctive variant of paraganglioma characterized by extensive collagen deposition resulting in a pattern of growth that resembled an invasive malignant neoplasm named sclerosing paraganglioma is described. Case: We present a 28-year-old woman presented with dysphagia with right sided neck mass Magnetic resonance imaging (MRI) showed 7x4x3cm bilobulated large tumour originating from right carotid bifurcation. Preoperative partial selective embolisation was done to provide an easy surgical excision. The patient underwent frozen section and surgical excision of this neoplasm. Carotid resection with reversed interposition saphenous vein graft was performed without complication. Histopathology showed a tumor with extensive collagenization seperating nests of tumor cells with a pseudoinfiltrative appereance. Tumor cells were large and round to polygonal, with moderately pleomorphic nuclei and abundant eosinophylic granular cytoplasm. Mitotic activity was low. Necrosis was not present. There was lymph node involvement. Tumor showed perineural infiltration. The tumor cells were positive for chromogranin A, synaptophysin and vimentin and negative for cytokeratin, TTF-1, CD34 or SMA. Sustentacular cells at the periphery of the tumor nests were positive for S-100 protein. Conclusion: Since the infiltrative nature of this lesion may lead to a misdiagnosis of medullary thyroid carcinoma, sclerosing paraganglioma should be included in the differential diagnosis of sclerosing lesions of the head and neck region. Appropriate immunohistochemical stains are useful for establishing the correct diagnosis.This is the first report of a metastatic sclerosing paraganglioma. This case demonstrates that sclerosing paraganglioma can be significantly symptomatic and might have a malignant potential requiring aggressive initial local treatment to include lymph node sampling and complete tumor resection. The patient is free of disease 12 months after its initial presentation.

PP2-240

C-KIT EXPRESSION IN GASTROENTEROPANCREATIC ENDOCRINE TUMORS

Yersu Kapran, Dilek Demir, Mine G. Gulluoglu, Ferhunde Dizdaroglu
Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey

We aim to investigate the c-kit immunoexpression profile of gastroenteropancreatic endocrine tumors (GEPET) and the relation between the c-kit expression and tumor localization as well as differentiation. Fifty five cases of GEPET were retreived from the archieve of the Department of Pathology, Istanbul

Faculty of Medicine, Istanbul University. Nineteen (34.5%) cases of pancreatic, 16 (29.1%) small intestinal, 8 (14.5%) gastric, 5 (9.1%) rectal, 5 (9.1%) appendiceal and two (3.7%) colonic GEPET were included in the study. The tumors were classified according to the WHO classification system as well-differentiated endocrine tumor-benign behaviour (n=15, 27.3%), well-differentiated endocrine tumor-uncertain behaviour (n=11, 20%), well-differentiated endocrine carcinoma (n=22, 40%) and poorly differentiated endocrine carcinoma (n=7, 12.7%). All tumors were immunostained for chromogranin A, synaptophysin, Ki-67 and c-Kit. The c-Kit immunoexpression was detected in 20% (n=3) of the well-differentiated endocrine tumor-benign group, 9.1% (n=1) of the well-differentiated endocrine tumor-uncertain behaviour group, 31.8% (n=7) of the well-differentiated endocrine carcinoma cases and 42.8% (n=3) of the poorly differentiated endocrine carcinoma cases. Rectal endocrine tumors showed the most frequent c-Kit immunoexpression followed by colonic and gastric endocrine tumors. Even though it was observed that the poorly differentiated tumors tend to express c-Kit more frequently, this result was not statistically significant. The c-Kit immunoexpression in GEPET ranged from 9.1-42.8% according to differentiation level and clinicopathological parameters of the tumors. In the differential diagnosis of the tumors of the gastrointestinal tract and pancreas, particularly with a poorly differentiated morphology it should be kept in mind that the GEPET may express c-Kit.

PP2-241

Ki67 EXPRESSION IN THYROID CARCINOMAS WITH LUNG METASTASIS: COMPARED WITH CLINICO-PATHOLOGICAL PARAMETERS AND FOLLOW-UP.

Mehmet Salih Deveci[1], Bulent Kurt[1], Armagan Gunal[1], Guzin Deveci[1], Altay Tolga Senturk[1], Seyfettin Ilgan[2]
[1] Pathology Department, Gulhane Military Medical Academy, School of Medicine, Turkey
[2] Nuclear Medicine Department, Gulhane Military Medical Academy, School of Medicine, Turkey

BACKGROUND: Invasion to the surrounding tissues of thyroid and vascular involvement are still most important prognostic features in metastatic thyroid carcinomas. The aim of this study is to investigate expressions of proliferation marker Ki67 and also to compare other clinico-pathological parameters. METHODS: Fourteen cases were diagnosed as thyroid carcinoma with detected lung metastasis in 1995-2001 years, some of which were consulted to our hospital (Gulhane Military Medical Academy, Pathology Department) from different laboratories. Of 14 thyroid carcinoma cases, 12 were papillary carcinoma (1 tall, 1 columnar, 1 solid, 2 classic, 3 follicular and 4 oxyphilic variant) and 2 follicular carcinoma (1 Hurthle cell and 1 with insular component). All slides were reviewed and a representative block of each tumor was selected. Immunohistochemically, Ki67 was stained using avidin-biotin peroxidase technique by autostainer (Dako labvision). Positive nuclear Ki67 expressions were quantitatively counted by KS 400 software (computer assisted analysis system). Staining in invasive thyroid carcinomas without metastasis was also evaluated as control. The clinico-pathological parameters such as age (≤45 vs. >45 year), gender, tumor size (<3 cm vs. ≥ 3cm, invasion to surrounding tissues of thyroid, vascular involvement, presence of solid areas, differentiation (well or poor/ agressive variants) were evaluated compared with Ki67 expression (<5% vs. ≥ 5%). RESULTS: Invasive thyroid carcinomas without metastasis showed generally 1 or 2% Ki67 expression. Of 14 thyroid carcinoma with lung metastasis, 7 (50%) showed ≥5 % Ki67 expression (mean 10%), some of which were inside the proliferative cores. Others were around 1-2% similar to invasive thyroid carcinomas without metastasis. Vascular invasion was detected in 11 (78%) cases. Nine cases (64%) were more than 45 years old. Solid area was noted in 2 cases. There was invasion to surrounding tissues of thyroid in 7 cases (50%). CONCLUSIONS: In this series vascular involvement seems to be closely associated with lung metastasis in thyroid carcinoma. Ki 67 expressions may probably be potential prognostic value, especially because of the presence of proliferative cores with higher expression.

PP2-242

CONTRIBUTION TO THE DIAGNOSTIC ACCURACY OF HBME-1, GALECTIN 3 AND CYTOKERATIN 19 IN ENCAPSULATED (NONINVASIVE) FOLLICULAR VARIANT PAPILLARY THYROID CARCINOMAS

Guzin Deveci, Mehmet Salih Deveci, Armagan Gunal, Bulent Kurt
Pathology Department, Gulhane Military Medical Academy, School of Medicine, Turkey

BACKGROUND: The diagnosis of encapsulated (noninvasive) follicular variant papillary thyroid carcinoma (eFV-PTC) may be sometimes problematic and histologically mistaken by nonneoplastic (cellular thyroid nodules) and benign or malignant neoplasm (follicular adenomas and minimal invasive follicular carcinomas) thyroid lesions. The aim of this study is to investigate the contribution to eFVPTC diagnosis of immunohistochemical markers that are commonly used in papillary thyroid carcinoma. METHODS: Twenty-two cases were diagnosed as eFV-PTC in 2004-2007 years, some of which were consulted to our hospital (Gulhane Military Medical Academy, Pathology Department) from different laboratories. All slides were reviewed and a representative block of each tumor was selected. Immunohistochemically, HBME-1, Galectin-3 and Cytokeratin (CK) 19 markers were stained using avidin-biotin peroxidase technique by autostainer (Dako labvision). Intensity and distribution of expression in positive immunohistochemical staining was semiquantitatively categorized as mild, moderate and marked (intensity vs. distribution: +1, <25%; +2, 25-50, +3, >50, respectively). Staining in normal thyroid tissue surrounding tumor was also evaluated as control. RESULTS: Normal thyroid tissues showed generally focal-weak positivity (+1) with HBME-1, Galectin 3 and CK 19. However, these markers in eFV-PTC were moderate (+2) or marked (+3) intense staining in more than half of the cases. Of the 22 eFV-PTC cases, 16 were positive with Galectin-3 (72%), 21 (95%) HBME-1 and 22 (100%) CK 19. Combination of HBME-1(+)-CK19 (+) was positive in 21 (21/22 95%), Galectin-3 (+)-HBME-1 (+) or Galectin-3 (+)-CK19 (+) in 16 (16/22 72%) cases. CONCLUSIONS: The combination of HBME-1 and CK 19 positivity is highly sensitive in eFV-PTC diagnosis. However, Galectin-3 is not helpful marker in supporting the diagnosis in this series.

PP2-243
PREVALENCE OF HEPATITIS G EXPOSURE IN PATIENTS ON CHRONIC DIALYSIS

Ali Eslamifar[1], Arezoo Aghakhani[1], Rasool Hamkar[2], Amitis Ramezani[1], Farrokhlagha Ahmadi[2], Latif Gachkar[3], Ali Khameneh[1]
[1] Pasteur Institute of Iran, Iran
[2] Tehran University of Medical Sciences, Iran
[3] Shahid Beheshti University of Medical Sciences, Iran

Background: Hepatitis G virus (HGV) is a blood-borne virus. The predominant route of its transmission is parenteral. The aim of this study was to assess the prevalence of HGV exposure in hemodialysis (HD) and continuous ambulatory peritoneal dialysis (CAPD) patients. Methods: This study was performed in a main dialysis centre in Iran. 77 Patients on HD and 13 patients on CAPD were enrolled in study. HGV exposure was detected serologically by presence of anti HGV envelope protein E2 (anti-E2) by an ELISA assay. Patients were also screened for hepatitis B surface antigen (HBsAg), hepatitis B surface antibody (anti-HBs), and hepatitis C antibody (anti-HCV).In anti-E2 positive patients; HGV RNA was detected by RT-PCR using primers derived from the NS5A region of the viral genome. Results: Anti-E2 was positive in 3.89% of HD and none of the CAPD patients. Mean age of anti-E2 positive patients was 53.3+/-26.5 years. In none of them, HGV RNA was detected. 66.66% of them had received blood transfusion. The duration of dialysis in them was 68+/-64 months. Co-infection with HCV or HBV was not significant in these patients. Conclusion: HGV exposure rate was not high in dialysis patients in our study and was not different according to the dialysis modality. The appearance of anti-E2 was accompanied with clearance of serum HGV-RNA. No relationship was noted between HGV exposure and age, sex, history of blood transfusion, time on dialysis, HCV or HBV markers.

PP2-244
ULTRASTRUCTURAL FINDINGS COMPARED WITH CLINICAL AND LABORATORY PARAMETERS IN CASE OF ACUTE HEPATITIS C VIRAL INFECTION

Valerie Groma[1], Valda Zalcmane[1], Aija Leidere-Reine[2]
[1] Laboratory of Electron Microscopy, Institute of Anatomy and Anthropology, Riga Stradins University, Latvia
[2] Riga Stradins University, Riga, Latvia

Background. A complex evaluation of clinical, laboratory and morphological findings provides an adequate approach useful for a positive hepatitis C viral (HCV) infection outcome, in general, and selection of therapy course, in particular. A spectrum of liver tissue injury, and its correlation with clinical and laboratory data in acute HCV is not completely understood. The present study aimed to investigate dynamics of clinical, laboratory and ultrastructural parameters from an acute onset of HCV infection and along a 6 months long patient's follow-up period providing a basis for better understanding of applications of antiviral therapy. Methods. Liver biopsies were obtained from 6 patients with an acute HCV infection aged from 22 to 41 year. All patients matched this study had consistent serum HCV RNA positivity. Ultrastructural data were assessed by transmission electron microscopy of liver biopsies. Five patients in the study group received an interferon therapy with interferons including pegylated ones, namely, 4 of them received realdiron, 1 – pegasys. Results. Four of the treated patients revealed rather stable laboratory and virological recovery along the duration of follow-up but 1 patient revealed sustained HCV RNA positivity without cytolysis. Outcome of the disease during the observation period varied and showed the following peculiarities: stable recovery in 3 treated cases, chronization in 1 case. There was an early laboratory and virological remission observed in one treated patient followed at the end of follow-up by HCV RNA positivity without cytolysis, and positive cytolysis dynamics revealing a HCV RNS negativity already after 3 months period in 1 untreated patient. Extensive apoptosis of intrasinusoidal lymphocytes and activation of Kupffer cells were constantly present ultrastructural findings. The hepatocyte ultrastructure showed a varying amount of mitochondria and lipid inclusions, changes of the nuclear chromatin and nucleoli. Changes of the cellular shape and cytoplasmic density, extensive blebbing suggested a presence of apoptotic cell death. A case with chronization course revealed a local perisinusoidal and pericellular accumulation of collagen microfibrils indicative of fibrosis. Conclusion. The present study showed that application of electron microscopy providing a better understanding of events along the liver cell death and early chronization of the process studied is a useful tool in selection of a strategy of antiviral therapy.

PP2-245
EFFECT OF ADAMANTYLAMIDE DIPEPTIDE AS ADJUVANT THERAPY TO PRAZIQUANTEL IN MICE INFECTED WITH DIFFERENT S. MANSONI ISOLATES

Sanaa Botros[1], Madiha Mahmoud[1], Olfat Hammam[1], Faten Salah[1], Zdenek Zidek[2], Karel Masek[2]
[1] Theodor Bilharz Research Institute,Warrak El-Hadar, Imbaba, Giza, Egypt
[2] Institute of Pharmacology, Academy of Sciences of the Czech Republic

This work investigated the possible use of AdDP as adjuvant therapy to praziquantel (PZQ) in miceinfected with PZQ-insusceptible Schistosoma mansoni isolate in a trial to increase the susceptibility of this isolate to the drug. Two batches of C57 BL/6 mice were infected with PZQ-susceptible and insusceptible S. mansoni isolates, and each batch was divided into five groups. Seven weeks postinfection, the experimental group received AdDP (5 mg/kg) in addition to PZQ in reduced dose (3X100/kg). Three of the remaining four groups were treated controls; they received AdDP, PZQ in reduced dose and in full dose (2X500/ mg/kg), and the fourth group was infected untreated. In mice infected with PZQ-susceptible or -insusceptible S. mansoni isolate, praziquantel alone, and in addition to AdDP, reduced worm and egg loads and increased percentage dead eggs. Also, they improved the histopathological changes (reduction in granuloma diameter, percentage fibrotic area with increased percentage degenerated eggs). Inducible nitric oxide synthase (iNOS), nitric oxide (NO) in culture of peritoneal macrophages, and number of CD68-positive cells were decreased with improved alanine amino transaminase. In mice receiving combined therapy AdDP-PZQ, the antischistosomal efficacy and the reductions in the inflammatory granulomatous reactions, NO in cultured peritoneal macrophages, percentage fibrotic areas recorded, were comparable to in mice receiving full dose of PZQ, with significantly higher reduction in CD68 cells denoting enhanced antischistosomal efficacy and healing of the inflammatory reactions in the liver.

UNDIFFERENTIATED EMBRYONAL SARCOMA OF THE LIVER: A CASE REPORT

Caner Ozbey[1], Guzide Ayse Gokhan[1], Gulsum Ozlem Elpek[1], Mustafa Melikoglu[2]
[1] Akdeniz University School of Medicine Department of Pathology, Antalya, Turkey
[2] Akdeniz University School of Medicine Department of Pediatric Surgery, Antalya, Turkey

Background: Undifferentiated embryonal sarcoma of the liver (UESL), a primitive malignant neoplasm, is a rare pediatric malignancy. Case presentation: A 9-year-old girl presented with epigastric mass and severe abdominal pain. Abdominal computed tomography scan revealed a huge tumor in the left hepatic lobe which was hyperechogenic in doppler sonography. Subsequently, the patient underwent a left hepatic lobectomy. The specimen

showed a mass measuring 13X12X8 cm in the left lobe of the liver. The tumor was well circumscribed but incompletely pseudocapsulated. The cut surface revealed a gray-white soft mass with multilocular appearance together with extensive areas of hemorrhage, necrosis, and degenerative foci including a cystic space filled with gelatinous material. On microscopy the tumor showed proliferation of atypical spindle cells admixed with polygonal or round cells and multinucleated giant cells which were loosely arranged in a myxomatous background. The multinucleated giant cells often contained eosinophilic hyaline globules in the cytoplasm. In histochemical staining these globules were PAS-positive and diastase-resistant. In the tumor periphery some ducts were lined by a single layer of cuboidal cells resembling normal bile ducts showing strong reactivity with CK19. Immunohistochemical staining with vimentin, desmin, smooth muscle actin , S-100, AFP, alpha-1-antitrypsin (AAT), alpha-1-antichymotrypsin, CD68, CD31 and CK19 revealed that tumor cells express vimentin, CD68, AAT, alpha-1-antichymotrypsin. The patient remains well with no evidence of local recurrence or metastasis 10 months after the operation. Conclusion: Our case support that UESL might show a divergent differentiation toward histiocytic, fibroblastic, myoblastic, myofibroblastic, or lipoblastic lines. Moreover, the case presented here emphasizes that although there is no specific immunohistochemical marker for UESL, vimentin and histiocytic markers such as CD68, AAT is are useful markers in the diagnosis.

PP2-247

USEFUL IMMUNOHISTOCHEMICAL MARKERS IN DIFFERENTIATING HEPATOCELLULAR CARCINOMA AND METASTATIC ADENOCARCINOMA

Ayca Uygur, Gulsah Kaygusuz, Saba Kiremitci, Cemil Ekinci
Ankara University, School of Medicine, Department of Pathology, Ankara, Turkey

Background: Differentiating hepatocellular carcinoma (HCC) from metastatic adenocarcinoma (MA) in the liver can be difficult, especially if the tumor shows pseudoglands or poorly differantiated morphology in a patient with unknown primary tumor. For such cases, an appropriate immunohistochemical panel should be used to make the correct diagnosis. We aimed to examine the value of immunohistochemical panel composing Hepatosit Ag, pCEA, CD10, Villin, CD34, TTF-1, MOC-31, CK7 and CK20 in the differential diagnosis. Method: 68 HCC and 107 MA cases diagnosed at Ankara University, Department of Pathology between 1999 and 2006 were studied. 6 tissue microarray blocks (TMA) were built using manual microarrayer (Beecher's Instruments) and stained with the markers mentioned above. The canalicular staining was evaluated for pCEA, CD10 and Villin whereas, the presence of diffusely stained endothelial cells around the tumor aggregates were noted for CD34. Cytoplasmic and or membranous staining was assessed for other markers. Results: : Of the HCC cases 95,6% with Hepatosit Ag, 50,7% with CD10, 46,2% with pCEA, 42,6% with CD34, 26,5% with TTF-1, 20,6% with Villin, 19,1% with MOC-31 showed positivity. Specific canalicular staining pattern with pCEA, CD10 and Villin was observed in most of HCC cases. Of the MA cases 99,1% with MOC-31, 86,8% with pCEA, 81% with Villin, 36,9% with CD10, 7,5% with TTF-1, 1,9% with Hepatosit Ag showed positivity. With pCEA, CD10 and Villin cytoplasmic or membranous staining was observed. MA cases had no specific staining patterns for pCEA, CD10, Villin and CD34 observed in HCC cases. Both CK7 and CK20 were negative in 61,8% of HCC cases whereas, MA cases demonstrated different staining profile according to the primary tumor. Conclusion: With the staining of Hepatosit Ag in HCC, MOC-31 in MA and pCEA, CD10 and CD34 in both groups, we suggest that these markers should be included to the panel for the accurate diagnosis. CK7 and CK20 negativity would provide an additional information for the diagnosis of HCC.

PP2-248

HISTOLOGICAL CHARACTERISTICS OF CHRONIC HEPATITIS C ACTIVITY AND ITS IMPACT ON LIVER FIBROSIS DEVELOPMENT

Olga Zinchenko, Olga Reshetnikova, Leonid Pinskiy, Olga Teleshova, Inna Goryanikova
Lugansk State Medical University, Ukraine

The number of patients with hepatitis C (CHC) is on the increase worldwide. Progression of the liver fibrosis as the main complication of the CHC may result in disability and death of the patients. The aim of the present research was to develop the morphological methods of defining the CHC histological activity and estimation of its impact on liver fibrosis progress. Forty-four CHC patients examined and diagnosed based on the complex of clinical-biochemical indices and excluding the viral hepatitis of the different etiology. Histological slides examined morphologically. There has been studied the impact of the histological activity and density of the lymphocyte and monocytes infiltration in various zones of liver lobes for the display of fibrosis in patients with CHC. Results showed that the most significant impact on the fibrosis progress in patients with CHC had a display of the porto-periportal necrosis and inflammatory infiltration of the portal tracts. There have been developed significant complex morphological criteria of CHC activity, which contain the average number of lymphocyte and monocytes infiltration cells of 1000 sq mkm of biopsy and average area of an infiltration cell in the periportal zone of the liver lobes in patients with CHC.

PP2-249

EXPRESSION P53, P21, P27, P16 AND KI67 IN HEPATOCELLULAR CARCINOMAS

Vassiliki Zolota, Anna Liava, Vassiliki Tzelepi, Niki Pagoni, Theodore Petsas, Crisoula Karatza, Chrisoula Scopa, Athanassios Tsamandas University of Patras, Greece

Background: Cell cycle control is a crucial event in the regulation of human normal tissues functions, and abnormalities of regulatory cell cycle genes are considered to contribute to the development of several human malignancies. This study investigates the expression of cell cycle proteins p53, p21, p27 and p16, and the degree of cell proliferation (Ki67 expression) in HCC and their correlation with classic pathologic tumor features and patients survival. Methods: Formalin-fixed, paraffin-embedded 4μm sections obtained from 75 HCC (hepatectomy and FNA materials), were subjected to immunohistochemistry (streptavidin-biotin peroxidase) using monoclonal and polyclonal antibodies for p53, p21, p27, p16, and Ki67. Results were expressed as % of positive cells. Mean follow up time was 29.32 months (range 1-86 months). Results: Expression of p53, p16, p21 and p27 was recorded in: 45/75(60%), 52/75(69%), 42/75(56%), and 58/75(77%) cases, respectively. The mean index for Ki67 was 22.35±±9.15. p53 and p21 were more frequently expressed in advanced stage tumors (p=0.011 and 0.0017, respectively). Statistical analysis revealed: I) direct correlation between lower disease-free survival and a) vascular invasion presence (p=0.00062), b) advanced tumor stage (p=0.00071) and c) proliferating index (Ki67+ cells) (p=0.0069). II) correlation of p53 expression with lower disease-free survival only in p21(+) tumors (p=0.013). III) direct correlations between a) p21 and p27 (r=0.3266, p=0.01933), b) p21 and p53 (r = 0.58644, p = 6.1231E-6), c) p27 and p53 (r = 0.28291, p = 0.04426). Cox regression analysis revealed that independent prognostic factors were: a) vascular invasion (CI:1.167-5.408, p=0.019), b) tumor stage (CI:0.043-0.650, p=0.01) and c) proliferating index (Ki67+ cells) (CI: 1.078-44.073, p=0.039). Conclusions: This study demonstrates that in cases of HCC, vascular invasion, tumor stage and proliferation index (Ki67 expression) are independent predictors of the outcome of the patients. p53 was associated with poor prognosis only in tumors overexpressing p21. This implies that high levels of p21 in tumor cells associated with aberrant p53 protein expression may result in tumor recurrence.

PP2-250
ANGIOGENESIS AND VASCULAR ENDOTHELIAL GROWTH FACTOR EXPRESSION IN HEPATOCELLULAR CARCINOMA

Vassiliki Zolota, Vassiliki Tzelepi, Anna Liava, Niki Pagoni, Theodore Petsas, Crisoula Karatza, Chrisoula Scopa, Athanassios Tsamandas University of Patras, Greece

Background: Evaluation of angiogenesis in hepatocellular carcinoma (HCC) may be crucial in the effort to develop and perform an effective antiangiogenic therapy for this tumor. This study investigates the presence of angiogenesis and vascular endothelial growth factor (VEGF) expression in HCC and correlates them with tumor pathology and patients' survival. Methods: The study included 75 HCC cases (hepatectomy and FNA materials) obtained from equal number of patients. Liver tissues were evaluated for a) degree of angiogenesis (DOA) (immunostain with anti-CD34 antibody [Biogenex, Ca, USA]), b) VEGF protein presence (immunostin with anti-VEGF antibody [DBS Pleasanton, CA, USA]). CD34 staining pattern was reported as: a) number of single complete vessels counted in 10HPF, b) presence of branching, sinusoid-like channels scored as follows:0, no sinusoid-like pattern; 1+ weakly stained discontinuous and focal vessels; 2+ weakly stained diffuse branching vessels/focal well-formed vessels; 3+ diffuse well-formed sinusoid-like vessels. Results were correlated with angiographic data, tumor pathologic features and patients' survival. Mean follow up time was 29.32 months (range 1-86 months). Results: The DOA (either the number of complete vessels or the presence of sinusoid-like channels) in HCCs was correlated with tumor size: HCCs with diameter < 2 cm) showed less DOA, compared to HCCs with a diameter >2 cm ($p=0.011$ and $p=0.0037$). In addition HCC showed higher DOA compared to non-neoplastic adjacent liver. Tumor vascularity on angiography did not correlate with DOA. VEGF protein expression was higher in solid areas of the tumors compared to acinar/pseudoglandular areas ($p=0.0012$). Cirrhotic non-neoplastic livers showed higher DOA and VEGF expression compared to non-cirrhotic livers ($p=0.0017$ and $p=0.026$, respectively). The DOA in HCC was correlated with lower disease-free survival ($r=-0.68$, $p=0.0027$ $r=-0.59$, $p=0.0034$). Cox regression analysis revealed that DOA was independent prognostic factor (CI:1.203-5.413, $p=0.015$). Conclusions: This study shows that angiogenesis in HCC may contribute in the dismal prognosis of this tumor. VEGF may be associated with the angiogenic process of the cirrhotic liver, but not with angiogenesis of HCC.

PP2-251
SOLID-PSEUDOPAPILLARY TUMOR OF THE PANCREAS

Vera Ferlan-Marolt[1], Lojze Pleskovic[2], Borut Stabuc[3], Bostjan Luzar[1]
[1] Institute of Pathology, Medical Faculty University of Ljubljana, Ljubljana, Slovenia
[2] Department of Abdominal Surgery, University Medical Centre, Ljubljana, Slovenia
[3] Department of Gastroenterology, University Medical Centre, Ljubljana, Slovenia

Background: Solid-pseudopapillary tumor (SPT) of the pancreas is a clinicopathologically distinctive, yet histogenetically mysterious pancreatic neoplasm that could be misdiagnosed as adenocarcinoma, acinar cell carcinoma end endocrine tumor. A greater awareness of this unique, low-grade malignant entity gives reasons to precise histopathological diagnosis that should be associated with surgical resection. Methods: Among retrospectively reviewed pancreatic tumors diagnosed in the last 10 years 3 cases of SCT were evaluated. They comprised 1 male and 2 female patients in age 49-72 years. Clinicopathological data obtained from medical records were completed with histological examination including immunostaining. Results: Due to indolent clinical course and unremarkable laboratory investigations the tumours were discovered only by imaging procedures. The patients underwent surgical resection. Huge and encapsulated cystic tumors found in the head and tail of the pancreas were completely removed and histopathologically evaluated. The neoplastic growth patterns were composed of solid and pseudopapillary areas. The cells expressed distinct immunostaining for vimentin, NSE, CD10, CD 56; keratin, alpha1antitrypsin and glucagon in 2 cases; and fail to stain for chromogranin, synaptophysin and Ckit. After pancreatic resection with complete removal of the growths the patients recovered successfully. In one case, however, local recurrence of the tumor developed after 7 years. Partial resection was performed. Postoperative complication was acute pancreatitis that was treated conservatively. During the next 2 years the patient felt healthy and began with normal physical activity. Conclusion: SCT should be regarded as a slow growing tumor with low malignant potential and favourable prognosis after aggressive treatment such as complete growth resection. Due to infiltrative growth potential local recurrence may break out. Nevertheless, even in the presence of metastases long- term survival is expected.

PP2-252
HEPATOBILIARY PAPILLOMATOSIS WITH INTRADUCTAL PAPILLARY ADENOCARCINOMA

Vera Ferlan-Marolt[1], Blaz Trotovsek[2], Bostjan Luzar[1]
[1] Institute of Pathology, Medical Faculty University of Ljubljana, Ljubljana, Slovenia
[2] Department of Abdominal Surgery, University Medical Centre, Ljubljana, Slovenia

Background: Biliary papillomatosis (BP) is characterised by intraductal papillary proliferation of biliary epithelial cells that could reveal various degrees of dysplasia and high risk of malignant transformation. Any part of the biliary tree can be affected including intra and extrahepatic bile ducts, gall-bladder and ampullary region. The course of the disease depends upon recurrent cholangitis followed with biliary cirrhosis or the development of biliary carcinoma. Case presentation: A 52-year-old apparently healthy man was referred to the hospital to regular health control including liver biochemistry. Slightly abnormal tests of liver functions led to abdominal ultrasonography and computed tomography. In the left liver lobe a large, space-occupying lesion was revealed, accompanied with dilatation of the intrahepatic ducts and the upper common bile duct. According to suspicion on a neoplastic growth in the liver left hemihepatectomy was performed together with cholecystectomy and resection of the hepatocholedochal duct. In the resected liver a well demarcated multilocular tumor was found, measuring 5,5 x 6 x 4 cm. It demonstrated soft and friable protrusions to the major bile duct, so as to the central cavities appearing to be dilated lumina of the intrahepatic ducts. Microscopical observation revealed multifocal papillo-villous intraductal projections of biliary epithelium. In some areas these cells represented malignant characteristics, in the others the features of benign biliary papillomatosis were evident. Besides, minimal expansile invasion was detected in the fibrous border of the growth. The histopathological diagnosis pointed out the presence of biliary carcinoma with the background of the benign lesion expressing various degrees of dysplasia, as well. After an uneventful postoperative course the patient has been disease free with serologically negative tumor marker CA 19-9 for 20 months. Conclusion: BP is a rare borderline malignant lesion involving the biliary tree. Malignant transformation may start with multicentric foci of epithelial cells with altered phenotypes.The presented case of coexisting BP and intraductal papillary carcinoma might prove the concept of gradual steps in the development of the same neoplastic entity.

PP2-253

HEPATOCELLULAR CARCINOMAS WITH MALLORY BODIES AND/OR INTRACELLULAR HYALINE BODIES: CORRELATION WITH STEATOHEPATITIC FEATURES

Aigelsreiter Ariane[1], Halasz Judit[2], Lackner Carolin[1], Sostaric Julia[1], Reihs Robert[1], Stark Konrad[1], Kufferath Iris[1], Pichler Martin[1], Stumptner Cornelia[1], Zatloukal Kurt[1], Denk Helmut[1]
[1] Institute of Pathology, Medical University Graz, Austria
[2] 2nd Department of Pathology, Semmelweis University Budapest, Hungary

Background: Mallory bodies (MBs) and intracellular hyaline bodies (IHBs) present in hepatocellular carcinoma (HCC) cells are the result of overexpression and accumulation of the stress protein sequestosome1/p62 (p62). MBs contain p62, keratins and ubiquitin as major components, whereas IHBs are characterized by their p62 and ubiquitin content. Classical MBs arise if abnormal keratins are present in addition to p62, but if p62 is present alone IHBs are formed by aggregation. Our aim was to evaluate and correlate the association of steatohepatitic features in HCCs with the presence of IHBs and MBs. Method: 126 HCCs (surgical specimens) were selected from the archives of the Department of Pathology, Medical University of Graz. All available sections were evaluated for steatohepatitic features and inclusion bodies by light microscopy. In 92 selected cases immunohistochemistry for the presence of keratin 8/18, p62 and ubiquitin was performed, using a tissue microarray, and correlated with steatohepatitic features. Statistical analysis was performed by the Fisher test. Results: Of all HCCs (n=126) 17 cases (13.5%) contained both MBs and IHBs, whereas in 27 cases only MBs (21.4%) and in 14 cases only IHBs (11.1%) were found. 68 cases (54.0%) expressed no inclusion bodies. HCCs with MBs as well as HCCs with MBs and IHBs showed significantly ($p<0.001$) more frequent infiltration by neutrophils compared to HCCs with IHBs only and HCCs without inclusion bodies. In addition, HCCs with any type of inclusion showed significantly ($p<0.001$) more cellular ballooning compared to the HCCs without inclusion bodies. Moreover, HCCs with inclusion bodies showed significantly more steatosis ($p<0.05$) versus HCCs without inclusion bodies. Conclusion: HCCs with MBs as well as HCCs with MBs and IHBs are associated with neutrophilic granulocyte inflammation, whereas HCCs with IHBs are characterized by small tumor cells with dense cytoplasm without significant inflammation. Since oxidative stress is a decisive factor in the development of steatohepatitis and since p62 as well as abnormal proteins, including keratins, are preferentially induced by oxidative stress it is reasonable to assume that oxidative stress is a major player in HCCs displaying steatohepatitic features. The eventual prognostic significance remains to be elucidated.

PP2-254

THE SIGNIFICANCE OF THE FOCAL HEMOSIDEROSIS IN CHRONIC HEPATITIS

Maria Sultana Mihailovici, Mihai Danciu, Catalina Mihai, Razvan Constantinescu, Carol Stanciu
University Of Medicine and Pharmacy "Gr. T. Popa" Iasi, Romania

Background: In the past 20 years, many studies showed a correlation between the abnormal iron parameters and the chronic viral hepatitis (CVH). More recently, Di Bisceglie et al (1992) demonstrated that 35-40% of patients with CVH had had high levels of serical iron, but with normal concentration of iron in the liver. Other studies (van Thiel et al 1994, Olynyk et al 1995, Piperno et al 1996) remarked that CVH patients with a high iron concentration in liver were non-responder after Interpheron alfa therapy. Aim: Histological evaluation of hemosiderin presence and distribution using Perls' reaction on liver needle biopsy from patients with CVH and its' correlation with the response to antiviral therapy. Material and methods: Biopsies were routinely processed using paraffin embedding and HE, van Gieson staining and Perls' reaction. The CVH diagnosis relayed upon the evaluation of the necro-inflammatory degree (Ishak et al, 1994) and of the fibrotic stage (METAVIR system, 1994). Semi-quantitative evaluation of hemosiderin in Kupffer cells and/or in hepatocytes was set as mild, moderate or high. Results: From 634 patients with CVH, Perls' reaction was positive in 157 patients (24.76%). In the majority of these cases (72.61%) the hemosiderin load was mild, affecting both hepatocytes and Kupffer cells in the periportal zones of the lobules. The hemosiderin presence and intensity was correlated with the viral type (HBV and mixt polyviral rather than HCV), with the hepatitis degree and stage, but not also with the antiviral therapy. Conclusion: These preliminary data recommend Perls' reaction as a routine practice, to prove the hemosiderin accumulation. We noticed that hemosiderin accumulation was significant in chronic B viral hepatitis with high necro-inflammatory degree.

PP2-255

MATRIX METALLOPROTEINASE EXPRESSION IN NONTUMORAL PANCREAS, PANCREATIC INTRAEPITHELIAL NEOPLASIA AND DUCTAL PANCREAS CARCINOMA: ROLE IN CARCINOGENESIS AND PROGNOSIS

Hale Kirimlioglu[1], Vedat Kirimlioglu[2], Sezai Yilmaz[2]
[1] Inonu University Medical School, Pathology Department, Malatya, Turkey
[2] Inonu University Medical School, General Surgery Department, Malatya, Turkey

AIM: The aim of the study was to investigate whether the expression of a specific matrix metalloproteinase (MMP) correlated with the carcinogenesis, metastasis and prognosis of pancreatic cancer. METHODS: Seven different MMPs, MMP-2, MMP-3, MMP-7, MMP-9, MMP-10, MMP-11, MMP-14, were examined in 28 pancreatic adenocarcinoma by immunohistochemistry. The expression of the MMPs were evaluated in nontumoral pancreas tissue, pancreatic intraepithelial neoplasia (PanIN) and in the areas of the pancreas carcinoma tissue undergone to Whipple procedure. RESULTS: There was expression by immunohistochemistry for MMPs 7,10,11 and 14 in all of the pancreatic cancers. But MMP-2, MMP-9 and MMP-3 expression were detected in only 29% (8/28), 86% (24/28), 57% (16/28), of the pancreas carcinomas respectively. In nontumoral pancreas tissue there were differences in the expression of the MMPs in the different components of the pancreas. Endocrine islets were stained strong with MMP-9, slight with MMP-3, MMP-10, MMP-11 and MMP-14 but not with MMP-2 and MMP-7. There was not any expression of MMP-2, MMP-9, MMP-10 and MMP-14 in the acinar cells. The pancreas ducts were stained with all of the MMPs but MMP-2 stained ducts only in the 50% (14/28) of the cases. The only MMP which is not expressed in the PanIN areas was MMP-2. In the PanIN areas the MMP staining intensities were higher than carcinoma. If there was a mucinous differantiation in an adenocarcinoma, MMP expression was decreased. In three of the cases extracellular mucin secretion was present, in those cases although the epithelium did not expresse MMP, secret was positively stained. CONCLUSION: In our study, although we could not find any prognostic significance of the MMP expression as in the previous studies supposed, we found highest overexpression in the PanIN areas and the expression of MMPs in most of the pancreatic adenocarcinomas. Those results indicate that MMP expression could have a key role in carcinogenesis and progression of the pancreas adenocarcinomas.

PP2-256
THE EXPRESSION OF MATRIX METALLOPROTEINASES IN INTRAHEPATIC CHOLANGIOCARCINOMA, HILAR (KLATSKIN TUMOR), MIDDLE AND DISTAL EXTRAHEPATIC CHOLANGIOCARCINOMA, GALL BLADDER CANCER, AMPULLARY CARCINOMA; ROLE OF MATRIXMETALLOPROTEINASES IN TUMOR PROGRESSION

Hale Kirimlioglu[1], Nese Karadag[1], Ilknur Turkmen[2], Sezai Yilmaz[3], Vedat Kirimlioglu[3]
[1] Inonu University Medical School, Pathology Department, Malatya, Turkey
[2] Elbistan State Hospital, Pathology Department, Turkey
[3] Inonu University Medical School, General Surgery Department, Malatya, Turkey

AIM: Carcinomas of the biliary tree are rare tumours of the gastrointestinal tract with a rising incidence during the recent years. Biliary neoplasms are classified into intra- and extrahepatic cholangiocarcinoma (CC) (Klatskin tumour, middle and distal extrahepatic tumours), gallbladder cancer, and ampullary carcinoma. We aimed to find out the expression profile of Matrix metalloproteinase (MMP) -2, MMP-9 and MMP-14 in the biliary neoplasms classified according to their localization. METHOD: Ten gall bladder, 8 distal bile duct carcinomas, 8 Klatskin tumors, 8 intrahepatic CCs, 10 ampullary carcinomas were included in study. The immunohistochemical expression of the MMP-2, MMP-9 and MMP-14 were detected in the nontumoral, metaplastic, dysplastic and tumoral epithelia. The tumor differentiation, angiolymphatic and perineural invasion, and the stage of the tumor were determined. RESULTS: The nontumoral epithelia of the gall bladder, intrahepatic ducts, Klatskin tumor did not express MMP-2. The expression of MMP-2 was detected in 75% (6/8) of the distal part of the biliary ducts, and 50% (5/10) of the ampullary carcinoma. The metaplastic and dysplastic epithelia were positively stained in all of the gall bladder, distal CC and ampullary tumors. In the intrahepatic CC the hepatocytes were positively stained but the infiltrative tumors were spared. Klatskin tumors also were not stained with MMP-2. The gall bladder carcinoma, distal CC and ampullary carcinomas expressed MMP-2 in 30%, 30% and 40%, of the cases respectively. MMP-9 and MMP-14 were expressed in normal, metaplastic, dysplastic epithelium and tumoral cells in all of the cases of the groups. Expression of MMPs were higher in subjects with neural invasion, but there was no correlation between MMP expression and tumor differentiaiton, angiolymphatic invasion and the stage of the tumor. CONCLUSION: When we sort the tumors of the biliary system as intrahepatic and extrahepatic CCs, MMP-2 expression was present in the extrahepatic CCs including gall bladder carcinomas. Like the intrahepatic CC, Klatskin tumors also did not express MMP-2. This can be related with its growing manner. MMP-9 and MMP-14 were present in metaplasia, dysplasia, carcinoma sequence in all of the biliary tract tumors that suggests that MMPs play an important role in carcinogenesis. The higher expresion of the MMPs with neural invasion suggests the significant role in those tumors in the invasion activity.

PP2-257
NESTIN IN NEOPLASTIC AND NORMAL ENDOCRINE PANCREAS

Lale Sokmensuer[1], Cenk Sokmensuer[2]
[1] Hacettepe University Faculty of Medicine Department of Histology and Embryology, Ankara, Turkey
[2] Hacettepe University Faculty of Medicine Department of Pathology, Ankara, Turkey

Background: Pancreatic endocrine cells are multifunctional, differentiated cells originating from the differentiation of foregut endodermal precursors. Identification and transplantation of endocrine precursor cells appear to be the ultimate solution to diabetes mellitus, which requires lifelong treatment. Knowledge about specific markers that are used in the determination of precursor cells is limited. Material Methods: In this study, the expression of nestin in well-differentiated pancreatic neuroendocrine tumorswas investigated. In addition, developmental characteristics of nestin expression in the fetal and adult pancreas were examined. The study included 17 well-differentiated neuroendocrine tumors or carcinomas (PENs) diagnosed between 1988 and 2006 in the Department of Pathology of the Faculty of Medicine of Hacettepe University. In addition to tumor cases, pancreatic tissue was obtained from the autopsies of 5 fetuses (range of gestational age: 17-32 weeks) and 5 adults (age range: 42-67 years) that were performed for reasons other than cancer in the same department. Results: Findings indicated that nestin is expressed in proliferating and metabolically active cells, such as endothelium, independent of developmental and neoplastic processes, rather than endocrine precursor cells of the pancreas. Conclusion: It was concluded that nestin cannot be used as the only marker to identify pancreatic endocrine cell precursors for transplantation.

PP2-258
IMMUNOREACTIVITY FOR HEPCIDIN IN THE LIVER OF BETA THALASSEMIA PATIENTS

Daniela Fanni[1], Luca Pilloni[1], Gabriella Mancosu[1], Cristina Manieli[1], Giancarlo Senes[1], Renzo Galanello[2], Gavino Faa[1]
[1] Dipartimento di Citomorfologia, Sezione Anatomia Patologica, University of Cagliari, Italy
[2] Dipartimento di scienze Biomediche e Biotecnologiche, University of Cagliari, Italy

BACKGROUND. Hepcidin is a 25-aminoacid peptide synthetized in the liver that acts as a systemic iron-regulatory hormone responsable for iron balance and homeostasis. In turn, hepcidin synthesis is increased by iron loading and decreased by anemia and hypoxia. Enterocytes, macrophages and kupffer cells are the most important target cells of hepcidin activity. In enterocytes it halts iron absorbtion, wihile in macrophages and kupffer cells it blocks iron relise, trapping iron within. Inhibition of the cellular iron efflux, by binding to and inducing the degradation of the iron exporter ferroportin, is considered the most important mechanism of its action. The molecular mechanisms that regulate hepcidin production are only beginning to be understood, but its dysregulation is involved in the pathogenesis of a spectrum of iron disorders. Recently, differences in hepcidin serum levels have been reported in thalassemia patients: carriers of thalassemia intermedia (TI) showed hepcidin levels remarkably lower then in patients with thalassemia major (TM). The aim of our study was to analyze the localization of hepcidin in liver of both in TM and in TI patients. METHODS. For that reason, needle liver biopsies from 5 TM and 5 TI patients were immunostained with hepcidin specific antibody (Alpha Diagnostic International, Inc). RESULTS. In all TI subjects we detected a strong immunoreactivity for hepcidin in Kupffer cells. On the contrary, in TM patients immunoreactivity for hepcidin was absent in the majority of the cases. A mild immunoreactivity was observed along the cell membrane of hepatocites in 2 out of 5 cases; no immunoreactivity for hepcidin was detected in Kupffer's cells. CONCLUSIONS. The immunohistochemical pattern for hepcidin clearly differenciates TM from TI patients and confirms at tessue level the previously reported differencies in hepcidin serum levels between TM and TI patients. Our data support the hypotesis that kupffer cells could have a major role in hemocromatosis of TI patients. Indeed the observation of the immunoreactivity for hepcidin in Kupffer cells could suggest a possible site of sequestration of hepcidin in liver macrophages, which correlates with the very low or undetecteble hepcidin serum levels in TI patients. What's more, hepcidin sequestration in Kupffer cells could give an explanation to the previously reported serum hepcidin deficiency and, eventually, excessive intestinal iron absorption.

PP2-259

THE CLINICAL SIGNIFICANCE OF PPAR-γ EXPRESSION IN PANCREATIC CARCINOMA

Constantinos Giaginis[1], Eleftheria Katsamangou[1], Adamantia Zizi-Serbetzoglou[2], Gregorios Kouraklis[3], Stamatios Theocharis[1]
[1] Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Greece
[2] Department of Pathology, Tzaneio General Hospital, Pireaus, Greece
[3] Second Department of Propedeutic Surgery, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background: Peroxisome proliferator-activated receptor-γ (PPAR-γ) is a ligand-activated nuclear transcription factor that regulates differentiation and induces cell growth arrest and apoptosis in different cancer cell types. In the present study, the expression of PPAR-γ was examined in pancreatic carcinoma histopathological specimens and was correlated with clinicopathological variables and patients' final outcome. Method: PPAR-γ expression was examined immunohistochemically on paraffin-embedded pancreatic carcinoma tissue sections obtained from 52 patients. The PPAR-γ positivity, overexpression (expression in more than the mean percentage value), intensity of staining and cellular pattern of distribution (nuclear, cytoplasmic, cytoplasmic and nuclear) were correlated with patients' gender, age and TNM stage; tumors' histological grade of differentiation, proliferative capacity (Ki-67 immunohistochemical expression); and patients' survival. Results: PPAR-γ positivity was noted in 40 out of 52 (77%) of the examined pancreatic carcinoma cases and PPAR-γ overexpression in 16 out of 40 (38%) positive cases. PPAR-γ intensity of staining was mild in 7 out of 40 (17%), moderate in 22 out of 40 (55%) and intense in 11 out of 40 (28%) positive cases. The pattern of PPAR-γ distribution in pancreatic tumor cells was nuclear in 19 out of 40 (48%), cytoplasmic in 6 out of 40 cases (15%) and cytoplasmic and nuclear in 15 out of 40 (37%) positive cases. PPAR-γ intensity of staining was statistically significantly correlated with tumors' histological grade (p=0.012). PPAR-γ overexpression and pattern of cellular distribution presented a trend of correlation with tumor size (T, p=0.078) and nodular metastases (N, p=0.060), respectively. PPAR-γ intensity of staining presented also a trend of correlation with patients' survival (p=0.061). PPAR-γ positivity, overexpression, intensity of staining and cellular pattern of distribution were not statistically significantly correlated with tumors' proliferative capacity and the other clinicopathological parameters examined. Conclusion: Our data support evidence for participation of PPAR-γ in the biological mechanisms underlying carcinogenesis in the pancreatic tissue. Further molecular and clinical studies are required to delineate and confirm the significance of this receptor in prognosis and management of pancreatic carcinoma patients.

PP2-260

EXPRESSION OF L1 AND ITS RELATED MOLECULES AS A PROGNOSTIC FACTOR IN CHOLANGIOCARCINOMA

Shengjin Li[1], Song Mei Huang[1], Song Yi Choi[1], Hyo Jeong Hong[2], Jin-Man Kim[3]
[1] Department of Pathology, Chungnam National University School of Medicine, Korea
[2] Korea Research Institute of Bioscience and Biotechnology, Korea
[3] Cancer research Institute and Department of Pathology, Chungnam National University School of Medicine, Korea

Background: Cholangiocarcinoma is a malignancy of the biliary tree, arising from any portion of intrahepatic or extrahepatic bile duct epithelium, and that is hardly control with curative surgical resection or conventional chemoradiation therapy. Consequently, better early diagnostic methods and new therapeutic managements for improving the survival of patients with cholangiocarcinoma are pressingly needed. L1, a novel target gene for Wnt/β-catenin-TCF signaling, transforms cells and increases cell motility, growth transformation, and tumorigenesis. In addition, cholangiocarcinoma accompanies reduced expression of E-cadherin and β-catenin and EGFR mutation. Design: In the present study, we investigated the immunohistochemical expression of specific anti-L1 monoclonal antibody, E-cadherin, β-catenin and EGFR in 143 patients with cholangiocarcinoma and estimated the correlations between the clinicopathologic characteristics and the expression of these antibodies. Result: High expression of L1 (≥20% carcinoma cells stained) was observed in 38.5% (55 of 143 cases) of cholangiocarcinoma, including 27% (10 of 37 cases) of Grade 1 tumors, 37.8% (28 of 74 cases) of Grade 2 tumors and 53.1% (17 of 32 cases) of Grade 3 tumors and strongly expressed in the invasive front of tumor cells of cholangiocarcinoma. Membranous expression of E-cadherin and β-catenin were reduced in cholangiocarcinoma (93%, 92.3% respectively). Nuclear β-catenin expression was noted in 17.5% (25 of 143 cases) cholangiocarcinoma. High expression of EGFR was observed in 63.6% of cholangiocarcinoma. There is statistically significant relationship between the expression of L1 and reduced membranous expression of E-cadherin, β-catenin or high expression of EGFR. There is also significant relationship between the expression of L1 or EGFR and histologic grading, pathologic T stage, venous/lymphatic invasion or perineural invasion in cholangiocarcinoma (p value all less than 0.05). Conclusion: The results suggest that L1 is a new factor for poor prognosis of patients and plays a crucial role in tumor invasion in cholangiocarcinoma. E-cadherin and β-catenin together with L1 might contribute to tumor progression. EGFR is also an important prognostic factor in cholangiocarcinoma.

PP2-261

PRELIMINARY STUDY REGARDING IMPORTANCE OF THE CYTOPATHOLOGICAL DIAGNOSIS IN MALIGNANT PANCREATIC TUMORS

Carmen Florina Popescu[1], Iancu Emil Plesea[2], Violeta Comanescu[1], Adrian Saftoiu[2], Sergiu Cazacu[2], Tudorel Ciurea[2]
[1] Emergency County Hospital Craiova Romania
[2] University of Medicine and Pharmacy Craiova Romania

Background The purpose of this study consist of a preliminary assessment of the cytopathologic examination for the diagnosis of pancreatic tumors with clinical suspicion of malignancy after echografic examination. Method 38 cases with clinical suspicion of pancreatic (P) malignant (M) tumor (T) and investigated using endoscopic-ultrasound-guided fine needle aspiration cytology (EUS-FNA) were selected. Classical cytopathological examination, on minimum 2 smears stained with May-Grunwald-Giemsa (for quick cytopathological diagnosis) and minimum 2 smears stained with Papanicolaou (for better visualization of nuclear details) for each case, was performed in all 38 cases. The smears were cathegorised as: benign (B), suspicious probably M, and M. The following cytopathological parameters were assessed: smear cellularity; presence, disposition, shape and number of cells with malignant features; presence of other B cells (P ductal cells, inflammatory cells, red cells). In cases with smears with suspicion of malignancy or M ones, cellular blocks were obtained (double centrifugation with ethanol 100%, formalin fixation and processing using the classical method for wax embedding) on which we performed immunohistochemical staining (IHCst) to identify the P epithelial fenotype of the M cells (anti-AE1/AE3 cytokeratines, anti-CA19-9, anti-CK20 cytokeratine and proliferation marker Ki67), and the site of a secondary PMT (HMB-45 and S100 protein). Results The smears obtained from 13 cases were diagnosed as benign. In 9 cases the smears had inflammatory background which confirmed the

diagnosis of pseudotumoral pancreatitis (Pt) at echoendoscopic examination. In 4 cases, there were frequent foamy cells and few clusters of B canalicular cells, so the final cytodiagnosis was chronic pseudocystic Pt. In 5 cases, with suspicious probably M smears, IHCst for Ki67 was performed; 3 cases were considered B with reactive cellular changes because Ki67 labelling index was under 5%; the other 2 cases were diagnosed as M because the index was very high. In 20 cases there were clustered cells showing obvious M criteria (M smears). In 21 cases considered as M, positive IHC staining for AE1/AE3 and CA19-9 confirmed the diagnosis of P adenocarcinoma. In 1 case negative IHCst for these markers and positive IHCst for HMB45 and S100 were conclusive for metastatic PT from an ocular M melanoma. Conclusions Preliminary data suggested that cytopathologic examination (on the smears and cellular blocks) on material provided by EUS-FNA is a reliable tool for the diagnosis of PMTs.

PP2-262
CLINICAL SIGNIFICANCE OF RCAS1 EXPRESSION IN PANCREATIC ADENOCARCINOMA

Olga Noussia[1], Demetrios Davides[2], Constantinos Giaginis[1], Apostolos Zarros[1], Adamantia Zizi-Serbetzoglou[3], Gregorios Kouraklis[2], Stamatios Theocharis[1]
[1] Department of Forensic Medicine and Toxicology, Medical School, National Kapodistrian University of Athens, Athens, Greece
[2] Second Department of Propedeutic Surgery, Medical School, National and Kapodistrian University of Athens, Athens, Greece
[3] Department of Pathology, Tzaneio Hospital, Piraeus, Greece

Background: The tumor associated antigen "receptor-binding cancer antigen expressed on SiSo cells" (RCAS1) inhibits the growth of cells that express its receptor, inducing apoptosis. RCAS1 has been recognized as a significant biological marker assessed in human biological fluids and cancer tissue samples. The aim of the present study was to evaluate the clinical significance of RCAS1 expression in cases of human pancreatic adenocarcinoma. Method: Immunohistochemical expression of RCAS1 was performed on paraffin-embedded pancreatic adenocarcinoma tissue sections obtained from 76 patients. The RCAS1 positivity, overexpression (expression in more than the mean percentage value), and intensity of staining were correlated with patients' gender, age and TNM stage; tumors' histopathological grade of differentiation, proliferative capacity (Ki-67 immunohistochemical expression); and patients' survival. Results: RCAS1 positivity was noted in 65 out of 76 (86%) pancreatic adenocarcinoma cases. The observed pattern of RCAS1 immunostaining was cytoplasmic and membraneous. RCAS1 overexpression was noted in 36 out of 65 (55%) of the positive cases. RCAS1 intensity of immunostaining was classified as mild in 11 (16%), moderate in 27 (42%) and intense in 27 (42%) out of 65 positive cases. RCAS1 positivity was statistically significantly correlated with tumors' histopathological grade ($p=0.026$), whereas a trend of correlation with tumor size (T, $p=0.071$) was also noted. RCAS1 intensity of immunostaining and overexpression presented a trend of correlation with tumors' histopathological grade ($p=0.061$ and 0.089, respectively). RCAS1 positivity, overexpression and intensity of immunostaining were not statistically significantly correlated with tumors' proliferative capacity and the other clinicopathological parameters examined. RCAS1 positivity, overexpression and intensity of immunostaining were not statistically significantly correlated with patients' survival. Conclusion: Our data support evidence for implication of RCAS1 in pancreatic neoplasia as correlations with clinicopathological variables in pancreatic adenocarcinoma cases have been noted. However, the prediction of survival using RCAS1 expression in pancreatic adenocarcinoma patients seems uncertain.

PP2-263
AUTOIMMUNE PANCREATITIS IN HETEROTOPIC PANCREAS MIMIC DISTAL COMMON BILE DUCT CARCINOMA: A CASE REPORT.

Nevra Dursun[1], Fadime Bahadir[1], Tugce Guzel Cay[1], Cem Leblebici[1], Soykan Arikan[1], Suha Goksel[2], Erol Rustu Bozkurt[1]
[1] The Ministry of Health Istanbul Training and Research Hospital, Istanbul, Turkey
[2] Cerrahpasa Medical Faculty, Department of Pathology, University of Istanbul, Istanbul, Turkey

CONTEXT:The incidence of pancreatic heterotopia is 0.55% to 15% among autopsy specimens. The most frequent location is upper gastrointestinal tract, specially in the duodenum, stomach and jejenum. Pancreatitis in heterotopic pancreas is rarely described, and clinical symptoms caused by this heterotopic inflammation are uncommon. CASE REPORT: We report a case of heterotopic autoimmune pancreatitis, of a 39 year old non-alcholic man who was admitted to Istanbul Education and Training Hospital Emergency Service for extensive right abdominal pain, weight loss and jaundice. ERCP and MR cholangiography demonstrated a distal common bile duct stricture suspicious of carcinoma. He underwent pancreaticoduodenectomy. Macroscopic examination revealed a nodule measuring 10x5x5 mm immediately adjacent to the ampulla of Vater in the wall of the duodenum. Histologically, it was composed of pancreatic tissue, including ducts, acini, and well-formed islets. There was dense lymphotic cell infiltrate surrounding ducts. Immunohistochemical evoluation of the lymphotic cell infiltrate showed predominance of T cells (positive for CD3 and UCHL-1) with fewer B cells (positive for CD20). CONCLUSION: In our case it was impossible to differentiate between chronic pancreatitis and pancreas carcinoma preoperatively. This is a rare entity and remains difficult to diagnose, despite advances in radiological and endoscopic imaging techniques. In the absence of unequivocal imaging and when there is a suspicion of underlying malignancy, pancreaticoduodenectomy may be the only treatment option, as in this case.

PP2-264
LEIOMYOSARCOMA OF THE LIVER IN A HIV POSITIVE CHILD. REPORT OF A CASE

Berrin Caylak, Banu Bilezikci, Bulent Celasun, Beyhan Demirhan
Baskent University, Turkey

Primary hepatic leiomyosarcomas are extremely rare neoplasms. The first reported case of primary hepatic leiomyosarcoma was found in a 9 years old girl with AIDS. The leiomyosarcomas are seen with increasing frequency in immunosupressed patients like HIV-infected individuals and organ transplant recipients. Our patient was a 4 years old HIV positive girl with leiomyosarcoma in the liver . Our patient had multiple lymphadenopathy. Abdominal CT showed contrast enhancing multiple lesions some with central necrosis in the liver. Histological examination of a biopsy sample showed a tumor composed of atypical spindle cells arranged in intersecting bundles and showing immunohistochemical features of smooth muscle cells. The differential diagnosis is with Kaposi's sarcoma and gastrointestinal stromal tumor (GIST) were considered. Immunohistochemical stains showed staining with actin and desmin, while CD34 and CD117 were negative. The insidence of leiomyosarcoma is increasing unusual sites are involved in the immunosupressed population. To our knowledge, this is the youngest patient with leiomyosarcoma of the liver reported to date.

PP2-265
TO EVALUATE THE CORRELATION OF SERUM TRANSAMINASE VALUES WITH HISTOLOGICAL ACTIVITY AND FIBROSIS IN HEPATITIS

Selvinaz Ozkara, Bilgen Sari, Ilkay Tosun, Guray Kilic
Department of Pathology, Haydarpaşa Numune Education and Research Hospital ,Turkey

ABSRACT: The aims of this study were to assess the predictive values of age, gender and serum aminotransferase values on the histological findings in patients with chronic hepatitis. METHODS: This retrospective study was based on data related patients with HBV, HCV infection and steatohepatitis who were seen at our pathology department from 2003 to 2007. Three hundred and ninety-eight (398) consecutive patients, including 87 cirrhotics, with chronic hepatitis were studied. Serum alanine aminotransferase (ALT), aspartate aminotransferase (AST) levels and hepatic activity index in all liver biopsies, were assessed. Liver biopsies were graded for the degree of fibrosis and histological activity by using modified histological activity index (HAI) of Ishak K et al. Normal liver, steatohepatitis and cirrhosis were also recorded. Cirrhosis was defined by a fibrosis score 5-6 in "modified HAI" classification. RESULT: The mean age of patient population was (43,11±15,44); 226 patients (%56,8) were male. By Mann Whitney U testing and Spearman's correlation analyses, serum AST values emerged as the most important predictive variable of hepatic fibrosis (r:0,311; p<0,01). A correlation was found between AST values and histological activity (r:0,295; p<0,01). On the other hand, serum ALT values did not correlate with (r:0,094; p>0,05) the extent of hepatic fibrosis but did correlate weakly with histological activity (r:0,242; p<0,01). In cirrhotics vs noncirrhotics, there were no significant differences between mean serum ALT (120,7±21,48 vs 116,11±13,49 units/liter) , but a correlation was found serum AST (129,36±21,43 vs 82,09±10,98 units/liter) levels. There were no significant correlations between age, gender or AST/ALT ratio, with the extent of histological activity or fibrosis. CONCLUSION : Serum AST values correlate well with histological activity and with the extent of hepatic fibrosis. These finding suggest that, among other factors, serum AST values should be considered in decisions regarding the need for liver biopsy and treatment in patients with chronic hepatitis.

PP2-266
CLINICAL SIGNIFICANCE OF EPHRIN RECEPTOR A1 EXPRESSION IN PANCREATIC ADENOCARCINOMA

Stamatios Theocharis[1], Constantinos Giaginis[1], Elli Chatzopoulou[2], Gerasimos Tsourouflis[3], Fotini Samiou[1], Gregorios Kouraklis[3]
[1] Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Greece
[2] INSERM U711, Medical School, Pitie Salpetriere Hospital, University Pierre and Marie Curie, Paris, France
[3] Second Department of Propedeutic Surgery, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background: Ephrin receptors (Ephs) belong to the largest family of tyrosine kinase receptors that mediate bi-directional signals between adjacent cells, being clustered after ligand binding. They are divided into two sub-groups: EphA (A1–A9) and EphB (B1–B6). Ephs and their cell-presented ligands, the ephrins (ephs), have been shown to be overexpressed frequently in a variety of cancer types. In the present study, the expression of Eph A1 subtype was examined in pancreatic adenocarcinoma histopathological specimens and was correlated with clinicopathological variables and patients' final outcome. Methods: Immunohistochemical expression of Eph A1 was performed on paraffin-embedded pancreatic adenocarcinoma tissue sections obtained from 67 patients. The Eph A1 positivity, overexpression (expression in more than the mean percentage value) and intensity of immunostaining were correlated with patients' age and TNM stage, tumor histological grade of differentiation, proliferative capacity (Ki-67 immunohistochemical expression) and patients' survival. Results: Eph A1 positivity was noted in 58 out 67 (87%) of the examined pancreatic adenocarcinoma cases. Eph A1 overexpression was noted in 26 out of 58 (45%) positive cases. Eph A1 intensity of immunostaining was classified as mild in 25 (43%), moderate in 32 (55%) and intense in 1 (2%) out of 58 positive cases. Eph A1 intensity of immunostaining was statistically significantly correlated with tumor size (T, p=0.007) and disease stage (p=0.040). Additionally, a trend of correlation between Eph A1 intensity of immunostaining and tumor histological grade (p=0.055) was noted. Eph A1 overexpression presented also a trend of correlation with disease stage (p=0.056). Eph A1 positivity, overexpression and intensity of immunostaining were not statistically significantly correlated with tumors' proliferative capacity and the other clinicopathological parameters examined, as well as with patients' survival. Conclusion: According to our data, implication of Eph A1 in pancreatic tumorigenesis is suggested. Further molecular and clinical studies are required to define the significance of other Ephs and their ligands (ephs) in prognosis and management of pancreatic carcinoma patients.

PP2-267
AUTOIMMUNE PANCREATITIS

Nesrin Turhan[1], Dilek Oguz[1], Sabite Kosar[2], Erkan Parlak[2], Burhan Sahin[2]
[1] Department of Pathology, Turkiye Yuksek Ihtisas Hospital, Ankara, Turkey
[2] Department of Gastroenterology, Turkiye Yuksek Ihtisas Hospital, Ankara, Turkey

Background: Autoimmune pancreatitis (AIP) is a recently described unique type of chronic pancreatitis(CP) that is thought to involve an autoimmune mechanism. It accounts for less than 1% of cases of CP. Recognition of this entity is clinically important because it is reversible when diagnosed. Methods:We identified only five cases with AIP among 131 patients (3.8%) with CP followed in our pancreas unit. We evaluated the clinicopathologic findings in 5 patients with AIP. Intraoperative biopsy was performed in one patient, surgical resection was performed one of the other patient, 3 of the other patients diagnosed by clinical and radiologically. Results: The 5 patients consisted of 3 women and 2 men, their ages ranged from 37 to 58 years old. Presenting manifestations in 5 patients included abdominal pain, jaundice and weight loss. None of the patients had history of alcohol abuse or other predisposing factors of chronic pancreatitis.All cases were seronegative. Association with an autoimmune disorder was seen in one case.In the first case intraoperative biopsy showed lymphoplasmacytic infiltration with periductal, interstitial fibrosis. Histological description was CP without any cytological atypia. As a concequence of the biopsy result was suggestive of AIP which was supplemented by clinical, laboratory and radiological findings. In the second case surgical resection was performed becouse of suspicion of pancreatic tumor. Macroscopic features showed diffuse firm enlargement of the pancreas without distinct mass. Histopathologic findings were intense inflammatory cell infiltration around medium-sized and large interlobular duct with a cuff-like periductal fibrosis. The periductal infiltrates were composed mainly of lymphocytes and plasma cells. In addition acute inflammatory component (granulocytic epithelial lesion) was detected. The affected ducts were narrowed by an infolding of their epithelium often giving their lumen a star-like appearance. Fibrosis of the pancreas predominantly showed a periductal. There were also fibroinflammatory areas. Venulitis was mainly present in fibrotic areas All 5 patients were responsive to steroid therapy. Conclusion: The diagnosis of AIP is based on clinical, radiological and biochemical findings. Autoimmune pancreatitis may mimic pancreatic-head carcinoma.

Excluding the diagnosis of pancreatic-head carcinoma and confirming the diagnosis of AIP may avoid unnecessary pancreaticoduodenectomy. Reliable minimally invasive methods are need to diagnosis AIP.

PP2-268
A NOVEL MODEL FOR SPATIAL RECONSTRUCTION OF ANGIOARCHITECTURE OF LIVER LOBE IN CHRONIC HEPATITIS C

Jasmina Gligorijevic, Vesna Zivkovic, Vuka Katic,
Nikola Gligorijevic
Institute of Pathology Nis, Serbia

Background It is indicated that, instead of morphological variety, there is essentially a common pathway of liver cirrhosis. It is nothing but process of breakup and rebuilding of liver lobules. Stil the formal pathogenesis of liver cirrhosis is unresolved. The aim Three-dimensional reconstruction of alteration of liver lobule and its angioarhitecture in chronic hepatitis C (HHC) in order to determine the formal pathogenesis regarding the transformation from chronic hepatitis to liver cirrhosis. Material and methods Ten liver byopsies with HHC were rutinly prepared for light microscopy. A liver tissue from autopsy of a men died of sudden cardiac death was used as a control. Serial sections of parafin blocks were stained by trichrom Mallory and by immunohistochemical methods for demonstrating smooth muscle actin and CD34. The analisis was done on Leica DMR (Leica Micro-Systems, France) microscope. Histological images were captured and digitalised by Leica DC300 digital camera and were stored as JPG files (8 bit, 2088x1552 pixel images) on hard disc. The collected images were than imported into Adobe® Photoshop® CS where the collor and contrast corrections were made so that the fields that were threated for CD34 could be isolated. The bitmaps that contained only the CD34 threated fields were than imported into Autodesk® Architectural Desktop and were marked as vectorised object, giving us the abbillity to reconstruct the 3D structure. Results Computed reconstruction gave various forms of altered angioarchitecture. Portal vein was preserved in all cases. The pathological changes begin on the parenchymal portion: the second step branches of the portal vein showed an increase and decrease in number and disturbance in special arrangements. In severely damaged parts of the liver tissue normal angioarhitecture was lost. It seems that parenchymal nutrition rest on the remaining third-step portal branches. Hepatic vein system seemed to be preserved. Conclusion Distortion of portal vessels reflect changes in lobular architecture. The method for three-dimensional reconstruction succesfully helped in visuelisation the early histological signs of cirrhosis developing in the course of chronic hepatitis C.

PP2-269
SINUSOIDAL CAPILLARIZATION IN DISPLASTIC NODULES AND EARLY HEPATOCELLULAR CARCINOMA

Jasmina Gligorijevic, Djordjevic Biljana, Vesna Zivkovic,
Ljubinka Velickovic, Maja Milentijevic, Nikola Gligorijevic
Institute of Pathology Nis, Serbia

Background Although hepatocellular carcinoma (HCC) receives an exclusively arterial blood supply, the majority of well differentiated HCCs of indistinctly nodular type (early HCC) receive aditional portal blood. Although the pathological diagnosis of high-grade dysplastic nodule (DN) and early HCC is controversal,when face the differential diagnosis, the type of vascularisation can be helpful in processing small surgical byopsies. The aim Analisis of arterialisation and changes in sinusoidal capilarisation in displastic nodules and HCC. Material and method We immunohistochemically stained 17 displastic nodules of low grade and 9 of high grade and 7 hepatocellular carcinoma, two of them being early HHC for CD34, indicating sinusoidal capillarisation. Distribution of sinusoidal capillarization was graded semiquantitatively. Resuts Sinusoidal capillarization was common finding in HHC. The relation to displastic nodules was significantly higher (p< 0,0027). There were significant differences among moderately differentiated and early HCC. In moderately differentiated HCC, endothelial cells of the sinusoidal blood spaces are positive for CD34, whereas those in early –stage HCC are only partially positive. In our cases of early HCC with "nodulle in nodulle appearance" those findings were of crutial diagnostic value. Conclusion Distribution of sinusoidal capillarization in displastic nodules support them as premalignant lesions. Uniform distribution of CD34 in HCC of moderat degree of differentiation versus incomplete distribution in small, early-stage HCCs can be of diagnostic value.

PP2-270
GALLBLADDER ADENOCARCINOMA AND P53 AND C-ERBB2 IMMUNOHISTOCHEMICAL EXPRESSION

Stephanos Milias, Thomas Zaramboukas
"ISTODIEREVNITIKI" Pathology Laboratory, Thessaloniki, Greece

Background: The gallbladder adenocarcinoma is rare, but is a carcinoma with unfavourable prognosis. The aim of this study was to evaluate the immunohistochemical expression of p53 and c-erb-B2 and their possible role in tumorigenesis in gallbladder adenocarcinomas. Method: 17 archival cases of gallbladder adenocarcinoma and one case of bile duct adenocarcinoma were reviewed. Eighteen cases of chronic cholecystitis, nine with gallstones, were also selected. The patients with adenocarcinoma were 12 female and 6 male and their age ranged 48-78 years old. Paraffin sections from the selected cases were stained immunohistochemically for p53 and c-erb-B2 Results: Thirteen cases were diagnosed as low differentiated and the rest 5 cases as moderately differentiated adenocarcinomas. The serosa was infiltrated in 11/18 cases and the adipose tissue in 7/18 cases. Four cases showed infiltration of the cystic and/or the bile duct, 4 cases had lymph node metastases, 5 cases liver metastases and 2 cases peritoneal implants. P53 overexpression was found in 8 cases (44.4%), while c-erbB2 overexpression was found in 2 cases (11.1%). None case showed co-expression of p53 and c-erbB2. Two cases of chronic cholecystitis, not related to gallstones, showed p53 overexpression. Conclusion: According to the English literature, the percentages of p53 and c-erbB2 overexpression in gallbladder adenocarcinomas are quite divergent. It seems that p53 gene mutation may play a role in tumorigenesis of gallbladder adenocarcinoma, which is possibly more significant and independent from the c-erbB-2 overexpression.

PP2-271
NEUROENDOCRINE CARCINOMA OF GALLBLADDER

Stephanos Milias[1], Thomas Zaramboukas[1],
Christos Konstantaras[2]
[1] "ISTODIEREVNITIKI" Pathology Laboratory
Thessaloniki, Greece
[2] Surgical Department of Agios Loukas Hospital,
Thessaloniki, Greece

Background: To present a rare case of incidental finding of neuroendocrine carcinoma of the gallbladder and the problems that occur. Method: A female patient 73 years old underwent laparoscopic cholecystectomy due to symptoms of chronic cholecystitis. Results: Microscopic evaluation revealed a small neoplasm, 4mm in greatest diameter, located near the cystic duct. The neoplasm infiltrated the mucosa, submucosa and partially the muscular layer. Small tubular structures were observed with very mild nuclear atypia and with no obvious mitotic activity. In immunohistochemical examination the neoplastic cells were positive for keratins AE1/AE3, S100 protein (nuclear and cytoplasmic), synaptophysin, Chromogranin A and NSE. The morphological and immunohistochemical findings were

suggestive for neuroendocrine carcinoma. Conclusion: The neuroendocrine carcinoma of the gallbladder is a rare entity. The few studies published contain small numbers of cases. Therefore, there is not enough evidence to support the best choice of treatment and the possible biological behavior.

PP2-272
PSEUDOTUMOROUS TYPE OF AUTOIMMUNE PANCREATITIS

Milena Cosic Micev[1], Marjan Micev[1], Vera Todorovic[2], Srboljub Knezevic[1], Ivan Jovanovic[1]
[1] Institute of Digestive Diseases, Clinical Centre of Serbia, Belgrade, Serbia
[2] Institute for Medical Research, University of Belgrade, Serbia

Autoimmune pancreatitis is defined as chronic fibro-inflammatory process of the bilio-pancreatic ductal tract, dominantly involving pancreas and causing organ dysfunction. An autoimmune basis for this disease is strongly supported by laboratory findings and frequent association with rheumatoid arthritis, Sjogren's syndrome, inflammatory bowel disease and other autoimmune manifestations. This entity has prevalence between 5-6 % of all chronic pancreatitis, although it is apparently a heterogeneous disease. Besides the most common diffuse type and rarely presented systemic type with widespread extrapancreratic involvement, at least a third of cases are localized pseudotumourous forms. An excellent response to corticosteroid therapy in most cases makes Whipple's resection unnecessary. We report three cases of pseudotumourous form of autoimmune pancreatitis from the Department of Histopathology Registry during 8 years (1997-2004) in 2 male (52,67 ys average age) and 1 female patients (34 ys age) operated in Clinical centre of Serbia. In all three cases there were moderately elevated serum levels of CA19-9 and suggestive CT scan low-attenuation or isoattenuation mass in the head of the pancreas, in addition to obstructive jaundice and abdominal pain, mimicking pancreatic cancer. Detailed histopathological analysis was performed on localized well-defined tumour-like lesions measuring 4-5,5 cm in diameters, presenting firm rubbery consistency in the head of the pancreas. All cases microscopically revealed admixture of diffuse or ill-defined dense lymphoplasmacytic infiltrate surrounding interlobular ducts and irregular sclerosing fibrosis predominantly affecting interlobular septa. Immunohistochemistry revealed the predominance of T cell lymphocytic immunophenotype around and within ductal epithelium and IgG4-positive plasma cells, which confirmed the morphological diagnosis. In two cases there was additional lobular involvement of the infiltrate and in one case a prominent myofibroblastic proliferation with foci of oedema of fibrotic tissue formed inflammatory pseudotumor in the periampullar region. In conclusion, these cases represent a failure of preoperative diagnostics as it was impossible to ascertain malignancy on preoperative biopsy and there was a need for more biochemical and clinical tests leading to an autoimmune disease and reaching the correct preoperative diagnosis. However, preoperative histological confirmation of the autoimmune pancreatitis is also very difficult and could be easily misdiagnosed as other types of chronic pancreatitides.

PP2-273
EXPRESSION OF P16 PROTEIN AND CYCLIN D1 IN PERIAMPULLARY CARCINOMAS

Nese Calli-Demirkan[1], Nilay Sen-Turk[1], Sema Arici[2], Ersin Tuncer[2], S. Ender Duzcan[1]
[1] Department of Pathology, School of Medicine, University of Pamukkale, Denizli, Turkey
[2] Department of Pathology, School of Medicine, University of Cumhuriyet, Sivas, Turkey

Background: The majority of the tumors in periampullary region are pancreatic adenocarcinoma and adenocarcinoma of ampulla of Vater's. Ductal adenocarcinomas (DAC) constitute agreater proportion of pancreatic head carcinomas. Recent studies have identified that pancreatic intraepithelial neoplasia (PanIN) plays a role in development of DAC. Also, inactivation of p16 tumor supressor gene is an important factor in carcinogenesis of pancreas adenocarcinoma. The aim of this study is to compare histopathological features of carcinoma of ampulla of Vateri (AVC) with DAC in the periampullary region and to determine diagnostic and prognostic values of p16 protein, cyclin D1 expression and PanIN lesions in tumoral and peritumoral pancreatic tissues. Materials and Methods: Tissue samples from DAC and AVC were obtained from 20 and 11 patients, respectively who had undergone pancreticoduodenectomy for periampullary carcinoma at the Departments of Pathology of Universities of Pamukkale and Cumhuriyet. The group of patients included 12 women and 19 men. Their median age was 62,32 years (range 26-85 years). The factors analyzed include tumor characteristics (diameter, margin status, lymph node status, perineural invasion, differentiation, duodenal invasion), grade of PanIN, p16 and cyclin D1 expression at tumoral and peritumoral pancreatic tissues. Results: We found no significant difference between two groups in terms of the presence of PanIN at peritumoral pancreatic tissues statistically ($p>0,05$). In DAC group, perineural invasion was more frequent than the AVC group ($p=0,01$). In all cases, the loss of p16 protein expression was correlated with perineural invasion significantly ($p=0,0001$). When desmoplasia and lymphoplasmocytic stromal infiltration were examined, it was found that desmoplastic reaction was encountered more in DAC group rather than AVC group significantly ($p=0,01$). Cyclin D1 expression was found as non significant in neither of the groups ($p>0,05$). Conclusion: These results suggest that the loss of p16 protein may be an indicator of poor prognosis of periampullary cancer related principally due to perineural invasion, regardless of histopathological type. DAC and AVC may be distinguished by the presence of desmoplastic stromal reaction. The existence of PanIN lesion seems to be not specific findings for DAC.

PP2-274
VALUE OF HEPATOCYTE PARAFFIN 1 ANTIGEN (HEP PAR 1) AND VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) IN PREDICTING EARLY HCC AND DIFFERENTIATING SOME METASTATIC HEPATIC LESIONS IN PATIENTS WITH CHRONIC LIVER DISEASE

Zakaria Soheir[1], Akl Maha[2], Hamam Olfat[2], El Raziky Maysa[1], Seyam Motaz[3], Hunter Sherin[1], Zimmerman Robertz[4], El Kady Nabil[5], Salama Rabab[5]

[5] Tropical Medicine Department Faculty of Medicine, Cairo University, Egypt

HCC is now a rather common malignancy in Egypt, usually develops on top of liver cirrhosis secondary to chronic viral infection (B/C) which increased the risk of HCC in the Egyptian patients. Hepatocyte paraffin 1 antibody (Hep Par 1) has been reported to be a sensitive marker for HCC in paraffin sections and previous studies showed that it is 90% specific for hepatocytes and is useful for differentiating HCC from liver metastases. Our aim is to assess the expression of (Hep Par 1) and vascular endothelial growth factor (VEGF) in fine needle liver biopsy specimens from patients having hepatocellular carcinoma compared to patients having chronic viral hepatitis (B or C) and to study their clinical significance as possible markers for early prediction of malignancy in chronic viral hepatitis and cirrhotic patients. The material of this study comprised 80 patients

suffering from chronic liver disease examined during the period from 2004-2006.All patients were subjected to clinical examination, abdominal ultrasonography, serological investigations, liver needle biopsies and histopathological diagnosis. They were classified as 30 patients with HCC, 30 patients with LC and 20 patients with CH (B/C), beside 10 patients with metastatic liver disease (control group). Unstained liver sections from every case were treated with the monoclonal antibodies for both Hep par 1 and VEGF. In our study we found that more VEGF expression in "CH" group than in liver cirrhosis "LC" and HCC patients. Both LC and HCC groups exhibit moderate (51-75%) and intense expression (>75%) of VEGF, indicating that angiogenesis is higher in LC and HCC than in chronic hepatitis, so VEGF plays a role in prediction of the possibility of malignancy in CH patients. We found that most of CH and LC patients show focal expression of Hep par 1, while most of HCC patients show diffuse Hep par 1 expression (≥90%) and this was significantly higher in HCC than in CH and LC patients, so Hep Par 1 when diffuse in CH and LC patients could indicate susceptibility to turn malignant. VEGF plays a role in prediction of the possibility of malignancy in CH patients as angiogenesis was found higher in liver cirrhosis and HCC than in chronic hepatitis, while VEGF expression in liver metastases was not intense. Well differentiated HCCs with diffuse and intense Hep par 1 expression warrant earlier intervention before further progression of malignancy. Hep par 1 plays an important role in the differentiation between primary HCC and liver metastases being negatively expressed in all metastatic patients.

PP2-275
CLEAR CELL PANCREATIC ADENOCARCINOMA

Barbara Christoforidou[1], Natalia Vladika[1], Doxakis Anestakis[1], Spiros Oikonomou[2], Frideriki Patakiouta[1]
[1] Pathology Department, Greece
[2] A' Department of Surgical Oncology, Greece

Background: Adenocarcinoma of ductal origin compromises 85-90% of all pancreatic tumors. Currently the WHO recognizes clear cell carcinoma as a "miscellanous" carcinoma with ductal phenotype and presence of mutation in the k-ras oncogene. We report a case of pancreatic ductal adenocarcinoma with predominantly clear cell morphology (> 95% clear cells). Report of the case: A 78 year-old man presented in March 2006, with right upper quadrant pain. He underwent a series of evaluations, including a computed tomographic scan of the abdomen, which revealed a mass in the tail of the pancreas. The patient reported an 8 Kg weight loss during the last three months. Distal pancreatectomy and splenectomy was performed. The specimen received for pathologic analysis was a 8X3.3X2 cm recection of the distal pancreas with the attached spleen. A vaguelly circumscribed, firm, white tumor, 3 cm in diameter was found, extended into the peripancreatic soft tissue. Microscopic examination revealed highly atypical glands composed of pleomorphic cells with abudant clear cytoplasm (> 95% clear cells). Glands were surrounded by a desmoplastic stroma. The background pancreas showed atrophy, along with a spectrum of pancreatic intraepithelial neoplasia (PanIN). Histochemically intraluminal and intacytoplasmic PAS+ and PASD+ mucin droplets were revealed. Immunohistochemically the cells were positive for CK7 and CAM 5.2 and were focally positive for CK20. These cells also expressed monoclonal carcinoembryonic antigen. Stainings for the neuroendocrine markers, synaptophysin and chromogranin were negative, as were stains for vimentin, HMB-45 and CD10. The differential diagnosis includes pancreatic neuroendocrine tumors, solid pseudopapillary tumor, PEComa, mixed ductal-endocrine carcinoma, solid serous cystadenoma and metastatic renal cell carcinoma. The possibility of a neuroendocrine tumor is excluded in this case by the absence of neuroendocrine markers in the neoplastic cells. PEComa is characterized by positivity for HMB-45, which is negative in our case. Likewise, the tubuluglandular growth pattern and mucin production combined with the absence of vimentin and CD10 expression excludes metastatic renal cell carcinoma. Conclusion: We present a unique case of poorly differrentiated clear cell ductal adenocarcinoma of the pancreas. In the proper morphologic context supported by immunohistochemistry, clear cell carcinoma can be regarded as a rare variant of ductal adenocarcinoma. The patient, twenty days after the operation died, due to postoperative hemorrhage.

PP2-276
MONONUCLEAR CELL PHENOTYPES IN NONALCOHOLIC FATTY LIVER DISEASE: COMPARISON WITH CHRONIC HEPATITIS C

Cigdem Celikel[1], Emine Bas[1], Naziye Ozkan[1], Deniz Duman[2], Erol Avsar[2]
[1] Marmara University School of Medicine, Department of Pathology,Turkey
[2] Marmara University School of Medicine, Department of Gastroenterology,Turkey

AIM: Cytokine release from inflammatory cells, lipid peroxidation, and generation of reactive oxygen species are among the factors currently thought to be important in the pathogenesis of nonalcoholic fatty liver disease (NAFLD). However, innate and adaptive immune response could also have an influence in the pathogenesis of NAFLD. The aims of this study were to evaluate the frequency and distribution of intrahepatic mononuclear cell phenotypes and to assess the relationship of these cells with the grade and stage of NAFLD. METHODS: Liver biopsies of patients with NAFLD (n=40) and chronic hepatitis- C (CH-C) patients with more than 10% steatosis in their liver biopsies (n=20) were selected for immunohistochemical staining to analyze the type and distribution of mononuclear inflammatory cells. CD4 and CD8 T-lymphocytes, CD20 (B lymphocytes), CD83 (dendritic cells), and CD56 (NK) cells were detected using monoclonal antibodies on paraffin-embedded tissue. Grading and staging of the liver biopsies of NAFLD patients were evaluated with Brunt's system. RESULTS: In both NAFLD and CH-C groups, T cells were found in portal tracts and in regions of focal necrosis. Immunohistochemistry showed mild to moderate (1+ to 2+) numbers of T cells, with CD4 predominance in NAFLD. In contrary, the percentages of CD4 and CD8 cells were approximately equal in CH-C. The number of CD8 lymphocytes in NAFLD was significantly lower than that in CH-C ($p<0.05$). B cells were only rarely present in NAFLD in contrast to CH-C. CD56-positive cells were rare in both lobule and portal areas of CH-C, but CD56 staining in biopsies of NAFLD showed prominent immunoreactivity throughout the lobules especially in perivenular regions. Dendritic cells were observed mostly in portal areas associated with CD8 lymphocytes in CH-C, but in pericentral areas in NAFLD. The magnitudes of CD4(+)T-cell and NK-cell responses were correlated with the extent of liver cell damage in NAFLD. CD56-positive cells were more common in biopsies with bridging fibrosis, compared to mild perivenular fibrosis in NAFLD patients ($p<0.05$). CONCLUSION: Our results suggest that NK cell response, and also T lymphocytes, in particular CD4 (+) T cells, are critical for the pathophysiology of NAFLD.

PP2-277
ALTERED S-ADENOSYLMETHIONINE METABOLISM IN A MALLORY BODY MOUSE MODEL

Pichler Martin[1], Hatz Martina[1], Aigelsreiter Ariane[1], Mischinger Hans-Jorg[2], Denk Helmut[1], Zatloukal Kurt[1]
[1] Institute of Pathlogy, Medical University Graz, Austria
[2] Department of Surgery, Medical University Graz, Austria

Background: Alcoholic (ASH) and nonalcoholic steatohepatitis (NASH) are highly -prevalent diseases in developed countries and are precursors of life- threatening disorders such as cirrhosis or hepatocellular carcinoma. S-adenosylmethionine (SAMe) is a

key metabolite in hepatocytes and acting not only as the most important methyl donor, but is also involved in the regulation of hepatocyte growth, apoptosis and dedifferentiation. The steady-state level of SAMe is regulated by a network of enzymes and altered methionine metabolism contributes to the pathogenesis of ASH. The aim of our study was to identify and to measure the expression pattern of SAMe regulating enzymes in a well-established animal model that shows morphologic features of human steatohepatitis such as Mallory body formation, liver cell necrosis, apoptosis, steatosis, fibrosis and ductular reaction. Methods: Swiss albino mice were fed a 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC)-containing diet and animals were killed after 1 week and 2.5 months of DDC-treatment, as well as after 1 month DDC-free diet (=recovery) and 3 days DDC-refeeding following 2.5 months DDC intoxication. The expression of enzymes involved in SAMe synthesis and degradation were determined by Real-time quantitative RT-PCR. Results: Compared to normal mouse liver, the enzymes MAT1A and Ahcy were downregulated after 1 week of DDC-feeding (2.3 and 2.2 fold), 2.5 months DDC-feeding (3.3 and 2.9 fold) but normalised after administration of a DDC-free diet to mice for 1 month to 2.5 months pretreated animals. In contrast, MAT2A was overexpressed 1.4 fold after 1 week of DDC administration, 1.6 fold after 2.5 months of DDC administration but normalized in the recovery phase. Refeeding mice DDC for 3 days after one month of recovery on a DDC-free diet downregulated expression of MAT1A (2.9 fold) and Ahcy (2.7 fold) but induced expression of MAT2A (2 fold). Conclusion: Our data demonstrate that in the DDC animal model, reproducing pathological features of steatohepatitis, a deregulation of SAMe-metabolizing enzymes occurs. As a switch from MAT1A to MAT2A expression and depletion of hepatic SAMe is also found in human ASH, our findings support the hypothesis that SAMe and subtle interaction of its regulating enzymes play a pathophysiological role in chronic metabolic liver disorders. The biologic significance of this altered expression pattern is unclear but dysbalance in methylation reactions may lead to changes in DNA and histone methylation, thereby influencing gene expression in the affected liver.

PP2-278

IMPACT OF TUMOR SIZE AND VASCULAR INVASION ON SURVIVAL OF PATIENTS WITH SMALL HEPATOCELLULAR CARCINOMA

Luciana Kikuchi, Denise Vezozzo, Aline Chagas, Evandro Mello, Alberto Farias, Ricardo Pietrobon, Flair Carrilho, Venancio Alves
Sao Paulo University School of Medicine, Brazil

BACKGROUND: Hepatocellular carcinoma (HCC) is the most common primary liver cancer. Liver cirrhosis is the major risk factor for this tumor. Screening for HCC in patients with cirrhosis has been recommended, with the belief that detection and treatment of early HCC improves patient survival. The aims of this study were to analyze the overall survival of small HCC in cirrhotic patients and identify independent predictors of survival, in Brazil. METHODS: Between January 1998 and December 2003, seventy-four cirrhotic patients with hepatocellular carcinoma were evaluated satisfying the following criteria: HCC of 3 cm or smaller and a maximum of three lesions. Predictors of survival were identified using the Kaplan-Meier and the Cox model. RESULTS: Mean age was 58 years-old (32-77), 71% of patients were male, 64% had hepatitis C, 60% were Child-Pugh A, mean MELD score was 11 and 79% had portal hypertension. At the time of diagnosis, 71% had one tumor, the size of the main tumor was smaller than 20 mm in 47%, mean AFP level was 131 ng/ml. Three patients had portal vein thrombosis, suggesting vascular invasion. Fifty patients (67.5%) were included in the liver transplant list, but it was performed in only four patients. Tumor resection was possible in four patients. Forty-eight (64.8%) patients received percutaneous treatment (radiofrequency ablation or percutaneous ethanol injection). Nine patients did not receive any cancer treatment. The overall survival rates were 80%, 62%, 41% and 17% at 12, 24, 36 and 60 months, respectively. The mean length of follow-up after HCC diagnosis was 23 months (median 22 months, range 1–86 months) for the entire group. During follow-up a total of 39 deaths related to liver failure or HCC progression occurred. Univariate analysis of the 74 patients showed that MELD score was greater than 11 ($p = 0.016$), Child-Pugh classification ($p = 0.007$), AFP > 100 ng/ml ($p = 0.006$), more than one lesion ($p = 0.041$), tumor diameter > 20 mm ($p = 0.009$) and presence of vascular invasion ($p < 0.0001$) were significant predictors of survival. Cox regression analysis identified vascular invasion (RR = 14.60 - IC 95% = 3.3 – 64.56 – $p < 0.001$) and tumor size > 20mm (RR = 2.14 - IC 95% = 1.07 – 4.2 – $p = 0.030$) as independent predictors of decreased survival. Treatment of HCC was related to increased overall survival. CONCLUSION: Identification of small tumors of up to 2 cm diameter is related to increase survival. Nevertheless, vascular invasion, despite the small diameter of the lesions, is a factor associated with dismal prognosis.

PP2-279

INTRANUCLEAR INCLUSIONS IN THE LIVER: A RETROSPECTIVE STUDY IN 200 LIVER BIOPSIES

Yesim Gurbuz, Birsen Besnili
Kocaeli University Medical Faculty Pathology Department,Turkey

INTRODUCTION: Intranuclear inclusions in liver biopsies are common histopathological findings. Their importance and clinical significance is not clear. Although they may have morphological similarity with the intranuclear glycogen accumulation they have characteristic appearance with clear borders. MATERIAL METOD In order to examine the significance and the intensity of intranuclear inclusions we included 200 cases of liver biopsies examined in 2005 and 2004 in our department to our study (55 Chronic B hepatitis, 49 Chronic C hepatitis, 4 malignancies, 3 PBS, 89 other diagnosis). The clinical information was taken from the pathology archive files. The biopsies that contain less than 3 portal tract or inadequate liver tissue were not included. The biopsies were examined in high power field by two pathologist in order to find existence and intensity of intranuclear inclusions and intranuclear glycogen accumulation. The results were classified according to disease etiology, Grade and stage of the chronic hepatitis according to modified Scheuer system. RESULTS: Intranuclear inclusions were in different sizes with distinct borders, some of them contain homogeneous eosinophilic inclusions. We observed double inclusion in one case. Intranuclear inclusion was observed in 77 (38%) of the cases and 18 (8.5%) was intensive. In viral hepatitis inclusion were observed in 121(60.5%) of the cases, in peritumoral are intranuclear inclusion was observed in 4(25%) of the cases and none of the PBS cases contain intranuclear inclusion. There was grade and stage of 79 of the cases and intranuclear inclusion was observed in 2(50%) of Grade 0, 10(30%) of Grade 1, 18(41.86%) of Grade 2, 3, 0(0%) of Grade 4 and 3(42.85%) of Stage 0, 6(21.42%) of Stage 1, 20(51.28%) of Stage 2, 3, 1(15.66%) of Stage 4 biopsies. Intranuclear glycogen accumulation was observed in 49 (24.5%) of the cases. Intranuclear glycogen accumulation was observed in 22 (28.57%) of cases with and 27 (21.95%) of cases without intranuclear inclusion. CONCLUSION: The existence of intranuclear inclusions is more that expected in liver biopsies. Their incidence is more common in viral hepatitis than other etiological agents. Their existence is not related with inflammation and fibrosis of the liver. There is no relation between intranuclear inclusions and intranuclear glycogen accumulation.

PP2-280
THE SIGNIFICANCE OF PARENCHYMAL CHANGES AND HISTOLOGICAL EOSINOPHILIA IN PREDICTING SUBSEQUENT EPISODES OF ACUTE LIVER GRAFT REJECTION

Beyhan Demirhan[1], Banu Bilezikci[1], Nihan Haberal[2], Sinasi Sevmis[2], Zubeyde Arat[1], Mehmet Haberal[1]

[2] Baskent University School of Medicine General Surgey Department ,Turkey

Background. It is suggested that centrilobular alterations may be possible indicators of subsequent episodes of acute rejection or early chronic rejection or graft loss. Aim. The purpose of this study was to identify any differences between the histopathological findings in the first rejection episode biopsies in cases with and without subsequent episodes of acute rejection. Methods. We assessed the predictive value of centrilobular necrosis, central vein endothelialitis, pericentral inflammation, hepatocyte ballooning, cholestasis, hepatocyte apoptosis, lobular inflammation, presence of portal eosinophils as well as characteristic portal tract features in the poor response to anti-rejection treatment. The findings in twenty two cases with a single acute rejection episode (Group 1) were compared with those of 23 with multiple episodes (Group 2). Only the first biopsy samples of the latter group were taken into consideration. Results. Time to the first episode of acute rejection, rejection activity index (RAI) were similar (63 vs 62 days RAI: 5.2 vs RAI: 6.1) between the 2 groups. Hepatocyte apoptosis(90% vs 82%), hepatocyte ballooning (77% vs 82%), central vein endothelialitis (59% vs 69%), were common features in both groups (group 1 and group 2 respectively). The incidence of pericentral inflammation, centrilobular necrosis and presence of portal eosinophils were significantly higher in the group 2 (78% vs 50%), (65% vs 27%) and (95% vs 68%) ($p < 0.05$). Conclusion. Patients with pericentral inflammation and centrilobular necrosis during the first episode of acute rejection may be more likely to have subsequent episodes of acute rejection.

CORRELATION OF CAVEOLIN-1 EXPRESSION AND PROFILERATION MARKERS IN HUMAN PANCREATIC CANCER

Cristiana Tanase[1], Mihaela Mihai[1], Carmen Ardeleanu[1], Elena Raducan[1], Eleonora Codorean[1], Mihnea Ioan Nicolescu[1], Simona Olimpia Dima[2], M. Leabu, Laurentiu Mircea Popescu[1], Mihail Eugen Hinescu[1], Irinel Popescu[2]
[1] Victor Babes" National Institute of Pathology,Romania
[2] Fundeni Clinical Institute, Romania

Caveolin 1 (Cav-1) the structural protein of caveolae, is recognized as a key switch, functioning either as a tumor supressor or as a promoter of metastasis and tumor cell survival. This study examined the expression level of Cav-1 in different pancreatic tumors. Cav-1 and proliferation markers (Ki67, p53) were determined by immunohistochemistry in 12 pair samples (tumoral/peri-tumoral) from human pacreatic cancer. The labelling index for Ki67 was 20% in tumor tissue specimens, but around 3.5% in their matched peritumoral samples. Staining for P53 was positive in 66% of tumor samples and negative results in the peritumoral samples. A positive expression of Cav-1 was associated with positivity for proliferation markers in tumor and vascular endothelial cells (tumoral tissue). By contrast, in peritumoral samples Cav-1 expression was confined to some endothelial cells. A positive corelation between the proliferative activity and overexpression of Cav-1, in concordance with tumoral grading were noted. Moreover, Cav-1 expression in tumors was in accordance with increased level of serum tumor markers (CEA, CA19.9). Further research may settle if the clinical outcome can be predicted by measuring Cav-1 expression in pancreatic tumors.

PP2-282
PROBLEMS OF DIFFERENTIAL DIAGNOSIS IN PRIMARY AND METASTATIC NODULAR LESIONS OF LIVER: AN ANALYSIS OF A SERIES WITH 169 CASES

Ahu Senem Demiroz[1], Sibel Erdamar Cetin[1], Gulsen Ozbay[1], Serap Aslan[1], Ilknur Erenler[2], Gulen Bulbul Dogusoy[1], Suha Goksel[1]
[1] Department of Pathology, University of Istanbul, Cerrahpaşa Faculty of Medicine, Istanbul, Turkey
[2] Department of General Surgery, University of Istanbul, Cerrahpaşa Faculty of Medicine, Istanbul, Turkey

Background: Metastatic tumor/primer liver tumor ratio is 40:1 in Europa-North America, 2.6:1 in Japan. Primer tumors of liver are more common than metastases in Southeast Asia. The aim of this study is to determine metastatic tumor/primer liver tumor ratio in our series and analysis of criterias that could be helpful in differential diagnosis by reviewing nodular liver lesions Method: We have reviewed and analyzed consecutive 189 liver specimens (composed of trucut , wedge or excisional biopsies of liver) with nodular lesions diagnosed at the Cerrahpasa Medical College between 2004 and 2006. Results: 169 of 189 of cases are tumoral lesions. 70(%41) of them are primary liver tumors and 88(%52) of them are metastatic tumors, although 11(%7) of tumors are tumors of unknown origin. 36 of them are hepatocellular carcinomas, 4 of them are cholangiocarcinomas, 2 of them are hepatocellular adenomas, 3 of them are focal nodular hiperplasies and 1 of them is hepatoblastoma. According to origine they are classified as follows: Adenocarcinoma (AC) of colon:27(%14), pancreatic ductal AC: 7(%4), lung AC: 4 (%2), breast: 3(1.5), ovary: 3(1.5), endometrium carcinoma: 1 (%0.5), servix carcinoma: 1 (%0.5); and testis carcinoma: 1 (%0.5), surrenal gland carcinoma: 1 (%0.5), squamous cell carcinoma: 1 (%0.5), liposarcoma: 1 (%0.5). We could not specify the origine of metastases in 21 cases and could not differentiate cholangiocarcinoma from metastatic adenocarcinoma in 11 cases. 13 case with neuroendocrine tumor features are not idendified as primary or metastatic since it is not found any primary after detailed examination in clinically. After a panel of immunhistohemistry including keratin subtypes and endocrine markers, these tumors remaine unclear. Conclusion: The most common metastatic tumor in liver is colorectal adenocarcinoma..This finding is same as in literature. The most important problem in differential diagnosis of nodular lesions in liver is in between primary neuroendocrine tumors and metastatic gastro-entero-pancreatic neuroendocrine tumors and also in between primary cholangiaocarcinoma and metastatic adenocarcinoma. There is no further technique (immunhistochemistry or molecular) that help in this differentiation, so far.

BACKGROUND: Grading and staging system for nonalcoholic steatohepatitis (NASH) proposed by Brunt et al in 1999 was accepted and used widely since then. We experienced many cases of NASH with some histological features of inflammation and fibrosis different from those decribed by Brunt et al. The purpose of this study is to evaluate the histological features of NASH and to determine the differences in Turkish population. METHOD: Totally 597 cases of NASH diagnosed by 14 experienced pathologist from 12 institutions, reevaluated according to the criteria including Brunts' and certain additional features such as grade, type and distribution of steatosis; frequency and distribution of balooning, severity and predominant cell type of lobular inflammation (LI); presence and severity of portal inflammation (PI) and interface activity; presence and extent of perisinusoidal, periportal and bridging fibrosis (PSF, PPF, BF) and presence of cirrhosis. RESULTS: Steatosis was found as Grade I in 180(30,2%), II in 220(36,8%), III in197(33%) of cases. Distribution of steatosis was in zone3 in 202(33,8%), zone1 in 12(2,1%) , azonal in 383(64,1%). Excluding grade III steatosis in which zonality is difficult to determine, distribution was azonal in 47,7% of grade I, 50,5% of grade II steatosis.116(19,4%) of cases showed mixed macro/microvesicular steatosis. Grade of LI was 0 in 21 (3,5%), 1 in 356(59,6%), 2 in 173 (29%), 3 in 47 (7,9%) . LI was polymorph predominant in 70(11,7%), mononuclear predominant in 275 (46,1%), and mixed in 231(38,7%) cases. Mild PI was seen in 312(52,3%), moderate in 110(18,4%) and prominent in 13(2,2%) of cases. PSF was observed focally in 291(48,7%) and diffuse in 120(20,1%) cases; no PSF was present in 186(31,2%) cases. PPF was focal in 220(36,9%), diffuse in 109(18,3%) cases. BF was found in 85(14,2%) and cirrhosis in only 12 (2%) cases. Higher grade of steatosis was significantly correlated with the higher degrees of LI ($p<0.01$) and PSF ($p<0.05$). In 22,6% and 11,8% of cases which had no PSF had focal and diffuse periportal fibrosis, respectively. The most remarkable features were the type of lobular inflammation (46,1% mononuclear, 11,7% polymorphonuclear); location of steatosis (64,2% azonal); presence of periportal fibrosis in the cases with no perisinusoidal fibrosis (34,4%). CONCLUSION: Our results suggest that original (1999) Brunt's NASH classification needs to be revised, and the features such as azonal distribution of steatosis, microvesicular steatosis, mononuclear cell predominancy in lobular inflammation and periportal fibrosis without perisinusoidal fibrosis are worth to be emphasized as seperate parameters.

PP2-284

THE VALUE OF CYTOKERATIN 20 AND 7 IN DETERMINATION OF PRIMARY AND METASTATIC LIVER ADENOCARCINOMAS

Funda Yilmaz[1], Deniz Nart[1], Banu Yaman[1], Serap Karaaslan[1], Murat Zeytunlu[2], Murat Kilic[2], Irem Paker[1], Ahmet Coker[1]
[1] University of Ege, Faculty of Medicine, Department of Pathology, Izmir, Turkey
[2] University of Ege, Faculty of Medicine, Department of General Surgery, Izmir, Turkey

The liver is a very common target of metastatic tumors. At the time of initial presentation, the localization of the primary tumor is frequently unknown. The histological examination of metastatic adenocarcinomas is not sufficient for diagnosis as it may have similar appearance with different primary localizations. However, accurate identification of the site of origin of metastasis has prognostic and therapeutic advantage for patients. Immunohistochemistry has an important role in identifying the primary site. Cytokeratin (CK) 20 and CK7 expression are the most helpful procedures in differential diagnosis. Seventy-two liver specimens (resection material and core needle biopsy) were evaluated (25 cholangiocarcinoma, 28 colorectal adenocarcinoma, 7 pancreatic adenocarcinoma, 6 extrahepatic cholangiocarcinoma, 4 gastric adenocarcinoma, 1 lung adenocarcinoma, 1 breast carcinoma). Primary tumor localization could be established in all. Immunohistochemical algorithm with two monoclonal CK antibodies, CK20 and CK7 was tested on 72 tumor sections. Statistical analysis was evaluated with Fisher's exact test. All metastatic colorectal adenocarcinomas were CK20 (+) (Fisher's exact test, $p<0,001$). The CK20 (+)/CK7 (-) pattern was highly characteristic for this group (23/28, %82). All primary cholangiocarcinomas were immunoreactive with CK7 (Fisher's exact test, $p<0,001$) and the CK20 (-)/CK7 (+) pattern seemed to be specific for cholangiocarcinomas (19/25, %76). Pancreatic adenocarcinomas showed CK20 (+)/CK7 (+) pattern in 6 out of 7 but there were not enough cases for statistical analysis. In conclusion, CK20 (+)/CK7 (-) pattern is highly accurate for the determination of colorectal origin whereas, CK7 (+)/CK20 (-) pattern is characteristic for cholangiocarcinomas.

PP2-285

COMPARISON OF DIFFERENT CHRONIC HEPATITIS SCORES WITH RESPECT TO INTEROBSERVER VARIABILITY: A STUDY OF TURKISH NATIONAL WORKING GROUP OF HEPATO-PANCREATO-BILIARY PATHOLOGY

Grading and staging of chronic hepatitis (CH) using a scoring system for the semiquantitative assessment of the severity of the histological lesions is still one of the valuable tools in the management of patients with CH. One of the criteria for the best scoring system is good interobserver variability. We carried out a blinded trial to assess the interobserver variability among five experienced hepatopathologists using the Knodell, Ishak, METAVIR systems. Forty-seven liver biopsies from 23 patients with chronic hepatitis C were scored separately by five pathologists on the slides stained with hematoxylin-eosine and routine connective tissue and iron stains. The results were analyzed using ICC (one-way random model), by using SPSS for Windows (version 13.0). P values less than 0.05 were accepted significant. Reliability was accepted good over 0.75, moderate

between 0.50- 0.75 and poor under 0.50. RESULTS: The best interobserver agreement was achieved using the fibrosis score in Ishak's system (ICC: 0.82) which was followed by METAVIR fibrosis score (ICC: 0.76). There was moderate agreement with Knodell fibrosis score (ICC: 0.71). For all scoring systems, the agreement between the five pathologists was poor for the assessment of lobular necroinflammatory activity, where as, it was moderate for interface hepatitis. For portal inflammation, which is not scored in METAVIR system, it was poor for Knodell and moderate for Ishak system. CONCLUSIONS: 1) the interobserver variability is acceptable for the assessment of stage (fibrosis) in the available scores, the most detailed (Ishak system) being the best; 2) the assessment of grade has great interobserver variability in all scoring systems.

PP2-286
COMPARATIVE EVALUATION OF HISTOLOGICAL FINDINGS IN CHRONIC HEPATITIS B AND C

Doinita Crisan[1], Delia Mihaela Herghea[2], Corneliu Dorin Olinici[1], Magda Petrescu[3], Liliana Rogojan[3]
[1] Dept of Pathology, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania
[2] Institute of Oncology, Cluj-Napoca, Romania
[3] Dept. of Pathology, Universitary Emergency Hospital, Cluj-Napoca, Romania

Background. It is generally agreed that liver biopsy is a very specific diagnostic tool used to assess the nature and the severity of chronic hepatitis. The morphology of the lesions produced by the hepatitis viruses B and C is not very specific and an accurate diagnosis is quite impossible without clinical and serological data. Aim. Comparative analysis of histological modifications in liver biopsy of patients with chronic hepatitis B and C. Material and Methods. We examined 324 consecutive percutaneous needle liver biopsies from patients with clinical diagnosis of chronic hepatitis B (67 cases) and C (257 cases). None of the patients in the study had serological evidence of co-existing viral hepatitis. The cases with histological liver cirrhosis were excluded. All specimens were fixed in formalin, embedded in paraffin, and cut at 5 µm. The slides were stained with haematoxylin and eosin, Masson trichrome, and Gomori reticulin. In order to asses the necroinflammatory activity and the fibrosis we evaluated the components of the Ishak modified histological activity index (HAI). The portal, periportal and lobular inflammation were graded into mild, moderate and severe. The scoring system for fibrosis included: no fibrosis (0); portal fibrosis (1); periportal fibrosis without septa (2); septa formation (3). Additional parameters like bridging necrosis (absent/present), lymph follicles formation (absent/present), cholestasis (absent/present) and steatosis (absent, mild, moderate, severe) were evaluated. Statistic analyses were performed with Winstat computer program. Differences were considered significant when P values were less than 0.05. Results. There were few significant differences between the two forms of hepatitis. Only the portal inflammation, the lymph follicle formation and the steatosis presented significantly higher values in patients with hepatitis C. Conclusion. The etiologic diagnosis of chronic viral hepatitis can not be made on histological bases.

PP2-287
SIGNIFICANCE OF HISTOLOGIC LESIONS OF PLACENTAL MEMBRANES IN DIAGNOSIS OF PLACENTAL HYPOXIA

Jerzy Stanek
Department of Pathology, Christchurch School of Medicine, Christchurch, New Zealand

Introduction. Features of global chronic placental hypoxia (preplacental, uteroplacental and postplacental) and acute hypoxia (infarctions) are well recognized placenta disc lesions. Only recently the clinical and placental correlations of acute (laminar necrosis) and chronic (microscopic chorionic pseudocysts) placental membrane lesions were recognized. However, the practical significance of hypoxic chorionic disc and placental membrane lesions have never been compared. Materials and Methods. 20 clinical (maternal and fetal) and 35 gross and microscopic placental features were compared ($\chi 2$) among 168 placentae having at least one disc lesion (infarct and/or global ischemia) and at lest one membrane lesion (microscopic chorionic pseudocysts and/or laminar necrosis) (Group 1), 750 placentae with at least one hypoxic disc lesion but no membrane lesion (Group 2), 480 placentae with at lest one membrane lesion but no disc lesion (Group 3), and 3192 placentae without hypoxic villous or membrane lesions (Group 4). Results. 30% of placentae showed histological hypoxic lesions. Of those, hypoxic membrane lesions without hypoxic villous lesions were seen in 30%, and in conjunction with villous hypoxic lesions, in 45% of placentae. Therefore, recognizing placental hypoxic lesions increases the sensitivity of placental examination in diagnosing placental hypoxia by 15%. Two thirds of preeclampsia cases were in Groups 1-3. Preeclampsia, chronic hypertension, abnormal cardiotocography, induction of labour, antepartum bleeding, caesarean sections, perinatal mortality, fetal growth restriction and some placental factors (abnormal coiling/insertion of umbilical cord, decidual arteriolopathy, meconium staining, perivillous fibrin deposition, retroplacental haematoma, erythroblastosis of fetal blood) statistically significantly ($p \leq 0.05$) correlated with hypoxic placental lesions, being in general the highest in Group 1. Two thirds of placentae did not show hypoxic lesions, congenital malformations and acute chorioamnionitis being most prevalent in Group 4. Umbilical cord compromise (clinical) and fetal thrombotic vasculopathy did not show significant distribution between Groups 1-4. Conclusion. Including placental membrane hypoxic lesions in the placental microscopic diagnosis increases the sensitivity of placental examination in the retrospective diagnosis of placental hypoxia. In the overwhelming majority of placentae there are no histological features of placental hypoxia either in membranes or chorionic disc as other types of pathology are more prevalent.

PP2-288
THIN CORD SYNDROME (TCS): A RARE CAUSE OF FETAL INTRAUTERINE DEATH

Horn Lars-Christian[1], Stepan Holger[2], Faber Renaldo[2]
[1] University of Leipzig, Institute of Pathology, Germany
[2] University of Leipzig, Department of Obstetrics & Gynecology, Germany

Background: Little attention has been paid to the pathologic features of the umbilical cord, which might fatally damage the fetus. We determined the association of hypercoiling (more than 1 coil per 5cm) and thinning with consecutive constriction of the umbilical vessels (thin-cord-syndrome; TCS) and intrauterine fetal death (IUFD). Methods: 303 cases of consecutive fetal autopsies over a five-year period, including spontaneous and induced abortions of the second trimester of pregnancy, were examined using a standardized protocol. Results: The mean maternal age was 28.5 years, the mean gestational age 19.1 weeks

(range: 12.6 – 24.5 weeks). Thirty-six percent of all cases were induced abortions because of congenital malformations, 8.9% resulted from legal abortions, regulated by German law. 167 cases (55.1%) were spontaneous abortion specimens. The leading cause for IUFD in the spontaneous abortion group was an amnion infection (34.7%), followed by abruptio placentae (15.6%). In 25.1%, placental dysmaturity with consecutive placental insufficiency was responsible for IUFD. Pathologies of the umbilical cord as the cause of IUFD were seen in 10.2% of the cases. Most of them (15/17) were cases with thin-cord-syndrome. In 14.4% of all spontaneous abortion specimens the cause of IUFD could not be determined by autopsy. There was an apparent difference in the frequency of thin-cord-syndrome in the spontaneous abortion group (15/167 = 9%) as compared to the non-spontaneous group (2/136 = 1.5%). Conclusions: A remarkably high percentage (17/303 = 5.6%) of all cases showed TCS. In case of spontaneous abortions, TSC was causative for intrauterine death in 9% (15/167). Careful pathologic examination of the umbilical cord is recommended to detect TCS and reduce the cases with unexplained intrauterine death.

PP2-289

IMBALANCE OF MONONUCLEAR CELL INFILTRATES IN THE PLACENTAL TISSUE FROM FETUSES AFTER SPONTANEOUS ABORTION VERSUS THERAPEUTIC TERMINATION FROM WEEK 8TH TO WEEK 12TH OF GESTATIONAL AGE

Maria Lambropoulou[1], Dimitrios Tamiolakis[1], John Venizelos[2], Theodoros Jivannakis[2], Ekaterini Chatzaki[2], Theodoros Constantinidis[2], Vasilios Liberis[3], Georgios Galazios[3], Panagiotis Tsikouras[3], Nikolas Papadopoulos[1]

[2] Department of Histology-Embryology, Democritus University of Thrace, Greece
[3] Department of Obstetrics & Gynecology, Democritus University of Thrace, Greece

Placental macrophages (Hofbauer cells) are located close to trophoblastic cells and fetal capillaries, which make them, perfect candidates for involvement in regulatory processes within the villous core. Their capacity of producing several cytokines and prostaglandin synthesizing enzymes, and expressing vascular endothelial growth factor, indicate possible role in the placental development and angiogenesis in order to support pregnancy. The numbers of cells expressing the various markers of the monocyte-macrophage lineage change throughout pregnancy. In the present study, we investigated the immunohistochemical expression of mononuclear infiltrations in paraffin embedded placentas, from fetuses after spontaneous abortion (8th, 10th, and 12th week of gestational age), and those after therapeutic abortion at the same time, using a panel of monoclonal antibodies for the identification of leukocytes (CD45/LCA), B-lymphocytes (CD20/L-26), T-lymphocytes (CD45RO/UCHL1), CD68 and CD14 cells. Immunologic factors in human reproductive failure are plausible mechanisms of infertility and spontaneous abortion. Approximately 25% of cases of premature ovarian failure appear to result from an autoimmune etiology. The recruitment of immune cells, particularly monocytes and T cells, neovascularization around foci of invading peritoneal lesions, and the possible development of antiendometrial autoantibodies support an immunologic basis of this disorder. Here we describe the detection, isolation and characterization of CD45RO, L26, and CD68/CD14 positive cells from human early pregnancy deciduas. These cells were found in close vicinity to endometrial glands, with preference to the basal layer of the decidua. We conclude that, 1) maternal cells, apparently CD45RO/UCHL1 positive cells, cross the maternofetal barrier and participate in spontaneous (involuntary) abortions, 2) a small proportion of maternal cells (approximately 30%), apparently CD68/CD14 positive cells also cross the maternal fetal barrier and cause growth delay and recurrent reproductive failure. Further investigation of involvement of the intercellular adhesion molecules 1 and 2, platelet endothelial cell adhesion molecule, vascular cell adhesion molecule and E-selectin in leukocyte accumulation will be needed to support the passage of maternal cells to the fetus. The results were statistically significant ($p<0.0001$, student's t-test).

PP2-290

A STROMAL MYOID CELL LINE PROVOKES THYMIC T-CELL IMMIGRATION AT THE SECOND AND THIRD GESTATIONAL TRIMESTERS

Maria Lambropoulou, Demetrio Tamiolakis, John Venizelos, Theodoros Jivannakis, Zoe Bili, Iordana Grammatikopoulou, Christos Gaitanidis, Sophia Iliopoulou, Vasilios Tsoulopoulos, Helias Papadopoulos, Nikolas Papadopoulos
Department of Histology - Embryology, Democritus University of Thrace, Greece

Background: Once lymphoid precursors enter the thymus form the blood stream, they come into contact with thymic stromal cells that guide their maturation into funcionally competent T cells. Thymic myoid cells are one such cell type. They have been described as a regular constituent of the thymus of embryonic and young vertebrates and express muscle proteins including myosin, desmin, acetylcholine receptor (AChR), C-protein, MyoD, troponin T, rapsyn, and utrophin. It has been emphasized recently that the thymic myoid cells play an important role in the protection of thymocytes from apoptosis, and in the process of T-cell differentiation and maturation. The aim of the present study is to provide a quantitative estimation of thymic myoid cells and T-cell population in different stages of development. A probable interaction between these two populations could explain an additional mechanism to the active T-cell migration from the thymus that is a direct contact to a specific myoid cell line. Materials and Methods: Paraffin-embedded specimens from the thymus of forty five human embryos at the first, second and third trimester of gestation respectively, were investigated by conventional histology, and immunohistology for the presence in the stroma of the thymic medulla, of myosin in the myoid cells, and UCHL1 (pan T- cell) antigen in the medullary thymocytes. Results: Our results demonstrated a quantitative difference in the second and third trimester of development concerning the expression of myosin in the stromal myoid cells of the thymic medulla over the equivalent expression of the protein in the first trimester. Similar changes in the above periods were found concerning the population of medullary thymocytes expressing UCHL1 antigen. Conclusions: Our results indicate that: 1) Thymic myoid cells play an important role in the thymic microenvironment as they are well conserved throughout species evolution. 2) The increased population of myoid cells in the medullary area during mid and late gestational age, in comparison with first trimester, probably reflects the increased demand of the growing fetus for mature T lymphocytes. Contractions of myoid cells mediated by their cytoplasmic structural proteins, including myosin which is well preserved during development, might aid the movement of thymocytes expressing UCHL1 antigen, across or out of the gland, suggesting a potential involvement of myoid cells in the thymic function. Further studies on larger series are needed to corroborate this.

PP2-291

BER-H2 (CD30) IMMUNOHISTOCHEMICAL STAINING OF HUMAN FETAL TISSUES

Maria Lambropoulou, Demetrio Tamiolakis, John Venizelos, Theodoros Jivannakis, Iordana Grammatikopoulou, Zoe Bili, Sophia Iliopoulou, Vasilios Tsoulopoulos, Helias Papadopoulos, Nikolas Papadopoulos
Department of Histology - Embryology, Democritus University of Thrace, Greece

OBJECTIVE: CD30 antigen has long been considered to be restricted to the tumour cells of Hodgkin's disease and of anaplastic large cell lymphoma as well as to T and B activated lymphocytes. It is now apparent that the range of normal and neoplastic cells, which may express CD30 antigen, is much wider than was at first thought. In order to gain insight into the physiological function of CD30 antigen, we studied the distribution of its expression in the tissues of fetuses from week 8th to week 16th. MATERIALS AND METHODS: We investigated the immunohistochemical expression of CD30 antigen in paraffinembedded tissue samples representing all systems from 30 fetuses after therapeutic abortion at 8th to 10th and 12th to 16th week of gestation, respectively, using the monoclonal antibody Ber-H2. RESULTS: Our results demonstrated that CD30 is expressed early in human fetal development (8th to 10th week of gestation) in several fetal tissues derived from all three germ layers (gastrointestinal tract, special glands of the postpharyngeal foregut, urinary, musculoskeletal, reproductive, nervous, endocrine systems), with the exception of the skin and hematolymphoid system (thymus), in which the antigen is expressed later on (10th week onwards). Expression of CD30 was restricted to the hematolymphoid system in the 12-16 weeks of gestation. No expression of the marker was observed in the respiratory and cardiovascular systems during the entire period examined. CONCLUSIONS: CD30 antigen is of importance in cell development, and proliferation. It is also pathway-related to terminal differentiation in many fetal tissues and organs.

PP2-292
HISTOPATHOLOGIC EVALUATION OF PLACENTAS AND CORRELATION WITH FETAL OUTCOME

Funda Canaz, Sare Kabukcuoglu, Turgay Sener, S. Sinan Ozalp
Departments of Pathology and Obstetrics and Gynaecology, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey

Background: Complete pathologic evaluation of placenta provides valuable information for perinatal care. Placental examination can answer specific questions about in utero insults, improvement of the risk assessment for future pregnancies and ascertainment of newborn risk for long-term neurodevelopment sequelae. Method: We conducted a prospective study of all pregnacies at 28 to 42 weeks of gestational age, delivered at the Department of Obstetrics and Gynaecology of Eskisehir Osmangazi University Hospital from November 2004 to July 2005. All maternal and neonatal records were reviewed. In this study, 329 placentas were examined macroscopically and microscopically by two pathologists. The study groups are classified according to the existence of maternal and fetal risk factors in pregnancies. Placentas from pregnancies with risk factors (n=237) and placentas from normal pregnancies (n= 92) were included in the study. Threehundredtwentynine singleton pregnancies showed significant correlation between the weight of placenta, the weight of newborn and gestational age (P<0.001). When these study groups were compared according to their histopathologic findings, it was found that there were more placental chorioamnionitis (P<0.001), acute and chronic intervillositis (P<0.05), central infarct (P<0.05) and abnormality of villous maturation (P<0.05) in the pregnancies having risk factors and these findings were statistically significant. Histopathologic findings including chorioamnionitis (p<0.001), funisitis (P<0.05), fibromusculer sclerosis (P<0.05), excessive syncytial knots (P<0.05), peripheral and central infarction (P<0.05), perivillous fibrin deposition (P<0.05) and presence of large infarct areas in gross examination (P<0.001) were significantly associated with perinatal morbidity in newborn. Presence or absence of villitis (P<0.001), deciduitis (P<0.05), hemorrhagic endovasculitis (P<0.05), perivillous fibrin deposition (P<0.05), maternal floor infarct (P<0.05), villous edema (P<0.001), nucleated fetal red blood cells in villous vessels (P<0.001) were significantly associated with perinatal mortality in newborn. In this study, the presence of perinatal morbidity, fetal and maternal risk factors were significantly associated with the type of health insurance of pregnant women (P<0.001). Conclusion: This study suggests that our hospital is an important reference center of region for high risk pregnancies and newborns and placental pathology should be a routine component of perinatal diagnosis.

PP2-293
THE EFFECTS OF AIR POLLUTION AND SMOKING ON PLACENTAL CADMIUM, ZINC CONCENTRATION AND METALLOTHIONEIN EXPRESSION

Hulya Cetin Sorkun[1], Ferda Bir[2], Metin Akbulut[2], Umit Divrikli[3], Gulten Erken[4], Huriye Demirhan[1], Ender Duzcan[2], Latif Elci[5], Ismail Celik[6], Unsal Yozgatli[7]
[1] Health Services Vocational School of Pamukkale University
[2] Department of Pathology, Pamukkale University
[3] Department of Chemistry, Pamukkale University
[4] Department of Physiology, Pamukkale University
[5] Department of Chemistry, Faculty of Arts and Science, Pamukkale University
[6] Department of Biochemistry, State Hospital, Denizli
[7] Department of Gynecology and Obstetrics, State Hospital, Denizli ,Turkey

Background: This study is designed to determine the placental zinc (Zn) and cadmium (Cd) levels in mothers who were smokers, mothers thought to be exposed to air pollution, and non-smokers to reveal the relationship among the expression of placental metallothionein (MT) binding these metals and blood progesterone level. Methods: Placental Zn and Cd levels were measured by atomic absorption spectrometry. Presence of placental MT was determined by immunohistochemically. Placental changes were examined by light microscope after H&E and PAS staining. Immunohistochemical MT staining, of syncytiotrophoblastic and villous interstitial cells were scored as positive or negative. Results: Among the 92 mothers included in the study, 33 were smokers (group I), 29 were exposed to air pollution (group II) and 30 were living in rural areas, not exposed to air pollution and non-smokers (group III). Mean birth weight of their off-springs was 3198.62±380.01 g and mean weight of the placenta was 561.38±111.55 g. In Group I, mean placental Cd and Zn were 0.063±0.022 μg/g and 39.84±15.5 μg/g, respectively, higher than other groups. In Group II, mean placental Cd and Zn levels were higher than those of Group III. Blood progesterone levels of subjects in Group I, (121 ng/mL) was the lowest of all groups. While the mean count of villi was highest in Group III; the highest mean count of syncytial knots was in Group II. Thickening of vasculo-syncytial membrane was most prominent in Group I. Similarly, MT staining was positive and very dense in 72.7% (24/33) of cases in Group I ($p \leq 0.05$). MT staining was positive in 69.0% (29/20) and denser in Group II cases compared to 36% (11/30) in Group III ($p \leq 0.05$). Conclusion: This study showed that smoking increased Cd levels in placenta and accompanied with an increase in placental MT expression immunohistochemically. The effects of exposure to air pollution are equally harmful as smoking related effects.

PP2-294
CHORANGIOSIS: THE POTENTIAL ROLE OF SMOKING AND AIR POLLUTION

Metin Akbulut[1], Hulya Cetin Sorkun[2], Ferda Bir[1], Ayhan Eralp[3], Ender Duzcan[1]
[1] Department of Pathology, School of Medicine, Pamukkale University
[2] Health Services Vocational School of Pamukkale University
[3] Department of Histology and Embriology, Gaziantep University, Turkey

Background: Chorangiosis is considered to be strongly associated with various feto-maternal and placental conditions including pre-eclampsia, diabetes, hypertension, major congenital anomalies, and has been found to correlate with increased fetal morbidity and mortality. In this study, our aim is to investigate the pathologic effects of maternal smoking, and air pollution on the pathogenesis of chorangiosis. Methods: We investigated 94 placentas macroscopically and microscopically over a three months period (March 2006-May 2006) at Denizli State Hospital with a hope to identify the frequency of chorangiosis and potential role of maternal smoking and air pollution. Placental changes were examined by light microscopy after H&E, and immunohistochemical evaluation of CD 34, CD 68, and muscle specific actin were used to confirm the diagnosis. Results: Among the 94 mothers included in the study, 33 were smokers (group I), 31 were thought to have exposed to air pollution (group II) and 30 were living in rural areas without air pollution and maternal smoking (group III). Chorangiosis were found in 16 % (15/94) of all placentas which they were composed of 7/15 (47 %) cases in group I, 5/15 (33 %) cases in group II and 3/15 (20 %) cases in goup III. Vascular changes were found mainly in the smoking and air pollution group. There appeared to be no correlation of these vascular changes with placental weight, parity, gestational age, major congenital anomalies, and maternal factors including diabetes and pre-eclampsia. Conclusion: We present the hypothesis that smoking and air pollution may have a contributory role in the development of chorangiosis. We suggest that chorangiosis may be just an adaptive response to maternal hypoxia and studies addressing the role of smoking and air pollution in chorangiosis may provide new insights into the pathogenesis of this condition.

PP2-295

MATERNAL VASCULOPATHY IN PREECLAMSPIA: TRIAL OF CORRELATION BETWEEN HISTOLOGICAL ABNORMALTIES IN PREECLAMPTIC PLACENTAS AND CLINICAL MANIFESTATIONS

Chatti Faten[1], Ben Abdelkader Atef[2], Hidar Samir[3], Bel Hadj Jrad Besma[1], Yacoubi Mohamed Tahar[2], Korbi Sadok[2]
[1] The High Institution of Biotechology, Monastir, Tunisia
[2] Department of Pathology, Farhat Hached Hospital Sousse, Tunisia
[3] Departement of Gynecology, Farhat Hached hospital Sousse, Tunisia

Background: Preeclampsia (PE) is associated with significant maternal and fetal morbidity and mortality. It is an idiopathic multisystem disorder linked to human pregnancy especially to the placental formation. Material and methods We investigated 129 preeclamptic placentas during a four year period (2003-2006) in order to identify the potential usefulness of the macroscopic and microscopic placental examination in corroboration between placental vasculopathy and clinical manifestations of the disease. This study was done at the department of pathology, Farhat Hached hospital. Only the placentas from preeclampsia complicated pregnancy was included, gestational diabetes and chronic vascular pathologies were eliminated. The diagnosis of preeclampsia was confirmed by the clinical criteria assigned on the ACOG (American College of Obstetricians and Gynecologists) classification.The placental lesions that were studied included maternal decidual vasculopathy, infraction, abruption placentae, intervillous thrombi, subchorionic thrombi, lesions of the stem villi (fibrosis, calcifications, thrombi, obliterative endarteritis) and NIFD (ischemic necrosis with fibrin deposition). Standard statistics including the student t test were used. Results Among women with PE, 16, 3% had severe disease and 70.5% were primigravid women. The gestational ages at the delivery ranged between 26 and 41 weeks of gestation. The frequencies of the placental lesions were respectively, decidual vasculopathy (17.1%), infraction (38.2%), abruption placentae (7%), intervillous thrombi (18.6%), subchorionic thrombi (5.4%), lesions of the stem villi (fibrosis (34.9%), calcifications (0.8%), thrombi (1.6%), obliterative endarteritis (10.1%) and NIFD (10.9%). These finding demonstrate that maternal vascular changes and NIFD which characterize the PE, are found in approximately (28%). The correlation study showed that the maternal vascular changes is significantly correlated with primigravid women (p=0.021) and the rate of intervillous thrombi is increased with lower gestational age (p=0.026). Conclusion A case controle study will be adequate to confirm the placental histological differences induced by the PE and a multivariate statistic analysis should be done in order to correlate the placental microscopic findings to the clinical manifestations of PE.

PP2-296

CORRELATION ANALYSIS OF THE FETO-PLACENTAL PARAMETERS IN CASES OF INTRAUTERINE FETAL GROWTH RETARDATION

Olga Reshetnikova, Olga Kononenko, Inna Goryanikova, Sergiy Morozov
Lugansk State Medical University, Lugansk, Ukraine

A number of studies suggest that some disproportions and restrictions in fetal and placental growth may lead to various pathologies in adults. The aim of the present research was to identify alterations in correlations between placental and fetal parameters in cases of fetal growth restriction (FGR) at 20-25 weeks of gestation (wg). Methods: 18 cases with FGR and high placenta/fetal weight index (PFI) compared with 20 controls in cases of induced abortions for socio-economic reasons at 20-25 wg. Recorded data included: weights of placenta (PW) and fetus (FW), fetus length (FL); head (Ch), chest (Cch), abdominal (Ca) circumferences, weights of fetal kidneys (KW), liver (LW) and heart (HW), as well as some indices(FPI, FW/FL, LW/PW, HW/PW, KW/PW). The correlation analysis of the morphometric data was performed. Results: FGR group had smaller parameters of FW, FL, Cch, Ch, and Ca. All FGR cases had decreased LW; KW and HW. PW was unchanged at 20-22 wg and increased at 23-25 wg, compared with controls. The negative correlation found between PW and LW/PW, FPI and LW at 20-22 wg and between PW and HW/PW at 23-25 wg. The longer gestation the more new positive strong correlations have discovered within the FGR group. Positive strong correlations discovered between FPI on the one hand and HW, KW, LW, KW/PW on the other hand. Conclusions: the study suggests that the increase in the number and the intensity of correlations between morphometric parameters might represent (a) a discrepancy between the fetal and placental growth at 20-25 wg and (b) alterations in fetal organ adaptation mechanisms, which may result in future pathologies.

PP2-297

ANALYSIS OF PERINATAL MORTALITY UNDER CONDITIONS OF THE EASTERN INDUSTRIAL REGION OF UKRAINE

Olga Reshetnikova, Inna Goryanikova, Olga Kononenko, Sergiy Morozov
Lugansk State Medical University, Ukraine

National data estimate the rapidly increasing rates of perinatal mortality in the Eastern Ukraine in the past several years. Probability of dying in perinatal period in Lugansk Region, Eastern Ukraine is higher that it can be expected in Ukraine (14, 4‰ compared with 8,3-8,7‰) The aim of the present study was to find out the main causes of the fetus and newborns death in the perinatal period in the industrial region of Ukraine. The statistical data derived from the registers of the Regional Children's Hospital of the City of Lugansk (Eastern Ukraine) for 2000-2006 were analyzed. The results have shown that 426 numbers of perinatal deaths reported in Lugansk region in 2000-2006, included 131 antenatal, 33 intranatal and 262 neonatal deaths. The death cause analysis showed that intrauterine death of the

fetus in the majority of cases resulted from hypoxia caused by acute or chronic placental insufficiency and maternal complications of pregnancy (pre-eclampsia, uterine rupture -18, 5% of cases). The developmental defects (33, 3%) and hypoxia (24, 2%) were responsible for the most cases of intranatal deaths. In 2000-2002, the infection pathology (toxoplasmosis, septicemia, pneumonia, and meningoencephalitis) was the biggest killer in neonatal period, being responsible for almost 27 deaths. The second main cause was cardio-vascular and central nervous systems pathology (25 cases). From 2003 until 2006, number of neonatal deaths from congenital defects (48 cases) exceeded the number of lethal infection pathology cases (23 cases). Conclusions The comparative analysis offered the main reasons for the high perinatal mortality rate in Eastern Ukrainian Industrial region, which include high exposure to environmental hazards, such as the Chernobyl clean-up and industrial pollution of the atmosphere. High rates of congenital defects may indicate the pathogenic impact of the long-term radiation factor on maternal health fetal development.

PP2-298
EXPRESSION FACTORS OF ANGIOGENESIS IN THE PLACENTA

Dmitriy Sokolov, Andrey Kolobov, Marianna Lesnichiya, Igor Kvetnoy, Olga Arzhanova, Selkov Selkov
Scientific Research Institute of an Obstetrics and Gynecology of a Name of D. O. Otta of RAMS, Russia

The purpose of the present research is analysis of change of an expression of the following factors and receptors in a tissue of a placenta in norm and at an eclampsia: VEGF, TSP-1, VEGF-R3, TGFγ-R1. In total 10 placentas pregnant with normal pregnancy (control) and 10 placentas pregnant with an eclampsia are investigated. A delivery carried out by caesarian sections. For carrying out of immunohistochemical reaction with antibodies to VEGF, VEGF-R3, TSP-1 and TGFγ-R1 (1:50, Novocastra) used the standard protocol. At immunohistochemical research of tissue specimens of a placenta it is marked, that expression VEGF-R3 cells of a syncytiotrophoblast of villi and decidual cells of a basal plate was lower at an eclampsia (the area of an expression 4,89±1,01%), than at normal pregnancy (11,7±0,52%, $p<0,05$). At immunohistochemical research of tissue specimens of a placenta it is marked, that expression VEGF cells of a syncytiotrophoblast and decidual cells of a basal plate was authentically lower at an eclampsia (0,58±0,13%), than at normal pregnancy (3,11±0,49%, $p<0,05$). On the contrary, expression TSP-1 was above at an eclampsia (0,61±0,05%), than at normal pregnancy (0,08±0,01%, $p<0,05$). Thus expression TSP-1 was marked in a stroma of villi and in the control is submitted by individual fields of positive reaction in the stromal elements located near to vessels of mediate villi while at an eclampsia had diffuse character and prevailed in stromal elements of terminal villi. Expression TGFγ-R1 was marked mainly in range of syncytial capillary membranes by cells of a syncytial nodes. Thus expression TGFγ-R1 was lower at an eclampsia (0,21±0,02%), than at normal pregnancy (0,96±0,25%, $p<0,05$). The low expression of VEGF and VEGF-R3 in a placenta, and a high expression of TSP-1 around of vessels of a placenta at an eclampsia reflects disorder of balance of proangiogenic and antiangiogenic factors aside the last, that can be the cause of disorder of processes of an angiogenesis in a placenta. Low expression TGFγ-R1 on endothelial cells of a placenta at an eclampsia can testify both to disorder of their function, and about compensatory reaction of these cells in reply to action of antiangiogenic factors. On the other hand, it is possible, that TGFγ-R1 doesn't accept appreciable participation in mechanisms of disorder of processes of an angiogenesis in a placenta.

PP2-299
COMPARISON OF PLACENTAL PTEN AND BETA1 INTEGRIN EXPRESSION IN EARLY SPONTANEOUS ABORTION, EARLY AND LATE NORMAL PREGNANCY

Cigdem Tokyol[1], Fatma Aktepe[1], Fatma Husniye Dilek[1], Mehmet Yilmazer[2]
[1] Afyon Kocatepe University Department of Pathology, Turkey
[2] Afyon Kocatepe University Department of Gynecology and Obstetrics, Turkey

Background: The objective of this study is to investigate the expression of PTEN and □1 integrin in placental tissues of early spontaneous abortion and first and third trimesters of normal pregnancy. Method: A total of 43 placental tissue samples were evaluated using immunohistochemistry for PTEN and □1 integrin. Group 1 included placental tissues of volunteer termination of normal pregnancy during the first trimester ((5-10 wk gestation). Group 2 included placental tissues of normal vaginal delivery at the third trimester of pregnancy (36-40 wk gestation). Group 3 included placental tissues of pregnancy termination because of spontaneous abortion during the first trimester (5-10 wk gestation). Women with serious systemic disease and anembriyonic pregnancies were not included in the study. Results: PTEN expression of villous trophoblast was decreasing as the pregnancy advanced. PTEN staining of decidual cells was significantly stronger in tissue samples from early spontaneous abortion than in tissue samples from early and late normal pregnancy ($p=0.003$, $p=0.001$, respectively). There was no significant difference between □1 integrin expression of villous trophoblast and decidual cells in three groups. Conclusion: Our findings suggest that altered patterns of PTEN expression may be associated with abortion, but it seems that □1 integrin does not contribute to this process as a signaling protein. Further evaluation is needed highlight this subject.

PP2-300
OSTEOGENESIS IMPERFECTA WITH STRAIGHT BONES

Mitul Sharma[1], Zosia Miedzybrodzka[1], Rajendranath Sinha[1], Robert Mcmahon[2], Graeme Murray[1]
[1] Aberdeen Royal Infirmary, Aberdeen
[2] Western General Hospital, Edinburgh, GreatBritain

BACKGROUND The term osteogenesis imperfecta (OI) encompasses a heterogeneous group of heritable connective tissue disorders, all of which are characterised by increased bone fragility leading to susceptibility to fracture and resultant skeletal deformity. The phenotypes range from those that are lethal in the perinatal period to those that are mild, and virtually asymptomatic. This variability has been attributed to a wide ranging array of genetic abnormalities in the genes COL1A1 and COL1A2. Of the four groups, OI type II is characterised by extreme bone fragility leading to intra-uterine or early perinatal death. Affected infants are small for gestational age (dwarfism). Here, we present a phenotypically normal fetus with radiographically diagnosed OI in whom further studies revealed a hitherto unreported mutation in the COL1A1 gene. It is possible that this new mutation is responsible for an unusual phenotype where OI is not associated with dwarfism. METHODS CLINICAL SUMMARY A primigravida presented at 20 weeks gestation. Ultrasound revealed deformity of the limbs together with dilated cerebral ventricles. Termination of pregnancy was undertaken and a severely macerated female fetus was delivered. On post mortem examination there was no evidence of dwarfism, or any other abnormality of the upper or lower limbs on external examination. In view of the ultrasound findings, however, a whole body X-ray was performed together with cytogenetic studies. RESULTS X-ray report: This revealed grossly abnormal appearances, classical of OI with multiple fractures involving all long bones and most of the ribs. The skull showed no ossification of the vault. Genetics report: Normal female karyotype. PCR

examination of genomic DNA revealed a missense substitution in exon 1 of COL1A1. This mutation is predicted to interfere with post-translational processing of the collagen pro-peptide. DISCUSSION The prenatal diagnosis of OI is usually straightforward due to dwarfism detected on ultrasound. In this case however, there was no phenotypical evidence of dwarfism, although a post-mortem X-ray showed the features typical of OI. Genetic studies detected a unique mutation in this case, hitherto not described in OI. It may possibly explain the absence of limb shortening. This case emphasises the importance of performing X-ray examination in all post-mortems on fetuses with ultrasound detected anomalies. It is possible that this case represents a sub-group of lethal type II OI. Unfortunately, loss of cell lines has rendered further detailed studies in this case impossible, but the possibility of other similar cases being detected in future exists.

PP2-301
GENERAL CHARACTERISTICS OF THE PERINATAL AUTOPSIES PERFORMED IN OUR CLINIC IN 2006
Ulviye Yalcinkaya, Omer Yerci
UUMS Department of Pathology , Turkey

Aim: Perinatal autopsy may reveal the reason in perinatal and neonatal deaths, may increase the accuracy of perinatal diagnostic methods, may help to predict the risk of recurrence, and may guide families in planning future pregnancies. Materials and Methods: In this study 39 cases sent to our Department of Surgical Pathology in UU School of Medicine for perinatal autopsy were evaluated. The gender, reasons of death in utero, abortion, and death after birth were noted. Special attention was paid on whether or not organ anomalies were present. Results: There was a 1.3:1 male to female ratio. There were 4 cases of death after birth, 14 cases of spontaneous death in utero, and 21 cases of medical abortion due to anomalies diagnosed after US scan and/or chromosome analysis. Central nervous system anomalies were the most frequent type of anomaly (n = 23). Conclusion: Perinatal autopsy may help diagnosing the reasons of perinatal death and thus may help prevent such deaths.

PP2-302
HERPESVIRUS INFECTION – APOPTOSIS AND ANGIOGENESIS IN HUMAN PLACENTA
Andrey Kolobov, Ludmila Koroleva, Dmitriy Sokolov
Ott's Institute of Obstetrics and Gynecology RAMS, Saint-Petersburg, Russia

The leading part in proliferation and differentiation endothelial cells plays the vascular endothelial growth factor (VEGF). Thus proliferate go in parallel with apoptotic changes. The purpose of the present research became studying expression in various parts of human placentas VEGF-R3, p53 and Mcl-1 in conditions of the infectious defeat caused by viruses of family of a herpes (a virus of a simple herpes and a cytomegalovirus). Material and methods: 81 placentas from herpesvirus by an infection, from them with a virus of a simple herpes - 32 supervision, with a cytomegalovirus - 43 supervision, a combination of two viruses - 6 supervision is studied. In control were 20 placentas without herpesvirus infection. Immunohistochemical studying expression VEGF-R3, p53 and Mcl-1 spent on the paraffin sections prepared from samples of placentas. Results: The area expression p53 in syncytiotrophoblast and cytotrophoblast has made in the central part of a placenta 1,40±0,24% (in control - 0,45±0,03%), in peripheral - 1,58±0,55% (in control - 0,39±0,05%) ($p<0,05$). In endothelial cells of umbilical vessels the area expression p53 was 2,28±0,19% (in control - 0,05±0,01%) ($p<0,05$). The area expression Mcl-1 has made in syncytiotrophoblast and cytotrophoblast of the central departments of a placenta 1,87±0,17% (in control - 2,7±0,14%), in peripheral - 1,53±0,02% (in control - 3,7±0,6%) ($p<0,05$). However, in endothelial cells of umbilical vessels the area expression below also has made 1,28±0,31% (in control - 1,16±0,3%) ($p>0,05$). At the same time, the increase in the area expression p53 and decrease in the area expression Mcl-1 in placentas with the chronic subcompensated insufficiency in comparison with placenta with the chronic compensated insufficiency is noted. The area expression VEGF-R3 in syncytiotrophoblast and cytotrophoblast has made in the central departments of a placenta 2,31±0,43% (in control - 3,71%±0,3%), in peripheral - 4,35±0,31% (in control - 5,92%±0,46%) ($p>0,05$). In endothelial cells of umbilical vessels the area expression VEGF-R3 was 2,8±0,1% (in control - 3,1±0,4%) ($p>0,05$). Thus, herpesvirus infection in a placenta leads to formation insufficiency of placenta through strengthening expression p53.

PP2-303
MORPHOGENESIS OF ENDOMETRIUM POLYPS CANCER
Irina Derizhanova, Vladimir Voloshin, Nina Voloshina
Rostov State Medical University, Russia

Aims: to study clinical particularities and the structure of the carcinoma arising in polyps of the uterus mucous membrane (EP). The data of the clinical observations were analyzed. Endometrium scraps and the exscised uterus bodies and appendages from 27 patients with histologically proved EP cancer were subjected to common histological and histochemical examinations, the receptors of estrogen (ER) and progesterone (PR), as well as the markers of Ki67 (MIB-1) proliferation and p53, bcl-2 àpoptosis being simultaneously clearly seen. Endometrioid adenocarcinoma (ÅÀ) was diagnosed in 20 of these patients. The patients' age averaged 51,8 years, most of whom had (75,0%) their menstrual cycle keeping. 85,0% of these patients suffered adiposity, 75,0% - had hypertension, 65,0 % - diabetes. In all 20 patients ÅÀ was accompanied with àdenomiosis, uterus leiomyoma and hyperplasia of the ovarium theca. 75,0 % of the patients demonstrated follicular cysts. In 15 cases ÅÀ in Ò1à stage was well differentiated (G1). In 5 patients with Ò1b stage EA was of grade 2 (G2). ÅÀ was found to develop in polyps with diffuse (12) or focal (8) complex atypical hyperplasia. Diffusal (7) or focal (13) simple (6) and complex (14) hyperplasia was seen in surrounding endometrium. The receptors of sexual hormones in epithelium polyps and ÅÀ were exhibited abundantly. As epithelium àtypia grew, the ER content, PR in particular, was noted to decrease. The expression of Ki67, p53 was gradually intensifying, it being best seen in the foci of a moderate differentiation. Serous (SA) adenocarcinoma (G2) of T1c, Ò2 stages was found in 6 women aged 62 – 75 - years - old with the episodes of bleeding during menopausa. The tumor was embedded in adeno-fibrous polyps accompanied by endometrium cyst atrophy. No sings of àdenomatosis and epithelium metaplasia were revealed. PR in the tumor was not revealed either. Poorly positive reaction to ER was demonstrated in some single epithelial cells, SA stroma and in the surrounding polyp. Expression Ki67 and p53 in cells was positively higher, compared to that of in the polyp surrounding epithelium and in àtrophic endometrium, with bcl-2 being reduced. In 1 patient aged 62 was found SA, moderate EA end centre endometrial intraepithelial carcinoma in adeno-fibrous polyps accompanied by the atrophic endometrium. Conclusion: Cancer formed in polyps was morphogenetically different. ÅÀ correspondent to estrogen-dependent neoplasia made up 74,1%. SA (22,2%) was considered to be estrogen-independent carcinoma.

PP2-304
MATURE PLACENTAL TERATOMA CASE REPORT
Nagehan Ozdemir Barişik[1], Melin Ozgun Gecer[1], Suzan Kucukyorganci[1], Aylin Ege Gul[1], Nimet Karadayi[1], Cem Cahit Barisik[2]
[1] Dr. Lutfi Kirdar Kartal Training and Research Hospital Department of Pathology, Turkey
[2] Haydarpasa Numune Training and Research Hospital Department of Radiodiagnostic, Turkey

Background: We report an an extremely rare case of mature teratoma in placenta.A search of English literature revealed less than 20 cases have been reported until now.
Case: The patient 27-year-old pregnant woman was admitted to our hospital for the delivery. Macroscopical examination of placenta revealed 10x10x6 cm. mass lesion located on fetal/maternal surface of placenta. The placenta was covered with amnion sac but lacks of umbilical cord. Histopathologic examination showed that the lesion was composed of dermal appendages, mature bone, cartilagineous tissue, smooth and striated muscle fibers. There were no immature tissues.
Conclusion: Mature placental teratoma was first reported by Morville in 1925. Pathological findings, histogenesis, differantial diagnosis with review of the literature will be discussed.

PP2-305
PERINATAL AUTOPSY EXPERIENCE OF CELAL BAYAR UNIVERSITY FACULTY OF MEDICINE:
Nalan Nese[1], Yesim Baytur[2], Nermin Tansug[3]
[1] Celal Bayar University Faculty of Medicine Department of Pathology, Turkey
[2] Celal Bayar University Faculty of Medicine Department of Perinatology, Turkey
[3] Department of Pediatrics, Turkey

BACKGROUND: If perinatal autopsy was performed in appropriate conditions it is very beneficial for parents. A good knowledge about frequency of anomalies and limitations of autopsy is very important. This is a perinatal autopsy archive study of our laboratory. METHOD: From 1997 to 2007 April, 152 perinatal autopsy were documanted and classified according to fetus week, anomalies and causes of abortion. From 11 week to one month newborn autopsies were included. RESULTS: 183 fetuses or newborns were sent to our department for autopsy. 31 of 183 were excluded because these are still not reported. 20/152 in term or premature newborns died because of after-birth reasons that were not noticed in utero. Remaining 132 fetuses were aborted during pregnancy for different reasons. Of them, 62 were aborted by drugs because of detected vital anomalies and 70 were spontaneously aborted. 77 cases were male and 64 were female. Sex and week of gestation were not pointed out in perinatal autopsy report in 11 and 9 cases, respectively, as these were small and autolytic fetuses. Placentas were not send in 20 of the 70 spontaneous abortion cases. In the remaining 50, 20 cases showed placental pathological findings which might be the cause of death and 12 cases proved neither fetal nor placental anomalies. 28/70 were extremely autolytic. Five of 152 were multipl pregnancies and 10/152 had umblical cord anomalies. Fetal anomalies were detected in 73 cases. Of these, 4 fetuses reported as hydrops and 2 as cystic hygroma. CVS anomalies in 19/73, skeletal system anomalies in 17/73, CNS anomalies in 42/73, GIS anomalies in 14/73, face anomalies in 11/73, urogenital system anomalies in 18/73, gastrochisis/ omphaleocel in 5/73 and severe respiratory system anomalies in 11/73 cases were detected. Examples of syndromes and chromosome anomalies were Down Syndrome, trisomy13 and trisomy18, Meckel-Gruber Syndrome, Fraser Syndrome, Potter sequence, Dandy-Walker Syndrome, Ellis-vanCreveld Syndrome, Turner Syndrome and Di George Syndrome. CONCLUSION: Most frequent anomalies were seen in CNS and most of them were neural tube defects, followed by CVS anomalies. Although the number of perinatal autopsies in Turkey increases, systematic autopsy can not be performed properly in many centers because of lacking experienced personal, time and genetic examination means. Lack of strong correlation between pathologists and clinicians is an other problem. In spite of all these difficulties, perinatal autopsy may give important information to parents and perinatologist for next time.

PP2-306
EXPRESSION OF VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF), HYPOXIA INDUCIBLE FACTOR 1 ALPHA (HIF-1α), TRANSFORMING GROWTH FACTOR-β1 (TGFβ1), AND (TGFβ3) IN GESTATIONAL TROPHOBLASTIC DISEASE
Filiz Bolat[1], Nihan Haberal[1], Nurdan Tunali[2], Erdogan Aslan[3], Nebil Bal[1], Ilhan Tuncer[1]
[1] Baskent University Faculty of Medicine, Department of Pathology, Turkey
[2] Cukurova University Faculty of Medicine, Department of Pathology, Turkey
[3] Baskent University Faculty of Medicine, Department of Gynecology and Obstetric, Turkey

Background: The aim of this study was to invastigate the relationship between vascular endothelial growth factor (VEGF), transforming growth factor (TGF-β1- TGF-β3) and hypoxia inducible factor 1 alpha (HIF-1α) expression in gestational trophoblastic diseases for clarifying the possible histogenesis. Methods: Twenty-one partial hydatidiform moles (PHM), 19 complete hydatidiform moles (CHM), 13 choriocarcinomas, and 20 nonhydropic spontaneous abortion (control group) were evaluated by means of immunohistochemical tecniques with antibodies to VEGF, HIF-1α, TGFβ1 and TGFβ3. Immunohistochemically, extent of positivity (0%=0, 1-24%=1, 25-49%=2, 50-74%=3, and greater than 75%=4) and intensity (no staining=0, weak staining=1, medium staining=2, and strong staining=3) were recorded. Results: The age range of the patients was 17-88 years (mean age, 27.97±9.28 years). The expressions of VEGF in spontaneous abortion and choriocarcinoma higher than in the PHM and CHM. HIF-1α was strongly expressed in the choriocarcinoma than the other subgroups. Nonhydropic spontaneous abortion (control group), showed the highest TGFβ1 expressions among the case subgroups, followed by PHM, CHM, and choriocarcinoma ($p<0.001$). The expression of TGFβ3 was seen all groups, but its level was maximally expressed in choriocarcinoma. Conclusions: Expression of these molecules and detection of correlation between some molecules showed that the pathogenesis of gestastional trophoblastic disease is a complex mechanis. Highest VEGF, HIF-1α, TGFβ3 expression in choriocarcinoma might be involved in the development of tropoblastic diseases.

PP2-307
HISTOPATHOLOGICAL EXAMINATION OF PLACENTAS WITH ANTIPHOSPHOLIPID SYNDROME
Diana Staribratova
Plovdiv Medical University, Bulgaria

Antiphospholipid syndrome is characterized by recurrent arterial or venous thromboembolism or pregnancy loss in association with antibodies directed against anionic phospholipids or plasma proteins bound to anionic phospholipids. METHODS: We examined sera and placenta tissue from 6 patients in reproductive age with antiphospholopid syndrome and 6 controls. RESULTS: Positivity for anti-phospholipid antibodies was found mainly against anti-prothrombin antibodies in 32%, and anti-annexin V antibodies in 43.5% women. No significant levels of aPLs were found in 6 controls. Immunohistopathology of placenta (p53) also exhibited some biological changes in the trophoblast presented by apoptotic bodies and necrotic cells in trophoblast, and very few microtrombotization in some intervillous spaces and in placenta vessels. CONCLUSION: Though routine histological examination of placentas in the setting of antiphospholipid syndrome can provide important clinical information in a minority of cases, our study shows the persistence of pathological placental findings consistent with aPLs antibodies as one of the high risk factor of repeated reproductive failure.

PP2-308

A COMPARATIVE EVALUATION OF APOPTOSIS AND GROWTH FACTORS IN FETAL KIDNEYS AND CYSTIC RENAL DISEASES

Filiz Bolat, Nurdan Tunali
Cukurova University Faculty of Medicine, Departments of Pathology Adana, Turkey

Background: In this study, the severity and distribution of transforming growth factor-α (TGF-α), vascular endothelial growth factor (VEGF) expression and apoptosis were evaluated in adult kidney tissue, fetal kidney tissue, autosomal recessive polycystic kidney disease (ARPKD), and cystic renal dysplasia (CRD). Methods: 28 cystic renal diseases (22 CRD, and 6 ARPKD), 15 fetal kidney tissue (5 from each gestational stage), 5 adult kidney tissue samples were analysis immunohistochemically for apoptosis, TGF-α and VEGF expression. Staining of cells was scored as no staining (-), weakly staining (+), and strongly staining (+++) for TGB-α and VEGF. Apoptosis was evaluated by TUNEL method. Results: With the last stages of gestation, the staining severity of TGF-α and VEGF decreased in the proximal tubules of the fetal kidney tissues ($p<0.001$). In all the gestational stages, strongly positive staining was observed in the distal tubules. In collecting ducts and in the epithelial members of the nephrogenic zone, weakly staining was observed. In the indifferentiate mesenchyme of the nephrogenic zone and in the kidney medulla, no staining was observed. In the adult renal tissues, the proximal tubules were weakly stained with TGFα, while the distal tubules and collecting ducts were strongly stained. However, the proximal tubules and collecting ducts were mildly stained with VEGF, while the distal tubules were strongly stained. In cases with RPKD and CRD, larger cyst were faintly stained with TGF-α and VEGF, whereas smaller cysts were intensely stained. In all three trimesters of gestation, the proximal-distal tubules and collecting ducts of the fetal kidney tissues had few apoptosis development. With the last stages of gestation, the rate of apoptosis decreased in the undifferentiated mesenchyme of nephrogenic zone ($p=0.003$), while the rate of interstitial apoptosis increased ($p=0.006$). In the cases with RPBH and CRD, the rate of apoptosis in cysts of larger diameter was higher than that in the cysts of smaller diameter. Conclusions: TGFα has a mitogenic effect on the growth of fetal kidneys especially seen in proximal tubules. Parallelism between VEGF and TGFα expression suggested that these growth factors may play an important role in the renal development. Apoptosis is thought to be important for the management of cell proliferation as are the growth factors in nephron morphogenesis. Our findings indicated that in cystic renal diseases, TGFα, VEGF, and apoptosis have a role in cyst development and growth.

PP2-309

A 10 YEAR RETROSPECTIVE ANALYSIS OF FETAL NEONATAL AUTOPSIES

Engin Cigerciogullari[1], Figen Aksoy[1], Beyhan Tuysuz[2]
[1] Istanbul University, Cerrahpasa Medical Faculty, Department of Pathology, Istanbul, Turkey
[2] Istanbul University, Cerrahpasa Medical Faculty, Department of Pediatrics, Istanbul, Turkey

AIM AND METHOD: 902 autopsies between 10 weeks of gestation-deaths in first month of life, applied in Cerrahpasa Medical Faculty between 1995-2005 were selected for the analysis. The cases were divided into the following groups: Major abnormalities involving 1 organ system, 2- 3 organ systems, external abnormalities (limbs, face, ear), syndromes, associations, metabolic diseases, infections, neoplasms, cystic hygromas, immune and non-immune fetal hydropses , placental pathologies (infections, ischemic causes, miscallenaous causes and two additional groups. One group was negative autopsies defined as autopsies with no detected macroscopical (internal-external) or histopathological abnormalities. The other group was fetal losses due to intrauterine mechanical factors or complications of prematurity. CONCLUSIONS: The largest group in number was negative autopsies (32%, 293/902). A negative autopsy is itself a diagnosis and is important for follow up of future pregnancies. The second largest group was placental pathologies, infectious subgroup (10%, 94/902). The infections seem to be an important cause of fetal losses. It rises to 15% (133/902)together with infections of fetus. The largest subgroup having 1 major abnormality was fetuses with central nervous system (CNS) abnormalities (9.5%, 86/902). Another notable finding was the frequent involvement of renal system in two major abnormalities group (84%, 16/19). Abnormalities of other organ systems were carefully looked for when renal abnormality was detected in screenings. 1/3 percent of single umbilical artery cases are accompanied by CNS abnormalities. That is why a careful search is needed for additional CNS abnormalities on single umbilical artery cases.

BILATERAL SERTOLI -LEYDIG TUMOR OF THE OVARY WITH RETIFORM PATTERN

Amel Trabelsi, Sarra Mestiri, Atef Ben Abdelkader, Med. Tahar Yacoubi, Badreddine Sriha, Sassi Bouguizéne, Sadik Korbi
Pathology Department, F. Hached Hospital, 4000 Sousse, Tunisia

Background: Sertoli-Leydig tumor of the ovary is rare, representing less then 1 % of all ovarian tumors. The mean age of patients is usually 25 years, and is usually unilateral. The retiform pattern is seen in young patients and malignancy depend on differentiation at histopathological examination. Method: We report a case of 35 year-old woman that consulted in emergency for an acute abdominal pain. Results: Radiological investigations showed a right ovarian tumor. The patient underwent a right ovariectomy with biopsy of the peritoneum. Histological examination concluded to a Sertoli-Leydig tumor with a retiform pattern; One year later, the patient presented with a left ovarian mass. Microscopically, the mass was also a Sertoli-Leydig tumor with a retiform pattern. Clinical outcome was favourable with no local recurrence two years after. Conclusion: Sertoli-Leydig tumor of the ovary is rare and is usually unilateral; malignancy is based on the degree of differentiation at histopathological examination.

PP3-2
PRIMITIVE NEUROECTODERMAL TUMOR OF THE CERVIX: A CASE REPORT

Amel Trabelsi, Sarra Mestiri, Lilia Ben Yacoub-Abid, Fatma Kebir, Soumaya Rammeh, Moncef Mokni, Atef Ben Abdelkader, Sadok Korbi
Service de Pathologie, Hopital F. Hached, 4000 Sousse, Tunisia

Background: Primitive neuroectodermal tumor of the cervix is extremely rare in this location, raising for the pathologist differential diagnosis difficulties. Immunohistochemistry is of great value to lead to the correct diagnosis. Method: We report a case of 50 year-old menopausal Tunisian woman who presented with vaginal bleeding. Physical examination revealed a 2,5 cm cervical exophytic mass. Results: The specimen biopsy showed a round small cell malignant proliferation. Diagnosis of primitive neuroectodermal tumour of the cervix was retained after immunohistochemical results (positivity of mic-2 : CD 99). The patient underwent a radical surgical treatment followed by adjuvant chemotherapy. Clinical outcome was marked by local recurrence 18 months later and the patient died 6 months later. Conclusion: Primitive neuroectodermal tumor of the cervix is uncommon, raising diagnostic difficulties. Its prognosis is usually unfavourable.

PP3-3
OVEREXPRESSION OF LAMININ-5 GAMMA 2 CHAIN IN CLEAR CELL CARCINOMA OF THE OVARY

Noriko Kato, Teiichi Motoyama
Department of Pathology, Yamagata University School of Medicine, Japan

Background: One of the characteristic microscopic features of ovarian clear cell carcinoma (CCC) is the densely hyaline basement membrane material expanding the stroma. The biological significance of this material, however, has remained unclear. Recent studies have shown that laminin-5 (LN-5), a major component of the epithelial basement membrane, plays a more active role in cell migration or tumor invasion. Method: Twenty-five surgically resected CCCs were examined for LN-5 expression immunohistochemically, using an antibody against LN-5 gamma 2 chain. For comparison, 5 borderline clear cell tumors, 10 serous adenocarcinomas, and 10 endometrioid adenocarcinomas were examined. Three CCC cell lines were analyzed in vitro for migration over excessive recombinant LN-5, with or without function-blocking antibody against integrin α3. Results: All of the 25 CCCs showed a focal or diffuse immunoreactivity with the LN-5 gamma 2 chain in the tumor stroma; whereas, borderline clear cell tumors, serous or endometrioid adenocarcinomas rarely showed a stromal immunoreactivity. Cytoplasmic accumulation of the LN-5 gamma 2 chain was far less common than stromal accumulation, suggesting an accelerated secretion in CCC. In vitro, CCC cell lines showed a significant increase of cell migration over excessive LN-5, and the migration was blocked by an antibody against integrin α3. Conclusion: The stromal accumulation of the LN-5 gamma 2 chain is common in ovarian CCC but rare in borderline clear cell tumors or other ovarian carcinomas. It is indicated that an interaction between CCC cells and extracellularly accumulated LN-5 is responsible for cell migration and the subsequent stromal invasion of CCC.

PP3-4
REDUCED EXPRESSION OF THE METASTASIS SUPPRESSOR KAI-1 IN UTERINE TUMORS OF EPITHELIAL AND STROMAL ORIGIN: CORRELATION WITH P53 STATUS

Juliane Nowak[1], Christoph M. Bamberger[2], Thomas Loning[3], Maria Sajin[4], Karin Milde-Langosch[5], Sylvia L Asa[6], Ana-Maria Bamberger[2]
[1] Department of Pathology, University of Toronto, Canada
[2] Section on Endocrinology and Metabolism of Ageing, University Clinic Hamburg - Eppendorf, Hamburg, Germany
[3] Department of Pathology, Centre for Cytology and Gynecopathology, Germany
[4] Department of Morphopathology, University of Bucharest, Bucharest, Romania
[5] Department of Gynecology, University Clinic Hamburg-Eppendorf, Hamburg, Germany
[6] Department of Pathology, University of Toronto, Canada

Background: The ability of tumor cells to metastasize often requires additional genetic changes, which result in activation and inactivation of metastasis stimulating and metastasis suppressor genes. Recently KAI1 has emerged as a tumor-suppressor and more specifically as a metastasis suppressor. A loss of KAI-1 expression is associated with the advanced stages of many human malignancies and results in the acquisition of invasive and metastatic capabilities by tumor cells. The underlying mechanisms responsible for this down-regulation of KAI-1 expression remain to be resolved. Method: In the present study, immunohistochemistry and Western blot analysis were performed on uterine tumors, hyperplasias and normal endometrium to investigate the expression pattern and cell-type specific localization of KAI-1 and to correlate it with the expression of p53 and histological and clinical data. Result: 29 (69.04%) of 42 endometrial carcinomas showed reduced or absent KAI-1 expression, which correlated with strong expression of p53 ($P < 0.001$). 13 tumors (30.95%) of 42 demonstrated a moderate score (4-7) of Kai-1 expression. It is interesting that these carcinomas were all well-differentiated tumors of malignancy grade G1/G2, which showed low expression of p53. There were significant correlations between KAI-1 expression and histological type, tumor grading and clinical stage ($P < 0.001$). Most of the investigated sarcomas of the uterus (including 5 carcinosarcomas, 8 endometrial stromal sarcomas and 2 leiomyosarcomas) were clearly negative for KAI-1, whereas these tumors displayed a strong immunostaining for p53. Conclusion: In conclusion, our results demonstrate a strong inverse correlation between KAI-1 and p53 expression and it thus seems, that reduced KAI-1 expression possibly as a result of disregulated/mutated p53 gene could be an important step in uterine carcinogenesis.

PP3-5
COMPARION OF MICROIMMUNOFLUORECENCE, ELISA, RAPID DETECTION KIT (DIMA) AND GIMENEZ STAINING FOR DETECTION OF CHLAMYDIA INDUCED CERVICITIS

Nour Amirmozafari, Homa Forohesh, Liella Gang
Iran University of Medical Sciences, School of Medicine, Tehran, Iran

Backgroud: Chlamydia trachomatis is one of the most prevalent causative agent of STD. It causes a variety of genital tract complications such as urethritis, cervicitis, endometritis, epididymitis, and lymphogranuloma venereum. The prevalence rate of Chlamydia cervicitis is varied in different societies. In a recent study, the rate in sexually active American women was in the range of 5-15%. The purpose of this study was to evaluate the prevalence rate of Chlamydia induced cervicitis in Iranian women, and to compare the efficacy of different detection techniques. Method: A total of 137 women with cervicitis were admitted for this study. Two endocervical swabs were obtained. One was used for the rapid Dima test, and the other swab was subjected to Gimenez staining. Blood samples were also obtained for serological tests. Results: ELISA indicated that 18 patients had positive IgG antibody levels in their blood, and 4 of them had IgM antibodies against Chlamydia trachomatis. Ten patients had significant IgG levels and 3 of them had anti-Chlamydia IgM according to the MIF test results. Dima rapid detection test was able to show positive results for only 5 patients. We were not able to detect any Chlamydia inclusion bodies with direct microscopy after Gimenez staining. Conclusion: The MIF technique which is generally considered to be the Gold Standard serological detection method, showed the prevalence rate of Chlamydia cervicitis to be 7.2%. There was no statistically significant difference in IgM titers detected by ELISA and MIF methods. But there was statistically significant different IgG titer rates between ELISA and MIF. Therefore, it is suggested that any ELISA positive IgG titer samples be rechecked and reconfirmed by MIF. Due to the lack of any Chlamydia inclusion body detection by direct microscopy, Gimenez staining is not recommended as a diagnostic tool.

PP3-6
ACCURACY AND RELIABILITY OF FROZEN SECTION DIAGNOSIS IN A SERIES OF 183 OVARIAN TUMORS

Farah-Klibi Faten
Charles Nicolles Hospital Tunisia

Objective: Frozen section is an important diagnostic tool in determining the nature of ovarian masses. However, it still has some pitfalls. This retrospective study was conducted to determine the accuracy of frozen section diagnosis of ovarian masses and to discuss the type and the reasons of inaccuracies associated with this procedure. Methods: From January 2002 to April 2005, 183 ovarian specimens were examined by frozen section. The frozen section results were compared with the final diagnosis in paraffin sections. The sensitivity (Se), specificity (Sp) and predictive values of frozen section diagnosis were calculated. The 95 % confidence interval of each parameter was determined. Results: Ovarian masses accounted for 11,1 % of all specimens examined extemporaneously. The frozen section diagnosis was benign in 85,8 % of the cases, borderline in 3,8 % and malignant in 7,7 %. The frozen section diagnosis was deffered to permanent sections in 2,7 % of all cases. Overall diagnostic agreement was 96,6 % (Kappa=0,85). Six cases (3,4 %) were incorrectly diagnosed by frozen section. There was one false-positive and five false-negative cases. All of them were due to erroneous interpretation. The majority of the cases of disagreement were mucinous and borderline tumors. The Se for benign, borderline and malignant tumors were 99,3 %, 66,7 % and 87,5 % respectively. The Sp for benign tumors was 80 %, for borderline tumors 99,4 % and for malignant tumors 100 %. The positive predictive value was 96,8 % for benign tumors, 85,7 % for borderline tumors and 100 % for malignant tumors. Conclusion: Frozen section diagnosis seems to be a reliable method for the surgical management of patients with ovarian masses with a high sensitivity for malignant tumors and a low false-positive rate. However, diagnostic problems can occur in mucinous and borderline tumors wich require extensive sampling.

PP3-7
OVEREXPRESSION OF COX-2 AND HER-2/NEU IN PAGETS´S DISEAE OF THE VULVA AND THE BREAST

Lars-Christian Horn[1], Sandra Purz[1], Christine Krumpe[1], Karl Bilek[2]
[1] University of Leipzig, Department of Gynecologic & Perinatal Pathology, Germany
[2] University of Leipzig, Department of Obstetrics & Gynecology, Germany

Background: Paget´s disease (PD) of the breast as well as the vulva is a rare condition that accounts for about 4% of breast neoplasms and 1% of vulvar malignancies. Recurrent disease after breast and vulvar surgery might be a challenge. To evaluate therapeutically relevant molecules, tissue from mammary and vulvar PD lesions was investigated immunohistochemically. Methods: Histopathologic samples from eleven patients with mammary PD and eight patients with vulvar PD were stained with antibodies against estrogen and progesterone receptors, HER-2/neu and COX-2 followed by semiquantitative evaluation of the staining results. Results: All tested mammary lesions as well as seven out of eight vulvar PD were negative for estrogen and progesterone receptor. Strong membranous staining for HER-2/neu (Score 3) was seen in all cases. Six out of eight vulvar and ten out of eleven mammary PD showed COX-2 overexpression. Conclusions: PD of the breast and the vulva is not under hormonal control of estrogens and progesterons, therefore, anti-hormonal therapy is not indicated. The high frequency of Her-2/neu and COX-2 overexpression, however, suggests that these molecules could be therapeutically relevant in patients with PD. These results require further investigation.

PP3-8
HIGH FREQUENCY OF LYMPHOVASCULAR INVASION IN EARLY ADENOCARCINOMA OF THE UTERINE CERVIX

Keiko Abe[1], Chikako Suzuki[2], Atsushi Arakawa[2], Masaaki Suzuki[3], Toshiharu Matsumoto[2]
[1] Department of Humanpathology, Juntendo University School of Medicine, Sanikukai Hospital, Tokyo, Japan
[2] Department of Obstetrics and Gynecology, Juntendo University School of Medicine, Japan
[3] Sanikukai Hospital, Tokyo, Japan

Abstract Backgrounds: The prognostic factors of adenocarcinoma of the uterine cervix were said to be the stage of disease and lymph node metastasis. The incidence of lymph node metastasis was reported to be significantly higher in the patients with adenocarcinoma than in those with squamous cell carcinoma of the uterine cervix even in stage Ib. The other report said that the risk of nodal metastases is higher in the patients with cervical adenocarcinoma showing stromal invasion over 5mm in depth. These studies suggested that lymphovascular involvement increased in the early stage of adenocarcinoma of the uterus. Methods: There were eight patients who underwent radical hysterectomy and bilateral salpingo-oophorectomy in 2000-2006 at Sanikukai Hospital in Tokyo. The average age of the patients was 47.1 years (36-75 in range). One or two specimen were selected for the following examinations. Each specimen was stained with Hematoxyline-Eosine and Elastica-van-Gieson. Immunohistochemical staining was also performed for anti-D2-40. Results: Histological type of the eight patients was four

endometrioid type, two endocervical type and two adenocarcinoma in situ. Stages of eight patients with cervical adenocarcinoma showed that 4 cases of stage Ib2, two cases of stage Ib1 and two cases of adenocarcinoma in situ. Three cases of four Ib2 cases showed prominent lymphatic invasion. Two of the four Ib2 cases revealed vascular invasion. Lymph vessel invasion was found on the peripheral area of the tumor, with the background of markedly lymph vessel proliferation. On the other hand, both stages of Ib1 and adenocarcinoma in situ did not show any lymphovascular involvement. No lymph nodes metastasis was found in all of the eight cases. Conclusion: Lymphovascular invasion was frequently observed in adenocarcinoma of the uterine cervix stage Ib2 even in the condition of no lymph nodes metastasis.

PP3-9

LYMPHANGIOLEIOMYOMATOSIS IN THE FEMALE GENITAL TRACT

Takuo Hayashi[1], Toshio Kumasaka[1], Keiko Mitani[1], Yasuka Miyakuni[1], Yoko Gunji[2], Koichi Suda[1], Kuniaki Seyama[2]
[1] Department of Humanpathology of Juntendo University School of Medicine, Japan
[2] Department of Respiratory Medicine of Juntendo University School of Medicine, Japan

Background: Lymphangioleiomyomatosis (LAM) is a rare, multisystem disorder of unknown etiology that affects exclusively young women and characterized by proliferation of abnormal smooth muscle-like cells (LAM cells). LAM is usually recognized of its pulmonary manifestations characterized by cystic destruction of the lung parenchyma due to proliferation of LAM cells. LAM cells can also involve the extrapulmonary organs including the lymphatic system. However, through analysis of female genital tract in patients with LAM has not been reported. Method: Six cases with LAM involving the female genital tract (3 surgical specimens and 3 autopsy cases) were collected from archives of the Department of Humanpathology at Juntendo University. A uterus was cut from cervix to fundus to identify the LAM lesions (average, 26.4 specimens per case; range, 2-78). Adnexa were serially cut from isthmus to fimbria at 5-mm thickness, including ovary and mesovarium (average, 16.4 specimens per case; range, 2-30). Retroperitoneal lymph nodes were obtained from 5 cases. Immunohistochemical staining was carried out using monoclonal antibodies against α-smooth muscle actin (α-SMA, dilution 1:200, Dako Cytomation, Carpinteria, CA), HMB45 (dilution 1:50, Dako Cytomation), Flt-4 (VEGFR-3,dilution 1:50,R&D Co Ltd., Minneapolis, MN), and CD10 (dilution 1 : 200, Novocastra Laboratories Ltd., New Castle, UK). Results: 1) Patients' age ranged from 25 to 83 years (mean 41.3 years) when the specimens were obtained. Two patients had tuberous sclerosis complex (TSC). 2) All cases showed LAM lesions in the adnexa and the retroperitoneal lymph nodes, while four of 5 cases did them in the uterus. 3) LAM lesions were detected in the serosa and/or subserosa of the uterus in all cases. However LAM lesions were not identified in the endometrium. 4) Proliferating patterns of LAM cells in the uterus were categorized into two types: nodular and diffuse type. All of sporadic LAM patients revealed nodular type and two TSC-LAM patients did diffuse type of uterine LAM lesions. 5) LAM cell clusters (LCCs) in the lymphatic vessels were detected in all cases. Conclusion: The anatomic distribution of LAM in the female genital tract is similar to that of metastatic cancers to the uterus, and LAM lesions are accompanied by LCCs in the lymphatic vessels in all cases. These results suggest that LAM lesions in the female genital tract may be disseminated from the extragenital tract through lymphatic vessels.

PP3-10

COX- 2, HER- 2/NEU AND HORMONE RECEPTOR ANALYSIS IN PRIMARY PAPILLARY CARCINOMA OF THE PERITONEUM

Lars-Christian Horn[1], Sandra Purz[1], Michael Hockel[2], Jens Einenkel[2]
[1] Institute of Pathology, Division of Gynecologic and Perinatal Pathology, University of Leipzig, Germany
[2] Department of Obstetrics and Gynecology, University of Leipzig, Germany

Background: Primary peritoneal carcinomas (PPC) are rare but aggressive malignancies. Evaluating therapeutic relevant molecules PPC were investigated immunohistochemically. Methods: 26 PPC were stained with antibodies against estrogen and progesterone receptors, HER-2/neu and COX-2 with semiquantitative evaluation of the staining results. Results: Twenty one out of the 26 PPC (80.8%) were negative or showed only weak expression for estrogen receptor. One half of the tumors showed moderate or strong positivity for progesterone receptor. Only three PPC (11.5%) showed strong immunoreaction for HER-2/neu (Score 3). Nearly two thirds of the PPC represented COX-2 overexpression. Conclusions: PPCs are probably not under hormonal control of estrogens and lack HER-2/neu overexpression in the majority of cases. So, anti-hormonal or antibody therapy with herceptine is not indicated. The use of COX-2 inhibitores might be helpful in PPC.

PP3-11

ALTERATION OF CELL-CYCLE REGULATORY PROTEINS AND TUMOR BIOLOGY OF SMALL CELL NEUROENDOCRINE CARCINOMAS OF THE UTERINE CERVIX

Lars-Christian Horn[1], Jeanett Edelmann[2], Bettina Hentschel[3], Karl Bilek[4], Uwe-Gerd Liebert[5], Jens Einenkel[4], Steffen Hauptmann[6], Cornelia Leo[4]
[1] Institute of Pathology, Division of Gynecopathology, University of Leipzig, Germany
[2] Institute of Legal Medicine, University of Leipzig, Germany
[3] Institute of Medical Informatics, Statistics and Epidemiology, Germany
[4] Department of Obstetrics and Gynecology, University of Leipzig, Germany
[5] Institute of Virology, University of Leipzig, Germany
[6] Department of Pathology, University of Halle-Wittenberg, Germany

Background: Small cell neuroendocrine carcinomas (SmCC) of the uterine cervix are rare tumors. The knowledge regarding protein-expression of several checkpoint candidates of cell-cycle-regulation, their proliferative activity and the prognostic impact of only focal neuroendocrine differentiation is limited. So, SmCC were identified from our files and studied immunohistochemically with HPV-analysis. Methods: Immunohistochemical anlysis consisted neuroendocrine markers, p53, p16, p14. pRb-1, cyclin D1 and Ki-67. PCR-analysis, using general primers was performed for HPV-analysis. In cases with mixed tumors, the percentage of SmCC-component was calculated and correlated with survival. Results: Nine out of 677 tumors (1.3%) were classified as SmCC after Grimelius-staining and immunohistochemistry for NSE, chromogranin A, synaptophysin and CD 56. Two SmCC`s represented p53- and one case p14-positivity. Cyclin D1-staining was completely negative. All buat one SmCC were negative for pRb-1. All cases showed strong nuclear and/or cytoplasmic p16-immunostaining. Seven tumors represented HPV-positivity for high risk types. Four patients died of the tumor after a median time of 36.7 months (range 15 to 56 months), representing a 5-year-survival-rate of 56%. Even a SmCC-component of 17% was associated with fatal course in mixed cases. SmCC represented significant lower proliferation (Ki-67 labeling-index) than the non-small-cell

component in the same tumor (12.8 vs. 70.8%; p<0.001). Conclusions: The overexpression of p16 in all cases but a loss of cyclin D1 and pRb1 in the majority of cases, might indicate a widespread disruption of the Rb-pathway which could be responsible for the aggressive course of SmCC. Even a small SmCC-component in mixed carcinoma of the uterine cervix was associated with adverse outcome. Proliferative activity, determined by Ki-67 labeling index, is of no prognostic value.

PP3-12
ASSOCIATION OF P63 WITH TUMOR CELL DISSOCIATION AND JUXTATUMORAL STROMAL REMODELLING IN CERVICAL CARCINOMA

Lars-Christian Horn[1], Nicole Hommel[1], Bettina Hentschel[2], Karl Bilek[3], Ulrike Roschlau[1], Ulf-Dietrich Braumann[4], Jens Einenkel[3]
[1] Institute of Pathology, Division of Gynecologic Pathology University of Leipzig, Germany
[2] Institute for Medical Informatics, Statistics and Epidemiology, University of Leipzig, Germany
[3] Department of Obstetrics and Gynecology, University of Leipzig, Germany
[4] Interdsiziplinary Centre of Bioinformatics, University of Leipzig, Germany

Background: p63 (syn. KET and p51) is located at the short arm at chromosome 3 (3q27-29) with tumor suppressive and oncogenic properties. Its overexpression has been reported in carcinomas of the head and neck and the lungs. The present study evaluates p63-expression on carcinoma of the cervix uteri in correlation to tumor-stromal interaction. Methods: Paraffine embedded tumoral tissue from 140 patients with cervical carcinoma FIGO stage III and IV, treated with radiation therapy, were examined immunohistochemically. Staining results were evaluated using an immunoreactive score (staining intensity (1-3) x percentage of positive stained nuclei). The score values were compared to histologic tumor type, tumor grade, pattern of invasion and grade of juxtatumoral stromal remodelling (i.e. desmoplastic change). Results: Squamous cell carcinomas showed more often p63-expression than adenocarcinomas (p=0.0001). Poorly differentiated tumors (grade 3) represented a reduced p63 expression (p=0.001). Carcinomas with high tumor cell dissociation (characterised by spray-like pattern of invasion) and those with strong peritumoral stromal reaction were also associated with a loss of p63-expression (p<0.02 and p=0.074). There was no correlation between p63-expression and response to radiation therapy nor to overall survival. Conclusions: p63 is associated with high tumor cell dissociation and strong remodelling of juxtatumoral stroma in carcinoma of the cervix uteri. But, the mechanism how acts p63 in the context of the alteration of tumor cell adhesion and stromal remodelling is not well understood at time.

PP3-13
PATTERN OF INVASION (TUMOR CELL DISSOCIATION) AS PROGNOSTIC FACTOR IN CARCINOMA OF THE UTERINE CERVIX

Lars-Christian Horn[1], Uta Fischer[2], Bettina Hentschel[3], Georgios Raptis[1], Karl Bilek[2], Christine E Richter[1], Ulf-Dietrich Braumann[4], Jens Einenkel[2]

[2] Department of Obstetrics and Gynecology, University of Leipzig, Germany
[3] Institute for Medical Informatics, Statistics and Epidemiology, University of Leipzig, Germany
[4] Interdisciplinary Centre of Bioinformatics, University of Leipzig, Germany

Background: Different patterns of invasion (representing different grades of tumor cell dissociation) are associated with prognostic outcome in cancer. We evaluated the prognostic value of different patterns of invasion (PI) in cervical carcinomas (CX). Methods: 611 surgically treated CX (FIGO IB to IIB) were re-evaluated histologically regarding the PI, using a three-level scoring system. Closed PI was defined as cohesive growth with well-delineated (pushing) borders. In finger-like PI the tumor grows in solid cords/trabecles. Highly dissociative growth in small groups or single cells was defined as spray-like PI. Types of PI were correlated to tumor stage, histo-morphologic factors and prognostic outcome. Results: 60% of the tumors showed a spray-like PI, 30% a finger-like PI, and only 7.4% were of the closed type. Spray-like PI showed a significant correlation with advanced stage disease, lymphovascular space involvement, poorly differentiated tumors and pelvic lymph node metastases. Spray-like PI was accompanied by a reduced 5-year overall survival when compared to the finger-like and closed PI (68.7% vs. 80.9% vs. 88.5%; p=0.0004). The prognostic impact of the PI disappeared in node-positive patients (p=0.06), but persisted in patients without pelvic lymph node disease (p=0.03). In multivariate analysis, using COX-regression model, the PI represented as independent prognostic factor. Conclusions: Spray-like PI, (i.e. highest degree of tumor cell dissociation) is associated with advanced tumor stages, increased rate of recurrency and a reduced overall survival. In separate analysis of patients with and without lymph node metastases, the impact of PI persisted only in node-negative cases as an prognostic factor.

PP3-14
SURVIVIN EXPRESSION IN THE MANAGEMENT OF ENDOMETRIAL CANCER PATIENTS

Maria Lambropoulou[1], Dimitrios Stefanou[2], George Alexiadis[1], Grigorios Tripsianis[3], Demetrio Tamiolakis[1], Ekaterini Chatzaki[4], Vasilis Liberis[5], Nikolas Papadopoulos[1]

[4] Department of Pharmacology, Democritus University of Thrace, Greece
[5] Department of Obstetrics & Gynecology, Democritus University of Thrace, Greece

Background: Survivin is a member of the inhibitor of apoptosis (IAP) family and is also involved in the regulation of cell division. Our objective was to study survivin expression in endometrial cancer and its correlation to clinicopathological parameters. Materials and Methods. A series of 110 cases of primary untreated endometrial carcinoma hosts were studied. Survivin immunoreactivity was assessed by immunohistochemistry using a polyclonal antibody, and evaluated semiquantitatively according to the percentage of cells demonstrating distinct nuclear or diffuse cytoplasmic staining. Correlation was made with tumor stage, grade, myometrial invasion, and histologic type. Association with disease outcome was also investigated. Results. Survivin overexpression, indicated by nuclear and cytoplasmic staining of at least 10% of the tumor cells, was found in 47 (42.7%) cases. A statistically significant association was demonstrated between survivin overexpression and FIGO stage (p=0.048), histological grade (p=0.024) and myometrial invasion (p=0.021). No significant association was found with histologic type of the tumor (p=0.164). Interestingly, patients with survivin positive tumors had significantly shorter survival rate (p=0.048). Conclusions. Survivin is a specific marker of endometrial cancer and strongly correlates with tumor stage, grade and myometrial invasion. It is also an independent prognostic indicator of poor outcome.

PP3-15

PROGNOSTIC SIGNIFICANCE OF CYTOPLASMIC EXPRESSION OF C-erb-B2 IN ENDOMETRIAL CARCINOMAS

Maria Lambropoulou[1], Dimitrios Stefanou[2], George Alexiadis[1], Demetrio Tamiolakis[1], Grigorios Tripsianis[3], Ekaterini Chatzaki[4], Gerasimos Vandoros[1], Anastasia Kiziridou[1], Nikolas Papadopoulos[1]

[1] Department of Histology-Embryology, Democritus University of Thrace, Greece

[2] Department of Pathology, University of Ioannina, Greece

[3] Department of Medical Statistics, Democritus University of Thrace, Greece

[4] Democritus Department of Pharmacology, University of Thrace, Greece

Overexpression of the epidermal growth factor type II receptor c-erb-B2 has been associated with resistance to chemotherapy and poor survival in several human tumors. The aim of this study was to investigate the expression of cerbB2 in endometrial cancer with attention both to membranous and cytoplasmic staining, to study its correlation to established clinicopathological parameters, and to elucidate the significance of cytoplasmic signaling. Tumor tissue from 110 patients with primary untreated endometrial carcinomas was available. C-erb-B2 reactivity was assessed by immunohistochemistry using a polyclonal antibody, and evaluated semiquantitatively according to the percentage of cells demonstrating membranous or diffuse cytoplasmic staining. Correlation was made with tumor stage, grade, myometrial invasion, and histologic type. Association with disease outcome was also investigated. C-erb-B2 overexpression, indicated by membranous and cytoplasmic staining of at least 10% of the tumor cells, was found in 47 (42.7%) cases. Cytoplasmic expression of c-erb-B2 was observed more frequently than membranous (69.09% versus 5.5%), and was correlated to established clinicopathological parameters. Synchronous cytoplasmic and membranous signaling was noticed in 7.9% of cases. A statistically significant association was demonstrated between c-erb-B2 overexpression and FIGO stage (p=0.048), histological grade (p=0.024) and myometrial invasion (p=0.021). No significant association was found with histologic type of the tumor (p=0.164). Interestingly, patients with c-erb-B2 positive tumors had significantly shorter survival rate (p=0.048). These results indicate that c-erb-B2 is a specific marker of endometrial cancer and strongly correlates with tumor stage, grade and myometrial invasion. It is also an independent prognostic indicator of poor outcome. C-erb-B2 antibody demonstrated a similar cytoplasmic and membranous staining. Cytoplasmic staining is as important as membranous staining and is a specific finding as well.

PP3-16

IMMUNOHISTOCHEMICAL EXPRESSION AND CORELATION OF PROLIFERATING CELL NUCLEAR ANTIGEN (PCNA) AND MIB1 IN HYPERPLASTIC AND NEOPLASTIC ENDOMETRIUM: POSSIBLE PROGNOSTIC VALUE

Ermina Iljazovic[1], Elmir Čičkusic[1], Zinaida Karasalihovic[1], Jasminka Mustedanagic[2], D. Ljuca, Silvija Avdic[1], Jugoslav Stahov[3]

[1] University Clinical Center Tuzla, Polyclinic for Laboratory Diagnostic, Bosnia and Herzogovinia

[2] University Clinical Center, Clinic for Gynecology and Obstetricion, Bosnia and Herzogovinia

[3] Statistic Department, Nature Mathematic science, University of Tuzla, Bosnia and Herzogovinia

Background: Endometrial neoplasia describes a spectrum of proliferative disease that constitues both a morphologic and biologic continuum beginning with mild hyperplasia and ending with poorly differentiated adenocarcinoma. The proliferative activity of a hyperplasia and tumor has long been considered to bear a relationship to its clinical course. The main goal is to examine immunohistochemical expression of proliferation indices (PCNA and MIB1) in hyperplastic endometrium and endometrial adenocarcinoma and to identify possible prognostic value one of them. Methods: We conducted a retrospective study of 60 patients who had simple (n=20), complex (n=20) endometrial hyperplasia with or without atypia and endometrioid adenocarcinoma (n=20). The archival paraffin blocks from the uterine specimens were recut and assessed for histologic reexamination and PCNA and MIB1 immunostaining. Results were statistically analyzed with respect to marker expression and localization to the stromal or glandular component. Results: The PCNA index in the all forms of hyperplasia and adenocarcinoma was higher than MIB1 index (p< 0,0001; CI: 95,1%, median difference 4,5) in both, stroma and glandular components. There were no significant differences (one-factor analysis of variance [ANOVA]) in PCNA expression in hyperplastic endometrium and endometrial adenocarcinoma (F=0.48; P= 0 62; df =2,57). The MIB1 score was significantly lower and more heterogeneous in different hyperplastic and neoplastic lesions. Statistically significant difference (Scheffe test) was found in MIB1 immunoreactivity between simplex and complex hyperplasia (p= 0,0006), and complex hyperplasia and adenocarcinoma (p<0,0001), while there is no difference between simplex hyperplasia and adenocarcinoma (p=0.84). Conclusion: PCNA has a higher but constant expression in endometrial carcinoma and in hyperplasia than MIB1. These findings support that MIB1 may play a role in endometrial carcinogenesis, and that MIB1 index seems to be a better and significant prognostic parameter in hyperplastic endometrium than PCNA.

PP3-17

A STUDY COMPARING EFFECTS OF INTRAUTERINE LEVONORGESTREL AND SYSTEMIC MEDROXYPROGESTERONE AS TREATMENT FOR ENDOMETRIAL HYPERPLASIA. ASSESSMENT BY LIGHT MICROSCOPY AND MORPHOMETRY

Anne Oerbo[1], Anne Beate Vereide[2], Marit Arnes[3], Kurt Larsen[1], Inger Pettersen[1], Bjorn Straume[4]

[1] Department of Pathology, University Hospital of Northern Norway, N-9038 Tromsø, Norway

[2] Department of Obstetrics and Gynecology, University Hospital of Tromsø, N-9038 Tromsø, Norway

[3] Department of Pathology, Institute of Medical Biology, Faculty of, Norway

[4] Institute of Community Medicine, Faculty of Medicine, University of Tromsø, N-9038 Tromsø, Norway

Background: Endometrial carcinoma, showing increasing incidence in the Western world is generally developing through endometrial hyperplasia. Correct diagnostics and optimal treatment of endometrial hyperplasia is therefore of great importance. The female sex steroid hormone progesterone and different synthetical mimics, progestins, have shown a potent antiproliferative effect in the human endometrium. This effect has been utilized in clinical regimens in the treatment of endometrial proliferative disorders, endometrial hyperplasia as well as endometrial cancers. According to the literature no standard therapy regimen for progestine has been agreed upon in treatment of endometrial hyperplasia. To investigate if local application of the levonorgestrel impregnated intrauterine device was a better therapy for endometrial hyperplasia (EH) compared to per oral gestagen treatment, two patient groups were compared. The diagnostic evaluation was based on subjective (WHO criteria) and objective (prognostic data-based morphometric and stereological method/ D-score, predicting the risk of cancer development for each single patient) evaluation. Method: Women between 30 and 70 years with EH and D-score>0 were treated with levonorgestrel impregnated intrauterine device (n=26) and the results compared to a historic group of women treated with

per oral gestagen (n=31). In both treatment groups only patients with low risk (D-score >1) and uncertain risk (D-score 0-1) of cancer development were included. Endometrial specimens were investigated prior to treatment and after 3 months of therapy. The endometrial samples from the two groups were examined by light microscopy and objective databased morphometry to assess tissue characteristics and to evaluate nuclear size variation. Results: After 3 months all patients treated with levonorgestrel intrauterine device showed regression of hyperplasia, whereas, 14 of 31 patients in the per oral group still had persisting disease. Morphometric analysis showed reduction in nuclear size for both treatment groups, including the D-score >1 as well as the D-score 0-1 patients. However, the reduction was most obvious for the levonorgestrel intrauterine device treated patients with initial D-score of 0-1. Conclusion: The present study indicates that levonorgestrel intrauterine device is a superior alternative to per oral treatment of endometrial hyperplasia. This study showed that the hyperplasia patients with the highest malignant potential (D-score 0-1) were those taking most benefit from local high dose levonorgestrel therapy.

PP3-18

bcl-2, BAX AND APOPTOSIS IN ENDOMETRIAL HYPERPLASIA AFTER HIGH DOSE GESTAGEN THERAPY

Anne Oerbo[1], Anne Beate Vereide[2], Turid Kaino[3], Georg Sager[4]
[1] Department of Pathology, Institute of Medical Biology, Faculty of, Norway
[2] Department of Obstetrics and Gynecology, University Hospital of Tromsø, N-9038 Tromsø, Norway
[3] Department of Pathology, University Hospital of Northern Norway, N-9038 Tromsø, Norway
[4] Department of Pharmacology, Institute of Medical Biology, Faculty of, Norway

Objectives. The aim of the study was to investigate apoptosis as a growth regulatory mechanism of gestagen in endometrial precancers and to compare differences in the immunohistochemical expression of proteins in the apoptotic cascade after high and low dose gestagen regimens. Method. Pre- and post treatment paraffin-embedded endometrial hyperplasia specimens from women treated with levonorgestrel intrauterine device (n = 26) and women treated with 10 mg medroxyprogesterone for 10 days per cycle (n = 31) were examined for changes in the expression of Bcl-2 and BAX and the amount of apoptosis after 3 months of treatment. Expression in tissue specimens for Bcl-2 and BAX were evaluated by H-score. Apoptosis was assessed by counting apoptotic cells per 100 negative cells within ten different high power field (40X). Results. All the patients in the IUD group (n=31) but only about half of the patients in per oral group (16 of 26) responded to treatment. The glandular reduction in Bcl-2 expression was markedly greater for the IUD patients than for the patients who received oral gestagen. The decrease in BAX expression after IUD treatment was less than the reduction of Bcl-2. Decrease in glandular Bcl-2 after 3 months of treatment was coincident with a significant increase in the measurable amount of apoptotic bodies. In stromal cells increase in expression of Bcl-2 and BAX was found after gestagen treatment, the response being more extensive for the IUD group. The non- responders had no Bcl-2 expression in stroma after 3 months of therapy. The number of apoptotic bodies in endometrial glands increased significantly after 3 months of treatment with gestagen intrauterine device. No difference was observed for the per oral therapy. Conclusion. Our results indicate that proteins in the apoptotic cascade are regulated by gestagen therapy in human endometrial precancers. Expression of these proteins is shown to be dependent on type and administration form of the gestagen. Stromal Bcl-2 expression appears to be a potential biomarker which can separate responders of gestagen treatment from non-responders after oral administration.

P16 INK4A IMMUNOSTAINING: A USEFUL TOOL TO IDENTIFY OCCULT PREMALIGNANT LESIONS OF THE UTERINE CERVIX IN HPV-POSITIVE PATIENTS

Susana Moyano[1], Stefania Landolfi[1], Sonia Garcia[2], Natalia Basini[1], Immaculada Alonso[2], Elias Campo[1], Aureli Torné[2], Jaume Ordi[1]
[1] Department of Pathology, Hospital Clinic, Barcelona, Spain
[2] Department of Obstetrics and Gynecology, Hospital Clinic, Barcelona, Spain

Background: The usefulness of p16INK4a in reducing interobserver variability; its ability to detect small foci of cervical intraepithelial neoplasia (CIN); and the close relationship between high-risk human papillomavirus (HR-HPV) infection and CIN, led us to evaluate whether p16INK4a staining could help to recognize under- or over-estimated CIN lesions, which may have clinical impact in the management of cervical disease. Method: Of 1259 women having a histological study and a simultaneous HR-HPV detection using the Hybrid Capture 2 (HC2) test, we selected all patients (n=139) testing positive for HR-HPV having a negative biopsy (group A), 26 women testing negative for HR-HPV with a biopsy of CIN 1 (group B) and 11 women testing negative for HR-HPV and having a biopsy of CIN 2-3 (group C). The following groups were randomly selected as controls: 50 cases negative for HR-HPV and with negative biopsy (group D); 50 cases positive for HR-HPV and with biopsy of CIN1 (group E) and 50 cases positive for HR-HPV and with biopsy of CIN2-3 (group F). Results: All cases from group D were either completely negative or showed only focal p16INK4a immunostaining, whereas all biopsies from group F were positive for p16, with 98% showing diffuse and strong staining. Thirty-four out of 139 biopsies (24.5%) from the group A were positive for p16INK4a. Thirty of these cases (21.6%) were reclassified as harboring a CIN (11 CIN 1, 19 CIN 2/3) after reevaluation. Both the number of cases reclassified as CIN of any grade or as CIN 2/3 were significantly higher for cases with HR-HPV load above 100 RLU ($p<0.005$). Conclusion: Our results indicate that particular attention should be paid to biopsies from patients having positive HC2. The risk of harboring small foci of CIN of any type or a CIN 2/3 is significantly higher for patients with high HR-HPV load. Immunostaining with p16INK4a should be considered as a highly desirable adjunct to the histologic evaluation of cervical biopsy specimens.

PP3-20

ATYPICAL (BIZARRE) STROMAL CELLS IN VARIOUS CONDITIONS OF THE FEMALE GENITAL TRACT: AN IMMUNOPATHOLOGIC REPORT OF 9 CASES

Stolnicu Simona[1], Gonzalez-Rocha Talina[2], Mendoza Eladio[3], Nogales Francisco F[2]
[1] University Of Medicine Targu Mures, Romania
[2] University Of Granada, Spain
[3] Hospital Virgen Del Rocio, Seville, Spain

INTRODUCTION: Atypical stromal cells of the female genital tract have been reported in various conditions of the vulva, vagina, cervix and endometrium, predominantly associated with polypoid lesions. Their atypicality includes them in the differential diagnosis of various conditions. Their origin and pathogenesis are unknown. MATERIAL AND RESULTS: We describe the presence of atypical stromal cells in a series of 8 cases comprising: fibroepithelial polyp of the vulva (1), fibroepithelial polyps of the vagina (3), normal cervix (1), of stromal response to a squamous carcinoma of the cervix (1 case) and endometrial polyps (2). Immunohistochemical studies were performed in order to elucidate its origin and proliferative capacity using the following antibodies:CAM 5.2, desmin, S 100 protein, actin, caldesmon, RE, RP and Ki 67. CONCLUSIONS: These studies demonstrated fibroblastic or myofibroblastic features, suggesting that they may represent a reactive or degenerative process of mesenchymal stem cells from

subepithelial stroma. Although they have a benign clinical course, awareness of the pathologic and immunohistochemical spectrum of these cells is crucial in their correct differentiation from other lesions as microinvasive carcinomas, sarcomas, blue nevi and intermediate trophoblastic lesions, which also exhibit bizarre stellate cells. The differentiation with superficial myofibroblastoma is difficult since this entity does also share this cellular component that originates from a specialized band of subepithelial mesenchyme in the lower female genital tract

PP3-21

FOLLICULAR-LIKE PATTERN IN METASTASES OF FEMALE GENITAL TRACT LEIOMYOSARCOMAS AND RHABDOMYOSARCOMAS. A PITFALL IN DIFERENTIAL DIAGNOSIS

Simona Stolnicu[1], Talina Gonzalez-Rocha[2], Jose Fernandez Aneiros[3], Luis Jose Sarasa[3], Lucian Puscasiu[1], Francisco F Nogales[4]

[4] University Of Medicine Granada Spain

INTRODUCTION: We present an unusual and unreported follicular-like change in the abdominal and vaginal metastases of four cases of leiomyosarcoma (LMS) and rhabdomyosarcoma (RMS) of the female genital tract; three of them originated in the uterus and the remaining one in the vaginal wall. RESULTS: This pattern was not present in the primary tumour and consisted in a moderately atypical spindle cell population, sometimes exhibiting lobular growth, which presented many pseudofollicular spaces with an apparent cuboidal lining and basophilic contents in their lumina. Primary tumours corresponded to 3 highly differentiated leiomyosarcomas of the uterus and vagina respectively and a carcinosarcoma with rhabdomyosarcoma component in the remaining one. Immunohistochemically, the tumour cells from the primary and metastases were diffusely positive for vimentin, actin, desmin, caldesmon and myosin in the last case, which demonstrated the smooth or striated muscle identity of the tumours. The luminal contents were positive for both mucicarmine and PAS stains. CONCLUSIONS: Since similar follicular- like spaces are characteristic of tumours such as juvenile granulosa cell tumour (JGCT)and small cell carcinoma associated with hypercalcemia (SCC with HC), this phenomenon should be taken into account in their differential diagnosis which should also include the alveolar patterns of various sarcomas as well as malignant melanoma which also may conform such pseudofollicular spaces.

PP3-22

REPRODUCIBILITY OF CERVICAL HISTOLOGIC INTERPRETATIONS BETWEEN PATHOLOGISTS

Alenka Repše Fokter, Simona Šramek Zatler, Boris Kavčič, Zlatko Iternička, Marjeta Jene Kladnik
Department of Pathology and Cytology, Celje General Hospital, Celje, Slovenia

Background: The interpretive reproducibility of cervical cytology and histopathology is critical to cervical cancer prevention programs. In the medical community, histopathologic interpretations are generally considered as the reference standard upon which treatment of cervical disease is based. Therefore the aim of our study was to determine the interpathologist and intrapathologist reproducibility of histologic cervical specimen interpretations at our Department. Methods: We reviewed 60 randomly selected histologic cervical specimens, which were originally diagnosed by one of four pathologists at our Department. The original number of specimens was equally distributed between the pathologists (each pathologist 15 specimens). After review we calculated intraobserver reproducibility for each pathologist (15/15) and interobserver reproducibility, where all the pathologists had to interpret all 60 histologic specimens. We also compared cytologic and histologic interpretations if cytologic interpretations were available. Results: The average interobserver agreement was 73,8% (70% - 78,3%). The lack of reproducibility was most evident for negative and less severe interpretations. For high grade SIL lesions the average reproducibility was 91,7% (88,9%-97,2%). The average intraobserver agreement was 76,7% (60%-86,7%), and for high grade lesions 93,8%. Cyto-histologic correlation showed excellent results (100%) for H-SIL lesions and moderate for low grade lesions. Conclusion: Interpretive variability is substantial in cytology and histopathology. Our results showed excellent reproducibility of cervical histologic specimens for high grade squamous lesions and only moderate for low grade squamous lesions, which is in concordance with some previous studies on larger series.

PP3-23

OVARIAN CELLULAR FIBROMAS: A CLINICOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL ANALYSIS OF TEN CASES

Neli Basheska, Irina Prodanova, Katerina Kubelka-Sabit, George Zografski
Department of Histopathology and Clinical Cytology, Institute of Radiotherapy and Oncology, Medical Faculty, Skopje, Republic of Macedonia

BACKGROUND: Traditionally, cellular fibroblastic tumors of the ovary were classified as either cellular fibroma (CF) or fibrosarcoma. A recent study suggests that cellular fibromatous neoplasms with bland cytology and elevated mitotic counts are associated with favourable prognosis and should be diagnosed as "mitotically active cellular fibroma" (MACF) rather than fibrosarcoma. In addition to clinicopathological features, immunohistochemistry may aid in further differentiating between CF and MACF, but its role has not been analyzed so far. METHOD: We retrospectively analyzed the clinicopathological and immunohistochemical features of 10 cases of ovarian cellular fibroblastic tumors diagnosed either as CF or fibrosarcoma in the last seven years. Patient records and archival pathology specimens were reviewed and immunohistochemistry was performed using pan-cytokeratin, EMA, vimentin, inhibin-alpha, calretinin, CD10, CD99, alpha-smooth muscle actin (SMA), desmin, S-100, c-kit, estrogen (ER), progesterone receptor (PR), p53, bcl-2, and MIB-1 antibody. RESULTS: Utilizing criteria proposed by Irving et al. the tumors were reclassified as CF (0-3 MFs/10 HPFs, n=5) and MACF (>4 MFs/10 HPFs, n=5). The mean age of patients with CF and MACF was 44 and 36 years, respectively. All tumors were unilateral, and the mean tumor size of CFs was 6.0 cm and 13.3 cm for MACFs. The majority of the tumors were solid; four of them had a cystic component, while ovarian surface rupture was present in one CF and one MACF. All tumors consisted of cellular, intersecting bundles of spindle cells showing slight or moderate pleomorphism. The mean highest mitotic count was 2.3 MFs/10 HPFs for CF, and 7.6 MFs/10 HPFs for MACFs. Follow-up of 4 to 79 months (mean 38 months) was available in 9 patients and was uneventful in all cases. One patient with MACF died 15 days following the operation as a result of the intercurrent disease. Immunohistochemical analyses showed that spindle cells in majority of the tumors were immunoreactive for vimentin, alpha-SMA, inhibin-alpha, calretinin, PR, and bcl-2. All tumors were negative for pan-cytokeratin, EMA, CD10, CD99, c-kit, ER, and p53, while one CF was positive for S-100, and one MACF showed positivity for desmin. In addition, the MIB-1 labeling index (LI) in MACFs was higher (mean 14.4%, range 10-25%), than that in CF (mean 5.6%, range 3-10%). CONCLUSION: Our results confirm the immunophenotypic similarity between ovarian fibromas and cellular fibromatous neoplasms, and suggest that the use of MIB-1 LI may help in differentiating between CF and MAFC.

PP3-24
PRIMARY MELANOMA OF THE UTERINE CERVIX – CASE REPORT
Grazyna Pasz – Walczak
Department of Pathology, Chair of Oncology, Medical University of Lodz, Poland

Only 5% of melanocytic malignancies in women originate in the genitalia. Primary malignant melanoma of the cervix is an extremely rare histological variety of cervical tumor, with only 54 cases reported. These lesions arise from melanocytes, which may be found within the mucosa lining the female genital tract. Primary malignant melanoma of the cervix is diagnosed by the presence of junctional melanocytic abnormality and the absence of distant metastases. We present a case of the malignant melanoma of the uterine cervix in 84-year-old postmenopausal women. The suspition of malignant melnoma was recognaised on a routine Papanicolaou-stained cervical smear. The gynecologic examination showed a cervical dark tumor, with extention into the vagina, the parametrium was free. Microscopic examination of the biopsy led to diagnosis of malignant melanoma (Fig.1). The cells were positive for S-100 (Fig.2)and HMB45 (Fig.3) in immunohistoceminal stain.The tumor was stage IIA of the International Federation of Gynecology and Obstetrics classification. Chest x-ray and abdominopelvic computed tomografy scanning were normal. Radical hysterectomy with bilateral salpingo-oophorectomy, pelvic and paraaortic lymphadenectomy, partial vaginectomy, and adjuvant radiation or chemotherapy have been advocated by some investigators. In our case, due to old age the patient received palliative radiation therapy to the pelvis, total dose 20Gy. Cervical melanoma is a rare disease of which no retrospective studies exist, only case reports.Primary malignant melanoma of the uterine cervix carries a very poor prognosis. The small number of reported cases makes it difficult to evaluate the diagnosis and treatment. Immunohistochemistry plays very important role in the diagnosis of this tumor in the early stage. This is essential since cervical melanoma is incurable with standard therapies.

PP3-25
THE IMPORTANCE OF USING THE CYTOBLOCK TECHNIQUE FOR WOMEN WITH BLEEDING SYMPTOMS
Mathilde E. Boon[1], Saskia M. Duineveld[2],
Elisabeth Ouwerkerk-Noordam[1], Dwen Dias[2]
[1] Leiden Cytology and Pathology Laboratory, Leiden, The Netherlands
[2] Goa Medical College, Department of Pathology, Goa, India

Background: Cervical sampling was changed fundamentally when in the eighties of the past century the Cytobrush was introduced. Finally, the Ayre spatula was completely replaced by various brushes. The more immature lesions, including the preneoplastic CINs, are often located in the endocervical canal and are effectively sampled by the brushes. Our results indicate that inflammatory changes can lead to cervical bleeding, probably because inflammation is accompanied by angiogenesis. It is a well known fact that (pre)invasive cervical carcinoma is rich in newly formed small blood vessels, leading to post-coital bleeding. Our purpose was to use such cervical samples to prepare Cytoblocks and exploit the paraffin section made thereof for additional immunostaining for women with bleeding symptoms. Methods: The 261 cervical samples were processed by the Shandon Cytoblock Preparation System. The vials still containing the brush were placed in a shaker for 10 minutes to dislodge the material trapped between the bristles of the Cervex-Brush. Specimens fixed in BoonFix were concentrated by centrifugation (10 min at 3000 rpm). The Cytoblock cassette (containing the concentrated material infiltrated with agar) was removed from the Cytospin and histoprocessed in the Pathos (Milestone, Italy) applying m sections were cut and stainedμmicrowave technology. From each block several 4 with the Papanicolaou method. On the Papanicolaou-stained paraffin sections made thereof a histological diagnosis was given rendered on the minibiopsies. Results: Of the total 261 women screened, 237 had a benign diagnosis, with only 138 having a completely normal histology. In 42 cases an inflammation was suggested. The CIN cases contained minibiopsies with classical feature of cervical neoplasia which were discerned with ease in the excellent paraffin sections with optimal nuclear morphology. In the two cases of squamous cell carcinoma, many minibiopsies examined displayed squamous cells connected with extended desmosomes and hyperchromatic nuclei containing a macronucleolus. The (pre)invasive cases had many Ki-67 positive nuclei displaying an S-phase staining pattern. In the Ki-67 stained sections, the glandular architecture of the two AIS cases and the two adenocarcinoma cases was highlighted. Conclusion: In the histologic paraffin sections there were enough minibiopsies to allow concise diagnosis including evaluation of proliferation. Signs of cervical angiogenesis, including post-coital bleeding, can be a strong argument to prepare Cytoblocks from samples collected by sampling brushes.

PP3-26
FREQUENCY AND CHARACTERIZATION OF ANTERIOR PITUITARY COMPONENT IN OVARIAN MATURE CYSTIC TERATOMAS
Elena Rigoli, Donata Micello, Nikolaos Papanikolau,
Stefano La Rosa, Cristina Riva, Carlo Capella
Department Of Human Morphology, University Of Insubria Varese, Italy

Background: Adenohypophyseal tissues and pituitary-type tumors, namely functioning corticotroph and lactotroph adenomas, have been rarely reported in ovarian mature cystic teratomas (OMCTs), but the frequency of this feature is, to date, unknown. The purpose of this study was to evaluate the incidence of a pituitary component in a large series of OMCTs. Methods: An archival series of 200 consecutively collected and of 4 selected OMCTs was revised. On the basis of the morphological finding of cellular nests or solid islands, suggesting an endocrine tissue, 56 cases were selected for the immunohistochemical study. Immunoreactions for Chromogranin A, GH, PRL, ACTH, βFSH, βLH, βTSH, α-subunit and thyreoglobulin were routinely performed. Results:Anterior pituitary cells were detected in 8 OMCTs including 6 cases among the consecutive series (incidence: 3%) and 2 selected cases. Anterior pituitary component was frequently observed near a struma ovarii (6 cases) in form of small groups or strands of polygonal endocrine cells encircling or penetrating into the thyroid parenchyma. In one case, an adenomatous micronodule associated with a strumal carcinoid was present . In two cases the pituitary cells were localized beneath a respiratory mucosa. The following immunoreactivities were obtained: Chromogranin A (7/8 cases), PRL (6/8 cases), GH (5/8 cases), α-subunit (4/8 cases), βFSH (2/8 cases), ACTH (1/8 cases). The adenomatous micronodule showed diffuse PRL+ e focal GH+. Conclusions: Adenohpophyseal cells are present in 3% of OMTCs. The immunoprofile of pituitary cells demonstrates PRL expression in the majority of the cases, suggesting that hyperprolactinemia could contribute to the clinical syndrome of amenorrhea and/or infertility in a subset of young patients with OMTCs

PP3-27
LYMPHOEPITHELIOMA-LIKE CARCINOMA OF THE ENDOMETRIUM: AN UNUSUAL VARIANT OF ENDOMETRIAL CARCINOMA
Kalliopi Patsiaoura, Ioannis Amplianitis, Afroditi Pantzaki,
Alexandra-Anastasia Moulla, Despina Alataki
Hippocration General Hospital, Greece

Lymphoepithelioma is a distinct neoplasm with unique histologic features and a consistent etiologic association with the EB virus. The neoplasm was first identified in the nasopharynx, but since

then carcinoma identical to lymphoepithelioma and designated lymphoepithelioma-like has been reported in many other organs. While lymphoepithelioma-like carcinoma of the cervix is well established lymphoepithelioma-like carcinoma of the endometrium is extremely rare with 3 cases reported to date. A 73 year-old woman with postmenopausal bleeding was admitted to hospital. The physical examination and the laboratory evaluation were both unremarkable. A total hysterectomy with bilateral salpingo-oophorectomy was performed. The hysterectomy specimen revealed a tan polypoid tumor filling the endometrial cavity and protruding partially into the cervical canal. Microscopically, the myometrium was diffusely infiltrated by a neoplasm composed mainly of plump cells with distinct cytoplasmic borders, vesicular nuclei and prominent nucleoli. The neoplastic cells were arranged mostly in groups with a syncytial appearance surrounded by an intense inflammatory infiltrate mainly with lymphocytes and plasma cells. Immunohistochemically, the neoplastic cells revealed strong keratin and EMA as well as focal estrogen and progesterone receptors positivity. The immunostains for synaptophysine, chromogranine, a-SMA, CD10, inhibin, and CEA were totally negative. In accordance with the previously reported cases the immunohistochemical analysis for the EBV was negative. The morphologic and immunohistochemical findings supported the diagnosis of a lymphoepithelioma-like carcinoma of the endometrium. We present this case as being both interesting and extremely rare and review the related literature.

PP3-28
UTERINE LIPO-LEIOMYOMA WITH FOCI OF CARTILAGINOUS DIFFERENTIATION

Kalliopi Patsiaoura, Ioannis Amplianitis, Aphroditi Pantzaki, Eleftherios Anagnostou, Anastasios Chatzitolios
Department of Pathology, Hippokrateion General Hospital, Thessaloniki, Greece

The presence of foci with cartilaginous differentiation within an otherwise typical uterine leiomyoma or lipoleiomyoma is an extremely rare phenomenon, with only 3 reported cases so far in the literature. A 47-year old woman with a history of HGSIL, submitted to hospital due to uncontrolled vaginal bleeding. A total abdominal hysterectomy with bilateral salpingo-oophorectomy was performed. In the uterine corpus two intamural tumors, with diameters of 5,5 cm and 3 cm respectively, were observed. The tumors were both well-circumscribed, whitish with a soft consistency. Microscopically, the tumors were mostly composed of intervening fascicles of smooth muscle cells. Increased cellularity, cytologic atypia, necrosis or mitotic activity were totally absent. Between the smooth muscle cells, foci composed of mature cartilaginous tissue, as well as areas composed of well-differentiated adipocytes were noticed. These areas showed strong positivity for the S-100 immunostain. The histologic and immunohistochemical findings were consistent with the diagnosis of uterine lipo-leiomyoma with foci of cartilaginous differentiation. We present the case because of its rarity and we review the few reported cases in the literature, regarding its histogenesis and the related differential diagnostic problems with the other mesenchymal neoplasms of the myometrium.

PP3-29
ENDOMETRIOSIS AND ENDOMETRIOID CARCINOMA OF THE OVARY

Laura Yébenes[1], Paloma Ramos[1], Ana Blasco[1], Pedro Valenzuela[2], Isabel Álvarez[3], Antonio Ruíz[1]
[1] Pathology Department Príncipe de Asturias Hospital, Spain
[2] Obstetrics and Gynaecology Department Príncipe de Asturias Hospital, Spain
[3] Ramón y Cajal Hospital Pathology Department, Spain

BACKGROUND: We present a retrospective analisis of 22 cases of endometrioid ovarian carcinoma, reviewed to identify endometriosis and its malignant transformation. METHOD: Twenty-two patients with endometrioid ovarian cancer were included in the review. Their clinical and histological data were retrospectively reviewed. The origin of the tumor was considered endometriosis-related when the presence of malignant changes in endometriosis glands leading to endometrioid carcinoma were found. RESULTS: Endometriosis was detected in three cases (3/22=14%). One of them presented a clearly benign to malignant transformation area. In another patient, the transition zone was abrupt and present in both ovaries. In the third, a pre-menopausal woman, ovarian endometriosis with only focal endometrioid carcinoma was observed. The three of them had a clear-cell carcinoma component. The presence of a clear-cell component was significantly greater in patients with endometriosis than in patients without endometriosis. Each patient had a different clinical presentation: increase in abdominal perimeter, post-menopausal vaginal haemorrhage and hypermenorrhea. Preoperative CA 125 levels were avalaible in 15 of the patients (15/22=68%). Endometriosis was found in two of these 15 patients, both with the highest CA 125 measured levels, exceeding 1700 U/ml. In the remaining of the patients, including the third one with endometriosis, CA 125 value did not exceed 35 U/ml. CONCLUSION: Although this association is not very frequent, patients with ovarian endometriosis and high CA 125 serum level should be managed with special care, regardless of their pre-menopausal or post-menopausal status.

PP3-30
PRIMARY OVARIAN HEMANGIOENDOTHELIAL SARCOMA - REPORT OF A CASE

Ioannis Amplianitis
Department of Pathology ‘‘Hippokrateion’’ General Hospital, Thessaloniki, Greece

A primary ovarian hemangioendothelial sarcoma, also known as ovarian hemangiosarcoma or angiosarcoma is a very rare neoplasm - fewer than 25 cases have been recorded to date. A 89 year - old woman was admitted to the hospital because of a cystic tumor mass on her left ovary. She was offered a unilateral salpingo- oophorectomy. Grossly, the ovary revealed a unilocular cystic tumor of a maximum diameter 5.5 cm, with clear fluid contend, which histologically proved to be a benign serous cystadenoma. Peripherally and within the ovarian stroma, an infiltrating neoplasm composed of vascular spaces of varying size, lined by endothelial cells with prominent atypical appearance was recognized. Extra-ovarian expansion was not observed. Positivity for the vascular markers CD34 and Factor VIII confirmed the endothelial origin of the neoplasm and supported the diagnosis of ovarian hemangioendothelial sarcoma. The immunostains for pankeratin, inhibin and calretinin were negative. The neoplasm, though rare, raises differential diagnostic considerations, involving the germ cell tumors, mostly the immature teratoma, the ovarian lymphangiosarcoma and hemangiopericytoma, as well as the metastatic spread to the ovary from primacies in the spleen or the breast. The histogenesis of the neoplasm remains uncertain. The concurrence of an epithelial neoplasm, as observed in our case, has been previously reported. We present the case as being both rare and interesting and review the related literature, regarding the differential diagnostic problems and the histogenetic considerations.

PP3-31
A CASE OF MUCINOUS MICROGLANDULAR ADENOCARCINOMA OF THE ENDOMETRIUM

Hannachi Sassi Samia, Driss Maha, Mrad Karima, Abbes Imen, Dhouib Rym, Ben Hamida Naziha, Ben Romdhane Khaled
Department of Pathology Salah Azaeiz Institute, Tunisia

Microglandular adenocarcinoma (MGA) is a rare type of endometrium carcinoma with only thirteen cases have been reported in the literature, according to our knowledge. MGA may mimic morphologically some benign and malignant lesions of the cervix. We report the fourteenth case of a 63-year-old, para 7 gravida 7, postmenopausal Tunisian woman consulted for uterine bleeding of 3-month duration. Histopathologic evaluation of the curettage specimen made the diagnosis of mucinous MGA. The patient underwent a total hysterectomy and bilateral salpingooophorectomy with pelvic lymph node sampling. Histology showed a stage IB grade II mucinous MGA. Because MGA is an uncommon type of endometrium adenocarcinomas and has potential problems in differential diagnosis with some lesions of the cervix, we discuss the clinical, histological and immunohistochemical characteristics of MGA useful in differential diagnosis.

PP3-32
ENDOCRINE AND IMMUNE PARALLELS IN LICHEN SCLEROSUS (LS) AND VULVAR INTRAEPITHELIAL NEOPLASIA (VIN): IMMUNOMORPHOLOGICAL STUDY

Gleb Sychugov, Eugene Kazachkov, Ella Kazachkova, Eugenia Malachova
Medical Academy, Chelyabinsk, Russia

Background. Immunomorphological study of vulvar biopsy specimens taken of 19 women aged from 37 to 65 diagnosed with LS and VIN, grade 3 was undertaken (LS - 10, VIN - 9). Method. Paraffin sections were incubated with monoclonal antibodies to progesterone (PGR), estrogene (ER) receptors, CD3, CD4, CD20, CD68, HPV types 6,11,18, polyclonal antibodies to IgA, IgG, IgM ("Novocastra"). Results. HPV was found in cellular nuclei of stratified squamous epithelium (SSE) in all subjects. Volume density of ER-positive cells in LS was 1.65±0.14%, in VIN - 2.95±0.19%, while PGR-positive - 3.93±0.21% and 5.46±0.23% respectively. ER-positive and PGR-positive cells expression in SSE was mainly noted in basal layers, particularly in acanthotytic bands, where hormone sensitive cells representation was total. Volume density of various subpopulations of lymphocytes and macrophages did not change significantly aggravated: for CD4-lymphocytes it averaged 0.5±0.08%, CD8-positive – 1.05±0.16%. CD4/CD8-ratio was 0.47. The number of IgG-producing cells remained stable and averaged 39%. As VIN got more severe the number of IgA-producing cells decreased from 28% in LS to 17% in VIN3, the number of IgM-producing cells increased from 33% to 44%. Conclusion. Thus, as VIN becomes more severe some changes in local humoral immune status are observed, particularly an increased level of IgM-producing cells. Cellular immunity transformation is expressed in the decreased number of CD4-lymphocytes.The number of cells expressing receptors to sex hormones increased significantly at the site of SSE growth.

PP3-33
FIBROSIS AND SMOOTH MUSCLE METAPLASIA IN INTESTINAL ENDOMETRIOSIS

Makoto Jinushi[1], Atsushi Arakawa[2], Keiko Abe[2], Toshiharu Matsumoto[2], Tomoko Itoga[1], Mari Kitade[1], Hiroyuki Takeuchi[1]
[1] Department of Obstetrics and Gynecology, Japan
[2] Department of Pathology, Japan

Background: In case of endometriosis of the colon, serosa and muscularis propria are involved much more frequently than submucosa and mucosa. This finding suggest that lesions of endometriosis spread from the serosa to the mucosal layer. Itoga et al. examined the histological findings of endometriosis in the rectovaginal space, and showed that the degree of fibrosis and smooth muscle metaplasia might increase with relation of the age of ectopic endometrial tissue. This conclusion also suggested that fibrosis and smooth muscle metaplasia could represent the chronic phase of ectopic endometrial lesion. We examined the degree of fibrosis in the ectopic endometrium in each layers of the colon, for decision of which lesions early or chronic phase are. Method: Three women with endometriosis of the rectum were archived from the medical records of our hospital. All of them underwent surgical resection of the rectum. These materials were fixed by 10% formalin at least overnight. Ninety-four lesions were selected from these three specimens. These lesions were located at the subserosa (ss-lesion) (13 lesions), at the muscularis propria (mp-lesion) (78 lesions) and at the submucosa (sm-lesion) (3 lesions). No lesions were observed in the mucosa (m-lesion). Each lesion was classified into four groups in accordance with the degree of fibrosis surrounding the endometrial duct. The classification of the degree of fibrosis was, Group1: endometrial duct without stromal tissue surrounding fibrosis, Group2: endometrial duct surrounded by only endometrial stroma, Group3: endometrial duct partially surrounded by fibrous tissue, Group4: endometrial duct completely surrounded by fibrous tissue. Results: 1) Ectopic endometrial tissues were most frequently observed in the muscularis propria (sm 3, mp 78 and ss 13). 2) The lesions in the muscularis propria showed various stromal and fibrosis features (Group1 17%, Group2 32%, Group 3 22% , Group4 29%). 3) On the other hand, the lesions in the submucosa and subserosa revealed some endometrial ducts surrounding by fibrosis, completely or focally. (sm: Group3 33%, Group4 67%; ss: Group3 30.8%, Group4 69.2%). 4) Especially, in the lesions of the subserosa, smooth muscle metaplasia was found in the extensive spread of fibrous tissue. Conclusion: Ectopic endometrium in the subserosa with prominent fibrosis and smooth muscle metaplasia might represent the long-standing lesion of the enodometriosis in the colon. The first site of endometrial tissue infiltrated into the colon could be identified as the subserosa of the colon.

PP3-34
TISSUE MICROARRAY STUDY OF TUMOUR BIOMARKERS IN HPV INDUCED CERVICAL NEOPLASIA

Ita Hadžisejdić[1], Maja Grahovac[2], Dražen Kovač[1], Maja Krašević[1], Blaženka Grahovac[1]
[1] Department of Pathology, Rijeka University School of Medicine, Croatia
[2] Department of Dermatovenerology, Medical School, University of Zagreb, Croatia

The aim of this study was to analyse expression patterns of tumour biomarkers Ki 67, p53, p16 (INK4A) and epidermal growth factor receptor (EGFR), in cervical carcinoma using tissue microarray technology (TMA). Methods: The expression of Ki67, p53, p16(INK4A) and EGFR was studied in series of 34 cervical cancer samples: 6 cervical intraepithelial neoplasia (CIN III), 14 squamous cell carcinomas (SCC), and 14 adenocarcinomas (ADC). TMA slides containing triplicate of 1.0 mm cores were constructed and subjected to immunohistochemical protein analysis. Results: High-risk HPV-DNA was identified in 94 % (32/34) of the cases. HPV-16 predominated in SCC and CIN III, while HPV 18 and HPV 16/18 mixed infection were detected in ADC. Ninety-one percent of samples (31/34) exhibited strong proliferative activity (+2 and +3 Ki 67 immunopositivity), 64% (22/34) exhibited high expression of p16(INK4A), 73% (25/34) demonstrated high expression of p53 and 61 % (21/34) of uterine cervix neoplasia exhibited high EGFR expression. According to the histological type, SCC and ADC demonstrated high expression of Ki67, p16(INK4A) and p53. In CIN III only high expression was detected for Ki67, while p16(INK4A) and p53 were expressed at low level. Substantial differences were shown in EGFR expression: SCC and CIN III demonstrated high level of EGFR expression, in 92 % (13/14) and 100% (6/6) samples, respectively. In eighty-five percent of

ADC's the expression of EGFR was absent (9/14) or (+1) intensity (3/14). Only two tumours demonstrated moderate/strong (+2) level of expression. Conclusion: Our study has demonstrated the reliability of tissue microarray technology in protein expression studies. Preliminary data revealed substantial differences in tumour markers expression in different histological types of cervical neoplasia. To confirm these results, larger studies are needed. Especially, EGFR expression in ADC and adenosquamous carcinoma should be investigated to elucidate the role of EGFR expression in these histological types of cervical carcinomas.

PP3-35
OVARIAN SEX CORD TUMOR WITH ANNULAR TUBULES - REPORT OF A CASE

Milco Ristovski[1], Rubens Jovanovic[1], Vanja Filipovski[1], Slavica Kostadinova Kunovska[1], Elizabeta Milanova[2]

The sex cord tumor with annular tubules (SCTAT) was discovered as a distinctive entity when its unusual appearing microscopic pattern was encountered repetitively in a pathology consultation practice. This tumor is a distinctive ovarian neoplasm, the prominent component of which shows morphological features intermediate between those of the granulosa cell tumour and those of the Sertoli cell tumour. The aim of this paper is to report the first case of SCTAT in our Institution. Methods: We used clinico-biochemical data, macroscopic and microscopic morphology analysis, as well as immunohistochemical analysis of FFPE tissue samples. Results: A 23-year-old woman presented hirsutism and meno-metrorrhagia. Tumorous formation on the left adnexa was palpated. Ultrasound findings indicated septate cystic tumor on the left ovary. Erythrocyte Sedimentation Rate was 30/60 and CA-125 more than 40 U. (ref. 30 U.). Karyotype of the leucocytes from the peripheral blood was 46, XX. Gross examination revealed that the tumor was unilateral with smooth surface. It measured 25x22x12 cm. Cut surface exhibited multilocular cystic compartments filled with translucent gelatinous content. The compartments were separated with yellowish septa of variable width. Microscopic examination showed simple and complex annular tubules with prominent basement membrane-like material around the tubules. The lumina of tubules contained hyaline bodies. Small sheets of solid clear cells were also present, as well as calcified necrotic fields. Tumor cells were positive for cytokeratin cocktail and alpha-inhibin, they showed intermediate signal for WT1 (Wilms Tumor 1) and negative stain for cytokeratin 5/6. We can conclude that SCTAT is a very rare entity with unclear histogenesis, unpredictable prognosis and, very often, with miss out on morphology recognition.

BILATERAL OVARIAN WELL-DIFFERENTIATED SERTOLI-LEYDIG-CELL TUMOR(S) ASSOCIATED WITH UNILATERAL SEROUS CYSTADENOMA – A CASE REPORT

Elvira Stacher, Farid Moinfar
Department of Pathology, Medical University, Graz, Austria

Background: Bilateral Sertoli-Leydig-Cell Tumors of the Ovary, especially in association with unilateral Serous Cystadenoma, are exceedingly rare. We present a case of a 61 year old woman with this diagnosis, in which the Sertoli-Leydig-Cell Component shows leiomyogenic (heterologous) differentiation. On routine examination bilateral ovarian cystic tumors were detected by ultrasonography. Bilateral oophorectomy was performed, the left ovary was sent for frozen section diagnosis. Macrosopically the left ovary measured 27x16x7cm, had a weight of 1965 grams and showed multiple cysts with numerous greyish to yellowish solid nodules measuring up to 1cm. The right ovary (no frozen section diagnosis obtained) measured 4x2,5x2cm and and showed on cut surface a 2,5x1,5x0,5 cm brown to grey solid-cystic tumor. Method: The tissue was processed and stained (H&E, immunohistochemistry) according to standard protocols. To confirm the sex-cord stromal component, immunohistochemistry for α-Inhibin (Serotec, dilution 1:20) was also performed. Results: Left ovary: The frozen section revealed a serous cystadenoma/adenofibroma. The examination of the formalin-fixed paraffin-embedded tissue displayed in addition infiltrates of a well differentiated Sertoli-Leydig-Cell Tumor. The Sertoli-Leydig-Cell Tumor showed irregular infiltration of the cysts. The tumor cells lacked significant cytologic atypia and mitotic activity. Immunohistochemistry revealed intense and diffuse positivity for α-Inhibin. Within the well-differentiated sex-cord stromal tumor there were mesenchymal areas showing fascicular arrangement of spindle cell with eosinophilic, fibrillary cytoplasm. These heterologous areas were immunoreactive for smooth muscle actin. Right ovary: The tumor of the right ovary resembled a well differentiated Sertoli-Leydig-Cell Tumor. Conclusion: To the best of our knowledge, this is the first described case of a Sertoli-Leydig-Cell Tumor of the ovary occurring in a serous cystadenoma. Leiomyogenic differentiation and bilaterality are further interesting features of this particular case.

PP3-37
IS CD10 IMMUNEXPRESSION HELPFUL IN DETECTING OCCULT STROMAL CELLS IN OVARIAN ENDOMETRIOSIS?

Funda Eren, Ipek Erbarut
Marmara University School of Medicine Department of Pathology, Istanbul, Turkey

The diagnosis of endometriosis is based on finding glands lined by endometrioid epithelium surrounded by densely packed small fusiform cells with scanty cytoplasm and bland cytology typical of nonneoplastic endometrial stromal cells. These features may be obscured by hemorrhage, inflammation and fibrosis and diagnosis of endometriosis could be difficult. CD10 has been shown to stain some non-hematological tissues including endometrial stromal cells. In this study our aim is to detect CD10 immunreactivity in cases of presumptive ovarian endometriosis and to determine the value of CD10 in achieving a definitive diagnosis. 14 cases of ovarian biopsies diagnosed as not diagnostic but compatible with endometriosis between the years 2001-2007, were retrieved from the archives of Marmara University Department of Pathology. All slides were reevaluated and selected sections were stained with CD10 by immunohistochemistry. A case of definitive endometriosis and an endometrial tissue were used as positive controls. 2 cases with follicular cysts and inclusion cysts were used as negative controls. In 12 of the 14 cases (86%) strong CD 10 immunreactivity was seen in the stroma underlying a mainly attenuated epithelium. These areas were unnoticed in H&E sections due to fibrosis or hemorrhage. Areas that may simulate endometriosis were negative for CD 10 both in the study cases and negative controls except one. In this one case luteinized follicular cells showed weak cytoplasmic positivity for CD10. In two cases (24%) CD10 immunreactivity were negative. Overall strong positivity for CD 10 is a specific marker for endometrial stromal cells but it should remain in mind that weak staining may be seen in luteinized cells. However, such lesions are not difficult to differentiate morphologically. In conclusion, our study showed that CD 10 immunreactivity is useful and can be used in differential diagnosis of controversial cases of endometriosis.

[3] Trakya University, Medical Faculty, Department of Biochemistry
[4] Trakya University, Medical Faculty, Department of Physiology

Background: We aimed to evaluate histopathological changes, to detect HIF-1α levels and to determine MDA levels in prepubertal rat ovaries, which were subjected to torsion and detorsion and treated with L-Carnitine or N-Acetyl Cystein (NAC). Methods: Forty prepubertal female Sprague-Dawley rats were used in the study. In group 1, only laparatomy was performed. In group 2, right ovaries were subjected 3 h of ischemia and removed sugically. In group 3, an ischemic period of 3 h was followed by reperfusion for 24 h. In groups 4 and 5, either L-Carnitine (100mg/kg) or NAC (20mg/kg) was infused intraperitoneally on 150th min of ischemia and ovaries were reperfused on 180th min. After 24 hours of reperfusion right ovaries were removed. Blood samples were collected before sacrification of each rat to determine serum IL-6 levels. All ovarian tissues were subjected to histopathological examination and MDA levels were determined biochemically. Immunohistochemically HIF-1α antibody was applied to all ovaries. Histopathologically a score between 0 and 9 was formed for each ovary, which was composed of sum of grades of vascular congestion, edema and paranchymal hemorrhage, each graded between 0 and 3. Immunohistochemically HIF-1α staining was scored between 0 and 9 which was the sum of separate evaluations of staining intensities of granulosa cells, theca interna cells and theca externa cells, graded between 0 and 3. Results: HIF-1α did not show any nuclear staining while there was expressive cytoplasmic staining with an unknown significance. Histopathological scores and tissue MDA levels as well as HIF-1α scores, were significantly higher in groups 2 (all $P<0.001$) and 3 ($P<0.01$, $P=0.05$ and $P<0.001$ respectively) then group 4. They were higher significantly in group 2 ($P<0.001$) then group 5. Histopathological scores and MDA levels were significantly high in group 3 when compared to group 5 ($P<0.01$ and $P<0.05$ respectively. Serum IL-6 levels were significantly high in group 2 when compared to groups 4 and 5 (both $P<0.01$). Conclusion: Histological pathologies of ovarian tissues seem to decrease after 24 hours of reperfusion of the torsioned ovaries. Tissue MDA levels and serum IL-6 levels also support those results. However, reperfused ischemic ovaries treated by both L-Carnitine and NAC, showed better recovery than the untreated group, though L-Carnitine seems to be more effective then NAC.

PP3-39

PROGNOSIS OF SQUAMOUS CELL CARCINOMA (FIGO STAGE IA2, IB AND IIA) OF THE UTERINE CERVIX PREDICTED BY MALIGNANCY GRADING SCORE EVALUATION

Tormod Eggen, Marit Arnes, Bjorn Moe, Straume Bjorn, Marika Ostman, Anne Orbo
University Hospital of North Norway, Norway

BACKGROUND Most reliable prognostic factor for squamous cell carcinoma (SCC) of the uterine cervix is staging according to FIGO. Pelvic lymph node metastasis implies less favorable prognosis and such patients are usually offered adjuvant treatment. Some patients lacking metastasis will also experience relapse and would probably benefit from adjuvant treatment, but predicting such tumor behaviour has proven difficult. The malignancy grading score (MGS) system based on 8 histological parameters (structure, polymorphism, mitotic rate, mode and stage of invasion, vascular invasion, cellular response) was introduced in the seventies, but has not been taken into general use. We wanted to investigate if the MGS system and image analysis would be suitable tools for identification of high-risk metastasis-free patients. METHOD In the study 82 patients diagnosed with- and treated for early stage SCC at the University Hospital of North Norway were included. Nineteen patients had been given adjuvant treatment due to lymph node metastasis, lack of radical exciscion or high risk profile. Nine patients experienced relapse and 7 died during follow-up of 5-16 years. Information including lymph node metastasis, resection margins, depth of infiltration, tumor diameter and clinical stage according to FIGO was taken from the hospital files. On the biopsy material initially evaluated, an MGS-score was given in each case by two pathologists independently. Finally, image analysis was performed. RESULTS We found metastasis, unfree resection margins and deep infiltration to significantly predict a poor outcome. Interestingly, the MGS system proved highly significant in separating patients with high risk of relapse from those with low risk. This was true when the material was evaluated as a whole and also when node positive patients were excluded. The inter-observer reproducibility was evaluated by Cohen's Kappa to 0,9. Image analysis proved unable to predict prognosis. CONCLUSION The MGS system is a fairly simple method and can easily be implemented into routine diagnostics. Its ability to predict relapse in patients lacking metastasis at time of initial surgery is therefore especially interesting. Image analysis offers no additional information.

PP3-40

INVESTIGATION OF FASCIN PROGNOSTIC SIGNIFICANCE IN ENDOMETRIAL CARCINOMAS

Mattheos Bobos[1], Ioannis Kalogiannidis[2], Alexios Papanikolaou[2], Georgios Makedos[2], Eleni Nenopoulou[1]
[1] Department of Pathology, Aristotle University Medical School, Thessaloniki Greece
[2] 4th Department of Obstetrics and Gynecology, Aristotle University Medical School, Thessaloniki Greece

Background: Fascin is an actin cross-linking protein that has been implicated in cell motility and migration. The absence or low expression of fascin in normal epithelia is dramatically altered in many human carcinomas. The aim of this retrospective study was to investigate fascin expression in endometrial carcinoma cases and correlate with clinicopathological factors and survival data. Methods: FFPE tissue specimens from 58 patients with endometrial adenocarcinoma were arrayed (5 cores of 0.6mm) using the tissue microarray technology. Clinical, pathological and survival data were collected from all patients and correlated with the immunohistochemical data. Results: The mean age of patients was 63 years (range 35-80). The majority of the cases (96%) was of endometrioid subtype and 79% of FIGO Stage I. Fascin expression was detected in 44/56 (76%) of cases, more common in grade 1 tumors, tumors with diameter <2cm, and with superficial myometrial infiltration ($p = 0.2$, $p = 0.1$ and $p = 0.1$, respectively). The estimate overall survival (OS), cancer related survival (CRS) and disease free survival (DFS) of patients with positive fascin were not significantly higher from those with lack of fascin expression. DFS was not significantly improved when expression was correlated with different clinicopathological parameters (age, FIGO staging, grade, myometrial infiltration, tumor diameter, extrauterine disease). Conclusion: According our data, it seems that fascin expression in patients with endometrial cancer is related with favorable grade, myometrial invasion and tumor diameter. In contrast to previous study we didn't find any impact in patients' survival.

PP3-41
DOCUMENTATION OF 938 OVARIAN LESIONS (NEOPLASTIC-NONNEOPLASTIC) IN A PERIOD OF SIX YEARS
Seyran Yigit, Betul Bolat Kucukzeybek, Mehmet Ali Uyaroglu
Ataturk Training and Research Hospital, Izmir, Turkey

Background : The aim of this study is to establish the relative frequency and distribution of neoplastic and nonneoplastic lesions of the ovarian materials sent to the Pathology Laboratory of Ataturk Research and Training Hospital, Izmir, Turkey during 2000-2005. Method : In the institutional database, during these 6 years, 938 ovarian lesions were evaluated according to histopathological diagnosis retrospectively. They were also subclassified according to the neoplastic nature, origin and localisation of the tumor . Results : Out of 938 ovarian lesions reviewed, 736 (78,46 %) were neoplastic and 202 (21,54 %) nonneoplastic. Of 736 neoplastic lesions, 692 (92,02 %) were primary and 44 (5,7 %) metastatic. Out of 692 primary tumors 527 (76,15 %) were epithelial, 120 (7,34 %) germ cell tumor and 45 (6,50 %) sex-cord stromal tumor. Krukenberg tumor was the most frequent metastatic tumor (40 %) noted.Out of 202 nonneoplastic lesions 80 (39 %) were endometriotic cyst. Conclusion: The data demonstrate that the profile of the studied ovarian lesions in Ataturk Research and Training Hospital quantitatively parallels most of the literature reviewed

PP3-42
SUBEROYLANILIDE HYDROXAMIC ACID, A HISTONE DEACETYLASE INHIBITOR, SELECTIVELY INDUCES GROWTH SUPPRESSION AND CELL DEATH OF ENDOMETRIAL STROMAL SARCOMA CELLS IN VITRO
Andelko Hrzenjak, Farid Moinfar, Marie-Luise Kremser,
Bettina Strohmeier, Kurt Zatloukal, Helmut Denk
Medical University Graz, Department of Pathology, Austria

Background: Endometrial stromal sarcomas are rare uterine malignancies and molecular mechanisms involved in their pathogenesis are poorly understood. Beside surgical excision, very often followed by recurrences, other therapeutic methods like radio- and/or chemotherapy seem to be less efficient. Covalent modifications of histone proteins, in particular de/acetylation of lysine residues, play an important role in the regulation of gene transcription in normal and cancerous cells. Nevertheless, the studies about these processes in solid mesenchymal tumors are limited. In our recent work we have shown increased HDAC2 expression in ESS samples and cognate ESS-1 cell line in comparison to normal endometrial stroma cells. Methods: For in vitro experiments endometrial stromal sarcoma cells (ESS-1) and human endometrial stromal cells (HES) were grown under standard conditions. After treatment with suberoylanilide hydroxamic acid (SAHA) in different concentrations, the cells were harvested at 24, 48 and 72 hours and analyzed by flow cytometry and Western blotting. Cells were also continuously monitored and changes in cell-growth and morphology were documented by cell-observer. Results: Our study shows that SAHA, which inhibits the activity of histone deacetylases class I and II, is able to mediate the cell cycle and expression of some genes related to malignant phenotype of endometrial stromal tumors. We were able to show for the first time that SAHA caused a dose dependent decrease in viable cell number and an increase in percentage of dead endometrial stromal sarcoma cells over time. In our in vitro experiments SAHA (3μM) led to differentiation and to death of ESS-1-cells, but not of HES-cells. Exposure of HES-cells to SAHA resulted in slightly decreased cell proliferation without evidence of cell death. SAHA also increased the p21WAF1 expression and caused significant changes in the cell cycle by inhibiting the G1/S transition in ESS-1 cells. Recovery experiments indicated that these changes became irreversible when the tumor cells were treated with SAHA for longer than 24 hours. Conclusion: Taken together our study suggests that HDACs might be considered as potential drug-targets in the therapy of endometrial stromal sarcomas. For different hematologic malignancies and solid tumors SAHA has recently entered the phase II and III clinical trials. Our data suggest that SAHA might be also a promising therapeutic agent for endometrial stromal sarcoma. Further studies are needed to prove its efficacy in vivo.

PP3-43
EXPRESSION OF IL-32 AND ITS PROGNOSTIC RELEVANCE IN CERVICAL SQUAMOUS CELL CARCINOMA
Shengjin Li[1], Song Mei Huang[1], Do Young Yoon[2], Jin-Man Kim[3]
[1] Department of Pathology, Chungnam National University College of Medicine, Korea
[2] Bioscience and Biotechnology, Konkuk University Graduate School, Korea
[3] Cancer Research Institute and Department of Pathology, Chungnam National University College of Medicine, Korea

Background: IL-32 is a recently discovered cytokine that induces TNF, IL-1, IL-6, and chemokines. This study examines the expression of IL-32 and its association with clinicopathological features in cervical cancer patients. Design: The following samples were analyzed: 40 paraffin-embedded specimens of cervical squamous cell carcinoma patients treated with radiation therapy or post-operation radiation therapy. The patients were grouped into FIGO stage IB (n=16) and stage IIA-IIIB (n=24). All tissues were subjected to immunohistochemical staining for IL-32 and clinical correlation with FIGO stage and survival, and the following results were obtained. Result: IL-32 expression was observed in 55% (n=22) of all tumor tissues and was strong in the tumor invasion site. The expression was located mainly in cytoplasm as well as in some tumor cell nuclei. When IL-32 expression was investigated according to the groups with regard to the FIGO stage IB and IIA-IIIB, there was a statistically significant (Chi-square test) IL-32 expression frequency in the stage IIA-IIIB (71%) compared to stage IB (31%) (P value = 0.014). The staining intensity showed borderline significance with advanced stage (P value = 0.064). However, IL-32 expression was not correlated with survival of the patients (P value = 0.79 and 0.90 in stage IB and IIA-IIIB, respectively). Conclusion: IL-32 expression is frequently observed in cervical squamous cell carcinoma cells. Our results show that the (enhanced) expression of IL-32 by carcinoma cells is correlated with advanced stage of patients with cancer of the uterine cervix. The expression of IL-32 in itself is not associated with worse survival in these patients

PP3-44
HISTOPATHOLOGICAL STUDY AND DNA IMAGE ANALYSIS IN HYDATIDIFORM MOLE AND NON-MOLAR ABORTION: A STUDY OF 89 CASES IN TUNISIA
Hanene Landolsi, Nabiha Missaoui, Mohamed Tahar Yacoubi,
Moncef Mokni, Atef Ben Abdelkader, Sihem Hmissa,
Sadok Korbi
Department of Pathology, F. Hached Hospital, Sousse, Tunisia

Background: Complete hydatidiform mole (CHM) and partial hydatidiform mole (PHM) are two gestational trophoblastic diseases. Commonly, CHM is genetically androgenic and diploid whereas PHM is triploid. The absence of standardized morphological criteria and the presence of atypical cases in put major problems in the histopathological recognition of these diseases. Aims: to review histological diagnosis of molar and non molar first-trimester pregnancy by two pathologists and to evaluate the correlation between the final diagnosis and some histological criteria leading to the diagnosis of mole. Then we evaluate the correlation of consensus histological diagnosis with

ploidy status for molar pregnancy. Material and methods: We proceeded on a retrospective study of 89 specimens of abortus conception, 35 CHM, 12 PHM and 42 hydropic abortions (HA). Kappa value (K) was calculated for interobserver agreement, and to compare initial and consensus diagnosis. The final histopathogical diagnosis, was compared to the results of DNA contents detected by imaging analyser (Samba 200) studying all cases of molar pregnancy. Results: In the consensus histological diagnosis the cases were reclassified into 30 CHM (initial diagnosis (ID): 27 CHM and 3 PHM), 13 PHM (ID: 7 PHM and 6 CHM) and 46 HA (ID: 42 HA, 2 CHM and 2 PHM). There was agreement among the two pathologists in 77 cases (K= 0.72, 0.52 and 0.95 respectively for CHM, PHM and HA). We objectivate a significant statistical correlation between the final diagnosis and some histological criteria leading to the diagnosis of mole: large villi ,hydropic swelling, cistern, scalped outlines, trophoblastic hyperplasia, vacuolisation of tropholastic cells, polarisation of the trophoblastic cells, atypia and trophoblastic necrosis, free trophoblastic cells, absence of vessels and fibrosis into the villous axis. Others criteria were significantly distinctive between CHM and PHM: diffuse hyperplasia of trophoblastic cells, polarisation of trophoblastic cells and the presence of trophoblatic inclusions in the core of the villi. The ploidy results showed that 56.6 % (17/30) of CHM were diploid and 53.8% (7/13) of PHM were triploid. Conclusion: Our study demonstrates that some histopathological criteria can distinguish between PHM, CHM and non molar abortion. The study of DNA content correlate to the clinical outcome is useful in some difficult cases in which these morphological criteria were not easily reproducible.

PP3-45
E-CADHERIN EXPRESSION IN ADENOMYOSIS

J Julia Romadanova, Olga Popova, Julia Gorbacheva,
Irina Voloshchuk
Moscow Medical Academy, Russia

Background. E-cadherin is one of the major molecules that determine epithelial cells adhesion and physiology. The aim of the study was to reveal the possible role of E-cadherin in ectopic loci formation in adenomyosis. Methods. E-cadherin determination using enzyme-linked immunosorbent assay was performed in endometrial and myometrial samples of 53 patients with adenomyosis and 24 women without adenomyosis. Immunohistochemical study with antibodies to E-cadherin was made on paraffin-embedded tissue sections of hysterectomy material from 12 women with adenomyosis and 4 women with benign lesions excepting adenomyosis. Results. E-cadherin concentration in endometrium of adenomyosis group was 15.95±7.72 ng/ml while in control group 8.98±4.09 ng/ml (p=0.007). In myometrium of adenomyosis group E-cadherin concentration was 1.76±1.92 ng/ml, in control group 0.66±0.27 ng/ml (p=0.05). Correlation between E-cadherin concentration and disease duration was revealed. In cases with anamnesis of adenomyosis less than 3 years E-cadherin concentration in endometrium was 8.77±2.24 ng/ml, in cases with duration of disease 4-7 years 15.96±4.36 ng/ml (p=0.002) and in cases with duration 8 years and more 24.88±13.53 ng/ml (p=0.03). In myometrium these values were 0.61±0.09, 1.64±0.99 (p=0.05), 4.61±2.99 ng/ml (p=0.01) respectively. Immunohistochemically strong membrane expression of E-cadherin was revealed in all glands both in eutopic and ectopic endometrium. Intensity of reaction was higher in ectopic loci than in eutopic endometrium. Conclusion. No evidences of homophilic adhesion disturbance of epithelial cells in adenomyosis were revealed. Increased E-cadherin expression according to disease duration allows to suppose compensatory intensification of adhesion in response to long-term existing of ectopic loci.

PP3-46
HISTOLOGICAL AND IMMUNOHISTOCHEMICAL STUDY OF SEX-CORD STROMAL TUMOURS OF THE OVARY

[2] Department of Pathology. Corporació Parc Taulí-UDIAT, Parc Taulí s/n, 08208 Sabadell, Spain
[3] Department of Gynecology. Hospital de Sabadell-Corporació Parc Taulí, Parc Taulí s/n, 08208 Sabadell, Spain
[4] Department of Oncology. Hospital de Sabadell-Corporació Parc Taulí, Parc Taulí s/n, 08208 Sabadell, Spain

Background: Sex cord-stromal tumours (SCST) are rare ovarian tumours, with diverse but similar microscopic patterns, a characteristic immunohistochemical (IHC) expression and a usual benign behaviour. We analysed clinical, macroscopic, microscopic and IHC parameters, in order to better classify these tumours and to predict the prognosis. Method: 12 SCST (except thecoma-fibroma group) were retrieved from our files (1989-2004), and we analysed histologic features (architectural and nuclear pattern, mitosis and presence of luteinized stromal cells) and the IHC profile (CAM 5.2, inhibin, calretinin, s-actin, EMA, CK7 and neuroendocrine markers). Results: The initial diagnosis were 9 granulosa cell tumours (8 adult – AGCT- and 1 juvenile – JGCT-), 2 Sertoli-Leydig cell tumours –SLCT- (1 well-differentiated and 1 of intermediate differentiation) and 1 unclassified SCST. The patients ranged from 16 to 75 years old (mean, 45 years), the youngest was the JGCT. The known clinical presentation was vaginal bleeding (2), pelvic pain (4) and incidental finding (1). All tumours were unilateral, solid or solid-cystic (9/12) and ranged from 0,6 to 30 cm. The tumours presented an admixed variety of patterns: macrofollicular (6/12), solid (6/12), insular (3/12), microfollicular (4/12), watery-silk (2/12), and tubular (2/12). Nuclei were grooved in 10/12, and round with nucleoli in 2. Call-Exner bodies were mainly seen in microfollicular and watered-silk patterns. No significant atypia was observed and mitotic count ranged from <1/10HPF to 12/10HPF. The tumours stained positively for calretinin (8/8), s-actin (5/8), CAM5.2 dot-like (6/8) and diffuse (2/8) and inhibin (1/8). All were negative for EMA, CK7 and neuroendocrine markers. Luteinized stromal cells were highlighted with inhibin and calretinin. We reclassified the well differentiated SLCT as Sertoli cell tumour (SCT) and the SLCT of intermediate differentiation and the unclassified SCST as AGCT. Only the SCT and one AGCT presented pelvic-abdominal recurrences 9 and 15 years later, respectively. The mitotic activity (6/10 HPF) and the poorly defined margins seemed to be the prognostic factors in the SCT. The recurrent AGCT corresponded to the largest tumour in our series. Conclusions: SCST exhibit several growth patterns. The insular, solid and tubular patterns raise the most differential diagnosis among the SCST and with other ovarian neoplasms. Nuclear grooves (hallmark of the GCT) and the IHC profile described will help in establishing the diagnosis. Some histologic features could be associated with an adverse outcome.

ENDOMETRIAL CARCINOMA WITH "PREVIOUS INADEQUATE SPECIMEN SAMPLING" IN ENDOMETRIAL BIOPSY

Ana Blasco[1], Laura Yébenes[1], Gabriel Olmedilla[1], Paloma Ramos[1], Pedro Valenzuela[2], Antonio Ruíz[1]
[1] Department of Pathology, Príncipe de Asturias University Hospital, Alcalá de Henares, Madrid, Spain
[2] Department of Obstetrics and Gynecology, Príncipe de Asturias University Hospital, Alcalá de Henares, Madrid, Spain

BACKGROUND: Endometrial biopsy reported by pathologists as “inadequate specimen sampling” (“insufficient material” or “no representative sampling”) can lead to an erroneous idea of absence of malignancy. The aim of this study is to find out the overall rate of biopsies diagnosed as “inadequate sampling”, and its repercussion on the time-delay in establishing the diagnosis of endometrial cancer. METHOD: Clinical data and pathological reports from 227 patients with endometrial carcinoma, over a period of fourteen years (from 1989 to 2003) were retrospectively reviewed, and the “insufficient” or “no representative” samples proportion in endometrial biopsies, prior to histological confirmation of malignancy, was calculated. RESULTS: Eighteen out of these 227 patients (7.9%) had a previous pathological report of “inadequate sample for diagnosis”. Only two of those eighteen cases (11.1%) underwent a new biopsy in less than a month, and twelve (66.6%) had a delay in the rebiopsy of more than three months. CONCLUSIONS: Assessment of specimen adequacy is important for pathologist interpreting endometrial biopsies. Endometrial biopsies reported as “inadequate sample for diagnosis” should not be considered, for practical purposes, as a benign sample, and early rebiopsy should be recommended.

PP3-48

EXPRESSION OF SURVIVIN AND TOPOISOMERASE II ALPHA IN OVARIAN CARCINOMA: CORRELATION WITH CLINICOPATHOLOGICAL PARAMETERS AND PROGNOSIS

Derya Gumurdulu[1], E. Handan Zeren[1], Baris Guzel[2], Gulsah Seydaoglu[3], Seyda Erdogan[1], Suzan Zorludemir[1], Mehmet Ali Vardar[2], Aytekin Altintas[2]
[1] Cukurova University, Faculty of Medicine, Department of Pathology, Adana, Turkey
[2] Cukurova University, Faculty of Medicine, Department of Obstetrics and Gynecology, Adana, Turkey
[3] Cukurova University, Faculty of Medicine, Department of Biostatistic, Adana, Turkey

Background: Ovarian carcinomas account for four percent of all female cancers and for 25% of cancers of female genital organs. The clinicopathological parameters, such as clinical stage, tumor grade, histological type may reflect the aggressiveness of ovarian tumors and clinical outcome. The additional prognostic information closely related to tumor cell biology is essential for the identification of patients with poor prognosis. Survivin is a member of the inhibitor of apoptosis protein (IAP) family that has been reported to be broadly expressed in a wide range of malignant tumors but not in most corresponding normal tissues. Topoisomerase IIα (T2a) is an enzyme with an important role in DNA topology, repair and replication. It is a cell-cycle-related protein, expressed in normal as well as neoplastic cells in the S, G2 and M phases. The aim of this study was to investigate the association of survivin and T2a expression with clinicopathological parameters and prognosis. Materials and methods: Formalin-fixed, paraffin-embedded tissue sections from 61 ovarian carcinomas were obtained from the files of the Cukurova University, Faculty of Medicine, Department of pathology. We performed primer antibodies to survivin, T2a and Ki67 by immunohistochemically. Nuclear staining for all antibodies were considered as positive reactivity, percentage of positive cells was scored on a three-tiered system with <10% as negative. and we evaluated the relationship between expressions of survivin, T2a, Ki67 and prognosis. Results: The age of patients ranged from 17 to 78 and the mean age was 52.16 ± 14.84. The 61 cases in the study comprised 35 serous carcinomas,, 12 endometrioid carcinomas, 6 mucinous carcinomas, 2 clear cell carcinoma and 6 mixed carcinoma of the ovary. Survivin expression was found in %27.9 (17 of 61) of the tumors. T2a positivity was noted in %91.8 (51 of 61) of the tumors. There was a correlation between Ki 67 and T2a expression (r=0.28, p=0.030). Survivin and T2a expression did not correlate histological type, stage or overall or disease-free survival. Conclusion: The immunohistochemical assessment of survivin and T2a does not seem to be helpful in the prognostic characterisation of ovarian carcinoma. The most important prognostic factors are stage and histological type. Further studies addressing to find the additional prognostic parameters will likely provide valuable insights into the behaviour of ovarian carcinoma.

PP3-49

IMMUNOHISTOCHEMICAL STUDY OF THE EXPRESSION CD44 IN SEROUS, BORDERLINE, MALIGN SURFACE EPITHELIAL OVARIAN TUMORS AND METASTATIC OVARIAN TUMORS

Gamze Yurdakan[1], Nilufer Onak Kandemir[1], Sacide Colak[1], Aylin Ege Gul[2], Nimet Karadayi[2], Sukru Oguz Ozdamar[1]
[1] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Dr. Lutfi Kirdar Kartal Research and Training Hospital, Department of Pathology Istanbul, Turkey

Backround: Carcinogenesis and metastasis are a multistep process involving complex interactions between tumor cells and the environment. The main cause for the motion of the tumor cells in invasive carcinomas may be loss of completeness intercellular adherence junction. One of these adhesion receptors, CD44 binds to extracellular matrix component hyaluronic acid. In the present study, to elucidate role of CD44, we investigated a series of benign, borderline, and malignant ovarian serous neoplasms. Materials and Methods: Archives paraffin- embedded formalin-fixed blocks from benign serous tumors (n=11), benign mucinous tumors (n= 8), borderline serous tumors (n=6), borderline mucinous tumors (n=1), primer malign ovarian serous tumors (n=9) and metastatic ovarian tumors (n=12) were immunohistochemically stained for CD44. Percentage of reactive tumor cells and stromal cells with CD44 were scored. Positive staining in at least 10% of cells with strong staining considered being positive. Staining intensity was scored from 1+ to 3+. CD44 protein was preferentially expressed along the basolateral domain of plasma membrane of tumors cells. Some of tumor cells were reactive with CD44 in cytoplasm. Results: CD44 was not only detected in 1 (5, 2%) of benign tumors. Remain of the tumors were reactive with CD44 in differential percentage and localization. CD44 staining was evaluated in 4 (8, 33%), in 21 (43, 75%), in 16 (33, 33 %), in 7 (14, 58%) of all tumors as grade 0, 1, 2, 3 respectively. Statistically significant associations were found between serous and mucinous benign tumors (p=0.0001), borderline and malign serous tumors (p=0.001), malign serous tumors and metastatic carcinomas (p=0.054), and primary malign ovarian tumors and metastatic carcinomas (p=0.002) as compared CD44 staining grade. Grade 0,1,2,3 stromal staining was determined in 14 (29, 16%), in 31 (64, 58 %), in 1 (2, 08 %) and in 1 (2, 08 %) ovarian tumors respectively. But no difference was in reaction with CD44 in stromal cells statistically. In primary malign tumors, CD44 was detected more than primary benign ovarian tumors and was different statistically (p=0.0001). Conclusion: These results suggest that CD44 expression may be important in differential diagnosis between borderline and malign serous tumors, primary malign ovarian tumors and metastatic carcinomas. Also CD44 expression is a characteristic factor in stromal invasion for ovarian serous carcinomas. A large number of samples are necessary to verify prognostic significance of CD44 expression in tumor progression.

PP3-50
COMPARISON OF TWO VERSUS THREE GRADES FOR ENDOMETRIAL CARCINOMA: AN ASSESMENT OF INTEROBSERVER RELIABILITY IN ENDOMETRIAL SAMPLES AND HYSTERECTOMY SPECIMENS
Sema Ozuysal, Ilker Ercan, Hulya Ozturk Nazlioglu, Ulviye Yalcinkaya, Berna Calisir
Uludag University School of Medicine Bursa, Turkey

OBJECTIVE:To compare the agreement in determining the histological grade of endometrial adenocarcinomas in endometrial samples and hysterectomy specimens using the three-grade FIGO classification and the two-grade system. METHODS: Endometrial samples and subsequent hysterectomy specimens from 55 patients with endometrioid adenocarcinoma were graded according to the FIGO and the binary system (BS) proposed by Lax et al. All tumours were graded independently by four pathologists on two separate occasions. The reliability coefficient for two-facet crossed design (specimen x observer x occasion) based on generalizability theory was calculated for each grading system in endometrial samples and hysterectomy specimens. We used the generalizability coefficient (GC) as a measure of interobserver reliability and the factors which could influence it (different psychological status of the observers at different times, changes in the laboratory conditions, etc).GC was interpreted as follows: 0.00 to 0.40, poor; 0.41 to 0.60 low; 0.61 to 0.80 moderate; and 0.81 to 1.00, high. The pathologists were separated into two groups as "experienced in gynecologic pathology" and "with limited experience in gynecologic pathology". Exact agreement percentages were calculated as the percent of all cases in which the grades were identical in endometrial samples and hysterectomy specimens. The FIGO and BS were compared by using chi–square test and kappa values were calculated for each grading system. RESULTS: GCs were 0.93 for endometrial samples, and 0.83 for hysterectomy specimens for FIGO system. The BS revealed GCs of 0.89 and 0.83 for endometrial samples and hysterectomy specimens, respectively. The GC levels were higher for experienced pathologists both when using the FIGO (endometrial samples= 0.92 hysterectomy samples= 0.92), and the BS (endometrial samples=0.92 hysterectomy samples= 0.90) compared to the group with limited experience in gynecologic pathology (FIGO- 0.89- 0.49; BS- 0.68- 0.60). The agreement rates between the endometrial sampling grade and the hysterectomy grade in FIGO and BS were 247/439 (%56.2) and 361/439 (%82.2) respectively ($p<0.05$). Kappa values were 0.29 ($p<0.05$) in FIGO system and 0.38 ($p<0.05$) in BS. CONCLUSION: In this study high GC values were obtained both for the FIGO and BS. GC levels were higher for experienced pathologists in both the FIGO and BS than the group with limited experience in gynecologic pathology. The agreement rates between the endometrial sampling grade and the hysterectomy grade were higher in the BS compared to the FIGO system.

PP3-51
BABES-PAPANICOLAOU TEST METHOD TO VERIFY LSIL TREATED LESIONS
Eliza Gramada, Geanina Micu, Ionela Celea, Adina Ene, Andrei Murariu, Florica Staniceanu
Colentina University Hospital, Department of Pathology, Bucharest, Romania

Background: The quality verification of the treatment applied by the gynecologist is realised by periodical cytological cervico-vaginal examinations using Babeş-Papanicolaou test. This test may indicate the presence or the absence of pathologycal cells. Material and method: In the Department of Pathology from Colentina Universitary Hospital, the authors took for study a lot of 83 patients, with the age between 20-30 years, treated by the gynecologist with Podofilin or electrocautherisation for mild dysplasia and plan condyloma. The study analyzed the koilocytic cells, the intermediate squamous epithelial cells with nuclear increased size and/or mild dyscariosis, pathological changes present in mild dysplasia and plan condyloma. The smears were stained with Papanicolaou stain and the 2001-revised Bethesda System was used in order to interpret the results. Study results: From all the treated patients, 69 patients were present for a control test (63,13%), 52 of them (75,36%) being treated for plan condyloma. Among these, using the cervico-vaginal examinations, 15 cases (28,84%) have had normal aspect, 9 cases(17,30%) presented inflammatory aspects of the reparing type, 28 cases (53,84%) presented koilocytic cells. From the 17 cases (24,67%) with mild dysplasia, a number of 11 cases (64,70%) presented normal Pap smears, and 6 cases (35,30%), presented ASC-US subtype modifications. Conclusion: The study displays that, from the number of the patients examinated, almost 40% completely recovered while the other 60% remained with pathological modifications. These data prove the necessity of cytodiagnostic reevaluation after treatment.

PP3-331
UTILIZING OF KI 67 EXPRESSION AND ESTROGEN AND PROGESTERONE RECEPTORS IN DIFFERENTIAL DIAGNOSIS OF SMOOTH MUSCLE TUMORS OF THE UTERUS
Nilgun Dicle, Sevil Sayhan, Duygu Ayaz, Sibel Kececi, Hakan Camizoglu
Ege Dogumevi ve Kadin Hastaliklari Egitim Hastanesi, Izmir, Turkey

BACKGROUND: Smooth muscle tumors of the uterus are frequent and most of them are benign. Some leiomyomas may have unusual morphologic features difficult to distinguish from leiomyosarcomas. Smooth muscle tumors of uncertain malignant potential (STUMP) represent a variant of uterine leiomyomas and remain a dilemma due to their uncertain clinical behavior. MATERIAL AND METHODS: One thousand four hundreds and twenty patients operated for smooth muscle tumor of uterine origin between 2005-2007 at our hospital's department of gynecology. Seven leimyosarcoms and 7 STUMP cases were reported during this term. The average age of STUMP and leiomyosarcoma cases was 42 and 57 years respectively. The average size of STUMP and leiomyosarcoma cases was 6.8 and 12 cm respectively. Seven leiomyomas with similar age and sizes were selected to compare with STUMP cases. Number of mitosis, presence of necrosis, atypia, Ki 67 expression, presence of estrogen and progesterone receptors were evaluated in paraffin embedded tissue. CONCLUSION: There is limited experience in the clinical behaviors of problematic uterine smooth muscle tumors like STUMP. Several parameters are used to facilitate the appropriate diagnosis. Besides the criteria of the WHO classification we found that the expression of Ki 67 and the presence of estrogen and progesterone receptors in uterine leiomyomas, STUMP and leiomyosarcomas is helpful in differential diagnosis.

E-CADHERIN EXPRESSION IN TUR MATERIALS WITH LOW AND HIGH GRADE UROTHELIAL CARCINOMAS: A STUDY OF 30 CASES

Elif Ozer, Derya Arslanoglu, Haluk Pulat, Mehmet Gonultas, Muzaffer Caydere, Hesna Muzeyyen Astarci, Huseyin Ustun
Ankara Education and Research Hospital, Pathology Department, Turkey

The cadherins are a family of transmemrane glycoproteins and are the primer mediators of intercellular adhesion. Cadherins are responsible for cell adhesion and transmembrane protein and expressed in all tissues. E-cadherin, the epithelial spesific cadherin mediates the selective adhesion of epithelial cells and required for the interaction and maintenance of normal epithelial integrity. Loss of E-cadherin expression leads to dissociation of cells from cohesive tissues and generates dedifferentiation and invasiveness in a variety of solid tumors, revealing the crucial role of E-cadherin as a suppressor of tumor invasion and metastasis. This study comprised with 30 transurethral resection of urinary of bladder tumor specimens. We immunostained 15 cases of low grade papillary urothelial carcinomas and 15 cases of high grade papillary urothelial carcinomas for E-cadherin using tissue arrays. We observed that E-cadherin expression in low grade tumors is more pronounced than high grade malignancias. In 5% of low grade tumors E-cadherin expression was indistinct than aspected. We think that this must be due to the increased potential of invasiveness and metastasis, contrary to their histological features. We propose to use E-cadherin as a prognostic marker in TUR materials for urothelial carcinomas.

PP3-53
RELATIONSHIP BETWEEN GLEASON SCORE AND NUCLEAR SIZE AND SHAPE FACTORS IN PROSTATIC ADENOCARCINOMA

Sibel Bektas[1], Burak Bahadir[2], Banu Dogan Gun[2], Gurkan Kertis[2], Sukru Oguz Ozdamar[2]
[1] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey

Background: The Gleason grading system which depends on differentiation of the glandular structures is the most common used grading system in prostatic adenocarcinoma. Recently several quantitative morphometric methods have been developed to test the objectivity of the Gleason grading system. The aim of this study is to assess the size and shape characteristics of the tumor cell nuclei, and compare the results of measurement with Gleason score of the cases by using computer-assisted analysis system. Methods: This study included 130 cases with prostatic adenocarcinoma, 100 (77%) were needle biopsy specimens and 30 (23%) were prostatectomy specimens. The ages of patients ranged 46 to 94 (Mean: 67±8.26). Each slide were reevaluated and rescored by the same pathologist without having any knowledge about the prior diagnoses. About 150 nuclei with sharply demarcated contour were included for morphometric analysis for each case. After transferring microscopic images to the computer, nuclear area, nuclear length, nuclear perimeter, roundness factor, and form ellipse were automatically measured by an image analysis program. The relationship between Gleason score and these variables were determined by correlation analysis with Spearman and Pearson correlation coefficient. Results: Among all the specimens, Gleason score were significantly correlated with mean nuclear area (r: 0.516, p=0.01), with mean nuclear length (r: 0.298, p=0.01) and with mean nuclear perimeter (r: 0.303, p=0.01). However, in the needle biopsy group Gleason score were significantly correlated with mean nuclear area (r: 0.522, p=0.01), with mean nuclear length (r: 0.398, p=0.01), with mean nuclear perimeter (r: 0.432, p=0.01) and with mean form ellipse negatively (r: -0.213, p=0.05). In the prostatectomy group Gleason score were correlated with mean nuclear area (σ: 0.619, p=0.01) and mean roundness factor negatively (σ: -0.425, p=0.05). Conclusions: As a result, nuclear size and shape factors especially mean nuclear area were found concordant with Gleason score. Nuclear size and shape assessment may support to evaluate pathologic status of the disease in the prostatic adenocarcinoma. On the other hand, the association of clinical outcome and morphometric parameters could not be evaluated because of the short observation period in this study. Therefore, more detailed studies with long period of observation are required to asses more accurate results.

PP3-54
INTRAOBSERVER AND INTEROBSERVER REPRODUCIBILITY OF THE FUHRMAN NUCLEAR GRADING FOR RENAL CELL CARCINOMA

Sibel Bektas[1], Figen Barut[1], Burak Bahadir[2], Banu Dogan Gun[1], Nilufer Onak Kandemir[1], Aylin Ege Gul[3], Sevinc Keser[3], Nimet Karadayi[3], Sukru Oguz Ozdamar[1]
[1] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[3] Lutfi Kirdar Kartal Training and Research Hospital, Department of Pathology, Istanbul, Turkey

Background: Several systems have been proposed for grading renal cell carcinoma. Classification of renal cell carcinoma has been divided into four categories according to nuclear size and the presence of nucleoli, the most widely used grading system reported by Fuhrman. However, there are few studies in the literature assessing the intraobserver and interobserver variability of this system. The objective of the current study was to evaluate the intraobserver and interobserver reproducibility of the Fuhrman nuclear grading system. Methods: In this study, pathology slides from 46 cases of renal cell carcinoma (Conventional: 37, chromophobe: 5 and papillary: 4) were rescored according to Fuhrman nuclear grading system by two pathologists. The intraobserver variation was determined as the first pathologist's observation on two different occasions. Interobserver variation was determined by the second pathologist who did not known the result of the first. Both intraobserver and interobserver reproducibility were assessed using Cohen's kappa statistics. Results: The original Fuhrman nuclear grade was grade 1 in 4 patients (8.7%), grade 2 in 30 patients (65.2%), grade 3 in 11 patients (23.9%), and grade 4 in 1 patients (2.2%). After slides review by same pathologist, nuclear grades were reassigned as follows: grade 1 in 8 patients (17.4%), grade 2 in 23 patients (50%), grade 3 in 14 patients (30.4%), and grade 4 in 1 patients (2.2%). Intraobserver reproducibility of the Fuhrman nuclear grading system was found to be substantial (κ = 0.66). Fuhrman nuclear grading of the second pathologist was grade 1 in 11 patients (23.9%), grade 2 in 27 patients (58.7%), grade 3 in 7 patients (15.2%), and grade 4 in 1 patients (2.2%). Interobserver reproducibility of the Fuhrman nuclear grading system was found to be moderate (κ = 0.42). We found low intraobserver and interobserver agreement for the Fuhrman nuclear grade 2 and grade 3, respectively. Conclusions: Despite strong intraobserver reproducibility of the Fuhrman nuclear grading system, one should consider moderate interobserver reproducibility and low agreement for the grade 2 and grade 3. Further studies are required to confirm our results in larger series.

PP3-55

CONCORDANCE OF NUCLEAR MORPHOMETRIC ANALYSIS WITH FUHRMAN NUCLEAR GRADING IN CONVENTIONAL RENAL CELL CARCINOMA

Sibel Bektas[1], Figen Barut[1], Gurkan Kertis[1], Burak Bahadir[1], Banu Dogan Gun[1], Nilufer Onak Kandemir[1], Nagehan Ozdemir[2], Nimet Karadayi, Sukru Oguz Ozdamar[1]
[1] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Lutfi Kirdar Kartal Training and Research Hospital, Department of Pathology, Istanbul, Turkey

Background: Nuclear grade, stage and tumor size are generally used for estimating prognosis of renal cell carcinoma. Ouantitative image analysis has been applied to renal cancers for diagnostic and prognostic purposes. The aim of this study was to investigate whether there is any correlation between the results of morphometric measurement and Fuhrman nuclear grading score, pathologic stage and size of conventional (clear cell) renal cell carcinoma. Methods: Morphometric nuclear parameters such as mean area, mean roundness factor, mean form ellipse, mean length, mean breadth and mean perimeter were evaluated in hematoxylin and eosin stained slides of 37 conventional renal cell carcinoma by using computer assisted image analysis system. The relationship between Fuhrman nuclear grading score, pathologic stage, tumor size and morphometric results were determined by correlation analysis with Pearson correlation coefficient. Results: Mean nuclear area were correlated with pathologic stage (r: 0.413, p=0.05) and with Fuhrman nuclear grade (r:0.588, p=0.01). Mean nuclear length were correlated with pathologic stage (r:0.446, p=0.01) and with Fuhrman nuclear grade (r:0.580, p=0.01). Mean nuclear breadth were correlated with pathologic stage (r:0.377, p=0.05) and with Fuhrman nuclear grade (r: 0.544, p=0.01) and with tumor size (r:0.366, p=0.05). Mean nuclear perimeter were correlated with pathologic stage (r: 0.449, p=0.01) and with Fuhrman nuclear grade (r:0.593, p=0.01). Mean nuclear roundness factor were correlated with pathologic stage (r: 0.418, p=0.05) and with Fuhrman nuclear grade (r: 0.456, p=0.01). The correlation between mean nuclear form ellipse and Fuhrman nuclear grade, pathologic stage, and tumor size was not statistically significant. Conclusions: In this study, the relative concordance of morphometric results and pathologic stage, Fuhrman nuclear grade, and tumor size exhibited the importance of nuclear morphometric analysis in conventional renal cell carcinoma. Studies including larger series of cases investigating detailed nuclear morphometric analysis of conventional renal cell carcinoma are needed.

CHROMOPHOBE RENAL CELL CARCINOMA

Nadia Kourda, J Kourda, R Noomene, A Derrouiche, O Lamine, M Ferchiou, M Chebil, Sara Baltagi Ben Jilani, R Zermani
Charle Nicolle's Hospital Department of Pathology, Tunisia

INTRODUCTION: Chromophobe renal cell carcinoma (CRCC) is an uncommon,which accounts for average 5% of all renal neoplasm. CRCC shows an intermediate prognosis between conventional cell carcinoma and oncocytoma. Oncocytoma, a benign renal tumour, is considered the aim histological differential diagnosis of CRCC. A careful anotomopathologic study, special coloration and immunostaining, allow differentiating these two entities. We report 21 cases of CRCC. The aim of our study was to evaluate the incidence, clinical presentation, anatomopathological and immunohistochemical findings, prognosis, and clinical outcome of CRCC. METHODS: Hospital records and pathological slides were reviewed for 21 patients CRCC treated at Charles Nicolle Hospital between 1999-2006. The relevant clinical and pathologic data were extracted from the clinical charts and collected into a unique database. The following parameters were noted in each patient: age, sex, symptoms at diagnosis, tumour diameter, TNM stage and grade, histological cell type, follow-up time, local recurrence, disease progression, and death. RESULTS: 21 cases of CRCC; 8 (38%) were men and 13 (62%) women. The mean patient age was 54.8 (range 31to 74 years). The tumour was located in the right kidney in 11 patients (53%) and in the left kidney in 10 (47%); no familial or bilateral disease was observed. An incidental diagnosis was founded only in two cases and accounted for 9.5% of the cases. The other patients were symptomatic. The mean tumour size was 7,9 cm (between 2,5 to 16,5cm). Grossly, it was in 95%, a mediocortical and a necrotico-hemorragic tumour. On microscope, most of the pathologic features were typical. However, in 24% we needed immunostainnig using cytokeratine 7, vimentine, CD117 and PS100. At diagnosis, 10 patients (48%) had Stage pT1a, 1 (4.7%) pT1b, 5 (24%) pT2, 1 (4.7%) pT3a, 3 (14%) pT3b, and 1 (4.7%) pT4. The lymph node status was pN0 in 19 (90.5%), and N1 in only 2 patients (9.5%). Of the 21 patients, there were no metastatic disease at diagnosis, and 1 had pulmonary metastasis. The nuclear grade was, grade 1 in 1case, grade 2 in 17 (81%), and grade 3 in 3 (14%). Radical nephrectomy was performed in 20 patients (95%). After a median follow-up of 3 years (Range 2 to 5), one local recurrence was observed. The 5-year overall survival rate for CRCC was 90%. Of the 21 patients, 3 died of unrelated causes and renal cancer, respectively. CONCLUSION: The results of our study have confirmed a general favourable outcome for CRCCs, which are predominantly low-stage and low-grade tumours. These tumours had little local aggressiveness. Although metastases at diagnosis and disease progression after nephrectomy are rare, this neoplasm should be distinguished from renal oncocytoma. PS100 A1 seems to be a powerful marker to differentiate these two entities.CONCLUSION: The results of our study have confirmed a general favourable outcome for CRCCs, which are predominantly low-stage and low-grade tumours. These tumours had little local aggressiveness. Although metastases at diagnosis and disease progression after nephrectomy are rare, this neoplasm should be distinguished from renal oncocytoma. PS100 A1 seems to be a powerful marker to differentiate these two entities.

RENAL ONCOCYTOMA. PATHOGICAL FINDINGS

Nadia Kourda, O. El Lamine, R. Noomene, A. Derrouiche, J. Kourda, M. Ferchiou, M. Chebil, Sarrah Baltagi Ben Jilani, R. Zermani
Charle Nicolle's Hospital Department of Pathology, Tunisia

INTRODUCTION: We report the clinical and histopathological features of 10 cases of oncocytoma. One diagnostic problem is distinguishing oncocytoma from other renal epithelial tumours with pink cytoplasm. Oncocytomas are the most common benign epithelial tumours. It accounts about 10% of renal tumours. MATERIALS AND METHODS: Hospital records and pathological slides were reviewed for 10 patients with renal oncocytoma treated at Charles Nicolle Hospital between 1999-2006. The clinical data included age and gender. Microscopic examination was performed on all cases. RESULTS: The median age of the patients was 54,9 years (range 23-84 years). All our patients were symptomatic (10/10) flank pain (8/10) hematuria (2/10). They occur more frequently in women than in men (Female's predomination (9/10)) and have a peak incidence in the seventh decade as same as RCC. On gross examination, most of the tumours were cortical in 6 cases, and the median tumour size was 74 mm (range 30-120 mm). Oncocytomas were solitary renal tumours in the ten cases we study. Multiple and/or bilateral cases were not observed. Most of these tumours were well-circumscribed encapsulated (6/10) neoplasm, with a uniform mahogany (6/10) or red dark color (4/10). A central, white satellite scar was seen in 3 cases. Necrosis (3/10), hemorrhage (2/10). Histollogically, different architectural pattern was found with nesting (7/10), acini (4/10) and/or"tubulocystic" (4/10) architecture with a myxoid and/or hyalinized stroma (3/10). A

moderate to abundant amount of eosinophilic cytoplasm with central, small, oval–round nuclei is found in all our cases. DISCUSSION: Light microscopic differentiation of oncocytomas from RCC specifically eosinophilic variants of the chromophobe type can be very challenging. The nuclear features are an important discriminating feature; RCCs have wrinkled, raisinoid nuclear membranes, whereas oncocytomas have round nuclei with nucleoli. Additional staining techniques and immunostaining may be helpful. In fact, Hale's colloidal iron positive staining is strong and diffuse in chromophobe RCC, whereas oncocytomas exhibit focal, weak positivity. Cytokeratin 7 is often negative in oncocytoma. Conclusion: Based on our findings, oncocytomas and RCC have similar clinicopathologic features. On the other hand, the nuclear features are an important discriminating feature; RCCs have wrinkled raisinoid nuclear membranes, whereas oncocytomas have round nuclei with nucleoli, immunohistochemical stain has been helpful in some studies. Knowledge of these distinguishing histological and immunohistological features will enable to better differentiate these two pathologic entities.

THE EFFECT OF ORAL HIGH ALUMINIUM INTAKE ON RAT SPERMATOGENESIS

Iran Rashidi[1], Ali Reza Mozaffari[2]
[1] Pathologist. Head of Department & Member of Expert Committee, Iran
[2] M. D. – Internist, Iran

ABSTRACT: Introduction : Aluminum is a silver-white flexible metal with a vast number of uses. It is poorly absorbed and efficiently eliminated; however, when absorption does occur aluminum is distributed mainly in bone, liver, testes, kidneys, and brain (1) . Aluminium poising causes wide range of disorders, including: a decrease in the release of neurotransmiters and inhibition of voltage dependent calcium channels. The role of calcium on GnRH release and its action is detected so, in this studying, the effect of high aluminium intake on rats spermatogenesis is investigated. Methods and Materials: The experiment performed in four groups, a control group and three experimental groups consumed 0.625, 1.25 and 2.5 mg aluminium per gram diet for 60 days. Epididymis and vas deferens were dissected cut and diluted with normal salin. In all groups weight of vas deferens , epididymis, testis and whole animal, sperm count per gram deferens and epididymis tissues were determined then, the testicular tissues fixed in formalin for study of histopathology. Results: The results have shown that in experimental groups which consoumed 1.25 and 2.5 mg aluminium per gram diet, the vas deferens, epididymis, testis and animal weight were significantly decreased. In this animals the number of sperm per gram tissues from vas deferens, epididymis were reduced. The maturation arrest is seen in seminoferous duct and it haven‘t spermatogenesis. Conclusion: This studying indicated that high aluminium in take in rat have an inhibiting effect on spermatogenesis and this effect is dose dependent.

PP3-59

COMPARISON OF HIF-1α IMMUNREACTIVITY WITH TUMOR STAGE, GRADE, ANGIOGENIC PROFILE AND PROLIFERATIVE INDEX IN BLADDER UROTHELIAL CARCINOMAS

Hale Deniz[1], Metin Karakok[2], Faruk Yagci[3], Muhammet Emin Guldur[4]
[1] Gaziantep Pediatric Hospital, Turkey
[2] Gaziantep University, Medical Faculty, Department of Pathology, Turkey
[3] Gaziantep University, Medical Faculty, Department of Urology, Turkey
[4] Gaziantep Gynecologic and Obstetric Hospital, Gaziantep, Turkey

BACKGROUND: Hypoxia-inducible factor-1α (HIF-1α) is a critical regulatory protein of cellular response to hypoxia. In this study, we evaluated the relationship of HIF-1α immunreactivity with clinicopathologic parameters such as tumor stage and grade, as well as angiogenic profile and proliferation index. METHOD: The expression of HIF-1α was assesed in 70 primary bladder urothelial carcinoma tissue samples immunohistochemically. Vascular endothelial growth factor (VEGF) immunreactivity and microvessel density (MVD) were used to evaluate the angiogenic profile. MVD was calculated by immunohistochemical staining of endothelial cells with CD34. Proliferation index was determined by the percentage of Ki-67 nucleer staining in tumor cells. RESULTS: There was a significant relationship between HIF-1α immunreactivity and stage, as well as histological grade of the tumor ($p<0,001$). HIF-1α immunreactivity was also closely related to VEGF expression ($p<0,001$), MVD ($p=0,002$) and proliferation index ($p<0,001$). VEGF, MVD and proliferation index were found to be closely related to tumor stage and histological grade. There was no correlation between HIF-1α immunreactivity and lamina propria ($p=0,13$), muscularis propria ($p=0,009$) or vascular invasion ($p=0,1$). CONCLUSION: In this study, HIF-1α expression was found to be closely related to prognostic parameters (stage, grade, angiogenic profile and proliferation index) in urothelial carcinoma of the bladder. For this reason, it may be a useful marker to determine the prognosis and to choose the appropriate treatment modality.

PP3-60

IMMUNOHISTOCHEMICAL EXPRESSION OF P53, P16 AND P21 IN UROTHELIAL CELL CARCINOMA AND THEIR CORRELATION WITH CLINICOPATHOLOGICAL FEATURES

Adamandia Zizi-Sermpetzoglou, Xanthippi Grammatoglou, Chryssoula Glava, Maria-Eleni Nikolaidou, Nerantzoula Petrakopoulou, Thivi Vasilakaki
Department of Pathology, Tzaneion General Hospital of Piraeus, Piraeus, Greece

Background: Transitional cell carcinoma (TCC) comprises approximately 90% of all primary tumors of the urinary bladder. Several types of mutations of cell cycle regulatory genes are commonly in those tumors. Alterations in the p53 are a predominant component in the TCC. Recently another gene – INK4A, which is located in chromosome 9p21, encodes proteins p16 and p19 which regulate the pRb and p53 pathways. P21 is both a p53-inducible and p53-indipendent cyclin-dependent kinase inhibitor that can arrest the cell by inhibiting DNA replication. The aim of this study was to determine the association of p53, p21 and p16 expression with clinocopathological features. Materials and methods: Immunohistochemical staining for p53, p16 and p21 was carried out on serial sections from (archival) specimens of 108 patients who underwent transurethral resection for TCC. Based on percentage of nuclear reactivity, p53 was considered as wild-type (0% to 10%) or altered (>10%); p21 was scored as wild-type (>10%) or altered (<10%); and p16 status was considered wild-type (1% to 50%) or altered (0% or >50%). Results: Positivity of p53 was detected in 80/108 (81,5%). P21: absence or focal positivity (<10%) of tumor cells was detected in 72/108 (66,7%) of the carcinomas. Absence of p16 was detected in 40/108 (37%) of the tumors. The p53 phenotype seems to be the strongest predictor of bladder cancer associated with bladder cancer progression. P21 expression was correlated with tumor grade and stage. P16 expression was related to recurrence and survival but not to tumor progression. The alteration of each marker was independently associated with disease progression (p[LTEQ]0,30) and disease-specific survival (p[LTEQ]0,37). Conclusion: This study suggests that p53 and p21, as well as p53 and p16, have cooperative and synergistic effects in the promotion of bladder cancer progression.

PP3-61
PROGNOSTIC VALUE OF EGFR AND HER 2 IN UROTHELIAL CARCINOMA
Adamandia Zizi-Sermpetzoglou, Xanthippi Grammatoglou, Maria-Eleni Nikolaidou, Nerantzoula Petrakopoulou, Chryssoula Glava, Thivi Vasilakaki
Department of Pathology, Tzaneion General Hospital of Piraeus, Piraeus, Greece

Introduction: Bladder cancer is a common malignancy with highly growth patterns. HER 2 is one of the most frequently amplified oncogenes and a potential therapeutic target in bladder cancer. EGFR has been associated with genes of bladder tumor. The aim of this study was to investigate the expression of EGFR and HER 2 and examine their prognostic value in the progression of bladder cancer. Materials and methods: We examined the immunohistochemical expression of HER 2 and EGFR in formalin-fixed paraffin samples from 109 cases of urothelial carcinoma (TUR) corresponding in 77 cases of invasive (stage pT1-4, grade 1 to 3) and 32 cases of noninvasive (pTa, grade 1 to 3) carcinoma. Results: EGFR expression was stronger in invasive tumors (p<0,0001) and in high grade tumors (<0,0001). 52 of the 77 investigated invasive (67,5%) and 26 of the 32 noninvasive (81,3%) carcinomas showed overexpression of HER2 protein. Of 77 invasive carcinomas 23 (29.9%) showed 3+ positivity , 29 (37.7%) showed 2+ positivity and 25 (32,4%) were scored as negative with a score of +1 and 0. Of the 32 cases no sample was evaluated as 3+ positive, 26 (81,25%) showed a 2+ positivity and 6 (18,75%) cases were identified as 1+ positive or negative. Conclusion: The combination of HER 2 and EGFR or the correlation between these markers and histological grade will yield prognostic information that is more powerful than what histologic grade alone can provide. The staining pattern of EGFR and its widespread expression in bladder cancer make it a good target for antigrowth factor or gene therapy. The validation of over expression of HER 2 oncogene in bladder cancer may allow for the potential use of Herceptin antibody therapy.

PP3-62
CAVERNOUS HEMANGIOMA OF THE BLADDER. A CASE REPORT
Nerantzoula Petrakopoulou[1], Xanthippi Grammatoglou[1], Chryssoula Glava[1], Spiridon Koutsoukis[1], Maria Politou[2], Thivi Vasilakaki[1]
[1] Department of Pathology, Tzaneion General Hospital of Piraeus, Piraeus, Greece
[2] Department of Pathology, General Hospital of Rhodos, Greece

Objectives: Bladder hemangiomas are exceptional benign tumors representing 0,6% of the bladder tumors. They present as solitary unique lesions and can regress spontaneously as a result of fibrosclerosis suggesting a conservative approach wherever possible. They have a low potentional for recurrence. Asymptomatic hemangiomas do not require treatment. Case report: We report a case of a 52-year-old woman who was admitted to our hospital with the chief complaint of macroscopic haematuria, accompanied by lower abdominal pain. Cytoscopy revealed a red sessile tumor 1,2cm in diameter at the internal urethral orifice. Transurethral resection of the tumor was performed. The specimen was pathologically diagnosed as cavernous hemangioma of the urinary bladder. The typical microscopical feature was the presence of dilated and congested vascular spaces in the lamina propria of the mucosa of the urinary bladder. The patient was treated with biopsy and fulguration and she developed no recurrence 2 years after. Conclusions: Hemangioma of the urinary bladder is rare. The diagnosis is made histologically. Hemangiomas are classified into cavernous, capillary or arteriovenous types based on conventional criteria from other sites. A low incidence of recurrence is seen and the patients have a favorable outcome. Biopsy and fulguration are effective for hemangioma of the bladder when the lesion is small.

PP3-63
TERTIARY GLEASON PATTERN IN RADICAL PROSTATECTOMY SPECIMENS
Arsenal Sezgin, Hakan Postaci, Guliz Ozkok
Izmir Training and Searching Hospital, Department of Pathology, Izmir, Turkey

BACKGROUND: The Gleason system is one of the most widely used grading system for prostatic adenocarcinoma. The Gleason score consisting of the sum of the grades of the primary (predominant) and the secondary (second most prevalent) grades, is an important prognostic parameter for prostatic carcinoma. Although the Gleason grading system does not account for the existence of a tertiary (third most prevalent) pattern, more than two predominant Gleason patterns can be present in one prostatectomy specimen. METHOD: Between 1998 and 2003, 51 patients underwent radical prostatectomy for clinically localized prostate cancer in our hospital. Prostatectomy specimens were examined retrospectively for Gleason scores including a tertiary grade and pathological stage including margin status, seminal vesicle invasion and extraprostatic extension. RESULTS: Overall, of the 51 patients, 18 (%35.3) were found to have a tertiary pattern. In previous studies concerning the prevalence of a tertiary Gleason pattern in prostate cancer, presence of more than two patterns were reported between %16-50. Of the 18 prostatectomy specimens with a tertiary pattern in this study, 11 presented tertiary pattern 5. The Gleason score was >= 7 in 16 (%89) of the prostatectomy specimens with a tertiary pattern. All of the prostatectomy specimens (%100) with a tertiary Gleason pattern had positive margins. Extraprostatic extension was observed in 8 (%44.4) and seminal vesicle invasion was observed in 6 (%33.3) of the 18 cases with a tertiary pattern. In our study, the prevalence of a tertiary pattern was found to be consistent with previous studies published before. CONCLUSION: Prostatic carcinoma shows multiplicity and hetereogenity in many cases and it is possible that a third and even a fourth most prevalent pattern can be identified. In recent years, the prevalence of a tertiary pattern in radical prostatectomy specimens has become more important. High grade tertiary patterns are found to be associated with a more advanced pathological stage. Although further studies are needed, the presence and percentage of a tertiary, particularly less differentiated Gleason pattern can be accepted as a potential new predictive factor for prostate cancer behaviour.

PP3-64
IMMUNOHISTOCHEMICAL EXPRESSION OF RHOE IN BENIGN PROSTATE GLANDS AND PROSTATIC ADENOCARCINOMA
Gabriel Matheu[1], Joan Maria Benejam[2], Priam Villalonga[3]
[1] Servei d'Anatomia Patològica Fundación Hospital Manacor, and Institut Universitari d'Investigació en Ciències de la Salut (IUNICS). Illes Balears, Spain

[3] Institut Universitari d'Investigació en Ciències de la Salut (IUNICS), and Departament de Biologia Fonamental, Universitat de les Illes Balears, Spain

BACKGROUND: RhoGTPases are key regulators of the cellular cytoskeleton, but also regulate many other processes, including cell proliferation and transformation. Accordingly, there is increasing evidence for a role of Rho proteins in human cancer, and increased expression levels of Rho-family members are found in a variety of tumours. RhoE/Rnd3 is a member of the Rnd subfamily that, in contrast to other GTPases, do not hydrolize GTP and remain always in their GTP-bound active conformation. RhoE is a ubiquitously-expressed protein antagonizing RhoA function, promoting disassembly of actin stress fibres and focal adhesions. Recently, it has been shown that RhoE can also regulate cell proliferation and transformation. RhoE overexpression inhibits cyclin D1 expression leading to

cell cycle arrest in fibroblasts and also in prostate cancer cells, in correlation with its lower expression levels in prostatic tumor samples relative to benign tissue, which have supported a tumor supressor role for RhoE in prostate cancer. METHOD: Formalin-fixed and paraffin-embedded prostatic tissue sections obtained from 12 radical prostatectomy specimens were examined by immunohistochemical staining for RhoE (labelled streptavidine-biotine method, goat anti-Human RhoE antibody, Santa Cruz Biotech. Inc.®). The selected samples included benign prostatic glands (n=12) and adenocarcinoma scoring Gleason grade (G) 3 (n=10), G4 (n=9) and G5 (n=2). The staining index (SI) scoring system was defined by staining intensity on a scale of 0 to 4 multiplied by the estimated percentage of stained cells. Benign glandular epithelium was considered as positive internal control and graded 4+. RESULTS: All samples of benign prostatic glands showed positive citoplasmic staining for RhoE. RhoE expression was decreased or absent in malignant glands compared to benign epithelia. In addition, RhoE expression in prostatic adenocarcinoma was inversely correlated to the higher Gleason-grades of tumors. SI for G3=1.31; G4=0.41; G5=0. CONCLUSIONS: RhoE expression, detected by immunohistochemical analysis in prostatectomy specimens, is lower in neoplastic glands than in neighbouring benign epithelia. And RhoE expression levels inversely correlates to Gleason grade. The loss of expression of RhoE can support its tumor supressor role in prostate cancer, and may serve as a marker of prostate cancer progression.

PP3-65
SERTOLI CELL MALIGNANT NEOPLASM IN A REDUCTIVE TESTIS. A CASE REPORT

Irini Zinovieva, Ioannis Nesseris, Efthymia Balassi, Niki Agnantis
Ioannina University Hospital, Greece

AIM: To present a rare malignant testicular neoplasm with location in a reductive testis, which has been treated clinically as an extratesticular tumor. MATERIALS AND METHODS: A 25-year-old male presented with a solid paratesticular mass measuring 4,5X3X1,8 cm. The intraoperative biopsy specimen, sent for a frozen section diagnosis, concerned a "paratesticular tumor" which was positive for malignancy. A tumor excision followed. The paraffin-embedded sections have been studied microscopically on hematoxylin-eosin preparations. An immunohistochemical study followed. RESULTS: The microscopic examination showed a neoplasm with a biphasic histological structure featuring tubular formations lined by high columnar, cuboidal and flat cells. Among them there were spindle cells. The neoplasm showed high pleomorphism, foci of necrosis and a high mitotic rate (30 mitoses per 20 high power fields). The immunohistochemical study showed positive for vimentin, MIC2, NSE, synaptophysin, antichymotrypsin, hCG, pancytokeratin and C-kit. The neoplasm was negative for EMA, CEA, ER, PLAP and chromogranin. CONCLUSION: A rare tumor can create diagnostic difficulties in intraoperative frozen section biopsy when is developed from testicular embryonic remnants and is mimicking a paratesticular neoplasm.

PP3-67
HISTOMORPHOLOGICAL AND IMMUNOHISTOCHEMICAL EVALUATION OF POSTRADIOTHERAPY PROSTATE NEEDLE BIOPSIES

Arzu Saglam[1], Gokhan Ozyigit[2], Fadil Aksoy[2], Sevket Ruacan[3], Arzu Sungur[1]
[1] Hacettepe University Faculty of Medicine, Department of Pathology, Ankara, Turkey
[2] Hacettepe University Faculty of Medicine, Department of Radiation Oncology, Ankara, Turkey
[3] MESA Hospital, Department of Pathology, Ankara, Turkey

Introduction: Prostate needle biopsies have an important role in the follow-up of patients treated with radiotherapy, especially with regard to prognosis. However histomorphological interpretation of post-radiotherapy prostate needle biopsies is a challenging venture, mostly because practicing pathologists are not familiar with the histomorphological changes secondary to therapy. Methods: In this preliminary study, we evaluated the histomorphological changes induced by therapy in 46 of our patients treated with combined hormonal therapy and radiotherapy. All patients received the same therapy regimen and were rebiopsied after completion of radiotherapy. We used immunohistochemistry against Ki-67, vimentin, prostate specific antigen, chromogranine, p63 and high molecular weight cytokeratin in addition to H&E sections. Furthermore we compared the original diagnosis of these biopsy samples with the ones given after detailed morphological and immunohistochemical evaluation during this study. Results: The most prominent changes noted after therapy were as follows: acinar atrophy with decrease in acinus/stroms ratio (% 95.7'sinde), acinar distortion (%34.8), basal cell hyperplasia (%34.8), stromal fibrosis (%47.8), stromal edema (% 41.3) and vascular changes characterized by myointimal hyperplasia and luminal narrowing (%43.5). Nuclear enlargement (%100), nucleolar prominence (%80.4), bizzaar nuclei (%54.3) and cytoplasmic vacuolization (%93.5) was noted in the cells lining the prostate glands. Rare atypical cells in the stroma were seen to be basal cells positive for p63. Even though, originally 9 cases were reported to have residual adenocarcinoma and 3 reported as suspicious for adenocarcinoma, adenocarcinoma was confirmed in only 4 of these cases, 3 of which presented with distant metastasis during follow-up. The other cases were seen to display therapy induced changes. Most of these cases were diagnosed by practicing pathologists not experienced in prostate pathology and not familiar with the changes induced by therapy. Interestingly the morphological changes described above were not obvious in the neoplastic component of the 4 cases with residual foci of adenocarcinoma, even though they were noted in the adjacent nonneoplastic component of these cases. Conclusion: We concluded that H&E morphology is sufficient in diagnosing post-therapy needle biopsy specimens provided that the pathologist is experienced enough and familiar with the changes produced with therapy and that immunohistochemistry can aid diagnostic decision making in difficult cases.

PP3-68
MULLERIANOSIS OF THE URINARY BLADDER: A DIAGNOSTIC PITFALL IN BLADDER BIOPSY SPECIMENS

Sonuc Buyuk[1], Ismet Basar[2], Suleyman Ulucay[2], Arkin Akalin[3], Dilek Ertoy[4], Burcu Albayrak[5], Mehmet Muderiszade[5]

[2] Department Of Urology,Dr. Burhan Nalbantoglu State Hospital, Nicosia, North Cyprus
[3] Nicosia Diagnostic Centre, Nicosia, North Cyprus
[4] Department Of Pathology, Faculty Of Medicine, Hacettepe University, Ankara,Turkey
[5] Department Of Pahology, Dr. Burhan Nalbantoglu State Hospital, Nicosia, North Cyprus

Müllerianosis is an entitiy characterized by the presence of different Müllerian-derived tissues in the wall of this organ. The terms endocervicosis and endosalpingiosis are used when only endocervical and tubal type glands are present respectively. When endoservical, tubal and endometrial glands are found in combination in the bladder it is defined as müllerianosis. It is a rare entitity and to our knowladge up to now six cases have been reported. We present a further case in a 37- year-old woman who had 2 caesarean sections before. The patient didn't have any bladder symptoms unlike cases that have been reported earlier . She only complained from dysmenorrhea and metrorrhagia. A

bladder mass was found by pelvic ultrasonography during routine control for diabetes mellitus. Ultrasonographic findings consisted of 16x19x30 mm solid hypoechoic lesion occupying the base and posterior wall of the bladder projecting into the lumen. A complete transurethral resection , including the deep muscular layer, yielding 10 chips was performed . Cystoscopic gross appearence was different from the usual transitional cell carcinoma or adenocarcinoma, and was rather displaying a cystic form. Once the resection started, the inner surface and consistency of the tissues were mimicking the gross appearence of adenocarcinoma (of a solid tumour). Histologically there were intermediate to large-sized, irregularly shaped , haphazardly arranged, endocervical type glands in the lamina propria and in the muscularis propria, some of which were cystically dilated. In some areas rupture of the glands and inflamatory respond were seen . Siderophages also were noted in lumens and in the stroma. In focal areas there was endometrial type glands which were typically surrounded by endometrial stroma. Well differantiated adenocarcinoma has been taken into concideration. Since there was no atypia and desmoplastic reaction ,the presence of endometrial type glands and its typical stroma and the metaplastic change of superficial urothelial epithelium into the endocervical type epithelium lead us to the correct diagnosis. Although our clinicopathological findings supported metaplastic origin, still the clinical history of prior caesarean section puts doubts to this.

PP3-69

DISTRIBUTION PATTERNS OF NEURAL NETWORK ON SURFACE OF PROSTATE AND EXTENDING PATTERNS OF PERINEURAL INVASION OF PROSTATIC CANCER. A MORPHOLOGICAL STUDY USING 3-D RECONSTRUCTION METHOD

Mareyuki Endoh[1], Taiyi Jin[2], Ryoji Chiba[1], Noriyuki Iwama[1], Hironobu Sasano[2]
[1] Dept. of Pathology Sendai Kousei Hospital, Japan
[2] Dept. of Pathology Tohoku University Hospital, Japan

Background: Perineural invasion would be frequently observed prostatic acinar adenocarcinoma. Although, not only distribution patterns of the invasion but also its patterns of neural network on surface of prostate were not clarified completely. So as to elucidate the mechanism of perinaural invasion, we selected several cases of prostatic cancer with extensive perineural invasion. However the distribution patterns were three-dimensional and complicated, thus we analyzed completely serial sections of prostatic cancer specimens with a computer assisted 3-D reconstruction system for this study. Materials and methods: Four surgical specimens of total prostatectomy, with cancers having extensive perineural invasion, were used. After formalin fixed and paraffin embedded, complete serial sections were mede from the specimens as 4 um thickness and H&E stained. Every four serial sections were used for strict tracing the pattern of nerve branch and carcinoma invasion, and the data were digitalized. The data were incorpotaded in a computer assisted 3-D reconstruction system and 3-D images were constructed in all its aspects for morphological analysis in detail. Result: Each number of serial sections was 170, 262, 265 and 267 sheets and their thicknesses were 510, 786, 795 and 801 um, thus searched total thickness of the prostatic tissues reached 2,892um. The 3-D images in all its aspects were apparently indicating the distribution patterns of the neural networks and extending patterns of the carcinoma, as shown in the conclusion below. Conclusion: The 3-D images showed the neural networks made complicated distribution patterns with apparent ganglions. The nerves extended narrow branch toward prostatic parenchyma. Even if tiny perinaural invasion would be showed in prostatic parenchyma, the extension of cancer could be spreading widely for outside of the prostate through the neural network. However, the invasion hardly extended from perineural space into surrounded soft tissue. The finding might explained a hypothesis that perineural invasion should not be a prognostic factor of prostatic cancer.

PP3-70

DECLINING DIAGNOSTIC VALUE OF HIGH-GRADE PIN IN PROSTATIC BIOPSIES

Jurg Vosbeck[1], Seife Hailemariam[2], Lukas Bubendorf[1]
[1] Institute for Pathology, University of Basel, Switzerland
[2] Cantonal Institute for Pathology, Liestal, Switzerland

Background: The detection of isolated high-grade prostatic intraepithelial neoplasia (HG-PIN) in prostatic core biopsies has long been considered an important risk factor for a concomitant adenocarcinoma. Given an estimated risk of 30%, re-biopsy within 6 months has usually been recommended. However, the diagnostic importance of HG-PIN has recently been questioned. Here, we investigate the diagnostic relevance of isolated HG-PIN in the biopsy material submitted to our institutes of pathology during the past 10 years. Methods and results: 125 patients with a diagnosis of isolated HG-PIN were identified in our databank from 1995 to 2005. All histological slides were re evaluated by the authors according to standardised criteria, and compared to the result of re-biopsies. Criteria for HG-PIN were unequivocal morphology with nuclear crowding, nuclear atypia with hyperchromasia and prominent nucleoli, as well as subepithelial retraction. 39 cases (31%) did not meet our stringent review criteria for HG-PIN and were excluded from further investigations. So far, a re-biopsy was done in 40 of the remaining 85 patients. Two of these re-biopsies (5%) showed an adenocarcinoma, and 9 (23%) showed isolated HG-PIN. 29 re-biopsies (73%) were inconspicuous. Conclusion: The diagnostic importance of isolated HG-PIN in a contemporary PSA-screened population is low, questioning the necessity of a short-term re-biopsy. Molecular markers may help to better stratify the diagnostic importance of HG-PIN in the future.

PP3-71

IMMUNOHISTOCHEMICAL STUDY OF COX-2 EXPRESSION IN PROSTATE CARCINOMA; RELATION TO APOPTOSIS AND ANGIOGENESIS

Seyda Erdogan[1], Suzan Zorludemir[1], Derya Gumurdulu[1], Gulfiliz Gonlusen[1], Gulsah Seydaoglu[2], Emine Bagir[1], Bulent Soyupak[3], Zuhtu Tansug[3]
[1] Cukurova University, Medical Faculty, Department of Pathology, Turkey
[2] Cukurova University, Medical Faculty, Department of Biostatistic, Turkey
[3] Cukurova University, Medical Faculty, Department of Urology, Turkey

Background: COX-2 play role in tumorigenesis of a variety of human malignancies by stimulating cell proliferation, inhibiting epithelial differentiation, inhibiting apoptosis, mediating immune suppression and increasing the production of mutagens. The objective of this study is to determine if there is relationship between COX-2, apoptosis and angiogenesis in prostate carcinomas. Material and Methods: Paraffin-embedded tissue specimens from 49 prostate adenocarcinoma were retrieved from the files of the pathology department of Cukurova University, Medical Faculty. COX-2, Bcl-2, VEGF and M30 were studied immunohistochemically. The results of staining for COX-2, Bcl-2 and VEGF were analyzed semiquantitatively by using an immunohistochemical scoring system (HSCORE) that combines the percentage of immunoreactive cells (quantity score) and an estimate of staining intensity (staining intensity score). Apoptosis was figured out by monoclonal antibody M30, which reacts with the product from the cleavage of cytokeratin 18. The number of M-30 positive cells per 1000 cells was expressed as apoptotic index. Results: The age of the patients ranged from 48 to 73 years old (average, 63.8±6.4). Twenty-one (42.8%) of the cases were Gleason score ≤ 6 and 28 (57.2%) were Gleason score ≥7. COX-

2 expression was detected in 81.6% of cases. It was significantly correlated with Bcl-2 expression (r=0.49; p<0.0001). There was no correlation between COX-2 and VEGF expression (p>0.05). Gleason score was negatively correlated with M30 (r=-0.28; p=0.04). No significant relation between Gleason score, VEGF and Bcl-2 was observed. Negative correlation between COX-2 expression and mean survival was also observed (p=0.007). Conclusion: Our study indicates that COX-2 plays role at the carcinogenesis of prostate carcinoma through inhiting apoptosis rather than promoting angiogenesis. This result may offer new insights into the treatment strategies. In addition, it may be useful for the prediction of clinical outcome.

PP3-72
PROGNOSTIC VALUE OF THE EXPRESSION OF E-CADHERIN, β CATENIN AND CD44 IN BLADDER CANCER

Duygu Dusmez Apa[1], Tuba Karabacak[1], Murat Bozlu[2]
[1] Mersin University Faculty of Medicine Department of Pathology Mersin, Turkey
[2] Mersin University Faculty of Medicine Department of Urology Mersin ,Turkey

Background: Loss of expression of adhesion molecules may contribute to cancer progression. Epithelial cadherin (E-cadherin) interacts with cytoskeletal proteins through the catenin complex. CD 44 is also a surface adhesion molecule. The present study was undertaken to investigate the alterations in the expression of E-cadherin, BETA catenin, and CD44 in urothelial carcinoma of the bladder, and their prognostic value. Methods: 54 patients with primary urothelial carcinoma of the bladder were included in this study. The median age was 64 (range: 29-84 years), with 49 men and 5 women. Tissue samples were obtained by radical cystectomy in patients with invasive tumours and transurethral resections in patients with superficial tumours. The histological grading was performed according to the WHO-ISUP criteria. Patients were grouped as low grade and high grade. The pathological staging was done according to the TNM classification. The tumours were grouped as superficial (Ta and T1) and invasive tumours (T2, T3, and T4). Among the 54 tumours, 24 were classified as low grade and 30 as high grade. 42 were classified as superficial tumours and 12 as invasive tumours. The proportion of immunostained cells was used as a criteria for the evaluation. Results: The staining showed a membrane pattern, except for the CD44 where staining was also found in the cytoplasm. Loss of membranous E-cadherin immunoreactivity was higher in invasive and high grade tumours, but this finding was not statistically significant. Loss of expression of BETA catenin was significantly associated with higher grade (p=0.001), but CD44 failed to show the same correlation. Both BETA catenin and CD 44 were not associated with invasiveness. Conclusion: Several studies have examined the role of E cadherin in urothelial carcinoma revealing clear associations of decreased expression, with high grade and advanced stage tumours. Our study confirms this data although not statistically significant. These findings suggest that the expression of E-cadherin and BETA catenin might be useful prognostic markers for the clinical assessment of bladder cancer. Whereas several studies have shown an altered expression pattern of CD44, some reports suggested that it has no association with clinico-pathological variables. Our findings correlated with the second group. This retrospective study with a limited number of cases does not allow definite conclusions. Large prospective clinico-pathological studies to validate the prognostic value of E-cadherin and BETA catenin immunoreactivity should be performed.

PP3-73
SHORT TERM HIGH DOSE CORTICOSTEROIDS INDUCE APOPTOSIS IN PROSTATIC EPITHELIUM

Bahar Muezzinoglu[1], Mohammad Sayeedudin[2], Gustavo Ayala[2], Thomas M. Wheeler[2]
[1] Kocaeli University Medical School Department of Pathology Kocaeli Turkey
[2] Department of Pathology, Baylor College of Medicine, Houston. TX, USA

Background: Corticosteroids (CS) induce apoptosis in various human cells. However, published data quantifying apoptosis in prostate glandular epithelium following short term high-dose CS is lacking. Design: Prostate tissue from 36 organ donors who died from head trauma and given high-dose CS for cerebral edema were evaluated. The prostate was the last organ removed of those organs consented for donation. Most of the prostate was frozen but a mid-transverse section was immediately fixed in 10% neutral buffered formalin. Apoptosis was quantitatively scored on this H E whole-mount section per 10 hpf in 4000 total epithelial cells counted. Age-approximated, non-tumor bearing autopsy prostate tissue (n=47) with no recent CS treatment served as controls. Result: The mean age for donors and controls was 32 and 39, respectively. For donors, mean apoptotic index (AI) of peripheral zone (PZ) was 1.47% compared to 0.72% in transition zone (TZ) (p< 0.05). Zonal apoptotic indices were significantly higher than the control autopsy prostate PZ and TZ epithelium; however, there was no significant difference in ejaculatory duct and seminal vesicle epithelium (table). Two donors had incidental prostatic adenocarcinoma and the tumor cells had AI of 0.1% and 0.02 % Conclusion: Short term high dose CS induces apoptosis in prostate glandular epithelium both in the PZ and TZ, an almost 50 fold increase over controls in both of these zones. However, ejaculatory duct and seminal vesicle epithelium remained unchanged in terms of AI.

PP3-74
VALUE OF HIGH GRADE T1 SUBSTAGING IN BLADDER CANCER

Isabel Trias, Isabel Español, Noemi Vidal, Santiago Bucar
Clinica Plato Fundacio Privada, Spain

BACKGROUND Since 90's there is in the literature a discussion on the value of substaging high grade T1 bladder cancer (HGT1). In our center we perform substaging according to Younes criteria since 1996 and we have demonstrate a statistically significant difference in progression for initial high grade T1b and T1c (T1b,c) urothelial carcinomas (deep invasive submucosa) vs T1a (lamina propia invasive carcinomas). From 2001 we treat T1b,c with a specific protocol that includes re-TUR after 1st BCG instilation and then a radical surgery if its shows T1c or more, or pursuit with BCG treatment if there is T1a, T1b, CIS or non-tumoral tissue. Some of the arguments against the value of substaging is that many of the so called deep invasive submucosal carcinomas could be underdiagnosed T2's. The aim of this study is to know if substaging detects real high risk neoplasias or simply reflects infrastaged (not detected T2) carcinomas. METHODS We have reviewed our reTUR performed during 2001-2006 for HGT1. We define reTUR as the procedure performed before 2 months after the initial TUR. We also reviewed 27 cases (T1b,c) looking for evidence of lymphovascular invasion with H&E. RESULTS. 53 HGT1:12T1a; 22T1b,c (9/22 -group A- followed the entire protocol and 13/22 -group B- didn't); 15T1; 4TX, with 17/53 re-TUR. 9 came from T1b,c group A, 1 fromT1b,c group B, 3 from TX , 2 from T1a and 2 from T1. Group A re-TUR (9/9) results were 1HGT1c (radical cystectomy showed pT0 pN1) ,1HGT1A , 7 non-tumoral tissue. For group B there was 1/13 re-TUR with HGT1C . For the remaining 7 re-TUR patiens we found 2HGT1 (1 from TX 1 from T1a) and 5 non-tumoral tissue (2 from TX, 1 from T1A, 2 from T1). There was no muscle infiltrating carcinomas in any of the re-TUR. 4/13 T1bc group B and 2/15

T1's patients progressed, none of T1bc group A, none of T1a and none of TX progressed. Vascular invasion was found in 6/27 cases, 2/27 were doubtful and 19/27 were without invasion . 3/6, 1/2, 2/19, progressed. CONCLUSIONS. There is no evidence to consider HGT1b,c as understaged T2. We think that deep invasive HGT1 have a high risk of progression and merits a particular treatment protocol. Deep invasive submucosa carcinomas have the capacity of lymphovascular invasion and lymph node metastases.

PP3-75

THE INCIDENCE AND CLINICOPATHOLOGICAL SIGNIFICANCE OF MULTIFOCAL PROSTATE CANCER

Deniz Filinte[1], Ozdal Dillioglugil[2], Bahar Muezzinoglu[1]
[1] Kocaeli University Medical School Department of Pathology, Kocaeli, Turkey
[2] Kocaeli University Medical School Department of Urology, Kocaeli Turkey

Background: The presence of multiple foci of prostate cancer within the same gland is not an uncommon finding. Various studies reported incidence of multifocality in prostate cancer between 67-87%. There is an index tumor (measured by largest volume), presumed to be the driver of prognosis and one or more separate accessory tumors. Design: Ninety-four radical prostatectomies were performed between 2003 and 2006 and processed as whole specimens with all tumor foci mapped. The cases didnot have any preoperative theraphy. The tumors were further analyzed in terms of number of tumor foci. Chi square test was used for the correlations between multifocality and and patient age, preoperative PSA, extracapsular extension, surgical margin positivity, lymph node metastasis and seminal vesicle invasion. Cases operated between 2003 and 2005 had preoperative sextant core needle biopsy. For cases operated in 2006 preoperative transrectal biopsy had 12 cores. Results: As a whole, in 41.5% of cases (39 cases) prostate cancer was multifocal. For cases operated in 2006 this incidence was 67.7% The mean number of foci was 1.68. The age and the preoperative PSA value were not different in unifocal and multifocal tumors. Unifocal tumors had more frequent extracapsular extension (ECE) than the multifocal tumors.(p=0.038). Lymph node metastasis, seminal vesicle invasion and surgical margin positivity didnot have any significant difference in terms multifocality. Conclusion: In our cases, unifocal prostate tumors are more frequent than the multifocal tumors. With the standard 12 core biopsy protocol the incidence of multifocal tumors are increasing when compared to sextant biopsies. Unifocal tumors are at higher pathological stage than the multifocal tumors. This may be attributed to, assimilation of smaller volume cancers by the large volume index cancer at the time of diagnosis.

PP3-76

EFFECT OF SOY ISOFLAVONE SUPPLEMENTATION ON PROSTATE TISSUE, MARKERS OF PROLIFERATION AND APOPTOSIS AND HISTOPATHOLOGICAL ENDPOINTS OF TUMOR GRADE, VOLUME AND STAGE

BACKGROUND Isoflavones are among the most promising potential anticarcinogenic compounds in soybeans. Epidemiological studies indicate that consumption of soybean-containing diets is associated with a lower incidence of certain human cancers like prostate cancer. METHOD Men diagnosed with localized prostate cancer who have agreed to undergo radical prostatectomy, brachytherapy or cryotherapy were enrolled in the study (21 African American, 12 White, and 1 Asian). Subjects were given soy isoflavone capsules containing 150, 300 or 600 mg genistein (PTI G-2535) or placebo capsules. The study included a four-arm, double blind, placebo-controlled parallel group dose ranging trial: arm 4 -placebo; arm 3 -150 mg; arm 2 -300 mg; arm 1 -600 mg. Both biopsy and radical prostatectomy specimens belong to this eligible patient group were examined by using H&E and immunohistochemical biomarkers. Biomarkers of cell growth, bcl-2, MIB-1, cyclinD1, CDK5, CDK6; biomarkers of cell differentiation, apoptosis, and growth control, bax, p21, p53, Cx43 and biomarkers of angiogenesis, MVD, VEGF expression in tissues were evaluated by immunohistochemistry. The results were compared with the pathological stage and tumor volume on radical prostatectomy specimens. RESULTS No statistically significant change from pre to post treatment levels in any group and no statistically significant difference between the placebo and experimental groups in terms of change from pre to post levels for Cx43, MIB-1, p21, bcl-2, bax, p53, cyclin D, CDK5, CDK6, MVD and VEGF were found. Statistical analysis revealed no significant differences between the groups except in margin positivity, which was much lower in group 1 compared to other groups. CONCLUSION Our results did not show any difference between our study groups with respect to markers of proliferation and apoptosis. This may be partly due to small sample size.

PP3-77

THE IMPACT OF UNUSUAL HISTOMORPHOLOGICAL VARIANTS ON PATIENT OUTCOME WITH HIGH GRADE MUSCLE-INVASIVE UROTHELIAL BLADDER CARCINOMA: CLINICOPATHOLOGICAL STUDY OF 63 CASES

B. Handan Ozdemir, Gulnur Guler, Aysel Colak
Baskent University, Faculty of Medicine, Ankara, Turkey

Our aim is to investigate the unusual histomorphological variants of high grade muscle-invasive urothelial cell carcinoma of the bladder and to assess its influence on prognosis. For this purpose we re-examine total 350 cases with urothelial bladder carcinoma. Of 350 cases 63 (18%) showed diverse morphologic features including micropapillary (10 cases), microcystic (8 cases), lymphoepithelioma-like carcinoma (3 cases), sarcomatoid carcinoma (eight cases, including pseudoangiosarcomatous type), osteoclast-rich undifferentiated carcinoma (4 cases), clear cell (5 cases), lipoid cell (5 cases), nested (3 cases), plasmacytoid/lymphoma-like variant (4 cases), rhabdoid cell (3 cases), signet ring cell (2 cases), small cell carcinoma (4 cases), inverted type (3 cases), and syncytiotrophoblastic giant cells (1 case). The extension of these non-conventional histomorphological features in tumor and the number of histological differentiation types in each tumor were examined. We found that the extension of unusual morphologic features with any proportion of conventional urothelial carcinoma had an unfavorable impact on survival time. Survival time of patients decreases significantly with increasing amount of non-conventional histological type in tumor. We also noticed that the increased number of differentiation types had an unfavorable influence on patient outcome. In conclusion we suggest that the assessment of the extension and the number of unusual histological differentiation types may be an important prognostic factor in high grade and muscle-invasive tumors.

THREE DIFFERENT SIMULTANEOUS TUMORS IN ONE PATIENT; CLEAR CELL TYPE RENAL CELL CARCINOMA, LOW GRADE COLLECTING DUCTUS CARCINOMA AND MICROPAPILLARY UROTHELIAL CARCINOMA

Ipek Isik Gonul[1], Asli Cakir[1], Sinan Sozen[2], Omur Ataoglu[1], Turgut Alkibay[2]
[1] Gazi University School of Medicine, Department of Pathology, Turkey
[2] Gazi University School of Medicine, Department of Urology, Ankara, Turkey

Background: The coexistence of multiple and synchronous primary neoplasms in the genitourinary system has rarely been described in the literature. The case represented here was much more exciting since collecting ductus carcinoma has a low grade morphology,which is very rare. Method: Our case was a 57-year-old man who presented with prostatism for 2 months. Cystoscopy showed a mass in bladder, and abdominal CT revealed two masses in the middle segment and lower pole of the right kidney. With the preoperative diagnosis of high grade urothelial carcinoma, total cystoprostatectomy with urinary diversion and obturatory lymph node dissection was performed and 2 months later he underwent partial nephrectomy for the excision of renal tumors. Result: Grossly, 5x4x3 cm nodular lesion was found in the left lateral wall of the bladder. Microscopically, high grade infiltrative urothelial carcinoma with squamous differentiation and micropapillary growth pattern invaded the perivesical fatty tissue. Two metastatic lymph nodes were identified. One of the masses of the kidney had a pale gray, sponge-like cross section and it was 5.5 cm in its maximum diameter. Histology revealed a tubulocystic architecture characterized by dilated tubules lined by cuboidal to columnar cells that often have a hobnail pattern in a desmoplastic stroma. Tumor cells were positive for HMWK, vimentin, EMA and RCC. The lower pole kidney tumor was an obvious clear cell renal cell carcinoma with Fuhrman grade 2. EMA, vimentin and CD 10 immunoreactivity was detected but HMWK was negative. Conclusion: When synchronous tumors are diagnosed, standart sequential therapies may need to be reconsidered because of the possible problems concerning the effectivity of the treatment. Our patient is now being treated by a chemotherapy protocol against the metastatic carcinoma of the urinary bladder. Although we know that collecting ductus carcinoma is an agressive variant of renal carcinomas and must be treated seriously, our case was one of the very rare reported examples of “low grade” morphology with favorable prognosis. Therefore, it was not considered as our priority.

PP3-79

INVESTIGATION OF CYP 1A1 AND GST M1 GENE POLYMORPHISMS AND P53 IMMUNHISTOCHEMICAL STAINING WITH CLINICAL AND PATHOLOGIC FEATURES IN PATIENT WITH TRANSITIONAL CELL BLADDER CARCINOMA

Tulin Ozturk[1], Haydar Durak[1], Oguz Ozturk[2], Turgay Isbir[2], Canser Cakalir[1]
[1] Istanbul University Cerrahpasa Faculty of Medicine Department of Pathology, Turkey
[2] Istanbul University Institute of Experimental Medicine Department of Molecular Medicine, Turkey

INTRODUCTION: Bladder cancer is the second most common malignancy of the genitourinary tract and the fourth most common type of neoplasm in men in many industrialized countries. Genetic status of the individuals and environmental interactions are thought to play an important role. Individual differences in cancer susceptibility may be mediated in part through polymorphic variability in the bioactivation and detoxification of carcinogens. The aim of this study was to identify the polymorphisms of the GST M1 and CYP 1A1 genes, making correlation between those polymorphisms and the P53 expression as well as comparing with pathological clinical parameters with the patients with transitional cell carcinoma of the bladder. RESULTS: We obtained pathologically proven transitional cell carcinoma samples from 100 (19 female, 81 male: mean age 63.69±14.42 years) bladder cancer patients who underwent transurethral resection (TUR) or radical cystectomy between 2000 and December 2005 at Istanbul University Cerrahpasa Faculty of Medicine, Department of Pathology. Healthy individuals, 101 total; 33 female, 68 male; mean age 56.46±12.86 years were chosen as the control group.DNA was extracted from formalin – fixed, paraffin –embedded blocks of the patients. We used cut-off value for P53positivity of 10% of cells or more. There is no significant difference in gene polymorphisms between the patients and control group, however, CYP 1A1 heterozygote mutant genotype was less common in patient group. GST M1 null genotype is not different between patients and conrol groups but increasing risk for perineural and vascular invasion, multifocality, involvement of the pelvic lymph nodes, metastatic spread and death from the disease. and also invasive growth pattern is greater in the patients with GST M1 null genotype. These patients show higher p53 expression as well.There is a significant difference in p53 expression between CYP 1A1 homozygote wild and both mutant genotypes. CONCLUSION: In our study, although there was no significant difference between patient and control groups for GST M1 nullgenotype we found that the patients with GST M1 null genotype had poor outcomes than the others. P53 immunoreactivity was also statistically higher in the patients who have GST M1 null genotype.

A RETROSPECTIVE STUDY ON BLADDER NEOPLASMS

Gulistan Gumrukcu, Senay Tosun, Bilgen Sari, Selvinaz Ozkara, Pembegul Gunes, Murat Erkan
Haydarpasa Numune Education and Research Hospital , Department of Pathology , Istanbul, Turkey

In Haydarpasa Numune Hospital of Pathology Laboratuary , the bladder TUR and cytology cases which have been examined between 2003 August-2007 February monts were documented. 893 TUR ve 26 urine cytology , that belongs to 505 patients, which have been sent to our laboratuary between retrospectively reviewed. The cases were between 6-91 years old. There were 802 men and 117 women. 654 of all cases were reported malign and the other 265 were benign. The 52 cases of the group , which was reported malign, were papillary urothelial neoplasia- low malignant potential, 287 low grade carcinomas and 301 high grade carcinomas. One case of all the cases in that malign group was squamous cell carcinoma, 1 case high grade malign lenfoma infiltration, 1 case embryonal rhabdomyosarcoma, 2 cases carcinosarcomas of the bladder, 2 cases adenocarcinoma infiltration, 1 case dissemine insitu carcinoma and the other 2 cases were described as amyloidosis. According to Mostofi grade, 286 of the low grade carcinomas cases , were grade II and only 1 case was grade III. 116 of the high grade carcinomas cases reported as grade II, 185 as grade III. Lamina propria invasion in 26 cases has been diagnosed low grade carcinomas group. In 147 cases of the high grade carcinomas detrusor muscle invasion defined. 40 cases reported as inistu carcinoma determined. In 162 cases squamous differantiation was reported. The 3 of the benign lesions were inverted papillom, 3 flat hyperplasia, ,1 nephrogenic adenoma, 1 papillom and 12 cases were reported papillary urothelial hyperplasia. When 180 cases described as chronic specific and nonspecific chronic cystitis, the other cases defined as normal urothelial mucosa.

PP3-81
SURVIVIN, INHIBIN AND p16INK4a EXPRESSION IN PROSTATIC ADENOCARCINOMAS

Figen Ozturk[1], Hulya Akgun[1], Fatma Tokat[1], Atilla Tatlisen[2]
[1] Erciyes University School of Medicine, Department of Pathology, Kayseri,Turkey
[2] Erciyes University School of Medicine, Department of Urology, Kayseri,Turkey

BACKGROUND: Prostate carcinoma is one of the most commonly occurring malignancies in Western men and is a leading cause of carcinoma-related deaths. The aims of this study were to characterize and compare the expression patterns of survivin, inhibin and p16INK4a in primary prostate adenocarcinomas. METHODS: Immunohistochemical staining for survivin, inhibin and p16INK4a was carried out on archival specimens from 21 patients who underwent transurethral resection. Six of the 21 patients were low grade prostate carcinomas (final Gleason grade 2-6) and 15 were high grade prostate carcinomas (final Gleason grade 7-10). The percentage of cells that expressed survivin, inhibin and p16INK4a were classified qualitatively into 4 categories (0, +1,+2, and +3) based on intensity of staining and percentage of cells. Chi-square test and Fisher's exact test were utilized for the analysis. RESULTS: The median patient age was 63 years (40-76). p16INK4a analysis showed positive staining in 83.3 % of the low grade and 100% of the high grade carcinomas specimens. Five patients (23.8%) were positive for inhibin and 7 patients (33.3%) were positive for surviving, all of which were high grade prostate carcinomas. A statistically significant difference was found among p16INK4a, and survivin and inhibin expression. p16INK4a expression was significantly higher in prostate carcinomas (95.2%). We compared p16INK4a immunostaining scores with surviving and inhibin expressions. Regarding the inhibin and survivin immunohistochemical expression, 25% (5/20) were concomitant p16INK4a and inhibin positive, 35% (7/20) were p16INK4a and survivin positive cases. CONCLUSION: In this study, we have demonstrated p16INK4a staining might be a diagnostic aid particularly in prostate carcinomas and survivin and inhibin expression might be helpful for differentiating particularly high grade carcinomas. Increased expression of p16INK4a may be involved in the carcinogenesis of the prostate and may be a potential therapeutic target. Additional studies are needed to confirm the potential value of p16INK4a, survivin and inhibin expression in prostate adenocarcinomas.

PP3-82
EPIDEMIOLOGY OF TESTIS TUMOURS AFTER 50 YEARS OLD

Camparo Philippe[1], Comperat Eva[2], Bertocchi Céline[1], Richard Francois[2], Capron Frédérique[2], Houlagtte Alain[1]
[1] HIA Val de Grace, Paris, France
[2] Hopital Pitié Salpétrière, Paris, France

Objective : In attempt to identify causes of testicular tumors among adult after 50 years old. Materials and methods : A retrospective study was made from patients treated in the military hospital Val de Grace and hospital la Pitié Salpétrière in Paris. Clinical data and diagnosis were obtained from pathologic reports. Populations were divided according age of onset : group 1 : post pubertal patients of less than 40 years old, group 2 : patients between 40 and 49 years old, and group 3 : patients of 50 or more years old. Statistical analyses were made with Epiinfo 6.04d. Results : Between 1994 and 2006, 392 testis tumors were treated in the military hospital Val de Grace (252) and la Pitié Salpétrière (140). Mean age of patient was 35 (median 31 extreme 16-85). 281 tumors (72%) occurred in group 1, 52 tumors (13,3%) were observed in group 2 and 59 (15%) in group 3. Germ cell tumors were the most common tumors observed representing 70,9%. Sex cord stromal tumors (SCT) represented 10% and other tumors 19,1%. Regarding age of onset, germ cell tumors represented 77,23% in group 1, and 80,77% in group 2. Non-seminomatous germ cell tumors and seminomas were observed with the same frequency before 40 years old. Seminomas were the main germ cell tumor observed after 40 years old (57,69% vs 23,08% for non seminomatous germ cell tumors in group 2). In group 3, germ cell tumors represented only 32,2% cases (seminomas 23,7%, NSGT 8,5%). Sex cord stromal tumors represented 18,6% and other tumors 49,1%. Among these, lymphoma were the most common (10 cases, 17%). Tumors developed from mesothelia represented 6,8% (adenomatoid tumors 2 cases, malignant mesothelial tumor 2 cases) and spermatocytic seminomas 3,4% (2 cases). Five tumours were developed from testis adnexa (2 sarcomas and 3 benign tumors), 2 were testicular metastasis (one prostatic and one colonic cancer), 2 were benign epidermoïd cyst and 3 pseudotumoral lesion (2 orchiepididymitis and 1 amyloid pseudo tumor of the testis). Conclusion: Germ cell tumors are the most frequent tumor observed in adult testis but their incidence drop dramatically after 50 years old. At this age, sex cord stromal tumors and lymphomas are common and the use of lymphoid markers CD20 and CD79a, plus inhibin, Melan A and calretinin may be usefull in the diagnosis of a testicular tumor. Spermatocytic seminomas and adnexial tumors are very uncommon and one should consider the possibility of a metastatic origin in a tumor with atypical histologic patterns.

PP3-83
PRIMARY MUCOSA-ASSOCIATED LYMPHOID TISSUE (MALT) LYMPHOMA OF THE URINARY BLADDER

Ahmet Midi[1], Cem Comunoglu[2], Sinan Ekici[3], Alper Eroglu[3], Onder Peker[1]
[1] Maltepe University, Department of Pathology
[2] Oruc Pathology Laboratory
[3] Maltepe University, Department of Urology , Istanbul, Turkey

Background: Primary malignant lymphoma of the bladder is a rare tumor and account for less than 0.2% of all extranodal lymphomas. We here present a case of primary low-grade B- cell lymphoma of the MALT type of the urinary bladder. Case report: Fifty-six year old male patient presented with frequent urination, dysuria and periumbilical pain. Cystoscopic biopsies from bladder neck, right and left bladder wall, and base were taken. Histological findings revealed a dense lymphoid infiltrate. Widespread and dense mucosal lymphoepitelial lesions were present. The infiltrate mainly were composed of centrocyte-like cells and infrequent immunoblast/centroblasts. Scattered lymphoid follicles that had active residual germinal centers were seen. Immunohistochemically CD3, CD20, CD30, CD23, CD5, BCL-2, Cyclin D1, and Ki-67 were performed. CD3 was positive in 10% of the small cells, CD20 was positive in 90% of all cells, CD30 was negative, CD23 was positive at follicular dentritic cells in residual germinal centers, CD5 was positive in 10% of the small cells, BCL-2 was positive in 90% of all cells, Cyclin D1 was negative, and Ki-67 was positive in 20% of the neoplastic cells. With these histomorphological and immunuhistochemical findings, a diagnosis of extranodal marginal zone lymphoma (Malt lymphoma WHO-REAL), was given. Conclusion: Urinary bladder's lymphomas are divided into three clinical groups: 1- Primary lymphoma localized in the bladder, 2- Lymphoma presenting in the bladder as the first sign of disseminated disease (Nonlocalized lymphoma), 3- Secondary lymphoma. Our case was a primary lymphoma. Clinical and histopathological diagnosis of the MALT type lymphomas may be difficult. Immunohistochemical findings help us in recognition of these tumors in cases displaying lymphoepithelial lesions and a dense lymphocytic infiltration.

PP3-84
MORPHOLOGICAL AND IMMUNOHISTOCHEMICAL CRITERIA OF PROGNOSIS IN RENAL CELL CARCINOMA
Margarita Rybakova[1], Salman Al-Shukhri[2], Yulia Ponomareva[2], Andrei Loukyanov[2]
[1] Department of Pathology, St Petersburg State Medical University, St Petersburg, Russia
[2] Department of Urology, St Petersburg State Medical University, St Petersburg, Russia

Aim of the study. To estimate histopathological and immunohistochemical features of renal cell carcinoma with regard to clinical course and prognosis. Material and methods. Biopsy specimens from 47 patients (aged 35-75) with renal cell carcinoma were studied histologically and immunohistochemically. Grading was performed according to Fuhrman. Immunohistochemistry was done for Ki-67, p53, bcl-2, CD34, N-cadherin and bax. Clinical records were evaluated with regard to type of surgery (resection or nephrectomy), tumor size, relapse and metastases. 13 patients showed relapsing and/or metastatic disease during 6-18 months follow-up after surgery, in 34 - the disease was local and non-progressive. Statistical analysis included p values and correlations. Results. Nearly all cases with progressive disease showed marked histological atypia. In these cases the capsule was thin or absent, the tumor had 3d -4th nuclear grade, and was characterized by low expression of N-cadherin and high proliferation rate (assessed by Ki-67 immunostaining). No clear difference was seen in bcl-2 and bax expression between the groups. A common feature associated with progressive disease was abundance of sinusoidal vessels, and invasion of tumor cells into these vessels was frequently seen. Expression of p53 gene product showed strong positive correlation with tumor nuclear grade. Conclusion Renal cell carcinomas with marked histological atypia, 3d -4th nuclear grade, having thin or no capsule, with abundance of sinusoidal vessels, low expression of N-cadherin and high proliferation rate are associated with progressive disease and unfavorable prognosis. Size of the tumor had minor influence on clinical course and prognosis in our setting.

p27 AND HIGH MOLECULAR WEIGHT CYTOKERATIN EXPRESSION IN PROSTATIC ATROPHY AND POST-ATROPHIC HYPERPLASIA
Cumhur Ibrahim Bassorgun, Betul Unal, Irem Hicran Ozbudak, Bahar Akkaya, Mehmet Akif Ciftcioglu
Akdeniz University, School of Medicine, Department of Pathology, Antalya, Turkey

Background: Longstanding chronic inflammation and atrophy of the prostatic glands have known as linked entities. Development of carcinoma in a background of chronic inflammation has shown recently in several organs. This association between inflammation and carcinoma has also been supposed as a potential mechanism regarding the prostatic carcinogenesis. Atrophy of the prostate is identified as a reduction in the volume of preexisting glands and stroma and can be divided into two major patterns, diffuse and focal. Recently, a theory was suggested as the atrophy of prostate glands and the subsequent proliferation of the glandular epithelium represent the initial lesion, which can develop into cancer. Prostatic epithelium is stained with cytokeratins and p27 immunohistochemically. p27 is a cyclin-dependent kinase inhibitor which decreases in majority of prostatic adenocarcinomas and high-grade prostatic intraepithelial hyperplasia. In this study, we evaluated the expression of p27 and high molecular weight cytokeratin (HMWC) in prostatic epithelium. Method: The study was performed in 15 prostate tissues with prostatic atrophy and post-atrophic hyperplasia. Prostate tissue samples were stained with p27 and HMWC immunohistochemically. Percentage of nuclear staining in epithelial cells with p27 was assessed semiquantitatively. T-test was used for statistical analyses. Results: All atrophic and post-atrophic hyperplastic epithelial cells were stained with HMWC discontinuedly. The average count of p27 positive cells per 1000 cells were found 67 in atrophic glands and post-atrophic hyperplastic glands, but 79 in normal prostatic glands. There were statistically significant difference between p27 values of atrophic, post-atrophic hyperplastic glands and normal prostatic glands ($p=0.001$). Conclusion: Downregulation of p27 is seen in prostatic epithelial cells of atrophy and post-atrophic hyperplastic glands. Considering the suppressor role of p27 on cell proliferation, downregulation of p27 may be a marker of carcinogenesis. Specific staining pattern of HMWC may be helpful to distinguish foci of atrophy from normal prostate glands.

[3] Ljudevit Jurak Universitiy Department of Pathology, Sestre Milosrdnice University Hospital Zagreb, Croatia
[4] Clinical Hospital Osijek, Croatia

Introduction: The mixed germ cell – sex cord stromal tumor of the testis is defined as neoplasm having neoplastic germ cells elements and neoplastic sex-cord stromal elements arranged in a diffuse pattern. Case report The case of a 45-year-old man with painless right sided testicular tumor is reported. Radiologic and laboratory investigations including serum alpha-fetoprotein (AFP) and human chorionic gonadotropin (HCG) showed no abnormalities. A right radical orchidectomy was performed. A histologic examination showed biphasic tumor which was composed of two different types of cells. The majority of the tumor consisted of quite unifom predominantly spindle cells, which were immunohistochemically positive for vimentin and S-100 protein and focally for α-inhibin. The second cell type were large cells with abundant clear cytoplasm arranged in a small clusters at the periphery of the tumor. These cells showed no reactivity for immunostains mentioned above neither for cytokeratines MNF 116 and 7, AFP, HCG and PLAP. Conclusion As any rare neoplasm the mixed germ cell – sex cord stromal tumor of the testis makes a huge diagnostic problem. Clinical and biological behavior of this type of testicular neoplasm is not yet completely discovered.

PP3-87
PREDICITVE VALUE OF HISTOPATHOLOGICAL FEATURES OF HIGH GRADE PROSTATIC INTRAEPITHELIAL NEOPLASIA FOR PROSTATIC ADENOCARCINOMA
Gupse Turan, Bahar Muezzinoglu
Kocaeli University Medical School Department of Pathology, Kocaeli, TURKEY

Background: High grade prostatic intraepithelial neoplasia (HGPIN) is considered precursor of prostate carcinoma. Its detection in biopsy specimens warrants repeat biopsy for concurrent or subsequent carcinoma. Aim: In this study we aimed to determine the incidence of cancer in prostate needle biopsies after an initial diagnosis of HGPIN and ascertain whether histologic and/or clinical findings can help to predict the increased risk of finding cancer on repeat biopsy. Methods: There were 49 patients diagnosed as isolated HGPIN between January 1996 and December 2005 and had at least one repeat biopsy. Each case was reviewed and the following histopathological features were evaluated on each needle biopsy: number and

percentage of cores involved by HGPIN, number and percentage of HGPIN glands, percentage of gland involved by HGPIN, linear measurement and percentage of HGPIN glands in whole biopsy, pattern of HGPIN, feature of pattern (pure vs combined); nucleolar prominence, pleomorphism and mitotic activity in HGPIN glands. Clinical parameters including the age and preoperative PSA levels were recorded. The pathological results in repeat biopsies were divided into 3 groups: benign, HGPIN and cancer. Relationship of morphological findings of HGPIN and the clinical outcome were evaluated by chi-square and t test. Results: Prostate cancer was detected in %16.3 of the cases in repeat biopsies. Pure pattern of HGPIN and presence of pleomorphism in HGPIN were predictive to determine the cancer on repeat biopsy ($p=0.013$, $p=0.02$ respectively). The difference between groups for other morphological or clinical parameters were not significant ($p>0.05$). Conclusion:Our results indicate that presence of cellular pleomorphism and pure pattern of PIN in needle biopsies are the histological features requiring close follow up for unsampled synchronuous or metachronous prostate cancer.

PP3-88

IS THE OUTER PERIPHERAL ZONE / SUB CAPSULAR TISSUE COMPARTMENT OF THE PROSTATE MORE SUSCEPTIBLE TO CARCINOGENESIS AND EARLY NEOPLASTIC TRANSFORMATION? A TOPOGRAPHIC MORPHOLOGIC AND TISSUE MICRO ARRAY IMMUNOHISTOCHEMICAL STUDY

Gokben Yildirim Kupesiz[1], Charles Butler[2], Vashali Pansari[2], Wael Sakr[2]
[1] Department of Pathology, Akdeniz University, Antalya, Turkey
[2] Harper University Hospital, Karmanos Cancer Institute & Wayne State University Hospital, Detroit, USA

Background: The approach to prostate cancer detection using needle biopsies evolved in recent years to obtain more biopsy cores and to concentrate on sampling the outer and sub capsular areas of the gland including the apical/anterior compartment. Several studies have demonstrated that this modification from the traditional “sextant” method results in better detection of particularly smaller tumors. Our objectives were to 1-document the anatomical distribution of morphological lesions characteristic of early prostatic neoplasia including high grade prostatic intraepithelial neoplasia (HGPIN) and small foci of prostatic carcinoma (PCA) in two large series of radical prostatectomy specimens and of prostate gland examined in a post mortem setting. 2- To explore whether the outer glandular epithelium is likely to express markers associated with early changes of carcinogenesis. Method: Foci of PCA and HGPIN were mapped in a series of 83 consecutive, entirely embedded glands obtained during autopsies of young men (age 22-55) and in a series of 227 radical prostatectomy specimens (RPS) harboring small tumors (total tumor volume <=1 c). The distance of PCA and HGPIN foci from the outer surface of the gland was measured. Using the hematoxilin and eosin stained section, tissue microarrays (TMAs) were constructed from benign glandular epithelium of both subcapsular and inner peripheral zone locations from both the RPS and the autopsy prostates. The TMAs were stained with cell cycle regulator/proliferative markers (p27 and Ki-67) and with Glutathione S-Transferase 1 (GSTP1), Results: Of the 235 foci of PCA found in the 83 autopsy gland, 191 (81%) were within 5 mm of the outer surface of the gland. Similarly 176 of the 223(79%) foci of HGPIN in this cohort had the same distribution. For RPS, 112 (49%) of the small volume tumors were also within 5 mm of the outer surface. GSTP 1 showed less diffuse distribution and with lower intensity in the outer versus the inner compartment of the gland. Similar pattern was found with p27 immunoreactivity while the proliferation rates were low in both compartments but slightly higher in the most outer epithelium. Conclusion: Most small volume PCA, (both sub clinical and low stage clinically detected), and most HGPIN are present in the outer subcapsular prostatic tissue. Our morphologic and TMAs findings indicate a higher vulnerability of the epithelium in the outer peripheral zone to early neoplastic transformation and are consistent with the recent biopsy sampling approaches.

PP3-89

MORPHOLOGICAL FEATURES OF KIDNEY CYSTS OF III BOSNIAK CLASSIFICATION TYPE

Pasechnik Dmitry
Rostov Medical University, Russia

Kidney cysts of III Bosniak classification type are the most complex problem in malignancy potential assessment and adequate treatment strategy selection. The aim of the research was to investigate morphological features of III type kidney cysts. 15 kidneys operated under following conditions were investigated: kidney cancer (5), multilocular cysts with possible malignant transformation (5), multicystic dysplasia of the kidney (3), benign cysts (2). There were investigated 10 males and 5 females. The median age was 54.8±2.35 years. All samples were of the following histological structure: clear cell renal cell carcinoma with cystic degeneration (4 cases), cystic renal cell carcinoma (6 cases), multicystic dysplasia of the kidney (3 cases), angiomyolipoma with hemorrhages and cystic degeneration (1 case). There was one case of synchronous multifocal tumor of the kidney: 3 angiomyolipomas were combined with cystic nephroma adult type. Cystic renal cell carcinomas are characterized by single cysts inner lining preferably of rounded or columnar cells with clear vacuolated cytoplasm, which are much in common with typical clear cell renal cell carcinoma. Similar cells were revealed in cystic cavities fluid under cytological investigation. All tumors were well-differentiated (Fuhrman nuclear grade -1) without invasive growth out of kidneys. Cystic nephroma was characterized by inner lining consists of cubical or hobnail cells monolayer with eosinophilic cytoplasm without signs of nuclear atypism and invasive growth. Thereby III type kidney cysts to Bosniak classification represent the heterogeneous group of tumorous and nonneoplastic diseases demanding preoperational and intraoperational morphologic assay to make a correct choice of type and extent of surgical treatment.

PP3-90

eNOS AND iNOS EXPRESSION IN UROTHELIAL TUMORS OF THE URINARY BLADDER

Ipek Isik Gonul[1], Asli Cakir[1], Nalan Akyurek[1], Serhat Gurocak[2], Sinan Sozen[2], Turgut Alkibay[2]
[1] Gazi University School of Medicine, Department of Pathology
[2] Gazi University School of Medicine, Department of Urology, Ankara, Turkey

Background: NO (nitric oxide) is one of the main factors responsible for the cytotoxic activity that macrophages exert against tumor cells. It also plays an important role in tumor growth and angiogenesis. NOS (nitric oxide synthase) has been found in various tumor types suggesting that NO may be produced in tumor tissue. The purpose of this study was to analyze the expressions of endothelial (eNOS) and inducible (iNOS) isoforms of NOS in the urothelial tumors of different grade and stage and to compare it with clinicopathological findings. Method: The medical records of 87 patients with primary urothelial carcinomas were reviewed. Grade according to WHO 2004 classification, pathological stage, invasion patterns of invasive tumors (nodular, trabecular, infiltrative, micropapillary) and stromal response types (edema and congestion, desmoplasia, fibroblastic proliferation, inflammatory response) were assessed by light microscopy. Paraffin embedded tumor sections were stained immunohistologically with eNOS and iNOS antisera and semiquantitative evaluations were performed. Association of eNOS and iNOS immunoreactivity with tumor grade, stage, invasion patterns and stromal response was examined with their

prognostic significance in predicting tumor recurrence. Statistically p values of less than 0.05 was considered statistically significant. Results: Both iNOS and eNOS expressions in tumor cells were heterogeneous, ranging from diffuse but weak expression to focal but severe staining. 73 % and 88% of tumors showed iNOS and eNOS expressions respectively. eNOS was also identified in endothelial cells. Stromal inflammatory cells showed varying degrees of iNOS expression but it was occasional. Neither eNOS nor iNOS immunoreactivity did correlate with tumor grade, stage or invasion patterns ($p>0.05$). On the other hand, tumor grade and stage were found to be statistically correlated with the invasion patterns of tumors ($p<0.05$). Conclusion: Although biological role of NO in urothelial carcinomas is still unclear, this study demonstrated that both iNOS and eNOS were being expressed in urothelial tumors. Our results were inconsistent with the literature in that we observed eNOS expression in tumor cells together with the endothelial cells of the capillaries. A clear correlation with tumor grade, stage and recurrence rate was not identified.

PP3-91
EXPRESSION OF CYCLIN D1, p16 AND Ki67 IN PROSTATE CARCINOMA

Chariklia Kouvidou[1], Grigoris Karpenisiotis[2], Dimitrios Anagnostakis[1], Haralambos Zorzos[1], Evgenia Lianou[1], Dimitrios Karanastasis[2], Konstantinos Stravodemos[3], Kitty Pavlaki[4]

[2] Department of Urology, ELPIS Hospital, Athens, Greece
[3] Department of Urology, LAIKO Hospital, Athens, Greece
[4] Deprtment of Pathology, Med School, University of Athens, Greece

Background: Alterations in cell cycle regulators and subsequent deregulation of the G1-S transition may cause uncontrolled cell cycle progression and may implicate in the development and progression of prostate cancer. The aim of this study was to investigate the expression of cyclin D1, p16 and Ki67 in prostate carcinoma and to correlate them with clinicopathological parameters. Materials and methods: Formalin-fixed paraffin-embedded tissue from 50 cases of radical prostatectomy was stained by immunohistochemistry for cyclin D1, p16 and Ki67. The anti-cyclin D1 (Neomarkers), the anti-p16 (NeoMarkers) and the anti-Ki67 antibody (MIB-1, Dako) monoclonal antibodies were used at dilution 1:30, 1:50 and 1:30, respectively. A step of microwave heating in a solution of sodium citrate was performed prior to incubation with the antibodies. Associations between p16 (<20% vs. [GTEQ]20%), Gleason's score (<7 vs. [GTEQ]7) and cyclin D1 (<10% vs. [GTEQ]10%), were evaluated using Fisher's exact test, while for Ki67 (median 8%, range 2%-30%) with all the above, Wilcoxon was adopted. Results: Cyclin D1 positive nuclear staining was found in 12/50 (24%) prostate carcinomas (14% of low and 86% of high grade). Benign prostate acini showed focal scattered cyclin D1 positivity of the basal and secretory epithelial cells. P16 positive nuclear and cytoplasmic staining was observed in 23/50 (31% of low and 69% of high grade). Positive staining was not found in benign prostate or hyperplastic acini. Ki67> median was found in 36/50 (40% of low and 60% of high grade). Cyclin D1 expression showed a statistically significantly correlation with higher Gleason's score ($p=0.04$) and advanced tumour's stage ($p=0.03$).There was a tendency for a significant relationship between p16 expression and Gleason's score (p-value=0.13) and a statistically significantly correlation between p16 and stage ($p=0.0003$). A trend for an inverse relationship between cyclin D1 and p16 was detected ($p=0.09$). A trend for a parallel expression between cyclin D1 and Ki67 was found. Conclusions: Cyclin D1 functions mainly in promoting cell proliferation and seems to play a role in the pathogenesis of prostate carcinoma. Increased p16 expression during tumour progression suggests that the senescence pathways are still intact in large number of prostate carcinomas.

PP3-92
FAS LIGAND EXPRESSION IN PROSTATE ADENOCARCINOMAS AND ITS RELATIONSHIP WITH HISTOPATHOLOGICAL FEATURES

Sema Bircan[1], Korkut Bozkurt[1], Nilgun Kapucuoglu[1], Alim Kosar[2]
[1] Suleyman Demirel University School of Medicine, Department of Pathology, Isparta, Turkey
[2] Suleyman Demirel University School of Medicine, Department of Urology, Isparta, Turkey

Background: Fas ligand (FasL) is a type II transmembrane tumor necrosis factor family protein, known to trigger apoptosis in cells that bear the FasL receptor, Fas. The aim of the study was to examine the expression of FasL in benign prostatic epithelium (BP) and prostate carcinoma (PC) and to investigate its relationship with histopathological features in PCs. Method: The study included 51 primary PCs (22 radical prostatectomy and 29 transurethral resection) and 28 BP specimens. All slides were re-evaluated histopathologically. In all cases Gleason grading and scoring, and in radical prostatectomy cases, extraprostatic extension, vascular and perineural invasion, high grade prostatic intraepithelial lesion (HGPIN), surgical margin status were recorded. Using tissue microarray slides, FasL examination was performed immunohistochemically. The staining was evaluated semiquantitatively as percentage of the stained cells as 1+, focal (<10%); 2+, moderate (10-50%); 3+, diffuse (>50%), and staining intensity was considered negative (0), mild (+), moderate (++), strong (+++). Results: Cytoplasmic and focal membranous FasL immunoreactivity was observed in 82.1% of BP (23/28) and 94.1% of PCs (48/51). The percentage of stained cells in PCs were classified as 10 (19.6%) focal, 10 (19.6%) moderate and 28 (54.9%) diffuse, and in BP cases, 8 (28.6%) focal, 10 (35.7%) moderate and 5 (17.9%) diffuse, respectively. The percentage of the stained cells with FasL in PCs was significantly higher compared with that in BP tissues ($p=0.003$). The PC cases with higher Gleason scores showed significantly much higher positively stained cells compared with that in lower ones ($p=0.045$). The intensity of FasL staining was also significantly different between PC and BP specimens ($p=0.005$). Mild (+) and moderate (++) staining was seen in 15 (53.6%) and 8 (28.6%) of BP specimens, respectively. Conversely, 20 (39.2%), 18 (35.3%) and 10 (19.6%) PC cases showed mild (+), moderate (++) and strong (+++) staining, respectively. In radical prostatectomy cases, the percentage of FasL staining was also significantly higher in cases with higher Gleason score and HGPIN compared with that in cases with lower Gleason score and without HGPIN ($p=0.022$, $p=0.024$, respectively). Conclusions: The increased FasL expression and its association with higher Gleason scores in prostatic adenocarcinomas suggest that FasL may be important biologic marker in the growth and progression of prostatic cancer and potential target of therapeutic intervention.

PP3-93
PATHOLOGIC CHARACTERISTICS OF PROSTATE CANCER IN AFRICAN AMERICAN AND CAUCASIAN MEN DIAGNOSED AND TREATED AT OR BELOW 50 YEARS OF AGE: RACIAL DIFFERENCES ARE MOST EVIDENT IN THE YOUNGER AGE BRACKET

Gokben Yildirim Kupesiz[1], Isaac Powell[2], David Grignon[3], Wael Sakr[3]
[1] Department of Pathology, Akdeniz University, Antalya, Turkey
[2] Department of Urology, Harper University Hospital, Karmanos Cancer Institute & Wayne State University Hospital, Detroit, MI, USA
[3] Department of Pathology, Harper University Hospital, Karmanos Cancer Institute & Wayne State University Hospital, Detroit, MI, USA

Background: Data from Wayne State University suggest that the racial discrepancies in the incidence and outcome of prostate cancer between African American (AA) and Caucasian (C), men

maybe more pronounced within the younger patient groups. The objective of this study was to compare pathological findings in both the diagnostic needle biopsy (NB) and the radical prostatectomy specimens (RPS) for the subset of men diagnosed, and the overlapping but no identical subset, who were treated by surgery at our institution. Design: For the NB subset, diagnostic serum PSA, number of cores involved by tumor and Gleason score for each involved core were recorded. For the RP subset, pathological stage, Gleason score, calculated tumor volume and extensiveness of high grade PIN were documented. Statistical analysis of the findings comparing pathological parameters between the two races for each subset was performed. Result: For the biopsy subset, 116 AA and 81 C patients were included in the study. The mean and median age for both groups were identical. Mean and median diagnostic PSA for AA were 7.4 and 5.5 ng/ml compared to 7 and 7:00 and 5.6 ng/ml for C [p< 0.05 for both values]. Forty five of the 116 (39%) AA patients, had three or more core involved by carcinoma compared to 19 of 18 (23%) C patients [p<0.05]. Nine Ten of 116 (8%) and 4 of 81 (5%) AA and C patients respectively had a biopsy Gleason score of 8 [p<0.06]. The RP cohort, included a nearly identical number of AA and C, (82 and 83 patients respectively). Organ confined (pT2), disease was found in 52 of 83 (63%) AA vs 44 of 82 (53%) C, [p<0.05]. While Gleason score distribution was similar, slight difference was found in the percentage of patients having Gleason pattern 4 or higher as their primary pattern (17% AA, 13 % C, [p= NS]). Larger tumors of 4 cc or greater were found in 31% of AA compared to 19% of C patients, [p<0.05]. Extensive HGPIN with diffuse involvement of the gland was evident in 52% vs 22% AA and C men respectively, [p<0.0005]. Conclusion: Our data suggest that the difference in pathological parameters indicative of a more aggressive prostate cancer appear to be sharper within the younger cohort of AA and C patients diagnosed with the disease. These data may indicate a potentially different pathogenesis of the disease in the younger African American population.

PP3-94
POTENTIAL DIFFERENCES IN THE CLINICOPATHOLOGICAL PROFILE OF FAMILIAL/HEREDITARY AND SPORADIC PROSTATE CANCER

Gokben Yildirim Kupesiz[1], Isaac Powell[2], David Grignon[3], Wael Sakr[3]
[1] Department of Pathology, Akdeniz University, Antalya, Turkey
[2] Department of Urology, Harper University Hospital, Karmanos Cancer Institute & Wayne State University Hospital, Detroit, MI, USA
[3] Department of Pathology, Harper University Hospital, Karmanos Cancer Institute & Wayne State University Hospital, Detroit, MI, USA

Background: There is increasing evidence implicating family history as a distinct risk factor associated with the development and possibly the aggressiveness of prostate cancer. Recent epidemiologic studies suggest a stronger familial aggregation for prostate cancer than that associated with colon or breast cancer, two malignancies with well recognized familial components. The objective of this study was to compare the clinicopathological characteristics of the patients with family history to that of the remaining radical prostatectomy patients. METHOD: Between1991 and 1997, the 1,321 patients treated by radical prostatectomy for clinically localized prostate cancer were considered for the study. The clinical history /record of our database indicated that 1074 (81.3%) of those patients were considered as having “sporadic” prostate cancer with no familial links while 247 (18.6%) met the criteria for familial/ hereditary distribution of the disease, (information self reported by patients). Of the 247, 120 were Caucasians, 114 African Americans and 13 belonged to other ethnic groups. Patients with affected first degree relative (father) or second degree relative (brother “s”) were used for this study. Results: The median preoperative PSA was 8.0, 7.9, 7.7 ng/ml in control group, father family history and brother history groups respectively. [p=NS], while the mean age at surgery was significantly younger for men with a history of a father having PCA vs the control 57 and n65 years respectively [p<0.05]. The percentages of patients with organ confined diseases were 40.4%, 47.1%) and 43.6% for patients with history of a father, a brother or no family member having PCA respectively. The corresponding figures for patient with extraprostatic extension were 18%, 16.9 % and 15 % respectively. Approximately one third 29.7% of patients with history of a father having PCA had Gleason Score 6 compared to 18.8% for patients with history of a brother having PCA and to 22.8 % for the control group. There were no differences among patients with Gleason Score 7 or higher. Median tumor volume was 3.33, 4.14 and 3.42 for patients with a history of a father, brother or no family member with PCA respectively. Conclusion A subset of patients with family history (those who have a first degree relative; father), with PCA had an earlier age of onset. The several parameters compared otherwise between the sporadic and the familial cases were not significantly different.

PP3-95
PRESERVATION OF ANTIGENICITY IN NECROTIC POST-CHEMOTHERAPY CHORIOCARCINOMA

Enric Condom Mundó[1], August Vidal Bel[1], Fina Climent Esteller[1], Xavier Garcia Del Muro[2], Josep Maria Piulats Rodriguez[2], Josep Ramon Germà Lluch[2], Eladio Franco Miranda[3]

[2] Servei d'Oncologia Mèdica. IDIBELL. Institut Català d'Oncologia. L'Hospitalet de Llobregat. Barcelona, Spain
[3] Servei d'Urologia. IDIBELL. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat. Barcelona, Spain

Introduction. Immunohistochemistry is occasionaly used to demonstrate cell lineage in spontaneously necrotic tumors, mainly carcinomas and lymphomas. Antigen preservation in necrotic post-chemotherapy germ cell tumors of the testis has not been reported. Objective. To test the immunoreactivity of necrotic metastates of testicular germ cell tumors. MATERIAL AND METHODS. Immunostaining for Cam5.2, EMA, CD10, αFP, PLAP and HCG on formalin fixed paraffin embedded tissue from resected residual metastatic masses (retroperitoneal lymph nodes: 9 specimens; lung: 6; liver: 2: mediastinal lymph nodes: 1) in patients treated with chemotherapy for germ cell tumors of the testis. Results. In the specimens from 12 patients necrotic tumor immunostaining was retained for Cam5.2, CD10 and HCG. The stained cells were mainly shadow syncytiotrophoblastic giant cells. The time from completion of chemotherapy to the resection of the residual tumors ranged from three to ten weeks. Post-chemotherapy HCG serum levels were normal in all cases (pre-chemotherapy levels were elevated in each case). PLAP, EMA, αFP and CD30 did not stain the necrotic tumor tissues. CONCLUSION. Necrotic post-chemotherapy germ cell tumors of the testis may retain immunoreactivity for Cam5.2, CD10 and HCG, thus allowing a positive diagnosis of necrotic choriocarcinoma.

PP3-96
EXPRESSION OF MUCINS AND CD10 IN ADENOCARCINOMA OF THE URINARY BLADDER

Ljubinka Jankovic-Velickovic[1], Vukica Katic[1], Jasmina Gligorijevic[1], Vesna Zivkovic[1], Biljana Djordjevic[1], Goran Marjanovic[2]
[1] Institute of Pathology Nis, Nis, Serbia
[2] Clinic of Hemathology and Clinical Immunology Nis, Serbia

Introduction: Mucins (MUCs) are high molecular weight membrane glicoproteins. Expression of MUC 1, 2, 5AC, and 6 genes may change during malignant transformation of epithelial

tissues according to characteristic pattern. CD10/neutral endopeptidase (NEP) is a membrane-bound zinc metallopeptidase which is expressed in urothelial neoplasms and normal urothelium. The aim of this study was to evaluate the expression of MUC1, MUC2, MUC5AC, MUC6 and CD10 in order to determine immunoprofile of the primary adenocarcinoma of the urinary bladder. Methods: Research was performed in 3 patients with vesical adenocarcinoma, at the Institute of Pathology Clinical Centre Nis. The specimens were fixed in 10% formaldehyde and embedded in paraffin. The sections were stained with HE. We detected mucin by immunohistochemical staining using the following monoclonal antibodies from Novocastra, Newcastle, UK: MUC1, MUC2, MUC5AC, MUC6 and CD10. As a control we used the normal surrounding urothelium. Results: All of the vesical adenocarcinoma displayed expression of MUC 1 (luminal membrane staining) and MUC 2 (cytoplasmic staining); MUC 6 in 2/3 cases, while MUC5AC was not detected. Expression of CD10 was present in one case. In the normal urothelium MUC1 was limited predominantly to the apical membranes of the umbrella cell layer, while CD10 was found to be expressed weakly or reaction was negative in the apical portion of the cytoplasm along the luminal surface. Conclusions: The mucin expression profile in adenocarcinoma of the urinary bladder allows the identification of MUC 1 together with intestinal mucin (MUC 2), and in certain cases MUC6. Expression of CD10 is indicative for absorptive-cell differentiation in vesical adenocarcinoma.

PP3-97

METANEPHRIC ADENOMA: A RARE BENIGN TUMOUR OF KIDNEY

Guldal Yilmaz[1], Eda Akpinar[1], Berkan Resorlu[2], Yasar Beduk[2], Ayse Sertcelik[1]
[1] Ankara University, School of Medicine, Department of Pathology, Turkey
[2] Ankara University, School of Medicine, Department of Urology, Ankara, Turkey

Introduction: Metanephric adenoma is a rare epithelial tumour composed of small, uniform, embrionic-appearing cells. It occurs in children and adults with female predominance. Approximately 50% of these tumours are incidental findings and they are categorized as benign metanephric tumours of kidney. Case Report: A 31-year-old female patient suffering from abdominal pain underwent ultrasonographic examination and a right renal mass was detected. Computerized tomography revealed a cystic renal mass located in the medial portion of upper pole of right kidney, which measured 3.5x3 cm in dimension. The laboratory findings, including blood counts and biochemical data, were in normal range. With the presumption of renal carcinoma an operation was planned and she underwent partial nephrectomy. Pathological examination, macroscopically, revealed a centrally cystic mass of 3.5x3x3 cm in dimention, with central haemorrhage and cut surface of grayish-tan in colour. Microscopically, a highly cellular tumour composed of tightly packed small, uniform, round tubular and acinar structures, encapsulated with thick fibrous tissue was seen. The cells were monotonous, with small uniform round to oval nuclei with delicate chromatin and inconspicious nucleoli. The cytoplasms were pale and scant. There was loose oedematous and focally hyalinized stroma. At the periphery of the tumour, there were many psammoma bodies. No mitotic figures were seen. Immunohistochemically, the tumour cells show diffuse and strong nuclear staining for WT-1, and cytoplasmic staining for vimentin and high molecular weight keratin. Also, moderate CD57 staining was detected in most tumoural cell cytoplasms. EMA, CK7 and low molecular weight keratin showed only focal positive staining. CD10 and RCC were negative. Conclusion: Metanephric adenoma is an uncommon, morphologically distinct tumour type, with characteristic histopathological features. Despite its size, it is benign and should be distinguished particularly from papillary renal cell carcinoma type 1 and Wilms' tumour. These unique features of metanephric adenoma should be pathologically and clinically recognized because of its invariably benign course.

PP3-98

CYTOKERATIN 7 AND ANTIMITOCHONDRIAL ANTIBODY EXPRESSIONS IN DIFFERENTIAL DIAGNOSES OF RENAL EPITHELIAL NEOPLASMS WITH EOSINOPHILIC CYTOPLASM

Ayhan Ozcan, Yildirim Karslioglu, Armagan Gunal, Bulent Kurt, Omer Gunhan
Department of Pathology, Gulhane Military Medical Academy and School of Medicine, Ankara, Turkey

BACKGROUND: The distinction between epithelial renal tumors with eosinophilic cytoplasm, namely, chromophobe renal cell carcinoma (ChRCC), the eosinophilic (granular) variant of clear cell (conventional) renal cell carcinoma (CRCC), and oncocytoma may remain questionable in some cases because of overlapping morphologic features. We evaluated cytokeratin 7 (CK 7) and antimitochondrial antibody (AMA) expressions to determine their potential value in distinguishing these tumors. METHOD: In this study, 22 renal tumors were included. They consisted of 11 ChRCCs, nine oncocytomas and two eosinophilic variant of CRCCs. Immunohistochemical study was performed on formalin-fixed, paraffin-embedded tumor tissue samples of these cases for CK 7 and AMA using streptavidin-biotin method. RESULTS: CK 7 staining: Seven cases of 11 ChRCCs showed strong cytoplasmic immunoreactivity with conspicuous peripheral accentuation. Among the nine oncocytomas, one case was positive, three cases were completely negative and five cases showed only focal staining in less than 5% of the tumor cell population. For two eosinophilic variant of CRCCs, only one of them was immunoreactive with CK 7. AMA staining: Five of 11 ChRCCs showed diffuse cytoplasmic coarse granular immunostaining with peripheral accentuation. Eight of nine oncocytomas demonstrated with diffuse cytoplasmic, but fine granular staining, and lastly, in one of the two eosinophilic variant of CRCCs, diffuse cytoplasmic and haphazardly distributed coarse granular immunoreactivity was observed. Combined interpretation of CK 7 and AMA stainings: Five of 11 ChRCCs showed combined CK 7 (+) and AMA (+) with diffuse coarse granular with peripheral accentuation. Eight of nine oncocytomas were CK 7 (-) and AMA (+). One of the eosinophilic variant of CRCCs was also CK 7 (-) and AMA (+) like in most of the oncocytomas, but the staining pattern of AMA was randomly distributed coarse granular, rather than fine granular which was observed in oncocytomas. CONCLUSION: When we reviewed all cases retrospectively with these immunohistochemistry results, we concluded that three of the ChRCCs were needed to be diagnosed as oncocytomas and two of them were eosinophilic variant of CRCCs. Similarly, one eosinophilic variant of CRCC was actually a ChRCC according to the CK 7 / AMA expression patterns. Lastly, only one of the nine oncocytomas was immunohistochemically consistent with the ChRCC. In conclusion, these results suggested that using CK 7 and AMA together may be a discriminative diagnostic tool in the differential diagnoses of renal epithelial tumors with eosinophilic cytoplasm, in addition to distinctive immunostaining patterns of AMA expresion

ONCOCYTIC PAPILLARY RENAL CELL CARCINOMA

O El Lamine, Nadia Kourda, A Bouzouita, M Sfaxi, R Noomene, B Tayahi, J Kourda, M Ferchiou, M Chebil,
Sarrah Baltagi Ben Jilani, R Zermani
Charle Nicolle's Hospital Department of Pathology, Tunisia

Introduction: Papillary renal cell carcinoma (RCC) is subclassified in type 1 displaying cells with scanty pale, cytoplasm arranged in a single layer and in type 2 showing

pseudostratified cells with eosinophilic cytoplasm. However, the existence of more variants of papillary RCC may be inferred by the recognition of few cases with different morphological features. Materials and methods: We report a series of 3 oncocytic renal papillary tumors with the aim of determining their clinicopathologic features. Results: Two patients were male and 1 female (median age, 66 years). All our patients were symptomatic (3/3) flank pain (1/3), hematuria (2/3). All of them were treated by radical nephrectomy. On macroscopic exam, Tumors (median size, 5,5 cm) were intrarenal , unifocal and well limited, with no extrarenal extension. Histologically, they consisted of thin, nonfibrotic papillae lined by a single layer of oncocytic cells, with finely granular eosinophilic cytoplasm and round regular nucleus exhibiting central nucleolus (Fuhrman grade 2). All cases were positive keratin 7, vimentin, racemase and ckit positivity in one case. Then immunohistochemical profiles and the pathologic features argued against the diagnosis of oncocytoma and suggested our cases to be part of the papillary renal cell carcinoma group. Discussion: Papillary architecture is not a feature of renal oncocytoma. In contrast, papillary renal cell carcinomas are defined by their papillary or tubulopapillary architecture. Papillary renal tumors with oncocytic cells might be a distinct variant in the papillary renal cell carcinoma group. All These results suggest that adult papillary renal tumors with oncocytic cells might be a distinct variant in the papillary renal cell carcinoma group. This distinction is of importance because oncocytomas are benign tumors with an indolent course, whereas type 2 papillary carcinomas are malignant tumors associated with a poor outcome. In conclusion, we describe an oncocytic variant of papillary RCC with distinct clinicopathologic features from type 1 and type 2.

[4] Departament of Pathology and Molecular Immunology, Instituto de Ciências Biomédicas de Abel Salazar, University of Porto, Largo Professor Abel Salazar, Porto, Portugal

Background: N-butyl-N-(4-hydroxybutyl) nitrosamine (BBN) induced urothelial carcinogenesis is a useful model for studying urothelial tumours. The present study investigated the expression of Ki-67, p53 and E-cadherin in chemically induced rat urothelial lesions. Material and Methods: Female Fisher 344 rats (n=40) were given 0.05% BBN in their drinking water for 10 and 20 weeks and then euthanized. Twenty animals were used as negative control. Results: At the 10th week 100% of rats exposed to BBN exhibited simple hyperplasia, 40% nodular hyperplasia, 90% dysplasia, 20% papiloma, 10% of papillary neoplasm of low-malignant potential, and 20% squamous metaplasia; after 20 weeks 30% of rats had developed simple hyperplasia, 80% nodular hyperplasia, 100% dysplasia, 40% papilloma, 50% papillary neoplasm of low-malignant potential, 70% low-grade carcinoma, 20% high grade carcinoma, 10% invasive carcinoma, and 60% squamous metaplasia. Ki-67, p53 and E-cadherin were analysed immunohistochemically in paraffin embedded tissue. Low- and high-grade papillary carcinoma showed labelling and apoptotic index greater than other lesions ($p<0.05$). Simple hyperplasia and squamous metaplasia showed a similar E-cadherin pattern when compared with normal urothelium, with their expression confined to the cell membrane. Nodular hyperplasias, dysplasias and papillomas exhibited weak E-cadherin expression. All papillary neoplasm of low-malignant potential, low-and high-grade carcinoma revealed an increase in cytoplasm reactivity and cell discontinuous membrane positivity. E-cadherin immunoreactivity correlated significantly with p53 index ($p<0.05$) and Ki-67 ($p<0.05$) antigen index. Conclusion: We concluded from our data that immunohistochemical Ki-67, p53, E-cadherin staining may provide additional information on rat urothelial carcinogenesis.

MALACOPLAKIA OF THE GENITOURINARY TRACT: A CLINICOPATHOLOGICAL STUDY OF 5 CASES

Faten Limaiem[1], Amina Mekni[1], Ines Chelly[1], Salma Bellil[1], Issam Msakni[1], Slim Haouet[1], Nidhameddine Kchir[1], Mohamed Moncef Zitouna[1], Mohamed Horchani[2], Khadija Bellil[1]
[1] Department Of Pathology. La Rabta Hospital. Tunisia
[2] Department Of Urology La Rabta Hospital Tunisia

Introduction: Malacoplakia (MPK) is a rare granulomatous inflammatory disease that predominantly affects the urinary tract (60%) with a predilection for the bladder while renal parenchymal involvement is less common, occurring in 16% of cases. Testicular and prostatic MPK are exceedingly rare. This benign lesion is histologically characterized by histiocytes containing distinct basophilic inclusions called “Michaellis-Gutmann bodies” which are believed to result from abnormal macrophage function. Patients & Methods: Between January 1999 and February 2007, 5 cases of genitourinary tract MPK involving the prostate (n = 2), the bladder (n = 1), the kidney (n=1) and the testis (n=1) were diagnosed at the pathology department of La Rabta Hospital. Medical records and microscopic slides of each patient were retrospectively reviewed. Results: There were 3 male and 2 female patients aged between 50 and 80 years (mean age = 65,40 years). The chief complaints were fever (n=3), dysuria (n=3), nocturia (n=2), bladder outlet obstructive symptoms (n=2), lumbar pain (n =1) and testicular swelling (n =1). One patient underwent right nephrectomy for a cystic renal mass associated with pyelonephritis. Radical orchidectomy was performed in another patient. A prostatic (n=2) and vesical (n=1) biopsy under ultrasonic guidance was realized in the remainder of cases. Histological examination of the surgical and biopsy specimen showed a granulomatous inflammatory process characterized by the presence within histiocytes (von Hansermann‘s cells) and also extracellularly in the stroma, of concentrically layered, target or ring-like structures that reacted positively to periodic Schiff reagent. The final pathological diagnosis was malacoplakia. During the follow-up period that ranged between 6 months and 3 years, all patients were well and alive.

PP3-102
DIAGNOSTIC AND PROGNOSTIC VALUES OF c-KIT, Ki–67, MATRIX METALLOPROTEINASE-1 (MMP-1) EXPRESSIONS IN GERM CELL TUMORS OF TESTIS

Sema Kizilgedik Dogdas, O. Fahrettin Goze
Cumhuriyet University Faculty of Medicine Pathology Department, Sivas, Turkey

Germ cell tumors constitude 90-95% of all the testis tumors. Testicular germ cell tumors may be either in pure or in mixed form. Pure germ cell tumors are divided into two groups as seminomatous (seminoma and spermatocytic seminoma) and non-seminomatous (embryonal carcinoma, yolk sac tumor, trophoblastic tumor and teratoma) tumors. Mixed germ cell tumors include mainly embryonal carcinoma-teratoma, teratoma-seminoma, choriocarcinoma and different combinations of the others. H&E stained slides of 49 cases found in the archieves of Cumhuriyet University Faculty of Medicine Pathology Department which were diagnosed as germ cell tumor were reexamined according to the criterias of WHO defined in 2004. Slides obtained from paraffine blocks were stained with PLAP,

C-kit, Ki-67 and MMP-1 immunohistochemically. When pure and mixed germ cell tumors were reexamined distribution of the tumors were found as 30 cases of seminoma, 25 cases of embryonal carcinoma, 13 cases of yolk sac tumor, 14 cases of teratoma and two cases of spermatocytic seminoma. Statistical analysis of the study was done among the tumors with different histopathological types which also include intratubular germ cell neoplasia. In respect to PLAP and C-kit expression there is a significant difference betweeen seminoma and non-seminomatous tumors which have strong and intermediate membranous staining property ($p<0.05$). The highest Ki-67 proliferation index was determined in spermatocytic seminoma (0.63±0.01) and embryonal carcinoma (0.50±0.12). The difference between these two tumors and the others having low proliferation index such as seminoma, yolk-sac tumor, and teratoma was also significant ($p<0.05$). As a result, strong and intermediate membranous staining with PLAP and C-kit is a reliable marker in differential diagnosis between seminoma and non-seminomatous tumors. PLAP expression suggested the diagnosis of IGCN more than C-kit. When we considered the Ki-67 staining property, spermatocytic seminoma and embryonal carcinoma had higher proliferation indexes than the other germ cell tumors. Increase in Ki-67 index with an increase in primary tumor stage showed that those markers are important in prognostic aspect.

[3] Department of Pathology, Anticancer Oncological Hospital of Athens 'St. Savvas', Athens, Greece
[4] 1st Social Security Hospital, Urologic Clinic, Athens, Greece

BACKGROUND: Fractal analysis is being applicated in the field of urological pathology with increasing frequency. In the present study, fractal analysis was performed in order to be investigated whether prostate cancer neovascular network fractal dimension (FD) differs from that of normal prostate vasculature. METHOD: Archival material from 34 cases of prostate cancer as well as 10 normal or hyperplastic prostates were examined. From each case two representative CD34 immunohistochemically stained fields (x200) were randomly selected and digitised as high quality JPEG files. Using especially designed image analysis applications the images were automatically processed to threshold the vascular section, by the use of a modified and extended clastering method for colour images based on an algorythm proposed by Otsu. The solid areas of the binary images were then converted to an outline of single pixels, and finally the fractal dimension was estimated using a box - counting algorythm implemented in our application. RESULTS: The normal prostate vasculature presented a mean FD of 1,959. The corresponding value of prostate cancer neovascular network was 1,3297. Both values were statistically different from the topological dimension (= 1,000). The difference of the two values was statistically significant (all $p<0,05$). CONCLUSION: Our findings suggest that by using the proposed methodology the vascular network of prostate cancer presents fractal charateristics. Thus, FD seems to be an important morphometric parameter possibly valuable for the future development of an unbiased and reproducible image analysis system for the study of prostate cancer pathology.

PP3-104
HYBRID RENAL CELL CARCINOMA WITH EOSINOPHILIC CHROMOPHOBE AND UNDIFFERENTIATED FEATURES DEMONSTRATING A THIRD FEATURE WITHIN IPSILATERAL ADRENAL METASTASES

Ozden Tulunay[1], Guldal Yilmaz[1], Yasar Beduk[2]
[1] Medical School of Ankara University, Departments of Pathology, Ankara, Turkey
[2] Medical School of Ankara University, Departments of Urology, Ankara, Turkey

Background: Hybrid renal cell carcinoma (RCC), containing tumor cells displaying cytological features of different subtypes in the same kidney has been described recently. Although rare, synchronous renal primary malignancies can be observed. Identification of the hybrid character of an RCC has important diagnostic, and potentially, prognostic ramifications. Case report: A 55-year-old male admitted to the intensive care unit, due to idiopathic myelofibrosis, with left lumbar pain of 20 days duration. His past medical history was unremarkable otherwise, and there was no family history of a hereditery disease. Serological studies demonstrated minimal increase in serum BUN and creatinin levels. Abdominal CT 2 cm solid mass in the mid-portion of the left kidney and a×revealed a 3.2 1.5×0.9 cm solid mass in the left adrenal gland. Patient underwent a left radical nephrectomy. Findings: The resected left kidney weighed 357 g, with a 10.5×4.5 cm.×2.8×2.7 cm mass in the mid-portion, measuring 17×3.6 Microscopically, the tumor was an eosinophilic variant of chromophobe RCC (ChRCC/eo) with areas of undifferentiated carcinoma (UC). UC with necrosis and high nuclear grade of Furhman (Grade 3), formed multiple foci within ChRCC/eo, and revealed large polygonal cells with condensed eosinophilic/granular cytoplasm with increased Nuclear size, pleomorphism, high mitotic activity, and 4.5×2 cm,×demonstrated transitions with ChRCC/eo. The left adrenal gland, 6.5 2×1.2 cm solid mass, consisted of a tumor displaying cytological×with a 2.7 features of UC and of mucinous tubular carcinoma (MTC). The adrenal vein and periglandular lymphovascular spaces were extensively invaded by UC panCK, CK7, and EMA were diffusely and strongly positive in all tumor subtypes while, CEA E12 only focally, in UC Conclusion: Hybrid RCCsβwas positive only in MTC, and 34 exhibit characteristic histologic features that set them apart from classical RCC. This type of hybrid tumor seems to be associated with a more aggressive behavior, and warrants diagnostic caution. This case is the first of its type reported in the literature, which is a combination of ChRCC/eo, and UC within the same tumor of the kidney and of a synchronous third subtype, MTC, within the synchronous metastases in the ipsilateral adrenal gland.

PP3-105
RETROPERITONEAL LYMPH NODE METASTASES FROM BURNT-OUT PRIMARY TESTICULAR SEMINOMA. REPORT OF TWO CASES

S. Bellefqih, K. Joseph, A. Durlach, J. Brandt, P. Birembaut
Laboratoire Pol Bouin, Departement d'Urologie, CHU Hopital Maison Blanche, Reims-France

The burnt-out phenomenon in germ-cell neoplasia is defined by the presence of an extragonadal germ cell tumour with no tumour at the testis. This tumour has spontaneously regressed with no treatment. We report two cases of burnt-out primary testicular tumours revealed by a retroperitoneal metastatic seminoma. Case 1 A 30-year-old man, with a history of cryptorchidy, was admitted for exploration of a left iliac lymph node mass, 7 cm in diameter. A biopsy specimen suggested a metastasis from a germ cell tumour. At clinical examination, the left testis was small. Case 2 A 40-year-old man presented with flank pain. Abdominal CT scan showed a 9 cm mass left retroperitoneal between the aorta and inferior cava. A lymphadenectomy was performed.

Frozen section analysis suggested lymph node metastasis from testis seminoma. Scrotal ultrasonography in these 2 patients revealed a small left testis containing a 5 mm (case 1) and 1 cm (case 2) hypoechogenic area. Chest CT was normal. They had a left radical orchidectomy and the lymphadenomectomy. The macroscopic examination of the pulp (case 1: 34 g , 3x2 cm; case 2: 46g, 3,5x2,5) showed a 8 mm juxtahilar (case 1) and 1.5 cm central (case 2) fibrous scar. Histological examination showed a testicular atrophy with sclerosis of the seminiferous tubules, hyperplastic Leydig cells, and foci of intratubular germ cell neoplasia unclassified type. associated with fibrous scar and calcifications. Lymph node (n=3) examination confirmed a pure seminomatous germ cell metastatic tumour with an epithelioid giant cell reaction associated with lymphocyte infiltrate. Immunohistochemical staining in lymph node specimen showed a cytoplasmic membrane immunoreactivity for placental alkaline phosphatase and CD117. Chemotherapy was administred. Testicular ultrasonography is today the gold-standard technique and any parenchymal echostructure abnormality should be verified histologically

PP3-106
A SEARCH FOR THE USEFULNESS OF ANTIBODY COCKTAIL (AMACR (P504S)+HMW-CK+P63) IN PROSTATIC NEEDLE BIOPSIES WITH A PROPOSAL OF A NEW SCORING SYSTEM

Dilek Demir, Isin Kilicaslan, Yasemin Ozluk, Veli Uysal
Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey

BACKGROUND We aimed to search for the usefulness of an antibody cocktail, combining alpha-methylacyl CoA Rasemase (AMACR), high molecular weight cytokeratin (HMW-CK) and p63 antibodies, in differentiating prostate cancer (Pca) from high-grade prostatic intraepithelial neoplasia (HGPIN), atypical small acinar proliferation (ASAP) and benign glands. We also tried to evaluate whether to use HMW-CK singly or to use the antibody cocktail. MATERIALS-METHODS: We included 109 prostatic needle biopsies displaying features of ASAP, HGPIN and Pca in H&E stain. Benign glands were detected in all biopsies as a control group. Each lesion were analyzed separately. HMW-CK and p63, as basal cell markers, were expected to be positive in basal cells of benign glands and HGPIN, whereas AMACR was expected to be positive in the tumoral cells. The result of the interpretation of the antibody cocktail were scored from (-1) to (7) based on the percentage and the intensity of staining. We checked the statistical significance of the diagnostic value of the antibodies, individually and together. RESULTS Thirty five lesions of carcinomas were all negative for basal cell markers, whereas those markers were detected to be positive in HGPIN and benign glands. The staining pattern was patchy or diffuse, respectively. In ASAP lesions, immunohistochemistry demonstrated basal cell staining in 67.7% (23/34) and no staining was found in 32.3% (11/34). It did not differ whether we use p63 or HMW-CK as a basal cell marker. We detected strong positivity for AMACR in carcinomas in more than 75% of the tumor. Strongly positive staining for AMACR in more than 75% of cells was seen in 31.4% (17/54) of HGPIN and 26.4% (9/34) of ASAP. Benign glands were negative for AMACR. The immunoreactivity score of carcinomas were 7 in 32 and 6 in 3, whereas it was ≥6 in 16.6% (9/54) of HGPIN and 23.5% (8/34) of ASAP. None of the benign tissues displayed a score of ≥5. We observed a superiority in terms of specificity for antibody cocktail (96.3%) over HMW-CK (85.1%) in ASAP. The sensitivity for both antibodies were 100%. CONCLUSIONS As a result, we suggest that combining AMACR with a basal cell marker may improve diagnostic performance, especially in ASAP lesions. We recommend the use of antibody cocktail as a simple and cost-effective method in routine practice.

Pulmonary Pathology

PLEUROPULMONARY ABNORMALITIES IN PATIENTS WITH MULTIPLE MYELOMA

Jurgen Knolle[1], Stefanie Hege[1], Beatrix Bohnsteen[2], Jens Schreiber[2]
[1] Dessau Medical Center, Institute for Pathology, Germany
[2] Department of Pulmonary Medicine, Dessau, Germany

Background: Multiple Myeloma (MM) is a low malignant Non–Hodgkin's lymphoma. Pleuropulmonary abnormalities in patients with MM require a broad differential diagnostic spectrum. Method: We retrospectively analysed the clinical histories and findings of 22 patients with MM in whom bronchoscopies were performed because of pulmonary infiltrates, both alveolar and interstitial. The series included 16 men and 6 women; the median age was 64 y (46 – 83 y). Results: Bronchoscopy enabled differential diagnosis in all pts. and was performed without complications regardless of cytopenias. In 16 pts. (72,7%) infections were diagnosed. Rare manifestations were diffuse pleural and pulmonary infiltrations with atypical plasma cells (n=1), light chain deposition disease (n=1), diffuse alveolar hemorrhage (DAH) (n=1), amyloidosis (n=1) and toxic pneumonitis (n=2). Subclinical DAH was found in 7 pts. (31.8%). In one patient an intercurrent disease was diagnosed. Conclusion: We conclude that the most common causes of pulmonary abnormalities in pts. with MM are infections. However there are rare differential diagnoses, which are presented in more detail.

PP3-108
SOLITARY FIBROUS TUMOUR OF PLEURA- 16-YEARS REVIEW

Jelena Stojsic, Branislava Milenkovic, Maja Ercegovac
Institute for Lung Diseases and Tuberculosis, Clinical Centre of Serbia, Belgrade, Serbia

Background: Solitary fibrous tumour of pleura (SFTP) originate from primitive submesothelial fibroblasts differentiated to hemangipericytoma-, neurofibroma- and fibroma-like pattern. SFTPs are pedunculated with visceral, parietal and mediastinal pleura. Extrathoracic SFTPs are rare. Method: Analysis was made on 47 SFTPs diagnosed on surgery extirpated tumours during last 16 years. Results: SFTPs was diagnosed in 25 females and 22 males. Patients' age ranged from 27 to 71 years, average 52.1 and predominance in 6. life decade. Eighteen tumours were localized on the right and 13 from the left site and 14 in mediastinum. Twenty tumours originated from visceral, 13 from parietal and 14 from mediastinal pleura. SFTPs Tumour size varied from 30mm to 540mm, mean 117cm. The greatest SFTP measured 4900g, occuping the whole right hemithorax, involving pulmonary tissue, visceral and parietal pleura and ribs. The other giant SFTPs measured 235mm (2430g), 240mm(2850g) and 350 mm (3600g). Predominant morphological pattern according cellularity was: 28 mixed, 11 purely hypo- and 8 purely hypercellular and rarely purely hypo- or hypercellularity. Predominant morphological pattern was: hemangio-19, neurofibro-19 and fibroma-like pattern 9. Three of them were malignant on surgery. Three SFTPs recidived 3 months to 6 years after surgery. Diagnosis of SFTP was precised by histochemical (van Gieson, Masson-trichrome) or by immunohistochemical stains (vimentin, CD34, bcl-2). Preoperative needle biopsy was performed in 17 patients with suggestive diagnosis of mesenchymal tumour of variable morphological pattern and unpredictive biological behavioring. Conclusion: Diagnosis of SFTPs on preoperative biopsy can be estimated by percutaneous needle biopsy applying CD34. Precise diagnosis of SFTPs is useful for planning surgery. Hypercellularity, increased mitotic activity, nuclear polymorphism and invasion of tumour capsule are suggestive for suspicion on malignancy. Tumour size is not

mandatory for malignancy. On gross examination of tumour node it is necessary to obtain numerous tissue samples specially with tumour capsule for precise the biological behavior of SFTP.

PP3-109
PULMONARY ANGIOMYOLIPOMA: CLINICOPATHOLOGICAL ANALYSIS OF 2 NEW CASES AND 10 PREVIOUSLY REPORTED CASES

Irem Hicran Ozbudak[1], Konstantin Shilo[2], Jeffrey R. Galvin[3], Teri J. Franks[2]
[1] Department of Pathology, University of Akdeniz School of Medicine, Antalya, Turkey
[2] Department of Pulmonary and Mediastinal Pathology, Armed Forces Institute of Pathology, Washington, DC, USA
[3] Department of Radiologic Pathology, Armed Forces Institute of Pathology, Washington, DC, USA; Department of Diagnostic Radiology and Pulmonary/Critical Care Medicine, University of Maryland School of Medicine, Baltimore, MD, USA

Background: Angiomyolipoma is a rare mesenchymal tumor that most often arises in the kidney, but can also occur in extrarenal locations. Angiomyolipoma of lung is very rare and to date only 10 cases have been reported in the literature. Method: Three cases of pulmonary angiomyolipoma were identified in the registry of the Department of Pulmonary and Mediastinal Pathology, Armed Forces Institute of Pathology, from 1977 to 2007 (one of which was previously reported). The clinical, radiologic and pathological findings of these three cases were reviewed and were compiled with findings abstracted from the cases reported in the literature. Results: Twelve patients included 4 males and 8 females (male:female, 1:2) with a mean age of 52 years (range, 28 to 68). Pulmonary angiomyolipoma occurred de novo in 10/12 (83%) patients and in association with tuberous sclerosis in 2/12 (17%) patients. Pulmonary lesions presented as isolated findings in 7/12 (58%) patients, but were also seen in association with renal (3/12 patients, 25%), hepatic (2/12 patients, 17%) and splenic (1/12 patient, 8%) angiomyolipoma. Radiologically, tumors were well-circumscribed nodules with fat density that were located in the lung parenchyma in 10/12 (83%) patients and as an endobronchial lesion in 2/12 (17%) patient. Tumors ranged in size from 0.4 to 9.5 cm (mean, 2.2 cm). Microscopically, all tumors demonstrated variable amounts of mature adipose tissue, smooth-muscle cells and tortuous, small- to medium-sized, thick-walled blood vessels. Minor histologic features included: epithelioid smooth-muscle cells containing melanin pigment, histiocytes, multinucleated giant cells, plexiform vascular channels, atypia and mitosis. Tumor smooth-muscle cells were immunoreactive with HMB-45 (6/9, 67%), actin (6/7, 86%), desmin (2/4, 50%) and S-100 (2/6, 33%). Conclusion: Pulmonary angiomyolipomas are rare tumors with only 12 cases known to date. They show a female gender bias. Pulmonary angiomyolipomas typically arise de novo as parenchymal nodules. The combination of thick-walled vessels, smooth-muscle cells and adipose tissue is distinctive and aids separation from other benign and malignant pulmonary mesenchymal lesions.

PP3-110
EXTRAMEDULLARY HEMATOPOIESIS IN PULMONARY SPINDLE CELL TUMORS: RARE AND UNUSUAL ASSOCIATION

Irem Hicran Ozbudak[1], Konstantin Shilo[2], Jeffrey R. Galvin[3], Teri J. Franks[2]
1 Department of Pathology, University of Akdeniz School of Medicine, Antalya, Turkey
2 Department of Pulmonary and Mediastinal Pathology, Armed Forces Institute of Pathology, Washington, DC, USA
3 Department of Soft Tissue Pathology, Armed Forces Institute of Pathology, Washington, DC, USA

Background: Extramedullary hematopoiesis is defined as development and growth of hematopoietic tissue outside the bone marrow. It tends to occur as a compensatory phenomenon in the organs of reticuloendothelial system. Involvement of other organs and some tumors such as pilomatricoma and hemangioblastoma is recognized. Only one case of pulmonary carcinoid with intratumoral hematopoiesis is reported in the English language literature. Method: Two cases of lung tumors with extramedullary hematopoiesis were identified in the registry of the Department of Pulmonary and Mediastinal Pathology, Armed Forces Institute of Pathology. Herein, we describe the pathological and immunohistochemical features of these two cases. Results: A 72 year-old male presented with 3.5 cm right middle lobe, pleural based solitary fibrous tumor. The tumor was composed of CD34 positive spindle cells with variable collagen deposition. Scattered nests of extramedullary hematopoiesis were distributed throughout the lesion. They exhibited trilineage hematopoiesis and contained numerous dysplastic megakaryocytes. A 64 year-old male presented with a 7 cm peripheral left lower lobe intermediate grade sarcoma with myxoid features. Tumor cells were immunoreactive for smooth muscle actin, muscle specific actin and vimentin, while the pancytokeratin, CAM5.2, EMA, desmin, HMB-45, S-100, CD34, Factor VIII were negative. Hematopoietic cells consisting of megakaryocytes, erythroblasts and rare myeloid precursors were present as small clusters throughout the tumor. No hematopoietic cells were identified in vessels or adjacent lung parenchyma in either case. Megakaryocytes and erythroid precursors were immunoreactive with Factor VIII and hemoglobin respectively. Conclusion: Tumors of the lung displaying foci of intratumoral extramedullary hematopoiesis are rare. However, awareness of this association is helpful in avoiding misdiagnosis of a hematopoietic malignancy and upgrading of spindle cell tumors based on the dysplastic megakaryocytes which resemble pleomorphic tumor cells.

PP3-111
INFLAMMATORY MYOFIBROBLASTIC TUMORS OF THE LUNG ARE NEGATIVE FOR HHV-8

Fabio Tavora[1], Irem Hicran Ozbudak[2], Konstantin Shilo[1], Jean M. Przybocki[3], Guanghua Wang[3], William D. Travis[4], Teri J. Franks[1]
[1] Department of Pulmonary and Mediastinal Pathology, Armed Forces Institute of Pathology, Washington, DC, USA
[2] Department of Pathology, University of Akdeniz School of Medicine, Antalya, Turkey
[3] Department of Molecular Pathology, Armed Forces Institute of Pathology, Washington, DC, USA
[4] Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Inflammatory myofibroblastic tumors are uncommon lesions composed of spindled myofibroblasts within a variable fibroinflammatory background. Although the true nature of these lesions has not been fully elucidated, identification of consistent cytogenetic alterations in the anaplastic lymphoma kinase (ALK) gene suggests that they may represent a neoplastic proliferation. Furthermore, few cases of inflammatory myofibroblastic tumor have been reported to harbor human herpesvirus (HHV)-8 infection, implicating HHV-8 in its pathogenesis. In this study, the largest to date series of pulmonary inflammatory myofibroblastic tumors were tested for the presence of HHV-8 by immunohistochemical and molecular methods. Method: Twenty cases with classical features of inflammatory myofibroblastic tumor were selected for the study. Immunohistochemical studies for latent nuclear antigen of HHV-8 (clone 13B10, 1:50, Vector Laboratories, Burlingame, CA) and for ALK (clone ALK-1, 1:100, Dako, Carpinteria, CA) were performed according to the manufacturers' instructions. Four open reading frames (ORF) of HHV-8, including ORFK2, ORF16, ORF26, ORF72, were targeted with real time PCR.

Results: The study cohort included 9 men and 11 women with a mean age of 37 years (range, 1 to 81). Microscopically, the tumors were composed of predominantly spindled myofibroblasts. On immunohistochemical studies, 4/20 cases (20%) demonstrated diffuse cytoplasmic positivity with ALK-1. Imunohistochemical staining for HHV-8 was negative (0/20, 0%) in all cases. All inflammatory myofibroblastic tumor cases tested with real time PCR were negative (0/20, 0%) for all four ORF, while 10/10 (100%) samples of Kaposi sarcoma, serving as positive control, were positive. Her2 gene, tested for the presence of amplifiable DNA in the tissue lysate, was positive in all (20/20, 100%) of the inflammatory myofibroblastic tumors. Conclusion: This study documents the absence of HHV-8 in a series of pulmonary inflammatory myofibroblastic tumors and suggests that further investigation is needed in elucidating other potential etiologic factors for this lesion.

PP3-112
IDENTIFICATION OF RELEVANT LUNG ADENOCARCINOMA BIOMARKERS BY MASS SPECTROMETRY BASED N-GLYCOPROTEIN PROFILING OF PLEURAL EFFUSIONS

Alex Soltermann[1], Reto Ossola[2], Sandra Kilgus-Hawelski[1], Arnold Von Eckardstein[3], Tobias Suter[4], Ruedi Aebersold[2], Holger Moch[1]
[1] Institute for Surgical Pathology, University Hospital Zurich, CH-8091, Switzerland
[2] Institute for Molecular Systemsbiology, Swiss Federal Institute of Technology, CH-8093, Switzerland
[3] Institute for Clinical Chemistry, University Hospital Zurich, CH-8091, Switzerland
[4] Clinics of Immunology, University Hospital Zurich, CH-8091, Switzerland

Background: Late stage lung adenocarcinoma is frequently accompanied by pleural effusion. Tumour cells in the effusion may be the source of proteins, which are potentially detectable in tumour tissue or serum. In particular, N-glycosylated proteins (N-GP) can be secreted into body fluids and are therefore considered potential biomarkers. We aimed for establishing a mass spectrometry based N-GP effusion profile for cytology specimens. Methods: Malignant pleural effusions of 5 patients with lung adenocarcinoma and 5 non-malignant controls were used for N-GP capturing by solid phase extraction. Following trypsin digest and PNGase F release, a liquid chromatography separation connected online to a tandem mass spectrometer was performed. The resulting peptide spectra were screened against IPI and NCI databases. Results: Concentration differences between malignant and non-malignant effusions were found for total protein, LDH, cholesterol, glucose, CA-125 and CEA (p's < 0.05). 174 non-redundant N-GP were detected in the total of 10 samples with probability ≥ 0.9, 29 of them exclusively in malignant effusions. The overall specificity for the N-glycomotif was 89%. Identifications were compared with serum of 4 healthy donors and A549 cell culture supernatant as well as published data sets. Specific protein markers were correlated with their corresponding immunoreactivity in either effusion fluid (CA-125, interferon gamma) or tumour cells or tissue (periostin, CD166), respectively. By applying strict criteria and using data mining, a potential lung adenocarcinoma marker signature of 6 proteins, including periostin, CD166, multimerin 2, lysosome-associated membrane glycoprotein 2, latent TGF beta binding protein 2 and surfactant protein A, was elaborated. Conclusion: The N-GP capturing and LC-MS/MS protocol enables the confident identification of several relevant biomarkers for lung adenocarcinoma.

PP3-113
VALUE OF VARIOUS CYTOHISTOLOGICAL TECHNIQUES FOLLOWING FIBEROPTIC BRONCHOSCOPY IN THE DIAGNOSIS OF LUNG CANCER

Nicoletta Maounis[1], Eleni Ellina[1], Aikaterini Blana[1], Maria Chorti[2], Agathi Lekakou[3], Nikos Trakas[4], Aikaterini Pierakou[2], Aphroditi Emmanouilidou[1]
[1] Department of Clinical Cytopathology. General Hospital,Greece
[2] Department of Pathology General Hospital, Greece
[3] 1st Pulmonary Department General Hospital, Greece
[4] Department of Biochemistry General Hospital, Greece

Introduction: The aim of the present study was to evaluate the value of various diagnostic techniques following fiberoptic bronchoscopy in the diagnosis of lung carcinoma. Material and methods: A total of 2005 patients underwent diagnostic bronchoscopic procedures during a 3-year period for various neoplastic and nonneoplastic lung diseases. Histologic examination of specimens obtained by forceps biopsy and cytological evaluation on brushing, washing and post-bronchoscopic sputum smears were performed. The diagnostic value of the procedures was analyzed by Mc Nemar's exact test. Results: Eight hundred thirty patients had at least one of the techniques positive for lung malignancy (41,39%). Mean age 67.46; range 22-91 years. %). Of the above 830 tumors, 302 were diagnosed as squamous cell carcinoma (36.4%), 134 as adenocarcinoma (16.1%), 11 as BAC (1.3%), 148 as small cell lung carcinoma (17.8%), 191 as non- small cell lung carcinoma (23%), 8 as mixed (1.0%),12 as metastatic (1.4%), 4 as carcinoids (0.5%) 1 as lymphoma (0.1%) and 19 as suspicious for malignancy (2.3%). Forceps biopsy specimens gave positive results in 34.3% of our malignant cases, brushing in 52.8%, washing in 69.4% and post-bronchoscopic sputum in 28%. Collection of brushing specimens in addition to washing and post-bronchoscopic sputum increased the diagnostic yield of bronchoscopy from 78.8% to 87.5% (p=0.0001). Furthermore, the addition of forceps biopsy increased the diagnostic yield of the combination of the three cytological techniques from 87.5 to 98.8% (p<0.0001). In conclusion, the best diagnostic yield for the diagnosis of lung cancer, in our material which included visible and non-visible pulmonary lesions, was obtained with the association of brushing and bronchial washing specimens. Furthermore, the application of both cytology and histology can achieve better results.

PP3-114
PROGNOSTIC SIGNIFICANCE OF VASCULAR AND INTERSTITIAL REMODELING PROCESSES IN NONSPECIFIC INTERSTITIAL PNEUMONIA: SYSTEMIC SCLEROSIS VERSUS IDIOPATHIC

Erika De Carvalho, Edwin Parra, Romy De Souza, Alexandre A´B Saber, Juliana Machado, Vera Capelozzi
University of São Paulo Medical School, Departments of Pathology and Rheumatology, Brazil

Aims and Methods: Pulmonary biopsy specimens were examined from 40 patients, 22 with idiopathic nonspecific interstitial pneumonia (NSIP) and 18 with nonspecific interstitial pneumonia associated with systemic sclerosis (SSc). We compared the septal and vascular matrix remodeling, vascular grade, pulmonary function tests and survival between the two groups. Results: The content of septal collagen and elastic fibers, as well as the elastic fibers in the vascular interstitium, were higher in the SSc group (p=0.01, p=0.001 and p<0.0001, respectively). Among pulmonary function tests the DLCO/VA was affected to a greater extent in the SSc group (59% of the predicted value in SSc and 97% in the idiopatic group). There were no differences in the collagen content of the vascular interstitium, vascular grade, or survival between the two groups. Conclusions: Although the fibrotic process is more intense in the SSc group, it does not affect the

prognosis of these patients, as it has been described in idiopatic lung fibrosis. It seems that the fibrogenic process has a minor role in SSc when compared with the idiopatic group. Because the elastotic process is higher in the SSc group, this might suggest that autoimmune inflammatory mechanisms affecting the elastic fiber system could play a greater role in the pathogenesis and pulmonary remodeling process of SSc-NSIP than in idiopathic-NSIP.

PP3-115
PARENCHYMAL AND VASCULAR INTERACTIONS IN THE PATHOGENESIS OF NON SPECIFIC INTERSTITIAL PNEUMONIA IN SYSTEMIC SCLEROSIS AND IDIOPATHIC INTERSTITIAL PNEUMONIA

Edwin Parra, Erika De Carvalho, Romy De Souza, Alexandre A´B Saber, Vera Capelozzi
University of São Paulo Medical School,Departments of Pathology and Rheumatology, Brazil

Background: Interstitial lung disease is a well recognized prognostic factor in systemic sclerosis (SSc). As the prognosis in nonspecific interstitial pneumonia (NSIP) has been described to be better in collagen vascular disorders compared to the idiopathic forms, we hypothesize that the mechanisms of repair and remodeling are different between these two forms of the disease. Objectives: To compare the mechanisms of repair and remodeling between SSc associated nonspecific pneumonia and the idiopathic form, its impact on pulmonary function tests and survival rates. Methods: We analyzed 18 biopsies from patients with NSIP associated with SSc and 22 with idiopathic NSIP and compared the epithelial and vascular densities as well as vascular activity by immunohistochemistry with antibodies directed against Cytokeratin-7, Surfactant protein-a, CD34, and VCAM-1. Results: Epithelial cell density was lower in SSc-NSIP when compared with idiopathic-NSIP ($p<0.0001$). Type II pneumocytes and Clara cells were reduced in idiopathic NSIP ($p=0.02$) . A decrease in microvessel density was found in SSc-NSIP compared to idiopathic-NSIP ($p<0.0001$). The vascular activity measured by VCAM expression was higher in NSIP-SSc when compared to the idiopathic group ($p<0.0001$). The DLCO/VA in SSc-NSIP was more compromised . A direct association between vascular density and DLCO/VA was found ($p=0.02$). There was no difference in the survival rate between the two groups after a follow-up of 36 months. Conclusions: Alterations in the epithelium and vasculature seem to differ in the pathogenesis of SSc-NSIP when compared to the idiopathic form of the disease. Further studies may be required to assess the significance of these findings and explore if they can provide prognostic and/or treatment information. Financial Support: FAPESP,CNPq.

AIRWAY COLLAGEN AND ELASTIC FIBERS REMODELING IN IDIOPATHIC INTERSTITIAL PNEUMONIAS

Edwin Parra, Gustavo Noleto, Vera Capelozzi, Marco Antonio Capelozzi
University of São Paulo Medical School, Department of Pathology, Brazil

Background: Structural alteration of the airways and lung parenchyma, "remodeling", is a recognized feature of pulmonary fibrosis. In this study, we sought to validate the importance of bronchiolar remodelling and to study the relationships between bronchiolar collagen/elastic system and survival in the major histological pattern of idiopathic interstitial pneumonias (IIPs). Material and Methods: We examined bronchiolar collagen/elastic system fibres in 9 non-specific interstitial pneumonia (NSIP), 24 idiopathic pulmonary fibrosis (IPF), 5 bronchiolites obliterants (OP) and 18 acute interstitial pneumonia (AIP) cases. We used the Picrosirius-polarization method and Weigert's resorcin-fuchsin histochemistry to evaluate the amount of bronchiolar collagen/elastic system fibres. Results: The bronchiolar measurement of collagen fibres content was higher in AIP ($p=0.08$) than lungs of OP, UIP and NSIP. In addition, was a not difference of elastic fibres inter groups. Conclusion: We concluded that a not differences of progressive bronchiolar fibroelastosis occurs in IIP histological patterns, probably indicating who not interview in to parenchymal injury.Financial Support: FAPESP,CNPq.

PP3-117
TYPE V COLLAGEN PARTICIPATION IN PATIENTS WITH SYSTEMIC SCLEROSIS: PRELIMINARY STUDY

Edwin Parra, Walcy Teodoro, Vera Capelozzi
University of São Paulo Medical School, 1Department of Pathology and Discipline of Reumathology, Brazil

Background: Systemic sclerosis (SSc) is a polymorphic and heterogenic systemic disorder with inflammation, fibrosis and vascular damage. Recently, the pathogenesis of SSc has been extensively studied regarding its autoimmunity aspects related to extracellular matrix remodelling, with an emphasis on the collagens at the inflammatory site. The present paper describes the importance of type V collagen morphologic disorganization, distribution and quantitation in pulmonary interstitium in patients with SSc. Methods: We used immunofluorescence and morphology analise to evaluate and quantified the deposition of collagen I, III and V, and correlation with the active alveolar septal, bronchiolar and arterial interstitum remodeling in open lung biopsies of 11 SSc. Results: The interstitum of alveolar septal, bronchiolar and vascular changes were characterized by morphologic disorganization of fibrillar collagen with diverse disarray, thickness and strong green birefringence of the type V collagen. The quantification of alveolar septal, bronchiolar and vascular collagen I was higher in all groups. In addition, the increase of collagen V in vascular interstitum was major than to collagen III ($p=0.05$), in contras the collagen III septal and bronchiolar interstitum was major than to collagen V. Conclusions: We concluded and suggested that the collagen type V fibrils are increased, in disarray and combine to other collagen (I and III) make larger than normal lungs, creating an abnormal spatial organization principally in vascular interstitium. Financial Support: FAPESP.

PP3-118
STATISTIC ANALYSIS OF MORTALITY AND DISEASE INCIDENCE IN CHRONIC LUNG DISEASES AMONG THE POPULATION OF SEMIPALATINSK REGION WITH LONG-TERM RADIOACTIVE AND POLLUTED ENVIRONMENT

Gulmira Sagindikova, Evguenija Kogan
Moscow Medical Academy, Russia

Work is aimed at examining the prevalence of chronic pulmonary pathology, characteristic of mortality and disease incidence in chronic lung disease (CLD) among the population of Semipalatinsk region having been subjected to long-term radioactive and polluted environment. Public health authorities 1969-2003 reports on spread, mortality and disease incidence of respiratory apparatus among the population of the Semipalatinsk region have been analyzed. 7274 habitants of the Semipalatinsk region have been screened and questionnaired and frequently revealed CLD types in the Semipalatinsk region have been epidemiologically researched. 631 autopsy notes with CLD diagnosis of Morbid Anatomy Bureau of Semipalatinsk for 1996-2003 years period has been studied. Research has revealed tendency to increase in disease incidence and CLD mortality in the course of growth of exposure rate and close location to testing area. Conclusion: tendency to increase in CLD incidence within 1992-2003 years period, i.e. after nuclear tests cessation has been revealed that proves the radiation value as etiopathogenetic factor.

PP3-119
SUDDEN DEATH CASES DUE TO TUBERCULOSIS
Alexandra Enache[1], Fotios Chatzinikolaou[2], Natalia Vladika[2], Ioannis Moisidis[2]
[1] Department of Forensic Medicine,University of Timisoara, Romania
[2] Department of Pathology,Theageneio,Cancer Hospital,Thessaloniki,Greece

Aim:in this study we investigate the sudden death cases caused by tuberculosis with different localisations. Materials and methods: We performed a retrospective analysis on the forensic necropsies from IML Timisoara in a period of four years 2002 - 2005. There were 36 cases of death by pulmonary tuberculosis (1.23% of the cases). Results: the majority of the victims, 94.44% were males. 27.77% of the victims were aged between 40 and 49 years. Homeless victims' cases represented 27.77% of the cases, 73.33% of these not being hospitalized for this disease. On 18 of the cases (50%) we found fibrocavitary form, 12 of the cases (33.33%) has fibronodular form, 4 cases (11.11%) has an ulcerative form and 2 case was of miliar form (5.55%). Some cases presented unassociated pulmonary tuberculosis, some presented pulmonary tuberculosis associated with broncho-pneumonia (12 cases), 1 case presented tuberculosis associated with pulmonary carcinoma, some presented pulmonary tuberculosis associated with tuberculosis pericardic and hepatic granular tuberculosis (1 single case) and an association of pulmonary tuberculosis and hepatic tuberculosis granulia. In 61.11% of the cases (22 cases) the pulmonary tuberculosis was associated with hepatic steatosis or cirrhosis and 4 cases (45%) had increased alcohol rate. We did not observe any evidence suggesting the existence of HIV. Conclusions: The study shows that sudden death caused by pulmonary tuberculosis mainly affects male alcohol consumers and social cases. It is necessary to observe. the possible cohabitation of HIV/bK.

PP3-120
A MIXED SQUAMOUS CELL AND GLANDULAR BRONCHIAL PAPILLOMA: A CASE REPORT
Ferda Aksoy[1], Gokhan Haciibrahimoglu[2], Irfan Yalcinkaya[2], Murat Keles[2], Leyla Yagci Tuncer[3]
[1] Sureyyapasa Chest Diseases and Thoracic Surgery Training and Investigation Hospital, Department of Pathology Istanbul, Turkey
[2] Sureyyapasa Chest Diseases and Thoracic Surgery Training and Investigation Hospital, Department of Thoracic Surgery, Turkey
[3] Sureyyapasa Chest Diseases and Thoracic Surgery Training and Investigation Hospital, FDepartment of Pulmonology, Turkey

Bronchial papillomas are very rare representing less than 0.5 % of lung tumours. The histological types are squamous, glandular and mixed. Papillomas should be differentiated from malignancies by endobronchial biopsy, because complete resection appears to be curative. We describe a case of bronchial mixed squamous cell and glandular papilloma of the bronchus diagnosed by frozen section. The case is a 51 years old male smoker, who was admitted with dyspnea and hemoptysis. Physical examination revealed no abnormalities. Thorax computed tomography slices showed a minimal consolidated lesion in left lower lobe. In bronchoscopic examination a swinging polypoid tumour in left main lower bronchus was detected. Bronchoscopic biopsy was not diagnostic. A left thoracotomy was performed for diagnosis and treatment. The lesion which was 1x1.5x 2 cm in size was removed and a frozen section examination was performed. The lesion was diagnosed as bronchial papilloma with frozen section. Postoperative histopathological examination confirmed the diagnosis as "mixed squamous cell and glandular papilloma". This extremely rare encounter of mixed squamous cell and glandular bronchial papilloma is presented with the review of the literature.

PULMONARY MALT LYMPHOMA: 3 CASE REPORTS
Ferda Aksoy[1], Erdal Okur[2], Asim Kutlu[2], Haluk Calisi[3], Ebru Sulu[3], Semih Halezeroglu[2]
[1] Sureyyapasa Chest Diseases and Thoracic Surgery Training and Investigation Hospital, Department of Pathology Istanbul, Turkey
[2] Sureyyapasa Chest Diseases and Thoracic Surgery Training and Investigation Hospital Department of Thoracic Surgery, Turkey
[3] Sureyyapasa Chest Diseases and Thoracic Surgery Training and Investigation Hospital Department of Pulmonology, Turkey

Primary pulmonary lymphomas are relatively rare tumours that comprise less than 1 % of all lymphomas. Approximately 70-80 % of primary pulmonary lymphomas are marginal zone B-cell lymphomas of Mucosa-Associated Lymphoid Tissue (MALT) type.In this paper 3 MALT lymphoma cases are presented. Case I: A 52 years old male patient was admitted with a solitary pulmonary nodule of 2 cm in diameter. Transthorasic needle aspiration was performed. Cytologic examination revealed atypical lymphocytes which reminded a low grade lymphoma. A thoracotomy was performed and the lesion was removed with wedge resection. Case II: A 56 years old male patient was referred with solitary pulmonary nodule of 2.5 cm. in diameter. The lesion was removed with thoracotomy and frozen section was performed which revealed tumour of lymphoid tissue. Histopathological examination of both cases revealed marginal Zone B-cell lymphoma of the Malt type. Case III: A 37 years old female was admitted with cough and dyspnea. CT examination showed multiple bilateral patchy consolidations. Transbronchial biopsy was negative. VATS biopsy was performed. Histopathological examination revealed marginal zone B-cell lymphoma of the MALT type. All cases were referred to medical oncology clinic. Pulmonary lymphomas could be found as solitary or multiple nodules in radiographic examination, so it should be reminded in diagnosis of solitary pulmonary nodule and interstitial lung disease.

PP3-122
DIFFERENT HISTOLOGICAL PATTERN IN SYSTEMIC SCLEROSIS WITH INTERSTITIAL LUNG DISEASE (ILD)
Romy Souza[1], Edwin Parra[2], Claudia Borges[1], Vera Capelozzi[2], Jorge Kavakama[3], Ronaldo Kairalla[4], Eloisa Bonfá[1]
[1] University of São Paulo Medical School, Department of Rheumatology, Brazil
[2] University of São Paulo Medical School, Department of Pathology, Brazil
[3] University of São Paulo Medical School, Department of Radiology, Brazil
[4] University of São Paulo Medical School, Department of Pneumology, Brazil

Background: The new histological pattern of idiopathic interstitial pneumonia (IIP) named Centrilobular Fibrosis (CLF) characterized by an aggressive bronchocentric scarring, basophilic intraluminal contents, and consequent parenchyma involvement may be relevant in systemic sclerosis (SSc). In fact, the high frequency of esophageal involvement in SSc patients is compatible with the suggested mechanism of CLF proposed by the authors, which is the pulmonary aspiration caused by the gastroesophageal reflux (GER). Materials and Methods: Twenty-eight consecutive patients who fulfilled the ACR criteria for SSc and had ILD on HRCT had been recruited to an open-lung biopsy as part of an ongoing prospective treatment protocol. Sections had been analyzed by two pathologists specialized in lung diseases and classified according to the new consensus classification of IIP and to the diagnostic criteria for CLF. Results: NSIP and CLF pattern had been the predominant patterns in SSc patients, observed in 67.8% and 21.4%, respectively. Intraluminal basophilic content has distinguished the two main groups. In fact, all 6 patients with CLF had this

feature whereas in only 6 of the 19 NSIP patients this parameter had been observed (p=0.007). Higher frequency of foreign bodies and bronchocentric distribution of the lesions in patients with CLF had been observed when compared to those with NSIP, but not reach statistical significance (p>0.05). As expected, peripheral injury had been found absent in 100% of CLF cases, compared with a frequency of 57.9% in the NSIP, though it had not reaching statistical significance (p>0.05). Other three characteristics had been found in the totality of the CLF patients: epithelium necrosis, basement membrane exposure and bronchiectasia. Conclusion: This is the first report of CFL in ILD of SSc patients, characterized by an intraluminal basophilic content, high frequency of foreign bodies and a bronchocentric distribution of the lesions. Since chronic aspiration had been suggested as the main pathophysiological mechanism for this severe form of lung involvement, the identification of this subgroup of patients will certainly contribute for a more appropriate therapeutic approach. Financial Support: FAPESP.

PP3-123
CILIARY DYSMORPHOLOGY: ULTRASTRUCTURAL FINDINGS IN 12 PATIENTS

Gulay Ozbilim[1], Aysen Uguz[2], Irem Hicran Ozbudak[1], Fatih Celmeli[2], Hakan Er [3]
[1] Akdeniz University, School of Medicine, Department of Pathology, Antalya, Turkey
[2] Akdeniz University, School of Medicine, Department of Pediatrics, Antalya, Turkey
[3] Akdeniz University, School of Medicine, Department of Histology, Antalya, Turkey

Background: Various ciliary abnormalities are found in patients with nonneoplastic diseases,such as unexplained recurrent upper and /or lower respiratory tract infections in children with or without Kartegener ‘s triad (sinusitis,bronchiectasis and situs inversus). Primary ciliary dysmorphology is an autosomal resessive disorder in childhood. Abnormal cilia which have specific electron microscopic features can be detected by transmission electron microscopic study. Method: Herein, we investigated 37 children with severe chronic /recurrent upper and lower respiratory tract problems for presence of primary ciliary dysmorphology. A plastic nasal brush was used to collect the tissue samples from nasal mucosa. Nasal brushing materials were evaluated by transmission electron microscopic. Other possible etiologic causes of severe and recurrent upper and lower respiratory tract problems were also evaluated by immunological tests, including atopy,respiratory function test, sweat test,reflux sintigraphy and radiologic studies. RESULT: Primary ciliary dysmorphology was shown in 12 of 37 children electronmicroscopically. Mean age of the patients was 11 years at diagnosis. Five of them were male and seven of them were female. Family history of cousin marriages was determined in 4 patients. Six patients had bronchiectasis ,6 patients had chronic sinusitis, 1 patient had gastroeosophageal reflux, 2 patients had situs inversus (including Kartegener’s triad). Ultrastructural examination of samples from nasal brushing revealed at least one of the following abnormalities: 1)Loss of normal 9+2 microtubules pattern , 2)Compound cilia, 3)Multiple axonemes in a single cilium, 4)Dysorganization of axonemes including loss of dynein arms, 5)Increasing in number of intracellular cilia. Conclusion: Primary ciliary dysmorphology is a cause of recurrent upper and /or lower respiratory tract infections in approximately one third of the patients. Electronmicroscopic study of nasal brushing is the valuable method in diagnosis of PCD patients with or without Kartegener’s triad and it may be recommended for unexplained recurrent upper and /or lower respiratory tract infections

PP3-124
EXPRESSION OF THE c-KIT AND Ki–67 PROLIFERATION INDEX IN PATIENTS WITH LUNG CANCER

Cumhur Ibrahim Basorgun[1], Gulay Ozbilim[1], Irem Hicran Ozbudak[1], Alpay Sarper[2], Abdullah Erdogan[2]
[1] Department of Pathology, School of Medicine, Akdeniz University, Antalya, Turkey
[2] Department of Thoracic Surgery, School of Medicine, Akdeniz University, Antalya, Turkey

Background: Kit is a transmembran tyrosine kinase receptor which is the product of protooncogene c-kit. Stem cell factor, ligand of c-kit, is co-expressed in various solid tumors, including carcinomas of the lung. The aim of this study was to determine the expression of c-kit and Ki-67 labelling index and the differences between histopathologic subtypes. Methods: In this study, resection materials of 75 lung carcinomas were used. Sections were taken from parafin-embedded blocks and stained immunhistochemically with c-kit and Ki-67 antibodies. Cytoplasmic and membranous staining density and percentage of stained areas were evaluated semiquantitatively. Mann-Whitney U and chi-square test were used for statistical analyses. Clinical data, information on tumor stage and histomorphologic details were reviewed. Results: Seventy-five patients included 70 males and 5 females (male:female, 14:1). Tumor samples of 30 squamous cell carcinomas, 30 adenocarcinomas and 15 small cell carcinomas were studied. Membranous or cytoplasmic c-kit immunoreactivity was documented in 9 of 15 small cell carcinomas (60%), 26 of 30 squamous cell carcinomas (86%) and 25 of 30 adenocarcinomas (83%). The average of Ki-67 labelling index was found 82% in small cell carcinomas, 62% in squamous cell carcinomas, 34% in adenocarcinomas and statistically significant differences were shown between histologic subtypes (p=0.000). No significant association was found between c-kit immunoreactivity and Ki-67 labelling index (p=0.706). Conclusions: C-kit is expressed in a high percentage of lung tumors; however there is no association between c-kit expression and histologic tumor subtypes. Ki -67 labelling index is higher in small cell carcinomas. Among non small cell lung carcinomas, Ki-67 labelling index is higher in squamous cell carcinomas than adenocarcinomas. There is no correlation between c-kit expression and Ki-67 labelling index in lung tumors.

PP3-125
ROENTGENOMORFOLOGIC PREDICTORS OF HORMONAL THERAPY RESPONSE IN PULMONARY SARCOIDOSIS

Oksana Kichigina, Evguenija Kogan, Vera Osipenko
Moscow Setchenov Medical Academy, Russia

Sarcoidosis is systemic, relatively high-quality granulomatosis of unknown etiology, which is characterized by the accumulation of T-lymphocytes and mononuclear phagocytes, by the formation of the non-secreting, non-caseous epitelioid-cell granulomas and by the disturbance of the normal architecture of the diseased organ. There is a large quantity of sarcoidosis classification, which do not always accurately reflect the nature of clinical and roentgenological data with the answers to the ongoing therapy. Aim. The aim of the study was to investigate correlation of the X-ray and morphological variants of lung sarcoidosis depending on the nature of granulomatous inflammation and special features of answers to the anti-inflammatory hormonal therapy. Materials and methods. High resolution multispiral CT scan and open lung biopsies of lung and lymph nodes have been studied from 40 patients with sarcoidosis. Results. Patients were divided into two groups according to the localization of sarcoid granulomas. First group (27 patients) had perivascular and subpleural arrangement of granulomas – places of pulmonary lymphatic collectors, the second group (13) – did not have subpleural and perivascular granulomas , granulomas were localized predominantly in

interstitium of respiratory part of the lung. Positive response to therapy has been found in 22 patients of the first group(80%) and 5 patients (20%) didn't show negative dynamics. In 2 group positive dynamics was observed only in 4 patients (34%) and 9 (66%) didn't show any. Conclusions. Hormonal therapy response in patients with sarcoidosis correlates with granuloma location and is better when sarcoid granulomas are accumulated in lymphatic collectors of the lung.

PP3-126
GEOGRAPHY OF MESOTHELIOMA AND ASBESTOS EXPOSURE

Claudio Bianchi, Tommaso Bianchi
Center for the Study of Environmental Cancer - Italian League against Cancer - Monfalcone, Italy

BACKGROUND The etiological relationship between exposure to asbestos and malignant mesothelioma is well established. However, it remains uncertain if the effects of asbestos are the same in all the populations. We collected the available data about the geographical distribution of mesothelioma. METHODS Some 300 researchers (including epidemiologists, pathologists, clinicians, etc.) were interviewed by a questionnaire to obtain information on mesothelioma incidence, and on the percentage of asbestos-related mesotheliomas in the various countries. In addition, literature data on mesothelioma were reviewed. RESULTS 1) Reliable data on mesothelioma incidence/mortality are available for a relatively low number of countries, corresponding to about 15% of the world population. 2) The highest annual crude incidence rates (over 25 cases per million) are reported or estimated for few countries (Australia, Belgium, UK). Intermediate rates (11-25 cases per million) are estimated for some countries of Europe (France, Germany, Italy, Scandinavian countries, The Netherlands), and New Zealand. Crude incidence rates lower than 11 cases per million are estimated for many countries of Europe (central Europe, Iberian peninsula, Ireland), some countries of America (Canada, USA), Asia (Cyprus, Israel, Japan, Turkey), and Africa (Morocco, Tunisia). 3) A parallelism between mesothelioma incidence and asbestos consumption in previous decades is observed in a large part of countries. 4) Marked differences in mesothelioma incidence from one region to another are seen in several countries (Croatia, Italy, Japan, Spain, Sweden, UK, etc.), with case clustering in areas with shipyards and asbestos-cement factories. 5) Very low incidences of mesothelioma are reported from some countries with high asbestos production and/or consumption, such as Russia, Thailand, South Korea. 6) Major difficulties are encountered in the histological diagnosis of mesothelioma. In some countries the original diagnosis of mesothelioma has not been confirmed by expert panels in a high proportion of cases. In addition, major difficulties are often encountered in mesothelioma registration. CONCLUSIONS Differences in previous asbestos exposure may explain a large part of the differences in mesothelioma geography. The apparent discrepancies between asbestos consumption and mesothelioma incidence have probably to be attributed to different factors (underestimation, low life expectancy, recent history of industrialization), rather than to ethnic differences in susceptibility to asbestos.

PP3-127
CONGENITAL MALFORMATIONS OF THE LUNGS AS POSSIBLE PRECURSOR OF CANCER

Ludmila Shestakova[1], Evgenia Cogan[2], Michail Paltsev[3], Yurij Cotlovsky[4]
[1] Moskow Setshenov Medical Academy, Russia
[2] Moscow Setshenov Academy, Russia
[3] Moscow Setshenov Medical Academy, Russia
[4] Krasnojarsky Medical Academy, Russia

Aim. A retrospective study was carried out on 110 cases with malignant lung tumors arising within congenital malformation areas. Matherial. There were 91 males / 82 % / and 19 females / 18 % / with ages ranging from 23 to 65 years. In 18 cases / 22% / congenital lung malformations had been revealed 1-15 years earlier lung cancer development. Methods included routine histology, immunohistochemistry of oncomarkers (p53, bcl-2, c-fos, c-myc, K-ras, c-erbB2, TTF-1, CK 8,19, AE1/AE3, Ki-67, PCNA, EGF, TGF-β), PCR for p53 mutations. Results. Correlations between type of congenital malformation and histological variant of lung cancer were established. Morphologic analysis revealed five groups of patients: 80 cases / 73% / with different types of adenocarcinoma / papillary, solid adenocarcinoma with mucin productions, bronchioloalveolar adenocarcinoma / inside congenital cystic adenomatoid malformations of the lungs; 9 cases / 8% / - different grade squamous cell carcinoma incide bronchogenic cysts; - 9 cases / 8% / - different grade squamous cell carcinoma or adenocarcinoma incide simple hypoplasia; - 7 cases / 6.5% / - different grade squamous cell carcinoma or adenocarcinoma inside congenital bronchiectasis; 5 cases / 4.5 % / - adenocarcinoma or carcinoid inside intralobar sequestration. Precancer lesions in congenital malformation and lung cancer cells had similarities in expression of p53, bcl-2, c-myc, K-ras, CK19. p53 mutation were found in lung cancer cells, as well as in epithelial cell of precancer lesion in congenital malformation. Conclusion: obtained results may proof contribution of congenital malformations in the development of and lung cancer.

PP3-128
VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) AND ITS RECEPTORS (VEGF-R1-Flt-1, VEGF-R2-KDR/Flk-1) AS PROGNOSTIC INDICATORS IN SMALL CELL LUNG CARCINOMAS (SCLC)

Evdokia Arkoumani[1], Georgia Hardavella[2], Yiotanna Dalavanga[3], Petros Galanis[4], Stavros Constantopoulos[2], Dimitrios Stefanou[1]
[1] Department of Pathology, University of Ioannina, Medical School, Ioannina, Greece
[2] Department of Pneumonology, University of Ioannina, Medical School, Ioannina, Greece
[3] Department of Anatomy, Histology and Embryology, University of Ioannina, Medical School, Ioannina, Greece
[4] Laboratory of Epidemiology, University of Athens, School of Nursing, Athens, Greece

Background: Tumor angiogenesis is a highly regulated process influenced by the host microenvironment and mediators. VEGF and its receptors (VEGF-R1-Flt-1, VEGF-R2-KDR/Flk-1) are good markers of vascular proliferation but their expression and relevance to tumor spread in SCLC is less clear. The present study aims to investigate angiogenesis and the expression of VEGF, VEGF-R1-Flt-1 and VEGF-R2-KDR/Flk-1 in SCLC and to establish their interrelationship and prognostic influence. Method: Immunohistochemical study of 50 SCLC was performed on paraffin sections with VEGF, VEGF-R1-Flt-1 and VEGF-R2-KDR/Flk-1 antibodies (DBS California-Menarini Hellas). Mean vascular density (MVD) was assessed and rectospectively correlated with the clinical outcome. Results: A group of 50 patients (5 women, 45 men, mean age 64,3 years) included 25 with limited and 25 with extensive stage SCLC. 6%, 34% and 40% of tumor specimens presented high expression of VEGF, VEGF-R1 and VEGF-R2 respectively. 1/3 specimens presenting high VEGF expression, 18/20 having high VEGF-R2 expression and 12/17 with high VEGF-R1 expression corresponded clinically to metastasis. Mean survival for patients with high VEGF expression was 8,3 months and with low expression was 10,83 months. Mean survival corresponding to high VEGF-R1 and VEGF-R2 was 10,94 and 6,75 months respectively and to low was 10,35 and 9,41 months respectively. Conclusion: VEGF is expressed less than its two receptors (VEGF-R1-Flt-1, VEGF-

R2-KDR/Flk-1) in SCLC. VEGF-R1 and VEGF-R2 expression are more closely correlated with metastasis than VEGF although the latter and VEGF-R2 seem to be positively correlated with poor patient outcome.

PP3-129

EXPRESSION OF VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) AND ITS RECEPTORS (VEGF-R1-Flt1, VEGF-R2-Flk1) IN NON SMALL CELL LUNG CARCINOMAS (NSCLC): CORRELATION WITH LYMPHANGIOGENESIS AND CLINICAL OUTCOME

Georgia Hardavella[1], Evdokia Arkoumani[2],
Yiotanna Dalavanga[3], Stavros Constantopoulos[1],
Niki J. Agnantis[2], Dimitrios Stefanou[2]
[1] Department of Pneumonology, University of Ioannina, Medical School, Ioannina, Greece
[2] Department of Pathology, University of Ioannina, Medical School, Ioannina, Greece
[3] Department of Anatomy, Histology and Embryology, University of Ioannina, Medical School, Ioannina, Greece

Background: Angiogenesis is an essential process in tumor growth and metastasis. VEGF and its receptors are considered to be good angiogenic markers but their correlation with lymphangiogenesis and patient outcome in NSCLC is yet to be defined. The present study aims to evaluate angiogenesis and the expression of VEGF, VEGF-R1-Flt1 and VEGF-R2-Flk1 in NSCLC, to correlate them with lymphangiogenesis (CD105 expression) and clinical outcome. Method: 96 NSCLC specimens were analyzed immunohistochemically using VEGF, VEFG-R1-Flt1, VEGF-R2-Flk1 and CD105 antibodies (DBS California-Menarini Hellas). Mean vascular density (MVD) and intratumoral lymphatic microvessel density (ILMVD) were determined and rectospectively correlated with clinical outcome. Results: 13 women and 83 men (mean age 64,03 years) were included in our study. 15,6% were in stage I, 46,8% stage II, 40,4% stage III, 2,1% stage IV. 25% presented high VEGF expression, 40,6% high VEGF-R1-Flt1 and VEGF-R2-Flk1 expression and 87,5% high CD105 expression (ILMVD>25). 63 patients presented metastasis, 27% of which had high VEGF expression, 42,9% high VEGF-R1-Flt1 expression, 44,4% high VEGF-R2-Flk1 and 95,2% high ILMVD ($p<0,05$). ILMVD was significantly correlated with the stage of the disease ($p<0,05$) whilst angiogenic factors were not. Conclusion: Lymphangiogenesis proved to be of superior significance in being correlated with clinical outcome and predicting metastasis in NSCLC in comparison with VEGF and its two receptors (VEGF-R1-Flt1, VEGF-R2-Flk1) that seem to be of little significance.

PP3-130

CLINICOPATHOLOGIC FEATURES AND PROGNOSTIC SIGNIFICANCE OF LUNG TUMORS WITH MIXED HISTOLOGIC PATTERN

Ebru Cakir[1], Funda Demirag[1], Mehtap Aydin[1], Ebru Unsal[2]
[1] Ankara Ataturk Chest Disease and Chest Surgery Education and Research Hospital Department of Pathology, Turkey
[2] Ankara Ataturk Chest Disease and Chest Surgery Education and Research Hospital Department of Chest Disease, Ankara, Turkey

Background: Tumors with mixed histology are seen less often than the tumors with single histology in the lung. The prevalence is approximately in the range of 2-4%. The biologic behavior and clinicopathologic characteristics of these tumors have not been well described. We evaluated the clinicopathologic features and prognosis of lung tumors with mixed histology and compared them with the tumors that have single histology. Method: The study group consisted of 39 patients with a mixed histologic pattern and control group consisted of 41 patients with a single histology on the surgical specimen which were diagnosed between 1997-2007 at Ankara Ataturk Chest Disease and Chest Surgery Education and Research Hospital.In the study group three types of tumors were identified: adenosquamous carcinoma, combined neuroendocrine tumors and biphasic tumors (epithelial + mesenchymal malignant components). The combined neuroendocrine tumors were further divided in small cell carcinoma (SCLC)+non-neuroendocrine carcinoma (NNEC), small cell carcinoma+large cell neuroendocrine carcinoma (LCNEC) and LCNEC +NNEC. Clinicopathologic characteristics, pTNM and survival rates were evaluated and compared with the population of resected lung tumors with single histology. Results: There were 20 adenosquamous carcinoma, 9 SCLC+ NNEC, 5 SCLC+LCNEC, 2 LCNEC+NNEC, 3 biphasic tumors as study group and 25 squamous cell carcinoma, 16 adenocarcinoma as control group. There was no significant difference for mean age, sex, smoking history, asbestos exposure and tumor size between study and control group ($p>0.05$). Among adenosquamous carcinomas advanced stage (IIIa or IIIb) was significantly more evident than the single histology group but survival rates were not different ($p=0.328$). Among combined neuroendocrine tumors advanced stages was more evident than adenosquamous carcinomas and single histology group ($p=0.014$). Survival was significantly worse for patients with combined neuroendocrine tumors than for patients with adenosquamous carcinoma and single histology group ($p=0.0002$). Median survival of biphasic tumors was 21 months (range 10-36). Univariate analysis revealed that tumor stage was significantly associated with the survival rate for all groups ($p=0.016$). Conclusion: Tumors with mixed histology are rarely seen in the lung. Among these tumors adenosquamous carcinoma and combined neuroendocrine tumors present more aggressive clinic behaviour than the tumors with single histology.

PP3-131

STUDY OF THE POSSIBLE HORMESIS EFFECT IN AN EXPERIMENTAL PASSIVE TOBACCO MODEL IN THE EVOLUTION OF LUNG CANCER INDUCED BY URETHANE

Patricia Maluf Cury, Ludmilla Nadir Santiago,
Juliana De Camargo Fenley, Lucia Campanario Braga,
José Antonio Cordeiro
Faculdade de Medicina de São José do Rio Preto, Brazil

Background: In a previous study, we verified an unexpected reduction of the number of pulmonary nodules in mice exposed to the cigarette smoke. One of the possibilities for such event would be a dose response effect called hormesis, which is represented by a J-shaped curve. The aim of the present study was to verify whether passive cigarette smoke might act by hormesis in an experimental model of lung cancer carcinogenesis. Method: 3mg/kg urethane was injected in male Balb-c mice, with 7 to 13 life weeks. After that, they were exposed to passive tobacco smoke twice a day, for five times a week, in a closed chamber. The animals were randomly divided into four groups. G0: only received urethane; G1: exposed to the smoke of three cigarettes per 10 minutes each time; G2: exposed to the smoke of three cigarettes per 10 minutes, twice; G3: exposed to the smoke of six cigarettes per 10 minutes, twice. Autopsy was performed after 16 weeks and the number of nodules and hyperplasia in lung was counted. Results: The statistics analysis showed that there was not significant difference when we compare the mean number of nodules and the hyperplasia between the studied groups ($p=0,146$ and $p=0,513$, respectively). Conclusion: The studied model did not show evidences of hormesis effect. Balb-C mice apparently are resistant to cigarette smoke exposure. Financial Support: FAPESP – Fundação de Amparo à Pesquisa do Estado de São Paulo.

PP3-132
RESPIRATORY BRONCHIOLITIS – ASSOCIATED INTERSTITIAL LUNG DISEASE WITH FIBROSIS IN YOUNG PATIENTS PRESENTING WITH SPONTANEOUS PNEUMOTHORAX

Elvira Stacher[1], Stefan Scheidl[2], Helmut Popper[3]
[1] Insitute of Pathology, Medical University Graz, Austria
[2] Department of Pulmonology, University Hospital, Medical University Graz, Austria
[3] Institute of Pathology, Medical University Graz, Austria

Background: Respiratory Bronchiolitis (RB) is a common incidental finding in lung specimens of smokers. It is defined as a bronchiolocentric accumulation of pigmented alveolar macrophages and is usually an incidental histological finding. In association with clinical symptoms such as shortness of breath, abnormalities of pulmonary function tests and/or CT scan findings the diagnosis of Respiratory Bronchiolitis-associated Interstitial Lung Disease (RB-ILD) can be considered. It is known that RB and RB-ILD are associated with a higher prevalence of spontaneous pneumothorax. Method: We retrospectively reviewed tissue of 14 cases of RB-ILD of young patients (age less than 35 years) presenting with spontaneous pneumothorax and requiring surgical pleurodesis. Among the study group there were 3 females and 11 males, the age ranged from 19-34 years with a mean age of 23,9 years. In 8 cases a CT-scan was available. The H&E-stained sections were examined, and of areas with marked fibrosis also a Movat-stain were performed. Results: In 10 of 14 cases (1 female, 9 males) we observed a marked fibrosis, predominantly in subpleural and centrilobular areas. The Movat-stain allowed to discern early fibrosis with immature Collagen Type III and late scarring with mature collagen Type I. Conclusion: We think that Respiratory Bronchiolitis – Interstitial Lung Disease may progress to fibrotic lung disease since the occurrence of Collagene Type I is an irreversible event. This disease therefore deserves more attention and should be mentioned in the pathohistological report.

PP3-133
ASBESTOS: MYTH, HISTORY, RELIGION

Claudio Bianchi, Tommaso Bianchi
Center for the Study of Environmental Cancer - Italian League against Cancer - Monfalcone, Italy

BACKGROUND The most ancient evidences regarding the use of asbestos were traced in Finland and Sweden. In particular, asbestos was used in pottery in Eastern Finland from about 4000 B. C.. In the Mediterranean region the commerce of asbestos in the Classic Age is documented. In ancient era and in the Middle Ages the properties of asbestos were the subject of legends, myths, and theological comments. METHODS In the present study some Latin, Greek, and Italian literature texts were reviewed. RESULTS In the first century, the Latin encyclopaedist Pliny the Elder describes asbestos under various names in his Historia Naturalis. In one of these descriptions, asbestos is defined as a plant which grows in the desert of India. Pausanias, a Greek geographer of the second century, reports the presence of asbestos in the lamp placed in a temple in the Acropolis of Athens. An apocryphal gospel, the Protoevangelium of James, reports that different materials, including asbestos, were used in making the curtain of the Jewish Temple. After the Liber Pontificalis, a book in which the biographies of the first Popes are collected, an asbestos wick was placed on the candle in the middle of the Lateran baptistery in Rome. Asbestos is also quoted by the Christian Fathers of the Church, Basil the Great (339-379), and Augustin of Hippo (354-430). Basil states that the bodies of the three boys of Babylon, who after the tale of the Bible resisted to fire, had the nature of asbestos. An interesting description may be found in the Milione (Travels of Marco Polo) of the Italian traveller Marco Polo (1254-1324). In a region of Central Asia, Marco Polo saw towels that were placed in the fire without burning. In addition, he reports that the Great Khan, the emperor of China, sent an asbestos towel as a gift to Rome; such towel had to be used “to wind the sudarium of our Lord”. CONCLUSIONS The review of the above texts shows that in the past the ‘positive’ features of asbestos were strongly emphasized. This agrees with the fact that asbestos was also used in medicine. Finally, the frequent association of the mineral with places of worship and with religious issues makes asbestos in some way sacred.

PP3-134
MIXED SQUAMOUS CARCINOMA AND OSTEOSARCOMA (CARCINOSARCOMAS) OF THE LUNG HAVE A CGH MAPPING SIMILAR TO PRIMITIVE SQUAMOUS CARCINOMAS AND OSTEOSARCOMAS

Javier Pardo[1], Enrique De Alava[2], Jesus Javier Sola[1], Angel Panizo[1], Gregorio Aisa[1], Natalia Rodriguez-Spiteri[1]
[1] Clinica Universitaria de Navarra. Universidad de Navarra, Spain
[2] Centro de Investigacion del Cancer-IBMCC. Universidad de Salamanca, Spain

Background: Carcinosarcomas (CS) are malignant tumors with a mixture of carcinomatous and differentiated sarcomatous elements. We selected from the surgical files of the Department of Pathology, University of Navarra three cases of CS composed of squamous carcinoma (SC) and osteosarcoma tissues. Methods: Clinical parameters were recorded. All cases were studied by light microscopy, immunohistochemistry and CGH technique. CGH assay was made in both carcinomatous ans osteosarcomatous areas, using as controls two lung squamous carcinomas and two lung metastatic osteosarcoma. Results: All patients were male and their age was 72, 43 and 58 years respectively. The size of the neoplasms was 7, 5.5 and 5 cm in maximum diameter. Only one patient had lymph node metastasis at presentation. All three patients died of their disease 4, 9 and 14 months after surgery. Pathologically, all cases had similar proportion of both squamous and osteosarcomatous structures by light microscopy. Immunoreactivity was positive for AE3AE1, CAM 5.2, CK-7, EMA, E-cadherine, p53 and CEA in carcinomatous areas and for vimentin and CD-68 in sarcomatous component. Foci of chondroid differentiation were positive for S-100. Chromosomal imbalances using CGH were identified in all tumors from predominant epithelial and mesenchymal areas. Overall, a total of 55 copy number changes were detected with a median of 18 abnormalities per case (range: 12-26): 48 gains, 6 losses and one high level amplifications. We found similar chromosome alterations in carcinomatous areas and lung squamous carcinoma and in osteosarcomatous areas and metastatic osteosarcoma respectively. Conclusions: This study provided an accurate demonstration that the CGH alterations in osteosarcoma component in carcinosarcomas of the lung are similar to CGH changes of soft tissue osteosarcomas. Additional functional studies are needed to determine the biological and clinical significance of the CGH changes and theorize about the histogenesis of this unsual tumor.

PP3-135
IS D2-40 A USEFUL MARKER DISTINGUISHING MALIGN MESOTHELIOMA, PULMONARY ADENOCARCINOMA AND BENIGN MESOTHELIAL PROLIFERATIONS?

Hale Deniz[1], Yasemin Kibar[2], Muhammet Emin Guldur[3], Kemal Bakir[2]
[1] Gaziantep Pediatric Hospital, Turkey
[2] University of Gaziantep, Medical Faculty, Department of Pathology, Turkey
[3] Gaziantep Gynecologic and Obstetric Hospital, Gaziantep, Turkey

Background: Pulmonary adenocarcinomas, malign mesotheliomas and sometimes benign mesothelial proliferations may show great resemblance histomorphologically. For this reason an immunodiagnostic panel is usually needed for differential diagnosis. Recently D2-40, a lymphatic marker, is suggested to be useful for mesothelial differentiation. Aim of this study is to compare D2-40 immunostaining in malignant mesothelioma, pulmonary carcinoma and benign mesothelial proliferations. Method: In this retrospective study, D2-40 immunostaining was investigated in 37 cases of malign mesothelioma, 36 cases of pulmonary adenocarcinoma and 31 cases of benign mesothelial proliferation. Diagnosis of malign mesothelioma were previously confirmed by a panel including calretinin, CK5/6, CEA. Results: Predominantly membranous immunoreactivity was observed in 51% of malignant mesothelioma and 55% of benign mesothelial proliferations. All of the 36 pulmonary adenocarcinomas were negative. These results were statistically significant ($p<0.001$). Conclusion: We believe that D2-40 may be helpful in differential diagnosis of malign mesothelioma from pleural involvement of pulmonary adenocarcinoma.

PP3-136
PROGNOSTIC SIGNIFICANCE OF OSTEOPONTIN EXPRESSION IN MALIGNANT PLEURAL MESOTHELIOMA

Susanna Cappia[1], Luisella Righi[1], Paolo Ceppi[1], Marco Volante[1], Elisa Bacillo[1], Francesco Ardissone[1], Dario Mirabelli[2], Giorgio V. Scagliotti[1], Mauro Papotti[1]
[1] Department of Clinical & Biological Sciences, University of Turin at San Luigi Hospital, Turin, Italy
[2] Cancer Epidemiology Unit, University of Turin at San Giovanni Battista Hospital, Turin, Italy

Background: Malignant pleural mesothelioma (MPM) is an asbestos-related type of cancer with a median survival time of approximately 10 months. Long survivors are usually rare and currently no clear prognostic factor are strongly associated with such status. Recently, in asbestos exposed individuals, high osteopontin (OPN) serum levels were correlated to the presence of mesothelioma, but not with other asbestos-related conditions (pleural plaques or interstitial lung disease) and it has been proposed as a serum marker of mesothelioma in asbestos exposed subjects. Since OPN is a glycoprotein involved in cell-matrix interactions and cell signalling that was shown to be correlated with invasion, metastatic spread and decreased survival in several carcinomas and melanoma, the aim of this study was to analyse the prognostic role of OPN in MPM. Method: From a large database of 395 MPM cases diagnosed between 1989 and 2003 in a single institution, 26 cases with long survival (>24 months, mean 39.2 months) were extracted. The male/female ration was 16/10, median age 63.5, epithelioid versus biphasic histology 24 and 2/26, respectively, and extensive versus limited pleural involvement 17 and 9, respectively. None was surgically resected and treatment was talc pleurodesis associated with cisplatin-based chemotherapy All cases were matched to control cases with comparable clinical-pathological characteristics, except for a fatal outcome within 15 months (mean 8.9 months). OPN expression was detected by immunohistochemistry on archival biopsy specimens, the results quantified scoring extent and intensity of the immune reaction (scale 0-300), and the expression levels compared with survival and other parameters. Results: Tissue immunoreactive OPN was found in all cases, with a median score of 90 (range 5-285). Interestingly, OPN levels were significantly higher in short survivors compared to long surviving patients (Mann-Withney U-test, $p<0.0001$). At univariate analysis, Kaplan-Meier curves showed that patients with low (< median) OPN expression had longer survival compared to those with higher expression levels (38.7 vs 11.5 months, $p=0.00001$), while performance status, age, gender and extent of pleural involvement had no impact on the outcome. Conclusion: As shown in several carcinomas, OPN expression levels in mesothelioma cells have a prognostic significance, being this protein probably involved in tumor progression and dissemination. It could represent a novel target for growth control strategies of this highly aggressive neoplasia.

MEDIASTINAL B LARGE CELL LYMPHOMA A STUDY OF 11 CASES

Atef Ben Abdelkader[1], Mohamed Tahar Yacoubi[1], Moncef Mokni[1], Lilia Abid[1], Adnen Laatiri[2], Sadok Korbi[3]
[1] Department Of Pathology, Tunisia
[2] Department of Hematopathology, Tunisia
[3] Depatment of Pathology, Tunisia

Background : Mediastinal B large cell lymphomas is rare, distinguished from the other locations of lymphoma by its clinical and radiological features, its histopathological appearance and by a poor prognosis. The aim of this study is to specify the clinico-pathological particularities, the management and the behaviour of this entity. Material and Methods : We studied 11 cases of mediastinal B large cell lymphomas diagnosed in the department of pathology during a period of 11 years (1993-2003). Clinical, radiological and biological informations provided from patient files. We used the index performance status (IPS) of the OMS to evaluate the clinical activity level of patients. Slides were reviewed to confirm the diagnosis . An immunohistochemistric study was performed to specify the proliferative index of tumors. The staging of tumors was evaluated according to the clinical staging system of Ann Arbor. Results : Our population was composed of 7 women and 4 men with a mean age of 25 years. The predominant presenting symptom was superior vena caval syndrome. The diagnosis was confirmed with an expression of CD20 by tumor cells in all cases. The IPS was low in 7 cases, which were stage IV of Ann Arbor system. Patients were treated chemotherapy associated to radiotherapy in three cases. Remission was noted in four cases and recurrence in three cases. No response was seen in four cases. Conclusion : Mediastinal B large cell lymphoma occurs preferentially in young females, most commonly revealed by superior vena caval syndrome. The diagnosis should be confirmed by histopathology and immunohistochemistry. A good response is a rule to radiation therapy and chemotherapy but recurrences are frequent.

PP3-138
HETEROGENEITY OF MANTLE CELL LYMPHOMA

Jirka Macak, Jana Smardova, Iva Kroupova, Barbora Ravcukova, Martin Klabusay, Leos Kren
Department of Pathology, University Hospital Brno, Czech Republic

Background: the aim of this study is to investigate the heterogeneity of mantle cell lymphoma (MCL) in morphology, immunohistochemistry, FISH and molecular biology. Material and Methods: in the archive of Department of Pathology University Hospital Brno we found 27 cases of MCL in lymph nodes. Classical histology, immunohistochemistry, FISH method and from native tissues FASAY (Functional Analysis of Separated Alleles in Yeast) were performed. Results: in series of 27 cases of MCL were 17 men and 10 women. Most patients were in age of 61-80 years. Morphologically, diffuse infiltration with medium size lymfoid cells was found. Mitotic rate (number of mitoses/10HPF) in first category (0-5 mitoses) in 13 cases; second category (6-10 mitoses) in 8 cases; third category (11-20 mitoses) in 4 cases; fourth category (21-30 mitoses) in two cases. Highly characteristic marker for MCL, hyalinne deposits, was recognized in 20 cases. FISH for t(11;14) was performed in all cases and 51-100% of tumour cells were positive. Immunohistochemistry revealed positivity with marker CD 5 in 19/27 cases (30% cases were negative); CD 20 in 27/27; CD 43 in 23/27; cyclinD-1 in 19/27 (30% cases were negative); bcl-2 in 26/27; p53 in 22/27. The proliferation marker Ki-67 was detected in approx. 20% of cells in 16 cases and 30-60% of cells were found in 11 cases. For status p53 by FASAY method, 12 native tumour tissues were examined. In the two of them, abberation in the p53 gene was revealed and missense p53 mutations R282W and C288S were detected by DNA sequencing. Conclusions: our results show that MCL was uniform in morphology and in type of infiltration, which was in all cases diffuse. Very useful marker for diagnosis seems to be hyaline deposits stcattered in the lymphoma tissue. Number of mitoses enable us include 6 cases of the blastoid variant of MCL. In immunohistochemicstry, CD 5 and cyclinD-1 markers were negative in 30 cases. Abberation of p53 gene is rare in MCL. This work was supported by grant NR/9305-3 of The IGA MZ CR.

PP3-139
PROLIFERATION MARKERS IN ZAP70+ AND ZAP70- B CELL CHRONIC LYMPHOCYTIC LEUKAEMIA

Petra Mandakova, Katerina Kamaradova, Hana Kortankova, Jana Siftancova, Eliska Stranska, Vit Campr
Department of Pathology and Molecular Medicine, Charles University in Prague, 2nd Medical Faculty, Prague, Czech Republic

Background: B cell chronic lymphocytic leukaemia (B-CLL) is a low grade lymphoproliferative disorder. Generally, most patients are asymptomatic with a long survival, but there exists a subset of cases with a more aggressive course. The expression of protein ZAP70, often associated with non mutated status of IgVH genes, and expression of CD38 molecule divide B-CLL into prognostically relevant subgroups. In this study we correlated these subgroups with the expression of various proliferation markers (CD71, proliferation index (PI) and Ki67). Methods: We analyzed 50 samples from 40 patients with B-CLL/SLL (bone marrow, lymph nodes, peripheral blood and tonsils). The expression of ZAP70 and CD38 molecules on CD19+CD5+ tumor cells were assessed in cell suspensions by means of flow cytometry, as well as the expression of CD71 (transferrin receptor). The PI was defined as a number of cells in S and G2/M phase of cell cycle determined by flow cytometry analysis. Ki67 was detected immunohistochemically in formalin-fixed paraffin-embedded material if available. Results: 32 samples from 26 patients were ZAP70+ and 17 samples from 14 patients were ZAP70-. The expression of CD38 subdivided samples into ZAP70+CD38+ (30 %), ZAP70+CD38- (35 %), ZAP70-CD38+ (4 %) and ZAP70-CD38- (31 %). The higher proportion of sample infiltration, higher CD71 expression and higher proliferation was found in ZAP70+ patients compared to B-CLL without expression of ZAP70. The information on status of CD38 brought no significant difference. Conclusion: B-CLL is clinically as well as biologically a heterogenous disorder. This fact is reflected by description of various markers which divide the disease to subcategories with different prognosis. In the investigated set of patients we showed that the ZAP70 positivity of B-CLL cells is followed by a higher expression of proliferation markers and implicates a heavier tumor infiltration of the tissue. We conclude that the expression of ZAP70 is associated with a higher proliferative activity and thus can be a good marker of more aggressive disease with worse prognosis. This study was supported by Research Project FNM MZO 00064203 n. 6704.

PP3-140
FIRST EXPERIENCES WITH DETECTION OF JAK2 MUTATION IN PARAFFIN EMBEDDED BONE MARROW BIOPSIES OF POLYCYTHEMIA VERA PATIENTS

Juraj Marcinek[1], Luká Plank[1], Tatiana Burjanivová[1], T. Balhárek[1], Peter Szépe[1], Zora Lasabová[2]
[1] Department of Pathology and National Consultation Centre of Hematopathology Jessenius Faculty of Medicine, Comenius University and Faculty Hospital in Martin, Slovakia
[2] Department of Molecular Biology, Jessenius Faculty of Medicine, Comenius University in Martin, Slovakia

Background: Point JAK2 mutation (V617F) was recently identified in association with Ph1- myeloproliferative diseases (MPD) in almost all polycythemia vera (PV) patients and in cca 50% of patients with essential thrombocythemia and chronic idiopathic myelofibrosis. The mutation shows association with typical laboratory and clinical findings, while its prognostic significance remains uncertain. It might be identified by direct DNA sequencing, allele-specific PCR (ASPCR), real-time PCR, DNA-melting curve analysis, etc. In majority of published papers fresh peripheral blood or bone marrow (BM) cell analysis was used, but only limited experiences based on retrospective analyses of BM biopsies are known. The aim of this study was to prove the possibility of DNA analysis obtained from the regular BM biopsies with the aim to implement JAK2 mutation detection into the routine praxis of our hematopathology center. Methods: The paraffin-embedded BM biopsies of PV patients diagnosed in the period January 2004 – March 2007 were selected from the files and reevaluated histologically and clinically. BM sections were deparaffinized in graded alcohols and xylene and digested with proteinase K over two nights. DNA was extracted using the Wizard® genomic DNA purification kit (Promega). Detection of the V617F mutation was performed by allele-specific hot start multiplex PCR with one common reverse and two separate forward primers. In the presence of the V617F JAK2 mutation two PCR products of different sizes were amplified, while in the presence of wild-type DNA only one fragment is amplified. Results: BM biopsies of 53 patients fulfilled WHO criterias of PV diagnosis established by BM biopsy and/or by hematologist. In addition, the clinicians were subsequently asked to report the follow up. At the time of abstract submission, results of JAK2 detection of 19 patients were available. BM biopsy showed typical PV morphology in 18 cases and MPD NOS in 1 case and the diagnosis was confirmed also by follow up in 13 of them. JAK2 mutation was detected in 16 of 19 patients and in all of 12 cases sharing both typical morphology and clinical behaviour of PV. Conclusion: Although the importance of JAK2 detection for MPD typing is limited, its diagnostic implementation is usefull and its possible therapeutic significance might not be excluded. Our preliminary results confirmed a high sensitivity of JAK2 detection by using routine BM biopsy material. Further analyses will follow, incl. the atempts to identify its homozygous and heterozygous forms. Supported by Grant UK/84/2007.

PP3-141
OPPORTUNISTIC INFECTIONS IN HIV+/AIDS PATIENTS – COMPARATIVE AUTOPSY STUDY

Florica Staniceanu[1], Sabina Zurac[1], Gianina Micu[1], Alexandra Bastian[1], Luciana Nichita[2], Cristiana Popp[1], Andrei Murariu[1], Claudiu Socoliuc[1], Liana Tudorica[1], Adrian Streinu-Cercel[3]
[1] Colentina University Hospital, Bucharest, Romania
[2] Carol Davila University of Medicine and Pharmacy, Bucharest, Romania
[3] Matei Bals Institute, Bucharest, Romania

Background: Patients with HIV/AIDS have an important immunodepression, which makes them susceptible for opportunistic infections which are, in most cases, the main cause of death. Material and method: We made a comparative study of autopsy findings regarding infectious pathology including all AIDS patients submitted to autopsy in our department as follows: group A – patients HIV positive autopsied between 1997-2001 (27 cases) and group B – 19 cases between 2002-2006. Results: The cause of death in our two groups varied as it follows: • group A: - opportunistic infections (single or combined) - 22 cases (7 cases of each tuberculosis and systemic candidosis, 4 cases of pneumocystosis, 2 cases of cryptococcosis, 1 case of each Cytomegalovirus infection and systemic aspergillosis). - nonspecific infections - 4 cases - other causes – 1 case (non-hodgkinian malignant lymphoma) • group B: - opportunistic infections (single or combined) – 13 cases (3 cases of tuberculosis, 2 cases of each pneumocystosis, toxoplasmosis, progressive multifocal leukoencephalopathy and Cytomegalovirus infection, 1 case of coccidioidomycosis and 1 case of systemic aspergillosis. - nonspecific infections – 4 cases - other causes – 2 cases (one cerebral malignant lymphoma and one myocardial infarction). There is a definite change in the spectrum of lethal opportunistic infections in AIDS related deaths in Romania - a lower rate of tuberculosis in group B comparing with group A, disappearing of lethal systemic candidosis and occurence of other type of opportunistic infections: toxoplasmosis and progressive multifocal leukoencephalopathy due to JC virus infection. The most probable cause of this trend is high active antiretroviral therapy (HAART) which assures a tolerable level of immunity for these patients. The majority of the group B patients who died by opportunistic infections were recently found HIV+ (1-3 months) and HAART was either not used or very recently administrated. Conclusion: Opportunistic infections are an important health problem and a frequent cause of death in HIV positive patients. This study provides informations about changes occurred in the main causes of AIDS related deaths, data that may be useful for improving the medical management of the HIV+/AIDS patients.

PP3-142
BONE MARROW (BM) PATHOLOGY CONTRIBUTES TO "IN SITU" UNDERSTANDING OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IMMUNOPATHOGENESIS: ANALYSIS OF A SERIES OF 92 PATIENTS

Theodora Papadaki[1], Kostas Stamatopoulos[2], Niki Stavroyianni[2], Maria Fameli[1], Anastasia Athanasiadou[2], Chrysavgi Lalayanni[2], Anastasia Hadzidimitriou[2], Ioanna Athanasiadou[2], Evi Puliou[1], Achilles Anagnostopoulos[2], Athanasios Fassas[2], Dimitra Anagnostou[1]
[1] Evangelismos Hospital, Greece
[2] G. Papanicolaou Hospital, Greece

We conducted a detailed analysis of BM biopsy (BMB) samples from a series of 92 CLL patients and explored associations with clinical features and outcome, CD38 expression, and IGHV mutation status. Patient group: M:F=54:38, median age: 66 years, Binet stage-A/B/C: 76/12/4. Peripheral blood immunophenotype: (1) CD38+: 35/92 cases (2) IgG+: 19/92 cases. Mutated/unmutated IGHV genes (M-IGHV/A-IGHV): 59/33 cases. Formalin-fixed, decalcified, paraffin-embedded sections of BMBs were examined: (1) morphologically (H&E); (2) immunohistochemically (ABC technique). The following antibodies were used: CD20, CD79a, CD3, BCL-2, CD5, CD23, SIg/CIg (kappa/lambda/mu/delta/gamma/alpha), CD27, myeloperoxidase, PGM1 (CD68), glycophorin-C, CD61. All cases showed neoplastic lymphocytic infiltration (20-95% of BM cellularity). In all cases, neoplastic lymphocytes expressed CD20/CD79a/CD5/CD23. In the vast majority of cases, the neoplastic population consisted almost exclusively of small lymphocytes. Medium- or large-sized cells were admixed in 4 and 2 cases, respectively. A moderate number of monocytoid-like cells with clear cytoplasm were identified in 3 cases. Finally, 5 cases exhibited lymphoplasmocytoid differentiation in a small proportion of the neoplastic population. Three patterns of neoplastic lymphocytic infiltration were identified: (1) interstitial: 41 cases; (2) nodular/nodular+interstitial: 31 cases; (3) diffuse: 20 cases. Moderate-to-significant reduction of the granulocytic series was observed in 47/92 cases. The remaining cases showed hyperplastic granulocytic series with a left shift and, occasionally, dysplastic changes of mature forms. Hyperplasia of the erythroid and megakaryocytic series -often with dyserythropoiesis and dysmegakaryopoiesis- in a context of normal/decreased hemoglobin levels and platelet counts was observed in 52/92 and 72/92 cases, respectively; the remaining cases showed moderate-to-significant reduction of either series. Significant correlations were identified between: (i) nodular

infiltration and M-IGHV genes (p<0.001); (ii) diffuse infiltration and shorter time-to-progression (p=0.05). In conclusion, BMB examination: (1) permits identification of the rare CLL subtype with plasmocytoid differentiation (WHO); (2) allows evaluation the BM stroma and the hematopoietic marrow and provides important evidence for CLL-associated hematopoietic autoimmunity. Finally, the present study indicates that the favorable prognosis of the nodular pattern of infiltration in CLL may be interpreted in the context of its association with M-IGHV genes.

PP3-143

A CASE OF V617F(+) MYELODYSPLASTIC / MYELOPROLIFERATIVE DISORDER

Ozden Ozer[1], Emre Eskazan[2], Huseyin Bekoz[3], Kamil Peker[1], Sirin Yuksel[4], Ender Altiok[4], Burhan Ferhanoglu[2]
[1] Istanbul Patoloji Grubu, Turkey
[2] Cerrahpasa Tıp Fakültesi, Hematoloji Departmanı, Turkey
[3] Onurlu Saglık Hizmetleri, Turkey
[4] Acıbadem Genetik Tanı Merkezi, Turkey

Background: Mutations involving the JAK-2 tyrosine kinase have been described in a great majority of Polycytemia Vera(PV)and to a lesser extend in Essential Thrombocytemia(ET) and Chronic Idiopathic Myelofibrosis(CIMF). Myelodysplastic syndromes(remained mostly (-) for JAK-2 mutation except a unique subgroup with persistant presence of anemia, ringed sideroblasts and thrombocytosis. While some of these were referred as Refractory anemia with ring sideroblasts –Thrombocytosis (RARS-T) in the literature some were classified as Myeloproliferative / Myelodysplastic Disorder– unclassifiable (MPD/MDS–u). Here we are reporting a patient with a V617FJAK(+) MPD/MDS-u, characterised by anemia, ring sideroblasts, thrombocytosis,granulocytosis and multilineage dysplasia.Material&Methods: A 53 year old male presented with recurrent gastrointestinal bleeding. He was found to have anemia,thrombocytosis, granulocytosis and hepatosplenomegaly. In contrast to an iron deficiency anemia, expected in a setting of recurrent bleeding, he had macrocytic anemia. Upon completion of his acute management, the patient underwent a bone marrow biopsy in the outpatient setting. His bone marrow biopsy showed hypercellularity(%100) due to granulocytic and megakaryocytic expansion. Erythroid precursors were decreased and there was multilineage dysplasia. Numerous ring sideroblasts were identifed on the Prussion blue stain. The case was classified as MPD/MDS-u and a correlation with JAK-2 mutation was suggested by the pathologist. Real time PCR with melting curve analysis was performed for V617FJAK-2 on genomic DNA isolated from peripheral blood. Results : Our case characterised by anemia, thrombocytosis, ring sideroblasts, leucocytosis and multilineage dysplasia, classified as MPD /MDS–u revealed V617FJAK-2. Discussion : Detection of JAK-2 mutation with different diseases raises the possibility of presence of additional mutations determining the final disease phenotype. V617F mutation is known to render JAK-2 constitutively active resulting in abnormalmyeloproliferation. Therefore, in the myeloproliferative disease PV, JAK-2 mutation may be the sole genetic anomaly, correlating with the promising results obtained with JAK-2 inhibitors. However, in the MPD/MDS category, sole JAK-2 inhibition may not be sufficient in controlling the dysplastic component. Although, effects of JAK-2 inhibitors remain to be tested in clinical practice,further studies are needed to uncover cooperating mutations in this category.

PP3-144

c-MYC GENE TRANSLOCATION AND INCREASED COPY NUMBER PREDICT POOR PROGNOSIS IN ADULT DIFFUSE LARGE B CELL LYMPHOMA (DLBCL), ESPECIALLY IN GERMINAL CENTER-LIKE B CELL (GCB) TYPE

Yoon Kyung Jeon[1], Sun Och Yoon[1], Young A Kim[2], Ji Eun Kim[2], Chul Woo Kim[1]
[1] Department of Pathology, Seoul National University College of Medicine, Seoul, Korea
[2] Department of Pathology, Seoul National University Boramae Hospital, Seoul, Korea

Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous disease showing variable clinical presentations, histology, and molecular and cytogenetic features. In this study, c-MYC, BCL2, and BCL6 gene translocation and gene copy number change were comprehensively investigated in adult DLBCLs using interphase fluorescence in situ hybridization (FISH) analysis in formalin-fixed paraffin-embedded tissues, and their clinicopathologic features and prognostic implications were analyzed, especially in the context of germinal center B-cell like (GCB) and non-GCB type of DLBCLs based on immunohistochemistry. C-MYC translocation was observed in 9% (14 of 156), and increased gene copy number (ICN) was in 7.1% (11 of 156) of DLBCLs. Of the 14 cases with c-MYC translocation, 12 had IgH gene as a fusion partner. C-MYC translocation was significantly more common in GCB type DLBCLs than non-GCB type (22% [9 of 41] in GCB vs 4.9% [5 of 103] in non-GCB, p = 0.004). C-MYC translocation or ICN was not associated with Ki-67 labeling index. However, c-MYC translocation or ICN exhibited association with decreased BAX expression and increased BIM expression (p = 0.022 and 0.001, respectively). Clinically, c-MYC translocation was closely related with advanced IPI group (p = 0.005). In univariate survival analysis, c-MYC aberration including translocation or ICN was associated with shorter overall survival (p = 0.012) in adult DLBCLs, especially within GCB type (p = 0.030). BCL2/ IgH translocation in DLBCLs was only observed in 3.4% (5 of 145) in our cohort, which was much lower in comparison with the reports of Western countries. BCL2 ICN was detected in 11.7% (17 of 145), more frequently in non-GCB type DLBCLs than GCB type (16% [15 of 94] in non-GCB vs 2.5% [1 of 40] in GCB, p = 0.038). BCL2 ICN and/or BCL2/IgH translocation was well correlated with BCL2 protein expression (p = 0.031). BCL2 aberration such as ICN or translocation tended to show adverse effect on the overall survival of patients, but without statistical significance. BCL6 translocation was observed in 17.5% (24 of 137), which was most common gene aberration in our study. However, BCL6 translocation had no influence on the prognosis of DLBCL patients. In conclusion, we suggest that the evaluation of c-MYC gene status including translocation and increased gene copy number and the analysis of the results in the context of DLBCL phenotype might be important to predict the prognosis of DLBCL patient and determine the therapeutic strategies.

PP3-145

A SIX-MONTH ART INTERRUPTION IN HIV-INFECTED PATIENTS IMPROVES ADIPOSE TISSUE MORPHOLOGY AND GENE EXPRESSION

Cervera Pascale
Hopital St Antoine, France

To determine the ability of adipose tissue to recover after six-month ART interruption, subcutaneous abdominal adipose tissue of forty well-controlled HIV-patients with thirty three completed the study was studied at inclusion and after 6 months. Adipose tissue morphology, mithochondrial DNA and gene expression were evaluated. At M6, clinical parameters were not significantly modified, but inflammation markedly improved with a decreased in numbers of macrophages, and of adipocytes or inflammatory

cells stained with TNFα and IL6. The expression of adipogenic factor PPAR gamma and of markers associated with mitochondrial function and biogenesis, COX2 and PGC1α, was improved. Mitochondrial alterations were improved with decreased COX4 mRNA and increased mtDNA and COX2/C0X4 ratio. These data clearly outline the delerious impact of the thymidine analogues on adipose tissue. Even if no modification was clinically noticed, a 6-month treatment interruption allows a partial recovery of adipose tissue alterations.

PP3-146

SIMIAN VIRUS 40 IN KOREAN PATIENTS WITH NON-HODGKIN'S LYMPHOMAS

Young A Kim[1], Ji-Eun Kim[1], Yoon-Kyung Jeon[2], Chul-Woo Kim[2]
[1] Department of Pathology, Seoul National University Boramae Hospital, Korea
[2] Department of Pathology, Seoul National Univertiy Hospital, Korea

DNA sequencies coding for simian virus 40 (SV40) large T antigen have been detected in various human tumors, including non-Hodgkin's lymphomas (NHLs). But the relationship between SV40 and NHLs was controversial and needs to be studied. 89 cases of NHLs and 20 control lymph node tissues were tested for SV40 sequences using PCR amplification and sequencing. Viral sequences were present in two (2.2%) of 89 NHLs and were absent in 20 control tissues. Two SV40 positive cases were both intestinal diffuse large B cell lymphomas, and immunohistochemical staining for SV40 large T antigen was completely negative. These results suggest that SV40 is unlikely to have played a pathogenetic role in most of lymphoproliferative disorders in the Korean population.

PP3-147

UNUSUAL SITES OF B-CLL INVOLVEMENT: BIOPSY DIAGNOSIS OF B-CLL INFILTRATES PRESENTING IN EXTRANODAL AND EXTRAMEDULLARY TISSUES

Tomas Balharek, Lukas Plank, Peter Szepe, Juraj Marcinek, Zuzana Kviatkovska, Martina Barthova
Department of Pathology and National Consultation Centre of Haematopathology, Comenius University, Jessenius Faculty of Medicine and Faculty Hospital, Martin, Slovakia

Background: Majority of B-CLL/SLL cases with the diagnosis established by a biopsy is based on examination of lymph node (LN) or bone marrow (BM) specimens using WHO classification. Less commonly the patients show extranodal and/or extramedullary B-CLL manifestation, requiring an endoscopic or surgical intervention and biopsy verification of the tumor infiltrate. The aim of this study was to evaluate the possibilities of an appropriate B-CLL/SLL biopsy diagnosis in such cases. Methods: We reviewed records of 716 biopsies of B-CLL/SLL patients performed in the interval 01/2004 – 03/2007 and selected those presenting in other than LN and/or BM localisations. All the cases were reevaluated in sections stained with HE and Giemsa staining and by immunohistochemical detection of CD20, CD23, CD43, CD3 or CD45RO and Ig light chain. In addition, the biopsy register was analyzed to identify all other previous or subsequent biopsies of the patients. Results: From all reviewed biopsies only 15 cases (2,1%) represented infiltrates of other than LN or BM tissues, 3 of them represented a high grade transformation of B-CLL. In 5 patients the disease was diagnosed by tonsillectomy and in 10 cases by involvement of non-lymphoid organs: upper respiratory tract (n=3), trachea (n=1), thyroid gland (n=1), skin (n=3) and soft tissues (n=2). B-CLL/SLL diagnosis was confirmed: a.) by typical morphology and phenotype (n=12), incl. 2 cases of CLL with coincidental diffuse large B-cell lymphoma and classical Hodgkin lymphoma, resp. b.) by previous or subsequent BM (n=6) or LN biopsy (n=3) confirming the B-CLL diagnosis, incl. also cases problematic at the actual time of biopsy. These cases included: 2 limited and partially necrotic specimens insufficient for the complex analysis, especially in relation to confirmation CD23 positivity and 1 skin biopsy of a patient with B-CLL showing diffuse large B-cell lymphoma without residual CLL infiltration. Conclusion: The biopsy examination of B-CLL infiltrates appearing in the extranodal localisation seems to represent a rare event. These cases may cause diagnostic and differential diagnostic problems, while it might be difficult to follow the WHO criteria in limited material from unusual sites of involvement. Also the evaluation of high grade transformation might be problematic. In such cases the diagnosis should be supported by a complex clinical evaluation and/or by a BM and LN biopsy. Supported by Grants of Slovak Ministry of Health Nr. 2005/12-MFN-04, VEGA Nr. 1/4285/07 and Comenius University Nr. UK/83/2007.

PP3-148

PROGNOSTIC SIGNIFICANCE OF Bcl-2, P53 PROTEIN EXPRESSION AND Ki67 PROLIFERATIVE INDEX IN DIFFUSE LARGE B-CELL LYMPHOMA

Betul Bolat Kucukzeybek[1], Sadi Bener[2], Aylin Orgen Calli[2], Tugba Dogruluk Paksoy[3]
[1] Department of Pathology, izmir Training Research Hospital, Turkey
[2] Department of Pathology, Izmir Ataturk Training and Research Hospital, Turkey
[3] Department of Pathology, KahramanmarasYenisehir Government Hospital, Turkey

Background: Diffuse Large B-Cell Lymphoma (DLBCL) is a high grade neoplasm which has a heterogeneous properties in clinical, morfological, immunophenotypical aspects. DLBCL exhibits varies markedly in response to treatment and prognosis. Clinicopathological and biological factors must be investigated and evaluated to determinate the prognose of the disease. In our study we searched effects of p53 (tumor supressor gene) which is a cell cycle regulator, bcl-2 oncoprotein which is an inhibitor of apoptosis and a cell proliferation marker Ki-67, on prognosis and relations with clinical parameters. Method: Total of thirty five patients who had been diagnosed as nodally located DLBCL at the Izmir Ataturk Training and Research Hospital between January 1999-June 2006 were included in this study. The Ann Arbor classification used to detemine the stage of patients. Patients were evaluated according to the age, sex, stage, B symptoms, extranodal involvement, lactate dehydrogenase (LDH) level and also immunohistochemically; p53 expression, bcl-2 oncoprotein expression and Ki-67 proliferation index. Statistical anlyses were performed using Chi-square, Fishers Exact and Log-rank test. Results: High Bcl-2 expression was identified in 9 patients (%25.7), high P53 expression was identified in 10 patients (%28.6) and high Ki67 expression was observed in 23 patients (%65.7). There was no statistical significant corelation between the p53, bcl-2 expression, Ki 67 proliferation index and age, sex, stage, B symptoms, extranodal involvement, LDH level, overall survival ($p>0.05$). There was no statistical significant relationship between p53, bcl-2, Ki 67 expression and prognosis ($p>0.05$). There wasn't a statistical significant relationship between overall survival and age, sex, stage, B symptoms, extranodal involvement, LDH level ($p>0.05$). Conclusion: As a result in our study we found that bcl-2 and p53 protein expressions, Ki67 proliferation index have no effect on overall survival of patients with DLBCL. The prognostic importance of p53, bcl-2 protein expression, Ki 67 proliferation index in DLBCL which has a biological and clinical heterogenity, can be understood in large series studies which have subclasses and with immunohistochemical markers which have optimal cut off values.

PP3-149
SPLENIC MARGINAL ZONE LYMPHOMA WITH ABERRANT CD5 EXPRESSION: REPORT OF A CASE
Fulya Oz Puyan[1], Ufuk Usta[1], Cigdem Ozdemir[1], Burhan Turgut[2], Erman Ozturk[2], A. Kemal Kutlu[1]
[1] Trakya University Medical Faculty Department of Pathology, Edirne, Turkey
[2] Trakya University Medical Faculty Department of Hematology, Edirne, Turkey

Splenic marginal zone lymphomas (SMZLs) are low-grade B-cell lymphomas that characteristically lack CD5 expression. However, rare cases of marginal zone lymphomas have been reported with CD5 coexpression which show an aggressive clinical course than the CD5- negative SMZLs. We represent here a 44-year-old male with splenomegaly and leucocytosis in laboratory findings. Peripheral blood smears showed monocytoid B cells with villous projections. Flow cytometry of the peripheral blood revealed CD19, CD20, CD22 and FMC7 positivity without CD5, CD23, CD10, CD38, and CD103 positive expression. The spleen histology showed a distinctive pattern of white pulp infiltration by abnormal B lymphocytes with marginal-zone differentiation. Immunohistochemical findings of the spleen were consistent with flow cytometric analysis of the peripheral blood. Mononuclear cells showed CD20 positivity without CD5 and CD23 expression, However bone marrow biopsy revealed an interstitial and nodular lymphoid infiltration with strong CD5 immunopositivity. Clinicians and pathologists must be aware of this unusual aberrant CD5 expression in SMZLs on bone marrow infiltrate in order to reach a correct diagnosis.

PP3-150
CD 30 POSITIVE T- CELL LYMPHOPROLIFERATIVE DISORDER: A CASE REPORT
Fulya Oz Puyan[1], Emre Tekgunduz[2], Aysegul Ilgili[1], Gulsum Pamuk[2], Omer Yalcin[1], Oner Dogan[3]
[1] Trakya University Medical Faculty Department of Pathology, Edirne, Turkey
[2] Trakya University Medical Faculty Department of Hematology, Edirne, Turkey
[3] Istanbul University Istanbul Medical Faculty Department of Pathology, Turkey

Introduction: CD30-positive T-cell lymphoproliferative disorders (CD30+ T-LPD) of the skin include a heterogeneous group of diseases which differ in their clinical and histological presentations. Lymphomatoid papulosis (LyP), primary cutaneous anaplastic lymphoma (C-ALCL) and borderline lesions constitute CD30+ T-LPD. The diagnosis of C-ALCL and LyP is very difficult as many of them have overlapping clinical, histologic, and immunophenotypic features. Most patients within this spectrum of disease have an excellent prognosis with 5-year-survival rates of 100% for LyP and %90 for C-ALCL. Extracutaneus spread and regional lymph node involvement may be seen on patients with multifocal tumor lesions. LyP is generally managed by observation whereas C-ALCL is treated with spot radiation or surgical excision with systemic chemotherapy reserved for cases with large tumor size or extracutaneous involvement. Therefore it is necessary to differentiate these types of disorders from each other. We report here a case of CD30+ T-LPD with multiple skin nodules and no signs of generalization, lymph node or internal organ involvement. Case Report: A 63-year old male represented with increasing number of skin papules and nodules on his belly, arm, back and subcostal region. The largest one 4x3 cm in size enlarged rapidly and became ulcerated. The patient had a history of bladder carcinoma in 1998 without any postoperative chemo- or radiotherapy. The physical examination revealed no lymphadenopathy or organomegaly. Initial biopsy showed a subepidermal dense infiltrate of large lymphocytes with irregular nucleus and abundant clear-eosinophilic cytoplasm intermixed with a few reactive cells. Immunohistochemistry revealed strong and widespread CD30 positivity with expression of T-cell associated antigens. The clinical, histologic, and immunohistochemical findings pointed to a borderline lesion of CD30+ T-LPD. The patient was treated with one dose of CHOP protocol. After the 3 month-follow-up period a rapidly regress of all the nodular lesions was noticed. Conclusion: This report adds to the clinical and morphologic spectrum of the CD30+ T-LPD with uncertain progress and treatment. Accurate recognition of this lymphoma and follow up is needed.

PP3-151
CYTOGENETIC ABERRATIONS OF CHROMOSOME 1 IN B-CELL NON HODGKIN LYMPHOMAS: CORRELATIONS WITH DISEASE SUBTYPE
Govind Bhagat, Shivakumar Subramaniyam, Subhadra Nandula, Vundavalli Murty
Columbia University, New York, USA

Background: B-cell non Hodgkin lymphomas (B-NHL) comprise a variety of distinct entities that are associated with characteristic chromosome (chr) abnormalities. Many B-NHL acquire additional, recurrent cytogenetic aberrations during disease evolution. Abnormalities of chr 1 are considered a frequent secondary event in the cytogenetic progression of certain B-NHL. We undertook this study to analyze the location and frequency of chr 1 abnormalities in a large series of B-NHL to determine differences and common regions of alterations in distinct types of B-NHL. Methods: G-band karyotypes with clonal abnormalities, obtained from tissue submitted for cytogenetic analysis for suspected B-NHL, were reviewed to detect chr 1 abnormalities. All numerical and structural chr 1 aberrations were mapped on an ideogram to identify specific regions of gains and losses and sites of translocations. The B-NHL were classified according to current WHO criteria. Results: Chr 1 abnormalities were detected in 110/275 (40%) cases comprising 103 (37.4%) B-NHL; 58 diffuse large B-cell lymphomas (DLBCL), 21 follicular lymphomas (FL), 13 Burkitt lymphomas (BL), 5 mantle cell lymphomas (MCL), 5 marginal zone B-cell lymphoma (MZBCL), 1 chronic lymphocytic leukemia (CLL), and 7 (2.5%) reactive lymphoid hyperplasias (RLH). Isolated chr 1 abnormalities were detected in 2 B-NHL. Intra or interchromosomal translocations were found in 77/103 (74.7%) B-NHL and 4/7 (57%) RLH. Gains of chr 1 resulting from duplications, triplications, and homogeneously staining regions were observed in 47.6%, 6.8%, and 1.9% B-NHL, respectively and in 37.5% RLH. HSR were only detected in DLBCL. Deletions were identified in 33/103 (32%) B-NHL and 1/7 (14.3%) RLH. Gains were restricted to 1q and losses predominantly involved 1p, only 9 (8.7%) B-NHL showed 1q losses. The single CLL had a 1q translocation. The majority of rearrangement breaks were localized to chr 1q21.1 in all B-NHL subtypes. However, differences in common regions of gain/amplification (1q21-23 in BL and MZBCL and 1q21-31 in FL and DLBCL) and deletion (1p32-34 in MCL and 1p36 in FL and DLBCL) were noted. Conclusions: In addition to a high frequency of secondary chr 1 alterations, we detected primary chr 1 abnormalities in B-NHL and RLH. Common and different cytogenetic aberrations of chr 1 in B-NHL subsets indicate shared as well as distinct pathways of lymphoma progression. Elucidation of genes whose expression levels are altered due to chr 1 copy number changes could help identify tumor suppressor genes and protooncogenes of prognostic relevance.

PP3-152
PRIMARY FOLLICULAR LYMPHOMA OF THE GALLBLADDER
Leyla Abid, Olfa Ismail, Aida Ayadi, Faouzi El Mezni
Department of Pathology, AMami Hospital, 2080 Ariana, Tunisia

Primary lymphomas of the gallbladder are extremely rare, and follicular lymphoma has been reported only twice. We report the third case of follicular lymphoma grade 1 limited to the gallbladder , found in the laparoscopic cholecystectomy specimen from a 80 year old woman with symptomatic gallstones. The patient was admitted to the hospital due to the symptoms and signs of acute cholecystitis. Ultrasound examination demonstrated gallstones within the gallbladder, the wall was not thickened. There was no lymph node enlargement in the abdominal cavity. On microscopy, the wall of the gallbladder was extensively infiltrated by lymphoid cells forming neoplastic follicles. The neoplastic infiltrate was composed of small to medium sized centrocytes with cleaved nuclei, inconspicuous nucleoli and scant pale cytoplasm. Additionally, less than to 5 centroblasts per high power field were found throughout the background of cleaved follicle centre-like cells. Immunohistochemical study showed that these cells were positive for B–cell marker CD20, CD79a. The majority of neoplastic cells showed bcl-2 immunoreactivity. Furthermore, they were CD5 and cyclin D1 negative. Our case demonstrates that follicular lymphoma can be limited to the gallbladder and confirm that it can occur in an organ normally devoid of lymphoid tissu.

PP3-153
CYCLIN D1 AND TROP-2/GA733-1 IMMUNOHISTOCHEMICAL INVESTIGATION IN ANAPLASTIC LARGE CELL LYMPHOMAS

Mattheos Bobos, Vassiliki Kotoula, Vassiliki Kaloutsi, Georgia Karayannopoulou, Ioannis Kostopoulos
Department of Pathology, Aristotle University Medical School, Thessaloniki, Greece

Background: Anaplastic large cell lymphoma (ALCL) is a rare non-Hodgkin lymphoma with special immunophenotypic and molecular characteristics. The protein Cyclin D1 is a major regulator of the G1 to S phase transition of the cell cycle and a well known proto-oncogene. In lymphomas, up-regulated cyclin D1 protein resulting from the translocation t(11;14)(q13;q32) has been reported in MCL, MM and cases classified as B-CLL and prolymphocytic leukaemia. Recently, has been reported that nuclear expression in 7/10 C-ALCL was detected using polyclonal antibody against cyclin D1. Trop-2/GA733-1, a cell surface glycoprotein, is a calcium signal transducer, may play an important role in the control of cell-cell adhesion and is frequently expressed at high levels by human carcinomas. A fusion transcript between CCND1 and TROP2 genes has been isolated from human tumors and has been found to possess potent transforming activity. Moreover, a cryptic promoter in the coding region of CCND1 gene drives the expression of TROP2 in the absence of exogenous promoters. The aim of the present study was to study the expression of cyclin D1 in ALCL. In addition, we tested for first time in paraffin material the mAb Trop-2 in order to examine the expression profile in ALCL. Methods: We utilized 52 FFPE biopsies classified as ALCLs according to the latest WHO criteria. For the study purposes, whole tissue sections and sections from 41 arrayed ALCL cases were used for IHC. The rabbit monoclonal anti-human cyclin D1 (clone SP4) and the mouse monoclonal anti-human cyclin D1 (clone DCS-6) antibodies were used for detection of cyclin D1 protein. An immunoenzymatic doublestaining method was also performed (Envision G/2 System/AP) for Cyclin D1 (SP4 or DCS-6) and CD30 mAb. For Trop-2/GA733-1 investigation the mouse anti-human mAb (551317, BD) was used. Results: None of the ALCL cases expressed nuclear or cytoplasmic cyclin D1 protein with both mAbs. All the ALCL tested cases were also negative for Trop-2 expression. Trop-2 predominantly membrane staining pattern was observed in squamous cells of the epidermis and in the epithelial cells of merocrine sweet glands. In 2 ALCL cases (1 C-ALCL and 1 systemic ALCL) scattered neoplastic cells showed slight nuclear positivity. Conclusions: The absence of Cyclin D1 protein in our study of ALCL cases is in line with previous reports. Trop-2 absence in lymphoma cells may indicate that this protein is not involved on the tumor growth. The nuclear staining in rare tumor cells requires further investigation.

PP3-154
COMBINED SKIN LESION CONSISTING OF BASAL CELL CARCINOMA AND LANGERHANS CELL HISTIOCYTOSIS

Ann Goussia[1], Ioannis Nesseris[1], Eufemia Balasi[1], Efstathios Lykoudis[1], Christos Kalogeropoulos[2], Maria Bai[1]
[1] Department of Pathology, Medical School, University of Ioannina, Greece
[2] Department of Ophthalmology, Medical School, University of Ioannina, Greece

Background. Langerhans cell histiocytosis (LCH) is a neoplastic proliferation of CD1α, S100-protein positive dendritic Langerhans cells (LCs) characterized by a highly variable clinical presentation and biological behavior. The pathogenesis of the disease is unknown. There is an association of disseminated LCH with other malignancies, mainly leukemias and lymphomas, although many of these cases may be related to therapy. Moreover, uncommonly combined lesions consisting of LCH and lymphomas or solid tumors have been reported in patients without previous history of systemic disease. In these cases the development of systemic LCH has not been described. We report a highly unusual case of combined skin lesion consisting of basal cell carcinoma (BCC) and LCH. Case report. A 63-year-old healthy man presented with a skin nodule involving the upper left eyelid. An excision biopsy was performed. The histopathological findings of the excised lesion (greater diameter:1.4 cm), were those of BCC. However, in the reticular dermis, adjacent to the BCC, a diffuse infiltration composed of large cells with moderate abundant cytoplasm and grooved or indented nuclei was observed. An admixture of small lymphocytes, plasma cells and few eosinophils was also present. Immunohistochemically, the large cells were CD1α, S-100, CD68, CD3, CD45 and vimentin positive and EMA, pan-CK, MPO, CD30, B and T-cell markers negative. Discussion. Combined skin lesions consisting of LCH and BCC represent an uncommon condition. We are aware of only one similar reported case localized in the scrotum. The nature of LCs in combined lesions remains elusive with debate as to whether they represent a true neoplasm or an exaggerated reactive proliferation, propably induced by factors released by the adjacent tumor cells. X-chromosome inactivation assays in some of these lesions showed that, at least in a proportion of cases, LCs are polyclonal.

PP3-155
IMMUNOHISTOCHEMICAL EXPRESSION OF CELL CYCLE REGULATORY PROTEINS IN MULTIPLE MYELOMA

Ilias Pessach[1], Sevasti Kamina[2], Ann Goussia[2], Eufemia Balasi[2], Evangeli Lampri[2], Angelos Skyrlas[2], Maria Stoura[1], Helen Kapsali[1], Panagiotis Kanavaros[3], Niki J. Agnantis[2], Konstantinos L. Bourantas[1], Maria Bai[2]
[1] Department of Hematology, Medical School, University of Ioannina, Greece
[2] Department of Pathology, Medical School, University of Ioannina, Greece
[3] Department of Anatomy-Histology-Embryology, Medical School, University of Ioannina, Greece

Background. The mechanisms involved in cell cycle deregulation in multiple myeloma (MM) are largely unknown. Therefore, the immunohistochemical expression of G1/S cell cycle regulatory proteins were analyzed in relation to the proliferation profile (Ki67, cyclin A, cyclin B1) and clinicopathological parameters in MM. Materials and Method. Bone marrow biopsy specimens from 45 patients with MM were studied by immunohistochemistry, using antibodies directed against cyclin

D1, cyclin D2, cyclin D3, cyclin A, cyclin B1, Ki67, p53, Rb and p16 proteins. Correlations between continuous variables were calculated using Spearman's coefficient test and overall survival was estimated using the Kaplan–Meier method. Results. Expression (more than 10% of neoplastic cells) of cyclin D1, cyclin D2, cyclin D3, cyclin A, cyclin B1, Ki67, p53, Rb and p16 proteins was found in 17/45 (37.8%), 18/42(43%), 3/43(7%), 11/44(25%), 0/43(0%), 20/44(45.5%), 17/45(37.8%), 35/44 (79.5%) and 37/44 (84.1%) cases, respectively. The expression of Ki67 protein was positively correlated with the expression of cyclin A and cyclin D2 proteins ($p<0.001$ and $p=0.001$, respectively). Moreover, Ki67 and cyclin A expression was increased in parallel with the expression of Rb ($p=0.016$ and $p<0.001$, respectively) and p16 proteins ($p=0.043$ and $p=0.005$, respectively). A positive correlation was also found between Rb and p16 expression ($p=0.003$). Although, cyclin D1 and p53 protein were overexpressed, their expression was not correlated with the expression of Ki67, cyclin A or cyclin B1 proteins. The histological stage was positively correlated with Ki67, cyclin A, cyclin D2 and p53 expression ($p=0.03$, $p=0.04$, $p=0.003$ and $p=0.026$, respectively). Kaplan–Meier analysis showed that the histological stage was significantly associated with patient overall survival ($p=0.036$). The expression of the studied cell cycle regulatory proteins did not show any prognostic significance. Conclusions. The findings of this study suggest that in MM: a) cyclin D1 and cyclin D2 proteins are overexpressed, b) the expression of cyclin D2 is increased in parallel to proliferative activity and may be involved in the deregulation of cell cycle, and c) the expression of Rb and p16 proteins follows proliferative activity suggesting no abnormal loss of these proteins.

PP3-156

MICROVESSEL DENSITY AND EXPRESSION OF THE ANGIOGENIC PROTEINS VEGF, VEGFR1, VEGFR2 AND HIF-1α IN HODGKIN AND REED-STERNBERG CELLS OF CLASSICAL HODGKIN LYMPHOMA

Evangeli Lampri[1], Nafsika Simou[1], Evangelos Briasoulis[2], Ann Goussia[1], Sevasti Kamina[1], Lazaros Nikiforidis[2], Asimina Demou[3], Vasiliki Malamou-Mitsi[1], Nikolaos Pavlidis[2], Niki J. Agnantis[1], Panagiotis Kanavaros[4], Maria Bai[1]
[1] Department of Pathology, Medical School, University of Ioannina, Greece
[2] Department of Oncology, Medical School, University of Ioannina, Greece
[3] Department of Pathology, Ioannina General Hospital G. Hatzikosta, Greece
[4] Department of Anatomy-Histology-Embryology, Medical School, University of Ioannina, Greece

Background. Few studies have focused on angiogenesis in classical Hodgkin lymphoma (cHL). Therefore, in the present study the microvessel density (MVD) and the immunohistochemical expression of angiogenesis related-proteins in Hodgkin and Reed-Sternberg cells (HRS) of cHL were analysed. Materials and Method. Biopsy material from 95 cases with cHL (mixed cellularity:60, nodular sclerosis:23, lymphocyte depletion:3, unclassified:9) were studied immunohistochemically for the expression of VEGF, VEGFR1, VEGFR2 and HIF1a proteins. In addition, MVD was estimated after immunostaining for CD34 (MVD-CD34) and CD105 (MVD-CD105) proteins and evaluated as the mean (±SD) vessel count/high-power microscopic field (HPF). The results were correlated with clinicopathological data. Results. Expression (at least 10% positive HRS cells) of VEGF, VEGFR1, VEGFR2 and HIF1a proteins was found in 78/90 (86.7%), 32/95 (33.7%), 18/89 (20.2%) and 46/81 (56.8%) cases, respectively. The MVD-CD34 and the MVD-CD105 were 61(±28.7) and 12(±7.65), respectively. VEGF expression was positively correlated with VEGFR2 expression and MVD-CD34 ($p=0.003$ and $p=0.02$, respectively). A similar correlation was found between VEGFR1 expression and MVD-CD34 ($p=0.04$). Moreover, an inverse correlation between the expression of VEGFR2 protein and the clinical stage of the disease was found ($p=0.02$, $r=-0.505$). Conclusion. The present study shows that the VEGF, VEGFR1, VEGFR2 and HIF1a proteins are expressed in HRS cells of cHL. VEGF produced by HRS cells may act in a paracrine and autocrine fashion in cHL and possibly is implicated in the pathogenesis of the disease.

PP3-157

ALTERATIONS OF THE p53, Rb AND p27 TUMOR SUPPRESSOR PATHWAYS IN DIFFUSE LARGE B-CELL LYMPHOMAS

Elena Tsanou[1], Ann Goussia[1], Angelos Skyrlas[1], Sevasti Kamina[1], Ioannis Sainis[2], Eufemia Balasi[1], Niki J. Agnantis[1], Panagiotis Kanavaros[1], Maria Bai[1]
[1] Department of Pathology, Medical School, University of Ioannina, Greece
[2] Department of Anatomy-Histology-Embryology, Medical School, University of Ioannina, Greece

Background. Diffuse large B-cell lymphomas (DLBCL) display defects in cell cycle and apoptosis regulation. Therefore, the immunohistochemical expression patterns of the proteins p14, p21, Hdm2 and cyclin D2 were analyzed in relation to the previously reported expression of other major cell cycle proteins (p53, Rb, p16, p27, Ki67 and cyclins A, B1, D2, D3 and E), apoptosis-associated proteins (bcl2, bcl-xl, bax, bak, bad and bid) and the B-cell differentiation immunophenotypes. Materials and Method. Seventy nine cases of de novo DLBCL (37 nodal and 42 extranodal) classified according to WHO classification were studied by immnohistochemistry, using antibodies directed against p14, p21, Hdm2 and cyclin D2 proteins. Results and Conclusions. Expression of the proteins p14, p21, Hdm2 and cyclin D2 was observed in 62/71 (87%), 22/76 (29%), 35/74 (47%) and 11/77 (14%) cases, respectively. Immunohistochemical alterations of the p53 [p53-Hdm2-p21-p14], Rb [Rb-p16-cyclin D (D2 or D3)] and p27 [p27-cyclin E] pathways were found in 56/77 (73%), 53/79 (67%), 54/79 (68%) cases, respectively. Concomitant alterations of the p53-Rb, p53-p27 and Rb-p27 pathways were found in 40/77 (52%), 38/77 (50%) and 36/79 (46%) cases, respectively. Three concomitant alterations of p53-Rb-p27 pathways were found in 28/79 (35%) cases. The main findings of the present study were the following: 1) alterations of the p27 pathway were associated with higher expression of Ki67 ($p=0.023$), 2) concomitant alterations of the p53-Rb pathways and the p53-p27 pathways were associated with higher expression of cyclin A ($p=0.015$ and $p=0.021$, respectively) and 3) concomitant alterations of the p53, Rb and p27 pathways were associated with higher expression of cyclin A ($p=0.013$). Since cyclin A supports DNA replication, centrosome duplication and mitosis, these findings indicate that concomitant alterations of the p53, Rb and p27 pathways in DLBCL may have cooperative effects resulting in increased neoplastic cell proliferation. This might explain, at least partially, the association between concurrent aberrations of the p53, Rb and p27 pathways and aggressive clinical behavior in DLBCL.

ANGIOGENESIS AND MYELOMA : A COMPARATIVE STUDY OF CD34 AND CD138 IN PRE- AND POST-TREATMENT BONE MARROW BIOPIES

Karima Mrad[1], Maha Driss[1], Salwa Ladeb[2], Neziha Ben Hamida[1], Houda Arbi[1], Radhia Ben Ghorbel[1], Houda Azaiez[1], Mongia Zitouni[1], Abdelrahman Abdelkefi[2], Khaled Ben Romdhane[1]
[1] Salah Azaiez institute, Tunisia
[2] Centre de Greffe de Moelle Osseuse, Tunisia

Background and aims: Bone marrow (BM) angiogenesis is increased in multiple myeloma and is an important prognostic factor for survival. Given its potential antiangiogenic effect, we

evaluated if thalidomide therapy would affect the BM microvessel density (MVD). Material and methods : We tested both CD34 and CD138 on paraffin sections of bone marrow biopsy using a labelled streptavidin-biotin peroxydase method. MVD and % of CD138 positive cells were compared between pretreatment biopsies and those obtained following therapy. Slides stained with antibodies to CD34 were scanned under low power (x100) to identify three hot spots or areas with the greatest number of microvessels. These three areas were then evaluated at x400 magnification. Large vessels and vessels within the bony spicules and under the periosteum were excluded. Areas of staining without discrete breaks were counted as single vessels. The presence of a lumen or red cells was not required for the identification of microvessels; any highlighted endothelial cell or cell cluster separate from the adjacent microvessels was counted as a distinct vessel. The number of vessels in one x400 field was determined for each hot spot; the average was taken as the MVD. Results : On the basis of the MVD, the patients were grouped into high- and low grades using the mean MVD as the cutoff. The mean MVD for the entire group was 18 (range, 3–54). Good responders (9 patients) with a mean decrease of 60% in CD138 cells (range 30-100%) had a low-grade MVD (mean 15) and a decreasing MVD (pre-treatment MVD : 19, post-treatment MVD : 10). Patients with disease progression (5 patients) had a high MVD (mean 23) with an increasing MVD (pre-treatment MVD : 20, post-treatment MVD : 26). Conclusion : Our results confirm a significant decrease of MVD with thalidomide therapy. Although not conclusive, this result lends further support to the hypothesis that angiogenesis is a relevant therapeutic target in myeloma.

PP3-159
MYELOID SARCOMA OF THE LYMPH NODE WITH EXTENSIVE NECROSIS

Hulya Ozturk Nazlioglu[1], Tulay Ozcelik[2]
[1] Uludag University Medical School, Department of Pathology, Bursa, Turkey
[2] Uludag University Medical School, Department of Hematology, Bursa, Turkey

Myeloid sarcoma is a tumour mass of myeloblasts or immature myeloid cells occurring in an extramedullary site. The tumour mass may precede or occur concurrently with acute or chronic myeloid leukemia. A 38-year-old woman was admitted to hospital because of a left axillary lymph node enlargement. She was previously diagnosed as having Acute Myeloid Leukemia-M5 (AML-M5) and was treated with chemotherapy. Fine-needle aspiration cytology of the lymph node was consistent with lymphoma. Excisional biopsy specimen of the lymph node revealed diffuse infiltration of myeloblasts positive for CD43 and myeloperoxidase staining on immunohistochemistry, and changed the diagnosis from malignant lymphoma to myeloid sarcoma. We report an unusual case of acute myeloid leukemia presenting with myeloid sarcoma with a lymph node lesion exhibiting extensive lymph node infarction. A high index of suspicion for myeloid sarcoma is necessary to avoid missing this lesion. The critical factors for detecting this tumor are to be aware of this disease, cooperation between clinician and pathologist and the application of spesific immunohistochemical antibodies to detect the myeloid origin.

INTRODUCTION: Epstein-Barr virus (EBV) and Human Herpesvirus 8 (HHV8) are well known lymphotropic oncogenic agents. Our goal was to identify the proportion and the histological types of lymphoid neoplasms that express EBV and HHV8 in tumoral cells of a large series of cases diagnosed in Spain. MATERIAL AND METHOD: Tissue microarrays (TMA) were constructed from paraffined tumoral tissue of lymphoid neoplasms diagnosed in 5 Spanish hospitals from 1998 to 2003. EBER in situ hybridization for EBV and LANA immunohistochemistry for HHV8 were performed on histological sections of the TMA. RESULTS: From 182 obtained biopsies, 24% were Hodgkin's lymphomas (HL) and 76% were non-Hodgkin's lymphomas (NHL). 93,5% of NHL were of B cell origin whereas 6,5% were of T/NK cell. HLs were all HHV8 negative while only one case of NHL was HHV8 positive (an extracavitary PEL in a HIV+ patient). 22,7% of HL and 10,9% of NHL were EBV positive (EBV+). 19,4% (13/67) of the high-grade B-cell NHLs (Diffuse large B-cell, Burkitt and Burkitt-like) were EBV+ while all the low-grade B-cell NHL (0/60) were EBV negative. 11,1% (1/9) of T/NK NHL were EBV+. 10% of the cases were associated with an immunodeficiency and showed an expression significantly higher of EBV than cases from immunocompetents (9.1% vs. 55,6% $p<0.0001$). In the immunocompetent group, there was a significant difference between HLs and NHLs EBV expression (21,4% vs. 4.9%; $p=0.003$) and, by histological subtypes, the high-grade B-cell NHLs were EBV+ in a 9,3% of the cases and, in this group, diffuse large B-cell NHL showed an expression of 7,7% (4/52). CONCLUSIONS: When studied with TMA, the expression of HHV8 in the tumoral cells of lymphoid neoplasms is very infrequent (0.54% of lymphoid neoplasms) and when found, an underlying immunodeficiency should be excluded. By contrast, EBV is expressed in a higher proportions, mostly in HLs and high-grade B-cell NHLs and, in a significantly higher proportion, in the setting of an immunodeficiency. (PI 04-0091, PI 04/1440, 04/1467, 05/1527)

PP3-161
MACROPHAGES AND DENDRITIC CELLS IN THE MICROENVIROMENT OF THYMIC NEOPLASMS. CORRELATION TO VASCULAR DENSITY AND HISTOLOGIC TYPE

Vassiliki Tzelepi[1], Vassiliki Zolota[1], Athanassios Tsamandas[1], Paraskevi Zyli[1], Georgia Sotiropoulou Bonikou[2]
[1] Department of Pathology, Medical School, University of Patras, Greece
[2] Department of Anatomy, Medical School, University of Patras, Greece

Background: Tumor associated macrophages (TAMs) are key components of the tumor microenvironment and seem to promote tumor growth. Their number is increased in various neoplasms. Dendritic cells (DCs) are basic components of the innate inflammatory response. Their role in tumor microenviroment is unclear. The presence of TAMs and DCs in thymic neoplasms has not been thoroughly evaluated before. This study investigates the presence of TAMs and DCs in thymomas and correlates them with microvessel density (MD). Method: A total of 20 thymomas (4AB, 2B1, 4B2, 6B3 and 4C according to WHO histologic classification and 3T1, 10T2, 4T3 and 3T4 according to TNM staging) were immunostained using antibodies to S100, PGM1, CD34 and CD31 proteins. For all antibodies, areas with the

highest density of positive cells were selected at low power magnification (x40), and the total number of immunostained cells or vessels was counted at high power (X400). At least three high power fields were counted and the mean value was marked as labeling index (LI). Results: LIs for microvessels according to histologic subtype were as follows (mean value±SD): AB 73.25±23.78, B1 54±43.8, B2 42.2±26.9, B3 32.83±24.02 and C 36.5±24.26. Tumors were subdivided for statistical purposes in two groups. Surprisingly, AB, B1 and B2 thymomas demonstrated higher MD compared to B3 and C (58.9±28.75 vs 34.3±22.8, respectively, p=0.049). S100 positive DCs were always identified within the tumor parenchyma. DCs number was higher in AB, B1 and B3 (17.125±12.26) compared to B3 and C (3.3±2.62) thymomas (p=0.003). A positive correlation between DCs and MD was also recorded (p=0.007). PGM1 positive TAMs were diffusely found in the tumor parenchyma in all AB, B1 and B2 tumors. In contrast, 50% of the B3 and C thymomas exhibited a tumor-stroma interface preference for TAMs localization. No statistical correlation between histologic type and TAMs number was seen [AB/B1/B2 45.67±16.67, B3/C 39.10±18.6336 (p=0.432)]. In addition, MD, DCs and TAMs were not correlated to tumor stage. Conclusions: A decrease of DCs is noted in less differentiated thymomas and implies that impairment of the host defense accompanies and possibly supports the progression of thymic neoplasia. TAMs do not seem to play an important role in thymic tumors, albeit their presence at the invasion front in the less differentiated tumors suggests a possible role in tumor invasion. Finally, further studies are needed to elucidate the exact role of vascular density in thymomas.

PP3-162
IMMUNOHISTOCHEMICAL EXPRESSION PATTERNS OF NEURAL AND NEUROENDOCRINE MARKERS, NEURAL GROWTH FACTOR RECEPTORS AND THE TUBULIN-β2 AND -β4 ISOTYPES IN THYMUS

Michael Doukas[1], Alexandra Papoudou-Bai[1], Georgios Karatzias[2], Ann Goussia[1], Kalliopi Stefanaki[3], Yiotanna Dalavanga[2], Niki J. Agnantis[1], Maria Bai[1], Panagiotis Kanavaros[2]

[3] Department of Pathology, Agia Sophia Hospital of Athens, Greece

Background. Increasing evidence suggest that neuroimmune networks play key roles in the thymic histophysiology and pathology. Therefore, we analyzed the distribution of human thymic cells expressing major neural and neuroendocrine markers and the neural growth factor receptors (NGFR) in combination with the expression patterns of various cytokeratins. Additionally, since some tubulin-β isotypes are preferentially expressed in neuronal cells, we analyzed the immunotopographical distribution of thymic cells expressing tubulin-β2, -β3 and -β4. Materials and Method. Twenty cases of normal thymuses were analyzed by immunohistochemistry for the expression of the protein gene product 9.5 (PGP 9.5), chromogranin A (CHRA), synaptophysin (SYN), neuron specific enolase (NSE), tyrosine hydroxylase (TH), CD56, CD57, neurofilaments (NFs) (140-160kDa), the NGFRs (TrKA and p75), the tubulin-β2 and -β4 isotypes and the cytokeratins (CKs) 7, 8, 10, 13, 14, 18 and 19 proteins. Results. Thymic epithelial cells (TEC) expressed PGP 9.5, CHRA, SYN, NSE, TH, CD56, CD57, NFs, TrKA, p75, tubulin-β2 and -β4 isotypes and the CKs 7, 8, 10, 13, 14, 18 and 19. PGP 9.5 was preferentially expressed in cortical TEC whereas SYN, CHRA, NSE, TH and NFs were preferentially expressed in medullary TEC and Hassall corpuscles. Variable levels of expression of tubulin-β2 and -β4 were observed in all TEC subtypes whereas tubulin-β3 was undetectable in TEC. Subcapsular and cortical TEC display higher expression levels of tubulin-β4 and lower expression levels of tubulin-β2 in comparison to those observed in medullary TEC and Hassall corpuscles. Conclusions.The diversity of the immunotopographical distribution and the expression levels of neural and neuroendocrine markers, the NGFRs, the tubulin-β2 and -β4 isotypes and the CKs in the distinct subtypes of TEC may reflect the diversity of their biological functions and/or their different stages of differentiation. The present results provide further immunohistological evidence that numerous neural and neuroendocrine factors may be required for the development and the function of the human thymic microenvironment.

CIRCULATING LEVELS AND PROGNOSTIC SIGNIFICANCE OF VASCULAR ENDOTHELIAL GROWTH FACTOR AND ITS RECEPTOR IN CHILDHOOD ACUTE LEUKEMIA

Mitra Mehrazma, Khadije Arjomandi, Behzad Torkamani Poor
Iran University of Medical Sciences, Ali-Asghar Hospital, Iran

BACKGROUND:Vascular endothelial growth factor (VEGF) and its receptors (VEGF-R1 and R2) are major regulators of angiogenesis, which plays a key role in the growth and dissemination of solid tumors and hematologic neoplasms. METHOD: To assess serum VEGF and VEGF-R1 levels and their prognostic significance in newly diagnosed acute leukemias (ALL and AML), we used a radioimmunoassay (RIA) to quantify their levels in stored samples obtained before treatment from 53 pediatric patients. Bone marrow blast percentage was counted at day of diagnosis and 2 weeks after induction therapy . RESULT:s VEGF level was between 2.7 and 138 pg/ml sVEGF-R1 level was between 0.0020 and 0.1836 ng/ml. A reverse correlation was observed between plasma sVEGF and especially sVEGFR1 levels and the rate of complete remission in pediatric patients with acute leukemias. CONCLUSION: Concentration of sVEGF and sVEGF-R1 in plasma should be considered a significant factor in response to treatment and considerable reduction of bone marrow blast percentage. In contrast, there was no relationship between their levels and WBC or blast count at diagnosis, or between VEGF level and such established prognostic factors as age, cytogenetics or FAB category.

PRIMARY LYMPHOMA OF THE THYROID GLAND. A CLINICAL PATHOLOGICAL REVIEW OF 3 CASES SEEN AT THE PATHOLOGY UNIT OF THE GENERAL HOSPITAL OF MEXICO

Monica Romero[1], Dulce Maria Macias[1], Marco Antonio Duran[2], Mercedes Herrnandez[1]
[1] Hospital General de Mexico, Mexico
[2] Hospital General de Mexico, Mexico

Introduction Primary lymphomas of the thyroid gland constitute approximately 8% of all thyroid neoplasms. They are often associated (80% of the time) to Hashimoto and lymphocytic thyroiditis. The most frequent histological types are: large cell diffuse lymphoma B, marginal zone MALT type lymphoma, follicular lymphoma, plasmacytoma and peripheral t/nk lymphoma. Material and methods A retrospective review (2000-2005) was done of all pathological surgical sample records of the thyroid gland. A total of 115 cases of thyroid neoplasms were found: 64 (5.7%) corresponded to thyroiditis, 26 (40%) to lymphocytic thyroiditis, 24 (37.5%) to Hashimoto´s thyroiditis and 14 (21.8%) to unspecified chronic thyroiditis. Three lymphomas were found which had been submitted to the following specific immunohistochemical tests: cd 20, cd79a, cd 45, cd45 RO, cd2, bcl2, bcl6. cd 5, VEB, calcitonin, chromogranin and specific neuron enolase. Results The three lymphoma patients were females 56, 58 and 70 years of age. The symptomatology constituted a gradual and symmetrical growth of

the thyroid gland, with one of the patients having had cervical compression syndrome. Two cases corresponded to large cell diffuse lymphoma of the centroblastic variety. No marginal zone lymphoma cases nor thyroiditis were found, while one Malt type of the marginal zone associated to Hashimoto thyroiditis having LBDCG transformation zones was found. All were positive for cd 20 and two for bcl2 and negative for the rest of the antibodies. Conclusions Primary thyroid lymphomas were found in 2% of the cases we reviewed and are considered infrequent. The associated diseases, lymphoid and Hashimoto thyroiditis were also found to be infrequent (5.7%). This was probably due to the low frequency of primary thyroid lymphomas in our series.

PP3-165
IMMUNOEXPRESSION OF Skp2 AND CUl1, MOLECULES IMPLICATED IN p27Kip1 DEGRADATION IN AGGRESSIVE AND INDOLENT B-CELL LYMPHOMAS

Chaido Sirinian[1], Nikolaos Giannakoulas[2], Panagiotis M. Zikos[3], Panagiota Matsouka[2], Maria Melachrinou[1]
[1] Department of Pathology, University of Patras Medical School, Patras, Greece
[2] Department of Internal Medicine, Division of Hematology, University of Patras Medical School, Patras, Greece
[3] Hematology Division, "Agios Andreas" General Hospital of Patras, Patras, Greece

Background: Reduced levels of p27Kip1 (p27) are frequently observed in human cancers and associated with aggressive tumor behavior and poor prognosis. There is evidence that Skp2, a member of ubiquitin-ligase SCF (Skp1-Cul1-Rbx1-F box) complex, promotes p27 degradation. Moreover, Skp2 deregulation has been implicated in oncogenesis and lymphomagenesis. The aim of this study was to investigate the expression of Skp2 and Cul1, components of ubiquitin-ligase SCF complex, in aggressive and indolent B-cell lymphomas, and compared them with p27 expression and proliferation index (PI). In addition, the prognostic significance of Skp2 and/or p27 expression was studied in cases with available clinical data. P21Cip1 (p21) expression was also examined, because p21 is a good substrate for the ubiquitin-ligase SCF complex. Method: Formalin-fixed, paraffin-embedded tissue from 126 B-cell lymphomas [64 aggressive (DLBCLs) and 62 indolent (18 SLLs, 14 FLs, 11 MCLs, 19 MZLs)] were immunostained with antibodies for Skp2, Cul1, p27, p21 and MIB-1 using Envision detection kit. Clinical data for statistical analysis were available for 87 cases (40 aggressive, 47 indolent). The median follow up period was 33 months (22 mo for aggressive, 40 mo for indolent). Results: The mean value of Skp2 immunoexpression in aggressive and indolent lymphomas was 33.2% and 7.7%, respectively ($p<0.001$). The corresponding values for Cul1 were 36.4% and 14.7% ($p<0.001$), for p27 32.5% and 62.6% ($p<0.0001$), for p21 13.7% and 6.6% ($p=0.025$) and for MIB-1 68.7% and 27.1% ($p<0.001$). Skp2 showed an inverted correlation with p27 ($p=0.035$) and a positive correlation with Cul1 ($p=0.002$) and PI ($p=0.007$) in aggressive lymphomas. In addition, Skp2 had a similar correlation with p27 ($p=0.025$) and PI ($p<0.001$), but not with Cul1, in indolent lymphomas. There was also an inverted correlation between the expression of p27 and PI ($p=0.008$). Overall probability of survival was 35% for the whole group. This was 51.7% and 31.5% for patients with aggressive and indolent lymphomas, respectively ($p=0.074$). Skp2 and p27 expression did not correlate patients' prognosis. Conclusion: Our findings demonstrate a significant positive correlation between Skp2 expression and proliferation index and suggest the p27 degradative function of Skp2 in aggressive and indolent lymphomas. The positive relationship between Skp2 and Cul1 expression in aggressive lymphomas indicates their implication in p27 degradation.

PP3-166
PRIMARY BREAST LYMPHOMAS. A FOUR CASE REPORT

Monica Romero, Mercedes Hernandez, Marco Antonio Duran, Avissai Alcantara
Hospital General de Mexico, Fac. de Medicina, Mexico

Introduction The lymphomas that affect breasts may be primary or infiltrates as systemic manifestations of the disease. The most common histological types are large cell diffuse B lymphomas and extra-nodal B mucosa-associated lymphatic tissue lymphomas (marginal zone or extra-nodal lymphomas). Material and methods This is a report of four cases with primary breast lymphomas. The criteria for diagnosis were based on Wiseman´s and Liao´s proposal which includes: 1) specimen biopsy that involves a lymphoma in close relation to breast parenchyma and 2) no evidence of systemic disease at diagnosis. The clinical and histological data were reviewed, as well as immunohistochemical reactions. Results The average age of the patients was 29 years old. Three patients had problems with their right breasts and another bilaterally. There was progressive increase in volume, pain at palpation and skin affection, in addition to purulent secretion from the nipple. No affected lymph ganglia were palpated in three of the patients. Three of the patients died a few months (2-5) after diagnosis with infiltrations to their central nervous system. All four were large cell diffuse lymphomas of immunophenotype B, three were centroblastic, one had clear cells and another had extensive areas of necrosis with a starry-skied focal pattern simulating Burkitt´s lymphoma. They were positive to cd 20, cd 79 a, bcl2, bcl6, and cd 10. Conclusions Primary lymphomas of the breasts are infrequent. In our cases, the lymphomas were seen in young women. One was associated to pregnancy and another to AIDS. The differential diagnosis should be done with scarcely differentiated lobule and duct carcinoma for which immunohistochemistry reactions are very useful.

PP3-167
LANGERHANS CELL SARCOMA EXPRESSING CD56 IN A 60 YEAR OLD PATIENT WITH MYELODYSPLASTIC SYNDROME

Konstantinos Giaslakiotis[1], Athina Androulaki[1], Theodora Papadaki[2], Pinelope Pinelope Korkolopoulou[3], Eustratios Patsouris[3]
[1] Department of Pathology, Laiko University Hospital, Athens, Greece
[2] Hemopathology Department, Evangelismos Hospital, Athens, Greece
[3] Department of Pathology, Medical School, National and Kapodistrian University of Athens, Athens, Greece

BACKGROUND: Langerhans cell tumors as currently defined in the WHO classification are a rare group of neoplastic proliferations showing CD1a and S-100 protein expression and displaying Birbeck granules by ultrastructural examination. Langerhans cell sarcoma (LCS) is the aggressive counterpart showing overtly malignant cytologic features and increased mitotic activity. The association of myeodyplastic syndrome with Langerhans cell tumors is extremely rare. Recently it has been suggested that CD56 expression is related to aggressive biological behavior in Langerhans cell tumors. We report a case of LCS expressing CD56 in a 60 year old patient with myelodysplastic syndrome initially diagnosed in the lymph node diagnostic material. METHODS: Formalin fixed, paraffin-embedded tissue sections were stained with H&E and immunohistochemically according to established protocols. RESULTS: Histological examination revealed effacement of the normal structure by a neoplastic proliferation showing nodular and sinusoidal growth pattern. Tumor cells ranged between round and oval displaying a lobulated nuclei with delicate nuclear membrane, chromatin abnormalities and prominent nucleoli. Distinct features of Langerhans cell tumors with the characteristic

nuclear grooving also were encountered, although infrequently. Eosinophils were rarely scattered. The mitotic rate was 10/10 HPF. Immunohistochemically, tumor cells were strongly positive for CD1a and S-100 protein and slightly positive for vimentin. CD56 was strongly positive. Only very weak CD68+ cells were seen. The proliferation marker Ki67 (MIB-1) reached 15%. Tumor cells failed to express CD3, CD20, CD21, CD35, CD30, CD34, pancytokeratin, HMB-45, Melan A and chromogranin. CONCLUSION: Our report further supports the association of Langerhans cell tumors with myelodyplastic syndrome, reinforcing the hypothesis of a common stem cell disorder. CD56 expression could enhance the prediction of the potential of an aggressive biological behavior in Langerhans cell tumors with borderline morphological features of malignancy.

PP3-168
EXPRESSION AND PROGNOSTIC SIGNIFICANCE OF SURVIVIN AND P 53 IN HODGKIN LYMPHOMAS

Suheyla Bozkurt[1], Nagehan Barisik[2], Isik Kaygusuz[3], Mahmut Gumus[4], Emine Bas[1], Sezer Gezer[2], Mahmut Bayik[3], Tulay Tecimer[1]
[1] Marmara University Pathology Department, Turkey
[2] Dr. Lutfi Kirdar Kartal Research and Training Hospital Pathology Department, Turkey
[3] Marmara University Hematology Department, Turkey
[4] Dr. Lutfi Kirdar Kartal Research and Training Hospital Oncology Department, Istanbul, Turkey

Aim: Apoptosis represents a critical pathway whose abnormalities are linked with carcinogenesis. p 53, tumor supressor gene and inducer of apoptosis, suvivin a member of the inhibitors of apoptosis protein family are important regulators whose abnormal expression or mutation is correlated with several human cancers. To investigate their relationships to carcinogenesis and/or prognosis of Hodgkin lymphomas we analyzed their immunohistochemical expression in Hodgkin lymphomas. Material-Method: Paraffin sections from 56 Hodgkin lymphomas (28 noduler sclerosis, 18 mixed cellularity, 4 lymphocyte-rich, 1 nodular lymphocyte predominant, 5 classical-not specified) were examined with monoclonal antibodies anti-p53 and survivin using streptavidin-biotin immunohistochemical tecnique. Survivin was evaluated for both staining density and percentage of staining. Staining density evaluated as fallows:negative, mild, moderate, severe; percentage evaluates as fallows: +,<25%; ++, 25-50%; +++, 50-75%; ++++, >75% of Hodgkin/Reed Sternberg cells positive. p 53 was evaluated as fallows: negative <10%; +,10-25%; ++, 25-50%, +++, 50-75%;++++ ,>75% of Hodgkin/Reed Sternberg cells positive. Results: p 53 protein was detected in 20 cases. Survivin expression was detected in all cases with variable values. Survivin expression showed significant positive correlation with only age of the patients($p<0.05$). Expression of survivin and p53 did not showed significant correlation with subtypes, stage, survival time and recurrences in Hodgkin lymphomas($p>0.05$). Conclusion: Altough survivin and p53 expression was detected in Hodgkin lymphomas, these results showed that these markers not considered as a prognostic factors for Hodgkin lymphomas.

PP3-169
EXPRESSION AND PROGNOSTIC SIGNIFICANCE OF COX-2 AND P 53 IN HODGKIN LYMPHOMAS

Nagehan Barisik[1], Suheyla Bozkurt[2], Mahmut Gumus[3], Isik Kaygusuz[4], Nimet Karadayi[1], Emine Bas[2], Mahmut Bayik[4], Tulay Tecimer[2]
[1] Dr. Lutfi Kirdar Kartal Research and Trainig Hospital Pathology Department, Turkey
[2] Marmara University Pathology Department, Turkey
[3] Dr. Lutfi Kirdar Kartal Research and Trainig Hospital Oncology Department, Turkey
[4] Marmara University Hematology Department, Istanbul, Turkey

Aim: Cyclooxigenase(COX) is a rate-limiting enzyme that plays an important role in the inflammatory process and catayses the conversion of arachidonic acid to the prostaglandins and tromboxanes. One of two isotopes, COX-2 is usually not detectable in normal tissues. COX-2 is associated various human cancers especially colorectal adenocarcinomas and it is related to tumor progression. p 53, tumor supressor gene and inducer of apoptosis whose abnormal expression is correlated with several human cancers. To investigate their relationships to carcinogenesis and/or prognosis Hodgkin lymphomas we analyzed their immunohistochemical expression in Hodgkin lymphomas. Material-Method: Paraffin sections from 40 Hodgkin lymphomas (20 noduler sclerosis, 14 mixed cellularity, 2 lymphocyte-rich, 4 classical-not specified) were examined with monoclonal antibodies anti-p53 and COX-2 using streptavidin-biotin immunohistochemical tecnique. COX-2 was evaluated for both staining density and percentage of staining. Staining density evaluated as fallows:negative, mild, moderate, severe; percentage evaluates as fallows: +,<25%; ++, 25-50%; +++, 50-75%; ++++, >75% of Hodgkin/Reed Sternberg cells positive. p 53 was evaluated as fallows: negative <10%; +,10-25%; ++, 25-50%; +++, 50-75%;++++ ,>75% of Hodgkin/Reed Sternberg cells positive. Results: p 53 protein was detected in 14 cases. COX-2 expression was detected in all cases except one with variable values. Expression of COX-2 and p53 did not showed significant correlation with subtypes, stage, survival time and recurrences in Hodgkin lymphomas($p>0.05$). Although it was not statisticaly significant, COX-2 expression was higher in nodular sclerosis and mixed cellularity subtypes compared to lymphocyte rich and classical-not specified subtypes($p=0.054$). Conclusion: The expression of COX-2 and p53 is confirmed in H&RS cells of classical Hodgkin lymphoma. But, due to absence of association with stage, survival and recurrences of the disease these markers not considered as a prognostic factors for Hodgkin lymphomas.

Follicular dendritic cell sarcoma (FDCS) is a neoplastic proliferation of spindle to ovoid cells with morphologic and phenotypic features of follicular dendritic cells. It is a rare neoplasm with most studies representing single case reports or small series. The aim of this presentation is to present a rare case of FDCS in 27 year-old woman, previously diagnosed and treated as B cell immunoblastic non-Hodgkin`s lymphoma. The first diagnosis was made on a cervical lymph node biopsy five years ago, when she was treated with five cycles of CHOP regimen and complete remission of the disease followed. Four years later new tumor mass in the left midneck region appeared and was surgically treated. On the dissection one could barely recognize destroyed architecture of lymph node by infiltrative fleshy ten grey tissue that even involve subcutaneous and dermal tissue. There was no ulcerative lesion. Histological examination of the tissue sections stained with HE, Giemsa, Reticulin, PAS and Van Gieson revealed spindle to ovoid cell proliferation arranged in fascicles and storiform pattern. There were areas with plexiform architecture and myxomatous degenerative changes. In some of the cells there were PAS negative clear vacuoles. The cells had elongated oval nuclei with granular chromatin and small but distinct nucleoli enclosed in lentiform and syntitial slightly eosinophylic cytoplasm. There were fluid-filled cystic spaces with angiomatous features and only small solid areas with large

pleomorphic cells were found. Mitotic index was low. These tumor cells enclosed fibrous trabeculae with blood vessels surrounded by cuff of lymphocytes. Epidermal layer of the skin was intact but there was infiltration in the lower papillary dermis. Immunohistochemical analysis revealed positivity of the cells for Vimentin, HLA DR, CD21, CEA (nonspecific?) and spotty positivity for ESA. The stainings for cytokerains, S100, HMB45 and lymphocytic subpopulations were negative. Ki67 evaluated low proliferative index of 15%. Based on HLA DR and CD21 expression and the morphological appearance we made a diagnosis of FDCS and revised the previous diagnosis of B immunoblastic lymphoma. We found the same immunophenotype of the neoplastic cells that morphologically resemble large immunoblastic cells. However they were CD20 negative and CD21 positive. We can conclude that FDCS could have pleomorphic expression that ranges from lymphoid like appearance to spindle cell like or neurogenic-like neoplastic lesion. Immunohistochemical analysis is very helpful in distinguishing various entities.

HUMAN IMMUNODEFICIENCY VIRUS-ASSOCIATED LYMPHOMAS. RECLASSIFICATION WITH TMA-BASED IMMUNOHISTOCHEMISTRY AND MOLECULAR BIOLOGY, ITS ASSOCIATION TO EPSTEIN-BARR VIRUS INFECTION AND EXPRESSION OF NUCLEAR FACTOR KAPPA-B AS PROGNOSTIC FACTORS

Daniel Montante Montes De Oca, Fredy Chablé Montero, César Lara Torres, Braulio Martinez Benitez, Nancy Camorlinga Tagle, Brenda Marquina Morán, Arturo Ángeles Ángeles, Carmen Lome Maldonado
Department of Pathology. Instituto Nacional de Ciencias Medicas y Nutricion, Mexico

Objectives: To know the clinical and pathological features of human immunodeficiency virus (HIV)-associated lymphomas, its association to Epstein-Barr virus (EBV) infection and expression of nuclear factor kappa-B (NF-kB) as prognostics factors. Material and Methods: HIV-associated lymphomas were selected in a period of 18 years. All the cases were reviewed, and they were reclassificated on the basis of morphology, TMA-based immunohistochemistry and molecular biology. Clinical features were obtained from the clinical records. Results: Fifty-seven cases were obtained. The average age of presentation was 40 (+/- 10) years, 95% were men and 5% women; 92.9% cases were in C3 stage. Seventy-eight patients presented B symptoms. The length of symptoms was from 0 to 48 months, with average of 6 months. The most frequent anatomic localization was nodal in 22 cases, oral cavity, CNS, colon, and rectum in 6 cases each one, and pulmonary in 5 cases. Bone marrow infiltration was present in 13 (23.2%) cases. Twenty-nine cases were in clinical TNM-stage IVB (51.7%). Thirty-six cases were reclassificated; 21 cases were excluded due to insufficient material. Twenty five cases (69.4%) corresponded to diffuse large B-cell lymphoma; of which, 48% were post-germinal origin, 40% centrofolicullar and 12% indeterminate origin. Six cases (16.6%) were reclassificated as Burkitt lymphoma; 3 of them displayed extensive plasmacytoid differentiation. Three cases (8.3%) corresponded to plasmablastic lymphomas and two cases (5.5%) were Hodgkin lymphoma. Twenty-one cases were EBV-associated (EBER positive), 19 cases were positive to NF-kB, and 12 were both positive. The global survival was of 15 months; in the cases that were EBV-positive, the average survival was of 17.3 months, and 14.5 months when NF-kB was positive. When both of them were positive, the survival decreases to 12.6 months. Conclusions: HIV-associated lymphomas are relatively frequent in our population. The prognosis is poor and the survival is short; that is the reason because is necessary to use the current and precise classification in those neoplasms. The VEB and NF-kB expression in HIV-associated lymphomas did not have significant impact on the prognosis; nevertheless, they constitute an important mechanism in the oncogenesis of this neoplastic process.

PP3-172
EPSTEIN-BARR VIRUS TUMORAL CELL EXPRESSION AND ITS IMPACT ON OVERALL SURVIVAL IN NON-HODGKIN LYMPHOMAS IN TARRAGONA, SPAIN

Ramon Bosch[1], Marylene Lejeune[1], Eva Domingo[2], Joaquin Jaen[1], Mª Teresa Salvado[1], Barbara Tomas[1], Luis Pons[1], Carlos Lopez[1], Patricia Escriva[1], Xavier Ortin[3], Marta Rodriguez[3], Tomas Alvaro[1], Llorenc Font[3], Silvia De Sanjose[4]
[1] Pathology Department Hospital de Tortosa Verge de la Cinta, Spain
[2] Hematology Department CSU Bellvitge. Barcelona, Spain
[3] Hematology Department Hospital de Tortosa Verge de la Cinta, Spain
[4] Catalan Institut of Oncology, Barcelona, Spain

BACKGROUND: Epstein-Barr virus (EBV) expression has been associated with an adverse prognosis in non-Hodgkin lymphomas (NHL) in few studies. AIM: To define the prognostic impact of EBV tumoral cell expression in a serie of NHL from Tarragona area in Spain. MATERIAL AND METHODS: We revised all the NHL cases diagnosed at our pathology department from the year 1990 to 2000 and we identified 265 NHL (rejecting bone marrow biopsies). After excluding the immunodeficient patients and cases without available paraffined tissue, 256 NHL cases were studied with EBER in situ hybridization. RESULTS: 24 cases (9.4%) were EBER positive (EBER+) [1 Burkitt (25%), 11 DLBC (12.36%), 1 Follicular lymphoma (2.86%), 3 small lymphocytic lymphoma (8.11%), 5 peripheral T-cell lymphomas of unspecified type (38.46%) and 3 extranodal NK/T-cell lymphoma of nasal type (100%)]. The EBER+ patients demonstrated substantially poorer overall survival (OS) [EBER+ vs. EBER-; 27 months (95% CI, 14-41 months) vs. 79 months (95% CI, 64-94 months), respectively, P=0.0013]. When studied by histological types, EBER+ remained statistically significant for poorer OS only for DLBC [EBER+ vs. EBER-; 23 months (95% CI, 3-43 months) vs. 60 months (95% CI, 47-72 months), respectively, P=0.0452] and for small lymphocytic lymphoma [EBER+ vs. EBER-; 23 months (95% CI, 12-34 months) vs. 88 months (95% CI, 59-118 months), respectively, P=0.0256]. Globally, in multivariate analysis for all LNH, EBER+ patients showed substantially poorer OS with 2.36-fold risk for death (95% CI, 1.3-4.3) while a high IPI status showed a 4.0-fold risk (95% CI, 2.6-6.0). When analysed by histological type, only the IPI status remained as a poorer independent survival factor. CONCLUSIONS: In our area, EBV expression in the tumoral cells of immunocompetents NHL patients appears to be associated with a poor OS, specially in DLBC and small lymphocytic lymphomas. However, in Cox multivariate analysis, EBV status did not affect survival with statistical significance in DLBC and small lymphocytic lymphomas. The absence of this signification could be explained, at least partially, by the small number of the EBV positive cases in this series that could affect the results. Further investigations in a larger series, in our area, are required.

PROMOTER HYPERMETHYLATION OF GSTP1, SHP1, DAPK, p16, RB, AND p53 GENES IN DIFFUSE LARGE B-CELL LYMPHOMAS: PREVALENCE AND PROGNOSTIC SIGNIFICANCE IN TUNISIAN PATIENTS

Khaled Amara, Mounir Trimeche, Sonia Ziadi, Mohamed Hachana, Moncef Mokni, Badreddine Sriha, Sadok Korbi
Laboratory of Pathology, CHU Farhat Hached, Sousse, Tunisia

Background: Promoter hypermethylation is an important mechanism of inactivation of tumor suppressor genes in various human cancers including lymphomas. Diffuse large B-cell lymphomas (DLBCL) are heterogeneous in their clinical presentation, morphology, and molecular alterations. The aim of this study was to determine the prevalence and clinicopathological significance of gene promoter methylation in DLBCL in Tunisian patients. Methods: Sixty DLBCL cases diagnosed at the laboratory of Pathology at Farhat-Hached University Hospital of Sousse (Tunisia) were investigated for the methylation status of a panel of six tumor suppressor genes potentially involved in B-cell malignancies, comprising GSTP1, SHP1, DAPK, p16, RB1, and p53 by methylation-specific polymerase chain reaction. Effect of each gene methylation status on patient's overall survival were estimated by the Kaplan-Meier method and compared with the log-rank test. Multivariable survival analyses were performed with the Cox proportional hazards model. Results: Aberrant promoter hypermethylation of DAPK, GSTP1, SHP1, p16, RB1 and p53 was detected in 75%, 70%, 65%, 53%, 20% and 3.3% of cases, respectively. All cases demonstrated aberrant hypermethylation in at least one gene. There was no significant correlation between overall gene hypermethylation status and patient's age, gender, or clinical stage. Regarding the clinical follow-up data, available for 17 patients, promoter hypermethylation of DAPK and p16 were significantly associated with shortened survival (P=0.007 and P =0.016, respectively) and remained poor prognostic factor in multivariate analysis (P = 0.013 and P = 0.039, respectively). Conclusion: our results indicates that promoter hypermethylation is a frequent event in diffuse large B-cell lymphomas in patients from Tunisia, and that DAPK and p16 promoter regions may serve as a potential prognostic marker for predicting survival in patients with diffuse large B-cell lymphomas.

PP3-174
APPENDICEAL LYMPHOMA PRESENTING AS ACUTE APPENDICITIS: A CASE REPORT

Engin Cigerciogullari, Hilal Aki, Tiraje Celkan, Sergulen Dervisoglu
Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Malignant lymphoma comprises 1-4% of the malignant neoplasm of the gastrointestinal tract, but appendiceal lymphomas are very rare, also acute appendicitis is an extremely rare initial presenting of appendiceal lymphoma. We describe a case of a 14-year-old male, who had lymphoma of appendix presenting as acute appendicitis. His symptoms were vomitting and pain in the right lower quadrant of the abdomen. Due to the rebound and tenderness of Mc Burney's point on physical examination, appendectomy was performed as a result of the clinical diagnosis of acute appendicitis. Histopathologic evaluation showed diffused proliferation of large and medium size lymphoma cells on mucosa and submucosa layers with acute inflamation on muscular and serosa layers. Immunohistochemical examination revealed that the lymphoma cells were positive for B cell markers. This case was diagnosed as a diffuse large cell lymphoma of the B cell type according to the WHO classification. Despite the fact that lymphoma of appendix is rare, clinically physicians and surgeons have to be aware of the differential diagnosis of acute appendicitis, because, all of cases clinically as acute appendicitis, it is not always true acute appendicitis.

PP3-175
PEARSON SYNDROME: A CASE REPORT AND CLINICOPATHOLOGIC REVIEW

Hilal Aki, Engin Cigerciogullari, Zeynep Karakas, Didem Apay, Gulyuz Ozturk
Istanbul University, Cerrahpasa and Istanbul Medical Faculties, Istanbul, Turkey

Pearson marrow-pancreas syndrome is very rare fatal disorder that involves the hematopoietic system, exocrine pancreas, liver, kidneys in early infancy. Due to the diversity of clinical symptoms, the diagnosis can be difficult. We report on a 6 months-old boy who had presented with macrocytic anemia, neutropenia, thrombocytopenia, fever, hepatosplenomegaly and slight lactic asidosis.On bone marrow aspiration, his bone marrow was characterized by marked vacuolization of erythroblasts and myeloid precursors. Molecular analysis was made from the patient's blood leukocytes to detect a deletion of mitochondrial DNA. When a neonate's or infant's bone marrow aspiration exhibits vacuolization of myeloid and erythroid precursors and also clinically the patient has metabolic acidosis of unknown cause, the possibility of Pearson syndrome should be considered.

PP3-177
IMMUNOHISTOCHEMISTRY IN HODGKIN'S LYMPHOMA: DIAGNOSIS CHANGES BEFORE AND AFTER APPLICATION, TO IDENTIFY MORPHOLOGIC AND BIOLOGIC GREY ZONE LYMPHOMAS

Nuray Bassullu[1], Nukhet Tuzuner[2]
[1] Departments of Pathology, Ministry of Health, Antakya Goverment Hospital, Hatay, Turkey
[2] Departments of Pathology, Cerrahpasa Medical Faculty, Istanbul, Turkey

BACKGROUND: There is a diagnostic grey zone between Classic Hodgkin lymphoma (CHL) and some histologic types of non-Hodgkin lymphoma (NHL), including anaplastic large cell lymphoma (ALCL) , T-cell-rich B-cell lymphoma (TCRBCL) and mediastinal large B cell lymphoma. Some morphological and/or phenotypic features are common in both CHL and those particular NHL types. METHOD AND RESULT: In this study, the cases of HL, diagnosed and subtyped without immunohistochemistry (IHC) were reinterpreted after the performance of IHC and the cases shareing common features with NHL were isolated. In addition the cases confused with HL in the morphological and/or biological grey zone but diagnosed after IHC as ALCL and TCRBCL were taken in the study group and together with HL, and all were reevaluated. After the reinterpretation of 508 cases, the diagnosis of CHL was reestablished in 390 cases out of 429 (90,9 %).In 35 cases (8,1 %) the diagnosis was changed to NHL. NHL subtypes were ALCL in 11 cases,TCRBCL in 21 cases, PTCL (peripheral T-cell lymphoma) in 1 case, DLBCL(diffuse large B-cell lymphoma) 1 case and B cell ALCL in 1 case. In 2 cases the differentiation between HL and TCRBCL, in 2 cases the differentiation between ALCL and HL couldn't be achieved. Out of 11 cases in which the differential diagnosis between HL and NHL couldn't be achieved initially, the diagnosis was established as ALCL in 3 cases(27,3 %) and as HL in 7 cases (63,6%) after the reevaluation of the cases. In 1 case the differentiation between NLPHL and TCRBCL couldn't be made. In 31 cases of TCRBCL,the initial diagnosis wasn't changed. Out of 37 cases initially diagnosed as ALCL the differentiation between ALCL and HL couldn't be achieved in 1 cases . CONCLUSION: The grey zone between HL and NHL can either be a biological grey zone as a result of common pathogenesis or it may be a morphological grey zone due to the morphological similarities.In conclusion, as the biology and the origin of RS cells were cleared out, the differentiation of HL from other aggressive lymphomas such as TCRBCL or ALCL became possible at least to an extend. However, in cases displaying CD 15 negativity and high ratios of CD20 positivity, the differential diagnosis was still troublesome.

PP3-178

CLINICAL ROLE OF FLOW CYTOMETRY IN REDEFINING BONE MARROW INVOLVEMENT IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) – A NEW PERSPECTIVE

Dipti Talaulikar[1], Bruce Shadbolt[2], Jill Bell[3], Kowsar Khan[3], Jane Dahlstrom[4]

[2] Department of Epidemiology, The Canberra Hospital and Australian National Univeristy Medical School,Canberra, ACT, Australia
[3] Department of Haematology, ACT Pathology, The Canberra Hospital, Canberra, ACT, Australia
[4] Department of Anatomical Pathology, ACT Pathology, The Canberra Hospital and Australian National Univeristy Medical School, Canberra, ACT, Australia

Aims: The clinical role of flow cytometry in staging bone marrows in Diffuse Large B-cell Lymphoma (DLBCL), especially its impact on outcome, remains ambiguous. The aims of this study were to determine the contribution of flow cytometry to conventional staging, and to study impact on survival. Methods and results: One hundred and thirteen cases of DLBCL diagnosed at The Canberra Hospital from 1996-2005 were identified for this retrospective study. On blinded analysis of Bone marrow (BM) aspirates, trephine biopsy slides, and flow cytometry data, involvement on morphology (M) was detected in 23 (20.3%) cases and on flow cytometry (F) in 25 (22.1%) cases with discordance noted in 18 cases (15.9%). Together, the 2 diagnostic techniques (M + F) detected 33 cases (29.2%). Cases with and without marrow involvement on conventional staging alone (M) had no significant difference in survival (p=NS). However, when bone marrow involvement was defined as positivity on morphology and/ or flow cytometry (M + F), the median survival of patients with involvement was significantly worse than patients without involvement (p=0.02). Conclusions: Flow cytometry positive cases should be included in a summative model to define bone marrow involvement in DLBCL as it may have a potential impact on outcome.

PP3-179

IMMUNOHISTOCHEMICAL EXPRESSION OF CD34 IN LYMPH NODE AND BONE MARROW OF PATIENTS WITH HODGKIN'S LYMPHOMA

Tatjana Terzić[1], Vesna Čemerikić –Martinović[2], Maja Peruničić-Jovanović[3], Ljubomir Jaković[3], Sanja Radojević-Škodrić[1], Gordana Basta-Jovanović[1]
[1]Institute of Pathology, School of Medicine, University of Belgrade, Serbia
[2]Histolab, Belgrade, Serbia,
[3]Institute of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: Bone marrow infiltration is present in 5-15% of patients with Hodgkin's lymphoma (HL). It is usually associated with prominent fibrosis and proliferation of blood vessels. Limited information exists about the significance of neoangiogenesis in HL. In this study we analyzed immunohistochemical expression of CD34 in lymph node and bone marrow of patients with HL. Methods: We identified 39 patients with HL (25 male and 14 female, median age 43 years), 25 patients with bone marrow infiltration by HL and 14 patients without bone marrow infiltration. Slides from paraffin embedded lymph node and bone marrow biopsy were stained with hematoxylin&eosin and reticulin fibers (Gordon-Sweet). Microvessels were visualized by immunohistochemical staining for CD34. We counted the number of vessels per high power field (x500) in two the most vascularized areas. Results: Microvessels density (MVD) in lymph node with HL was lower than in reactive lymph node (37±1,73). There was statistically significant difference ($p<0,05$) between MVD in lymph node of HL patients with bone marrow infiltration (14,75± 5,23) and MVD in lymph node of HL patients without bone marrow infiltration (20±3,95). In patients with HL, but without bone marrow lymphoma infiltration, we found increase of MVD in bone marrow (9,15±5,06), compared with control bone marrow (3,50±0,71), but correlation was not statistically significant (p=0,205). We observed that MVD inside the bone marrow lymphoma infiltrate (17,63±9,27) in HL patients was higher than MVD in HL patients without bone marrow infiltration (9,15±5,06). This correlation was statistically significant (p=0,03). Conclusion: Lower MVD in lymph node of HL patients than MVD in reactive lymph node suggests that lymphoma proliferation leads to the destruction of the existing vessels rather than neoangiogenesis within lymph node. But, our findings suggest that neoangiogenesis in bone marrow infiltration by HL was extensively increased. Therefore, the density of microvessels may provide useful prognostic information and basis for the therapeutic investigation of anti-angiogenic agents in the cases of HL with bone marrow infiltration.

PP3-180

THE DIFFERENTIAL DIAGNOSIS OF MAST CELL PROLIFERATIONS ON FIVE REPRESENTATIVE CASES

Cevriye Cansiz, Gulsah Kaygusuz, Eda Akpinar, Isinsu Kuzu
Ankara University, School of Medicine, Department of Pathology, Ankara, Turkey

The term mastocytosis denotes a heterogenous group of disorders characterized by abnormal growth and accumulation of mast cells (MC) in one or more organ systems. It subdivides into the indolent systemic mastocytosis (ISM), Systemic mastocytosis with an associated clonal hematologic non-mast cell lineage disease (AHNMD), aggressive systemic mastocytosis (ASM) and mast cell leukemia (MCL). It is important to differentiate the mast cell diseases from the cytokine related mast cell hyperplasia in the bone marrow underlying other inflammatory processes or tumors without typical skin lesions or organ involvement. Demostrating the missense mutations on c-Kit gene is becoming important for astimating result of targeted drugs for treatment modalities. Our aim in this study is to discuss the diagnosis of different types of mast cell involvements in the bone marrow of 5 cases with their clinical and pathological presentations. Three of these cases were fulfulling the criteria of ASM with multiorgan involvement. One of these cases couldn't be diagnosed for 5 years although she had splenectomy 3 years ago.Differing from the other SM cases the skin involvement could not be demonstrated in this case and her skin complaints were accepted as secondary symptom related to histamine effect. Two of the cases were fulfilling the criteria of AHNMD. One of these cases had cured Hodgkin's Lymphoma history diagnosed 13 years ago and cured secondary acute myeloid leukemia (AML) history diagnosed 2 years ago. The bone marrow was in remission for AML but there were focal paratrabecular infiltration of spindle shaped mast cells fulfilling the criteria of atypical type 1 mast cell infiltration. The mast cells were not recognised on the first two bone marrow biopsies taken for the remission control of AML. The second AHNMD case was Waldernstroms macroglobulinemia developed under the treatment of rheumatoid artritis. The bone marrow was interstitionally infltrated by monoclonal lymphoplasmocytic B cells and multifocal paratrabecular groups of mast cells. The mast cell infiltration became more clear and increased on the second biopsy taken for her disease follow up. The mast cell population were confirmed by immunohistochemistry for every case by their positive staining with CD117, CD68 and mast cell tryptase. Conclusion: Neoplastic mast cell proliferations should be diagnosed and classified correctly for performing the appropriate treatment modality. And should be differentiated from secondery reactive mast cell proliferations in order to avoid unnecessary toxic treatment.

PP3-181
THE RELEVANCE OF T CELLS AND FOLLICULAR DENDRITIC RETICULUM CELLS ON PREDICTING THE CLINICAL BEHAVIOUR OF FOLLICULAR LYMPHOMAS

Ayse Ozgun[1], Duygu Enneli Kankaya[1], Sare Altas[2], Gulsah Kaygusuz[1], Sule Mine Bakanay[3], Muhit Ozcan[3], Isinsu Kuzu[1]
[1] Ankara University, School of Medicine, Department of Pathology, Ankara, Turkey
[2] Ataturk University, School of Medicine, Department of Pathology, Erzurum, Turkey
[3] Ankara University, School of Medicine, Department of Hematology, Ankara, Turkey

Follicular lymphomas (FL) are most commonly seen in western populations (22-35 %) whereas their incidence is around 8-10% in Turkish population. Recent studies including large series of FL cases revealed that the well known histopathological prognostic criteria may not be enough for estimating their clinical behaviour. This situation has brought the idea of focusing on the characteristics of microenvironment besides neoplastic cells. Our aim in this study is to compare the microenvironment and proliferation status of follicular lymphomas with known prognostic histopathological criteria. Methods: 33 follicular lymphoma patients (16 female, 17 male) with a mean age of 54,5 (28-75), diagnosed between the years 2002-2007, were included in this study. All cases were reviewed by examining their histological and immunohistocemical features. The WHO criteria was used for histological grading. As well as the known prognostic histopathological parameters, the presence of residual reactive follicules, the preservation of follicular dendritic reticulum cell (FDRC) network, the density of T lymphocytes and histiocytes within the follicules and the proliferation status of the neoplastic follicules by Ki-67 staining were evaluated. Chi square, Mann Whitney U, Kruskal Wallis tests were used for statistical analysis. Results: Eight cases were graded as grade 1, 12 cases as grade 2, 13 cases as grade 3. There was statistically significant correlation between histological grade and Ki-67 index ($p<0.05$), while such correlation was not present between the histological grade and the bcl-2 expression, the density of CD3 positivity and the ratio of diffuse areas. The cases having higher proliferation index (>49%) showed significantly decreased density of reactive T cells ($p=0,01$). No correlation was found between Ki-67 index, the preservation of FDRC network and the expression of bcl-2. Conclusion: Our results suggested that the proportion of reactive T lymphocytes within the neoplastic follicules may predict the biological behaviour of FL. In according to our data, preservation of FDRC network is not associated with histological grade, proliferation status or T cell population in FL.

PP3-182
FIVE YEARS STATITICAL ANALYSIS OF HENOCH SCHOENLEIN PURPURA AND IT'S RELATION WITH SEASONS

Fakhrozaman Pezeshkpour, Ramin Ghasememi, Mohammad Javad Yazdanpanah, Hamid Ahanchian
Ghaem hospital, Department of Dermatology, Mashhad university of Medical sciences, Mashhad, Iran

Abstract: Introduction and purposes: HS purpura is the most distinctive subgroup of hypersensitivity vasculitis that is characterized by purpura in buttocks and lower extremities, involvement of kidney, joint and abdomen. The main aims of this study include: Determination of the correlation between HS purpura frequency and seasons. We also determined the distribution of age and sex and frequency of HS purpura. Methods: This descriptive study was done between1993 to1998 in patients referred to dermatology clinic and pediatric emergency of Ghaem hospital. The diagnosis was based on clinical and pathological findings. Results: There were 40 patients, with M/F ratio 0.8. 13 patients (32.5%) presented in spring, 7 (17.5%) in summer, 11 in autumn (27.5 %) and, (22.5%) in winter. All of the patients had typical skin lesions, 57.5 % in lower extremity 22.5% in upper and lower extremity, 17.59 in upper, lower extremity and trunk. And 2.5% only in upper. The most frequent non cutaneous lesion belongs to abdominal and joint involvements (39%). Conclusion: The most frequent seasonal distribution was in spring and the least frequent was in summer and there was a significant differences between the two seasons ($p=0.05$). But there was not such significant difference among all seasons. The most frequent site of skin lesions was the lower limbs (97.5%).

FEED FORWARD NEURAL NETWORK AS A DIAGNOSTIC HELP IN IMMUNOFLOURESCEIN PATTERNS OF SKIN DISORDERS

Sulen Sarioglu[1], Mustafa Sakar[2], Banu Lebe[1]
[1] Dokuz Eylul University Faculty of Medicine Department of Pathology, Izmir ,Turkey
[2] Dokuz Eylul University Faculty of Medicine Department of Clinical Engineering, Izmir, Turkey

BACKGROUND: Examination of the tissues by microscopy still depend upon the visual cognitive abilities of the pathologists. Although automatisation seems to be far away, image analysis methods are in progress. Measurements of area, volume and stained area percentage methods by image analysis may be applied especially for determining prognostic factors. Neural networks are mathematical algorithms that depend upon the functionality of small neural clusters. The study is designed in order to find if Feed Forward Neural Network (FFNN) depending upon automatic image analysis measurements in DIF images from skin disorders might help the pathologist. METHOD: Images from anti IgG, IgA, IgM, C3 and fibrinogen DIF stained sections from the skin biopsies from patients with immunodeposition were collected to a computer from immunoflourescence microscope. The patterns of deposition were grouped as: basement membrane linear (BML), basement membrane granular (BMG), epidermal intercellular (IC), vascular (V), negative and nonspecific background staining. Variables that might be helpful in the differential diagnosis were evaluated and total size, node, link, end point and branch were selected. The training set included 193 images from 32 cases with positive DIF results. An experienced pathologist suggested a possibility range for each image about the 6 categories. After the training process of FFNN the values for each variable were analyzed statistically for comparing the groups. For determining the automatic self made decision process based on learning, 100 images from 40

cases were analyzed by FFNN. The decisions of the pathologist and the category with highest possibility level selected by FFNN were compared. RESULTS: All the variables were significantly different when all the groups were considered (One Way Anova p<<0,000), when groups were compared separately, all values for all variables for IC pattern was significantly different from other groups, but the others gave mixed results. Of the 100 images FFNN gave the highest possibility in 83% images, in concordance with the pathologist, but gave the right result as the second possibility in 14 cases. For the IC pattern best results were obtained (89% first possibility) followed by V (85%), BML (84%) and BMG (76%). CONCLUSIONS: DIF image FFNN may help inexperienced pathologists in future. Selection of total size, node, link, end point and branch as variable seems valuable. The FFNN may provide better results with long term training.

PP3-184

EVALUATION OF MUTANT p53 GENE FREQUENCY IN PATHOLOGIC SAMPLES OF PATIENTS WITH NON-MELANOTIC SKIN CANCERS AND ITS CORRELATION WITH CLINICOPATHOLOGIC ASPECTS

Mahnaz Banihashemi, Fakhrozaman Pezeshkpoor, Norieh Sharifi
Qaem Hospital, Iran

Introduction: We aimed to investigate frequency and immunoreactivity of mutant p53 gene in non-melanotic skin cancers (NMSC) and to correlate its Over-expression with clinicopathologic aspects. Methods: Sixty paraffin-embedded pathology blocks with NMSC registered Diagnosis, including 39 BCC and 21 SCC were analyzed immunohistochemically To assess over expression of p53 protein related to sun-exposure ,age and gender Not only have we divided the samples to positive mutation samples and negative Mutation ones ,we sorted samples in the quality method to 0(negative), +1(mild), +2(moderate) and +3(severe) for p53 mutation based on visual impression and severity of staining. We also quantified proportion of the cells expressing p53 within a tumor; obtaining the percentage of the stained nuclei. Result: The frequency of mutant p53 gene in BCC and SCC was 82.1% and 71.4% respectively. Age and gender did not affect over expression of p53 significantly Frequency of mutant p53 gene was 89.1% among sun-exposed sites and 42.9% among unexposed sites to UV radiation (p<0.001). When sun-exposed effect was studied in BCC and SCC separately; 87.1% of sun-exposed BCC showed p53 mutation (P=0.137)while 93.3% of sun-exposed SCC significantly showed p53 mutation (P=0.002). however ,sun exposure of the tumor site increases the severity of p53 staining-when mutation existed-in SCC and BCC significantly (P=0.015 & 0.005 respectively). Also, exposure to ultra violet radiation increases the mean of percentages of stained nuclei-when mutation existed- in SCC and BCC significantly (P=0.04 & 0.008 respectively). Conclusion: Chronic UV radiation can\\\'t induce p53 mutation in BCC but when the mutation occurs due to any other factor, in increases the quality of the activity of mutated p53 gene. In SCC chronic exposure to UV induces mutation in TP53 and also it increases the activity of mutated gene in both quality and quantity.

Purpose: This paper studied the effect of post-burn local hyperthermia on burn induced injury. Methods: A second-degree burn injury was induced on the right and left flanks of Balb/c mice.Thirty-two burn wounds were divided into four groups. Opioid receptor blocking was done for groups 3 and 4 by intra-peritoneal administration of Naloxone (NLX) 30 min before the thermal injury. Local hyperthermia (45°C, 30 s) was applied only for the peripheral area of burn wounds of groups 2 and 4. Twenty-four hours after burn injury, the burned wounds were assessed for the level of iNOS (by immunohistochemistry) and the number of hair follicles (as an indicator of tissue injury). Results: The wounds that received hyperthermia (group 2) had significantly more hair follicles ($p < 0.001$) compared to the control wounds (group 1). There was no significant difference between the number of hair follicles and acute inflammation of group 1 and group 3 (NLX + burn). Group 4 (NLX + burn + hyperthermia) had significantly fewer hair follicles compared to group 1 ($p < 0.001$), group 2 ($p < 0.001$) and group 3 ($p < 0.001$). The level of iNOS in groups 1, 3 and 4 was not significantly different but significantly more than group 2 ($p < 0.001$, $p < 0.001$ and $p < 0.001$, respectively). Conclusions: The results showed that local hyperthermia after second degree burn decreased the tissue injury and iNOS expression. It is also concluded that endogenous opioid response may have a key role in the above mentioned effects of post-burn local hyperthermia.

CASE OF THE BROOKE-SPIEGLER SYNDROME

Pouran Layegh[1], Nourieh Sharifi Sistani[2],
Fakhrozaman Pezeshkpour[3], Mohammad Abadian[3]
[1] Dermatology Department,Qaem Hospital, Mashad University of Medical Sciences, Iran
[2] Pathology Department,Qaem Hospital, Mashad University of Medical Sciences, Iran
[3] Dermatology Department, Qaem Hospital, Mashad University of Medical Sciences, Iran

Case Report : The patient is a 26-year old woman, presented with cutaneous lesions on her scalp and face. These lesions had first appeared when she was 14 years old and primarily on her scalp which later developed on the face and had gradually increased in size and number over the years. In the patient's family, her father and brother, who was 13 years old had similar lesions on their faces. On examination, a group of round to oval –shape skin –coloured papules with a smooth pearly surface measuring 2-6 mm in diameter were seen in the mid-face, particularly in the nasolabial folds, the upper lip and less commonly on the forehead and the periocular areas.In addition to this, a variety of tumoral and nodular lesions was also seen on the scalp. The tumors of the scalp were pinkish –red, dome-shaped to some extent peduncular with surface telangiectasia and induration on palpation. They were measured 0.5-1.5 cm in diameter, the larger lesions were hairless and the smaller ones had less hair than normalAlso there was a subcutaneous firm nodule with a diameter of 0.5 ×0.5 cm on the patient´s right forearm. Her general condition was good; she had no known underlying disease and no previous history of taking any kind of medications. The histopathology examination of the scalp nodule revealed a dermal lesion with defined borders composed of islands of basaloid cells arranged in a jigsaw puzzle-like pattern and separated by hyaline basement membrane material. Two populations of basaloid cells (with a large nucleus centrally and smaller nuclei in a palisading pattern of the periphery) were observed, which can represent Cylindroma. In the facial papules basaloid inclusions with immature (basic) follicular papillae and horncysts were seen which were surrounded by fibrous stroma and are typical of trichoepithelioma .The patient's forearm nodule composed of sheets of small dark staining basaloid cells peripherally and larger cells with paler nuclei centrally, consistent with spiradenoma According to the clinical feature and the histopathology findings, the diagnosis of was Brooke _Spiegler syndrome made.

HISTOLOGICAL ANALYSIS OF HUMAN SKIN FROM EGYPTIAN MUMMIES
Dina Tiniakos[1], Norah Caldwell[1], Vasso Zafiri[2], Athanassios Sakarellos[2], Christos Kittas[1], Theodoros Pitsios[2]
[1] Laboratory of Histology & Embryology, Medical School, National & Kapodistrian University of Athens, Greece
[2] Museum of Anthropology, Medical School, National & Kapodistrian University of Athens, Greece

Background. Four Egyptian mummies of the Hellenistic/Roman period (332 B.C.-395 A.D.), an adult man, an adult woman and two young male children, are included in the ethnologic collections of the Museum of Anthropology, University of Athens, Greece. The biological age of the mummies, based on anthropometric and dental studies, is estimated at 25-35, 40-50, 7-8 and 2.5-3 years, respectively. Anatomical and imaging (x-Ray, computed tomography scan) studies combined with 3-D virtual reconstruction of scull and bones were undertaken. The aims of the present study, which to our knowledge is the first histological study on Egyptian mummies in Greece, were to optimize the conditions of mummified tissue specimen preparation for histological analysis using light microscopy and to evaluate the preservation state of tissue components. Method. Samples of skin tissue from all four mummies were taken without damaging the remains. Four different methods of tissue rehydration were applied for specimens from each mummy using a) 10% sodium bicarbonate in distilled water (dH_2O), b) fabric softener, c) 5% glucose in dH_2O and d) 3% dimethylsulfoxide in dH_2O, followed by fixation in 10% neutral formalin and embedding in paraffin. Serial 5 m- thick tissue sections were cut from each paraffin block and the histochemical stains hematoxylin-eosin and Masson Trichrome were performed. Results. Immersion of the specimens in 10% sodium bicarbonate solution for 8 hours was considered the optimal (most rapid and with best tissue preservation) rehydration method for the desiccated mummy skin. Histological analysis using light microscopy showed absence of epidermis in all tissue sections examined, while the dermis appeared well preserved with identifiable collagen fibers in the dense, irregular fibrous tissue which stained lightly with Masson Trichrome stain. No visible cells or cell remnants were present. Conclusions. We performed a, unique in Greece, histological analysis of 1700-2300-year-old human skin from Egyptian mummies. Rehydration in sodium bicarbonate solution followed by routine fixation and embedding was considered the best method for morphological and histochemical analysis of mummified human tissues. Collagen fibres and possible blood vessels were identified in the dermis of the mummified skin.

PP3-188
A STUDY OF MONOCYTIC AND DENDRITIC CELL MARKERS IN BENIGN CUTANEOUS FIBROUS HISTIOCYTOMA (DERMATOFIBROMA)
Daisuke Nonaka, Luis Chiriboga
New York University School of Medicine, USA

Background: Controversies have existed regarding the histogenesis of fibrous histiocytomas (FHs) as well as the issue regarding whether they represent a neoplastic or reactive process. Based on the expression of factor XIIIa (fXIIIa), the proliferating cells of these lesions have been considered to be dermal dendrocyte by some investigators. We report on the expression of various novel monocytic and dendritic cell markers on dermatofibromas (DFs) and, for comparison, giant cell tumor of tendon sheath (GCTTS). Design: A total of 38 cases of DF and 10 cases of GCTTS were stained with CD1a, CD11c, CD68, CD83, CD123, CD205 (DEC-205), CD207 (Langerin), CD208 (DC-LAMP), CD209 (DC-SIGN), fXIIIa, muscle specific actin (HHF-35), smooth muscle actin (SMA), and calponin. Results: CD163, CD68 and fXIIIa were diffusely expressed in approximately two-thirds of the DFs, with the remaining cases being focally positive; myeloid dendritic cell markers including CD83, CD205, and CD208, and Langerhans cell markers such as CD1a and Langerin were negative; plasmacytoid dendritic cell marker, CD123, was completely negative; SMA and calponin were variably expressed in half of the cases; and HHF-35 was focally stained in only two cases. CD11c and CD209, which can be expressed in both myeloid dendritic cells and macrophages, were focally positive. Both CD68 and CD163 were diffusely stained in GCTTSs; fXIIIa was variably expressed in 8/10 cases; dendritic cell markers were negative; and smooth muscle markers were also negative except for focal staining of SMA in one case. CD11c and CD209 were also focally expressed. Conclusion: DFs are composed predominantly of cells with macrophage markers with a variable amount of myofibroblastic elements, without evidence of specific dendritic cell phenotype. GCTTSs are composed of cells of macrophage derivation. Our results support the notion that monocyte/macrophage represent the potential histogenesis of DFs.

PP3-189
HISTOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL ASPECTS IN FEW TYPES OF CUTANEOUS SARCOMAS
Costache Mariana[1], Simionescu Olga[2], Ene Ana-Maria[3], Sajin Maria[1]
[1] V. Babes National Institute of Pathology, Romania
[2] UMF Carol Davila , Romania
[3] Faculty of Biology University of Bucharest, Romania

The present study describes the histopathological and immunohistochemical aspect in different cases of cutaneous sarcomas which are representative and also rare in the medical practice (dermatofibrosarcoma protuberans, malignant fibrous histiocytoma, leyomiosarcoma, rhabdomyosarcoma, hemangiopericytoma, malignant hemangioendothelioma). Material and method: We have done a retrospective study within a period of two years concerning on a group of 35 patients who presented cutaneous sarcomas. We used surgical excision pieces, which had been fixed in buffered 10% formalin, paraffin embedded and sectioned at 3µm, then stained routinely by Hematoxylin - Eosin was used in the majority of cases and special stains (Gomory - silver impregnation) in several others, than examined by light microscopy. For the immunohistochemical (IHC) staining the following antibodies were used: CD34, CD31, Actin, Myoglobin, Desmin, Cytokeratin, Vimentin. Results:The primary cutaneous sarcomas have a various neoplastic forms; can occur at any age; these neoplasms to children are rare. Both sexes are affected. As an essential and distinctive feature of these tumours there is a risen tendency of recur. Clinically,the most sarcomas appear solitary and have a profound invasion; the usual locations are the extremities and the retroperitoneal region. The lesions are present as nodules or plaques. Frequently, in ultimate stages, the tumour may necrosise and ulcerate. Histopathologically, they are characterized by invazivity, being not encapsulated and unpreciselly delimitate by the neighbouring tissues. The cellular and nuclear atypia of size, form and colour, as well as atypical mitoses are frequently present. The tumours prouve high cellularity with the tendency of desposing the cells in different oriented fascicles. The vascular tumours show irregular vascular lumens surrounded by neoplastical proliferations. Immunohistochemical staining showed a diffuse positivity for vimentin; CD34 and CD31 was positive in vascular structures; cytokeratin was negative and actin and myoglobin were positive in tumour cells and in vassels walls. The cutaneous sarcomas represents a heterogeneous group of tumours with many histopathological aspects. However, a large group of them consists in problems of positive and differential diagnosis. The

immunophenotyping of such a tumour is important because in correlation to the anatomo-clinical features permits a good differential diagnosis and rules out a large number of tumoral lesions.

PP3-190
LANGERHANS CELLS AS A CLUE FOR TUMOROUS NATURE OF DERMATOFIBROMA
Ivana Ilić, Zdenka Hutinec, Jadranka Ilić-Forko
University Medical Center Zagreb, Serbia

Background. Dermatofibroma is a common benign lesion usually found on extremities and trunk of adults. Despite its frequency and benign nature it is still unknown whether this is an inflammatory lesion or a true neoplasm. In most inflammatory lesions of the skin the number of epidermal Langerhans cells is higher than in normal epidermis. The number of epidermal Langerhans cells in the dermatofibroma could be a useful, although indirect, clue for defining whether this entity is closer to the inflammatory lesions or to the neoplasms. Method. In our study we included 10 patients with dermatofibroma, 10 with dermatofibrosarcoma protuberans and 10 with postoperative scar. All lesions were immunochistochemicaly stained with CD1a (Clone O10, dilution 1:50, Dako Cytomation, Glostrup, Denmark) to highlight Langerhans cells. We counted the number of Langerhans cells in the epidermis above the lesion. The intraepidermal CD1a positive cells were enumerated as a percentage of 100 keratinocytes. Two concomitant areas of high power field were counted and mean +/-SD percentage was calculated in each specimen. For comparing the differences between mean number of epidermal Langerhans cell in scar, dermatofibroma and dermatofibrosarcoma protuberans we used Student t-test. $p < 0.05$ was regarded as statistically significant. Results. By comparing the number of Langerhans cells (mean+/-SD) in epidermis above the scar (7.62+/-1.38), dermatofibroma (2.05+/-0.61) and dermatofibrosarcoma (2.76+/-1.31), we found that there is no statistically significant difference between mean number of epidermal Langerhans cells above the dermatofibroma and dermatofibrosarcoma ($p=0.160$). The difference between means of epidermal Langerhans cells number above dermatofibroma and above scar is found to be statistically significant ($p<0.0001$). Conclusion. This was an indirect way of showing the neoplastic nature of dermatofibroma. If dermatofibroma was an inflammatory lesion, we expected dermatofibroma to have higher number of epidermal LC, just like we found in scars.

PP3-191
DOES MERKEL CELL CARCINOMA REPRESENT AN EPITHELIAL TUMOUR WITH NEUROENDOCRINE DIFFERENTIATION
Vuka Katic, Jasmina Gligorijevic, Katarina Katic,
Boban Stamenkovic
Institute of Pathology, Medical Faculty Nis, Serbia

Background: Merkel cell carcinoma (MCC) is uncommon malignant skin tumour with a poor prognosis and rapid progression. Most MCCs occur in elderly individuals, on sun-exposed areas of the body, with the head and neck being the most common sites, followed by the extremitaties and trunk. However, the origin of the MCC is still controversial, because its cells have both epithelial and neuroendocrine elements. To answer on this dilemma we have investigated an expression of neuroendocrine and epithelial markers in MCC. Aims: The origin of the Merkel cell carcinoma is still controversial because its cells have both epithelial and neuroendocrine elements. To answer on this dilemma we have investigated an expression of neuroendocrine and epithelial markers in Merkel cell carcinoma. Methods: The study group was composed of 6 cases, with the mean age of 68 years. Multiple subcutaneous masses and lymph node metastases were surgically ressected.Paraffine blocks of the formaldehyde-fixed tumorous tissue were cut and stained with H&E, PAS, HID-AB pH=2,5 and LSAB2 techniques.The following antibodies (Dacopatt) were used: Chromogranine A, Neurone specific enolase (NSE), panCytokeratin, Melan A, CD20 and CD45Ro. Results: The tumours involved the dermis, with sparing of the epidermis. A variety of histological subtypes were recognized, including intermediate, small cell, mixed intermediate and small-cell variantsMitoses were tipically numerous, and atypical forms were frequently seen. Lymphovascular invasion was extrmely common finding. MCCs expressed both neuroendocrine and epithelial differentiation. They showed positive labeling with epithelial membrane antigen, dot paranuclear panCytokeratin, as well as positive labeling with Chromogranine A and NSE, markers for neuroendocrine differentiation. Conclusion: Merkel cell skin carcinoma is immunohistochemically epithelial malignant tumour with neuroendocrine differentiation.

[2] Oncology Department, Miguel Servet University Hospital, Zaragoza, Spain

BACKGROUND: Prognostic variables of melanoma in TNM classification (AJC 2001) are Breslow thickness, ulceration of epidermis and Clark level. Besides, some other variables have been considered such as regression and mitotic index. Malignant melanoma is one of the tumours with a highest rate of spontaneous regression, around 15% of all cases. Regression has been associated with an increase of angiogenesis and a higher risk of developing metastases. METHODS: We have studied 116 cutaneous melanomas, of which we had all clinical and outcome data along 3 years at least. We have considered histological variables such as Breslow thickness, Clark level, presence of ulceration, histologic type, mitotic index, lymphoid response and tumour regression. We have also performed an immunological study of beta-catenin, Ki-67, Bcl2, p16, EGFR, c-Kit and cyclines (B1, D1 and D3). RESULTS: Descriptive study shows regression in 15 of the 116 studied patients (12,9%). In univariate analysis there are differences in survival-without-recurrence rate, being shorter the rate of patients with tumour regression ($p=0,0073$). Multivariate analysis shows that recurrence rate is 5,6 times higher in patients with tumour regression, and risk of death is 3,51 times higher for these patients. Presence of regression is associated with a higher risk of recurrence and a shorter specific survival for melanoma. CONCLUSIONS: Most bibliographic data seem to indicate that regression is not a significant prognostic factor, but it is related to an increase of angiogenesis, and therefore with a higher capacity of distant dissemination. In many studies regression does no seem to be a significant prognostic factor, probably because it is difficult to be defined and assessed. Other studies affirm that it can be an important factor, especially when Breslow thickness is less than 1 mm, and most of all when regression is extensive. In our case series, 33,33% of the patients with regression areas had a Breslow of 1 mm or below, and presence of regression correlates with an increase of the risk of recurrence and death.

PP3-193
ASSESSMENT OF THE DEMODEX FOLLICULORUM IN HUMAN CUTANEOUS LESIONS
Narcisa Mederle[1], Ovidiu Mederle[2], Marius Raica[2]
[1] Veterinary Medicine Faculty, Timisoara, Romania
[2] University of Medicine and Pharmacy, Timisoara, Romania

Introduction Since the epizootic conditions of the appearance of dermatoses are common and the clinical signs often lead to confusions, a skin smear, correctly executed and interpreted, is helpful in the diagnosis of demodicosis and in the differential diagnosis between skin lesions. Cited by many authors as a saprophyte of the human skin, Demodex Folliculorum is the cause of many skin lesions, such as folliculitis, desquamations, prurit, hyperseborrhea of the facial region. Material and method 14 patients (3 men and 11 women) diagnosed with different dermopathies (endocrine, allergic, bacterial) which were non – responsible to the usual therapy were examined. The patients had erythema, folliculitis, desquamations, hyperseborrhea of the facial region. The skin smears were clarified in lactic phenol and paraffin oil and were microscopically examined. From the positive smears we have made measurements of 31 adult acarians. Results The microscopic exam of the skin smears showed the adult form of Demodex Folliculorum in all the patients. No evolutive stages of the parasite (egg, larva, nymph) were found. Medium sizes of the female and male parasites were 238/47 μm and 212/46 μm, respectively. The explanation for the absence of the intermediate stages of the parasite is that the samples were taken from the superficial skin, careful not to produce supplementary lesions or to leave scars (especially in women). Conclusions The microscopic exam of the skin smears of 14 patients diagnosed with dermatoses with other aetiology than parasitic and non responsible to treatment has shown the presence of the adult form of Demodex Folliculorum. The morphologic description and the dimensions of the adult Demodex Folliculorum were in correlation with bibliographic data.

PP3-194
EXPRESSION OF HPV, p53, Bcl-2 AND PCNA IN PREMALIGNANT AND MALIGNANT EPIDERMAL TUMORS

George Burkadze[1], Oleg Kvlividze[2], Gulisa Turashvili[1], Liana Gogiashvili[2]
[1] Department of Clinical Pathology, N. Kipshidze Central University Clinic, Tbilisi, Georgia
[2] A. Natishvili Institute of Experimental Morphology, Tbilisi, Georgia

Background. Bowen's disease is an intraepithelial squamous cell carcinoma which has been related to human papillomavirus (HPV) infection. Non-melanoma malignant skin tumors such as invasive squamous cell carcinoma and basal cell carcinoma have also been associated with HPV. The interaction between ultraviolet light and HPV infection has been suggested to be a major mechanism for skin carcinogenesis. The purpose of our study was to assess the immunohistochemical characteristics of Bowen`s disease and invasive epidermal tumors. Methods. We examined immunocompetent patients with Bowen`s disease and malignant epidermal tumors such as invasive squamous cell carcinoma and basal cell carcinoma. Ten patients were involved in each group. Biopsy specimens were fixed in 10% neutral buffered formalin and embedded in paraffin. The paraffin sections were stained by hematoxylin-eosin and von Gieson. Immunohistochemistry was performed using monoclonal antibodies against HPV, oncoprotein p53, anti-apoptotic protein Bcl-2, and proliferation marker PCNA. The percentage of positive cells was determined as strongly, moderately or weakly positive. Results. Premalignant and malignant epidermal lesions failed to show specific clinical features suggesting that they are unlikely to be reliably distinguished on clinical signs alone and morphological examination seems to be mandatory. Immunohistochemistry revealed that HPV infection was 1.5 times more frequent in Bowen`s disease, than in invasive skin tumors. HPV+/p53+ types of Bowen`s disease showed higher PCNA expression in comparison to HPV-/p53+ types. Bcl-2 expression was associated with HPV-negativity. In HPV+ and HPV- types of basal cell carcinoma and squamous cell carcinoma, the incidence of p53 and PCNA expression was similar. However, the strong expression of both markers (p53, PCNA) was related to the lower grade of squamous cell carcinoma. Conclusion. HPV infection appears to play a role in development of Bowen`s disease and malignant epidermal tumors. Independently of p53 expression, HPV-positive cases of Bowen`s disease exhibit higher proliferation activity, whereas HPV-negative cases are also Bcl-2-positive. Independently of the presence of HPV infection, basal cell carcinomas and squamous cell carcinomas show similar incidence of p53 expression and proliferation activity, and lower grade squamous cell carcinomas are associated with stronger expression of p53 and PCNA.

PP3-195
EVALUATION OF CORRELATION BETWEEN CLINICAL AND PARACLINICAL DIAGNOSIS IN FEMALE PATIENTS WITH DIFFUSE NON-CICATRICIAL ALOPECIA

Pouran Layegh, Fakhrozaman Pezeshkpoor, Maryam Jannati Pour
Qaem Hospital, Mashad University of Medical Sciences, Iran

Background: Alopecia in all its patterns is a common symptom in patients who referred to dermatology clinics. It may cause anxiety and stress in these cases. There are four main diagnosis for a woman presenting with the chief complaint of diffuse, nonscaring hair loss: 1) Female pattern hair loss (androgenetic alopecia) 2) Acute and chronic telogen effluvium 3) Diffuse alopecia areata 4) Loose anagen hair syndrome. Management of hair diseases is very difficult, so we aimed to evaluate the correlation between paraclinical diagnosis (hormone studies, scalp skin biopsy/ histopathology) and clinical diagnosis (history and physical examination) in female patients with diffuse non-cicatricial alopecia refer to clinic of dermatology of Ghaem Hospital. Method: in this prospective study, we filled out the questionnaires for 41 cases and their history, physical examination and hormonal and histopathological studies were recorded and final diagnosis was assessed. Then the correlation between clinical and paraclinical diagnosis were evaluated with Chi square test. Results: Most of patients had androgenetic alopecia. Clinical and paraclinical diagnoses were the same in 94.1 % of these cases. Diffuse alopecia areata was diagnosed by pathologic studies in all cases. Clinical diagnosis and hormone studies were the same in most cases of androgenetic alopecia and telogen effluvium. Conclusion: Pertinent history, physical examination and biopsy are suggested in all patients with diffuse alopecia. Hormone studies are not needed unless they have been other signs of hyperandrogenemia.

PP3-196
EXPRESSION AND LOCALIZATION OF THYMIDINE PHOSPHORYLASE/ PLATELET-DERIVED ENDOTHELIAL CELL GROWTH FACTOR IN CUTANEUS MALIGNANT MELANOMAS

Gultekin Kaner[1], Fatma Kaya Dagistanli[2], Selma Yilmazer[2]
[1] Istanbul University, Cerrahpasa Medical Faculty, Department of Pathology, Turkey
[2] Istanbul University, Cerrahpasa Medical Faculty, Department of Medical Biology, Turkey

Backgraund: Angiogenesis is a significant prognostic factor in melanoma, but the angiogenetic factors controlling the neovascularization are not well defined. Platelet-Derived Endothelial Cell Growth Factor (PD-ECGF), also known as thymidine phosphorylase (TP) stimulates endothelial cell mitogenesis and chemotaxis in vitro and is strongly angiogenic in vivo. TP is overexpressed in various tumors and plays an important role in angiogenesis, tumor growth, invasion and metastasis. The aim of the study was to examine the expression

of TP in melanomas. Method: In this study the expression of thymidine phosphorylase was examined immunohistochemically in 14 cases with melanomas. Result: TP was strongly expressed not only in macrophages in and around tumors but also in fibroblasts and keratinocytes. Immunoreactivity of TP was rarely seen in melanoma cells. TP positive reaction was also observed in ecrine gland epithelium. Conclusion: These results suggest that TP expressing infiltrative macrophages and stromal cells in and around tumors may contribute to angiogenesis and involved in the growth and metastasis of malignant melanomas.

PP3-197
L1 EXPRESSION IS NOT RELATED WITH SENTINEL LYMPH NODES METASTASIS IN MELANOMA PATIENTS

Lorenzo Memeo[1], Raffaella Giuffrida[1], Tiziana Perin[2], Adriana Scogna[2], Vincenzo Canzonieri[2]
[1] Department of Experimental Oncology, Mediterranean Institute of Oncology, Catania, Italy
[2] Division of Pathology, CRO- Aviano National Cancer Institute, IRCCS, Aviano, Italy

Background: Recently, the expression of the cell adhesion molecule L1 has been associated with the metastatic phenotype in both human and murine model of malignant melanoma. Thies et al showed a positive association between L1 expression and metastasis in a 10-year retrospective study. L1 is a transmembrane protein and consists of an extracellular region, containing six immunglobulin-like domains followed by five fibronectin III-like repeats, a transmembrane domain and a short, phylogenetically-conserved cytoplasmic domain. Although originally described as a neuronal cell adhesion molecule, L1 expression is not restricted to nervous tissues, but has also been detected in lymphocytes, granulocytes, in epithelial cells of the intestinal and urogenital tract, and in the epidermis. In addition to expression in normal tissues, L1 has also been detected in several highly malignant tumours, including osteogenic sarcoma, squamous cell carcinoma of the lung, rhabdomyosarcoma and retinoblastoma. Therefore we decided to study L1 expression by immunohistochemistry in 52 non-consecutive patients with cutaneous malignant melanoma which underwent sentinel lymph node biopsy (SNB). Methods: L1 immunostaining was evaluated in melanoma cells by a semiquantitative scoring system. The cut-off for the overexpression was set at 20% of positive cells, irrespective of staining intensity. Results: Breslow Score Index (BSI) in all cases ranged from 0.44 mm to 8 mm. Out of the 52 melanoma patients, 23 (44%) had lymph nodes metastasis and 17 of them had the Breslow Index Score (BSI) available, ranging from 0.9 mm to 8 mm (12 cases with BSI >1,5mm). The 29 melanoma without lymph nodes metastasis had a BSI ranging from 0.44 to 4.85 mm (16 cases with BSI >1.5 mm). L1 overexpression in primary tumors was found in 10/23 (43%) cases with sentinel lymph node metastasis, and 16/29 (55%) cases with no evidence of sentinel lymph node metastasis When L1 expression was evaluated in combination with a BSI < 1.5 mm, it was found overexpressed in 3/5 cases with lymph node metastasis and in 4/13 without lymph node metastasis. When cases were stratified for a BSI > 1.5 mm, L1 overexpression was found in 6/12 cases with lymph node metastasis, and in 12/16 without lymph node metastasis. Conclusion: Our data suggest that, in the melanoma settings, L1 plays an important role in predicting long term survival but is not statistically significant in predicting sentinel lymph node metastasis.

PP3-198
LYMPHOEPITHELIOMA LIKE CARCINOMA OF THE SKIN FOLLOWING 5-FLUOROURACIL TREATMENT

Huseyin Kemal Turkoz, Deniz Ozcan
Okmeydani Training and Research Hospital, Department of Pathology, Turkey

Background: Primary lymphoepithelioma like carcinoma (LELC) of the skin is a cutaneous malignancy with microscopic smilarities to undifferentiated nasopharyngeal carcinoma. It is a very rare neoplasm and just over 30 cases have been reported in the medical literature to date. Relation with previous actinic keratosis was not observed in the reported cases. Methods: We report a case of LELC on the right cheek of a 79 years old female who was treated with 5-fluorouracil for breast carcinoma five years before the onset of LELC. 5-fluorouracil is known to increase sensitivity to sun light. Patient had multiple actinic keratosis on her face three years after the 5-Fluorouracil therapy. All but one of the lesions regressed following topical diclofenac therapy and avoidance of direct sun light. The only remaining lesion was surgically removed with safe margins. Histologically, there was no connection between the tumor and the epidermis. There was no displasia in the neighbouring skin. The entire dermis and superficial subcutaneous tissue were occupied by atypical epithelial cell nests with a syncytial pattern of growth. Tumor cells were positive for cytokeratine and S-100 positive clear cells resembling Langerhans cells were scattered between tumor nests. Conclusions: None of the previously reported cases have been announced to be associated with neighbouring dysplasia or previous actinic keratosis in the vicinity of tumor location. This is the first LELC case which can be connected with sun light exposure and actinic keratosis as the precursor lesion of skin carcinoma of squamous type.

PP3-199
A NEW CONCEPT OF MELANOCYTIC NEOPLASIA PATHOGENESIS BASED ON THE PHENOTYPE OF COMMON ACQUIRED NEVI

Anna Batistatou[1], Aikaterini Zioga[1], John Panelos[1], Daniela Massi[2], Sevasti Kamina[1], Konstantinos Charalabopoulos[3], Niki Agnantis[1]
[1] Department of Pathology, University of Ioannina Medical School, Ioannina, Greece
[2] Department of Human Pathology and Oncology, University of Florence, Florence, Italy
[3] Department of Physiology, Clinical Unit, University of Ioannina Medical School, Ioannina, Greece

Background: To date, there are no known molecular hallmarks for nevus development but much progress has been made on the classification of melanocytic nevi. Common acquired nevi are classified into junctional, compound and dermal, based on the topography of nevus cells. The aim of this study was to examine whether common acquired nevi excised from the same individual share similarities in their microscopic appearance and in their molecular profile. Method: We retrieved from our files all the reports on excised nevi during the period 2/2005-2/2006. From these we selected only those that were more than one per patient and were diagnosed as common acquired nevi, compound or dermal. In total, our material consisted of 84 nevi from 31 individuals (♀:♂=25:6, mean age: 31 years). Three patients had four excised nevi, 16 had three and 12 had two excised nevi. The histological slides were reviewed and all phenotypical characteristics were recorded. Furthermore, the immunohistochemical expression of E-cadherin (E-cad) was evaluated, using the monoclonal antibody (CM170B, Biocare Medical, Menarini Hellas). Results: Multiple nevi from the same individual share similar morphology, including secondary changes, some of which are not common. Such features include exophytic, papillomatous, acrochordon-like or endophytic architecture, cytologic characteristics, such as nuclear inclusions, predominant type A, B or C cells, multinuclear nevus cells, fatty metaplasia and “active” nevus cells. Regarding the immunohistochemical expression of E-cadherin in these nevi similar changes in expression in nevi of each individual were noted. Conclusion: On the basis of these observations, we hypothesize that melanocytes of the whole body, although

dispersed in the entire epidermis, are all genetically similar in the same individual and changes predisposing to neoplasia are possibly a global melanocytic event characteristic for each person.

PP3-200
LOSS OF BMI-1 EXPRESSION IS ASSOCIATED WITH THE CLINICAL PROGRESS OF MALIGNANT MELANOMA

Ingeborg M Bachmann[1], Hanne E Eknes[2], Arie P Otte[3], Lars A Akslen[2]
[1] The Gade Institute, Section for Pathology, University of Bergen, and Department of Dermatology, Haukeland University Hospital, Bergen, Norway
[2] The Gade Institute, Section for Pathology, University of Bergen, Haukeland University Hospital, Bergen, Norway
[3] Department of Biochemistry, Swammerdam Institute for Life Sciences, University of Amsterdam, Amsterdam, The Netherlands

Background The incidence of cutaneous melanoma is increasing, and there is a continuous search for improved prognostic markers and novel therapeutic approaches. BMI-1, a candidate stem cell marker is part of the Polycomb group of genes (PcG), which are important in embryonic gene regulation and tumor development. It has been suggested that BMI-1 protein is important in cell cycle regulation since both p16/INK4a and p14/ARF are downstream BMI-1 targets. Further, BMI-1 has been linked to the development of human malignancies of the haematopoietic and lymphatic systems, but its role in melanocytic tumors of the skin is unknown. Method BMI-1 staining in tumor cells was studied by immunohistochemistry of TMA sections made from 178 benign and malignant melanocytic lesions. We used two different monoclonal antibodies (clone F6, Upstate, Lake Placid, NY and the non-commercial clone 6C9). The arrays were scored blindly and there was good correlation between the two investigated antibodies (Spearman's rho correlation coefficient 0.62, $p<0.0001$). The staining was recorded using a semi-quantitative and subjective grading, considering both the intensity of staining and the proportion of tumor cells showing unequivocal positive reaction. A staining index (SI) was calculated as a product of staining intensity (0-3) and area of positive tumor cell nuclei (1<10 %, 2=10 %-50 %, 3>50 %). Results The immunohistochemical staining of BMI-1 showed a predominately nuclear staining pattern. BMI-1 expression was found to be significantly weaker in melanomas than in benign nevi. In established melanomas, loss of BMI-1 expression was associated with features of aggressive tumors, like increased tumor cell proliferation, presence of necrosis, and increased expression of both N-cadherin and β3-integrin. Low levels of BMI-1 expression were significantly associated with decreased patient survival. Conclusions In conclusion, we demonstrate for the first time that loss of the candidate stem cell marker BMI-1 expression is associated with increased proliferative capacity, features of aggressive melanoma subgroups and reduced patient survival in established vertical growth phase melanomas. We also demonstrate that expression of the BMI-1 protein is reduced in melanomas when compared with benign nevi.

PP3-201
A ZONAL COMPARISON OF MIB-1, CYCLIN D1, ESTROGEN AND PROGESTERONE RECEPTOR EXPRESSION IN NEVI FROM WOMEN IN PREGNANCY, PUBERTY OR NONE OF THE TWO

Anna Batistatou, Aikaterini Zioga, John Panelos, Michael Doukas, Nafsika Simou, Niki J. Agnantis
Department of Pathology, University of Ioannina Medical School, Ioannina, Greece

Background: Pregnancy and puberty influence the clinical appearance of common acquired melanocytic nevi, however the histologic changes are controversial and the possible factors implicated are still under investigation. The aim of the present study is to investigate the possible differences in MIB-1 immunoreactivity (a cycle-associated nuclear antigen), in expression of cyclin D1 (a nuclear protein synthesized in early G1) and in expression of estrogen (ER) and progesterone receptors (PR) in common nevi from women in pregnancy, puberty, or none of the two. Method: Our material consisted of 43 common acquired compound or dermal nevi: 11 from pregnant women, 20 from age-matched women that were not pregnant and did not take contraceptive pills, and 12 from girls in puberty. For immunohistochemical staining the antibodies against MIB-1 (DAKO), Cyclin-D1 (Diagnostic Biosystem, Menarini Hellas), ER (Novocastra) and PR (Novocastra), and the EnVision system (DAKO) were used. Positive and negative nevus nuclei were counted in at least six randomly selected fields (X400) in each of the upper (superficial zone), middle (middle zone) and lower (deep zone) third of the dermal part of the nevus. Results: The nevi from pregnant women, exhibited a statistically significant increase in MIB-1 immunoreactivity, more pronounced in the deep zone, compared to controls. In nevi from girls in puberty the counts were in between the other two categories. Cyclin D1 expression was weak and detected in <5% of nevus cells in nevi from all categories, but was more pronounced in nevi from pregnant women. ER expression was rarely detected, only in the pregnant women nevi. The majority of nevi in all three categories expressed PR. Conclusion: Nevi from pregnant women differ from those of non-pregnant women regarding MIB-1 immunoreactivity, cyclin D1 and ER expression. In girls in puberty, nevi exhibit an increase in the MIB-1 index.

PP3-202
THE IMPORTANCE OF TENASCIN AND UBIQUITIN IN ESTIMATION OF WOUND AGE

Ekin Ozgur Aktas[1], Safiye Aktas[2], Hulya Guler[1], Huseyin Karaali[1]
[1] Ege University Faculty of Medicine Department of Forensic Sciences, Izmir, Turkey
[2] Dr Behcet Uz Children Research Hospital, Izmir, Turkey

Background: Human wound age determination is of prime importance in forensic sciences. The different reactions of tissues to different natures of wounds require modern diagnostic methods to determine wound age. Ubiquitin is a small protein required for ATP-dependent, nonlysosomal intracellular protein degradation, which eliminates most intracellular defective proteins with a rapid turnover. It is expressed in nuclei of neutrophil leucocytes, macrophages and fibroblasts in wound area. Tenascin is an extracellular matrix glycoprotein. It is expression is restricted in adult tissues although it is widely distributed in embryonic tissues. The aim of this study is to determine the importance of ubiquitin and tenascin in wound age. Method: This study included 170 wound biopsies prospectively obtained from 89 forensic autopsy cases with known wound age. Ubiquitin and tenascin were immunohistochemically applied on formalin-fixed paraffin-embedded tissues. Pearson correlation analysis was performed. Results: Seventy four cases (83.15%) were male, while 15 cases (16.85%) were female. The mean age was 39.44 years. Among 170 wound samples 74 (43.5%) were gunshot wound, 20 (11.8%) were blunt injury and 76 (44.7%) were sharp weapon injury or surgical excision. Tenascin was negative in 123 cases (72.4%) in all series; it was negative in 98.3% in cases with wound age under 24 hours. It was positive in 91.8% in cases with wound age over 24 hours. Mean number of cells that express ubiquitin was 10.56%, while it was 4.25% in cases less than 24 hour wound age and, it was 26.14% in cases over 24 hours wound age. In correlation analysis both tenascin and ubiquitin were positively correlated with wound age. But in

cases with wound age over 40 days tenascin becomes negative and ubiquitin is still expressed in fibroblasts. Conclusion: We conclude that tenascin and ubiquitin together is useful in determining wound age semi quantitatively.

PP3-203
MERKEL CELL CARCINOMA – TWO CASE REPORTS

Anastasia Nikolaidou[1], Rodi Kotakidou[2], Christos Tsalikidis[3], Athena Kriaka[2]
[1] Department of Pathology, General Hospital of Kilkis, Greece
[2] Department of Pathology, General Hospital "G. Gennimatas", Thessaloniki, Greece
[3] 2nd Department of Surgery, University Hospital of Alexandroupoli, Greece

BACKROUND: Merkel cell carcinoma (MCC) is a distinctive cutaneous malignancy also known as neuroendocrine carcinoma of the skin. It is a rare disease in which malignant cells are located on or gust beneath the skin and in hair follicles. MCC has a malignant potential and thus prompt aggressive treatment is indicated. METHODS & RESULTS: We report two cases, a 28 years old male with a subcutaneous tumor located in the upper left arm measuring 2 cm and a 66 years old female with a subcutaneous tumor located in the buttock measuring 4 cm. The tumors were completely excised and submitted for histopathological examination. The latter showed dediffentiated malignant neoplasms consisting of small and medium sized cells with scanty cytoplasm, oval, hyperchromatic nuclei and numerous mitotic figures. The tumor cells were arranged in a diffused pattern or formed tiny nodules. The tumor extended deeply into the subcutaneous fat. The diagnosis of MCC was confirmed by histological and immunohistochemical analysis. The tumor cells stained positively for neurospecific- enolase, synaptophysin , chromogranin A, cytokeratin 20 and cytokeratin AE1/AE3. CONCLUSION: The differential diagnosis of MCC contains a vast variety of entities among which primary or metastatic malignant tumors are included. It is therefore important to combine physical examination detailed historical data and thorough histological immunohistochemical, ultrastructural even cytogenetic study in order to establish a prompt diagnosis

PP3-204
UNCOMMON METASTASES OF MELANOMA WITHOUT KNOWN PRIMARY LESIONS

Anastasia Nikolaidou[1], Elisavet Pazarli[1], Michael Katsamakas[2], Christos Tsalikidis[3], Andreas Tsalikidis[2], Anastasia Kiziridou[4]
[1] Department of Pathology, General Hospital of Kilkis, Greece
[2] Department of Surgery, General Hospital of Kilkis, Greece
[3] 2nd Department of Surgery, University Hospital of Alexandroupoli, Greece
[4] Department of Pathology, ''Theagenion'' Anticancer Institute of Thessaloniki, Greece

BACKGROUND: Clinically and histologically melanomas exhibit variant patterns of presentation. Melanoma is one of the malignant neoplasms that can regress, partially or completelly. The incidence of complete regression is 2,4 - 8,7 %. This means that many tumors considered to be primary could be metastases after the true primary lesion has regressed. METHOD AND RESULTS: We report four cases of male patients, 69 – 81 years old with unusual metastases, two with gastric melanoma, one at the inguinocrural area and one of the oral mucosa. None of them had a history of primary dermal melanoma. Two of the patients presented with symptoms of the gastrointestinal tract, one patient for treating incarcerated inguinal hernia and the fourth for ulcerative lesion of the oral cavity. The first two patients underwent gastroscopy and a biopsy was taken from an ulcerative neoplastic lesion of the stomach, the third one had a mass the size of tangerine surgically excised from his inguinocrural area and the fourth had un ulcerative lesion also excised. According to the morphological and immunohistochemical findings (positivity for melanoma antigen, HMB-45, S-100 protein and vimentin and negativity for CEA, EMA, cytokeratin AE1 & AE3 and low molecular weight keratin) we diagnosed malignant melanoma in all cases. CONCLUSION: The cases we present are rare, especially in a general hospital. If there is no history of a prior melanoma, problems as far as the identification of the neoplasm can be set. Independently of the primary site or secondary tumor, we must keep in mind that melanomas must be included in differential diagnosis of a neoplasm with poor differentiation.

PP3-205
MERKEL CELL CARCINOMA IN INGUINAL LYMPH NODE IN THE ABSENCE OF A PRIMARY SKIN TUMOR - A CASE REPORT

Persefoni Xirou[1], Ioannis Dimitriadis[1], Kaliopi Gianna[1], Doxakis Anestakis[1], Barbara Christoforidou[1], Konstantinos Setzis[2], Frideriki Patakiouta[1]
[1] Department of Pathology, "Theagenion" Cancer Hospital, Thessaloniki, Greece
[2] Department of Surgery, "Theagenion" Cancer Hospital, Thessaloniki, Greece

Introduction: Merkel cell carcinoma (MCC) is an aggressive primary neuroendocrine neoplasm of the skin, probably originating from precursor cells which give rise to keratinocytes and Merkel cells. It occurs mainly in elderly individuals, slightly more commonly in women, the head, neck and extremities being the most common location. Purpose: We report a rare case of MCC confined within an inguinal lymph node at the time of presentation. Case report: A 56 year old man presented with a large deep-seated mass in the right inguinal region, measuring 6 cm in maximum diameter, which was surgically resected. Histological examination revealed a lymph node extensively involved by malignant neoplasm with histological and immunohistochemical features of Merkel cell carcinoma. After thorough investigation of the patient, no primary skin tumour was found. Discussion: Merkel cell carcinoma is a highly malignant primary tumour of the skin, known for its propensity to metastasize early. MCCs within lymph nodes in the absence of a primary tumour have been sporadically reported. These rare malignant neoplasms might repesent metastases from an occult or totally regressed primary carcinoma. Other proposed explanations for their occurrence are malignant transformation of preexisting intranodal epithelial inclusions or anomalous carcinomatous differentiation of stem cells of the lymphoreticular system.

PP3-206
MALIGNANT GLOMUS TUMOR ARISING FROM A BENIGN GLOMUS TUMOR: A CASE REPORT

Roberto Salmaso[1], Marina Gardiman[1], Donatella Mannicci[2], Amihood Cohen[3], Ambrogio Fassina[4]
[1] Department of Oncological and Surgical Sciences Section of Pathology Padua University, Italy
[2] Department of Gynecological Science, Padua University, Italy
[3] Department of Plastic Surgery, Padua University, Italy
[4] Department of Oncological and Surgical Sciences, Section of Pathology, Unit of Cytopathology Padua University, Italy

Glomus Tumours (GT) are benign tumours originatin from modified smooth muscle cells of the normal glomus body. GT are solitary, small size, painful lesions usually localized in the upper extremities, with predilection of subungueal regions. Rarely, GT may display unusual features as large size, infiltrative growth, mitotic activity, nuclear pleomorphism and necrosis.A 46 year old man presented with a painful, rapidly enlarging, dermal-ipodermal nodule noted three months before on the medial face of the right leg. The lesion was surgically removed without problems and grossly was cm 2,2 in diameter, solid, non necrotic

and well circumscribed from the surrounding adipose tissues. Microscopically, the lesion appeared multinodular, circumscribed by a fibrous capsule, and composed by a population of round and fusiform cells with round nuclei and eosinophilic cytoplasms. The neoplastic glomic cells were organized in monotonous nests and sheets and formed collars around many blood vessels with prominent endothelial cells. Near the margins of the surgical excision, there were two accessory highly cellular nodules, with marked nuclear atypia, elevated mitotic index (> 30 mitoses / 50 HPF) with atypical mitotic figures, and with rare vascular channels.Immunohistochemical staining for alpha-smooth muscle actin and type IV collagen were suggestive for the glomic origin of the lesion, while MIB-1 reactivity demonstrated a strong difference between the two accessory nodules (> 17%) and the larger neoplastic nodule (< 2%). We concluded for a final diagnosis of malignant glomus tumour (MGT) arising in a benign glomus tumour. The differential diagnosis of MGT is broad. In the skin it can be confused with skin adnexal neoplasms including nodular hidradenoma, hidradenocarcinoma and eccrine spiradenoma. Demonstration of S-100 protein expression and HMB-45 positivity permits the distinction of malignant melanoma and clear cell sarcoma from MGT. Also small round blue cells tumour can be confused with MGT (cytokeratin 20 negative) including Merkel cell carcinoma (cytokeratin 20 positive), Ewing sarcoma and PNET (both muscle actins negative). In the deep soft tissues, MGT (CD 34 negative) should be distinguished from hemangiopericytoma (CD 34 positive), leyomiosarcoma and rhabdomyosarcoma. MGT is a low-grade malignant tumour, locally aggressive but rarely metastatizing, although more than 25% of the reported cases developped metastasis. A wide local excision with histopathologically free margins and close follow up is considered the treatment of choice.

PP3-207
A DERMATOFIBROSARCOMA PROTUBERANS (DFSP) OCCURRING IN A SITE OF MULTIPLE CORTICOID INJECTIONS

Mameri Saâdia, Bouzid-Bendisari Kheira
CHU Béni-Messous, Algeria

Background: DFSP is a mesenchymal sub-cutaneous tumor characterized by a strong tendency to recur, rarely metastasizing, which grows very slowly. In some instances, inflammatory conditions like trauma, sites of injections, vaccinal scars, burns have preceded the apparition of the DFSP. Method: We report one case concerning a woman of 53 years old .She has been affected 8 years ago by a DFSP on the left shoulder. This one occurred on the site of multiple corticoïd injections for a severe rheumatoid polyarthritis. The clinical exam reveals a round mass, firm covered by a very thin skin, badly limited in the hypodermis with a pink section. Many tumor specimens are realized and stained by hematoxylin-eosine. Results: The microscopic analysis shows a dermal tumor with a Grenz zone.It is composed of spindle cells arranged in a classical storiform pattern (cartwheel pattern).An immunostain for CD34 gives a diffusely and intensively positivity confirming the diagnosis of DFSP. Conclusion: Some patients relate their DFSP to a prior trauma. Only few authors report factors or conditions which precede the apparition of the lesion while others consider these factors just like a coincidence. This aspect must be known in order to control every imperfectly cicatrisation after a vaccination or repeated injections. This imperfectly scar must be analysed because the recommended surgical resection of a DFSP is a wide deeply excision with margins as large as possible.

PP3-208
SILVER STAINED ORGANIZER REGIONS AND IMMUNOGLOBULINS IN CUTANEOUS KERATOACANTHOMAS AND SQUAMOUS CELL CARCINOMAS

Kiriaki Aroni, Aikaterini Mastoraki
Department of Dermatopathology, Kapodistrian University of Athens, Greece

Background: The aim of the study was to investigate the epidermal cells biological activity in Keratoacanthomas (KAs) and Squamous Cell Carcinomas (SCCs) by counting the number of silver stained Nucleolar Organizer Regions (AgNORs), to estimate the quantity of Ig-producing cells and the inflammatory cellular infiltrate (ICI) in these entities and to achieve a comparative evaluation of them. Method: Thirty KAs (10 in growth stage, 10 in mature stage and 10 in involution stage) and 28 SCCs (9 well differentiated-G1, 7 moderately differentiated-G2, 5 poorly differentiated-G3 and 7 pseudoadenoid) were investigated. Results: The KAs examined had a mean number of 1.727 AgNORs (S.D. 0.232) and IgG predominated in most cases. IgG and IgE increase at the involution stage, IgA remains at almost the same level in the three stages and IgM decreases during the maturity stage. The SCCs examined had a mean number of 2.105 AgNORs (S.D. 0.446). IgG predominated and gradually increases in proportion to the degree of malignancy. Conclusion: There is a significant difference in the number of AgNORs among the three stages of KA with an increase in the growth and involution stage and a drop during the maturity stage. The proportion of Ig subclasses was different in the three tumor stages in contrast to the cellular infiltrate. In SCCs, the number of AgNORs and the percentage of Igs and ICI increased gradually in proportion to the degree of malignancy.

PP3-209
ECCRINE SPIRADENOMA MIMICKING THYMOMA

Stephanie Vgenopoulou[1], Georgia Levidou[2], Athina Androulaki[1], Grigorios Kouraklis[3]
[1] First Department of Pathology, University of Athens, Laiko Hospital, Greece
[2] National and Kapodistrian University of Athens, School of Medicine, First Department of Pathology, Greece
[3] Second Department of Surgery, University of Athens Medical School, Laiko Hospital, Greece

Eccrine spiradenomas are well demarcated, lobular, often painful adenomas that can be encountered almost anywhere on the body. Occasionally, eccrine spiradenomas show a heavy lymphocytic infiltrate with a resulting appearance reminiscent of thymoma. Here we present such a case. Our case was investigated immunohistochemically with a wide range of antibodies, including lymphocytic and epithelial markers. A comparative study of histological and immunohistochemical characteristics of eccrine spiradenomas in contrast to thymomas was carried out. After a comprehensive study of both morphological and immunohistochemical parameters, we reached a diagnosis of eccrine spiradenoma. The lymphocytic markers CD1a and CD99 which are markers of an immature T-cell phenotype, were found to be negative in our case, verifying the diagnosis of spiradenoma. Despite overlapping histomorphological features of eccrine spiradenoma and thymoma, the immunophenotype of the lymphocytes is helpful in the differential diagnosis of the two entities. In thymomas, the T-cell population has an immature immunophenotype and shows positive staining for CD1a and CD99, while in spiradenomas, the T-cell population has a mature immunophenotype and is hence negative for the above mentioned markers.

PP3-210

THE SIGNIFICIANCE OF HISTOLOGICAL PATERNS IN POSITIVE PPD TEST SITE

Aptullah Haholu[1], Faruk Ciftci[2], Ozlem Karabudak[3], Ali Kutlu[4], Bulent Bozkurt[4], Huseyin Baloglu[1]
[1] Gulhane Medical Academy Haydarpasa Training Hospital Deparment of Pathology, Turkey
[2] Gulhane Medical Academy Haydarpasa Training Hospital Deparment of Chest Disease, Turkey
[3] Gulhane Medical Academy Haydarpasa Training Hospital Deparment of Dermatology, Turkey
[4] Gulhane Medical Academy Haydarpasa Training Hospital Deparment of Allergy, Turkey

BACKGROUND: The histologic features of tuberculin skin test site is not uniform. It may be related to status of tuberculosis. The aim of this study was to compare the histological patterns of tuberculin skin test reaction of the patients with active and latent pulmonary tuberculosis and to investigate the histopathological differences between them. METHODS: Forty-eight PPD positive cases were chosen for the study among the patients admitted to Gulhane Medical Academy, Haydarpasa Training Hospital, Department of Chest Disease in the year 2006. Thirty of the subjects had active tuberculosis. A 3 mm punch-biopsy specimen was taken from the central portion of the skin reaction after obtaining informed consent from these PPD positive subjects. They were processed in a usual way. Sections were stained with hematoxylin-eosin and examined under light microscope. The histological patterns of reactions were classified into three types: (a) Perivascular (PV) type, (b) Basal spongiotic dermatitis (BSD) type, (c) erythema multiforme (EM) type. The histological patterns in active tuberculosis and latent tuberculosis were comparatively evaluated by statistical analysis. RESULTS: There were 17 (56.7%) EM type, 9 (30%) BSD-type and 4 (%13.3) PV-type inflammatory reactions among 30 active tuberculosis patients. There were 2 (11.1%) EM-type, 7(38.8%) BSD-type and 9 (50%) PV-type inflammatory reactions among 18 latent tuberculosis patients. The EM type inflammations were frequently seen in active tuberculosis group than in latent tuberculosis (56.7% vs. 11.1%) ($p<0.05$). However, the PM type inflammations were less frequently seen in active tuberculosis group than in latent tuberculosis (%13.3 vs. 50%) ($p<0.05$). The BSD type inflammation frequencies between both groups were not significant. Interestingly, the bullae formations were only seen in 7 subjects with active tuberculosis. CONCLUSION: The histological pattern of PPD reaction sites may be an important sign reflecting the nature of the tuberculosis, which may be either latent or active. The bullae formation, another histological finding in our study, seems to be a specific sign for active pulmonary tuberculosis. Further detailed immunohistopathological studies of PPD biopsies including large number of cases might give important clues about tuberculosis immunology.

PP3-211

CHARACTERISTICS OF PRIMARY CUTANEOUS B-CELL LYMPHOMAS: CLINICOPATHOLOGIC FEATURES, IMMUNOPHENOTYPIC PROFILE AND PROGNOSTIC FACTORS

Lebriz Uslu[1], Cuyan Demirkesen[1], Oya Oguz[2], Nahide Onsun[3], Nukhet Tuzuner[1]
[1] Department of Pathology, Cerrahpasa Medical Faculty,Istanbul University, Istanbul, Turkey
[2] Department of Dermatology, Cerrahpasa Medical Faculty,Istanbul University, Istanbul, Turkey
[3] Department of Dermatology, Vakif Gureba Teaching Hospital, Istanbul, Turkey

Background: In the recent WHO-EORTC classification for cutaneous lymphomas, primary cutaneous B-cell lymphoma (PCBL) include cutaneous follicle center lymphoma (PCFCL), cutaneous marginal zone B-cell lymphoma (PCMZL), diffuse large B-cell lymphoma, “leg type” (PCLBCL-LT) and diffuse large B-cell lymphoma, “other type” (PCLBCL-O). Both PCFCL and PCMZL are indolent lymphomas with good prognosis, while PCLBCL has an intermediate-level prognosis. Method and results: In our study, 40 patients with PCBL were reviewed and reclassified according to the new classification scheme. All of the patients, diagnosed during 11-year period (1996-2007), were analyzed for clinicopathologic features, expression of several markers including CD20, Bcl-2, Bcl-6, MUM-1 and Ki-67, in situ hybridization for Epstein-Barr virus, and of Borrelia burgdorferi. The histologic features and the immunophenotypic profiles of each lymphoma group were stated. The patients were classified into the following categories: PCFCL, 16 patients, PCMZL, 16 patients, PCLBCL-LT, 6 patients and PCLBCL-O, 2 patients. The associations between histology, skin site, the number of lesions and survival were determined. Conclusion: The results underlined the clinical significance of the new classification, the importance of the localization and the number of lesions.

PP3-212

PRIMARY CUTANEOUS CD30(+) LYMPHOPROLIFERATIVE DISORDERS: LYMPHOMATOID PAPULOSIS AND PRIMARY CUTANEOUS ANAPLASTIC LARGE CELL LYMPHOMA

Erdem Caglar[1], Cuyan Demirkesen[1], Oya Oguz[2], Nahide Onsun[3], Nukhet Tuzuner[1]
[1] Department of Pathology, Cerrahpasa Medical Faculty,Istanbul University, Istanbul, Turkey
[2] Department of Dermatology, Cerrahpasa Medical Faculty,Istanbul University, Istanbul, Turkey
[3] Department of Dermatology, Vakif Gureba Teaching Hospital, Istanbul, Turkey

Background: Primary cutaneous CD30(+) lymphoproliferative disorders (LPD) are considered as the second most common group among primary cutaneous T-cell lymphomas (CTCL). Method and results: We reviewed 74 cases displaying atypical CD30(+) large cells in their biopsies. All of the patients, diagnosed during 12-year period (1995-2007), were analyzed for clinicopathologic features, expression of several markers including CD3, CD5, CD4, CD8, CD56, CD30, ALK, EMA, cytotoxic proteins such as granzyme B and in situ hybridization for Epstein-Barr virus (EBV). The patients were categorized as: Lymphomatoid papulosis (LyP), 34 patients, primary cutaneous anaplastic large cell lymphoma (ALCL), 16 cases, borderline CD30(+) LPD, 5 patients, ALCL, B-cell type, 1 patient, MF transformed into CD30(+) large cell lymphoma, 9 patients. One case of LyP and one case of CD30(+) borderline LPD suffered also from mycosis fungoides (MF). ALCL, B-cell type was associated with EBV. Other than these, there were 2 cases of scabies and 6 cases of arthropod bite, showing numerous CD30(+) large T-cells. Conclusion: The results underlined the importance of clinicopathologic correlation. Sometimes the course should be used as decisive criteria for the definite diagnosis. The prognosis of primary cutaneous CD30(+) LPD were excellent, however, MF, transformed into CD30(+) large cell lymphoma had an aggressive course.

PP3-213

PRIMARY CUTANEOUS T-CELL LYMPHOMAS OTHER THAN MYCOSIS FUNGOIDES AND PRIMARY CUTANEOUS CD30 (+) LYMPHOPROLIFERATIVE DISORDERS

Murat Ozbalak[1], Cuyan Demirkesen[1], Oya Oguz[2], Nahide Onsun[3], Nukhet Tuzuner[1]
[1] Department of Pathology, Cerrahpasa Medical Faculty,Istanbul University, Istanbul, Turkey
[2] Department of Dermatology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey
[3] Department of Dermatology, Vakif Gureba Teaching Hospital, Istanbul, Turkey

Background: Among primary cutaneous T-cell lymphoma (CTCL) Mycosis fungoides (MF), together with its variants and subtypes, is the most common type of CTCL. The second most common type is primary cutaneous CD30(+) lymphoproliferative disorders (LPD), accounting for approximately 30% of CTCL. In the recent WHO-EORTC classification for cutaneous lymphomas, the rest is classified as subcutaneous panniculitis-like T-cell lymphoma, extranodal NK/T-cell lymphoma, nasal type, primary cutaneous aggressive epidermotropic CD8(+) T-cell lymphoma (provisional), cutaneous γ/δ T-cell lymphoma (provisional), primary cutaneous CD4(+) small/medium-sized pleomorphic T-cell lymphoma (provisional) and , primary cutaneous peripheral T-cell lymphoma, unspecified. Method and results: In our study, 17 patients with CTCL other than MFand primary cutaneous CD30(+) LPD, were reviewed and reclassified according to the new classification scheme. All of the patients, diagnosed during 10-year period (1996-2006), were analyzed for clinicopathologic features, expression of several markers including CD3, CD5, CD4, CD8, CD56, CD30, granzyme B and in situ hybridization for Epstein-Barr virus. The patients were classified into the following categories: Subcutaneous panniculitis-like T-cell lymphoma, 1 patient, extranodal NK/T-cell lymphoma, nasal type, 4 patients, primary cutaneous CD4(+) small/medium-sized pleomorphic T-cell lymphoma, 3 patients, primary cutaneous peripheral T-cell lymphoma, unspecified, 5 patients. There were 3 MF and 1 pagetoid reticulosis patients, who were transformed into CD30(-) large T-cell lymphoma. Two patients were diagnosed as CD4(+)/CD56(+) hematodermic neoplasm (blastic NK cell lymphoma). Conclusion: The clinical and histologic features, the immunophenotypic profiles and their association with prognosis were analyzed.

PP3-214

CLEAR CELL HIDRADENOCARCINOMA ARISING IN A NEVUS SEBACEUS

Roberto Salmaso[1], Marina Gardiman[1], Amihood Cohen[2], Donatella Mannicci[3], Luciano Giacomelli[4], Ambrogio Fassina[4]
[1] Department of Oncological and Surgical Sciences Section of Pathology, Padua University, Italy
[2] Department of Plastic Surgery, Padua University, Italy
[3] Department of Gynecological Science, University of Padua, Italy
[4] Department of Oncological and Surgical Sciences, Section of Pathology, Unit of Cytopathology, Padua University, Italy

The nevus sebaceus of Jadassohn (SNJ) is a hamartomatous proliferation of the skin and adnexa arising in the face and scalp of adults, with frequent association with several neoplasms, most commonly basal cell carcinoma, trichoblastoma, tichoepitelioma and syringocystadenoma papilliferum. We report the case of a 46 year-old female with hidro-adenocarcinoma demonstrating both apocrine and eccrine differentiation arising in a long standing nevus sebaceus on the scalp. Microscopically, the epidermis showed focal benign basaloid hyperplasia and irregular follicles. A small dermal collection of basaloid sebocytes was suggestive of a sebaceoma. The large part of the lesion was composed of lobules of epithelium with focal cystic spaces. The cells showed high mitotic activity and nuclear pleomorphism, with cytoplasmic vacuoles containing abundant glycogen. Cells with eosinophilic cytoplasm were evident in areas adjacent to groups of basaloid cells with no vacuolation very similar to basal cell carcinoma differentiation. Ductal differentiation with well-formed papillae and focal cribriform structures were also present. Other portions demonstrated a high-grade neoplasm with prominent nuclear atypia and a solid pattern of growth resembling ductal breast carcinoma. EMA strongly stained tumor cells and highlighted the ductal origin of these structures. Less than 4% of cells stained for progesterone and estrogen receptors. Her2/neu reactivity was focally present showing 1+ membranous reactivity in 10% of cells. Anti-p63 labelled the basaloid cells surrounding the tumor lobules. A breast primary was ruled out by clinical and radiological examination. Other tumors showing conspicuous cytoplasmatic vacuolation enter the differential diagnosis, including clear cells squamous carcinoma, trichilemmal carcinoma and metastatic clear renal cell carcinoma, lung, liver and female genital tract. This report illustrates an extraordinary adnexal neoplasm with multiple lines of differentiation arising "de novo" in a SNJ.

PP3-215

FOLLICULO-SEBACEOUS CYSTIC HAMARTOMA: REPORT OF 16 CASES

Fernando Terrasa[1], Alexandra Gené[2], David R Berk[3], Carlos Saus[2], Rosa Taberner[1], Daniel Santa Cruz[4]
[1] Hospital Son Llatzer, Mallorca, Spain
[2] Hospital Son Dureta, Mallorca, Spain
[3] Washington University School of Medicine, St. Louis,MO, USA
[4] Cutaneous Pathology, St. Louis, MO, USA

BACKGROUND Folliculo-sebaceous cystic hamartoma (FSCH), described by Kimura et al. in 1991, is an uncommon malformation composed of epithelial and nonepithelial elements that grow into an infundibular cyst-like structure, with sebaceous glands and ducts radiating from it, and surrounded by a fibrous stroma with variable amounts of vascular or adipose tissue. Some authors have reported neural elements or myxoid change in the stroma. METHODS We performed a retrospective search from 3 institutions between 1999 and 2006 and identified 16 cases. Specimens from all 16 cases had been fixed in formalin and routinely processed. Five □m sections were obtained and stained with hematoxylin and eosin. Alcian blue stain was also done in some cases to highlight myxoid change in the stroma. RESULTS We report 16 cases of FSCH including 11 women and 5 men, ranging from 24 to 87 years-old. Six lesions occurred on the nose, 5 on the trunk, 3 on the scalp, 1 on the cheek and 1 on the labia minora. Epidermal induction, similar to that encountered in dermatofibroma, was present in 10 cases. Reactive melanocytic hyperplasia was present in 5 cases, including 1 which was prominent, similar to junctional nevus. Myxoid stromal change occurred in 4 cases. Hair shafts in the infundibulum were present in 4 cases. One case that presented as several papules around a scar was a recurrence of a hamartoma removed 7 years earlier. CONCLUSIONS FSCH is a rare benign skin lesion, probably underdiagnosed due to its wide range of histological appearances. We report here 16 cases of FSCH, the largest series of this lesion to date. Some rarely described features such as myxoid stromal change, presence of hair shafts in the infundibulum, epidermal induction and melanocytic hyperplasia appear to be fairly common. We also report a previously undescribed mucosal location (labia minora), and the first local recurrence. Histological recognition of FSCH is crucial to distinguish it from other mucinous or hamartomatous lesions.

PP3-216

ROLE OF MISMATCH REPAIR PROTEINS AND TELOMERASE IN CELL KINETICS OF SUPERFICIAL SQUAMOUS CELL CARCINOMA OF THE SKIN

Alfredo Blanes[1], Inmaculada Ruiz[1], Juan José Sánchez-Carrillo[1], Blanca Cabra De Luna[1], Salvador J Diaz-Cano[2]
[1] University Hospital of Malaga School of Medicine, Malaga, Spain
[2] Department of Histopathology, King's College Hospital, London, United Kingdom

Background: The cell kinetic of superficial squamous cell carcinoma (SCC) has revealed controversial results due to the heterogeneity of lesions considered, making more difficult to assess key elements in squamous cell tumor progression. This study analyzes kinetic, cell survival and mismatch repair in a series of high-grade intraepithelial and microinvasive SCC. Design: We selected bowenoid actinic keratosis (HG-AK, 22 cases), SCC in-situ (37 cases) and microinvasive SCC (<3mm depth, 36 cases) that have appropriate archival material. Representative samples were evaluated by standard immunohistochemistry for MCM2 (minichromosome maintenance-2), telomerase, mlh1, msh2 and TP53. The immunoexpression was assessed in the whole lesion and the positive cells as percentage of tumor cells. Appropriate controls were run in each sample. The results were statistically compared using analysis of variance and Student t-test, and considered significant if $P<0.05$. Results: MCM2 inmunoreactivity was observed in 9% of cellularity of AK-HG, 19.17% of SCC IN-SITU and 28.58% of SCC MICRO. TELOMERASE was expressed in 55.75% (AK-HG), 48.08% (SCC IN-SITU) and 72.39% (SCC MICRO). MLH1/MSH2: in 7.73% (AK-HG), 19.04% (SCC IN-SITU) and 20.15% (SCC MICRO) (NULL: 58% AK-HG, 12.7% SCC IN-SITU and 10.86% SCC MICRO) and finally, TP53 inmunoreactivity in 30.5% (AK-HG), 32.78% (SCC IN-SITU) and 36.63% (SCC MICRO). Both MCM2 and TP53 expression increased from HG-AK to microinvasive SCC, revealing no statistically significant differences. Telomerase showed significantly upregulated expression in microinvasive SCC when compared with intraepidermal lesions ($P=0.0037$) and mlh1 expression was significantly down-regulated in HG-AK ($P=0.0022$). Conclusions: 1) The invasion capacity in superficial SCC is marked by up-regulation of telomerase in lesions preferentially expressing abnormal TP53. 2) The differential growth pattern of intraepidermal SCC is kinetically related with down-regulation of mismatch repair proteins.

PP3-217

A COLLISION TUMOR OF THE SKIN ASSOCIATING BASAL CELL CARCINOMA AND NODULAR MALIGNANT MELANOMA (MALIGNANT BASOMELANOCYTIC TUMOR)

Alexandra Bastian[1], Geanina Micu[1], Razvan Andrei[1], Luciana Nichita[1], Carmen Ardeleanu[2], Florica Staniceanu[3], Virginia Chitu[4]
[1] Colentina University Hospital, Department of Pathology, Bucharest, Romania
[2] Victor Babes Institute, Bucharest, Romania
[3] Colentina University Hospital, Bucharest, Romania
[4] Colentina University Hospital, Department of Dermatology, Bucharest, Romania

Background: The coexistence of two malignant tumors in the same histological specimen is rare. A collision tumor consisting in basal cell carcinoma and malignant melanoma (malignant basomelanocytic tumor) has been rarely reported. Most of these case reports presented in situ malignant melanoma component. Material and method: We report the case of an 86 years old woman with a whitish, ulcerated tumor of the left cheek, macroscopically measuring 3/1.5/0.8 cm. Results: Histological examination revealed basal cell carcinoma solid type with adenoid areas that invades the reticular dermis admixed with ulcerated and amelanotic, nodular malignant melanoma, Clark level IV and Breslow index 5.9 mm (maximum thickness of the tumor). In some areas the distinction of the two lesions was difficult. Cords and islands of basal cell carcinoma invade malignant melanoma nodule with intimate association of these two cell populations. Both lesions have been closely attached to the epidermis, data supporting primary cutaneous origin of both of the tumoral proliferations. Immunohistochemical studies showed that the malignant melanoma component was positive for S100 protein, HMB45 and CD63 and negative for CK34betaE12 and BerEp4, while the basal cell carcinoma component of the tumor was negative for S100 protein, HMB45 and CD63 and positive for CK34betaE12 and BerEp4. Conclusion: This collision tumor could be interpreted as a tumor with bidirectional keratinocytic and melanocytic differentiation or a coincidence, an extremely rare event.

PP3-218

PROGNOSTIC FACTORS FOR RECCURRENCES IN BASAL CELL CARCINOMA

Alexandra Bastian[1], Geanina Micu[1], Irina Tudose[1], Adina Ene[1], Razvan Andrei[1], Sabina Zurac[1], Eliza Gramada[1], Dragos Simeanu[1], Florica Staniceanu[1], Dorina Giurcaneanu[2]
[1] Colentina University Hospital, Department of Pathology, Bucharest, Romania
[2] Colentina University Hospital, Department of Dermatology, Bucharest, Romania

Background: Basal cell carcinoma (BCC) is the most common cutaneous malignant tumor that occurs at any age with increased incidence after the 4-th decade. BCC rarely metastasize (reported incidence of 0.0028-0.5%), but it causes a considerable morbidity by invading and destroying the surrounding tissue and location especially involving the head and neck region. Method: We studied 366 cases diagnosed in our department with BCC in two consecutive years. Among these, 335 cases were primary BCC (group A) and 31 were recurrences of a previously resected BCC (group B). We analyzed clinical informations, location, histological types and the integrality of excision. Results: Insignificant differences were recorded in respect of sex or age between the two groups, but the location of the tumors was different between the two groups. All the group B cases occurred in the head area (nose 32.25%, zygomatic 16.12%, perioral 12.90%, temporal 6.45%, orbital area 6.45%, frontal 3.22%, laterocervical 3.22%) while group A included 206 cases (61.49%) in the head area (orbital area 21.94%, nose 12%, zygomatic 6.56%, temporal 6.26%, frontal 4.18%, perioral 1.19%, laterocervical 0.89%) and 129 cases (38.50%) with other locations. There was a preponderance of adenoid, keratotic and metatipic types in both group A and B. We noticed that the infiltrative type of BCC was quite rare: 23 cases in group A (5.67%) and 4 in group B (1.09%). Incomplete excision was found in 93 cases (27.76%) of the group A and 13 cases (41.93%) of the group B. Conclusion: The aim of entire excision of BCC is difficult to obtain because of both macroscopic indistinct margins of tumors and the need of maximal skin preservation that appear in specific areas as eyelid or nose. There is even more difficult to entirely remove the recurrent BCC because of the preexisting scars that interfere with complete excision. Despite our expectations, we found a low correlation between the infiltrative histological subtype of BCC and recurrence. The location and the completeness of the excision have a stronger influence on the recurrence rate than the histological type. The adequate excision of the primary tumor is the key of surgical treatment in BCC.

PP3-219

LYMPHOEPITHELIAL CARCINOMA OF THE LARYNX IN A 60-YEAR-OLD TUNISIAN MAN

Sarra Mestiri, Amel Trabelsi, InéS Kalamoun, Lilia Ben Yacoub-Abid, Thouraya Aachech, Badreddine Sriha, Moncef Mokni, Sadok Korbi
Service de Pathologie, Hopital F. Hached, 4000 Sousse, Tunisie

Background: Lymphoepithelial carcinoma of the larynx is extremely rare, representing less of 0,5 % of larynx carcinomas, it is uncommonly associated with Epstein Barr Virus. Method: We report a case of a 60 year-old Tunisian man, who presented with hoarseness, dyspnea. Laryngoscopy showed a tumor of the left larynx extending to the pharynx. Biopsy and the resection specimen were both submitted for histopathological study. In-situ hybridization was performed in the latter to detect the presence of Epstein-Barr virus . Results : Histopathological examination of the specimen biopsy showed an undifferentiated carcinoma with a prominent lympho-plasmocytic infiltrate. A pharyngolaryngectomy with left neck dissection was performed and the final diagnosis retained was a lymphoepithelial carcinoma non EBV induced. A post-operative radiotherapy was indicated. Clinical outcome was favourable one year later without any recurrence nor metastasis. Conclusion: Through this case and literature review, the diagnosis and therapeutic problems raised by this very rare tumor are discussed.

PP3-220

CHRONIC SINO-NASAL PROGRESSIVE DESTRUCTIVE DISEASE IN COCAINE ABUSERS: A MORPHOLOGICAL STUDY AND ELABORATION OF A GRADING

Barbara Paola Banzatti, Francesco Klinger, Valeria Bandi, Angelo Virgilio Pagliari, Marco Klinger
Plastic Surgery Institute - University of Milan - Plastic Surgery Unit - Istituto Clinico Humanitas - IRCCS – Milano, Italy

Background In the last decade cocaine consumption as a recreational drug by snorting or sniffing has worlwide increased. Cocaine can cause tissue damage virtually in every organ system. Cocaine's adverse effect on the nasal cavity was recognized and described first by Owens in 1910 and cause heterogeneous spectrum of lesions from ulceration and nasal septum perforation to idiopathic central facial destructive granuloma. Mehod A population of 16 cocaine abusers patients was carefully investigated by the standard clinical, laboratory, radiological methods and multiple biopsies of the nose. Results In all cases the erythrocyte sedimentation rate was elevated, but the complete blood count, antinuclear, antimithocondrial, anti-DNA, antineutrophil cytoplasmatic antibodies (c-Anca) and bacteriological cultures were normal. Computed tomography showed destruction of nasal septum in 11 cases, of inferior and middle turbinate in 3 cases, of medial wall of maxillary sinus and of hard palate in one patient. Biopsy specimens showed no evidence of malignancy, vasculitis or granulomatosis. In nasal mucosa microscopy found an acute, chronic and partly necrotising inflammation process. Interesting in this condition there are "onion skin" deposits of perivascular fibrosis with numerous eosiniphils. Plasma cells and lymphocytes mainly of T cell type were present in early stage. Conclusion Cocaine damage nose by a combination of intense vasoconstriction and irritation. The ischemia and irritation of the nasal mucosa lead initially to an acute inflammation clinically visualize as a dystrophic lesions (initial stage or grade 1 of cocaine lesion), then a chronic inflammation characterized by ulceration and crusting (intermediate stage or grade 2) and finally various and deeply necrosis process that cause a destruction of normal anatomic strctures such as septum, turbinate and palate (advance stage or grade 3). The altered muco-ciliary clearance and air flow together came up infection cause a continued expansion and progression of the clinico-pathologic process.

PP3-221

SURVIVIN AND INDUCIBLE NITRIC OXIDE SYNTHASE PRODUCTION DURING 4NQO-INDUCED RAT TONGUE CARCINOGENESIS: A POSSIBLE RELATIONSHIP

Daniel Araki Ribeiro[1], Darcio Kitakawa[2], Maria Aparecida Custódio Domingues[2], Luiz Antonio Guimaraes Cabral[2], Mariangela Esther Alencar Marques[2], Daisy Maria Favero Salvadori[2]
[1] Federal University of Sao Paulo, UNIFESP, Brazil
[2] Sao Paulo State University, UNESP, Brazil

Background. This study was undertaken to investigate, by immunohistochemistry, the expression of survivin and inducible nitric oxide synthase during 4NQO-induced rat tongue carcinogenesis. Methods. Male Wistar rats were distributed into three groups of 10 animals each and treated with 50 ppm 4NQO solution through their drinking water for 4, 12, and 20 weeks. Ten animals were used as negative control. Results. Although no histopathological abnormalities were induced in the epithelium after 4 weeks of carcinogen exposure, survivin and iNOS were expresssed ($p<0.05$) in some cells of the 'normal' oral epithelium. In pre-neoplastic lesions at 12 weeks following carcinogen exposure, the levels of survivin and iNOS were increased ($p<0.05$) when compared to negative control, being the strongest effect observed to iNOS. In well-differentiated squamous cell carcinoma induced after 20 weeks of treatment with 4NQO, survivin and iNOS were expressed in some tumor cells. Lack of immunoreactivity for both markers was observed in the negative control group. Conclusion. Taken together, our results support the belief that expression of survivin and iNOS are early events during malignant transformation and conversion of the oral mucosa.

PP3-222

PLACENTAL GLUTATHIONE S-TRANSFERASE CORRELATES WITH CELLULAR PROLIFERATION DURING RAT TONGUE CARCINOGENESIS INDUCED BY 4-NITROQUINOLINE 1-OXIDE

Daniel Araki Ribeiro[1], Renata Nunes Da Silva[2], Daisy Maria Favero Salvadori[2], Mariangela Esther Alencar Marques[2]
[1] Federal University of Sao Paulo, UNIFESP , Brazil
[2] Sao Paulo State University, UNESP , Brazil

Background. Taking into consideration that glutatione S-transferase (GST) and cellular proliferation play a crucial role during carcinogenesis, the goal of this study was to investigate the expression of placental GST, called GST-P, and proliferating cellular nuclear antigen (PCNA) by means of immunohistochemistry during rat tongue carcinogenesis induced by 4-nitroquinoline 1-oxide (4NQO). This is a useful model for studying oral squamous cell carcinoma phase by phase. Method. Male Wistar rats were distributed into 3 groups of 10 animals each and treated with 50 ppm 4NQO solution by drinking water for 4, 12 or 20 weeks. Ten animals were used as negative control. Results. GST-P positive foci were detected in non-neoplastic oral cells at 4 weeks of 4NQO administration. In the same way, GST-P positive cells were detected in pre-neoplastic lesions and squamous cell carcinomas induced after 12 and 20 weeks-treatment, respectively. None of the control animals expressed GST-P positive cells. Regarding cellular proliferation, PCNA positive nuclei were higher at 12 and 20 weeks following 4NQO exposure ($p<0.05$) when compared to negative control. Conclusion. These results suggest that the expression of GST-P is correlated with cellular proliferation, in which GST-P is associated with risk and progression of oral cancer, whereas PCNA is closely involved during neoplastic conversion.

PP3-223
DIAGNOSTIC VALUE OF CYTOKERATIN MARKERS IN DIFFERENTIAL DIAGNOSIS OF SALIVARY GLAND TUMORS
Mohamad Javad Ashraf[1], Neda Bagheri[1],
Mohamad Shaghasemi[1], Negar Azarpira[2]
[1] Shiraz university of Medical Sciences, Iran
[2] Transplant Research Center, Iran

Inroduction: Salivary gland tumors have one of the most complex histopathologic features of any organ/tissue. In this study we want to evaluate diagnostic value of various cytokeratin markers and smooth muscle actin in differential diagnosis of pleomorphic adenoma (PA) and adenoid cystic carcinoma (ACC). All of the cases had both typical and atypical areas and we suppose that pattern of positivity of cytokeratin markers with SMA in atypical areas can help in proper diagnosis of poorly differentiated tumors. Material and Methods: We selected 35 cases of salivary gland tumors from the pathology files of Khalili Hospital between 2002-2006. These cases were 19 PA, 16 ACC .We performed immunohistochemical staining with six cytokeratin markers (CK7, CK8, CK13, CK14, CK17 and CK18) and SMA. Positivity was defined if 10% or more of the cells were immunostained. Result: In PA group CK7 and CK8 showed 100% positivity in both typical and atypical area. Positivity of CK13 in typical area was 0% but in atypical area was 10.5%. SMA immunoreactivity in typical and atypical areas was 36.8% and 21% respectively (P-value 0.003). 100% of cases showed CK18 positivity in typical area whereas 42% of cases in atypical area were positive.57.9% of cases showed CK17 positivity in typical area and 26.3% in atypical area . In ACC group 87.5% of cases showed SMA positivity in typical areas and 62.5% in atypical areas . CK7 positivity was present in 93.5% of cases in typical areas and 93.8% in atypical areas (p-value = 0.00). 100% of cases revealed CK8 positivity both in typical and atypical areas. None of the cases showed immunoreactivity for CK13 in typical or atypical areas. 93.8% of cases showed immunoreactivity for CK14 in typical areas and 81.3% in atypical areas. 31.3% of cases revealed positivity for CK17 in typical areas whereas none of the cases showed positivity in atypical areas. Conclusion: The following conclusions were obtained: 1- Five markers, SMA, CK7, CK8, CK13, CK14 have significant correlation between typical and atypical areas of both pleomorphic adenoma and adenoid cystic tumors. 2- Positivity of SMA and CK8 is more infavor of ACC rather than pleomorphic adenoma. 3- Coexpression of CK7 and CK14 and simultaneous negativity of CK13 and CK18 are significantly more infavor of pleomorphic adenoma than adenoid cystic carcinoma.

PP3-224
METACHRONOUS DEVELOPMENT OF NASAL KAPOSI'S SARCOMA AND MALIGNANT MELANOMA IN A NON AIDS-RELATED PATIENT
Ioannis Venizelos, Zoi Tatsiou, Lambros Kambas,
Despoina Sioutopoulou
Department of Pathology, Hippokration Hospital,
Thessaloniki, Greece

Primary malignant neoplams of the nasal cavities is believed to comprise about 1% of all human malignancies. Moreover, nonsquamous cell malignant neoplasms are very infrequent, comprising about 0.5% of all malignant tumors in this site. Among the few reported cases of Kaposi's sarcoma (KS) involving the head and neck region, only 6 had primary presentation in the nasal cavity and 5 of them were related to the acquired immune deficiency syndrome (AIDS). Nasal malignant melanomas (MM) are rare, accounting for less than 1% of all MM. Metachronous development of nasal KS and MM in a non-AIDS related patient has not been reported. We report the case of a 59-year-old woman who was admitted in our hospital due to rhinorragia. On physical examination it was found a purplish tumor with maximum diameter 0,8 cm mostly obstructing the left nasal cavity and arising from the nasal septum. There was no peripheral lymphadenopathy, hepatosplenomegaly or skin lesions. Hematological examination and chest x-ray was normal. All laboratory tests for bacteria, viruses, HIV, fungi, parasites as well as complete immunological studies for autoimmune diseases were negative. Histological examination of the excised tumor revealed features of KS. Immunohistochemical examination showed positivity of the neoplastic cells for CD34 whereas they were negative for S100, HMB45, Melan A, EMA, SMA and CD45. The patient received no further treatment and 6 years later she was readmitted due to difficulty in breathing. On rhinoscopy a polypoid tumor was found in the left nasal cavity which was considered to be a relapse. The tumor was excised within free surgical margins, it had 3,2 cm maximum diameter and a dark colored cut surface. Histological examination showed features of MM. Immunohistochemicaly, the neoplastic cells were positive for S100, HMB45 and Melan A whereas they were negative for CD34, CD45, SMA and EMA. The patient received no further treatment and 1 year later she is in an excellent condition with no evidence of local recurrence or metastasis, both clinically and radiologically. In the present study we report a unique case of primary KS of the nasal cavity with metachronous development of MM in the same location, in a patient with adequate immune system.

PP3-225
A CASE OF CERVICAL ECTOPIC MENINGIOMA: CHALLENGING IN FROZEN SECTION
Mohammad Hossein Sanei, Nezamaldin Berjis,
Parvim Mahzouni, Azar Naimi
Isfahan University of Medical Sciences, Iran

Background Primary extracranial and extraspinal meningiomas are rare.they are usually limited to the head and neck region or to the paravertebral soft tissues. histologic diagnosis (particularly of fresh specimens) is often difficult. Case report A 16-year-old girl presented with a cervical mass.It was a sizable mass with an approximate diameter of 5 cm.It was diagnosed in fine needle aspiration as a pleomorphic adenoma. The diagnose of surgon,during the operation was paraganglioma and frozen section suggested an infiltrative tumor. Histologically, the lesion showed uniform spindle cell proliferation separated by hyalinized collagen bundles . The spindle cells were often arranged in sweeping fascicles and concentrically wrapped in tight whorls. Immunohistochemically, tumor cells were positive for EMA and vimentin,while showed negativity for cytokeratin, chromogranin,NSE and thyroglobuline. A diagnose of ectopic meningioma was established based on microscopic appearance and immunohistochemical profile of tumor. Conclusion Although rare,ectopic meningioma should be considered in differential diagnosis of any mass lesion in head and neck region,comosed of spindle cells.

PP3-226
THE Ets-1 TRANSCRIPTION FACTOR IS INVOLVED IN PTERYGIAL ANGIOGENESIS
Wallid Naib-Majani[1], Winrich Breipohl[1], Elham Elshazli[2]
[1] Department Of International Medical Education and Development University Of Bonn Germany
[2] Research Institute Of Ophthalmology, Egypt

Introduction : Pterygial pathology is characterized by abnormal corneal epithelial proliferation, stromal modulation, matrix degradation, and a strong tendency for otherwise absent corneal vascularization. As the proto-oncogene c-ets1 is known to play a key role in angiogenesis and matrix degradation in other tissues. If its involvement in corneal vascularization was to be checked. Method: 25 pterygia in two Groups. Group 1 consisted of five

clinically active, group 2 consisted of 20 samples clinical non active pterygia. were investigated with 35 S-labeled ets-1 antisense and sense in-situ hybridization of c-ets-1 transcription factor. Results: The cytoplasm of blood vessel endothelial cells showed strong expression of c-ets-1 mRNA in all group 1 pterygia. In contrast, no expression of c-Ets-1 or c-ets-1 was found in the pterygia of group 2. Conclusion: Proto-oncogene c-ets 1 expression has been shown for the first time in the metaplastic pterygium, an eye tissue of unknown pathogenesis.

ERDHEIM-CHESTER DISEASE, A CASE REPORT AND REVIEW OF LITERATURE
Maysa Al-Hussaini[1], Eman Hijazi[2]
[1] King Hussein Cancer Center, Jordan
[2] Private Sector, Jordan

Erdheim-Chester disease (ECD) is a rare form of non-Langerhans histiocytosis of unknown origin, characterized by adult onset with multi-systemic involvement, in which diffuse sclerosis of the dia-metaphysis of the long bones, especially in the lower limbs, is the most consistent finding. Orbital involvement is a rare feature seen in less then a third of cases. we are presenting a case of a 42 year old lady, who presented initially to the ophthalmology clinic with a 2 year history of progressive marked proptosis of the left eye, complicated by complete loss of vision and pain of 2 weeks duration. There was mild proptosis of the right eye, the vision however was preserved. enucleatin of the left eye revealed the presence of histiocytosis of non Langerhans cell type. Discussion of this rare form of presentation of ECD as well as review of the literature is presented.

PP3-228
DERMATOFIBROSARCOMA OF HEAD AND NECK. PATHOLOGIST POINT OF VIEW
Nadia Kourda, B Tayahi, A Landoulsi, M Helali, F Farah, J Kourda, O Lamine, M Ferchiou, A Adouani, Sarrah Baltagi Ben Jilani, R Zermani
Charle Nicolle's Hospital Department of Pathology, Tunisia

Background : Dermatofibrosarcoma protuberans (DFSP) is a rare locally aggressive malignant neoplasm. It is most commonly found on the trunk and rarely on the head and neck. In fact only 12% to 15% of the cases are localized in the head and neck region. It represents 1.4% of the soft tissue sarcomas of this area, and its main feature is the high rate of recurrence. This study defines the clinical behavior of DFSP evaluates the role of pathologist in surgical margins analysis, and identifies factors that predict local control. Methods: Hospital records and pathological slides were reviewed for 5 patients with pathologically confirmed head and neck (DFSP) treated at Charles Nicolle Hospital between 1999-2006. Results: This study included 5 cases (3 men and 2 women; mean age 38 years, (range 28–48 years) of DFSP. 4 cases were primary tumors and 1 was recurrences after surgery excision. The tumors were located in the following areas: the scalp in two cases, the cheek in three cases. In all cases clinical and instrumental examinations showed absence of regional and distant metastases. Tumor size ranged from 4 cm to 10 cm. All 5 subjects were treated by surgical excision of the tumor. 2 our 5 subjects cases were with positive margin. These 2 patients had a recurrence of the disease, after 12 months of follow up. The new lesion was treated by resection with a 5-cm margin. Conclusions: Wide margin resection of head and neck DFSP predicts negative histological margins and impacts favorably on local recurrence-free survival.

PP3-229
OSTEOPLASTIC TRACHEOPATHY
Simion George[1], Ilie Marius[1], Chirculescu Florin[2], Marinescu Elena[1], Sajin Maria[1]
[1] Department of Pathology, Emergency University Hospital Bucharest, Romania
[2] Department of Cardiothoracic Surgery, Emergency University Hospital Bucharest, Romania

Background: Osteoplastic tracheopathy is a very rare disease that presents itself as multiple submucosal nodules composed of mature bone and cartilage. Method: We report the case of a 35-year-old male diagnosed with schizophrenia 12 years ago and tried to attempt suicide by sedative ingestion. These induced comatose (GCS = 5), which required oro-tracheal intubation. The patient recovered from comatose and stabilized within 4 days. 4 months later the patient presents respiratory distress that accentuates progressively. He's diagnosed with hypercapnic acute respiratory failure (PCO2 = 120 mmHg) and subglotic tracheal stenosis. The fiberoptic bronhoscopic procedure reveals a 2.5 cm in depth / 1 cm in width subglotic tracheal stenosis, caused by multiple partially necrotic granulomas, developed mainly on the left lateral wall. After a moderate hemoptoic episode and the aggravation of respiratory troubles surgery is considered necessary: tracheal subcricoid segmentary resection with termino-terminal anastomosis. The method used for diagnose was paraffin-embedded tissue and stained with hematoxylin and eosin (H&E). Results: Histopathological out findings revealed the presence of bone and cartilage nodules and plaques mainly in subepithelial tissues, underline tracheal epithelium acanthosis and papilomatosis with richly vascularised stromal repairing tissue. Only isolated epithelial ulcerations are seen. Conclusions: In this case the lesion's etiology seems to be inflammatory, as a consequence of the oro-tracheal intubation.

PP3-230
HISTOPATHOLOGY OF FLOOR OF MOUTH LEUKOPLAKIA: A MIMIC OF ORAL LICHEN PLANUS?
Séamus Napier, Jacqueline James, Rajeev Shah
Histopathology, Royal Hospitals, Belfast, Northern Ireland

Background: Oral lichen planus (OLP) is reputed to have characteristic clinical and histopathological appearances that should allow confident diagnosis. What is not well recognised is that the histopathological features of OLP may overlap with changes due to tobacco use. The floor of mouth (FOM) is rarely affected by OLP but can develop leukoplakia in smokers. Defining the spectrum of histopathological findings of FOM leukoplakia biopsies will highlight the proportion of tobacco-associated lesions that exhibit changes similar to those seen in OLP. Method: Laboratory records were trawled for FOM biopsies from August 2000 to December 2003. When cases of carcinoma, dysplasia and other "non-leukoplakia" diagnoses were excluded, 59 suitable cases were identified. Original slides of these 59 patients were reviewed by an oral pathologist blinded to the initial diagnosis and the following features recorded semiquantitatively: degree and type of keratosis, altered epithelial thickness, intraepithelial lymphocytes, apoptotic cells, lymphoid follicles and melanin pigmentation. The findings were compared to the clinical summary and smoking history. Results: A tobacco history was recorded for 53 (90%) of patients: 50 were current smokers, 3 were "non-smokers". No smoking history was available for 6 (10%) patients. All cases exhibited hyperkeratosis and alterations of epithelial thickness, most often a mixture of ortho- and parakeratin with adjacent areas of atrophy and hyperplasia. Intraepithelial lymphoctyosis was seen in 49 (83%) cases, of which 44 (75%) were known to be smokers. Apoptotic cells were present in 35 (59%) cases and were numerous in 9 (15%) cases, of which 33 (56%) were known to be smokers. Abundant melanin pigment accumulation was seen in only 20

(34%) cases, of which 19 (32%) known to be smokers. Conclusions: The presence of clusters of intraepithelial lymphocytes, apoptotic cells and/or melanin pigment in FOM mucosa is strongly associated with a history of smoking, particularly when abundant. These "interface mucositis"-like changes mimic oral lichen planus and question the validity of such a diagnosis in patients who smoke.

PP3-231
IMMUNOEXPRESSION OF PDGF AND PDGFR IN DIFFERENT DEGREES OF CARCINOMA EX-PLEOMORPHIC ADENOMA INVASION

Cristiane Furuse[1], Patricia Ramos Cury[1], Albina Altemani[2], Venâncio Avancini Ferreira Alves[3], Ney Soares De Araújo[4], Vera Cavalcanti De Araújo[1]
[1] São Leopoldo Mandic Dental Research Center, Campinas, SP, Brazil
[2] State University of Campinas School of Medicine, Campinas, SP, Brazil
[3] University of São Paulo School of Medicine, São Paulo, SP, Brazil
[4] University of São Paulo School of Dentistry, São Paulo, SP, Brazil

Background: Immunoexpression of PDGF and PDGFR was investigated along the progression of pleomorphic adenoma to carcinoma ex pleomorphic adenoma (CXPA) using sixteen cases of CXPA in different degrees of invasion –intracapsular, minimally and frankly invasive carcinoma. Method: To this aim, we counted positive cells in different areas including reminiscent pleomorphic adenoma, in situ and peripheral areas of both intracapsular and minimally invasive tumours as well as in the frankly invasive carcinoma with only epithelial component and/or myoepithelial component. A minimum of 500 cells at 400X in the most marked areas (hotspots) was counted for each site by the computer-assisted image analysis. Results were presented as % of positive stained cells. Results: PDGF and PDGFR were observed in the cytoplasm of the cells but PDGFR was also present in some nuclei. Reminiscent pleomorphic adenoma showed focal stained of PDGF and PDGFR in luminal and plasmacytoid cells and in the cells of myxoid and condroid areas. In situ areas of intracapsular and minimally invasive types showed only strong expression in malignant luminal cells (100%). Both PDGF (71%) and PDGFR (80%) were present in the peripheral areas of intracapsular and minimally invasive with irregular distribution. In frankly invasive ones of the epithelial type, the percentage of positive cells was 90% for PDGF and 80% for PDFGR. In areas with small nests, negative cells were more evident. In frankly invasive type with myoepithelial component, 92% for PDGF and approximately 100% for PDGFR were observed. Conclusion: It seems that the expression of PDGF and PDGFR is involved at the beginning of the malignant transformation since its increase is present in in situ areas when compared with the reminiscent PA. But, their absence in the focal areas in the periphery of the tumours and in some cells of the small groups leads us to the hypothesis that they are not involved in the invasive process what merits further investigation.

PP3-233
ERCC1 IMMUNOHISTOCHEMICAL EXPRESSION IS RELATED TO HISTOLOGICAL DIFFERENTIATION AND PREDICTS OBJECTIVE RESPONSE AND DISEASE-FREE SURVIVAL IN PATIENTS TREATED BY CISPLATIN-BASED CHEMOTHERAPY FOR LOCALLY ADVANCED HEAD AND NECK SQUAMOUS-CELL CARCINOMA

Adriana Handra-Luca[1], Juana Hernandez[2], Giannis Mountzios[2], Estelle Taranchon[2], Jean Lacau-St-Guily[3], Jean-Charles Soria[4], Pierre Fouret[5]
[1] APHP Hopital Jean Verdier Universite Paris 13/Nord, France
[2] Institut Gustave Roussy, France
[3] APHP Hopital Tenon, France
[4] Institut Gustave Roussy Universite Paris 11, France
[5] Institut Gustave Roussy Universite Paris 6, France

Background: The excision repair cross-complementation group 1 (ERCC1) enzyme plays a rate-limiting role in the nucleotide excision repair pathway which recognizes and removes cisplatin-induced DNA adducts. The relation between ERCC1mRNA expression and resistance to platinum compounds has been studied in advanced-stage gastric, ovarian, colorectal, esophageal, and non-small-cell lung cancer. ERCC1 immunohistochemistry was predictive of the survival benefit of cisplatin-based chemotherapy in non-small cell lung cancer. Purpose: The goal of this study was to examine whether ERCC1 immunohistochemical expression in locally advanced head and neck squamous-cell carcinoma (HNSCC) was correlated to clinico-pathological characteristics and p53 mutations of patients treated with a cisplatin-based chemotherapy. Design: Pre-therapeutic biopsy samples from 96 patients with a known tumor response were evaluated for ERCC1 immunohistochemistry. The median of the H-score (the proportion of stained tumour nuclei multiplied by the staining intensity of nuclei) was used as cutoff. P53 mutations had been previously studied. Results: Patients' age varied between 51 and 67 years. Tumors were classified as T1/T2 (18) or T3/T4 (78), and nodal involvement was classified as N0 (46), N1 (13), N2 (22) or N3 (15). Of 96 patients, 68 (71%) had tumors that expressed ERCC1 intensively and diffusely, at high levels. Tumors with low ERCC1 were less differentiated than those with high levels (p=0.03). There was no difference for any other characteristics including age, gender, T, N, M, tumor localization or p53 mutation. Among 28 patients with tumors with low ERCC1, 22 (79%) had an objective response as compared to 38 of 68 (56%) patients with tumors with high ERCC1 (p=0.04). Using the logistic regression method, the 28 patients (29 %) with low ERCC1 had a four time greater odds of benefiting from an objective response to chemotherapy (OR 4.3, 95% CI: 1.4–13.4; p=0.01) as compared to the group of 68 patients with high ERCC1. ERCC1 and p53, but not their interaction, were independent predictors of tumor response. In a Cox model adjusted on age, T, N, M, tumor differentiation, and tumor localization, low ERCC1 was associated with a lower risk of cancer death (RR 0.42, 95% CI: 0.20-0.90; p=0.04), while p53 status had no prognostic value. Conclusion: The results of our study suggest that: 1) tumours with low ERCC1 were less differentiated and that, 2) those patients having HNSCC with low ERCC1 are more likely to benefit from cisplatin chemotherapy as compared to patients with high ERCC1.

PP3-234
PATHOLOGIC ESTIMATION OF ORAL MUCOSA LESIONS

Aphrodite Nonni, Pagona Ctena-Agapitou, Andreas Lazaris, Ilias Papadopoulos, Nikolaos Kavantzas, Emmanuel Agapitos, Sophia Tseleni-Balafouta, Efstratios Patsouris
1st Department of Pathology, Medical School, National and Kapodistrian University of Athens, Greece

Background In periodontal destruction, bacterial substances mainly interact with inflammatory cells and stimulate epithelial cells either towards proliferation or death. Actinomycosis is an infectious disease that frequently has chronic granulomatous and suppurative lesions; however, intraorally and periodontally types of actinomyces infection occur rarely. Heat shock proteins (HSPs) are produced by cells as a protection against stress and may play a role in course of infections. CD43 is a cell surface glycoprotein with an intracellular domain implicated in signal transduction and consequent activation of phagocytes. Material and methods Thirty one oral mucosa specimens infected by

actinomyces were studied with regard to the immunohistochemical expression of HSP70, histiocytic marker CD68 and CD43. Gram stain was performed in all cases. Results The inflammatory reaction consisted mainly of lymphocytes and plasma cells with a focally increased presence of neutrophils. The percentage of macrophages, as assessed by CD68 immunoreactivity, did not exceed 10% of the inflammatory infiltrates. HSP70 was overexpressed in inflammatory cells as well as on actinomyces' surface and epithelial cells of the basal layer with a concomitant heavy inflammatory reaction. When actinomyces expressed HSP70 strongly, the adjacent epithelium above the basal layer was denuded; on the contrary, when HSP70 expression on actinomyces was low, the neighboring epithelium was hyperplastic. CD43 was expressed mainly in mononuclear inflammatory cells and it was practically negative in neutophils; the latter is probably linked with the increased presence of actinomyces in the examined samples. Conclusions HSP70, when expressed on actinomyces' surface is likely to interact with adjacent epithelium. The absence of CD43 on neutophils seems to favor the colonization of oral mucosa by actinomyces and the progress of the infection-induced lesions.

PP3-235
p53 EXPRESSION IN SINONASAL MUCOSA OF LEATHER WORKERS

Annarita Palomba[1], Tonina Iaia[2], Mauro Biancalani[3], Stefano Conti[4], Giuseppe Battista[5], Milena Paglierani[1], Alessandro Franchi[1]

[3] Division of Anatomic Pathology, Department of Laboratory Medicine, "S. Giuseppe" Hospital, Empoli, Italy
[4] Division of Otolaryngology Head and Neck Surgery, "S. Verdiana" Hospital, Castelfiorentino, Italy
[5] Department of Prevention, University of Siena, Italy

Background. The association between sinonasal intestinal-type adenocarcinoma and the exposure to leather dusts has been widely documented, but the identification of precursor lesions and early alterations of p53 expression in the exposed nasal mucosa has so far received little attention. Methods. Biopsies of the mucosa of the middle turbinate were obtained from 40 subjects who had been employed in leather factories for 9-48 years (median 27 years). Thirty-three subjects had been employed in leather tanning activities, 21 in shoe making activities, and 14 had been exposed to both. Tissue samples were routinely processed for histologic examination and immunostaining for p53 was performed using the monoclonal antibody DO7 (Dako Co., Glostrup, Denmark). For statistical analysis, cases showing >20% of positive cells were considered positive. Results. In 22 biopsies (55%) we observed nuclear positivity for p53 in surface nasal epithelium. Immunoreactivity was present in basal and supra-basal epithelial cells in squamous metaplastic epithelium, while native schneiderian epithelium and goblet cells were negative in most cases. Concerning glandular epithelia, positivity was detected in 35 samples, 8 of which showed >20% of positive cells. Overall, p53 expression in surface epithelia was more frequently found in subjects employed in leather tanning than in subjects employed in shoe making or in both activities (p=0.06, Fisher's exact test). p53 expression in surface epithelia was significantly associated with longer exposure to leather tanning activities (p=0.02, Mann Whitney U test), while no correlation was found with shoe making activities, or with global work exposure. Similarly, no correlation was found between p53 expression in glandular epithelia and work exposure parameters. Conclusions. In nasal mucosa, a site at high risk of developing intestinal type adenocarcinoma in subjects exposed to leather dust, epithelial cells frequently overexpress p53 protein, and this appears to be related particularly to leather tanning activities. Further molecular studies are needed to clarify the role of p53 overexpression in the pathway leading to the development of these tumours in exposed subjects.

PP3-236
THE ENAMEL MATRIX DERIVATIVE (EMDOGAIN®) ENHANCES HUMAN TONGUE CARCINOMA CELLS GELATINASE PRODUCTION, MIGRATION AND METASTASES FORMATION

Matti Laaksonen[1], Juho Suojanen[1], Sini Nurmenniemi[2], Esa Läärä[3], Timo Sorsa[1], Tuula Salo[2]

[3] Division of Statistics, Department of Mathematical Sciences, Faculty of Science, University of Oulu, Oulu, Finland

Background: Enamel matrix derivative Emdogain® (EMD) is widely utilized in periodontal therapy to regenerate lost connective tissue and to improve the attachment of the teeth. Gelatinases, matrix metalloproteinases -2 and -9, are supposed to have an essential role in the progression of oral cancer growth and metastasis formation. The aim of this study was to determine the effects of EMD on human tongue squamous carcinoma (HSC-3) cells in vitro and in vivo. Methods: Subconfluent cultures of HSC-3 cells and spontaneously immortalized oral mucosal keratinocytes (HMK) were incubated for 48 h in serum-free culture media containing 0, 100 or 200 µg/ml of EMD. Gelatinase production was analyzed using gelatine zymography and enzyme-linked immunosorbent assay (ELISA) kits. For transwell cell migration assay both cell lines were pre-incubated with EMD and allowed to migrate overnight. The attached cells on the lower side were stained and quantitated. In a set of experiments, a cyclic anti-gelatinolytic CTT-2 peptide was added to the transmigration assay. Cell proliferation was analyzed using microtiterplates coated with or without EMD. The cells were incubated from 12 to 96 h. The proliferation was determined using Cell Proliferation ELISA BrdU kit. For in vitro wound closure assay BSA pre-coated confluent cell culture plates were wounded and exposed to various concentrations of EMD. After incubation the wound areas were measured. For in vivo metastasis assay HSC-3 cells were injected subcutaneously into the back of athymic nude mice. After three days of inoculation, mice were injected subcutaneosly with or without EMD daily during five days of treatment. After scarification the number of the metastases were counted. Results: EMD at concentrations of 100 µg/ml and 200 µg/ml significantly induced the production of MMP-2 and -9 from HSC-3 cells. EMD also slightly induced the gelatinase production from HMK cells. Furthermore, EMD induced the transmigration of HSC-3 cells, but reduced the migration of HMKs in transwell assays. The in vitro wound closure of HSC-3 cells was significantly accelerated by EMD, whereas it did not effect on the wound closure of HMKs. The migration of both cell lines was inhibited by a specific cyclic anti-gelatinolytic peptide CTT-2. EMD had no effect on HSC-3 cell proliferation. EMD significantly induced metastases formation, but had only a limited effect on mice survival bearing human tongue HSC-3 carcinoma xenografts. Conclusion: We suggest that the use of EMD for patients with oral mucosal malignancies should probably be avoided.

PP3-237
A COMPARISON BETWEEN THE FREQUENCY RATE OF MALIGNANT & PREMALIGNANT WHITE ORAL LESIONS AND THE REST OF WHITE ORAL LESIONS REFERRED TO THE RECORDS OF TEHRAN UNIVERSITY (IRAN) PATHOLOGY CENTER
Parisa Piroozmand, Zahra Hosseini, Donya Sadri
School of Dentistry, Islamic Azad University, Tehran, Iran

BACKGROUND: White lesions of oral mucosa is caused by thickening of keratin layer, epithelial hyperplasia, intraepithelial edema and reduced vascularity in the underlying lamina propria that in some cases transformation into malignancy may occur. The aim of this study is to assess knowledge of potentially malignant white oral lesions indices rates, in order to prevent oral cancer. METHODE: In this descriptive study a total of 4799 documents of patients referred to the records obtained from the pathology section of Tehran University were reviewed from the year 1995 to 2005. Documents of affected patients by white oral lesions were evaluated. Variables (sex, age, lesion type, location of oral involvement, microscopic diagnosis) were assessed by Chi-Square analytical test. RESULTS: Of our samples, 425 patients (9%) were affected by white oral lesions, of them, 7.06% were premalignant and 22.35% were malignant and the rest (70.59%) had no report of malignancy and were benign. Among premalignant white lesions idiopathic leukoplakia with mild dysplasia had maximum percentage. Based on the results of this study, the maximum percentage of premalignant lesion occurrence were reported to be among the males over the age of 50 on the buccal mucosa vs. malignant lesions which were predominantly reported in females over the age of 50 on the tongue. CONCLUSION: Obtained results showed that 9% of oral lesions are white with less prevalence rate compared with that obtained in previous studies. This may arise from deficit consideration and carelessness of dental staff during examination and exclusion of white lesions. However it is found that 22.35% of white lesions are malignant, bigger percentage than that obtained by similar investigations. This may also arise from less consideration in primary diagnostic approaches performed by dentists. Considering prevalence of premalignant and malignant lesions among elderly patients, paying more attention during clinical examination is mandatory particularly for high risk patients.

PP3-238
INTRAMUSCULAR HEMANGIOMA OF THE RETROPHARYNGEAL SPACE. A CASE REPORT
Ivan Boricic[1], Zorica Stojsic[1], Dimitrije Brasanac[1], Nada Tomanovic[1], Dragoljub Bacetic[1], Anton Mikic[2]
[1] Institute of Pathology, School of Medicine University of Belgrade, Serbia
[2] Institute of Otorhinolaryngology, School of Medicine University of Belgrade, Serbia

Intramuscular hemangioma is a distinctive type of benign vascular tumor confined to the skeletal muscle. This tumor is prone to recur and behaves in a locally aggressive manner. The most common site of involvement is the lower limb, followed by the head and neck region. To our knowledge, only one case of intramuscular hemangioma arising in the retropharyngeal space has been reported in the English literature. We, herein, report a further case in a 51-year-old woman. The tumor manifested as a left-sided neck swelling of 15-day duration. The patient was found to have bulging of the posterior oropharyngeal wall on indirect laryngoscopy and an ill-defined left-sided retropharyngeal mass on computed tomography scan. The tumor was excised by a transoral approach and microscopically diagnosed as intramuscular hemangioma, the complex malformation subtype. It was mainly composed of irregularly shaped large- and medium-sized blood vessels, reminiscent of arteries and veins. The second vascular component corresponded to capillaries, lined by prominent endothelial cells. Vascular channels were set in a fibrous-fatty stroma with entrapped striated muscle fibers. In addition, isolated bundles of smooth muscle fibers were present throught the tumor. Some of these structures contained lumens and were attached to vessel walls. We assume that at least some of these smooth muscle bundles could be malformed blood vessels, as well. Intramuscular hemangioma should be considered in the differential diagnosis of any soft tissue mass found in the retropharyngeal space.

PP3-239
THE EXPRESSION OF Ets, E-CADHERIN AND Ki-67 IN HEAD AND NECK SQUAMOUS CELL CARCINOMA. AN IMMUNOHISTOCHEMICAL STUDY
Paul Nagy[1], Barnabás Horváth[2], Ferenc Salamon[1], Zsuzsa Schaff[3]
[1] National Medical Center, Department of Pathology , Hungary
[2] National Medical Center, Department of Otorhinolaryngology , Hungary
[3] Semmelweis University, 2nd Department of Pathology, Hungary

Background: Despite the development of diagnostic tools and therapy, squamous cell carcinoma of the head and neck (HNSCC) may present challenges to pathologists and clinicians as well. A particularly difficult problem is the treatment of regional metastases. We examined immunohistochemically molecules involved in the metastatic process: ets-1 transcription factor that regulates expression of matrix metalloproteinase-3, E-cadherin that is responsible for homotypic cell-cell adhesion, and cell proliferation marker Ki-67. We studied their possible relations relevant to the clinical practice. Method: 98 patients (87 males and 11 females) with HNSCC were treated only surgically in our institute during a period of 3 years . We divided the primary tumor samples into two groups. Group N(0) (n=49) were selected from patients without synchronous lymph node metastasis or nodal recurrence in a follow-up period of 2 years and Group N(+)(n=49) were from patients with lymph node metastases. Using immunohistochemistry the targets mentioned above were detected in paraffin-embedded specimens representing the primaries and the metastases as well. The following clinicopathological parameters were taken into account: sex, age, tumor localization, grade and stage. The results were statistically analyzed. Statistical significance was defined as $p<0.05$. Results: Correlation between ets-1 expression and clinicopathological setting, metastasis and Ki-67 labeling index (LI) was not significant. Reduced expression of E-cadherin showed significant correlation with metastasis, survival and Ki-67 LI. In addition, we found that the degree of E-cadherin expression in primary tumors may differ from that of the metastases. Conclusion: Ets-1 can be demonstrated mainly in the peritumoral stromal cells and has no direct prognostic significance. However, testing the Ki-67 labeling index and E-cadherin expression may be useful in identifying high-risk patients who need more aggressive therapy. Moreover, these markers may be valuable in a panel of prognostic factors for HNSCC.

PP3-240
ANGIOGENIC SWITCH DURING TUMOR PROGRESSION OF CARCINOMA EX-PLEOMORPHIC ADENOMA (CXPA)
Andresa Soares[1], Priscila Juliano[1], Vera Araujo[2], Randal Adam[1], Konradin Metze[1], Albina Altemani[1]
[1] State University of Campinas - Brazil
[2] São Leopoldo Mandic - Brazil

BACKGROUND: Angiogenesis is considered to be a critical process for tumor growth, invasion and metastasis. CXPA is the principal form of malignancy arising in pleomorphic adenomas (PA) and is usually a high-grade neoplasm, with frequent

metastases and a poor clinical outcome. We investigated the question whether an angiogenic switch would take place during the malignant transformation of PA into carcinoma and during tumor progression. METHOD: In 8 cases of early CXPA (intracapsular and minimally invasive), 8 of advanced CXPA (widely invasive tumors) and 10 cases of PA without malignant transformation, tumor vascularisation was assessed by measuring total microvascular area (TVA) and microvessel density (MVD) in CD34 and CD105 stained sections. In digitalized images the texture of the CD34 stained capillaries was analyzed calculating Shannon´s entropy (as a measure of the CD34 staining heterogeneity) and the fractal dimension, which represents the complexity of the architecture. RESULTS: Whereas the CD34 values did not differ among the tumors, MVD for CD105 increased significantly during tumor progression (PA without malignant transformation: mean 3.3; early CXPA: 9.0; widely invasive CXPA: 33.6) with carcinomas without myoepithelial differentiation revealing higher values (mean 46.5) than carcinomas with such cellular differentiation (mean 16.3). In relation to TVA, in advanced CXPAs the TVA value was higher (mean 179.4) than in early carcinomas (mean 63.8) and tumors with myoepithelial differentiation showed higher values (mean 260.2) than those without (mean 118.9). In widely invasive tumors with myoepithelial differentiation the carcinoma cells often formed large hypovascularized aggregates surrounded by large vessels whereas in those without myoepithelial differentiation the cell aggregates were smaller with thinner vessels around them. Entropy and the fractal dimension raised during carcinogenesis (lower in adenomas and higher in frankly invasive carcinomas), which is equivalent to an increase in heterogeneity of the endothelial CD34 expression and complexity of the vessel architecture. CONCLUSION: During the progression from adenoma to carcinoma there is an increasing complexity of the vessel architecture. The antibody CD105 reflects better the angiogenic switch than CD34. The degree of angiogenesis and the total vascular area have distinctive patterns in CXPA with and without myoepithelial differentiation. Low angiogenesis associated with high TVA value is more characteristic of CXPA with myoepithelial differentiation. FAPESP-04/07960-0

PP3-241
POTENTIAL PROGNOSTIC IMPORTANCE OF THE EXPRESSION OF MATRIX METALLOPROTEINASE MMP9 AND TISSUE INHIBITOR OF METALLOPROTEINASE TIMP2 IN PATIENTS WITH LARYNGEAL SQUAMOUS CELL CARCINOMA

Jozef Kobos[1], Elzbieta Salacinska-Los[1], Wioleta Pietruszewska[2]
[1] Department of Pathology of the Age of Development Medical University of Lodz, Poland
[2] Department of Otolaryngology Medical University of Lodz, Poland

Matrix metalloproteinases belong to the family of human endopeptidases involved with degrading of the extracellular matrix. MMP9 belongs to the group of matrix proteins called gelatinases and TIMP2 acts as an inhibitor of metalloproteinases and also may promote growth inhibition. The aim of the study was the evaluation of the immunoexpression of matrix metalloproteinase MMP9 and tissue inhibitor of metalloproteinase TIMP2 in patients with laryngeal squamous cell carcinoma. Our material consisted of 67 cases of laryngeal squamous cell carcinoma (LSCC) from the files of the Department of Pathology Medical University of Lodz. For immunohistochemical study we used Novocastra Company antibodies and EnVisio (DAKO) visualisation system. The MultiScanBase CSS Ltd. Company image analysis system was used for scoring the intensity of expression of evaluated proteins. Only tumor cells with distinct cytoplasmic immunoexpression were classified as positive. Our date showed that the significantly higher number of TIMP2 positive cells were observed in grade three LSCCs than in low and intermediate grade tumors. We also noted that the intense MMP9 expression was present more frequently in patients with high grade carcinomas but the results were not significant. We seen the MMP9 positive neoplastic cells mostly at the margins of tumor areas adjacent to the stroma. We also found the positive correlation between MMP9 and TIMP2 expression in evaluated carcinomas. In conclusion we believe that the TIMP2 and MMP9 expression might be useful prognostic markers in patients with oral squamous cell carcinoma.

PP3-242
PLEOMORPHIC ADENOMA (MIXED TUMOR) OF THE MINOR SALIVARY GLANDS

Christos Makos[1], Anastasia NikolaIdou[2], Rodi Kotakidou[3], Symela Amanatidou[4]
[1] Department Of Oral And Maxillofacial Surgery, General Hospital Of Kilkis, Greece
[2] Department Of Pathology, General Hospital Of Kilkis, Greece
[3] Department Of Pathology, General Hospital "G. Gennimatas'', Thessa-Loniki, Greece
[4] Technisian, Greece

BACKROUND: Pleomorphic adenoma is an epithelial tumor of the salivary glands. The first prescription was made by Billroth and Von Bruns in 1859 and the initial name "mixed tumor" was given by Minssen in 1874 as a manifestation of a mixed epithelial and mesenchymal origin. Today, the prevalent name is pleomorphic ade-noma because of the proved isolated epithelial origin and the pleomorphic histological picture per location. The frequency is estimated about 60-80% of the salivary gland tumors and a 90-96% of the benign salivary gland tumors with a 85-90% of the cases located in the parotid glands and mainly to the distal caudal section. A pleomorphic adenoma in the minor salivary glands is not often. The purpose of this work is to pre-sent cases of pleomorphic adenomas of the minor salivary glands clinically presented as sebaceous cysts and or lipomas and to discuss about this entity. METHODS-RESULTS: The clinical, surgical and histological pictures in cases with pleomorphic adenomas of the minor salivary glands are presented and the particulari-ties in histological sections and stains are referred. CONCLUSION: Definite diagnosis in the above mentioned pleomorphic adenomas of the minor salivary glands is emphasized by histological evidences. Because of the relative small size of the tumor and the expansion in the cheek and labial subcutane-ous tissue these tumors clinically could be misdiagnosed as sebaceous cysts, pilar cysts and or lipomas.

[2] Department of Otorinolaryngology Head and Neck Surgery, General Hospital of Kilkis, Greece
[3] Department of Pathology, General Hospital ''Ippokratio'', Thessaloniki,Greece
[4] Molecular Carcinogenesis Group, Department of Histology and Embryology, School of Medicine, University of Athens, Greece

BACKROUND: The purpose of this study was to determine the relationship between human papillomavirus (HPV) infection in patients with invasive squamous cell carcinoma, in situ carcinoma, keratosis and mild-severe dysplasia of the larynx. HPV has been implicated as a risk factor in this carcinogenic process after cigarette smoking and chronic alcohol consumption. MATERIALS & METHODS: Formalin-fixed, paraffin-embedded tissue was obtained from 20 males (aged 60-79) with

laryngeal neoplasias. Extraction of total DNA from sections was performed using the QIAamp DNA mini kit (QIAGEN). Quality and integrity of extracted DNA was tested by PCR amplification of an amplicon of the IFN-γ gene. A nested, multiplex, highly sensitive PCR method (~1fg; 103 viral copies) was used for HPV detection and genotyping. In this assay consensus primers for first-run amplification of a broad spectrum of mucosal HPV genotypes, including all high-risk HPV genotypes, were combined with nested PCR amplifications of type-specific primers. RESULTS: Out of the 20 samples, two of them (10%) were found positive for the high-risk subtype HPV16 (case 3, invasive carcinoma, moderately differentiated) and the low risk subtype HPV43 (case 16, invasive carcinoma, well-moderately differentiated), respectively. CONCLUSION: Both high and low risk HPVs (HPV16 and HPV43, respectively) were detected in patients with invasive laryngeal squamous cell carcinomas. The presence of, especially, high-risk HPV genotypes may identify a subset of patients at risk to develop invasive laryngeal squamous cell carcinoma. Nevertheles, examination of larger numbers of patients are required to expand these findings.

PP3-244
IMMUNOHISTOCHEMICAL DETECTION OF E-CADHERIN AND BETA-CATENIN IN SALIVARY GLAND TUMORS

Theodoros Papadas, Nikolaos Mastronikolis, Maria Gkermpesi, Panagiota Ravazoula
University Hospital of Patras, Greece

BACKGROUND & OBJECTIVE: E-cadherin links to the cytoskeleton via catenins and mediates cell-cell homophilic adhesion. Beta-catenin not only regulates cell-cell adhesion, as a protein interacting with cadherin, but also functions as an important component of the Wnt signaling pathway which has been found to be closely associated with tumor formation. This study was performed to examine the expression of E-cadherin and beta-catenin in salivary gland tumors in order to evaluate their possible roles in the formation of salivary gland tumors. MATERIAL & METHODS: Archival formalin-fixed, paraffin-embedded tissue sections of 48 mixed tumors (pleomorphic adenomas), 17 Warthin tumors, 5 mucoepidermoid carcinomas, total 70 tumors, were studied immunohistochemically using an Envision/horseraddish peroxidase (HRP) technique. Healthy salivary glands were used as controls. RESULTS: Membrane and cytoplasmic associated E-cadherin and beta-catenin expression was present in 54/70 and 68/70 of the tumor types studied, respectively. E-cadherin and beta-catenin showed a similar distribution; however, E-cadherin was less frequently expressed than beta-catenin. Expression of both proteins was stronger in Warthin tumors and in mucoepidermoid carcinomas. Reduction and/or absence of E-cadherin were only observed in mixed tumors. CONCLUSION: This study suggests a direct association of E-cadherin and beta-catenin expression with neoplastic histology phenotype of salivary gland tumors.

PP3-245
EXPRESSION OF METALLOPROTEINASES IN SALIVARY GLAND TUMORS

Maria Gkermpesi, Nikolaos Mastronikolis, Theodoros Papadas, Dimitra Koumoundourou, Panagiota Ravazoula
University Hospital of Patras, Greece

Matrix metalloproteinases (MMPs) are involved in extracellular matrix turnover. MMPs belong to a family of zinc-dependent endopeptidases and are classified according to their substrate specificity. Although MMPs are among the potential key mediators of cancer invasion, their involvement in premalignant lesions is not clarified. The aim of our study was to evaluate the expression of gelatinase A (MMP-2) and gelatinase B (MMP-9) in salivary gland tumors. Material and Methods: We examined immunohistochemicaly formalin-fixed, paraffin-embedded tumor samples from 70 patients (48 pleomorphic adenomas,17 warthin tumors and 5 mucoepidermoid carcinomas) for MMP-2 and MMP-9 (Chemicon Laboratories) expression. Results: Cytoplasmic MMP-2 staining was detected in epithelial component of all pleomorphic adenomas and warthin tumors, and also in stoma fibroblasts and endothelial cells. MMP-9 cytoplasmic staining was detected in myoepithelial cells of pleomorphic adenomas, in epithelial cells of warthin tumors and in inflammatory cells in stroma. Nuclear immunostaining for MMP-9 was also detected in epithelial component of pleomorphic adenomas. In mucoepidermoid carcinomas MMP-2 and MMP-9 were also immunoexpressed in squamous malignant component. Conclusions: Our results suggest that MMP-2 and MMP-9 expression is an early event in salivary gland tumorogenesis. Our findings suggest roles of MMPs in tumor initiation in addition to invasion.

DESMOPLASTIC FIBROBLASTOMA OF THE LARYNX

Fred Ellinger[1], Karla S. Pereira[1], Adriana Brentegani[1], Fernando Siemann[1], Thiago Y. Miura[1], Silvio B. Uvo[1], Luiz C. Silva[1], Frederico G. N. Ellinger[1], Christopher D. M. Fletcher[2]
[1] FAMEMA, Brazil
[2] Brigham and Women's Hospital, United States

BACKGROUND Desmoplastic fibroblastoma (DM) is a rare benign soft tissue tumor of fibroblastic origin, first described by Evans in 1995. It affects mainly adult males, most commonly limbs and trunk and has no recurrences. It is characterized by a paucicellular proliferation of stellate shaped fibroblasts in a collagenous or myxoid background. Two cases have been described in the palate and one in the parotid gland. The authors describe the first case in the larynx. METHOD Representative slides were stained by hematoxilin and eosin and immunohistochemistry study was conducted using the Envision Plus detection system (Dako, Carpinteria CA) according to well established technique. Clinical and follow-up information were obtained from the files of the clinician. RESULTS Case presentation: ASA, 51 years old male presented complaining of "sore throat" and a foreign body sensation. Direct laryngoscopy reavealed a two centimeters, deglutation mobile nodule, in the larynx. It was locally ressected. Grossly the nodule was white-grayish, firm, well demarcated, measuring 1,9 X 1,9 X 1,6 cm. Microscopically there was a well demarcated hypocellular nodule, underneath a squamous mucosa, composed of proliferating spindle and stellate fibroblasts. The stroma was collagenous and focally myxoid. The diagnosis was desmoplasic fibroblastoma. Because of the unusual location of the lesion, the case was sent in consulation to Dr. C.D.M. Fletcher who agreed with the diagnosis. He also performed and immunohistochemical study. The lesional cells were focally positive for CD-34, while negative for smooth muscle antigen (SMA) and S-100 protein. DISCUSSION AND CONCLUSION Desmoplastic fibroblastoma is a benign fibroblastic tumor that most frequently affects males between the 5th and 7th decades of life. It presents as an asymptomatic mass usually in the subcutis, but fascial and muscular involvement can occur. It occurs most often in the soft tissues, but two cases have been described in the palate and one in the parotid gland. It is well-demarcated, white-grayish, firm and nodular. It is typically a paucicellular proliferation of spindle and stellate regular fibroblasts over a collagenous stroma that can be focally myxoid and can be SMA, CD-34 and keratin positive. Two cases studied showed a 2;11 (11q12) translocation. To the best of our knowledge, this is the first case described in the larynx. The case is presented to call attention that visceral cases of desmoplastic fibroblastoma can occur.

PP3-247
LYMPHANGIOMATOUS POLYP OF THE PALATINE TONSIL: REPORT OF TWO CASES OF A RARE TONSILAR LESION
Fred Ellinger, Fernando Siemann, Thiago Y. Miura, Karla S. Pereira, Adriana Brentegani, Luis C. Silva, Frederico G. N. Ellinger
FAMEMA , Brazil

BACKGROUND Benign tumors of the palatine tonsil are rarer than malignant ones. The most common is the squamous papilloma. Lymphangiomatous polyp of the tonsil is a rare lesion typically occurring in the palatine tonsil and considered a hamartoma. Until 2000, 36 cases have been plublished in the literature. We describe two cases to divulge this uncommon lesion. METHOD The two cases were seen recently in the Department of Pathology of the Faculty of Medecine of Marília. Hematoxylin and eosin–stained slides were reviewed. Clinical and follow-up information were obtained from the patients hospital charts. RESULTS Case reports: Clinical findings Case 1: P.M.R., fourteen years old white female with essential leukopenia and palmo-plantar hyperhydrosis presented to the department of othorhynolaryngology complaining of a sensation of a "meat ball" in the throat on deglutition, of two years duration. Examination showed a polyp in the left palatine tonsil. Bilatered tonsilectomy was performed with a diagnosis of left tonsilar polyp. The patient is currently asymptomatic. Case 2: E.W.S., nineteen years old mulatto male presented with a history of a foreign body sensation in the throat and choking, of two years duration. Examination found a polypoid mass in the right palatine tonsil. Bilateral tonsilectomy was performed and the postoperative course was uneventful. Pathologic findings Case 1 and 2: Macroscopy: In both cases a pedunculated tonsilar polyp was found. They were yellow-brownish, firm and measured 1,7 cm and 2,0 cm in greatest dimension in cases 1 and 2 respectively. Microscopy: histological appearances were similar in both cases. The pedunculated polyps were lined by non keratinizing squamous epithelium. The core of the polyps was composed of poorly cellular fibrous tissue containing numerous dilated vessels, mainly lymphatics. Underneath the epithelium, lymphoid tissue composed of small lymphocytes and some follicles, even with germinal centers, was focally found. There was focal epithelial lymphotropism with formation of small lymphocytic aggregates within the epithelium. Mature plasma cells were present in smaller numbers. Case 2 showed more abundant lymphoid tissue and larger clusters of lymphocytes within the epithelium than case 1. Pathologic diagnosis: Case 1 and 2: Lymphangiomatous polyp of palatine tonsil. CONCLUSION: Lymphangiomatous polyp of the tonsil is a rare benign hamartomatous lesion with typical location and histological appearance, here presented so that pathologists can learn to recognize and diagnose it.

PP3-248
INVESTIGATION OF EPSTEIN-BARR VIRUS (EBV) PREVALENCE IN THYROID CARCINOMAS IN TUNISIA
Mounir Trimeche, Sonia Ziadi, Mohamed Hachana, Khaled Amara, Badreddine Sriha, Moncef Mokni, Sadok Korbi
Laboratory of Pathology, CHU Farhat Hached, Sousse, Tunisia

Background: Epstein-Barr virus (EBV) infection has been linked with several malignancies of lymphoid and epithelial cell origin. It has been recently suggested that EBV may be involved in the progression of thyroid papillary carcinoma to undifferentiated carcinoma in Japanese patients. The purpose of our study was to evaluate the prevalence of EBV in thyroid carcinomas in Tunisia. Methods: To achieve this issue, 101 thyroid specimens from 101 patients, comprising malignant tumors (41 papillary carcinomas, 6 follicular carcinomas, 7 anaplastic carcinomas, 2 medullary carcinomas), and benign lesions (31 follicular adenomas, 10 multinodular goiters, 2 Hashimoto thyroiditis, and 2 Basedow disease), were randomly-selected. EBV infection was investigated by EBER1/2-in situ hybridization on formalin-fixed and paraffin-embedded tissues. Results: EBER1/2 was not detected in epithelial cells in any of the 101 specimens, but in 6 cases, EBV positivity was found in scattered normal lymphocytes. Conclusion: Given the sensitivity of the technique used, theses results do not support a relationship between EBV and thyroid carcinomas, in spite of EBV being high prevalent in our population when other tissue specimens are concerned.

PP3-249
INVESTIGATION OF HUMAN PAPILLOMAVIRUS (HPV) IN BREAST CANCER AMONG WOMEN FROM TUNISIA
Mounir Trimeche, Mohamed Hachana, Sonia Ziadi, Khaled Amara, Badreddine Sriha, Moncef Mokni, Sadok Korbi
Laboratory of Pathology, CHU Farhat Hached, Sousse, Tunisia

Introduction: Human papillomavirus (HPV) infection has been associated with a variety of benign and malignant epithelial lesions. The association of HPV with a subset of breast carcinomas has been reported but remains controversial. The aim of this study was to evaluate the frequency of HPV infection in breast carcinoma in Tunisia. Methods: 96 randomly selected invasive ductal carcinomas of the breast were investigated for the presence of HPV DNA sequences by polymerase chain reaction (PCR). DNA was extracted from frozen tumor tissues. HPV sequences were investigated by three different methods including the E1350L/E1547 primers amplifying a 180-bp sequence in a highly conserved region of a wide spectrum of anogenital HPV, the pU-1M/PU-2R primers specific for the oncogenic HPV types 16, 18, 31, 33, 52, 58, and the PU-31B/PU-2R primers for the low-risk HPV 6 and 11. Results: PCR for the detection of a 268-bp sequence in the β-globin gene demonstrated the presence of amplifiable DNA in all cases. No HPV-related DNA sequences were identified by PCR in any case of breast carcinomas tested. Discussion: Although our results may reflect a geographic feature, they do not support a relationship between the anogenital HPV tested and breast carcinomas; however, the possibility that other types of HPV contribute in the breast carcinogenesis can not be excluded.

PP3-250
ALLELIC IMBALANCE OF THE SHORT ARM OF CHROMOSOME 3 IN NASOPHARYNGEAL CARCINOMA AMONG PATIENTS FROM TUNISIA
Mounir Trimeche, Sonia Ziadi, Hend Braham, Mohamed Hachana, Khaled Amara, Moncef Mokni, Sadok Korbi
Laboratory of Pathology, CHU Farhat Hached, Sousse, Tunisia

Background: As part of North Africa, Tunisia is one of the world's intermediate-risk areas for nasopharyngeal carcinoma. Loss of heterozygosity on the short arm of chromosome 3 (3p) is the most frequent genetic change reported in nasopharyngeal carcinoma from endemic areas. Method: We investigated the chromosome 3p for loss of heterozygosity in 47 microdissected primary nasopharyngeal carcinoma specimens and corresponding non-cancerous tissues from Tunisian patients using six microsatellite polymorphic markers. Results: Loss of heterozygosity was identified in 87.2% of cases on at least one of the six markers tested. The highest frequency of loss of heterozygosity was found at D3S1038 (60%), D3S1067 (57%), D3S1568 (52%), and D3S1076 (44%). Nine cases showed coexistence of loss of heterozygosity for three consecutive adjacent markers, suggesting a common deleted region flanked by D3S1568 (3p21.31) and D3S1067 (3p21.1-14.3), centered at D3S1076. Furthermore significant higher frequency of loss of heterozygosity were observed in patients older than 25 years than in patients under 25 years at the locus D3S1076 (57% versus 17%; p=0.02). Conclusion: These findings supports the hypotheses suggesting that loss of heterozygosity on chromosome

3p in nasopharyngeal carcinoma is a common genetic event irrespective of geographic and ethnic origins, and suggests that one or more gene(s) affected by loss of heterozygosity at the locus D3S1076 were specifically involved in the pathogenesis of adult form of this cancer.

PP3-251
CLINICOPATHOLOGIC STUDY OF CARCINOMA ASSOCIATED WITH SINONASAL INVERTED PAPILLOMA: NOT ASSOCIATED WITH EPSTEIN-BARR VIRUS

Shih-Ming Jung[1], Pao-Hsien Chu[2], Chi-Ru Yeh[1], Wen-Yu Chuang[1], Ngan-Ming Tsang[3]
[1] Department of Pathology, Chang Gung Memorial Hospital and Chang Gung Children Hospital, Chang Gung University College of Medicine, Taoyuan, Taiwan
[2] Department of Internal Medicine, Taiwan
[3] Department of Radiation Oncology , Taiwan

Background: Carcinoma associated with sinonasal inverted papilloma is uncommon. Patients with inverted papillomas and carcinomas may occur in three patterns: 1) those who have carcinoma with recurrent inverted papilloma; 2) those whose tumors are predominate typical inverted papilloma with only focal invasive carcinoma or carcinoma in situ; 3) those who have carcinoma with a pattern similar to that of papilloma. Status of Epstein-Barr virus in the pathogenesis of inverted papilloma is controversial. We investigated the role of Epstein-Barr virus in carcinoma associated with sinonasal inverted papilloma. Method: Carcinoma associated with sinonasal inverted papilloma were retrieved from the surgical pathology files. Tumor DNA was extracted from paraffin blocks. Oligonucleotide primers for detecting LMP-1 gene were used to evaluate for the presence of Epstein-Barr virus DNA by a polymerase chain reaction (PCR) amplification. Results: Eleven cases were identified. Seven patients were female and four were male. The mean age was 52 (31-72) years. Two patients had moderately differentiated squamous cell carcinoma 162 and 148 months after excision of inverted papilloma with recurrences in the interim. Three cases presented inverted papilloma with focal invasive squamous cell carcinoma or carcinoma in situ. Six cases had carcinoma with a pattern similar to that of papilloma. Genomic DNA extraction was not workable in four of eleven cases. Epsten-Barr virus was not detected in the seven cases by PCR. Conclusions: The study demonstrates that the pathogenesis in carcinoma associated with sinonasal inverted papilloma is not dependent on concurrence of Epstein-Barr virus infection.

PP3-252
SOLITARY FIBROUS TUMOR OF THE UVULA

Vazquez Navarrete Sofia, Murga Tejada Carlos
Hospital Del Sas La Linea, Spain

Solitary fibrous tumor (SFT) is an uncommon spindle cell neoplasm rarely located in the oral cavity. We report a very unusual case of SFT located in the úvula.We have not found another one in this location in the literature. CASE REPORT A 80-years-old woman had a polipoid lesium 2 cms located in the úvula. The lesion was removed with a clinical diagnosis of Papiloma.Microscopically we found a spindle cell tumour with atipia , but no necrosis and some mitotic figures (< 4 in 10 HPF). The cells showed a strong immunoreactivity for vimentin and CD34, and variable for bcl-2 and negativity for other immunomarkers. The patient has been follow-up for 7 years (2000-2007)and in spite of a very small recurrence (may 2006) after removal of the new lesion, she is well and free of disease. Diagnosis of SFT extrathoracic is difficult and, although uncommon it should be considered in the differential diagnosis of oral soft tissue tumors.

HUMAN SALIVARY GLAND BRANCHING MORPHOGENESIS: MORPHOLOGICAL LOCALIZATION OF CLAUDINS AND ITS PARALLEL RELATION WITH DEVELOPMENTAL STAGES REVEALED BY EXPRESSION OF CYTOSKELETON AND SECRETION MARKERS

Silvia Vanessa Lourenco[1], Claudia Malheiros Coutinho-Camillo[2], Marcilei Eliza Cavicchioli Buim[2], Sabrina Hitomi Uyekita[3], Fernando Augusto Soares[4]
[1] Department of General Pathology, Dental School, University of São Paulo; Laboratory of Immunopathology, Institute of Tropical Medicine and Department of Dermatology, Medical School, University of São Paulo, São Paulo, Brazil
[2] Department of Pathology, Hospital A. C. Camargo, São Paulo, Brazil
[3] Department of Dermatology, Medical School, University of São Paulo, São Paulo, Brazil
[4] Department of General Pathology, Dental School, University of São Paulo; Department of Pathology, Hospital A. C. Camargo, São Paulo, Brazil

Background: The development of salivary glands from simple precursor epithelial buds to functional glands is a highly complex and dynamic process termed branching morphogenesis, where tissue generate branched structures that subsequently differentiate into mature glands. Tight junctions (TJ) are thought to be the principal structures that contribute to cell polarity, by acting as an intramembrane barrier to prevent lateral movement of membrane proteins that form specific sites in the apical or basolateral membranes, thereby playing a critical role in the physiological functions of tubular organs. Several lines of evidence have demonstrated that claudins are directly involved in the formation of TJ strands as well as their barrier function. Method: Using immunohistochemistry and immunofluorescence we have mapped the distribution of claudins-1, 2, 3, 4, 5, 7 and 11 and compared it with the expression of differentiation markers in human salivary glands obtained from foetuses ranging from weeks 4 to 24 of gestation. Results: Expression of all claudins, except claudin-2 was detected in the various phases of human salivary gland development, up to fully mature salivary gland. The expression of all claudins increased according to the progression of salivary gland maturation evidenced by the classical markers – cytokeratin 14, cytokeratin low molecular weight, smooth muscle actin and human secretory component. Conclusion: Tight junction proteins – claudins appear to be important in the final shape and physiological functions of human salivary glands and are parallel related with markers of salivary gland differentiation.

[3] University of São Paulo School of Medicine, São Paulo, SP, Brazil
[4] University of São Paulo School of Dentistry, São Paulo, SP, Brazil

Background: Carcinoma ex-pleomorphic adenoma (CXPA), a rare salivary gland tumour, is an important model to study the complex mechanism of tumour malignization and progression.

Our group has already studied various aspects of this tumour concerning cells and stroma. Collagen is the major component of extracellular matrix proteins. Interaction between cells and collagen can regulate cellular gene expression, differentiation and growth. Besides it plays an important role in tumorigenicity. Recently, it was demonstrated that type I collagen induces disruption of E-cadherin-mediated cell-cell contacts and promotes cell proliferation. The aim of this study was to analyze the expression of type I collagen in CXPA. Method: Seventeen cases of CXPA, classified according to the degree of invasion in intracapsular, minimally invasive carcinoma and frankly invasive carcinoma with epithelial and/or myoepithelial component were immunostained for type I collagen. Results: Two patterns of type I collagen were disclosed: fibrilar; and amorphous or dense fibers. The fibrilar was interpreted as newly formed collagen and the amorphous or dense fibers as the mature collagen. The amorphous and dense fibers were observed in reminiscent pleomorphic adenoma stroma, in the capsule of the intracapsular type, in most of the stroma of intracapsular and invasive types of CXPA, and also as a dense line surrounding the glandular structures of the in situ areas. The fibrilar component was found in focal peripheral areas of the intracapsular and minimally invasive types, interpreted as invasion front. In frankly invasive type with only epithelial component the fibrilar pattern was found in focal areas involving small nests of cells and scattered throughout the stroma. When the tumour had myoepithelial cells as component, the fibrilar collagen, if present, was never in direct contact with tumoral cells. Conclusion: Fibrilar and dense fibers of type I collagen was observed in all types of CXPA. In CXPA with only epithelial component, focus of fibrilar collagen in peripheral border of the tumours and its presence surrounding and permeating small nests of cells in invasive type lead us to suggest that it should be an important component of the matrix in the invasion process of CXPA with epithelial component. Nevertheless, the same can not be postulated for the CXPA with myoepitelial component.

HPV IN SITU HYBRIDIZATION ANALYSIS OF JUVENILE LARYNGEAL SQUAMOUS PAPILLOMATOSIS

Samiah Zafar[1], Herman Yee[1], Youming Huang[2], Hannah Wen[3], Beverly Wang[3]
[1] New York University School of Medicine, USA
[2] Mount Sinai School of Medicine, USA
[3] New York Univeristy School of Medicine, USA

Background: Laryngeal squamous papillomas are benign neoplasms, often affecting the true vocal cords of children. They can be multiple with local recurrence, referred to as papillomatosis. Papillomas are thought to be associated with Human papilloma virus (HPV), demonstrated by using polymerase chain reaction (PCR). HPV in situ hybridization (HPV-ISH) is a novel technique that can be applied on paraffin-embedded tissue with well-preserved histological architecture. We analyzed for low and high risk HPV types in the laryngeal papillomas by HPV-ISH. Materials and Methods: Twelve excisional biopsy specimens of the larynx were retrieved from 4 patients over a 4 year period (2003-2007) from Mount Sinai Medical Center. Age ranged from 4months to 9 years (average 5 years). All tissue was formalin-fixed and paraffin embedded. Automated HPV in situ hybridization (ISH) analysis was performed for the hybridization on 4μm thick tissue sections, using a Bench Mark XT (Ventana Medical Systems, Tucson, AZ) with DNA probes for low risk HPV (6,11) and high risk HPV (16,18,31,33,35,39,51,52,56,58, and 66). Positive and negative controls were hybridized alongside the study cases. Positive staining was visualized using the precipitating chromogenic reaction NBT/BCIP with a nuclear localization. Results: Laryngeal papillomas are soft excrescences grossly. Histologically, they are composed of multiple slender, finger-like projections coved by squamous epithelium with central fibrovascular cores. In 1 patient (Case 1), focal mild cellular atypia was seen in a recurrent biopsy. No significant high-grade dysplasia seen in any of the biopsies. HPV-ISH revealed that 4 specimens from 2 patients (Cases 1 and 4) were positive for low risk HPV (50%). Three of these 4 specimens were recurrences from the same patient (Case 1). All twelve specimens of 4 patients were negative for high risk HPV (Table). Conclusions: Localized juvenile laryngeal papillomatosis is a benign condition related to HPV infection, with no evidence of high risk HPV. The identification of low risk HPV by ISH may be useful to predict local recurrence. HPV- ISH is a useful technique that can be easily performed on paraffin embedded tissue.

PP3-256
SIGNET-RING CELL SALIVARY DUCT CARCINOMA - A CASE REPORT

Maria Papagianni[1], Ioannis Dimitriadis[1], Doxakis Anestakis[1], Thomas Sidiras[2], Frideriki Patakiouta[3]
[1] Department of Pathology, Greece
[2] Department of Otorhinolaryngology, Greece
[3] Department of Pathology, Theagenion Cancer Hospital, Thessaloniki, Greece

Background:Salivary duct carcinoma (SDC) was first described by Kleinsesser in 1968 and was classified as an independent entity by the 1991 Revised World Health Organization. It is a rare but highly malignant tumour. Purpose: We report a rare case of primary high-grade ductal carcinoma of salivary gland with signet-ring cells, that was confirmed by autopsy. Case report: A case of a high-grade ductal carcinoma of salivary gland originated “de novo” in parotid gland is presented. A 73 year-old male came to our hospital for a parotid swelling. He was treated by superficial parotidectomy. The tumour was unencapsulated, poorly circumscribed, grayish white, measuring 2,8cm in maximum diameter. The results of gross, microscopic, and immunohistochemical examinations are described. Microscopic examination showed that the tumour was entirely consisted of large signet-ring cells, positive for PAS and PAS-diastase. Lymphatic, vascular and nerve invasion were detected. Immunohistochemically, the tumour cells were positive for Ker7, Pankeratin, CEA, KerLMW and EMA, and negative for S-100 protein, KerHMW, PSAP, PSA, ER, PR, TTF1. Further ENT-investigations including endoscopy and scans (MRT, ultrasound) showed no pathologic findings. In particular, growth of cervical lymph nodes and distant metastases were not revealed. Discussion: Salivary duct carcinoma is one of the most aggressive types of salivary gland carcinoma and is characterized by local invasion, lymphatic and hematogenous metastases and poor prognosis. The occurrence of signet-ring cells within salivary duct carcinoma is an extremely rare finding. The poor prognosis and aggressiveness of salivary duct carcinomas dictates aggressive therapy.

PP3-257
RELATIONSHIP BETWEEN ACTINOMYCES AND CLINICOPATHOLOGIC FINDINGS IN ROUTINE TONSILLECTOMY AND ADENOIDECTOMY SPECIMENS

Banu Dogan Gun, Burak Bahadir, Havva Gokce, Arzu Sonmez, Sukru Oguz Ozdamar
Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey

BACKGROUND: Tonsillectomy and adenoidectomy are frequently performed operations but there is little information about the histological features. In this study it is aimed to investigate the presence of actinomyces in tonsillectomy and adenoidectomy specimens and analyse the patient’s profile and

main pathological changes. METHOD: The medical records of patients who underwent tonsillectomy and adenoidectomy at Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, in the period between January 2001 and December 2006 were included. RESULTS: Out of 387, 179 (46.25%) were female and 208 (53.75%) were male patients. Mean age was 12.69 years ranging from 2 to 67 years. There were 309 (79.85%) in the pediatric age group and 78 (20.15%) were adults. Main surgical indication was concomitant presence of recurrent throat infections and stenotic symptoms of upper airways. In 62 (16.03%) patients an adenoidectomy and tonsillectomy was performed, 248 (64.08%) underwent tonsillectomy alone and 77 (19.89%) adenoidectomy alone. There was actinomyces in 42 (10.85%) of the 387 patients, of whom 17 were adult and 25 were pediatric. That is, actinomyces was present in 17 of the 78 adult patients (21.7%), and 25 of the 309 pediatric patients (8.09%). It was almost always seen in tonsillectomy specimens, but in one of the adenoidectomy specimen. In adult population,; Actinomycosis was present in all of the obstructive patients (17/17), but none in tonsillitis cases (0/17); however in pediatric population actinomycosis ratio was nearly equal; 48% and 52%, in terms of lymphoid hyperplasia cases (12/25) and inflammatory conditions (13/25), subsequently. CONCLUSION: The presence of actinomycetes may indicate an etiologic role for this organism in adenoid and tonsillar inflammatory conditions and hypertrophy. Our results indicate that actinomycetes may play an active role in the etiology of hypertrophy of tonsillar disease in adult populations and as well as tonsillitis in pediatric patients as the causative agent.

PP3-258
EXPRESSION OF α-, β-, AND y-CATENINS IN LARYNGEAL CARCINOMAS: CORRELATION WITH CLINICO-PATHOLOGICAL FEATURES

Elena Collantes-Bellido[1], Juan Ignacio De Diego[2], Alejandra Caminoa[1], Maria Del Pilar Prim[2], Marta Mendiola[1], BeléN San José[3], Manuel Nistal[1], David Hardisson[1]
[1] Department of Pathology. Hospital Universitario La Paz. Universidad Autónoma de Madrid, Madrid, Spain
[2] Department of Otorhinolaryngology. Hospital Universitario La Paz. Universidad Autónoma de Madrid, Madrid, Spain
[3] Section of Biostatistics. Hospital Universitario La Paz. Universidad Autónoma de Madrid, Madrid, Spain

BACKGROUND: Carcinoma of the larynx is one of the most frequent tumor in developed countries. Although several genetic and epigenetic alterations are characteristic of laryngeal carcinomas no definitive prognostic markers for advanced tumours have been identified. Catenins are a family of proteins including the α-, ß-, and y-catenins. In the last years, it has been demonstrated that alterations in the cadherin-catenin adhesion complexes are involved in tumor initiation, progression and metastasis. The aim of this study was to evaluate the immunoreactivity of the α-, ß-, and y-catenins in laryngeal squamous cell carcinomas (SCC) and to correlate their expression with clinicopathologic features. PATIENTS AND METHODS:This study involved a series of 279 formalin-fixed, paraffin-embedded laryngeal SCC. We constructed eight tissue microarray blocks where immunohistochemical staining was performed. Monoclonal antibodies against α-catenin (clone α-catenin-1, Dako, 1:35) ß-catenin (BD Biosciences, clone 14, 1:700), and y-catenin (BD Biosciences, clone 15, 1:1000) were applied using the Envision (Dako) method. The membranous expression of the catenins was scored as preserved, reduced or absent. RESULTS: Most of the tumors were located in the supraglottis (39.3%), followed by the glottis (25.5%), and subglottis (3%). The remaining cases were transglottic. Tumors were histologically classified as well (25%), moderately (42.6%) and poorly (32.4% differentiated. Overall, more than 75% of the tumors showed a reduced membranous expression of β- and α-catenin, especially in poorly differentiated carcinomas. In contrast, only 31.1 % of the cases showed a reduced expression of y-catenin expression. Conserved membranous y-catenin expression was associated significantly with tumor size (T1 vs T4), location (glottis vs non-glottis) and differentiation (well differenciated vs poorly differentiated carcinomas) ($p<0.005$. No other associations between catenin expression patterns and recorded clinicopathological variables were detected. DISCUSSION: Several studies have suggested that loss of β-catenin protein is associated with tumour progression, metastasis and poor patient prognosis in many types of cancer, and this may be attributable to its role in cell adhesion. In this study, we have show that loss of expression of α-, and β-catenins is a common abnormality in SCC of the larynx. A preserved membranous pattern of y-catenin was found in glottic, well-differentiated and small tumors. However, expression of α-, ß-, and y-catenins did not correlate with the prognosis of the patients.

PP3-259
SECOND PRIMARY SQUAMOUS CELL CARCINOMA ARISING IN CUTANEOUS FLAP RECONSTRUCTIONS OF HEAD AND NECK CANCER PATIENTS: A RARE LONG-TERM COMPLICATION

Yan Monnier[1], Philippe Pache[2], Philippe Monnier[2], Snezana Andrejevic-Blant[1]
[1] Institute of Pathology, CHUV-Hospital, Faculty of Biology and Medicine, University of Lausanne, 1011-Lausanne, Switzerland
[2] Department of Otolaryngology and Head and Neck surgery, CHUV-Hospital, Faculty of Biology and Medicine, University of Lausanne, 1011-Lausanne, Switzerland

The advances in reconstructive surgery have allowed surgical eradication of tumours which were considered inoperable in the past. Currently, surgical reconstructions by means of various types of skin flaps are commonly performed for advanced primary tumours of the head and neck. These techniques have been shown to increase loco-regional control of the disease and to improve functional rehabilitation. Early complications of regional and distant free flap transfers have been extensively described. However, there is still limited knowledge on the potential long-term complications of these techniques. Here, we report the cases of two patients with antecedents of squamous cell carcinoma of the head and neck (HNSCC), experiencing the development of a second primary SCC on the cutaneous surface of the flaps used for reconstruction. Growth of the second primary tumours occurred within a minimum of three year-interval. Both lesions arose at distance from the original mucosa of the oral cavity and from the deep surgical margins of the flaps. This observation ruled out any putative spread of a second primary tumour from the oral mucosa nearby the flaps. This is a rare complication of skin flaps reconstruction in HNSCC patients. Given the important expansion of these interventions in patients with head and neck cancers, this type of complication may become more frequent in the future and merit to be recognized by pathologists as a distinct entity. Interestingly, it seems that the well-known risk of a second primary HNSCC development in patients with previous head and neck carcinoma also applies to foreign tissues implanted in the area at risk. Therefore, long-term follow-up of patients previously treated for HNSCC, not only require careful evaluation of the normal mucosa of the upper aero-digestive tract but also of the cutaneous surface of the flap used for reconstruction.

TWO DIFFERENT SALIVARY GLAND TUMOURS LOCATED IN PAROTIS GLAND AND PARAPHARYNGEAL REGION SYNCHRONOUSLY: A CASE REPORT

Mehmet Kefeli[1], Ilkser Akpolat[1], Senem Cengel[2], Filiz Karagoz[1], Yucel Tanyeli[2], Bedri Kandemir[1]
[1] Ondokuz Mayis University, Faculty of Medicine, Department of Pathology ,Turkey
[2] Ondokuz Mayis University, Faculty of Medicine, Department of Ear, Nose and Throat,Turkey

BACKGROUND: The presence of more than one salivary gland tumour is a rare condition. Cytologic and histologic findings of a patient having two different tumours located in different regions (parotis gland and parapharyngeal area) at the same time are presented. CASE: A 58 years old male patient was admitted to the hospital with a mass in left side of the neck for 3 months. Physical examination revealed a mobile, painless, left jugulary mass (lymph node?) which was 4x3 cm in dimensions and revealed a parapharyngeal mass behind left tonsilla palatina. On the CT examination of cervical region and pharynx, two soft tissue masses are identified. The first mass was in the left parapharyngeal region and it was about 3,5x3x3 cm in dimensions, well-circumscribed and showed heterogeneous contrast uptake. The second one was 4,5x2,5x2 cm in dimensions, sharply delineated and homogeneous. It was located in the caudal region of the left parotid gland and partially embedded in to the gland. Initial clinical diagnosis was metastatic malign tumour. Fine needle aspiration was carried out for the cervical mass. Cytologic findings were consistent with Warthin tumour. The parapharyngeal mass was excised and microscopic examination diagnosis was pleomorphic adenoma. The servical mass was excised as partial parotidectomy 3 months later and microscopic examination diagnosis was Warthin tumour. When these two masses were evaluated with operative and clinical findings, they were determined unrelated anatomically. CONCLUSION: Although cytological examination is difficult in salivary gland lesions because of its complex morphology, fine needle aspiration of salivary gland lesions is a simple and cheap procedure which allows surgeon to decide the appropriate treatment before operation.

PP3-261
SYNOVIAL SARCOMA: A RETROSPECTIVE ANALYSIS OF 12 CASES

Amel Trabelsi, Sarra Mestiri, Ben Yacoub- Abid Lilia, Hanene Gasri, Med. Tahar Yacoubi, Soumaya Rammeh, Atef Ben Abdelkader, Sadok Korbi
Pathology Department, F. Hached Hospital, 4000 Sousse, Tunisia

Background: Synovial cell sarcoma is a mesenchymal malignancy that represents 10% of all soft tissues sarcomas. It most often occurs in the lower limbs of young adults. Our study aim is to report clinical and histopathological findings, treatment and outcome of such tumors. Methods: This is a retrospective study of 12 patients diagnosed with synovial sarcoma, retrieved from 1990 to 2005, at the pathology department of F. Hached hospital (Sousse, Tunisia). Results: The median age of patients was 21 years. The sex ratio was of 1. The most common sites of involvement were: The lower limbs (10 cases), the upper limbs (1 case) and the oropharynx (1 case). The revealing symptoms were: limb swelling in 11 cases, pain in 3 cases, dyspnea (1 case), cough (1 case) and a pulmonary metastasis (1 case). Our cases were classified according to the WHO's classification in: monophasic type (8 cases), biphasic type (3 cases) and undifferentiated type (1 case). The tumors were classified in grade 2 (8 cases) and in grade 3 (4 cases), according the FNLCC recommandations. The treatment consisted in surgical removal in 10 cases (consisting in an amputation in 3 cases); adjuvant chemotherapy was indicated in 3 cases, a post-operative combination of chemo-radiotherapy was indicated in 1 case. Therapeutic abstention was indicated in 1 case. Another patient refused treatment. Clinical outcome was unfavourable with death occurrence in 6 cases. Conclusion: Synovial cell sarcoma carries usually a poor prognosis, that is correlated to multiple factors such as: anatomic location, size of tumor, histological type, grade, treatment modalities, especially the quality of surgical resection.

PP3-262
GIANT CELL TUMOR OF BONE: A CLINICOPATHOLOGICAL STUDY 14 CASES

Amel Trabelsi, Sarra Mestiri, Soumaya Rammeh, Fatma Kebir, Wided Stita, Lilia Ben Yacoub Abid, Med. Tahar Yacoubi, Sadok Korbi
Pathology Department, F. Hached Hospital, 4000 Sousse, Tunisia

Background: Giant cell tumor of bone are particular by their morphologic features and the absence of accurate prognostic parameters. Method: This is a retrospective study of 14 cases of giant cell tumor of bones diagnosed at the pathology department of F. Hached hospital in Sousse between 1987 and 2004. Radiographic and histopathological features were reviewed and confronted with both clinical data and patient's follow-up. Results: 5 patients among six with a grade 1 tumor had a local recurrence; 1 patient among 8 with a grade 2 tumor had a local recurrence, another one developed pulmonary metastases after a local recurrence; 7 patients had neither recurrence nor metastasis after treatment. Conclusion: Histopathological parameters cannot be by their own predictive of a local recurrence or metastasis. Clinical and radiological features must be also taken in consideration.

PP3-263
LETHAL COMPLICATIONS OF RHEUMATOID ARTHRITIS - A RETROSPECTIVE CLINICOPATHOLOGIC STUDY OF 161 AUTOPSY PATIENTS

Miklós Bély[1], Ágnes Apáthy[2]
[1] Policlinic of the Hospitaller Brothers of St. John of God in Budapest, Hungary
[2] National Institute of Rheumatology and Physiotherapy, Budapest, Hungary

The aim of this study was to determine: (1) the spectrum and incidence of complications related to RA such as systemic vasculitis (SV) systemic AA amyloidosis (AAa), lethal septic infection (SI), carditis (endo-, myo-, epi-, or pancarditis), interstitial pneumonitis, interstitial lymphoid hyperplasia, polyserositis, glomerulonephritis, atlanto-axial subluxation, etc, (2) the mortality of complications related to RA, and (3) the clinically missed diagnosis of these. Patients and Methods A randomized autopsy population of 161 in-patients with RA was studied. RA was diagnosed clinically according to the ACR criteria. The complications of RA and cause of death were confirmed histologically. Results The lethal complications of RA were: Systemic vasculitis, which was found in 36 (22.4 %) of 161 RA patients, and led to death in 19 (11.8%) of 36 patients. SV was recognized clinically in 7 (19.4 rel%) of 36, and not recognized in 15 (78.95 rel%) of 19 patients with lethal complication of SV. AA amyloidosis complicated RA in 34 (21.1%) of 161 patients. AAa led to death by uremia in 17 (10.56%) of 34, and was clinically recognized in 9 (52.95 rel%) of 17 lethal cases, and not recognized in 8 (47.05 rel%) of 17 patients. Lethal septic infection was detected in 24 (14.9%) of 161 RA patients at autopsy, and was recognized clinically in 11 of 24 (45.8 rel%) cases. Cardiac insufficiency was the direct cause of death in 29 (18 %) of 161 patients, and was always recognized clinically. A rare form of interstitial pneumonitis (characterized by intensive interstitial lymphoid infiltration and secunder lymphoid follicle) led to death in 2 (1.24 %) of 161 cases, and was never diagnosed clinically. Interstitial nephritis in two (1.24 %), glomerulonephritis in one (0.62 %) of 161 RA patients led to death by uremia. The underlying disease leading to uremia was never recognized clinically. In 2 (0.9 %) of 161 patients acute liver necrosis (“yellow atrophy”), subacute liver necrosis (“red atrophy”) were the direct cause of death, clinically labeled as hepatorenal insufficiency but basically not recognized as the underlying disease leading to death. Discussion Two thirds of deaths were related to RA. Systemic vasculitis, AA amyloidosis and lethal septic infection were the most important major complications of RA. They were responsible for the death in 60 (53.1 rel%) of 113 cases related to RA (37.3 % of 161 RA patients). In this study systemic vasculitis was the most likely lethal complication to be missed clinically with high probability.

PP3-264
PATHOANATOMIST'S VIEW ON CERTAIN PROBLEMS IN PRESENT-DAY ONCOLOGY

Alexander Zubritsky
Municipal Institution "Taldom Central Regional Hospital",Russia

Mesothelioma is a comparatively rare neoplasm, more frequently affecting the pleura and peritoneum, less often - the pericardium. The diagnosis is imperfect, being usually delayed, and it is not by chance that this tumour remains an enigma for the oncologist. The accurate diagnosis is made at best while a pathomorphological examination of the removed tumour, at the worst - during a post-mortem examination.The author carried out a retrospective analysis of the pathoanatomical material at the Municipal Institution "Taldom Central Regional Hospital" (NCRH) during 1984-2004. Of the 1387 postmortem examinations of adults, we revealed only one case of malignant diffuse highly differentiated papillary mesothelioma of predominantly the visceral peritoneum.Below is our case report.A 79-year-old woman was admitted to the Surgical Department of the TCRH on 6th February 1994, complaining of abdominal pain, and lack of defecation for two weeks, having considered herself sick during two months when she had developed lack of appetite and less of flesh. At examination by the physician on duty, the following diagnosis was made: partial ileus, predetermined, in all likelihood, by a colonic tumour. Surgery performed on 15th February 1994 was laparotomy: ovarian cancer with metastases into abdominal organs. The cytological study of ascitic fluid: adenocarcinoma. The woman died on day 8 after surgery. The final clinical diagnosis: ovarian cancer, involving abdominal organs;ascites;disseminated atherosclerosis.At post-mortem examination: the dead body of an undernourished elderly woman;the abdominal cavity contains up to 300 ml of reddish, muddy fluid.The greater omentum is deformed, solid, in the form of detached conglomerate. Pathoanatomical diagnosis:malignant diffuse mesothelioma predominantly of the visceral peritoneum with the histological form of papillary adenocarcinoma;acquired mechanical ileus; serous-fibrous peritonitis;generalized progressing atherosclerosis of the aorta, of the ileal arterias stage IV, degree 5 (according to Avtandilov). Hence peritoneal mesothelioma as the primary cause of death amounted to 0.072% amongst 1387 postmortem examinations of adult patients of our general somatic hospital over 21 years.In our opinion,one should reconsider the policy of regional oncologists towards improvement of the material and technical basis,activization of their activities and making courageous decisions aimed at using vitally important emergency chemotherapy in order to increase the survival rate.

PP3-265
SUBCUTANEOUS SOLITARY FIBROUS TUMOUR OF THE BACK

Barbara Paola Banzatti, Francesco Klinger, Valeria Bandi, Angelo Virgilio Pagliari, Marco Klinger
Plastic Surgery Institute - University of Milan - Plastic Surgery Unit - Istituto Clinico Humanitas - IRCCS – Milano, Italy

Background Wagner in 1870 is credited of the first histologic description of solitary fibrous tumour (SFT) an uncommon spindle cell neoplasm recognized as a distinct entity among primary pleural neoplasm by Klemperer in 1931. In the last years has been observed that SFT is anatomically ubiquitous and multiple new extrapleural locations of this rare mesenchymal neoplasm have been reported. SFT may be difficult to diagnose outside the usual locations because of its histologic variability and its back of distinctive features. Method A 42-year-old female presented with a slow-growing and painless subcutaneous mass in her back that was initially clinically suspected of being an epidermal cyst or a lipoma. The patient underwent simple excision under local anaesthesia of the tumour which was observed to be located in the deep subcutis and focally in close proximity of the fascia at tumour base without involvement of the underlying musculature. Results Histologically the excised tumour consisted of a proliferation of spindle cells arranged in a storiform pattern embedded in a fibrous matrix. A prominent vascular pattern, focal myxoid and thick hyalinized collagen fibers were observed. There were few normal mitotic figures, but no abnormal mitoses. The tumour cells were positive for CD34, bcl-2, CD99 and vimentin whereas stains for S-100, EMA, cytocheratin, desmin and alpha-smooth muscle actin were negative. Based on these findings a diagnosis of SFT was made. Conclusion Clinically SFT presents as a slow-growing mass in middle-aged adults with no sex predilection. The histogenesis of this tumour remains a matter of controversy. It has been recently suggested that SFT may represent the neoplastic transformation of bcl-2/CD34 fibroblastic-like dendritic cells involved in antigen presentation within the connective tissue. Grossly SFT are well

demarcated, but partially encapsulated neoplasm. Histologically is characterized by a morphological appearance of alternating hypo- and hypercellular areas of spindle-shaped cells, dense bands of collagen and a vascular pattern. Differential diagnosis is sometimes difficult and is possible a mistaken with a variety of other soft tissue and spindle cell neoplasm including dermatofibrosarcoma protuberans, synovial sarcoma, schwannoma, spindle cell lipoma and cutaneous myofibroma. Immunohistochemistry is particularly important in the identification of rare and atypical soft tissue tumour. Immunohistochemically the diagnosis of SFT has been refined by the availability of immunohistochemical marker such as CD 34, bcl-2 and vimentin.

PP3-266
COMPARISON OF TWO METHODS OF ABDOMINAL FAT PAD ASPIRATION AND BIOPSY IN DIAGNOSIS OF AMYLOID DEPOSITION IN PATIENTS WITH LONG STANDING RHEUMATOID ARTHRITIS

Gholamhussein Alishiri[1], Nasrin Shayanfar[2], Roya Setareshenas[2], Jafar Forghanizadeh[3]
[1] Department of Rheumatology, Baqiyatallah University of Medical Sciences, Tehran, Iran
[2] Department of Pathology, Iran university of Medical Sciences, Rasol akram Hospital Tehran, Iran
[3] Department of Rheumatology, Iran university of Medical Sciences,Rasol Akram Hospital, Tehran, Iran

Objective: To comparing two methods of abdominal fat pad aspiration and needle biopsy in diagnosis of secondary amyloidosis in patients with long standing rheumatoid arthritis (RA). Method: 220 consecutive patients (53 males and 167 females) with a history of at least 5 years of RA in two rheumatology clinics were studied. Abdominal subcutaneous fat pad aspiration (ASFA) and abdominal subcutaneous fat pad biopsy (ASFB) was performed. Specimens were stained by alkaline congo red method. All specimens examined for presence of apple green birefringence under polarized light. For confirmation, all positive biopsy specimens and 40 negative controls with long standing RA (duration>15y) stained for AA protein by IHC method. Results: Amyloid was positive in 16 patients(7.3%). Nine of them were positive in both methods. Amyloid deposition was positive in 11(5%) patients with ASFA and in 15 (6.8%)patients with ASFB. All had 1+ deposits except in 2 of ASFB specimens, which had 2+ deposits. The sensitivity of ASFA and ASFB were 57% and 78.9% respectively. Conclusion: According to this study, the sensitivity of ASFA is lower than ASFB, however because ASFA is technically simple and less aggressive than ASFB, It is recommended that ASFA be used as first step in screening of patients with amyloidosis.

PP3-267
HISTOPATHOLOGICAL ASSESSMENT OF THE EFFECT OF NON- ABSORBABLE PROSTHETIC MESH ON THE SPERMATIC CORD CONTENTS: AN EXPERIMENTAL STUDY

Omran Zeinab[1], Abbas Mohamed[2], Nosseir Mona[1]
[1] Theodor Bilharz Research Institute (TBRI), Department of Pathology, Egypt
[2] Department of General Surgery Theodor Bilharz Research Institute (TBRI), Giza, Egypt

Background: Previous studies have documented that the use of synthetic prosthesis in repair of inguinal hernia markedly reduces the incidence of recurrence. However, little is known about the effect of these prostheses on the spermatic cord contents. This work was carried out to study the histopathological changes in response to contact with the commonly used prostheses (Prolene & Mersilene) on spermatic cord contents in male dogs. Materials and Methods: Thirty two male dogs were included in this study. The spermatic cords and testes were harvested from 2 dogs as a base line for the normal histology. The remaining 30 dogs were divided into 3 main groups. In the first (control) group (GI,n=10), the spermatic cord was delivered, its coverings were dissected and left intact on one side but on the other side it was skeletonized by removing its coverings. In the second group (GII,n=10), a strip of polypropylene (Prolene) mesh was wrapped snugly without strangulation around the dissected intact cord on one side and the skeletonized cord on the other side. A polyester (Mersilene) mesh was similarly applied in the third group (GIII,n=10). In each group, the spermatic cords and testes were examined histopathologically one week, and three months postoperatively. Results: At one week, the microscopic examination of the spermatic cord contents revealed more acute inflammatory reaction in mesh groups than the control. This reaction considerably subsided after three months with varying degrees and patterns of fibrous tissue deposition. These changes were more noticed in GIII than GII and in skeletonized cords than intact ones. The testes of all animals showed no histopathological changes. Conclusion: This experimental study proved the safety of the used non-absorbable prostheses on the spermatic cord contents and testes. Prolene mesh without skeletonization of the cord revealed more favorable results than Mersilene one.

PP3-268
CYCLOOXYGENASE-2 EXPRESSION IN BENIGN AND MALIGNANT CHONDROID TUMORS

Hye-Rim Park[1], Yong-Koo Park[2]
[1] Dept of Pathology, College of Medicine, Hallym University, Anyang, Korea
[2] Dept of Pathology, College of Medicine, Kyung Hee University, Seoul, Korea

Background: Recent studies have shown increased levels of cyclooxygenase-2 (COX-2) in various human malignancies to include various bone and soft tissue tumors. However, little is known with regard to COX-2 expression patterns in chondroid tumors. Method: Immunohistochemistry assays were performed for COX-2 in enchondromas (n=10), chondroblastomas (n=11), chondromyxoid fibromas (n=5), conventional chondrosarcomas (n=17), clear cell chondrosarcomas (n=7), and mesenchymal chondrosarcomas (n=6). Results: Among the benign chondroid tumors, chondroblastomas revealed characteristic strong positivity in 6 of 11 cases (54.5%). All enchondromas and chondromyxoid fibromas were negative except in one case. In conventional chondrosarcomas, three cases (17.6%) were strongly reactive with COX-2 and all positive cases represented grade III chondrosarcomas. Clear cell chondrosarcomas were found to be focally positive in two cases (28.5%), while all mesenchymal chondrosarcomas were negative. Conclusion: These findings suggest that COX-2 overexpression in conventional chondrosarcoma may represent both a negative prognostic factor and also an advanced histologic grade. Interestingly, expression of COX-2 in chondroblastomas could be an important factor for inducing peritumoral inflammatory changes in these specific tumors.

PP3-269
EXPRESSION OF VASCULAR ENDOTHELIAL GROWTH FACTOR-C AND ITS RECEPTOR IN OSTEOSARCOMAS

Hye-Rim Park[1], Yong-Koo Park[2]
[1] Dept of Pathology, College of Medicine, Hallym University, Anyang, Korea
[2] Dept of Pathology, College of Medicine, Kyung Hee University, Seoul, Korea

Background: Vascular endothelial growth factor-C (VEGF-C) and its receptor, vascular endothelial growth factor receptor-3 (VEGFR-3) have been implicated as important factors in the

formation of lymphatic vessels, but its role in osteosarcomas has not yet been fully investigated. This study aims to define the expression of VEGF-C and VEGFR-3 in primary and metastatic osteosarcomas and their relationship to various clinicopathologic parameters. Method: Thirty three primary osteosarcomas and two pulmonary metastatic samples were immunostained for VEGF-C and VEGFR-3. In addition, VEGF-C and VEGF-D mRNA expression levels in three different human osteosarcoma cell lines and control fibroblasts were evaluated by real-time quantitative polymerase chain reaction (PCR). Results: Both VEGF-C and VEGFR-3 were mainly expressed in the cytoplasm of the tumor cells. Of the 35 patients with osteosarcoma, 16 patients (45.7%) showed strong positive reaction with VEGF-C. Four cases (11.4%) were negative and 15 cases (42.9%) showed weak immunoreactivity. For VEGFR-3, 12 patients ((34.3%) showed strong positive reaction. Fifteen cases (42.9%) were negative and 8 cases (22.8%) showed weak immunoreactivity. A significant positive correlation (Rs=0.42, p=0.01) was found between the expression of VEGF-C and VEGFR-3 in osteosarcomas. The expression of VEGF-C was significantly associated with osteoblastic subtype and high histologic grade in osteosarcomas. However, the expression of VEGF-C showed no significant correlation with the presence of metastasis. Expression of VEGFR-3 was not related to any clinicopathologic features analyzed. Two of the three tested osteosarcoma cell lines showed amplification of VEGF-C mRNA compared to control cells. No amplification of VEGF-D was noted in these cell lines. Conclusion: Our data suggest that VEGF-C and its receptor are expressed in osteosarcomas. Although the level of VEGF-C was high, it does not seem to have a direct influence on tumor metastasis in osteosarcomas.

PP3-270
RETROPERITONEAL LYMPHANGIOLEIOMYOMATOSIS ARISING FROM CYSTIC ENDOMETRIOSIS

Masaharu Fukunaga[1], Aki Mistuda[2], Makiko Fukunaga[3], Kazutoshi Shibuya[4]
[1] Department of Pathology, Jikei University Daisan Hospital, Japan
[2] Department of Pathology, Toho Univeristy School of Medicine, Japan
[3] Department of Pathology, Nihon University, School of Medicine, Japan
[4] Deparment of Pathology, Toho University School of Medicine, Japan

Aim and design: A case of retroperitoneal lymphangioleiomyomatosis (LAM) arising from cystic endometriosis was described. Results: A 25-year-old woman with no history of tuberous sclerosis or hormonal therapy presented with a painless, palpable abdominal mass. Computed tomographic and magnetic resonance imaging studies of the abdomen demonstrated a 4 cm cystic mass in the retroperitoneum. Macroscopically, the excised retroperitoneal cyst was multilocular and measured 4.0 X 3.5 X 3.5cm. Histologically, the lesion demonstrated three components. The first were multiple cysts or glands lined by columnar epithelial cells with cilia. The second component was a condensation of endometrial-type small stromal cells immediately subjacent to the cystic epithelium or glands. The third component was a thick exterior wall composed of plump spindle cells with clear to palely eosinophilic cytoplasm in a fascicular pattern, and slit-like vascular spaces, resembling LAM. Immunohistochemically, the epithelium and glands were positive for cytokeratin 7. The endometrial-type stroma cells were positive for vimentin and CD10. The cells of the LMA-like component showed positive staining for HMB45, alpha-smooth muscle actin, muscle actin and h-caldesmon. Conclusions: The lesion, LAM arising from endometriosis, represents a distinctive pathologic entity that should be recognized and studied further. This type of lesion should be included in the differential diagnosis of retroperitoneal cystic lesions.

PP3-271
ONCOGENIC OSTEOMALACIA ASSOCIATED WITH PHOSPHATURIC MESENCHYMAL TUMOR, A CASE REPORT AND REVIEW OF LITERATURE

Maysa Al-Hussaini
King Hussein Cancer Center, Jordan

Oncogenic osteomalacia is an acquired syndrome characterized by renal phosphate wasting, hypophosphatemia, normal serum calcium levels and low serum 1,25-dihydroxyvitamin D osteomalacia caused by mesenchymal neoplasms that are termed phosphaturic mesenchymal tumors (PMTs). The condition improves or completely disappears after removal of the tumor. This is a case of a 22-year-old male who presented with a 1-year history of increasing bone pain and difficulty in walking. This was associated with generalised muscle weakness. Physical examination was unremarkable. Laboratory investigation revealed the presence of hypophosphatemia, phosphaturia, elevated alkaline phosphatase levels in the presence of normal calcium and parathyroid hormone levels. By MRI a paraspinal heterogenous well circumscribed mass was seen.Complete excision of the mass was performed. By microscopic examination, phosphaturic mesenchymal tumor was diagnosed. Oncogenic osteomalacia as well as phosphaturic mesenchymal tumor are disscused along with review of the literature.

PP3-272
GIANT CELL BIPHASIC SYNOVIAL SARCOMA WITH MASSIVE OSTEOID AND BONE FORMATION SIMULATING OSTEOSARCOMA

Lankar Abdelaziz[1], Laouar Omar[2], Oukid Nadia[1], Belghersa Lamine[1], Kassouri Med Lamine[3], Bouzitouna Mahdjoub[3], Maza Rabeh[3]
[1] Department of Pathology University Hospital Annaba-Algeria
[2] LAOUAR-Algeria
[3] Department of Orthopedical Surgery University Hospital Constantine-Algeria

Introduction Synovial sarcoma with giant cells and predominant osteoïd and bone formation is a rare variant difficult to distinguish from osteosarcoma especially in presence of lytic areas. Case report We report a case in a man aged 49 years admitted in Orthopaedic Department for pathologic fracture of the upper right femoral metaphysis. Radiography shows a well-circumscribed and calcified tumour of 37mm diameter with lytic areas in upper metaphysis and diaphysis of the right femur. The surgeon discovers a hard, reddish, rounded mass with focal calcifications occupying the external hillside of the fracture and infiltrating the neighboring bone. Histopathologic examination leads to a diagnosis of giant cell biphasic synovial sarcoma with massive osteoïd and bone formation. The pattern is biphasic with epithelial component expressing intensely CK and EMA, numerous mononuclear and giant cells and extensive osteoid and bone formation. Discussion Diagnosis is difficult because of the existence of lytic areas accompanying the tumor, massive osteoïd and bone formation and the character of the tumour cells associating a mononuclear background and giant multinucleated cells. It is important for the pathologist not to misdiagnosis this rare entity of synovial sarcoma because of its different course from osteosarcoma. The main argument which plead in favour of synovial sarcoma is essentially biphasic pattern with glandular and squamous component expressing CK and EMA.

PP3-273
ALVEOLAR SOFT PART SARCOMA OF BONE, A CASE REPORT
Fariba Abbasi, Ahmad Reza Afshar
Urmia University of Medical Sciences, Iran

Background:Alveolar soft part sarcoma (ASPS) is a distinct sarcoma that was defined by Christopherson et al in 1952.The incidence of ASPS has been reported to be less than 1% of all the primary soft tissue malignancies.Primary involvement of bone by ASPS is extremely rare. ASPS usually grows as a painless mass without functional impairement.Grossly,the tumor is well circumscribed,usually firm,grayish- yellow.Microscopically, the tumor cells are separated by fibrovascular tissue into nests.The cells are large and have vesicular, prominent nuclei and a granular cytoplasm.Mitoses are exceptional.Intracytoplasmic PAS positive diastase resistant crystalline material is diagnostic of the tumor. Case presentation:We report a 20 year old man with swelling of left heel.Radiography showed a well- defined large lytic lesion of calcaneous bone.Microscopic examination of curettage derived sample showed proliferation of large polygonal cells with vesicular nuclei and eosinophilic cytoplasm arranged in nests.Intracytoplasmic needle like PAS positive structures were seen.Immunohistochemical staining for S-100 protein was negative.Staining for desmin and vimentin was focally positive. Results:The mentioned microscopic findings confirmed the diagnosis of ASPS..Three months after curettage of the lesion metastatic foci were revealed in lung. Conclusion:Primary involvement of bone by ASPS is extremely rare,however it should be considered in differential diagnosis of primary lytic bone lesions with distant metastases,in particular metastatic hypernephroma in a young patient.

PP3-274
CLEAR CELL ADENOCARCINOMA OF ABDOMINAL WALL
Thouraya Achach, Soumaya Rammeh, Amel Trabelsi,
Lilia Ben Yacoub-Abid, Wided Stita, Fatima Zahra Kebir,
Mounir Trimech, Moncef Mokni, Sadok Korbi
Department of Pathology. Hospital Farhat Hached, Sousse, Tunisia

Background Endometriosis is a frequent benign disorder. Several observations of the coexistence of endometriosis and cancer have been published. Malignancy arising in extra-ovarian endometriosis is a rare event. Method Through a new case of clear cell adenocarcinoma associated with endometriosis foci occurring in the abdominal wall of a 49-year-old woman, we highlist the possibility of endometriosis malignant transformation and we review recommended criteria for this diagnosis. Results The patient was operated 20-years before for uterus leiomyoma. Actually, she presented with a large painful abdominal mass. After radiologic exploration, she was operated with a diagnosis of desmoid tumor. Histological examination showed a clear cell adenocarcinoma associated to endometriosis foci. Exploration of uterus and ovary did not show any malignancy or endometriosis. Conclusion When confronted to an extraovarian tumor with endometrial appearances, pathologists should concider a primary tumor and an origin in endometriosis. The demonstration of endometriosis might require the examination of multiple sections. Confirmation that a tumor is of endometrial type is of clinical importance.

MALIGNANT PERIPHERAL NERVE SHEATH TUMOUR ARISING IN ASSOCIATION WITH ECTOMESENCHYMOMA: DOES IT REALLY EXIST?
Guillermo Muñoz[1], Francesco Felipo[1], Isabel Marquina[1],
Mar Pascual[1], Ana Fuertes[1], Celia Del Agua[2], Luis Plaza[1]
[1] Pathology Department, Miguel Servet University Hospital, Zaragoza, Spain
[2] Pathology Department, Alcañiz Hospital, Alcañiz(Teruel),Spain

BACKGROUND: Two situations have been described in which a MPNST is associated with ganglioneuromatous or ganglioneuroblastomatous tissue; the first, when one of the tissues transforms into a MPNST; the second, when the ganglioneuromatous portion of an ectomesenchymoma does the same. Ectomesenchymoma is a tumour that usually appears during paediatric age, and it is composed by rabdommyoblastic elements, mature ganglion cells and neuroma-like structures. MATERIAL AND METHODS: Newborn male that presents a right paratesticular mass of 4x3x1,5 cm, wich is removed. RESULTS: Histological study reveals three well differentiated areas; one has a nodular pattern, and it is composed by small round blue cells with Homer-Wright rosettes, reactive for neuroendocrine and skeletal muscle immunohistochemical markers. Other areas are fusiform and loose, and present abundant scattered mature ganglion cells. It is also seen densely cellular areas consisting of spindle atypical cells with a high mitotic index, reactive for S-100 protein. It is diagnosed as malignant ectomesenchymoma with areas of high grade MPNST, originated from the schwannian constituent of ganglioneuroblastoma. CONCLUSION: Does the possibility of a MPNST developing from the ganglioneuromatous portion of an ectomesenchymoma actually exist? Two cases of complex tumours which contain neuroblasts or ganglion cells and also mesenchymal elements, usually rhabdomyosarcoma have been described, although there are authors who are uncertain about them based on the fact that, in spite having MPNST, neither of them reports clear images of it. Besides, Conzutto et al. believe that an ectomesenchymoma must not have features of MPNST. Our case shows evident areas of rhabdomyosarcoma and ganglioneuroblastoma, with focus of MPNST, which leads us to consider it an ectomesenchymoma that undergoes transformation to MPNST.

PP3-276
PRIMARY OSSEOUS RHABDOMYOSARCOMA WITH FOCAL MATRIX FORMATION MIMICKING OSTEOSARCOMA: A CASE REPORT
Radzislaw Kordek[1], Piotr Sowa[1], Dorota Jesionek-Kupnicka[1],
Michał Panasiuk[2], Marek Kmieciak[2], Cezary Chudobinski[3]
[1] Department of Oncology, Medical University Lodz
[2] Department of Orthopaedic Surgery, Copernicus Memorial Hospital Lodz, Poland
[3] Department of Radiology, Copernicus Memorial Hospital Lodz , Poland

We present an unusual case of primary osseous pleomorphic rhabdomyosarcoma with focal matrix formation mimicking osteosarcoma. The patient was a 21-year-old man who suffered for two months with pain and slight enlargement of his left calf. The plain film demonstrates large, predominantly osteolytic mass in the region of proximal fibula with typical features of malignant primary tumour. On open surgical biopsy, the tumour was consisted of atypical cells, some presenting spindle morphology. Between them, there were bands of densely hyalinized matrix with osteoid appearance, but without definite lacunae or calcifications, and the diagnosis of osteosarcoma was established. Consequently, the tumor was removed. The tissue presented more pleomorphic cells with some definite rhabdomyoblasts. Desmin, actin, Myf4 and MyoD1 were positive in tumor cells and the diagnosis of rhabdomyosarcoma was eventually established. A few cases of primary pure rhabdomyosarcoma of bone were reported, and there were also reported cases of other bone tumours with rhabdomyosarcomatous differentiation: dedifferentiated chondrosarcoma, fibrosarcoma and osteosarcoma. Our case does nor meet criteria for sclerosing rhabdomyosarcoma as matrix formation is focal and cells are spindle and pleomorphic, but it shows the another possiblity for mistake with primary osseous tumour.

PP3-277
CORRELATION BETWEEN MICROVASCULAR DENSITY AND DIFFERENTIATION GRADE IN SOFT TISSUE TUMOURS

Ovidiu Mederle[1], Narcisa Mederle[2], Dragos Andrei Izvernariu[1], Marius Raica[1]
[1] University of Medicine and Pharmacy, Timisoara, Romania
[2] Veterinary Medicine Faculty, Timisoara, Romania

Introduction Although there are thousands of publications on the subject of tumour angiogenesis, their great majority refer to carcinomas, and the publications on the subject in soft tissue tumours are very rare and, until present, with discordant results. According to this perspective, we have made the assessment of microvascular density in soft tissue tumours. Materials and methods 54 cases of soft tissue tumours (43 malignant and 11 benign tumours) were studied according to the following protocol: surgical samples were fixed in buffered formalin, embedded in paraffin, sectioned at 5 μ, then stained for morphological diagnosis (H&E), and for immunohistochemical detection of microvessels (smooth muscle actin – SMA, CD31 and CD34). Weidnet method of microvessel counting was used. Results All the tumours included in the study have presented rich blood vessel network, the majority (>80%) of the blood vessels from within the tumour area being of immature and intermediate type (positive for the endothelial markers and negative for SMA). This aspect was more obvious in the case of liposarcoma and malignant fibrous histiocytoma, but with no correlation with the differentiation degree. The highest values of microvascular density (MVD) were recorded in liposarcoma and malignant fibrous histiocytoma, in straight correlation with the high number of immature and intermediate blood vessels. We have noticed major differences in the blood vessel number between benign and malignant tumours, which were statistically significant ($p<0.02$). We have also noticed significant differences between the group composed of leiomyosarcomas and fibrosarcomas on one side, and liposarcoma and malignant fibrous histiocytoma on the other side ($p<0.05$). The results of microvascular density assessments were concordant for either endothelial marker used (table). Microvascular density was significantly higher in the malignant tumours than in the benign ones. Tumour MVD/CD34 MVD/CD31 Benign tumours 10.3 9.4 Fibrosarcoma 34.6 32.2 Liposarcoma 61.2 58.3 Malignant fibrous histiocytoma 58.9 55.7 Leiomyosarcoma 21.5 22.4 Conclusions Malignant soft tissue tumours have a rich blood vessel network, especially the liposarcoma and malignant fibrous histiocytoma. The majority of the blood vessels from within the tumour area are of immature and intermediate type. MVD does not correlate with the differentiation degree, but have significantly higher values in malignant tumours then in the benign ones.

[4] Department of Pathology and Laboratory Medicine, Veterans General Hospital-Kaohsiung, Kaohsiung, Taiwan

Background: Histological assessment for prognostication of myxofibrosarcomas remains challenging, for which we recently identified Skp2, an oncoprotein involved in S-phase progression, as an independent prognosticator . Methods: We assessed S-phase fraction (SPF) and DNA ploidy of myxofibrosarcomas and the association between SPF and Skp2. Flow cytometric findings were analyzed by CellQuest software for 75 primary myxofibrosarcomas and correlated with clinicopathological factors, Skp2 labeling index (LI), metastasis-free survival (MeFS), and overall survival (OS). Results: Forty-eight and 27 cases were classified as diploid and non-diploid, respectively. High SPF (≧20%) was detected in 32 of 61 interpretable cases. Skp2 overexpression (LI ≧ 10%) was seen in 36 of 72 cases with successful scoring. Non-diploidy was associated with higher FNCLCC grades ($p=0.006$), remarkable necrosis ($p=0.010$), and Skp2 overexpression ($p=0.018$). Noticeably, SPF was significantly related to Skp2 LI ($p<0.001$, $r=0.458$) and other clinicopathological factors, including FNCLCC grade, AJCC stage, and mitotic rate, etc. Non-diploidy predicted shorter OS ($p=0.0045$) and MeFS ($p=0.0489$), whereas SPF ≧ 20% was associated with inferior MeFS ($p=0.0252$) alone. In multivariate analyses, non-diploidy remained as an independent predictor for both OS ($p=0.020$, RR=3.337) and MeFS ($p=0.013$, RR=5.780), together with Skp2 overexpression ($p=0.014$ for OS; $p=0.017$ for MeFS) and positive margins ($p=0.004$ for OS; $p=0.002$ for MeFS). Conclusion: Skp2 overexpression promotes S-phase progression in myxofibrosarcomas, with a strong association between Skp2 LI and SPF. However, SPF, probably overshadowed by Skp2, provides no independent prognostic utility. Non-diploidy, along with Skp2 overexpression and positive margins, is independently predictive of adverse outcomes.

PP3-279
INTRAMUSCULAR HEMANGIOMA. REPORT OF 41 CASES

Samir Amr, Salwa Sheikh
Dhahran Health Center, Dhahran, Saudi Arabia

Intramuscular hemangiomas are uncommon soft tissue tumors with potential for recurrence. There are two large series in the literature (Allen and Enzinger: 89 cases; and Beham and Fletcher: 74 cases). Several single case reports or series of few cases are reported. We report herein a series of 41 cases. During 30-year period (1974-2003), a total of 41 cases of intramuscular hemangiomas were diagnosed at our laboratory. There were 16 males and 25 females. The mean age at presentation was 20 years with a range from 1 to 62 years. 15 patients (38%) were less than 15 years, and 33 (80%) were less than 30 years of age. The tumors were located in the upper limbs (10 cases), lower limbs (13 cases), trunk (8 cases) and head and neck (10 cases). The tumors were classified according to the type of blood vessels dominating the lesion. In some instances, a mixture of histologic patterns was observed in the same case. The commonest variant was the cavernous type (22 cases). Other variants included capillary (6), venous (6) and mixed (7). Several tumors showed the presence of thrombi (9) or phleboliths (10). Occasional tumors showed Masson lesion (Intravascular papillary endothelial hyperplasia). Most lesions showed variable amount of fatty tissue. Four tumors recurred locally, most probably due to incomplete excision on initial surgery.

PP3-280
CANINE OSTEOSARCOMA: HISTOGENETIC AND CELL PROLIFERATION CHARACTERISTICS
Josemara Cavalcanti, Eliane Amstalden
UNICAMP-State University of Campinas, SP, Brazil

Osteosarcoma is the most common of all malignant canine bone tumors and has a high aggressiveness potential. From the histological point of view it is a tumor with a heterogeneous cell pattern that is characterized by the production of bone matrix and/or immature bone by atypical osteoblasts. Systematic studies with a objective to evaluate histogenetic aspects and the cellular proliferation index in canine osteosarcomas have not yet been described. The objective of this study was to determine the differentiation of the cellular elements and evaluate the cell proliferation index of these tumors correlating them with their different morphological subtypes, using markers such as: vimentin, osteocalcin, S-100 protein, 1A4, HHF53, factor VIII, AE1/AE3, CD31, CD34 and Ki-67. A retrospective study was performed using 65 cases of canine osteosarcoma, clinically evaluated according to sex, breed, age and topography of the lesions. Tumors were classified according to their histological subtype in: nonproductive, moderately productive and productive osteoblastic tumors, chondroblastic, fibroblastic, giant cell type, telangiectatic and undifferentiated subtypes. Males from the Rottweiler breed with an average age of 7,4 years were more frequently affected by osteosarcoma. In 77,4% of cases, the lesions were on the appendicular skeleton (mainly on femur). The identified histological subtypes were: osteoblastic (47,7%), fibroblastic (23,1%), chondroblastic (21,5 %), giant cell type (4,7%), telangiectatic (1,5%) and undifferentiated(1,5%).In 98,2% of all tumors there was vimentin reactivity. Immunoreactivity to osteocalcin occurred in osteoblastic, chondroblastic and fibroblastic cells of 91% of all osteosarcomas. The S-100 protein was expressed in 79,7% of the cases (100% of the chondroblastic subtype). A significant proportion of osteosarcomas expressed positively to 1A4 and HHF35 antibodies. All osteosarcomas were negative for AE1/AE3 and CD31 and CD34 testing. Ki-67 analysis revealed a high cell proliferation index in all cases nonproductive osteoblastic osteossarcoma subtype. Canine osteosarcomas are constituted by a diverse cell population, composed of osteoblastic, chondroblastic, myofibroblastic and mioblastic elements, which are probably originated from a single pluripotent mesenchymal cell or from immature osteoblasts that go thru a differentiation process. Nonproductive osteoblastic osteosarcoma presented a considerably high cell proliferation index that may relate to a more aggressive behavior.

PP3-281
FIBROMATOSIS-PRIMARY AND FIRST RECURRENT TUMORS. A FLOW CYTOMETRIC AND CLINICAL ANALYSIS IN SEARCH TO PREDICTORS OF OUTCOME
Eliane Amstalden[1], Frederic Preffer[2], Andrew Rosenberg[2]
[1] State University of Campinas, SP, Brazil
[2] Massachusetts General Hospital, Boston, MA, USA

Fibromatosis is a benign fibrous tissue tumor that has a significant propensity to locally recur. To help identify features predictive of aggressive behavior, we analyzed retrospectively, a large series (68 cases) of deep seated and plantar fibromatosis. We determined the phases of cell cycle and DNA concentration, recorded clinical information, and evaluated a variety of histological features (degree of cellularity, mitotic index, stroma composition, margin of growth, and status of resection margin) of primary (50 cases) and first recurrent (18 cases) tumors. We correlated these findings with the patient's outcome to ascertain prognostic parameters. The patients included thirty-eighty males and 30 females who ranged in age from 5-79 (mean 34) years. All tumors were resected and nineteen patients also received radiotherapy. Recurrences developed in 38 patients. Tumor size ranged from 1 to 16 (mean= 6.7) cm. Flow cytometric analysis was performed on 51 tumors (35 primary and 16 first recurrent tumors). All tumors were diploid and greater than 93% of the analyzed cells were in the G0/G1 (resting) phase. The morphologic and flow cytometric findings in fibromatosis were similar in the primary and first recurrent tumors and were not associated with any prognostic features. However patient age, involvement of surgical margins and tumor size were predictive of local recurrence.

PP3-282
AGGRESIVE ANGIOMYXOMA. A REPORT OF TWO CASES IN MEN
Alva MartíNez-Angoa, Mario Alfonso Reséndiz-Morán, Ernesto Carrera-González, Mercedez Hernández-González
Hospital General de México, Mexico

These are the first two cases of aggresive angiomyxoma diagnosed and treated in men in the General Hospital of Mexico City. The first case was a 69-years-old man, presented with an inguinal mass, at first diagnosed as an hernia. The second case was a 32-year-old man with an increased volume in the scrotum diagnosed as lymphedema. The aggresive angiomyxoma (AA) is a soft tissue neoplasm found in pelvis or perineum, locally aggressive but not metastatic, it is frequently found in women, but it is very rare in men. However, it seems to have a better prognosis in men. The tumors in both men and women must be differentiated from intramuscular myxoma, myxoid neurofibroma and angiomyofibroblastoma, all of them benign neoplasms without any risk of relapse or local invasion. In several cases, the AA can be mistaken with a malignancy, because of the size and infiltration of surrounding tissues. So it is important to recognize it to select the correct treatment and give a prognosis.

PP3-283
REACTIVE ANGIOENDOTHELIOMATOSIS IN A PATIENT WITH CHRONIC RENAL FAILURE
George Zimmer[1], Alex Ochsner[2], Herbert Koppl[1], Urs Wagner[1], Hans-Martin Riehle[1], Christian Bussmann[1], Markus Zuber[2], Carole Gengler[3], Louis Guillou[3]
[1] Viollier Histopathologie, Basel, Switzerland
[2] Departement Chirurgie, Chirurgische Klinik, Kantonsspital Olten, Switzerland
[3] Institut Universitaire de Pathologie, Lausanne, Switzerland

BACKGROUND: Reactive angioendotheliomatosis (RAE) is a rare condition of unknown pathogenesis characterized by a reactive cutaneous vascular proliferation that often occurs in the setting of coexistent systemic disease. Different terms have been used for this lesion, including systemic proliferating angioendotheliomatosis, diffuse dermal angiomatosis and glomeruloid angiomatosis. METHODS: We describe a case of RAE in a patient with chronic renal failure. RESULTS: A 66-year-old woman presented with a dermal swelling of the left thigh. No previous trauma was recorded. The patient had several concomitant diseases, including diabetic chronic renal failure, anaemia, hypertension, coronary heart disease, mitral and aortic valve disease. Calcium serum level was normal. Histologically, the lesion was characterized by a diffuse proliferation of anastomosing capillaries within the dermis and subcutis. Endothelial cells showed focal hobnailing, but lacked significant atypia or significant mitotic activity. Media calcinosis was observed in some dermal arteries as well as foci of subcutaneous fat necrosis. Immunhistochemically, endothelial cells expressed CD31 and CD34 and were negative for HHV8. Smooth muscle actin stained pericytes. CONCLUSION: RAE is a rare, probably under-recognized benign lesion, which can easily be confused with other benign and malignant vascular neoplasia. RAE is

commonly associated with underlying systemic diseases, including renal or hepatic failure, chronic infections, rheumatoid arthritis, valvular heart disease, and cryoglobulinemia. Immunoreactivity for HHV8 has been detected in up to 40% of the cases.

PP3-284
DISTRIBUTION OF CHONDROCYTES CONTAINING ALPHA-SMOOTH MUSCLE ACTIN IN HUMAN NORMAL, OSTEOARTHROTIC AND TRANSPLANTATED ARTICULAR CARTILAGE

Ctibor Povysil
Institute of Pathology, 1st Medical Faculty and University General Hospital, Prague, Czech Republic

Background: Relatively little is known about the expression of a contractile actin isoform, alpha smooth muscle actin, in the normal human articular chondrocytes and in chondrocytes during certain pathological conditions. The aim of our work was to evaluate the occurence of alpha-smooth muscle actin in normal, osteoarthrotic and transplantated articular cartilage by means of immunohistochemistry. Method: Histology and immunohistochemistry were performed on paraffin embedded cartilage specimens obtained during total hip replacement for femoral neck fracture (15cases) and or osteoarthrosis (15 cases). Moreover, tibial plateau were retrieved from seven males with haemophilic arthropathy undergoing total knee arthroplasty. We also used samples from 9 patients with autologous chondrocytes transplantastion in the region of the traumatic defect in the distal femur 10 months after operation. Results: Approximately 20% of the chondrocytes in the superficial region of normal cartilage expressed alpha-smooth muscle actin as demonstrated by immunohistochemistry. It was readily apparent that fever cells in deep region contained alpha-smooth muscle actin. In the osteoarthrotic cartilage and cartilage from haemophilic patients occurred predominantly cells comprising clonal grouping stained for alpha-smooth muscle actin. In regions with formation of fibrocartilagineous repair tissue the majority of cells stained also positive. In the case of transplantated autologous chondrocytes the samples obtained 10 months after operations new cartilage had partly hyaline character and the majority of cartilage cells contained alpha-smooth muscle actin. Conclusion: Our study showed that significant percentage of articular chondrocytes express alpha-smooth muscle actin in health, disease , response to injury, defect healing and after autologous transplantation. They may utilize the contractile actin isoform in manipulating the extracellular matrix of articular cartilage.

PP3-285
CUTANEOUS LEIOMYOSARCOMA

Anastasia Nikolaidou[1], Christos Makos[2], Elisavet Pazarli[1], Theodoros Balampanidis[3], Rodi Kotakidou[4], Symela Amanatidou[5]
[1] Department of Pathology, General Hospital of Kilkis, Greece
[2] Department of Oral and Maxillofacial Surgery, General Hospital of Kilkis, Greece
[3] Department of Otorinolaryngology Head and Neck Surgery, General Hospital of Kilkis, Greece
[4] Department of Pathology, General Hospital ''G. Gennimatas'', Thessaloniki, Greece
[5] Technician, Greece

BACKGROUND: Superficial leiomyosarcomas are rare soft tissue tumors that account for less than 3% of all cutaneous soft tissue neoplasms. They further divided into cutaneous and subcutaneous and they usually occur in the extremities. METHOD AND RESULTS: We report a case of an 80-year-old female patient who came for excision of a firm protruding nodule at the temporal area, measuring 3,5 cm. Histological examination of the specimens of the resected nodule showed a spindle-cell tumor with morphologic and immunohistochemical features compatible with leiomyosarcoma; the tumor was positive for smooth-muscle actin, caldesmon, desmin and vimentin but negative for S-100 protein, HMB-45 and pankeratin. CONCLUSION: Immunohistochemical study seems necessary due to the difficulties in the differential diagnosis, which includes spindle-cell dermal carcinoma, spindle-cell melanoma and malignant fibrous histiocytoma. Furthermore the location of this particular neoplasm is considered very rare.

PP3-286
GLOMANGIOMA OF THE THIGH: CASE REPORT. CLINICOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL FINDINGS

Lydia Abou-Asabeh, George Sfyroeras, Konstantinos Moulakakis, Nikolaos Bessias, Calypso Barbatis
Hellenic Red Cross Hospital, Greece

Background: Glomus tumors are usually benign perivascular neoplasms composed of cells resembling modified smooth muscle cells of the normal glomus body with three variants: the solid type, glomangioma and glomangiomyoma. They are sporadic but autosomal dominant inheritance with linkage to chromosome 1p21-22 (locus VGLOM), leading to mutation of the glomulin gene has been reported. The thigh is an exceptionally rare site with less than 10 published cases. Methods: A 41-year-old female presented with a disturbing, painless mass at the inner side of her right thigh. An MRI scan revealed a mass fed by a branch of the deep femoral artery situated in between the adductor muscles of the right thigh. The tumor was excised and it was an encapsulated, 3.5 cm, brown, friable mass with recognisable transversing fibrous bands. The tissue was formalin fixed and examined with H+E, PAS, PAS-diastase and with the immunohistochemical method of Envision-HRP for detection of vimentin, α-SMA, desmin, CD 34, factor VIII, CD 99, Bcl 2, c-kit, chromogranin, mixed cytokeratins, ki 67, S-100 and p 53. Results: The tumor was an encapsulated, non invasive mass with a complete fibrous vascular capsule, surrounded by fibrofatty tissue with scattered striated muscle fibers. The bulk of the tumor mass comprised large vascular channels with thin or hyalinised wall and in between the cellular areas were composed of oval cells with uniform hyperchromatic nuclei (ki 67 <1%,) and eosinophilic cytoplasm arranged in compact, trabecular masses, single cells or as perivascular wreath like. The neoplastic cells were vimentin, α-SMA, CD 34, Bcl 2 positive with focal strong expression of desmin. With PAS-diastase a distinct perivascular linear positivity was noted and a histological diagnosis of glomangioma was made. Conclusion: This is a case of a well circumscribed glomangioma of the right thigh, with an aberrant immunophenotype in an unusual site which required differential diagnosis from hemangioma, cellular leiomyoma and neuroendocrine tumors.

PP3-287
SOFT TISSUE SARCOMAS: REVIEW OF 614 CASES

Pelin Bagci[1], Nuray Kepil[1], Hale Demir[1], Sergulen Dervisoglu[1], Didem Colpan[2], Fazilet Dincbas[2], Nil Molinas Mandel[3], Murat Hiz[4], Pembe Cagatay[5]
[1] Istanbul University Cerrahpasa Medical Faculty,Department of Pathology, Istanbul, Turkey
[2] Istanbul University Cerrahpasa Medical Faculty,Department of Radiation Oncology, Istanbul, Turkey
[3] Istanbul University Cerrahpasa Medical Faculty, Department of Medical Oncology, Istanbul, Turkey
[4] Istanbul University Cerrahpasa Medical Faculty,Department of Orthopaedic Surgery, Istanbul, Turkey
[5] Istanbul University Cerrahpasa Medical Faculty,Department of Biostatistics, Istanbul, Turkey

BACKGROUND: Even with the reform in molecular genetics , soft tissue sarcomas (STS) are still among the main problems of diagnostic pathology and the pathogenesis of most soft tissue tumors is still unknown. We need larger epidemiologic studies to define the pathogenesis and to find out the most effective therapy options. METHOD: We reviewed 614 cases diagnosed in our department between the years 2000- 2007 according to the latest WHO classification; and analyzed them considering age, sex, etiology, localization, recurrence, metastasis, and therapy. RESULTS: Fifty-five percent of the cases were between 21-60 years; and the median age was 46 years. In the first two decades of life trunk and abdomen and then lower extremities were the most popular localizations. There were no significant relation between age and sex. Immunhistochemistry was used for the tumors in early ages (<40), but histological analyses were enough in adult tumors. Tumors of uncertain differantiation group were mostly diagnosed type (21%). Highest recurrence rate was seen in abdominal tumors and especially in liposarcomas. Lung was the first site for metastasis and the highest metastasis rate was seen in synovial sarcoma. There were only 2 postradiotherapy sarcomas; a synovial and a pleomorphic sarcoma. The prefered therapy option was mostly surgery; but chemotherapy and radiotherapy were also used for the aproppriate tumors. CONCLUSION: The median age in our material is younger then in the English literature. Distribution of localization is the same; but there is no correlation between gender and other variables. Tumors of uncertain differantiation constitute the largest part of our review. As we cannot obtain the origin of many sarcomas even with immunhistochemistry, histopathologic examination is still the gold standart in sarcoma diagnosis.

PP3-288
REPORT OF THREE CASES OF MESENTERIC FIBROMATOSIS. IS IMMUNOHISTOCHEMISTRY NECESSARY FOR THE DIAGNOSIS?

Hariclia Kalekou[1], Ioannis Efstratiou[2], Stavroula Pervana[2], Ioannis Skandalos[3]
[1] Pathology Department, Saint Paul General Hospital, Greece
[2] Papageorgiou General Hospital Institute of Pathology, Greece
[3] Surgical Department, Saint Paul General Hospital, Greece

Mesenteric fibromatosis is a form of deep fibromatosis. According to the 2002 WHO classification fibromatoses belong to the category of intermediate , locally aggressive tumors which are characterized by infiltrative growth and local recurrences but no metastatic potential. Both sporadic cases and cases associated with familial adenomatous polyposis have been described. The purpose of this study is to report the histologic and immunohistochemical findings in 3 cases of mesenteric fibromatosis and discuss the role of immunohistochemistry in the diagnosis of these tumors. Two of our patients were female, aged 64 and 29 years and one male, aged 33. One gave a history of previous abdominal surgery, one presented with abdominal discomfort six months postpartum and the third presented with acute abdomen. None had familial adenomatous polyposis. In the first case the tumor extended from the mesentery to the pancreas infiltrating large vessels and was only partially excised. In the other two cases the tumors involved the mesentery, infiltrated the wall of the small and the large bowel respectively and were excised together with a segment of the involved bowel. All three cases exhibited a proliferation of spindle cells with myofibroblastic features forming long fascicles and associated with collagenous and focally loose stroma. Despite the variable cellularity and the infiltrative border, mitoses were absent to rare and there was no atypia or pleomorphism. Inflammatory infiltrates were distinctively absent. The immunohistochemical evaluation of the tumors included staining for Keratin AE1/AE3, CD34, S100 protein, smooth muscle actin, desmin, CD117 which were all negative and for β-catenin which was positive with characteristic nuclear staining. The diagnosis of mesenteric fibromatosis usually relies on careful observation of the histologic features in H+E sections. The immunohistochemical evaluation is a helpful adjunct in cases in which there is doubt regarding its distinction from sclerosing mesenteritis and gastrointestinal stromal tumor(GIST) or as part of protocol immunohistochemistry in spindle cell lesions of the mesentery. Our finding of nuclear β-catenin positivity in the three cases studied is consistent with previous studies that have shown β-catenin positivity in mesenteric fibromatosis as compared to the negativity in GIST and in sclerosing mesenteritis.

PP3-289
MORPHOLOGICAL AND CLINICAL CHARACTERISTICS OF THE PERIODONTAL TISSUES INFLAMMATION RESULTED FROM THE JAW FRACTURES

Volodymyr Gavrilov, Sergiy Morozov
Lugansk State Medical University, Lugansk, Ukraine

Numerous epidemiological data suggested that periodontal tissues inflammation resulted from the conservative therapy of jaw fractures have high incidence rate in Ukraine. The aim of present study was to find out the morphological and clinical markers of the effectiveness of the improved design of a dental splint device combined with the ‘Uimisbol’ gel &Bolus Alba treatment in patients with jaw fractures. Methods. 25 volunteers were enrolled while receiving dental care for the jaw fractures. Each patient had a fixing of the jaw by the improved Tigershtedtt’s splints. The gel “Uymisbol” &Bolus Alba treatment was used locally on the fracture area in the form of the oral applications. The main active substance in “Uymisbol” was a plant extract of the Comarum palustre. 10 patients were treated in routine way without ‘Uimisbol’ gel &Bolus Alba application (group of comparison). Histological slides of gum tissue biopcies stained with H&E, Van Gison, and then stereological evaluation by point count method performed. The volume fractions of inflammatory infiltrates, vascularity, areas of dystrophy and necrosis of connecting tissue and others were determined. The results showed in the group of comparison the increase of volume fractions of inflammatory infiltrates, vessels, foci of periodontal connective tissue dystrophy and necrosis. The conservative therapy with the gel “Uymisbol” resulted in the reduction of hyperemia and vessels number. Inflammatory infiltrates and areas of connecting tissue dystrophy revealed occasionally. The improved device did not damage periodontal tissues in aesthetically important areas of oral cavity Conclusion These findings suggested the jaw fractions without improved treatment stimulate persistent inflammation in the gum of patients. On this background there is braking of repair processes, which can unfavorably alter bone repair processes. The use of gel “Uymisbol” &Bolus Alba treatment, possessing antioxidant, osteotropic, anti inflammatory and immune stimulating properties allows normalizing gum tissue’s metabolism, to recover the normal parameters of gum tissues and accelerate bone repair.

PP3-290
CYTOGENETIC STUDY OF 108 ADIPOSE TISSUE TUMORS

Piera Balzarini[1], Paola Dal Cin[2], Andrea Tironi[1], Elisa Rossi[1], Mariella Chiudinelli[1], Paolo Pandolfi[3], Maria Flocchini[3], Piergiovanni Grigolato[1]
[1] 2nd Department of Pathology, University of Brescia, Spedali Civili, Brescia
[2] Cytogenetic Laboratory, Brigham and Women's Hospital, Boston
[3] Plastic Surgery Unit, Spedali Civili, Brescia

Background. Cytogenetic investigation of soft tissue tumours, revealing clonal chromosome alterations associated to specific gene sites, allows better comprehension of pathogenesis and more

precise classification of soft tissue neoplasms. We studied 108 adipose tissue tumours from 105 patients, 63 males, 42 females, mean age 52 (range 23-79). Tumour sites were mainly shoulder, forehead, dorsum, arm and cervical region. Size of tumours was ranging between 0.5 cm and 10.5 cm. Methods. All the 108 adipose tissue tumours were cytogenetically analysed. Chromosome preparations were performed after short-term culture, using standard cytogenetic technique and karyotype were established according to ISCN nomenclature. Hystopathologic features and karyotype of tumours were investigated and reported independently. Results. According to pathological diagnosis, 73 tumours were conventional lipoma, 12 fibrolipoma, 10 angiolipoma, 7 spindle cell lipoma, 1 lipomatosis, 4 atypical lipomatous tumours/well differentiated liposarcoma (ALT/WDL), 1 de-differentiated liposarcoma. Cytogenetically, 51,4% of lipomas showed abnormal karyotype involving 12q13-15 (58,3%), other sequences of chromosome 12, mainly 12p11-12 and 12q24 (22,2%) and chromosome 6 (16,7%). Angiolipomas showed a normal diploid karyotype in 90% of cases. Spindle cell/pleomorphic lipoma showed monosomy of chromosome 13 and 16 in 42,9% of cases, translocation of 6p21-23 with Xp21.1, 1p32 and 11q13 in 42,9% of cases and balanced translocation of chromosome 12 in 28,6% of cases. Five liposarcomas, 4 ALT/WDL and 1 de-differentiated liposarcoma, showed a complex karyotype, characterized by ring- and giant-supernumerary chromosomes. One case of ALT/WDL was a recurrence and the morphology was deceptively benign in despite of the presence of ring- and giant-chromosome. Conclusion. In the 108 cases of adipose tissue tumours analised cytogenetic studies confirm differences between lipoma and liposarcoma. Although the same chromosome can be involved in benign and malignant neoplasms, aberrations are quite different. The present case-study shows that in conventional lipoma chromosome 12 frequently translocates with 3q27-28, while in liposarcoma chromosome 12 gives rise to ring- and giant- chromosomes. So far even when lipomatous tumour has minimal atypical morphology, cytogenetic analysis still shows it's sarcomatous nature. Although histopathological examination is the gold standard in lipomatous tumour diagnosis, cytogenetic analysis can help in difficult cases.

PP3-291

PRIMARY EMBRYONAL RHABDOMYOSARCOMA OF LONG BONE IN A CHILD 5 YEARS OLD. A CASE REPORT AND REVIEW OF THE LITERATURE

Catherine Michail-Strantzia, Irene Bonou-Boukouvalea, Panagiota Giamarelou, Chris Zambakidis, Helen Kosmidis
Children's Hospital of Athens "P. & A. Kyriakou", Greece

Background: RMS is a well documented soft tissue sarcoma. The majority of RMS that involve bone in children are metastatic or represent secondary involvement by contiguous growth of a soft tissue lesion. This case is the sixth one involving the femur in childhood. Design: We present the Clinico-Radio-Pathological findings in a boy 5 years old, who submitted with a painful left knee's joint due to a left limb swelling. Results: The x-ray, CT-scan and MRI of the left femur revealed a diaphyseal large lytic lesion with cortical destruction and reactive periostic "onion skin-like" proliferation, compatible with a Ewing's Sarcoma. The histological and immunohistochemical investigation evaluated a high grade spindle cell sarcoma, with a herringbone pattern of proliferation, enlarged, bizarre or polygonal cells and abundant mitosis without any producing of malignant osteoid. The diagnosis of RMS has been prevailed over the diagnosis of Ewing's Sarcoma and supported by the positive reaction in Desmin, Vimentin, Myf-4 and MyO-D1 abs. The patient has been treated according to the RMS protocol and five months later the bone tumor has been completely resected showing histologically 95% tumor necrosis and two nodules of live RMS without any evidence of malignant osteoid production. Conclusion: We ordinarily do not make the diagnosis of a RMS in a bone tumor. Although the clinical and radiological data are compatible with those of a Ewing's Sarcoma, the immunohistochemical results support the diagnosis of a RMS involving the periosteum and the adjacent skeletal mass. RMS described in children's bones have not specific radiographic features and show bone destruction by a lytic process. Histologically they do not differ from RMS of soft tissue and any type of them can occur in bone. The presence of other component, such as cartilage, bone or undifferentiated sarcomatous elements in bones raise the suspicion that the lesion in question may represent dedifferentiation phenomenon rather than a primary RMS of bone or may be a part of a malignant mesenchymoma.

PP3-292
SYSTEMIC AND CORONARY VASCULITIS IN RHEUMATOID ARTHRITIS - A RETROSPECTIVE CLINICOPATHOLOGIC STUDY OF 161 AUTOPSY PATIENTS

Miklós Bély[1], Ágnes Apáthy[2]
[1] Policlinic of the Hospitaller Brothers of St. John of God in Budapest, Hungary
[2] National Institute of Rheumatology and Physiotherapy, Budapest, Hungary

Systemic vasculitis (SV) is one of the main, and the most likely lethal complication to be missed clinically with high probability of rheumatoid arthritis (RA). The aim of this study was to determine: (a) the prevalence, the mortality, and the clinically missed diagnosis of SV at autopsy in RA, (b) the prevalence, the mortality, and the clinically missed diagnosis of coronary arteritis and arteriolitis (CAa). Patients and Methods A non-selected autopsy population of 161 in-patients with rheumatoid arthritis was studied. RA was confirmed clinically according to the criteria of the ACR. Vasculitis was diagnosed histologically. Results (a) SV was found in 36 (22.4%) of 161 RA patients. SV directly led to death in 19 (11.8%) of 36 patients (due to coronary arteritis and/or arteriolitis in 12, pulmonary and bronchial arteriolitis with disseminated lobular-sublobular pneumonia in 3, cerebral vasculitis and multifocal brain necrosis in 2, thrombovasculitis of renal artery and renal necrosis in 1, or thrombovasculitis of mesenteric artery and hemorrhagic intestinal necrosis in 1 patient). SV was recognized clinically in 7 of 19 with the lethal complication of SV. (b) Coronary arteritis and/or arteriolitis were associated with SV in 25 of 36 cases (15.5 %). CAa led directly to death in 12 of 25 patients (due to coronary arteritis and thrombosis of the main coronary artery with a large myocardial infarct in 1, coronary arteriolitis and multiple focal microinfarctions of the myocardium (myocardiocytolysis) in 11 cases). Coronary arteritis and/or arteriolitis was detected clinically only in 3 of 25 patients. Discussion In RA various organs are involved by vasculitis with different incidence. The leading and most endangered target is the heart, which was involved in this study in two thirds of 36 RA patients with SV. In most cases the arterioles and the small arteries are affected by vasculitis. Three types of vasculitis (non-specific, fibrinoid necrotic, granulomatous) may be present simultaneously in different vessels or combined in one. Different stages of inflammation can be found simultaneously, reflecting histologically the relapsing nature of this type of vasculitis. In most of the cases the clinical diagnosis of vasculitis is based on the visible skin involvement. Vasculitis of the skin does not necessarily run parallel with the heart involvement. Coronary vasculitis should be kept in mind, and it is very important to look for minor, transient, and recurrent clinical signs of cardiac disease, especially if there is a history of vasculitis.

PP3-293
PATHOGENESIS SILENT MYOCARDIAL INFARCTION IN RHEUMATOID ARTHRITIS - A RETROSPECTIVE CLINICOPATHOLOGIC STUDY OF 161 AUTOPSY PATIENTS

Miklós Bély[1], Ágnes Apáthy[2]
[1] Policlinic of the Hospitaller Brothers of St. John of God
[2] National Institute of Rheumatology and Physiotherapy, Budapest, Hungary

Coronary vasculitis is the main cause of silent myocardial infarction in rheumatoid arthritis (RA), and the most likely lethal complication to be missed clinically with high probability. The aim of this study was to outline the pathogenesis of silent myocardial infarction due to coronary arteritis and/or coronary arteriolitis (CAa) in RA. Methods A non-selected autopsy population of 161 in-patients with RA was studied. RA was confirmed clinically and CAa was diagnosed histologically. Results 1. SV was found in 36 (22.36%) of 161 RA patients. CAa was associated with SV in 25 of 36 cases (15.5 %, 69.44 rel%). Subepicardial (main) coronary arteritis with, or without intramural coronary arteriolitis were present in 14 (56 rel%) of 25 patients. Coronary arteritis and thrombosis of the main coronary artery with a large myocardial infarct led directly to death in 1 (4 rel%) of 25 patients Coronary arteriolitis with multiple focal microinfarctions of the myocardium (myocardiocytolysis) was the direct cause of death in 11 (44 rel%) of 25 cases. 2. Three types of vasculitis (non-specific, fibrinoid necrotic, granulomatous) were present simultaneously in different vessels or combined in one. Different (acut-subacute-subchronic-chronic) stages of inflammation can be found simultaneously. Discussion All types of autoimmune vasculitis are of a relapsing (recurrent) nature. Histologically different stages of inflammation can be found simultaneously, reflecting histologically the relapsing nature of vasculitis. Vasculitis of the main coronary arteries with or without thrombosis may result in ischemia and may lead to a large myocardial infarct, macroscopically similar to myocardial necrosis due to coronary atherosclerosis and/or thrombosis. Vasculitis of the arterioles and small arteries can lead to local ischaemia and to regressive changes. This process is more or less widespread and multifocal, depending on the number of involved vessels. The necrotic foci are small and they are present in different stages of necrobiosis; small (1-2 mm of diameter) homogeneous areas alternating with small lytic foci of myocardium, and scars of a similar size simultaneously side by side. Because of the recurrent nature of immune vasculitis the regressive changes accumulate with time in the myocardium and may lead to unexpected sudden death. Clinically it is difficult to recognize the small accumulating myocardial necrosis (myocardiocytolysis). The history of vasculitis, transient cardiac complaints, low voltage electrocardiogram (ECG) may help in the diagnosis.

PATHOBIOLOGY OF ATHEROGENESIS

Vasileos Anestiadis[1], Vladimir Nagornev[2] , Eremei Zota[3], Ilie Tsiple[1], Vasile V. Anestiadi[1]
[1] Centre for Pathobiology and Pathology, Academy of Sciences, Chisinau, Moldova
[2] Research Institute of Experimental Medicine, Academy of Medical Sciences, Saint-Petersburg, Russia
[3] Medical University, Chisinau, Moldova

Background. We have studied the role of the immune inflammation (IINF) in the set-up and development of atherosclerosis, both in experimental material and in samples of human coronary arteries, obtained during surgical operations, from 250 patients. Methods. The material has been studied by ultrastructural and immunohistochemical methods. Results. The role of the lymphocytes in the atherogenesis (AG) is viewed from the standpoint of their input into the expression of the lymphocytes and monokines, into the regulation of the production of chemokines and in situ antibody synthesis. The input of the smooth muscle cells (SMC) into the AG is analyzed not only from the standpoint of the proliferation of the synthetic phenotype of the SMC and the synthesis of connective tissue matrix proteins, but also taking into account their involvement into IINF reactions, expression of cytokines and class II antigens. During initial AG the depositing and/or formation into the subendothelial intima layer of modified LDL, which acquired autoantigenic properties, is the triggering factor, which stimulates the expression by endothelial cells of chemoadhesive molecules, which connect with the ligands of non-granular leucocytes. Activated monocytes/macrophages and T-cells, which penetrate

into intima, even during the most early stages of the AG, start a cascade of reactions, that makes sure the development of the early phase of the inflammation. Conclusion. The involvement of the intimal cells into the inflammatory reaction (macrophages, SMC and endothelial cells begin to produce class II antigens) transfers the acute phase of the inflammation into a chronic one, like the delayed hypersensitivity reaction.

PP3-295
TWO AUTOPSY CASES OF A NEW CORONARY DISEASE (ISOLATED EOSINOPHILIC CORONARY PERIARTERITIS)

Kajihara Hiroki[1], Tachiyama Yoshiro[2], Hayashi Yuzo[3]
[1] Div. Path., Dept. Health Sci., Prefectural University of Hiroshima, Japan
[2] Div. Path., Hiroshima Nishi Medical Center, Japan
[3] Div. Path., Hiroshima City Asa Hospital, Japan

Ist case: A 40y male presented symptoms of angina pectoris for 9 years and expired with symptoms of unstable angina. At the time of admission, 26 days before death, blood examination showed WBC5,000/mm3(St 3%, Seg 38%, Ly 47%, Eo 4%, Ba 5% and Mo 3%). At the autopsy, the heart weighed 430g and both right and left coronary arteries of the subepicardial region were grayish white in color and elastic hard. Histologically, inflammatory infiltration was localized only in adventitia of coronary arteries located in the subepicardial region. Inflammatory cells infiltrated in the adventitia were mostly eosinophils. The medial smooth muscle cells were slightly hypertrophied and the intima showed irregular thickening with fibrosis. Inflammatory change could not be found, not only in the intramural coronary arteries, but also in the arteries of other tissue and organs. IInd case: A 28y female suffered from bronchial asthma for 4 years and showed symptoms of angina pectoris about 3 months before death. Blood examination showed WBC8,600/mm3 with slight eosinophilia. At the autopsy, the heart weighed 220g and epicardial coronary arteries were grayish white in color, the same as case I. Histologically, inflammatory cells, mainly of eosinophils, infiltrated also in the adventitia of both right and left epicardial coronary arteries. The medial smooth muscle cells were well preserved, but the intima of these arteries showed irregular thickening with fibrosis. No findings of angiitis could be detected in the blood vessels except subepicardial coronary arteries. As a result of these autopsy findings described above, this type of coronary arteritis could be termed "Isolated Eosinophilic Coronary Periarteritis", a new coronary disease.

PP3-296
RENOVASCULAR HYPERTENSION CAUSED BY GIANT-CELL ARTERITIS – CASE REPORT

Vesna Mihajlovic-Bozic[1], Svetislav Tatic[2]
[1] Department of Pathology, Institute for Cardiovascular Diseases, Clinical Center of Serbia, Belgrade, Serbia
[2] Institute of Pathology, Belgrade University School of Medicine, Serbia

Background: Giant-cell arteritis (GCA) affects almost exclusively persons older than 50 years of age, and disease risk is highest among those who are 75 to 85 years of age. Two thirds of those affected are women. Giant cell arteritis typically causes vasculitis of the extracranial branches of the aorta and spares intracranial vessels. Transmural inflammation of the arteries induces luminal occlusion through intimal hyperplasia. Clinical symptoms reflect end-organ ischemia. We reported a case of a 15-year-old male teenager with severe heart and acute renal failure as the dominant clinical manifesations of renovascular hypertension (RVH) caused by atypical (GCA). Unrecognized RVH and treatment of the consequent heart failure by angiotensin-converting enzyme inhibitors (ACEI) probably contributed to progression of renovascular disease to bilateral renal artery occlusion. Contrast angiography of the abdominal aorta and renal arteries disclosed bilateral renal artery occlusion and the patient was reffered for surgical revascularization. The diagnosis of giant-cell arteritis is established by biopsy. Material and methods: Surgical specimen is a part of the wall of the right renal artery. The material was fixed in formalin, filtered and embedded in paraffin. Serial sections of the renal artery were stained:H&E, Masson trichrome and Elastic Van Gieson. Microscopic finding of the resected right renal artery consistent with giant cell arteritis: Numerous multinucleated giant cells mainly close to the internal elastic lamina surrounded by nonspecific lymphocyte infiltrates. The elastic lamina is partially fragmented or thickened. The lumen is partially occluded by intimal hyperplasia with superimposed organized thrombus. Disscusion: Fibromuscular dysplasia is the most common cause of RVH in children and GCA is an exceptionally rare cause of RVH. Primary or isolated involvement of renal arteries is more, often described in Takayashu arteritis. The onset of symptoms in GCA may be acute or insidious. Conclusion: Unrecognized RVH treated with ACEI probably provoked acute renal failure and contributed to recurrent heart failure and “flash” pulmonary edema in our teenage patient with atypical GCA. Prompt normalization of heart function and arterial hypertension occured after adequate therapy which is related with GCA.

PP3-297
BONE FORMATION IN CARDIAC VALVES

Ivo Steiner
Department of Pathology, Charles University Faculty of Medicine and Faculty Hospital, Hradec Kralove, Czech Republic

Background: Dystrophic calcification is the most common pathological finding in operatively excised cardiac valves. Several reports describe bone in calcified cardiac valves (heterotopic ossification; bony metaplasia) and recent studies have identified bone proteins in such valves. Method: Histological and immunohistological examination of 1177 calcified cardiac valves operatively excised at the Department of Cardiac Surgery. Results: There were 128 patients (10.9 %) with bone and/or cartilage formation in the excised valve (119 aortic, 9 mitral). The incidence was higher in men (12.8 %) than in women (8.5 %). The average age of patients with metaplasia (64.1 years) did not differ from the average age of those without it (64.3 years). It was higher in females (66.9 years) than in males (62.6 years). Metaplastic changes were encountered in all types of calcific aortic valve disease (senile, bicuspid valve, postrheumatic). The marrow of the heterotopic mature lamellar bone was usually formed by adipose tissue. There was often chronic inflammation with an infiltrate composed predominantly of polyclonal plasma cells. Rarely, complete hematopoiesis was present. Conclusion: Heterotopic bone formation is closely related to the process of calcification, such that its presence has been described particularly in the aortic valve, in the calcified annulus of the mitral valve and, rarely, in arterial atherosclerotic plaques. In the past, calcific aortic disease was thought to be due to “degenerative”, time-dependent, wear-and-tear of the leaflets with passive dystrophic calcium deposition. Now, there is compelling data to suggest that calcific aortic disease is an active disease process similar to atherosclerosis. A crucial role in the process of calcific aortic stenosis is played by valvular interstitial (fibroblast-like) cells that, under various stimuli, become activated to myofibroblast-like cells. A subset of valvular myofibroblasts may differentiate into an osteoblastic phenotype capable of promoting formation of nodules of calcium and bone. Cartilage in calcified valves indicates that endochondral ossification, similar to that seen in bone fracture healing, is operative. Our results imply that bony metaplasia does not appear to be a late stage in the process of valvular calcification, but rather develops in parallel with it. HEPATOMA WITH CARDIAC METASTASIS: AN ADVANCED CANCER REQUIRING ADVANCED TREATMENT
Pao-Hsien Chu, Shih-Ming Jung
Chang Gung Memorial Hospital, Taiwan

Background Hepatocellular carcinoma with cardiac metastasis is very rare and has a poor prognosis. Surgery is frequently reserved for symptomatic patients. This investigation first report the clinical and pathologic findings, and then demonstrates the pathophysiology. Methods This study included eight patients with hepatoma involving the heart, treated by surgical excision. Detailed clinical parameters were reported. Results The patient population comprised two (25%) women and six (75%) men. The mean age of subjects was 50 years old, with an age range of 40 to 70 years old. The presentations included: asymptomatic (75%), heart failure (25%), and pulmonary embolism (12.5%). All lesions involved the right atrium, and extended to the lung (12.5%), inferior vena cava (25%), and left atrium (12.5%). The level of tumor marker, alpha-fetal protein, was not correlated with the severity of metastasis or disease prognosis. Moreover, the availably estimated doubling time was less than 3 months. The pathological findings included variable hemorrhage and necrosis. The survival time following surgery also varied from one month to longer than 30 months. Discussion. Hepatoma metastasis to the heart was detected in all eight patients. This study demonstrates that surgery might help the outcome in such cases.

PP3-299
Z DISC PATHOLOGY IN CYPHER-NULL MICE: A 3D ELECTRON MICROSCOPIC STUDY
Pao-Hsien Chu[1], Anderea Thor[2], Ju Chen[2], Maryann E. Martone[2]
[1] Chang Gung Memorial Hospital, Thawian
[2] University of California, San Diego, USA

Comparative studies of the relationship between structure and function offer a promising means of understanding the significance of differences in cytoarchitecture (Not sure what you mean, since you are not studying function?). The three-dimensional organization of the sarcomere in the striated muscle of Cypher-null mice, which exhibited dilated cardiomyopathy and skeletal muscle failure, was studied to assess the ultrastructure of the Z disc. Three-dimensional reconstruction of the Z disc was performed on 1 μm thick sections of the diaphragm and heart tissues using electron tomography in both embryonic and new-born Cypher-null mice. Three-dimensional information was extracted from thick sections using stereo pairs and tomographic reconstructions from single axis tilt series from ethanolic phosphotungstic acid (EPTA) staining sections. Oure results show that both the three-dimensional reconstructions and the selectively stained thick sections of the Z disc demonstrated a discontinuous appearance. This investigation used the Telescience Project merging technologies to clearly demonstrate severe fragmentation of the sarcomeric Z disc of embryonic heart and newborn diaphragm of Cypher-null mice, which had not been documented using previous 2D techniques. The analytical results of this investigation strongly confirm that Cypher plays an important role as a linker-strut in the Z disc of striated muscles.

MACROPHAGE-SUBENDOTHELIAL EXTRACELLULAR MATRIX CONTACT IN THE ATHEROGENESIS, ELASTIN CONTACT INDUCES TNF-α UPREGULATION
Ichiro Mori[1], Tomonori Higuchi[2], Misa Nakamura[1], Tomoko Wakasa[1], Kennichi Kakudo[1]
[1] Department of Pathology, Wakayama Medical University, Japan
[2] Department of Pathology, Nara Medical University, Japan

[Background] One of the earliest events of atherogenesis is endothelial injury. When subendothelial tissues are exposed to the blood flow, first exposed is endothelial basement membrane or internal elastic lamina which are mainly composed of elastin, laminin, and collagen type-IV. These extracellular matrices (ECM) are reported to be recognized by elastin-laminin receptor (ELR). We hypothesize that macrophage (MΦ)-subendothelial ECM contact triggers atherosclerogenesis. We already reported that MΦs contacted to elastin release M-CSF. This time, we investigated TNF-α. [Methods] Primary cultured MΦs were prepared from mouse bone marrow cells. Insoluble elastin and collagen (type I) were suspended in αMEM, and applied to adherent MΦs. Total cellular RNA and protein were extracted, and northern blot analysis and western blot analysis for TNF-α were performed. To investigate whether this reaction is specific for elastin, we treated MΦs with galactose, which is said to uncouple the ELR molecular complex, and treated with both elastin and collagen. [Results and conclusion] MΦs contacted to elastin showed 11.8±1.7 S.D upregulation of TNF-α mRNA with its peak at 2 hours, and 1.34±0.05 S.D increase of TNF-α protein with its peak at 6 hours. Type-I collagen also induced TNF-α mRNA upregulation with its peak at 2 hours. The elastin induced upregulation was inhibited by galactose pretreatment while no inhibition was found in collagen-MΦ contact. MAP-K inhibition experiment revealed that MEK 1/2 and JNK/SAPK were involved in this reaction while p38 is not. These results strongly suggest that MΦ-subendothelial ECM contact is a key event of atherosclerogenesis.

PP3-301
MORFOLOGICAL STUDY OF CONGENITAL HEART MALFORMATIONS WITH ENDOCARDIAL FIBROELASTOSIS
Snezana Duganovska[1], Goradana Petrusevska[1], Liljana Spasevska[1], Miljana Tolovska[1], Biljana Dimova[1], Roza Kacarska[2]
[1] Institute of Pathology, Medical Faculty, University "St. Cyril and Methodius", Skopje, Macedonia
[2] Pediatric Clinic, Clinical Centre, Skopje, Macedonia

AIMS: Our study aimed to identify endocardial fibroelastosis (EFE), as a rare but important finding among hereditary heart endocardial malformations, which brings to persistence of fibrous thickening that is a cause of cardiac insufficiency and exitus letalis in early childhood. METHODS: We used autopsy material which has been collected during 19 autopsies, performed at the Institute of Pathology, Faculty of Medicine in Skopje. The patients were neonates and children, not older than 2 years. Histological sections of analyzed hearts were stained with HE, VanGieson-Elastica, Trichrome-Masson and Reticulin-Gomori. RESULTS: EFE was more frequent in males than in females (11/19 cases).Two of the patients showed presence of primary fibroelastosis as an isolated congenital heart malformation; in the rest 17 cases, secondary EFE combined with isolated or complex congenital malformations of the heart and large blood vessels, were found. The analysis of the anatomical location and place of the fibroelastosis in the ventricular system showed that it was more often situated in the left ventricle. More precise morphological analysis has revealed that the endocardium was thickened (to 2mm) along its wall diffusely and had porcelain white color. There was a hypertrophy of the heart, with bigger and wider LV; the apex belongs to the LV, lumen of the LV was wider, interventricular septum was pushed to the RV. The secondary EFE is usually associated with other heart malformations, the endocardium was confluent or focally thickened and accompanied with: SHLS (7 cases); DAP (3 cases); CoAo (2 cases) and pulmonary stenosis, SHDS, ASD, VSD and earlier closing of foramen ovale with one case of each. Histolopatological findings in endocardium showed proliferation of elastic tissue and collagen fibers which were parallel to the

surface. Inflammatory cells in both endocardium and myocardium were not found. The most frequent cause of death in the cases with EFE was insufficiency of LV (10/19) where severe pulmonary hypertension was found in one case. In the rest of the cases pulmonary hemorrhage 2/19 was present, bronchopneumonia in 2/19, aspiration in 1/19, enterocolitis in 1/19, brain hemorrhage in 1/19 and sepsis in 1/19 cases. CONCLUSIONS: Morphological analysis as well as histopathological findings has shown that most of the analyzed complications were due to mechanical obstruction of the blood flow. The most frequent was secondary EFE accompanied with other CHM, which was the cause of: "inlet" and outlet" obstructions; anoxia in utero; earlier closing of the FO.

PP3-302
INDUCTION OF MITOCHONDRIAL BIOGENESIS IS A MALADAPTIVE MECHANISM IN CARDIAC REMODELING

Mariangela Sebastiani[1], Carla Giordano[1], Claudia Travaglini[1], Massimo Zani[1], Chiara Nediani[2], Elisabetta Borchi[2], Massimiliano Mancini[3], Robert Taylor[4], Pietro Gallo[3], Giulia D'Amati[3]

[3] Dipartimento di Medicina Sperimentale, Sapienza, Universita' di Roma, Rome, Italy.
[4] Mitochondrial Research Group and Institute of Human Genetics, Newcastle University, Newcastle upon Tyne, United Kingdom

Objectives. The purpose of this study was to clarify the molecular mechanisms linking mtDNA dysfunction to cardiac remodeling. Background. Defects of the mitochondrial genome cause a heterogeneous group of clinical disorders, including mitochondrial cardiomyopathies (MIC). The molecular events linking mtDNA defects to cardiac remodeling are unknown. Both energy derangements and increase of mitochondrial-derived reactive oxygen species (ROS) could play a role in the development of cardiac dysfunction in MIC. In addition, mitochondrial proliferation could interfere with sarcomere alignment and contraction. Methods. We performed a detailed morphologic and molecular analysis on failing hearts from three patients with MIC, failing human hearts due to ischemic heart disease (IHD) or dilated cardiomyopathies (DCM), and non-failing hearts. Results. MIC hearts showed marked mitochondrial proliferation, with myofibril displacement. Consistent with morphologic features, increase in mtDNA content per cell and induction of genes involved in mitochondrial biogenesis, fatty acid metabolism and glucose transport were observed. Down-regulation of these genes characterized DCM and IHD hearts. Furthermore, up-regulation of uncoupling proteins and a pronounced increase in mitochondrial-derived ROS was observed in MIC as compared to failing hearts due to other etiologies. The observed increase in free radical production was not paralleled by the induction of antioxidant enzyme activity, despite marked up-regulation of the corresponding genes. Conclusions. Our results suggest that mitochondrial biogenesis is a maladaptive response in MIC and, possibly, in other metabolic cardiomyopathies. In fact, increased oxidative stress, mechanical interference with sarcomere alignment and contraction, and, possibly, uncoupled respiration are detrimental factors to myocytes function, besides energy deficiency.

COULD SUDDEN CARDIAC DEATHS HAVE BEEN PREVENTED: AN AUTOPSY STUDY

Patrick Gallagher[1], Hayley Burnley[1], Debbie Chase[2], Paul Roderick[2], Paul Poberts[3], John Morgan[3]
[1] Pathology, Southampton University Hospitals, Southampton, United Kingdom
[2] Public Health Medicine, Southampton University Hospitals, Southampton, United Kingdom
[3] Wessex Cardiac Unit, Southampton University Hospitals, Southampton, United Kingdom

The objective of this study was to identify which, if any, sudden cardiac death (SCD)victims could have been identified before their death and considered for an implantable cardioverter defibrillator (ICD) on the basis of their previous cardiac history.Autopsy proven cases of SCD were identified over a one year period in a defined population. They were categorised by a modification of Davies method. Those with evidence of myocardial scarring, coronary narrowing or ventricular hypertrophy may have died as a result of a ventricular arrhythmia. However cases with clear evidence of acute coronary thrombosis or acute infarction were excluded. Hospital and GP records were examinaed for information on previous symptoms, investigations and past history of cardiac disease. Two cardiac electrophysiologists judged the appropriateness of each case against pre defined criteria. 366 of 975 post mortems were sudden cardiac deaths and in 232of these there was no evidence of acute thrombosis or infarction. 215 lived within the catchment area, 54% were male and the median age was 75 years. Agreement between experts was good (kappa score 0.64). One case was considered appropriate for ICD insertion. 41% of cases had no evidence of cardiac events or prior heart disease. 49% of the remainder had previous cardiac events or symptoms suggestive of cardiac arrhythmias but had not been referred for further investigations. In particular some patients with a previous myocardial infarction were not referred for 24 hour ECG tracings and some of those with suspected heart failure did not have echocardiography. Our study has shown that 40% of SCDs could not have been predicted A significant proportion of the remaining patients were not referred for appropriate investigations.

PP3-304
APOPTOSIS-RELATED FACTORS P53, BCL-2 IN ACUTE AND CHRONIC ISCHEMIC CARDIAC DISORDERS

Angelos Tsipis, Anna Maria Athanassiadou, Pauline Athanassiadou, Nicolaos Kavantzas, George Agrogiannis, Efstratios Patsouris
Department of Pathology, Medical School, University of Athens, Greece

Background: Cardiac myocyte death during ischemic injury has been thought to occur exclusively by necrosis, but recently several studies have demonstrated that large numbers of myocytes undergo apoptosis in response to ischemic disorders. P53 limits cellular proliferation by inducing cell cycle arrest and apoptosis in response to cellular stresses such as DNA damage, hypoxia, and oncogene activation. P53 mediates apoptosis through a linear pathway involving bax activation, cytochrome c release from mitochondria, and caspase activation. The Bcl-2 family of proteins constitutes a critical checkpoint in cell death. These proteins contain agonists and antagonists of apoptosis, and alterations in their ratio determine the life or death of a cell. Proapoptotic proteins include Bax, Bak, Bad, and Bcl-xs whereas Bcl-2 and Bcl-xL are antiapoptotic. The aim of this study was to investigate the expression of apoptosis-related proteins p53, bcl-2 in acute and chronic ischemic cardiac disorders and their association with myocyte death in ischemic hearts. Method: We studied myocardial samples of hearts with histologic findings of acute myocardial infarction (group A, n=15), old myocardial

infraction (group B, n=15), and chronic ischemic heart disease (group C, n=15). Myocardial samples of normal heart were also included in this study (control group, n=15). An immunohistochemical method was performed with the use of p53 and bcl-2 antibodies, in order to investigate the expression of apoptosis-related proteins p53, bcl-2 in ischemic cardiac disorders. Results: The percentage of bcl-2 positive samples was 66% in acute myocardial infarction (Group A, 10/15 positive samples). In old myocardial infraction and chronic ischemic disease the bcl-2 positive samples demonstrated weak staining as in the control group. P53 positive samples was 20% in acute myocardial infraction (Group A, 3/15 positive samples), 80% in old myocardial infraction (Group B, 12/15 positive samples), 80% in chronic ischemic heart disease (group C, 12/15 positive samples) and 20% in control group (3/15 positive samples). Conclusions: The elevated expression of p53 is associated with the progressive loss of myocytes by apoptosis and may play a role in the evolution of the chronic heart failure in patients with old myocardial infraction and chronic ischemic disease. The increased expression of bcl-2 in acute myocardial infraction represents a possible compensatory mechanism of salvaged myocytes.

PP3-305
THE VASORELAXATION OF RAT RENAL ARTERY INDUCED BY WINE POLYPHENOL RESVERATROL

Ljiljana Gojković-Bukarica[1], Jasmina Marković-Lipkovski[2], Helmut Heinle[3]
[1] Institute of Clinical Pharmacology, Pharmacology and Toxicology, Faculty of Medicine, Serbia
[2] Institute of Pathology, Faculty of Medicine, Belgrade, Serbia
[3] Institute of Physiology, Tubingen, Germany

BACKGROUND: Resveratrol, a stilbene polyphenol found in grapes and red wine, has recently been found to produce vasorelaxation in endothelium-dependent and endothelium-independent manner. The aim of this study is to determine the mechanism(s) of relaxation produced by resveratrol in the isolated rat renal artery (RA). METHOD: RA rings were precontracted with phenylephrine. In order to assess the endothelial integrity of the preparation we have used acetylcholine. Endothelium was removed mechanically by rubbing with a steel wire. Failure of arteries to relax to acetylcholine was considered as indicator of state of endothelial denudation. For detection of K+ channels in smooth muscle, peptide-specific antibodies in immunoperoxidase were used. RESULTS: Resveratrol (1–100 microM) produced concentration-dependent relaxation of RA rings with endothelium (EC50~10 microM, n=10) and without endothelium (EC50~15 microM, n=12). Methylene blue and L-NAME did not antagonize the resveratrol-induced relaxation of RA rings with endothelium. In order to analyze the contribution of different types of K+ channels in resveratrol-induced relaxation in the RA, various K+ channel blockers were used. The relaxation of RA was not blocked by glibenclamide, a selective ATP-sensitive K+ channel blocker, and tetraethylammonium, a non-selective blocker of calcium-dependent K+ channels. 4-aminopyridine, non-selective blockers of voltage-dependent K+ (Kv) channels, antagonized resveratrol-induced relaxation of RA in a noncompetitive manner. Margatoxin, highly selective blockers of Kv1.1-1.6 channels shifted the concentration response curves induced by resveratrol to the right without significant inhibition of maximal responses. Kv1.3 channels were detected in endothelium but not in the smooth muscle of RA using peptide-specific antibodies in immunoperoxidase. CONCLUSION: It is likely that endothelial Kv1.3 channels are involved in relaxation of RA produced by resveratrol. However, further experiments with smooth muscle peptide-specific antibodies need to be performed.

FATAL DRUG INDUCED HYPERSENSITIVITY MYOCARDITIS AFTER MINOCYCLINE-THERAPY

Peter Dorfmuller[1], Olivier Chosidow[2], Francois Cook[2], Jean-Louis Trouillet[3], Pascal Leprince[4], Eva Comperat[1], Frédérique Capron[1], Isabelle Brocheriou[1]
[1] Service d'Anatomie et de Cytologie Pathologiques, Groupe Hospitalier Pitié-Salpêtrière, Université Pierre et Marie Curie, Paris, France
[2] Service de Dermatologie, Hôpital Tenon, Université Pierre et Marie Curie, Paris, France
[3] Service de Réanimation Médicale, Groupe Hospitalier Pitié-Salpêtrière, Université Pierre et Marie Curie, Paris, France
[4] Service de Chirurgie Thoracique et Cardio-Vasculaire, Groupe Hospitalier Pitié-Salpêtrière, Université Pierre et Marie Curie, Paris, France

Background: Acute Hypersensitivity Syndrome (HSS) is an allergic-type complication of drug therapy with associated symptoms such as rash and fever associated with blood-eosinophilia and multiorgan involvement. Allopurinol, anticonvulsants, sulphonamides and tetracyclines are amongst the most frequent causative agents. A genetic predisposition has been associated with HSS which shows a higher overall-prevalence in the African-American population, especially with minocycline. Visceral lesions such as interstitial pneumonitis, hepatitis, interstitial nephritis or myocarditis can be lethal. Case and clinical findings: A 34-year-old black African woman, without any prior medical history, was admitted to the emergency unit in October 2006 with fever, arthralgias and dyspnea. She had been treated by minocycline 2 weeks before admission for chlamydial genital infection. The physical examination showed tachycardia, erythematous papular exanthema on arms, erythematous angina, facial oedema and leucocytosis. No infectious source was identified. Drug induced HSS after minocycline was suspected and she received high dosed corticotherapy. After initial improvement of her dyspnea, she was discharged after 1 week, against medical advice, and stopped her medication. One month later, she was readmitted with severe hypotension, dyspnea and major left ventricular systolic dysfunction. Support by a central extracorporeal-membrane-oxygenation was provided during open-heart surgery and myocardial biopsy was performed. She died 6 days later after multiple organ failure. Microscopic findings: Myocardial biopsy showed mixed inflammatory infiltrates with interstitial and perivascular distribution, mainly consisting in lymphocytes, plasmocytes, histiocytes and an increased proportion of eosinophiles. This acute eosinophil-rich myocarditic pattern was associated with pronounced interstitial edema and recent necrosis of myocytic fibers explaining myocardial pump failure. Conclusion: Eosinophilic myocarditis (EM) may occur in the setting of a hypereosinophilic syndrome, parasitic infections, malignancy or vasculitis. EM has been sporadically described in HSS, but the majority of reports are post-mortem observations due to frequent fatal outcome. Minocycline is often prescribed as the first-line therapy in acne or genital infection. Although fatal side effects are rare, HSS should be taken into consideration by the pathologist when confronted to eosinophil-rich necrotizing myocarditis. In our case, endomyocardium biopsy has been helpful for the diagnosis which often remains unsuspected.

PP3-307
KAWASAKI DISEASE

Zvezdana Dolenc - Strazar, Klara Limbaeck - Stokin
Institute of Pathology, Medical Faculty, University of Ljubljana, Slovenia

Introduction: Kawasaki disease (KD) is acute self-limited vasculitis effecting mainly children under 5 years. Etiology is still unknown. Currently debate is about infectious trigger leading to

self-directed immune response. Coronary arteries are predominantly involved; aneurysms may lead to sudden death, infarction and ischemic heart disease. Treatment in the acute phase is directed towards reducing inflammation of the artery wall and preventing thrombosis, at the late phase against myocardial ischemia and infarction. Case report: Three and a half year old boy was admitted to hospital, four days after he was taken ill, with fever and classical symptoms of KD. Viral tests were negative. Among usual therapeutics, he was treated with aspirin and repeated doses of iv-immunoglobulin, without success. Echocardiography showed diffuse dilatation of coronary arteries, which persisted till the death. After three and a half months of hospitalizations, after receiving infliximab, fever dropped and laboratory tests normalized for the first time, but he died 10 days later, four months after onset of the illness, with signs of myocardial infarction. At autopsy the heart was enlarged. Histology showed acute myocardial infarction of left ventricle with some older necrotic areas with granulation tissue. Main coronary arteries were diffusely dilated, diameter of RCA aneurysm was 8 mm, and of others between 3-4 mm. Due to progressive myointimal proliferation aneurysms had very reduced lumen diameter. In distal part of coronary arteries there were organized thrombi in recanalisation. Beside bronchopneumonia, hemorrhagic pulmonary infarction and cyanosis of internal organs, there were no other major abnormalities. Conclusion: Clinical picture of typical KD is characterized by fever and at least four of five principal features which are rash, conjuctival injection, cervical lymphadenitis, inflammation of the lips and oral cavity, swelling of the hands and feet. Especially in infants, some of the criteria are lacking. It is very important to diagnose these cases early, as they are at risk of developing coronary artery aneurisms and stenosis. Myocardial infarction is the principal cause of death and may occur in acute phase, but commonly year or even years later, especially in patients with giant aneurysms when measuring more than 8 mm in diameter. Surgical bypass procedures are effective when stenoses are proximal, what was not the case in our patient. There were reports in literature that a small group of KD patients can benefit from transplantation, with no report of recurrence.

PP3-308
CLINICAL AND PATHOLOGICAL FINDINGS IN FAST-PROGRESSING OBSTRUCTIVE HYPERTROPHIC CARDIOMYOPATHY (OHCM) IN CHILDREN AND ADULTS

Alexandra Gudkova[1], Margarita Rybakova[1], Konstantin Borisov[2], Evgeny Shlyakhto[1], Leo Bokeria[2]
[1] Pavlov State Medical University, Department of Faculty Therapy, Saint-Petersburg, Russia
[2] Bakulev Research Center of Cardiosurgery, Moscow, Russia

Aim: To compare clinical and pathological features in severe cases of obstructive hypertrophic cardiomyopathy in children and adults. Materials and methods. Nineteen children (of them, 17 survived and 2 died) and forty-seven adults (30 survived and 17 died) with OHCM were observed. OHCM diagnosis was verified by means of echocardiography, MRI, macro- and micromorphometry of affected tissues. Myocardial samples were taken during cardiac surgery or urgent autopsies. Microscopic preparations were stained with H&E, or van Giezon stain. The degree of disturbed tissue architecture, as chaotic rearrangement of cardiomyocytes, was estimated by a semiquantitative method using a 5-point morphometric score (M. Sutton et al., 1980). Results. Mid-ventricular OHCM location in pediatric group was as common as 63,2 % (12/19). In adult patients, this variant was diagnosed in 40.4% of cases (19/47). In general OHCM group, mid-ventricular OHCM was registered in 31 of 66 patients (46,7 %). Transmural myocardial scars have been revealed in 4 of 10 (40 %) autopsied HCM patients with mid-ventricular OHCM, and in 2 of 7 (28.5 %) deceased HCM patients with left ventricular outflow obstruction. In three adult patients with mid-ventricular OHCM, an apical aneurysm of top area was revealed, in absence of significant hemodynamic coronary stenosis, as evidenced by coronarograpy. In pediatric OHCM, a degree of cytoarchitectonic disorders in the right half of interventricular septum varied from 2.25 to 3.00 (2.87±0.05) units, thus being higher than at adults ($p < 0{,}001$). In adult patients, this parameter varied from 0.25 to 3.00 (1.92±0.10). Stromal portion of the right part of interventricular septum in the children varied from 1.08 to 6.67 % (3.62±0.30). In adults with OHCM, this parameter changed from 2.12 up to 10.60 % (5.36±0.34), thus being higher than in pediatric patients ($p < 0.005$). Conclusions. Increased grade of tissue «disarray» is a sufficient feature of OHCM in children. Meanwhile, enlarged area of myocardial stroma is a significant sign of OHCM progression in adults. In the patients with severe variants of the disease, occurrence of mid-ventricular OHCM is comparable to incidence of HCM with left ventricular outflow tract obstruction. Mid-ventricular OHCM progression is more often complicated by transmural myocardial scars. Higher frequency of apical aneurysm, developing at the top area, is detectable in adult patients with mid-ventricular OHCM.

PP3-309
RELATION OF MORPHOLOGICAL STRUCTURE OF HIBERNATING MYOCARDIUM TO CONTRACTILE RESERVE IN HUMANS

Elena Stefanovic[1], Petar Otasevic[1], Ljiljana Lausevic-Vuk[1], Predrag Milojevic[1], Bosko Djukanovic[1], Milena Jovic[2], Lidija Zolotarevski[2]
[1] Dedinje Cardiovascular Institute, Belgrade, Serbia
[2] Military Medical Academy, Belgrade, Serbia

Objective.The aim of this study was to investigate the morphologic characteristics of the hibernating human myocardium and to correlate its with dobutamine stress echocardiography (DSE). Methods and results.We evaluated 15 patients with coronary disease (58 +/- 12 years old, ejection fraction 38+/-14 %) with a corresponding wall motion abnormality on DSE (up to 10 micrograms kg (-1) min(-1) before coronary bypass surgery. During surgery, transmural myocardial biopsies from hypokinetic or akinetic area were perfomed (n=15). The samples of myocardium were analyzed by histopathology and immunohistochemistry to investigate the extent of interstitial fibrosis, intracellular and interstitial proteins. Among the 15 biopsied segments included in the study, 7 recovered function as assessed with DE (an echocardiography) one month after bypass surgery. Segments with DE viability showed less fibrosis and less vimentin expression, more glycogen, a higher ration of alpha-smooth muscle actin, actin and desmin then those without recovery. The degree of severity of the morphological changes (three stages) correlated well with the demonstration of inotropic reserve during DSE and with the extent of postoperative functional recovery (wall-motion score index, NYHA). Conclusion. Morphologic evidence of hibernating myocardium correlates with DSE findings wich has high diagnostic accuracy for the detection of myocardial viability.

THE ASSOCIATION FOR EUROPEAN CARDIOVASCULAR PATHOLOGY

Ulrik Baandrup[1], Cristina Basso[2], Patrick J Gallagher[3], Gaetano Thiene[2], Allard Van Der Wal[4]
[1] Aarhus, Denmark
[2] Padua, Italy
[3] Southampton, United Kingdom
[4] Amsterdam, The Netherlands

Although there are comparatively few pathologists who specialise in cardiovascular pathology all practicing pathologists are aware of the great importance of cardiovascular diseases. Ischaemic

heart disease, stroke and peripheral vascular disease are major causes of morbidity and mortality in all societies. Much of the improvement in life expectancy in the western world has been the direct result of improved prevention and treatment of these disorders. The Association for European Cardiovascular Pathology is an affiliated society of the European Society of Pathology. As a professional association it is committed to setting the standards of practice throughout Europe and providing post graduate education and training in cardiovascular pathology. We alternate our annual meetings between the European Society of Pathology and free standing meetings held in the late autumn. Our last meeting held in Aarhus, DK in November 2006 included three separate symposia, invited keynote presentations and clinicopathological presentations. In Istanbul we are organising a Surgical Pathology slide seminar on Cardiovascular Disease and a Symposium on Sudden Cardiac Death. We extend a warm invitation to all delegates to attend our evening meeting On Monday 10th September where a series of clinicopathological cases will be presented. The poster will describe the activities of our Association, the format and venue of future meetings and educational opportunities in Cardiovascular Pathology

PP3-311
REACTIONS OF MYOCARDIUM TO THE PRESENCE OF IMPLANTABLE ELECTRONIC MEDICAL DEVICES

Katarina Múčková[1] , Sepši Milan[2], Šindler Martin[3], Souček Ondřej[1], Kir Michal[4]
[1] Departement of Pathology, Faculty Hospital Brno, Czech Republic
[2] Departement of Internal Medicine and Cardiology, Faculty Hospital Brno, Czech Republic
[3] Departement of Forensic Medicine, St. Anne's Faculty Hospital Brno, Czech Republic
[4] Institute of Biostatistics and Analyses, Masaryk University Brno, Czech Republic

Background: In view of constantly increasing number of electronic medical devices (EMDs) implantations, the possible alterations of cardiac structures associated with the presence of EMD electrodes are studied. Although transvenous implantable leads are coated with inert materials to minimize the reaction of human tissues, the experiment on dog hearts showed inflammatory and degenerative changes developing in the atrial wall after implantation of pacemaker (Pacing Clin Electrophysiol. 2003 Mar;26(3):685-91). Methods: The hearts of 182 autopsy cases (130 males, 52 females) with EMDs (pacemakers and implantable cardioverter-defibrillators) were examined. The mean patients´ age at the time of EMD implatation was 76,8(±9,8). Different anatomic parameters of each heart were registered together with the number of fixations of leads to various cardiac structures. The tissue samples obtained from places of electrode insertions and each heart ventricles were processed using standard histological techniques. The tissue sections stained with hematoxylin-eosin were examined microscopically to identify inflammatory reaction, the presence of granulation tissue, fibrosis, hyaline scar, calcification and other changes in myocardium adjacent to the lead. Results: The mean weight of examined hearts was 544,48 g (±155,80), the mean left ventricle thickness was 16,22 mm (±4,19), the mean right ventricle thickness 4,86 mm (±1,94). 70% of all leads were attached to the cardiovascular structures by the band of fibrous tissue. 49,1% of all leads were fixed to the tricuspid valve or some of papillary muscles (potentially harmful fixation). The histological examination showed fibrosis and hyaline scar tissue in the electrode-myocardial interface. There was no correlation between the point of the fixation of lead and macroscopic parameters of right and left ventricles. The type of leads (pacing versus defibrillator), the type of stimulation (unipolar versus bipolar), and the percentage of stimulation did not influence the character of reaction in places of insertions. The mild reduction of the tricuspid valve circumference was observed in cases with long-time insertion of the lead. The occurrence of thrombi in heart cavities was minimal (2%)in association with electrodes. Conclusion: Implantation of EMD is followed by a reaction of the myocardium adjacent to the place of insertion. Potential harmful effect of EMDs was observed in cases with a long- time insertion of the lead. The research is supported by grant MH CZ 1A/8598-3.

PP3-312
CARDIAC MYXOMA WITH GLANDULAR COMPONENT: CASE REPORT

Arzu Tasdemir [1], Ozlem Canoz [1], Kutay Tasdemir [2]
[1] Erciyes University Medical Faculty Department of Pathology, Turkey
[2] Erciyes University Medical Faculty Department of Cardiovascular Surgery, Kayseri, Turkey

Cardiac myxoma is the most common primary cardiac tumor. Glandular epithelial differentiation is a rare phenomenon. A striking observation, seen in approximately 1-5% of cardiac myxomas. Here, we present a case of a cardiac myxoma with glandular component removed from the left atrial wall of a 38-year-old woman. Cardiac myxomas are the most common primary cardiac tumor in adults. Myxoma constitute approximately 50% of primary tumors of the heart. The sporadic tumor occurs in middle-aged woman, usually in the left atrium. A glandular component in cardiac myxoma is uncommon. The histogenesis of this feature is enigmatic. The presence of the epithelial element as glandular structure is an example of one spectrum of the multidirectional differantiation. Alternative cardiac myxoma was described as entrapped foregut rest or intracardiac endodermal heterotopia in some literatures. The results suggest that cardiac myxomas is the occurence of a glandular component embedded within the myxomatous stroma. Malignancy of the glandular component in cardiac myxoma has been reported, but in many cases this needs to be set apart from tumor embolization and local recurrence.

PP3-313
SYPHILITIC AORTITIS WITH RUPTURED THORACIC AORTIC ANEURYSM, A CASE REPORT

Khalid Al-Shibli, Hedda Soloy-Nilsen
Pathology Department, Nordland Central Hospital-Norway

Background: Aortic aneurysm is an important cause of morbidity and mortality. The symptoms caused by it can mimic other diseases and hence it is usually under diagnosed. Therefore, ruptured thoracic aortic aneurysm is a not uncommon post-mortem finding. Syphilitic aortitis is a rare entity nowadays, but cases are still seen and its diagnosis needs a high index of suspicion. We report her post-mortem case of ruptured thoracic aortic aneurysm due to tertiary syphilis. Methods: We report post-mortem findings of a 71 years old man, who developed severe chest pain with vomiting and collapsed at home. man developed severe chest pain with vomiting and collapsed at home. Resuscitation was done with no benefit and the patient died after 30 minutes from reaching the hospital. No history of diabetes or systemic hypertension. Results: Post-mortem examination revealed a ruptured thoracic aortic aneurysm measuring 12x12cm involving the arch and descending parts of the aorta with hemothorax. The aortic valve showed mild dilatation and the same for the left ventricle. The heart weight was 475gm. No significant atherosclerosis was noted in any part of the aorta or in other major arteries. Microscopic examination of the aorta showed chronic inflammatory infiltrate, most sever in the adventitia and media with large number of plasma cells mostly around the vasa vasorum with endarteritis obliterans picture. Microscopy showed no significant atherosclerosis or cystic medial degeneration. The abdominal part of the aorta was

not dilated and showed no significant atherosclerotic changes. Post-mortem examination revealed no features of Marfans syndrome or connective tissue diseases. Conclusion: Syphilis continues to be a cause of significant morbidity and mortality. It is a great mimicker for many diseases in its different stages. Missing a diagnosis will deprive the patient from a chance of an effective and specific treatment with a high chance of cure. High index of suspicion is required for the diagnosis of aortic aneurysm as a cause of chest and abdominal pain; and tertiary syphilis should be considered as a possible cause for thoracic aortic aneurysms.

PP3-314
CAUSE, FREQUENCY AND TIME OF ONSET OF ASYMPTOMATIC ACUTE MYOCARDIAL INFARCTION IN ABRUPT UNEXPECTED DEATHS IN A FORENSIC AUTOPSY MATERIAL

Elin Mortensen[1], Torleiv Rognum[2], Bjørn Straume[3], Leif Jørgensen[4]
[1] Dept fo Pathology, University Hospital of North Norway, Tromsø, Norway
[2] Insitute of Forensic Medicine, University of Oslo, Norway
[3] Institute of Community Medicine, University of Tromsø, Norway
[4] Department of Pathology, University of Tromsø, Norway

Background: Acute myocardial infarction is frequently found at autopsy in persons dying suddenly. The aims of this study was to determine the time between onset of an asymptomatic myocardial infarction to the time of abrupt deaths and to determine whether there are morphological signs of spasm of the epicardial coronary arteries at autopsy in persons dying abruptly and unexpectedly. Methods: In a forensic autopsy service cases of sudden deaths were selected consecutively, one group with a preliminary diagnosis of coronary heart disease, and a control group with cases of a non-coronary cause, mainly self-inflicted death. Complete autopsy was carried out with particular emphasis on the heart examination. Without knowledge of which group the case belonged, multiple histological sections from the coronary arteries and the myocardium were examined. The age of the lesions was estimated by observing several time-related phenomena: macroscopic evidence of myocardial infarct or, microscopic presence of C9-positivity, and increasing quantity of CD15 positive leucocytes in sections from the myocardium. The degree of spasm is quantified by picture analysis, measuring the degree of folding of the internal elastic lamina in cross sections of elastin stained proximal and distal part of the coronary arteries. Results: Acute coronary lesions (rupture of necrotic plaque, thrombi, etc.) were found in 13 coronary cases, and myocardial infarcts, with onset within 5-6 hours prior to death in 13 cases, no infarct in 2 cases. In the non-coronary group, acute coronary changes were found in 4 cases, small recent infarcts in 7. The degree of folding was significantly greater in the distal section of right coronary artery in cases of the coronary group compared to the folding in the same section of the non-coronary cases. There were no significant differences in the other arteries. Conclusion: Sudden, unexpected deaths in persons with coronary disease occur within the first several hours after the onset of an asymptomatic myocardial infarction. Small, acute infarcts were found incidentally also a minority of the non-coronary group. Also,our findings indicate that a spasmic contracture of an artery may be diagnosed post mortem. In several of the coronary cases spasm of the distal part of the right coronary artery may have caused focal ischemia in the central parts of the cardiac conducting system precipitating a lethal arrhythmia.

PP3-315
AN EXPERIMENTAL MODEL OF MYOCARDIAL INFARCTION IN PIGS: REPERFUSION DAMAGE, DYNAMICS OF HEALING PROCESSES

Leos Kren[1], Zdenek Pavlovsky[1], Jiri Mayer[1], Jaroslav Meluzin[1], Ladislav Groch[1], Petr Rauser[2], Michal Vlasin[2], Ivan Hornacek[1]
[1] University Hospital Brno, Czech Republic
[2] University of Veterinary Medicine Brno, Czech Republic

Background: The goal of experiments was to create an animal model of myocardial infarction and to evaluate ischemic/reperfusion damage and dynamics of healing processes. The prospective use of the model is to evaluate fate, quantity and the best way of application of stem cells in the management of myocardial infarction. Material and Methods: Four experimental animals, female pigs, with weight from 30 to 40 kg were used. An experimental myocardial infarction was performed via occlusion of r. interventricularis anterior for 40 minutes. The hearts were examined 1 hour, 3 days, 5 days and 7 days after the procedure. Results: Macroscopically, red infarction, characteristic for ischemia with reperfusion was found. Microscopically, healing process with granulation tissue production/collagen deposition was remarkably accelerated in coparison with data in the literature. Also, besides of deposition of intracellular calcium, large deposits of extracellular calcium were found. Conclusion: dynamics of healing processes in myocardial infarctions in young female pigs is remarcably accelerated compared to data in the literature (probably because of examining tissues from significantly older human patients described in the literature). Also, not well described is a fenomena of large deposition of extracellular calcium, which may possibly interfere with healing processes.

PP3-316
PAPILLARY FIBROELASTOMA WHICH OCCURED IN THE POSTERIOR LEAFLET OF THE MITRAL VALVE: REPORT OF A CASE

Mihriban Gurbuzel, Saime Gul Barut
Haseki Education and Research Hospital, Istanbul, Turkey

Papillary fibroelastoma (PFE) is a rare benign tumor arising from the cardiac endotelium.They are usually located on valves, mostly the aortic valve.These tumors can be responsible for strokes, transient ischemic attacs, anjina pectoris, infarction and sudden death.Echocardiographic diagnosis, followed by surgical excision, may prevent these complications.Here, we report a rare case of papillary fibroelastoma because of its uncommon apperance in the posterior leaflet of the mitral valve. CASE: A 33-year-old male was hospitalized with a diagnosis serebrovasculer accident.Echocardiography revelaled a mass attached to the posterior mitral leaflet.The mass was removed by surgery.It was 0.7x0,6x0,5cm. diameter graywhite color and contain small papillary projections. On the microscopic evaluation,there was a lining of endocardial cells covering a core of hyalinized hypocelluler stroma. We identified PFE and supported immunhistochemically. The endotelial cells on papillary projection are reactive for CD34 and the stromal cells are weakly reaktive for S100. DISCUSSION: Papillary fibroelastomas are primary cardiac tumors of valvuler tissue. They are usually seen in elderly patients. But PFE of the mitral valve in 3-year-old child has also been reported. Transthorasic echocardiography may lead to suspicion of a PFE, but transoesophageal echocardiograhy is required for confirmation. It is identified histologically. This tumor may occur as isolated lesion or concomitant valve stenosis or other cardiac abnormalities. It is an important source of emboli. The lesions consist of a slender or broad fibrocollagenous stalk from which numerous papillary villous projections. Promt surgical excision is indicated in most cases. Anticoagulation is only recommended in situations of high surgical risk and during the wait for surgery.

PP3-317
MORPHOLOGICAL CHANGES OF CEREBRAL VASCULAR STRUCTURES IN HYPERTENSIVE PATIENS DEAD WITH INTRACEREBRAL HAEMORRHAGE

Iancu Emil Plesea[1], Stelian Danut Enache[2],
Corneliu Cristian Georgescu[1], Mirela Corina Ghilusi[2],
Dan Cioroianu[1], Oltin Tiberiu Pop[1], Alexandru Camenita[2],
Mihaela Tenovici[3], Cornelia Enache[2]
[1] University of Medicine and Pharmacy Craiova, Romania
[2] Emergency County Hospital Craiova, Romania
[3] National Railways System Universitary Hospital Craiova, Romania

Background The purpose of this study was to assess the spectrum of cerebral vascular wall (VW) changes in patients with clinical suspicion of primary intraparenchymal hematoma, confirmed after autopsy. Method 82 cases, clinically diagnosed with hypertension (HT), died with stroke and confirmed with intracerebral haemorrhage at autopsy were selected. The studied material consisted of nervous tissue situated near and distant from the haemorrhagic focus (HF). The specimens were processed following the classical histological technique and stained with usual stainings (H-E, van Gieson and Goldner trichromes) and immunohistochemical stains for basement membranes (BM) (Collagen-IV) and endothelial cells (CD34). Results Extraparenchimal large arteries showed only classical atheroslerotic lesions (AthL) which were found in most of the patients. The severity and extention of AthL presented wide individual and interindividual variations and were not correlated with the patients' age. The atrophy of the middle layer resulted in significant loosening and subsequent aneurismal spindle-shaped dilatations in certain extracerebral arterial segments. In some cases, thrombi in the lumen of large arteries were found, which partially occluded them. Intraparenchymal arteries and arterioles showed the entire range of VW degeneration steps caused by HT: thickening and folding of the inner elastica, hypertrophy followed by degeneration of the middle smooth muscle layer (SML), substitutive progressive and extensive fibrosis, starting from the outer adventicial layer and hyaline degeneration (HyD) of the collagen fibres which replaced the middle and outer VW layers. All observed changes had a focal irregular distribution, not related with the proximity of HF. Capillary walls showed focal or circumferential thickening of BM caused by the encreasing of collagen-IV material, followed by HyD of collagen fibres. The CD34 immunostaining showed that endothelial cells kept their structural integrity. Spindle-shaped dilatations and rupture of impaired VW in areas with hyalinization were also observed. Conclusions The VW changes are different depending on vessel histological structure and function. The sequence of cerebral VW degenerative lesions results in HyD of excessive fibrillar material from arteriolar wall or from BM. Weakening of wall resistance by hyalin material and minimal resistance of the surrounding parenchyma, explains vascular rupture due to HT, with subsequent HF only in cerebral parenchyma. The more adequate term for describing the VW changes seems to be sclerosis with HyD.

PP3-318
ARRHYTHMOGENIC RIGHT VENTRICULAR CARDIOMYOPATHY AS A CAUSE OF SUDDEN DEATH IN 12 YEARS OLD GIRL

Jordanka Brachkova
Medical University Pleven, Bulgaria

BACKGROUND: Arrythmogenic Right Ventricular Cardiomyopathy (ARVC) has recently been recognized as a cause of ventricular tachycardia and sudden death in young people. According to the WHO, ARVC is distinct from the more familiar forms of cardiomyopathy (dilated, hypertrophic and restrictive) and is characterized by three features: progressive fibrofatty replacement of right ventricular myocardium, strong familial transmission and presentation with symptomatic arrhythmias or sudden death. Although a gene defect was localized on chromosome 14, the pathogenesis remains obscure. The disease almost always occurs after puberty. METHODS: Autopsy and routine histology. CASE: Twelve years old girl was operated for ductus thyreoglossus persistens. Two hours after operation she started bleeding from operational wound. Despite of chemostasis and reanimation procedures , she died three hours later. Autopsy investigation revealed : Thymic follicular hyperplasia (95gr.) and adrenals atrophy ; Degenerative changes with apoptotic body between cardiomyocytes and its replacement by fibrous scars; Subendocardial and interstitial fibrosis and edema in right atrium wall and large amounts of fat in right subepicardium and around coronary vessels was seen as well. The right ventricular wall was severely thinned with extensive fatty infiltration and loss of myocytes. Subepicardial fatty tissue and myocardial fatty tissue replacement was most severe in apical parts of right ventricle. Thymic follicular hyperplasia was accompanied with necrotic Hassal's body and many eosinophyles and neutrophyles in medulary sone. Edema and inflammatory cells infiltrates composed from eosinophils, plasma cells, lymphocytes, neutrophils and mast cells was in subepithelial connective tissues of pharynx and epiglottis CONCLUSION: Cause of death was shock which first clinical symptom was bleeding in site of operation. Bleeding is consequence of acute congestive heart failure due to arrithmogenic right ventricular cardiomyopathy. In this case ARVC is accompanied with thymic hyperplasia, adrenal glands atrophy and ductus thyreoglossus persistens, which are probably involved in pathogenesis of ARVC.

PP3-319
EXPRESSION OF TELOMERASE AND Ki-67 IN MYOCYTES AFTER MYOCARDIAL INFARCTION

Angelos Tsipis, Anna-Maria Athanassiadou,
Pauline Athanassiadou, Nicolaos Kavantzas,
George Agrogiannis, Efstratios Patsouris
Department of Pathology, Medical School, University of Athens, Athens, Greece

Background: The presence of myocyte proliferation in the adult heart remains controversial. Telomerase replaces telomeric repeat DNA lost during the cell cycle, restoring telomere length. This enzyme is present only during cell replication and its activity reflects the extent of proliferation. Ki-67 is a nuclear antigen, strictly correlates with cell proliferation and is expressed in all phases of the cell cycle except G0. The aim of this study was to investigate the presence of myocyte replication by analyzing the expression of telomerase and Ki-67 in myocytes after myocardial infarction. Method: We studied myocardial samples of twenty hearts with histologic findings of myocardial infarction. Myocardial samples of ten normal hearts were used as controls. An immunohistochemical method was performed with the use of telomerase and Ki-67 antibodies, in order to investigate the expression of these markers in infarcted hearts. Results: The percentage of Ki-67 and telomerase positive expression samples was 85% (17/20 positive samples) and 70% (14/20 positive samples) in myocardium infarction, respectively. Moreover, we report that 70.5% of Ki-67 positive samples expressed telomerase. Positive expression of telomerase and Ki-67 appeared rarely in control group. Conclusions: The increased expression of Ki-67 and telomerase in infarcted myocardium, suggest the presence of myocyte proliferation and this may be a compensatory mechanism that could be replace damaged myocardium.

PP3-320
IMUNOHISTOCHEMICAL STUDY OF THE ADIPOSE TISSUE IN A FATAL CASE OF ARRHYTHMOGENIC RIGHT VENTRICULAR DYSPLASIA
Peter Ghenev[1], Ivan Stankulov[2], Anton Tonchev[3], George Chaldakov[3]
[1] Department of Pathology, Medical University of Varna, Varna, Bulgaria
[2] Department of Forensic Medicine, Medical University of Varna, Varna, Bulgaria
[3] Division of Cell Biology, Medical University of Varna, Varna, Bulgaria

Arrhythmogenic right ventricular dysplasia (ARVD) is a heritable disorder characterized by progressive degeneration and fibro-fatty replacement of right ventricular myocardium, causing ventricular tachyarrhythmias and resulting in sudden death at a young age. We report a young man without prior complaints dying suddenly during minor physical effort. The gross autopsy findings in the heart were minimal. The histologic features in both right and left ventricles were typical of ARVD, and consisted of fatty infiltrates with typical cardiomyocyte degeneration of the right ventricle and subepicardial regions of the left ventricle. Several lines of evidence suggest that impairment of cell-to-cell adhesion and involvement of desmosomal proteins may be the underlying pathogenic mechanism in ARVD, via accelerating apoptosis of myocardial cells. As fat replacement is most essential for the diagnosis of ARVD, the aim of the present study is to analyze immunohistochemically ARVD-related adipocytes compared to these from the subcutaneous fat. It is becoming increasingly evident that adipose tissue is a multifunctional organ that produces and secretes multiple factors that can act in both paracrine and endocrine fashion. So it is our opinion that adipose tissue in ARVD is not an innocent bystander and adipocyte-secreted cytokines probably play a substantial part in ARVD pathogenesis.

PP3-321
ONE STEP CLOSER TO DISCLOSING THE MORPHOLOGICAL SUBSTRAT OF SYNDROM X
Tigran Ghevondya
National Institute of Health, Armenia

Background: The name and existence of several definitions of the syndrome X point to vagueness of this condition. In present research we adhere to opinion, that the X-syndrome is the phenomena of angina pectoris and myocardial ischemia documented by electrocardiography without evidence of stenosis or a spasm of heart coronary arteries. Some researchers explain such pains through spasm of fine arteries of heart. There are no methods to study lifetime morphology of syndrome X at the same patient. We started with the assumption, that among died from first heart attack the number of persons suffered from X-syndrome at lifetime should be much more, than among healthy people. The aim was to clarify whether quantitative spatial peculiarities of intramyocardial arterial bed exist at died from the first heart attack? Method: Present research is carried out on 80 hearts received from practically healthy persons died of the violent reasons and on 60 hearts of patients died from acute myocardial infarction. Methods of X-ray micro-angiography of hearts; planimetry of X-ray films of myocardial strips; specimens cutting in three planes; scanning of histological slides under microscope; stereological calculation of volume density of arterial bed and statistics were used. Results: Both X-ray films data and data from histological slides show statistically reliable differences of the arterializations in different parts of a left ventricle wall. It has been revealed almost ninefold difference in mean value of parameters of volume density of arteries calculated for injected hearts in comparison with the data of non-injected hearts. The wide variation of value of a parameter both in healthy and in hearts with a myocardial infarction is found out. Thus the degree of arterializations in heart muscle with infarction was significantly much lower than arterializations of healthy hearts. The difference was obvious both between the data of X-ray films and data of stereological analysis of injected and non-injected hearts. Conclusion: The types of myocardial angioarchitectonics possessing low volume density are less favorable for heart in respect to blood supply of a myocardium and these types most frequently meet at hearts attacked by acute myocardial infarction. It is possible to assume, that the syndrome X meets more often at persons, who have less favorable angioarchitectonics, which brings to faster ischemia even by week spasms of coronary or small intramuscular arteries.

PP3-322
PRIMARY MALIGNANT PERICARDIAL MESOTHELIOMA: A CASE REPORT
Selvinaz Ozkara, Ilkay Tosun, Murat Erkan, Fugen Vardar Aker, Pembegul Gunes
Department of Pathology, Haydarpasa Numune Education and Research Hospital, Istanbul, Turkey

BACKGROUND: Primary malignant pericardial mesothelioma (PMPM) is extremely rare and overall poor prognosis. On reviewing the literature it appears that approximately 72% of all PMPM were actually diagnosed on autopsy. This obviously indicates a silent nature of this highly malignant and lethal tumor. The case of primary pericardial mesothelioma presenting as constrictive pericarditis is reported here, because of rarity. CASE: A 42-year-old male presented with two months history of progressively worsening breathlessness and central chest discomfort on effort. The diagnosis of constrictive pericarditis was made based on CT evidence of pericardial thickening and hemodynamic evidence of constrictive physiology. The history did not reveal any pertinent information such as exposure asbetos fibers. At surgery, the pericardium was thick, white, homogeneous, and very strongly adherent to the myocardium. As a result, resection of the pericardium was incomplete. Postoperatively the patient's condition deteriorated rather rapidly with low cardiac output state and he died soon after (one month) surgery. No post-mortem was possible. Several hard pericardial samples with irregular shapes were analyzed, the largest measuring 5x5x2cm. Microscopic examination revealed cancer infiltration of the pericardium with a multiple connected nodule morphology. These nodules consisted of large eosinophil cytoplasm, a vesicular nucleus and prominent nucleolus. The cells formed cord-like or tubular structures, confirming the mesothelial origin of the malignancy. Immunohistochemistry was positivity for calretinin, EMA and P53, while staining for desmin was negative. The final diagnosis was "malignant pericardial mesothelioma, epithelial type". CONCLUSION: Pericardial mesothelioma is extremely rare, although it is the most common primary pericardial tumor. Its incidence was <0.0022% among 500,000 cases in a large necropsy study. Approximately 200 cases have been reported so far and only 25% of these were antemortem diagnoses. PMPM is an aggressive disease and in our patient this was responsible for his death within one month of diagnosis. Herein, we report this rare case of PMPM and present a brief review of the relevant literature.

PP3-323
PEDIATRIC CARDIAC SARCOMAS, A SERIES OF 16 NEW CASES WITH LITERATURE REVIEW
Allen Burke[1], Fabio Tavora[2], Irem Ozbudak[3], Teri Franks[2], Markku Miettinem[2]
[1] CVPath Institute, Inc., Bethesda, MD, USA
[2] Armed Forces Institute of Pathology, Washington, DC, USA
[3] Akdeniz University School of Medicine, Antalya, Turkey

Background: Malignant primary cardiac tumors are extremely rare in infants and children, and there are no series published to date. We present a pathological series of pediatric cardiac sarcomas with clinical follow-up. Methods: Pathologic and clinical information from 23 primary heart tumors in patients ≤ 16 years at presentation were retrospectively reviewed. Chart record and histologic material were available in all cases. Follow-up information was obtained from contacting health care provider or patient family in 10 patients. A literature review for primary heart sarcomas in children published since 1980 was performed. Results: Of the initial 23 tumors in the series, 7 were reclassified as inflammatory myofibroblastic tumor (IMT) or benign fibrous histiocytoma, based on pathologic features and benign clinical follow-up. Sixteen cases remained as primary heart sarcomas. There were 14 males and 2 females, mean age of 10.4 years (range 0-16). Clinical presentation was variable and included recurrent pericardial effusion (1), respiratory distress (2), pulmonary emboli (1), shortness of breath (5), arrhythmia (2), chest pain (4), congestive heart failure (1) and constrictive pericarditis. Six patients presented with tumor in the left atrium, 2 in the left ventricle, 4 in the right atrium, 2 in the right ventricle, 2 in the pericardium and 1 in the mitral valve. Histologically, there were 5 leiomyosarcomas, 3 undifferentiated round cell sarcomas, 2 pleomorphic undifferentiated sarcomas, 3 angiosarcomas, 2 rhabdomyosarcomas, 1 osteosarcoma, and 1 fibrosarcoma. The youngest patient with angiosarcoma was 14 years, the youngest patient with pleomorphic sarcoma 12 years, and the ages at presentation of leio-, rhabdo- and undifferentiated round cell sarcomas ranged from 1 – 16 years. Three patients presented with metastatic disease, all with lung metastases. In cases with follow-up, mean survival was 8.7 months; all patients were dead of disease, with one alive with recurrence. Of the review of 12 published reports, 4 were considered likely IMT, based on histologic description and benign follow-up. The remaining 8 were angiosarcomas (2), rhabdomyosarcomas (3) liposarcoma (1), fibrosarcoma (1) and sarcoma, not otherwise specified (1). Prognosis was uniformly fatal, with survival up to 13 months. Conclusions: Primary pediatric sarcomas of the heart have a dismal prognosis, are of varied histologic types, have a male predominance, occur most frequently in the atria, and should be clearly separated from cardiac IMT.

PP3-324
INFLAMMATORY PSEUDOTUMOR OF THE HEART: A CASE REPORT

Chtourou Imen, Bahri Zouari Ibtissem, Chaari Chiraz, Zribi JihèNe, Gouiaa Naourez, Makni Saloua, Sellami Boudawara Tahya
Pathology Department, Habib Bourguiba Hospital, Sfax, Tunisia

Introduction: Inflammatory pseudotumor is a rare entity which most commonly involves the lung and the orbit. It rarely occurs in the heart: only 14 cases are reported in the literature mainly in children and adolescents. In this report, we review the relevant literature and discuss the pathogenesis, clinical manifestation, the diagnosis and the treatment of cardiac inflammatory pseudotumor. Case report: A 31 year old woman presented since seven days a fever which was followed by chest pain. The clinical examination was normal. Viral serologies and the assessment immunological were normal. Radiological explorations (ultrasonography, thoracoabdominal tomography and magnetic resonance imaging) revealed the presence of a cardiac mass which measured 24x13mm suggesting a thrombus. Anti coagulant treatement was administrated, but no improvement was observed. Consequently, the patient was operated. Histological examination of the mass showed spindle shaped cells with eosinophilic cytoplasm and elongated bland nuclei; these cells were accompanied by a variable number of inflammatory cells including lymphocytes, macrophages, plasma cells and eosinophils. En immunohistochemical stain, the spindle cells expressed actin and vimentin, but were negative for keratin, S-100 protein, CD34 and CD1a. Basing of this finding, the diagnosis of inflammatory pseudotumour of the heart was made. Conclusion: Inflammatory pseudotumour of the heart is rare, occurs mainly in children. Clinical presentation is variable. Tumor location and its characteristics can be observed by radiological findings but histological examination is necessary to make diagnosis. Complete surgical resection is the treatment of choice.

PP3-325
UNUSUAL CARDIAC TUMORS OTHER THAN MYXOMA. PRESENTATION OF 2 CASES

Ahu Senem Demiroz[1], Cem Leblebici[2], Buge Oz[1], Sergulen Dervisoglu[1], Feriha Oz[1]
[1] Department of Pathology, University of Istanbul, Cerrahpasa Faculty of Medicine, Istanbul, Turkey
[2] Department of Pathology, Istanbul Education and Reseach Hospital, Istanbul, Turkey

Background: The presentation of heart tumors is very rare. About 75% of primary tumors are benign, and 75% of these are atrial myxomas. Malignancy is found in fewer than half of primary tumors of the heart. The majority (95%) are sarcomas, primarily angiosarcomas and undifferentiated sarcomas. Primary cardiac tumors are high-grade sarcomas with a high metastatic potency that often becomes evident early after surgery.The presence of metastatic tumor to the heart usually indicates widespread metastases. Lung carcinomas are the most commonly encountered tumor followed by breast and pancreas cancer and melanoma. We present 2 cases with rare heart tumors Case 1: 24 year old woman presented with cardiac arrhythmia and was found to have a mass on mitral valve and left atrium. Histopathology of the resected specimen was a high grade osteosarcoma composed of fibroblastic, chondroblastic and osteoblastic components. An immunohistochemical study was performed by using S-100 antigen to differentiate the osteosarcoma from malignant peripheral nerve sheath tumor. There was positive staining in histiocytes but negative staining for tumor cells. So the histological and immunohistochemical findings of the permanent sections of the mass were consistent with primary cardiac osteosarcoma. Case2: 44 year old man presented with chest pain. His radiological findings revealed a mass in right atrium. Histopathology of the incisional biopsy was an undifferentiated malignant tumor with partial epitheloid pattern, showed extensive necrosis and invasion through pericardium and myocardium. Metastatic undifferentiated carcinoma was taken into differential diagnosis, but keratin was negative and no suspicious primary focus was found. Immunohistochemical results didn't support the relatively common primary malignant cardiac tumors such as rhabdomyosarcoma and angiosarcoma. Malignant paragangiioma was excluded due to chromogranin negativity and malignant melanoma was excluded due to HMB 45 and Mart-1 negativity. Conclusion: Sarcomas as unusual primary cardiac tumors should be taken in differential diagnosis when cardiac myxoma and metastatic carcinomas are excluded.

PP3-326
THE RELEVANCE OF CO-MORBIDITIES FOR IN HOSPITAL LETHALITY OF PATIENTS WITH ACUTE MYOCARDIAL INFARCTION: CLINICO-MORPHOLOGICAL STUDY

Eleonora Vataman[1], Vladimir Vataman[2]
[1] Institute of Cardiology, Chisinau, Republic of Moldova
[2] Medical and Pharmaceutical University, Chisinau, Republic of Moldova

Aim: To assess the impact of co-morbidities on myocardial infarction outcomes during acute phase of the disease. Methods: The survey vas based on retrospective analyze of necropsy

protocols for a 10-years period. 1269 cases of in-hospital death of patients (mean age 67,9±0,55 years) with myocardial infarction were studied. Statistical analysis included clinical features of myocardial infarction and its complications; co-morbidity; results of morphologic study. The aim of statistical analysis was to determine the factors which might have crucial role for the evolution of myocardial infarction and which could be used for predicting some fatal complications: acute ventricular aneurysm, cardiac rupture, pulmonary oedema, acute cerebrovascular accident, etc. Results: The group included 698 (55%) men and 571 (45%) women. Mean hospitalization period was 10,9±0,88 days. The frequency of co-morbidities were: arterial hypertension (27,1%); diabetes mellitus (21,2%), pulmonary diseases (11,5%), kidney pathology (11,5%), hepatitis/cirrhosis (3,7%), gastro-intestinal pathology (4,2%), obesity (7,6%). Causes of death were: pulmonary oedema – 40,3%, acute heart failure – 29,7, cardiogenic shock – 19%, sudden death- 14%, left ventricular parietal wall rupture – 12,2%. Other important complications: rhythm disturbances (chronic atrial fibrillation – 12,7%, high gradation extrasystoles- 4,6 %), stable conduction abnormalities (atrio-ventricular block – 2,36%, complete left bundle block – 2,36%), development of left ventricular endocavitary thrombosis (6,7%), periinfarctic pericarditis (1,73%). Among clinical parameters, responsible for the development of myocardial infarction complications and death, discriminant analysis revealed myocardial infarction characteristics: depth (transmural – 33,9%), location (46,3% - anterior, 30% - posterior), width (anterior extended – 27,5%, circular – 23,5%, posterior extended – 19%), evolution (repeated – 39,5%, recidivant – 13,5%), presence of left ventricular aneurysm (total – 12%, acute – 4,4%, chronic – 8,2%). Co-morbidities were not found as specific determinants of lethal outcomes in acute phase of myocardial infarction.

PP3-327
DYNAMICS OF ADAPTABLE RESERVES AT THE PATIENTS SUFFERING FROM ISCHEMIC HEART DISEASE AGAINST THE BACKGROUND OF TREATMENT WITH CITOPROTECTOR BIOR

Lina Remish[1], Ivan Butorov[2], Vladimir Remish[3], Vasile Anestiade[3]
[1] Academy of Sciences of Republic Moldova, Republic of Moldova
[2] Medical State University of Republic Moldova, Republic of Moldova
[3] Scientific Centre of Pathobiology and Pathology of the Academy of Sciences of Republic Moldova, Republic of Moldova

Both pharmacological means and the program for improvement of quality of a life and increase of tolerance to physical load of the patient with IHD should be used reasonably, render positive influence on the basic links of pathogenesis of the illnesses and increase nonspecific resistance of an organism. The purpose of research - to study the dynamics of adaptable reserves of the cardiovascular system at the patients with the ischemic heart disease during treatment. Material and methods of research. 135 patients with ischemic heart disease from which 21 (15,5%) had stenocardia I CF, 98 (72,6%) – a stenocardia II CF and 16 (11,9%) – a stenocardia III CF were under supervision. The most frequent risk factors were: an arterial hypertension -78 the patients (57,8%), hypercholesterolemia - 82 (60,7%). All patients received traditional medicamentous treatment, 82 patients (the basic group) in addition received cytoprotector BioR by 1, 0 ml intramuscularly daily during 20 days. Results of research. The analysis of dynamics of the clinical symptoms and syndromes against the background of the carried out therapy has shown, that in patients of the basic group pains in heart, a short breath, instability of arterial pressure decreased for 6-7 days earlier, than in group of comparison. It is established, that in patients with initial depression of processes of tissue respiration the increase of the constant of the speed oxygen absorption (from 0,032±0,003 up to 0,040±0,002 sec, $p < 0,001$), alongside with the reduction of the exhaustion time of oxygen stocks (from 155,2±10,8 up to 131,7±11,2 sec, $p < 0,001$), and after treatment time of exhaustion of half of oxygen stocks (from 39,6±1,2 up to 32,7±1,6 sec, $p < 0,001$) has been revealed. That demonstrates the improvement of processes of recycling of oxygen by the tissue. In patients of the control group positive changes have also been revealed, but they are less expressed and are statistically doubtful. The improvement and increase of compensative-adaptive possibilities of the organism during application BioR are also testified by the positive changes of the hemodynamics parameters in the patients. So, the heart index has increased with 1,41 ± 0,03 up to 1.56±0,04 l/mines/m², ($p < 0,001$), while in group of the control - with 1,43 ± 0,05 up to 1.48±0,06 l/mines/m², ($p > 0,01$); the Volume of performed work in the patients of the basic group has increased by 32,7%, in group of the control – by 6,7%; tolerance to loading has increased by 19,8% ($p < 0,001$) in the patients of the basic group, and only by 5,85% ($p > 0,01$) in control group. The involvement of cytoprotector BioR in the complex therapy of patients with IHD promotes the increase of the compensative-adaptive reactions of an organism and clinical efficiency of the treatment.

PP3-328
SUDDEN DEATH FROM TUBERCULOUS MYOCARDITIS

Butcovan Doina, Tinica Grigore, Grigoriu Carmen
Cardiology Center Iasi, Romania

Tuberculosis is an important public health problem considering to spare four organs: heart, skeletal muscle, thyroid and pancreas. We present a case of tuberculous myocarditis diagnosed on a post-mortem cardiac biopsy to a girl patient of fifteen years old, presented with unknown history of tuberculosis, but having a juvenile rheumatoid arthritis for who received corticosteroids for a long period of time. Clinical evaluation revealed rhythm disturbances on electrocardiogram, right cardiac failure and right upper lobe consolidation on chest X-ray. Microscopical examination of necroptic biopsies evidentiated specific lung giant-epithelioid granulomas with caseous necrosis and extensive infiltrative tuberculous lesions on the right lung associated with myocardial epithelioid granulomas without evident caseous necrosis. Tuberculous etiology was confirmed by applying a specific stain for Mycobacterium tuberculosis, obtaining a positive Ziehl-Neelsen result. We hypothesize that the mechanism of death was severe ventricular arrhythmia due to granulomatous proliferation in the structures of the interventricular septum. Because the involvement of myocardium in tuberculosis is rare, the increasing recognition of the entity and the use of endomyocardial biopsy may help us for detecting of more cases of this "curable" form of cardiopathy.

PP3-329
CARDIOVASCULAR CAUSES OF SUDDEN UNEXPECTED DEATH; SIX YEARS PROCESS IN COUNCIL OF FORENSIC MEDICINE

Arzu Akcay Turan[1], Ercument Aksoy[2], Oguzhan Melez[3], Oguzhan Ekizoglu[4]
[1] Council of Forensic Medicine, Istanbul, Turkey
[2] University of Marmara, Faculty of Medicine, Department of Forensic Medicine, Istanbul, Turkey
[3] Council of Forensic Medicine, Istanbul, Turkey
[4] University of Istanbul, Faculty of Medicine, Department of Forensic Medicine, Istanbul, Turkey

Background: Cardiovascular deaths constitute the major cause of sudden and unexpected deaths. Aim: To evaluate the pathological changes of 1424 cases reported as cardiovascular deaths,

autopsied in Council of Forensic Medicine in Istanbul, Turkey Methods: Autopsy reports of sudden unexpected deaths of cardiovascular origin between the years of 1999-2001 were retrospectively analyzed. In the sudden unexpected cardiovascular originated deaths between 2002 and 2004 whole hearts were sampled and examined systematically after being fixed. Findings of these two periods were compared in order to the role of cardiac sampling and systematic evaluation in the diagnosis of sudden unexpected deaths. Results: 1424 autopsy cases were analyzed. 1240 (87,1%) of these cases were male and their age range was 56± 15, 184 (12,9%) were female and the age range was 49± 20. 657 (46%) of these cases were died suddenly, 619 (43,5%) were found death and 98(6,9%) were died at the hospital. We found chronic ischemic changes in 724 (50,8%), acute infarction in 177 (12,4%), valvular disease in 44 (3,1%), myocarditis in 21 (1,5%), cardiomyopathies in 7 (0,5%) and left ventricular hypertrophy in 326 (22,9%) cases and the rupture of an aortic aneurysm was the cause of death in 32 (2,2%) cases and 79 (5,5%) cases were morphologically negative. When compared to the group of only myocardial sections are carried out at autopsy, the incidence of cardiomyopathies (7,8%), congenital heart diseases (3,1%) and acute infarction (14,1%) was detected to be high in the group where heart were whole sampled. Discussion: Pathological changes detected during the autopsy in a systematic manner will not only support the clarification of the cause of death, but also provide in depth knowledge about sudden and unexpected deaths.

PP3-330
DETECTION OF APOPTOSIS IN ENDOMYOCARDIAL BIOPSY SPECIMENS FROM PATIENTS WITH DILATED CARDIOMYOPATHY

Sofija Glumac[1], Anna Batistatou[2], Petar Otaševic[3], Zoran Popovic[1], Zorica Stojsic[1], Aleksandar Neskovic[4], Jovan D. Vasiljevic[1], Niki Agnantis[2]

[2] Institute of Pathology, Medical School, Ioannina, Greece
[3] Institute for CV Desease Dedinje, Belgrade, Serbia
[4] Cinical Center Zemun, Serbia

Background: Apotposis is a regulated energy-consuming process and physiologically found in embryogenesis and the maturation of multiple cell systems, and pathologically in various diseases. Apoptotic cardiomyocyte death is encountered in various heart diseases such as DCM, myocarditis, coronary artery disease, reperfusion injury, as well as right ventricular dysplasia, and hypertensive heart disease. The most widely used method to identify apoptosis in human histological material is the TUNEL assay. Design: The aim of the present multicentric study was to asses the apoptotic index by TUNEL method in endomyocardial biopsies from patients with DCM. Apoptosis was detected by using the TUNEL method in 33 patients. The values of apoptotic index were expressed as means with standard deviations. Biopsies were performed at the Instutute of Cardiovascular Diseases Dedinje, Belgrade. Results: The mean age of patients with dilated cardiomyopathy (DCM) was 29 males and 4 females. The mean age of patients was 44 (31-59 years). All cases of DCM were diagnosed both clinically and pathologically DCM was detected in 26 cases (79%). In this group of patients, the most common diagnosis was advanced DCM (9 cases or 35 %), followed by mild DCM (7 cases or 27 %), early stage of DCM (3 cases or 11%); recovery phase (6 cases or 23%) and hereditary CM (1 case; 4%). In 3 cases (9 %) Idiopatic dilated cardiomyopathy was found and the most common diagnosis was early DCM (1 cases;33 %), mild DCM (1 case; 33%) and focal myocarditis (1 case; 33%).DCM and insuffitientio valvulae mitralis were found in 4 cases (12 %) and in this cases pathohistological diagnosis were: early DCM (2 cases; 50 %); advanced DCM (2 cases; 50 %). TUNEL-positive myocytes were found in 26 of 33 cases with DCM (78,8%). The apoptotic index ranged 1,4 - 10,4%. The mean apoptotic index for the whole analyzed group of DCM was 3,3 ± 2,485%. Conclusion: The present study focused on the morphological analysis of apoptosis in DCM in endomyocardial biopsies specimens. We have found relatively high percentage of apoptosis in our series, in 78.8% of cases, as well as relatively high apoptotic index. These results could be explained by manifested cardiac failure of our patients, and represent midle values in other reported series.

DIFFERENTIAL DIAGNOSIS PROBLEMS IN CHORIOCARCINOMA

Eliza Gramada[1], Sabina Zurac[1], Alina Georgescu[1], Razvan Andrei[1], Florica Staniceanu[1], Carmen Ardeleanu[2], Bogdan Mastalier[3]
[1] Colentina University Hospital, Department of Pathology, Bucharest, Romania
[2] Victor Babes Institute, Bucharest, Romania
[3] Colentina University Hospital, Department of Surgery, Bucharest, Romania

Background: Choriocarcinoma is a relative rare malignant tumor of gestational trophoblastic disease. Most cases present myometrial invasion, but rarely locoregional metastases (vulva, vagina, broad ligament) or in other organs (lung, brain, spleen, gastrointestinal tract, liver) can be found. Material and method: We present a case of a 41-years-old woman who was admitted in emergency in Universitary Colentina Hospital for massive vaginal bleeding; a tumoral abdominal mass was present at clinical examination. For these reasons the patient underwent a surgical intervention (total hysterectomy and bilateral oophorosalpingectomy). Results: Gross appearance: the uterus is much larger (16/12/7,5cm), fluctuent at palpation; the uterine cavity was occupied by numerous cysts measuring 0,3 to 1 cm across with serous/serohematic content forming an adherent mass to the endometrial mucosa; there are necrotic areas especially in fundic zone. Microscopical examination revealed rare hydropic villi and a tumoral proliferation composed of trophoblastic cells with insular/ cordonal pattern invading the myometrium. Tumoral cells have a marked cellular and nuclear pleomorphism, with frequent atypical mitoses. Occasionally, in periphery of the tumor, giant multinucleated tumoral cells with marked cytonuclear atypia could be identified. This atypical aspect of trophoblastic cells invited us to a large debate of the differential diagnosis with invasive mole caused by the presence in a limited aria of the hidropic villi. Hormonal tests have been performed (beta HCG >40 000 mU/ml) and immunohistochemical tests: positive reaction for betaHCG in hydropic villi and in trophoblastic elements; p53 was positive 10-15% and Ki67 was positive 3-4% in trophoblastic elements, all of them confirmed the histopathological result. Conclusion: We presented this case both for the rarity of gestational trophoblastic disease and for the difficulty to sustain the histopathological diagnosis. We want to evidentiate the utmost importance of the periodical examinations in pregnancy.

PP4-2
EXPRESSION OF AURORA KINASES A AND B IN OVARIAN CARCINOMA: CORRELATION WITH CLINICOPATHOLOGICAL FEATURES

Marta Mendiola[1], Jorge Barriuso[2], Adrian Mariño-Enriquez[1], Gines Hernandez-Cortes[3], Elia Perez[4], Aurora Dominguez-Caceres[1], Andres Redondo[2], Juan Angel Fresno-Vara[2], Asuncion Suarez[1], Jose Palacios[5], David Hardisson[1]

[5] Dpt. of Pathology, Hospital Universitario Virgen del Rocio, Sevilla , Spain

BACKGROUND: Ovarian carcinoma is the most important cause of gynaecological cancer-related mortality in the western world with a poor 5-year survival. Combination platinum-paclitaxel chemotherapy has become a standard first line treatment. Aurora kinases are involved in mitosis and cell division process. Overexpression of Aurora kinases, particularly Aurora-A, has been reported in many cancers. The aim of this study was to evaluate the expression of Aurora kinases A and B in ovarian carcinomas and to correlate their expression with clinicopathological features. MATERIALS AND METHODS: The study was conducted on 68 ovarian carcinomas treated by surgery followed by paclitaxel plus carboplatin-based chemotherapy. A complete response to chemotherapy was observed in 66.2% of cases. Median follow-up of survivors (38.2%) was 33 months. Antibodies against Aurora-A (Novocastra, 1:100), Aurora-B (Bethyl, 1:50), estrogen receptor (ER) (Novocastra, 1:100), progesterone receptor (PR) (Dako, 1:100), p53 (Novocastra, 1:100) and Ki67 (Dako, 1:100) were applied using the Envision (Dako) method. The immunohistochemical expression of Aurora-A and –B was evaluated as present or absent, regardless of intensity and percentage of cells that exhibit immunostaining. Additionally, we analyzed the amplification of Aurora-A gene by FISH. RESULTS: Overall, 58.8% and 92.1% of ovarian carcinomas showed overexpression of Aurora-A and –B, respectively. Expression of Aurora-A and –B did not correlate with FIGO stage. However, disease free survival (DFS) was significantly higher among patients with Aurora-A protein expression (P=0.02). A clear trend for longer DFS was also observed in Aurora-B expressing carcinomas (p=0.06). Additionally, a trend for positive correlation between Aurora-A expression and complete response to chemotherapy was also observed (p=0.09). Amplification of Aurora-A was found in 26.7% of cases examined, and was not associated with overexpression of Aurora-A by immunohistochemistry. There was no significant association of Aurora-A amplification and the recorded clinicopathological variables. Expression of ER, PR, p53 and Ki67 did not show association with clinico-pathological variables. CONCLUSION: Aurora-A expression seems to have a prognostic value in patients with ovarian cancer treated with a platinum-taxol based regimen. The present results are consistent with a role of Aurora kinases as a determinant of chemosensitivity of ovarian carcinomas. However, these results should be confirmed in a larger series of ovarian carcinomas. Grant (MEC) SAF2004-0825-C02-02

A CASE REPORT: EXTENSIVE IN SITU SQUAMOUS CELL CARCINOMA OF THE ENDOMETRIUM AS SUPERFICIAL EXTENSION OF INVASIVE CERVICAL CARCINOMA

Cigdem Himmetoglu[1], Gamze Mocan Kuzey[1], Ali Ayhan[2]
[1] Hacettepe University Faculty of Medicine Department of Pathology, Turkey
[2] Hacettepe University Faculty of Medicine Department of Gynecology and Obstetrics, Turkey

Background: We report a case of 67-year-old woman with cervical squamous cell carcinoma (SCC) with extensive in situ squamous cell carcinoma of endometrium.SCC is the most common tumor of the female genital tract.However primary SCC of endometrium is extremely rare and its diagnosis requires absence of cervical malignancy. It is commonly encountered in postmenopausal women, where chronic pyometra or endometritis and long-lasting use of an intrauterine device are proposed etiologic factors.Ichthyosis uteri is a rare condition describing epidermalisation of the uterine cavity.It was described as an endometrial response to iatrogenically-introduced caustic substances and with a variety of inflammatory conditions of the endometrium. Case:A multiparous woman with new onset

vaginal bleeding administered to our Gynecology and Obstetrics Department's outpatient clinic.Physical examination revealed a massively enlarged, barrel-shaped cervix.Following a biopsy, she underwent a type III radical hysterectomy, bilateral salpingo-oophorectomy and pelvic-paraaortic lymph node sampling.Macroscopic examination revealed a 4 cm × 4 cm exophytic mass obliterating the endocervix and extending into the lower uterine segment.Sectioning revealed stromal invasion to almost 100% of the cervical wall.The uterus has become "pyometria" and uterine wall was extremely thinned.The endometrium was flat and glistening but was otherwise unremarkable.Microscopically,cervical neoplasm was a moderately differentiated,large cell keratinizing SCC.Extensive sampling of the endometrial wall revealed complete epidermalisation and areas where cells displayed high grade squamous intraepithelial lesion or carcinoma in situ.There was no evidence of extrauterine disease, parametrium was free of disease, 2 lymph nodes were metastatic.The patient received chemotherapy, now alive without diseases. Conclusion: Our case is a cervical SCC associated with extensive ichthyosis uteri-like changes of the endometrium that, additionally,had superimposed carcinoma in situ. These coincident findings may be explained that a SCC in the cervix and the associated HPV extended proximally,colonizing a pre-existing ichthyosis uteri.The second potential explanation is that within a background of extensive ichthyosis uteri, a SCC developed in the lower uterine segment.Neoplastic potential of ichthyosis uteri is largely unknown and theoretically longstanding,mature and even keratinizing squamous epithelium in the endometrium would be subject to the same potential changes in other visceral sites.

PP4-4

OVARIAN MUCINOUS CYSTADENOCARCINOMA WITH MURAL NODULE

R. Nilgun Demirbag[1], Gulbin Oran[1], Pınar Cilesiz Goksedef[2], Gonca Kolukfaki Batmaz[2]
[1] Haseki Training and Research Hospital, Department of Pathology, Turkey
[2] Haseki Training and Research Hospital, Department of Obstetric and Gynecology, Turkey

Solid mural nodule within a mucinous cystic ovarian tumor is extremely rare. Sarcoma-like mural nodules are not just limited to mucinous tumor. They can also seen in squamous cell carcinoma, cystic teratoma and granulosa cell tumor. A 78 year-old woman presented with abdominal pain caused by a mass. USG detected a 199x150 mm cystic mass.The mass contained a solid area of 73x47 mm and had a rich neovascularisation. The serum levels of CA125, CA15.3, AFP, CEA were normal and CA 19.9 was slighly eleveted at 50,9 U/ml. Grossly the ovarian tumor measured 17x16x11 cm. The outer surface was smooth and gray-white in colour. The cut surface showed a hemorrhagic mural nodule of 8x8x5 cm. Microscopically, tumor showed features of a malignant mucinous epitelial tumor. Mural nodule composed of round or ovoid cells with pleomorfic nuclei and prominent nucleoli. There was clear nuclear atypia and mitotic figures were inconspicous. There were scattered multinucleated giants cells with plemorfic hyperchromatic nuclei. Lymphovasculer and stromal invasion were present around the tumoral focus. Immunohistochemically the atypical cells in the mural nodule were negative with SMA and desmin. They expressed vimentin and multinuclear giant cell were CD68 positive. There were scattered CK positive atypical glands and isolated cells. In the literature, rare cases of ovarian mucinous tumors have been described that contain foci of sarcoma-like nodules. This case report describes the pathologic features of this rare entity with review of the literature.

PP4-5

DISTRIBUTION OF OVARIAN TUMORS IN ZONGULDAK KARAELMAS UNIVERSITY MEDICAL FACULTY HOSPITAL BETWEEN 2001-2007 YEARS

Figen Barut[1], Gurkan Kertis[1], Aykut Barut[2], Sibel Bektas[1], Banu Dogan Gun[1], Burak Bahadir[1], Gamze Yurdakan[1], Sukru Oguz Ozdamar[1]
[1] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Zonguldak Karaelmas University, Faculty of Medicine, Department of Obstetric & Gynecology, Zonguldak, Turkey

Introductıon: Ovarian tumors are one of the common form of neoplasia in women. It is the fifth leading cause of cancer mortality in women. There are numerous types of ovarian tumors, both benign and malignant. Majority are benign. The purpose of this study is to evaluate the epidemiology of ovarian cancer in Zonguldak and surrounding cities, retrospectively. Methods: Between May 2001 and March 2007, 769 ovarian biopsies from 494 cases which undergo operation for variable cause are reviewed in Karaelmas University Medical Faculty Pathology Department. Tumors and other pathologic changes were classified. Results: Patients ages are between 10 days to 85 years and average is 45.46 (SD±13,45) years. Ovarian tumor's ratio is (n: 123) 24,9% in all cases. Distribution of this 123 ovarian tumor: 90 (%73,2) are benign, 9 (%7,3) are borderline and 24 (%19,5) are malignant. 68 of the cases (55,3%) are tumors of surface epithelial origin of the ovary {26 (38,2%) are benign serous, 18 (26,5%) benign mucinous, 2 (2,9%) benign brenner, 7 (10,3%) borderline serous, 2 (2,9%) borderline mucinous, 9 (13,2%) malignant serous, 1 (1,5%) transitional cell carcinoma, 1 (1,5%) endometrioid carcinoma, 1 (1,5%) clear cell carcinoma, 1 (1,5%) malignant mixt mullerian tumor}; 34 of the cases (27,7%) are germ cell tumors {33 (97,1%) mature cystic teratoma, 1 (2,9%) teratoma with malignant transformation}; 10 of the cases (8,1%) are sex-cord stromal tumors {1 (10%) adult granulosa cell tumor, 1 (10%) juvenil granulosa cell tumor, 4 (40%) fibroma, 2 (20%) fibrothecoma, 1 (10%) sclerosing stromal tumor, 1 (10%) sex-cord stromal tumor of not other specified}; one of the cases (0,8%) is vascular tumor (cavernous hemangioma); one of the cases (0,8%) is undifferantiated carcinoma and 9 are (7,3%) metastatic tumors. Conclusion: Among cancers of the female genital tract, the incidence of ovarian cancer ranks below only carcinoma of the cervix and the endometrium. Ovarian cancer mortality takes the first place when compared with all other gynecological malignancies. In our study cystadenoma and cystadenocarcinoma are the most frequent benign and malignant tumors respectively and most of them are serous. When compared with the literature, tumors of surface epithelial origin of the ovary are less frequent, but metastatic tumors to ovary are more frequent in both whole and malignant groups. Germ cell tumor's ratio is higher according to literature. We also have cavernous hemangioma which is an extremely rare tumor of ovary.

PP4-6

CLINICO-MORPHOLOGICAL PECULIARITIES OF SEPTICEMIA IN LABOR AS A SEPARATE NOSOLOGICAL FORM AMONG THE CAUSES OF MATERNAL DEATH

Andrey Milovanov[1], Alexander Matsionis[2], Nina Mikhanoshina[2]
[1] State Research Institute of Human Morphology of the Russian Academy of Sciences, Russia
[2] Rostov Regional Institute of Pathology, Russia

Background -Pyoseptic diseases account for 15% of the main causes of maternal death and are usually classified as postnatal sepsis Methods - We studied 15 autopsies of puerperas who died over a 10 year period (1996 - 2006) from pyoseptic diseases in the Rostov Province, and we analyzed their afterbirths and partum histories. Microscopic examination of uteri, spleens and lymph nodes, as well as fetal membranes and placentas, was

performed by standard methods of light microscopy, with hemotoxillin and eosin staining; PAS reaction was also used, and immunohistological verification of cells from the inflammatory infiltration in the above organs. Results - Microscopic and immunohistochemical examination of the uterus showed, in 50% of cases, shallow invasion of the cytotrophoblast cells in the placental bed, incomplete gestation restructuring of the endometrial segments of the uteroplacental artery; in 60% of cases we found focal, low-grade infiltration with granulocytes, T-lymphocytes, and macrophages; myometry revealed, in 60% of cases, focal low-grade, mostly perivascular, infiltration with granulocytes, T-lymphocytes, and macrophages. The inflammatory infiltrate in the placental fetal membranes was represented by a great number of granulocytes, plasmacytes, macrophages, and rare T-lymphocytes. The inflammatory infiltrate contained no B-lymphocytes. In 73% of cases we observed effacement of the spleen pattern, dysfunction of the humoral and cell protection - depletion of the lymphoid tissue and its replacement with granulocytes and macrophages; the lymph nodes in 86% cases also showed effacement of the pattern, with only fragments of the lymphoid follicles preserved, while the parafollicular zone was characterized by depletion of T-lymphocytes and diffuse infiltration with granulocytes and macrophages. Conclusion - Early antenatal infection of the afterbirth, which is these cases is the entrance gate for penetration of bacterial, fungous, and viral agents into the mother's blood flow. We found a relative intactness of the uterus, because the revealed inflammatory changes in the basal endometry and myometry should be regarded as normal inflow of leucocytes and lymphocytes to the area affected by necrosis and rejection of the decidual tissue and remains of the fetal membranes. The rapidity of development of the clinical manifestations of septicemia in labor, and of the infection and toxic shock, leading to death of the puerperas within the first days of the postpartum period, is accounted for by the apparent deterioration of the immune system function.

PP4-7

HIGH-GRADE ESS ARISING FROM OVARIAN ENDOMETRIOSIS, WITH ASSOCIATED FOCI OF ENDOMETRIOID ADENOCARCINOMA: REPORT OF A CASE.

Cristina Manieli, Giuseppina Parodo, Sara Pillai, Gavino Faa
Department of Cytomorphology, Section of Pathology,
University of Cagliari, Italy

Background: Endometriosis malignant transformation is a well documented phenomenon that occurs most commonly in the ovaries, frequently associated with endometrioid or with clear cell adenocarcinomas. Endometrioid stromal sarcoma (ESS) is a sarcomatous tumor characterized by a diffuse proliferation of neoplastic cells similar to the normal stromal cells present in the proliferative endometrium. Among these, ESS arising in endometriosis of the ovary is an extremely rare tumor. Here we present, for the first time, a case of an high-grade ESS arising from ovarian endometriosis associated with endometrioid adenocarcinoma foci. A 51-years-old white woman, with no significant gynecological history, presented with increasing abdominal distension, and weight gain. After an exploratory laparotomy a 10 cm right ovarian mass with neoplastic ascitis and multiple tumoral nodules in the omentum and in the peritoneum was found. Given the advanced stage, debulking surgery was performed. No alteration of the uterine corpus were revealed under clinical, ultrasonographic and laparoscopic examinations. The patient died after 1 month for the diffuse metastatic disease. Method Immunohistochemical studies were performed by indirect staining methods using antibody against cytocheratin 7, 20, 8-18, vimentin, epithelial membrane antigen (EMA), inhibin, calretinin, S100 protein, HMB45, smooth muscle actin, desmin, estrogen receptor (ER), progesterone receptor (PR), NSE, cromogranin, sinaptofisin, CD99, CD45, CD30, Ki-67 (Mib-1), CD10. Results The ESS tumor nodules were composed mostly by sheets or cords of closely packed round or oval uniform cells, with pale and scanty cytoplasm and intersected by dense fibrous band. Some of these neoplastic cells occasionally were found around numerous small thick-walled blood vessels. More than 10 MF per 10 HPF were counted. Extensive necrosis and hemorrhage and vascular and perineural invasion were present in the tumor. Endometriosis, identified in the cystic areas, in some areas was associated with endometrioid adenocarcinoma foci (G2, nuclear grade 3). ESS tumor cells immunohistochemical stain was positive for vimentin, CD10 and focally for EMA and around 80% of nuclei were Ki-67 (Mib-1) positives. All the other immunohistochemical markers performed were negative. In the multiple foci of of endometrioid adenocarcinoma the neoplastic glands resulted diffusely positive for EMA and CK7, and negative for CD10. Conclusion: According to our knowledge this is the first report of a high-grade ESS associated with concomitant endometrioid adenocarcinoma foci.

PP4-8

MULTIPLE OXYPHILIC TYPE ADENOMATOID TUMORS OF THE UTERUS COEXISTING WITH ENDOMETRIAL ADENOCARCINOMA IN A RENAL TRANSPLANT RECIPIENT.

Antigoni Karakosta, Maria Karagiannis, Rosaria Mennonna, Eleni Sotiriou, Panagiota Pantoula, Sofia Xyristaki, Aikaterini Parasi
Pathology Department, General Hospital of Nikaia “Agios Panteleimon”, Piraeus, Greece

Backround: Uterus is the most common site of occurrence of adenomatoid tumors in the female genital tract. Multifocal cases, as well as oxyphilic variants, have rarely been described. To our knowledge, this is the second case, coexisting with endometrial adenocarcinoma of the uterus and the fourth case, in a renal transplant recipient. Case: This is a report of the coexistence of a multifocal uterine adenomatoid tumor with a poorly differentiated endometrioid adenocarcinoma, FIGO stage IB. Both were incidental findings in a 56 years old woman, undergoing hysterectomy because of large leiomyomas. Two of the adenomatoid tumors, found macroscopically, had gelatinous appearance while the third was found microscopically. All consisted of large oxyphilic epithelioid type cells, with a solid or trabecular pattern resembling leiomyoblastoma. Slit–like and adenoid pattern was rarely found. Immunohistochemically, the tumor cells stained for Vimentin, Pankeratin, Calretinin, Keratin 5/6 and HBME-1, while no immunoreactivity for Actin, Desmin. H-Caldesmon, CD34 and CD31 was found. The Ki67 index was low. Conclusion: Uterine adenomatoid tumors are rare tumors, which may cause differential diagnostic problems, but the knowledge of their morphological spectrum and the characteristic immunoprofile allows their diagnosis. Very interesting features of our case are the multicentricity and the oncocytic appearance of the tumor, as well as the coexistence with a poorly differentiated carcinoma, in an immunocompromissed status of a renal transplant recipient.

PP4-9

PRIMARY VAGINAL MUCINOUS ADENOCARCINOMA ARISING ON A PREEXISTING ADENOMA. A RARE CASE REPORT.

Aikaterini Apostolaki, Eleni Ieremia, Efthimios Koniaris, Maria Gazalidou, Maria Mpiteli, Apostolikas Nikiforos
Pathology Department, Anticancer Oncologic Hospital of Athens “St. Savvas”, Athens, Greece

Background: Primary vaginal mucinous adenocarcinomas (PVMA) are rare neoplasms that develop in patients with in utero exposure to diethylstilbestrol (DES). We report a case of PVMA of intestinal type arising on a preexisting adenoma, in a patient without intra-uterus DES exposure. Awareness of this lesion is important as it must be distinguished from metastatic

adenocarcinomas especially from colon or endocervix. Method: A 13mm polypoid mass was found on the posterior vaginal wall of a 52-year-old menopausal woman during routine gynecological check up. The patient did not have any symptoms of vaginal bleeding, mucus secretion nor a history of diethylstilbestrol exposure. Complete excision of the polypoid mass was performed and the histological examination showed adenocarcinoma of intestinal type arising on a tubular adenoma. To preclude possible metastasis from the gastrointestinal tract, sigmoidoscopy, colonoscopy and gastroscopy was ordered showing no primary gastrointestinal lesions. Results: Grossly, the specimen was a lobulated, circumscribed, brown-colored solid lesion measuring 13mm. Histologically, it was a tubular adenoma of medium degree of dysplasia with glands made of columnar and goblet cells without any Paneth and neuroendocrine differentiation. The adenoma focally transformed to areas with higher density of glands, placed back-to-back, with multistratification of nuclei, loss of cell polarization and cribriform architectural arrangement, similar to in situ intestinal adenocarcinoma arising on an adenoma. The adenocarcinomatous area was showing early focal invasion of the underlying stroma with accompanying chronic inflammatory infiltration and slight desmoplasia. Dysplastic glandular epithelium was replacing the normal vaginal non-keratinized stratified squamous epithelium in adjacent sites. The immunohistochemical profile of the lesion revealed expression of CK 20 and CEA and negativity in CK 7. Alcian blue positivity was indicative of intestinal type mucin. Conclusion: PVMA is a rare tumor of the lower female genital tract and its occurrence is higher among women who have been exposed to DES during intra-uterus life. However, cases of no such association to DES have also been reported. The differential diagnosis involves metastatic mucinous adenocarcinoma of the endocervix and of the intestines. In the first case, the adenocarcinoma cells contain sulfomucin, a mucin specific for adenocarcinoma of the endocervical type. In the second case, the mucin is the intestinal type o-acetylated sialomucin.

PP4-10

HIGH CELLULAR LEIOMYOMA WITH EXTENSIVE CYSTIC DEGENERATION MIMICKING LOW GRADE ENDOMETRIAL STROMAL SARCOMA. A CASE REPORT WITH PECULIAR MACROSCOPIC APPEARANCE

Apostolaki Aikaterini, Efthimios Koniaris, Eleni Ieremia, Antigoni Papathanasaki, Maria Sevastiadou, Nikiforos Apostolikas
Pathology Department, Anticancer Oncological Hospital ‘St. Savvas’, Athens, Greece

Background: High Cellular Leiomyoma (HCL) is a subtype of Cellular Leiomyoma (CL) with accentuated cellularity composed of small, round or spindle cells lacking moderate to severe cytological atypia and necrosis. HCL is often misdiagnosed as Endometrial Stromal Tumor (EST). We present a case of HCL in the form of an intramural, solitary, well-defined myometrial cyst. Method: A 38-year-old woman presented with a pelvic mass, causing urinary urgency and stagonoid hemorrhage. On palpation, and ultrasonographically, an enlarged cystic uterine mass was observed, displacing the urinary bladder and slightly obstructing the ureters causing dilation of the pyelocalyceal system. On CT and MRI scan no other notable lesions were discovered. Total hysterectomy was performed with bilateral salpingectomy. Results: Grossly, the uterus measured 13.5x11x10.5cm and the left and right salpinx measured 3.5 and 3.7cm respectively. On dissection, a voluminous cystic mass was observed in the ventral myometrial wall measuring 9cm in greatest diameter and filled with a yellowish serous liquid content. On cross section, the mass was whitish-yellowish-to-tan, nodular-appearing, with extensive cystic degeneration and soft in consistency. A small leiomyoma measuring 1.5cm was also found. The endometrial surface was not affected. Histologically, the tumor was characterized by a monotonous appearing hypercellular mass with slightly irregular peripheral borders. It was composed of relatively uniform cells showing no or minimal cytological atypia, having round or ovoid nuclei with finely granular and evenly dispersed chromatin, small inconspicuous nucleoli and scanty cytoplasm. At foci, typical smooth muscle bundles and few thick walled vessels were encountered. Furthermore, cystic changes were also spotted among the stromal neoplastic cells. Low mitotic activity (infrequent mitotic figures, <5/10HPF) was evident. The margins of the tumor were relatively well-delineated with focal finger-like irregularities of 3mm and isolated neoplastic cells infiltrating the adjacent myometrium. Necrotic foci and invasion of the lymphatic and vascular channels were not observed. Conclusion: Differential diagnosis includes Endometrial Stromal Nodule (ESN) and low grade Endometrial Stromal Sarcoma (ESS). Although morphologically the neoplasm is consisted with low grade ESS and despite the slightly irregular peripheral borders of the neoplasm, HCL is strongly considered. Our case was positive in vimentin/ER/PR/desmin/SMA and negative in CD10, the latter typically staining endometrial stromal tumors.

PP4-11

DIVERSITY OF MORPHOLOGY, PROGNOSIS AND CLINICS OF ENDOMETRIAL CARCINOMA

Regina Kleina
Riga Stradins University, Latvia

Endometrial carcinoma (EC) is the 3rd common cancer of female in Latvia with 30,8%o and there is tendency for increase. The aim of our research is to evaluate stage, variants, prognostic factors and immunohistochemical spectrum of EC. Materials and Methods. We have analyzed retrospective material of operated uterus from 60 cases with the characteristics of lymph nodes, tubes, ovaries and expression of estrogen, progesterone, CD 44 and synaptophysin markers. Coherence between clinical symptoms we analyzed by Speerman rank system, but correlations between morphological changes by diagrams. Results. 60% of EC were endometroid adenocarcinomas, 23%-villoglandular variant, 15%-with squamous differentiation, 2%-clear cell adenocarcinoma. Age of patients: 44-82 years. EC were of I to IV stage and myometrial invasion from 0, 1 to 2 cm. Clinical information showed uterine bleeding in 43%, obesity - 5% of patients. Number of deliveries and abortion were variable. In 31, 6% of cases EC were proved in such precursor lesions as endometrial polypus and atypical hyperplasia. Mean age of menopause – 52 year. Late menopause was in 36% of patients. The size of the uterus in majority of cases was normal. Clinical diagnosis of benign process was changed to malignancies by pathologists in 14, 6 % of cases. Metastasis were proved only in 3, 3% of female. In 92% of patients lymph nodes were not exceeded for histological examination. In ovaries were different cysts. Expression of estrogen, progesterone markers were: negative in 23, 8 %, positive-57, 2 %, but in 19 % of cases estrogen was negative, but progesterone –positive. Conclusions.1.Diagram analyses showed the most aggressive invasion in myometrium by villoglandular variation of EC. 2. There were no statistically significant differences between different clinical data but we proved direct correlations between nononcological changes in ovaries with increased risk ofendometrial carcinoma at earlier age of patient. 3. Immunoreactivity of estrogen and progesterone receptors was more expressed in G1, G 2 of EC but lack of lymph nodes in our research group decreased the possibility of real prognosis.

PP4-12
HOW OFTEN HSIL ACCOMPANIES LSIL: IS AGE IMPORTANT?
Handan Cetiner[1], Ayse Gurbuz[1], Gozde Kir[2], Ates Karateke[1]
[1] Zeynep Kamil Hospital, Pathology Department, Turkey
[2] Umraniye Hospital, Pathology Department, Turkey

BACKGROUND: High-grade squamous intraepithelial lesion (HSIL) has much greater potential for progressing than does low-grade intraepithelial lesion (LSIL). So it may be the important to identify the subset of women at higher probability of having "LSIL harbouring the HSIL" lesions in follow-up biopsy specimen whose cytologic specimens show atypical squamous cells of undetermined significance (ASC-US), atypical squamous cells; cannot exclude HSIL(ASC-H) and LSIL. METHOD: Sixty-five consecutive patients whose follow-up cervical biopsies were available and have ASC-US, ASC-H and LSIL lesions in their conventional smears were enrolled. We divided them in two groups: age 40 and under and over age 40. All follow-up biopsy results were evaluated and cases were excluded which the histologic examination didn't show any squamous lesion. RESULTS: Six patients were excluded because of not showing any squamous lesion in their follow-up biopsy specimen.There were 39(66%) women age 40 and under and 20(34%) women over age 40 who have cytologic abnormalitiy as ASC-US, ASC-H and LSIL. In younger age group; 30(77%) women showed LSIL and 9(23%) women showed HSIL in their biopsy specimen. In over 40 group; there were 8(40%) LSIL and 12(60%) HSIL showing biopsy specimens. CONCLUSION: Compared to younger women with abnormal low-grade cervical cytology, women over 40 years of age, had higher rate of having 'LSIL harbouring HSIL' in their follow-up biopsy. Since current study has small sample group further studies involving large number of cases and detailed statistical analysis must be made. If these findings confirmed in future studies then it may be possible to say that HSIL lesion is more expectable in follow-up biopsy of women over 40 years of age with a diagnosis of ASC-US, ASC-H or LSIL in cervical cytology.

PP4-13
ENDOCERVICAL-LIKE MUCINOUS BORDERLINE TUMORS OF THE OVARY : A CLINICOPATHOLOGIC ANALYSIS OF 9 CASES
Raoudha Doghri, Maha Driss, Samia Sassi, Imen Abbes, Karima Mrad, Ryme Dhouib, Naziha Ben Hamida, Khaled Ben Romdhnae
Institut Salah Azaïz, Tunisia

Endocervical-like mucinous borderline tumors (EMBTs) are rare distinct entity of the ovary that seems to be under recognized. These tumors are characterized by a papillary architecture reminiscent of serous tumors but composed of endocervical-like mucinous epithelium. The latter may be admixed with other mullerian-type epithelium, including those of serous, endometrioid, squamous and eosinophilic epithelial cells. We have studied nine EMBTs including 2 cases with intraepithelial carcinoma and one case with stromal miroinvasion. The patients averaged 35.5 years of age. None tumor was bilateral. Endometriosis was identified in three cases and one patient was known to be pregnant at the time of diagnosis. All patients were stage I. Of the 5 patients which have a follow-up data, only one patient was complicated by recurrence in the conserved contra lateral ovary with a peritoneal implant, three years later. The present study describes our experience with endocervical type mucinous tumors. The frequency of occurrence, criteria for the diagnosis of intraepithelial carcinoma and microinvasion are discussed.

PP4-14
GENOMIC INTEGRATION OF ONCOGENIC HPV AND GAIN OF THE HUMAN TELOMERASE GENE TERC ARE STRONGLY ASSOCIATED EVENTS IN PROGRESSION OF UTERINE CERVICAL DYSPLASIA TO INVASIVE CANCER
Anton Hopman[1], Wendy Theelen[1], Simon Herrington[2], Larry Morrison[3], Frenk Smedts[4], Frans Ramaekers[1], Ernst-Jan Speel[1]
[1] Department of Molecular Cell Biology, University of Maastricht, Netherland
[2] Bute Medical School, St. Andrews, UK
[3] Vysis Inc, Downers Grove, IL, USA
[4] Foundation of Collaborating Hospitals of Eastern Groningen, Winschoten, Netherland

Background: Recently proposed markers for progression of CIN II/III to cervical carcinoma include integration of HPV into the host genome, genomic instability and an increase in chromosome 3q copy number. In particular, the gene coding for the RNA component of telomerase (TERC) at 3q26 has been implicated as possible candidate gene. Since it is not known to date how these events are temporarily related during cervical carcinogenesis, the aim of the present study was to assess the correlation between TERC copy number and physical status of HPV in high grade solitary precursor lesions of the uterine cervix (CIN II/III, n=17), lesions associated with a microinvasive cervical carcinoma (CIN III&mCA, n=13), and advanced invasive cervical carcinoma (invCA, n=7). Method: Fluorescence in situ hybridization (FISH) was applied to assess the copy number of the TERC gene and HPV integration and to correlate TERC gain with HPV integration during progression in cervical neoplasia. The TERC gene probe was applied in a mixture together with probes for the centromeres of chromosomes 3 and 7, used to determine the ploidy of these lesions. Results: Our study revealed that CIN II/III lesions with episomal HPV frequently show tetrasomy for TERC. In these cases the TERC gene copy number parallels the DNA ploidy of the lesions. Furthermore, TERC was increasingly gained with progression of CIN II/III (3 of 17), via CIN III&mCA (7 of 13) to invCA (5 of 7). In the cases exhibiting gain of TERC the virus was predominantly integrated. The finding that the combination of gain of TERC (three copies) and genomic integration of HPV was seen in 8 out of 10 diploid lesions, indicates that these events occur prior to overall aneuploidization. Our data show that gain and aneusomy for the TERC gene is strongly correlated with viral integration, which in turn is associated with the progression of CIN III to mCA and invCA ($p<0.001$). Conclusion: Genomic integration of oncogenic HPV and gain of the human telomerase gene TERC are strongly associated events in progression of uterine cervical dysplasia to invasive cancer.

[4] Laboratori de Papillomavirus, IDIBELL, Institut Català d'Oncologia L'Hospitalet de Llobregat Barcelona, Spain
[5] Servei d'Oncologia Mèdica, IDIBELL, Institut Català d'Oncologia L'Hospitalet de Llobregat Barcelona, Spain

INTRODUCTION: The vast majority of uterine cervical carcinomas are human papillomavirus (HPV) related neoplasms. In women with a cervical cancer and a distant lesion the histologic distinction of metastatic cervical cancer versus another primary tumor can be difficult and has important clinical implications. OBJECTIVE: To study the presence of HPV DNA in primary cervical cancer and in second neoplasms in the same patient. MATERIAL AND METHODS: Four patients with squamous cell carcinoma (in bone, lung, lateral neck lymph node and pleural fluid) and two with adenocarcinoma (in ascitic fluid) and a past history of uterine cervical cancer (diagnosed 1 to 11 years before) were studied. HPV DNA detection was performed both in the cervical tumors and in the second neoplasms (formalin fixed, paraffin embedded tissues) using a PCR based technique with GP5+/6+ primers for detection of the HPV L1 gene followed by reverse line blotting hybridization for genotyping. RESULTS: In five patients DNA of the same HPV type was found in the cervical tumor and in the second neoplasm (HPV16 in 4 squamous cell carcinomas and HPV18 in one adenocarcinoma), thus allowing to classify the second tumors as metastatic. In the remaining patient HPV DNA was not detected in any of the tumors tested. CONCLUSIONS: In women with a past history of an HPV-related cancer and a second neoplasm detection and typing of HPV DNA is helpful in the differential diagnosis between metastases and a second unrelated malignancy.

PP4-16
EFFECTIVENESS FOR EVALUATION OF LYMPHATIC INVASION IN ENDOMETRIOID ADENOCARCINOMA OF THE UTERINE CORPUS

Yasuka Miyakuni, Yuki Yamada, Keiko Abe, Atsushi Arakawa, Hiroshi Sonoue, Toshiharu Matsumoto
Juntendo University , Japan

Backgrounds: Lymph-vascular involvement is one of the important prognostic factors in the patients with carcinoma of the uterine cropus. Conventionally, it has been determined morphologically using hematoxylin and eosin sections. In addition to that, various immunohistochemical stains have been attempted in order to confirm the accuracy of diagnosis of lymph-vascular involvement with section stained H&E. Recently, D2-40 immunostaining was demonstrated as the best immunohistochemical marker for the endothelium of the lymph vessel. The aim of this study is to clarify the effectiveness of immunohistochemical staining with D2-40 in determination of lymphatic invasion. Methods: We investigated that 40 patients with adenocarcinoma confirmed to the uterine corpus, who were underwent radical hysterectomy. The stages of tumors were 26 cases in pT1b, 14 cases in pT1c, and 7 cases were positive node among 40 cases. From each material, one section containing the deepest invasive part was selected for examination and stained with H&E and D2-40 immunohistochemically. Lymphatic invasion was evaluated by either H&E staining or D2-40. The concordance of these results was assessed using the kappa statistic (κ). Additionally, the relationship between lymph vascular involvement and lymph node metastasis was examined by using Fisher's exact test. Results: The evaluation of lymphatic invasion with H&E staining resulted in 24 positive cases (positivity of 60%) and 16 negative cases (negativity of 17.5%). The result with D2-40 immunostaining showed 7 positive cases (positivity of 17.5%) and 33 negative cases (negativity of 82.5%). The concordance between H&E and D2-40 was moderate (57.5%, κ=0.53). The negative cases in the evaluation with H&E staining were always negative in the evaluation with D2-40. As a result, lymph vascular involvement might have been over-estimated by H&E staining. The correlation between lymphatic invasion and lymph node metastasis showed statistical significance, in both results with H&E and D2-40 (p=0.011 and p=0.0001, respectively). Conclusion: Lymphatic invasion determined by D2-40 staining could be much more accurate predictive factor for lymph node metastasis.

ENDOMETRIAL CYTOLOGY IN DIAGNOSIS OF ENDOMETRIAL CARCINOMA

Pricop Mihai[1], Musca Simona[2], Stolnicu Simona[3], Maxim Razvan[1]
[1] University of Medicine and Pharmacy "Gr. T. Popa" Iasi, Romania
[2] Laboratory of Histopathology, Clinical Hospital of Obstetrics-Ginecology "Cuza Vodă" Iasi, Romania
[3] Department of Pathology, University of Medicine Targu Mures, Romania

Cytodiagnosis of the precancerous lesions of the endometrium has remained unclear compared to that for cervical lesions. Endometrial cytology and biopsy have been performed for patients with atypical genital bleeding, who were over fifty, postmenopausal or nulliparous. The cytologic diagnosis of endometrial cancer using material obtained with the Inocurette endometrial sampler was assessed for 64 patients.The cytologic findings for benign and malignant samples are described and illustrated in detail. Relative to other endometrial sampling devices, the Inocurette is inexpensive and was easily used by the gynecologist and well tolerated by the patients, with no complications and minimal discomfort.

PP4-18
EVALUATION OF COMBINED BCL-2/MDM-2 IMMUNOHISTOCHEMICAL EXPRESSION AS A PROGNOSTIC FACTOR IN EARLY STAGES OF INVASIVE CERVICAL CARCINOMAS

Irina Prodanova, Katerina Kubelka-Sabit, Neli Basheska
Department of Histopathology and Clinical Cytology, Institute of Radiotherapy and Oncology, Medical Faculty, Skopje, Republic of Macedonia

BACKGROUND: The present study was designed to evaluate the immunohistochemical expression of apoptosis regulating proteins (bcl-2, mdm-2 and p53) in correlation with proliferation (Ki-67), human papillomavirus (HPV) infection and other histopathological and clinical parameters in early stage cervical carcinomas and the estimation of their prognostic significance. Special attention was given to combined bcl-2/mdm-2 immunophenotypes in predicting the recurrence of the disease. METHOD: The subject of this study was a series of 83 surgically treated patients with cervical carcinoma confined to the uterine cervix (pT1b1/1b2), who subsequently received complete radiotherapy. The presence of HPV DNA was determined by the conventional method of in situ hybridization (ISH) and catalyzed reporter deposition signal amplification ISH. The immunostaining was performed using avidin-biotin-peroxidase complex method and the expression of the biological markers was semiquantitatively evaluated as the percentage of immunostained cells. RESULTS: During the clinical follow-up (mean 120.7, range 4.4-181 months) a relapse was diagnosed in 9 (10.8%) patients and the expected 5-, 10- and 15- year disease-free survival was 92.7%, 90.8% and 86.6%, respectively. The results of the univariate analysis indicate that significant predictive indicators for recurrence are: lymphonodal status, maximal tumor diameter, depth of stromal invasion, histological type and HPV DNA presence and type. Immunohistochemical markers showed the following correlations: increased expression of Ki-67 (P=0.031) and bcl-2 negativity (P=0.047) correlated with poor disease-free survival, while mdm-2 positivity showed borderline significance (P=0.051) and p53 expression had no influence on disease-free survival. Additional evaluation of combined bcl-2/mdm-2 expression showed that cases with bcl-2+/mdm-2- and bcl-2-/mdm-2+ immunophenotype had better survival (P=0.048) compared to bcl-2+/mdm-2+ and bcl-2-/mdm-2- phenotype. In the multivariate analysis, histological type, HPV DNA presence and the expression of Ki-67 have been selected as

the most significant independent prognostic parameters (P=0.0024). CONCLUSION: The evaluation of combined bcl-2/mdm-2 immunohistochemical expression provides more relevant information for the prediction of the recurrence of the disease than their individual expression. However, neither individual expression of bcl-2 and mdm-2 nor their combined immunohistochemical expressions are independent predictors of prognosis in early stages of invasive cervical carcinomas.

PP4-19
SCLEROSING STROMAL TUMOR OF THE OVARY WITH SEX CORD ELEMENTS

Stephanie Vgenopoulou[1], Athina Androulaki[1],
Maria Sotiropoulou[2], Antonios Lagadas[3]
[1] First Department of Pathology, University of Athens, Medical School, 'Laiko' Hospital, Greece
[2] Department of Pathology, 'Alexandra' Hospital, Athens, Greece
[3] Department of Gynecology, 'Laiko' Hospital, Athens, Greece

Screrosing stromal tumor of the ovary is a distinctive type of benign stromal tumor characterized by a cellular pseudolobular pattern. The tumor cell population is composed of fibroblasts and round cells separated by hypocellular, oedematous or collagenous tissue. In the recent literature there have been very rare reports of the coexistence of sex cord elements in, otherwise typical, sclerosing stromal tumors of the ovary. We present a case of a seventeen-year-old girl with a sclerosing stromal tumor in which sex cord elements were observed. Multiple histological sections were studied and immunohistochemistry was performed with a wide spectrum of antibodies. Morphological and immunohistochemical findings led to the diagnosis of sclerosing stromal tumor with sex cord elements. The tumor cells stained positive for desmin, vimentin and SMA. Sclerosing stromal tumors comprise a very distinct type of ovarian stromal tumors with very characteristic histology, which is presented in detail.

PP4-20
THE IMPORTANCE OF THE TUMOR SUPPRESSOR GENE DESIGNATED PTEN AND OF THE PROLIFERATION MARKERS Ki-67 AND PCNA IN THE EVALUATION OF THE MALIGNANCY POTENTIAL IN ENDOMETRIAL HYPERPLASIA

Sajin Maria, Chefani Alina Elena, Lazaroiu Anca Mihaela,
Simion George, Secara Diana, Carstoiu Monica
Universitary Emergency Hospital Bucharest, Romania

Introduction: Endometrial Hyperplasia (increase in gland/stroma ratio, disorder number and shape of the glands like modifications of the glandular epithelium: exhibits loss of nuclear polarity, stratification, etc) is a lesion frequently associated with the uterine leiomyomas Purpose: The Study was realized at the Universitary Emergency Hospital Bucharest, Romania on 210 endometrium biopsies taken in the period 2004-2005 from women with ages between 45 and 55. Material and methods: Hematoxylin –eosin stained slides of endometrial formalin fixed, paraffin embedded tissue has emphasized in 105 cases the simple hyperplasia (SH), in 75 cases the complex hyperplasia (CH), in 11 cases the simple atypical hyperplasia (SAH) and in 23 cases the complex atypical hyperplasia (CAH). We performed the indirect tristadial ABC method of IHC for 3 antibodies: PTEN, Ki-67 and PCNA on formalin fixed embedded tissue taken by biopsies from 50 cases (8 SH, 8 CH, 34 SAH and CAH). Results: PTEN was focal positive for SAH, diffuse for CAH and for 1-2 cases of SH and CH. Ki-67 and PCNA were also very frequent in group SAH and CAH. Conclusion: PTEN, Ki-67 and PCNA take part in the process of endometrial carcinogenesis following probably molecular pathways and determine the malignity potential of atypical hyperplasia of endometrium.

PP4-21
EGFR AND HER2/NEU EXPRESSION IN ENDOMETRIAL CARCINOMA. CORRELATION WITH TYPE AND STAGE

Maria Sotiropoulou, Irini Papaspyrou, Christos Eftychiades,
Christos Evaggelakos, Pantelis Markoulis,
Demetra Theocharidou, Vassilios Pavlou, Sofia Markaki
Histopathology Department, Greece

BACKGROUND: Epidermal Growth Factor Receptor (EGFR - Her1) and Human epidermal growth factor type II (Her2/neu) are members of the subfamily of tyrosine kinase transmembrane receptors. The expression of EGFR and Her2/neu has been documented in a variety of malignant neoplasms of epithelial origin as breast, ovary and lung. The expression of these markers correlates with advanced stage, poor prognosis and metastasis. The status of these oncoproteins in endometrial carcinoma, however, is not entirely clear. Aim of this study was the evaluation of EGFR and Her2/neu in endometrial carcinoma (endometrioid and serous –type I and II), the relation to other prognostic factors and the possible therapeutic implications. MATERIAL and METHODS: Forty one cases of endometrial carcinoma were selected, 22 endometrioid (type I) and 19 serous (type II). Formalin fixed-paraffin embedded tissues were immunohistostained with EGFR (clone 31G7, Zymed, CA, USA) and Her2/neu (clone CB11, Bio Genex, CA,USA). Over-expression of Her2/neu was defined as moderate or strong membranous staining (≥2+ staining) in more than 10% of the cells. EGFR's expression was interpreted as positive (any membranous staining) or negative. Tumors were subdivided into two stage groups, 1 and ≥2. RESULTS: Patients ranged in age from 27-84 years, mean age 59,81 in endometrioid and 68,26 in serous carcinomas. Her2/neu was over-expressed in 9,9% of type I and 41,1% of type II (P< 0,001) and in stage ≥2 in comparison to stage 1 (54,5% vs 25%). EGFR's expression was demonstrated in 40,9% and 31,6% of type I and II carcinomas, respectively. Stage 1 type I carcinomas expressed EGFR in statistically significant percentage, compared to stage ≥2 (77,8% vs 15,4% , P<0,05). CONCLUSIONS: Her2/neu usually is over-expressed in serous type of endometrial carcinoma. Moreover, the expression increases with stage. EGFR especially is expressed in endometrioid type carcinoma and mainly in low stage. Newly developed drugs that target these receptors may have a role in the treatment of endometrial cancer. These results, obtained by immunohistochemistry, have to be confirmed using molecular methods (CISH or FISH).

PP4-22
EXPRESSION OF MASPIN IN TYPE I AND II ENDOMETRIAL CARCINOMA, ITS CORRELATION WITH VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) AND CLINICAL PARAMETERS

Maria Sotiropoulou, Irini Papaspyrou, Christos Evaggelakos,
Demetra Theocharidou, Pantelis Markoulis, Vassilios Pavlou,
Sofia Markaki
Histopathology Department , Greece

BACKGROUND: Maspin (mammary–specific serpin) is a tumor suppressor gene that inhibits the invasion and angiogenesis. Maspin is expressed in normal human mammary and prostate epithelial cells but is down –regulated during cancer progression. Interestingly, the protein's prognostic significance in various cancers is highly impact by its cellular localization (nuclear vs cytoplasmic).Vascular endothelial growth factor (VEGF) plays important role in angiogenesis. The aim of this study is to determine the maspin's pattern expression in endometrioid (EC) and serous uterine carcinomas (SC), its correlation with VEGF and the clinicopathologic variables. MATERIAL AND METHODS: We examined maspin and VEGF expression in 22 endometrioid and 19 serous uterine carcinomas. Paraffin blocks

from each case were immunostained, using antibodies against maspin (clone EAW24, NeoMarkers, USA) and VEGF (clone CI 153-694, DD Pharmigen ,USA) by established methodology. The immunoreactivity of maspin and VEGF was semi-quantitatively scored, based on the intensity and percentage of positive cells (0- +3). Moreover, was estimated the maspin's cellular distribution as cytoplasmic and/or nuclear.. RESULTS: The mean age was 59,8 years for patients with endometrioid carcinoma and 68,3 years for patients with serous carcinoma. Patients' distribution by FIGO grading of EC was as follows: 15 G2 and 7 G3. FIGO surgical stage was as follows: 17 stage I, 6 stage II and 18 stage III. Maspin's expression was detected in 5/22 (22,7 %)of ECs-5/7 (71,4 %) of G3 tumors- and 11/19 (58 %, P<0,001)of SCs. In squamous metaplasia of ECs, the stain was absolutely nuclear. There was not correlation between maspin's expression and vascular invasion on one side and stage on the other. All tumors expressed VEGF (ECs showed lower intensity and had heterogeneity- 36,36 % 1+, 50% 2+, 13,64 % 3+ - despite of SCs which all had strong intensity- 3+). CONCLUSIONS: Maspin and VEGF expression was found in uterine carcinomas related to type (I or II) and grade. Maspin cytoplasmic expression in contrast to other carcinomas is directly associated with the biological aggressiveness (serous phenotype, and grade) and may result in deregulation of tumor inhibitor properties.

PP4-23

PRIMARY VULVAR EWING'S SARCOMA/PERIPHERAL NEUROECTODERMAL TUMOR: DIAGNOSTIC CONFIRMATION WITH CD 99 IMMUNSTAINING AND REVERSE TRANSCRIPTASE –POLYMERASE CHAIN REACTION

Handan Cetiner[1], Gozde Kir[2]
[1] Zeynep Kamil Hospital, Pathology Department, Turkey
[2] Umraniye Hospital, Pathology Department, Turkey

BACKGROUND: Ewing's sarcoma (ES) is a rather common, highly malignant primary malignant tumor of bone and soft tissues, and a single pathologic entity with primitive neuroectodermal tumor (PNET). They most commonly involve the deep soft tissues. Situation of this tumor in superficial locations is rare, female genital tract is also an unusual location. We describe a case of ES/PNET occuring as a primary neoplasm in the vulva. To our knowledge, this is the seventh such case reported in the literature METHODS Tumor tissue sections were stained with hematoxylin and eosin, periodic acid schiff (PAS) and PAS-diastase. Immunohistochemical staining for the MIC2 gene product CD99, pankeratin, chromogranin A, synaptophysin, desmin, leucocyte common antigen (LCA), HMB-45 were performed. The t(11;22)(q24;q12) translocation in tumoral tissue was revealed by reverse transcriptase polymerase chain reaction (RT-PCR). CASE REPORT. A 23-year-old woman with 4x4cm left labia majora mass and bilateral pelvic lymphadenopathies is presented. An incisional biopsy revealed a small round cell tumor. The patient underwent left radical hemivulvectomy, inguinal, femoral and paraaortic lymphadenectomy. Tumor was solid, hemorrhagic mass, 6 cm in maximal dimension with 6x4 cm skin ellipse on it. Cut surface was grayish-yellow and friable with infiltrative margins. Diffusely growing cell masses, lobules were seperated by fibrovascular connective tissue.The tumor cells were characterized by dark or vesicular, round nuclei with one to two indistinct nucleoli and scant pale cytoplasm. Immunohistochemical stains revealed that the tumor cells were diffusely immunreactive for vimentin and CD99 (the product of MIC2 gene). Cytokeratin, desmin, HMB-45, LCA, chromogranin, synaptophysin were all negative DISCUSSION: Most frequently extraskeletal ES/PNETs are localized in soft tissues of lower extremities, paravertebral region, chest wall and retroperitoneal region. Gynaecological system is an unusual cite for ES/PNET as is rare involvement of vulva. ES/PNETs have to be kept in mind in spite of its rarity when small round cell tumor is seen at superficial locations as vulva especially in children and young adults.

PP4-24

IMMUNOHISTOCHEMICAL STUDY OF PAX-2 IN ENDOMETRIAL HYPERPLASIA AND CARCINOMA

Maria Sotiropoulou, Irini Papaspyrou, Pantelis Markoulis, Demetra Theocharidou, Christos Evaggelakos, Vassilios Pavlou, Sofia Markaki
Histopathology Department, Greece

BACKGROUND: Pax-2 is a paired box gene which has been reported to be activated by estrogen in endometrial carcinoma but not in normal endometrium. However, there are limited studies about Pax-2 expression in endometrial hyperplasia and carcinoma. This study examines the Pax-2 expression in endometrium, aiming to discover any help in the differential diagnosis between atypical hyperplasia and well differentiated endometrioid adenocarcinoma, knowing the major problem in inter observer variability. Moreover, the distinct pattern of Pax-2 expression would be help in the comprehension of endometrial carcinogenesis, related to unopposed estrogen stimulation. METHODS: Immunohistochemical analysis of Pax-2 expression was performed on 57 endometrial specimens: 18 non atypical hyperplasia, simple or complex (SH/CH), 13 atypical hyperplasia (CAH) and 26 endometrioid carcinomas (EC). We used a rabbit polyclonal antibody, Pax-2 (1:50 dilution, Zymed, CA, USA) in established methodology. We estimated only nuclear staining, using a semi-quantitative method as follows: 0=< 5%, 1+=5-25%, 2+=26-50%, 3+=51-100%.Normal endometrial glands, as were uniformly strong positive, were served as positive control. RESULTS: Pax-2 was uniformly expressed in normal endometrium (atrophic or functional). Non-atypical hyperplasia's epithelial nuclei were positive in 16 cases (88,9%, 2+or 3+) while only in 4 cases of CAH (30,76%).Mainly, mild to moderate Pax-2 expression demonstrated in 8 endometrioid carcinomas (30,8%, 4:1+ , 3:2+, 1:3+). CONCLUSIONS: Normal endometriun expresses Pax-2 uniformly and strongly .There is a loss of expression from non- atypical to atypical endometrial hyperplasia and endometrioid carcinoma. The same expression between atypical hyperplasia and endometrioid carcinoma doesn't permit the use of antibody as a tool in the differential diagnosis .There is a need of further studies in order to be comprehended the relation between Pax-2 expression and ER, the methylation status of the gene and the possibility to convert this polyclonal antibody to a monoclonal one.

PP4-25

PRIMARY INVASIVE SQUAMOUS CELL CARCINOMA OF THE VAGINA: HPV DNA DETECTION, AND P16INK4A, p53, AND PRB IMMUNOEXPRESSION IN 22 CASES

Marco Ferreira, Mateus Crespo, Luis Martins, Ana Félix
Servico de Anatomia Patológica, Instituto Português de Oncologia de Lisboa Francisco Gentil, EPE, Lisboa, Portugal

Background: Primary invasive squamous cell carcinoma (SCC) of the vagina is rare, and the role of human papilloma virus (HPV) in its pathogenesis remains unclear. Alterations of the cell cycle regulatory proteins p16INK4a, p53 and pRb are poorly known in primary invasive SCC of the vagina. The aim of our study was to investigate HPV DNA, and p16INK4a, p53 and pRb immunoexpression in 22 cases of primary invasive SCC of the vagina. Material and Methods: Tumors (n=22) were classified according to the WHO classification. HPV genotyping (INNO-LiPA HPV Genotyping v.2) was performed in 21 cases. Immunohistochemical staining for p16INK4a, p53 and pRb was assessed in the whole series. Statistical analysis was performed with Fisher's Exact Test and with Student's t-test. Results: The

patients' age ranged from 36 to 88 (mean 65.17) years. Six cases were keratinizing SCC, and the remaining 16 cases were non-keratinizing SCC (8 "common" non-keratinizing, 3 basaloid, and 5 warty types). The median age of patients with keratinizing SCC was 73.83 yrs. and that of non-keratinizing SCC patients was 62.93 yrs. (p=0.057). HPV DNA was detected in 17 cases (80.9%): 13 (86.7%) non-keratinizing SCC (in one case HPV genotyping was not performed) and 4 (66.7%) keratinizing SCC (p=0.31). The HPV genotypes identified were: 6, 11, 16, 18, 31, 33, 35, 40, and 58. HPV 16 DNA was the most prevalent, being identified in 7 specimens (33.3%); 16 cases (76.2%) had high-risk HPV DNA. In 4 cases (19.0%) multiple HPV genotypes were isolated. p16INK4a was express in 15 cases (68.2%), p53 in 18 cases (81.8%), and pRb in 12 cases (54.5%). Most HPV DNA positive cases were p16INK4a positive (HPV positive: 70.6% vs. HPV negative: 50%), without statistical significance. Likewise, there was no statistical association between HPV DNA detection, and p53 or pRb expression or patients' age. Conclusions: 1) Similarly to uterine cervix SCC, primary SCC of the vagina is frequently associated with HPV DNA, most cases having high risk HPV DNA, with HPV 16 predominance. 2) There was no statistical difference between HPV DNA detection in keratinizing and non-keratinizing SCC, in contrast to vulvar SCC. 3) p16INK4a expression was not associated with HPV DNA detection. 4) p53 is frequently overexpressed in primary SCC of the vagina.

PP4-26
DIFFUSE OVARIAN STROMAL TYPE METAPLASIA IN TUBAL SUBEPITHELIAL TISSUE

Handan Cetiner
Zeynep Kamil Hospital, Pathology Department, Turkey

BACKGROUND: Even there were few numbers of reports about 'ovarian thecal metaplasia in adrenal glands' in the pathology literature, no case reports describing diffuse ovarian stromal metaplasia of tuba uterina exist. CASE REPORT: A 48-years-old woman, gravida 2, para 2, presented with a 3 weeks history of vaginal bleeding. Pelvic ultrasound (USG) examination revealed a simple adnexal cyst. Also USG revealed 6 cm diameter leiomyomatous mass in uterus. The patient underwent total abdominal hysterectomy bilateral salpingooophorectomy. Grossly: the right fallopian tube was cystic measuring 6cm in diameter and was containing serous fluid.The outer surface of the cystic tube was smooth while inner surface was thick and folded diffusely and had a tan-white color. Other tube and bilateral ovaries had not any specific feature. Microscopically; the stroma of the cystically dilated tuba showed diffusely transformation to dense ovarian stroma under the typical tubal epithelium..There were luteinized stromal cells singly or in the form of small clusters.. These cells were immunreactive for alpha-inhibin. DISCUSSION Other than endometriosis the tubal epithelium may undergo metaplastic changes. Despite of these few cases of epithelial type metaplasia, we couldn't find any ovarian stromal type metaplasia mentioning report in the literature other than focal fimbrial stromal transformation to ovarian stromal type especially in postmenopausal women.In current case; the change is diffuse and related with hydrosalpinx. To our knowledge, we report the first case of diffuse ovarian stromal type of metaplasia in fallopian tube and suggest that it can be the origin of any type of sex-cord stromal tumors of ovarian type.

PP4-27
MICROVESSEL DENSITY AND IMMUNOHISTOCHEMICAL EXPRESSION OF THE ANGIOGENIC PROTEINS VEGF, VEGFR1 AND VEGFR2 IN NORMAL, HYPERPLASTIC AND NEOPLASTIC ENDOMETRIUM

Nektaria Zagorianakou[1], Ann Goussia[1],
Panayiota Zagorianakou[1], Emilios Pakos[2], Perikles Tsekeris[2],
Ioannis Nesseris[1], Vasiliki Malamou-Mitsi[1], Niki J. Agnantis[1],
Maria Bai[1]
[1] Department of Pathology, Medical School, University of Ioannina, Greece
[2] Department of Radiation Therapy, Medical School, University of Ioannina, Greece

Background: Vascular endothelial growth factor (VEGF) may play an important role in the multistep process of endometrial carcinogenesis by its effect on angiogenesis and tumor cell proliferation. Therefore, the immunohistochemical expression of VEGF, its specific receptors VEGFR1 and VEGFR2, and the microvessel density (MVD) were analysed in normal, hyperplastic and neoplastic endometrium in relation to MIB1/Ki67 and p53 protein expression as well as to clinicopathological parameters. Materials and Methods: The expression of VEGF, VEGFR1 and VEGFR2 proteins was studied by immunohistochemistry in 31 cases of normal endometrium (15 proliferative and 16 secretory), 36 cases of endometrial hyperplasia (19 simple and 16 complex) and 80 cases of endometrial carcinomas (56 endometrioid and 24 non-endometrioid). MVD was also estimated in all specimens after immunostaining for CD34 antigen and evaluated as the mean (+SD) vessel count/high power microscopic field (HPF). Spearman's correlation coefficient test was used for the statistical analysis. Results. The expression of VEGF protein was estimated in epithelial cells. In normal endometrium, a significant higher VEGF protein expression was observed in proliferative than in secretory endometrium ($p<0.0001$). Moreover, VEGF protein expression was significantly higher in hyperplastic than in normal endometrium and in carcinomatous than in hyperplastic endometrium ($p=0.002$ and $p<0.0001$, respectively). In endometrial carcinomas, significant positive correlations were found between VEGF/VEGFR1 ($p<0.0001$), VEGF/VEGFR2 ($p=0.049$), VEGF/MVD ($p<0.001$), VEGF/histological grade ($p=0.007$), VEGF/MIB1 ($p=0.005$) and VEGF/p53 ($p=0.01$). Conclusions: The results of this study suggest that VEGF may play an important role in endometrial carcinogenesis by acting a) as a paracrine growth factor promoting angiogenesis and b) as an autocrine growth factor promoting tumor cell proliferation. Moreover, VEGF protein expression may be regulated by p53 in endometrial cancer.

PP4-28
HEPATOID CARCINOMA OF THE OVARY

Hulya Ozturk Nazlioglu[1], Sema Ozuysal[1], Hakan Ozan[2]
[1] Uludag University Medical School, Department of Pathology, Bursa, Turkey
[2] Uludag University Medical School, Department of Gynecology and Obstetrics, Bursa, Turkey

Hepatoid carcinoma (HC) is a rare malignant tumour defined as a primary extra-hepatic tumour morphologically mimicking hepatocellular carcinoma (HCC). It has been described in several organs including the ovary.Differentiating this tumor is not only a challenge but also critical, since treatment modalities and operative strategies are dependent upon the exact nature of the hepatoid cancer. We present a rare case of HC of the ovary .A 51-year-old woman was hospitalized with abdominal pain and distention. Physical examination revealed pelvic mass, and abdominopelvic computed tomography showed bilateral ovarian and multiple colonic masses. There was no tumoral mass in the

hepatic parenchyma, other than capsular penetrations of the colonic tumor. Serum CA 125 level was high (638 U/ml), but serum Alpha Fetoprotein (AFP) was not elevated (1.5 ng/ml). The patient was treated with hysterectomy and bilateral salphingooopherectomy, followed by chemotherapy. Colonic tumours were accepted as inoperable. Histopathologic examination revealed a tumour consisting of large neoplastic cells having vesicular nuclei and abundant eosinophilic cytoplasm resembling hepatocellular carcinoma. Neoplastic cells expressed both CA 125 and AFP .The patient had a poor survival and she died after 20 months following the diagnosis.Based on a review of the literature, we discuss the guidelines for differentiating these tumours and utilize these criteria to differentiate these tumours irrespective of their primary tissue of origin. In conclusion, HC of the ovary should be included in the differential diagnosis of ovarian tumors composed of large eosinophilic cells.

PP4-29
MASPIN EXPRESSION IN ENDOMETRIAL HYPERPLASIA AND CARCINOMA, AND ITS RELATION WITH ANGIOGENESIS

Ozlem Erdem[1], Cagatay Taskiran[2], Cigdem Vural[1], Omur Ataoglu[1]
[1] Gazi University Department of Pathology, Turkey
[2] Gazi University Department of Obstetrics and Gynecology, Turkey

Background: The purpose of this study was to evaluate the prognostic significance of maspin expression in endometrial hiperplasia and cancer, and also to investigate its relation with angiogenesis. Methods: A total of 19 women with complex atypical hyperplasia, 44 patients with simple hyperplasia without atypia, and 67 patients with endometrial carcinoma were included. Maspin expression was assessed by immunohistochemistry and tested for possible significant relation with age, FIGO stage, histologic type, grade, depth of myometrial invasion, lymphovascular space involvement, lymph node metastasis, and overall survival . Angiogenesis was determined by vascular endothelial growth factor staining. Results: Maspin expression was detected in only three patients with endometrial hyperplasia. In patients with endometrial cancer, cytoplasmic and nuclear maspin expressions were detected in 36 (53.7%) and 18 (26.9%) patients, respectively. No significant relation was noted between prognostic variables and staining localizations. The 5-year OS rate for patients with cytoplasmic staining was 91%, compared to 87% for patients without staining (p=0.31). The values for nuclear expression were 100% and 87%, respectively (p=0.16). The cytoplasmic and nuclear maspin expressions were found to be significantly correlated with VEGF (r=0.278, p=0.02; and r=0.295, p=0.02, respectively). Conclusion: This is the first study investigating the relation between maspin expression and angiogenesis in endometrial cancer. Although no significant correlation was noted between the expression of maspin and clinicopathologic prognosticators and no survival difference was noted for cytoplasmic and nuclear expression of maspin, a tendency was detected for nuclear staining similar to the literature. Further series will clarify the exact prognostic role of maspin in gynecologic malignancies including endometrial cancer.

PP4-30
RETROSPECTIVE ANALYSIS OF GYNECOLOGICAL SARCOMAS:

Alp Usubutun[1], Cigdem Himmetoglu[1], Guldeniz Aksan[2], Sertac Esin[2], Ali Ayhan[2], Turkan Kucukali[1]
[1] Hacettepe University Faculty of Medicine Department of Pathology, Turkey
[2] Hacettepe University Faculty of Medicine Department of Gynecology and Obstetrics, Turkey

Background: Gynecological sarcomas, comprised mostly of uterine origin, are rare and generally care a poor prognosis. Histological prognostic features are confusing due to absence of large patient data. The aim of this study was retrospective re-analysis of all the gynecological sarcomas in our institution to evaluate the morphological prognostic factors. Method: Out of 182 cases treated in our institution with gynecological sarcoma diagnosis between 1968-2007, 149 cases were available for pathological examination. Clinical data were obtained from patients' medical records. All cases were examined by the same pathologist. The histologic type, presence and percentage of necrosis, mitotic count per 10 HPF, the grade of atypia, cellularity, lymphovascular space involvement (LVI) and lymph node metastasis (LNM) were evaluated. Survival analysis (Kaplan-Meier) and long rank test were used for statistical analysis. A new scoring system was developed by combining mitotic count (1-5=1, 6-10=2, >10=3), percentage of necrosis (<25%=1, 25-50%=2, >50%=3) and nuclear atypia (mild=1, moderate=2, severe=3). Results: Of the 149 gynecological sarcoma cases, 49.7%(74) were leiomyosarcoma (LMS), 32.2%(48) were carcinosarcoma and 10.1%(15)were endometrial stromal sarcoma (ESS). The uterus was the site of origin in 86.6%(129) of cases. The age at diagnosis varied between 16 - 84 years (mean: 53). Patients were followed-up for a period of 1 to 197 months (mean: 26.5). Considering all the sarcoma cases clinical stage, histologic type, grade of atypia, percentage of necrosis, LNM and mitotic rate were found to be statistically significant for survival (p<0.005). Necrosis and LNM were found to be the prognostic parameters among LMS cases; whereas in carcinosarcomas necrosis, LVI and LNM emerged as statistically significant factors. In addition, the analysis of LMS cases using the newly developed scoring system was found to be a valuable prognostic factor (p=0.0004). Conclusion: Whatever the histologic type and site of origin, this study shows that mitotic rate, percentage of necrosis and grade of atypia are the histological prognostic factors-with varying influence-in gynecological sarcomas. Besides, LVI and necrosis for carcinosarcoma, and necrosis for LMS come out to be the the prominent and statistically significant factors. There appears that no single histological factor is enough to determine the prognosis in gynecological sarcomas. However, this scoring system, combining some of the morphological features, was found to be a valuable prognostic factor for LMS.

PP4-31
HISTOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL CORRELATIONS BETWEEN ADENOMYOMATOUS POLYPS, HYPERPLASTIC POLYPS AND ENDOMETRIAL MALIGNANCIES

Cornelia Amalinei, Raluca Balan, Irina Draga Caruntu, Corina Cianga, Petru Cianga, Stefan Butureanu, Alexandra Pangal
University of Medicine and Pharmacy, Romania

Background: Endometrial polyps are considered markers of increased cancer risk, revealing endometrium tendency to develop proliferative lesions. Beside well recognized precursors of endometrioid endometrial carcinoma represented by diffuse endometrial hyperplasia and, in a lesser degree, by hyperplastic endometrial polyps, when associated with cytological atypia, a large interest in recent years has centered on endometrial polyps with myomatous stroma, including those with atypical features. Polypoid adenomyomas cover a large spectrum of proliferative benign and premalignant changes, being designated as low malignant potential lesions. The aim of our study was to investigate the correlations between histopathological and immunohistochemical features of these neoplasias. Method: As a material, we used 46 polypoid adenomyomas and hyperplastic polyps, selected from our files after excluding frank cancers, conventional polyps, functional polyps, atrofic polyps, mixed

endometrial-endocervical polyps, and decidual pseudopolyps. Results: Histopathological examination identified cytological atypia and associated areas of malignancy. Immunohistochemical staining for ER, PR, MMP-2, MMP-9, Ki-67, and cyclin D1 revealed a significant correlation with hormonal status, expression of stromal components and proliferative activity in cases that associated great cytologic atypia and malignant transformation respectively. Differential diagnosis was difficult due to the typical fragmentation of curretage specimens and included florid hyperplasia, adenomyoma, adenocarcinoma with polypid growth, and mesenchymal tumors. Conclusion: Correct identification of stromal and cellular alterations often provides a crucial clue to the therapeutic orientation and assures prognostic improvement. Identification of histopathological and immunohistochemical markers of intense proliferation associated with invasion activity is important in positive and differential diagnosis with carcinomas, carcinosarcomas and adenosarcomas.

PP4-32
EXPRESSION OF EGFR AND C-KIT (CD117) IN UTERINE LEIOMYOSARCOMAS

Delia Perez Montiel[1], David Cantu De Leon[1], Jose Luis Aguila Ponce[1], Saul Suster[2], Jose Chanona Vilchis[1]
[1] Instituto Nacional de Cancerologia, Mexico
[2] Ohio State University Medical Center, Mexico

Objectives: Determine the expression of epidermal growth factor receptor (EGFR) and a growth factor receptor with tyrosine kinase activity, c-kit (CD117), in uterine leiomyosarcoma and correlate with clinical and pathologic characteristics. Materials and Methods: Twenty-seven cases of uterine leiomyosarcomas were immunohistochemically evaluated for the expression of EGFR and c-kit (CD117) and correlated with clinical and pathological features. Results: EGFR was positive in 13 cases (48.1%), 71% of patients were younger than 50 years (p=0.002). Statistical analysis showed that expression of EGFR was not an independent predictive factor for recurrence (p=0.22). EGFR expression was also not related to clinical stage or other clinical and pathological features (p=0.7). Mean survival in cases positive for EGFR was 17 months in comparison with EGFR negative cases, for which mean survival was 60 months (p=0.068). C-kit (CD117) was positive only in one case of uterine leiomyosarcoma (3%), therefore, no valid statistical conclusions could be established. Conclusions: Treatment of uterine leiomyosarcomas is generally poor; the use of targeted therapies may help to improve long term control and survival. Expression of two specific targets for cancer therapy, EGFR and C-kit, did not appear to demonstrate any specific correlation with survival or clinical and pathological features in uterine leiomyosarcomas.

PP4-33
HISTOGENESIS OF LIPOMATOUS COMPONENT IN UTERINE LIPOLEIOMYOMAS

Filiz Bolat[1], Fazilet Kayaselcuk[1], E. Tuba Canpolat[1], Serkan Erkanli[2], Ilhan Tuncer[3]
[1] Baskent University Faculty of Medicine, Department of Pathology, Turkey
[2] Baskent University Faculty of Medicine, Department of Gynecology and Obstetric, Turkey
[3] Baskent University Faculty of MedicineDepartment of Pathology, Turkey

Background: Uterine neoplasm composed of an admixture of smooth muscle and adipose tissue are relatively common and have been designated as lipoleiomyomas. The origin of this tumor is still controversial and it has not been sufficiently studied. Aim of our research was to investigate the immunohistochemical phenotype of the fat cells in uterine lipoleiomyomas for clarifying their origin. Methods: Archived tissue samples of 10 uterine lipoleiomyomas were selected and analyzed immunohistochemically for vimentin, desmin, and HMB45 expression. Results: The patients ranged from 31 to 63 years of age (mean age 53.5±9.9). Seven tumors affected the uterine corpus, and were located intramural; two cases were subserosal, and the one was in the cervix. All tumors were constituted by irregular bundles of smooth cells and mature large adipose cells. The amount of adipose component varied from 5 to 95 % of the tumor mass. Cytological atypia and necrosis were not seen. The immunohistochemical investigations revealed obvius reactivity to vimentin and desmin in perivascular and tumor smooth muscle cells. Adipose cells in the tumors demonstrated uniformly vimentin expression and inconsistent desmin immunreactivity. All adipose cells were negative for HMB45 antigen. However, HMB45 antigen was weakly positive in spindle shaped tumor cells of two cases. Conclusions: The immunohistochemical findings suggest a complex histogenesis for these tumors, which may arise from perivascular immature mesencyhmal cells or direct transformation of smooth muscle cells into adipocyte by means of progressive intracellular storage of lipids.

PP4-34
VULVAR CARCINOSARCOMA: A CASE PRESENTATION

Jasmina Atanackovic, Svetlana Milenkovic, Jasmina Tadic, Milena Cosic Micev, Marjan Micev
Clinical Centre of Serbia, Department of Histopathology, Belgrade, Serbia

Vulvar carcinosarcoma is extremely rare and the least frequent of all genital localizations with just a few reported cases. In the limited data in the literature, the additional problem of estimating the rarety of this tumour represents inconsistent terminology of these neoplasms. Carcinosarcoma in the genital tract, often reported as malignant Mullerian mixed tumour, in most cases was accepted as being metaplastic or sarcomatoid carcinoma. A proportion of these cases in the vulvar region were confirmed as keratin-positive sarcomatoid carcinoma or squamous cell carcinoma with spindle cell sarcoma-like transformation of the stroma. However, carcinosarcoma is defined as mixed epithelial and mesenchymal tumour with malignant both epithelial and mesenchymal component, either homologous or heterologous by cellular origin. Recently, the clonal origin of the first case of squamous carcinomatous and leiomyosarcomatous diffefrentiation in the same tumour has been genetically proved. We report a case of vulvar carcinosarcoma diagnosed in a 66 year-old woman who underwent radical vulvectomy with bilateral inguinal lymphadenectomy because of rapidly grown tumour in the right labial region. Histopathological analysis presented ill-defined mass measuring 70 mm in maximal diameter and revealed the admixture of well differentiated squamous cell carcinoma and distinctive spindle cell sarcomatous areas with fibrosarcoma-like aspect. Final report showed FIGO II stage without deposits in any of 14 lymph nodes. Immunohistochemical analysis were performed on 4 microns sections from formalin fixed and paraffin-embedded samples using LSAB+ immunostaining method with AEC visualization for: vimentin, smooth muscle actin - alpha, desmin, S-100 protein, CD34, HHF35, GFAP, CD117, NSE, EMA, AE1/AE3, High molecular weight cytokeratins, p53 protein, and proliferative activity measured by Ki-67 protein labelin index. Morphologically readily seen sarcomatous component immuno-histochemically showed the presence of strong cytoplasmic positivity only for vimentin, contrasting to strong positivity for all epithelial markers in the carcinoma; Ki-67 protein labelling index was 42% and immunopositivity for p53 (about 55%). In conclusion, we believe that morphological and immunohistochemical characterizations of two neoplastic populations represent true carcinosarcoma. Besides differential diagnostic significance, it remains unclear whether biclonality or sarcomatoid metaplastic carcinomatous or stromal transformation bear more unfavourable prognosis in these aggressive tumours.

PP4-35

P53, COX-2 EXPRESSIONS AND MICROVESSEL DENSITY IN OVARIAN CARCINOMAS

Aysel Caglar[1], Elife Sahan[2], Aysenur Akyildiz Igdem[2], Nusret Erdogan[2]
[1] Bagcilar Education and Training Hospital, Pathology Department, Istanbul, Turkey
[2] Taksim Education and Training Hospital, Pathology Department, Istanbul, Turkey

Ovarian carcinomas are the sixth of the most common carcinomas. Surface epithelial and stromal tumors are the most common neoplasms in ovarian carcinomas. In molecular studies, the mutation of p53, which is a tumor supressor gene, is positive in %50-60 of invasive serous carcinomas. Neoangiogenesis is an important factor in carcinogenesis. The growth of tumor is thought to be prevented by antagonists of angiogenesis and it can be an effective treatment method. Cyclooxygenase is an important catalyser enzyme in the synthesis of prostoglandins from arachidonic acids. It is suggested that by the epidemiological studies, inhibition of cox-2 with the help of nonsteroidal antiinflamatuar drugs can prevent ovarian carcinomas. We studied on 17 primary serous adenocarcinomas, 3 primary musinous cystadenocarcinomas, 6 borderline serous tumors, 4 borderline musinous tumors,10 serous cystadenomas,10 musinous cystadenocarcinomas retrospectively and researched clinical and histopathological features. For cox-2 expression, the difference between musinous tumors and serous tumors was meaningful.For p53 positivity, the difference between malignant, borderline and benign ovarian tumors and serous versus musinous tumors was meaningful. The difference between malignant, borderline and benign ovarian tumors for MVD>60 was meaningful. There was no correlation between cox-2, p53 and MVD and survival. For reducing the diameter of tumors by neoadjuvant and adjuvant therapies, the methods for reducing the vascularity can be useful. For the treatment of ovarian carcinomas, the experimental studies of p53 gene therapy should be developed. In current pathology practice; in ovarian tumors suspicious for malignancy by the histomophological findings; the positivity of p53, high microvessel density, old age, bilaterality are the helpful factors for differentiating malignant and borderline tumors. For evaluating the role of cox-2 in ovarian tumors there is need for larger series of cases which are chemotherapy resistant and /or chemotherapy responsive in oncology services.

PP4-36

ATYPICAL IMMATURE METAPLASIA OF CERVIX-THE SIGNIFICANCE OF KI-67 IN DIFFERENTIAL DIAGNOSIS WITH SQUAMOUS INTRAEPITHELIAL LESIONS

Ovgu Aydin, Ahu Senem Demiroz, Haydar Durak, Nuray Kepil, Sennur Ilvan, Zerrin Calay
Department of Pathology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Background: Atypical immature metaplasia (AIM) of cervix is an epithelial alteration with uncertain biological and clinical significance. The main issue is to differentiate AIM from squamous intraepithelial lesions, especially high grade squamous intraepithelial lesion (HGSIL) with which it has many morphological similarities. The histological criteria of AIM are a uniform basal cell population, minimal nuclear crowding, variable hyperchromatism, preserved cellular polarity, enlarged or multiple nuclei confined to suprabasal areas and absence of abnormal mitoses. Method and Result: In our study histological feaures and Ki-67 proliferation index were evaluated in the cervical biopsy specimens from 23 cases; including 5 AIM , 6 low grade squamous intraepithelial lesions (LGSIL), 12 HGSIL. The mitotic index and Ki-67 counting in the basal one-third, middle one-third and superficial one-third of epithelium were assessed seperately.For Ki-67 immunoreactivity percentage, at least 200 cells from informative areas were evaluated. The mean Ki-67 indices of AIM, LGSIL and HGSIL were 10,4; 7,9; 37,3 respectively. Overall Ki-67 index was higher than that of LGSIL and lower than HGSIL though the range of Ki-67 indices of AIM overlapped that of both LGSIL and HGSIL. When the Ki-67 indices were evaluated for each 1/3 layer seperately; the discriminative values were found to be for upper and mid third of epithelium rather than the basal third. When the histological features and the Ki-67 indices were evaluated together; 1 biopsy which was thought to be AIM turned out to be HGSIL. Conclusion: AIM is a poorly defined entity and the pathologist can have some hard time when dealing with this lesion especially in the differential diagnosis with HGSIL. Histological criteria are inadequate in such situations and Ki-67 index should be used in assesment of such atypical proliferations of cervix .

PP4-37

COMPARISON OF ESTROGEN, PROGESTERONE EXPRESSION AND ANGIOGENESIS WITH OTHER PROGNOSTIC PARAMETERS IN ENDOMETRIAL CARCINOMAS

Serap Koc, Nimet Karadayi, Dilek Yavuzer, Nagehan Ozdemir Barisik
Dr. Lutfi Kırdar Kartal Educational and Research Hospital, Department of Pathology, Turkey

BACKGROUND: Besides the established prognostic parameters in endometrial carcinomas, recent researches revealed that estrogen, progesterone status, angiogenesis, HER-2/neu expression and tumour DNA ploidy have significant prognostic value. This study investigates the relationship between estrogen, progesterone receptor expressions, microvessel proliferation (angiogenesis) and established prognostic parameters. METHOD: Sixty two endometrial carcinoma diagnosed at Dr. Lutfi Kırdar Kartal Educational and Research Hospital are included in this study. Estrogen, progesterone and CD34 receptors are assessed immunohistochemically at sections from the blocks which are the best representative of histological grade, which have the deepest myometrial invasion and in which stroma can be viewed easily. Results are compared with other prognostic parameters including patient age, tumour type, histological grade, myometrial invasion, vascular invasion, lymph node metastasis, endocervical involvement and stage. RESULTS: A statistically significant difference is found between estrogen receptor positivity and tumour type or histological grade ($p<0.01$). A statistically significant difference is found also between progesterone receptor positivity and tumour type or grade ($p<0.01$). Any significant relation is not established between either receptors and other parameters. A significant relation is not found between microvessel proliferation and other prognostic parameters. Although a consistency is seen between estrogen and progesterone expressions, they do not have a significant relation with angiogenesis. CONCLUSION: For the endometrial tumours whose clinical behaviour can not be precisely assessed pre-operatively, the contributions of prognostic parameters investigated post-operatively are important. However, all of the cases do not act in accordance with available prognostic parametres. Such cases act more agressively. The aim is to detect those cases during planning treatment and step up to a more agressive treatment plan. There are several parameters in literature and we chose to assess steroid receptor status and angiogenesis. Although we found significant relation between hormon receptor status and tumour type and histological grade, unlike some reports, we could not find any relation with angiogenesis

PP4-38

A MOLECULAR STUDY ON SELECTED BRCA-1 AND BRCA-2 GERMLINE MUTATIONS IN BREAST, OVARY AND FALLOPIAN TUBE CANCER CASES IN TURKEY

E. Handan Zeren[1], Elif Guveloglu[1], Melek Ergin[1], Demet Aras[1], Derya Gumurdulu[1], Fatma Bayram[1], M. Ali Vardar[2], Orhan Demircan[3].
[1] Cukurova University, Faculty of Medicine, Dept. of Pathology, Adana, Turkey
[2] Cukurova University, Faculty of Medicine, Dept. of Gynecology, Adana, Turkey
[3] Cukurova University, Faculty of Medicine, Dept. of Surgery, Adana, Turkey

Background: Germline mutations in BRCA1 and BRCA2 genes increase the susceptibility to ovarian, peritoneal, fallopian tube, and breast cancers. 185delAG and 5382insC in BRCA1 and 6174delT in BRCA2 are well known, common mutations among Ashkenazi Jewish people and as frequent as 2.6% of the population. In a background of the mosaic Turkish population and its close relationship with Middle Eastern countries, we aimed to detect these three mutations in a series of young cancer patients. Materials and Methods:A total of 112 histologically confirmed breast (invasive ductal carcinomas), ovary, and fallopian tube (serous carcinomas) cancer patients under the age of 45 regardsless their family history are included. All cases were genetically tested for the three BRCA1-2 founder germline mutations (185delAG and 5382insC in BRCA1 and 6174delT in BRCA2). The analysis was performed on genomic DNA extracted from paraffin embedded tumor tissues. We used a simple and rapid method for the simultaneous detection of these three mutations. Allele-specific oligonucleotide primers designed on the basis of BRCA1 and BRCA2 sequences were used. Mutation in one of the alleles was detected by the presence of two bands. For the 185delAG mutation, the mutant and wild-type amplicons were 354 and 335 bp, whereas those of 5382insC were 295 and 271 bp, and those of 6174delT were 171 and 151 bp. Results:All breast carcinoma cases were negative for the three mutations. Among others, a case of ovarian serous carcinoma from a 42-year old woman, showed mutation in BRCA1 5382insC. The patient had no history of familial ovarian and/or breast cancer. The tumor was unilateral and revealed high grade morphologıc features. Conclusion: Detection of a BRCA1 mutation in a series of younger ovarian cancer patients is an important finding and may point more mutations among the population.

PP4-39

ADULT GRANULOSA CELL TUMOR OF THE OVARY: STUDY OF 20 CASES

Maurício De Angelo Andrade, Joyce De Brito Pupo, Liliana De Angelo Andrade
Universidade Estadual de Campinas, Brazil

Background: Among various ovarian neoplasms, granulosa cell tumors of the adult type (GCT) correspond to less than 5%. They have low malignancy and are capable of recurring even after many years. They present many diverse histological aspects, whose differential diagnoses must be made with other primary or metastatic tumors in the ovary. Objective: to describe and to analyze clinical and pathological aspects of GCT and relate them to the evolution of the disease. Method: in a 10-year (1995-2004) review of the UNICAMP Clinical Hospital files, twenty CGT diagnoses were found, and these records were reviewed, correlating clinical aspects with morphological patterns, mitotic index, stage of the disease and frozen section diagnosis accuracy. Results: the ages varied from 27 to 79 years (mean: 53 years) and the follow-up from 12 to 96 months (mean: 42). The main symptoms were: postmenopause bleeding (45%), abdominal pain (35%) and palpable mass (25%). In gross analyses, most of the tumors were yellowish (60%) and the solid aspect was more common (40%) than the cystic or solid-cystic. Only three of the nine cases submitted to intra-operative frozen section biopsies were diagnosed as GCT (33%). The histological patterns were: 40% solid, 15% macrocystic and 45% of combined patterns, with low mitotic index. The clinical stage was: 13 cases in Ia (65%), 2 cases in Ic and 5 in IIIc. Only the stage of the disease was related to the recurrences. In 3 of 14 hysterectomies there was simple endometrial hyperplasia without atypia. Conclusion: The diagnosis of CGT generally occurs after the menopause, and intra-operative biopsies are seldom conclusive. Only the advanced stage was related to the worst prognosis.

PP4-40

DIFFUSE LARGE B-CELL NON-HODGKIN LYMPHOMA (DLNHL) - MIMICKING A PRIMARY GYNECOLOGICAL TUMOR

Ljiljana Tomic[1], Vlado Jeremic[2], Olga Rdaic-Tasic[3], Milena Djukic[4]
[1] Department of Pathology, The Clinic for Obstetrics and Gynecology “Narodni Front”, Belgrade, Serbia
[2] Department of Surgical Gynecology, The Clinic for Obstetrics and Gynecology “Narodni Front”, Belgrade, Serbia
[3] Department of Pathology, Medical Military Academy, Belgrade, Serbia
[4] Department of Pathology, Mother and Child Health Institut "dr Vukan Cupic", Belgrade, Serbia

BACKGROUND: Bilateral ovarian involvement mimicking a gynecologic malignancy in adults is extremely rare. Here, we report a patient with DLNHL, mimicking a gynecologic tumor. Aim: To determine the origin of the tumor, using immunophenotyping, with the introductory help of cytological imprints that had been taken simultaneously with the intraoperative frozen-section tissue samples. The very cytological imprints gave the clue way and reveal the possible true origin of the tumor-cells, differentiating lymphoblasts from others like “small round blue cell”- tumors. METHOD: A 57 year old Serbian rural woman, presented with the complaint of persistent lower abdominal distension with dull pain, and night sweats. Imaging studies revealed a huge ovarian mass, suggesting a large ovarian tumors. Surgery-laparatomia with total hysterectomia and bilateral adnexetomia and total omentectomia with intraoperative frozen-section analyses was performed. DLNHL diagnosed by a combination of: cytology, morphology and immunophenotype together with clinical features (“B-symptoms”-associated with lymphoma), managed with surgery and chemotherapy (MABTHERA). Subsequently patient staged, according Ann Arbor classification-IV B. RESULTS: The average diameter of the ovaries was 16 cm (range 12-20 cm), grossly- lobular surface, pink-grey color, soft consistency. Microscopic findings: ovaries, myometrium as well as peritoneal implants were completely replaced by the monotonous, uniform population of tumor cells-centroblasts. By the use of IHH: tumor cells have shown excessive immunopositivity towards CD20, CD79a, Ki67 (80%) and bcl2 (40%) while negative towards CD3, CD5, CD138, MPO, ALK and CK. CONCLUSION: Although rare secondary ovarian tumors i.e.lymphomas should be considered in the differential diagnosis of female adults with ovarian masses. Bilateral ovarian masses or large masses indistinguishable from the ovaries, particularly in the presence of other metastatic foci (secondary deposits in lungs), may help distinguish primary from secondary ovarian malignancies.

PP4-42

PREDICTORS OF RESIDUAL DISEASE ON HYSTERECTOMY AFTER LOOP ELECTROSURGICAL EXCISIONAL PROCEDURE WITH POSITIVE MARGINS

David Cantu De Leon[1], Delia Perez Montiel[1], Diana Copado Mendoza[2], Olivia Gomez Alvarado[2], Jose Chanona Vilchis[1]
[1] Instituto Nacional de Cancerologia, Mexico
[2] Instituto Tecnologico y de Estudios Superiores de Monterrey, School of Medicine, Mexico

Background: Loop electrosurgical excisional procedure (LEEP) is the treatment of choice in patients with cervical intraepithelial neoplasia (CIN). Positive surgical margins may be the most important prognostic factor for residual disease and patients have to undergo hysterectomy for definitive treatment with a rate as high as 50% of specimens negative. This study was performed in intent to identify predictors for residual disease in hysterectomy specimens of patients with positive margins in LEEP specimens. Material and methods: Pathological files were reviewed from 1998 to 2003. Cases with LEEP and positive margins that were undertaken to hysterectomy were identified. Histopathologic slides from the LEEP and hysterectomy were reviewed to confirm margin status, grade of lesion, and residual neoplasia. Variables such as age, parity, number of sexual partners, time from LEEP to hysterectomy, size of lesion, percent of affected fragments, and number of positive margins (endocervical, exocervical, or both) were analyzed. Univariate analysis was performed using Chi-square test, t test, and Wilkoxon Rank Sum. Multivariate logistic regression analysis was used to test relationships between preoperative factors and presence of residual disease on the final pathologic report. Results were considered statistically significant if $p < 0.05$. Results: 98 specimens were evaluated, median age was 42 years (range 25-78), age at first intercourse 17y (range 12-34), number of sexual partners 2 (range 1-10), parity 5 (range 1-16), and days prior to hysterectomy 48 days. Of LEEP specimens median size of lesion was 0.5 cms (range 0.1 to 2cm.). Median of percent of fragments affected was 40% (5-100%). Exocervical involvement was present in 6%, endocervical 64%, both 30% respectively. Median number of fragments with endocervical margins affected 3 (range 0-11), exocervical 0 (range 0-10). Of hysterectomy specimens 56 (58%) were negative residual disease, 2 (2.1%) CIN II, 2 (2.1%) CIN III, 31 (32.3%) In situ carcinoma, 2 (2.1%) microinvasive, 3 (3.2%) invasive carcinoma. On multivariate analysis variables that independently predicted residual disease were age (OR= 1.049, p= 0.05) and percent of affected fragments (OR= 9.74, p=0.038). Conclusion In our institution we have a high rate of negative hysterectomy specimens which is similar to other reports. Age and extent of disease (percent of affected fragments) are statistically significant predictors of residual disease rather than positiveness of margins as well as number of positive margins.

PP4-43

RARE TYPES OF CARCINOMAS LOCALIZED IN THE ENDOMETRIUM

Raluca Balan[1], Cornelia Amalinei[1], Irina Draga Caruntu[1], Vlad Gheorghita[2]
[1] Morphology Department, University of Medicine and Pharmacy, Iasi, Romania
[2] The 3rd Clinical Hospital of Obstetrics and Gynecology, Iasi, Romania

Background: There have been reported rare examples of unusual carcinomas arising in the endometrium, but the data consist largely of case reports precluding a detailed clinicopathologic analysis. Material and method: We present 3 cases of endometrial carcinomas, each of them with different clinicopathologic features. The specimens were surgically treated, routinely processed and stained with H&E, PAS, van Gieson, and a panel of immunohistochemical antibodies. Results: One case was histopathologically diagnosed as synchronous carcinoma of the endometrium and uterine cervix, one was a metastatic mucous adenocarcinoma in the endometrium, primary located in the ovary, and the last one was diagnosed as poorly differentiated endometrioid carcinoma of the endometrium, developed in a background of inflammation. Conclusions: Cervicitis, salpingitis, endometritis, and myometritis may represent an important background for the development of an endometrial carcinoma. Immunohistochemical studies may be helpful for distinguish a metastatic carcinoma from an independent tumor, but the differential diagnosis usually can be determined by conventional clinicopathologic criteria. The distinction is very important because the prognosis and treatment are different.

PP4-44

REAPPRAISAL OF OVARIAN METASTASIS FROM GALLBLADDER AND EXTRA-HEPATIC BILE DUCT CARCINOMA

Yoji Wani, Kaori Uchino, Kenji Notohara, Choutatsu Tsukayama
Kurashiki Central Hospital, Japan

Background: Metastatic ovarian tumor derived from gallbadder or extra-hepatic bile duct (GB/BD) is estimated about 7% in overall ovarian metastasis. Especially, tumor-forming metastasis (classical or tubular Krukenberg tumor; KT) is extremely rare and most of all are limited in case reports. The aim is to reappraise ovarian metastasis originating in GB/BD. Methods: From autopsy files, 40 female GB/BD carcinomas were reviewed. We evaluated presence of the ovarian metastasis, number of other metastatic organs, presence of peritoneal dissemination, histology. Furthermore, 11 KTs from eight (7; surgical) cases were clinicopathologicaly evaluated. Results: Patients were 56 to 97 years of age. In 12 (30%) cases, ovarian metastasis was identified (bilateral: 4, unilateral: 8). The mean number of involved organs other than ovary was 4.42 (0-7) in contrast to 2.96 (0-6) in cases without ovarian metastasis. 11 cases were involved by peritoneal dissemination. All but one ovary was macroscopically normal or atrophic. Only one (1/12: 8.3%) KT, which measured 5x4 cm, showed multilocular appearance. Histologically, the metastatic cases consisted of 8 tubular adenocarcinomas, 2 signet-ring cell carcinomas. The rest was one case of clear cell, papillary adenocarcinoma, respectively. KT patients were 49 to 71 years of age. Five primary sources were gallbladder and three were bile ducts. With surgical cases, two were at stage II, III, respectively other than three at stage IV. The duration between biliary surgery and oophorectomy were 5 to 68 months. The laterality was shown as unilateral; 3 as bilateral; 5. In 11 ovarian tumors, the specimens ranged from 3.1 to 17 cm in greatest diameter and four were just described such as newborn's or adult head's size. They showed predominantly solid (4), solid and cystic (2) and multilocular (5) appearance. Eight tumors composed of tubular adenocarcinoma (one with foci of signet-ring cells) and each one was papillary adenocarcinoma and signet ring cell carcinoma. All cases were associated with cancerous ascites or peritoneal dissemination. From 7 to 12 months (mean; 9.8) after oophorectomy, 5 patients were died of disease and two was alive with disease for 12, 13 months, respectively. Conclusion: Ovarian metastasis from GB/BD carcinomas is not unusual at the advanced stage, but rare with KT. Classical KT is rare while most cases are tubular ones. KTs may be early or primary manifestation of metastasis in some cases, but frequently associated with peritoneal dissemination, the prognosis is poor.

PP4-46

PERITONEAL INCLUSION CYSTS: A CLINICOPATHOLOGIC STUDY OF 20 CASES

Metin Akbulut[1], Osman Zekioglu[2], Mustafa Cosan Terek[3], Necmettin Ozdemir[2]
[1] Pamukkale University, Department of Pathology, Denizli, Turkey
[2] Ege University, Department of Pathology, Izmir, Turkey
[3] Ege University, Department of Obstetrics&Gynecology, Izmir, Turkey

Background: Peritoneal inclusion cysts are uncommon mesothelial proliferations that typically occur in the peritoneal cavity of women in the reproductive age. It was reported that they have tendency for recurrence, however; malign transformation has never been reported in the literature. This study was planned to determine the clinicopathologic features of peritoneal inclusion cysts. Methods: All patients with a diagnosis of peritoneal inclusion cyst were studied retrospectively from a retrospective

database at Ege and Pamukkale University Hospital between January 1995 and March 2007. Results: Twenty patients with a confirmed diagnosis of peritoneal inclusion cyst were identified. All the patients were women ranging in age from 20 to 56 years old (mean 37 years). The associated clinical conditions were endometrioid adenocarcinoma for 1 patient, endometriosis for 3 patients, mature cystic teratoma for 2 patients, pregnancy for 4 patients, leiomyoma of the uteri for 7 patients. The commonest location of the tumor mass was below the pelvic diaphragm. The size of the tumor was larger than 5 cm in 5 patients. The tumors presenting in the peritoneum were multilocular and large. The rest of the tumors were small. The septa consisted of loose fibrovascular tissue. No smooth muscle and no significant amount of inflammatory cells were present. Microscopically, the majority of cysts were lined with a single layer of flattened or cuboid mesothelial cells. These cells stained positively for calretinin and were negative for endothelial marker CD31. Conclusion: Peritoneal inclusion cyst is a rare and distinctive lesion of mesothelial origin. Most of the patients have a history of a previous pelvic operation, and endometriosis without recurrence, suggesting a role for inflammation in the pathogenesis of the cysts as a peritoneal reactive proliferation rather than the neoplastic process.

PP4-47

"FETAL-PLACENTAL UNIT": PROTOCOLIZED STUDY OF 2847 PLACENTAL SPECIMENS AND 432 FETUS IN THE LAST 7 YEARS.

Ana Puras[1], JM Ezpeleta[2], A López Cousillas[1], A Echegoyen[1], P Fernandez Seara[1], Y Ruiz de Azua[1]
[1] Departments of Pathology Hospital Virgen del Camino Pamplona, Spain
[2] Departments of Obstetrics Hospital Virgen del Camino Pamplona, Spain

Introduction: Both placenta and fetus have a common origin (Fetal- Placental Unit) for that reason it should be studied together in cases of fetal death. In other cases, obstetric and clinical information should be carefully recorded. In this condition, placental examination and their study will be useful for patients, obstetricians and pediatricians. The indications for placental examination should be recomended in diverse causes of fetal, placental, maternal u obstetric disorders possibles of maternal or fetal problems. This could be use to prevent and control pathologies in following pregnancies. Material and Methods: In our Pathology Department have been examined 2847 Placentas since year 2000. They were received fresh and the handling of the placentas was according to a stablished protocol that includes: reception, description, cultures, frozen sections of umbilical cord, postdelivery drainage, membranes roll, disc weight after removing cord, membranes and clots, formalin fixation, disc sectioning and standarized sampling for microscopic examination. Fetus were all autopsied, Rx taken, photographs if needed and any anomaly described. Results: Every pathology report was sent to the Obstetrician and Perinathology Departmens, and those with funiculitis in frozen section by urgent shipment. Every autopsy report included the placental report, and a summary about the correlation of findings. The fetal reports were also sent to the Obstetrician and Perinathology Departments, and rewied in the Clinical- Pathological Conference. Conclusions: 1- The application of this Protocol developed in consensus with the Obstetrics Department, has been very useful in the clinical-pathological correlation of the feto placental pathology, and in the handling of the obstetrical pathology in following pregnancies. 2- Frozen sections of umbilical cord have been useful in early detection of fetal inflammatory response and adverse neonatal outcome.

PP4-48

PREVALENCE AND CHARACTERISTICS OF ENDOMETRIAL POLYPS IN PATIENTS WITH ABNORMAL UTERINE BLEEDING

Biljana Djordjevic, Ljubinka Velickovic, Vesna Zivkovic, Miljan Krstic, Miljan Milic
Institute of Pathology, Medical Faculty, University of Nis, Serbia

Background/Aim. The prevalence of endometrial polyps in the general female population is about 24%. Abnormal uterine bleeding is frequently the presenting symptom of endometrial polyps. The aim of this study was to determine prevalence and characteristics of endometrial polyps in patients with abnormal uterine bleeding. Methods:. The prevalence and characteristics of endometrial polyps were investigated in 961 patients with abnormal uterine bleeding who underwent dilatation and curettage (D&C) between January and December 2006. Statistical analysis was performed. Results: Endometrial polyps were found in 211 (21.94%) patients with abnormal uterine bleeding. Histopatologically, 175 (82.93%) polyps were benign, 29 (13.74%) polyps had simple and complex hyperplasia, 5 (2.37%) polyps had atipical hyperplasia, and 2 (0.95%) polyps had endometrial carcinoma. According to the malignant potential, endometrial polyps were divided into a group of benign (benign polyps and polyps with simple and complex hyperplasia) and a group of premalignant and malignant (polyps with atypical hyperplasia or endometrial carcinoma). Group of premalignant and malignant polyps were associated significantly with older age, postmenopause and hypertension. Conclusions. The prevalence of endometrial polyps in patients with abnormal uterine bleeding according our data was 21.94%. Atypical hyperplasia and endometrial carcinoma were rarely confined to a polyp. Older age, postmenopause and hypertension may incrise the risk of premalignant and malignant changes in endometrial polyps.

PP4-49

THE PROGNOSTIC IMPORTANCE OF GLUT 1 AND KI-67 EXPRESSION IN OVARIAN EPITHELIAL TUMOURS

Muberra Segmen Yilmaz, Dilek Yavuzer, Nimet Karadayi, Aylin Ege Gul
Dr. Lutfi Kirdar Kartal Education and Research Hospital, Department of Pathology, Istanbul, Turkey

BACKGROUND: In epithelial malignancies, aberran expression of glucose transporter 1 (Glut 1), a glucose transport protein located at cell surface and its relation with neoplastic progression is well known. Beside this, protein derived Ki-67 antigen which is observed during proliferative cell cycle indicates proliferation of tumour cells. We studied Glut 1 and Ki-67 expression in benign, borderline, malignant serous and mucinous ovarian tumours, their significance as a prognostic factor in borderline and malignant tumours, their relation with serum Ca 125 levels and other prognostic parameters. METHOD: Ninety two cases (34 serous carcinoma, 4 mucinous carcinoma, 9 borderline serous tumour, 6 borderline mucinous tumour, 19 benign serous cyctadenocarcinoma, 15 benign mucinous cystadenocarcinoma, 5 ovarian endosalphingiosis) in which Glut1 Ab-1 and Ki-67 investigatement of immunohistochemical studies on sections obtained from paraffin blocks were diagnosed at Dr. Lutfi Kırdar Kartal Education and Research Hospital. Patients were analysed according to age, tumour grade, stage and serum Ca 125 levels. RESULTS: In benign, borderline, malignant serous and mucinous tumours and ovarian endosalphingiosis, regarding Glut 1, Ki-67 expression and serum Ca-125 levels were found to be significantly different ($p<0.01$). Glut 1 did not show any staining in benign cases and endosalphingiosis while 86.7% of borderline cases and 97.4% of malignant cases revealed positive staining. More than 1% positive nuclear staining was observed with Ki-67 in 35.3% of benign cases, 80% of borderline cases and 89.5% of malignant cases. Moreover, Glut 1 staining degree with serous

tumours was found significantly higher than mucinous tumours ($p<0.05$). Malignant and borderline cases were significantly correlated with each other due to their Ki-67 and Glut 1 staining degrees ($p<0.05$). Also, statistically significant correlation was found between Glut 1 staining degree with tumour stage and tumour grade ($p<0.05$). Ca 125 levels of serous tumours were found higher than musinous tumours ($p<0.05$). Invasive tumours had higher Glut 1, Ki-67 staining degrees and mean serum Ca 125 levels than borderline tumours ($p<0.05$). CONCLUSION: This study revealed that Glut 1 expression in serous and mucinous ovarian tumours is related with malignancy progression and other prognostic parameters. Although Ki-67 expression is related with malignancy progression, any other significant relation is not found with other prognostic parameters of malignant tumours.

PP4-50

A TEN YEAR REVIEW OF THE PATHOLOGY OF IMAGE-GUIDED PERITONEAL CORE BIOPSIES IN WOMEN PRESENTING WITH PERITONEAL CARCINOMATOSIS

Sally Osborn[1], Matthew Hewitt[2], Michael Weston[3], Tim Perren[4], Geoffrey Lane[5], John Spencer[3], Nafisa Wilkinson[6]
[1] Dept of Histopathology St James's University Hospital, Leeds, United Kingdom
[2] Dept of Obstetrics and Gynaecology UCC, BUPA Ireland Research Centre, Cork University Maternity Hospital, Cork, Ireland
[3] Dept of Clinical Radiology, St James's University Hospital, Leeds, United Kingdom
[4] Cancer Research UK Clinical Centre, St James's University Hospital, Leeds, United Kingdom
[5] Dept of Gynaecology, St James's University Hospital, Leeds, United Kingdom
[6] Dept of Histopathology, St James's University Hospital, Leeds, United Kingdom

BACKGROUND: The commonest cause of peritoneal carcinomatosis in women is ovarian or primary peritoneal carcinoma. Presentation in the vast majority of women is with disseminated abdominal disease. Surgery in advanced cases is unlikely to achieve optimal debulking in some patients and therefore, primary neoadjuvant chemotherapy with the aim of achieving substantial cytoreduction to be followed by interval debulking surgery is a management option. Other patients with advanced disease are too ill for major cytoreductive surgery and chemotherapy is the treatment of choice. Therefore, an accurate histological diagnosis to establish the primary site of origin is paramount for the management of these patients. Image-guided peritoneal biopsy is a simple and safe technique to provide sufficient tissue in the majority of cases to reach an accurate diagnosis. METHOD: A series of 201 women who presented to a teaching hospital with peritoneal carcinomatosis over a ten year period underwent image-guided (abdominal ultrasound or computer tomography) peritoneal core biopsy, following multidisciplinary team review. Multiple cores were obtained and examined with haematoxylin and eosin. Ancillary techniques were used where indicated by the clinical situation; this was particularly helpful in the distinction of endometrioid adenocarcinoma from metastatic colorectal carcinoma. The slides of any known previous malignancies were reviewed and compared with the current biopsy to exclude recurrence. RESULTS: A primary site of origin was identified in 188 women; of these 164 were mullerian in origin, the majority of which were serous papillary carcinoma (130). The remainder were endometrioid 7, mucinous 4, clear cell 3, squamous cell carcinoma 1, mixed endometrioid and serous 2, carcinosarcoma 7, poorly differentiated mullerian carcinoma 10. 24 originated from other sites (gastrointestinal tract 9, breast 6, lymphoma 3, pseudomyxoma 2, hepatobiliary 2, renal 2). In 7 women the biopsy showed poorly differentiated carcinoma with no primary site identified and in 5 women the biopsies showed benign changes. In 1 patient the initial biopsy led to a misdiagnosis and a laparoscopic biopsy was required to make the definitive diagnosis. In 10 women there was insufficient material on the initial biopsy to make a diagnosis, a final diagnosis was made on repeat biopsy. CONCLUSION: In conclusion, peritoneal core biopsy in a multidisciplinary setting, together with appropriate biochemical markers, is a quick, efficient and safe method of making a reliable, definitive diagnosis in the vast majority of women with peritoneal carcinomatosis.

PP4-52

EXPRESSION OF MATRIX METALLOPROTEINASE-2 AND ITS TISSUE INHIBITOR IN ASSOCIATION WITH CD44V6 IN THE NEOPLASTIC SEQUENCE OF SEROUS OVARIAN TUMOURS

Duygu Enneli Kankaya[1], Ebru Erol[1], Arzu Ensari[1], Yasemin Genc[2], Ayse Sertcelik[1]
[1] Ankara University, School of Medicine, Department of Pathology, Ankara, Turkey
[2] Ankara University, School of Medicine, Department of Biostatistics, Ankara, Turkey

Background: Variants of CD44, a cell surface adhesion molecule, have been suggested to be important in cancer invasion and metastasis and proposed as a potential prognostic marker in many epithelial and non-epithelial malignancies. Matrix metalloproteinases (MMPs) and their tissue inhibitors (TIMPs) are also known to play a role in invasion and metastasis of many tumours. There have been controversial results regarding the significance of MMPs, TIMPs and CD44v6 for the development and progression of ovarian tumors. Therefore, the aim of the present study was to investigate the expression of CD44v6, MMP-2, and TIMP-2 in ovarian serous neoplasms and to evaluate their clinical significance. Methods: A total of 56 cases, which include 9 serous cysts, 10 serous cystadenofibromas, 3 borderline serous tumours and 34 serous carcinomas was included in the study. Clinical parameters such as age of the patient, tumour size, grade, stage were retrieved from the patient files. Tissue microarray blocks were constructed by taking 3 cores 2 mm in diameter for each case and immunohistochemistry was performed for the evaluation of the expression of CD44v6, MMP-2, TIMP-2 in sections of 3 μm thick. Expression of CD44v6 was evaluated by scoring intensity and percentage of staining, while expression of TIMP-2 and MMP-2 were evaluated only by scoring staining intensity on an arbitrary grading scheme of (+)-(+++). Kruskal- Wallis and Pothoc test were used for statistical analysis. Results: Both MMP-2 and TIMP-2 were expressed by the fibroblastic cells in ovarian stroma as well as vascular endothelium as well as the epithelium while CD44v6 was only expressed in the epithelial tissue. No difference between stromal and epithelial expressions of MMP-2 and TIMP-2 in any of the study groups was observed.The expression of TIMP-2 and MMP-2 were significantly higher in borderline and malignant group than benign group ($p<0,05$), while no such difference was observed between borderline and malignant cases. TIMP-2 expression was higher in serous cystadenofibromas compared with serous cyst ($p<0,05$). There was no significant difference in the CD44v6 expression between the study groups. No correlation was found between the expressions of all three markers and the clinical features of the patients. Conclusion: MMP-2 and TIMP-2 expressions seem to correlate with the neoplastic sequence of serous ovarian neoplasms whereas no such correlation was observed in CD44v6 expression. These findings suggest that there is increased degradation of extracellular matrix by MMPs in parallel with neoplastic progression.

NEPHROBLASTOMA WITH BONE METASTASIS IN A 30-YEAR WOMAN, A CASE REPORT
Amel Trabelsi, Soumaya Rammeh, Sarra Mestiri,
Yacoubi Med. Tahar, Sihem Hmissa, Moncef Mokni,
Korbi Sadok
Pathology Department, F. Hached Hospital, 4000 Sousse, Tunisia

Background: Nephroblastoma is rare in adults and thought to have a worse prognosis than its counterpart seen in children. Bone metastasis of nephroblastoma are very rare in the 2 age groups. Method: We report a case of 30 year-old woman, that consulted for abdominal distension associated to pain in the left hip. Results: Imaging findings showed a right renal tumor measuring 18 cm with a condensing lesion of the superior extremity of the left iliac bone. The patient underwent a right nephrectomy and biopsy of the left iliac bone. Histologically, the renal tumor was a biphasic nephroblastoma without cellular anaplasia. The bone biopsy showed a round cell proliferation similar to the blastema cells seen in the renal tumor. The patient had 3 courses of chemotherapy without clinical improvement then has been out of sight. Conclusion: Nephroblastoma in adult with bone metastasis is very rare with a poor prognosis.

PP4-54
PAPILLARY CARCINOMA OF THE KIDNEY: A RETROSPECTIVE STUDY OF 6 CASES
Mestiri Sarra, Trabelsi Amel, Ghaieb Amel,
Ben Yacoub-Abid Lilia, Aachech Thouraya, Rammeh Soumaya,
Mokni Moncef, Korbi Sadok
Pathology Department, F. Hached Hospital, Tunisia

Background: Papillary carcinomas of the kidney are relatively rare tumors, counting for 4% of renal cancers. Two types are actually recognized, that differ by their morphological and prognostic features. Method: In a retrospective study, we have studied the clinicopathological and imaging features of 6 cases of papillary carcinoma retrieved in an 11- year period (1995-2005) at the pathology department of F. Hached hospital. These tumors were graded according to the new 2004's OMS histopathological classification of renal tumors. Results: In our study, there were 5 men and one woman. The age median was of 68 years with extremes ranging between 57 and 83 years. The tumors were asymptomatic in 3 cases, they were revealed by lumbar pain in 3 cases. A lombar contact and a lombar sensibility were found in 2 cases. Imaging findings were various, but ultrasonography and CT-scan found a neoplastic process in 5 cases. Histopathological examination found that type 2 papillary carcinoma was correlated to a higher nuclear grade, to an advanced infiltration stage and to a poorly prognosis. Treatment consisted in a radical nephrectomy in 5 cases and in a tumorectomy in one case. Conclusion: Actually, it is important to classify papillary carcinoma into type 1 or 2 because of the prognostic implications.

PP4-55
THE MORTALITY AND CLINICALLY MISSED DIAGNOSIS OF AA AMYLOIDOSIS IN RHEUMATOID ARTHRITIS
Miklós Bély[1], Ágnes Apáthy[2]
[1] Policlinic of the Hospitaller Brothers of St. John of God in Budapest, Hungary
[2] National Institute of Rheumatology and Physiotherapy, Budapest, Hungary

Introduction AA amyloidosis (AAa) is one of the most important complications of rheumatoid arthritis (RA). Aim of this study was to determine: 1. the mortality due to AAa in RA, 2. the clinically missed diagnosis of AAa in RA, 3. the correlations between severity, mortality, and clinical recognition of AAa. Patients and Methods A randomized (non-selected) autopsy population of 161 in-patients with RA was studied (diagnosed clinically according to the criteria of the American College of Rheumatology-ACR). The basic disease, the complication(s), and the cause of death were determined and analyzed retrospectively, reviewing the clinical and pathological reports, tissue samples, and the histological slides. Amyloidosis and severity of amyloidosis was determined histologically. The correlations were determined by χ^2-test, comparing the mortality and clinically missed diagnosis of AAa with mild (<) amyloidosis. Results≤1), or severe (1 1. Systemic secondary (AA) amyloidosis was observed in 34 (21.1%) of 161 patients. Thirteen (38.2 rel%) of 34 patients revealed a "severe" degree of amyloid A deposition, massively involving many tissue structures of examined); and 21 (61.8≤organs (with average amount of amyloid A deposits / patient 1 rel%) cases were regarded as "mild", involving only a few tissue structures in some organs (with average amount of amyloid A deposits / patient <1). 2. Seventeen (50 rel%) of 34 patients died of uremia, and 9 (26 rel%) of 17 were diagnosed clinically. 3. There was a significant and positive correlation between severity and mortality of AAa (χ^2=7.97, p<0.004), or clinical recognition of AAa (χ^2=5.98, p<0.01), furthermore between mortality and clinical recognition of AAa (χ^2=9.67, p<0.001). Conclusions AA amyloidosis should be regarded as one of the most insidious complications of rheumatoid arthritis (RA), which may furtively lead to death (Bély, 1993). The clinical recognition of AAa is quite effective. In half of the lethal cases amyloidosis has been recognized clinically, but all of these were in a late, advanced stage of amyloidosis, with massive renal amyloid deposits and uraemia. The early diagnosis of AAa is important, because early recognition of amyloidosis allows an early start of therapy and therefore entails a better prognosis. Biopsy is suggested in all hospitalised RA patients, with or without clinical signs of amyloidosis.

PP4-56
STAGE DEPENDENT QUANTITATIVE DIFFERENCES OF (AA) AMYLOIDOSIS IN RHEUMATOID ARTHRITIS
Miklós Bély[1], Ágnes Apáthy[2]
[1] Policlinic of the Hospitaller Brothers of St. John of God in Budapest, Hungary
[2] National Institute of Rheumatology and Physiotherapy, Budapest, Hungary

Introduction Development of systemic AA amyloidosis (AAa) is a progressive, cumulative process. Aim of this study was to determine 1. the quantitative differences of amyloid A deposits in RA patients complicated with AAa at death, 2. the quantitative differences of amyloid A deposits in different tissue structures of various organs. Patients and Methods A randomized (non-selected) autopsy population of 161 in-patients with RA was studied. RA was diagnosed clinically according to the criteria of the American College of Rheumatology. AAa was detected histologically. The quantitative differences of amyloid A deposits on different structures of various organs at death were evaluated by semi-quantitative, visual estimation of amyloid deposits on a 0 to 3 plus scale. Results AAa was observed in 34 (21.1%) of 161 patients. Thirteen (38.2 rel%) of 34 patients revealed a "severe" degree of amyloid A deposition, massively involving many tissue structures of examined organs (with average amount of); and 21 (61.8 rel%) cases were regarded as≤amyloid A deposits / patient 1 "mild", involving only a few tissue structures in some organs (with average amount of amyloid A deposits / patient <1). Discussion The process of amyloid A deposition is a progressive and time dependent phenomenon. Minimal or moderate amyloid A deposits (with average amounts of amyloid A deposits / patient <1), involving only a few tissue structures in some organs representing the early stage of amyloidosis. Massive amyloid A deposits (with average amounts of), massively involving many tissue structures of≤amyloid A deposits / patient 1 examined organs represents the late (advanced) stage of amyloidosis.

During the progression of amyloidosis, amyloid A protein deposition begins in the organs and tissue structures that are frequently involved and later show marked deposition of amyloid. Where deposits are infrequent or less marked, deposition starts later. Amyloid deposition in the wall of blood vessels (capillaries, arterioles, small arteries) will be followed by deposition of amyloid A along collagen fibers, basal membranes, and reticulin fibers (fat tissues). The amyloidosis of peripheral nerves is a late, end stage phenomenon. The chronologic sequence of amyloid A deposition regarding the organs is: GI tract, heart, kidney, spleen, liver and the adrenal glands. Other organs like lungs, pancreas, thyroid gland, aorta, skeletal muscle, synovial membrane, lymph nodes, peripheral nerves, bones and skin are involved less frequently and amyloid A deposition starts later in them.

PP4-57

NEPHROTIC SYNDROME AND ACUTE RENAL FAILURE IN NON-HODGKIN LYMPHOPLASMOCYTIC LYMPHOMA WITH MONOCLONAL GAMMOPATHY

Tatjana Terzic[1], Natasa Colovic[2], Milica Colovic[2], Bosko Andjelic[2], Biljana Mihaljevic[2], Jasmina Markovic-Lipkovski[1]
[1] University of Belgrade, Faculty of Medicine, Institute of Pathology, Serbia
[2] University Clinical Centre of Serbia, Institute of Hematology, Serbia

Background. Lymphoplasmacytic lymphoma is a rare disease that occurs in older adults, characterized by proliferation of small B lymphocytes, plasmacytoid lymphocytes or plasma cells with or without production of serum monoclonal protein. Renal lesions may occur quite rarely and may be the result of amyloidosis or depositing of monoclonal immunoglobulins or their subunits in one or more renal compartments including glomeruli, tubules, interstitium and blood vessels. Case report. We report two patients with lymphoplasmacytic lymphoma and monoclonal gammopathy of IgM and IgG type, nephrotic syndrome and acute renal failure. A 58-year-old man previously treated for pre-B acute lymphoblastic leukemia, developed 3 years later nephrotic syndrome as a complication of lymphoplasmacytic lymphoma and high paraprotein IgM kappa type. Biopsy of the kidney with light microscopic examination revealed 12 glomeruli with increase of mesangial matrix and mesangial cells. This proliferation was of segmental character with nodular appearance. Glomerular basal membrane was thickened and duplicated. Five glomeruli showed capsular adhesions. There were moderate tubular atrophy and interstitial fibrosis. The small arteries showed hyalinization of the walls. Imunofluorescence revealed mesangial and capillary wall positivity for IgM and kappa light chains and negativity for lambda light chains. Diagnosis of membranoproliferative glomerulonephitis was made. Treatment with cyclophosphamide was ineffective and patient died 2 months later. The second patient is 42-year-old female diagnosed with lymphoplasmacytic lymphoma and paraprotein IgG lambda type. Kidney biopsy disclosed 9 glomeruli, among them one was completely sclerotic. Glomeruli showed hypercellularity due to mesangial cell proliferation and infiltration with mononuclear leukocytes. There were moderate to severe tubular atrophy and interstitial fibrosis. Few tubules were extremely dilated filled with amorphous eosinophilic material with impression of microcystic formations. There were patchy interstitial infiltrates with mononuclear leukocytes. Immunofluorescence staining of glomeruli revealed mesangial and tubular wall positivity for immunoglobulin G, component of complement C3 and lambda light chains. Haemodyalisis and cytostatic therapy were without response and she died after 45 days. Conclusion. In our both cases light chain deposits were found. These light chains have probably caused glomerular as well as tubular changes which were observed.

PP4-58

RENAL MEDULLARY CARCINOMA IN A CHILD WITHOUT SICKLE CELL DISEASE: CASE REPORT

Lina Gomes Dos Santos[1], Aracy Carstens Cunha[2], Benedito Borges Da Silva[3], Jerusia Oliveira Ibiapina[4], Teresinha Castelo Branco Carvalho[4], Kelson James Almeida[3], Gildene Alves Da Costa[4], Daniel José Martins Barbosa[4], Euripedes Soares Filho[4], Jucelia Saraiva E Silva[5], Ana Maria Lima Furtado Veloso[4], Joao Bosco Parentes Vieira[3]
[1] Federal University of Piauí, Brazil
[2] Diagnose Cunha Lab, Brazil
[3] Federal University of Piauí, Brazil
[4] São Marcos Hospital, Brazil
[5] Estadual University of Piauí, Brazil

Background: Renal Medullary Carcinoma is a rare primary neoplasm of the kidney more commom in young adults and frequently associated to sickle cell disorders. It was described by Davis et al in 1995 as epithelial tumor arising from the renal calix of patients with sickle cell disorders. Case Report: A 15-year-old black child admitted with flank pain lasting one year, hematuria and weight loss. Examination showed a palpable mass in the left flank. Laboratory tests were performed and showed: hematocrit 25%, leukocytes 11,400mm3, normal values of electrolytes and renal/hepatic function parameters. Hemoglobin electrophoresis and falciform anemy test were negative. Computed tomography of abdome showed a centrally located mass in left kidney. Then, radical nephrectomy was performed and the pathological result was a well-circumscribed tumor with 10,0 x 8,0cm located in kidney medulla. Microscopically, the neoplasm consisted of solid sheets of cells, eccentric nuclei, prominent nucleoli and eosinophilic and granulated abundant cytoplasm with dense infiltrate of lymphocytes and polymorphonuclear leukocytes. Immunohistochemical stains performed were positive for vimentine, CK7 and CK8 and negative for CK20 and CD10. Despite of treatment stablished the patient died within twelve months. Conclusion: Renal Medullary Carcinoma, known as seventh sickle cell nephropathy, a rare and extremmelly aggressive renal tumor, leading to the death of the majority of patients, as happened in the present case.

PP4-59

RENAL INFLAMMATORY PSEUDOTUMOR: A CLINICOPATHOLOGIC AND IMMUNOHISTOCHEMICAL STUDY OF A NEW CASE

Petrescu Amelia Nicoleta[1], Berdan Gabriela[1], Ambert Valentin[1], Jinga Viorel[1], Popescu Mircea[1], Andrei Florin[2], Hulea Ionela[3], Gaitanidis Raluca[3], Niculescu Liviu[4]
[1] Th. Burghele" Hospital , Bucharest, Romania
[2] Victor Babes" Institute of Pathology, Bucharest, Romania
[3] Th. Burghele" Hospital, Bucharest, Romania
[4] University of Medicine and Pharmacy " Carol Davila", Bucharest, Romania

Renal inflammatory pseudotumor is an uncommon benign tumor that has been classified into separate group, but there is a risk that this lesion could be misdiagnosed. The aim of this work is to report a new case of 57 year old man presented in our hospital with hematuria, minimal grade fever and right flank pain. Magnetic resonance imaging (MRI) and sonography revealed a tumor of the right mediorenal parenchyma, 2,5 cm in diameter. The patient underwent right nephroureterectomy under the diagnosis of renal cell carcinoma. Macroscopically examination carried out the removed kidney showed a 2/2/1,5 cm yellowish, gelatinous, well circumscribed, mediorenal and pericaliceal mass. Material and methods: Fragments of the tumor were fixed in formaldehyde 10%, included in paraffin and the sections were stained with HE,VG and immunohistochemically: vimentine (VIM), MNF116, SyN, smooth muscle actin (ACT), DESMINE, CD68, S100. Results: The histological examination revealed a compact spindle cell proliferation, a hypocellular fibrous area in a

oedematous myxoid background infiltrated by small lymphocytes, histiocytes ,some plasma cells and small bone area. The spindle cells were diffuse positive for VIM, ACT, CD 68 and negative for desmin, MNF 116, SyN and S 100. Conclusions: The pathologic diagnosis was renal inflammatory pseudotumor and raises the problem of differential diagnosis as the clinical and imagistic aspects are similar to those of a renal carcinoma and the problem in establishing a preoperative correct diagnosis.

PP4-60
PAPILLARY RENAL CARCINOMA – A MORPHOLOGIC STUDY OF 36 CASES

Monica Gratiela Hortopan
Fundeni Clinical Institute Bucharest, Romania

ABSTRACT: The study consisted of 36 patients diagnosed and surgically treated in the Center of Urological Surgery, Dialysis and Renal Transplant from Fundeni Clinical Institute between January 2002 and December 2006. We have evaluated the histological spectrum of PRCCs and assessed significance of conventional pathologic prognostic parameters (Fuhrman's nuclear grade, pathologic stage, tumour size, multifocality, necrosis, and foam cells) and correlated these with outcome. The conclusion that we reached from our study are: 1. PRCC is a malignant tumour, diagnosed at a lower stage, with a distinct potential for progression and aggressive behaviour. 2. Evaluation of these tumours according to cell type, amount of foam cells, presence or absence of vascular invasion, nuclear grade, and pathologic stage provides useful prognostic information. 3. The better 5-year survival rate of papillary RCC (overall and for stage I tumours) compared with that of conventional RCC suggests that it is a tumour with lower malignant potential. 4. Differential diagnosis must be made with urothelial carcinomas, collecting duct carcinomas, metastatic papillary carcinomas (lung, thyroid, etc.)and clear cell carcinoma.

PP4-61
NESTIN EXPRESSION IN MEMBRANOUS GLOMERULONEPHRITIS

Jasmina Marković-Lipkovski[1], Ljiljana Gojković-Bukarica[2], Sanja Čitlučanin[1], Radmila Stevanović[1], Sanja Radojević-Škodrić[1], Gordana Basta-Jovanović[1], Biljana Stojmirović[3], Vida Nešić[3]

[3] Institute of Nephrology and Urology, Clinical Centre of Serbia, Belgrade, Serbia

Background. Nestin, an intermediate filament protein which has role in regulating cellular cytoskeletal structure, is restrictedly expressed in the podocytes of human adult kidneys. In the present study nestin expression was investigated in biopsy specimens of membranous glomerulonephritis (MGN). Method. During the last two years, 52 MGN were collected out of 534 kidney biopsy received to be diagnosed at our institution. The diagnoses were performed by light and immunofluorescent microscopy and in some cases by electron microscopy. Clinical data (including immunological analysis wiht ANA and antiDNA antibodies) were also taken into account. For immunomorphology, monoclonal anti-nestin antibody from mouse (SC-23927, clone 2C1.3A11, Santa Cruz Biotechnology) diluted 1:100 was applied on cryostat or paraffin sections using Labeled StreptAvidineBiotin (LSAB+ Dako®) method. Visualization was performed by Dako® AEC substrate. Ten kidney biopsies of patients without nephrotic syndrome, mainly with mesangioproliferative GN, were used for control staining. Results. 52 patients were middle-aged adults (mean age 46) and 4 patients were under age of 15, ratio female : male was 26 : 30. In idiopathic MGN routine immunofluorescence analysis revealed granular deposits of IgG and C3 along glomerular basement membrane (GBM), and by light mtcroscopy the glomeruli showed thickened basement membrane, but appeared normocellular. Mesangial proliferation in addition to uniform thickening of GBM was crucial finding for secondary MGN and immunofluorescence microscopy usually showed a "full house" pattern (fine granular deposits of IgA, IgG, IgM, C1 and C3 along the GBM). In 12 cases (21.4%) idiopathic MGN was diagnosed, and in 35 cases (62.5%) secondary MGN. In 9 cases (16.1%) etiology was undetermined. Nestin expression was variably present in glomeruli in different cases of MGN. Decreased expression was predominantly found in MGN of undetermined or secondary etiology. Conclusion. MGN revealed heterogenity concerning nestin expression. Nestin expression was especially diminished in MGN associated with so-called "full house" immunofluorescence findings.

PP4-62
SEVERAL PATHOGENIC MECHANISMS OF CONGENITAL GLOMERULOPATHIES

Maida Tussupbekova
Karaganda State Medical Academy, Kazakhistan

At present time, problems of kidney pathology of fetus and newborn at complicated pregnancy are not completely investigated. Different factors cause delay of fetus and newborn tissues maturity from their hestational age with persistence of embrional structures, became a cause of congenital developmental defects formation and make difficult adaptation of the organism to extra uterine life. Aim of the research: to study the structure of mortality and pathological morphology of kidneys of fetus and newborns at complicated pregnancy. The analysis 566 still-born children and 516 newborns, dead in perinatal periodwas done. There were allocated groups of research - control group, with anemia, and chronic pyelonephrotis. Object of research was both kidneys. Common histological methods, immune fluorescent investigation and morphometric research were made. Results of the research: The basic cause of death is asphyxia (35,6±2,3% against 54,4±1,9%),second place have respiratory disorders of lungs. Congenital developmental defects are on third place, their frequency is increased in two times till 17,6±1,8%, against 7,93±1,0%. Increase of cases of intra uterine infection till 16,7±1,8%, against 3,6±0,7% is also visible. Morphometric criteria of hestational and pathological immaturity of kidneys: number of layers and volumetric part of renal flomeruli, number of embryonic nephrons, and square of tubular surface. Hestosis of pregnant women is a high risk factor of renal dysembriogenesis. Pathological immaturity of kidney tissue at normal duration pregnancy and hestosis is diagnosed at 74,0±5% cases, focal and cystic cortical dysplasia of kidney structure was revealed at 13,0±4%. At histological research of kidneys of fetus and newborns in group with hestosis of pregnant women in 11,0±3% membranous and membranous –proliferative variants of glomerulopathies was revealed. At immune fluorescent investigation bright granular glow of IgM on basal membranes with blade changes of vascular glomeruli and line glow of C3 component of compliment were marked, these are testify about possible participation of anti renal immune factors of pregnant women in the development of congenital immune complex glomerulopathy. In the group of investigation pathological immaturity was revealed in 38,7±5,3% at presence of chronic pyelonephritis at mothers. Analysis of data of pathological morphological research of kidneys of fetus and newborns at complicated pregnancy describes some pathogenic mechanisms of congenital glomerulopathies development and causes, leading nephrogenesis disorders.

PP4-63

THE INFLUENCE OF TUBULAR PHENOTYPIC CHANGES ON THE DEVELOPMENT OF DIFFUSE INTERSTITIAL FIBROSIS IN RENAL ALLOGRAFTS

B. Handan Ozdemir, Nihan Haberal, F. Nurhan Ozdemir, Beyhan Demirhan, Mehmet Haberal
Baskent University, Faculty of Medicine, Turkey

It has been reported that myofibroblasts are the major cells in the development of interstitial fibrosis (IF) and therefore chronic graft dysfunction in renal allografts. In normal human kidney, tubular cells do not have myofibroblast differentiation and they don't have alpha-smooth muscle actin (alpha-SMA) expression. In this study we aimed to show that tubular cells can undergo phenotypic changes toward myofibroblasts and induce early IF and poor graft outcome in renal allografts. The expression of alpha-SMA and the formation of vinculin and paxillin containing adhesion complexes are the primary criteria for determining the differentiation of non-muscle cells such as renal tubule cells into contractile myofibroblasts. For this reason we immunostained first year renal allograft biopsies of 74 patients with alpha-SMA, Vinculin and Paxillin primary antibodies and the expression of tubules and glomerular cells were evaluated. Myofibroblast differentiation of renal tubules (alpha-SMA, vinculin and paxillin positive tubules) was found only 30 of 74 patients. In addition glomerular cells of 36 patients showed positive alpha-SMA, vinculin and paxillin staining. The development of diffuse IF was found significantly early in cases with tubules showing myofibroblast differentiation compared to cases with tubules that did not have myofibroblast differentiation ($p<0.01$). The presence of proteinuria in first year showed significant positive correlation with the glomerular alpha-SMA, vinculin and paxillin staining ($p<0.001$). Cases whom showed tubular and glomerular alpha-SMA, vinculin and paxillin staining showed worse graft outcome compared to cases that did not show tubular and glomerular staining ($p<0.001$). In conclusion our results showed that renal tubular and glomerular cells can show myofibroblastic differentiation and these cells have a role in the development of diffuse interstitial fibrosis and early proteinuria in renal allografts.

PP4-64

PERITUBULAR CAPILLARY AND VASCULAR MACROPHAGE INFILTRATION CORRELATES WITH MICROVASCULAR DESTRUCTION AND WORSENS STEORID RESPONSE AND RENAL ALLOGRAFT OUTCOMES FOLLOWING C4d NEGATIVE ACUTE REJECTION EPISODES

B. Handan Ozdemir, Nihan Haberal, Feza Karakayali, Beyhan Demirhan, F. Nurhan Ozdemir, Mehmet Haberal
Baskent University, Faculty of Medicine, Turkey

We aimed to understand the influence of peritubular capillary (PTC) and vascular macrophage infiltration on steroid response and renal allograft outcomes after acute rejection (AR) episodes. Seventy-nine patients with biopsy-proven AR in their first year after transplantation were included in the study. Thirty patients with normal first year renal allograft biopsies were also included in the study and used as a control group. All biopsies were C4d negative. Immunohistochemically we assessed the degree of macrophages (CD68) and HLA-DR-positive infiltrating cells in PTC's, glomeruli, and on vascular walls and tubules. In addition HLA-DR expression of PTC's was also evaluated. The decreasing intensity of peritubular capillary HLA-DR (PTC-DR) expression was accepted as the increasing degree of the destruction of PTC. Compared to control group AR cases showed significantly higher degree of macrophage and HLA-DR positive inflammatory cell infiltration in PTC's, glomeruli, and on vascular walls and tubules ($P<0.001$ for all). PTC destruction was significantly higher in AR cases than control group ($p<0.001$). PTC, glomerular and vascular macrophage infiltration showed significant correlation with PTC destruction and steroid response ($p<0.001$ for all). Severity of PTC destruction with accompanying higher degrees of macrophage infiltration in PTC's, glomeruli and on vascular walls caused unresponsiveness to steroid therapy ($p<0.001$) and poor graft outcome ($p<0.001$). Five-year graft survival was 95%, 37% and 22% for cases with grade 0, 1 and 2 PTC macrophage infiltration respectively ($P<0.001$). In addition five-year survival was 80%, 36% and 1% for cases with grade 0, 1 and 2 vascular macrophage infiltration respectively ($p<0.001$). In conclusion peritubular capillary and vascular macrophage infiltration are important predictors of steroid response and renal outcome following acute rejection in cases whom especially had negative C4d.

PP4-65

ROLE OF POLY (ADP-RIBOSE) POLYMERASE ON MICROVASCULAR INJURY AND INFLAMMATION IN RENAL ALLOGRAFT REJECTION AND ITS INFLUENCE ON RENAL GRAFT SURVIVAL

B. Handan Ozdemir, Turan Colak, Feza Karakayali, Beyhan Demirhan, Mehmet Haberal
Baskent University, Faculty of Medicine, Turkey

Introduction: The activation of poly (ADP-Ribose) polymerase (PARP) is well considered to play an augmenting role in inflammation and cell death. The aims of this study were to investigate the role of PARP in acute rejection (AR) and to assess the influence of PARP on renal survival. Methods: Study compromised 81cases and 55 of them had AR. Twenty-six cases had no pathology and used as a control group. PARP and HLA-DR expression of tubules, interstitium, arteries and peritubular capillaries (PTC's) were studied immunohistochemically and CD68 positive macrophage infiltration of tubules, interstitium, PTC's and arterial walls were evaluated. The decreasing intensity of PTC HLA-DR (PTC-DR) expression was accepted as the increasing degree of the destruction of PTC's. Results: AR cases showed higher degrees of tubular, interstitial and vascular PARP and HLA-DR expression compared to control group ($p<0.01$ for all). PTC-DR expression was lower and PTC-PARP expression was higher in AR cases compared to control group ($p<0.001$). Increasing of AR grade with the high level of PTC-PARP expression, caused decrease of PTC-DR expression and increase of PTC destruction ($p<0.01$). Tubular and interstitial HLA-DR expression, interstitial, tubular, vascular and PTC macrophage infiltration showed positive correlation with tubular, interstitial, PTC and vascular PARP expression ($p<0.01$ for all). In contrast PTC-DR expression showed negative correlation with all these parameters ($p<0.01$). Severity of PTC destruction with accompanying higher degrees of PARP expression on tubules, interstitium, arteries and PTC's caused unresponsiveness of steroid therapy ($p<0.01$) and poor graft outcome ($p<0.01$). Conclusion: Increased PARP activation leads to higher degrees of cell death and inflammation that AR cases with high renal PARP expression showed significant PTC destruction and renal inflammation. Therefore we suggest that PARP inhibitor drugs can combine with immunosuppressive therapy in order to control PTC destruction and renal inflammation

PP4-66

EFFECTS OF SULPHITES ON KIDNEY HISTOLOGY IN YOUNG AND ELDERLY RATS

Nagihan Yalcin[1], Murat Colakoglu[2], Vural Kucukatay[3], Erdogan Kocamaz[4]
[1] Department of Pathology, Pamukkale University, School of Medicine, Denizli, Turkey
[2] Department of Nephrology, Pamukkale University, School of Medicine, Denizli, Turkey
[3] Department of Physiology, Pamukkale University, School of Medicine, Denizli, Turkey
[4] Department of Histology and Embrylogy, Pamukkale University, School of Medicine, Denizli, Turkey

BACKGROUND:The human body is constantly generated from the metabolism of the sulfur containing amino acids. Sodium metabisulphite is used as an antioxidant and antimicrobial agent in a variety of drugs and functions as preservative in many food preparations. There is no knowledge about the histological effects of sulphites on kidneys. The aim of this study was to investigate the possible toxic effects of sulphites on kidneys by assessing histological findings in young and elderly rats. MATERIALS AND METHODS: Rats were assigned to four groups: Two sulphite administrated young and elderly groups, and two young and elderly control groups. Sulphite was administrated in the form of sodium metabisulphite 70mg/kg/day via drinking water. The kidney tissues were fixed on buffer formalin and then they were stained with H&E, methenamine silver, PAS and Masson's thricrome. RESULTS:There were no glomerular changes (i.e. thickness of basement membrane, focal segmental sclerosis), tubular changes, tubular interstitial changes or vascular changes. No differences between young and elderly sulphite administrated groups were observed histologically. CONCLUSIONS:In this study, the specimens were examined by light microscopy. Further studies done by electron microscopy are needed to support these findings.

PP4-67
HISTOPATHOLOGICAL STRUCTURE OF THE KIDNEY IN HIGH FAT DIET FED RATS: A LIGHT MICROSCOPICAL STUDY

Deniz Unal, B. Zuhal Altunkaynak, M. Eyup Altunkaynak
Department of Histology and Embryology, School of Medicine, Ataturk University, Erzurum, Turkey

Background: To characterize kidney in high fat induced obesity model we have examined renal structure in adult Sprague-Dawley rats fed a control diet (CD) or fat-rich diet (HFD) during three months. Methods: Ten adult female Sprague Dawley rats were fed a diet constituted highly of fat (%30) for duration of 3 months. Ten control rats were maintained with a standard rat chow. All animals were weighed per 10-day for 3 months. At the end of the experiment, the naso-anal length of the anesthetized rats was measured to calculate the body mass index (BMI), and subsequently, whole kidneys of the intracardially formalin-perfused animals were removed. Qualitative features of kidney were examined histologically. Results: Light microscopic investigation showed a dilatation in blood vessels and bowman capsule, mononuclear cell infiltration, degeneration in nephrons including glomerulosclerosis and tubular defects and an increase in the connective tissue in the kidneys from the treatment group. Conclusion: Eventually, we have thought that fatty diet causes obesity and may lead to renal failure as a result of histopathological changes.

PP4-68
EXPRESSION OF INSULIN-LIKE GROWTH FACTOR IN PROLIFERATIVE GLOMERULONEPHRITIS

Fulya Cakalagaoglu[1], Zeynep Tosuner[1], Naziye Ozkan[1], Serhan Tuglular[2], Beyza Macunoglu[2]

[2]Marmara University Faculty of Medicine, Department of Nephrology, Istanbul, Turkey

Background Insulin-like growth factor-1 (IGF-1), a peptide growth factor produced by collecting ducts, and its receptor, IGF-1 receptor are present in the glomeruli and basolateral membrane of renal proximal tubular cells. Animal studies showed that IGF restores nephron growth and contributes to tissue growth by causing arterioler dilatation, increasing the glomerular filtration rate and accelerating tubular regeneration.The present study aimed that analyse the expression of IGF-1 in proliferative glomerulonephritis(PGN) and focused on its biologic significance in glomerulonephritis. Methods.IGF -1 expression was studied in 34 non diabetic specimens: normal kidney (6), proliferative glomerulonephritis (GN,14), nonproliferative GN (14). All slides were immunohistochemistry stained with IGF-1(G-17; SC-1422; Santa Cruz Biotechnology; California). In all cases, IGF-1 expression was scored semiquantative by two pathologists (0-3) in glomeruli and tubulointerstitial. Routine histochemical and immunofloresanse stains were performed and evaluated all cases. Activity index, chronicity, interstitial injury and sclerotic glomeruli were examined in all cases. Results.In normal kidney there was strong IGF-1 immunreactivity in the proximal tubules and minimal IGF -1 expression in the glomeruli.We found increased IGF-1 immunexpression in glomeruli at Proliferative GN groups compared with nonproliferative groups. IGF-1 expression was correlated with the activity index for Proliferative GN groups. Tubulointerstitial IGF-1 expression was similar in proliferative and non proliferative GN groups. We did not found a statistically significant correlation between fibrosis and glomerul IGF-1 expression in two groups. Only significant correlation was between fibrosis and tubulointerstitial IGF-1 expression. Both groups had similar sclerotic glomeruli proportions. Conclusion: These data indicate that IGF-1 indicates the activity in proliferative glomerulonephritis, but larger group studies are needed to confirm our results

PP4-69
EFFECT OF FK506 IN EXPERIMENTAL GLOMERULONEPHRITIS: LIGHT MICROSCOPIC AND ULTRASTRUCTURAL STUDY

Fulya Cakalagaoglu[1], Naziye Ozkan[2], Emine Salva[3], Serap Arbak[4], Bahar Uslu[4]

[3] Marmara University, Vocational School of Health Related Professions, Pathology Laboratory Department, Istanbul, Turkey
[4] Marmara University, Medical Faculty, Histology and Embriology Department, Istanbul, Turkey

Background The anti-Thy1.1 model is a rat model of mesangial proliferative glomerulonephritis characterized by mesangial cell proliferation and accumulation of mesangial matrix expansion with subsequent resolution and return to almost normal histology. FK506 is an immunosuppresive drug used for treatment of autoimmune disease and after transplantation.In present study, we investigate the effect of FK506 on experimental glomerulonephritis model. Method We studied the expression of α-Smooth Muscle Actin(α-SMA), Proliferative Cell Nuclear Antigen(PCNA),Macrophage Calprotectin MAC), aminine, ascular Endothelial Growth Factor(VEGF) in paraffin embedded tissue section from kidney by immunhistochemical method and apoptosis with TUNEL.We studied kidney tissue with fluorescein isothiocyanate(FITC).IgG,IgM,IgA,C3,C1q and fibronogen. We examined ultrastructural finding with electron microscopy. Twenty male Wistar Albino rats were divided into four groups:GroupI Control(C):5 rats received of 0.1ml/100g normal saline(NS) intravenously(i.v) injection for 4 weeks;GroupII Glomerulonephritis(GN):5 rats received i.v injection of anti-Thy1.1(0.25µg/100g) at zero day. GroupIII Glomerulonephritis+FK506 (GFK):5 rats received i.v injection of anti-Thy1.1(0.25µg/100g) and then FK506(1mg/kg) for two weeks.GroupIV Control+FK506 (CFK):5 rats received i.v.injection of NS (0.1mg/100mg) and then FK506(1mg/kg) for two weeks.Serum creatinine,creatinine clearance and proteinuria were performed at the end of the study period.Renal tissue were assessed for light microscopic findings glomerul and tubulointerstitial injury.PCNA,α-SMA,VEGF,Laminin,MAC and

apoptosis were semiquantatively scored on glomerul and tubulointerstitial area.We examined renal tissue by electron and immunofluorecence microscopy. Results At the end of the study period,glomerular cell proliferation and tubulointerstitial injury were significantly increased in GN compared to G group. Glomerular immunohistochemical expression of PCNA, SMA, VEGF, MAC,apoptosis significantly increased in GN compared to C group.Also we found the electron dense deposit on glomerular capillary walls and mesangium with IgG and C3 by immunofluorecence microscopy.The expression of the PCNA,α-SMA and apoptosis were significantly decreased in GFK group compared to GN.But glomerular immunoexpression of MAC and VEGF were similar in GN and GFK groups.Also we found less proteinuria in GFK group compare to GN. Conclusion The present study suggests that FK506 may be useful in drug for the treatment of mesangial proliferative glomerulonephritis.

PP4-70

INVESTIGATION OF PROTECTIVE EFFECT OF PREDNISOLONE IN NEPHROPATHY INDUCED BY CO-TRIMOXAZOLE IN RAT

Ali Reza Mozaffari[1], Iran Rashidi[2]
[1] Internist, Department of Pathology-Ahwaz- Jondishapour Medical University, Iran
[2] Pathologist, Department of Pathology-Ahwaz- Jondishapour Medical University, Iran

Co-trimoxazole is a sulfonamide derivative, which is used as an antibacterial drug. Prednisolone is a dermo-corticostroid derivative, which is widely used as an anti-inflammatory and in the treatment of allergic reaction and collagen vascular diseases. Methods and Materials: The aim of this study was to find out the effect of co-trimoxazole on the renal interstitum and protective effect of predenisolone in rat. Four groups of animal were selected, namely A, B, C and control group. Groups A and B were treated with co-trimoxazole (150mg/Kg sulfa methoxazole + 30mg/Kg trimethoprim) while group C was treated with Co-trimoxazole and prednisolone (4mg/Kg) for 10 days. The reference group was only received some dose of water. The blood samples were collected from groups A and C 24 hours and from group B 14 days after the last dose of drug were administrated. Microscopic samples from kidney tissue were prepared for histopathological study. Results: The creatinine level in serum of group A (1.54) showed a significant increase as compared with the control group (1.04). In the group that received co-trimoxazole the histopathological study showed acute interstitial nephritis (AIN). In the group that treated with co-trimoxazole + prednisolone were not seen any histopathological changes . Conclusion: These results support the theory that AIN is drugs allergic reaction when co-trimoxazole is used.

PP4-71

COX 2 AND CD 34 EXPRESSION IN WILMS TUMOR (NEPHROBLASTOMA)

Gokben Yıldırım Kupesiz[1], Bahar Akkaya[1], Gulsun Tezcan[2], Alphan Kupesiz[2], Betul Unal[1], Hakan Gulkesen[3], Volkan Hazar[2], Gulten Karpuzoglu[1]
[1] Akdeniz University, School of Medicine, Department of Pathology, Antalya, Turkey
[2] Akdeniz University, School of Medicine, Department of Pediatrics, Division of Hematology-Oncology, Antalya, Turkey
[3] Akdeniz University, School of Medicine, Department of Statistics, Antalya, Turkey

BACKGROUND Wilms tumor (nephroblastoma) is the most common primary malignant renal tumor of childhood. It occurs in approximately 10 children per million under the age of 15 years and is usually diagnosed between the ages of 2 and 5 years. Approximately 90–95% of Wilms tumors involve one kidney. There has been much recent interest in the role of cyclooxygenase-2 (COX-2), one of the three enzyme isoforms that convert arachidonic acid to prostaglandins, in tumor development and progression. COX-2 expression is nearly ubiquitous in human cancers and has been correlated with poor prognosis [e.g., in tumors of the breast, cervix, colon, brain, and ovary]. Intriguingly, COX-2 seems to have multiple functions in tumor pathogenesis and thus represents an attractive therapeutic target. Among these, COX-2 seems to play a significant role as a positive regulator of tumor angiogenesis. METHOD Wilms tumor cases included to this study were obtained from archives of Akdeniz University Department of Pathology between 1997 and 2007. Immunohistochemical expression of COX -2 and CD 34 were independently evaluated and scored by two surgical pathologists. 17 patients (9 male / 7 female) were included in our group and their ages ranged from 1- 6 (Mean age 3.2). RESULTS In our study there was a significant negative correlation between angiogenesis, as measured by CD 34 expression and COX-2 expression ($p=0.018$, $r=-0.567$). There was no significant statistical correlation between gender, age and immunohistochemical results (COX -2 and CD 34 expression). There was also no difference between genders according to age. CONCLUSION In our study there was a significant negative correlation between angiogenesis, as measured by CD34 expression, and COX-2 expression. This would contradict the hypothesis that COX-2 acts as a pro-angiogenic stimulant, at least in Wilms tumor, and could suggest that COX-2 inhibits new blood vessel formation. Angiogenesis is regulated by a complex series of molecular pathways which, whilst they include the modulation of VEGF via PGE2 produced by COX-2, are subject to many other modulatory factors. Our study raises the possibility that COX-2 may influence tumor progression in Wilms tumor through mechanisms other than the promotion of angiogenesis.

PP4-72

SEVERE RENAL VASCULITIS IN A PATIENT WITH DRESS

Mehrenberger Marion[1], Guitard Joëlle[1], Ribes David[1], Kamar Nassim[1], Esposito Laure[1], Rostaing Lionel[1], Delisle Marie-Bernadette[2], Modesto-Segonds Anne[2]
[1] Department of Nephrology, Dialysis and Transplantation, CHU Rangueil, Toulouse, France
[2] Department of Pathology, CHU Rangueil, Toulouse, France

Introduction: Drug Rash with Eosinophilia and Systemic Symptoms (DRESS), is a severe generalized hypersensitivity reaction, characterised by fever, rash and internal organ involvement, such as liver and less frequently kidneys. It may be lethal in 10% of cases. Herein, we report on a case of a patient, who developed DRESS with renal insufficiency and proteinuria after allopurinol therapy, with the presence of a severe unexpected vasculitis at renal biopsy. Case Report : A 55 years-old woman, with a known impaired renal function due to nephroangiosclerosis, was admitted in 02/2006 for a gout crisis. Her serum uric acid, and creatinine levels were respectively 149 mg/l and 180 µmol/l. Allopurinol was introduced, but rapidly stopped because of myalgia, headache, and gastro-intestinal disorders. At that time, serum creatinine level was 188 µmol/l, with no proteinuria. Because of persistant hyperuricemia, allopurinol was re-introduced one month later. Eight weeks later, she presented with a diffuse maculopapular rash, fever (39°C), myalgia, and mild hypertension. Laboratory studies yielded the following results: serum creatinin level at 389 µmol/l, proteinuria at 0.8 g/d without hematuria, eosinophil count was 1192 / mm3, with mild cholestasis and C-reactive protein was 291 mg/l. The kidney biopsy revealed the presence of a severe leucocytoclasic necrotizing vasculitis with gigantocellular granulomas. There was no glomerulitis and no immune deposits. The diagnosis of DRESS with immuno-allergical vasculitis related to allopurinol was evocated. All immunological, bacterial and virological causes were ruled out. Allopurinol was stopped, and steroids initiated at the daily dose of 1 mg/k. Seven days later, serum creatinin level decreased to 220 µmol/l and cutaneous lesions

disappeared, but proteinuria remained elevated (1.6 g/d). Two months later, the patient presented with a nephrotic syndrom and severe hypertension. A second renal biopsy revealed interstitial fibrosis and tubular atrophy, with regression of vasculitis lesions. Unfortunately, 4 months later, hemodialysis had to be started. Conclusion: DRESS must be promptly recognized and all potential culprit drugs whithdrawn, such as aromatic anticonvulsants, sulfonamides, calcium channel blockers, ranitidine, thalidomide and allopurinol. A kidney biopsy should be performed in patients suspected to have DRESS with impaired renal function and/or proteinuria. It may reveal the presence of immuno-allergic vasculitis that may evolve rapidly to end stage renal disease despite steroid therapy.

PP4-73
RENAL AMYLOIDOSIS–CORRELATION MORPHOLOGY AND CLINICAL FEATURES

Fulya Cakalagaoglu[1], Aygun Ikinci[1], Mehmet Koc[2], Hakki Arikan[2]
[1] Marmara University Pathology Department, Istanbul, Turkey
[2] Marmara University Nefrology Department, Istanbul, Turkey

BACKGROUND Amyloidosis was defined as the deposition of proteins that have the capacity to form beta-pleated sheets.The most common presentation of AA amyloidosis is that of renal diease.AL amyloid also frequently involved the kidney.In these study,we investigated whether different patterns of amyloid deposition occur in the kidney and these patterns can be related to the clinical findings. METHOD:29 cases of systemic amyloidosis with renal biopsies processed and examined histopathologically at the Department of Pathology, Faculty of Medicine University of Marmara were reviewed.Also all cases were stained with Amyloid A component(Ab-1;MS-1219-R7;Neomarkers;Fremont CA;USA)and Amyloid P protein(Ab-1;Neomarkers;RB-1786-R7 Fremont CA,USA)using the Standard avidin–biotin–complex immunoperoxidase method.The chemical types of amyloidosis were categorized according to the following staining reactions:AA amyloid was permanganate–sensitive and immunoreactive for AA protein.AL amyloid was permanganate resistant and not immunoreactive for AA protein.Renal amyloidosis were categorized glomerular,vascular and tubulointerstitial by semiquantitive.We analyzed renal histologic findings,type of renal amyloidosis and clinical data. RESULTS.The age range of patients was 25-75 years.The male-female ratio was 19:11.3cases were categorized as AL and 26 were AA amyl.There was a predominence of the glomerular pattern in all cases.Also glomerular amyloid deposition was divided on the basis of morphological characteristics,into 4 types:a mesangial nodular type showing nodular mesangial deposits with sparse capillary wall involvement(16cases),a mesangio-capillary type disclosing diffuse amyloid in the mesangium(2cases), perimembranous type(6cases)and a hilar type showing amyloid deposits almost exclusively in hilar arterioles(3cases).14 cases of mesangial nodular type showed amyloid protein of AA type.Also we were compared glomerular amyloid deposition type and fibrosis.We found statistically significant correlation between hiler type deposition and fibrosis.We were showed that if patients had glomerular and tubulointerstitial deposition fibrosis would be worse.Proteinuria was the main clinical manifestation,present in all cases.Chronic renal failure and renal death appeared more common in hilar type of glomerular deposition with that of tubulointerstitial amyloid deposition. CONCLUSIONS.The results obtained suggest that the chemical type of glomeular amyloid protein is associated with significant differences in the morphological and prognostic features of the renal involvement.

PP4-74
MORPHOLOGICAL CHANGES AFTER LONG USAGE OF HEROIN THROUGH INJECTION

Alexander Alexandrov[1], Georgi Gergov[1], Elka Ivanova[1], Stanislav Hristov[1], Todor Todorov[2], Adrian Palov[3], Dimka Hinova-Palova[3], Tania Alexandrova[4]
[1] Center of Forensic Medicine and Deontology - “Alaxandrovska” UMBAL, Sofia, Bulgaria
[2] Center of Clinical Pathology - “Alaxandrovska” UMBAL, Sofia, Bulgaria
[3] Department of Anatomy, Histology and Embryology at Medical Faculty, Sofia, Bulgaria
[4] Emergency Medical Center – Vidin, Bulgaria

For the period 2003-2006 in the Centers of Forensic Medicine and Deontology and Clinical pathology at “Alaxandrovska” MBAL - Ltd., Sofia we had examined 33 patients (21 male and 11 female) that had died after a longtime intravenous usage of heroin and 23 patients with heroin dependency and clinical evidence of kidney damage who had undergone puncture biopsy (duration of the heroin dependency – 6 to 96 months). In order to determine the type of damages in the organism done directly by the toxic substance we studied macro- and microscopical (including electronic microscopical) morphological changes in different organs and systems – skin, underskin and underlying blood vessels – in the areas of the needle punctures (recent and old); lungs; heart; liver; kidneys and spleen. In all of the examined cases we discovered focused inflammatory changes on the skin and the underlying soft tissues in the areas most often used for the injection application of the narcotic. The most often morphological change seen was the fatty dystrophy. More rarely we encountered hepatitis with toxic origin, without the presence of fibrose changes in the liver parenchyma. The histological changed of these toxic liver damages are presented by vacuolization in the cytoplasm of the hepatocytes (fatty dystrophy), inflammatory infiltration of mononuclear cells and segment-nuclear leucocytes in the portal spaces of the liver (toxic hepatitis). In some cases there were inflammatory changes in the lungs, most often nonspecific (bronchitis, brohiolitis and focused pneumonia). In a particular case the morphological examination proved the presence of pneumonia caused by Pneumocystis carinii, damage of the lungs described in specialized literature by many leading authors. We succeeded in proving the agent of pneumocystis pneumonia not only by histochemical examinations (silver impregnation by Gomori-Grocott and PAS-reaction) but also at ultrastructural level by means of electronic microscopical examination. Kidneys are often affected in cases of longtime heroin usage. The percentage of the sclerotic glomerules of drug addicts, including those examined by us, is much higher than the one of people not addicted to drugs. The damage of the tubulo-interstitial apparatus (fibrosis, inflammatory interstitial infiltration and atrophic channels) is also a frequent morphological discovery in such individuals. Rarer are the kidney changes of the type of the glomerulopathies.

PP4-75
PHENOTYPIC ABERRATIONS IN MUCINOUS TUBULAR AND SPINDLE CELL CARCINOMA

Alexandrou Paraskevi, Liapis George, Evangelou Kostas, Kyrıakou Vasiliki
Pathology Department, Laiko General Hospital University of Athens, Greece

Mucinous tubular and spindle cell carcinoma (MTSCC) is a rare recently described variant of renal cell carcinoma with unique histological patterns which are sufficient to be designated by the World Health Organization as a distinct entity. We present a case of 55 year-old male who underwent a radical nephrectomy due to a tumor confined within the lower pole of the kidney. In gross examination the tumor was fairly circumscribed, measured 8.5 cm in greatest diameter and was tan-white in appearance. Microscopically the carcinoma was composed of variable proportions of tubular, tubulocystic, cord-like structures and

spindle cells together with rare compact areas in the presence of extracellular blue gray mucinous background (Alcian blue +). The tumor cells were cuboidal to columnar with focally atypical nuclear features with either no or rare mitoses. No tumor necrosis was found. Apart from the predominant components, unusual growth patterns and features were focally identified such as pseudo-papillae, well formed papillae with psammoma calcifications, multinuclear neoplastic cells, glomeruloid structures, hemangiopericytoma, oncocytoma and clear cell carcinoma – like areas. The tumor cells showed a diffuse cytoplasmic staining for vimentin, Cam5.2, CK7, CK18, CK19 and racemase. Both tubular and spindle cell areas were negative to Keratin 34BE12, CD10, CD15, and chromogranin. The diagnosis of MTSCC was based principally on the predominant morphologic features along with the immunohistochemical profile, consistent with the 2004 WHO classification pathologic criteria. Since there is a relatively small number of published cases of MTSCC, neither the morphologic variabilities nor the histogenesis have been elucidated. The current case highlights the aberrant phenotype of the tumor which may contribute to the establishment of the diagnostic pathologic criteria.

PP4-76
PRIMARY SYNOVIAL SARCOMA OF THE KIDNEY. PRESENTATION OF TWO CASES IN CHILDREN
Eugenia Garcia-Fernandez, Elena Ruiz-Bravo, Marta Mendiola, Purificacion Garcia-Miguel, Maria Luz Picazo
La Paz University Hospital, Spain

Background: Renal primary sarcomas represent 5 % of kidney infantile tumors. Clear cell sarcoma (CCSK) is the most common in children. In 1995 Beckwith described a series of primary embryonal renal sarcomas with mesenchymal monophasic embryonal cells. This tumor was morphologically consistent with monophasic spindle synovial sarcoma (SS) and harbored the same SYT-SSX gene fusion. These tumors are very rare in children with only 5 cases reported in the literature. METHODS: Two cases of renal pediatric SS were identified in the files of the Department of Pathology in our Hospital. Histological, immunohistochemical and molecular analysis were performed in both patients. RESULTS: Patient nº 1: An 8-year-old boy had a history of abdominal pain and hematuria. Abdominal CT revealed a right renal mass with necrosis and vena cava thrombosis. Under the impression of nephroblastoma he started systemic chemotherapy and afterwards a radical nephrectomy with vena cava thrombectomy. The specimen weighted 292 grs and had a multicystic tumor that measured 8×7cm. Histologically the tumor showed a mesenchymal proliferation of short monomorphous cells. This proliferation entrapped tubules; some were cystically dilated and had cells with a hobnail morphology. After the surgery the patient had intensive systemic chemotherapy and radiotherapy. He remains free of disease 6 years after. Patient nº 2: A 2-year-old girl with a mass that arose from the inferior side of the right kidney. Systemic chemotherapy and nephrectomy were performed. The mass weighted 568 grs and measured 11×8,5cm, was well circumscribed, white-tan with small cysts and had less than 20% of necrosis. Histologically, the tumor showed a hypercellular mesenchymal proliferation. The nuclei of the cells were round with an average mitotic rate of 20/10hpf. Immunohistochemical studies showed diffuse positivity with vimentin, CD99 and bcl-2. Both cases were confirmed by molecular analysis of the characteristical t(X; 18) that results in the fusion of SYT gene to the SSX1 or SSX2 genes. CONCLUSSION: The differential diagnosis of SS in children includes CCSK, mesenchymal nephroblastoma, congenital mesoblastic nephroma and cystic nephroma. The differential histological diagnosis in the case of CCSK is sometimes difficult. The positivity of CD99 and bcl-2 is helpful in distinguishing SS from other tumors. However confirmation of this entity is done by molecular analysis. These renal tumors have been described in young adults, but exceptionally in pediatric patients, with only 5 cases described in the literature.

PP4-77
COLOR CLASSIFICATION AND AUTOMATIC REGION IDENTIFICATION IN GLOMERULAR PATHOLOGY
Irina-Draga Caruntu, Simona Eliza Giusca
Gr. T. Popa University of Medicine and Pharmacy, Romania

Backgroud: The paper presents a new computerized technique for region identification in microscopic fields. It is based on the automatic separation of several chromaticity classes that are associated with different types of entities. Method: The method has been implemented by software modules developed in the Matlab environment and operates with indexed images. The material consisted of specimens from renal corpuscle biopsies, stained for light microscopy with haematoxylin-eosin and light green trichrome (Merck, Germany). The resulting microscopic fields exhibit a wide variety of colors, which have to be exploited in order to recognize the renal corpuscle elements: nuclei, connective tissue corresponding to the mesangium and fibrous crescent, Bowman space and capillaries (possibly containing blood cells). Results: The key issue of the proposed method is the iterative construction of a color map, whose entries are grouped in chromaticity classes, corresponding to the types of elements to be identified. Initially, each class contains a small number of representative colors selected by the user. Then, the classes are expanded, each iteration adding at least one new color to one or several of the existing classes. This step-by-step augmentation of the color map is automatically guided by a reciprocal validation of the included color(s) in the sense of the minimal distance computed in both the red-blue-green (RGB) and luminance-hue-saturation (YIQ) spaces. A number of images are considered for illustrating the correctness of the identified regions. These regions can be further used for quantitative analysis. Conclusions: The applicability of the technique is not limited to the renal corpuscle elements, but our focus on renal corpuscles is motivated by the difficult classification of the colors typical to such microscopic fields. It is worth mentioning that before elaborating this technique, we unsuccessfully tried to adapt segmentation procedures reported in literature, including the thresholding approaches experienced by us in some previous works. All these procedures failed because of the complexity of analyzed color images.

PP4-78
CLASSIFICATION AND SCORING SYSTEM OF RENAL AMYLOIDOSIS; EXPERIENCE WITH 288 CASES
Sait Sen, Banu Sarsik, Ayse Yazici
Ege University, Medical School, Department of Pathology, Izmir, Turkey

Amyloidosis refers to the extracellular deposition of fibrils composed of a variety of proteins, is multisystemic disease, associated with a different conditions. 25 different precursor fibrils are known up to date, of which seven fibrils were important for kidney. Although a variety of deposition patterns of amyloid have been described there are no universal renal classification and scoring system. This is necessary for predicting patient outcome, organ failure and also to establish an objective interpretation for clinical trials. In the present study, renal amyloidosis classification and scoring system were developed and applied. Cases of renal biopsy-proven amyloidosis were retrospectively evaluated (between 1990 and 2007). Amyloid was diagnosed using the stringent, alkaline, alcoholic CR staining method of Puchtler et al. The characteristic green birefringent polarization was taken as proof of the presence of amyloid. Glomerular amyloid depositions were classified similar to SLE 2003 ISN/RPS classification (class I to VI). Renal amyloid depositions (glomerular pattern and percent, vascular and interstitial) interstitial fibrosis, inflammatory infiltration and glomerular sclerosis were also scored. Renal amyloid prognostic score (RAPS) was found calculation of these scores. RAPS was divided into three stage (early, moderate and advanced

amyloidosis). Total 305 renal (294 native, 11 transplant) biopsies from 288 patients were reevaluated. AA was detected in 90% of the patients. Biopsies from nine cases are inadequate for classification and staging. Depositions were evaluated as 10%, 18%, 22%, 38%, 1%, and 8% respectively for class I to VI. RAPS stages were found as 14%, 51% and 31% respectively for stage I –III. Clinical validation of this system has not been completed. We believed that renal biopsy is most suitable tissue for assessing of amyloid deposition intensity. Our classification and scoring system was applied successfully. Clinical validation studies are required to confirm importance and reliability.

PP4-79

IMMUNOHISTOCHEMICAL AND MORPHOMETRICAL ANALYSIS OF THE TUBULOINTERSTITAL CHANGES IN PRIMARY GLOMERULOPATHIES

Slavica Kostadinova-Kunovska[1], Gordana Petrusevska[1], Vesna Janevska[1], Rubens Jovanovic[1], Ladislava Grcevska[2], Momir Polenakovic[2]
[1] Institute of Pathology, Faculty of Medicine, Skopje, Macedonia
[2] Department of Nephrology, Clinical Center, Skopje, Macedonia

Alterations in the tubulointerstitial renal compartment were found in almost all glomerular diseases. The aim of this study was to analyse the tubulointerstitial changes in primary glomerulopathies and correlate them with the clinical data. Methods: We made a study on 50 renal biopsies with primary glomerulopathies and 20 control cases. For morphometric analysis we made a software color extraction of the interstitial area on tissue sections stained with trichrom Masson and expressed the results as percentage of the total scanned area. We made immunohistochemical analysis with Cytokeratin, HLA-DR, Vimentin, SMA and E-cadherin. We also applied double staining method, coupling Cytokeratin with Vimentin and SMA. Results: We found fibrosis, mainly focal, occupying more than 9% of the cortical tubulointerstitial surface (mean 18,75%) in 98% of the biopsies. In these areas the tubules showed marked atrophy. The tubular epithelial cells showed diminished positivity for Cytokeratin and E-cadherin in the areas of fibrosis, and enhanced expression of HLA-DR, unlike the control cases. The epithelial cells in the atrophic tubules, especially in the foci with inflammatory infiltrate, showed positivity for Vimentin and SMA, which was not visible in the control tissue sections. This was better visualized on the double stainings where both epithelial and mesenchymal markers were present in same tubular section. The morphometric analysis showed that the percentage of tubules with cells positive for Vimentin and SMA did not exceed 10% and 5%, respectively, of the total scanned area. The analysis showed statistically significant ($p<0.01$) positive correlation between the extent of fibrosis and the serum creatinine concentration. The extent of fibrosis was also positively correlated with the same statistical significance to the percentage of tubules with cells positive for Vimentin, SMA and HLA-DR. These parameters for tubular injury also show strong correlation with the serum creatinine concentration. Only the percentage of tubules containg cells positive for SMA was found to be correlated to the degree of proteinuria at the time of the biopsy. Conclusion: The tubular epithelial cells undergo epithelial-mesenchymal transition during various glomerulopathies, thus contributing to the interstitial fibrosis. The changes in the tubulointerstitial compartment influence the course of the disease. The quantitative histological analyses should be included in the process of nephropathological diagnosis in order to evaluate the histological risk factors in glomerular diseases.

PP4-80

AN ELECTRON-MICROSCOPIC (EM) AND LIGHT-MICROSCOPIC (LM) MORPHOMETRIC STUDY IN CHILDREN WITH GLOMERULAR IMMATURITY AND NEPHROTIC SYNDROME (NS)

Aldona Wozniak, Malgorzata Janicka-Jedynska, Elzbieta Kaczmarek, Joanna Bulak-Joniec, Wieslawa Salwa-Zurawska
Department of Clinical Pathomorphology, Karol Marcinkowski University of Medical Sciences, Ponzań, Poland

Introduction: Very little information is available in the literature about the glomeruli maturation. It is thought that above 2 years of age the number of immature glomeruli should not exceed 10%. In children with NS glomerulopathies we encountered a small number of cases in whom immature glomeruli outnumber the percentage allowed to the given age. The aim of the study was: to compare the results of LM and EM evaluation and to carry out a morphometry. MATERIAL AND METHODS: The study group consisted of 66 children with NS. The diagnosis was established in LM and EM. The control group consisted of 30 children in the same age (with the same glomerulopathies MCD, DMH), but without glomerular immaturity. The morphometric study was performed. RESULTS: EM confirmed the diagnosis of MCD in 32, DMH in 6 and FSGS in 2 cases. The EM study did not confirm the LM diagnosis of MCD in 6 cases (5 DMH, 1 membranous glomerulopathy) and DMH in 1 case (MCD). EM revealed features of immaturity. There were differences in the intensity of foot processes effacement and microvillous transformation (between MCD and DMH). Morphometric studies revealed significant differences regarding the area involved by capillary loops (CLA) and glomerular volume. These values were significantly lower in the group with immature glomeruli, when the number of cells per 1000 μm2 of CLA was higher. There were no correlations between the size of glomeruli and the age of children with glomerular immaturity (such correlations were evident in the control groups).

PP4-81

PROGNOSTIC FACTORS IN DIFFERENT MORPHOLOGICAL VARIANTS OF RENAL CELL CARCINOMA (RCC) (ESPECIALLY IN RCC WITH SARCOMATOID FEATURES)

Malgorzata Janicka-Jedynska, Aldona Wozniak, Jakub Zurawski, Elzbieta Kaczmarek, Joanna Bulak-Joniec
Department of Clinical Pathomorphology, Karol Marcinkowski University of Medical Sciences, Ponzań, Poland

Introduction: There is increasing incidence of RCC, when the biological behaviour may be different, thus commonly used prognostic factors are not always sufficient in predicting prognosis. Because of many possibilities of treatment, the choice of the best therapy is of importance and searching for better prognostic markers is necessary. Abnormal expression of E-cadherin and MUC1 has been associated with penetration by neoplastic cells. Inhibitors of cycline kinase (p21, p27) are responsible for antiproliferative properties. Morphological subtypes of RCC may contain sarcomatoid areas related with poor prognosis. The aim was to evaluate the expression of above mentioned markers with respect to histological and clinical features. MATERIAL AND METHODS: We investigated the expression of E-cadherin, MUC1, p21, p27 in 64 cases of RCC (5-7 years of follow-up): 32 conventional RCC (CRCC), 12 papillary (PRCC), 10 chromophobe (CHRCC) oraz 10 with sarcomatoid areas. RESULTS: The expression of E-cadherin and MUC1 substantially differed between studied groups. The strongest E-cadherin immunoreactivity was observed in CHRCC, less intense in PRCC and in CRCC. It was only focal in sarcomatoid areas. A diffuse cytoplasmic staining pattern for MUC1 was noted in CHRCC, whereas PRCC and CRCC showed predominantly membranous reaction. The appearance of strong cytoplasmic immunoreactivity for MUC1 in CRCC and

sarcomatoid areas was related with higher grade of malignancy and poor prognosis. Differences with regard to p21 and p27 immunoreactivity were also observed. The lowest number of positively-stained nuclei was noted in CRCC and in sarcomatoid areas. Higher percentages were counted in PRCC and the highest in CHRCC.

PP4-82
IMMUNOHISTOCHEMICAL STUDY OF TUBULOINTERSTITIAL INFLAMMATORY CELL INFILTRATION IN HUMAN GLOMERULONEPHRITIDES

Gordana Petrusevska[1], Slavica Kostadinova-Kunovska[1], Ladislava Grcevska[2], Vesna Janevska[1], Rubens Jovanovic[1], Momir Polenakovic[2]
[1] Institute of Pathology, Faculty of Medicine, Skopje, Macedonia
[2] Department of Nephrology, Clinical Center, Skopje, Macedonia

The importance of the interstitial aspects of primary glomerular disease to overall renal function is continuously increasing. The aims of this study were to characterize the mononuclear inflammatory cells in the tubulointerstitium of the renal biopsies affected by glomerulonephritic lesions using a panel of monoclonal antibodies specific for leukocytic subpopulations. Correlations with tubulointerstitial changes and main clinical parameters of renal function were done. Methods: Renal biopsies from 50 patients with glomerulonephritides were studied. Ten control normal sections were obtained from kidneys removed for localized tumors. Paraffin sections were stained with HE, PAS, trichrom Masson, silvermethenamine Jones, as well as immunohistochemically with the following monoclonal antibodies: LCA, CD43, CD20, CD68, HLA-DR, E-cadherin. The morphometric analyses were done on sequentially taken images avoiding glomeruli and large vessels with an image analyzing system LUCIA M–NIKON. The extent of interstitial fibrosis was examined on trichrom staining. Results: 98% of the cases showed interstitial fibrosis higher than 9% of the surface of the total cross section, with a mean value of 18,75%. Mononuclear inflammatory infiltrate in the interstitium, mainly with focal distribution, was noticed in 90% of the cases. T lymphocytes were predominant (mean value 58,26%), the B cells were 18,62% and the macrophages were present with mean value of 22,92%. Positivity for HLA-DR showed 40,86% of the total inflammatory cells, a significantly higher value than the control group (23,5%). The tubular epithelial cells also showed higher expression for HLA-DR than the control group. The tubular cells, especially in cases with abundant inflammatory infiltrate manifested decreased expression for E-cadherin in comparison to the control group. Each of the inflammatory cells subpopulations, as well as the total inflammatory infiltrate showed strong correlations with the interstitial fibrosis. The clinical data showed strong association of the serum creatinine concentration with the number of cells from each of the leukocytic populations, as well as the total inflammatory cell count (Spearman R ranged between 0.44 and 0.47) and no correlation with the proteinuria. Conclusion: We can conclude that the interstitial inflammatory substrate may influence tubulointerstitial changes in the primary glomerulonephritides, as well as to determine the long-term prognosis of the disease, which implies further investigations in this field.

PP4-83
PRIMARY NON-HODGKIN LYMPHOMA OF URINARY BLADDER WITH RENAL INVOLVEMENT NINE YEARS LATER AND ABSENCE OF SYSTEMIC LYMPHOMA. A CASE REPORT

Jasmina Marković-Lipkovski[1], Tatjana Terzić[1], Sanja Radojević[1], Vesna Čemerikić-Martinović[2], Vitomir Govedarović[1], Gordana Basta-Jovanović[1], Radmila Stevanović[1], Dragan Mitrović[1], Biljana Stojimirović[3]
[1] Institute of Pathology, School of Medicine University of Belgrade, Serbia
[2] Institute of Hematology, Clinical Centre of Serbia, Belgrade, Serbia
[3] Institute of Urology and Nephrology, Clinical Centre of Serbia, Belgrade, Serbia

Background. Primary bladder non-Hodgkin lymphoma (PBNHL) is very rare, especially as extranodal B-small lymphocytic lymphoma (B-SLL). Also, late isolated renal manifestation of PBNHL is extremely unusual. Case report. A 56-year-old woman was presented with a solitary tumor of bladder wall, with history of dysuria and night sweating. She underwent ultrasound, computed tomography (CT) and laparatomy which showed a solitary round tumor situated at the left lateral bladder wall. A transvaginal needle biopsy of the tumor was performed and diagnosis of primary extranodal B-SLL was made in the absence of bone marrow, lymph node or blood involvement. She was treated for 6 months with chemotherapy (LOP protocol) until achievement of complete remission, confirmed by CT and cystoscopy. Nine years later, she developed nephrotic syndrome and impairment of renal function. The renal tissue, obtained by percutaneous biopsy, was also diffusely infiltrated by small lymphoma cells with widespread tubulointerstitial destruction. Biopsy specimen showed a few glomeruli with focal segmental mesangial sclerosis and capsular adhesion, associated with segmental glomerular depositions of IgM detected by immunofluorescent microscopy. Thus, typical lesions for focal segmental glomerulosclerosis were observed. Immunohistochemical analysis of lymphoma cells infiltrating renal parenchyma and bladder wall revealed the same immunophenotype of lymphoma cell: LCA+, CD79a+, CD20+, CD5+, CD23+/−, CD43+/−, bcl-2+, CD3−, CD45RO−, bcl-6−, Cyclin D1−, with very low proliferative activity (less than 5% Ki-67+ cells). A diagnosis of B-SLL was confirmed. Conclusion. Here we present a case of PBNHL with late isolated renal involvement, manifested with nephrotic syndrome. Widespread destruction of tubulointerstitium led to decrease of renal function. Glomerular changes typical for focal segmental glomerulosclerosis caused nephrotic syndrome. Glomerular lesions could be due to glomerular overloading phenomena because of large destruction of renal parenchyma with lymphoma cells.

PP4-84
DIABETIC NEPHROPATHY ASSOCIATED WITH CRESCENTIC PROLIFERATION

Eugen Mandache[1], Mihaela Gherghiceanu[1], Gabriel Mircescu[2]
[1] 'V. Babes' National Institute of Pathology Bucharest, Romania
[2] 'C. Davila' Hospital for Nephrology, Bucharest, Romania

The purpose of this study was to investigate the cell types involved in the extra-capillary proliferation occurred in two cases of diabetic nephropathies. During the last couple of years, 14 renal biopsies with diabetic nephropathy have been thoroughly investigated for nephropathologic diagnosis. Two cases of already known diabetic patients have been found to develop extra-capillary proliferation featuring cellular crescents, segmental or circumferential, here and there developing epithelial, tubular profiles. Since the literature does not mention such an association, the problem raised is if this extra-capillary proliferation belongs to the diabetic pathology, or it is a

consequence of some superimposed lesions. In one case the proliferation can be connected with some moderate IgA deposits, while in the second we could not find any other explanation. The crescentic proliferations have been thoroughly investigated in immunofluorescence, light and electron microscopy. One first remark was that all glomeruli with crescents had an intact basement membrane of Bowman capsule. The crescents contained only epithelial cells and fibrin in some places. This comes in agreement with the hypothesis that all monocytic cells penetrate the crescents from the periglomerular area through capsular breaks. A second remark concerns the glycogen content of proliferated parietal epithelial cells. While usually parietal epithelial cells are reach in glycogen rosettes, our samples showed crescents of clear cytoplasm cells with little glycogenic granules. The general conclusion was that in some conditions of diabetic nephropathy, injured glomeruli may develop extra-capillary proliferation with some distinct characteristics.

PP4-85

COMPLEMENT C3 AND HYALINE VASCULAR DEPOSITS IN IgA NEPHROPATHY

Mihaela Gherghiceanu[1], Eugen Mandache[1], Gener Ismail[2], Mihai Voiculescu[2], Sergiu Dumitrache[3]
[1] 'V. Babes' National Institute of Pathology, Bucharest, Romania
[2] Department of Internal Medicine-Nephrology, Fundeni Institute, Bucharest, Romania
[3] 'Carol Davila' Hospital for Nephrology, Bucharest, Romania

The aim of the study was to examine adult patients with IgA nephropathy (IgAN)and to analyze the effect of the clinical data and vascular lesions on renal failure progression. The clinical and pathologic materials of 25 IgAN patients were analyzed. The clinical data and histological features were recorded for each patient. The semiquantitative quantification was done for complement C3c and C3d vascular deposits evaluation. Clinical parameters were assessed at the known onset of the disease, at the time of renal biopsy, at the last outpatient check-up. Statistical analysis was done by segmentation, using the CHAID algorithm, included in the SPSS software. Hypertension was identified as the risk factor with the greatest impact upon risk of progression to renal failure among these patients ($p<0.0001$). Severe vascular lesions were significantly correlated ($p<0.005$) with a renal failure progression. Arteriolar C3c deposits were observed in 86.6% biopsies with IgAN, even in the biopsies from normotensive patients. Perinuclear vacuoles were observed in the smooth muscle cells in cases with C3c deposits in periglomerular arterioles in the biopsies from normotensive patients. The C3c and C3d deposition along the interstitial vascular wall was more severe in those with vascular lesions than in those without vascular lesions. C3d deposits were observed in arteries, arterioles and peritubular capillaries in all cases with hyaline vascular deposits. We have found focal arteriolar hyaline deposits, mostly in a nodular form, at the junction between arteriole and glomerular hilus in 48% of IgAN. The glomerular hilus was thickened and mesangium was enlarged at the vascular pole. Arteriolar hyaline deposits were correlated with development of the interstitial fibrosis and the percentage of C3d deposits area (morphometry – ImageJ). Vascular and tubulointerstitial lesions were identified as the most accurate histological prognostic factors regarding future evolution of IgA nephropathy. We suggest that complement activation at vascular level precede vascular lesions and subsequent hypertension. C3d vascular deposits and vascular hyaline reflect the disease degree and can be used as an important histological prognostic indicators.

PP4-86

SIGNIFICANCE OF CLINICAL PARAMETERS AND MORPHOLOGICAL ALTERATIONS IN ADULT-ONSET MINIMAL CHANGE DISEASE

Kemal Kosemehmetoglu, Dilek Ertoy-Baydar
Department of Pathology, Hacettepe University School of Medicine, Ankara, Turkey

BACKGROUND: Minimal change disease (MCD) in children is the major cause of nephrotic syndrome with good prognosis, while adult-onset MCD has some differences such as slower response to corticosteroids and subsequent relapses. It has been reported that light microscopical and immunofluorescense may affect the response to steroid therapy and the long-term course. METHODS: Among the glomerular pathologies diagnosed by kidney biopsy between 1981 and 2006, we selected 18 adult patients whose biopsy result was the MCD. Clinical information was obtained from the hospital charts. The histologic sections were re-evaluated and morphological features were noted. RESULTS: The median age at diagnosis was 32.5 years, %66 of the patients were younger than 40. The male to female ratio was 1.25. Swelling of legs and periobital edema were the most common presenting symptom. Six patients had hypertension. The mean daily proteinuria was 3.95 g/day and serum albumin level was 2.5 mg/dl. Serum creatinine was high in 24% of cases. Urinalysis showed microscopic hematuria in 38% of patients, granular/hyaline casts in 57%. Hypertriglyceridemia and hypercholesterolemia were detected in 81% at presentation. In one patient, NSAID use was a suspect in etiology. The mean number of glomeruli per biopsy was 27 with 11% average ratio of global sclerosis. There were mesangial widening in 6 cases, trace amounts of immune deposits (C3, IgM or IgA) in 8. Arterial and/or arteriolar nephrosclerosis was noted in 9 patients. Five biopsies revealed mild interstitial inflammation. Clinical follow-up data were available on 12 cases. Mean follow-up period was 66 months (range, 8-204 months). Four patients experienced complete remission with no relapse. 5 patients had multiple relapses, 3 of which responded cyclosporine therapy. Time to relapse varied between 6 to 80 months. Presence of microscopic hematuria was the only parameter that is likely to correlate with the development of relapse ($p=0.07$). In all patients renal function was preserved after treatment. CONCLUSIONS: MCD is typically expected to show no abnormalities in light microscopy. However, there may be minor light microscopic alterations in some cases. In our study group composed of adult patients, neither the presence of these changes nor trace positivity of immune reactants predict the patient's clinical course or responsiveness to steroid therapy. Hematuria is the only clinical parameter which was likely to associate with the occurrence of relapse. Adult onset MCD has a good long term outcome with well-preserved renal function.

PP4-87

HYDATIC CYST OF THE KIDNEY: A SERIES OF 39 CASES

Fakhfekh Ines, Khabir Abdelmajid, Kallel Rim, Abbes Karima, Sellami Ahmed, Gouiaa Noures, Fakhafakh Hamadi, Boudawara Tahya
EPS Habib Bourguiba SFAX, Tunisia

Introduction: Kidney's hydatic cyst was rare and characterised by its clinical characteristics and the therapeutic problems. The aim of this study was to identify the epidemilogic particularities, the diagnosis and therapeutic modalities of hydatic cyst in this exceptional localisation. Materials and methods We report a retrospective study relating to 39 cases of hydatic cyst of the kidney diagnosed and treated between 1982-2005 in Habib Bourguiba's hospital, during the same period 2377 cases of hydatic cyst were operated in the same hospital. Results The male/femaleratio was 0,42. The ages ranged from 6 to 69 years (mean age 42,5). Clinically, the flank pain represented the most

frequent symptomatology (86,5%), and cystic mass in 25 cases (62%), the hydaturia was present in 14% of cases. The intravenous urography highlighted a tumoral syndrome in 66,6% of the cases. Ultrasound evoked the diagnosis in 72,2% of the cases and classify the hydatic cyst according to Gharbi & coll's classification in type I (18 cases), type II (5 cases), type III (8 cases), type IV (6 cases) type V (2 cases). Computed tomography was practised among 6 patients. The treatment was surgical in all the case and often conservative (85%), the nephrectomy was practised in 6 cases (15%). The diagnosis was confirmed by pathologic exam. Discussion The renal's hydatic cyst accounts for 1.6% to 4% of all localizations in the human hydatidose. The clinical symptoms are variable. Imagery associated to serology allow to make the diagnosis. The treatment is surgical.

VASCULAR ENDOTHELIAL GROWTH FACTOR IN RELATION TO NUCLEAR FACTOR – KAPPA B IN RENAL CELL CARCINOMA

Gordana Dordevic[1], Koviljka Matusan[1], Emina Sinozic[1], Vanja Licul[2], Blazenka Grahovac[1], Nives Jonjic[1]
[1] Department of Pathology, School of Medicine, University of Rijeka, Croatia
[2] Clinical Hospital Centre Rijeka, Croatia

Objective: Renal cell carcinoma (RCC) is a malignancy with variable clinical course, partly attributable to specific genetic alterations of the different RCC types. Angiogenesis is important for tumor progression and metastatic spread. VEGF is a major factor which regulates angiogenesis while the nuclear factor-kappaB (NF-kB), a family of transcription factors; regulate a wide variety of cellular processes including cell growth, differentiation and apoptosis. The aim of this study was to evaluate the expression level of VEGF and to compare their values with the subcellular localization of NF-kB, proliferative rate of tumor cells and clinicopathological characteristics of RCC. Material and method: Immunohistochemical evaluation included VEGF expression, the subcellular localization of p65 member of NF-kB and Ki67 for proliferative rate of tumor cells in series of 16 RCC. Total RNA was extracted from the same tumor tissue samples, previously snap-frozen. Expression of VEGF was analyzed using quantitative Real-time PCR. Results: The difference in VEGF mRNA levels between conventional (11 clear cell RCC) and other histological types of RCC was not significant. Preliminary results indicate a more pronounce heterogeneity in VEGF expression within the group of clear cell RCC. VEGF mRNA levels show some positive association with VEGF protein expression evaluated as the percentage of positive cells and intensity of staining within the cells, while there was no association with NF-kB and Ki67. Larger tumors were characterized with higher value of VEGF expression, NF-kB and Ki67 and, moreover, the proliferation rate of tumor cells was higher in tumors with higher VEGF expression. Conclusion: Preliminary results indicate the heterogeneity in VEGF expression in conventional type of RCC. The association with tumor progression (tumor size and proliferation rate) indicates that VEGF is an important angiogenic factor in RCC. Although no association between NF-kB activity, VEGF expression and Ki67 was found on a small number of analyzed samples, our preliminary data suggest that the NF-kB may be important factor in renal carcinogensis by controlling cells proliferation. These findings need further validation of usefulness of NF-kB as a prognostic factor in RCC.

PP4-89

COLLOIDAL IRON STAINING PATTERNS IN RENAL CARCINOMA TYPES AND CORRELATION WITH ELECTRON MICROSCOPIC FINDINGS

Ipek Isik Gonul, Gonca Barit, Leyla Memis, Omer Uluoglu
Gazi University School of Medicine, Department of Pathology, Ankara, Turkey

Background: Morphologically overlapping features of granular cytoplasm in clear cell carcinomas, chromophobe cell carcinomas and renal oncocytoma may cause difficulties in definitive diagnosis on light microscopic examination. Colloidal iron staining is considered to be characteristic for chromophobe renal cell carcinomas. In this study, our aim was to evaluate the colloidal iron staining patterns systematically in a spectrum of renal neoplasms and compare the findings with ultrastructural features. Method: We studied 116 cases of renal tumors which consisted of 93 clear cell carcinomas with different growth patterns and Fuhrman grades, 6 chromophobe cell carcinomas, 3 angiomyolipomas, 5 pelvic urothelial carcinomas, 5 papillary carcinomas, 2 oncocytomas and 2 collecting ductus carcinomas. One diagnostic paraffine section from each case was stained with colloidal iron by Hale's method. Following determination of the staining patterns, the sites of sections with spesific staining were marked on the paraffine embedded tissue blocks and these areas were evaluated by electron microscopy after de-paraffinization and re-prosessing for electron microscopy. Results: We observed that other renal cell carcinomas apart from chromophobe cell carcinomas showed colloidal iron positivity. Four types of staining patterns were identified as follows: diffuse, strong, reticular staining, diffuse but weak, homogeneous cytoplasmic staining, focal, apical cytoplasmic, finely granular cytoplasmic staining and finally coarse granular cytoplasmic staining. Strong reticular staining was the only pattern observed in chromophobe cell carcinomas. On the other hand, other 3 patterns were seen in clear cell and papillary carcinomas together with renal oncocytomas. Urothelial carcinomas, angiomyolipomas and collecting ductus carcinomas were all negative. The ultrastructural features, particularly regarding the mitochondrial and microvesicular distribution were correlated with the light microscopic findings. Conclusion: Hale's colloidal iron and the presence of numerous microvesicles on ultrastructural examination have been considered characteristic for chromophobe renal cell carcinomas. However, this study clearly demonstrated that clear cell renal carcinomas, oncocytomas and even papillary carcinomas could be diffusely positive for colloidal iron. Although staining pattern significantly differ in these tumors, light microscopic and histochemical findings sometimes require an ultrastructural confimation for definitive diagnosis.

PP4-90

PATHOLOGICAL CHANGES IN KIDNEY BIOPSIES FROM PATIENTS WITH PLASMA CELL DYSCRASIA

Stela Bulimbasic[1], Arijana Racar-Pacic[1], Kresimir Galesic[2], Mirjana Sabljar-Matovinovic[3], Ivana Kovacevic-Vojtusek[4], Ivica Horvatic[2], Danica Ljubanovic[1]
[1] Department of Pathology, University Hospital Dubrava, Zagreb, Croatia
[2] Department of Nephrology, University Hospital Dubrava, Zagreb, Croatia
[3] Department of Nephrology, Clinical Hospital Merkur, Zagreb, Croatia

[4]Department of Nephrology, Vuk Vrhovac University Clinic for Diabetes, Endocrinology and Metabolic Diseases, Zagreb, Croatia

Background: Renal impairment/insufficiency are common systemic complications of many hematological malignancies and they also occur in the majority of patients with plasma cell dyscrasia. To analyze incidence and clinico-morphological presentation of kidney involvement during plasma cell dyscrasia, retrospective analysis was performed. Methods: Patients with diagnosis of plasma cell dyscrasia with kidney involvement were identified from Renal non-tumor pathology Registry at Department of Pathology, University Hospital Dubrava. All the light microscopy glass slides (H&E, PAS, Masson, Jones and Congo special stain) were reviewed, along with material used for immunofluorescence and EM analysis. Results: During period

from October 2003 to March 2007, 397 native kidney biopsies were analyzed. Kidney biopsies from 20 (5.04%) patients showed histological features consistent with diagnosis of plasma cell dyscrasia. This group included 7 male and 13 female patients. Patient age ranged from 38 to 76 years, median 60.9 years. All of them had proteinuria, which in 5 patients progressed to the nephrotic syndrome. An acute renal insufficiency were noted in 3 and chronic renal insufficiency in 4 patients. The most common histological patterns of renal involvement were AL amyloidosis (8 patients, 40 %) and cast nephropathy (7 patients, 35 %). In the remaining 5 patients, an acute tubular damage (3 patients, 15 %) and tubulointerstitial nephritis (2 patients, 10 %) were noted. Previous diagnosis of AL amyloidosis or immunoproliferative disorder/plasmocytoma had 4 and 3 patients respectively, while in the majority of patients, hematological evaluation and confirmation of diagnosis were completed after kidney biopsy. Discussion and conclusion: The plasma cell dyscrasia is frequently used as generic term for description of three distinct clinical entities: multiple myeloma, monoclonal gammopathy of unknown significance and dysproteinemia. They all have frequent renal involvement in common which can either present the first manifestation, or can occur later, during the course of disease. Morphological patterns of involvement vary, depending on which renal compartment is predominantly targeted. Commoner tubulopathic manifestation include Fanconi's syndrome and cast nephropathy, while glomerular damage can be manifested as AL amyloidosis or monoclonal immunoglobulin deposition disease. Using combination of light microscopy, immunofluorescence and EM, all of them can be properly diagnosed in kidney biopsy, which is important for later clinical management and therapy.

PP4-91

PRIMARY EXTRASKELETAL MESENCHYMAL CHONDROSARCOMA OF THE KIDNEY OF A YOUNG WOMAN: MORPHOLOGIC, IMMUNOPHENOTYPIC AND ULTRASTRUCTURAL ANALYSES: A CASE REPORT AND REVIEW OF THE LITERATURE

Ozlem Yapıcıer[1], Saime Sezgin Ramadan[1], Abdurrahman Ozgur[1], Kutlay Karaman[2], Levent Turkeri[3]
[1] Department of Pathology, Anadolu Health Care Center, Kocaeli, Turkey
[2] Department of Radiology, Anadolu Health Care Center, Kocaeli, Turkey
[3] Department of Urology, Anadolu Health Care Center, Kocaeli, Turkey

Background: Extraskeletal mesenchymal chondrosarcoma is a rare tumor that has been reported mostly in neurosurgical and orthopedic literature. Five cases of primary renal extraskeletal mesenchymal chondrosarcoma are reported in the English literature with a variable, nonspecific presentation and relatively an aggressive behaviour. We present a case of primary extraskeletal mesenchymal chondrosarcoma of the kidney in a 28-year-old woman. We describe the radiologic, light microscopic, immunohistochemical and ultrastructural features of the case and discuss the differential diagnosis of the ekstraskeletal mesenchymal chondrosarcoma at this unusual site. Case: Following an episode of macroscopic hematuria, a 28-year-old woman underwent a radical nephrectomy for a radiologically confirmed right-sided renal mass. A radical nephrectomy was performed. Since the computed tomograms of the chest, abdomen, and pelvis showed no other lesions or evidence of metastatic disease, the histopathologic diagnosis is primary renal ekstraskeletal mesenchymal chondrosarcoma with its typical combined undifferentiated mesenchymal cells and cartilage islands. Urinary system CT revealed a relatively well-demarcated 3-cm tumor with calcifications and peripheral enhancement associated with foci of hypodensity within enhancing solid components. Microscopically, the tumor was composed of primitive undifferentiated mesenchymal cells and well-defined islands of hyaline cartilage. The immunohistochemical study revealed diffuse vimentin positivity in the cytoplasm of the neoplastic cells. Pancytokeratin, epithelial membrane antigen, CD99, desmin and SMA were negative. S100 protein staining revealed dispersed positivity in cartilaginous areas. An electron microscopic study showed primitive precartilaginous mesenchyme displaying focal cartilaginous differentiation. Conclusion: The radiologic and the macroscopic aspect, together with the dual morphologic characteristics of differentiated cartilage islands interspersed within vascular undifferentiated mesenchyme, confirmed the diagnosis of primary extraskeletal mesenchymal chondrosarcoma of the kidney. In spite of its rarity, it is important to diagnose primary mesenchymal chondrosarcoma in kidney because its biological behaviour may be different from that of tumors of similar morphology. The differential diagnosis includes PNET/Ewing sarcoma and other rare sarcomas of kidney. The patient is free of disease nearly 13 months after its initial presentation.

PP4-92

ULTRASTRUCTURE OF GLOMERULAR DEPOSITS IN CRYOGLOBULINEMIA

Anastazija Hvala, Alenka Vizjak, Dusan Ferluga
Institute of Pathology, Faculty of Medicine University of Ljubljana, Ljubljana, Slovenia

Aims: Cryoglobulins are serum immunoglobulins precipitating at lower temperatures. They have been described as having a crystalline/fibrillar configuration. Our experience is not in line with such a description. Therefore, the aim of this study was to reevaluate systemically our kidney biopsy material with a particular emphasis to the ultrastructure of glomerular immune deposits in patients with primary and secundary cryoglobulinemia. Methods: In our archived bioptic material of 1992 kidney biopsies there were 18 biopsies of 14 patients with primary cryoglobulinemia (210-3600 mg/l) and 30 biopsies of 19 patients with autoimmune systemic connective tissue diseases, mostly systemic lupus erythematosus (SLE), and secondary mixed cryoglobulinemia (124-3300 mg/l). All biopsies were examind by light, immunofluorescence and electron microscopy (EM). For EM tissue samples were fixed in OsO4 and in some cases in formaldehyde, embedded in Epon 812 and stained with uranyl acetate and lead citrate. EM analysis of immune deposits was performed on highly magnified photos. Results: Deposits of various electron density were observed in glomeruli of all biopsies. In primary and in SLE associated cryoglobulinemia glomerular capillary wall deposits were found to be homogeneous or finely granular, with no evidence of any fibrillar structure. In 4 patients with SLE besides homogeneous, fingerprint deposits were also demonstrated. Glomerular and extraglomerular fingerprint deposits were demonstrated in two patients with low cryoglobulin levels, one with primary Sjögren's disease and the other with non-classified autoimmune systemic disease. In a patient with glomerular monoclonal IgG kappa deposits showing an ultrastructure of randomly oriented bundles of parallel fibrils described as characteristic for cryoglobulinemia type I, no detectable cryoglobulins were found in the serum. Conclusion: Our detailed EM study on kidney biopsy specimens reveals that glomerular immune deposits in patients with primary and secondary mixed cryoglobulinemia can be of various electron density, but usually homogeneous or finely granular. Furthermore, our study suggests that cryoglobulin deposits display an organised substructure with crystalline/fibrillar configuration, described originally in 1977 by Feiner and Gallo and frequently cited as characteristic, only occasionally in a minority of patients with cryoglobulinemia.

PP4-93
FSGS VARIANTS: CORRELATION OF HISTOPATHOLOGICAL FEATURES AND CLINICAL PRESENTATION
Guldal Yilmaz, Saba Kiremitci, Arzu Ensari
Ankara University Medical School, Department of Pathology, Ankara, Turkey

Background: Focal segmental glomerulosclerosis (FSGS) is a clinicopathologic syndrome characterized by nephrotic syndrome and glomerular sclerotic lesions. Recently, several morphologic variants of primary FSGS which have different prognostic and therapeutic implications were defined. These variants are (1) FSGS-Not Otherwise Specified (NOS), (2) FSGS-Cellular variant (CeV), (3) FSGS-with diffuse mesangial hypercellularity (DMH), (4) FSGS-Collapsing variant (CoV), (5) Glomerular tip lesion (GTL), and (6) C1q nephropathy. We have, therefore, decided to categorize the FSGS cases diagnosed in our Department and evaluate their clinical significance. Method: Renal biopsy samples of 48 cases of primary FSGS, which are stained with Hematoxylin and Eosin, periodic-acid Schiff, methenamin silver and trichrom, were revised and categorized according to the morphologic variant grouping. All cases were also examined by IFM and EM. Clinical data was retrieved from the patient files. Besides FSGS, the CeV is characterised by endocapillary hypercellularity occluding lumens while DMH has generalisad mesangial hypercellularity. The CoV has the wrinkled and collapsed glomerular basement membrane. GTL is defined by the presence of segmental lesions in the periphery of the glomerular tuft and synechia formation between the glomerular tuft and Bowman's capsule at the tubular pole. C1q nephropathy is defined by FSGS with variable mesangial hypercellularity and dominant paramesangial deposits of C1q. Results: Among these 48 cases, 11 (%22.9) were categorised as GTL, 5 (%10.4) as FSGS-CeV, 2 (%4.2) as FSGS-DMH, 2 (%4.2) as FSGS-CoV, 3 (%6.2) as mixed form of GTL and FSGS-DMH, 25 (%52.1) as FSGS-NOS. None of the cases was categorised as C1q nephropathy. IFM and EM did not show any difference between the variants of FSGS. Retrieving the clinical data, it was found that collapsing variant presented with proteinuria alone, and FSGS-DMH with both proteinuria and hematuria. FSGS-NOS, GTL and mixed form presented with either proteinuria alone or with hematuria. FSGS-CeV, usually presented with proteinuria alone, but in one patient it was associated by hematuria. In one patient the clinical data was lacking. Conclusion: As recent studies showed that identifying the morphologic variants of primary FSGS may provide further prognostic and therapeutic implications clinically, the renal pathologists should try to evaluate the morphologic variants of FSGS. IFM and EM do not seem to be useful in the differential diagnosis of FSGS variants.

Pulmonary Pathology

PP4-94
THE EXPRESSION OF E-CADHERIN IN NON SMALL CELL LUNG CANCER
Chrisoula Tsobanidou[1], Doxakis Anestakis[1], Ioannis Dimitriadis[1], Jakob Anjel[2], Nikolaos Barbetakis[3], Frideriki Patakiouta[1]
[1] Department of Pathology, "Theagenio" Cancer Institute, Thessaloniki, Greece
[2] Pulmonology Department, "Theagenio" Cancer Institute, Thessaloniki, Greece
[3] Thoracic Surgery Department, "Theagenio" Cancer Institute, Thessaloniki, Greece

Background: Several diagnostic and prognostic markers are being used in recent years, in order to investigate the pathogenesis of lung cancer. E-cadherin is a related new, very promising marker in cancer research, which is not widely investigated in lung cancer. E-cadherin is important for cell-cell adhesion. Reduction and/or loss of E-cadherin expression in non-small cell lung cancer correlates positively with malignant transformation of tumor and with the potential of these tumors for invasion and metastasis. The aim of the present study was to examine immunohistochemically the expression of E-cadherin in non-small cell lung cancer (NSCLC) and their relationship with clinicopathologic parameters such as histological type, grade, tumor size, sex ad age of the patients. Material and Methods: Adenocarcinomas, squamous cell carcinomas and large cell carcinomas fall within the spectrum of NSCLC. 42 patients (19 women and 23 men) with NSCLC treated surgically were examined retrospectively. The tumor specimens have been immunostained for E-cadherin. The tumors were squamous cell carcinomas (12 cases), adenocarcinomas (18 cases) and large cell carcinomas (14 cases). The age of the patients ranged from 44 to 78 (mean age 65 years). Immunohistochemistry was performed using an avidin-biotin complex method and monoclonal antibody against E-Cadherin. Membrane and cytoplasmic staining in >50% of tumors cells was considered as a positive expression of E-Cadherin. Results: Impaired E-cadherin expression (loss or cytoplasmic delocalization <50% of cells) was observed in 36 (85,7%) of 42 samples. Absent or reduced expression of E-cadherin was observed in 10(83,3%) squamous cell carcinomas , 13(72,2%) adenocarcinomas and 13(92,8%) large cell carcinomas. The Impaired expression of the E-cadherin was observed with a higher frequency in high- grade (squamous cell carcinomas and adenocarcinomas) than in low grade tumors (squamous cell carcinomas, adenocarcinomas and large cell carcinomas) 82% and 48% respectively, ($p<0.0001$). No relationship was found between E-cadherin impaired expression and tumor size or sex of the patient. Absent or reduced expression was seen in advanced age of the patients. Conclusion: Impaired E-cadherin expression was fount more frequently in high grade and more aggressive histological type tumors and as well as in advanced age of the patients.

PP4-95
EXPRESSION OF CD44 AND MMP-2: POSSIBLE ASSOCIATION WITH HISTOPATHOLOGICAL FEATURES OF INTRATHORACIC SOLITARY FIBROUS TUMORS
Funda Demirag[1],Ebru Cakir[1],Sibel Alpar[2],Irfan Tastepe[2],Sadi Kaya[3]
[1] Ataturk Chest Diseases and Chest Surgery Education and Research Hospital, Turkey
[2] Ataturk Chest Diseases and Chest Surgery Education and Research Hospital, Department of Chest Diseases, Turkey
[3] Ataturk Chest Diseases and Chest Surgery Education and Research Hospital, Department of Chest Surgery, Turkey

Background: Recent researches had showed that tumor cell adhesion molecular CD44 and matrix metalloproteinases (MMP-2) were expressed strongly in many tumors, and was associated closely with invasion and metastasis of the tumors. Although solitary fibrous tumors (SFT) have a good prognosis , a minority

bahave malignant. The aim of this study was to analyze CD44 and MMP-2 expression to question histopathological parameters. Method: We reviewed 10 patients who had undergone surgical resections for benign or malign SFT . Clinical findings and follow–up informations were obtained for all patients. Haemotoxylen-Eosin stained sections were reexamined for evalution of histopathological parameters (degree of cellularity, keloidal type collagen deposition, perivascular hyalinization, hemangiopericytoma-like area, nuclear pleomorphism, number of mitoses, necrosis, cyst formation, myxoid areas). All cases were positive for CD34. Immunostaining of CD44 and MMP-2 were performed by using the streptavidin-biotin method with mouse monoclonal antibody. The intensity of CD44 and MMP-2 were evaluated by light microscopy. Results: 10 patients underwent surgical resection . 8 SFT were benign and 2 SFT were malign. There were 3 men (%30) and 7 women (%70) of a mean age of 54.5 years (range 30 to 71 years). One patient had a history of asbestosis exposure . Complete resection was performed in all cases. The tumor arising from pleura was excised with pleurectomy. In one embedded intraparenchimal tumor, pneumonectomy was performed. According to England criteria, 2 malign SFT were contained multiple masses. 3 cases originated in the right hemithorax and 7 in the left. Tumor size ranged from 4.5-27 cm. Coagulative necrosis was observed in 2 benign SFT and 2 malign SFT. All cases expressed strong CD44. However only 2 malign SFT expressed focal MMP-2. Conclusion: Although MMP-2 positivity was observed in 2 malign cases, CD44 positivity was not associated with malignant criteria in solitary fibrous tumors.

PP4-96

MUC-1 EXPRESSION IN BENIGN PULMONARY LESIONS AND NORMAL LUNG TISSUES

Funda Demirag[1], Ebru Cakir[2], Hulya Bayız[3], Saliha Battal[3]
[1] Ataturk Chest Diseases and Chest Surgery Education and Research Hospital, Turkey
[2] Ataturk Chest Diseases and Chest Surgery Education and Research Hospital, Deparment of Pathology, Turkey
[3] Ataturk Chest Diseases and Chest Surgery Education and Research Hospital, Department of Chest Diseases, Turkey

Background: The mucin MUC-1, encoded on chromosome 1q21, is a high molecular weight transmembrane glycoprotein and is expressed normally at the apical borders of epithelial cells in the breast , colon, and lung. Expression of MUC-1 has several effects in cells, including inactivation of integrin mediated cell to matrix adhesion and E-cadherin mediated cell to cell adhesion as well as protection from cytotoxic lymphocyte. Our aims were to study association between the expression of MUC-1 and biologic nature benign pulmonary lesions and normal lung tissues. Method: We selected 4 intrapulmonary bronchogenic cyst, 2 sclerosing haemangioma, 2 usual interstitial pneumonia , 1 adenoid cystic malphormation and 16 normal lung tissues. Normal tissues were obtained from histologically normal lung tissue adjacent to carcinoma. Among the neoplatic tissues 9 were adenocarcinomas, 5 squamous cell carcinomas, 1 adenosquamous carcinoma and 1 mucinous type bronchioloalveolar carcinoma. Two normal lung tissues contained atypical adenomatous hyperplasia. MUC-1 expression was assessed by immunohistochemistry with monoclonal antibody against MUC-1 mucin. Membranous staining for MUC-1 was divided into complete and incomplete staining. Results: Apical surface of upper respiratory epitelium in all cases were stained completely with MUC-1. The surface cells in sclerosing haemangioma and atypical adenomatous hyperplasia were strong complete positive for MUC-1. The positivity with MUC-1 in normal tissues around the adenocarcinomas was stronger than squamous cell carcinoma. Conclusion: Complete MUC-1 positivity showed type II pneumocyte lineage. This feature will facilitate differential diagnosis of based type II pneumocyte pulmonary lesions.

PP4-97

HISTOLOGICAL FINDINGS IN CARDIOGENIC ALVEOLAR-CAPILLARY BARRIER DAMAGE

Mauro Canzian[1], Felipe Zampieri[2], Edwin Parra[2], Ronaldo Kairalla[3], Vera Capelozzi[2]
[1] Division of Pathology, Heart Institute (InCor), School of Medicine, University of São Paulo, SP, Brazil
[2] Department of Pathology, School of Medicine, University of São Paulo, SP, Brazil
[3] Division of Respiratory Diseases, Heart Institute (InCor), School of Medicine, University of São Paulo, SP, Brazil

Background: Chronic heart failure increases resistance to gas transfer across the alveolar-capillary interface. Acute pressure or volume overload can injure the alveolar blood-gas barrier. These alterations are generally reversible due to the reparative properties of the alveolar surface. However, when alveolar-capillary membrane is chronically challenged, remodeling of pathophysiologic and clinical parameters may take place. The resulting pulmonary histological changes in surgical lung biopsy specimens have been barely exploited. Method: We examined medical records of all cardiac patients with chronic heart failure, presenting lung diffuse infiltrates, who underwent surgical lung biopsy, from January 1982 to December 2005. Patients with congenital cardiopathy, infectious manifestations or under immunosuppressive treatment were excluded. Twenty-four patients met our study criteria. Histological features including alveolar collapse, edema, protein deposition, hemossiderin-laden macrophages accumulation and hemorrhage, venous and lymphatic ectasia, vascular sclerosis, capillary congestion and fibroblast foci were studied. Results: Twenty patients were men and 4 women, with a median age of 54 years (range 16 to 79 years). The main chronic heart failure causes were myocardial ischemia, heart valve diseases and dilated hypertensive and Chagas cardiomyopathies. Based on alveolar-capillary barrier changes three main groups were created. Group I comprised acute cardiogenic pulmonary edema, ranging from minimal "cuff" around of bronchovascular axis to severe alveolar fluid accumulation. The second group comprised chronic capillary congestion presenting different degrees of septal thickening, capillary dilatation and hemossiderin-laden macrophages alveolar accumulation. Group III were histologically characterized by diffuse alveolar damage, in focal or segmental distribution. In 3 of 5 patients belonging to group I, acute cardiogenic pulmonary edema was the main change due to myocardial ischemia. Among the 11 patients belonging to group II, 4 had myocardial ischemia whereas 3 had heart valve disease. Diffuse alveolar damage, found in 7 patients, didn't show any clinical picture predominance. Conclusion: Alveolar-capillary barrier injury due to chronic pressure or volume overload is manifested through different patterns of histological changes which recognition can influence prognosis and treatment. Patients with chronic heart failure should be evaluated to establish treatment protocols for acute pulmonary edema, chronic passive congestion and diffuse alveolar damage.

PP4-98

INTENSITY OF LUMINAL ALVEOLITIS IN PULMONARY TUBERCULOSIS

Zdravko Kosjerina
Institute of Lung Diseases, Serbia

Material and methods: Material of the study included the transbronchial biopsy samples obtained from 30 tuberculous patients. The quantity of inflammatory and immunocompetent cells was estimated by stereometric method numerical density. The term "perigranulomatous alveoli" is used to denote the alveoli surrounding a granuloma at the distance of 100 microns from its external edge. The remaining alveoli are refered to as "the alveoli far away from a granuloma". Results: Numerical density of all cells found in the lumen of the alveoli far away from a granuloma ranges between 18.327/mm^3 and 96.120/mm^3,

the mean value being 43.042/mm^3. Lymphocytes predominate - 21.778/mm^3 (50.6%), followed by macrophages 19.916/mm^3 (46.3%). Numerical density of all cells present in the lumen of perigranulomatous alveoli is found to range from 14.639/mm^3 to 197.628/mm^3, the mean value being 74.662/mm^3. Lymphocytes predominate 42.460/mm^3 (56.9%), followed by macrophages 29.555/mm^3 (39.6%). Discussion: The presence of inflammatory and immunocompetent cells on the surface and in the lumen of the alveoli accounts for luminal alveolitis. The presence of these cells in the lumen of the perigranulomatous alveoli accounts for perigranulomatous luminal alveolitis which has a significantly higher intensity than the luminal alveolitis in the alveoli far away from a granuloma. Thus the intensity of perigranulomatous luminal alveolitis is found to be 74.662 cells/mm^3, while the intensity of the luminal alveolitis in the alveoli far away from a granuloma is 43.042 cells/mm^3. Conclusion: Perigranulomatous luminal alveolitis in tuberculosis is 1.7 times as intense as alveolitis in the alveoli far away of a granuloma.

PP4-99

COMPARISON OF OSTEOPONTIN, β-CATENIN AND HNRNP B1 EXPRESSION IN LUNG CARCINOMAS

Muhammet Emin Guldur[1], Yasemin Kibar[2], Hale Deniz[3], Kemal Bakir[2]
[1] Gaziantep Gynecologic and Obstetric Hospital, Gaziantep, Turkey
[2] Gaziantep University,Medical Faculty, Department of Pathology, Gaziantep, Turkey
[3] Gaziantep Pediatric Hospital, Gaziantep, Turkey

BACKGROUND: This study was performed to compare osteopontin, β-catenin and hnRNP B1 immunoreactivities in small cell lung carcinomas (SCLC) and non-small cell lung carcinomas (NSCLC). Correlation of these three antibodies with grade and stage in NSCLC was also investigated. METHODS: Twenty-nine SCLC, 6 large cell carcinoma, 36 adenocarcinoma and 30 squamous cell carcinoma (SCC), totally 101 cases, were included in this study. Osteopontin, beta-catenin and hnRNP B1 expressions were immunohistochemically evaluated. In addition, these immunoreactivities were compared with grade and clinicopathologic stage in NSCLC. RESULTS: Osteopontin positivity was 6.9% in SCLC and 67% in NSCLC. When NSCLC types were individually considered, osteopontin positivity was 66.7% in large cell carcinoma, 80% in SCC and 55.6% in adenocarcinomas. β-catenin positivity was observed in 49.3% of NSCLC and none of SCLC cases. These results were statistically significant ($p<0.05$). No statistically significant difference was found in RNP immunostaning between SCLC and NSCLC ($p>0.05$). Neither grade nor stage of NSCLC was correlated with osteopontin, β-catenin or hnRNP B1 immunoreactivity. CONCLUSION: We observed that osteopontin and β-catenin are useful in differentiating SCLC from NSCLC. In this study, grade and stage of NSCLC were not found to be correlated with any of three antibodies. We propose that osteopontin and β-catenin may be useful in discriminating NSCLC with neuroendocrine differentiation and high-grade neuroendocrine tumors of the lung.

PP4-100

GLUCOSE TRANSPORTER-1 EXPRESSION IN PULMONARY NEUROENDOCRINE CARCINOMA

İrem Hicran Ozbudak[1], Fabio Tavora[2], Negar Rassaei[2], Konstantin Shilo[2], Wei-Sing Chu[3], Junya Fukuoka[4], Jin Jen[5], William D Travis[6], Teri J Franks[2]
[1] Department of Pathology, University of Akdeniz, School of Medicine, Antalya, Turkey
[2] Department of Pulmonary and Mediastinal Pathology, Armed Forces Institute of Pathology, Washington, DC, USA
[3] Department of Scientific Laboratories, Armed Forces Institute of Pathology, Washington, DC, USA
[4] Laboratory of Pathology, Toyama Medical & Pharmaceutical University, Toyama, Japan
[5] Laboratory of Population Genetics, National Institutes of Health, Bethesda, MD, USA
[6] Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Malignant cells are known to have accelerated metabolism, high glucose requirement and increased glucose uptake. Transport of glucose across the cellular membrane is mediated by facilitative glucose transporter proteins. Glucose transporter-1 (GLUT-1) is one of 14 members of this family and is typically not detectable in normal tissue or benign lesions. Elevated levels of GLUT-1 expression and/or activation have been shown to be associated with malignancy. Since only limited studies address the issue of GLUT-1 expression in lung carcinoma, we sought to investigate its expression in pulmonary neuroendocrine carcinomas. Method: Tissue microarray based samples of 178 neuroendocrine carcinomas, including 48 typical carcinoids (TC), 31 atypical carcinoids (AC), 27 large cell neuroendocrine carcinomas (LCNEC), and 72 small cell carcinomas (SCLC) from different patients were studied immunohistochemically for GLUT-1 (Polyclonal, 1/300, Dako, Carpinteria, CA) expression. A composite score including distribution and intensity of labeling was compiled from each core. Correlation of GLUT-1 expression with clinical-pathological variables was performed utilizing SPSS 13.0 (SPSS Inc., Chicago, IL, USA). Results: Forty seven percent (75/161) of pulmonary neuroendocrine carcinomas were immunoreactive with GLUT-1. Distinct membranous staining was observed in neoplastic cells with concentration along the luminal border of tumor islands. Normal bronchial epithelium and alveolar pneumocytes were negative. GLUT-1 expression correlated with tumor differentiation/type, $p<0.001$: 6.5% (3/46) cases of TC, 20.7% (6/29) of AC, 73.9% (17/23) of LCNEC, and 77.8% (49/63) of SCLC were positive for GLUT-1. Five year survival of GLUT-1 negative neuroendocrine carcinomas was 61% versus 21% GLUT-1 positive cases ($p<0.001$); however, this correlation was not independent of tumor type/grade. There was no correlation between GLUT-1 expression and gender, tumor size or stage. Conclusion: GLUT-1 is expressed in approximately half of pulmonary neuroendocrine carcinomas and displays membranous staining with predilection for the luminal surface of tumor islands. GLUT-1 shows strong correlation with neuroendocrine carcinomas differentiation/grade, but not with other clinicopathologic variables.

NUCLEAR ROUNDNESS IN NEUROENDOCRINE TUMORS OF THE LUNG

Zaklina Mijovic[1], Dragan Mihailovic[1], Milos Kostov[2]
[1] Institute of Pathology, University of Nis, Serbia
[2] Department of Pathoanatomy, Military Hospital, Nis, Serbia

INTRODUCTION: The most recent WHO classification of pulmonary neuroendocrine tumors recognizes four entities: typical carcinoid, atypical carcinoid, large cell neuroendocrine carcinoma and small cell carcinoma. AIM: The aim of this study was to estimate nuclear size and roundness in carcinoid tumors and small cell carcinomas of the lung. MATERIAL AND METHODS: At Institute of Pathology, University of Nis five cases of typical carcinoid tumor and ten cases of small cell carcinoma of the lung were analyzed on biopsy samples obtained by fiberoptic bronchoscopy. After formaline fixation and paraffin embedding, serial histologic sections were routinely stained with H&E. The nuclear size et roundness were estimated using image analyzer LUCIA M 3.51 ab (Nikon) at objective 40x, after binary image editing. In each case a hundred nuclei were measured. A statistical analysis was performed using Mann-Whitney test. RESULTS: The roundness of nuclei in typical carcinoid tumor (0.963±0.007) was significantly larger than in small cell carcinoma of the lung (0.908±0.021), $p<0.01$. No significant differences in nucler size were found. CONCLUSIONS: The

authors conclude that nuclear shape is more rounded in neuroendocrine lung tumors of low-grade -typical carcinoids in comparison to high-grade tumors -small cell carcinomas. Further studies on a larger number of patients are required to confirm these findings. Key words: roundness, carcinoid, small cell carcinoma.

PP4-102
COEXISTING PULMONARY TUBERCULOSIS AND MULTIFOCAL PULMONARY CARCINOID IN THE SAME LOBE: A CASE REPORT

Fillinger Janos[1], Heiler Zoltan[2]
[1] Koranyi National Institute for Lung Diseases Budapest, Hungary, Department of Pathology, Hungary
[2] Semmelweis Medical University Budapest, Hungary, Department of Thoracic Surgery, Hungary

The synchronous occurance of lung carcinoma and tuberculosis is well known , but coexistens with carcinoid tumor is very rare. One case was mentioned in the literature. In our Institute between 2003-2006 among 96 cases was one patient. A 38 years old woman has observed on screening chest X-ray multiplex nodules in lower left lobes. TTB was taken but cytological examination reveal necrosis.Bronchoscopy was negativ too.The patient underwent surgery for lobectomy. Intraoperativ cytology shows necrosis. Mediastinal lymph node dissection was performed simultanously. The histology showed tuberculosis acino-nodosa caseosa and multifocal appearence of typical carcinoid.With Zeel-Nielsen stain can be found some acid stain rod shape bacilli in granulomatous nodules. Immunhistochemical reaction in tumor cells was positiv with NSE,Chromogranin-A, Synapthophysin and panCytokeratin. Gatrointestinal examination looking for primary site for tumor was taken with negativ findings, serum chromogranin was in normal range. The patient has got antituberculotic therapy.Apropos of this case authors would like to present the diagnostic difficulties of multiplex nodules of lung. Which nodules must be investigated?

PP4-103
EXPRESSION OF p63, K903, TTF-1 AND CK-7 IN LUNG CARCINOMAS AND DIFFERENTIAL DIAGNOSIS

Zekiye Aydogdu Dinc[1], Nur Yucel[1], A. Kadri Cirak[2], Gultekin Tibet[2]
[1] Izmir SS Chest Disease and Surgery Hospital, Department of Pathology, Izmir, Turkey
[2] Izmir SS Chest Disease and Surgery Hospital, Clinic of Chest Disease, Izmir, Turkey

Background: Lung carcinomas are the leading cause of death by cancer in the world both males and females.Accurate morphologic dictinction between small cell (SCLC) and non-small cell lung cancer (NSCLC) has therapeutic significance. However evaluating morphology can be limited by crush artifact, tumor necrosis, limited tumor representation and overlapping morphologic features in small biopsies. Method:In this study, we evaluated a panel of antibodies , containing p63, K903, TTF-1 and CK7, for their efficiancy in distinguishing between morphologic types of lung carcinoma by immunohistochemical method. Formalin fixed parafin embedded tissue section of 23 squamous cell carcinoma (SCC),12 adenocarcinoma (AC), 5 large cell carcinoma(LCC) and 6 small cell lung carcinoma(SCLC), that belong 46 patients underwent surgery and bronchoscobic biopsy (for only SCLC cases) were used. Results:High proportion of SCC were positive with p63(% 94) and K903 (%88), whole SCLC were positive with TTF-1 (100) and most of AK were positive with CK7 (%76). Staining patern in tumor cells especially for p63 changed with tumor differantiation . Conclusion: Accurate histologic typing of lung tumors can be evaluate with a panel of immunohistochemistry, especially in the little biopsies that have limited morphologic features.

PP4-104
IMMUNOHISTOCHEMICAL ANALYSIS OF COX-2 EXPRESSION PATTERN IN SPORADIC LUNG CARCINOMAS OF NEUROENDOCRINE ORIGIN

Christos Valavanis, Maria Lekarakou, Helen Siatra, Prokopis Vogiatzis, Maria Britsou, Joanna Lekka, Petroula Arapantoni-Dadioti
Molecular Pathology Unit, Dept of Pathology, METAXA Cancer Hospital, Piraeus, Greece

BACKGROUND-OBJECTIVE: Cyclooxygenases are proteins that mediate the conversion of arachidonic acid to prostaglandins and other biolactive lipids.Prostaglandins are involved in cell growth regulation, angiogenesis and metastatic process. Two COX isoforms have been identified COX-1 and COX-2. In normal cells the COX-1 is expressed constitutively whereas COX-2 is usually undetectable but rapidly inducible by a variety of stimuli. COX2 overexpression has been detected in various tumors such as colon, gastric, breast, prostate and lung carcinomas. Up-regulation of COX-2 has been associated with resistance to apoptosis, angiogenesis, tumor invasiveness and poor prognosis. Deletion of COX-2 and selective COX-2 inhibitors can prevent lung cancer growth suggesting a promising therapeutic approach. Although a number of studies on COX-2 expression in NSCLC have been published, little is known on its expression in other types of lung carcinomas such as small cell carcinoma (SCLC) which is characterized by aggressiveness and chemoresistance. In this context we investigated the expression of COX-2 and its cellular and subcellular distribution in carcinomas of neuroendocrine origin such as SCLC and LCNEC (large cell neuroendocrine carcinoma). We also compared the COX-2 tumor expression levels to those of normal lung tissue obtained from the same patients.MATERIALS AND METHODS: Retrospective study of 90 cases of sporadic lung carcinomas of neuroendocrine origin (63 SCLC, 1 SCLC combined with adenocarcinoma component, 26 large cell neuroendocrine carcinoma LCNEC) obtained by bronchoscopic biopsies or FNBs and tumor or lung lobe resections. IHC detection of COX-2 protein expression using anti-COX-2 monoclonal antibody (clone COX 229, 1:100 dilution) and semiquantitative assessment of the expression levels.RESULTS AND CONCLUSIONS: A. In normal lung cells COX-2 expression was absent and rarely weak B. COX-2 expression in carcinomas was mainly cytoplasmic as follows : SCLC (N=59, ND=4) 28.8% with 3+ immunostaining, 25.42% with 2+, 30.5% with 1+ and 15.25% absence of expression, SCLC combined 1/1 with 3+ expression and LCNEC 30.77% displayed 3+ immunoreactivity, 11.54% moderate, 46.15% weak and 11.54% no expression. No significant tumor cell COX-2 expression heterogeneity was observed. In conclusion COX-2 expression was higher in tumor cells compared to normal ones suggesting a putative role of COX-2 in SCLC and LCNEC tumor progression and a promising therapeutic intervention by using selective COX-2 inhibitors against neuroendocrine lung tumors.

PP4-105
IMMUNOHISTOCHEMICAL ANALYSIS OF VASCULAR ENDOTHELIAL GROWTH FACTOR SECRETIVE ISOFORMS VEGF121, VEGF165 AND VEGF189 EXPRESSION PATTERN IN SPORADIC SMALL CELL AND LARGE CELL NEUROENDOCRINE LUNG CARCINOMAS

Christos Valavanis, Maria Lekarakou, Athanasios Simoulis, Maria Britsou, Maria Terzi, Gino Vecchini, Petroula Arapantoni-Dadioti
Molecular Pathology Unit, Dept of Pathology, METAXA Cancer Hospital, Piraeus, Greece

BACKGROUND-OBJECTIVE: Angiogenesis is an essential process in tumor progression A number of interacting factors, such as growth factors, receptor tyrosine kinases, matrix metalloproteinases and integrins are involved in this

phenomenon. VEGF is an important regulator of angiogenesis and its gene gives rise in six protein isoforms through alternative splicing. VEGF exhibits proliferatve action mainly restricted to endothelial cells, stimulates microvascular leakage and induces proteases expression in endothelial cells contributing to tumor invasion and metastasis. High levels of VEGF expression correlate with poor prognosis in a variety of cancers including lung cancer especially NSCLC. However, information on VEGF expression in other lung tumor types such as SCLC is limited and needs further investigation taking into account the high metastatic potential of this carcinoma. In this regard we examined the expression of VEGF isoforms 121, 165 and 189 and their cellular and subcellular distribution in sporadic small cell (SCLC) and large cell neuroendocrine (LCNEC) lung carcinomas.We also compared the VEGF tumor expression levels to those of normal lung tissue obtained from the same patients. MATERIALS AND METHODS: Retrospective study of 90 cases of sporadic lung carcinomas of neuroendocrine origin (63 SCLC, 1 SCLC combined with adenocarcinoma component, 26 large cell neuroendocrine carcinoma LCNEC) obtained by bronchoscopic biopsies or FNBs and tumor or lung lobe resections. Simultaneous immunohistochemical detection of three VEGF isoforms expression using anti-human VEGF monoclonal antibody (clone SP28 1:100 dilution) that reacts with the VEGF121, VEGF165 and VEGF189 splice variants of VEGF. Semiquantitative assessment of the expression levels. RESULTS AND CONCLUSIONS: A. In normal lung cells VEGF expression was absent and rarely very weak . B. VEGF expression in carcinomas was cytoplasmic as follows : SCLC (N=56, ND=6) 3.57% with 3+ immunostaining , 8.93% with 2+, 30.35% with 1+ and 57.14% absence of expression, SCLC combined 1/1 with moderate 2+ expression and LCNEC (N=24, ND=2) 4.17% displayed 3+ cytoplasmic immunoreactivity, 12.5% moderate, 37.5% weak and 45.83% no expression. No significant tumor cell VEGF expression heterogeneity was observed. In conclusion VEGF expression levels in SCLC and LCNEC tumor cells were low or negative and demonstrated no significant difference from normal lung epithelia. This finding may suggest that other angiogenic factors than VEGF are responsible for the high microvessel density observed in these neoplasms.

PP4-106

IMMUNOHISTOCHEMICAL STUDY OF EMBRYONIC-LETHAL ABNORMAL VISION-LIKE ELAV/HUR PROTEIN EXPRESSION PATTERN IN SPORADIC SMALL CELL AND LARGE CELL NEUROENDOCRINE LUNG CARCINOMAS

Christos Valavanis[1], Maria Lekarakou[1], Maria Terzi[1], Rebeca Kaltsa[1], Joanna Iakovidou[1], Petroula Arapantoni-Dadioti[1], Dimitrios Kontogiannis[2]
[1] Molecular Pathology Unit, Dept. of Pathology, METAXA Cancer Hospital, Piraeus, Greece
[2] Dept. of Immunology, Alex. Fleming Biomedical Research Institute, Vari, Attiki, Greece

BACKGROUND-OBJECTIVE: Embryonic lethal abnormal vision (ELAV)-like protein HuR belongs to the RNA recognition motif (RRM) protein superfamily and is involved in cell growth and differentiation through posttranscriptional regulation of RNA transcripts. HuR is implicated in the stability and translation of various mRNAs, such as those encoding oncogenes, angiogenic factors and immunosuppressive cytokines. This transcripts stabilization occur via HuR binding to AU-rich elements (ARE) in the 3′ untranslated regions (UTR) of mRNAs. Therefore, dysregulation of HuR expression through putative genetic alterations or posttranscriptional and/or translational changes might contribute to malignant tumor progression . Indeed, there is a growing body of evidence that HuR is overexpressed in brain tumors, breast, ovary, NSCLC and colon carcinomas. Thus, HuR could provide a target for new therapeutic approaches by altering post-transcriptional events of tumor cells. In this context we investigated the expression of HuR and its cellular and subcellular distribution in carcinomas of neuroendocrine origin. We also compared the HuR tumor expression levels to those of normal lung tissue obtained from the same patients. MATERIALS AND METHODS: Retrospective study of 90 cases of sporadic lung carcinomas of neuroendocrine origin (63 SCLC, 1 SCLC combined with adenocarcinoma component, 26 large cell neuroendocrine carcinoma LCNEC) obtained by bronchoscopic biopsies or FNBs and tumor or lung lobe resections. Immunohistochemical detection of HuR protein expression using anti-HuR monoclonal antibody (1:500 dilution) and semiquantitative evaluation of the expression levels. RESULTS AND CONCLUSIONS: A. In normal lung cells HuR expression was both nuclear 2+ and cytoplasmic 1+ immunostaining. B. HuR expression in carcinomas showed : SCLC 87.3%, SCLC combined 1/1 and LCNEC 92.3% displayed 3+ nuclear and 2+ cytoplasmic immunoreactivity . All tumor types were characterized by significant tumor cell HuR expression heterogeneity (almost 30-40% of the tumor cells had no expression at all). In conclusion HuR expression levels were higher in tumor cells compared to normal ones suggesting a putative role of HuR in carcinogenesis and tumor progression via oncogene mRNAs stabilization.An important feature was the high tumor cell percentage (30-40%) with no HuR expression at all suggesting a dysregulation of post-transcriptional machinery leading to putative higher mRNAs degradation rates of other important molecules such as oncosuppressive gene transcripts.

PRIMARY PULMONARY MENINGIOMA: REPORT OF A CASE AND REVIEW OF THE LITERATURE

Sevinc Hallac Keser[1], Sezer Gezgin[1], Hakan Karabulut[1], Nimet Karadayi[1], Benan Caglayan[2], Bulent Arman[3], Buge Oz[4], Philip Cagle[5], Enrique M. Gomez[5]
[1] Dr. Lutfi Kırdar Kartal Educational and Research Hospital, Pathology Department, Istanbul, Turkey
[2] Dr. Lutfi Kırdar Kartal Educational and Research Hospital, Thorax Diseases Department, Istanbul, Turkey
[3] Dr. Lutfi Kırdar Kartal Educational and Research Hospital, Thorax Surgery Department, Istanbul, Turkey
[4] Istanbul University Cerrahpasa Medical Faculty Pathology Deparment, Istanbul, Turkey
[5] The Methodist Hospital Houston, USA

Background: Meningiomas are well recognized in the central nervous system and comprise 15% of all intracranial tumors. Primary ectopic meningiomas are very rare neoplasms which are usually found in the head and neck region (scalp, orbit of the eye, temporal bone, sinonasal area, mandible and ear, paraspinal soft tissues) and less frequently in the mediastinum or retroperitoneum. Primary pulmonary meningioma is very rare. According to the recent literature, there are around 30 cases reported. Gross, histological and immunohistochemical features are similar to their intracranial counterparts. Although in some reports there is slight female predominance, other authors proposed that there is no predilection for sex, age and any particular lobe or segment of lung. These tumors usually present as a solitary pulmonary nodule, grow slowly, are benign in nature and have excellent prognosis. Clinically they can mimic any other pulmonary tumor including metastasis. Case report: A 34 year old woman was accepted to the Thoracic Surgery Department of our hospital with a four months history of cough, dyspnea and occasional hemoptysis. Flexible bronchoscopy revealed a mass lesion in the right lower truncus intermedius blocking bronchial lumen. Atelectasis at the right basal area was discovered with the chest x-ray. With the computed tomography of thorax, right lower atalectasis and intrabronchial solid mass lesion 5.3x3cm in diameters in the right medial-lower lobe was found. Right lung- medial and lower bilobectomy was performed with the clinical diagnoses of bronchial carcinoma or carcinoid

tumor. Gross specimen of lung tissue revealed a 2.5x2x2cm, grey-white, relatively well circumscribed, hard tumoral lesion blocking the intermediary bronchus lumen. Histologically the tumor was composed of cells with eosinophilic cytoplasm and round to oval nuclei in syncytial arrangement. Occasionally nuclear inclusions, rare mitosis and atypia were observed. Immunohistochemical examination showed positive staining for EMA (epithelial membrane antigen) and Vimentin. Stains for PanCytokeratin, Chromogranin, Synaptophysin, Neuron Spesific Enolase, HHF-35, S-100, HMB45, Desmin, CD68 , GFAP, TTF-1 and CD34 were negative. Conclusion: We present a case of primary pulmonary meningioma by reviewing the literature and discussing the differential diagnosis of this rare neoplasm.

THE ROLE OF IMMUNOHISTOCHEMISTRY IN DISTINGUISHING MALIGNANT MESOTHELIOMA AND ADENOCARCINOMA

Emine Bagir, Derya Gumurdulu, E. Handan Zeren
Cukurova University, Faculty of Medicine, Department of Pathology, Adana, Turkey

Background: Histological diagnosis of malignant mesothelioma (MM) and differentiation from adenocarcinoma (AC) is often difficult. In recent years, a large number of immunohistochemical markers have been increasingly applied for the differential diagnosis for these tumors. The aim of this study is to compare the value of MOC 31, HBME-1 and calretinin for discriminating between these malignancy. Materials and Methods: Eighty six cases of MM and twenty six cases of AC retrieved from the files of pathology department of Cukurova University Hospital were included in this study. Immunohistochemistry was performed on each case using avidin-biotin-peroxidese tecnique with antibodies to keratin, EMA, CEA, MOC-31, HBME-1 and calretinin. Results: Keratin was positive in all cases. EMA stained 76 of 86 MM (88.3%) and 23 of 26 AC (88.4%). CEA was positive in 23 of 26 AC (88.4%) and stained 17 MM cases (19.7%). MOC 31 stained 19 of 26 AC cases (73%) as well as 8 of 86 MM (9.3%). HBME-1 was positive 75 of 86 MM (87.2%), thick and membranous staining was prominent. HBME-1 stained 14 of 26 AC (53.8%). Calretinin was positive in %86.3 MM cases, both nuclear and cytoplasmic staining were noted. None of AC cases reacted for calretinin. Conclusion: This study confirms the importance of an immunohistochemical panel in the diagnosis of MM, and the important role of calretinin in this panel. A panel of four markers (two positive and two negative) usally allows for the distinction to be made between MM and AC. Calretinin, MOC 31 and CEA should be included in this panel.

ASSESSMENT OF THE PROTECTIVE EFFECT OF VITAMIN D ON RADIATION-INDUCED LUNG INJURY

Ferda Bir[1], Bahar Baltalarli[2], Gulcin Abban[3], Nese Demirkan[1]
[1] Pamukkale University, School of Medicine, Department of Pathology, Denizli, Turkey
[2] Pamukkale University, School of Medicine, Department of Radiation Oncology, Denizli, Turkey
[3] Pamukkale University, School of Medicine, Department of Histology, Denizli, Turkey

BACKGROUND: Vitamin D, especially its most active metabolite 1,25-dihydroxyvitamin D3 (calcitriol) is essential in regulating a wide variety of biologic processes, such as blocking mesangial cell activation. Recent studies indicate that calcitriol induces anti-fibrotic hepatocyte growth factor expression, which in turn blocks the myofibroblastic activation and matrix production in interstitial fibroblast. Myofibroblasts express alpha-smooth muscle actin, are present in the early phase of acute lung injury. The objective of this study was to assess the histopathological evaluation of the effectiveness of vitamin D as a protectant against radiation-induced lung injury. METHODS: The study included 18 Wistar female albino rats with an average weight of 250-300gr. All animals were divided into tree groups. Group 1: control (n=5), Group 2: irradiation alone (n=7), Group 3:irradiation and vitamin D via IM (n=7). Rats were exposed to 20 Gy radiation to the right lung in a Co60 radiotherapy machine where group 3 animals were treated with single dose of vitamin D3 (0.2mgr) injected I.M. for 2 hours before exposure of irradiation. Fifty days after post-irradiation rats were sacrified. The lungs were dissected and blinded histopathological evaluation was performed to asses for lung injury. Immunohistochemically we were stained alpha-smooth muscle actin to highlighted myofibroblasts. RESULT: Light microscopy of right lung sections fifty days after radiation revealed widespread distortion of architecture, with areas that showed markedly thickened alveolar walls. There was abundant vasculitic changes and extravasated neutrophils. Irradiation and vitamin D group of right lung sections also showed thickened alveolar walls but these finding focal rather than diffuse. No vasculer change determined of this group. Histopathologically the lung injury score was significantly lower for irradiation alone when vitamin D was l be needed to prove its safety. administered ($p \leq 0.05$). Also myofibroblastic differantiation score was significantly lower for the irrradiation alone than radiation and vitamin D group ($p \leq 0.05$). CONCLUSION: This study indicates that administration of vitamin D3 has an histological evidence of effectiveness as a protectant againts acute lung injury through blocking myofibroblastic activation. Further trials will be needed to prove its safety.

[2] Department of Thoracic and Cardiovascular Surgery, Evangelismos General Hospital, Athens, Greece
[3] University of Athens 1st Propaedeutic Surgical Clinic, School of Medicine,National and Kapodistrian University of Athens,Greece
[4] Institute of Experimental Surgery and Surgical Research, School of Medicine, National and Kapodistrian University of Athens, Greece

Background Endotoxin is a major cause of endotoxinemia, sepsis and pneumonia due to gram-negative bacteria as well. Experimental endotoxin administration via the tracheal route has been extensively used to study the biological and pathophysiologic pathways of inflammation. In particular, experimental endotoxin instillation in the respiratory tree has allowed an extended research with regard to the local response of the lungs to the pathogenic stimulus. Method This study aims to examine the effects of adrenaline subcutaneous infusion in experimental lung inflammation by administration of intratracheal lipopolysaccharide (LPS) in an in vivo animal model. Two groups of animals were used for that purpose, a control group (single LPS administration) and a study group (subcutaneous adrenaline infusion following LPS administration). Results We found that in both groups, a mixed monocytic and lymphocytic infiltrate is an early event during the course of inflammation, occurring approximately two hours post-endotoxin instillation. In the study group, we determined that adrenaline mediated the lung inflammation in a statistically significant degree. By the use of immunohistochemistry, we also identified an increased population of CD4 T-lymphocytes in the inflammatory infiltrate, further endorsing the hypothesis that T-helper lymphocytes, along with monocytes, secrete cytokines

which amplify the inflammatory response. Conclusion Our study establishes that systemic adrenaline administration after LPS instillation may ameliorate the inflammatory lung response in vivo.

PP4-111
LARGE CELL LUNG CARCINOMA –(LCLC)– APPROACH TO RECLASSIFICATION ACCORDING TO THE DEFINITION AND CRITERIA CHANGES IN 1999 AND 2004 WHO CLASSIFICATIONS

Cezary Jochymski, Robert Koktysz, Piotr Wiśniewski, Wojciech Kozlowski
Pathology Dept. Military Institute of Health Services Warsaw, Poland

In the Pathology Department of Military Institute of Health Services in the years 1996 to 2007 911 cases of Lung Non Small Cells Cancers have been observed. In this group 89 have been primarily diagnosed as Large Cells Lung Cancers according to definitions and criteria described in previously published WHO Lung Tumors Classifications. The new WHO Classification of Lung Tumors published in 2004 changes some of the morphological criteria and definitions especially in that group of Lung Cancers. Aim: The aim of this study is to reclassify observed and primarily diagnosed Large Cell Lung Cancers according to the changes in current classification using standard microscopy evaluation and histochemical or immunohistochemical methods. Methods: All 89 LCLC cases identified (54 postoperative, 28 from oligobiopsy and 6 interoperative frozen sections) have been reclassified independently by 3 pathologists experienced in pulmonary pathology – selected slides from all cases have been stained with mucicarmin, PaS and alcian blue, CKAE1-3, CK7, CK20, TTF-1, ChromograninA, Synaptophisin, Calretinin, Vimentin and Ki-67/MIB-1 antibodies. Results: From 89 selected LCLC 79,5% cases have been classified as variants of Large Cell Cancer (classic type 44,3%; basocellular 11,3%, neuroendocrine 12,5%, other subtypes 11,4%). 18 (20,5%) observed cases have been classified according to the new WHO criteria and definitions as: Adenocarcinoma – 8%, squamous carcinoma – 10% and sarcomatoid carcinoma – 2,5%. Statistical analysis of Clinical Stage Tumor size, Nodal involvement (pTNM) and some of epidemiological data have also been performed. There were no statistical differences in tumor size (pT), nodal involvement (pN) and observed Pathological Stage between newly classified LCLC and other cancers. Conclusions: New definitions and criteria of 2004 WHO classification change about 20% of previously made diagnoses of LCLC based on earlier editions of WHO Lung Cancer Classifications. It should be emphasised that in our own material about 12% of reclassified LCLC have an neuroendocrine differentiation identified by immunohistochemical methods. For exact diagnosis based on contemporary classification of the LCLC immunohistochemical methods are necessary.

PP4-112
EXPRESSION OF SP-B (M-PR) AND TTF-1 IN ATYPICAL ADENOMATOUS HYPERPLASIA (AAH), BRONCHIOLOALVEOLAR CARCINOMA (BAC) AND PULMONARY ADENOCARCINOMA

Rodoula Tringidou[1], Anna-Maria Athanasiadou[1], Katerina Tsouri[2], Athanasios Krasas[3], Evangelos Sepsas[3]
[1] Dept. of Histopathology, General Athens Hospital of Thoracic Diseases, Greece
[2] Dept. of Pneumonology, General Hospital of Leukadas, Greece
[3] 1st Thoracic Surgery Dept., General Athens Hospital of Thoracic Diseases, Greece

BACKGROUND: Atypical adenomatous hyperplasia (AAH) is reported as a focal premalignant change accompanying carcinomas in lungs that are not affected by fibrosis. The tumor that AAH most often accompanies is a peripheral adenocarcinoma. AAH may be also found in association with multiple adenocarcinomas. AIM OF THE STUDY: We examined the expression of surfactant protein B (mature and precursor/SP-BM, SP-BPr) and thyroid trancription factor-1(TTF-1) in two (2) cases of invasive parenchymal type lung adenocarcinomas develops probably from AAH through an intermediate stage of bronchiolalveolar carcinoma (BAC). PATIENTS: CASE 1: A woman patient aged 59ys with clinical history of bronchitis and asthma. For 20ys she has been on ''lediol'' treatment. Symptoms: cough – dyspnoea. Macroscopically: Surgical specimen of upper lobe of left lung with a tumor mass dim 3x2,8x2,5 cm localized 3 cm from the surgical bronchial edge. Microscopically: Mucin-producing invasive adenocarcinoma with multiple foci of AAH and lesion with BAC growth pattern. CASE 2: A woman patient aged 66ys with cough and dyspnoea has been treated with antibiotics after a recent episode of pneumonia with fever. CT and HRCT findings: Mass dim 4X6X2,5 cm on the upper lobe of right lung. FNB: Well differentiated adenocarcinoma type BAC. Macroscopically: Surgical specimen of upper lobe of right lung with a tumorous mass dim 3X2X3 cm. Microscopically: Peripheral BAC with foci of AAH in surrounding lung parenchyma. METHODS: Immunohistochemistry (IMC) was performed using a panel of primary antibodies such as: epithelial markers (CK 18, 19, 7), CEA, surfactant – protein B (M-Pr), thyroid transcription factor (TTF-1). RESULTS: Case 1: CK 18(+), CK 19(+), CK 7(+), CEA focally (+), SP-BM (-), SP-BPr(+), TTF-1(+). Case 2: CK 18(+), CK 19(+), CEA focally (+), SP-BM (-), SP-BPr(+), TTF-1(+). A variability of expression of SP-BM/SP-BPr was detected on cellular level in foci of AAH comparing with lesions of BAC or invasive adenocarcinoma. CONCLUSIONS: (1) The variability of differences in the expression of SP-B (M and Pr) in foci of AAH near BAC or invasive adenocarcinoma, may be helpful in early diagnosis of this type of lung cancer and in the future the use of these markers is expected to have prognostic value. (2) It is not clear whether multiple foci of AAH and adenocarcinomas (BAC or invasive adenocarcinoma) in the same patient represent independent neoplastic foci or probably clonally related to each other.

PP4-113
ENDOGLIN (CD105) EXPRESSION IN NON-SMALL CELL LUNG CANCER AND ITS CORRELATION WITH EGFR, CD34 AND OTHER HISTOPATHOLOGICAL PARAMETERS: PILOT STUDY

Nurija Bilalovic[1], Adela Cimic[1], Semir Vranic[1], Ilir Bejtovic[1], Adisa Chikha[1], Faris Gavrankapetanovic[2]
[1] Department of Pathology, Clinical Center of the University of Sarajevo, Bosnia and Herzegovina
[2] Department of Surgery, Clinical Center of the University of Sarajevo, Bosnia and Herzegovina

Introduction: Endoglin (CD105), a cell-surface glycoprotein, recently has been identified as an optimal indicator of the proliferation of human endothelial cells. In this pilot study, we wanted to explore its presence in non-small cell lung cancer (NSCLC) and its correlation with epidermal growth factor receptor (EGFR), CD34 as well as with other standard histopathological parameters. Material and methods: Thirty-eight samples of NSCLC, diagnosed in period 2005-2006 at the Department of Pathology, Clinical Center of the University of Sarajevo, were randomly selected and retrospectively analysed. 19 squamous cell carcinomas (50%), 15 adenocarcinomas (39.4%) and 2 samples of adenosquamous and large cell carcinomas (5.3%) were stained for endoglin, CD34 and EGFR using monoclonal antibodies. All immunohistochemical results were captured by Olympus Digital Camera and scored by three researchers independently. Mean value was taken as a final score of immunohistochemical analysis. Statistical Package for Social Sciences (Version 11.5, SPSS, Inc., Chicago, IL, USA) was used for statistical analysis. Results: Endoglin expression was negative in 22 samples (57.9%) whereas positive expression was detected

in 16 cases (42.1%). The mean number of blood vessels stained by endoglin was 17.18 per field (magnification 200x). It was slightly higher in squamous cell compared with adenocarcinomas whereas CD34 expression had the opposite distribution but without significant association in both cases. Endoglin significantly correlated with another vascular endothelial marker, CD34 (p=0.024, Spearman's Correlation Rank 0.364). Also, significant positive correlation was detected with vascular invasion, previously confirmed on routine HE samples (p=0.008, Spearman's Correlation Rank 0.423). Endoglin did not correlate with tumor size whereas CD34 inversely did (p=0.039, Spearman's Correlation Rank –2.076). CD34 inversely correlated with tumor grade (p=0.05, Spearman's Correlation Rank –0.289). Vascular endothelial markers did not correlate with EGFR whose expression was slightly higher among squamous cell carcinomas compared with other subtypes. Conclusion: Endoglin is reliable marker of neoangiogenesis and its presence was frequently found in NSCLC. It significantly correlated with vascular invasion, important marker of tumor aggressiveness.

PP4-114

DIAGNOSTIC CHALLENGE ON FROZEN SECTION: PULMONARY PAPILLARY PNEUMOCYTOMA (SCLEROSING HEMANGIOMA) AND IMPORTANCE OF CLINICAL DATA

Nurija Bilalovic[1], Adela Cimic[1], Semir Vranic[1], Zrinka Vidovic[1], Klaus Kayser[2]
[1] Department of Pathology, Clinical Center of the University of Sarajevo, Bosnia and Herzegovina
[2] UICC-TPCC, Institute of Pathology, Charite, Berlin, Germany

We report here a rare case of primary pulmonary papillary pneumocytoma (sclerosing hemangioma), diagnosed in a 45-year old Bosnian female. Well-demarcated, 1.2x1 cm large, soft, partially calcified, multinodular tumor located in right middle lobe was received for intraoperative analysis. The initial diagnosis was metastatic papillary carcinoma. The tumor was composed of polygonal cells with eosinophilic cytoplasm arranged in papillary pattern (CK7 and EMA positive). The stroma was mainly composed of small, round cells (TTF positive). In between the network of small blood vessels was present (CD31 and CD34 positive). Ki-67 staining (MIB1 antibody) revealed low percentage of positive cells (less than 5%). In consultation with the surgeon we found out that the lesion persisted for several years. This information enabled the final diagnosis as well as second opinion since the sample was consulted in another institution. Although this entity is very care, careful examination and clinical history are of critical importance for accurate diagnosis.

INFLAMMATORY MYOFIBROBLASTIC TUMOR (IMT) WITH ABNORMAL OCTREOSCAN® POSITIVITY: A MISLEADING CASE

Cinzia Giacometti[1], Marco Schiavon[2], Federico Rea[2], Marialuisa Valente[1], Elisabeth Brambilla[3], Fiorella Calabrese[1]
[1] Department of Medical and Diagnostic Sciences and Special Therapies, University of Padua, Padua, Italy
[2] Department of Cardiothoracic Sciences, University of Padua, Padua, Italy
[3] Department of Pathology, Centre Hospitalier Universitaire Albert Michallon, Grenoble, France

Background: Inflammatory myofibroblastic tumor (IMT) is a relatively uncommon lesion, which has been reported to occur in nearly every site in the body. We present an unusual clinical presentation of pulmonary IMT, clinically misdiagnosed as carcinoid due to Octreoscan® abnormal positivity. Case Report: In August 2005 a 52 year-old woman, former smoker of 10 cigarettes/day, was admitted in hospital with thoracic pain. At HRCT the nodule appeared as a focal parenchymal solitary lesion, sharply circumscribed. The 2-Deoxy-2-[18F]Fluoro-D-Glucose (FDG)-PET/CT scan showed increase in tracer activity of the lung mass, suggestive of malignant lesion. The Octreoscan® showed abnormal accumulation of radioactivity in the left hilar region of the lung. A clinical/radiological diagnosis of carcinoid was postulated. An intra-operative frozen section was done, however the confirmed diagnosis of carcinoid could not be achieved. The tumor was composed of spindle cells with a bland cytology, low nuclear atypia and absence of mitosis. The lesion was regarded as low-grade malignancy. The chosen therapeutic procedure was surgical excision (lobectomy). At histology, the lesion consisted of spindle cells arranged in storiform pattern and an admixture of inflammatory cells, with a predominance of hystiocites and lymphocytes. The tumor was negative for ALK1, cytokeratin, CD34, S100 protein and EMA. The inflammatory cells infiltrating showed a strong staining for somatostatin receptors (SSTRs; subtypes 2A and 5). A final diagnosis of IMT was made. Six months after the surgical excision, the patient is alive and well. Conclusion: SSTRs have been identified on human immune cells, including mononuclear leucocytes and peripheral blood lymphocytes. The positive finding of the Octreoscan in our case was due to large intra-tumoral infiltration by lymphocytes and monocyte which expressed SSTRs. To our knowledge, this is the first case of IMT documented with Octreoscan and with immunohistochemistry for SSTRs.

PP4-116

ACUTE REJECTION IN HUMAN LUNG TRANSPLANTATION: A POSSIBLE SYNERGIC ROLE OF RHINOVIRAL-CYTOMEGALOVIRUS CO-INFECTION

Cinzia Giacometti[1], Francesca Lunardi[1], Kim Oliani[2], Giuseppe Marulli[2], Monica Loy[2], Federico Rea[2], Claudio Schiraldi[2], Marina Saetta[2], Fiorella Calabrese[1]
[1] Department of Medical and Diagnostic Sciences and Special Therapies, University of Padua, Padua, Italy
[2] Department of Cardiothoracic Sciences, University of Padua, Padua, Italy

Background: Lung transplantation offers a chance of an improved quality of life and survival for many patients with advanced lung disease. Cytomegalovirus (CMV) and non-CMV viral respiratory infections often involve the lower respiratory tract and are associated with significant morbidity and mortality. The aim of the study was to assess the frequency of different viruses in bronchoalveolar lavage (BAL) specimens and to investigate a potential impact of the most frequent infections on allograft function. Methods: 240 monitoring BAL samples from 48 consecutive lung-transplant patients were analysed by polymerase chain reaction (PCR) and reverse transcriptase (RT)-PCR for Cytomegalovirus (CMV), Adenovirus, Rhinovirus (RN), Herpes Simplex Virus, Influenza Virus and Epstein-Barr Virus. Different clinical and morphological parameters, including acute rejection (AR), were recorded for a mean follow up time of 2.86 1.24 years. Results: High frequency of viral infections was detected in our BAL samples (160/240, 67%): particularly CMV and RN (122/160, 76% and 39/160, 24% respectively). Viral co-infections were found in 43/160 (27%) with frequent occurrence of CMV/RN (23/43, 53%). Patients with RN and RN/CMV positive BALs (group 1) were compared with patients with only CMV positive BALs (group 2) and with patients with CMV/other viruses (group 3). Group 1 showed a significant higher rejection index (n ARs/ n total biopsies) than group 2 (p=0.04). Recurrent infective episodes were more frequently detected in group 1 than in group 2 (p=0.006). No significant correlations were observed between group 2 and group 3. Conclusion: 1) CMV/RN is a frequent co-infection in lung transplant patients; 2) recurrent episodes of CMV/RN co-infection and the synergic action of the two viruses could play a crucial role in the induction of AR.

PP4-117
OXALOSIS AND NECROTIZING PULMONARY ASPERGILLOSIS: TWO CASES
Châari Chiraz, Makni Saloua, Chtourou Imen, Fakhfakh Ines, Gouiaa Naourez, Makni Saloua, Khabir Abdelmajid, Sellami Boudawara Tahya
EPS Habib Bourguiba SFAX, Tunisia

Introduction: The pulmonary oxalosis is a very rare pseudotumoral lesion; it is often secondary to an infection by Aspergillus niger and more rarely by Aspergillus flavus, Aspergillus fumigatus, Aspergillus luchurensis or by Beauveria bassiana. The diagnosis was based on histological examination Our aim is to discuss the diagnosis and the histogenesis of this pathologic association. Observations: We report two cases of chronic necrotizing pulmonary aspergillosis associated with oxalosis among two 17 and 69 year old men with a history of tuberculosis. The thoracic radiography revealed an hydroaeric level in the leg. The computed tomodensitometry revealed a pyopneumothorax and a collapses of the homolateral leg with tuberculosis lesions probably associated to an aspergillosis greff. The serology of aspergillosis was positive in the two cases. The histological analyse of the surgical specimans highlighting the birefringent calcium oxalate crystals by polarisation associated with branching septate hyphae. The culture yielded Aspergillus niger for the young patient. Conclusion: The oxalosis indicates evry intra-tissue oxalate crystal precipitation of calcium hereditary or acquired. Several authors described a brocho-pulmonary deposits of oxalate of calcium associated to an aspergillosis, the oxalic acid is a mycotoxin released especially by A.niger The diagnosis is based on mycologic examination with culture. The treatment is surgical in case of serious hemoptysy or a resistant surinfection to the medical treatment or to the drainage. The evolution is in general favourable.

PP4-118
EFFECTS OF PROPOLIS IN THE PROGRESSION OF URETHANE-INDUCED LUNG EXPERIMENTAL CANCER
Tamara Veiga Faria, Maristela Munhoz, José Antonio Cordeiro, Patricia Maluf Cury
Faculdade de Medicina de Sâo José do Rio Preto, Brazil

Background : Propolis, a natural beehive product has been known for centuries for a variety of beneficial traditional medicinal properties. The present study was conducted to ascertain the antineoplastic potential of propolis Design: 3mg/kg urethane was injected in male Balb-c mice, with 7 to 13 life weeks. One group with 13 mice was the control, and another group with 18 mice were submitted to 1.5 mg of Propolis diluted in 350 ml of drinking water . Food and water were given ad libitum. After 16 weeks, all animals were sacrificed and lung nodules and hyperplasias were counted in histological analysis. Results: There was no difference in the number of nodules and hyperplasias between the groups and the control (p= 0.69 and p=0.92, respectively). The final animal weight and food and water ingestion was similar in all groups. Conclusion: Propolis seems to have no effect in the progression of lung cancer in the dose used. It should be interesting to test this substance in higher doses.

PP4-119
SCLEROSING THYMOMA: CASE REPORT OF A RARE SUBTYPE
Isil Yildiz[1], Rıza Dogan[2], Pınar Firat[1]
[1] Hacettepe University, Faculty of Medicine, Department of Pathology, Ankara, Turkey
[2] Hacettepe University, Faculty of Medicine, Department of Thoracic Surgery, Ankara, Turkey

Sclerosing thymoma is classified as a rare subtype of thymoma in the WHO classification. Few reports of this entity have been made since its first description by Kuo in 1994. Here, we report a case of sclerosing thymoma in a myasthenia gravis patient. A 41 year-old male presented with dysphagia, ptosis and muscle weakness. Computerized tomography showed a 3,5x1,5 cm mass in the anterior mediastinum. With a preliminary diagnosis of thymoma, the patient underwent maximal thymectomy. The specimen was 18x6,5x3 cm in diameter and weighed 175 grams together with the surrounding adipose tissue. On cut surface of the thymectomy specimen a hard, homogenous, spicular mass measuring 4,5x3,5x1 cm and gray-tan in color was detected. Microscopically, the lesion was mostly composed of hyalinized collagen-rich stroma in which aggregates of spindle and polygonal epithelial cells admixed with lymphocytes were noticed. The epithelial cells showed neither atypia nor mitosis. No hemorrhage or necrosis was present. The neoplastic cells were found to be positive for pancytokeratin and negative for LCA and chromogranin. A diagnosis of sclerosing thymoma was made. It is claimed that sclerosing thymoma is occuring as the result of ancient/regressive changes in conventional thymomas. It is a rare and contentious entity which should be considered in the differential diagnosis of small mediastinal biopsies composed of fibrous tissue.

PP4-120
INVOLVEMENT OF APOPTOSIS IN AMIODARONE INDUCED PULMONARY TOXICITY AND FIBROSIS
Eftihia Kapatou[1], Angelos Skyrlas[1], Christianna Zachariou[1], Konstantinos Hatzistergos[1], Theofilos Koletis[2], Agathoklis Tsatsoulis[3], Maria Bai[1], Vassiliki Malamou-Mitsi[1]
[1] University of Ioannina, Medical School, Department of Pathology, Greece
[2] University of Ioannina, Medical School, Department of Cardiology, Greece
[3] University of Ioannina, Medical School, Department of Internal Medicine-Endocrinology, Greece

Background Amiodarone (AMD) is a potent anti-arrhythmic drug frequently used for treating ventricular and supraventricular arrhythmias. Despite its effective antiarrhythmical properties, the use of AMD is often limited by its toxic side effects. The most severe adverse effect of the drug is the Amiodarone-Induced Pulmonary Toxicity (AIPT), which includes alveolitis, phospholipidosis and irreversible fibrosis. However, the mechanism underlying the involvement of AMD to the pathogenic molecular machinery of the disease remains unclear. Recent studies suggest that apoptosis of alveolar epithelial cells (AECs) plays an important role in AIPT. In the present study we investigate the level of involvement of AMD to the triggering of apoptosis. Method The immunohistochemical expression of pro-apoptotic proteins, activated caspase-3 and apoptosis inducing factor (AIF), and anti-apoptotic proteins Bcl-2, survivin and c-Flip, was studied in 33 samples of pulmonary tissue from Wistar rats after oral administration of AMD for 14 days at a dose of 30 mg/kg/day (minimum therapeutic dose). Tissue samples from rats where the drug had not been administered served as controls. Apoptosis was detected by the TUNEL technique and the apoptotic index (AI) was calculated. Results Administration of AMD was correlated with increased apoptosis, increased expression of activated caspase-3, and decreased expression of Bcl-2, survivin and c-Flip. Specifically, we found that AMD had been administered to the 66.7% and 63.2% of samples that presented increased AI and increased expression of activated caspase-3, respectively. On the contrary, administration of AMD was significantly correlated with decreased expression of Bcl-2, survivin, and c-Flip ($p \leq 0{,}001$, $p \leq 0{,}001$, and $p=0{,}023$ respectively). AIF protein showed consistent expression (58.1% of samples) especially among the cellular pulmonary population located far from lymphocyte infiltrations, however did not exhibit any significant correlations. A significant correlation was also found between immunoexpression of activated caspase-3 and TUNEL positive AECs ($p=0.040$). The immunoexpression

pattern of Bcl-2, survivin, and c-Flip were also found to be significant correlated (Bcl-2 vs survivin and c-Flip p≤0,001 and p≤0,001 respectively, survivin vs c-Flip p≤0,001). Conclusion Apoptosis plays a crucial role in AIPT. In contrast to AIF protein, activated caspase-3 acts as the effector molecule of apoptosis in AIPT. Inhibition of the anti-apoptotic molecules Bcl-2, survivin, and c-Flip is also involved in AIPT.

[2] Gazi University Medical School, Department of Pulmonary Diseases, Ankara, Turkey
[3] Gazi University Medical School, Department of Thoracic Surgery, Ankara, Turkey

Background: The second mitochondria-derived activator of caspase/direct inhibitor of apoptosis-binding protein with low pI (Smac/DIABLO) was recently identified as a protein that is released from mitochondria in response to apoptotic stimuli and promotes apoptosis by antagonizing inhibitor of apoptosis proteins. Caspase-3 is a cysteine protease that plays an important role in the process of apoptotic cell death. However, the involvement of Smac/DIABLO and caspase-3 in NSCLC is not fully understood. Method: Expressions of Smac/DIABLO and caspase-3 were investigated immunohistochemically in 112 non-small cell lung carcinoma patients. Staining patterns were correlated with tumor histological type, TNM stage and prognosis. Results: Smac/DIABLO was detected in 12 (11%) and caspase-3 in 60 (53%) of 112 NSCLC cases. There was no significant relationship between Smac/DIABLO and caspase-3 expression and age, gender, histological type, TNM stage and prognosis. In addition, no significant correlation was found between Smac/DIABLO and caspase-3 expression. Conclusion: Our data demonstrate that expression of Smac/DIABLO is rare among NSCLC's, suggesting that Smac/DIABLO or its agonists is unlikely to be an appropriate target for therapeutic options in patients with these tumors.

BACKGROUND Inflammatory myofibroblastic tumor (IMT) is a subgroup of inflammatory pseudotumors and has been reported in multiple anatomic locations including lung. It is composed of a variable mixture of collagen, inflammatory cells and a spindle cell proliferation showing myofibroblastic differentiation. IMT occurs mostly in patients less than 40 years. The clinical findings depend on the site of the involvement. Some authors believe that IMT is a reactive process rather than a tumoral lesion, while some support the theory of IMT as being a low grade mesenchymal malignancy. METHODS We report of a case of IMT with an unusual clinical presentation. A 28 year-old man was referred to the hospital with massive hemoptysis. A mass, which was suspicious for arteriovenous malformation, aneurysm or malignancy, was detected in the right upper-lobe adjacent to the interlobar fissur, radiologically. Angiography was in normal limits. Because of the high risk for hemorrhage, a transthoracic aspiration biopsy was done peroperatively. The sample was generally hypocellular, however there were some cellular areas consisted of mesenchymal cells with vesicular nuclei bearing a centrally located nucleoli. In some cells binucleation was seen. The clinician was warned for a possible mesenchymal lesion which malignant potential could not be predicted. Because the borders of the tumor could not be differentiated from the adjacent parenchyma and the extensive hemorrhagic appearance of the lung, the patient underwent a right upper-lobectomy. RESULTS On macroscopic examination a peripheric mass, that had irregular borders and hemorrhagic cut surface, and measured 3 cm in diameter, was detected in the hilus of the lobe. Histology revealed a well-demarcated tumoral lesion composed of myxoid stroma, neovascularization and bland appearing spindle cells. Binucleated cells, atypia and pleomorphism, rare mitoses were also seen. Immunohistochemistry displayed positive reaction for vimentin, smooth muscle actin, CD31 and p53, whereas no staining was detected for S-100, CD34, desmin, cytokeratin, ALK-1 and HMB-45. The possibility of a metastatic tumor was excluded by PET screening. CONCLUSION IMT is a rare tumor with various histologic patterns that can be confused with other malignant and benign tumors. The diagnosis can be very difficult, especially at the time of surgery in the frozen room. The appropriate choice of treatment is the total excision of the lesion, besides IMT is believed to be a low-grade malignant tumor. Although most of the patients are asymptomatic, clinical presentations differ according to the localization and the components of the tumor.

PP4-123

ENDOBRONCHIAL HAMARTOMA: SHOULD THE DIAGNOSIS BE MADE ON A BRONCHOSCOPIC BIOPSY?

Yasemin Ozluk[1], Levent Tabak[1], Sukru Dilege[2], Yusuf Bayrak[3], Dilek Yilmazbayhan[4]

[3] VKV American Hospital, Istanbul, Turkey
[4] Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey

BACKGROUND Pulmonary hamartomas (PHs) are rare benign tumors composed of varying proportions of mesenchymal tissues and combined with entrapped respiratory epithelium. PHs are usually peripheric, however 3-20% of tumors are endobronchial. Endobronchial lesions clinically cause obstructive symptoms and are localized within the larger airways as broad-based polyps. Histological examination reveals mature cartilage tissue, surrounded by other mesenchymal elements and clefts of respiratory epithelium. In endobronchial hamartomas fat tissue may predominate and epithelial component may be shallow or absent. METHODS We report a case of an endobronchial hamartoma occuring in a 35 year-old man, who was admitted to the hospital with a 2 years of history of recurrent pneumonia and cough. Radiology demonstrated postobstructive pneumonia findings. A bronchoscopy was done with suspicion of a malignancy. Endoscopically, a polypoid lesion measured 0.5 cm in diameter was detected within one of the segment bronchi of right lower-lobe. RESULTS Histologically, bronchoscopic biopsy displayed structures of irregular chondroid and other mesenchymal elements in small tissue fragments . The possibility of a chondroid hamartoma was reported. However a malignant tumor could not be excluded. The patient underwent a segmentectomy procedure. In the frozen section room the mass defined by bronchoscopy could not be detected macroscopically. The bronchoscopy was repeated peroperatively and the mass was seen within an abnormally branching segmental bronchus. The segment carrying the mass was resected. Histologic examination

of the lesion confirmed the initial diagnosis with chondroid, myxoid mesenchymal and adipose tissue elements containing mass within the abnormal superior segmental bronchus. CONCLUSION PHs are benign lesions which have similar radiological and clinical features with malignant tumors. A biopsy is necessary for the differential diagnosis. Preoperative or peroperative diagnosis is important, since the definitive diagnostic procedure is segmentectomy or lobectomy. The presence of small, irregular chondroid and mesenchymal tissues can be seen in both mesenchymal and hamartomatous tumors. The pathologist and the bronchoscopist have to keep in touch to make the diagnosis.

LYMPHOVASCULAR INVASION PREDICTS RECURRENCE IN RESECTED STAGE I NON-SMALL CELL LUNG CARCINOMA

Sibel Percinel[1], Serpil Dizbay Sak[1], Berna Savas[1], Serkan Enon[2], Ayten Kayi Cangir[2]
[1] Ankara University, Medical Faculty, Department of Pathology, Ankara, Turkey
[2] Ankara University, Medical Faculty, Department of Thoracic Surgery, Ankara, Turkey

Introduction: Prognosis of patients with non-small cell lung carcinoma (NSCLC) still remains a major problem. Numerous biological markers have been evaluated for prognostic significance but the results have been conflicting. In NSCLC, the prognostic value of lymphovascular invasion (LVI) has been evaluated in early stage patients. Recently, LVI has been reported to be a prognostic factor in patients with resected NSCLC with intrapulmonary metastases. Perineural invasion (PNI) has already been regarded as one of the prognostic parameters to be included for the next staging revision. Materials and Methods: Intratumoral LVI and PNI were investigated in 58 patients who had Stage I (T1N0M0) NSCLC by hematoxylin and eosin stained sections. LVI was determined by the presence of tumor cells either in lymphatic or blood vessels. Survival curves were estimated using the Kaplan-Meier method. The prognostic value of individual clinical and pathological variables was analyzed by the log-rank test. Results: LVI was detected in 50% and PNI was detected in 20.7% of NSCLC cases. The median follow-up for the entire group was 35.5 months. In univariate analysis, neither LVI nor PNI was predictor of overall survival. However, LVI was found to be significantly predictive of recurrence. The estimated relative risk of recurrence in patients with LVI was 3 compared with patients without LVI. Conclusion: LVI predicted recurrence in resected TIN0M0 NSCLC cases.

PP4-307
DIAGNOSIS OF DIFFUSE PULMONARY INTERSTITIAL DISEASE BY TRANSBRONSCHIAL BIOPSY (TBB): OUR EXPERIENCE (322 CASES).

Ana Puras[1], Ana Echegoyen Silanes[1], Alfredo López-Cousillas[1], Marta Rezola Bajineta[1], Eduardo Urbiola Marcilla[1], Joan Boldú Mitjans[2]
[1] S. de Anatomía Patológica Hospital Virgen del Camino Pamplona, Spain
[2] S. de Neumología Hospital Virgen del Camino Pamplona, Spain

Introduction: Transbronchial pulmonary biopsy (TBB) is a good recognized method in the diagnosis of the Lung Interstitial Diseases and its utility has been proven throughout the years. Current technologies (immunohistochemical, molecular and other types of studies) allow a more precise diagnosis. The conditions that are necessary to assess these samples have been simplified in the last years, as well as the technical behavior of them. Also permit to obtain multiples samples of Interstitial Diffuse Diseases in different categories of hospitals. Material and methods: From 1985 to the present moment 322 TBBs have been made in our hospital to patients with suspicion of interstitial Disease, 307 of which were immunocompetent patients; a meticulous protocol has been followed with all of them for the complete use of the sample: initial seriation of minimal specimens (20 preparations, numbered and occasionally mounted in slides for immunohistochemical techniques) and a later staning, alternatively, of 8 of them: 4 H.E, 1 Masson, 1 PAS, 1 Perls, 1 Blue Alcián; the samples not stained initially, are stained afterwards, if they are necessary; and if not, they are filed. All the cases have been reviewed, in Clinical-Pathological Conferences, and the results of the biopsy have been assesed. They have been always valued with the bronchoalveolar lavage (BAL). Results: The diagnosed pathology has been: A) Sarcoidosis (23), Tuberculosis (4), Hypersensitivity Pneumonitis (30), Eosinophilic Chronic Pneumonia (9), “BOOP pattern” (27), Respiratory Bronchiolitis-Interstitial lung Disease (DIP pattern) (32), Constrictive Bronchiolitis (3), Lung hemorrhage (7, one of them a Goodpasture's Syndrome and other vasculitis), Usual Intersititial Pneumonia (33), Pneumoconiosis (11), Acute lesion (14) (Diffuse Alveolar Damage, Infectious Organizing Pneumonia, Iatrogenic damage,…), Infarct (2), Lymphangioleiomyomatosis. (2), Alveolar Proteinosis (2), Pneumocystis (1), Herpes virus (2), Aspergillosis (2), Bronchoalveolar Carcinoma (9), Lymphoma-Leukemia (4), Carcinomatous lymphangitis (5); B) The diagnosis was orientative in 34; C) Without alterations in 31; and D) The sample was insufficient in 34. Conclusions: 1.- The TBB was diagnostic or orientative, with a latter clinical confirmation in 80% of the cases. 2.- In 20% of the cases it the TBB was insufficient, or non valid (non representative of the process). 3.- The maximum use of the samples and the meticulous technical behavior, as well as the multidisciplinary team work, have contributed to it in a definitive way.

DEEP PENETRATING NEVUS, BLUE NEVUS AND SPITZ NEVUS – PROBLEMS OF DIFFERENTIAL DIAGNOSIS

Geanina Micu[1], Eliza Gramada[1], Cristiana Popp[1], Alina Stoica[1], Alina Georgescu[1], Sabina Zurac[1], Alexandra Bastian[1], Carmen Ardeleanu[2], Florica Staniceanu[1], Dorina Giurcaneanu[3]
[1] Colentina University Hospital, Department of Pathology, Bucharest, Romania
[2] Victor Babes Institute, Bucharest, Romania
[3] Colentina University Hospital, Department of Dermatology, Bucharest, Romania

Background: Deep penetrating nevus (DPN) is a variant of melanocytic nevus that can be clinically mistaken for malignant melanoma (MM), pigmented nevus (PN), blue nevus (BN) and Spitz nevus (SN). Also, the histopathological features prone to confusion with MM, SN and BN. The final diagnosis is established by histopathologic/ immunohistochemical studies. BN is a benign lesion with two recognized variants: the common blue nevus and the cellular blue nevus. It is believed to represent dermal arrest of neural crest melanocytes during embryonal migration towards epidermis. SN (benign juvenile melanoma, spindle and epithelioid cell nevus) is a benign melanocytic nevus, which shares some histopathological features with malignant melanoma. Material and method: We analyzed the nevocelular tumors diagnosed in our department during two years (2005-2006): 574 nevocelular nevi and 54 MM. There were two DPN, two BN and two SN. We studied the histological features of all tumors (cellularity, cellular polymorphism, mitotic figures and lymphocytic infiltrate), the integrality of resection and the immunohistochemical markers for melanocytic tumors (S100, HMB 45, Melan-A, NSE). Results: Most of the patients were women (5 out of 6), with medium age 39.6 years. Most lesions occurred on the face (4 out of 6), one case on the foot (plantar side), the other having lumbar localization. All the tumors were composed of clusters and fascicles of polygonal and spindle shaped cells, with abundant cytoplasm and bland nuclei, sometimes with visible nucleoli. Cellular and nuclear polymorphism was noted in all cases. Evident diminution in cell size (maturation) towards the base of the lesion was present. Mitoses were present in one DPN (mitotic index 10/100 high power fields), none of them atypical. None of the tumors had pagetoid invasion of the epidermis. The DPNs had additional large, multinucleated tumoral cells in the superficial part. Conclusion: DPN, BN and SN are benign melanocytic tumors, difficult to differentiate both one from the other and especially from a MM. The correct diagnosis has the outmost importance for the patient's treatment and prognosis.

PP4-126
POSITIVE AND DIFFERENTIAL DIAGNOSIS IN TUMORS WITH SEBACEOUS DIFFERENTIATION

Florica Staniceanu, Sabina Zurac, Geanina Micu, Alexandra Bastian, Eliza Gramada, Alina Stoica, Alina Slavnea, Ionela Celea
Colentina University Hospital, Department of Pathology, Bucharest, Romania

Background: Benign sebaceous lesions are frequent, but malignant cutaneous tumors with sebaceous differentiation are relatively uncommon. In this group sebaceous carcinoma is a rare variant of cutaneous tumor with an aggressive biological potential showing a marked tendency for both local recurrence (9-36%) and distant metastasis (14-25%). Method: We studied 18 cases of sebaceous tumors diagnosed in our department in the last four years; 4 of them were sebaceous carcinoma SC, 6 were basal cell carcinomas with sebaceous differentiation (BCCSD), 4 were Jadassohn's nevi (JN) and 4 were benign sebaceous proliferations (1 sebaceous adenoma (SA), 3 sebaceomas), analyzing histological patterns, cytoplasmic and nuclear aspects, mitoses, necrosis, invasion and IHC features. Results: There was a significant predominance of male patients (61.1%); the average age differed within the five groups of lesions: 63 for SC, 49.2 for BCCSD, 38.9 for JN and 74.2 for sebaceoma. All the SC were located in the ocular area (3 in the eyelid and one on the conjunctiva); the tumors belonging to the other groups were both ocular and extra ocular (mainly on the scalp). All the SCs were diagnosed as grade II and showed lobular proliferation of atypical vacuolated cells with sebocityc differentiation, necrosis and, in one of the cases, pagetoid invasion of the epidermis; the well differentiated areas showed some similarities with benign sebaceous tumors that are analyzed. The BCCSDs are considered to be borderline tumors as they do not metastasize so that the identification of conventional BCC features associated with mature sebocytic elements were essential to separate them from SC. While the SA revealed proliferation of fully differentiated sebocytes and basaloid cells, the sebaceomas were composed of mixed immature and mature sebocytes. JN presented marked acanthosis, papillomatosis and sebaceous hyperplasia with apocrine proliferation. Histological aspects and IHC data are discussed. Conclusion: Tumors with sebaceous differentiation have various clinical presentations and histopathological aspects that make differential diagnosis both important and difficult. On one hand, well-differentiated sebocytic component of malignant tumors can be mistaken for a benign lesion especially in small bioptic specimens; on the other hand, the BCC component in a malignant tumor with sebocytic differentiation must be separated from SC. Careful examination of numerous areas of the tumor and IHC test must be performed in order to establish the correct diagnosis.

PP4-127
IMMUNOHISTOCHEMICAL EXPRESSION OF HUMAN HERPES VIRUS–8 IN THE DIAGNOSIS OF KAPOSI'S SARCOMAS

Banu Dogan Gun[1], Burak Bahadir[1], Mustafa Ozkan Gun[2], Erdogan Gonulal[2], Neslihan Kokten[1], Nilufer Onak Kandemir[1], Nimet Karadayi[3], Sukru Oguz Ozdamar[1]
[1] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Zonguldak Ataturk State Hospital, Department of Pathology, Zonguldak, Turkey
[3] Dr. Lutfi Kirdar Kartal Research and Training Hospital, Department of Pathology Istanbul, Turkey

BACKGROUND: Kaposi's sarcoma is a low-grade vascular neoplasm that has been shown by molecular analyse to uniformly express latent nuclear antigen-1 of human herpes virus 8. In the present study we assesed the sensitivity and specifity of human herpes virus 8 latent nuclear antigen-1 in the diagnosis of Kaposi's sarcoma and its potential usefulness for distinguishing it from various mimickers. METHOD: In total, 35 cases of Kaposi's sarcoma from 25 patients and with 18 mimickers (two cases of spindle cell hemangioendothelioma, three cases of kapiller hemangioma, a case of cavernous hemangioma, two cases of pyogenic granuloma, a case of stasis dermatitis, three cases of fibromatosis, two cases of dermatofibroma, a case of pilar leiomyoma, a case of fibroma and two cases of blue nevus) were included in this study. Fixed, paraffin embedded tissue sections were examined immunohistochemically using human herpes virus 8 latent nuclear antigen-1. Strong diffuse nuclear staining was considered as positive. Also the following variables for Kaposi's sarcoma cases were analysed; age, sex, localization and stage of the tumor. RESULTS: Of the 25 Kaposi sarcoma's cases there were 16 males and 9 females, giving an overall male:female ratio of 1.7.The age of the patients ranged from 37 to 80 (mean 66.36) years. The lesions occured more commonly in the lower extremity (54.29%), upper extremity (25.71%) head and neck region (17.14%) and trunk (2.86%). Eight biopsy specimens were in the patch or plaque stage that reflects the early

stage of Kaposi's sarcoma and 27 were in nodular stage. In 35/35 cases of the Kaposi's sarcoma showed positive nuclear staining for human herpes virus 8 latent nuclear antigen-1 (sensitivity, 100%), whereas 3/18 of the mimickers; a case of capillary hemangioma, a case of stasis dermatitis and a case of a dermatofibroma was positive for this antigen (specifity, 83.34%). CONCLUSION: The high sensitivity of human herpes virus 8 in our cases of Kaposi's sarcoma (100%) were similar with other investigations using immunohistochemistry or polymerase chain reaction. However, human herpes virus 8 specifity of 83.34% detected in this study was a little lower when compared to the literature. The result indicate that its use for diagnostic purpose must be carried out with caution.

PP4-128
C-KIT (CD117) EXPRESSION IN CLASSIC KAPOSI SARCOMA

Nilufer Onak Kandemir[1], Banu Dogan Gun[1], Burak Bahadir[1], Gamze Yurdakan[1], Mustafa Ozkan Gun[2], Neslihan Kokten[1], Nagehan Ozdemir[3], Nimet Karadayi[3], Sukru Oguz Ozdamar[1]
[1] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Zonguldak Ataturk State Hospital, Department of Pathology, Zonguldak, Turkey
[3] Dr. Lutfi Kirdar Kartal Research and Training Hospital, Department of Pathology Istanbul, Turkey

Background: Kaposi sarcoma (KS) is a multicentric angioproliferative neoplasm characterized histologically by the progressive proliferation of spindle-shaped tumor cells that progresses from patches to plaques, with eventual formation of nodule. Human herpesvirus 8 (HHV8) is associated with all epidemiologic forms of KS and has been shown in vitro to induce the tyrosine receptor kinase c-kit in HHV8- infected endothelial cells. The aim of this study was to evaluate c-kit expression by immunohistochemistry in different proliferative stages of classic Kaposi sarcoma. Method: In total, 30 cases of Kaposi sarcoma; at various histologic stages (4 patch, 2 plage, 24 nodular); from 18 patients were included in this study. Formalin-fixed, parafin-embedded tissue sections were stained using immunohistochemistry with antibodies to c-kit. Strong diffuse cytoplasmic staining was considered as positive. Also the following variables for Kaposi's sarcoma cases were analysed; age, sex, localization and stage of the tumor. Result: Of the 18 Kaposi sarcoma's cases there were 12 males and 6 females, giving an overall male:female ratio of 2/1.The age of the patients ranged from 37 to 80 (mean 66.36) years. The lesions occured more commonly in the lower extremity (54.29%), upper extremity (25.71%) and head and neck region (20%). C- kit immunoreactivity of lesional cells was demonstrated in 19 (63.33%) cases. There was no difference in the intensty of c-kit staining between age, sex, localization and histologic stages of KS. Conclusion: These findings indicate that c- kit expression in lesional cells can be detected by immunohistochemistry in different histologic stages of KS. The detection of c-kit expression in KS reveals a potential target for pharmacologic intervention that warrants further study.

PP4-129
MAST CELLS AND P53 EXPRESSION IN PSORIASIS VULGARIS

Figen Barut, Sibel Bektas, Banu Dogan Gun, Burak Bahadir, Gamze Yurdakan, Sacide Colak, Sukru Oguz Ozdamar
Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey

Background: Psoriasis vulgaris is a chronic inflammatory T-cell mediated immune dermatosis, characterized by a high epidermal cell turnover, which results in a typical epidermal hyperplasia. As a result of the studies carried on by using antibody of "mast cell tryptase and toluidin blue stain", which are specific mast cell determiners, mast cells are found to be increased in psoriasis lesions. In addition, it is observed that there is an increase in cell proliferation of these lesions when p53 is used. The purpose of this study is to show the relationship between p53 protein accumulation that prevents epidermal hyperproliferation and mast cell number in its pathogenesis. Methods: In this study, punch biopsies of the 56 cases with diagnosis of psoriasis vulgaris have been investigated. The presence of mast cells in which the granules stain metachromatic with 1% toluidin blue solution has been investigated in cross-sections of formalin-fixed and parafin-embedded tissue samples. In addition, mast cells that show immunoreaction to mast cell tryptase antibody have been observed by streptavidin-biotin peroxidase technique. p53 proportion (number of positive nuclear cells/1000) in epidermal keratinocytes has been determined. Results: Fifty six cases with psoriasis vulgaris consisted of 31 (55.4%) females and 25 (44.6%) males. The ages of the cases range between 6 and 68. The average age is found 41.25 ± 14.14 (mean ± SD). In psoriasis cases, mast cells number (mean: 61.44± 25.98) and p53 proportion (mean: 454.93± 221.07) are found. In control group, mast cells number (mean: 74,61 ± 25,89) and p53 proportion (mean: 176,36 ± 109,18) were determined. A significant difference between psoriasis cases and control group in terms of mast cell number ($p<0.008$) and p53 proportion ($p<0.001$) was detected. No correlation has been found between mast cell number and p53 proportion. However, a moderate degree correlation ($r:0,30$, $p<0.05$) has been found between mast cell number and p53 proportion in the control group. Conclusion: Since the obtained correlation between mast cell number and p53 proportion of healthy skin is not valid for psoriasis cases, it is thought that these variables act differently in pathogenesis of psoriasis vulgaris.

PP4-130
EXPRESSIONS OF HEREGULIN IN MELANOCYTIC NEVUS, DISPLASTIC NEVUS, AND MELANOMA

Aslı Altaykan Hapa[1], Gul Erkin[1], Ozay Ozkaya[2]
[1] Hacettepe University, Department of Dermatology, Ankara, Turkey
[2] Hacettepe University, Department of Pathology, Ankara, Turkey

BACKGROUND. Heregulins are natural ligands for the growth factor family receptors called c-erbB-3 and c-erbB-4. Current studies suggest that thay can regulate a variety of responses including proliferation, differentiation, and survival. In addition, overexpressions were shown to be associated with stimulation of carcinogenesis. In this report, we study the expressions of heregulin in melanocytic, displastic nevi, melanoma and investigate their role in neoplastic transformation of melanocytes . METHOD. Using specific antibodies of heregulin, formalin-fixed paraffin embedded specimens of 13 melanoma, 8 displastic nevi, and 12 melanocytic nevi were examined for the expressions of heregulin. RESULTS. Nine of 13 (69%) melanoma, 7 of 8 (87%) displastic nevi, and 8 of 12 (66%) melanocytic nevi tissues showed moderate to strong immunoreactivity. Predominantly diffuse cytoplasmic staining was observed. Junctional melanocytic nests had stronger reactivity than dermal nests. Seventeen out of 33 (51 %) samples expressed heregulin in > 50 % of tumor cells. Additionally, keratinocytes at the upper layer of the epidermis also showed moderate to strong immunoreactivity in all samples. CONCLUSION. Although, heregulin expression were found in the majority of the tissues, we have demonstrated variable expression of heregulin in nevi and melanomas which do not differantiate between nevi and melanomas, but suggest an idea to investigate the heregulin as a new melanocyte marker. As the number of the tissues investigated in our study were taken into consideration, analysis of heregulin expression in larger series will enable us to identify as a useful marker.

PP4-131
MRNA VEGF-A EXPRESSION AND VEGF-A PROTEIN IN SKIN WOUND HEALING

Lovorka Batelja, Bruno Vuletić, Luka Brčić, Ivana Ilić, Sanja Kapitanović, Predrag Sikirić, Sven Seiwerth
Department of Pathology, Medical Faculty, University of Zagreb, Croatia

Introduction: Healing is a complex process of initial inflammation, granulation tissue formation and tissue remodeling. Angiogenesis is a necessary part of wound healing, and VEGF-A is a dominant mediator of physiological and pathological angiogenesis. VEGF-A is a mitogen for endothelial cells. Syntetic pentadecapeptide BPC 157 has so far demonstrated influence on healing process in morphological studies. To our knowledge most of healing studies involving VEGF were performed in vitro. Purpose of the study: to analyze in vivo wound healing by second intention through expression of mRNA VEGF- A and protein VEGF-A and attempt of compare them in control group and group treated with BPC 157. Methods: Full-thickness excisional wounds were made on the back of adults Wistar rats (3 animals / group). Animals were treated with BPC 157; 10 μg / kg, i.p. or eqivolume of saline.. Wounds were left uncovered and harvested 4, 6, 12, 24, 48, 72, 120, 168 hrs after injury. Half of the full thickness skin wound area was taken for histology/immunohistochemistry and molecular analysis respectively. For immunohistochemistry we used VEGF 147 antibody (Santa Cruz Biotechnology) following manufacturers protocol. For analysis mRNA VEGF expression analysis RT-PCR method was used. Results: In our study the expression of mRNA VEGF-A in control group followed the published data in wound healing by second intention (VEGF levels peaked at 6 and 48 hrs post-injury) and in group treated with BPC 157 mRNA VEGF showed a sinusoidal curve with three positive and two negative peaks tending toward basal level. Expression of VEGF-A protein was found in epidermis, dermis, hypodermis in both groups of animals, in vessels and in perivascular area. VEGF protein expression was significantly elevated 12 hrs post-injury in vessels of hypodermis in treated group and 48 hrs in perivascular area of hypodermis control group of animals. VEGF protein expression was significantly elevated 168 hrs post-injury in epidermis, and 12 hrs in vessels of dermis in control group. Conclusion: Our data suggest that BPC 157 has influence on mRNA VEGF and protein VEGF-A expression. Treatment with BPC 157 results with better controlled and prolonged expression of VEGF. Control group shows that in vivo wound healing by second intention confirms results of in vitro studies.

PP4-132
INFANTILE SYSTEMIC HYALINOSIS, A CASE REPORT

Ozge Gunduz[1], Sibel Ersoy Evans[1], Koray Boduroglu[2], Yasemin Alanay[2], Ozay Ozkaya[3]
[1] Hacettepe University, Department of Dermatology, Ankara, Turkey
[2] Hacettepe University, Ihsan Dogramaci Children 's Hospital, Department of Pediatrics, Clinical Genetics Section, Ankara, Turkey
[3] Hacettepe University, Department of Pathology, Ankara, Turkey

BACKGROUND. Infantile systemic hyalinosis (ISH) is an autosomal recessive, rare and fatal disease. Hyaline deposition occurs in multiple organ systems, including skin. It is characterised by painful joint contractures, small pearly papules on the head, flesh nodules in the perianal region, gingival hypertrophy, generalized osteopenia, diarrhea, recurrent infections and usually thickened skin. The onset occurs within the first few weeks of life and death occurs by two years of age as a result of recurrent pulmonary infections and diarrhea. Unfortunately, treatment is primarily palliative as there is no cure currently available. METHOD AND RESULTS. Herein, we report an 8-month-old boy that was referred for a rash that appeared on his neck approximately 4 months earlier. He was born after a full-term pregnancy by caesarean section due to breech presentation. He was the sixth child of non-consanguineous parents who were from the same village. There was no family history of ISH. At 2 months of age, his mother noticed decreased upper and lower limb movements. His physical examination revealed gingival hypertrophy, extensive pearly erythematous papules all around his neck, a 4x4 cm purple plaque located over the sacral area, multiple flesh nodules around perianal region and purple patches located over his right 3th and 4th proximal interphalangeal joints and on both ankles. There was also extension contracture and stiffness in his cervical region, flexion deformity of his limbs with frog-leg position. Radiological evaluation showed generalized osteopenia and metaphysial enlargement. Histopathological examination of one of the papules showed compact amorphous eosinophilic hyaline deposits in the dermis. With the characteristic clinical presentation and histopathological findings, a diagnosis of ISH was made. Unfortunately, the patient died at 16 months of age. CONCLUSION. When encountering an infant with joint stiffness, purplish discoloration over the joints and papules around the neck, ISH should be a differentiative diagnostic consideration.

PP4-133
THE VALUE OF IMMUNOPHENOTYPING AND T-CELL RECEPTOR GAMMA GENE REARRENGEMENT IN THE DIAGNOSIS OF MYCOSIS FUNGOIDES

Arbil Acıkalin[1], İlhan Tuncer[1], Melek Ergin[1], Yasargul Denli[2], Gulsah Seydaoglu[3]
[1] Cukurova University, Medical School, Department of Pathology, Adana, Turkey
[2] Cukurova University, Medical School, Department of Dermatology, Adana, Turkey
[3] Cukurova University, Medical School, Department of Biostatistics, Adana, Turkey

Background: Mycosis fungoides is characterized with neoplastic infiltration of skin by dominant CD4 positive T lymphocytes. However, the diagnosis may be difficult for both dermatologist and pathologist in early lesions, hence clinical and histomorphological features may be nonspecific. Our aim was to evaluate the value of immunophenotyping and T cell receptor γ gene rearrengement studies as an adjunct to the histomorphological diagnosis of mycosis fungoides. Method: Histomorphological, immunohistochemical and polymerase chain reaction analysis were performed on formaline fixed, parafine embedded tissue sections of 73 cases (39 mycosis fungoides with classical histomorphology, 16 with suspicious histology for mycosis fungoides, 18 benign inflammatory dermatoses as a control group). Histomorphologically, three major (epidermotropism, Pautrier microabscess, atypical lymphocyte) and two minor (spongiosis, collagen increase) criterias were evaluated on H&E slides. Antibodies to CD3, CD4, CD8 by using immunohistochemistry and T cell receptor γ gene rearrengement analysis with polymerase chain reaction were performed. Results: Significant differences were found in epidermotropism (p=0,000), presence of Pautrier microabscess (p=0,004) and atypical lymphocyte (p=0,000), CD4 percentage (p=0,006), CD4/CD8 ratio (p=0,010), and clonality (p=0,000). Besides, CD8 percentage was not statistically different between three groups. In our study, we found out diagnostic cut-off values for CD4 percentage and CD4/CD8 ratio. That was 26% (sensitivity 82%, specifity 69%) for CD4 percentage and 0,65 (sensitivity 74%, specifity 69%) for CD4/CD8 ratio. Conclusion: Histomorphological features are still gold standart for diagnosis of mycosis fungoides. However, in early mycosis fungoides and the suspicious cases, immunophenotypical evaluation and T cell receptor γ gene rearrengement with polymerase chain reaction analysis -not certainly- but may help to the diagnosis of mycosis fungoides.

[2] Department of Dermatology, University Hospital of Ioannina, Ioannina, Greece

Background: Seborrheic keratoses are common benign epidermal neoplasms with considerable variety of histologic features. They are rarely associated with other skin lesions, such as basal and squamous cell carcinomas and solar keratoses. The precence of co-existing melanocytic lesions is extremely rare. The aim of the present study is to examine the frequency of the association between seborrheic keratosis and melanocytic lesions and the possible origin of the latter. Method: A retrospective analysis of 500 consecutive cases of histologically diagnosed seborrheic keratoses from the Department of Pathology, University Hospital of Ioannina, Greece was carried out. In all cases immunohistochemical staining for Mart-1 (Melan-A, DAKO) was performed using the EnVision system (DAKO) and DAB as chromogen. Results: In only one of the 500 cases (0.2%) an associated, arising within, malignant melanoma was identified (superficial spreading, radial and vertical growth phase), while no benign melanocytic lesions were noted. Non-neoplastic melanocytes were immunohistochemically identified within all the seborrheic keratoses, dispersed in variable numbers. However, their number never exceeded that of the adjacent normal epidermis. Conclusion: The frequency of melanocytic lesions arising within a seborrheic keratosis is extremely low, at least in our region. The reported case of malignant melanoma could be interpreted as a collision tumor, with the melanoma spreading in the seborrheic keratosis, or as a de novo melanoma development within the pre-existing seborrheic keratosis. Evidence supporting the latter is the intriguing presence of melanocytes amongst the squamous and basaloid cells of the seborrheic keratosis, as shown.

PP4-135
SQUAMOUS CELL CARCINOMA COMPLICATING NEVUS SEBACEUS OF JADASSOHN IN A CHILD
Houda Mahmoudi-Brahim, Nejib Ben Yahia, Abdelmajid Dhouibi, Leila Njim, Adnene Moussa, Nada Touil, Abdelfattah Zakhama
Department of Pathology, Univesitary Hospital Center, Monastir, Tunisia

Background: Sebaceus nevi are uncommon congenital skin lesions with a well recognized potential for neoplastic changes. Such change, however, is rare before puberty. Method- Results: We present a case of squamous cell carcinoma arising in a naevus sebaceous of Jadassohn (NSJ) in a 12-year-old girl. Both these events are rare. We review the literature and discuss the association of malignant tumors on a NSJ, and the need of prophylactic surgical excision of this lesion during childhood. Conclusion: this case is unusual for two reasons: first, because squamous cell carcinoma is an uncommon malignancy in NSJ; and, second, because of the patient's unusually young age.

PP4-136
PROLIFERATING TRICHILEMMAL TUMOR OF THE VULVA
Sami Limem, AdnèNe Moussa, Leila Njim, Nada Touil, Rym Hadhri, Nejib Ben Yahia, Abdelfatteh Zakhama
Department of Pathology Fattouma Bourguiba Hospital 5000 Monastir, Tunisia

BACKGROUND: Proliferating trichilemmal tumors (PTTs) are rare cutaneous neoplasms that show features of typical pilar cysts but also show extensive epithelial proliferation, variable cytologic atypia and mitotic activity. PTT are benign lesions; however, the malignant potential of PTT is controversial, as only a small number of clinically or histologically malignant PTTs have been reported. We report an unusal case of PTT occuring on the vulva of a young woman. METHODS AND RESULTS: A 33-year-old woman presented with a gradually enlarging, painless nodule of the left labium majus. The excised tumor was well demarcated, measured 2.5 cm in greatest diameter and was covered by unremarkable skin. Based on the histopathologic findings, this tumor was diagnosed as PTT, despite the presence of moderate cytologic atypia and a florid mitotic activity. A squamous cell carcinoma was ruled out in the absence of infiltrative growth and tumoral necrosis. The patient is disease-free at last follow-up. CONCLUSION: To our knowledge, this is the third reported case of such a tumor occurring in this location. The range of the biological behaviour of this tumor is discussed. Complete surgical excision and accurate follow-up in all cases of PTT are recommended as local relapses and metastatic spread are possible and the biological behaviour of this neoplasm seems to be difficult to predict.

PP4-137
EXTRAMAMMARY PAGET'S DISEASE
Radulescu Doinita[1], Stolnicu Simona[2], Dumitriu Sorin[3]
[1] Department of Morphopathology, University of Medicine and Pharmacy 'Gr. T. Popa ' Iassy, Romania
[2] Department of Morphopathology ,University of Medicine and Pharmacy Tg. Mures, Romania
[3] 'St. Mary' Children Hospital, Iassy, Romania

Extramammary Paget disease (EMP) is a scaly erythematous eruption affecting apocrine gland bearing areas of the skin. It usually occurs in the genital, axillary or perianal regions. The majority of cases represent an apocrine adenocarcinoma in situ that has a high recurrence rate and may invade the dermis and then possesses metastatic potential. Primary EMP is an apocrine adenocarcinoma in situ that most likely arises from intraepidermal cells of apocrine gland ducts. We present 4 cases of EMP that occurred in the axillary, perianal and vulvar regions. The clinical findings were suggestive of eczema or Bowen's disease. The treatment of EMP is essentially by surgical excision with clear margins.

PP4-138
BASAL AND SQUAMOUS CELL CARCINOMAS: DIFFERENCES IN THE VASCULATURE, VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF), VEGF RECEPTOR-1 (VEGFR-1) AND VEGF RECEPTOR-2 (VEGFR-2) EXPRESSION
Amalia Tsiatoura, Anna Batistatou, Aikaterini Zioga, Niki J Agnantis, Dimitrios Stefanou
Department of Pathology, University of Ioannina, Medical School, Ioannina, Greece

BACKGROUND: Basal (BCC) and squamous cell (SCC) carcinomas are the most common skin carcinomas. It is well known that there is a significant difference in the behavior of these tumor types, with SCCs but not BCCs undergoing metastatic spread. Vascular endothelial growth factor (VEGF) is a homodimeric disulfide-linked glycoprotein involved in angiogenesis. Tumor angiogenesis is essential for tumor growth and appears to play an important role in tumor progression and development of metastases. The aim of the present study was to investigate whether the different biological behavior of BCCs and SCCs is associated with differences in their microvasculature and the molecules involved in neoangiogenesis. METHOD: We performed a retrospective study in 107 patients, 51 with BCCs (27 male, 24 female, average age 69.5 years, average maximal diameter 1.13cm) and 56 with SCCs (37 male, 19 female, average age 74.3 years, average maximal diameter 1.25cm). We

performed immunostaining on formalin-fixed, paraffin-embedded tissue sections using En Vision System (DAKO) and the monoclonal antibodies CD31 (Menarini Hellas), VEGF (VEGF Ab-3 JH121, Neomarkers, USA), VEGFR-1 (RP 077, DBS, USA) and VEGFR-2 (RP 076, DBS, USA). DAB was used as a chromogen. The percentage of the tumor cells that exhibited a positive immunoreactivity was determined using a ×40 objective lens. At least 1000 neoplastic cells were counted in each case and a semiquantitative method was used. RESULTS: Microvessel counts and VEGF and VEGFR-2 (but not VEGFR-1) expression differed in a statistically significant manner in the two tumor types, being more prominent in the SCCs. Furthermore, there were cases of BCCs with essentially no intratumoral blood vessels and no VEGF or VEGFR-2 expression. In SCCs, increased microvessel counts and VEGF, VEGFR-2 expression was significantly associated with low differentiation. CONCLUSION: The differences in the vasculature, VEGF and VEGFR-2 expression between SCCs and BCCs may, at least in part, account for their different biological behavior. Furthermore, SCC may represent a suitable neoplasm for antiangiogenic treatment in combination with conventional therapeutic approaches.

PP4-139

A PATIENT WITH SEBACEOUS CARCINOMA, SEBACEOUS EPITHELIOMA, KERATOACANTHOMA, BASAL CELL CARCINOMA, SEBORRHEIC KERATOSIS AND MULTIPLE ACTINIC KERATOSIS WITHOUT INTERNAL MALIGNANCY (MUIR-TORRE SYNDROME): A CASE REPORT

Nevra Dursun, Zuhal Gucin, Fadime Bahadir, H. Esra Pasaoglu, Kemal Behzatoglu, Nuri Osman Huten, Can Isler, Ummuhan Kiremitci
The Ministry of Health İstanbul Training and Research Hospital, Istanbul, Turkey

Muir-Torre Sydrome represents the association of multiple sebaceous tumors, or keratoacanthoma with visceral malignancies. Cutaneous neoplasms can precede or follow a diagnosis of visceral malignancy. A 75 year old man was admitted the dermatology clinic for multiple skin lesions on his face. 14 lesions were excised.We reported one sebaceous carcinoma, one sebaceous epithelioma, one keratoacanthoma, one basal cell carcinoma, one seborrheic keratosis and nine actinic keratosis. We thought this case as a Muir-Torre syndrome and searched for internal malignancies. Colonoscopy, whole body computed tomography and prostate biopsy had made. But internal malignancy could not find. This man was worked in municipal worker for 37 years, so exposed sun light for a long time. 15 years ago and 10 years two lesions were excised, 5 years ago one more lesion was excised again. This year all of 14 lesions all appeared within 1 month. Crusted papulonodular new skin lesions are devoloped after the last exicisions. The patients with multiple sebaceous tumors and keratoacanthoma must be evaluated for the presence of visceral malingnancies. Recognition of multiple sebaseous neoplasms by pathologists and communication to clinicians of its strong association with Muir-Torre syndrome is of diagnostic importance. Our patient is followed up for skin lesions and for internal malingnancies.

PURELY CUTANEOUS ROSAI-DORFMAN DISEASE

Kenani Nesrine[1], Mebazaa Amel[2], Yacoubi Tahar[1], Denguezli Mohamed[2], Belajouza Colanda[2], Nouira Rafia[2]
[1] Department of Pathology Farhat Hached Hospital Sousse,Tunisia
[2] Department of Dermatology Farhat Hached Hospital Sousse 4000, Tunisia

Background: Rosai-Dorfman disease (RDD) is a rare, benign, histiocytic disorder of unknown etiology. It's usually characterized by extensive painless lymphadenopathy often associated with many systemic manifestations. Extranodal involvement is seen in 25 to 43% of cases. Although the skin is the most common site of extranodal involvement, purely cutaneous RDD is very rare. We report a case of a 12-year-old girl who presented a particular purely cutaneous RDD. Methods: Among a rare case of purely cutaneous RDD, we discuss the epidemiological features, clinicopathological manifestations and treatment of this disease. Results: A12-year-old girl with a 3-month history of a widespread non pruriginous papulo-nodular eruption consulted in our department of dermatology. Physical examination revealed a profusion of firm erythematous papules and nodules, distributed mainly on cheeks, perioral region, the upper trunk, thighs and legs, mimicking a molluscum contagiosum eruption. No fever or lymphadenopathy was noted. Complete blood count was normal. Erythrocyte sedimentation rate was elevated to 60 mm/hr. Serum protein electrophoresis showed polyclonal hypergammaglobulinemia. Skin biopsy showed a reticular dermal nodular infiltration by lymphocytes, neutrophils and large vacuolated histiocytes with emperipolesis. Histiocytes were positive for PS-100 and CD68, and negative for CD1a. No systemic involvement was detected within a systemic work-up. These features were consistent with the diagnosis of purely cutaneous RDD. Because of the profusion of skin lesions, the patient was treated 20mg daily with acitretine for 4 months and surgical excision of large lesions. Skin lesions cleared progressively and continued to clear spontaneously after treatment interruption. Conclusion: Cutaneous variant of RDD (CRDD) has been rarely reported. About 3% of patients have disease detectable only in the skin. CRDD affects habitually older people with a preference for white females. Clinical features of this disease are nonspecific and there are no cutaneous sites of predilection. Typical histologic features are usually present in CRDD. Immunohistochemical studies are of great interest for the diagnosis.

PP4-141

HISTOPATHOLOGIC CLASSIFICATION IN BASAL CELL CARCINOMA AND COMPARISON OF P53 AND BCL-2 STAINING PATTERNS BETWEEN HISTOLOGIC GROUPS

Seda Yamak, Muzeyyen Astarci, Haluk Pulat, Mehmet Gonultas, Elif Ozer, Muzaffer Caydere, Huseyin Ustun
Ankara Education and Research Hospital, Ankara, Turkey

Basal cell carcinoma (BCC) is a skin tumor originating from pluripotential primordial germ cells in epidermis and skin appendage. It is usually local invasive and rarely makes metastasis. However, many studies were carried out with respect to this tumor due to its characteristics of considerable morbidity, risk of developing a secondary BCC in individuals having this malignity and rare but potential risk of causing metastasis. In several studies, it was presented that aggressive BCC's expressed more p53 and stained lesser with bcl-2. In our study, 75 patients, who were diagnosed as BCC between 2001-2005 at Pathology Department of Ankara Education and Research Hospital of the Ministry of Health were re-examined. Patterns were evaluated in respect of age, gender, localization, histological subtypes, staining patterns with p53 and bcl-2, ulcer, inflammation and presence of pigment. Although our findings do not indicate statistically satisfactory results, higher rate of staining by using bcl-2 and lower rate of staining by using p53 was noticed in non-aggressive histologic groups. However, there was no considerable difference between two markers in aggressive tumor sub-types. Our study pointed out that expression of bcl-2 and p53 may not be used as identifiers indicating aggressive or non-aggressive progress in BCC.

PP4-142
EPIDEMIC AND CLINICO-PATHOLOGIC PROFILES OF MELANOMA IN CENTRAL TUNISIA
Kenani Nesrine[1], Said Sana[2], Ghariani Najet[2], Kebir Fatima Zahra[1], Sriha Badreddine[1], Belajouza Colandane[2], Nouira Rafia[2]
[1] Department of Pathology Farhat Hached Hospital Sousse,Tunisia
[2] Department of Dermatology Farhat Hached Hospital Sousse 4000, Tunisia

Background: Melanoma is a malignant cutaneous tumor characterised by an important metastatic potential. The aim of the present investigation was to report the epidemic and clinico-pathologic profiles of melanoma in Tunisia. Methods: A retrospective study was made recording all patients diagnosed as melanoma at the dermatology and the pathology departments of Farhat Hached hospital in Sousse, from January 1985 to December 2006. Results: Fifty nine patients were assessed with a mean age of 60,7 years (range: 5-92 years). Women were more commonly affected, the sex ratio being 1,36 (34F/25M). Consultation average was 16 months (range: 15 days- 8 years). The melanoma occurred in 66% (n=39) on a normal skin. It was localised on: extremities in 51,7 % (n=30), legs in19,1% (n=11), trunk in13,8% (n=8), face and hair in 13,8% (n=8). One case of nail's melanoma was noted. The most common clinico-pathologic variant was the acro-lentiginous melanoma (ALM) diagnosed in 30 cases (51,7%). The other variants were: nodular melanoma (NM) in 16 cases (28%), superficial spreading melanoma (SSM) in 9 cases (16%) and lentiginous malignant melanoma (LMM) in one case (1,8%). Histo-pronostic criteria showed Clark level higher than IV in 75,6% (n=34) of patients. The mean Breslow was 7,15 mm (range: 0,6-15 mm). Conclusion: The melanoma is considered as the most malignant cutaneous tumor. InTunisia, the most frequent clinico-pathologic variant is represented by the acro-lentiginous melanoma (ALM) estimated to 51,7 % in our study, whereas the SSM (superficial spreading melanoma) is the most frequent clinical variant (70%) reported in other countries. Unfortunately, this disease is frequently diagnosed late, that's why prognostic indicators are pejorative. Educational programs are important to be established in order to improve the early detection of this tumor.

PP4-143
FOLLICULAR MUCINOSIS AND HODGKIN DISEASE
Luis Alfaro[1], Maria Jose Roca[2], Silvia Tena[1]
[1] Hospital Rey Don Jaime Castellon, Spain
[2] Hospital Lluys Alcanys Xativa, Spain

Follicular mucinosis is a peculiar cutaneous disorder, usually appearing as an incidental finding, but uncommonly associated with mycosis fungoides. Follicular mucinosis has been discovered besides in patients with malignant diseases, such as Kaposi sarcoma, chronic lymphocytic leukaemia, and Hodgkin's disease. We had this association developed in a 38-year-old male, who presented with lymph node enlargement in cervical, axillar, and inguinal regions, and simultaneously with cutaneous lesions in face and neck. A 2 cm axillar lymph node was excised, and also a cutaneous biopsy of the lesions was taken. The skin showed a normal epidermal layer, and a superficial and medium dermal inflammatory infiltrate. Lymphocytes and some eosinophils adopted and interstitial pattern, with focal extension to follicular epithelium. There were mucin deposits inside the follicles and dissecting epithelial cells. They stained with colloidal iron. Neither neoplastic lymphocytes nor atypical cells were seen. The lymph node showed on the histological study an architectural lack of structuration, with large nodules of small and medium round cells, and only scattered original follicles, with small germinal centres, entrapped among the rest of cellularity. Some cells had big nuclei, folded and multilobated, with pale chromatin, and small nucleoli, with the typical form of LH cells of lymphocyte predominance Hodgkin's lymphoma. Immunohistochemical study revealed B-cell markers expression in both small and LH cells, with minimum presence of reactive T CD3-positive cells. CD30 and EMA were negative, and bcl2 had a faint expression without nodular enfacement. The diagnosis was follicular mucinosis and nodular lymphocyte predominance Hodgkin's disease. Subsequent studies were done, and a bone marrow biopsy showed lymphomatous infiltration with nodular pattern similar to the one in lymph node. Although the association described is an uncommon event, there may have special significance based in the fact that several studies suggested a possible poor prognosis in patients with this two conditions. Our case seems to be in the same line, because the wide lymphomatous dissemination at the time of diagnosis, is not the usual presentation for lymphocyte predominance Hodgkin's disease.

PP4-144
SUPERFICIAL GRANULOMATOUS PYODERMA GANGRENOSUM
M. Nieves Saracibar, Blanca Caton, Julia De Diego, Nagore Arbide
Hospital Santaigo Apostol, Spain

Pyoderma gangrenosum (pg) is an idiopathic neutrophilic dermatosis described by brunsting et al, in 1930. Since its description, the pathogenesis of pg has remained obscure even as an ever-widening array of systemic diseases has been described in association with it. Classic pg can occur on any skin surface, but is most commonly seen on the legs, with one or more ulcers with raised edges. genitalia may be involved. Superficial granulomatous pyoderma is a variant of pg, important to recognize and differentiate from classic, with better prognosis and not associated with underlying diseases. there are approximately 55 cases in the literature. The most important histopahological characteristic is the granulomatous pattern and his diferential diagnosis with others granulomatous dermatosis. clinical history: A 78 year old male patient with type 2 diabetes mellitus developped a nodular lesion in his penis.clinical suspicion of carcinoma. after non-conclusive biopsies, a partial penectomy was performed. later he developed more lesions in scrotum. Histologically shows granulomatous formation with sinus tracts and numerous imflamatory cells and plasma cell infiltration. The differential diagnosis included fungal or mycobarcterial infection, bromoderma, ulcerative sarcoidosis and other types of cutaneous granulomatous disorders. We have to think in pgg in cases of granulomatous pattern even in atypical localizations.

PP4-145
IMMUNOHISTOCHEMISTRY HELPS DIFFERENTIATING HALO NEVUS FROM MELANOMAS WITH BRISK TUMOR INFILTRATING LYMPHOCYTES
Ozlem Erdem[1], Victor G Prieto[2]
[1] Gazi University Faculty of Medicine Department of Pathology, Ankara, Turkey
[2] University of Texas M. D. Anderson Cancer Centre Department of Pathology, USA

Background: Lymphocytic infiltration that accompanies melanocytic lesions causes difficulty in distinction between malignant and benign lesions on conventional histopathology. Although labeling of HMB-45 and expression of Ki-67 in benign and malignant melanocytic lesions has been investigated in many studies, little is known about the expression of these markers in melanocytic lesion with dense lymphocytic infiltrate. In this study; we aimed to investigate whether there is a possible differential expression of HMB-45 and Ki-67 in benign and malignant melanocytic lesions with or without intense lymphocytic infiltration. Methods: Immunohistochemistry was performed using formalin-fixed, paraffin-embedded tissue blocks from 68 melanocytic lesions; 13 halo nevi, 7 dysplastic nevi with

halo phenomenon, 17 dysplastic nevi without halo phenomenon, 15 invasive malignant melanoma with brisk lymphocytic infiltrate and 14 invasive malignant melanoma with nonbrisk lymphocytic infiltrate. Results: Both halo nevus and dysplastic nevus cases showed the same HMB-45 labeling pattern; strong labeling in the junctional component but only focal or weak in superficial dermal component. In melanomas, however, HMB-45 labeling was also evident in deep dermis as well superficial dermis. The number of Ki-67 positive cells in the melanoma cases with non-brisk infiltrate was significantly higher than that observed in any of the melanocytic lesions studied ($p<0.001$). Kaplan-Meier survival analysis revealed that neither Ki-67 expression nor HMB-45 labeling correlated with overall survival in melanomas. Conclusions: An immunohistochemical panel, including HMB-45 and Ki-67 might be useful in evaluating melanocytic lesions characterized by intense lymhpocytic infiltration.

PP4-146
TWO CASES WITH T PSEUDOLYMPHOMA

Ebru Zemheri, Tulay Zenginkinet, Ilkin Zindanci, Haydar Yalman, Mukaddes Kavala
Istanbul Goztepe Training and Research Hospital, Istanbul, Turkey

Background: Cutaneous pseudolymphomas encompass a heterogeneous group of benign reactive lymphoproliferative diseases of T- and B-cell which is clinically and histopathologically resembling malignant lymphomas. The clinical appearance of pseudolymphoma is variable and usually characterized by single or multiple, and small or large red-purple doughy or firm bumps that are usually located on the head and neck, but it can involve any area of the body. Histopathologic apperance of T-cell pseudolymphomas are characterized by a superficial bandlike infiltrate or, rarely, by a nodular pattern located in the upper dermis. Cases: 18 year-old patient with erythematous, indurated nodules on the right appearance of chin and 35 year-old patient with hyperpigmented dome shaped nodul on the nose were taken biopsy. Histologically and immunologically, we detected T-cell pseudolymphoma in both cases. Conclusion: Classification of cutaneous lymphoproliferative disorders can only be achieved by a combination of clinical, histopathologic, immunophenotypic investigation. The purpose of this article is to summarize the criteria in the differential diagnosis of benign or malignant T-cell lymphoid infiltrates of the skin. We reported two patients who had been histopathologically diagnosed as T-cell pseudolymphoma. Key words: T-cell, pseudolymphoma, skin

PP4-147
EPIDERMAL LANGERHANS CELLS AND DERMAL MAST CELLS IN BENIGN AND MALIGNANT NEOPLASTIC SKIN LESIONS

Canten Tataroglu[1], Nil Culhaci[1], Emel Dikicioglu Cetin[1], Zehra Kesen[2], Hicran Turhan[1]
[1] Adnan Menderes University Medical Faculty, Aydın, Turkey
[2] Denizli State Hospital, Denizli, Turkey

Immune cells of the epidermis and dermis participate in the tumor progression and development. Langerhans cells are epidermal antigen presenting dendritic cells. Mast cells represent a critical role in the immune system in the dermis. In the present study, we aimed to evaluate mast cells and Langerhans cells in some skin lesions including seborrheic keratosis, keratoacanthoma, actinic keratosis and squamous cell carcinoma. This study included 12 patients with seborrheic keratosis, 9 patients with actinic keratosis , 15 patients with keratoacanthoma and 35 patients with squamous cell carcinoma. Dermal mast cells and epidermal Langerhans cells were labeled with mast cell tryptase and S100 antibodies. In the data analysis, mast cells and Langerhans cells were counted and averaged in three representative area at x200 magnification. The number of the mast cells was significantly increased in the patients with squamous cell carcinoma in comparison with seborrheic keratosis (p:0.001). However, this parameter did not show significant difference between patients with seborrheic keratosis and actinic keratosis and between patients with seborrheic keratosis and keratoacanthoma ($p=0.733$, $p=0.417$). The number of the mast cells obtained from patients with squamous cell carcinoma did not show significant difference among patients with actinic keratosis and keratoacanthoma ($p=0.986$, $p=0.079$). The number of the Langerhans cells obtained from the patients with squamous cell carcinoma was significantly increased in comparison with seborrheic keratosis ($p=0.023$). Any difference was not observed between the patients with actinic keratosis and keratoacanthoma ($p=0.731$, $p=0.601$). Nevertheless, the number of the Langerhans cells was increased in the patients with squamous cell carcinoma in comparison with actinic keratosis ($p=0.002$). The numbers of the Langerhans cells and mast cells showed a lineer correlation only in the patients with actinic keratosis (r:0.8, p:0.008). Our data suggested that both epidermal Langerhans cells and dermal mast cells which have some contributions in the immune system, may have role in progression, development or regression of some skin tumors.

[3] Marmara University, Nursing School, Haydarpasa, İstanbul-Turkey
[4] Marmara University, Department of Pharmaceutical Biotechnology, Faculty of Pharmacy, Haydarpasa, İstanbul, Turkey.

Background: Chitosan is a natural cationic linear polymer that has recently emerged as an alternative nonviral gene delivery system.It has been advantageous biological properties in the application as wound dressing, namely biocompatibiltiy, biodegradability, anti-infectional activity and a property to accelarate wound healing.In experimental animal models, chitosan was shown to influence all stages of wound repair.The hemostatic activity of chitosan can be seen in the inflammatory phase. It also interacts with and regulates the migration of neutrophils and macrophages acting on repairing process. During the inflammatory stage, chitosan accelerates the infiltration of inflammatory cells.At the new tissue formation period, formation of granulation tissue takes place within the wound space. We have researched the different methods for staining chitosan in the experimental skin wound model.Histological analyses that performed for assessment in wound healing of chitosan products are important.Therefore, it is necessity a simple and effective method for proper histological identification of chitosan materials. Method: For skin topical application, Wistar rats were first anesthetized, their backs shaved and full thickness skin wound was made at two individual sites on the dorsum of the back of each animal.Thereafter, 100µg LMW chitosan per wound sites were topically given.Skin samples were harvested 24,48,72hours (acute term) and 1,2weeks (chronic term) after application.Specimens were paraffin embedded, sectioned and able to observe specific staining of the chitosan particles with Cibacron-Brillant Red-3BA and Iron Hematoxylin and also Safranin-O/fast Green and Iron Hematoxylin staining methods.

Results: CBR-3BA iron hematoxylin was used for identifying the presence of chitosan incorporated with chitosan-given to rats.Chitosan was observed as red particles, iron hematoxylin was resulted blue coloration of nuclei.Cytoplasm and collagen fibrils were appeared pink color.The second method for specific staining of chitosan used the Safranin-O/Fast Green.Chitosan particles was appeared green color and with iron hematoxylin yielded stained nuclei. Conclusion. Chitosan that is an attractive material in biotechnology, used widespread fields as tissue engineering and drug delivery.Therefore, simple and specific staining methods are critical.This staining methods were highly successful in locating small quantities of chitosan in a dermal wound model.These methods may key a role progressing in the histological study of chitosan-based biotechnological products.

BCL-2 OVEREXPRESSION AT LYMPHOCYTES IN SKIN LESION AND PERIPHERAL BLOOD IN PATIENT WITH PSORIASIS VULGARIS

Nebil Bal[1], İlhan Tuncer[2], Mete Baba[3], Filiz Bolat[2]
[1] Baskent University Medical Faculty Department of Pathology Ankara, Turkey
[2] Baskent University Medical Faculty Department of Pathology Ankara, Turkey
[3] Baskent University Medical Faculty Department of Dermatology Ankara, Turkey

Psoriasis is a chronic inflammatory skin disease which is characterized with healing and relapsing processes. Cellular immunity mediated by T cells is accused in pathogenesis. Bcl-2 is an anti-apoptotic gene related to the bcl-2 gene family, and its overexpression in lymphocytes has been shown in some chronic inflammatory and neoplastic diseases. 39 patient with psoriasis vulgaris were taken for study group and bcl-2 expression was investigated in skin biopsies by immunohistochemically which was taken from the active skin lesion and in peripheral blood by flowcytometric analysis. It was planned that to be done flowcytometric analysis before and after the topical steroid treatment. 10 pilonidal sinus cases were selected as negative control group for immunohistochemistry and 10 patient with active Systemic Lupus erythematosus (SLE) as positive control group for flowcytometric analysis. Bcl-2 overexpression was determined in dermal lymphocytes in different intensities in all the psoriatic skin lesions except one but not found in control groups. Flowcytometric analyses could be performed in 18 patients with psoriasis vulgaris before the treatment and in 10 of 18 patients after the treatment. Mean bcl-2 expression value was found 86.82 % at the beginig and 86.02 % after the treatment and 89,3 % in groups of active SLE patient. Significant correlation was found between psoriasis vulgaris and active SLE groups. The presence high levels of bcl-2 overexpression in dermal lymphocytes and in peripheral blood which was taken before the treatment thought that the bcl-2 overexpression may have an important role in the pathogenesis of psoriasis vulgaris. Patient with active lesion of psoriasis vulgaris exhibited levels of bcl-2 expression similar to those in active SLE, suggesting that raised bcl-2 levels may be characteristics of the inflammatory diseases. Although the skin lesions have improved with topical steroid therapy, the continuity of high levels of bcl-2 expression in peripheral blood indicate the insufficiency of the topical treatment. In conclusion, we speculated that systemic steroid therapy may be useful to reduce the bcl-2 expressing T lymphocytes levels in peripheral blood and that alternative theapy may be more effective in the treatment or in prevention of recurrences and systemic complications of psoriasis vulgaris. Further studies about the effects of systemic treatment on bcl-2 expression will be helpful.

EXTRAOCULAR SEBACEOUS CARCINOMA ARISING FROM THE SCALP

Chaabouni Najla[1], Sassi Samia[1], Abbes Imen[1], Dhouib Rym[1], Driss Maha[1], Mrad Karima[1], Labben Naceur[2], Ben Romdhane Khaled[1]
[1] Department of Pathology, Salah Azaeiz Institute, Bab Saadoun, Tunis, Tunisia
[2] Department of Pathology,Habib Thameur Hospital,Tunis,Tunisia

Sebaceous carcinomas of the skin are rare tumors. Most of them often occur on the skin of the head and the neck. They are slow-growing, locally aggressive and capable of metastatic spread. They exhibit a variety of histologic growth patterns which may cause differential diagnosis hardship. We describe a case of grade II sebaceous carcinoma in a 67-year-old Tunisian woman localized on the scalp. It was associated with a metaplastic squamous component that has led initially to a diagnosis of degenerated trichilemmal cyst or squamous cell carcinoma. But, histochemical (ORO +: oil red O stain for lipid) and immunohistochemical (EMA+, ACE -, CD15-) studies using formalin-fixed and paraffin-embedded tissue specimens confirmed the the diagnosis of sebaceous carcinoma. We discuss clinical, histological, histochemical and immunohistochemical profiles of this aggressive neoplasm.

Background: To present an unusal case of granuloma inguinale presented on the surface of haemorrhoids. Method: The patient was male, 46 years old, presented to the surgical department of our hospital, due to enlarging of haemorroids. The physical examination confirmed that there was cirsoid ectasia of the haemorroid veins. There was also an extended skin rash of the perigenital and perianal area. The patient underwent haemorrhoidectomy. Results: Four reddish nodules, 2.2-3.4 cm in greatest diameter were received. On the surface small, whitish, elevated lesions were observed. Microscopic examination revealed the usual findings of the veins of the submucosal. The mucosa was infiltrated with many lymphocytes, plasma cells and neutrophills, sometimes in small aggregates. There were also many histiocytes. The squamous epithelium showed pseudoepitheliomatous hyperplasia and focal small ulcerations. The Giemsa stain revealed that the histiocytes contained small intracytoplasmatic inclusion bodies which considered to be Donovan bodies. The patient was then examined by a Dermatologist who agreed with the histological diagnosis and added Doxycyclin in the treatment. Conclusion: Donovanosis is a tropical endemic disease, rare in the West countries. It is a sexually transmitted disease caused by Calymmatobacterium granulomatis. It usually affects the perianal and perigenital area. To our knowledge is not usual on the surface of haemorrhoids.

PP4-152

A CASE OF MONOCYTIC LEUKAEMIA CUTIS IN A PATIENT WITH MYELODYPLASIC SYNDROME TRANSFORMING TO ACUTE MYELOID LEUKAEMIA

Zribi Jihène[1], Ayadi Lobna[2], Makni Saloua[2], Bellaaj Hatem[3], Kallel Rim[4], Khabir Abdelmajid[4], Gouiaa Nourez[4], Sellami-Boudawara Tahya[4]
[1] Pathology Department Habib Bourguiba Hospital, Tunisia
[2] Pathlogy Department Habib Bourguiba Hospital, Tunisia
[3] Hematology Department Hedy Chaker Hospital, Tunisia
[4] Pathology Department Habib Bourguiba Hospital, Tunisia

Background: Leukaemias are a group of disorders characterized by the presence of white blood neoplasic cells in the blood stream and in bone marrow. Rarely infiltration of skin may be observed. Occasionally, skin lesions may precede haematological manifestations or may be concomitant with the diagnosis of systemic leukaemia; we report a new case of monocytic leukaeia cutis in a patient with myelodysplasic syndrome. Case report: A 66-year-old- women with a 3-year- history of myelodysplasic syndrome with abnormal bone marrow cytogenetics. Over the previous few months she had developed cutaneous lesions on the buttok and thigh; the skin biopsy showed a diffuse infiltrate of cells with bean-shaped nuclei in the upper dermis extending to the subcutis. Immunohistochemistry showed positivity for CD15, CD68 and CD 34. Immunostainingg for CD3 and CD20 was negative. These results were consistent with leukaemia cutis. Conclusion: Leukaemia cutis as the initial clinical presentation of a transforming myelodysplastic syndrome into acute myeloid leukaemia has been reported only very rarely. Our case underlines the need to look meticulously for skin changes and perform early skin biopsies in haematological patients. Skin lesions can represent the first clinical signs of an otherwise not evident bone marrow disorder.

PP4-153

BETA-CATENIN AND CYCLIN D1 EXPRESSION IN THE DETERMINATION OF THE BIOLOGICAL BEHAVIOUR OF KERATOACANTHOMA

Nese Calli-Demirkan[1], Aysegul Aksoy-Altinboga[1], Metin Akbulut[1], Ferda Bir[1], Nilay Sen-Turk[1], Nagihan Yalcin[1], Inci Gokalan-Kara[2]
[1] Department of Pathology, School of Medicine, University of Pamukkale, Denizli, Turkey
[2] Department of Plastic and Reconstructive Surgery, School of Medicine, University of Pamukkale, Denizli, Turkey

Background: Keratoacanthoma (KA) is a benign cutaneous tumor that has rapid growth phase similar to the malignant tumors. KA and squamous cell carcinoma (SCC) are sometimes difficult to distinguish by histopathological examination. The purpose of this study is to determine some histopathological criteria to make a distinction between SCC and KA and the pattern of β -catenin and cyclin D1 immunostaining to evaluate its potential value in difficult cases Material and methods: Immunoperoxidase staining of β -catenin, and cyclin D1 were performed at paraffin-embedded sections of 14 KAs taken from archival material. On reviewing the histology, seven of the 14 KAs were characterized as KA, and the rest as KA resembling SCC. Additionally, 16 well differentiated superficial spreading SCCs were examined. We evaluated macroscopical tumor characteristics (duration of the lesion, diameter, ulceration, symmetricity, central keratin crater) and microscopical findings at each group. Results: Ulceration was found more frequent in SCC(p=0,03) and the symetricity in KAs (p=0,005). Central keratin crater, duration of the lesion or intraepithelial polymorphonuclear abscesses were not significant parameters in the distinction between KA and SCC. Immunohistochemical analysis showed that; in KA group, 6/7 (%85,7) , in KA resembling SCC 1/6 SCCs (%16,7) and in SCC group 5/16 (%31,3) were membranous β -catenin positive in the deeper parts of the lesion . So; when the lesion became invasive, the deeper part of the lesion lost membranous localization of β -catenin(p=0,02). Cyclin-D1 expression was not significant between any groups. Conclusion: These findings suggest that macroscopical findings such as ulceration and symetricity of the lesion are more important than the central keratin crater, intraepithelial polymorphonuclear abscesses or duration of the lesion so as to distinguish KA from SCC. Additionally the loss of membraneous β -catenin expression at the deeper part of lesion may be helpful at the differential diagnosis between KA and KA resembling SCC.

PP4-154

CORRELATION OF EXPRESSION OF GROWTH HORMONE RECEPTOR AND GROWTH HORMONE ON DYSPLASTIC NAEVUS AND SKIN MALIGNANT MELANOMA CELLS

Danko Mueller[1], Cedna Tomasovic-Loncaric[1], Bozo Kruslin[2]
[1] Department of Pathology, University Hospital Dubrava, Zagreb, Croatia
[2] Institute of Pathology "Ljudevit Jurak", University Hospital "Sisters of Mercy", Zagreb, Croatia

AIM OF THE STUDY: To investigate possible differences in expression of growth hormone and its receptor among normal skin, dysplastic naevus and malignant melanoma group. MATERIAL AND METHODS: Twenty cases, ten males and ten females, from each of above mentioned groups were examined to analyse expression of growth hormone and its receptor. The results of immunohistochemistry were shown in semiquantitative manner and were analysed with help of statistical methods, including x2 – test and Kruskal-Wallis ANOVA test, with the level of importance <0,05. RESULTS AND CONCLUSION: The results showed that there was a higher expression of growth hormone receptor in malignant melanoma material, compared with dysplastic naevus and normal skin. Less impressive were results with growth hormone, although very similar pattern of immunohistochemical expression has been detected among mentioned groups. This was confirmed with both x2 – test and Kruskal-Wallis ANOVA test. Therefore we conclude that there might be a possibility to intervene the course of malignant melanoma and dysplastic naevus via growth hormone receptor antagonists. We strongly suggest studies on larger number of patients to be made.

PP4-156

RESEARCH OF THE ANTI-SCAR ACTIVITY OF THE PREPARATION ISONIDEZUM AS A REMEDY, INHIBITING THE CONNECTIVE TISSUE FORMATION

Vladimir Remish[1], Elena Raevskaya[2], Lina Remish[3], Vasile Anestiade[1]
[1] Scientific Centre of Pathobiology and Pathology of the Academy of Sciences of Republic Moldova, Moldova
[2] Medical State University of Republic Moldova, Moldova
[3] Academy of Sciences of Republic Moldova, Moldova

The Preparation Isonidezum as a remedy for the preventive maintenance of the postoperative intraperetoneal adhesions is produced by the pharmaceutical enterprise "Farmako" (Moldova). We used Isonidezum in cosmetology surgery for aesthetic correction of the postoperative scars in comparison with the ointment Dermaxinab, containing 0,05% Clobetanzoli propionatum. The purpose of research - To use the preparation Isonidezum with a new purpose- for a primary preventive maintenance of postoperative scars which were considered as an non- aesthetic complication after removal the nevi. Material and methods of research. We carried out the clinical test for two groups of patients, each of which consisted of 50 individuals requiring the removal of skin benign formations. Their age was of 15-60 years and 11-55 years, in two groups respectively. For confirmation of the clinical diagnosis all the skin formations have been subjected to the morphological analysis in the respective

groups of research: - nevocellular nevi - 34 cases (68%); seborrhea keratosis - 8 cases (16%); papillomas - 3 cases (6%); angiomas - 2 cases (4%); keloids - 2 cases (4%); dermatofibroma - 1 case (2%). In group of comparison: - nevocellular nevi - 45 cases (90%); seborrhea keratosis - 4 cases (8%); keratoacanthoma - 1 case (2%). Results of research. In the patients of the experimental group surgical treatment was accompanied by the subsequent processing of a zone of surgical intervention by the preparation Isonidezum. The borders of the wound were sutured by in layers, with the subsequent application on the wound of a sterile tampon impregnated by solution of Isonidezum. The keeping of the tampon on the wound under light pressure within 2 hours after removal of the formations was recommended. Patients of control group underwent to a usual cosmetic operation without subsequent application Isonidezum. For definition of clinical aspects postoperative scar (color, consistence, smoothness of the surface) patients of both groups were surveyed in 3 and 6 months after surgical intervention. As a result of the researches the occurrence keloids: in research group was one case, in the control group was 6 cases ($p<0,05$). Hence, the application of Isonidezum with these purposes showed the maximum preventive effect, no cases of the repeated referrals of the patients to doctors and cosmeticians. The remote consequences of the application of the preparation Isonidezum in these pathological conditions were not observed.

PP4-157

EXPRESSION OF p14, p16 AND p53 IN RELATION TO HPV IN (PRE)MALIGNANT SQUAMOUS SKIN TUMORS

Kusters-Vandevelde Heidi[1], Melchers Willem[1], De Koning Maurits[2], Quint Wim[2], De Wilde Peter[1], De Jong Elke[1], Aalders Sabine[1], Van De Kerkhof Peter[1], Blokx Willeke[1]
[1] Radboud University Nijmegen Medical Center, The Netherlands
[2] DDL Diagnostic Laboratories, Voorburg, The Netherlands

Background: The tumor suppressor p14 is thought to play a key role in cell cycle control, since p14 provides a crosstalk between the two main pathways governing cell growth, namely the p14-MDM2-p53 and p16-CDK4/6-RB pathway. The expression of p14 in keratinocytic intraepidermal neoplasia (KIN) lesions has not been studied yet. Immunohistochemical studies in cervical dysplasia have reported over-expression of both p14 and p16 in high risk HPV-associated cases. Relations between HPV (human papilloma virus) and the tumor suppressors p14/p16 and p53 in skin (pre)cancer have not been clarified yet. Aims: To study 1) p14 expression, in relation with p16 and p53 expression, in (pre)malignant squamous skin tumors, and possible relations with risk factors for cutaneous carcinogenesis (sun exposure and immune status), and 2) a possible role of HPV in (pre)malignant squamous skin tumors. Materials and methods: Immunostaining for p14, p16 and p53 was performed on paraffin embedded sections of 22 low grade KIN (LKIN) lesions, 49 high grade KIN (HKIN) lesions, and 34 CSCCs from 52 renal transplant recipients (RTRs) and 53 immunocompetent individuals (ICIs). HPV detection was performed using a short PCR fragment (SPF-LiPA) assay, allowing for the detection and genotyping of 25 mucosal HPV genotypes. Beta papillomavirus detection and genotyping was carried out with the PM-PCR RHA method for identification of the 25 established beta-PV types. Results: P14 expression proved independent of the expression of both p53 and p16, irrespective of immune status and sun exposure. We found a significant association between the presence of beta-PV and sun exposure in the RTRs ($p=0.002$). There was no significant association between the overall presence of beta-PV and protein expression, in both the RTRs and ICIs. Conclusions: Relations between p14/p16/p53 expression and HPV presence in skin neoplasia, is different from findings in cervical neoplasia. Main causes are probably that in skin cancer, besides HPV, also sun exposure is implicated, and that in skin lesions, HPV integration in the genome is rare, in contrast to cervical cancer. Our data support the hypothesis that HPV and ultraviolet radiation play a synergetic role in promoting carcinogenesis, probably enhanced by immunosuppression, since we found a significant association between the presence of HPV and sun exposure in the RTRs.

PP4-158

PAPULAR MUCINOSIS: REPORT OF TWO CASES AND REVIEW OF THE LITERATURE

Ozgur Mete[1], Nesimi Buyukbabani[1], Goncagul Babuna[2], Can Baykal[2]
[1] Istanbul University, Istanbul Medical Faculty, Department of Pathology, Istanbul, Turkey
[2] Istanbul University, Istanbul Medical Faculty, Department of Dermatology, Istanbul, Turkey

BACKGROUND: Papular mucinosis (PM) is a rare disease characterized by a symmetric distribution of erythematous to yellowish papules and/or plaques, most commonly involving the face, neck, upper trunk and arms. Some cases are associated with systemic diseases such as paraproteinaemia, dermatomyositis, scleroderma, systemic lupus erythematosus, non-Hodgkin's lymphoma and hypothyroidism. We report herein two cases of PM. The first case was an example of PM in conjunction with Hashimoto's thyroiditis which regressed following thyroid hormone supplementation. The second case was an example to the idiopathic form, which was not associated with any other pathology. REPORT OF THE CASES: Case 1: A 48-year-old woman had erythematous to yellowish, symmetric, 2-5 mm papules and nodules on her forearms since two months. Clinically disseminated granuloma annulare or sarcoidosis were suspected and a punch biopsy was done. Histopathological examination revealed mucin deposition in the dermis. Clinical findings were reassessed and the patient was diagnosed as a dermal mucinosis compatible with PM. Routine blood tests were unremarkable except the level of serum-free T4 10.9 pmol/L (normal range: 11-25), TSH 16.8 mIU/L (normal range: 0.4-4) and anti-thyroglobulin antibodies 379 IU/ml (normal range: 0-60 U/ml). Laboratory findings revealed hypothyroidism associated with Hashimoto's thyroiditis. Lesions regressed frankly after nine months of thyroid hormone supplementation. Case 2: A 13-year-old girl had multiple yellowish and white, symmetric, pruritic, papular lesions on the dorsal part of fingers and hands, forearms, neck, face, and suprapubic region. Clinical diagnosis was PM. Two punch biopsies, from the dorsum of the hand and from the neck were taken. Histopathological examination revealed mucin deposition in the dermis. In the biopsy taken from the hand a fibroblastic proliferation in deep dermis accompanied mucin deposition, which was reminiscent of the scleromyxedema variant. Routine blood tests were unremarkable and paraproteinaemia was not found. Lesions regressed frankly following four months of methylprednisolone (16 mg/day) and isoretinoin (40 mg/day) therapy. CONCLUSION: It is not clear why mucin production increases in pathological conditions. Mucin is secreted in small amounts by fibroblasts in the dermis. The cause is probably multifactorial: cytokines, immunoglobulins and serum factors induce fibroblast proliferation and mucin production. It is important to remember that the diagnosis of mucinoses depends upon clinical features and biochemical investigations.

PP4-159

THE EXPRESSION OF P63 AND P53 IN INTRAEPIDERMAL AND INVASIVE NEOPLASMS OF THE SKIN

Damlanur Sakiz[1], Tugba Taskin Turkmenoglu[2], Fevziye Kabukcuoglu[1]
[1] Department of Pathology Sisli Etfal Education and Research Hospital, Istanbul, Turkey
[2] Department of Pathology Mardin State Hospital, Mardin,Turkey

Aim: p53 is a well-known tumor supressor gene and its mutation is a common event in intraepidermal and invasive neoplasms of the skin. p63 is a homologue of the tumor supressor gene p53, which is expressed in human basal squamous epithelium. p63 plays a role in the development of squamous epithelium and, despite its homology to p53, it is considered to act as an oncogene. We evaluated p63 expression in usual skin cancers and intraepidermal neoplasms including Bowen's Disease, actinic keratosis (AK), in situ malignant melanoma (MM) an Paget's Disease to clarify the putative role of p63 expression in the development and differantial diagnosis of these lesions. Material Metod: The pathology database of the Sisli Etfal Education and Research Hospital was retrospectively reviewed to identify cases between 1999-2005. There were 17 squamous cell carcinomas (SCC), 23 basal cell carcinomas (BCC), 16 keratoacanthomas, 26 AKs, 22 Bowen's Diseases, 7 in situ MMs and 3 Paget's Diseases. In addiation, nonsunexposed normal skin tissues resected due to benign lesions acted as controls. Immunohistochemistry using antibodies against p63 and p53 was performed.Statistical analysis was done using the Kruskal Wallis, Mann Whitney and Wilcoxan Rank tests. The Spearmen test used for correlation analysis and $p<.05$ was considered significant. Results: There was a significant p63 staining in Bowen's Disease, AK, BCC, SCC and keratoachantomas respectively. In contrast, none of the in situ MM and Paget's Disease was positive for p63. Conclusion: Based on our findings, analysis of p63 expression may help in the differential diagnosis of Bowen's Disease and AK vs in situ MM and Paget's Disease, especially in small biopsies.

PP4-160
DIAGNOSIS AND FOLLOW UP OF KERATOACANTHOMA-LIKE LESIONS: A CLINICAL-HISTOLOGIC STUDY OF 43 CASES

Rf Magalhães[1], Gt Cruvinel[2], Gf Cintra[2], Maria L. Cintra[2], Appb Ismael[1], Am Moraes[1]
[1] Discipline of Dermatology, Department of Medical Clinic and School of Medical Sciences, UNICAMP, São Paulo, Brazil
[2] Discipline of Dermatology, Department of Pathology, School of Medical Sciences, UNICAMP, São Paulo, Brazil

Background: Keratoacanthoma (KA) is easily confused with Squamous Cell Carcinoma (SCC) either, on clinical- or histopathologic bases. However, KA undergoes spontaneous regression while SCC does not. In this way, to improve the histopathologic features that better discriminate the two tumors, clinical regression could be used as gold standard for KA. Our objective was to study the histopathologic features associated to clinical regression in KA-like lesions in which clinical course was assessed. Method: 43 biopsies of KA-like lesions were taken at patient admission. One month later, surgical excision was undergone in 18 growing lesions. Involuting lesions were left untreated even when histopathological reports of SCC were rendered. Classical histopathologic features and diagnosis were blindly recorded in both, biopsies- and surgical specimens. Results: Most lesions occured in elderly. Their settings were sun-exposed skin of head/neck and limbs. All tumors were described as having acute onset and rapid growth. No patient had recurrence following natural regression or excision. On clinical and histological basis, 32 lesions were assessed as KA and 11 as SCC. Features that indicated malignancy were observed in both groups (medium 1.63 in KAs and 6.18 in SCCs). Three out 32 KAs were assessed as KA-like undoubted SCC on blind histologic examination. No KA presented deep tumor extension beyond the level of the sweat glands. One KA showed perineural extension. Regressing stage KAs displayed less histologic signs indicative of malignancy. Conclusion: SCCs and KAs have more pathological similarities than differences. The differentiation of a KA in the proliferative stage from SCC may be impossible. The combination of the most useful features did not allow the nosologic diagnosis in difficult cases, but helped.

PP4-161
PHOTODAMAGE IN THE CAT SKIN: CLINICAL AND HISTOMORPHOMETRIC ANALYSIS

Ellen M P Almeida[1], Rosa A Caraca[2], Geórgia F Cintra[2], Randall L Adam[5], Elemir M Souza[3], Konradin Metze[2], Maria L. Cintra[2]
[1] Veterinary Division, Medical Sciences School, State University of Campinas (UNICAMP), São Paulo, Brazil.
[2] Departments of Pathology, Medical Sciences School, State University of Campinas (UNICAMP), São Paulo, Brazil.
[3] Departments of Dermatology, Medical Sciences School, State University of Campinas (UNICAMP), São Paulo, Brazil

Background: Photodamage (PD) is a term that describes the array of clinical and histologic changes caused by long-term exposure to solar radiation. In human beings, although the visible manifestations take years before become clinically evident, the underlying damage occurs from the earliest exposures. The dermatologic importance of PD lies in the considerable cosmetic and psychosocial distress it causes in the older persons and in its strong presumably etiologic relationship to skin cancer. Heavy ultraviolet (UV) exposure is also harmful to animals. On animal models, most of our knowledge in the effects of UV rays, is based on mice. Cats share the same environment as their owners, and may serve as sentinels for cancer development seen in human beings. The relatively high incidence of spontaneously occurring feline solar keratoses (SK) and the significant association between SK development and white coat make the cat a good model for photodamage research in natural populations. The purpose of the present study was to investigate clinical and histomorphometric features of cat skin under long term solar exposition. Methods: Ear skin of 34 domestic shorthair cats that were chronically exposed to sun were classified, on clinical basis, as follows: group 0: normal (n= 13); group 1: initial stage of photodamage (PD) (n= 10); group 2: advanced stage of PD (n= 11). Sex and age of the cat, as well as the color of the ear that had been submitted to biopsy were recorded. Histological sections were stained with haematoxylin-eosin and microscopic features were blindly and separately recorded by 2 examiners in 10 sequential linear high power fields (HPF). Dermal cellularity was studied through a cycloid morphometric grid positioned in ten sequential HPF. An objective assessment of the epidermal thickness and relative adnexal unit area was obtained in digitalized images, with the aid of an Axiophot photomicroscope (Carl Zeiss - KS300 system). Results: Through statistical methods, older age, white-colour ear, dermal edema and sclerosis, telangiectasis, reduced adnexal area and squamotized appearance of epidermal basal cells were significantly associated to advanced stage of photodamage. There was not dermal elastosis. The animals developed thickening of the epidermis since the initial phase. Conclusion: Our results indicate a high level of skin hypersensibility to sun rays in cats. The findings may be useful for clinical tests and in general veterinary pathology and dermatology.

Head and Neck Pathology

DOWNREGULATION OF CD9 PROTEIN, BUT NOT OTHER TETRASPANINS, IN ORAL SQUAMOUS CELL CARCINOMA: CORRELATION WITH POOR PROGNOSIS AND DECREASED DISEASE-FREE SURVIVAL

Marcilei Eliza Cavicchioli Buim[1], Silvia Vanessa Lourenco[2], Claudia Malheiros Coutinho-Camillo[1], André Lopes Carvalho[3], Fernando Augusto Soares[4]
[1] Department of Pathology, Hospital A. C. Camargo, São Paulo, Brazil
[2] Department of General Pathology, Dental School, University of São Paulo; Laboratory of Immunopathology, Institute of Tropical Medicine; Department of Dermatology, Medical School, University of São Paulo, Brazil
[3] Departament of Head and Neck Surgery, Hospital A. C. Camargo, São Paulo, Brazil
[4] Department of General Pathology, Dental School, University of São Paulo; Department of Pathology, Hospital A. C. Camargo, São Paulo, Brazil

Background: Squamous cell carcinoma of the oral cavity (OSCC) is a commom malignancy, characterized by a high degree of agression and metastasis to cervical lymph nodes. During the process of OSCC carcinogenesis, impaired function of metastase supressor genes appear to be crucial in the progression of cancer cells to a metastatic phenotype. Tetraspanins are proteins with functional roles in a wide array of cellular processes and have been reported to be associated with the biological behavior of solid tumors, especially with their metastatic potential. Other functions include cell adhesion, motility, differentiation and proliferation. Method: The present study investigated the expression of the tetraspanins CD9, CD37, CD63, CD81 and CD82 in OCSS using immunohistochemistry. Tissue Microarray (TMA) of 127 cases of OSCC and 10 normal tissue of oral cavity were evaluated immunomorphologically and semi-quantitatively, and results were compared to the clinical-pathological features. Multivariate Cox regression, Kaplan-Meier method and qui-square test were used for statistical analysis. Results: Expression of CD63, CD37 and CD81 was not detected in the cases studied (tumors and controls). Expression of CD9 and CD82 was observed on the membrane of basal layer cells in the controls of normal oral mucosa. CD9 expression was downregulated/ negative in 42/127 (33%) OSCC cases. Loss of CD9 expression in OSCC correlated with incidence of cervical lymph node metastasis (p=0.028). A bordeline significant relationship between CD9 downregulation and advanced disease (clinical stage T3/T4) (37.0%) (p=0.055) was verified. Significance between CD9 expression and other clinicopathological features was not statistically established. Disease-free survival rate of patients with CD9 down-regulated/negative (48.6%) was significantly lower than that in patients with CD9 positive expression (71.6%) (p=0.010). The 5-year overall survival rate of patients with CD9 downregulated/negative was 44.0% against 64.0% of CD9-positive cases (p=0.071). CD82 was downregulated/negative in 100/127 (79.0%) specimens, but no correlation was observed between CD82 expression, clinicopathological parameters, disease-free survival and 5-year overall survival (p= 0.705, p= 0.549 respectively). Conclusion: Our results suggest that downregulation of CD9 might be an indicator of poor prognosis in OSCC patients.

PP4-163
MALIGNANT PERIPHERAL NERVE SHEATH TUMOUR (MPNST) OF THE NASAL CAVITY. REPORT OF A CASE AND REVIEW OF THE LITERATURE

Vassilis Samaras[1], Anna Tanoglidi[1], Stelios Triantos[2], Maria Kefala[1], Georgios Papazoglou[2], Calypso Barbatis[1]
[1] Department of Pathology, Red Cross Hospital, Athens, Greece
[2] Department of Otorhinolaryngology, Red Cross Hospital, Athens, Greece

BACKGROUND: Peripheral nerve sheath tumours (PNST) are soft tissue neoplasms, arising from the neural sheath of autonomic, cranial, or peripheral nerves, which are rarely encountered in the nasal cavity and paranasal sinuses with 20 well-documented cases published in the English-language literature. We report a rare case of a high-grade MPNST of the nasal cavity in a woman. METHOD: A previous healthy 39-year-old woman was admitted to our hospital with left nasal obstruction without bleeding. Magnetic resonance imaging studies showed a obstructive mass of the left nasal cavity extending to the left paranasal sinuses, approaching the ipsilateral orbit with destructive malignant features. The patient underwent a total surgical removal of the mass and multiple tissue specimens were examined with hematoxylin/eosin as well as immunohistochemically for: Vimentin, Bcl-2, a-SMA, GFAP, S-100, α1-AT, C-Kit, CD34, CD31, CD57, HHV-8, Ki67, P53. RESULTS: Nasal mucosa covered by respiratory epithelium and infiltrated by a spindle cell, vascular neoplasm growing in a fascicular pattern, mimicking kaposi's sarcoma. The tumour was unencapsulated with indistinct borders and without necrosis. The cells had oval or elongated nuclei, with rare mitotic activity and the cytoplasm was clear or fibrillary eosinophilic. There were areas of mild cellularity and a chronic inflammatory infiltrate intra and extratumoral. Immunohistochemical staining of tumour cells showed diffuse intense positivity for Vimentin, Bcl-2, a-SMA, focal reaction for GFAP, S-100, α1-AT, C-Kit and all the other markers were negative. The Ki67 index was 5% while p53 protein was overexpressed (40%). Based on the immunophenotype a diagnosis of a high grade malignant peripheral nerve sheath tumour of the nasal cavity was made. The patient received adjuvant radiation with further surgical therapy. CONCLUSION: Approximately 45% of benign PNST occur in the head and neck region. These tumours undergo malignant transformation but MPNST can form de novo. High-grade MPNST require complete surgical resection, with wide tumour free margins, combined with adjuvant irradiation and chemotherapy. However, MPNSTs are thought to be incurable with current treatment modalities because of their metastatic potential. Our case required a differential diagnosis from a wide range of spindle cell neoplasms and particularly from leiomyosarcoma.

PP4-164
MALIGNANT TRANSFORMATION OF ORAL LICHEN PLANUS

Spomenka Manojlovic[1], Marinka Mravak Stipetic[2], Ivica Luksic[3], Darko Macan[3], Zoran Manojlovic[4]
[1] Department of Pathology, University Hospital Dubrava, Zagreb, Croatia
[2] Department of Oral Medicine School of Dental Medicine University of Zagreb, Croatia
[3] Department of Oral and Maxillofacial Surgery, University Hospital Dubrava, Zagreb, Croatia
[4] Polyclinic for Clinical Pharmacology and Toxicology Bonifarm, Zagreb, Croatia

INTRODUCTION: Oral lichen planus (OLP) is a chronic inflammatory disease with low, but proved risk of transformation to oral squamous cell carcinoma (OSCC). The reported rate varies from 0,4 up to 5% of cases. Oral cancer in patients with OLP has been identified as arising on the erythematous, atrophic

and erosive lichen-planus-affected oral mucosa. Immunohistochemical and more recently genetic studies have provided evidence of cellular and molecular events in OLP lesions that could preceede malignant transformation, suggessting that molecular assessment may become a valuable clinical tool for patient's follow-up. MATERIAL AND METHODS: We present five patients with squamous cell carcinoma of the buccal mucosa arised on the pre-existing oral lichen planus. Immunohistochemical analysis of the precursor lesions was performed by using p53 and Ki-67 antigens, and compared with the unaffected mucosa of the same patient, as well as with the matched control patient's mucosa. RESULTS AND DISCUSSION: Significantly stronger expression of Ki-67 and moderatly stronger expression of p53 protein staining was seen in the overlying epithelium in the OLP lesions preceded to SCC, in comparison to the unaffected and control mucosa. Presented cases document and alert on the propensity of oral lichen planus to undergo malignant transformation and stress the importance of regular follow-up of these patients. CONCLUSION: Clinical diagnosis of OLP has to be confirmed by histopathological analysis. As a premalignant lesion, OLP need to be assessed by use of immunohistochemical and genetic markers as well. Further research is essential for better understanding of the mechanisms and propensity of some OLP lesions to undergo malignant transformation.

PP4-165
CALCIFYING EPITHELIAL ODONTOGENIC TUMOR OF THE MAXILLA - CASE REPORT

Spomenka Manojlovic[1], Danko Mueller[1], Gorana Aralica[1], Jaksa Grgurevic[2]
[1] Department of Pathology, University Hospital Dubrava, School of Medicine, University of Zagreb, Croatia
[2] Department of Oral and Maxillofacial Surgery, University Hospital Dubrava, School of Dental Medicine, University of Zagreb, Croatia

INTRODUCTION: Calcifying epithelial odontogenic tumor also known as Pindborg tumor is very rare, locally invasive neoplasm, characterized by amyloid-like material that may become calcified. It accounts for less than 1% of all odontogenic tumors, without gender predilection and usually clinically presents as slow-growing, painless mass, most often envolving premolar and molar region. The mandible is affected twice as often as maxilla. Patients between 2nd and 6th decade, with a mean age of 40 years are usually affected. The vast majority of cases are intraosseous, with approximately 6% arising in extraosseous locations. CLINICAL DATA: A 36-year-old Caucasian male was admitted to our Hospital because of painless swelling, which lasted over 3 months in the region of hard palate and buccal aspect of maxilla on the right side. All radiographic findings showed a tumorous mass of the right maxillary sinus with disrupted structure of the ipsilateral upper jaw and intact orbital space. The last two loose molar teeth were extracted and the biopsy was performed which confirmed the diagnosis of calcifying epithelial odontogenic tumor. PATHOHISTOLOGY: The tumor volume was about 15 cm3 and histologically it was composed of small islands and sheets of polygonal cells with abundant eosinophilic cytoplasm, clear cell borders and noticeable intercellular bridges. Nuclei were pleomorphic, without mitotic figures. Eosinophilic, homogeneous hyaline material, within and around tumor cells, was proven to be amyloid-like, because when stained with Congo red, demonstrated the classic bright green birefringence viewed with polarized light under microscope. This amyloid-like material was often centrally calcified in the form of Liesegang concentric rings. DISCUSSION: There are around 200 cases described in the literature to the present. Long-term follow up is essential because there is a recurrence risk if the tumor was incompletely resected and in particular with the clear cell variant.

PP4-166
DEVELOPMENT OF A NEW FAST CHEMOSENSITIVITY TEST IN LARYNX CARCINOMA

Daniela Fanni[1], Luca Pilloni[1], Pier Paolo Coni[1], Giancarlo Senes[1], Alberto Ravarino[1], Zanino Pusceddu[2], Ernesto Proto[2], Gavino Faa[1]
[1] Dipartimento di Citomorfologia, Sezione Anatomia Patologica University of Cagliari, Italy
[2] Dipartimento di Scienze Chirurgiche e Trapianti d'Organo, Sezione di Otorinolaringoiatria, University of Cagliari , Italy

BACKGROUND: The aim of our preliminary study was to develop an accurate chemosensitivity test for larinx carcinomas (LKs). The final goal of our study was a test which could predict the effects of cisplatin on tumour cells prior the onset of treatment in order to individualize the pharmacological strategy. METHODS: We directly exposed for a short period (30 minutes) fresh samples from 3 LKs using cisplatin (Teva L01XA01) assessing 3 different cisplatin concentrations: low (6,25 µg/ml), medium (25 µg/ml) and high (75 µg/ml). We also utilized 2 control specimens, one to be immediately formalin-fixed and one to be incubated in the medium, but lacking cisplatin. Cases interpretation was performed by histological examination of H-E stained sections. The main objectives of this study were to characterize the morphological changes induced in tumour cells and to determine effects on molecular markers involved in proliferation and/or apoptosis. RESULTS: The preliminary observation of these 3 LKs allowed us to detect the elementary lesions that could have a role in the identification of the reactivity of tumour cells toward cisplatin: extracellular and/or intracellular oedema, apoptosis and at intratumoural necrosis. Although all 3 tumours showed an identical histotype and the same site of origin, case 1 and case 3 showed a striking morphological reactivity to cisplatin, on the contrary, case 2 did not show any significant morphological features due to cisplatin exposure. What's more cases 1 and 3 were characterized by decreasing nuclear immunoreactivity for cycline D1, p53 and PCNA. Therefore, at the molecular level, case 2 did not show any significant change in immunoreactivity for cycline D1, p53 and PCNA. CONCLUSION: Our data evidence that samples from 3 LKs may evidence different patterns to cisplatin exposure. Extracellular and/or intracellular oedema, apoptosis and necrosis were the most frequent findings observed in cisplatin-treated specimens. These observations induced us to focus our attention toward the follow up of these patients in order to compare our in "in vitro" data with the clinical response of patients, although, our findings need further validation on a larger number of neoplasias.

PP4-167
NGF-BETA/PRONGF AND THEIR RECEPTORS IN NORMAL HUMAN ORAL MUCOSA

Katsuhiko Hayashi[1], Trond Storesund[2], Olav Schreurs[2], Cuong Khuu[2], Camilla Husvik[2], Andreas Karatsaidis[2], Masashi Sugisaki[1], Karl Schenck[2]
[1] Department of Dentistry, Jikei University School of Medicine, Tokyo, Japan
[2] Department of Oral Biology, Faculty of Dentistry, University of Oslo, Oslo, Norway

BACKGROUND: Nerve growth factor β (NGF-β) and its precursor proNGF are important for differentiation and survival of neurons and dermal keratinocytes. NGF-β is secreted in the saliva of mouse and man. The aim of this study was to determine whether NGF can play a role in the differentiation and wound healing of oral mucosa by investigating its effects on oral keratinocytes. METHODS: mRNA production and protein expression of NGF/proNGF and their receptors TrkA and p75 NTR were analyzed in cultured human oral mucosal keratinocytes (OMK) by Western blot analysis and reverse transcribed PCR respectively. Proliferation of OMK upon NGF-β

stimulation was measured by BrdU incorporation. The effect of NGF-β on the migration of OMK was studied using a scratch assay. Expression of NGF-β and its receptors in biopsies from normal oral mucosa (NOM) and oral mucosal equivalents were examined using immunological staining. RESULTS: OMK expressed mRNA for NGF-β /proNGF and their receptors TrkA and p75NTR. Lysates from OMK did not contain mature NGF-β but several NGF-proforms with molecular weights between 32 and 114 kDa. Culture medium from OMK contained 75 kDa proNGF. Addition of NGF-β significantly enhanced proliferation of OMK cultures and in vitro scratch closure. Immunostaining of biopsies from normal oral mucosa showed the presence of proNGF in all epithelial layers. NGF staining was observed in the granular and upper spinous cell layers. TrkA immunoreactivity was detected in basal and parabasal cells, with weak to moderate staining in spinous and granular cell layers. p75NTR staining was seen in basal cell layers. CONCLUSION: NGF-β /proNGF (from saliva or from the keratinocytes themselves) has mitogenic and motogenic effects on OMK and may therefore aid in healing of oral wounds. Differential expression of NGF and NGF-receptors throughout the epithelium suggests a role in epithelial differentiation.

PP4-168
KARYOMETRIC ANALYSIS OF POSTIRRADIATION SIALOADENITIS

Dragan Mihailovic[1], Zaklina Mijovic[1], Milos Kostov[2], Cedo Kutlesic[1], Vesna Mihailovic[1]
[1] Institute of Pathology, University of Nis, Serbia
[2] Department of Pathoanatomy, Military Hospital, Nis , Serbia

Aim: The aim of this study was to estimate karyometric variables in postirradiation sialoadenitis. Material and Methods. At Institute of Pathology, University of Nis, four patients with postirradiation sialoadenitis, and twelve patients with normal parotid gland (control group) were analyzed. Nuclear area, mean and mode optical density (OD), standard deviation of OD, minimal and maximal OD, intergrated OD (IOD), nuclear perimeter and circulariry were analyzed by ImageJ software at objective x63 on routinely stained histopathological sections. Results: Histologically, atrophy of parenchyma and fibrosis were found in patients with postirradiation sialoadenitis. In postirradiation sialoadenitis, the nuclei were more irregular in contour (circularity=0.84±0.03), compared to control group (0.88±0.02)($p<0.01$). Mean and maximal ODs were significantly lower in patients with postirradiation sialoadenitis (0.39±0.04, and 0.51±0.03 a.u.), compared to control group (0.44±0.04, and 0.56±0.06 a.u., respectively)($p<0.05$). Conclusion: Our results suggest that radiation therapy causes irregularities of nuclear shape and loss of chromatin density.

PP4-169
CRANIAL MEASUREMENTS USED IN SEX AND AGE ESTABLISHMENT

Fotios Chatzinikolaou[1], Alexandra Enache[2], Natalia Vladica[1]
[1] Department of Pathology, Theageneio, Cancer Hospital, Thessaloniki, Greece
[2] Department of Forensic Medicine, University of Timisoara, Romania

Aim: The purpose of the study was to interpret and apply the most efficient parameters in establishing the sex and age of cranial fragments. Materials and Methods: Two skulls had been found in two different places, isolated, without other bones and unburied. After removing the leaves and the earth, the skulls were cleaned and measured. Results: The first skull was missing a mandible and had teeth 18, 23 ,24 and 27 with 11 and 12 lost post mortem and the other teeth lost ante mortem judging by the aspect of the alveolar margin. The second skull had the mandible, but with a fractured gonion and a coronoid process. The edentation was complete, with a partial fracture of the maximale alveolar process. The left zigomatic region presented a cominnutive fracture with the absence of some fragments of the anterior wall of the maxilar sinus. Cranial measurements highlighted some elements specifying the sex (the size of the foramen magna, of the left orbit), but also some elements unable to surely specify the sex (cranial parameter, cranial diameters, the mastoid and the aspect of the external face of the gonion). The teeth present in the first case presented decayed processes which lowered the possibility of appreciating the abrasion and the age. In the second case, for age establishment the aspects of the cranial sutures (the obliteration degree) were used. Conclusion: The sizes of certain cranial elements can be used for establishing the sex. In the absence of the teeth, age can be presumed by the degree of obliteration of the cranial sutures and the goniac angle.

PP4-170
CLEAR CELLS IN ODONTOGENIC TUMORS

Sabina Zurac[1], Peter De Wilde[2], Pieter Slootweg[2]
[1] Department of Pathology, Colentina University Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania
[2] Department of Pathology, Radboud University Nijmegen Medical Center, Nijmegen, The Netherlands

Background: Analysis of the English medical literature reveals a different comprehension of the clear cell (CC) component in odontogenic tumors, especially when tumors bearing both ameloblastomatous features and CC component are discussed. Four types of these tumors are described in the literature: three malignant (1. tumors entirely composed of CCs, 2. admixture of islands of CCs and cords of smaller cells, 3. admixture of islands of CCs and ameloblastomatous areas) and one benign (follicular ameloblastoma with extensive replacement of the stellate reticulum by CCs). Method: We performed an analysis of the microscopic characteristics of the CC component in 14 cases of odontogenic carcinomas (6 clear cell odontogenic carcinomas (CCOCs), 6 ameloblastic carcinomas (ACs) and 2 primary intraosseous squamous cell carcinomas (PISCCs)) versus the CC component in 30 otherwise ordinary ameloblastomas. We noticed the similar appearance of the CC in the different types of odontogenic carcinomas and we compared them with that of the CC in ameloblastomas. All statistical tests were performed with SPSS version 12.0.1 for Windows (Fisher's exact test and non-parametric Mann-Whitney-U test) with a level of statistical significance $P<0.05$. Results: There is definite similarity of the CCs in malignant odontogenic tumors without ectomesenchymal contribution despite the heterogeneity of the tumoral types. The cellular characteristics are statistically different in malignant versus benign odontogenic tumors. CCs with a nuclear/cellular ratio <0.5, elongated spindle-shaped nuclei, fine granular chromatin and small nucleoli are seen in benign lesions; CCs in malignant tumors are smaller with a higher nuclear/ cellular ratio, coarse granular chromatin and prominent nucleoli. ($P < 0.001$, except P nuclear shape = 0.03). These findings suggest that CCs represent a phenotypic cellular variant and not the hallmark of the lesion. We propose a reassignation of different types of CCOC: - CCOC, ameloblastomatous pattern (+/- squamous differentiation) - AC, CC variant; - CCOC, biphasic/monophasic pattern + squamous differentiation - PISCC, CC variant; - CCOC, biphasic/monophasic pattern, no squamous differentiation - odontogenic carcinoma not otherwise specified. Conclusion: CCOC in its current acceptation is an exceedingly rare tumor that might be reclassified as variants of different other types of odontogenic carcinoma. However, no matter if the CCOC name is retained or discarded, one should remember that benign odontogenic tumors may display CC component as well as the malignant ones.

PP4-171
EXPRESSION OF PROGNOSTIC AND PROLIFERATION MARKERS IN SALIVARY GLAND TUMORS
Rosa Maria Garcia-Martin, Ana Belen Enguita, Cristina Murillo, Esther Conde, Fernando Lopez-Rios, Claudio Ballestin
"12 de Octubre" University Hospital, Spain

Aims: The aim of the present study was to investigate the relationship between different prognostic and proliferation markers in salivary gland tumors. Methods: This study was performed to examine the expression of the antibodies, cathepsin D, methalloproteinases 1 and 2 (MMP-1, MMP-2), p53, MIB-1, PCNA, and Replication protein A (RP-A) in 100 salivary gland tumors. The expression of these antibodies was examined by immunohistochemistry in 9 normal parotid tissue, and various tumors of the salivary glands (14 pleomorphic adenomas (AP), 11 polymorphous low-grade adenocarcinoma, 16 mucoepidermoid carcinomas, 14 acinic cell carcinomas, 12 adenoid cystic carcinomas, and 8 not-otherwise-specified adenocarcinomas). Immunohistochemical studies were done on paraffin embedded tissue sections. Results: Cathepsina D antibody gave strong reactions in all neoplasms, P53 and Mib-1 were negative in normal parotid glands and AP but were highly expressed in all malignant tumors. MMP-1 was negative in normal parotid glands, and we observed low expression in AP, and high expression in carcinomas. MMP-2 was negative in normal salivary glands, whereas the expression was higher in both pleomorphic adenomas and carcinomas. Between pleomorphic adenomas, the myxoid type expressed MMP-1 and MMP-2 at higher levels than the cellular ones, although this latter type were showed significant expression of RP-A. The expression of MMP-2 in myxoid pleomorphic adenomas was similar to that of carcinomas. The expression of MMP-2, P53, MIB-1 and RP-A in high grade mucoepidermoid carcinomas was higher than in the low grade ones, although in this latter type, the protein expression of MMP-1 was high. RP-A expression was low in carcinomas. This protein plays an important role in DNA replication, recombination and repair. Conclusions: 1. - Pleomorphic adenomas of the myxoid type have an expression of MMPs similar to that of carcinomas. 2. - MMP-1 expression was low or negative in normal salivary glands and in pleomorphic adenomas, but was high in carcinomas. 3. - MMP-2 expression was negative in normal salivary glands, but was higher in pleomorphic adenomas than in carcinomas. 4. - Low grade mucoepidermoid carcinomas exhibited high MMP-1 expression whereas MMP-2 expression was high in high grade mucoepidermoid carcinomas. 5,-RP- A expression was low in carcinomas.

PP4-172
PROGNOSTIC SIGNIFICANCE OF FAS AND p53 IN THE SQUAMOUS CELL CARCINOMA OF THE LARYNX
M. Hakan Karabulut[1], Medine Murtazaoglu[2], Dilek Yavuzer[1], Aylin Ege Gul[1], Nimet Karadayi[1]
[1] Dr. Lutfi Kirdar Kartal Education and Research Hospital, Pathology Department, Istanbul, Turkey
[2] Hakkari State Hospital, Pathology Department, Hakkari, Turkey

Background; Fas receptor expression makes tumor cells susceptible to the host immune system. In some cases of the squamous cell carcinoma of the head and neck, Fas has reported to be down-regulated, but about its relationship with clinicopathologic parameters and prognostic predictive value, controversy still remains. p53 is the most commonly mutated gene in human cancer, its prognostic and diagnostic value has been studied and contradictory results reported especially in the head and neck cancers. Method; Paraffin embedded tissue blocks of 53 primary squamous cell carcinoma of the larynx were investigated for expression of Fas and p53 by immunohistochemistry. Relationship of these two proteins with the clinicopathologic data has been studied. Results; The degree of Fas expression revealed a positive relationship with the histologic differentiation and there was a positive relationship with the expression of p53 and tumor size. We were unable to show statistically significant relationship with other prognostic parameters and these two proteins. Conclusion; Increased expression of Fas protein seems to have a positive effect on histologic differentiation and expression of p53 may have a role on the tumor progression with its possible effect on tumor size. But because of the lack of significant relationship with the majority of the prognostic parameters for both of these two markers, their prognostic value seems to be limited.

PP4-173
SYNCHRONIC TUMORS OF THE LARYNX: LEIOMYOSARCOMA AND SQUAMOUS CELL CARCINOMA. A CASE REPORT
Aysun Uguz[1], Naciye Ozeren[1], Canan Ersoz[1], Fikret Cetik[2]
[1] Cukurova University, Medical Faculty, Dept. of Pathology, Adana, Turkey
[2] Cukurova University, Medical Faculty, Dept. of Otorhinolaryngology, Adana, Turkey

Background: The laryngeal smooth muscle tumors are rarely seen. In the literature one case of hypopharyngeal leiomyosarcoma, and two cases of laryngeal smooth muscle tumors including one angioleiomyoma, one leiomyosarcoma and one carcinoleiomyosarcoma were reported. On the other hand, squamous cell carcinoma is the most frequent tumor of the larynx. Coexistence of mesenchymal tumor and carcinoma is extremely rare in larynx. Case Report: A case who is 51 years old man was presented. He admitted to the hospital with disphagy complaint related with his smoking history. He had been smoked two pockets of cigarettes in a day for 20 years. In the laryngoscopy a mass on the left vocal cord was observed and performed biopsy procedure. In microscopic examination, leiomyosarcoma plus squamous cell carcinoma was detected. These two kinds of tumor were been seperately and side by side but they were not observed as intermingled areas of leiomyosarcoma and squamous cell carcinoma. Immunohistochemically smooth muscle actin was positive in leiomyosarcomatous area and pansitokeratin was positive in squamous cell carcinoma area and vice versa were negative. Discussion: These tumours may present diagnostic difficulties both histopathologically and clinically. The patients usually present no characteristic symptoms in early stage and the clinical symptoms are similar to squamous cell carcinoma however immunohistochemical investigation is helpful in distinguishing smooth muscle tumours from other connective tissue neoplasms and spindle cell squamous cell carcinoma. This report describes synchronic tumors of laryngeal leiomyosarcoma and squamous cell carcinoma along with its clinical and histopathologic features.

PP4-174
CORRELATION OF PCNA, Ki67 AND P53 EXPRESSIONS WITH HISTOPATHOLOGICAL GRADE IN MUCOEPIDERMOID CARCINOMA
Fulya Koybasioglu[1], Seyhan Ozakkoyunlu[1], Evrim Ozturk[2], Binnur U. Onal[2], Nuray Guneri[3]
[1] Ankara Dıskapı Training & Research Hospital, Ankara, Turkey
[2] Ankara Dıskapı Training & Research Hospital, Turkey
[3] Gazi University Faculty of Commerce and Tourism Education Department of Computer, Ankara, Turkey

Background: Mucoepidermoid carcinoma constitutes almost 10% of all salivary gland tumours and the most common site is parotid gland. Even though the prognosis of mucoepidermoid carcinoma correlates with the histological grade, the occasional precence of metastasis in low grade tumours demonstrate that low grade histological features are not always indicative of low- grade biological behavior. In this study, PCNA, Ki67 and p53 expressions were corralated with histopathological grade of

mucoepidermoid carcinoma. Method: We reviwed a total of 31 mucoepidermoid carcinoma cases reported in our department. The distribution of the tumours according to the glands were as follows: 19 parotid, 3 submandibular, 9 minor salivary gland. In microscopic examination, AFIP grading system yield 11 (35.5%) low grade, 11 (35.5%) intermediate and 9 (29%) high grade tumours. For statistical analysis Kruscal Wallis and Mann-Whitney U tests were used. Results: Mean Ki67 indices of histopathological grades were calculated as 1.8% for low, 2.5% for intermediate and 7% for high grade tumours. PCNA indices, on the other hand, were 36%, 43%, 66% respectively. In statistical analysis, a significant difference was obtained between the Ki67 and PCNA indices with the increasing grade of the tumor ($p<0.05$). P53 expressions did not demostrate any meanignful correlation with the histopathological grade. Conclusion: In conclusion, Ki67 and PCNA demonstrates a positive correlation with increasing histopathological grade in mucoepidermoid carcinoma.

PP4-175

NUCLEAR PROFILES AND EXPRESSION PERCENTAGES OF P27 STAINED AND UNSTAINED TUMOR CELLS IN LARYNX CARCINOMAS: COULD IT BE USED AS A PROGNOSTIC TOOL?

Guzide Ayse Gokhan[1], Yildirim Karslioglu[2], Caner Ozbey[1], Gulay Ozbilim[1], Kenan Guney[3], Murat Turhan[3], Kemal Hakan Gulkesen[4]
[1] Department of Pathology, Akdeniz University School of Medicine, Antalya, Turkey
[2] Department of Pathology, Gulhane Military Medical Academy, Ankara, Turkey
[3] Department of Ear, Nose, Throat, Head and Neck Surgery, Akdeniz University School of Medicine, Antalya, Turkey
[4] Department of Biostatistics and Medical Informatics, Akdeniz University School of Medicine, Antalya, Turkey

Background: This study was carried out on a set of twenty-eight laryngeal carcinomas to explore the P27 expression levels, as well as some nuclear planimetric variables of tumor cells. Our aim was to investigate the correlation of these data with conventional histopathological and clinical prognostic factors, if any. Method: Twenty-eight (28) laryngeal squamous cell carcinomas were studied retrospectively. We applied monoclonal antibody against P27 protein using streptovidin-biotin method. In addition to the expression level of P27 in each case, some nuclear planimetric variables of immunopositive and immunonegative tumor cells were measured using a computer assisted image analysis workstation. The expression level was considered as low when the tumor had $\leq$ 10% of P27 immunoreactivity. The potential relationships of these data to the tumor grade, stage, survival, and lymph node metastasis were assesed statistically. Results: Seventeen cases were Grade 1 (60%), remaining 11 (40%) were Grade 2 tumors. Among them, 14 cases had lymph node metastasis. In 19 cases (61%) P27 immunoexpressions were higher than 10%. In immunopositive cells, some nuclear variables suggested lower values than those in the immunonegative ones. These were: mean area (mean: 44.18), CV (mean: 43.39), perimeter (mean:25.8), f-max (mean:9.41) and f-min (mean:6) in immunopositive cells whereas mean area (mean:53.70), cv (39.36), perimeter (28.63), f-max (mean:1.39), f-min (mean:6.65) in immunonegative cells. All of these differences were statistically significant ($p<0.05$). Grade 1 tumor cells' nuclei which were labelled immunohistochemically showed significantly higher values of mean area, sd area and f-max than those in the Grade 2 ones. Differences between them are also significant ($p< 0.05$) Conclusion: Downregulation of P27 is known to be associated with poor prognosis in a number of malignancies. Although similar results were reported in larynx carcinomas, they are limited in number. Nuclear morphometric measurements have been reported as useful prognostic predictors in various cancers including larynx carcinomas. In this study, we concluded that P27 immunolabeling associated with the nuclear morphometry could be useful to predict the prognosis of larynx carcinoma. Further studies in larger series are needed to make more concrete deductions.

PP4-176

EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE

Eleftheria Delliou[1], Virginia Papamichail[2], Thivi Vasilakaki[3], Zafiroula Doudoulakaki[4], Diamanto Zizi[3]
[1] Laboratory of Pathology – Xanthi, Greece
[2] Laboratory of Pathology – Piraeus, Greece
[3] Department of Pathology of Tzaneio General Hospital of Piraeus, Greece
[4] Department of Otolaryngology of Sismanogleio General Hospital of Komotini, Greece

Objective: A case of an extranodal NK/T-cell lymphoma, nasal type is described. Methods & patients: A 75 years old female patient presented with malaise, weight loss and symptoms of nasal obstruction.. Clinical examination revealed an intranasal mass and an ulcerated lesion on hard palate with extensive mid-facial destructive lesions. Biopsy of the intranasal mass was undertaken. Results: The microscopic examination of the specimen using immunochemistry and the EBV + phenotype of the patient, suggested the presence of a T-cell lymphoproliferative lesion, characterized as NK/T-cell lymphoma, nasal type. Discussion-Conclusion: The nasal type NK/T-cell lymphoma is a rear type of predominantly extranodal non-Hodgkin lymphoma, previously known as lethal midline granuloma, which is associated with Epstein Barr virus. This lymphoma occurs most often in adults and is more common in males than females. It causes destruction of the mid-face, palatal and orbital walls. It can also involve skin, soft tissue, gastrointestinal and upper respiratory track. Histologic examination shows a diffuse lymphomatous infiltrate with angiocentric growth pattern and areas of necrosis. In most cases the lymphoma is composed of medium sized cells or a mixture of small and large cells. It must be mentioned that the cytological spectrum is very broad. Mitotic figures are easily found. Sometimes there might be a heavy admixture of inflammatory cells. The typical immunophenotype is: CD2+, CD56+ and cytoplasmic CD3+. Occasionally CD7 or CD30 are positive. CD43 and CD45RO are commonly expressed. CD4, CD5, CD57 are negative. It must be emphasized that the EBV positivity is essential for such a diagnosis. The prognosis is variable. Early stage disease may respond to radiotherapy alone, however late stage disease does not respond well to any available therapies.

PP4-177

A STUDY OF THE EFFECT OF PHARMACEUTICAL SUBSTANCES ON THE NASAL MUCOSA

Andreas Lazaris[1], Evangelos Nikolaidis[2], George Agrogiannis[1], Evangelia Ferekidou[3], Vasilios Papanikolaou[3], Apostolos Papalois[4], Sofia Tseleni[1], Eleftherios Ferekidis[3], Efstratios Patsouris[1]
[1] National and Kapodistrian University of Athens, School of Medicine, 1st Dept of Pathology, Greece
[2] General Hospital of Athenes "Hellenic Red Cross", Greece
[3] 1st ENT Department, University of Athens, Greece
[4] Experimental – Research Unit, ELPEN Pharma,Athenes,Greece

Background The study of the histological changes of the nasal mucosa, caused by local administration of vasoconstrictive agents (xylometazoline), with or without nasal rinsing with enriched sea-water solutions. Method Ten PMR-Landraze pigs (half of the total study population) were used. Therapeutic doses of the studied medication were administered over the period of one month and nasal mucosa biopsies were taken in pre-set times. Hematoxylin and eosin slices were reviewed under optic microscope. Each specimen was evaluated concerning the degree of: 1.Inflammation (quota of inflammatory cell infiltration)

2.Fibrosis (quota of slice surface covered by fibrous tissue) 3.Epithelial metaplasia (quota of squamous epithelial metaplasia) 4.Epithelial atypia (quota of atypic epithelial cells) 5. Necrosis Results Under the effect of the local acting vasocostrictive medication (xylometazoline) all of the studied parameters worsened. Similar results were observed when the administration of the agent was combined with nasal rinsing. However, inflammation worsened with a statistically significant slower rate, after ten days of combination of xylometazoline and nasal rinsing. Conclusion Preliminary results show the benefactory effect of nasal rinsing with enriched sea-water solutions, concerning the course of inflammation of nasal mucosa caused by the administration of local acting xylometazoline.

PP4-178
EVALUATION OF PROLIFERATION AND APOPTOSIS RATE OF OSTEOSARCOMA OF JAW

S. Elif Gultekin[1], Burcu Senguven[1], Omer Uluoglu[2]
[1] Gazi University Dental Faculty Department of Oral Pathology, Turkey
[2] Gazi University Medical Faculty Department of Pathology, Turkey

Background: Osteosarcoma is the primary malignant bone tumour affecting more frequently long bones of young people. Approximately % 6 of all ostesorcoma occurs in the jaws. Jaw Osteosarcoma (JOS) is generally accepted to be a pathologically distinct entity due to older age at presentation, longer median survival, local reccurences and low incidence of metastasis.It has been suggested that better prognosis of JOS than long bones (LOS), may related to the type and the lower grade of the tumor. The aim of this study is to investigate the proliferation and apoptotoic rate of tumor cells in JOS by comparing LOS and discuss the possible corelation with grading, cellularity and histologic type. Methods: The study was conducted on the paraffin embedded samples of a total of 10 ostesarcoma (5 JOS and 5 LOS) cases. Immunohistochemistry was performed using antibody against K i67,while in situ hybridization (Tunel method) was done for detection of apoptotic cells. The number of positive cells was determined by software and histological grading was done . Results: The mean age of the patients of JOS and LOS were 26.5 and 19 years, respectively. Most of the JOS cases were from maxilla (80%), while femur was the most common site in LOS. 60% of JOS and 80% of LOS cases were grade 3. Proliferation rate is higher in LOS than JOS cases. Ki 67 positivity was seen 40% of JOS and 60% of LOS cases which were high grade tumors (grade 3). There was not any positivite staining for apoptosis in both tumor groups. Conclusion: Ki 67 Expression may related to the grade of JOS and have more value than apoptotic index. Studies with large series is needed to confirm these findings.

PP4-179
PREVALANCE OF EBV, HPV 16 AND HSV-1 IN ORAL LICHEN PLANUS

Benay Tokman, Burcu Senguven, Cem Demir
Gazi University, Faculty of Dentistry, Dept. of Oral Pathology, Turkey

Background: Oral lichen plnus (OLP) is a chronic inflammatory mucosal disease of unknown etiology. OLP occurs more frequently than the cutaneous form and tends to be more persistent and more resistant to treatment. Although the etiopathogenesis of lichen planus is unknown, it is generally considered to be an immunologically mediated process that histologically resembles hypersensitivity reaction. Lichen planus is probably of multifactorial origin, sometimes induced by drugs or dental materials, psyhological factors, infective agents, often idiopathic. Viral infections have recently been linked with OLP. HSV-1, CMV, HHV-6, EBV HPV, HCV are viruses that have been studied in the etiopathogenesis of OLP. The aim of the present study was to explore a possible association of HPV16, HSV-1 and EBV with OLP. Method: The study was conducted on formalin fixed paraffin embedded tissue specimens of 65 OLP cases. Five-micrometer thick sections of formalin fixed and paraffin embedded biopsy samples were processed by the avidin-biotin-peroxidase complex (ABC) method for Herpes Simplex type 1 , Epstein Barr virus and Human Papilloma virus type 16 primary antibodies. The red-brown nuclear staining was accepted as positive staining for each antibody. To confirm HPV 16 positivity, nested PCR technique was also performed. 15 normal oral mucosal tissue specimens were used as control group. Statistical analysis were performed by Fısher's exact test and Pearson Chi square methods. Results: The number of OLP cases that were positive for EBV was 23 (35%), while HPV 16 was positive in 14 (21%) cases and HSV-1 was positive in 6 (9%) cases. One case was positive for all 3 viruses. 3 cases were positve for both EBV and HSV-1, 5 cases were positive for both EBV and HPV 16, and 1 case was positive for both HSV-1 and HPV 16. The control group was totally negative for all 3 viruses. EBV and HPV 16 positivity in OLP were statistically significant. Conclusion: Although the high prevalance of EBV and HPV 16 does not imply a direct causative relation, it suggested that these viruses might be involved in the pathogenesis of OLP, while HSV positivity might be a secondary infection as a result of possible local immunosupression. EBV and HPV 16 positivity in OLP which are both oncogenic viruses should be considered seriously.

PP4-180
EVALUATION OF HOST IMMUNITY BY THE DETECTION OF NATURAL KILLER CELLS AND THE EXPRESSION OF TUMOR NECROSIS FACTOR ALPHA AND ITS CORRELATION WITH PROGNOSIS IN ORAL SQUAMOUS CELL CARCINOMAS

Mahiye Reyhan Turkseven, Tulin Oygur, Benay Tokman
Gazi University Faculty of Dentistry, Dept. of Oral Pathology, Turkey

Background: Natural Killer (NK)cells are able to show early and spontaneous cytotoxic reaction against tumor cells. NK cells have responsibility in cytokine secretion that have role in antitumor immunity. These cytokines are able to regulate NK cell activity by the otokrine effect. In addition to its well known biological effects, TNF- α, also produced by NK cells, shows cytotoxic effect on some tumor cell lines. This research aimed to give a new insight to the interaction between host local immune response and the biological behaviour of the tumor by evaluation of intratumoral NK cells and TNF-α expression in oral squamous cell carcinoma Method: In 46 cases of OSCC, CD57(NK) and TNF- α antibodies were immunohistochemically detected. Levels of CD57 and TNF- α expressions were microscopically evaluated in 2 histological groups that were categorized in accordance with their grading scores of invasive margins. Furthermore, the clinical stages of 15 cases were correlated with CD57 and TNF- α expression levels. Results: While the number of CD57(+) cells was statistically lower in the group with worse prognosis, the level of TNF alpha was found statistically higher. Conclusion: Increased level of TNF alpha might have direct role on the decrease in NK cells for the high invasive group. TNF alpha that causes connective tissue destruction might support the invasion of the tumor cells.

PP4-181
GIANT CELLS LESIONS - RETROSPECTIVE ANALYSIS

Slobodanka Vukelic-Markovic, Zoran Mirkovic,
Ruzica Kozomara, Nebojsa Jovic, Srboljub Stosic
Clinic of Maxillofacial Surgery, Military Medical Academy, Belgrade, Serbia

Giant cell lesions mostly originate from the soft tissues, but rarely also from the bone. Giant cell lesions of gums are peripheral

giant cell granulomas (PGCG), but there are a number of lesions that occur in the jaws that contain giant cells within them: central giant cell granuloma (CGCG), giant cell tumor (GCT), brown tumor (BT) and cherubism (Ch). Histologically all of the giant cell lesions appear similar, if not identical, and they usually can be distinguished by clinical history, immunohistochemistry or genetic markers. During ten years period at the Clinic for Maxillofacial Surgery of the Military Medical Academy there were 29 patients with lesions containing giant cells: 22 PGCG, one CGCG, three GCT, two BT and one cherubism. All patients with PGCG were successfully treated by single wide surgical excision of exophitic gum tumor and ostectomy of underlying bone. CGCG appeared in a male mandible. It has been removed together with adjacent bone, with no relapse. Two of three cases of the GCT of the mandible appeared in women of the fifth decade and after one local relapse they died of lung metastases within three years time; the third case is a 14 years old boy with GCT of maxilla: during the last three years he went through the parcial, and ten moths later the subtotal maxillectomy and he is in a stable remission for almost two years. Both young men with terminal renal failure and BT of maxilla were successfully operated. The 16-year old boy with cherubism was only diagnosed by bone biopsy. Conclusion: Although these lesions are histologically similar, their precise distinction is important because of their different biologic behavior and treatment.

PP4-182
OUR EXPERIENCE WITH LOCALIZED CASTLEMAN'S DISEASE AT THE NECK
Zoran Mirkovic, Slobodanka Vukelic-Markovic,
Ruzica Kozomara, Zoran Damnjanovic, Nebojsa Jovic
Clinic of Maxillofacial Surgery, Military Medical Academy, Serbia

Background: Castleman's disease (angiofollicular lymph node hyperplasia or giant lymph node hyperplasia) appears as localized or ? rare - multicentric benign lymph node mass of the mediastinum, but it has been reported in abdominal anad retroperitoneal cavities, lungs, axillary and cervical region. Case report: during last 16 years there were four cases of Castleman's disease localized at the neck: 54 years old lady and three males: 20, 32 and 37 years old. All of them had asymptomatic, slowly growing tumor mass; diameter 9, 7, 8 and 9 cm respectively; without data about previous inflammatory episodes; under the upper part of the sternocleidomastoid muscle, with clinical presentation resembling lateral branchial cyst and clear ultrasonographic description of a solitary, clearly limited lymph node with abundant vascularization. Intraoperatively they were soft, fatty, bloody and easy removable. After pathohistologic verification of hyaline-vascular type of Castleman's disease in all three cases, patients are followed up during a period of 16, 5, 2 and one year with repeated ultrasonographic examination of the neck, axillas and abdomen and CT examination of the chest, but none of them developed any sign of local or multicentric relapse. Conclusion: Castleman's disease is the rarest benign lymph node hyperplasia in our surgical praxis. These four cases were successfully operated and carefully followed up for years. As we expected, none of them turned into multicentric form.

PP4-183
ANALYSIS OF THE POSTOPERATIVE AND POSTIRRADIATION RELAPSE RATE OF INTRAORAL PLANOCELLULAR CARCINOMA
Ruzica Kozomara, Slobodanka Vukelic-Markovic,
Nebojsa Jovic, Srboljub Stosic
Clinic of Maxillofacial Surgery, Military Medical Academy, Belgrade, Serbia

Frequency and importance of etiologic factors in onset of oral squamocellular carcinoma (OPCC) at tongue and the floor of the mouth, together with their pathohistologic and clinical features, point to high incidence of its relapse. According to available prognostic parameters, including tumor parameters (pathohistologic and TNM classification), it is not possible for certain to explain the disease relapse in patients with the same histologic type, stage and size of tumors which were treated in the same way (surgery and postoperative irradiation) and which were all pathohistologicly proved to be completely excised. During three years long clinical follow up of 84% male and 16% female patients, 43-80 years old, with OPCC of tongue and the floor of the mouth, we analyzed 12% patients in the second and 88% patients in the third stage of the disease, with 10% of T-1, 76% of T-2 and 14% of T-3 tumor size. The lesion was mostly localized at the middle third of tongue margin. 54% of patients showed the infiltrative tumor growth. All of the patients underwent tumor excision as well as regional lymphadenectomy. In 88% patients the dissection of the neck was performed: in 80% of patients it was suprahyoid ? 63% unilateral and 17% bilateral ? dissection, while 14% of the patients underwent radical and 7% supraomohyoid dissection of the neck. Pathohistologic examination confirmed positive lymh nodes in 71% cases of suprahyoid and all cases of radical and supraomohyoid dissection. Clinical follow up demonstrated relapse of the disease in 46% of the patients: in 65% of them it appeared early (during the first twelwe months after treatment), while in 35% of them in the period 12-36 months after treatment. Locoregional relapse appeared in 13% of the patients, but only as a late lesion. Simultaneous appearance of both local and locoregional relapse appeared early in 21% and lately in 8% of the patients.

PP4-184
EXPERIENCE WITH LARGE DENTIGEROUS CYSTS OF THE MANDIBLE
Slobodanka Vukelic-Markovic, Ruzica Kozomara,
Zoran Mirkovic, Nebojsa Jovic, Srboljub Stosic
Clinic of Maxillofacial Surgery, Military Medical Academy, Belgrade, Serbia

Mandibular odontogenic cysts are common, but could be challenging when exceed more than 5 cm of mandibular lenght. During last ten years there was 100 large mandibular cysts: 40 developmental (25 dentigerous, 12 keratocysts, 1 eruption, 2 calcifying odontogenic cyst) and 60 inflammatory (59 radicular and 1 residual cyst). There was 67 males and 33 females; 14-62 years old (mean age 36 years). Most of cysts involve angular region (37), mandibular body (31), ascendent ramus (3), symphysis (7) and two or more of these regions (22). Two patients had two different cysts, and two patients simultaneously had some other intraoral lesion: fibroma and hemangioma. More than half caused external visible assimetry, pain and drainage. All of them were enucleated and residual defect has been reconstructed with aloplastic material (Osteovit), rarely marsupialized (8) or mandibula enhanced with metallic plate over remaining buccolabial cortex. In three cases reoperation was needed after two-seven years. In two cases of keratocyst nevoid basal cell carcinoma syndrome (Gorlin syndrome) has been present: 59 years old woman (keratocyst found after several excisions of facial basalioma) and 35 years old man (keratocyst operated 12 years before occurence of multiple facial basaliomas); both with epidermal cysts, enlarged head circumference, rib anomalies and mild hypertelorism, as well as pectus excavatum at male.

PATHOHYSTOLOGIC ANALYSIS OF EFFECT OF CONCENTRATED PLATELETS ON OSTEOINTEGRATION OF DENTAL IMPLANTS
Zoran Mirkovic, Zoran Lazic, Slobodanka Vukelic-Markovic,
Smiljana Matic, Marija Bubalo
Clinic of Maxillofacial Surgery, Military Medical Academy, Belgrade, Serbia

INTRODUCTION: Biointegrity of an implant is based on expectation of their integration after placement within bony tissue by processes of remodelation and osteogenesis, so they could overtake functional load of the suprastructure. Aiming to create better conditions that influence to bone healing of dental implant, last few years growth factors are used in implantology. They are mediators of direct or indirect growth regulation of cells and tissues. Growth factors within CT-PRP important for bone regeneration are PDGF, TGF?, VEGF, EGF and other. AIM of this paper is to establish whether the application of CT-PRP method provides better osteointegration of dental implants. METHODS: The study was performed on six experimental dogs in which 24 BCT dental implants were placed: each got four implants ? two on the left side with CT-PRP and two on the right side without CT-PRP application. Osteotomized segments of the mandible were taken after 42, 70 and 98 days, and after preparation all were pathohistologically analyzed. Contact region of the implant with adjacent tissue has been analyzed pathohistologically by following of characteristic features of tissue reaction: connective tissue, osteoblasts and necrosis presence. RESULTS: Results obtained by pathohistological analysis demonstrated increase of connective tissue, outstanding osteoblastic activity and absence of necrosis in group where CT-PRP was applied, and increase of connective tissue, poor osteoblastic reaction and presence of necrosis during the first six weeks in group of implants placed in classic manner. CONCLUSION: According to results obtained from pathohistologic analysis the CT-PRP method has an advantage thanks to better osteointegration due to distinct osteoblastic reaction.

PP4-186
PRIMARY EXTRANODAL NON-HODGKIN MALIGNANT LYMPHOMAS OF THE HEAD AND NECK REGION ACCORDING TO THE WHO CLASSIFICATION
Yordanka Brachkova
Department of Pathology, Medical University Pleven, Bulgaria

BACKGROUND: The Working formulation commonly used to classify non-Hodgkin's lymphoma (NHL) in Bulgaria, has been recognized as imperfect for primary extranodal lymphoma in head and neck regions. PURPOSE: To study the clinicopathological and immunohistochemical features of extranodal NHL according WHO Classification. METHODS: Routine histology was performed and stained with H&E and immunohistochemistry, and clinical characteristics were recorded. RESULTS: Between 1997 and 2006, 22 patients with primary extranodal NHL of head and neck region were treated surgically.The patients included 12 male and 10 female; age 24-80 years; tumor localization: tonsil (n=10, 46%) sinunasal areas(n=4, 1.8%) nasopharynx (n=2, 0.9%), salivary glands 2, floor of mouth/gingiva 2, hypopharynx 2. Immunohistochemically, 20 tumors were of B- cell phenotype and 2 tumors were of T-cell phenotype. According to the WHO classification , 12 cases were diffuse large B-cell lymphomas (8 in tonsil,2 sinonasal), 3 were extramedulary plasmocytoma (paranasal sinuses-2, gigiva-1),1 was precursor B-lymphoblatic lymphoma (tonsila), and 1 was marginal zone B-cell lymphoma of mucosa associated lymphoid tissue (MALT), 1 was mantle cell lymphoma,1 was Burkitt lymphoma. Among the T-cell lymphomas, 1 was peripheral T-cell lymphoma (tongue) and 1 extranodal NK/T-cell lymphoma (epipharynx). CONCLUSION: Our date correspond with series from Western population, but there is a significant difference from Japan, Hong Kong and Korea

PP4-187
HER-2 OVEREXPRESSION AND GENE AMPLIFICATION IN SALIVARY DUCT CARCINOMA
Aleksandra Kolaric, Mats G Karlsson
Dept of Pathology, Örebro University Hospital, Sweden

Background Her-2 receptor overexpression in salivary duct carcinomas (SDC) was described in 1994. In the management of the look-alike tumour in the breast, Her-2 targeted therapy has been introduced and the evaluation of Her-2 receptor and gene status has been standardized and correlated to drug effects. In SDC, reports have confirmed Her-2 overexpression and gene amplification has been described. However, a variety of procedures has been used in these studies. Method 31 SDC were identified from the institutional archive, 28 of these were available for further analysis, including 8 of the 9 cases in the report of Hellquist. One block was stained and scored according to the Herceptest protocol (Dako, DK). Fluorescence in situ hybridization (FISH) including a Her-2 probe and a centromere 17 probe was performed and evaluated in 20 cells (Vysis, USA). A ratio (Her-2:centromere) of ≥2.0 was considered amplified. Cases with a high, not countable, signal were considered as clusters. Results Herceptest was negative (score 0) in twelve cases, 2+ in three and 3+ in eleven. All negative tumours had a normal genotype with a ratio ≤1.4. Of the three cases with score 2, one showed a normal FISH pattern, one low level amplification with ratio 2.2, whilst the third showed Her-2 cluster. All eleven cases with Herceptest 3+ showed gene amplification as clusters. In two cases a more than two-fold increase in centrome signals, one as clusters, indicated a more complex genotype. Two cases with intratumour heterogeneity were found, score 0/2+ and 0/3+. FISH was negative in Herceptest negative areas. 2+ area showed increased number of Her-2 as well as centromer signals indicating aberrations at chromosomal level, 3+ area showed clusters. Conclusion We conclude that Her-2 overexpression occurs more frequently in SDC than in ductal carcinoma of the breast. In breast carcinomas Her-2 gene amplification is considered the dominating mechanism for Her-2 overexpression and a prerequisite for targeted therapy. In SDC, a high frequency of overexpression in spite of a normal gene copy has been reported. In our series, no case showed overexpression at the 3+ level with a normal pattern for Her-2 gene signals. Gene amplification is the dominating mechanism for Her-2 overexpression also in SDC whilst a few cases with more complex genomic aberrations occur. The data imply that SDC is a potential target for anti-Her2 therapy and that Her-2 status should be evaluated with the same algorithm as in breast carcinomas.

PP4-188
PRIMARY LEIOMYOSARCOMA OF THE THYROID GLAND
Cigdem Celikel[1], Murat Sari[2], Burcu Tuzuner[1], Mine Yazici[2], Naziye Ozkan[1]
[1] Marmara University School of Medicine, Department of Pathology, Turkey
[2] Marmara University School of Medicine, Department of ENT, Turkey

Primary leiomyosarcoma of the thyroid gland is extremely rare and clinico-pathological information on this tumor is scant. We herein report a case of epithelioid leiomyosarcoma of the thyroid gland in which anaplastic carcinoma was suspected based on clinical and cytological features. The patient was a 79-year-old male who presented with a painful mass in the left neck region that had increased in size over a number of months. Ultrasonography revealed a mass lesion in the left lobe of the thyroid gland. Fine needle aspiration was performed. The cytological diagnosis was a malignant tumor compatible with carcinoma. In the surgical specimen of the thyroid left lobe and isthmus, there was a mass lesion measuring 6 cm in its greatest

dimension that was fleshy, necrotic and uncapsulated. Histologically, there was a solid, lobular pattern of growth comprised of epithelioid cells with increased cellularity, pleomorphism, a high mitotic rate, necrosis, and hemorrhage. Immunohistochemistry of the tumor cells clearly showed smooth muscle differentiation; the cells were positive for desmin, muscle-specific actin and vimentin and negative for cytokeratin, epithelial membrane antigen, carcinoembryonic antigen, thyroglobulin and calcitonin. The tumor cells also showed positive reactivity to c-kit proto-oncogene product. There was no evidence of metastasis in the radiological and clinical examination. No local recurrence and metastasis developed within 4 months after the initial operation. Leiomyosarcomas of the thyroid gland are distinctive tumors and can be distinguished from anaplastic carcinoma with the aid of immunohistochemistry.

PP4-189

HPV-RELATED SQUAMOUS PAPILLOMA OF THE OROLARYNGEAL TRACT. REPORT OF TWO CASES FROM THE TONSILS AND THE LARYNX

Maria Papaevangelou[1], Efthymios Koniaris[1], Nikolaos Zirganos[1], Vasileios Negris[1], Nikiforos Kapranos[2], Nikiforos Apostolikas[1]
[1] Pathology Dpt., Anticancer Oncological Hospital of Athens 'St. Savvas', Athens, Greece
[2] Molecular Pathology Dpt., 'Mitera' Maternity and Surgical Center, Athens, Greece

Background: A variety of HPV-related lesions have been reported in the oral cavity and in the larynx. A wide spectrum of architectural patterns ranging from simple Epithelial Hyperplasia (EH), to Verruca Vulgaris (VV) and from Condylloma Acuminatum (CA) to Squamous Papilloma (SP), characterizes these lesions. Here we report two cases of SP, one from the larynx and one from the tonsil. Method: The first case was traced in a 45-year old sailor who referred to our hospital for a sore throat and endoscopic removal of a small laryngeal, warty lesion took place. We received 6 tissue specimens measuring 0.3-0.5cm. The clinical history of the patients wife, revealed an HPV infection of the cervix. The second case involved a 26-year old female with a small papilloma measuring 0.5cm on her right tonsil. Results: Histologically, both lesions were warty-papillary with branching projections consisted of squamous epithelium overlying thin fibrovascular cores. The basal, parabasal cell hyperplasia, the mild anisonucleosis and the non-uniform perinuclear halos of both lesions, motivated us to screen the positivity with the different subtypes of the papilloma viruses. Immunohistochemistry revealed strong staining for HPV types 6 and 11 in both cases. Conclusion: The SPs are the most common benign laryngeal tumors (84%) caused by HPV. The adult-onset oral and laryngeal SP is a frequently relapsing disease. HPV types 6 and 11 which do not carry a high risk of malignant transformation have been detected with a variable frequency (8-60%). Virus transmission appears to be mostly horizontal or by autoinoculation. These patients have a history of a genital wart in 16% and their female sex partners 12.5%. Primary HPV infection may remain latent, requiring cofactors to develop into the clinical disease. A lack of orogenital contact does not protect the patients from adult-onset SP since they seem to be prone to HPV infections. Differential diagnosis involves kerstinized SP, CA and verrucous carcinoma. The diagnosis plays an important role for the appropriate treatment since the relapse is very common. Therapy in laryngeal papillomatosis involves 6 sessions of laser ablation of the papillomas and intralesional injections with cidofovir.

PP4-190

ATYPICAL LYMPHOCYTIC INFILTRATION (LYMPHOCYTOMA) OF THE INFERIOR ALVEOLAR NERVE: A CASE REPORT

Maria Siponen[1], Veli Matti Vartiainen[2], Tuula Salo[1], Jukka Rosberg[1], Meeri Apaja-Sarkkinen[3]
[1] Institute of Dentistry, University of Oulu, Finland
[2] Department of Diagnostics and Oral Medicine, Oulu University Hospital, Finland
[3] Department of Pathology, Oulu University Hospital, Finland

Lymphocytomas are non-neoplastic processes occurring mainly in the skin that are characterised histopathologically by polyclonal lymphocytic infiltrate. They may be associated with Lyme's borreliosis but in many cases etiology remains unclear. Differential diagnosis includes also small cell malignant lymphomas. 33-year-old male was referred to the Department of Oral and Maxillofacial Surgery at Oulu University Hospital for gradually developed sensory loss of the left lower lip. Radiological examinations (panoramic x-ray, CT-scan and MRI) revealed enlarged left mandibular canal, with an expansive, but well-defined soft tissue lesion. In the bone scan a local accumulation was seen in the left body of the mandible. A biopsy was taken from the inferior alveolar nerve. Histopathological findings suggested a lymphocytic infiltration of the nerve tissue. Immunohistochemistry showed both B- and T-lymphocytes in the infiltrate. Some of the B-lymphocytes were Bcl-2 and CD23 positive, which was considered to be related to residual mantle zones. Later the whole enlarged section of the inferior alveolar nerve was resected, and showed similar histopathological findings. Further medical examinations have not revealed any systemic disease and the patient has been well in the 16-month follow-up period.

PP4-191

THE IMPORTANCE OF HYALURONIC ACID IN VOCAL FOLD LESIONS IN DIFFERENTIAL DIAGNOSIS

Nil Comunoglu[1], A. Isin Dogan Ekici[1], Ferda Ozkan[1], Ismail Kocak[2], Bulent Eren[3], Selcuk Bilgi[1]
[1] Yeditepe University, School of Medicine, Department of Pathology, Turkey
[2] Yeditepe University, School of Medicine, Department of ENT, Turkey
[3] Uludag University, School of Medicine, Department of Forensic Medicine, Turkey

Background: We examined the influence of hyaluronic acid and basement membrane thickness alterations on biochemical properties of vocal fold lesions including vocal fold polyps, sulcus vocalis lesions, vocal fold cysts, and Reinke's edema. Method: Fifty-six laryngoscopic vocal fold biopsies from 49 patients, reported between 1.7.2005 and 27.2.2007 in Yeditepe University, School of Medicine, Department of Pathology, were evaluated retrospectively. Twenty-seven of these cases were vocal fold polyps, 7 were sulcus vocalis, 13 were vocal fold cysts, and 9 were Reinke's edema. Ten normal vocal fold mucosa samples from autopsy cases were included in the study as control group. In order to evaluate the hyaluronic acid in extracellular matrix and basement membrane alterations; hematoxylin-eosin, alcian blue pH 2.5, PAS, and colloidal iron stains were performed histochemically. We evaluated the staining pattern for each lesion and compared with that of control group. Data analysis was performed using SPSS Version 8.0 (Chicago, IL) statistical package. Frequency data were evaluated by the Kruskall Wallis test. A P value ≤ 0.01 was considered to be statistically significant. Results: We detected that sulphated hyaluronic acid in extracellular matrix was increased with neomatrix formation in vocal fold polyps, sulcus vocalis lesions, vocal fold cysts, and Reinke's edema when compared with control group. The difference was statistically significant ($p<0.01$). This increase was more remarkable in vocal fold polyps than sulcus vocalis

lesions, vocal fold cysts, and Reinke's edema. It was detected that basement membrane thickness increased in 4 pathologic lesion groups compared with control group in statistically significant manner ($p<0.01$). This increase in basement membrane thickness was most remarkable in sulcus vocalis lesions. Conclusion: The results suggested that hyaluronic acid plays an important role in determining biochemical properties of vocal fold lesions including vocal fold polyps, sulcus vocalis lesions, vocal fold cysts, and Reinke's edema. Furthermore we think that hyaluronic acid and basement membrane thickness alterations can be useful in differential diagnosis in vocal fold lesions.

PP4-192
THE RELATIONSHIP BETWEEN p63 EXPRESSIONS IN BASALOID AND CONVENTIONAL SQUAMOUS CARCINOMAS OF THE LARYNX

Semsi Altaner, Omer Yalcin, Fulya Oz Puyan, Ufuk Usta
Trakya University, Medical Faculty, Department of Pathology, Edirne, Turkey

INTRODUCTION: p63 is a p53 homologue that seems to play distinctive roles in the physiology of the squamous epithelia. p63 is similar to p53 but it has different activities. Our aim was to obtain new insights into the role of p63 in basaloid squamous cell carcinoma (BSCC) and conventional squamous cell carcinoma (CSCC). MATERIALS and METHODS: We examined the presence of p63 in 20 BSCC and in 20 CSCC cases retrospectively at immunohistochemical level. The expression of p63 was analyzed in paraffin-embedded specimens of 20 patients with BSCC and 20 patients with CSCC by using immunohistochemical staining methods. RESULTS: All cases with BSCC and CSCC stained positively with p63. Diffuse staining rates with p63 in the BSCC was significantly different from the ones in the CSCC group ($p<0.05$). 11 cases in the basaloid group and 4 cases in the conventional group showed diffuse staining with p63. Diffuse staining with p63 was evident on the sections from the specimens with poor prognostic factors in the basaloid group. CONCLUSION: In the present study, we determined p63 positivity in the all BSCC and CSCC cases of the larynx. In addition, diffuse staining pattern with p63 in the BSCC cases may have a value in distinguishing between the CSCC and BSCC. We suggest that p63 diffuse positivity has a relationship with the prognostic parameters and it seems to be a poor prognostic factor in BSCC of the larynx.

PP4-193
HR-CGH IN BASAL CELL ADENOMAS AND ADENOCARCINOMAS

Fabricio Passador-Santos[1], Sara Martorelli[2], Suzana Sousa[3], Vera Araujo[4], Fernando Soares[5], Luiz Kowalski[6], Silvia Rogatto[2]
[1] University of São Paulo -USP - School of Dentistry - Department of Oral Pathology, Brazil
[2] São Paulo State University - UNESP - School of Medicine - Neogene Laboratory, Brazil
[3] University of São Paulo - USP - School of Dentistry - Department of Oral Pathology, Brazil
[4] São Leopoldo Mandic - School of Dentistry, Brazil
[5] AC Camargo Hospital - Department of Pathology, Brazil
[6] AC Camargo Hospital - Department of Head and Neck Surgery, Brazil

Background: Salivary gland tumors (SGT) are rare neoplasms comprising from 2 to 4% of all head and neck tumors. The overall low incidence and histological diversity are major limitations for all biological studies on the salivary gland tumors. The molecular events associated with their development and clinicopathological heterogeneity remain unknown. Previous cytogenetic and molecular genetic analysis of these tumors have been limited in scope and size and did not account for their inherent morphological and biological heterogeneity. Basal cell adenomas (BCAs) and basal cell adenocarcinomas (BCACs) represent, respectively, the benign and the malignant counterpart of salivary gland tumors characterized by the proliferation of basaloid cells. Histologically, they can be very similar, especially when a few amount of material is available for analysis, such as incisional and fine needle biopsies. Method: High resolution comparative genomic hybridization (HR-CGH) using metaphase chromosomes can detect changes in chromosome copy number with a resolution of 3-20Mb. We applied HR-CGH technology in 10 cases (from nine patients) of basal cell adenomas and 5 cases (from four patients) of basal cell adenocarcinomas in order to evaluate and to compare the gains and losses profile in both tumors. Results: Interestingly, it was detected a characteristic pattern of gains and losses in both group of tumors. Losses in 4p14-p15.1, 10q25-q26, 14q24-q31 and 19q13.2-q13 and gains in 22q13 were found in the BCACs. On the other hand, BCAs showed gains in 2q37, 3p24-p26, 4q33-q35, 5q23-q31, 7p22, 10q25-q26, 11p15, 11q25, 15q26, 18p11.3 and 20q13.2-q13.3. Two samples from the same patient (BCAC2 and BCAC5) showed different copy number alterations. In this case, one sample shared the same pattern of chromosomal alterations observed in the basal cell adenomas. Conclusion: In overall, the results support the hypotheses that a set of genes differentiate BCAs and BCACs. These results provide new information on potential genetic events of biological significance in future studies of these salivary gland tumors.

PP4-194
IDENTIFICATION OF METASTATIC ADENOCARCINOMA AND REACTIVE MESOTHELIAL CELLS IN PLEURAL EFFUSIONS. VALUE OF AN IMMUNOCYTOCHEMICAL PANEL OF CD44, CALRETININ, CK7, CK20 AND TTF-1

Nur Yucel[1], Zekiye Aydogdu Dinc[1], Ali Kadri Cirak[2]
[1] Izmir SS Chest Disease and Surgery Hospital, Department of Pathology, Turkey
[2] Izmir SS Chest Disease and Surgery Hospital, Clinic of Chest Disease, Turkey

Background: Pleural effusions are frequently first clinical manifestation of metastatic disease. Lung, breast, ovarian carcinomas and malignant mesothelioma (MM) are leading the causes of malign pleural effusions. Cytologic differentiation of metastatic carcinoma and reactive mesothelial cells in effusion is sometimes a problem that cytomorphologic criters are insufficient. Recently, extensive research has resulted in expansion of the antibody panel that is available for effusion diagnosis, thereby reducing the risk for error Methot: We have used a panel of five monoclonal antibodies; Calretinin, CD44, CK 7, CK 20 and TTF-1, so as to identify the primary tumor site of metastatic carcinoma cells and reactive mesothelial cells in pleural effusions. Results: Applying an algorithm of immunocytochemical marker constellations, we were able to correctly diagnose proliferating mesothelial cells (% 100) and primary tumor sites in 23 of 30 patients. The best result was achieved for the identification of metastatic carcinomas of the lungs (88.1%).We established an algorithm comprising five immunocytochemical markers that enabled a correct diagnosis of primary tumor sites in 75%. Conclusion: The panel studied could be useful in diagnostic routine for the identification of primary tumors of unknown origin, metastatic to the pleural membranes and reactive mesothelial cells.

p16 EXPRESSION IN HUMAN PAPILLOMAVIRUS RELATED PREMALIGNANT HEAD AND NECK LESIONS

S. Elif Gultekin[1], J. Peter Klussmann[2], Soenke Weissenborn[3], Hans. P. Dienes[4]
[1] Gazi University Dental Faculty Department of Oral Pathology, Turkey
[2] University of Cologne Department of Oto-Rhyno-Laryngeology, Germany
[3] University of Cologne Virology Institute, Germany
[4] University of Cologne Pathology Institute, Germany

Background: Human papillomavirus (HPV) induced orophraynx carcinomas has been postulated as a distinct tumor entity in terms of biological behavior and treatment modality. p16 is a tumor supressor gene product ,which is a strong candidate of a valuable prognostic marker ,shown to be overexpressed in most oropharangeal carcinomas associated with high risk HPV. Material and Methods: The study was conducted on paraffin embedded specimens of 43 cases of tonsillar and laryngeal lesions which comprised 15 cases of dysplasia and 28 cases of papilloma. Eleven of 15 dysplasia cases were from tonsils and 4 of 15 cases were from larynx. Most of the tonsillar dysplasia specimens were from the dysplastic epithelium adjacent to tonsillar carcinoma (10 of 11 cases). Twenty four papilloma cases were from tonsils (14) and larynx (14). p16 expression was evaluated by ABC immunoperoxidase staining whereas the presence subtypes of HPV DNA was determined by polimerase chain reaction (PCR) . All dysplasia cases were graded and p 16 positivity was graded as high, medium, low degree (score1-2) on the basis of staining pattern and density. Results: Seventeen of 43 cases (39.5 %) showed the presence of HPV DNA. Of positive specimens, 7 of 17 (41.2 %) were papilloma and 10 of 17 (58.8 %) were dysplasia lesions. All HPV positive papilloma specimens were from larynx . Of positive dysplasia cases, 9 of 10 were tonsillar and 1of 10 was larynx lesions. Nine of 10 dysplasia cases adjacent to carcinoma showed HPV 16 positivity, where as 1 laryngeal dysplasia case had low risk viral load (HPV 6). All HPV positive laryngeal papilloma cases showed the presence of low risk HPV DNA load (HPV 6/11). High degree (score 3) p 16 overexpression was seen 12 of 15 (80 %) dysplasia and 1of 28 (3.6 %) papilloma cases. All HPV 16 positive dysplasia cases had high degree p 16 over expression,. Conclusion: The results showed HPV was not detected in tonsillar papillomas while HPV 11 /6 was found half of the larynx lesions. High risk HPV (HPV 16) was detected in tonsillar dysplasia lesions and showed positive correlation with p16 overexpression.

PP4-196

MIDDLE EAR CHOLESTEATOMA: CORRELATION BETWEEN IMMUNOHISTOCHEMICAL FINDINGS AND DISEASE EXTENSION AND BONE DESTRUCTION

Jovan Dimitrijevic[1], Nada Milanovic[2], Miodrag Colic[3], Vera Todorovic[4], Neda Drndarevic[4]
[1] Institute of Pathology, Military Medical Academy, Belgrade, Serbia
[2] Institute of Otorhinolaryngology, Military Medical Academy, Belgrade, Serbia
[3] Institute for Medical Research, Military Medical Academy, Belgrade, Serbia
[4] University of Belgrade - Institute for Medical Research, Department of Immunohistochemistry and Electron Microscopy, Belgrade, Serbia

Background: Cholesteatomas are accumulation of exfoliated keratin inside the middle ear, originated from keratinized squamous epithelium. These epidermoid cyst show independent and progressive growth with destruction of adjacent tissue, especially the bone tissue, with tendency to recurrence. According to some investigations, a characteristic signal of cholesteatoma is the infiltration in the perimatrix of immune system cells, and the increment in proliferation of the cholesteatoma matrix would be the results of the inflammatory process, suggesting that the perimatrix would be the main factor of cholesteatoma development. Method: The purpose of the current study was to analyze the immunohistochemical features of cholesteatoma in correlation with extension and bone destruction grades. Specimens were obtained from 30 patients (9 female and 21 male; mean age, 46 years) requiring middle ear surgery. To define the cell density and distribution of T and B cells, CD4+ and CD8+ cells, antigen-presenting cells, macrophages, Mercels cells, Langerhans cells, mastocytes, as well as expression of E-cadherin, we used CD3, CD4, CD8, CD68, CD1a, CD117, HLA-DR, triptase, CD19, CD38 and E-cadherin antibodies and ABC immunohistochemical procedures. Results: Generally, immunostaining suggests that the T cells (CD4+>CD8+) and antigen-presenting cells (HLA-DR+) are predominant cell populations in the cholesteatoma, as well as that triptase+ mastocytes more number in comparison to CD117+mastocytes. Langerhans cells (CD1a+) are often seen intraepithelialy. There was increase density of each CD3+, CD4+, CD68+ cells in cases of cholesteatoma with extensive erosion and sequestration of the underlying bone. In addition, it is evidence of increased number of intraepithelial CD8+ cells in same cases. No statistical differences in density of each HLA-DR+, CD1a+, CD117+/triptase+, CD19+, CD38+ cells was found between cholesteatoma with and without extensive erosion of the underlying bone. Also, results show that the expression and distribution of E-cadherin in middle ear cholesteatoma is not deranged with extensive bone erosion. Conclusion: It is well known that the progression of the cholesteatoma might be induced by the release of factors from the cholesteatoma matrix or perimatrix. Findings of our study suggested that cholesteatoma CD3+, CD4+, CD8+ and CD68+cells plays and active role in the process of bone destruction.

[3] Institute of Ophthalmology, Clinical Center of Serbia, Belgrade, Serbia

Background: The fundamental role of the immune system in conjunctival wound healing after glaucoma surgery is well established. Glaucoma filtering surgery fails most frequently due to fibrosis at the episcleral-conjunctival/Tenon's capsule interface. The success rate of glaucoma filtration surgery may be optimized through the use of a combination of pharmacological agents that modulate the inflammatory and proliferative phases of the wound healing reaction. The most commonly clinically used drugs are corticosteroids and the antimetabolites, including 5-FU. Currently, many new pharmacological agents are used to modulate the wound healing. Method: In a rabbit model of glaucoma, we were examined the effects of capecitabin, a 5-FU Prodrug, or 5-FU on prevention of episcleral fibrosis after trabeculectomy. Twenty four animals were included in the study. After trabeculectomy we placed 5% solution of 5-FU in one eye of each animals for two weeks and the fellow eye was received capecitabin. Eye specimens were investigated by histological examination. Results: Microscopic examination revealed no statistical significant change in the number of fibroblasts and granulocytes, as well as collagen fibers density in the episclera between experimental groups. However, we observed the significant decrease of number of mononuclear cells and

plasmocytes, and reticulin fibers density in the eyes treated with capecitabin. Conclusion: Although both 5-FU and capecitabin were effective in the prevention of episcleral fibrosis after trabeculectomy in the rabbit, capecitabin has stronger effect in suppression of chronic inflammation.

PP4-198

EFFECT OF TREPONEMA DENTICOLA ON HUMAN DENDRITIC CELLS PHENOTYPE AND FUNCTION

Patrıcıa Cury[1], Veronica Horewicz[1], Joao Carmo[2], Vera Araujo[1], Ney Araujo[2], Jose Barbuto[2]
[1] Sao Leopoldo Mandic Dental Research Institute, Brazil
[2] University of Sao Paulo, Brazil

BACKGROUND: Periodontitis is a bacterial infection characterized by chronic gingival inflammation, which leads to the loss of the tooth-supporting tissue. Dendritic cells play an important role as regulatory and effector cells in the pathogenesis of periodontitis and Treponema denticola is an important periodontopathogen. This study compares the effect of Treponema denticola on the phenotype and function of human dendritic cells obtained from peripheral blood mononuclear cells of volunteers with periodontal healthy or chronic periodontitis. METHODS: Peripheral blood was obtained from systemically healthy volunteers with periodontal healthy or chronic periodontitis. Monnonuclear cells were isolated and maturated in dendritic cells. Dendritic cells were pulsed with extract of Treponema denticola at 5µg/ml, 10µg/ml or 15µg/ml, irradiated and were then cocultured with allogeneic T cells for 7 days. Dendritic cells were marked with monoclonais antibodies anti-CD1a, anti-CD14, anti-CD80, anti-CD86, anti-CD83, anti-CD11c, anti-CCR7, anti-HLADR. RESULTS: In periodontal healthy volunteers the bacteria increased the maturation of the dendritic cells, while in the periodontitis volunteers, the maturation was decreased when HLADR and CD-11c were analyzed. Proliferation of T cells was higher in the healthy than in the periodontitis volunteers. CONCLUSION: Phenotype and function of dendritic cells from individuals with periodontal healthy and chronic periodontitis differs when dendritic cells are pulsed with Treponema denticola. This may explain at least in part the differeces in susceptibility to periondontitis.

PP4-199

CYTOKERATIN EXPRESSION PATTERNS OF PRECANCEROUS LESIONS OF THE LARYNX CLASSIFIED ACCORDING TO THE LJUBLJANA AND WHO CLASSIFICATIONS

Yesim Gurbuz[1], Evrim Kus[1], Omer Aydin[2]
[1] Kocaeli University Medical Faculty Pathology Department, Turkey
[2] Kocaeli University Medical Faculty Otorhinolaryingology Department, Turkey

INTRODUCTION: Ljubljana system for the precancerous lesions of the larynx is claimed to be more predictive for malignancy than WHO system. The main difference between these two classifications is the high percentage of involved epithelium in high grade displasia in WHO classification that corresponds to atypical hyperplasia in Ljubljana system. In normal laryngeal mucosa cytokeratin 14 (CK14) expression in basal, ciliated and non ciliated epithelium, CK8, CK18 and CK19 existence in non basal cells and CK13 expression in squamous and cuboidal cells were reported. In this study, we examined the cytokeratin expression patterns of precancerous lesions of the larynx classified according to Ljubljana and WHO classification in order to compare these two systems and altered cytokeratin expression in laryngeal carcinogenesis. MATERIAL METOD: We included 1 selected block from 42 laryngeal biopsies in our study (2 simple hyperplasia, 18 abnormal hyperplasia, 15 atypical hyperplasia, and 7 carcinoma insitu according to Ljubljana classification), (1 normal mucosa, 12 mild dysplasia, 9 moderate diysplasia, 12 severe dysplasia and 8 carcinoma insitu according to WHO classification). CK 7, 10, 13, 14, 16, 17, 19, 20 were detected by immunohistochemical metod. The relation between cytokeratin expression and subgroups were classified according to Ljubljana and WHO classification were detected by Chi square test. RESULTS In Ljubljana classification, CK13 expression was observed in 95% of simple hyperplasia, abnormal hyperplasia and 72.7% of, atypical hyperplasia and carcinoma insitu. CK16 expression is decreased with the intensity of the lesion ($p<0.053$). In WHO classification, CK10 expression was observed in 76.9% of normal mucosa and mild dysplasia, 48.3% of moderate, high dysplasia and carcinoma insitu ($p<0.083$). CK16 expression was detected in 76.9% of normal mucosa and mild dysplasia 41.1% of moderate, high dysplasia and carcinoma insitu ($p<0.033$). There was CK19 expression in 38.5% of the normal mucosa and mild dysplasia 75.9 % of moderate,high dysplasia and carcinoma insitu ($p<0.019$). CONCLUSION: WHO classification is more related with the cytokeratin expression than Ljubljana system. The reason may be the different levels of involvement of the squamous epithelium in two classification systems. There is increase in CK19 and decrease in CK10, 13 and 16 expressions in laryngeal carcinogenesis process.

PP4-200

MUC1, MUC2, MUC4, MUC5AC, MUC6 AND PS2 EXPRESSION IN SALIVARY GLAND NEOPLASIAS

Yesim Gurbuz[1], Deniz Filinte[1], Omer Aydin[2]
[1] Kocaeli University Medical Faculty Pathology Department, Turkey
[2] Kocaeli University Medical Faculty Otorhinolarngology Department, Turkey

INTRODUCTION: Mucins are high density molecules synthesized by epithelial cells. Thirteen different type of mucin is defined. MUC 1, MUC 2, and MUC 4 were observed in the salivary gland ductal system. MUC 6 expression has been found in normal and neoplastic salivary gland tissue. TFF-1 is the molecule which makes co-expression with MUC 5 AC and was detected in the salivary glands. MUC expression in salivary gland neoplasias is variable and not studied adequate. Salivary gland tumors are a group of the neoplasias with problematic differential diagnosis especially in small biopsies. In this study, MUC and TFF1 expression of a group of salivary gland neoplasia were examined in order to find an additional criterion for their differential diagnosis. MATERIAL METOD For this purpose, 41 salivary gland tumors (10 pleomorphic adenoma, 10 Warthin tumor, 10 adenoid cystic carcinoma, 5 mucoepidermoid carcinoma, 4 myoepithelioma and 2 basal cell adenoma) have been included in the study. MUC 1, MUC 2, MUC 4, MUC 5 AC, MUC 6, and TFF-1 expressions were detected immunohistochemically. The presence and the intensity of the expression were scored as 0 to 4. Relation between existence of MUC 1, MUC 2, MUC 4, MUC 5 AC, MUC 6, TFF-1 expressions and MUC 5 AC and TFF-1 expression patterns (MUC 5 AC +/TFF-1 +, MUC 5 AC -/TFF-1 -, MUC 5 AC +/TFF-1 -, MUC 5 AC -/TFF-1 +) of different tumors, malignant and benign groups were detected by Chi-square test. RESULT: MUC 1 and MUC 4 expression was detected in all mucoepidermoid carcinomas, MUC 2 expression was detected in 4 cases (80%). MUC 6 existence in the mucoepidermoid carcinoma and adenoid cystic carcinoma was 20% and 40%. MUC 5 AC+/TFF-1 + staining pattern was observed in 62.9% of the benign neoplasias, and in 6.7% of the malignant salivary gland tumors ($p< 0.0001$). MUC 5 AC -/ TFF-1 - staining pattern was observed in 11.5% of benign and 53.5% of malignant salivary gland tumors ($p < 0.004$). CONCLUSION MUC 5 AC+/TFF-1 + staining pattern is more common in benign salivary gland neoplasias compared with the malignant group. Co expression of these two molecules in benign salivary gland neoplasias is similar to their normal expression in normal tissue. MUC-5 AC and TFF-1 expression may be an additional differential diagnostic parameter in salivary gland neoplasias.

PP4-201
CHRONIC HYPERPLASTIC CANDIDIASIS OF THE LARYNX

Ugur Pabuccuoglu[1], Sulen Sarioglu[1], Enis Alpin Guneri[2], Cenk Ecevit[2]
[1] Dokuz Eylul University Faculty of Medicine Department of Pathology, Turkey
[2] Dokuz Eylul University Faculty of Medicine Department of Otorhinolaryngology, Turkey

Background: Candida species induce chronic inflammatory changes in the laryngeal epithelium comparable to chronic hyperplastic candidiasis (candidal leukoplakia) of the oral mucosa. However, hyperplastic candidiasis of the larynx is assumed to be rare. We here report a prospective series of 15 patients with chronic laryngeal candidiasis and discuss the diagnosis and management of these lesions. Methods : The histopathologic diagnosis of candidiasis was based on morphological features of causative fungi as well as associated epithelial changes. Patients were treated by type I, type II or type III resections. Excisions were followed by antireflux medications and systemic flucanozole treatment and patients were advised to stop smoking . Results : Of 15 patients with chronic laryngeal candidiasis, twelve were men (%75) and 3 (%25) were women. The ages of the patients ranged from 36 to 82 years. Hoarseness was the most common presenting symptom (13 cases). In 11 cases the history of smoking and in three cases associated alcohol consumption was recorded. Clinical impression was that of a hyperkeratotic lesion in 10 cases. Histopathological features associated with candidal organisms in biopsy specimens included; epithelial hyperplasia, keratosis and parakeratosis of varying severity, and polymorphonuclear leukocyte infiltration at the superficial layers of the laryngeal epithelium. Candidal hyphae were often scarce and located within the keratotic layer. Epithelial invasion by the hyphae was limited to uppermost epithelial layers. Periodic acid Schiff stain was very useful for the detection of fungal organisms. Mild epithelial dysplasia was noted in 1 case and moderate dysplasia was encountered in 2 additional cases. Histopathologically, in 8 cases fungal hyphae involved right vocal cords while in 5 cases they were noted in the left vocal cords. In one case bilateral vocal cords were affected. In the remaining case candidiasis was associated with squamous cell carcinoma. Conclusions: The possibility of hyperplastic candidiasis should be kept in mind when managing cases of keratosis and leukoplakia of the larynx. The pathologist must be aware of histopathological changes associated with hyperplastic laryngeal candidiasis and should apply special stains in order to detect fungi. This may influence the low incidence of laryngeal candidal leukoplakia, which in fact seems to be relatively higher in our experience. Laryngopharyngeal reflux may be an important predisposing factor in the development of laryngeal candidal leukoplakia.

PP4-202
DERMATOFIBROSARCOMA: CASE REPORT

Zoran Mirkovic, Slobodanka Vukelic-Markovic, Nebojsa Jovic, Sasa Jovic
Clinic of Maxillofacial Surgery, Military Medical Academy, Belgrade, Serbia

Dermatofibrosarcoma is rare tumor in head and neck region, it is asymptomatic and it rarely metastasizes. Here we present a case of on extremely aggressive, rapidly growing and mutilating DFS seemingly non-responsive to wide surgical excision. 42 years old men underwent surgical excision of discreet, painless left cheek soft tissue lesion. There were no palpable lymph nodes on the neck and chest radiography was normal. On histopathological examination, the lesion was thought to be dermatofibroma. Three years later, he presented with a recurrence at the site of excision. After excision the recurrent lesion was suggestive of dermatofibrosarcoma. During almost next three years the patient has been operated six times: each time the tumor rapidly and aggressively had grown outwards, destroying the whole middle third of the face, so at the moment of death only forehead, left eye, tongue and part of mandible had left. Comparing to dermatofibrosarcoma protuberans which appeared in our three patients, slowly relapsed and never tended to be aggressive, dermatofibrosarcoma itself, on the other hand, acted completely reverse, especially in this case where we have observed visible rapid growth of huge tumor masses destroying face, never giving regional or distant metastases.

[2] Department of Othorhinolaryngology and Head and Neck Surgery, Croatia

Plasma cell neoplasms and related entities are a group of lymphoid neoplasms of terminally diferentiated B cells that have in common the expression of a single clone of Ig secreting plasma cells. Multiple myeloma is the most common disorder. It is characterized by multiple tumorous mases of neoplastic plasma cells scattered throughout the sceletal system. About 3-5% of plasma cells neoplasms present as a solitary lesion of either bone or soft tissue. Aproxymately 80 % of all extramedullary plasmacytomas occur in the upper aerodigestive tract, especially the sinonasal tract, and 20 % in the other body sites. CASE: We present an anusual case of extramedullary plasmacytoma located in the neck of a 73 years old man. The patient initialy presented with tumorous mass in the right side of the neck. Ultrasonography showed tumorous mass. Ultrasound –guided fine needle aspiration of that lesion had been performed. Cytologic differential diagnosis was plasmacytoma or oncocytic tumor. In bone marrow aspirates we have found 8% plasma cells. Tumor was removed and hystological analysis revealed tumor composed of sheets mature plasma cells with round eccentric nuclei and abundant cytoplasm. Imunohystochemical analysis shoved positive reaction for CD 138 and IgA and negative for CD 20, CD 3 and IgM. Hystological analysis and immunohistochemistry confirmed diagnosis of plasmacytoma. CONCLUSION: Extramedullary plasmacytomas comprises less than 1% of all head and neck tumors. Extramedullary plasmacytoma of the neck region is extremely rare. Treatment consists of surgically or/and radiation therapy with tipically good prognosis.

Neuropathology

PP4-204
EXPRESSION OF THE PARATHYROID HORMONE-RELATED PROTEIN IN GLIAL TUMORS

Nagihan Yalcin[1], Nilay Sen Turk[1], Hulya Tosun[1], Nese Calli Demirkan[1], Bahar Baltalarli[2], Erdal Coskun[3]
[1] Department of Pathology, Pamukkale University School of Medicine, Denizli, Turkey
[2] Department of Radiation Oncology, Pamukkale University School of Medicine, Denizli, Turkey
[3] Department of Neurosurgery, Pamukkale University School of Medicine, Denizli, Turkey

BACKGROUND: It has been found that Parathyroid hormone-related protein (PTHrP) is expressed in a variety of tumors including breast, prostate, colon, lung, renal and ovarian cancers. In some recent publications, it has been noted that there is a relation between PTHrP expression and prognosis in glial tumors. The aim of this study is to evaluate the expression of PTHrP in glial tumors and to find out whether there is a relationship between this expression and grade. METHODS: We have examined the expression of PTHrP in glial tumors of 16 glioblastoma multiforme , 2 anaplastic astrocytoma, diffuse astrocytoma grade II and pleomorphic xanthoastrocytoma grade II using immunohistochemical staining. RESULTS: It has been found that PTHrP staining has been seen in 6 glioblastoma multiforme, a pleomorphic xanthoastrocytoma. The strongest and the most diffuse staining has been seen in the case of pleomorphic xanthoastrocytoma. The patient was a child. It has also been found that staining is very weak in 4 out of the 6 fixed glioblastome. Four cases showed weak staining out of six positive gliobastome. CONCLUSİON: PTHrP is expressed very low in human glial tumors in our study. Further studies of large series having more low grade astrocytomas should be done.

PP4-205
RARE OCCURRENCE OF OLFACTORY COLLOID CYST

Michael Doukas[1], George Alexiou[2], Andreas Zygouris[2], Dimitrios Pahatouridis[2], Spyridon Tsiouris[3], Sevasti Kamina[1], Andreas Fotopoulos[3], Spyridon Voulgaris[2], Maria Bai[1], Ann Goussia[1]
[1] Department of Pathology, Medical School, University of Ioannina, Greece
[2] Department of Neurosurgery, Medical School, University of Ioannina, Greece
[3] Department of Nuclear Medicine, Medical School, University of Ioannina, Greece

Background. Colloid cysts are rare benign intracerebral lesions accounting for 0.2% to 2% of all intracranial neoplasms. They are predominately located in the anterior aspect of the third ventricle; however, there are occasional reports of colloid cysts found in the fourth ventricle, cerebellum, leptomeninges, parietal region and frontal lobe. We present herein a highly unusual case of a colloid cyst residing in the olfactory lobe. Materials and Method. A 74-year-old patient underwent a brain CT scan that incidentally revealed a space-occupying lesion measuring approximately 2.5X1.8X2.5 cm, involving the olfactory lobe. Magnetic resonance (MR) imaging showed the lesion as hyperintense on T1, T2 and FLAIR sequences, without surrounding brain edema. The differential diagnosis included a mucocele, dermoid cyst, meningioma and a glioma. Brain scintitomography showed a lesion of low metabolism, a finding consistent with benignity. The patient underwent surgery and intraoperative a cystic lesion was revealed. The cyst was eroding the dura and the frontal lobe and due to the danger of CFS leak, a dura repair was performed Results. Histological examination of the resected material showed that the cyst was lined by a single and focally by a pseudostratified layer of columnar ciliated epithelial cells resting on a basal lamina. Mucus-filled cells were not found. The content of the cyst was consisted of an amorphous, eosinophilic, colloid-like material. Immunohistochemical examination showed positive staining of the lining cells for cytokeratin, epithelial membrane antigen and focally for carcinoembryonic antigen. The histologic diagnosis was consistent of a colloid cyst. Conclusion. Colloid cysts should be included in the differential diagnosis of lesions in the anterior fossa and that although benign they may be aggressive by eroding the dura and producing a mass effect.

PP4-206
SEVERE PRIMARY INTRACEREBRAL HAEMATOMA – CORRELATIONS BETWEEN MAIN CLINICAL, IMAGISTIC AND MORPHOLOGICAL ASPECTS

Iancu Emil Plesea[1], Stelian Danut Enache[2], Corneliu Cristian Georgescu[1], Dan Cioroianu[1], Mihai Popescu[1], Simona Bondari[1], Oltin Tiberiu Pop[1], Alexandru Camenita[2], Cornelia Enache[2]
[1] University of Medicine and Pharmacy Craiova, Romania
[2] Emergency County Hospital Craiova, Romania

Background: The study is an integrated assessment of clinical, imagistic and morphological parameters in patients with severe primary intracerebral hemorrhage (PICH) who died during hospitalisation. Method. The selected group consisted of 183 cases and was divided into 2 groups: 102 cases who lived more than 48 h and were confirmend by computed tomography (CT) and 82 cases that died within 48 h and were confirmed by authopsy. The study was retrospective. The studied material consisted of patient's medical records (medical records, CT films, autopsy protocols and histopathology - HP records). Assessed parameters were: clinical (seasons relation, age, sex, arterial blood pressure - HT, motor deficit - MD, degree of coma - C, Glasgow score at admission) and morphological static (PICH sites, size, perilesional edema - pE, microhaemorrhages - mH,) and dynamic (mass effect - ME, ventricular effusion - VE and subarachnoid effusion - SE). Results: The severe PICH showed a predilection for winter and summer but men (M) are affected more frequently in transition seasons. Sex distribution showed a slight M predominence. The most affected life decades are the 5th and the 7th with a regressive trend for M after the 6th decade and an increasing trend for women (W) towards the 7th decade. Around 70% of the patients had IIIrd and IVth stage HT at admission, 85% had MD and almost 50% Glasgow scores lower than 6. The most common sites of PICH were cerebral hemispheres, slightly more frequent in the left one. They had huge dimensions as compared to hosting encephalic structures. In lobar sites, more than one lobe were involved, mostly parietal, temporal and frontal lobes. Both CT and HP examinations revealed in many cases multiple mH both near and distant to PICH. Other morphologic predictive factors as pE and ME were constantly present. The VE involved at least one of the lateral ventricles. C is more frequent in W, after 60 years of age, in PICH occuring in winter or summer, and non-lobar PICH. That is also the case of MD, which is more frequent in PICH occuring in autumn and winter and lobar PICH. VE is more frequent in M, after 60 years of age, in PICH occuring in autumn and lobar PICH. Although less frequent, SE is slightly more frequent in W, PICH occuring in winter and non-lobar PICH, regardless of age. Conclusions: Our data suggest that PICH associated with one or more clinical and morphological poor outcome predictors (HT, MD, C, ME, VE and SE) results in patient's death, despite any sustained therapeutical intervention.

PP4-207
ANAPLASTIC MENINGIOMA ASSOCIATED WITH MENINGIOANGIOMATOSIS: CASE REPORT OF A RARE ENTITY

Suzan Zorludemir[1], Seyda Erdogan[1], Naciye Ozeren[1], Kenan Bicakci[2], Ilhan Tuncer[1]
[1] Cukurova University, Medical Faculty, Department of Pathology, Turkey
[2] Cukurova University, Medical Faculty, Department of Radiology, Turkey

Background: Meningoangiomatosis (MA) is a rare malformative lesion that is associated with seizure and/or headache. It occurs both in patients with neurofibromatosis (NF), as well as in sporadic cases. Rarely, MA has been described coexisting with meningiomas. As far as we could reach, anaplastic meningioma together with MA has not been reported yet. Material and Methods: A 16-year-old boy had 2 year history of seizure. There was no history of NF. Magnetic Resonance Imaging (MRI) at the second year revealed a contrast-enhancing lesion, with dural tail and peritumoral edema near the left tentorium.The lesion was completely excised. Results: Microscopically, the lesion composed of mitotically active spindle cells with moderately large hyperchromatic nuclei, in a coarsely fasicular pattern resembling sarcoma. Limited areas showed elongated cells in interwoven fasicles and in whorls with psammoma bodies consistent with transitional meningioma. In the cortex, there were abundant small intracortical vessels ensheathed by meningothelial cells; typical of meningoangiomatosis. Conclusion: We present a unique case of anaplastic meningioma which have arisen from meningoangiomatosis without NF-2 history and discuss the pathogenesis, radiologic, clinic and pathologic features on the base of the literature.

PP4-208
ANGIOCENTRIC GLIOMA: A RARE EPILEPSY-ASSOCIATED NEOPLASM

Seyda Erdogan[1], Suzan Zorludemir[1], Tarık Tihan[2], Filiz Cevlik[1], Metin Tuna[3], Erol Akgul[4]

[2] University of California, San Francisco (UCSF), Department of Pathology, USA
[3] Cukurova University, Medical Faculty, Department of Neurosurgery, Turkey
[4] Cukurova University, Medical Faculty, Department of Radiology, Turkey

Background: Angiocentric glioma is a distinct epilepsy-related entity which was not included in the World Health Organization (WHO) classification of Central Nervous System (CNS) Tumors yet. There are only two reports with 18 cases in the literature. Material and Method: A 3-year-old girl was admitted to the hospital with a history of seizure. MRI showed lesion at the right hippocampus and excised. Result: Microscopically, the lesion was composed of cells that were strikingly angiocentric to both large and small vessels. Tumor cells were uniform and usually bipolar. Atypical mitosis, necrosis were absent. Proliferation index was also negative with Ki-67. Conclusion: We present a case of newly described entity which should take part in the WHO classification of CNS tumors. And discuss the clinic, radiologic, histologic and ultrastructural features of this tumor on the base of the literature.

PP4-209
HISTOLOGICAL DISCREPANCIES IN MALIGNANT GLIONEURONAL TUMORS: A REPORT OF 4 CASES

Aydın İsisag[1], Nalan Nese[1], Eren Demirtas[2], Mine Tunakan[3], Turkan Rezanko[3], Cuneyt Temiz[4], Hasan Mirzai[4]
[1] Celal Bayar University, Faculty of Medicine, Department of Pathology, Manisa, Turkey
[2] Mikro Pathology Laboratory, İzmir, Turkey
[3] Ataturk Training and Research Hospital, İzmir, Turkey
[4] Celal Bayar University, Faculty of Medicine, Department of Neurosurgery, Manisa, Turkey

Background: Although not included in WHO 2000 Classification of CNS tumors, malignant glioneuronal tumor (MGNT) is widely accepted as a new entity which resemble any type of high grade (grade III or IV) malignant glioma with tumor cells expressing both neuronal and glial markers without mature ganglion-like cells. In this case series, 4 immunohistochemically proven cases of MGNT are reported in order to emphasize the histological discrepancies among seperate cases of this poorly understood tumor group. Cases: Four cases of MGNT from three different institutions are studied. Two of the patients were female and the other two were male, age 13 (Case 1), 50 (Case 2), 70 (Case 3) and 18 (Case 4) years and localizations were right parietooccipital-intraventricular, left occipital, right temporal and right occipital, respectively. All cases showed peritumoral oedema and contrast enhancement. Except for Case 1, tumors were well circumscribed and gross-totally excised followed by radio-chemotherapy. Patients Case 1 and Case 3 died because of the disease 12 months and 21 months after the initial diagnosis with recurrences while others are still alive for 16 months (Case 2) and 5 months (Case 4). For all cases, glial fibrillary acidic protein, synaptophysine, neurofilament protein and Ki-67 were applied and it was shown that first three of these markers were much or less co-expressed by the tumor cells despite the histological discrepancies among cases. Case 1 and Case 3 was composed of PNET-like areas and glioblastoma areas. Case 1 additionally contained loose and spindle-cell areas while Case 3 showed perivascular arrangement of tumor cells and some pseudopapillary structures. The bulk of the tumor in Case 3 was composed of areas of typically oligodendroglioma or anaplastic oligodendroglioma, which are found in also Case 4. Case 4 also presented psedopapillary structures, spindle-cell areas and epitheliod gemistocyte-like cell clusters intermingled with indifferentiated small cells. Necrosis, pseudopalisading of tumor cells around necrosis and brisk mitotic activity were apparent in all cases. Ki-67 proliferation indices were 55%, 72%, 20% and 43%, respectively. Conclusion: As histology of MGNTs can diverge greatly, all CNS tumors resembling malignant gliomas (especially glioblastoma) or supratentorial PNET should undergo immunohistochemical analyses with at least two neuronal markers as well as with glial fibrillary asidic protein in order to make accurate diagnosis and prognostic presumptions.

PP4-210
SYMPTOMATIC SPINAL LUMBAR JUXTAFACET CYST: A CASE REPORT

Evangeli Lampri[1], George Alexiou[2], Michael Doukas[1], Eufemia Balasi[1], George Fotakopoulos[2], Spyridon Voulgaris[2], Dimitrios Stefanou[1], Ann Goussia[1]
[1] Department of Pathology, Medical School, University of Ioannina, Greece
[2] Department of Neurosurgery, Medical School, University of Ioannina, Greece

Background: Juxtafacet cysts (JFC) are rare intraspinal lesions associated with the facet joints. Although they can be seen along the spinal cord, the lumbar region is the most commonly affected area. The putative mechanisms of cysts formation include spinal instability, arthropathy and trauma. Histologically, two types of JFC are recognized: the synovial and ganglion cysts or

pseudocysts. The two lesions have different histological features, however, studies based on detailed histological analysis revealed dual findings in the same sample, suggesting that these cysts are either parts or progression of the same disease. We report herein a case of symptomatic juxtafacet cyst presenting as L4-L5 radiculopathy. Case report: A 53-year-old man presented with a history of progressively increasing severe pain in the right lower extremity. Physical examination revealed a L4-L5 sensitive and motor deficit. Magnetic resonance imaging (MRI) revealed an intraspinal cystic mass at the segment L4-L5, with hypointense T1-weighted and hyperintense T2-weighted signal and peripheral enhancement. Surgical treatment was planned due to severe pain and neurologic deficit. Histological examination of the resected material showed the presence of a cystic formation with no evidence of epithelial or synovial lining. The wall of the cyst was fibrovascular, with myxoid areas, focal hemorrhage, rare hemosiderin deposits, collections of multinuclear giant cells and small calcifications. The immunohistochemical staning for glial fibrillary acid protein (GFAP) and neurofilament (NF) were negative, showing that the lesion was not derived from neural tissue. The diagnosis was consistent with a cystic formation of spine or juxtafacet cyst with morphology of a ganglion cyst. The postoperative course was uneventful and the patient was discharged on the third following surgery day. On follow-up examinations at 3 months and 1 year after surgery, the patient remained free of pain and symptoms. Conclusion: Juxtafacet cysts are uncommon cause of radiculopathy. We emphasize the need to be thoroughly familiar with this pathologic entity that should be considered in the differential diagnosis of spinal lesions.

[6] Dept. of Experimental Medicine and Pathology, University of Rome "La Sapienza"; IRCCS INM Neuromed, Pozzilli (IS), Italy

BACKGROUND Embryonal neoplasms of CNS affect early years of life and share an aggressive behavior. WHO classification includes five different well-defined entities: medulloepithelioma, ependymoblastoma, medulloblastoma, supratentorial PNET and ATRT. Recently, a new tumor combining features of ependymoblastoma and neuroblastoma named "embryonal tumor with abundant neuropil and true rosettes" have been reported. This lesion is characterized by the presence of areas of well-differentiated neuropil containing ependimoblastic rosette and undifferentiated neuroepithelial cells resembling classic PNET. We report four cases of this rare entity. METHOD The tumoral specimens were routinely processed, paraffin embedded, and H&E stained. Slides were processed for immunohistochemistry using antibodies for Vimentin, S-100, Desmin, Synaptophysin, Neurofilaments, Smooth Muscle Actin, GFAP and BAF47/INI1. The proliferation index was evaluated using anti-MIB-1 antibody. RESULTS Patient #1 was a 1.5 years-old female with a right frontal lesion; patient #2 was a 1.5 years-old male with fronto-temporal lesion; patient #3 was a 3 years–old female with bi-frontal tumor; patient #4 was a 1.5 with pontine lesion. The tumors showed a variable cellular density with fields composed by fibrillar neuropil-like matrix and by hypercellular areas, formed by small hyperchromic cells. Rare Homer-Wright rosettes were focally observed. Mitoses and apoptosis were frequent. The distinctive feature was the presence of numerous ependimoblastic rosettes, found in the hypercellular areas and/or in the fibrillary neuropil-like matrix. The rosettes were composed by pseudo-stratified embryonal cells, arranged around a central lumen. In one case, a sarcomatous-like component of elongated pleomorphic cells was present. The undifferentiated cells were negative for GFAP and synaptophysin whereas the neuropil-like matrix stained intensely for sinaptophysin and neurofilaments. The sarcomatous areas present in one case showed diffuse immunoreactivity for smooth muscle actin and for desmin. The tumors showed a nuclear staining for BAF47/INI1. The MIB-1 ranged from 10 to 30 % in the higher cellular areas. Interestingly, the ependimoblastic rosettes in the neuropil-like areas contained the more proliferative cellular component. CONCLUSION Embryonal tumor with abundant neuropil and true rosettes although presents some features common to other embryonal tumors, seems to have specific histopathological, neuroradiological and clinical features, delineating it as a new entity among pediatric brain tumors.

EXPRESSION OF NUCLEAR FACTOR –κB IN HUMAN ASTROCYTOMAS: RELATIONSHIP WITH PIκBA AND PROGNOSTIC SIGNIFICANCE.

Georgia Levidou, Angelica A Saetta, Penelope Korkolopoulou, Elias El-Haber, Polychronis Demenagas, Irene Thymara, Kalliopi Diamantopoulou, Efstathios Boviatsis, Euphtemia Thomas-Tsagli, Ioannis Panagiotidis, Efstratios Patsouris

National and Kapodistrian University of Athens, Department of Pathology, Athens, Greece

Background: NF-κB is a family of dimeric transcription factors that play a critical role in host defence by regulating the expression of immune genes. Several investigators have reported its constitutive activation in various human tumour cell lines, whereas its immunoexpression has been regarded as a marker of poor prognosis in several tumours. NF-κB activation is tightly regulated by its interaction with IκB inhibitory proteins. However, little information is available about the role of IκB phosphorylation in relation to NFκB activation, and the clinical significance of this interaction in astrocytomas. This study aimed to elucidate the role of NFκB in astrocytomas, focusing on p50/NFκB1 subunit, to determine its association with phosphorylated IκB, and to define the clinical impact of this interaction. Method: The levels of p50/NFκB1 and pIκBa proteins expression were quantified immunohistochemically in paraffin-embedded tissue from 73 patients with astrocytomas, by using a rabbit polyclonal anti-NFκB p50 and a mouse monoclonal anti-pIκBa antibody. Nuclear and cytoplasmic immunoreactivity was assessed separately for both antibodies. Results: Nuclear NFκB1/p50 immunoreactivity was detected in 66/72 cases (91.6%), whereas cytoplasmic immunoreactivity in 17/72 (23%). Concurrent cytoplasmic and nuclear expression was recorded in 17 cases (22%). pIκBa expression was found in 72/73 (98.6%) cases and was predominantly cytoplasmic with scattered nuclear positivity. Concurrent pIκBa and nuclear NFκB1/p50 immunoexpression was detected in 66 cases. All cases with nuclear NFκB1/p50 expression manifested pIκBa immunoexpression. pIκBa expression was positively correlated with nuclear NFκB1/p50 expression ($p=0.0054$) and adversely correlated with cytoplasmic NFκB1/p50 expression ($p<0.0001$). Nuclear NFκB1/p50 and pIκBa expression increased in parallel with tumour grade ($p= 0.0031$ and $p<0.0001$). In univariate survival analysis nuclear NFκB1/p50 and pIκBa expression adversely affected survival ($p<0.0001$ and $p=0.002$). Multivariate survival analysis selected NFκB1/p50 nuclear expression ($p=0.001$) as a significant prognostic factor. Conclusion: Our study reinforces the concept that NFκB1/p50 activation is largely dictated by its interaction with IκBa in human astrocytomas.

Additionally, NFκB1/p50 nuclear expression parallels tumour grade, a result that suggests its contribution to tumour agressiveness. Finally, our results suggest that nuclear NFκB1/p50 expression may serve as a useful independent marker for stratifying patients with astrocytoma in terms of prognosis.

PP4-213
CEREBRAL NEUROBLASTOMA IN ADULTS: REPORT OF THREE CASES

Marco Gessi[1], Michele Bisceglia[2], Libero Lauriola[3], Felice Giangaspero[4]
[1] Div. of Neuropathology, National Neurological Institute "C. Besta", Milan, Italy
[2] Div. of Anatomic Pathology, Ospedale "Casa Sollievo della Sofferenza", S. Giovanni Rotondo, Italy
[3] Dept. of Pathology, Catholic University, Rome, Italy
[4] Dept. of Experimental Medicine and Pathology, University of Rome "La Sapienza"; IRCCS INM Neuromed, Pozzilli (IS), Italy

BACKGROUND: The term "cerebral neuroblastoma" identifies an embryonal neoplasm of CNS belonging to the group of the supratentorial PNET (sPNET) showing various degree of neuronal differentiation. These tumors affect preferentially infants or children and appear to be extremely rare in adult life. We present three cases of cerebral neuroblastoma in adult patients. METHOD: Tumoral specimens were routinely processed, paraffin embedded, and H&E stained. Slides were processed for immunohistochemistry with the ABC system, using antibodies for Vimentin, S-100, Desmin, Synaptophysin, Chromogranin, Neurofilaments, Smooth Muscle Actin, EMA, CK, MAP-2, GFAP, p53 and Neu-N. The proliferation index was evaluated with anti-MIB-1 antibody. RESULTS: In patient 1, a 63 years-old female, MRI revealed a 4 cm infiltrating lesion affecting the left occipital lobe, with non-homogeneous contrast enhancement and necrosis. In patient 2, a 61 years old female, MRI showed a 7 cm well-demarcated right frontal mass, with intense non-homogeneous contrast enhancement. In patient 3, a 59 years old female, CT scans revealed a left parieto-occipital lesion with edema, midline shift and homogeneous contrast enhancement. Histopathological examination showed lesions with similar architecture but with large spectrum in cell composition. Tumors were formed by lobules separated by thin fibro-vascular septa, filled by a mixture of small elements with neuroblastic features as well as larger cells with neuronal or ganglion-like morphology, merged in a variable amount of neuropil. However, cells showed also a variable range of "anaplasia" characterized by bizarre giant cells, apoptotic bodies, necrosis and atypical mitoses. Immunohistochemistry revealed a variable positivity for synaptophysin, neurofilaments, chromogranin and Neu-N in isolated cells. GFAP and mesenchymal or epithelial markers were negative. The proliferation index, assessed by Ki67/MIB1 antibody was variable but focally elevated. p53 was negative. CONCLUSION: Cerebral neuroblastomas in adults are histologically similar to those occurring in pediatric age, although they seem to show a higher degree of severe anaplasia. They lack specific clinico-radiological features. Moreover they have to be distinct from malignant neoplasms more frequent in the adult age group as mixed glio-neuronal tumors and pure gliomas such as glioblastoma and anaplastic oligodendrogliomas.

PP4-214
ANCIENT SCHWANNOMA OF THE SPINAL CORD. A RARE CASE

Maria Papaevangelou, Efthymios Koniaris, Eleni Psichogiou, Maria Gazalidou, Amalia Patereli, Maria Sevastiadou, Nikiforos Apostolikas
Pathology Department Anticancer Oncological Hospital of Athens, 'St. Savvas', Athens, Greece

Background: Schwannomas of the Spinal Cord (SSC) are rare benign tumors. Most are sporadic and some can be part of hereditary syndromes. Histological malignancy of this neoplasm is rare. Method: A 51 year old patient admitted to our hospital for neurologic evaluation with symptoms of spinal compression because of a CT scan lesion on the spinal cord. The lesion was surgically removed and we received a well-circumscribed, elongated, cylindrical specimen which was measuring 8.4x2.2cm. The tumor was encapsulated and on dissection it was partly solid with whitish tint and partly multicystic. The cysts were filled with a bloody-serous liquid. Results: Histologically, multiple cysts comprised most of the tumor while the rest consisted of an inconspicuous or focally cellular component (Antoni type A) with a hint of nuclear pallisading that rendered the diagnosis difficult. Hyalinization, hemosiderin deposition and some nuclear atypia were the minor characteristics of the tumor. In Antoni B areas edema separated tumor cells. No mitotic figures were found. Immunohistochemically the tumor showed reactivity for S-100 protein, vimentin and CD68. Keratin, desmoplakin, neurofilaments and desmin are not expressed. Conclusion: In this presentation we aim to emphasize the polycystic appearance of a so called ancient SSC in a rare location. SSCs generally agreed that are neoplasms originating from Schwann cells, hence their name. Malignant transformation is an exceptionally rare event. Ancient SSC are usually large tumors of long duration. Although histologically are benign, biologically mimick malignancy.

PP4-215
CONGENITAL SUPRATENTORIAL CYSTIC HEMANGIOBLASTOMA; A CASE REPORT AND REVIEW OF THE LITERATURE

Hakan Karabagli[1], Pınar Karabagli[2]
[1] Konya Numune Hospital, Neurosurgery Clinic, Turkey
[2] Konya Education and Research Hospital, Patology Laboratory, Turkey

Congenital supratentorial hemangioblastomas are rarely encountered tumors even in pediatric population. Extensive review of the literature revealed that approximately 118 cases have been reported in the literature so far. However, only 6 of these occurred in infants, and 4 of them occurred during the first two months of life. A 5-week-old boy presented with emesis, irritability, bulging anterior fontanelle and a gradually expanding head circumference since birth. His previous medical and family history was uninformative in terms of cancer or inherited diseases. The MR scans demonstrated a large loculated cyst with a 3-cm heterogeneus mural nodule, first pushing the left frontal and parietal lobes, and then displacing in this region. The histopathologic diagnosis was reticular variant of hemangioblastoma. We reviewed the literature on congenital supratentorial hemangioblastoma and discussed the histopathologic characteristics and differential diagnosis associated with such lesions in this report

PP4-216
THE EXPRESSION OF OSTEOPONTIN IN HUMAN ASTROCYTOMAS: INTERSTITIAL EXPRESSION CORRELATES WITH MALIGNANCY GRADE AND ANGIOGENESIS

Koviljka Matušan[1], Senija Behrem[1], Nives Jonjić[1], Kamelija Žarković[2], Ksenija Lučin[1]
[1] Department of Pathology, Rijeka University School of Medicine, Rijeka, Croatia
[2] Department of Pathology, Clinical Hospital Rebro, Zagreb, Croatia

BACKGROUND: Osteopontin (OPN) is a phosphorylated protein secreted into the extracellular matrix by a variety of cell types. Numerous functions have been ascribed to osteopontin, including roles in bone remodelling, cell-adhesion, cell-mediated immunity, the ability to act as a cytokine in cell signalling,

resulting in proliferation and/or cell survival, and angiogenesis. OPN has also been detected in a number of human tumour tissues and assessed as a potential marker of tumour progression. METHOD: This study was aimed to analyse by immunohistochemistry the expression of OPN in 76 human gliomas of various grades of malignancy: 8 pylocytic astrocytomas, 10 grade 2 astrocytomas, 8 anaplastic astrocytomas and 50 glioblastomas. The staining results were scored in a semi-quantitative manner by assessing the percentage of positive tumour cells and the intensity of staining. We also assessed the intercellular distribution of staining, which was categorized as focal or diffuse, with the staining intensity expressed either as low or high. Since OPN has been implicated in angiogenesis, we analysed the correlation between OPN expression and microvessel densitiy in glioblastomas. Microvessels were stained with α-endoglin antibody (CD105) and counted in predominantly vascular areas (hot spots) at x 400 magnification. RESULTS: In normal brain tissue the expression of OPN was present in some glial and neuronal cells in the form of cytoplasmyc granular staining of low intensity, while microglial cells were strongly positive. In glial tumors intracellular OPN expression ranged from absent or low (score 0-5) to strong (score 6-10). Strong OPN expression was observed in 3 grade I (37.5%), 4 grade II (40%), 2 grade III (25%) and 21 grade IV (42%) astrocytomas. In some tumors OPN was also present interstitially, between tumor cells. This staining pattern was accentuated around tumor necrosis and, in most of the cases, also around blood vessels. Tumours with either a diffuse or strong expression were considered positive in intercellular distribution of OPN staining. Interstitial OPN expression was observed in 1 pylocytic astrocytoma (12.5%), 2 grade II astrocytomas (20%), 2 anaplastic astrocytomas (25%) and 25 glioblastomas (50%). We found the association of interstitial OPN expression and angiogenesis i.e. microvessel density was higher in tumors with high interstitial OPN expression (Mann Whitney test, $p<0.03$). CONCLUSION: Our results show the overexpression of OPN in human astrocytic tumors and suggest the role of OPN in astrocytoma progression and angiogenesis.

PP4-217

CAFFEIC PHENETHYL ESTER (CAPE) SUCESSFULLY REDUCES BRAIN DYSFUNCTION IN SEPSIS

Huseyin Fidan[1], Onder Sahin[2], Yuksel Ela[1], Aynur Kilbas[3], Olcay Eser[2], Murat Cosar[2], Irfan Altuntas[3]
[1] Department of Anesthesiology, Afyon Kocatepe University School of Medicine, Afyonkarahisar, Turkey
[2] Department of Pathology, Afyon Kocatepe University School of Medicine, Afyonkarahisar, Turkey
[3] Department of Biochemistry, Suleyman demirel University, School of Medicine, Isparta, Turkey

Background and goal of study: Sepsis and ensuing multi organ failure continue to be the major causes of morbidity and mortality in the intensive care units. Nuclear factor-Kappa beta (NFKB) activation is supposed to be one of the targets in the treatment of sepsis and ensuing mortality. We studied the effectiveness of caffeic phenethyl ester (CAPE), a known NFKB inhibitor, in cecal ligation and puncture (CLP) induced sepsis model of brain dysfunction. Materials and Methods: 40 rats are randomized to 5 groups. All rats were operated to induce sepsis with cecal ligation and puncture (CLP) except control and CAPE groups that were operated just with laparotomy. CAPE (50 µmole/kg) was administered to rats intramuscularly at the time of operation in CAPE and CA+SEP (0) groups. CAPE was administered to rats in CA+SEP (12) group 12 hours after CLP. All rats from each group were sacrificed 24 hours after CLP; half of brain coronally was taken out for histopathological, and the rest brain was taken out for oxidative stress parameters. Apoptosis was examined with Tunnel staining. Induced nitric oxide synthase (iNOS) and heat schock protein(HSP70) were examined with immunohistochemistry. Malonlydialdehyde (MDA), catalase (CAT), superoxide dismutase (SOD) and glutathione peroxidase (GSH-Px) were studied for oxidative stress evaluation. Results and Discussion: Immunohystochemical studies revealed that sepsis induced brain dysfunction in our model. Histopathologically apoptosis and iNOS and HSP70 expressions were studied in hippocampal CA1 region, prefrontal cortex and plexus choroideus. Although apoptotic measurement revealed no change between groups in hipocampal CA1 region, iNOS and HSP70 expressions were significantly increased in all other groups in comparison to control group. However, iNOS and HSP70 expressions were significantly reduced as CA+SEP (0) <

PP4-219

MEDICALLY INTRACTABLE EPILEPSY: REPORT OF THREE CASES

Ozgur Mete[1], Bilge Bilgic[1], Cicek Bayindir[1], Murat Imer[2]
[1] Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey
[2] Istanbul University, Istanbul Faculty of Medicine, Department of Neurosurgery, Istanbul, Turkey

Background: There is no precise definition of intractable epilepsy. Among the considerations are seizure frequency, seizure type, severity of attacks, and impact on quality of life. Twenty percent of epilepsy is intractable and surgery is an option in the attempt to cure or reduce the severity of medically resistant cases. We report herein 3 intractable epilepsy cases diagnosed as cortical dysplasia, Rasmussen encephalitis and Sturge-Weber syndrome for discussing their histopathological features. Case 1: A 2-year-old male has been suffering from generalized tonic and clonic seizures since 15 months. The histopathological examination revealed cortical dislamination, neuronal heterotopia in the white matter. Neuroimaging and histopathological findings were found compatible with cortical dysplasia. Case 2: A 14-year-old male has been suffering from progressive, focal and generalized seizures and also left hemiparesy on the forearm and leg since 3 years. Cranial MR showed right frontal and temporal atrophy. Functional right hemispherectomy was performed. The histopathological findings revealed neuronal loss, neuronophagia, microglial nodules and perivascular lymphocytic infiltration. The clinical, radiological and histological findings let us to diagnose the case as Rasmussen encephalitis. Case 3: A 2-year-old male has been suffering from progressive, generalized and focal seizures since 20 months. A pink macular lesion in the dermatome of N.trigeminus was remarked. MRI showed cortical atrophy and also increase in the thickness of leptomeninges. Being accepted medically intractable epilepsy, surgical procedure was performed. Leptomeningeal angiomatosis and cortical atrophy let us to diagnose Sturge-Weber syndrome with the presence of port-wine stains. Conclusion: Surgery in epilepsy is the resection of epileptogenic focus The pathological lesions are classified recently as: (a) hippocampal sclerosis (b) malformative lesions, (c) vascular lesions (d) tumors, (e) chronic inflammatory and infectious lesions, (f) ulegyric lesions (g) gliosis-astrocytic proliferation, (h) concomitant calcified lesions and (i) unspecified lesions. It is impotant to remember that Rasmussen encephalitis is a rare, chronic inflammatory disease that usually affects only one hemisphere. Furthermore, special attention has been given to the coexistence of focal cortical dysplasia and tumors, which include mixed neuroglial tumors. Finally, our cases and literature data stress that clinical, neuroradiological and histopathological correlation is important for the diagnosis of these lesions.

PP4-220

PROGNOSTIC FACTORS IN MENINGIOMAS

Deniz Ozcan[1], Aziz Hatiboglu[2], Celal İplikcioglu[2]
[1] Okmeydani Training Hospital, Pathology Department, İstanbul, Turkey
[2] Okmeydani Training Hospital, Neurosurgery Department, İstanbul, Turkey

ABSTRACT: Meningiomas are mostly benign tumors cured by surgical resection. But the behaviour of meningiomas are sometimes diffucult to predict. Some of them tend to recur, therefore longterm management in subtotally resected tumors remain controversial. The microscopic brain invasion, mitotic rate higher than 4/ 10 HPF, the presence sf sheeting, hipercellularity, prominent nucleoli, nuclear pleomorfism, small cells, decreased recurrence free survival (RFS). In this study MIB-1 LI , PR, ER, P 53 and EGFR expressions are compared with histopathological changes. METHOD: 148 meningioma cases operated in our Neurosurgical Department of Okmeydanı Hospital 20 cases were chosen for study.(4 angiomatous meningioma, 2 of which recurred, 5 meningioma cases, 5 atypical grade II meningioma cases, 6 malignant meningioma cases) are examined immunohistochemically using MIB-1 monoclonal antibody estrogen-progesteron receptor P53 and EGFR. RESULTS: There were a close association between MIB-1 LI indices and mitotic index and tumor grade. According to Spearman's rho (Spearman's Rho= 0,493) (p=0,027) P53 and EGFR immunohistochemistry revealed no useful prognostic information. ER, PR immunohistochemistry were variable, but usually ER were not expressed.

PP4-221

EXPRESSION OF HORMONE RECEPTORS PR & ER, ANGIOGENIC FACTORS VEGF – A & VEGF-R3, P53, MDM2, CERBB2 AND CD117 IN MENINGIOMAS

Kalliopi Diamantopoulou[1], Euphemia Thoma-Tsagli[1], Penelopi Korkolopoulou[2], Vassilia Leodara[1], Ioannis Antoniadis[3], Konstantinos Kouzelis[3]
[1] Pathology Department Gen Hospital Asklepieio Voula, Greece
[2] Pathology Department University of Athens, Greece
[3] Neurosurgery Department. Gen. Hospital Asklepieio Voula, Greece

Background: Meningiomas are mostly frequent and benign central nervous system tumors. Independently from the extent of tumor resection, reccurence and tumor progression often determine clinical outcome. In an attempt to understand meningioma tumor biology, we evaluated biomarkers possibly involved in tumor formation, reccurence and malignant transformation, such as progesterone and estrogen receptors, angiogenic factors VEGF – A and VEGF-R3, p53, MDM2, cerbB2 (Her-2/neu) and CD117 (c-kit) and their possible implication in therapeutic approaches. Methods: We examined 34 meningiomas operated in our hospital the last 4 years, 30 of which benign, 2 reccurent (WHO grade I) and 2 atypical (WHO grade II) immunohistochemically for Progesterone Receptors (PR), Estrogen Receptors (ER), Vascular Endothelial Growth Factor (VEGF-A) and its Receptor (VEGF-R3), p53, MDM2, cerbB2 and CD117. Results: PR were expressed in 27/32 (84%) WHO grade I meningiomas in a mean of 44,15%. ER were demonstrated in 12/32 (37,5%) in a mean of 5,5%. Neither PR nor ER were expressed in atypical meningiomas. VEGF-A was intensly demonstrated in most WHO grade I and II meningiomas mainly with cytoplasmic granular or dot-like distribution. In 2 reccurent cases it was faintly or negatively expressed. VEGF-R3 was variably detected with cytoplasmic and nuclear distribution in all meningiomas. p53 nuclear staining was shown in 18/32 (56,25%) benign meningiomas in a mean of 13,05% with negative staining in 2 atypical meningiomas. Nuclear MDM-2 overexpression was variably demonstrated in all benign, recurrent and atypical meningiomas in a mean of 60,90%. cerbB2 was scored 3+ positive staining in 1 benign meningioma (2%), 2+ in 6 meningiomas (17,6%), 1 of which atypical and 1+ and less in the rest (79,4%). CD117 was expressed focally and faintly in 4/34 (11,7%) benign mengiomas. Conclusion: Loss of progesterone receptors' expression is shown to be associated with increased reccurence, implying a better prognosis for positive expression, as were most of our benign and 2 atypical cases. Instead, presence of ERs in meningiomas may correlate with karyotype abnormalities. Hormone receptor status, especially in females, seems to be a possible anti-hormonal target of therapy. Angiogenic factors like VEGF-A and its Receptor VEGF-R3 may be involved in meningioma vasculature and likelihood of reccurence, so antiangiogenic agents should be encountered in therapy. Inactivation of p53 tumor suppressor and overexpression of MDM2 protein may promote meningioma progression and future reccurence, revealing a possible candidate to an aggressive treatment. In our cases the amount of expression of MDM-2 seems not to be correlated to histological grade and reccurence. cerbB2 (Her-2/Neu) and CD117 (c-kit), both members of the tyrosine kinase receptors' family, have not yet been detected in meningiomas but their possible overexpression, especially cerbB2, as in our limited number of cases, must be studied further.

PP4-222

TYPICAL AND UNUSUAL PATHOLOGICAL CHARACTERISTICS AND RADIOLOGICAL FINDINGS IN PRIMARY NEOPLASMS OF THE SPINAL CORD: UCSF EXPERIENCE

Agne Naujokas, Ashley Aiken, Philip Weinstein, Cynthia Chin, Tarik Tihan
UCSF, USA

Background: Limited biopsy samples and overlapping clinical/radiological features can complicate the diagnosis of primary neoplasms of the spinal cord. Typical features of each entity are well known, but deviations from these features are not well recognized. Our study is aimed to determine typical as well as unusual radiological and pathological characteristics of the primary spinal cord tumors. Material and Methods: We reviewed the clinical, radiological and pathological features of all primary neoplasms of the spinal cord diagnosed and treated at our institution between 1996 and 2005. Radiological and pathological materials were analyzed using standard evaluation forms, and the results were analyzed using a statistical software package (SPSS 11.1 for Windows). Appropriate permissions were obtained from the institutional Committee on Human Research (H41995-25437). Results: The entire cohort of 136 patients with primary spinal cord neoplasms consisted of 79 males and 57 females with a mean age of 43 years (range 1-89 years). Only 13 (10%) of these neoplasms occurred in the pediatric age group (<15years). There were 57 ependymomas, 44 schwannomas, 15 neurofibromas, 10 astrocytomas of various grades, 8 hemangioblastomas, 2 gangliocytomas, and 1 subependymoma. Forty four percent of schwannomas demonstrated cystic change radiologically as well as pathologically, 32% had marked inflammatory infiltrates, and 48% had significant degenerative atypia. Radiological evidence of hemosiderin was most prevalent in ependymomas. A significant number of non-pilocytic tumors demonstrated Rosenthal fibers in the neuropil surrounding the tumor. Radiologically some ependymomas could not be distinguished from schwannomas or pilocytic astrocytomas. Clinical features, radiological presence of cyst and T1-T2 characteristics were not helpful discriminators. Pathological material was insufficient in three cases, in which radiological features were helpful. Conclusion: In our series, a significant number of primary spinal cord tumors did not show typical features radiologically, and to a lesser extent histologically. Radiologically, presence of hemosiderin correlated best with an ependymoma, but otherwise pilocytic astrocytomas could not be distinguished from ependymal tumors. The main challenge in the pathological diagnosis was the sample size. Recognition of prevalence of atypical features is critical in correct diagnosis primary spinal cord tumors.

PP4-223

CEREBRAL MEDULLOEPITHELIOMA

Faten Limaiem[1], Amina Mekni[1], Salma Bellil[1], Ines Chelly[1], Raoudha Doghri[1], Slim Haouet[1], Nidhameddine Kchir[1], Mohamed Moncef Zitouna[1], Mohamed Zemmal[2], Khedija Bellil[1]
[1] Department of Pathology, La Rabta Hospital, Tunisia
[2] Department of Neurosurgery, La Rabta Hospital, Tunisia

Introduction: Intracranial medulloepithelioma (ME) is an uncommon, highly malignant primitive neuroectodermal tumour of the central nervous system (CNS) which pathologically recapitulates the neural tube. It usually develops in early childhood and may occur anywhere within the CNS, the most common site being periventricular. Aim of study: The aim of our study was to describe clinicopathological features and immunohistochemical profile of ME and to discuss differential diagnosis. Patients & Methods: Between January 1991 and March 2007, 4 cases of cerebral medulloepithelioma were diagnosed at the pathology department of La Rabta Hospital. Medical record and microscopic slides were available in all cases and were retrospectively reviewed. Results: Our study included four male children aged between 4 and 13 years (mean age = 10,75 years). All patients presented with symptoms of increased intracranial pressure including headache vomiting and lethargy. CT scan showed an isodense or hypodense non-enhancing well-circumscribed tumour involving the temporoparietal lobe in two cases, the frontoparietal lobe in one case and the temporoparietooccipital lobe in one case. Gross-total resection of the tumour was performed in 3 cases and partial resection in one case. Pathological examination of the surgical specimen showed a tumoral proliferation made neural tube-like structures composed of primitive appearing cells that formed a pseudostratified epithelium arranged in tubular, papillary or trabecular configuration. The neural tube-like structures were outlined by a continuous, PAS-positive basement membrane. Mitotic figures were abundant and tended to be located near the luminal surface. Immunohistochemically, tumour cells were in all cases strongly positive for vimentin but were negative for PS100, NSE and GFAP. Postoperatively, 3 patients underwent adjuvant radiotherapy in the tumour bed. During the follow-up period which ranged between 1 and 3 years, one patient died.

PP4-224

RT-PCR: DIAGNOSIS VALUE IN DOGS WITH SPONTANEOUS ACUTE-, SUBACUTE-, AND CHRONIC-DEMYELINATING DISTEMPER ENCEPHALITIS

Edson M. Scarpelli[1], Karime C. Scarpelli[1], Alexandre M. Amude[2], Geórgia F. Cintra[1], Amauri A. Alfieri[2], Maria L. Cintra[1]
[1] Department of Pathology - UNICAMP (State University of Campinas) SP, Brazil
[2] Laboratory of Animal Virology - UEL (State University of Londrina) PR, Brazil

Background: Distemper is an endemic disease, that is not restricted to carnivorous or to a single specie. Encephalitis due to canine distemper virus (CDV) has been associated with multiple sclerosis (MS) because of extensive demyelization in both and the postulated viral origin in MS. A domestic dog barely spends its life without contact with distemper virus (DV), mainly in developing countries; also, contact may occur through vaccination programs. Methods: Within three years, 45 dogs with signs of canine distemper (CD) were attended in Zoonosis Control Center of Taubaté, São Paulo, Brazil. Clinical data were recorded according to a protocol. The animals were euthanized, necropsied, photos were taken, and a brain sample was randomly selected for RT-PCR to CDV. In 7 healthy dogs (control group), submitted to euthanasia for different reasons, the same procedure was adopted. This study followed guidelines prescribed by the Brazilian Medical Research Centre and received approval from the Research Ethics Committee of the State University of Campinas. Results: in 31 out 45 dogs, a positive RT-PCR reaction was found in brain samples (group A); in the 14 remained dogs, negative results were obtained (group B); in all the 7 healthy dogs samples, positive PCR results were found (group C). On histological view, chronic-demyelinating encephalitis, typical of CD, was identified in group A animals and in 11/14 dogs in group B; 3/14 dogs in group B displayed no histological abnormalities. Focal lymphoid infiltrate was found in 5/7 animals and no abnormalities in 2/7 dogs in group C. Conclusion: For the endemic nature of CD and vaccination programs, positive results of RT-PCR do not allow the distinction of CDV from other diseases that share with it the same clinical manifestation. By the other side, false-negative RT-PCR could be the result of inadequate brain sample selection or be due to technical reasons. In this way, our findings stress the importance of clinical evaluation for proper CD diagnosis. The results may be useful for clinical research on CDV and sanitary programs of control of the disease.

PP4-225

PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA IN IMMUNOCOMPETENT PATIENTS: RETROSPECTIVE ANALYSIS OF 15 CASES

Aylin Okcu Heper[1], Ercan Armagan[2], Ayse Ozgun[1], Hasan Caglar Ugur[2], Esra Erden[1], Ali Savas[3], Isinsu Kuzu[1]
[1] Ankara University, School of Medicine, Department of Pathology, Ankara, Turkey
[2] Ankara University, School of Medicine, Department of Neurosurgery, Ankara, Turkey
[3] Ankara University, School of Medicine Department of Neurosurgery, Ankara, Turkey

Background: Primary central nervous system lymphoma (PCNSL) is a rare disease. It represents approximately %3 of the central nervous tumors and is most often seen in inmmunodeficient patients. The incidence has increased in last two decades. In this study we aimed to review retrospectively PCNSL cases which were diagnosed in Ankara University, Faculty of Medicine, Department of Pathology with their clinical, responses to therapy regiments and survival. Material-method: Total 15 cases diagnosed in 2002-2006 and confirmed immunohistochemically were included into the study. The patients were analysed in relation to sex, age, time of the symptoms, procedures, treatments, survival and pathological features. Results: All of the patients (8 male, 7 female) were immunocompetant and the time of the initial symptoms to pathological diagnosis was in range between 1 month to 4 months. The mean age of the patients was 47.7 (range, 27-66 years). The most common symptom was hemiparesy (%80), headache (%46.6) and seizures (%26.6). The lesions were mostly located in cerebral lobes. Except 1 case which had operated, all of the cases were dignosed by steriotactic biopsy. All of the cases were diffuse large B-cell lymphoma, which were confirmed by immunohistochemistry. In one case clonality was showed by PCR. Two cases were not recieved any treatment because they rapidly proggressed to death after the diagnosis. Ten cases received combined treatment of chemotherapy and radiotherapy. The others were treated with radiotherapy or chemotherapy alone. Two cases were excluded from the survival analysis as the absence of the follow-up data. Six cases were died of the disease during the therapy in a period of ranging from 1 month to 24 months after the diagnosis. Five cases were still alive with a follow-up period ranging from 6 months to 48 months. Coclusion: PCNSL is very agressive tumor despite the combined therapy regiments. Steriotactic biopsy is very valuable diagnostic procedure as it is less invasive procedure, especially for deeply located lesions and it provides rapid diagnosis for this type of tumor which is treated non-surgical therapies. Besides molecular methods may be used for conforming the clonality of the tumor, especially for differential diagnosis.

PP4-226
AN ALL-IRELAND CANCER BIOBANK AND INFORMATICS NETWORK FOR COLLABORATIVE TRANSLATIONAL RESEARCH

Eoin Gaffney[1], Ciaran Flanagan[2]
[1] St James's Hospital and Trinity College Dublin, Ireland
[2] I. D. E. A., Dublin, Ireland

INTRODUCTION: Translational research in cancer requires a large tissue sample volume and linked patient data. In Ireland, as in other European countries, cancer samples for research have not been collected with due quality control or stored consistently in accordance with standardised procedures. Insufficient sample aliquots have mitigated against the possibility of collaborative research. We therefore decided to develop an all-Ireland cancer biobank network with common informatics, to provide an infrastructure for collaborative translational research in the main hospitals of Ireland, north and south. METHODS: The Spanish Tumor Bank Network www.cnio.es was considered the most appropriate model for the Irish network, which includes two jurisdictions. The network concept was promoted among numerous stakeholder groups, including professional bodies, hospital management, medical staff, researchers, patient advocate groups, industry, and the public. Biobank Ireland Trust www.biobankireland.com was formed for public awareness and education, for fundraising, and to enable development of a restricted access online sample and informatics resource for potential research projects. No grants were sought, and no full-time personnel were assigned to the project. Disseminations included formal proposals and (international) presentations (ISBER 2005), and hosting and attending biobanking conferences. RESULTS: Progress has been slow and fitful! Informal networks of international biobanking experts were invaluable. Presentations, fundraising events, discussions with members of the public, and media coverage were all helpful. Also of significance was the inclusion in Ireland's national cancer strategy (2006) of an aspiration to develop a national cancer biobank infrastructure. Biobank Ireland Trust's business proposal forms the basis of the Irish network's proof of concept phase: the network will commence in two hospitals, following which it will be extended to 10 others. The estimated cost of the network, excluding capital costs, is €8-10m. over 6 years. COMMENT: A biobank network is more about people than science. Patient advocate groups and the public must be consulted at the outset. When biobanking becomes standard of care in pathology, a biobank network will improve cancer care directly and indirectly. The Irish network will be a template for research infrastructure in other human diseases, will facilitate collaborations with other countries and will enable provision of biobanking assistance to developing nations.

PP4-227
CYCLOOXIGENASE IN THE NORMAL HUMAN TISSUES – IS COX-1 REALLY A CONSTITUTIVE ISOFORM, AND COX-2 AN INDUCIBLE ISOFORM?

Katarina Odar[1], Maja Jerše[1], Tomaž Zupanc[2], Nina Zidar[1]
[1] Institute of Pathology, Medical Faculty, University of Ljubljana, Ljubljana, Slovenia
[2] Institute of Forensic Medicine, Medical Faculty, University of Ljubljana, Ljubljana, Slovenia

BACKGROUND: Cyclooxygenase is a key enzyme in prostanoid synthesis. It exists in at least two isoforms: cyclooxygenase-1 (COX-1) and cyclooxygenase-2 (COX-2). Despite the fact that COX isoforms have been widely studied in various pathological conditions, the data on their distribution and role in the normal tissues is still controversial. It is generally accepted that COX-1 is constitutively expressed in normal tissues as a housekeeper enzyme maintaining tissue homeostasis, whereas COX-2 is normally not present in most tissues, but can be induced by various stimuli. Some studies, however, suggest that distribution and function of COX isoforms is more complex. We therefore analysed the distribution of COX isoforms in the normal human tissues. METHOD: Our study included autopsy samples of various organs and tissues from 10 healthy trauma victims. Immuno-histochemistry was performed by a peroxidase-streptavidin method on formalin fixed, paraffin-embedded tissue, using monoclonal antibodies against COX-1 and COX-2. In addition, western blot analysis of COX-2 protein expression was performed on frozen tissue samples of the brain, heart, kidney, liver, lung, thyroid, adrenal gland, testis, aorta and coronary artery. RESULTS: Using immunohistochemistry, we found COX-1 expression in blood vessels (in endothelial and smooth muscle cells) in all tested tissues, and in occasional inflammatory cells and macrophages, particularly in mucosal membranes. COX-2 was widely expressed in the parenchymal cells of endocrine glands (adrenal cortex, pituitary gland, thyroid, pancreas), testis, liver, central nervous system, kidney and in the glands of the gastric and colonic mucosa. COX-2 was focally expressed in the lung, and almost absent in the spleen and prostate. In the heart, occasional positive cardiomyocytes occurred with increasing age. In all organs and tissues, we observed COX-2 positivity in ganglion cells, occasional inflammatory cells and macrophages and focally in endothelial cells of blood vessels. With western blot analysis, we found detectable levels of COX-2 protein in all the tissues tested, presenting with bands of different intensities. CONCLUSION: Our results indicate that COX-2 is widely expressed in the parenchyma of many human organs and tissues, whereas COX-1 is predominantly found in blood vessels. Therefore, tissue distribution and role of COX isoforms under physiological conditions is clearly more complex than generally believed. We will probably have to revise the concept of "constitutive" and "inducible" COX isoforms.

PP4-228
ERK AND PERK EXPRESSION, B-RAF MUTATIONS AND MICROSATELLITE INSTABILITY IN COLORECTAL CANCER

Angelika. A. Saetta, Fanie Gigelou, Penelope Korkolopoulou, Nikolaos Kavantzas, Georgia Levidou, Polyanthi Papanastasiou, Angeliki Stamatelli, Maria Karlou, Nikolaos V. Michalopoulos, Efstratios Patsouris
1st Department of Pathology, School of Medicine, National and Kapodistrian University of Athens, Greece

Background: The RAS/RAF/MEK/ERK signaling pathway plays a pivotal role in controlling cellular growth, differentiation and survival mediating cellular responses to growth signals. Activating B-Raf mutations which stimulate RAF/MEK/ERK kinase cascade resulting in phosphorylation and subsequent activation of ERK, have been associated with colon cancer exhibiting microsatellite instability (MSI) -an alternative pathway of carcinogenesis caused by defective mismatch repair (MMR) system. The aim of this study was to determine the B-Raf mutational status and to asses the immunohistochemical pattern of ERK and activated ERK (pERK) in relation to MSI and hMLH1 promoter hypermethylation, of patients with colon cancer so as to elicit any potential associations with prognostic value. Methods: B-Raf exon 11 and 15 mutations were investigated by single stranded conformation polymorphism (SSCP) and DNA sequencing in 94 patients diagnosed with colon cancer. Additionally, immunohistochemical expression of both total ERK and pERK was examined. The presence of MSI was determined by analysis of sensitive mononucleotide markers (BAT-25, BAT-26) and the methylation status of hMLHI promoter was assessed by methylation specific PCR. Results: Total ERK cytoplasmic or nuclear immuoreactivity was detected in 92.7% (51/55) and 85.4% (47/55) of the cases respectively. Nuclear pERK immunoreactivity was found in 71.7% (32/45) while 11 (24.4%) cases displayed cytoplasmic positivity. There

was no correlation between nuclear or cytoplasmic ERK LI and the presence of nuclear and/or cytoplasmic pERK immunoexpression. pERK nuclear immunoreactivity was positively correlated with tumor grade (p=0.0133) and Duke's stage (p=0.09), whereas the latter was of marginal significance. B-Raf mutations in exon 15 were found in 12 cases. The presence or the score of ERK and pERK immunoexpression, either nuclear or cytoplasmic was not correlated with B-Raf mutations, MSI status or hMLH1 promoter methylation. Conclusion: Our findings indicate that ERK and activated ERK (pERK) are frequently expressed in colorectal cancer, independently of B-Raf status. Moreover nuclear pERK expression correlated with tumor grade and Duke's stage, suggesting a possible further implication in tumor aggressiveness. The project is co-funded by the European Social Fund and National Resources-(EPEAEK II)-PYTHAGORAS II.

PP4-229

DOUBLE IMMUNOSTAINING METHOD. WHAT IS THE SIGNIFICANCE?

Naziye Ozkan[1], Fulya Cakalagaoglu[1], Emine Salva[2]
[1] Marmara University, Vocational School of Health Related Professions, Pathology Laboratory Department, Istanbul, Turkey
[2] Marmara University, Medical Faculty, Pathology Department, Istanbul, Turkey

Background.Immunostaining is a technique for identifying cellular or tissue antigen. Immunohistochemistry has been part of the routine technique of the pathology laboratory for over 20 years.These technique have significantly expanded the capabilities of the pathologist in diagnostic procedures.Immunohistochemical techniques were very sensitive and specific methods which utilize antigen-antibody complexes.Among the immunostaining methods the enzyme labelled streptavidin-biotin method is now widely used in routine testing. In study, immunohistochemical localization of α-Smooth Muscle Actin (α-SMA),Proliferative Cell Nuclear Antigen (PCNA) was performed using the streptavidin-biotin peroxidase (Str.ABC/HRP) and streptavidin-biotin alkaline phosphatase (StrABC/AP) immunostaining methods.The double immunostaining method described may have wide application since it can be used both for paraffin sections and cytology. It does not require specialized technique or apparatus. The aim of our study to compare the immunoexpression of PCNA and α-SMA in anti-Thy1.1 diffuse experimental glomerulonephritis rat model by Str.ABC/HRP,StrABC/AP and double (Str.ABC/HRP and Str.ABC/AP) immunohistochemistry methods (DIHC). Methods.Ten male Wistar Albino rats were divided into two groups of fifth: Group I Control(C): 5 rats treated with 0.1ml /100g normal saline intravenously (i.v) for four weeks; groupII glomerulonephritis (GN): 5 treated with anti-Thy1.1(0.25µg/100g) i.v at zero day. Kidneys from rats were collected as Instituional Animal Care and use Committee approved procedures.Representative tissue samples were stained with hematoxylin eosin (HE) and Gomori One Step Trichrome.In each case PCNA and α-SMA expression were semiquantatitively scored on glomeruli and tubulointerstitium by Str.ABC/HRP,Str.ABC/AP and double immunohistochemical methods staining slides. Results:At the end of the study period morphological changes including tubulointerstitial injury and glomerular cell proliferations were significantly increased in glomeulonephritis group compared to control group.With in immunohistochemical methods,glomerular immunoexpression of α-SMA was similar in two groups.Tubulointerstitial immunoexpression of α-SMA was similar in Str.ABC/AP and Str.ABC/HRP in GN compared to two groups,but different in DIHC.Immunoexpression of PCNA in all immunohistochemical methods on tubulointerstitial and glomeruli was significant increased in GN group compared to C. Conclusions.Double immunostaining was the method to detect two antigen in same site.That method was simple and reliable.

PP4-230

THE EFFECTS IN SKIN WOUND HEALING AND CELL PROLIFERATION OF THE PLASMID DNA ENCODING GM-CSF AND CHITOSAN

Emine Salva[1], Naziye Ozkan[2], Fulya Cakalagaoglu[2], Berna Karakoyun[3], Julide Akbuga[4]
[1] Marmara University, Vocational School of Health Related Professions, Pathology Laboratory Department, Haydarpasa, İstanbul, Turkey; Marmara University, Department of Pharmaceutical Biotechnology, Faculty of Pharmacy, Haydarpasa, Istanbul, Turkey
[2] Marmara University, Vocational School of Health Related Professions, Pathology Laboratory Department, Haydarpasa, Istanbul, Turkey
[3] Marmara University, Nursing School, Haydarpasa, Istanbul, Turkey
[4] Marmara University, Department of Pharmaceutical Biotechnology, Faculty of Pharmacy, Haydarpasa, Istanbul, Turkey

Background: Granulocyte macrophage colony-stimulating factor (GM-CSF) regulates proliferation, differentiation and function of hematopoietic progenitor cells. Whereas a very important problem with the use of GM-CSF is that it has short biological t50 and it is necessary to administer frequent injections of high dose of GM-CSF, however this approach has been limited by the toxicity of this protein. Chitosan (CS), a natural cationic polysaccharide, has a high potential as a non-viral vector for gene delivery. Topical delivery of therapeutically relevant genes to wounded skin may help accelerate wound healing. The objective of this study was to investigate the encapsulation of hGM-CSF encoding gene into chitosan complex and in vitro transfection efficiency and therefore in vivo effects of GM-CSF complex application were identified in normally healing wounds. Method: pORF-hGM-CSF plasmid DNA was extracted by the alkaline lysis method.CS-pDNA complexes were prepared.In vitro transfection studies, the effect of the proliferative of the GM-CSF was determined by MTT test. We have used the assay to measure proliferative GM-CSF at the 24,48 and 72 hours. For skin topical application, Wistar rats were first anesthetized by ketamine, their backs shaved and 6 mm long punch biopsy was made at two individual sites on the dorsum of the back of each animal.Thereafter, 100 µg GM-CSF/CS complex (1:1,N/P) and chitosan per wound sites were topically applied.Skin samples were harvested 24,48,72 hours (acute term) and 1,2 weeks (chronic term) after application.Specimens were paraffin embedded, sectioned, stained using H&E and Gomori One Step Trichrome. Results: The better in vitro GM-CSF gene expression was found with 1:1 (N/P ratio). The dose of plasmid in complex is also important in protein expression. In vivo study, the neovascularization, epithelization, cellular content and vascularity increased in GM-CSF/CS complex group compared to chitosan group in acute term. In chronic term, the chronic inflammation, neovascularization, epithelization, cellular content, granulation tissue formation and vascularity increased in GM-CSF/CS complex group compared to chitosan group. In acute and chronic terms, the collagen deposition increased in chitosan group compared to GM-CSF group. Conclusion: According to our results, chitosan/DNA complex is thought to have ability to be a good potential in the treatment with GM-CSF gene so that it is to be a suitable delivery system for gene of chitosan, be applied from skin with chitosan of the gene and able to potential therapeutic effect to wound.

PP4-231
FASCIN AND MIB-1 EXPRESSION IN SEROUS OVARIAN TUMORS
Evanthia Kostopoulou[1], Alexandros Daponte[2], Rodoula Papamichali[1], Athanasia Galani[3], Maria Netsika[3], Ioanna Chiotoglou[4], Konstantia Zachou[3], Dimitris Theodosiou[3], George Koukoulis[1]
[1] Department of Pathology, Medical School, University of Thessaly, Greece
[2] Department of Obstetrics and Gynecology, Medical School, University of Thessaly, Greece
[3] Department of Pathology, University Hospital of Thessaly, Greece
[4] Laboratory of Cytogenetics and Molecular Genetics, Medical School, University of Thessaly, Greece

Background: Fascin-1 is an actin-bundling protein that contributes to the formation of actin-based structures, including cellular surface protrusions that mediate cell movement. Studies in carcinomas suggest the emergence of fascin as a new prognostic indicator. Rare reports concerning fascin expression in ovarian carcinoma have not confirmed a clear-cut relation between immunostaining and established markers considered to reflect biological aggression. The aim of our study was to examine a group of serous ovarian tumors for possible relationships of fascin expression. The proliferative activity was also examined, since some studies suggested an inverse relationship between Ki-67 and fascin. Method: Fascin immunostaining was assessed in 70 specimens of serous ovarian tumors, with complete surgical staging when indicated, (45 carcinomas, 9 borderline tumors and 16 cystadenomas), retrieved from the files of the Pathology Department, University Hospital of Thessaly. Immunostaining was performed using two antibodies, IM20 (Novocastra, U.K.) and 55k-2 (Cellmarque, U.S.A.). Extent and intensity of immunoreactivity were semiquantitavely evaluated. Double staining for fascin and Ki67 was performed in carcinomas using the double Envision kit (Dako, Denmark) and MIB-1 antibody (DakoCytomation, Denmark). Western Blotting was performed on proteins isolated from tumor tissue kept at -80oC. Results: Fascin score was highest in carcinomas. Cystadenomas showed a score lower from carcinomas and borderline tumors ($p<0.0001$). Increased values (mean 4.70 vs 2) were observed in carcinomas of advanced stage (III/IV vs I) ($p=0.04$).Immunoreactivity was increased in metastases in comparison to primary tumors. Positivity was also found in the stroma of carcinomas, often intensified in the immediate vicinity. An interesting association between fascin and MIB-1 immunoreactivity was observed, the latter being lower in tumors showing increased fascin score. Conclusion: Our study showed that increased fascin immunoreactivity in serous ovarian carcinomas is associated with certain features of increased tumor aggressiveness. Increased score in specimens from metastatic sites suggests that fascin may be an important factor in ovarian carcinoma metastasis, as expected from its role in cell motility. We have also showed that cycling cells (MIB-1+) show lower fascin scores. Therefore, the actually invading cells, i.e. the "invasion fraction", may differ from the "growth fraction" of a given tumor. Future studies could determine if fascin may become a helpful marker in gynecological pathology.

PP4-232
SYNDECAN-1 AND VLA-4 INTEGRIN MOLECULES MAY CO-OPERATE IN MYELOMA CELLS UPON STIMULATION
Vadim Baykov[1], Tobias Slordahl[2], Randi Utne Holt[2], Anders Waage[2], Anders Sundan[2], Magne Borset[2]
[1] Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway; Department of Pathology, St Petersburg State Medical University, St Petersburg, Russia
[2] Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway; Department of Pathology, St Petersburg State Medical university, St Petersburg, Russia

Background CD138 (syndecan-1) expression is a distinctive feature of plasma/myeloma cells in the bone marrow (BM). The integrin VLA-4 (α4β1, CD49d/CD29)is the most common integrin on multiple myeloma (MM) cells. Both molecules are involved in adhesion of MM cells to matrix proteins and possibly in selective localization of multiple myeloma to the BM. Adhesion induces pro-survival signaling cascades, increases proliferation, promotes drug resistance and thus may contribute to tumor progression, although extramedullary spread of MM is believed to be associated with loss of cell adhesive properties. Adhesion of MM cells is substantially increased in vitro following stimulation by cytokines, mainly HGF,IGF-1 and SDF-1α. Existing data on CD138 and VLA-4 on MM cells with regard to clinical stage/progression are controversial, but soluble syndecan has been proved to be a strong negative prognostic factor. Possible interaction/cross-talk of integrins and syndecans is widely discussed; intriguing data have been demonstrated for carcinoma cells, but little evidence exists in MM so far. The aim was to study the expression and localization of syndecan-1 and VLA-4 on MM cells. Methods and Results 62 BM trephine samples from MM patients (9 pts in Durie stage I, 24 – st II and 29 – st III) were screened for CD138 and CD29 immunoreactivity. There was no significant difference between the groups. Precise localization of syndecan-1 and α4-integrins in the membrane of MM cells was studied by fluorescence laser scanning confocal microscopy (LSM-510, Zeiss, Germany) in INA-6 cells (MM cell line) following adhesion to fibronectin with or without stimulation with HGF, IGF-1 and SDF-1α. Scans were taken at the interface. In unstimulated cells α4 signal appeared as a central spot at the adhesion surface, surrounded by a ring-like CD138 signal, with clear separation of both signals in the majority of cells. Upon stimulation the signals from α4 and CD138 got co-localized in the majority of the cells in a ring-formed pattern, α4 moving laterally and merging with CD138-positive area. The same tendency was found in a primary MM cell sample. Conclusion This study is, to our knowledge, the first to indicate a possible co-operation between VLA-4 and syndecan-1 in MM cells. This involves lateral movement of VLA-4 molecules leading to co-localization of syndecan-1 and VLA-4 signals. Total syndecan-1 and VLA-4 integrin expression on MM cells has not been related to clinical stage in our setting. Further investigation is needed to elucidate possible role of the phenomenon in tumor progression.

PP4-233
ACTIVATED ERK EXPRESSION IN RELATION WITH B-RAF GENE MUTATIONS IN UROTHELIAL BLADDER CARCINOMA
Maria Karlou, Evmorfia Boltetsou, Angelica A. Saetta, Pollyanthi Papanastasiou, Georgia Levidou, Angeliki Stamatelli, Irene Thymara, Petros Pavlopoulos, Penelope Korkolopoulou, Efstratios Patsouris
1st Department of Pathology, Medical School, National and Kapodistrian University of Athens, Greece

Background: Ras/RAF/MEK/ERK signaling pathway is commonly activated in human cancers. However the effect of ERK signaling on the prognosis of primary urinary bladder cancer (UC) is not clearly understood. Activating mutations in the serine/threonine kinase B-Raf are observed in several tumor types such as melanomas and thyroid, colorectal and ovarian carcinomas. The aim of this study was to examine the prognostic significance of phosphorylated ERK1/2 expression as a hallmark of ERK activation in relation with the presence of B-Raf somatic point mutations in Greek patients with primary UC. Methods: Tumor samples from 132 patients with primary urinary bladder cancer were examined for pERK1/2 immunohistochemical

expression. PCR-SSCP and sequencing analysis were performed in 90 cases in order to detect activating mutations in exon 15 of the B-Raf gene. Statistical package STATA 9.0 for Windows was used for all statistical calculations. All results with a two-sided p ≤ 0.05 were considered statistically significant. Results: Nuclear immunoreactivity for pERK was detected in 99.2% (131/132) of cases, whereas cytoplasmic immunoreactivity in 97.7% of cases (129/132). The pERK nuclear expression was marginally related to tumor's histological grade and stage (1/2 vs 3, Fisher's exact test, p=0.082 and Ta vs T1/T2/T3 Fisher's exact test, p=0.084). In univariate analysis for invasive carcinomas higher histological grade (p=0.0003), advanced tumor stage (p<0.0001) and high nuclear pERK expression (p=0.039) were associated with worse prognosis. However, when analysis was restricted in muscle-invasive carcinomas, advanced stage (p=0.001) emerged as the only factor adversely associated with survival. Multivariate analysis in invasive as well as in muscle-invasive carcinomas selected only tumor stage as significant prognostic factor (p=0.024 and p=0.039 respectively). Mutations in exon 15 of B-Raf gene were not detected in the examined cases. Conclusion: ERK activation as well as B-Raf mutations are frequently detected in certain tumor types implying their importance as potential targets for anticancer treatment. Our findings suggest that pERK expression is common and occurs in a B-Raf-independent manner in primary urinary bladder cancer. The correlation of pERK expression with high histological grade and advanced tumor stage suggests a potential implication in tumor aggressiveness while elevated nuclear pERK expression seems to be an adverse prognostic factor, although not independent of classical clinicopathological prognosticators.

OVEREXPRESSION OF GLUTATHIONE SYNTHESIZING ENZYMES IN A MOUSE MODEL FOR DRUG-INDUCED STEATOHEPATITIS

Pichler Martin[1], Abuja Peter[1], Aigelsreiter Ariane[1], Mischinger Hans-Jörg[2], Denk Helmut[1], Zatloukal Kurt[1]
[1] Institute of Pathology, Medical University Graz, Austria
[2] Department of Surgery, Medical University Graz, Austria

Background: Mallory bodies (MBs) are a characterictic, cytoplasmic inclusion found in hepatocytes in alcoholic steatohepatitis and other chronic non-alcoholic liver diseases. Oxidative stress participates in the pathogenesis of such disorders as an imbalance in cellular oxidant/antioxidant homoeostasis can influence inflammation, fibrosis and apoptosis. Glutathione is the major antioxidant in hepatocytes that serves several biological functions and alterations in the glutathione level induced by toxic factors may promote the development of chronic liver disease. Our aim was to study the glutathione metabolizing pathway in an animal model that shows features of drug-induced steatohepatitis. Methods: Livers of 3, 5-diethoxycarbonyl-1, 4-dihydrocollidine (DDC)-intoxicated swiss albino mice were harvested after 1 week DDC-treatment, 2.5 months DDC-treatment, 1 month DDC-free diet (=recovery) and 3 days DDC-refeeding. Total RNA was extracted and enzymes involved in glutathione metabolism were analyzed by Real-time quantitative RT-PCR. Results: Real-time PCR data revealed a deregulation of glutamate-cysteine ligase (GCL) and GSH synthetase (GSHS) in DDC-exposed murine livers. Compared to normal mouse liver, the enzymes GCL and GSHS were both overexpressed after 1 week (1.7 and 2.6 fold) and 2.5 months DDC intoxication (1.9 and 3.1 fold), respectively, but returned to a normal level after administration of a DDC-free diet for 1 month after 2.5 months of DDC intoxication (recovery). Refeeding recovered mice a DDC-containing diet for 3 days after one month of DDC-free diet induced GCL (1.6 fold) and GSHS (3.4 fold). Conclusion: Our data suggest an activation of the glutathione synthesis pathway in liver exposed to DDC intoxication. The increased expression of GCL and GSHS may be in part a compensatory effect for a depletion of homocysteine/cysteine in the affected liver, as these metabolites are precursors in the glutathione synthesis and alterations of these metabolites are found in human ASH. Otherwise since oxidative stress is an important factor in the development of steatohepatitis, overexpression may be an indicator for increased oxidative stress defence in drug-affected hepatocytes.

PP4-235
MOLECULAR AND IMMUNOHISTOCHEMICAL ANALYSIS OF P53 MUTATIONS IN BREAST CARCINOMAS

Christianna Zachariou, Vassiliki Malamou-Mitsi, Angelos Skyrlas, Niki Agnantis
Department of Pathology - Molecular Pathology Unit, Medical School, University of Ioannina, Greece

Background.: Alterations of the p53 tumor suppressor gene are probably the most common genetic abnormalities in human malignancies. The majority of p53 mutations are missense and occur in the conserved DNA-binding domain (exons 5-8). In all, about 1150 different point mutations have been described, with more than 95% affecting exons 5-8. These mutations may lead to loss of DNA binding that is believed to be critical for the biological activity of p53. In breast cancer, frequency of p53 mutation is reported about 20%, lower than in other solid tumors. The implications for breast carcinogenesis however are unclear; in several studies it has been associated with more aggressive disease and worse overall survival. As direct sequencing of the gene is a time-consuming and laborious procedure, several prescreening methods have been developed. A modification of Denaturing Gradient Gel Electrophoresis (DGGE) known as GC-clamped DGGE appears to be more efficient and sensitive. Methods: DNA was extracted from 60 breast carcinomas of various histopathology and corresponding adjacent normal tissues. We used a PCR and GC-clamped DGGE assay, followed by sequencing, to investigate the presence of mutations within exons 5-8 of p53 gene. Additionally, we looked for p53 protein accumulation by immunostaining. Results: Out of 60 cases analyzed, 12 (20%) seemed to be carriers of a p53 aberration (7 in exon6, 2 in exon7, 2 in exon8 and 1 in exon5). The vast majority of mutations were documented in invasive ductal type-high grade tumors. In all (but one) cases that produced a variant DGGE-pattern, gene alterations were identified by sequencing and validated in TP53 Mutation Databases. Of these, two mutations: a missense at g.13418T>A (p.Y220N) and a deletion at g.13270delG have not been previously reported in breast cancer. The presence of mutations revealed strong correlation with high-grade breast carcinomas (p=0.002). Positive immunostaining of p53 protein was observed more frequently in invasive breast carcinomas (51%) than in in situ component (27%), with statistical significance (p=0.043). P53 overexression was associated with the presence of mutations in p53 gene (p=0.004). Conclusion: Our data indicate that PCR-DGGE is an efficient and highly sensitive prescreening approach for p53 mutation detection in DNA samples of breast cancer patients. The presence of mutations and p53 protein accumulation in invasive carcinomas, as well as the significant correlation between mutations and high tumor grade, reveal their possible implication in advanced stages of breast carcinogenesis.

PP4-237
HETEROTOPIC MESENTERIC OSSIFICATION: ULTRASTRUCTURAL FEATURES OF THREE CASES AND REVIEW OF THE LITERATURE

Deborah Malvi[1], Stefania Lega[1], Christine Betts[2], Maria Pia Foschini[1]
[1] Section of Anatomic Pathology, University of Bologna, Bellaria Hospital, Italy
[2] Department of Experimental Pathology, University of Bologna, Italy

Background: Heterotopic ossification is a reactive metaplastic bone-producing process, which occurs in soft tissues mainly as a consequence of trauma. This reactive metaplastic process is well known in somatic tissues and named "myositis ossificans". The histological finding of mature bone-tissue within the mesentery of the gastrointestinal tract is very uncommon and to our knowledge, less than 25 cases have been described in the literature. This kind of lesion may represent the soft-tissue counterpart of myositis ossificans and therefore, it has been designated under the term "heterotopic mesenteric ossification" (HMO). Purpose of the present paper is to describe the ultrastructural features of three cases. Method: Three patients were studied; they were male, aged 25, 48 and 58 years, respectively. All of them had a previous history of abdominal trauma and presented with intestinal obstruction. Results: Macroscopically, multiple, firm, greyish-white lesions were observed in the mesentery of small bowel in all cases and in one also in the omentum. Histologically the lesions were composed of steatonecrosis and haemorrhage surrounded by myo-fibroblastic proliferation, with spindle shaped cells, intermixed with an acute and chronic inflammatory infiltrate. At the periphery of these areas, eosinophilic material resembling osteoid was present. The "zone phenomenon" described in the myositis ossificans was observed. The myo-fibroblastic cells and osteoblasts were mitotically active, while they lacked atypia and atypical mitotic figures were absent. At ultrastructure, elongated cells immersed in the osteoid material were rich in rough endoplasmatic reticulum, contained vesicles and filaments and showed a well developed Golgi apparatus. The eccentric nuclei showed finely distributed chromatin with occasional prominent nucleoli. All these features are consistent with a secretory-like cell pattern and an active protein synthesis. Conclusion: The precise pathogenesis of HMO has still not yet been determined. Most probably it is related to metaplasia of mesenchymal stem cells, as a consequence of an exuberant reaction to trauma or injury, in predisposed individuals. The ultrastructural features observed here further support the hypothesis of stem cells actively producing osteoid material.

EWING SARCOMAS AND PRIMITIVE NEUROECTODERMAL TUMORS SEEN THROUGH THE PRISM OF EQUITY

Vesna Janevska[1], Rubens Jovanovic[1], Gjorgi Zafirovski[2], Slavica Kostadinova-Kunovska[1], Liljana Spasevska[1], Milan Samardziski[2], Gordana Petrusevska[1]
[1] Institute of Pathology, Faculty of Medicine, Skopje, R. Macedonia
[2] Clinic for Orthopaedic Surgery, University Clinical Center, Skopje, R. Macedonia

Background: It is now well known that these two entities are in fact two faces of the same malignant tumor designated ES/PNET. Not so long ago there were slightly different treatment protocols for the two entities, giving rise to debates among clinicians and pathologists about "give me the precise diagnosis". Methods: We analyzed 33 biopsy/operative archive specimens admitted at our institution from the Clinic for Orthopaedic Surgery, Skopje. All tissue samples had been fixed in 10% neutral formaline and paraffin embedded (FFPE), prior to sectioning and staining with H.E. and monoclonal antibodies. Twenty three cases were diagnosed as ES and 10 as PNET, according to the microscopic morphology and immunohistochemical staining pattern for the following markers: Chromogranin, NSE, Synaptophysin, S-100 and CD99. We performed additional immunohistochemical stainings for p53, Bcl-2 and Ki-67. All of the immunohistochemical stainings were performed using the DAKO Cytomation EnVision+HRP system. We also isolated DNA from FFPE for subsequent identification of EWS/FLI1 fusion [t(11;22)(q24;12)]. For EWS/FLI1 gene fusion identification we used Hot start–Touch down-direct PCR on Auto Q server-thermal cycler. Primer sequences were constructed using Gene Runner v.3.05 on reference sequences obtained from Ensemble Database ver. 41.36c with start:pos.11/ex7EWS; end: pos.478/ ex6 FLI1. Results: 61% of the patiens with ES were males, versus 60% with PNET ($p>0,05$). The mean age of the patients with ES was 19,5 years (min. 7, max. 55, SD=12,33), versus 20,3 (min. 4, max. 60, SD= 17,51) in PNET ($p>0,05$). As for the immunohistochemistry, we encountered slightly more frequent (but not significantly) positivity of PNET cases for p53 (weak 1+ staining signal) – 30%, versus 13% of ES cases ($p>0,05$). In PNET there were only 1+ intensity signals detected for Bcl-2 (33% cases), versus 38% of ES. More intensive expression (2+, 3+) was found exclusively in ES cases (9,5% and 4,8% respectively), however, with statisticaly non significant difference ($p>0,05$). Ki-67 showed similar expression frequency in both ES (13%) and PNET (10%) with 1+ intensity ($p>0,05$). EWS/FLI1 gene fusion was detected in 43,4% ES, compared 30% of PNET cases ($p>0,05$). Conclusion: Except for the potentially differential staining patterns of ES and PNET for NSE, Synaptophysin and Chromogranin, we found no other significant differences between ES and PNET neither for immunohistochemical expression of p53, Bcl-2 and Ki-67, nor for the presence of the EWS/FLI1 gene fusion.

PP4-239
A BRIEF REPORT OF SYNOVIAL SARCOMA CASES IN HACETTEPE UNIVERSITY: A MORPHOLOGICAL ANALYSIS

Cigdem Himmetoglu, Havva Solak Ozseker, Gokhan Gedikoglu
Hacettepe University Faculty of Medicine Department of Pathology, Turkey

Background: Synovial sarcoma (SS) is a morphologically, clinically and genetically distinct entity. Unlike its name, it does not arise from or differentiate toward synovium and is issued under the name Tumours of Uncertain Differentiation in the recent WHO classification. SS is a mesenchymal spindle cell tumour with variable epithelial differentiation including glandular formation and has a specific chromosomal translocation t(X;18)(p11;q11). Method: This study aimed at re-evaluation of the SS cases in our institution's pathology archive between 1990-2007 to create a brief idea about histopathologic features of SS and its relationship to prognosis. Results: From the 18 cases reported as malign mesenchymal tumor, some of which only favoring SS diagnosis, 15 were confirmed. More than half of the cases were male (8); the mean age at diagnosis was 32 years and there was a male predominance in the younger age group. Eight cases were consultation so macroscopic examination was available in 7 cases. Among those cases, the mean diameter of tumor varied between 2-10 cm. The most common locations were foot (3) and inguinal region (3), followed by upper extremity and head-neck region by 2 cases each, one case was located at the knee, the last 3 cases abdominal and lumbal. Excisional biopsy could be performed in 5 of the 6 cases operated in our institution and in none of the 5 cases in which lymph node dissection was done, metastasis was detected. Microscopically, 7 of 15 cases were biphasic, one consultation case was a monophasic ossifying SS located in heel. Tumor necrosis was present in 3 cases. An

immunohistochemical panel composed of at least EMA and pancytokeratin was performed in all cases. At least focal positivity with one of these markers were used in addition to morphologic features. Mitotic count in 10 high power field ranged between 2-43; 3 cases with counts more than 10 / 10 HPF. Five patients received their adjuvant therapy in our institution, 2 patients received chemotherapy. Three patients received chemotherapy and radiotherapy, one due to lung metastasis 2 years after the first diagnosis and all died due to disease. Seven cases are alive without disease and the mean follow up period is 11 months. Conclusion: In the literature up to 50% of SS recur, usually within 2 years, nearly 40% metastasize, commonly to lungs and bone. Tumor free local excision followed by postoperative radiotherapy improves the survival. Young age, tumors <5 cm in diameter, with <10 mitoses / 10 HPF, SS18/SSX2 variant gene and no necrosis are good prognostic factors.

PP4-240

OSTEOSARCOMA: REVIEW OF 107 CASES

Nuray Kepil[1], Pelin Bagci[1], Sergulen Dervisoglu[1], Didem Colpan[2], Fazilet Dincbas[2], Nil Molinas Mandel[3], Murat Hiz[4], Alp Ozkan[5], Inci Yildiz[5], Pembe Cagatay[6]

[3] Istanbul University, Cerrahpasa Medical Faculty, Department of Medical Oncology, Turkey
[4] Istanbul University, Cerrahpasa Medical Faculty, Department of Orthopaedic Surgery, Turkey
[5] Istanbul University, Cerrahpasa Medical Faculty, Department of Pediatric Oncology, Turkey
[6] Istanbul University, Cerrahpasa Medical Faculty, Department of Biostatistics, Turkey

BACKGROUND: Osteosarcoma (OS) is the most common bone tumor of childhood and young adulthood. Despite new therapy modalities and therapy agents, prognosis is poor. Epidemiologic and genetic researches are the most promising studies to understand the nature of this tumor. METHOD: We reviewed 107 cases diagnosed in our department between 2000- 2007 according to the latest WHO classification; and analyzed them considering age, sex, etiology, localization, histological parameters (necrosis rates), recurrence, metastasis, and response to therapy. RESULTS: The patients were between 7-73 years; and the median age was 28. There was male predominance (59%). Knee localization was seen in 57% of the cases, and most of them (49%) were in the 3rd decade. After 3rd decade knee localization decreased gradually and from the 5th decade of life OSs were seen at the trunk and extremity parts except knee. Conventional and blastic OSs were the most common types (77%), and 23% of the cases were malignant fibrous histiocytoma like OSs. Metastasis and recurrence were mostly seen in males. Ninty-one percent of the patients had Huvos grade III-IV tumor necrosis. Metastasis occured in 15% of the patients and 10% of them recurred. Sixty-six percent of the recurred patients and 87% of the metastatic cases had Huvos grade I-II tumor necrosis. Epiphysis invasion was seen in 94% of the cases; but in 91% of them articular space was intact. There were 3 postradiotherapy OSs and an OS associated with retinoblastoma in our material. CONCLUSION: Age, sex and localization distribution of the cases are the same as the English literature. But the percentage of knee localization is fewer and upper extremity localization is slightly more in our review. Response to chemoradiotherapy is the most important factor that effects the metastasis and recurrence rates. Neoadjuvant chemoradiotherapy and surgery are the gold standarts of dealing with OS.

DIAGNOSTIC AND PROGNOSTIC SIGNIFICANCE OF AGNOR IN OSTEOSARCOMA, CHONDROSARCOMA, EWING SARCOMA AND GIANT CELL TUMOUR OF THE BONE

Sibel Kayahan[1], Fikri Oztop[2], Gulcin Basdemir[2], Dundar Sabah[2], Nimet Karadayi[1]
[1] The Ministry of Health Dr. Lutfi Kıidar Training and Research Hospital, Turkey
[2] Ege University Medical Faculty, Turkey

Background: AgNOR method which is based on determination of nucleoli regulator regions (NORs) by silver staining is one of the cell proliferation markers and is useful for identification of prognosis as well as differentiation of benign and malign tumours. There are great advances on bone tumour differential diagnosis and establishment of prognostic parameters. Yet, the reason of different responses to chemotherapy at osteosarcoma (OS) and Ewing Sarcoma (ES) cases, sometimes non-existence of objective criteria to determine histological malignity degree at chondorsarcoma (CS), the reason of the aggressive behaviour of some bone giant cell tumours (BGCT) are certain questions waiting to be replied. Methods: In this study, 33 OS, 12 CS, 10 ES and 15 BGCT cases diagnosed at Ege University Medical Faculty Pathology Department are evaluated. Besides, 5 non-Hodgkin lymphoma cases are included for comparison with ES. Cytological preparations prepared by imprint method from tru-cut biopsies are fixed in ethyl alcohol. Silver staining is performed and slides are examined by light microscopy. AgNOR spots at 100 cell nuclei are counted and mean AgNOR value is calculated. Results: While OS cases have the highest AgNOR values, CS cases are on the second and ES are on the third rank. The lowest values belong to BGCT and AgNOR counts differ significantly among tumour groups. In addition, this method is helpful for differentiating ES and non-Hodgkin lymphoma or BGCT and OS. The histological grade of CS and AgNOR values have correlation since low grade tumours show less while high grade tumours show more AgNOR values. At OS cases where response to chemotherapy is higher than 90%, AgNOR values are also higher. Conclusion: AgNOR method has a limited value on differentiation of malign bone tumours as OS, CS, and ES. Although it is helpful for identification of response to chemotherapy at OS and prediction of metastasis at CS, such findings are not observed at ES. AgNOR seems to be useful for differentiating ES and lymphoma or BGCT and telangiectatic OS. At CS cases, it may be helpful for differentiation of low and high grade tumours.

EXPRESION OF p53 AND Ki 67 IN ATYPICAL MALIGNANT CHONDROBLASTOMA

Jelena Sopta[1], Mirjana Atanackovic[1], Vesna Mijucic[2], Nenad Lujic[3], Goran Tulic[4], Dejan Minic[1]
[1] Institute of Pathology, School of medicine,Belgrade,Serbia
[2] Institute for Oncology, Belgrade, Serbia
[3] Institute of Orthopedic Surgery “Banjica”, Belgrade, Serbia
[4] Institute for Orthopedic Surgery, Clinical Center of Serbia, Belgrade, Serbia

Chondroblastoma is a rare primary, usually benign bone tumor, but aggressive behavior is described. During the 20 years we report from Register of bone tumors of the Institute of pathology Belgrade 5 cases with unexpected clinical and histological characteristics which pointed at atypical chondroblastoma. Four patients were female and one was male, the youngest was 17 , the oldest was 50. The middle ages were older compared to the patients with typical chondroblastoma. Clinical features were: pain, swelling and restriction of movement. The history of the disease varied from 3 months to 4 years. Location were :2 humerus , femur, tibia and coxa. Radiological studies showed lytic, destructive and expansive lesion. In 3 patients clinically was presented recurrent tumor, after surgical therapy. Biopsy

tissue showed: fields with polyhedral tumor and giant cells, cartilaginous interstitial matrix, “chicken wire” calcification and cystic spaces with blood. But also increased cell and nuclear atypia, hyperchromasia, pleomorphism and abnormal mitotic figures pointed to aggressive chondroblastoma. Immunohistochemical studies revealed p 53 mutation (in 3 from 5 cases) and extensive proliferate activity KI67 positive in more than 75% of cells (in 4 of 5 cases). Surgical therapy was applied. Two years later one patient with p53 positive, and KI67 positive tumor have radiological confirmed lesion to the lungs suspected to metastatic deposits. Other patients are with no evidence of recurrent or metastatic lesions. These findings suggest that expression of p53 and KI67 are not in the correlation with biological behavior of aggressive chondroblastoma.

PP4-243
EXPRESION OF KI 67 IN MALIGNANT TRANSFORMATION OF CHRONIC PROLIFERATE FIBROBLASTIC PERIOSTAL LESIONS

Jelena Sopta[1], Mirjana Atanackovic[1], Aleksandar Djordjevic[2], Vesna Mijucic[3], Vera Vojinovic[3], Dejan Minic[1]
[1] Institute of Pathology, School of Medicine, Belgrade, Serbia
[2] Institute of Orthopedic Surgery “Banjica”, Belgrade, Serbia
[3] Institute for Oncology, Belgrade, Serbia

On the Register of bone biopsy, Institute of Pathology, Belgrade was registered 2 cases of malignant transformation of chronic proliferate fibroblastic periostal lesions. In our opinion this lesions should be analyzed as separate entities in bone tumors pathology. Both patients were males. First patient, 24 years old BM had a slow growing tumor in proximal part of tibia with 5 years long anamnesis. After the first biopsy lesion was described as a proliferate, posttraumatic fibroblastic lesion of periost. Patient had 6 relapses durind the 13 years until the final diagnosis- osteosarcoma. Second patient, ST was 34 years old when was performed the first biopsy of femoral lesion after trauma. In the period of 9 years he had 3 relapses and repeted byopsis. The final diagnosis was again osteosarcoma (low grade superficial). This cases have in common a few elements: sex of patients, long evolution of lesions (13, and 9 years), trauma in anamnesis, many relapses (6 and 3), primary diagnosis of proliferate periostal lesions and finally, lesions were firstly clinically manifested when patients were young adults (period of life when osteosarcoma is the most frequent). Radiography, CT scan, MR, scintigraphy and histopathology characteristics of lesions firstly pointed to fibroblastic periostal proliferate lesions with expressive osteoid production up to mature bone. After many relapses and repeated biopsies with identical morphological findings- no malignancy but intensive proliferation of periostal fiber tissue and production of mature bone arise transformation and lesions become low grade malignant tumors (low grade malignant osteosarcoma). Proliferate potential of this lesions was investigated by Ki67. Expression of Ki67 were les intensive in first biopsy and it become intensive in relapses, finale it was the most intensive in the last biopsy when was made diagnosis osteosarcoma. We conclude that increase of expression's intensity of Ki 67 prove to malignant transformations of posttraumatic proliferate fibroblastic periostal lesions.

PP4-244
MORPHOLOGICAL AND IMMUNOHISTOCHEMICAL STUDY OF 23 CASES OF DERMATOFIBROSARCOMA PROTUBERANS

Radulescu Doinita[1], Stolnicu Simona[2], Jalba Lucia[3], Dumitriu Sorin[4]
[1] Department of Morphopathology, University of Medicine and Pharmacy ‘Gr. T. Popa ‘ Iassy, Romania
[2] Department of Morphopathology, University of Medicine and Pharmacy Tg. Mures, Romania
[3] Mavromati’ County Hospital, Botosani, Romania
[4] St. Mary’ Children Hospital, Iassy, Romania

Aims: The dermatofibrosarcoma protuberans (DFSP) is a malignant soft tissue tumour, characterized by frequent recurrences and rarely metastases. The tumour occurs most commonly on the trunk, including chest, back, and abdominal wall. Less commonly, the neoplasm is located on the proximal extremities; it rarely involves the distal extremities. The head and neck, especially the scalp, are also commonly involved. The vulva and parotid gland are unusual sites of involvement. The tumour appears between 25 and 75 years old. DFSP presents under several morphological variants: fibrosarcomatous, myxoid, with giant cells, pigmented, myofibroblastic. This study aims, through the analysis of 23 cases of DFSP observed during 5 years, to specify the prognostic factors of these tumours. Methods: 23 cases of DFSP are viewed retrospectively. We made sections of paraffin blocks with hematoxylin-eosin and special histochemical stainings: P.A.S., Blue Alcian, Fontana, Trichrome of Masson. We also performed an immunohistochemical study using: CD 34, CD117, C Kit, S100 Protein, Factor VIII, CD 68. Results and conclusions: DFSP has a significant risk of local recurrence that depends on the local excision. A much higher recurrence rate is reported in tumours treated by superficial or incomplete excisions only. Local reccurence usually develops within three years after initial surgery. The global analysis reveals that the type of the variant, the cellular atypia, the mitotic index and necrosis are microscopic predictive factors for the evolution of the DFSP.

PP4-245
RHABDOMYOSARCOMA: HISTOLOGICAL AND IMMUNOHISTOCHEMICAL ASPECTS

Radulescu Doinita[1], Stolnicu Simona[2], Jalba Lucia[3], Dumitriu Sorin[4]
[1] Department of Morphopathology, University of Medicine and Pharmacy ‘Gr. T. Popa ‘ Iassy, Romania
[2] Department of Morphopathology ,University of Medicine and Pharmacy Tg. Mures, Romania
[3] Mavromati’ County Hospital, Botosani, Romania
[4] St. Mary’ Children Hospital, Iassy, Romania

Introduction: Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma of the childhood and adolescent periods and can seldomly be seen in adults too. Despite all research, a single prognostic classification for modelling the treatment is still needed. The clinicopathological features of our recorded rhabdomyosarcoma cases are reviewed and the major prognostic factors are discussed. Materials and method: We present 12 RMS cases located in chest wall, back, flank, abdominal wall, upper and lower extremities. Our patients were between 27 and 45 years old. We made sections on paraffin blocks with hematoxylin-eosin and special histochemical stainings: P.A.S., Van Gieson, Gomori. We also performed immunohistochemical reactions. Results and conclusions: Microscopically, we identified these RMS variants: embryonal, alveolar and pleomorphic. Desmin, Actin and Myogenin positivity of different intensities were observed in all cases. All the cases were treated by chemotherapy and radiotherapy whenever was needed. According to the clinical follow-up, the evolution was unfavorable when the tumour had more than 5 cm, when was located in upper and lower extremities, when was an alveolar or pleomorphic type and when had local recurrences.

PP4-246
MULTIPLE GLOMUS TUMORS OF THE ANKLE WITH PROMINENT INTRANUCLEAR PSEUDOINCLUSIONS

Jae Yeon Seok, Se Hoon Kim, Jieun Kwon, Yoon Hee Lee, Woo Ick Yang
Department of Pathology, College of Medicine, Yonsei University, Seoul, Korea, Brain Korea 21 Project for Medical Science, Korea

Glomus tumor is a neoplasm, composed of the modified smooth muscle cells of the glomus body. We report a case of multiple glomus tumors of the ankle which show varying histologic types: solid type (glomus tumor proper) and angiomatous type (glomangioma). Interestingly, the tumor cells of the present case show prominent intranuclear inclusions, a finding hitherto unreported in glomus tumors. Ultrastructural examination demonstrated that the nuclear inclusions are not true inclusion bodies but intranuclear cytoplasmic pseudoinclusions made by the cytoplasmic invaginations due to the deep and complex nuclear contours.

PP4-247
COMBINED STUDIES CONCERNING IDENTIFICATION OF HIGH STRESS ZONES AT THE ACETABULAR BONE-BIPOLAR PROSTHESIS INTERFACE

Dan Nelu Anusca[1], Iancu Emil Plesea[1], Nicolae Iliescu[2], Vasile Nastasescu[3], Mirela Corina Ghilusi[4], Claudia Valentina Georgescu[4], Oltin Tiberiu Pop[1]
[1] University of Medicine and Pharmacy Craiova, Romania
[2] University Politehnica Bucharest, Romania
[3] Technical Military Academy Bucharest, Romania
[4] Emergency County Hospital Craiova, Romania

Background The study is intending to determine the stress and strain state in the acetabular bone (AB) at the bone-bipolar prosthesis cup interface using combined numerical and experimental methods. Method AB stress state was analysed with the finite element method (FEM) and the photoelasticity on the plane models. For FEM, two calculus models were developed considering a frontal section (FP) and a sagital one (SP) through the upper part of a bipolar prosthesis and the surrounding zone of the AB. Numerical simulations were performed for both one and two legs standing positions (OLSP and TLSP) for both models. Main stress and equivalent stress fields distribution in the AB were obtained after processing of calculus results and the corresponding curves were plotted using a special post-processing program. With photoelasticity technique the isochromatic fringes field in the AB for the OLSP was recorded in a circular polariscope. Photoelastic data were processed and the distribution curve of the main stresses difference (б1–б2) on the AB surface was plotted. Results In OLSP, in FP, pmax was 25MPa and pressure area (PA) was situated on the upper acetabular wall (UAW), near the acetabular rim (AR) with values decreasing towards the medial plane. In SP, maximal pressure (pmax) is much smaller (8MPa) and PA was situated towards the anterior aspect of the UAW with a more uniform distribution of the values. The resulting PA is ovoid, with the greater diameter in the sagital plane and shifted towards the anterior aspect of the UAW. The pressure values have a decreasing trend from lateral to medial. In TLSP, overall pressure values were much smaller that those of previous condition. In FP, pmax was 4MPa and the PA was restrained to a small area in the close proximity of AR. In SP, PA is larger than in FP, placed on both sides of median line and with values decreasing from posterior (3MPa) to anterior (1,5MPa). The resulting PA is like an antero-posterior narrow strip, near the AR with decreasing values from posterior to anterior. The results of photoelastic investigations indicated the same area with high level on the contact surface as numerical simulations. Conclusion The experimental study revealed that PA is placed on UAW near the AR and is varying both in shape and dimentions (decreasing in TLSP) and loading level (decreasing in TLSP compared with OLSP, from lateral to medial and from posterior to anterior).

MICROARRAY-COMPARATIVE GENOMIC HYBRIDIZATION OF ALVEOLAR SOFT PART SARCOMA. -GENE COPY NUMBER PROFILING AND IDENTIFICATION OF CANDIDATE GENES-

Eun Ji Shon, Kyung Un Choi, Jee Yeon Kim, Mee Young Sol, Hyun Jeong Kang, Dong Hoon Shin, Ik Doo Kim, Won Young Park, Seong Muk Jeong, Jung Hee Lee
Department of Pathology, School of Medicine, Pusan National University, Busan, Republic of Korea

Background: Alveolar soft part sarcoma (ASPS) is a rare, histologically distinctive soft tissue sarcoma of unknown origin. Although ASPS is characterized by a specific alteration, der(17)t(X;17)(p11;q25), the entire spectrum of genetic events underlying the pathogenesis of ASPS is unclear. Method: Using microarray-based comparative genomic hybridization (aCGH), we examined DNA copy number changes of ASPS. aCGH composed of 4030 clones was performed with two cases of fresh frozen tumor tissue from 29 year-old male and 16 year-old female. Results: We identified 30 chromosome regions that were imbalanced in both tumors, and 11 of those regions were located on chromosome Xp (Xp11.3-p11.4, Xp21.1, Xp21.3, Xp22.11-p22.13, and Xp22.31-p22.33) Additional regions with increased copy number were observed at 1q25.1, 12p12.1 and 17p11.2. Loss was found on only one region, chromose 22q11.23. Several genes located within the amplified region of Xp included UTX, RPS6KA3, ZNF645, PHEX, USP11, PCTK1, UBE1, KAL1, ARSE, ARAF, SYN1, TIMP1, GYG2, BMX, ACE2, CXorf20, TMEM27, CA5BL, PDK3, PCYT1B, TMSB4X and XK genes. Conclusions: Our study showed genomic regions and new candidate genes that were associated with tumor pathogenesis of ASPS.

PP4-249
AN UNINVESTIGATED CASE OF A MEDIASTINAL RHABDOMYOSARCOMA WITH MASSIVE PERICARDIAL EXTENSION

Simion George[1], Ilie Marius[1], Barbulescu Catalin[2], Marinescu Elena[1], Sajin Maria[1]
[1] Department of Pathology, Emergency University Hospital Bucharest, Romania
[2] Department of Cardiothoracic Surgery, Emergency University Hospital Bucharest, Romania

Background: Primary mediastinal rhabdomyosarcomas are extremely rare. The tumors can occur in adults and children, and follow a very aggressive clinical course. Method: A 27-year-old female, originated from an isolated ethnic region, was admitted in ER presenting cough, chest pain, and respiratory distress, superior and inferior vena cava syndromes that aggravated in the past 3 weeks. A CT scan of chest revealed a giant anterosuperior mediastinal mass with extension in the middle compartment, somewhat not well-defined borders, and inhomogeneous tissue structure. The tumor had a mass effect on the vessels at the basis of the heart with tracheal compression, left superior lobar bronchi obstruction, and pleural effusion in the left costodiafragmatic sinus. The clinical examination revealed a blood pressure of 80/ 40 mmHg, AV=126/min, turgescent jugular veins, bilateral lower limb edema, a dull sound at the percussion of the left hemithorax. Given the resectable appearance on CT surgical resection was undertaken, but the patient suddenly died of cardiac failure. Results: The autopsy of the corpse was made. The examination showed a giant anterosuperior mediastinal tumor with extension in the middle compartment, the compression of the large vessels at the heart basis, trachea and left lobar superior bronchi. The tumoral mass encircled the entire heart, which circumferential infiltrated the pericardium as numerous white nodules. Another findings: left superior lobe pneumonia, parapneumonial sero-fibrinous pleurisy, liver and renal stasis. Classical histological method and immunohistochemistry were used for pathological

evaluation. Embryonal rhabdomyosarcoma composed in a great percentage of primitive cells devoid of rhabdomyoblastic differentiation, disposed in a very loose connecting stroma and rare cells with rhabdomyoblastic differentiation . IHC showed intensely positive reaction for vimentin, actin and weak positiving for desmin. Cytokeratin markers, CD20, CD34, CD68, CD117 and S100 are negative. Conclusion: Primary mediastinal rhabdomyosarcomas are extremely rare. In our 3 years old experience in collaborating with the Cardiothoracic Surgery Department this was the only soft tissue tumor from 16 mediastinal tumors. Since these tumors can remain clinically silent, they may have already reached large dimensions by the time of diagnosis. This is especially true for those masses originating from the chest wall.

PP4-250
DESMOPLASTIC SMALL ROUND CELL TUMOR-PROBLEMS OF DIFFERENTIAL DIAGNOSIS IN UNUSUAL LOCATIONS

Chmielik Ewa[1], Nasierowska-Guttmejer Anna[2], Lange Dariusz[1], Nikiel Barbara[1], Bialas Monika[1]
[1] Department of Tumor Pathology, M. Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Gliwice, Poland
[2] Department of Pathology, Clinical Hospital Ministry of Internal Affairs and Administration, Warsaw, Poland

Background: Desmoplastic small round cell tumor (DSRCT) is well defined neoplasm with distinct clinical, pathologic, immunohistochemical and molecular features. This tumor shows epithelial, mesenchymal and neural differentiation. DSRCT occurs mainly in peritoneal cavity of young males but can occur in unusual locations and then diagnosis could be difficult. The aim of the study is analysis histopathological and immunohistochemical features of primary, recurrent and metastatic DSRCT in soft tissue, cardiac muscle and cervical lymphnode locations and to make a detailed differential diagnosis. Method: three cases of DSRCT in unusual locations were found in our consultant files. We studied routine H&E-stained sections and immunohistochemically-stained sections (AE1/AE3, EMA, CK19, CK20, vimentin, desmin, WT1, CD56, CD99, synaptophisin, NSE, CD56, actin, SMA, Myf 4, Myo-D1, S-100, Melan A, HMB-45, TTF-1 and LCA). Results: All of the studied cases pertained to young adult men of ages: 25 (case 1), 27 (case 2) and 23 (case 3). The 25 years-old patient presented with mass in the left popliteal fossa and recurrent tumor after 9 months. The 27 years-old man presented with a neoplastic infiltration in the cardiac muscle. The third 23 years-old patient showed metastatic bilateral cervical lymphnodes. Tumors were made up of small nests and well-defined islands of cells separated by thin strands (case 1, case 3) or by broad desmoplastic strands (case 2). The neoplastic cells were small- to medium-size with scanty or focally clear, vacuolated cytoplasm. There was evidence of rosette formation in the case 1 recurrent tumor as well as glandular arrangement in the case 2 tumor. Necrosis was noted. The tumor cells of case 1 and case 3 showed typical immunophenotype of DSRCT- AE1/AE3, desmin, NSE possitivity accompanied by EMA, vimentin, WT1, CD56. The cells displayed diffuse cytoplasmic and membranous reaction for CD99. The tumors cells of case 2 were positive for keratin, EMA, vimentin, WT1, CD56, NSE, but negative for desmin. Considering their unusual location, the tumors presented herein yielded broad differential diagnoses including Ewing's sarcoma/PNET, alveolar and embryonal rhabdomyosarcoma, poorly differentiated synovial sarcoma, lymphoma, metastatic melanoma, metastatic small cell carcinoma, metastatic neuroendocrine carcinoma and Merkel cell carcinoma. Conclusions: DSRCT must be kept in mind when diagnosing primary tumors of soft tissue and metastatic lymphonodes in young men.

Primary chondrosarcomas (CHS) of xyphoid process are rare and commonly occurs in elderly individuals. Herein we present a case of primary myxoid grade I CHS in a young adult. A 28 years-old woman presented clinically with a slow growing painless swelling on anterior chest wall. X-rays and CT examinations revealed an area of radiolucency with variable mineralization, indistinct margins, approximately 5 cm, centered in the xyphoid process. Macroscopic evaluation of surgically resected specimen showed a lobulated mass with a lucent glistering appearance with gritty areas. Histologically, the tumor formed nodules that invade the surrounding fibroadipose tissue. The extent of cellular atypia was mild and mitoses infrequently detected. Focally, increased cellularity was observed. The stroma was predominantly myxoid. A small areas of tumor necrosis was also found. It is important for the correct diagnosis of primary CHS to stress the attention for clinicopathological correlation of all the available data before arriving at a diagnosis.

PP4-252
CASE REPORT : ATYPICAL GRANULAR CELL TUMOR

Selvinaz Ozkara, Ilkay Tosun, Onder Peker, Pembegul Gunes, Gulistan Gumrukcu
Department of Pathology, Haydarpasa Numune Education and Research Hospital, Turkey

BACKGROUND: Granular cell tumor (GCT) is an uncommon soft-tissue tumor that is usually benign and readily treated with complete resection. It is found more commonly in the dermal-hypodermal tissue of the head, neck, chest wall and upper extremities. Apart from GCT s also have been observed in sites of previous trauma, such as surgical scars, and are associated with inflamation. We desciribe herein a GCT observed at the site of operation scar on the chest wall. CASE: The lesion was detected in a 69-year-old woman, located at the region of coronary artery bypass surgery scars on the chest wall. This operation was about 1 years ago. The lesion was painless subcutaneous nodule, which gradually enlarged. Excisional biopsy was performed. Histologically, there was a tumor, in the dermis and subcutis . It consisted of agregates of polygonal and spindle cells, sperated by thin bundles of mature collagen. The cytoplasm was eosinophilic and granular. Tumor cell nuclei was large and vesicular. There was no necrosis. mitotic activity was: 4-5/10hpf. Immunohistochemically, tumor was positive for S-100 protein and CD-68; negative for desmin, actin, HMB-45, CD-34, pancytokeratin. CONCLUSION : Malignant GCTs account for %1-2 of all GCTs. Because the malignant variant shares many striking pathologic similarities with reliable histologic criteria have been debated. Recently, Fanburg-Smith et al. classified atypical, malignant, and benign GCTs on the basis of six histologic criteria: necrosis, spindling, vesicular nuclei with large nucleoli, increase mitotic activity (>2 x10hpf), high nuclear to cytoplasmic ratio, and pleomorphism. Neoplasm that met three or more of these criteria were classified as atypical, and those that met one or two criteria were classified as atypical. The present tumor showed spindling and increasing mitotic activity. It can be classified as atypical GCT, suggesting malignant potential. Herein, we report this rare case of atypical GCT and present a brief review of the relevant literature.

HISTOLOGICAL, GENETIC AND MOLECULAR DATA IN 96 CASES OF SOFT TISSUE TUMOURS, DIAGNOSED ON IPO – PORTO (PORTUGAL CANCER CENTRE – OPORTO)
Luís Afonso, Manuel Teixeira, Carlos Lopes
IPO - Portugal

INTRODUCTION: Diagnosis of soft tissue tumours is complex. Electron microscopy 20 years before and immunocytochemestry (ICC)nowadays, introduced important and decisive data to evaluate the histogenesis and differentiation of many sarcomas. In recent years, molecular pathology, essentially chromosomic alterations and genetic mutations studied by PCR techniques and/or FISH, are being added to the routine methods of diagnosis. The aim of this work is to evaluate the contribution of molecular pathology to the diagnosis of soft tissue sarcomas (visceral sarcomas were excluded) in Oporto Cancer Centre during the last 5 years (from 2001 until now). MATERIAL AND METHODS - A total of 96 soft tissue tumours diagnosed in the last 5 years was included in this study, with exclusion of visceral cases such as GIST. The material used was obtained from surgical specimens in most of cases (82 cases), and also from tru-cut biopsies (12 cases) and, in a small number of children tumours, also from fine needle aspiration material (2 cases). In these tumours, the following immunocytochemical antibodies were used in routine diagnosis: cytokeratins, EMA, vimentin, SMA, desmin, Myo D1, S-100 protein, CD31, CD34, CD99, CD10, HMB45. Genetic and molecular techniques included in most of cases: FISH and identification of fusion proteins using RT-PCR from paraffin sections. In a small number of cases a fresh tissue specimen was available, and conventional kariotype was performed. RESULTS In 17 cases diagnosed as synovial sarcoma by histology, the characteristic molecular alteration was present in 12. In 1 a diagnosis of Ewing sarcoma could be done and in 4 cases no other diagnosis was suggested.In Ewing sarcoma, concordance between histologic and molecular diagnosis was found in 12 from 14 cases. Regarding liposarcoma, 3 cases classified as myxoid by conventional histology were reclassified as well differentiated, and 1 as synovial sarcoma, after genetic study. On other hand, 2 cases classified as lipoma in conventional histology were reclassified as well differentiated liposarcoma after genetic study. COMMENTS: Molecular pathology was important to clarify the diagnosis of some cases of synovial sarcoma, Ewing sarcoma, liposarcoma and alveolar rhabdomyosarcoma, whose histology and ICC were not typical. In other cases, such as embryonal rhabdomyosarcoma, myxoid chondrosarcoma and malignant peripheral nerve sheath tumour molecular pathology was not so helpful but was informative to exclude other diagnosis and to give additional information whose real significance is not yet understood.

CLINICAL AND PATHOLOGICAL ASPECTS IN PROXIMAL AND DISTAL FEMORAL PATHOLOGICAL FRACTURES DUE TO THE METASTASIS
Sirbu Paul[1], Radulescu Doinita[1], Stolnicu Simona[2], Petreus Tudor[1]
[1] Emergency Hospital, University of Medicine and Pharmacy, Iasi, Romania
[2] Department of Pathology, University of Medicine, Targu Mures, Romania

This paper has investigated a group of 55 patients with surgically removed metastasis in proximal and distal femur, by clinical, pathological and therapeutic means. The patient mean age was of 53,5 years. The fracture site was described on the femoral neck (5 cases), on the trochanteric region (14 cases), on the subtrochanteric region (20 cases) and on the distal femur (16 cases). Part of the cases (42 patients) showed history of different primary tumor localization (lung carcinoma – 19 cases, breast carcinoma – 12 cases, prostatic carcinomas – 8 cases, renal carcinomas – 2 cases, larynx carcinoma – 1 case). All patients were operated by excising the tumor followed by cavity filling with acrylic cement and internal fixation, with immediate mobilization. In 52% cases the histopathological aspect of the metastasis was identical to the initial malignancy. In 13 cases where the primary malignancy was unknown, we have used histochemical methods to determine the tumor origin. Thus, we have determined more 4 primary tumors corresponding to the histopathological aspect of the metastasis (lung – 2 cases, breast – 1 case, ovary – 1 case). Despite the fact that rigid osteosynthesis provides the patient a psychological support by the early functional rehabilitation, the survival rate is influenced by the primary malignancy.

PP4-255
CATEGORIZATION OF MUSCULAR DYSTROPHIES : AN IMMUNOHISTOCHEMICAL STUDY OF 44 CASES
Elahe Keyhani[1], Kimia Kahrizi[1], Yousef Shafeghati[1], Mojtaba Azimian[2], Elham Darabi[1], Hossein Najmabadi[1]
[1] Genetics Research Center-University of Social Welfare & Rehabilitation Sciences, Iran
[2] Neurology Department-University of Social Welfare & Rehabilitation Sciences, Iran

BACKGROUND-The term " Muscular Dystrophy" which was first used by Erb in 1891 referred to a group of muscle disorders manifest by progressive muscle weakness of the voluntary muscles as a result of primary muscle degeneration.The disorders are frequently hereditary. By now many subsets of the disorders were described, all with nearly same clinical and histopathological findings; so further examinations such as Immunohistochemistry on muscle specimens & using blotting methods are essencial for differentiating the disorders . In Iran the IHC method first established in 2004 and a Neuromuscular core fascility formed in Genetics Research Center since then for the referred patients. METHOD-Patients:Muscle biopsies were obtained from Deltoid muscle of the patients who were clinically diagnosed as muscular dystrophy .High serum CK & myopathic pattern in EMG have been reported for all.Normal muscle tissue was used as normal control.Antibodies:Three settings of Immunostainings were applied for each patient ;1-Dystrophin antibodies,2-Alpha,Beta&Gamma sarcoglycan and Dysferlin,3-Merosin. RESULTS-From all 44 patients;5 cases revealed complete absence of Dystrophins(DMD);10 with partially stained with Dystrophins(suggested for BMD);8 cases of Sarcoglycans deficiency;4 patients with Dysferlinopathy;2 cases with Merosin deficiency (CMD);14 cases revealed positive staining with all of the antibodies and should be followed by the others (Calpain-3,Caveolin...);finally one of the patients showed only severe necrosis & degeneration . CONCLUSION-According to our study IHC is an essencial technique for the diagnosis & differentiation of muscular dystrophies.It should be followed by the blotting methods in most of the cases(BMD & Dysferlinopathy);Molecular methods also should be performed for definite diagnosis in some other cases(subtyping of Sarcoglycanopathies). In our pilot study , the most frequent muscular dystrophies was Dystrophinopathies followed by Sacoglycanopathies .A study on a larger group of Iranian patients with more antibodies should be followed.

PP4-256
INTRAABDOMINAL LOCALIZATION OF EXTRASKELETAL MYXOID CHONDROSARCOMA: CASE REPORT
Adela Cimic, Semir Vranic, Nurija Bilalovic
Department of Pathology, Clinical Center of the University of Sarajevo, Bosnia and Herzegovina

Extreskeletal myxoid chondrosarcomas with primary intraperitoneal localization are extremely rare with only several cases reported on Pubmed. We report a case of intraabdominal extraskeletal myxoid chondrosarcoma (EMC) in 57-year old

woman that was surgically treated because of the expansive tumor mass in her abdomen. The tumor that measured 11x11x7 cm, was located below diaphragm. On gross examination, it was a multinodular, chondroid tumor, well demarcated with central necrotic and gelatinous area. Microscopically, tumor was composed of chondroblasts arranged in cords, within myxoid stroma. Some of the cells were binuclear and bizarre. Peripheral area was less cellular compared with the central area. Mitotic activity of tumor cells was low classifying this tumor as a low-grade soft tissue tumor.

PP4-257

POLYVINYLPYRROLIDONE STORAGE DISEASE: A RARE CAUSE OF PATHOLOGIC FRACTURE

Chien-Chen Tsai[1], Wen-Chih Huang[1], Chih-Hung Chang[2]
[1] Department of Pathology, Far Eastern Memorial Hospital, Panchiao, Taipei, Taiwan
[2] Department of Orthopedics, Far Eastern Memorial Hospital, Panchiao, Taipei, Taiwan

[INTRODUCTION] Polyvinylpyrrolidone (PVP) had been widely used as a plasma substitute or a retardent in some drugs decades ago. In Taiwan, PVP has been prescribed inappropriately as blood tonics for nutrition support for a long time. However, local injection or systemic administration of PVP-containing drugs could cause PVP to be retained in the reticulo-endothelial system and lead to PVP storage disease. [CASE REPORT] A 65-year-old Taiwanese lady was suffered from right hip pain after a fall in Nov. 2005. Normocytic anemia (Hb: 9-10 g/dl) was noticed. Image studies showed right femoral subtrochanter fracture. During operation, the fracture site exhibited some soft, yellowish, and gelatinous material within the marrow space; therefore, a bony tumor or metastatic lesion was suspected. Histologically, it showed sheets of blue-grayish vacuolated cells in a myxoid and hemorrhagic background with minimal inflammatory reaction. These vacuolated cells were positive for mucicarmine and Congo red stains, but negative for Peroidic acid-Schiff (PAS) and alcian blue stains. Immunohistochemically, these cells were negative for cytokeratin and S-100 protein, excluding the possibility of metastatic carcinoma or myxoid liposarcoma. Tracing back this patient's medical history, she had been frequently given intravenous supplement of plasma substitutes as blood tonic at the local clinics for several years. The whole clinical and pathologic features suggested the diagnosis of PVP storage disease. [DISCUSSION] PVP storage disease, or PVP granuloma, occurred mainly in skin and soft tissue. Severe anemia and bony destruction were also noted in some cases, owing to massive infiltration of PVP storage cells in the marrow spaces. However, pathologic fracture due to PVP deposits in bones was rarely reported. For the pathologists, the differential diagnoses include metastatic epithelial tumors, such as signet-ring cell carcinoma and renal cell carcinoma. Chondromyxoid tumors of soft tissue, such as liposarcoma, chordoma, and chondrosarcoma, as well as other histiocytic storage disease, should also be considered. The characteristic histochemical staining results, combined with negative immunostains for cytokeratin and S-100, help reach the correct diagnosis. The clinicians and pathologists should be aware of this iatrogenic storage disease to prevent misdiagnosis.

PP4-258

MONOSTOTIC PAGET DISEASE OF THE PATELLA

Stephanos Milias[1], Epaminondas Molyvas[1], Abraham Ploumis[2]
[1] Department of Pathology 424 General Military Hospital, Thessaloniki, Greece
[2] Department of Orthopedics 424 General Military Hospital, Thessaloniki, Greece

Background: To present an unusual case of Paget Disease located at the patella. Method: The patient was female 46 years old, presenting with pain and swelling of the left patella. The clinical, radiographic and CT findings were more suggestive of Paget disease and they did not show any other bone affected. The patient underwent a needle biopsy. Results: Microscopic examination revealed areas with prominent osteoclastic activity, while the osteoclasts were larger than usual, containing many nuclei per cell. There were also fewer osteoblastic areas with rimming of osteoblasts. No atypia was observed. The stroma was vascular and partially fibrotic. The bony trabeculae were disorganised, forming focally a "mosaic" pattern and few "cement" lines. The findings were suggestive of Paget disease and particularly of the osteolytic phase. Conclusion: Monostotic Paget disease of the patella is extremely rare. The etiologic factors of Paget disease are not clear yet. It seems that both genetic and non-genetic, perhaps viral, factors are assosiated with the disease. Molecular studies may contribute to the understanding of the pathophysiology of Paget disease and provide new therapeutical procedures in the future.

PP4-259

OSTEOBLASTOMA-LIKE OSTEOSARCOMA. REPORT OF TWO CASES

Didier Meseure[1], Jean Marc Guinebretiere[1], Sabah Boudjemaa[2], Liliane Boccon Gibod[2]
[1] Pathology Department, Centre René Huguenin, Saint Cloud, France
[2] Pathology Department, Armand Trousseau Hospital,Paris,France

Background: Osteoblastic-like osteosarcoma (OLO) is a rare (1% of osteosarcoma) variety of osteosarcoma of low-grade malignancy with potential for recurrence when adequate surgical margins are not achieved and metastases. Differential diagnosis between osteoblastoma and OLO can be very difficult, because osteosarcoma may resemble osteoblastoma (clinically, radiologically and histologically), certain variants of osteoblastoma (agressive osteoblastoma, osteoblastoma with pseudosarcomatous features, multifocal osteoblastoma) may mimic osteosarcoma and osteoblastoma may rarely undergo malignant transformation. Distinguishing these two lesions is of great importance because their prognosis and treatment are different. In most cases, combination of clinical, radiological and pathologic features affords a clear distinction. The strongest histologic criteria to differentiate between them is tumoral permeation of the surrounding host tissue. Design and results:We report two cases of OLO in 8 year-old children (one male and one female). The first presented with a 7 months history of increasing pain in the right shoulder. A lacunar lesion of the first rib was resected, suggesting an osteoblastoma histologically. The lesion reccured in the subclavian region 18 months later and histological examination displayed a typical OLO. This patient underwent chemotherapy and radiotherapy. Three years later, there was a tumoral progression towards vertebrae and spinal tube, leading to the death of this patient one year later. The second patient had an osteolytic lesion located in the right iliac crest. The tumour revealed morphologic features of a benign-appearing osteoblastoma. Local reccurence occured one year later, owing to a wide curretage. Seven months later, a further extensive local reccurence had developped. An OLO was then diagnosed and the patient was treated with chemotherapy followed by en bloc resection of the iliac bone. She is now free of symptoms (8 months). Conclusions: Pathological diagnosis of OLO based on purely morphological parameters is difficult, especially on small biopsies. These two observations show that it is necessary to define clear morphologic and immunophenotypic characteristics for this low grade osteosarcoma often misdiagnosed as osteoblastoma. Alteration in suppressor gene p 53 localized on chromosome 17p13 seems to be an early event in the tumorogenesis of malignant osteoblastic tumours. Its characterisation might be helpful and need further investigations in these circumstances.

PP4-260
MYOSITIS OSSIFICANS PROGRESSIVA: A CASE REPORT
Ellouze Sameh, Mnif Lilia, Fakhfakh Ines, Ghariani Makki, Ayadi Lobna, Gouiaa Naourez, Mnif Jamel, Sellami-Boudawara Tahya
Pathology Department. H. Bourguiba Hospital Sfax, Tunusia

Introduction: Myositis ossificans progressiva is a rare autosomal dominant progressive disease of connective tissue. It consists on a heterotopic osteogenesis frequently associated to characteristic congenital malformations. Case report: We report a case of a 24 year-old girl which presented a heterotopic bone formation leading gradually to ankylosis. The diagnosis was clinically suggested and confirmed when we've discovered bone bridges. Discussion: Congenital malformations, most commonly of big toes and thumbs, are important criterias to draw on the diagnosis earlier and to avoid unnecessary biopsy or resection which may trigger off a flare of the disease. This lesion simulates microscopically an extraosseous osteosarcoma and juxtacortical osteosarcoma with a highly cellular stroma associated with new bone formation. The most important diagnostic feature is the zonal phenomenon of maturation. Therapeutic measures are essentially preventive and the prognosis is poor.

PP4-261
GIANT CELL GRANULOMA OF THE INFRA TEMPORAL FOSSA: A CASE REPORT
Chtourou Imen, Bahri Ibtissem, Fakhfakh Ines, Kallel Rim, Ayadi Lobna, Hachicha Lilia, Gouiaa Naourez, Sellami-Boudawara Tahya
Pathology Department; Habib Bourguiba Hospital, Sfax, Tunisia

Background: Giant cell granuloma (GCG) is an uncommon benign lesion that occurs almost exclusively whithin the jaw bone. Isolated cases of GCG occuring in the other cranial and facial bones have been documented. Location in temporal bone is extremely rare and less then 20 cases have been reported in the medical literature. Case report: A 46 year old man presented with a 3-year history of hearing loss on the left. Physical examination revealed a mass in the left preauricular area. Radiologic computed tomography showed a destructive multiloculated lesion of the left infratemporal fossa, the temporal and sphenoidal bones. This lesion eroded the left external auditory canal. Serum alcaline phosphatase, serum inorganic phosphate and calcium were all within the normal limits. A biopsy was performed. The microscopic examination of the specimen revealed a connective tissue stroma containing a large number of ovoid or spindle-shaped cells and multinucleated giant cells resembling osteoclasts. Foci of hemorrhage and deposit of hemosiderin were also present. There were some regular osteoid trabeculae. On immunohistochemical examination, both mononucleated and multinucleated cells expressed CD68 and focally S100 protein. Proliferate index assessed by KI-67 staining was estimated to 5-10%. The diagnosis of GCG was made. Conclusion: GCG is a rare benign lesion with distinct clinicopathological features. Modern neuro-imaging shows an expansile destructive multiloculated bone lesion mimicking a neoplastic mass. Histopathology is confirmatory of this benign lesion. Other giant cell containing lesions such as the giant cell tumour of the bone and a brown tumour of hyperparathyroidism need to be carefully excluded. Microsurgical excision is curative with a low recurrence rate.

PP4-262
A MODIFIED STAGING FOR SOFT TISSUE SARCOMA – PROGNOSTIC INDEX (STS-PI)
El Hindawi Ali[1], Akl Maha[2]
[1] Pathology Department Faculty of Medicine Cairo University, Egypt
[2] Pathology Department Theodor Bilharz Research Institute,Egypt

This study was carried out on 122 patients suffering from different types of soft tissue sarcomas and ranging in their ages from 17 to 72 years. They were admitted to "Aswan Cancer Institute" in Egypt for surgical resection of their tumors. The resected specimens were proved to be soft tissue sarcomas of various microscopic types with a minimum follow up period of 60 months (5 years) . The aim of our study is to find out a reliable scoring system for grading and staging of such sarcomatous tumors that could reflect a convenient clinco-pathological prognostic index. Following proper gross morphological, histopathological and immunohistochemical diagnosis of the specimens under the study, they were given scores according to the following five parameters, as follows: (a) According to Tumor microscopic type: Score 1 indicates favorable prognosis (as in dermatofibrosarcoma protuberans) and Score 2: for other types of sarcomas.(b) According to Tumor longest dimension: Score 1: for tumors < 5 cm and Score 2: for tumors > 5 cm. (c) According to Tumor depth: Score 1: for Superficial tumors and Score 2: for Deep tumors. (d) As regards Tumor histological grade, according to the French Federation of Cancer Centers Sarcoma Groups (FFCCSG system) : tumors were given three scores; Score 1: for Grade I tumors (well differentiated), Score 2: for Grade II tumors(moderately differentiated) and Score 3: for Grade III tumors (well differentiated). Grading is best done in relation to histological morphological criteria including ;(degree of cellularity, pleomorphism, mitosis and necrosis), and finally the last parameter is (e) According to the presence or absence of Tumor metastases (LN or organ metastases); tumors were given either Score 0: for absent metastases and Score 6: when metastases are present. So our suggested STS-PI is as follows : The suggested soft tissue prognostic index (STS-PI) for the studied cases was calculated by summing up the previous scores relevant to each tumor and was found and described as 4 CLASSES as follows: -CLASS A : 4 (best score) -CLASS B : 5, 6, 7 (good score) -CLASS C : 8, 9 (medium score) -CLASS D : 10 – 15 (poor score) The 5 years survival rate for the studied tumors was recorded in 7/8 CLASS A tumors (87.5%), in 30/44 of CLASS B tumors (68.2 %) , and in 17/59 CLASS C tumors (28.8%) and was 0/11 in class D tumors (0 %), pointing to a reliable STS-PI.

PP4-263
EWING SARCOMA, A RETROSPECTIVE STUDY
Aleksandra Bonevski[1], Dora Anzulovic[2], Kristina Meljanac[2], Luka Brcic[2], Lovorka Batelja[2], Iva Brcic[2], Sven Seiwerth[2]
[1] Children's Hospital Zagreb, Zagreb, Croatia
[2] Institute of Pathology, Medical School University of Zagreb, Zagreb, Croatia

BACKGROUND. Recently, new concepts in Ewing sarcoma/PNET diagnosis and treatment were introduced. Since 1998, immunohistochemical verification of ES/PNET diagnosis, using CD99, is routinely performed at our Institute. Since end 2003, molecular methods (RT-PCR for EWS/FLI1) were introduced. In 2003, an algorithm was adopted including molecular analysis for residual disease and early recurrence. In order to establish a baseline patient population, we performed a partly retrospective and partly prospective analysis. PATIENTS AND METHODS. 78 Ewing sarcoma/PNET, diagnosed at the Institute of Pathology, Medical School University of Zagreb and treated at the Children's Hospital Zagreb, in the period from 1990 to 2006, were included in this study. Of all analyzed tumors, 8 were extraosseal. Retrospectively, we submitted all collected tumor samples for both immunohistochemical and molecular analysis. Immunohistochemical analysis was successful in all analyzed samples. RT-PCR could not be successfully performed on samples older than 2000. From 2003, together 96 samples – tumor tissue, peripheral blood and 28 bone marrows were analyzed for characteristic translocations. RESULTS. Immunohistochemically, all tumor samples showed moderate to strong positivity, while EWS/FLI1 could not be demonstrated in

6. From the samples submitted according to the new algorithm, 39 were positive by RT-PCR, among them 10 peripheral blood samples. In some cases multiple analyses of blood samples yielded only one positive. In two diagnostically problematic and immunohistochemicaly equivocal cases of small blue cell tumors molecular analysis fostered the final opinion. CONCLUSION. Introduction of molecular techniques enabled us to solve some diagnostic problems and to detect disseminated disease prior to clinical evidence producing a potent tool for improved patient care and disease management.

PP4-264
DESMOID TUMORS OF THE CHEST WALL

Olfa Ismail[1], Leyla Abid[1], Adel Marghli[2], Jamal Ammar[3], Tarek Kilani[4], Faouzi El Mezni[5]
[1] Department of Pathology, A Mami Hospital, Ariana, Tunisia
[2] Department of Thoracic Surgery, A Mami Hospital, Ariana, Tunisia
[3] Department of Pneumology, A Mami Hospital, Ariana, Tunisia
[4] Department of Thoracic Surgery, A Mami Hospital,Ariana,Tunisia
[5] Department of Pathology, A Mami Hospital, Ariana, Tunisia

Introduction: Desmoid tumors (DT) are rare benign soft tissue neoplasms that arise from fascial or musculo-aponeurotic structures. Despite their benign microscopic appearance, they are characterized by invasion of contiguous structures and recurrence. Purpose: We retrospectively reviewed our institutional experience of DT of chest wall with emphasis on the clinical and pathologic characteristics. Material & Methods: Between January 1993 to January 2007, we retrospectively collected 6 cases of DT of chest wall. Medical records and microscopic slides were reviewed. Anti-bodies selected for immunohistochemical staining included vimentin, desmin, smooth muscle actin, S100 and CD 34. Results: There were 4 males and 2 females with mean age of 40 years. Only pediatric case was noted. Three patients had a history of previous trauma or surgery (thoracotomy for lung adenocarcinoma and sternotomy for a aorto-coranory bypass). Complaints included pain (n=4), palpable mass (n=3), sensory symptoms and cough. In CT scan, lesions appeared as wall chest soft tissue tumor (n=4) with extension to the neck in one case. One tumor was located in posterior mediastinum mimicking neurogenic tumor and other was misdiagnosed as lung neoplasm. Surgical treatment was performed in 5 cases. The size of specimen varied from 3 to 14 cm and included ribs in 3 cases. Histology revealed a densely collagenated acellular lesion interspersed with areas of moderate cellularity consisting of fibroblastic and myofibroblastic cells. Mitotic figures were absent.There was no infiltration of surrounding structures. Chirurgical biopsy was performed in massive tumor with pleural, mediastinal and pulmonary involvement. Vimentin and smooth muscle actin were observed in all cases. S100 and desmine in one case. CD34 was not expressed by any of these tumors. One patient presented one recurrence and was treated by local resection and radiation therapy. Chemotherapy was beginned in a pediatric case. Discussion: Clinical presentation of chest wall DT in the literature is similar to our serie, but we not note a female predominance. The pathogenesis of DT is not clear. Trauma has been strongly implicated and recent work revealed hight incidence of B catenin gene mutations. Definitive diagnosis requires histopathology. Neurogenic tumors, fibrosarcomas, calcifying fibrous pseudotumors and localized fibrous tumors of the pleura should be considered in the differential diagnosis. CD34, smooth muscle actin and B catenin stains are useful in this setting.

PP4-265
CLINICO-PATHOLOGICAL AND OUTCOME FEATURES OF FIBROUS DYSPLASIA: RETROSPECTIVE STUDY OF A SERIES OF 26 CASES FROM TUNISIA

Sonia Ziadi, Mounir Trimeche, Moncef Mokni, Sarra Mestiri, Badreddine Sriha, Sadok Korbi
Departement of Pathology, CHU Farhat Hached, Sousse, Tunisia

Background: Fibrous dysplasia is a rare condition in which defective maturation of osteoblasts results in abnormal bone formation. Is typically occurs in patients before 30 years of age with an equal ratio between males and females. FD presents in two forms: monostotic and polyostotic. The purpose of this retrospective study was to analyze clinical, histological and radiological characteristics and the outcome after treatment of this lesion in Tunisian population. Methods: Twenty six cases of histologicaly proven fibrous dysplasia diagnosed during a 15-year period from 1990 through 2005 at the Department of Pathology of the CHU Farhat Hached of Sousse, Tunisia. The following medical records were subjected to a detailed scrutiny: In patient clinical records, imaging studies, histopathological observations and outpatient clinical follow-up records. Results: In the present series male/female ratio was 1:4.2. Their ages ranged from 6 to 71 with an average age of 28.6. Monostotic fibrous dysplasia was found in 24 patients (92.3%), and 2 patients had polyosotic fibrous dysplasia (7.7%). Mc Cune-Albright syndrome and Mazabraud syndrome witch associating fibrous dysplasia were not noted in any case. The majority of the lesions were located in the upper maxilla and the mandible (65.4%). Imaging studies often show lesion with a ground glass matrix. Histopathological examination in the majority of these cases showed dysplastic bone surrounded by fibroblastic, some osteoblastic giant cells and hemosiderin filled macrophages. In the monostotic form, the clinical outcome was considered good in majority of cases; however, one patient has developed an osteosarcoma, three years later. In the two polyostotic cases outcome was less satisfactory because of fractures and deformities. Conclusion: This clinicopathological study revealed a female predominance so this can support the hormonal theory of fibrous dysplasia suggested by some authors.

PP4-266
EGFR, P53 AND CAVEOLIN-1 EXPRESSION IN ADAMANTINOMA OF LONG BONES

Ozgur Mete[1], Bilge Bilgic[1], Misten Demiryont[1], Harzem Ozger[2]
[1] Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey
[2] Istanbul University, Istanbul Faculty of Medicine, Department of Orthopaedic and Traumatology, Istanbul, Turkey

BACKGROUND: Adamantinoma of long bones comprises about 0.4% of all primary tumors. In 90% of cases, tibia is the main site of involvement. World Health Organization defined it as a low grade, malignant biphasic tumor characterized by a different morphological patterns, most commonly epithelial cells, which are surrounded by a bland spindle-cell osteo-fibrous component. Nowadays, the epithelial part of the tumor is accepted to be neoplastic. Aneuploidy and p53 overexpression have only been demonstrated recently in one study. Since many studies have indicated an important role for growth factors and associated receptors in tumor growth we studied the expression of epidermal growth factor receptor (EGFR) and also p53 immunohistochemistry. Caveolin-1 is a cell membrane protein and regulate intracellular signal transduction. It is usually found in mesenchymal tissue and is believed to act as a tumor suppressor or tumor promoter in many tumors. However, its expression has not been investigated in adamantinoma of long bones. For this reason we added caveolin-1 immunohistochemistry to our study. METHODS: A total of 8 resected adamantinoma of the tibia were included in this study.

All cases were classified according to the standard diagnostic criteria. Immunohistochemistry was performed by using anti-EGFR, p53 and anti-caveolin 1 antibodies. RESULTS: Nuclear p53, cytoplasmic and membranous Caveolin-1 and membranous EGFR reactivities were accepted as the positive immunostaining. Five cases (62.5%) showed focal and weak p53 expression only in epithelial areas. One case (12.5%) showed focal EGFR expression in the epithelial component. All cases (100%) showed strong caveolin-1 positivity in the epithelial part. Among them, 2 cases showed also focal caveolin-1 immunostaining in the fibrous component. Caveolin-1 expression was also found in endothelial cells. CONCLUSION: Although the percentage of p53 stained areas ranged from %10 to 30, our result supports that the epithelial part of the tumor is being neoplastic. As EGFR expression was present in one case it could not explain its relationship with tumor growth, but the down regulation of receptors may be one cause of this situation. Thus needs further investigations and correlations with epidermal growth factor expression. However, the high and strong caveolin-1 expression may be explained by its possible tumor promoter role in adamantinoma of long bones. Furthermore its predominant expression in the epithelial part of the tumor support the evidence that fibrous component of the tumor may be reactive.

PP4-267
CAVEOLIN-1 AND C-KIT EXPRESSION IN 12 MYXOID/ROUND CELL LIPOSARCOMAS

Ozgur Mete[1], Bilge Bilgic[1], Misten Demiryont[1], Harzem Ozger[2], Fulya Agaoglu[3], Emin Darendeliler[3]
[1] Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey
[2] Istanbul University, Istanbul Faculty of Medicine, Department of Ortopaedic and Traumatology, Istanbul, Turkey
[3] Istanbul University, Institute of Oncology, Department of Radiation Oncology, Istanbul, Turkey

BACKGROUND: Caveolin-1 is cell membrane protein and plays a major role in membrane traffic and signal transduction. Several studies have implied that caveolin-1 might have a tumor suppressor role; however, others have reported its tumor-promoting function. C-Kit expression has been utilized to identify patients with gastrointestinal stromal tumors (GISTs) who can be treated with imatinib. But its expression is not restricted to GISTs. Day by day, many tumors are adding to the c-kit positive tumors list and its expression in other soft tissue tumors is being an area of interest for therapeutic implications. Caveolin-1 and c-kit expression in sarcomas, especially in myxoid/round cell liposarcomas are not widely explored. For this reason, we decided to examine the expression of anti-caveolin-1 and c-kit antibodies in 12 cases of myxoid/round cell liposarcomas. METHODS: A total of 12 resected myxoid/round cell liposarcomas cases were included in this study. All cases were classified according to the standard diagnostic criteria. Three cases were composed of purely round cell liposarcoma and five cases were composed of purely myxoid liposarcoma. Four cases were composed of both myxoid and round cell liposarcoma. Immunohistochemistry was performed by using anti-caveolin-1 and anti-c-kit antibodies. RESULTS: The presence of membranous and/or cytoplasmic staining was accepted as a positive reaction for anti-caveolin-1 and c-Kit antibodies. Caveolin-1 expression was present in nine cases (75%) except three purely round cell liposarcomas and also in the round cell component of four cases containing both myxoid and round cell liposarcomas. Cytoplasmic c-Kit positivity was found in two cases. CONCLUSION: Round cell liposarcoma represents a histological continuum of myxoid liposarcoma. But the presence of round cell is a significance of unfavourable prognosis. Caveolin-1 expression has been investigated only in one recent study where focal and weak positivity was found in dedifferentiated liposarcomas. Our study results showed that caveolin-1 may have a potential role in the pathogenesis of myxoid and round cell liposarcomas. Furthermore, its absence in the non-lipogenic primitive round cell component let us to think that its down-regulation may be a hallmark of poorer outcome. As c-Kit has been found in only 2 of our cases, further investigations with larger series are needed to illuminate its usefulness for the therapeutic implications.

PP4-268
NEUROBLASTOMA IN ADULTS, PRESENTATION OF 2 CASES

Hale Demir[1], Ovgu Aydın[1], Haydar Durak[1], Sergulen Dervisoglu[1], Mustafa Ozguroglu[2] İsmet Sahinler[3]
[1] Istanbul University, Cerrahpasa Medical Faculty, Department of Pathology, Turkey
[2] Istanbul University, Cerrahpasa Medical Faculty, Department of Medical Oncology, Turkey
[3] Istanbul University, Cerrahpasa Medical Faculty, Department of Medical Radiation Oncology, Turkey

BACKGROUND: Neuroblastoma is one of the common malignant tumors of childhood but only about 100 cases have been reported in adults. The age range is 15-82 years with a median of 34 years. Male/ female distribution is equeal. Many of these tumors are reported in sites that are unusual for classical neuroblastoma (parotid, kidney, gluteal soft tissue, lower extremity). The survival rates are similar to those for INNS stage 3 and 4 childhood neuroblastomas. CASE 1: 50 year old male patient presented with paraoesophagial mass. Right thoracotomy was applied. 5x4x2 cm mass with a rib was excised and was sent to another pathology department, diagnosed as malignant tumor metastasis to paraoesophagial lymph node; and it was suggested that the tumor could be an osteosarcoma metastasis. The paraffin blocks were revised by Pathology Department of Cerrahpasa Medical Faculty. The diagnosis was neuroblastoma transformed from ganglioneuroma in paraoesophagial soft tissue confirmed by imunohistochemical staining with synaptophysin and chromogranin. CASE 2: 23 year old female patient presented with cervical mass. Two excision material, measuring 2x1.5x1 cm and 1.5x1x1 respectively were sent to another pathology center. According to the original pathology report, the materials were nodular and the cut surface was homogenous and yellow-white in colour. It was reported as neoplasm showing features of ganglioblastoma. The tumor cells were diffusely positive for NSE, focal positive with chromogranin negative for pancytokeratin and synaptophysin immunohistochemically. The paraffin blocks were revised by Pathology Department of Cerrahpasa Medical Faculty and diagnosed as neuroblastoma metastasis to lymph node. CONCLUSION: Neuroblastoma should be included in differential diagnosis of a small round cell tumor even in adult age especially in case of a background of schwannian stroma with scattered ganglion cells. This accompanying histology representing ganglioneuroma raises the possibility of dedifferentiation to neuroblastoma in the first case. The presence of an indolent form of a neuroblastoma is open to discussion for the second case.

PP4-269
THYROID METASTASIS FROM PELVIC MALIGNANT SOLITARY FIBROUS TUMOR AFTER 13 YEARS OF RESECTION AND COEXISTENT PARATHYROID ADENOMA

İrem Paker[1], Yuksel Kucuk Zeybek[2], Gokhan Icoz[3], Bulent Karabulut[2], Gulsen Kandiloglu[1]
[1] Ege University, Faculty of Medicine, Department of Pathology, Turkey
[2] Ege University, Faculty of Medicine, Department of Medical Oncology, Turkey
[3] Ege University, Faculty of Medicine, Department of General Surgery, Turkey

Solitary fibrous tumor is a rare spindle cell neoplasm which can be malignant. Here we report a 70 year-old woman presented with elevated calcium level during routine blood test. Her blood parathormone level was also increased. Ultrasonography of the thyroid showed the presence of multiple nodules and a parathyroid mass. Total bilateral thyroidectomy was performed. On gross examination of the thyroid, there were multiple nodules varying from 0.3 to 1.6 cm in diameter. Microscopically the largest nodule was well-circumscribed and composed of spindle cells. Immunohistochemically, the lesion was negative for CD34, CD68, CD117, EMA, pancytokeratin, TTF-1, smooth muscle actin, S-100 protein and positive for CD99. It was found out that the patient underwent laparotomy and a large pelvic mass was removed in 1993. This mass was diagnosed histologically as low grade malignant fibrous histiocytoma. She received radiotherapy and chemotherapy. In 2005, during the folow-up, lung and liver metastasis were detected by computed tomography scan. At the same time an abdominal mass was seen and biopsy of this mass revealed a morphology consistent with the previous tumor. Microscopically all specimens were reevaluated. Hemangiopericytomatous and storiform patterns were observed in the tumors. When we take the changes in the classification of soft tissue tumors into consideration, we diagnosed the tumor as malignant solitary fibrous tumor. As it is known, cellular form of solitary fibrous tumor can show malignant behaviour, in the form of recurrence and/or metastasis. The patient also received a diagnosis of parathyroid adenoma by the microscopic examination of the contralateral lobe and this mass was the main purpose of thyroidectomy. We reported this case because yet to our knowledge this is the first case of metastatic solitary fibrous tumor of thyroid coexistent with parathyroid adenoma.

PP4-270
COX-1 AND COX-2 EXPRESSION IN OSTEOSARCOMA AND BENIGN BONE TUMORS

Gulfiliz Gonlusen[1], Aysen Erer[2], Melek Ergin[2], Seyda Erdogan[2], Serdar Ozbarlas[2]
[1] Cukurova University Medical Faculty Dept. of Pathology, Turkey
[2] Cukurova University Medical Faculty Dept. of Pathology, Turkey

Background: Cyclooxygenase (COX) enzymes catalyze the conversion of arachidonic acid to prostoglandins, which have a variety of physiologic and pathologic roles. Two COX isoenzymes have been described to date: COX-1, which is constitutively expressed by most tissues, and COX-2, which is inducible by cytokines, growth factors, and hormones. Overexpression of COX-2 has been discovered in a variety of solid tumors and pediatric sarcomas. In our study; we aimed to investigate the similarity and differences of COX-1 and COX-2 expression in benign bone tumors and osteosarcoma. Material and Methods: Paraffin-embedded tissue specimens from 35 bone tumors (20 osteosarcoma, 6 giant cell tumor, 6 fibrous dysplasia, 3 osteoblastoma cases) were retrieved from the files of the pathology department of Cukurova University, Medical Faculty. COX-1 and COX-2 were applied by immunohistochemical method. The results of staining for COX-1 and COX-2 were analyzed semiquantitatively by using an immunohistochemical scoring system (HSCORE) that combines the percentage of immunoreactive cells (quantity score) and an estimate of staining intensity (staining intensity score). Results: Strong (HSCORE:2-3)COX-1 expression was detected in five (33.4%) and negative (HSCORE:0) or weak positivity (HSCORE:1) in 10 benign cases (66.6%)and there was no strong positivity with COX-1 in osteosarcoma cases (P:0.005). Whereas; there was no significant differences with COX-2 between benign bone tumors and osteosarcoma cases (P:0.730). No correlation was found between COX-1 and COX-2 expression in osteosarcoma cases (r:0.15). Whereas, mild negative correlation was detected between benign bone tumors with COX-1 and COX-2(r:0.38, p:0.5). Conclusion: We conclude that most cases of the benign bone tumors express COX-1 and COX-2 to varying degrees. Whereas there was no moderate or strong positivity with COX-1 in osteosarcoma cases. These results may be explained that cyclooxygenase enzymes do not play an important role in osteosarcoma pathogenesis.

PP4-271
ACRAL MYXOINFLAMMATORY FIBROBLASTIC SARCOMA (REPORT OF 5 CASES)

Esengul Uzuner[1], Misten Demiryont[1], Bilge Bilgic[1], Harzem Ozger[2]
[1] Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Turkey
[2] Istanbul University, Istanbul Faculty of Medicine, Department of Orthopedics and Traumatology, Turkey

BACKROUND: Acral myxoinflammatory fibroblastic sarcoma (AMFS) was first described in 1998 as a rare tumor of distal extremities. AMFS is usually localized in the fingers within the subcutaneous tissues. It develops in patients of all ages with a median of late 40s. Grossly, it is an infiltrative multinodular mass measured 1-8 cm in diameter. AMFS consists of bizarre cells which have enlarged vesicular nuclei with inclusion-like nucleoli and large eosinophilic cytoplasms. The stromal component of the tumor contains various amounts of myxoid and hyalen matrix mixed with inflammatory cells. METHODS: We report 5 cases of AMFS, occuring in 3 males and 2 females with their clinical, histological and immunohistochemical features. The mean age was 45 (range 26-64). The tumor sizes were ranged from 1 cm to 6 cm (mean 2.8 cm). The localizations of the tumors were as follows: 2 ankles, 1 toe, 2 hands (D5 and extensor surface). Three patients presented with painless swelling, one with pain and mass and one with only pain. The symptom duration of cases was between 3,5 months and 4 years. Four cases, which were sent to us for consultation, were previously diagnosed as myxoid type malignant fibrous histiocytoma, chondrosarcoma, low grade fibrosarcoma and sarcoma (NOS). RESULTS: Immunohistochemical studies revealed positivity for vimentin (4/4), CD68 (5/5) and CD34 (2/3). Positive immune reaction was focally observed only in 2 of 5 cases. No positive immunostaining was detected for pancytokeratin (4/4) and smooth muscle actin (3/3). Ki-67 proliferation indices were between 2-5%. Four cases was treated with local excision, whereas 1 case with local amputation. Recurrence was seen only in one that was localized at extensor surface of the hand. None of the cases showed metastasis with a median follow-up of 17 months. CONCLUSIONS: AMFS is a very rare entity that must be kept in mind in the differential diagnoses of tumoral and non tumoral lesions, such as tenosynovitis, nodular fasciitis, giant cell tumor, inflammatory myofibroblastic tumor, liposarcoma, epithelioid sarcoma and malignant fibrous histiocytoma. Although we detected recurrence only in one case and no metastasis, AMFS is known to be a low-grade sarcoma that shows recurrence and has metastatic potential.

PP4-272
HMGA1 REARRANGMENTS OCCUR IN A SMALL SUBSET OF SPINDLE CELL LIPOMAS

Fabiola Medeiros, Xiaoke Wang, Michele Erickson-Johnson, Antonio Nascimento, Andre Oliveira
Mayo Clinic, Rochester, MN, USA

Background: Spindle cell and pleomorphic lipomas are benign subcutaneous adipose tissue neoplasms typically occurring in the neck and back of older men. Conventional cytogenetic analysis often shows monosomy or partial losses of chromosomes 13 and 16. Rearrangements of 6p21 have been reported in these tumors, and one study has identified HMGA1 overexpression by immunohistochemistry in a single example (Dumollard JM et al Ann Pathol 2001; 21:303-10). Because we have recently encountered a classic case of spindle cell lipoma in the face of a

66-year-old man with rearrangements of chromosome 6p21, we hypothesized that the HMGA1, a gene occasionally rearranged in ordinary lipomas and other benign neoplasms – was involved. The aim of this study was to investigate the frequency of HMGA1 rearrangements in a series of 17 of such tumors. Method: Seventeen cases of spindle cell lipomas with typical histopathologic features were studied for rearrangements of HMGA1 and HMGA2 by fluorescence in situ hybridization (FISH) on paraffin-embedded sections. Fresh and frozen tissues were available from the index case for standard cytogenetic analysis and reverse-transcriptase polymerase chain reaction (RT-PCR). Results: Cytogenetic analysis was performed in one case and demonstrated the following karyotype: 46,XY, t(1;6)(p32;p21.3), del(13)(q12q14)[19]/46,XY[1]. FISH analysis showed a balanced rearrangement of HMGA1, and semi-quantitative RT-PCR confirmed transcriptional upregulation of this gene. Molecular cytogenetic studies of 16 additional spindle cell lipomas revealed a balanced rearrangement of HMGA1 in a single case. HMGA2 rearrangements were not found in any of the cases studied. Conclusion: Rearrangements of chromosome 6p21 with involvement of HMGA1 seem to occur in approximately 10% of spindle cell lipomas (2/17 in the present series), a frequency similar to that observed in ordinary lipomas. This finding suggests that HMGA1 may play a role in the pathogenesis of a subset of these tumors.

PP4-273
HYDATID CYST OF BONE; REPORT OF FIVE CASES
Aysen Erer[1], Seyda Erdogan[1], Melek Ergin[1], Serdar Ozbarlas[2], Gulfiliz Gonlusen[1]
[1] Cukurova University, Medical Faculty, Pathology Department, Turkey
[2] Cukurova University, Medical Faculty, Orthopedic Surgery Department, Turkey

Background: Hydatid cyst is a parasitic infection caused by larval stage of Echinococus granulosus in man and domestic animals. The incidence of hydatid cyst in liver, lung, kidney and brain are 59-75%, 27%, 3% and 1-2% respectively. Hydatic cyst in bone is extremely rare and found in only 0.5-2% of cases. In endemic areas, this ratio can increase to 4%. Material and Methods: In a comprehensive study of 109 cyst hydatid cases from pathology files of Cukurova University Medical Faculty between 2002-2007 years; we identified five bone hydatid cysts (5.5%). Results: The age distribution was between 18 and 55 years. Three of them were male, two patients were female. Among the five cases; four cases were admitted to our hospital with pain and one patient with pathologic fracture. The localization of the lesions was femur (two cases), tibia (one case), iliac bone (one case), acetabulum (one case). Conclusion: In this study, we present five hydatid cyst in rare localization and review the literature.

PP4-274
SKULL BASE CHORDOMAS A RETROSPECTIVE STUDY OF 14 CASES
Faten Limaiem[1], Ines Chelly[1], Amina Mekni[1], Salma Bellil[1], Fathia Maamouri[1], Slim Haouet[1], Nidhameddine Kchir[1], Mohamed Moncef Zitouna[1], Mohamed Khaldi[2], Khedija Bellil[1]
[1] Department of Pathology. La Rabta Hospital, Tunisia
[2] Department of Neurosurgery La Rabta Hospital, Tunisia

Chordomas are uncommon malignant neoplasms arising from remnants of the notochord. They account for 1–4% of all primary malignant bone tumours and are mainly localized in the sacrococcygium (55%). Skull base chordomas are extremely rare representing less than 1% of all intracranial tumours. The aim of the present study is to analyze clinicopathological features of chordomas and to discuss differential diagnosis. Over the 12-year period from January 1997 to December 2006, 14 cases of skull base chordomas were diagnosed at the pathology department of La Rabta hospital. Relevant clinical information and hematoxylin & eosin stained tissue sections were available for review in all cases. Clinical features, symptoms at diagnosis, treatment and outcome were retrospectively analyzed. There were 11 male and 3 female patients (sex ratio M/F = 3,67) aged between 19 and 72 years with a mean age at presentation of 46,57 years. The most frequent complaints were headache, diplopia and decreased vision. Prior to surgery, each patient was investigated with contrast-enhanced magnetic resonance imaging (MRI) and contrast-enhanced computed tomography (CT). Seven tumours involved the clivus, 3 were intrasellar, 2 were located in the cavernous sinus and 2 involved the sphenoid sinus. Surgical resection of the tumour was achieved in all patients. Pathological examination of the surgical specimen was compatible with classic chordoma in 12 cases and chondroid chordoma in 2 cases. Immunohistochemical study was performed in only 2 cases and showed positive immunostaining of tumour cells with cytokeratin, EMA, vimentin and S-100 protein.

PP4-275
ANGIOMATOID FIBROUS HISTIOCYTOMA: REPORT OF THREE CASES WITH CYTOLOGICAL AND HISTOLOGICAL FEATURES
Mine Gulluoglu, Semen Yesil, Dilek Yilmazbayhan, Misten Demiryont
Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Turkey

Angiomatoid fibrous histiocytoma (AFH) is an intermediate grade histiocytic tumor which occurs in children and young adults. In this case report, we present the cytological and histological features of three AFH cases. The patients were all male, and 28, 22 and 36 years old. The localizations of the tumors were supraclavicular, forearm and inguinal region, and their diameters were 10 cm, 4 cm and 2.5 cm, respectively. In the fine needle aspiration material of the supraclavicular mass showed highly cellular smears displaying polygonal and spindle shaped cells, either dispersed or forming three dimentional clusters in a lymphocyte-rich background. The tumor cells had ovoid or spindle-shaped nuclei, fine chromatin, small inconspicious nucleoli. The excisional biopsy material of all three patients showed similar histopathological features. The tumors were composed of multiple cellular nodules surrounded by fibrous pseudocapsule and contained blood filled cavities in a lymphocytic and inflammatory backgound. Groups of hemosiderin-laden macrophages were also present in varying amounts. All three tumors were positive for CD68 and epithelial membrane antigen, negative for endothelial markers and one of them was positive for desmin. The tumor localized in cervical area had been resected with indeterminate surgical margins and recurred in 6 months time. The reexcision material showed similar histomorphological features. AFH should be included in the differential diagnosis in a child or young adult patient having a slow-growing subcutaneous mass with cytological and histological features of an intermediate grade histiocytic mesenchymal tumor. The morphological features as well as immunohistochemical findings make the accurate diagnosis possible.

PP4-276
CASE REPORT: MELANOTIC NEUROECTODERMAL TUMOR OF INFANCY
Murat Sezak[1], Basak Doganavsargil[1], Yesim Ertan[1], Saffet Mutluer[2], Taner Akalin[1]
[1] Ege University School of Medicine, Pathology Department Izmir, Turkey
[2] Ege University School of Medicine, Neurosurgery Department Izmir, Turkey

Background: Melanotic neuroectodermal tumor of infancy (MNTI) is a rare benign neoplasm that may be locally aggressive. Since the first description by Krompecher in 1918, approximately

350 cases are reported in the medical literature. The tumor affects most commonly maxilla (%70) followed by the skull and mandible during first year of life. Early diagnosis and radical surgery are critical for long-term cure. Case presentation: We are presenting a 18 month old boy with a lump in the right temporal region since the age of 3 months. Because the tumor had a relatively fast grow, she was referred to our hospital. Radiological examination showed a tumor located in the right mastoid which was demarcated and radiolucent. It was not adhered to the dura mater. Tumor was completely excised by neurosurgeons. Microscopically, tumor have two components, one of them was composed of large polygonal epitelioid cells with deposits of melanin and the other component was smaller neuroblast-like cells characterized with round centrally located hyperchromatic nuclei and scant cytoplasm in a dense sclerotic fibrous stroma. Tumor cells were occasionally arranged as alveolar nests, small nests and solid sheets. Necrosis, hemorrhage, nuclear pleomorphism and mitoses were not evident. Immunohistochemically tumor was positive for HMB-45 and negative for synaptophysin, pancytokeratin, epithelial membrane antigen, protein S-100, glial fibrillary acidic protein, chromogranin A, ubiquitin. The postoperative course was uneventful. There was neither residual tumor nor recurrences at the control of 3., 6. and 15. months of post operation duration with radiologic evaluation (magnetic resonance images) .

PP4-277
PRIMARY SCHWANNOMA OF LYMPH NODE IN THE RETROPERITONEAL REGION

Deniz Peker[1], I. Willis[2], E. Saiz[1]
[1] Department of Pathology and Laboratory Medicine, Mount Sinai Medical Center, Miami Beach, USA
[2] Department of Surgery, Mount Sinai Medical Center, Miami Beach, USA

Intranodal schwannoma is an uncommon benign tumor of lymph node. We report a case of an intranodal schwannoma in the retroperitoneum of a 61-year-old woman. The patient underwent left total nephrectomy for the retroperitoneal mass thought to involve the kidney. Macroscopic examination of the specimen revealed a well-circumscribed 4.5x4.0x4.0 cm nodule located in the perihilar fat. Microscopically, the nodule was composed of a proliferation of bland spindled cells, which were immunohistochemically strongly positive for S100 protein, and negative for Actin 1A4, HHF35, Desmin, Melan A, Cytokeratin AE1/3, CD 68, CD 34, and CD 45. The pathological findings led to a diagnosis of a very rare case of primary intranodal schwannoma presenting as a retroperitoneal mass.

Infectious Diseases

PP4-278
DIGESTIVE ACTINOMYCOSIS, REPORT OF 4 CASES.

Mestiri Sarra[1], Trabelsi Amel[2], Yacoubi Med. Tahar[2], Ben Yacoub-Abid Lilia[2], Hmissa Sihem[2], Korbi Sadok[2]
[1] Pathology Department, F. Hached Hospital, Sousse, Tunisia
[2] Pathology Department, F. Hached Hospital, 4000 Tunisia

Background: Actinomycosis is a chronic granulomatous infection, that is relatively rare, caused by a Gram positive anaerobic bacteria. Digestive locations usually simulate a malignant process. Diagnoses difficulties usually lead to a surgical resection. Method: We report four cases of digestive actinomycosis, located to the appendix, the coecum and to the pancreas in respectively, 2 cases, 1 case and 1 case. The appendic ular location presented clinically as an appendicular syndrome. The two other localisations simulated a neoplastic process. Results: The 4 patients underwent a surgical resection. Histopathological examination has leaded to the correct diagnosis, showing a granulomatous infiltrate, surrounding colonies of actinomyces. Penicillin therapy was indicated in the 4 cases with a favourable clinical outcome. Conclusion: Abdominal location of actinomycosis is a rare with poorly specific clinical and radiologic features, the diagnosis is often made on surgical resection specimens. Treatment is based essentially on a well adapted antibiotherapy.

PP4-279
OCCURRENCE OF GASTRO-DUODENAL GIARDIASIS AND/OR HELICOBACTER PYLORI INFECTION AFTER GASTRIC ACID SUPPRESSION

Omran Zeinab[1], Moussa Mona[1], Nosseir Mona[1], Guirguis Nevine[2], Yehia Hisham[3], Elkhayat Hisham[3], Siam Moataz[3], Yousef Magdy[3]
[1] Theodor Bilharz Research Institute Pathology Departments, Egypt
[2] Theodor Bilharz Research Institute Parasitology, Egypt
[3] Theodor Bilharz Research Institute Hepatology and Gastroenterology Departments, Egypt

ABSTRACT Giardia lamblia (G. lamblia) is a common world-wide parasitic infestation. This study aims to detect gastric and/or duodenal G. lamblia colonization in patients receiving acid suppressing drug (Omeprazole) to assess its pathological repercussions on gastrointestinal mucosa and its link to Helicobacter pylori (H. pylori) micro-organisms.Forty patients (30-67 years of age) attending Endoscopy Unit of TBRI were enrolled. They were classified into two main groups; group (I): included 10 dyspeptic patients with no history of acid suppressing drug intake, group (II): included 30 patients complaining of dyspepsia or heart burn receiving proton pump inhibitor (Omeprazole) orally in a dose of 20 mg/day for 1-6 months [Benzimidazole = 5-Methoxy-2-(4-Methoxy-3,5-diMethyl-2-pyridyl-methylsulphinyl)] (C17H19 N3O3S= 345.4) as a treatment for gastro-esophageal reflux disease (GERD) or peptic ulcer.All cases were subjected to routine clinical examination, laboratory investigations and upper gastrointestinal endoscopy. Gastric and duodenal biopsies as well as duodenal aspirate were obtained from all cases. All biopsies were assessed using haematoxylin/eosin and Masson trichrome stains for histopathological evaluation, Geimsa stain for H. pylori detection and immunohistochemistry for proper identification of G. lamblia trophozoites.There was a clear male predominance in Giardia-positive patients. They tended to be older than control cases. Diarrhea, early satiety, abdominal pain or bloating were encountered more in positive cases. In acid suppressed patients (group II), giardiasis was detected in 40% of gastric biopsies, combined with H. pylori in 16.67%. Meanwhile; G. lamblia was evident in 76.67% of duodenal biopsies and 43.33% of duodenal aspirate. In gastric giardiasis, lymphocytic gastritis and intestinal

metaplasia were detected in 75% and 58.33% of cases respectively and were predominated in combined infection (100%). Duodenal giardiasis caused inflammatory infiltrate of the lamina propria in all cases (100%) with flattening and shortening of duodenal villi in 86.95% . Our results conclude that: Gastric acid suppression encourages G. lamblia colonization in the stomach manifested by lymphocytic gastritis or intestinal metaplasia. Gastric pathogenicity is more evident in combined G. lamblia and H. pylori infections. Duodenal biopsy is more accurate than duodenal aspirate in detecting G. lamblia infection. Caution in prolonged use of gastric acid suppressive drugs should be adopted in G. lamblia endemic areas.

PP4-280
RHEUMATOID ARTHRITIS ASSOCIATED WITH SPLENIC LEISHMANIASIS

Ioannis Venizelos, Zoι Tatsiou, Anastasios Chatzitolios, Alexandra Moulla
Department of Pathology, Hippokration Hospital, Thessaloniki, Greece

Rheumatoid arthritis (RA) is a chronic immune-complex disease which affects mostly women during the second and third decade of life. Due to prolong treatment with immunosuppressive drugs and the immunodeficiency which develops later in the course of the disease, it has rarely been described development of malignancies and opportunistic infections. Splenic leishmaniasis after treatment for RA has not been reported. We report the case of a 65-year-old woman who was admitted in our hospital with fever, night sweats, abdominal pain for the last 2 weeks, and weight loss (10 kgr) during the last 3 months. From her past medical history the patient was receiving treatment with methotrexate due to RA for the last 5 years. On physical examination it was found a palpable spleen, about 20 cm below the left costal margin. No peripheral lymphadenopathy, hepatomegaly or skin rushes was found. Hematological examination revealed pancytopenia. Because of the huge size of the spleen and the pancytopenia, a splenectomy was performed. Histological examination of the excised spleen revealed macrophages stuffed with ingested parasites, morphologically consistent with leishmania. The patient had no history of traveling to endemic areas with leishmaniasis. Test for leishmania using indirect immunofluorescence was strongly positive. A bone marrow biopsy revealed leishmania parasites in macrophages. The patient received treatment with amphotericine B and 3 years later she is in an excellent condition with the hematological abnormalities been resolved. In the present study we report the first case of splenic leishmaniasis after treatment for RA. Among other opportunistic infections, visceral leishmaniasis should be suspected after prolong treatment for RA.

PP4-281
SCHISTOSOMA HAEMATOBIUM (EGYPTIAN STRAIN): RATE OF DEVELOPMENT AND EFFECT OF PRAZIQUANTEL TREATMENT

Sanaa Botros, Olfat Hammam, Naglaa El Lakkany, Said Saif El Din, Fatma Ebid
Departments of Pharmacology and Pathology & Theodor Bilharz Research Institute,Warrak El-Hadar, Imbaba, Giza, Egypt

This study investigates the development of Egyptian strain of Schistosoma haematobium (S. haematobium) and the resultant immunohistopathological and biochemical changes of organs likely affected. Meanwhile the response of different developmental stages of S. haematobium worms to praziquantel (PZQ) was examined. S. haematobium-infected hamsters (400 cercariae/hamster) were classified into 4 main groups, they were treated 35, 55, 75 and 95 days post infection (PI). Each group was subdivided into three subgroups; two of them were treated orally with PZQ in a dose of 300 mg/kg or 500 mg/kg divided on two consecutive days, while the third one was left without treatment. Treated groups were sacrificed 20 days post treatment. Infection with S. haematobium became patent 75 days PI, tissue egg load and worm fecundity were higher 95 days and maximal 115 days PI with oogram pattern comparable to that in S. mansoni infection. In the liver, small cellular granulomas were observed 75 days PI with preponderance of CD4+ T-cell phenotypes. In the urinary bladder, only sub-mucosal focal Brunn's nests formation and angiogenesis without typical granulomas were observed. 95 and 115 days PI, confluent granulomata with multiple eggs in the center were observed in the liver and urinary bladder with preponderance of CD8+ positive T cells in the liver and hyperplasia of the urinary bladder lining epithelium with cystitis cystica and papillae formation. Higher worm eradication was recorded with the higher dose of PZQ tested in animals treated 75 and 95 days PI. In conclusion, in spite of the long prepatent period of the Egyptian strain of S. haematobium, sensitivity to PZQ was recorded early after infection. Granulomata were similar to that of S. mansoni in the livers and urinary bladders yet they were confluent with multiple eggs in the center, hyperplasia of the urinary bladder urothelium with cystitis cystica, papillae and Brunn's nests formation predictive of malignant changes with no hepatocyte dysplasia were detected.

PP4-282
A DIAGNOSTIC PITFALL IN SAMPLES FROM BRONCHIAL ASPIRATES: A FALSE HUMAN CONTAMINATION CAUSED BY AUREOBASIDIUM PULLULANS IN THREE PATIENTS

Hofman Paul[1], Butori Catherine[1], Le Fichoux Yves[2], Hofman Paul[1]
[1] Laboratory of Clinical and Experimental Pathology, University of Nice, Nice, France
[2] Laboratory of Mycologie, University of Nice, Nice, France

Background: A. pullulans is a saprophyte dematiaceous fungi, which can exceptionnally caused infection in human. Peritonitis, cutaneous infection, meningitis, or keratitis, abcesses in the spleen and jaw due to A. pullulans have been described in adults. In the lower respiratory tract, Aureobasidium species have been very exceptionally isolated. Patients and results: Three cases were observed in a single laboratory, the same week. The patients were: a 60-year-old man presented with a left upper lobe tumor and carcinomatous cells in bronchial smears; a 39-year-old woman with pneumonia and numerous inflammatory cells in bronchial smears; and a 67-year-old man with chronic cough and normal epithelial ciliated cells in bronchial aspirates. In all smears, numerous yeasts measuring from 3 microns to 5 microns were observed. In 2 cases, ellipsoidal unicellular smooth conidia, variable in size, sometimes budding, and originating from rare septate hyphae were noted. These fungi were stained with Papanicolaou, May Grunwald Giemsa, Alcian blue, mucicarmin, and Gomori-Grocott methods. The same fungi were isolated from saponin solution used for red cells lysis before smear staining. Diagnosis was made by comparing the morphology of fungi, both in bronchial smears and in saponin. Finally, fungal culture from saponin isolated A. pullulans. It was well identified due to the presence of large thick-walled black cells that have small single-celled conidia budding. Comments and conclusion: exogenous contamination by microorganisms can frequently caused false diagnosis of infectious diseases in pathology. However, these contaminations should be suspected when the same features are observed in different samples from the same laboratory, when the morphology is very unusual, and/or when non inflammatory cells are detected. A number of fungi of low virulence, including A. pullulans are often considered contaminants when isolated from healthy hosts. However, a recent review of the English literature revealed 25 clinical cases of Aureobasidium spp. infection. Moreover, A. pullulans has affinity for synthetic materials and surgically implanted Silastic devices, causing infection in human and making the differential diagnosis with false contamination very difficult.

PP4-283
PATOGENETIC VARIANTS OF CASEOUS PNEUMONIA FROM THE POINTOF VIEW OF TEACHING ABOUT PATHOMORPHISM OF TUBERCULOSIS
Eugene Kazachkov, Polina Tselischeva
State Medical Academy, Chelyabinsk, Russia

The aim of this research is to study the structure peculiarities of pathogenetic variants of caseous pneumonia (primary and secondary) in the 80th years of XX century and present days. Material and methods. The comparative patomorphologic analysis of the deaths cases of patients having tuberculosis of breathing organs based on the materials of specialized prosectorum of Chelyabinsk regional antituberculosis dispensary for 1986 (99 observations, 1st group) and 2006 years (105 dead patients, 2nd group) were held. Results. Was found the increasing of widespread destructive forms of tuberculosis infection such as fibrocavernous tuberculosis of the lungs (61%) and primary caseous pneumonia (PCP, independent clinic anatomic form of tuberculosis; 20%). The basic structural display of acute progressiveness of tuberculosis infection of the lungs is caseous pneumonia which can be as independent form of tuberculosis (PCP) and also it can be the stage of progress of another clinic morphologic forms of this infection (secondary caseous pneumonia: SCP). In 1986 PCP was registered in 3 cases (about 3%). The process was unilateral with the lesions of the higher lobe of the lungs. In 2006 PCP was founded in 20% of observations of tuberculosis of breathing organs. In the second group was a registered bilateral lesion of the lungs with the localization of the process more than in 3 lobes. Histological research showed that separating the zone of caseous necrosis polymorphocellular torus was introduced by lymphocytes, macrophages, neutrophils, few epithelioidcells. The density of demarcating cellular infiltrate in the observation of 2nd group was significantly lower than that of the 1st group. SCP developing in the terminal stage of another forms of tuberculosis: infiltrate, acute cavernous, fibrocavernous. The growth of the frequency of SCP with 23.2% in the 1st group, up to 68.6% in the 2nd group. In the most cases SCP was stipulated by progressiveness of fibrocavernous tuberculosis (60.8% in 1986 and 86% in 2006). Conclusion. For the last time the growth of observations with caseous pneumonia is registered. One of the structural peculiarities of modern pulmonary tuberculosis in the development of the (SCP) which in the most cases complicates the course of fibrocavernous tuberculosis. This situation from the point of the teaching about pathomorphism may be interpreted as a negative stage of pathomorphism of tuberculosis.

PP4-284
CYSTIC ECHINOCOCCOSIS OF THE THYROID GLAND: A CASE REPORT AND DIAGNOSTIC PROBLEMS
Kemal Behzatoglu, Pelin Yıldız, Sule Canberk, Meltem Oznur, Gulben Erdem Huq, Erol Rustu Bozkurt
Istanbul Educational and Research Hospital, Turkey

In humans, cystic echinococcosis is one of the most serious helminthic diseases worldwide. The larval stages (cysts) of Echinococcus granulosis are mainly located in liver and lung. Other locations of infection are rare, which may occasionally hinder its diagnosis. A 65-year-old woman was admitted with a swelling in the right lobe of the thyroid gland of 2 years duration. Laboratory investigations and thyroid function were normal. Thyroid scanning showed a cold nodule in the lower pole of the right thyroid lobe. Thyroid ultrasonography showed multiple cystic nodules in the thyroid gland. To maka a differential diagnosis of the thyroid nodule, fine-needle aspiration biopsy (FNA) was performed and diagnosed as nonspesific inflammation. During aspiration biopsy, the patient did not present a clinical picture of anaphylactic reaction. Subtotal thyroidectomy was carried out and histopathologic examnation revealed a hydatid cyst. Subsequent to the histologic diagnosis (which was hydadit cyst), review of the FNA biopsy showed acellular laminated fragments; it had not been taken into consideration before. In endemic regions-like our country, patients presenting with cystic nodular lesions of thyroid-unusual location of hydatidosis- hydatic cyst should be keept in mind.

PP4-285
GASTRIC PRESENTATION OF STRONGYLOIDIASIS IN A DIABETIC PATIENT
Safak Ersoz, Havvanur Turgutalp, Remzi Akdogan,
Ismail Saygın, Umit Cobanoglu, Sevdegul Mungan, Orhan Ozgur
Karadeniz Technical University Medical Faculty,Trabzon,Turkey

Strongyloides stercoralis is a common intestinal helminth. Strongyloidiasis is a worldwide parasitic infection affecting approximately 75 million people. Prevalence of up to 25% has been reported. In healthy hosts, the parasite usually does not cause any symptoms, or only mild symptoms those are limited to the small intestine. In immunocompromised host, massive infection may occur, that is causing hyperinfection syndrome or disseminated strongyloidiasis. There are few reports of gastric involvement, especially presenting as pylor stenosis. A 78 year-old male patient had admitted to local city hospital with complaints of epigastric pain, nausea and vomiting. He had those complaints since two months. An upper gastrointestinal endoscopy had revealed hyperemia and erosions at gastric antrum. The patient had been discharged after a twenty days treatment period with relieve of the symptoms. After a short period the same symptoms showed a recurrance and he was referred to our university hospital. Meanwhile he had a weight loss of 25 kg. At his admittance, physical examination was almost normal other than peripheral edema. Laboratory examination revealed a hyperglicemia of 161 mg/dl and hypokalemia with hypochloremia. An upper gastrointestinal endoscopic examination was performed again. In this procedure eosophagitis at the lower segment of eosophagus was observed. Cardia and fundus were normal, while edema was observed at corpus and antrum with pylor stenosis. In histopathological examination of gastric biopsy, adult forms of Strongyloides stercoralis were found in gland lumen and lamina propria accompained with mixed inflamatory cell infiltration and regenerative changes at gastric epithelium. As he refused the therapy, the patient did not receive a spesific treatment for strongyloidiasis. Here we report a case with diabetes mellitus and gastric strongyloidiasis leading to pylor stenosis.

[3] Baskent University Medical Faculty Department of General Surgery, Turkey

Hydatid cyst is a parasitic disease, formed by Echinococcus granulosus, which is a social and economic problem in developing countries that effects public health directly. Liver and lungs are the most common locations of hydatid cyst but it may develop in any part of the body. In this study we analyzed 154 cyst hydatid and presented cases with uncommon locations as spleen, bone, intraarterial, ovary, adrenal, heart, mesenteric, retroperitoneal, subcutaneous tissue, breast, intramuscular tissue. We concluded that the diagosis of cyst hydatic should be considered in patient with cystic mass if the patient lives in geographic region that have a high risk for Echinococcus granulosus or migrated from or visited an endemic area.

[4] Unité Médicale des Maladies Infectieuses et Tropicales, Centre Hospitalier de Cayenne, Cayenne Cedex, French Guiana

A 40-year-old woman had, received yellow fever vaccination before her travel in French Guiana, presented after 10 days at emergency room of Regional Hospital of Cayenne (French Guiana) with complaints of fever and general malaise since 3 days. On examination, she has arthralgia, arm and leg ecchymosis and petechia, paleness mucosa, headache and discrete confusion. Laboratory test showed an haemolytic anaemia, an thrombopenia in favour a thrombotic thrombocytopenic purpura (TTP)(Moschowitz Syndrom). Evolution go to worse at death the 09 January 2006 and autopsy was performed revealed widespread microthrombosis of small vessels in all the examined organs in conformity with suspected TTP. The onset of symptoms soon after vaccination and failure to identify any other cause suggest that the TTP was an adverse reaction to the yellow fever vaccine.

PP4-305
SHOCK SYNDROME AND ADVERSE OUTCOME OF A CASE OF DENGUE FEVER CAUSED BY DEN-2 VIRUS INAUGURAL OF 2006 EPIDEMIC DISEASES IN FRENCH GUIANA

Angela Fior[1], Philippe Dussart[2], Abdelfatteh Zeddini[1], Félix Djossou[3]
[1] Service d'Anatomie et Cytologie Pathologique, Centre Hospitalier de Cayenne, Cayenne Cedex, French Guiana
[2] Laboratoire de Virologie, Institut Pasteur de la Guyane, B. P. 6010, Cayenne, French Guiana
[3] Unité Médicale des Maladies Infectieuses et Tropicales, Centre Hospitalier de Cayenne, Cayenne Cedex, French Guiana

If in neighbouring states, French Guiana is regularly affected all 2 at 6 years for a Dengue fever epidemiological crisis because local conditions are more favourable at Aedes aegypti development. The four serotypes of Dengue fever are present in French Guiana but DEN-2 was more predominant in 2006 strong epidemic. This affected more than 13 700 subjects and caused four death directly release with DEN-2. In this epidemic, our cases was the second death, a four years old child, death at home on night 30-31 March. He consult tree days ago and present any sign of gravity. This case take all measures to confirm aggressively of serotype and more then 180 diseased was recovered with 57% by strong non hemorrhagic form. Blood samples not obtained, the aim of post mortem investigations was taking tissues and liquids for Dengue fever confirmation from Pasteur Institute of Guiana. These demonstrate a typical hypovolemic Dengue shock syndrome with poorly hepatic hemorrhagic lesions but diffuses acute histological alterations of sweat acini's.

INTRODUCING PATHONET, A VIRTUAL HISTOLOGY LABORATORY

László Fónyad[1], Attila Zalatnai[2], Béla Molnár[3], László Kopper[2]
[1] Department of Pathology, Semmelweis University, 3DHISTECH Ltd., Budapest, Hungary
[2] Department of Pathology, Semmelweis University, Hungary
[3] Department of Internal Medicine, Semmelweis University, 3DHISTECH Ltd., Budapest , Hungary

BACKGROUND Virtual microscopy has become accepted, both as a new research tool and as an application used in education and in routine surgical pathology as well. After the problem of high-quality, whole-slide-digitizing was solved we are working to built up a holistic virtual histology laboratory. AIMS During the past few years the staff of the 1. Dept. of Pathology, Semmelweis University, in association with 3DHISTECH Ltd. were continuously developing a web portal, mainly for pathologists, aiming to provide a platform, to share and consultate problematic cases, and to built up an open access knowledge pool, where interesting cases are to be discussed and virtual slide seminars are organized. As an University institute we also emphasize to provide easy-to-handle and up-to-date web-based digital reference book for our students, thus we uploaded both undergraduate and postgraduate educational materials, for medics and for pathology residents as well. The aim of this presentation is to acquaint the features of this virtual meeting place: Pathonet RESULTS Till the submission of this abstract, about a hundred users have registered on the portal, we had about 9000 page loads from abut 900 unique and 500 returning visitors so far which is a doubling in the number of visitors in a year. Till 2006, the portal guarantees the background for the Hungarian Slide Seminars. Previewing and the discussion of the cases in our institute is no longer made with optical, but the virtual slides. Preparing for exams the students can use another feature on the portal. In an e-book form the uploaded slides of the educational material will be completed with texts, macroimages and comments. From the beginning of the next semester the whole concept of histology teaching will be changed in our Institute. Instead of the optical microscopes we use computers and via the portal the students could revise the slides after practices and before exams. Recently we have developed a new, completely free feature for our registered users on our portal for editing cases and uploading whole slides on Pathonet server to use it as reference to their publications. The server generates a unique link to the slide. Installing the MiraxViewer and typing the link to a webbrowser or clicking on it if it appears on the online form of a journal article, the slide will open in a MiraxViewer window. CONCLUSIONS Pathonet portal is a user-friendly meeting place for pathologist.

PP4-289
"I'AM STILL LEARNING" – INTRODUCING E-SCHOOL, A NEW WAY TO STUDY PATHOLOGY

László Fónyad[1], Attila Zalatnai[2], Levente Ficsór[3], Máté Montvai[3], Béla Molnár[4], László Kopper[2]
[1] Department of Pathology, Semmelweis University, 3DHISTECH Ltd. , Budapest, Hungary
[2] Department of Pathology, Semmelweis University, Hungary
[3] 3DHISTECH Ltd. , Budapest, Hungary
[4] Department of Internal Medicine, Semmelweis University, 3DHISTECH Ltd. , Budapest, Hungary

BACKGROUND During the past years the developments on the field of virtual microscopy have reached a professionally accepted higher level. Now the question is no longer weather the digital microscope could be applied equivalently to the conventional microscopes but what additional benefits can we gain using the digital slides. One of the most popular field of using digital slides is education. As a University Institute,

teaching pathology, we also encounter the most serious challenges, measuring up to the expectations of our prime privileged customers, the students. AIMS On the 8th European Congress on Telepathology and 2nd International Congress on Virtual Microscopy we reported our first experiences on building up our telepathological workstation and testing it for gradual education. After the success of virtual microscopy on pilot histology practices we decided to replace the conventional microscopes to computers and in strong cooperation with 3DHISTECH Ltd. to design and create an educational software: E-School. RESULTS The E-School software-package now contains 3 major parts: an encoder, a viewer and an E-School server software. With the encoder you can encrypt your document, written in html format, so Universities or publishers of any kind can protect their materials and can ask license fee for them. Of course these documents can be free as well. The viewer can decode the documents and in case of non-free materials, via the E-School server the product keys could be handled by the product owners. The major advantage of the system is that digital slides, stored on a slide server or on DVD can be linked to the document allowing entire slide access. There is a self-testing and an exam module in the software-package as well. The educational material of our Institute is now fully digitized and a histology textbook is written with the E-School softwer. On the beginning of the next semester we launch our digital histology lab in regular practice. CONCLUSIONS In the era of e-learning it is outmost important for Univerities to provide a streamlined platform for her students where they can benefit all the possibilities of the advances in computer sciences. The E-School system is a good solution for compiling educational material for students and as the documents could be encrypted as well, it is also appropriate for publishing e-books of histology with real rich-in-details images and entire slide access.

AUTOMATED FLUORESCENT SLIDE SCANNING

Viktor Sebestyén Varga[1], Levente Ficsor[2], Viktor Kamarás[1], Béla Molnár[2], Zsolt Tulassay[2]
[1]3DHISTECH Ltd., Hungary
[2] Second Department of Medicine, Semmelweis University, Budapest, Hungary

Introductions: Today there are several whole slide imaging systems for bright field, but there is no product supporting fluorescence scanning. To digitize the daily workload of a routine histology laboratory walk away automation is needed. Our goal was to develop a system which is capable of scanning both bright field and fluorescent samples automatically. Materials: We used a Mirax Scan (Carl Zeiss MicroImaging, Thornwood, NY) whole slide imager with an optional filter changer with fluorescent filters for DAPI, FITC and Rhodamine. The light source was an X-Cite 120 metal halide lamp (EXFO, Vanier, QC). The Marlin F-146C (Allied Vision Technologies, Stadtroda, Germany) fire wire camera was applied for image capture. A Celsius PC (Fujitsu Siemens Computers, Maarssen, Netherlands) with dual 3.2 GHz CPU and 3 GB RAM was used for controlling the scanner microscope. We developed the software with Visual Studio (Microsoft, Redmond, WA) and C++ Builder (Borland Software, Scotts Valley, CA). Methods: Mirax Scan uses a preview camera to locate tissue samples on a slide. Fluorescent samples are usually invisible to such a low magnification camera in normal illumination. To overcomes this issue users are required to mark the sample with a marker pen. At fluorescent slides the exposure times can vary from few milliseconds to several seconds and the different channels have different exposure times. In the selected area Mirax Scan is auto focusing on grid points using a special algorithm developed for fluorescence, which is continuously adjusting the exposure time. On the focused field of views exposure times are measured for every selected fluorescent channel. The sample is then digitized using an interpolated focus map and the shortest exposure time in every channel respectively. Results: A 10 x 10 mm sample using a Plan-Apochromat 20x / 0.8NA objective with a resolution of 0.23 µm / pixel in 3 channels, with exposure times of 52, 100 and 48 ms was scanned in 40 minutes. The system was tested with success in a walk away scanning mode with 30 slides yielding focused images and slides. Field of view black and white image compensation was not necessary. Conclusions: Fully automated multichannel, fluorescent scanning is feasible. Longer scanning times compared to bright field are inevitable but acceptable since the required scanning volume is much lower on average. With further algorithm development and the use of cameras suited for fluorescence scanning can be sped up.

PARAGOMINUS WESTERMANI: CASE REPORT

Euridice Robles Perez[1], Ericka Sagrario Peña Mirabal[2]
[1] Instituto Nacional de Enfermedades Respiratorias, Mexico
[2] Instituto Nacinal de Enfermedades Respiratorias, Mexico

Male patient, 80 years old, history of pulmonary tuberculosis (class III, ATS) and diabetes type II. The patient started three days before hospital admission with cough and dyspnea. The day of his admission he presented fever and acute respiratory failure. Arterial blood gas analysis showed respiratory acidosis and blood sample with eosinophilia. He required orotracheal intubations and mechanical ventilatory support. Chest x-ray showed pulmonary bilateral reticulonodular infiltrates and bronchiectasis. The patient died 24 hours after hospital admission. At the post-mortem examination we found histological changes due to diabetes mellitus and tuberculosis. Lung tissue showed bronchiectasis with colonization by aspergillus sp. And paragominus westermani Paragonimiasis is a parasite disease with low frequency of presentation in Mexico, is acquired by eating row crab meat. The body sites affected are lungs and brain. Differential diagnosis is with tuberculosis and fasciolosis. Treatment is albendazol.

PP4-293
ADRENAL ADENOMATOID TUMOR

Liapis George[1], Evangelou Kostas[1], Alexandrou Paraskevi[1], Felekouras Evangelos[2], Delladetsima Ioanna[1]
[1] Pathology Department Laiko General Hospital University of Athens, Greece
[2] 1st Department of Surgery University of Athens Greece

Adenomatoid tumors are benign neoplasms of mesothelial origin more commonly observed in the paratesticular area of the testis and corpus uterus. Extragenital adenomatoid tumors have also been described in unusual sites such as heart, mesentery, pleura, lymph nodes and adrenal glands. We report on a case of adrenal adenomatoid tumor (AAT) incidentally discovered in a thirty two year-old woman. A surgical operation was performed. Grossly, a greyish-white, solid tumor measuring 6.5 x 5.2 x 3.5 cm occupied almost the entire adrenal gland while only a thin rim of adrenal tissue was preserved. Microscopically, the tumor was composed of anastomosing tubules lined by flat or cuboidal cells with scanty or moderate eosinophilic cytoplasm. An ensuing intricate tubular network resembled hemangioma. Cells with prominent cytoplasmic vacuoles as well as spindle cells were also present. The intervening stroma was scanty and was composed focally of smooth muscle fascicles. At the periphery of the tumor collections of lymphocytes with occasional follicle formation were seen. Immunohistochemically the neoplastic cells were strongly positive for calretinin, cytokeratin 5/6 and WT1, whereas they were negative for HMB-45, SMA, CD34, estrogen and progesterone receptors. In the reviewed literature 29 cases of AAT have been reported, all but one referring to men. As far as histogenesis is concerned, in our case there are no indications of hormonal influence on tumor progression while the development of the tumor within the adrenal gland may be attributed to the common mesodermal origin.

[2] Verge de la Cinta Hospital, Informatics Department, Spain

Background: Manual quantification of immunohistochemical stained cells is the most frequent method in the current practice in pathology. To avoid the manual subjectivity, a number of automated and semi-automated processes have been previously developed and described. In the present study, we have developed different semi-automated processes in order to quantify different immunohistochemical markers. To obtain a gold-standard reference, we have performed manual quantifications and we have also evaluated inter and intra-observer variability. Method: 196 digital color images were obtained from sections of Hodgkin's lymphoma biopsies and stained with various nuclear, cytoplasmatic and membrane markers. Each image was manually quantified twice by 3 different observers. To analyse the images, we developed a specific macro for each marker with a commercial analysis software. The global dataset obtained with the software, were dropped to an Excel Datasheet, where the number of cells was obtained after we introduced different corrector factors. To evaluate the agreement degree between manual and semi-automated method and to quantify our intra and inter-observers variability, a comparative statistical analysis was performed with SPSS 11.0. Results: Globally, the variability was higher for intra-observers than for inter-observers counts, except in nuclear stains were both types of variations have similar differences. The comparison between semi-automated and manual methods shows that both methods have the same way of cell quantification. Both manual and automatic quantification showed a higher variation when the images contained more than 100 positive nuclei. Discussion: This study quantifies variation observed in manual quantification and shows that the different semi-automated procedures developed for each marker in our laboratory represent a valid alternative to manual quantification. (PI 04/1440, 04/1467, 05/1527).

NEW APPROACH FOR AUTOMATIC QUANTIFICATION OF IMMUNOHISTOCHEMICAL NUCLEAR MARKERS IN DIGITAL IMAGES

Joaquín Jaén[1], Carlos López[1], Marylène Lejeune[1], Patricia Escrivà[1], Maria Teresa Salvadó[1], Ramón Bosch[1], Lluís Pons[1], Jordi Baucells[2], Xavier Cugat[2], Jordi Roig[2], Tomás Alvaro[1]
[1] Verge de la Cinta Hospital, Pathology Department, Spain
[2] Verge de la Cinta Hospital, Informatics Department, Spain

Background: Several procedures of digital image analysis have been developed for quantitative evaluation of nuclear immunohistochemical markers with prognostic, diagnostic and therapeutic significance in current medical practice. To our knowledge, do not exist effective algorithms that permit to obtain a precise cell quantification in digital images with a high grade of complexity. The aim of this study is to develop a new methodology capable to analyze correctly, images with high variability in their morphology, cellular density, stain intensity and cell distribution. Method: 118 digital images from 4 different immunohistochemical nuclear markers were captured with different grade of cell concentration and clusters composition. Two coordinated macros were elaborated to perform the automatic count of positive nuclei. The first macro was developed with a commercial software that allows the modification and segmentation of the images. All extracted information was dropped to an Excel datasheet, where we have developed a macro with Visual Basic and introduced different algorithms that manage the dataset obtaining a final number of positive nuclei on each image. All statistical analysis was performed with SPSS 11.0. Results: t-Student test, Spearman correlation and ICC, showed no significant differences between the manual and the automatic count, whatever the image complexity. Kaplan-Meier and Bland Altman graphic representations indicate that cluster composition and a high nuclei density, increase variability on both types of count, and globally in more than 90% of images, automatic count was similar to the manual. Conclusion: This study, describes a new methodology for the automatic count of digital images for different immunohistochemical nuclear markers. This method improves the quantification of images with a high complexity in their nuclear composition. Variability observed between human and automatic count are the same as inter or intra-observer variability, which is accepted in the current clinical practice. (PI 04/1440, 04/1467, 05/1527).

EFFECTS OF DIGITAL IMAGE COMPRESSION ON COMPUTER-ASSISTED IMAGE QUANTIFICATION OF IMMUNOHISTOCHEMICAL STAINED CELL NUCLEI

Carlos López[1], Joaquín Jaén[1], Marylene Lejeune[1], Patricia Escrivà[1], Maria Teresa Salvadó[1], Ramón Bosch[1], Lluís Pons[1], Jordi Baucells[2], Xavier Cugat[2], Jordi Roig[2], Tomás Alvaro[1]
[1] Verge de la Cinta Hospital, Pathology Department, Spain
[2] Verge de la Cinta Hospital, Informatics Department, Spain

Background: The analysis of digital images and standard compression algorithms in current clinical practice has been used since some years ago. Image compression may reduce the amount of computer memory required for store images. The consequences of image compression have been previously evaluated on different diagnostic techniques. The aim of this study is to analyse the consequences of computer-assisted quantification, between uncompressed Tiff format and different levels of image compression in Jpeg format of immunohistochemical stained cells. Method: Digital images were captured with the software Leica IM50 4.0, in Tiff format from tissue samples stained with immunohistochemical markers, Ki67 (n=24) and FOXP3 (n=24). In a second step Tiff images were converted with the software ACDSee 6.0 to Jpeg files with a compression factor of 0, 50 and 100%. All the captured and converted images (n=196), were analysed with two coordinated macros developed with an image analysis software and an Excel datasheet. Quantified parameters were the total stained positive area and the number of positive nuclei. Tiff images results were compared with the different compression factor in Jpeg format, with Kaplan-Meier and Bland Altman plots using SPSS 11.5 Statistical Software. Results: Globally, variations in the quantification of positive stained areas between Tiff and the different compressed files are similar. On the other hand, cell count differences are lower with a compression factor of 0% and higher with a 50 or 100% of compression. Nevertheless, all compressed formats have a similar variability when images have less than 100 nuclei, and in this case, this variability is lower than globally. Conclusion: This descriptive study shows that image compression is a source of variation in automatic count of digital images. In these conditions, image compression should be omitted for immunohistochemical digital image quantification, overall in images with more than 100 nuclei. (PI 04/1440, 04/1467, 05/1527)

PP4-298

MUCOEPIDERMOID PAPILLOMA OF CONJUNCTIVA

Cem Comunoglu[1], Ahmet Midi[2], Akin Banaz[3], Onder Peker[2]
[1] Oruc Pathology Laboratory, Turkey
[2] Maltepe University, School of Medicine, Department of Pathology, Turkey
[3] Dunya Goz Hospital, Department of Eye Diseases, Turkey

Background: Mucoepidermoid papilloma of conjunctiva is a papillary lesion. Columnar cells and Goblet cells line these papillary structures. Exophytic mucoepidermoid papilloma of conjunctiva has not been reported in the literature previously. Case report: Forty-three year-old male patient presented with a cojunctival lesion. Excisional biopsy was performed. Macroscopically the greatest dimension of the tumor measured 0,9 cm. Microscopically, a papillary lesion was seen. Lining epithelium was columnar cells and Goblet cells. A diagnosis of mucoepidermoid papilloma of conjunctiva was given. Conclusion: Conjunctival mucoepidermoid carcinomas have been described but there is no evidence of the presence of any precursor lesions. Two separate case reports describe inverted mucoepidermoid papillomas. Present case had a papillary configuration and did not contain an inverted component. Although conjunctival papillomas show HPV effects in present case cytopathic HPV effects could not be detected. It can be predicted that these lesions do not carry a potential of malignancy but because there is no previous information about biological behavior potential of these lesions, strict clinical follow-up is recommended. Whether mucoepidermoid papilloma is a precursor lesion of mucoepidermoid carcinoma of conjunctiva is a problematic issue which should be solved in future reports.

PP4-299

OXALATE CRYSTAL DEPOSITION ASSOCIATED WITH MULTIPLE INFARCTION IN THE SPLEEN OF A PATIENT WITH NON-CIRRHOTIC PORTAL HYPERTENSION

Engin Cigercioglullari[1], Suha Goksel[1], Abdullah Sonsuz[2], Hasan Tasci[3]
[1] Department of Pathology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey
[2] Department of Gastroenterolgy and Hepatology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey
[3] Department of General Surgery, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey

Splenic infarction is an unusual finding of cirrhotic or non-cirrhotic portal hypertension. Dystrophic oxalosis can be seen in thyroid, breast, and retina in many conditions. Oxalate deposition is well known in renal pathology, and had been reported in many organs in patients with primary and secondary oxalosis. We couldn't find oxalate deposition in the spleen in the literature. The presented case was a 59-year-old man with non-cirrhotic portal hypertension. Pathological examination of splenectomy revealed moderate splenomegali, multifocal infarctoid areas causing capsular retraction. Microscopic investigation revealed multifocal infarction of different ages. Gandy-gamma body formations were also present. Surprisingly, multifocal heavy oxalate crystal depositions around the necrotic area, and perivacular spaces in vessels nearest to infarction were seen. With the presentation of this case, spleen can be included in the oxalate depositing organs. The oxalate deposition in the spleen may be dystrophic due to infarction, or may also be the first sign of hyperoxaluria.

INTRODUCTION: Castleman's disease, or angiofollicular lymph node hyperplasia, is a relatively rare disorder characterized by benign proliferation of lymphoid tissue. Castleman's disease is usually related to chronic herpes virus infection and it is usually localized in the mediastinum. Retroperitoneal and especially pararenal localization is very rare. CASE REPORT: A retroperitoneal mass was incidentally found on the abdominal ultrasonographic imaging of a 51 year-old woman. Surgery was planned with a preoperative diagnosis of non-functioning adrenal gland neoplasia. The tumor was removed by retroperitoneal laparoscopic adrenalectomy. In gross examination the tumor was an encapsulated, homogenous pale colored mass measuring 4.0x5.5x5.5 cm. Microscopic examination showed a histologically normal adrenal gland, and a large lymph node rich in vascular structures. The nodal architecture was altered by an increased number of lymphoid follicles. These lymphoid follicles were unusually small and their germinal centers consisted of radially penetrating capillaries, some of which formed a characteristic "lollypop" structure. Many of these capillaries were surrounded by wide cuffs of hyaline substance. Multiple concentric layers of mature lymphocytes were surrounding the small germinal centers. Thus, the tumor was pathologically diagnosed as hyaline-vascular type angiofollicular lymph node hyperplasia (Castleman's disease) of a peri-adrenal gland lymph node. DISCUSSION: In this poster, we present a case of Castleman's disease localized in the retroperioneum next to the uninvolved adrenal and the kidney. Although it is an unusual localization Castleman's disease should be included in the differential diagnosis of retroperitoneal masses.

[3] Istanbul University, Istanbul Faculty of Medicine, Department of Dermatology, and Leprosy and Venereal Diseases Research Center, Turkey

BACKGROUND: Diagnosis of leprosy is most commonly based on the clinical signs and symptoms. Laboratory confirmation of leprosy requires the demonstration of acid-fast bacilli in a skin biopsy. We report herein 3 cases which were diagnosed as borderline lepromatous (BL), lepromatous (LL) and borderline tuberculoid leprosy (BT) last year in our department. Among them, only one case was clinically suspected as leprosy before the histopathological examination. REPORT OF THE CASES: Case 1: A 26-year-old man had been complaining of spontaneously regressing and recurrent erythematous anesthetic macules and infiltrated lesions on his forearms and legs since 2 months. N. radialis and ulnaris were bilaterally palpable. Clinically vasculitis, Sweet syndrome and syphilis were suspected and a punch biopsy was done. The histopathological diagnosis was BL. Case 2: A 56-year-old man had been suffering from erythematous macules and pathches on the whole body and nasal congestion

since 3 years. N. ulnaris, radialis, poplitealis and auricularis were bilaterally palpable. Clinical diagnosis was LL, which was fully compatible with the histopathological examination of the punch biopsy. Case 3: A 45-year-old man had pale anesthetic macular lesions with erythematous border on his face, arms and back since 4 years. Clinically erythema annulare santrifugum and erythema dischromicum perstans were suspected and a punch biopsy was done. The histopathological diagnosis was BT. CONCLUSION: Leprosy is endemic in tropical and subtropical Asia, Africa, Central and South America and the Pacific regions. In Turkey, 2 595 cases were registered to our leprosy research center. Seven new cases were detected last year. Three of them, which were diagnosed in our department, were presented. As reported to WHO by 115 countries in 2006, 296 499 new cases were detected last year. Clinically, the skin lesions often resemble those of lupus erythematosus, sarcoidosis, syphilis, erythema nodosum, erythema multiforme and cutaneous tuberculosis. The most effective way of preventing disabilities in leprosy, as well as preventing further transmission of the disease, lies in early diagnosis and treatment with multi-drug therapy.

Primary carcinoma with osteoclast-like multinucleated giant cells is a very rare tumor of the breast. We present the light and electronmicroscopic features of a case of invasive ductal carcinoma containing osteoclast-like multinucleated giant cells with regard to the histogenesis (origin) of giant cells. A 48-year-old woman with a 3 cm-mass in the middle part of her right breast was admitted to our hospital, and she underwent modified radical mastectomy. Macroscopically the tumor was well circumscribed with a grey-white cut surface. Microscopically the tumor was invasive ductal carcinoma with cribriform features and many osteoclast-like multinucleated giant cells between the neoplastic glands and within their lumina. Of the eleven axillary lymph nodes dissected, two were metastatic. The lymph-node metastasis also contained osteoclast-like multinucleated giant cells and stromal reactions. On immunohistochemical analysis, multinucleated giant cells were positive for CD68 and alpha-1-antitrypsin and negative for keratins, revealing their histiocytic origin. Neoplastic cells were positive for keratins and estrogen and progesteron receptors, and negative for c-erb B2. Ultrastructural analysis revealed multinucleated cells with many lysosomes, supporting their histiocytic origin, in vicinity of ordinary glandular cells, elsewhere intermixed with them. They contained neither cell junctions nor microvilli. We were able to detect cytoplasmic fusion of some mononuclear cells of the same character. We conclude that osteoclast-like giant cells are formed by fusion of mononuclear histiocytic cells.

REVIEW AND PERSPECTIVE

Melanocytic nevi simulant of melanoma with medicolegal relevance

Guido Massi

Received: 20 March 2007 / Revised: 15 June 2007 / Accepted: 18 June 2007 / Published online: 26 July 2007

Abstract A group of melanocytic benign nevi are prone to be misdiagnosed as nodular or superficial spreading melanoma. This review illustrates the most frequent forms of these nevi in direct comparison with their malignant morphologic counterparts. The nevi are: hyper-cellular form of common nevus to be distinguished from nevoid melanoma, Spitz nevus (vs spitzoid melanoma), Reed nevus (vs melanoma with features of Reed nevus), cellular atypical blue nevus (vs melanoma on blue nevus), acral nevus (vs acral melanoma), Clark dysplastic nevus (vs superficial spreading melanoma), desmoplastic nevi (vs desmoplastic melanoma), benign proliferative nodules in congenital nevi (vs melanoma on congenital nevi), epithelioid blue nevus (vs animal type melanoma) and regressed nevus (vs regressed melanoma). For each single 'pair' of morphological look-alikes, a specific set of morphological, immunohistochemical and genetic criteria is provided.

Keywords Melanoma · Melanocytic nevi · Simulators · Medicolegal lawsuit

Today, melanoma is the most frequent cause of medicolegal lawsuit for pathologists [144, 145]. This is because melanoma frequently has a deceptively bland nevus-like histological appearance, and it is doomed to be overlooked as a nevus, especially by pathologists not familiar with dermatopathology. All too aware of this, pathologists today tend to overdiagnose a melanoma whenever they come across a lesion that even slightly deviates from the ordinary. This overdiagnosis, although less catastrophic than the underestimation of a melanoma, has ominous consequences for the patient. In fact, enlargement of the surgical excision, lymph node sentinel procedure and systemic therapy are incapacitating therapies, and they should be spared to anyone not bearing a true malignant melanoma. Presented here is a review of benign melanocytic lesions very similar to malignant melanoma from an architectural or cytological point of view. This study is restricted to lesions with an intra-dermal component that can be confused with an invasive form of melanoma eligible for aggressive therapy. The choice and hierarchy of the items are based on my own experience on cases of benign lesions most frequently misdiagnosed as invasive melanoma by myself and by other colleagues.

The different entities are here presented on the hypothesis that each form of nevus has its own morphological malignant counterpart (Table 1) so that the differential diagnosis must be done by comparing the characteristics of the two morphological look-alikes that have their own peculiar histological characteristics (Table 2).

Nevi with high cellular density *vs* nevoid melanoma

A small but defined group of entirely benign lesions can be misdiagnosed as nevoid melanoma [127], a form of melanoma so named because of its striking cytological and architectural similarity with a common nevus. The lowest common denominator of such nevi is their growth in large solid sheets of cells without interposed collagen fibres, a pattern that is indeed one of the main clues for the diagnosis of nevoid melanoma [86].

The first type of nevus, which is likely to be confused with nevoid melanoma, is a cellular variant of a fairly common nevus popularized by Ackerman as Unna nevus

Table 1 Differential diagnosis between melanocytic nevi and their malignant simulators

Nevi		Melanomas
Common nevus	vs	Nevoid melanoma
Spitz nevus	vs	Spitzoid melanoma
Reed nevus	vs	Melanoma with features of Reed nevus
Common blue nevus	vs	Melanoma with features of blue nevus
Cellular Blue nevus	vs	Melanoma developed on blue nevus
Acral lentiginous nevus	vs	Acral lentiginous melanoma
Dysplastic Clark's nevus	vs	Superficial spreading melanoma ('lentiginous melanoma')
Desmoplastic nevus	vs	Desmoplastic melanoma
Spindle cell nevus	vs	Spindle cell melanoma
Proliferative nodules	vs	Intra-dermal melanoma in congenital nevus
Deep Penetrating Nevus	vs	Melanoma with features of deep penetrating nevus (plexiform melanoma)
Epithelioid blue nevus	vs	Animal-type melanoma
Regressing nevus	vs	Regressing melanoma

To minimize errors in diagnosing melanocytic neoplasms, one should always remember that for each single nevus, there is a melanomatous simulator, very close to its benign counterpart from an architectural and cytological point of view. The differential diagnosis has to be placed between the two look-alikes (i.e. between Spitz nevus and spitzoid melanoma) and not generically between nevus and melanoma. For each 'pair,' there is a specific set of characteristics and diagnostic criteria.

Table 2 Melanocytic nevi and their malignant simulators—main clues for the differential diagnosis

Nevi	Melanomas
Common nevus	Nevoid melanoma
Cellular monomorphism, dispersed nuclear chromatin, pinpoint nucleoli	Cellular pleomorphism, clumped nuclear chromatin, prominent nucleoli
Melanocytes interspersed among collagen fibres	Solid pattern of growth
Inconspicuous junctional component	Melanoma in situ-like pattern at the junction
No mitoses at the bottom of the lesion	Mitoses at the bottom of the lesion
Spitz nevus	Spitzoid melanoma
Small size and sharp lateral circumscription of the lesion	Large size, poor lateral circumscription of the lesion
Low mitotic rate, no mitoses at the bottom	High mitotic rate, mitoses at the bottom
Pigment regularly distributed	Pigment irregularly scattered, pigment at the base of the lesion
Large and confluent Kamino bodies	No or small Kamino bodies
Symmetric epidermal hyperplasia	Irregular epidermal alterations
Pagetoid spread only at the centre of the lesion	Pagetoid spread at the borders of the lesion
No expansive nodules in the dermis	Expansive nodules in the dermis and at the junction
FAS, P53, Bcl-2 scantly expressed, no chromosomal aberrations	FAS, P53, Bcl-2 expressed also at the bottom, chromosomal aberrations
Reed nevus	Melanoma with features of Reed nevus
Youngsters, lesion on the lower part of the body, no signs of solar damage	Old patients, on the face, signs of solar damage
Preserved and elongated epidermal rete ridges	Epidermal rete ridges 'consumed'
Strict nuclear monomorphism, no nuclear hyperchomasia, no mitoses	Cellular pleomorphism, nuclear hyperchromatism, mitoses
Superficial dermis only involved	Deep dermis involvement
Cellular atypical blue nevus	Melanoma on blue nevus
Random cellular atypia	Widespread cellular atypia
No nodules or solid masses of atypical cells	Nodules or large masses of highly atypical cells
No necrosis, only rare mitoses	Cellular necrosis, necrosis en masse, mitoses in number, atypical mitoses
Common blue nevus	Melanoma with features of blue nevus
No or inconspicuous junctional component	Melanoma in situ at the junction
No cellular atypia, no mitoses	Widespread atypia, mitoses
Acral lentiginous nevus	Acral lentiginous melanoma
Young age of the patient, small size of the lesion	Old age of the patient, large size of the lesion
In the superficial dermis only	Medium and deep dermis involved

Table 2 (continued)

Nevi	Melanomas
Mostly nested pattern at the junction	Lentiginous pattern prevalent at the junction
Eccrine ducts involvement in nests	Eccrine ducts involvement in a lentiginous array
No genomic alterations	Genomic alterations
Displastic Clark's nevus	Superficial spreading melanoma
Youngsters, no signs of solar damage	Old patients, occasionally signs of solar damage
Discontinuous cellular atypia	Diffuse cellular and architectural atypia
No significant pagetoid spread	Significant pagetoid spread, also present at the shoulders of the lesion
Cells mostly in nests both at the junction and in the dermis	Prevalent lentiginous array at the junction
Desmoplastic nevus	Desmoplastic melanoma
In young adults, small and well circumscribed lesion	In elderly patients, large and poorly circumscribed lesion
Presence of component of ordinary nevus or Spitz nevus or blue nevus	No nevus remnants
No signs of solar damage	Solar elastosis inside, around and below the lesion (in sun exposed areas)
Rare or no lymphocytic follicles	Lymphocytic follicles inside and around the lesion
Spindle cell nevus	Spindle cell melanoma
Vertically oriented, elongated fascicles	Roundish nests at the junction and in the dermis
Regular epidermal hyperplasia	Irregular epidermal alterations
No solid sheets of cells	Solid growth pattern (large nodules or solid sheets of cells)
Sparse and superficial mitoses	Mitoses at the base of the lesion
Proliferative nodules in congenital nevus	Intra-dermal melanoma on congenital nevus
Frequent	Rare
Cellular monomorphism, low mitotic rate	Cellular pleomorphism, high mitotic rate
Roundish silhouette	Irregularly shaped silhouette
Collagen fibres interposed	Growth in solid pattern, collagen fibres obliterated
Numerical chromosomal aberration	Structural chromosomal aberrations
Deep penetrating nevus	Melanoma with features of deep penetrating nevus
Random cytological atypia	Subtle, but widespread cytological atypia
Inconspicuous or absent junctional component	Melanoma in situ at the junction
Epithelioid blue nevus	Animal-type melanoma
Young age of the patient, small size of the lesion	Usually in elders, large size of the lesion
Sharp circumscription of the borders	Poor lateral and deep circumscription
Uniform cytology, occasionally presence of other type of nevus	Cellular pleomorphism, no nevus remnants
Regressing nevus	Regressing melanoma
Young age of the patient, small size of the lesion, multiple lesions	Old age of the patient, large size of the lesion, single lesion
No nodules of atypical cells, only sparse mitoses	Nodules of atypical cells, combined with mitoses
Rete ridges thinned but preserved	Rete ridges annihilated

None of the above reported criteria is specific. Criteria should be always used in clusters, and clinic–pathologic correlation is mandatory. Cases with conflicting criteria are possible and have to be diagnosed on individual base.

(named after the scholar who first described it) but also known as papillated or verrucoid common nevus [2, 3]. Unna nevus is typically located on the trunk and usually does not pose any diagnostic challenge whatsoever. On rare occasions, however, as said above, especially in young adults, the lesion is hyper-cellular, and cells appear overcrowded and they seem to overlap each other (Fig. 1). Collagen fibres are absent in these large masses or solid sheets of cells. Because the differences from a nevoid melanoma can be subtle [27, 95, 107, 112], it is indeed wise to study these lesions carefully and through serial sections:

– The main clue is, in our opinion, the cytological details [109, 110, 146, 158]. In nevoid melanoma, there is, with few exceptions, an evident hyperchromatism throughout the neoplasm and the nuclear features are atypical: The nuclear membranes are irregularly thickened with clumps of chromatin stuck to it, chromatin is coarse, and the nucleolus is prominent. Nuclei and nucleoli do not modify in size, colour and characteristics as cells go deeper in the dermis. In many cells, a sort of nuclear groove is also present. These aspects are absent in hyper-cellular nevi: Nuclei are small and not hyperchromatic, the chromatin is finely dispersed and the nucleolus is pinpoint.
– Although in most of the lesion, the growth pattern of hyper-cellular nevus and nevoid melanoma is indistinguishable, in nevus, the cells at the bottom of the lesion are dispersed among collagen fibres as in ordinary nevi, while in nevoid melanoma, pushing margins are most

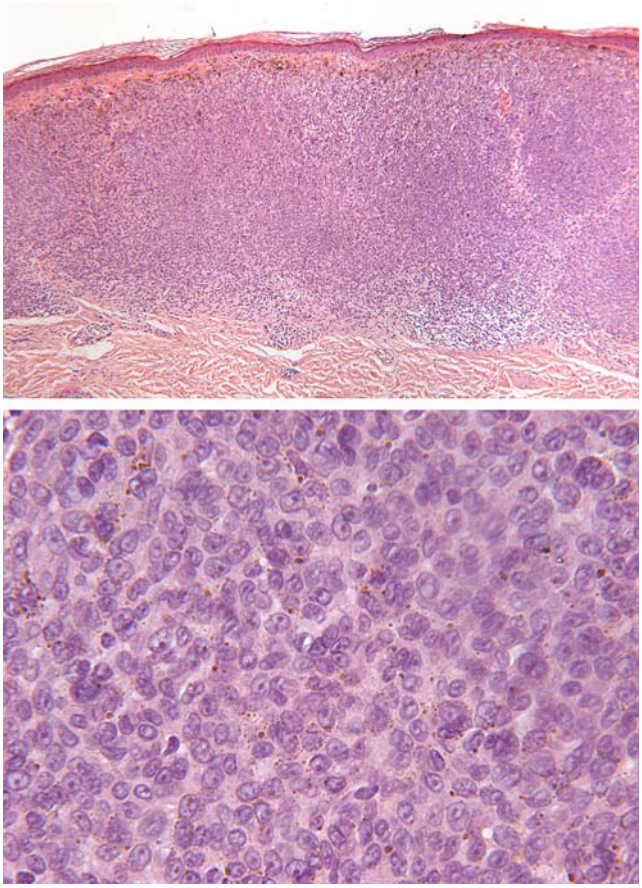

Fig. 1 This nevus shows a solid growth pattern similar to nevoid melanoma. In addition, cells seem overcrowded, and pigment is present at the base of the lesion. However, mitotic activity is nil, cells are monomorphous and have innocent looking nuclear details. The pigment is in coarse granules

frequently present. In melanoma, at the junction, large masses of cells seem to be directly connected with the epidermis or the epithelium of elongated or distorted hair follicles.

- In hyper-cellular nevi and nevoid melanomas, the junctional component can be identical; that is, it can be inconspicuous with only rare unremarkable melanocytes scattered at the basal layer [100]. However, melanoma frequently presents a melanoma in situ-like pattern at the junction: Atypical cells are aligned back-to-back substituting the keratinocytes of the basal layer. Atypical cells also involve the eccrine glands and follicular infundibulum. A subtle pagetoid spread (especially in the infundibulum) can be occasionally useful for the diagnosis of nevoid melanoma [154].
- Mitotic figures can be absent or undetectable both in highly cellular nevus and in nevoid melanomas. However, when present in large amounts (i.e. "easily found") or at the bottom of the lesion, they are a strong suggestion of melanoma, especially in a background of hyperchromatic cells.
- Pigment mostly present at the base always indicates a melanoma (this aspect regards the differential diagnosis between a common hyper-cellular nevus and a nevoid melanoma. Pigment at the base can be present in other forms of nevi). However, one should remember that nevoid melanoma can be entirely achromic.
- Immunohistochemistry could be helpful [73, 89, 90, 105, 121, 122]: In melanoma, HMB45 is positive in a number of cells at the deeper front of the lesion, a detail absent in nevi. The same can be said about Ki67, which, however, I use only at times. Authors report that p53 and cyclin D1 immunostain are useful, but also these immunostains seem to work much better in published papers than in everyday routine work [31]. It is clear, in my own opinion, that such ancillary techniques only provide an additional criterion that must be interpreted in the histological (and clinical) context.

Another form of cellular nevus similar to nevoid melanoma is a sub-set of congenital or acquired nevus termed neurocristic hamartoma, a melanocytic neoplasm present both in children and in adults, as a rule, in the head and neck regions [37, 92, 133]. Histologically, this entity has been reported in the literature in quite heterogeneous forms. However, in most cases, it is described as composed, at least in part, by solid sheets of round cells containing a spherical nucleus and regularly dispersed chromatin (Fig. 2). Cytoplasm is reduced to an almost undetectable pale rim, and cells have a lymphocytic appearance. The most striking aspect that can lead to the misdiagnosis of melanoma is the complete obliteration of the dermis, which is entirely occupied by a thick, patternless sheet of uniform nevus cells. The sub-cutis is also involved, on occasion massively, with cells infiltrating the adipose tissue. A few mitoses are also seen in these cases. These lesions are indeed rare but are likely to be diagnosed as melanomas (and to further complicate the matter, melanoma has been reported to develop in neurocristic hamartoma [102, 103]). To avoid this overdiagnosis of melanoma, the following criteria are adopted for the diagnosis of neurocristic hamartoma:

- Besides the large sheets of melanocytes, neurocristic hamartoma usually has other peculiarities namely, masses of spindle cells with collagen fibres interposed, features of neural differentiation [120] as well as aspects similar to cellular blue nevus, an entity to which neurocristic hamartoma is probably related [18, 65].
- In a few cases, the involvement of the pilar follicles is evident, and small dysmorphic follicles may be also present as the result of follicular induction (the so-called pilar neurocristic hamarthoma).

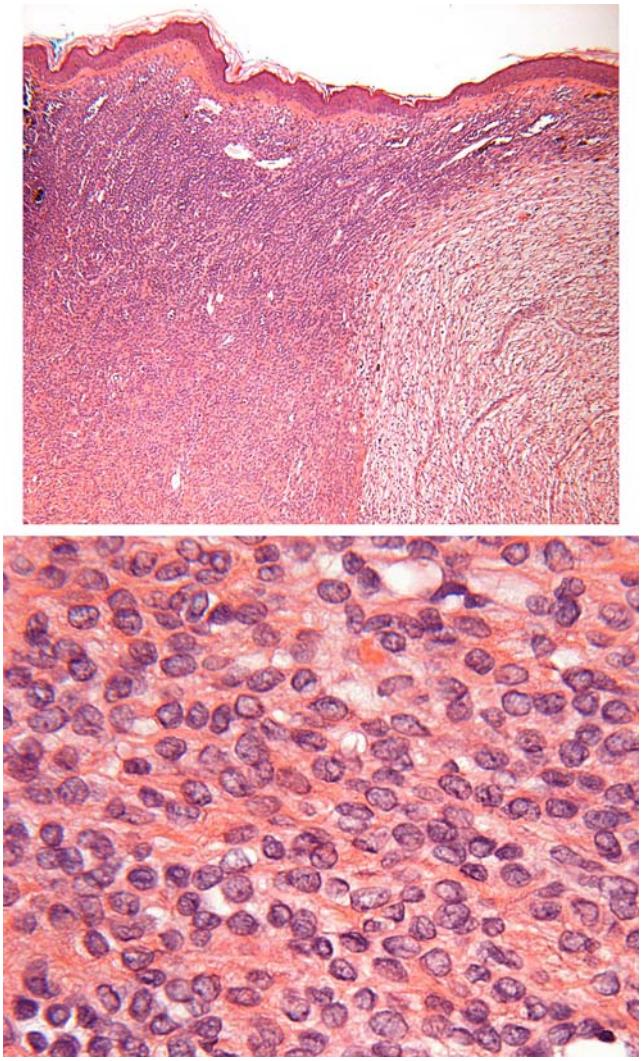

Fig. 2 This form of neurocristic hamartoma is composed on the left by a solid sheet of melanocytes, which occupies the entire dermis and the sub-cutis. The similarities with nevoid melanoma are striking, but cells have obvious benign features and no mitotic activity. On the right of the picture, at scanning magnification, maturation in spindle cell elements is seen

– In nevoid melanoma, a melanoma in situ pattern is occasionally seen at the junction, whereas neurocristic hamarthoma is entirely intra-dermal; in some cases, a grenz zone separates the epidermis from the nevus.

A third group of cellular melanocytic nevi, which can be confused with nevoid melanoma, includes nevi with large nodules of tightly packed small melanocytes (Fig. 3). These huge, irregularly shaped nodules are indeed very similar to the expansile nodules with selective advantage of growth, which is indicative of nevoid melanoma. Another misleading detail is the presence of pigment in these deep-sited nodules (and indeed pigment in the deep dermis is always a strong indication of malignancy).

In these cases, the differences from a nevoid melanoma are the following:

– These nevi have the general features of congenital nevi or of the so-called tardy congenital nevi (acquired nevi with congenital features) namely, periadnexal disposition of the melanocytes, Indian file alignment along the collagen fibres and large junctional nests.
– A benign looking cytological feature is present in the cellular intra-dermal or junctional nodules, where cells are small and uniformly distributed inside the nodule. Chromatin is evenly scattered within the nucleus, and the nucleolus is undetectable or pinpoint. Mitotic activity is virtually nil throughout the lesion. Most significantly, mitoses are absent at the bottom of the neoplasm.
– At the dermoepidermal junction, there is an innocent-looking proliferation of melanocytes arranged in nests.

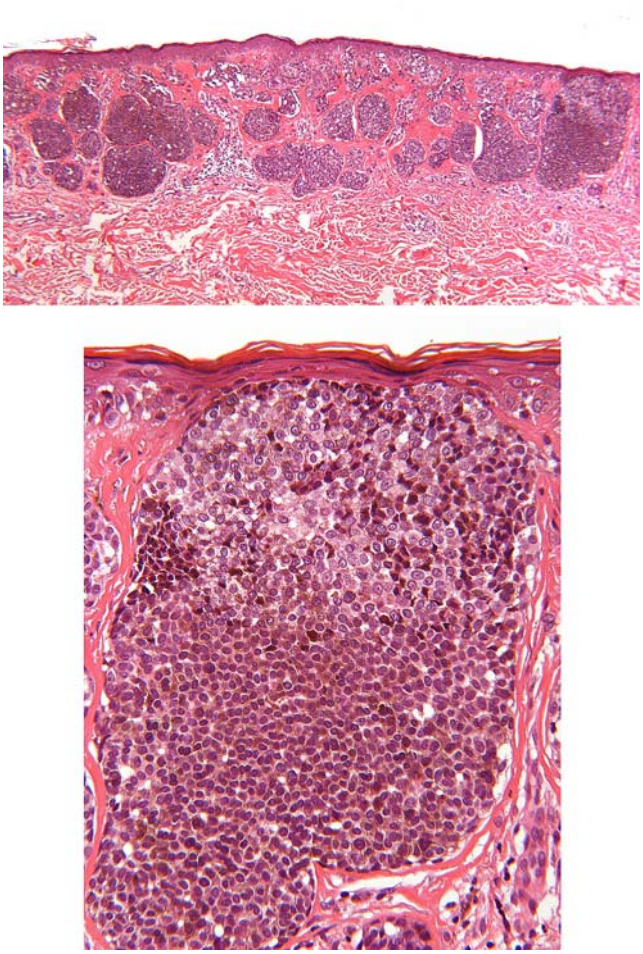

Fig. 3 In this nevus, the nests at the base of the lesion are larger than those at the top. Moreover, nests are confluent and bizarrely shaped. Pigment is mostly synthesized at the bottom of the neoplasm. Despite these alarming details, the bland cytology indicates a nevus (probably congenital). When regressing, traumatized or recurrent, this type of nevus becomes almost indistinguishable from a melanoma

Cells are typical, and a melanoma in situ type proliferation is absent. The epidermis is usually hyperplasic with elongated rete ridges.

Spitz nevus vs spitzoid melanoma

Spitz nevus is a benign melanocytic lesion composed of epithelioid or spindle cells. Cytological details can be highly atypical, and the lesion is regularly confused with a type of melanoma with spindle or epithelioid cells, called for this reason spitzoid melanoma. The similarities between a Spitz nevus and a spitzoid melanoma are so striking as to question the former's very nature and to suggest a sort of grey zone for lesions in which the resemblances with a melanoma are far more numerous than the differences. These lesions, in which a diagnosis does not seem to be based on solid ground, are called by some scholars atypical Spitz nevus, Spitz tumour or melanocytic neoplasms of indeterminate biological potential [11–14, 111, 132, 153]. For the time being, I prefer to maintain a clear-cut difference between benign and malignant lesions with Spitzian features [59, 96, 97].

In dealing with the differential diagnosis of Spitz nevus vs spitzoid melanoma, the following steps could be suggested:

- First of all, it is necessary to ascertain that the tumour in question is a melanocytic neoplasm with large spindle or epithelioid cells. To consider the nevus as a Spitz nevus, cells must be large and have a peculiar morphology. Prevalence of small cells or of cells with other features always questions the diagnosis of Spitz nevus. A neoplasm in which a combination of large and small elements is present is most likely another form of nevus (combined nevus, clonal nevus and so on) or most probably, a melanoma [7, 10].
- The presence at the dermoepidermal junction of numerous, large-sized and confluent Kamino bodies (eosinophilic, pink, periodic acid-Schiff-positive globules) always questions the diagnosis of melanoma [150]. Cases of melanoma with such bodies have been indeed reported, but the few photos presented in the papers failed to convince me.
- A number of spitzoid melanoma is found on sun-damaged skin: The absence of severe solar elastosis should promote further investigation [147]. Unfortunately, not all spitzoid melanoma arise on severely sun-damaged skin.
- The most common forms of Spitz nevus has a distinctive wedge-shaped silhouette, which is at least slightly distorted in most spitzoid melanoma.
- In melanoma, the intra-epidermal margins of the lesion are rarely sharp, even in its spitzoid variant. As a rule, a melanoma is surrounded by a lentiginous proliferation at the borders. In the dermis, at the bottom, melanoma usually has a compressive ('pushing') border. The dispersion of the cells among the collagen fibres is more consonant with a Spitz nevus.
- Although mitoses are not an indispensable requisite for the diagnosis of spitzoid melanoma, their absence, especially at the bottom of the neoplasm, should always challenge such a diagnosis [139]. Furthermore, the presence of mitoses should be sensibly evaluated: Numerous mitoses in fact can be present in rapidly growing Spitz nevus and in recurrent, regressing or traumatized Spitz nevus.
- In spitzoid melanomas, as in most melanomas, pigment is unevenly scattered and present also at the bottom of the lesion. Symmetrically distributed melanin deposits and the absence of pigment at the deepest front of the neoplasm are more indicative of a Spitz nevus. A most ominous indication of melanoma is the uneven distribution of the pigment inside the nests and between them.
- A 'perfectly' symmetrical epidermal hyperplasia, with the epidermis more expanded at the centre and gradually thinning at the periphery, is characteristic of a Spitz nevus. Usually, a melanoma with spitzoid features has a more irregular epidermal hyperplasia; moreover, areas of epidermal thinning are present: Such aspects are called 'consumption' of the epidermis and are indeed a useful indication of melanoma [23, 55, 64].
- Pagetoid spread of melanocytes above the junction is an important indication of melanoma but can be also present in Spitz nevus. However, in melanoma the pagetoid cells are more numerous, and the spread of cells involves the uppermost reaches of the epidermis and the lateral borders of the tumour.
- A symmetrical scattering of cells among undisturbed collagen fibres in the dermis ('dispersion') is indicative of a Spitz nevus. Melanomas grow in large expansile and compressing nodules with high cellular density.
- Pleomorphism is a characteristic of spitzoid melanoma, whereas cells with uniform nuclear details throughout the neoplasm or at the same level in the dermis ('zonation') are most probably benign.
- The presence of large nuclei is not tantamount of melanoma. In the epithelioid form of Spitz nevus (especially in youngsters), large vesicular nuclei with round nucleolus are possible: A more worrying detail is the presence of large nuclei with scant cytoplasm or large nuclei with large, amphophilic and angulated nucleolus.
- A general architectural disorder of the lesion does indicate a melanoma but at times is difficult to evaluate. A common indication of melanoma is the presence in the deep dermis of nests larger and more atypical than those in the superficial dermis. Large,

confluent, irregularly shaped, highly cellular masses always are indicative of melanoma.

- HMB45 immunostain decorates the melanoma cells unevenly throughout the lesion, whereas a sort of symmetric top-to-bottom zonal gradient is more indicative of Spitz nevus. Ki67 is positive in the intraepidermal and junctional component of Spitz nevus; on the contrary, melanoma-positive nuclei are found scattered irregularly all over the lesion [17, 122, 148]. A gradient is to be found also with cyclin D1, fatty acid synthase, P53 and bcl-2 and are more expressed in melanoma than in Spitz nevus. On the contrary, p21 seems more expressed in Spitz nevus than in melanoma. All these immunohistochemical results are at times contradictory, variable and difficult to interpret, and for the time being, final diagnosis cannot be trusted exclusively upon them.
- Bastian reported marked differences in the pattern of chromosomal aberration between Spitz nevi and melanoma: Cases with no aberration or an isolated gain on chromosome 11p were interpreted as benign; multiple aberrations (besides gain on chromosome 11p) indicate melanoma. However, 5% of melanoma do not have any chromosomal aberration. A serious limitation to the technique is that it may be confidently used only in pure melanocytic proliferation: Lymphocytic infiltrate can hamper the procedure.
- As regards to the age of the patient, one must always remember that as illustrated by a number of publications on so-called atypical, metastasizing and malignant Spitz nevi, spitzoid melanoma do occur in youngsters and even small children, and they may eventuate into metastatic disease with lethal outcome [10, 14, 96, 138, 139]. The criteria that allow a confident distinction between benign and malignant spitzoid lesions in such cases are basically the same as in adults.

However, in very young patients (less than 1 or 2 years old), striking cellular pleomorphism or occasional mitotic figures (also at the bottom of the lesion) or a growth pattern in solid sheets are possible in lesions with benign outcome. In these cases, however, one should consider:

- Only one of the above mentioned aspects is present; that is, cells are either atypical or pleomorph but not atypical and pleomorph. Cells grow occasionally in solid sheets, but mitoses must be scant. Cases of spitzoid melanoma under the age of 2 (which metastasized) had a striking combination of atypia, mitoses, pleomorphism and growth in solid sheets.
- As a rule, benign lesions are small and confined in the dermis, whereas spitzoid melanoma in this age group usually reach the sub-cutis [10, 96].

In synthesis, it is always wise to reconsider a diagnosis of spitzoid melanoma when the following are found in a suspected lesion with large epithelioid or spindle cells: many Kamino bodies, symmetrical epidermal hyperplasia, cellular monomorphism and no significant mitotic figures. Being cautious in diagnosing a melanoma in very young children is also important.

Rare variants of Spitz nevus are even more likely to be misdiagnosed as melanoma. In our own experience, these variants are: Spitz nevus with prominent dendrites, Spitz nevus with superficial growth pattern, angiomatoid Spitz nevus and Spitz nevus on volar skin.

A Spitz nevus, especially in dark skinned people, can be composed of melanocytes with elongated dendrites [46, 135]. In such cases, cells are even more atypical than in ordinary Spitz nevus and are mostly arranged at the junction in solitary units and in a lentiginous pattern (Fig. 4). Moreover, the lesion is quite large and does not have the wedge-shaped silhouette of a common form of Spitz nevus. This form is

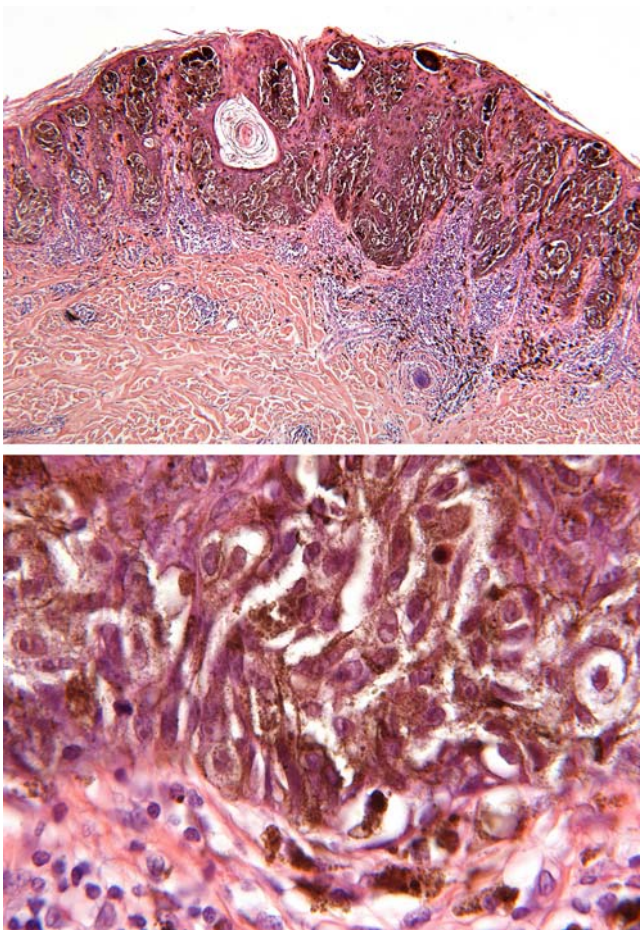

Fig. 4 In dark-skinned people, this form of heavily pigmented dendritic Spitz nevus is quite common and regularly confused as melanoma. The uniform epidermal hyperplasia and the symmetrical distribution of the melanin are both indications, at scanning magnification, of the benign nature of the lesion

unusual and badly categorized in the literature and is frequently confused with melanoma, with Clark's atypical nevus or with an atypical form of Reed nevus. The symmetrical silhouette of the hyperplastic lesional epidermis and the symmetrical distribution of the pigment both are hints of the lesion's benign nature. Cellular monomorphism is also a useful clue for not overdiagnosing this lesion.

A flat 'superficial spreading' silhouette is seen in rare cases of Spitz nevus with conventional cytological features [80]. These lesions are occasionally very worrisome because the dermal component is impressive, nodular and situated only in the centre of the lesion (Fig. 5). In these cases, the Spitz nevus resembles a superficial spreading melanoma with central invasion of the dermis (so-called early vertical growth phase). However, all the other criteria for the diagnosis of a benign lesion are present; in particular, the cytological features of a Spitz nevus are evident, especially at the dermo-epidermal junction: The diagnosis would not be difficult if it were to be based only on the junctional component where nests are discrete with an artificial cleft between them and the overlying hyperplastic epidermis ('capping'). Even in the intra-dermal component, which is apparently worrisome, the cells are large but monomorphous, organized in discrete nests separated by collagen fibres (and not in expansile nodules compressing dermal structures) and mitoticaly quiescent. The nucleus/cytoplasm ratio is that of a Spitz nevus (large nuclei with abundant, granular or ground glass cytoplasm with distinct borders).

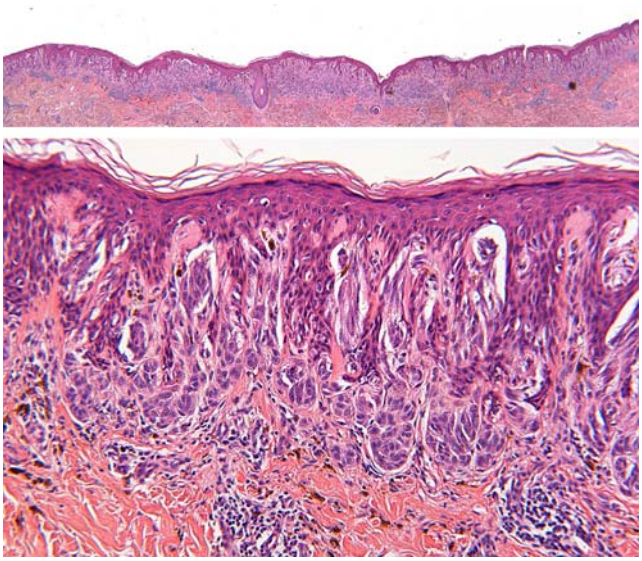

Fig. 5 Spitz nevus usually grows in the dermis with a wedge-shaped silhouette. In this case, the growth pattern is flat and resembles a form of superficial spreading melanoma early invasive of the dermis. At higher magnification, however, the cells appear monomorphous, nests are discrete and similar to each other in shape and size. 'Capping' above the nests and a few Kamino bodies are further reassuring features of the benign nature of the lesion

The angiomatoid Spitz nevus [40] is a form of nevus in which the dermis is rich with newly formed capillary vessels. A sparse infiltrate of epithelioid or spindle cells is present among the vessels. A scant inflammatory component is also seen. All these findings are easily confused with the granulation tissue of a regressing melanoma. This happens quite frequently because although the angiomatoid variant of Spitz nevus is rare, the finding of an area with vascular proliferation in a Spitz nevus is not so uncommon. Cellular characteristics are the major clue in ruling out a melanoma. In fact, in angiomatoid Spitz nevus, cells are epithelioid and spindle with abundant cytoplasm and are usually scattered among collagen fibres without forming nodules. Mitoses are virtually nil. Moreover, the lesion is usually small and well circumscribed, just the opposite of a regressing melanoma.

Spitz nevus in volar skin can have striking details indicating melanoma: Cells are large, and there is an evident pagetoid spread of melanocytes above the junction. However, cells are gathered in discrete nests, with a minimal lentiginous component. In the dermis, they are organized in small discrete nests, cords or single cells with no evident mitotic activity (these aspects are better seen at the lateral borders of the neoplasm). Finally, the lesion is restricted almost always to very young patients, in whom a form of volar invasive melanoma is exceedingly rare.

Reed nevus vs melanoma with features of Reed nevus

Reed nevus (pigmented spindle cell nevus) is a variant of Spitz nevus that, at the beginning, is characterized by heavily pigmented elements, which, in the course of time, first become dendritic and then elongated spindle melanocytes. In each step of its evolution, the Reed nevus can be misdiagnosed as melanoma [87, 101, 125, 134].

In its early stage, the Reed nevus (Fig. 6) is rich in pigment, poor of melanocytes and with an inflammatory dermal infiltrate, and in this setting, it can be confused with a regressing melanoma with tumoural (nodular) melanosis [28]. The following features could indicate the correct diagnosis:

- Reed nevus, especially in this early stage, is a small lesion, while a regressing melanoma is a large one.
- The nevus is located on the limbs (mostly on the legs) and lower trunk and abdomen. A melanoma with regression occurs everywhere in the body, mostly on the trunk.
- In the nevus, the cells at the junction are dendritic or spindle but typical, while, on the contrary, in melanoma, melanocytes have hyperchromatic nuclei.
- In regressed melanoma, the cells of nodular melanosis are readily identified as macrophages; if residual

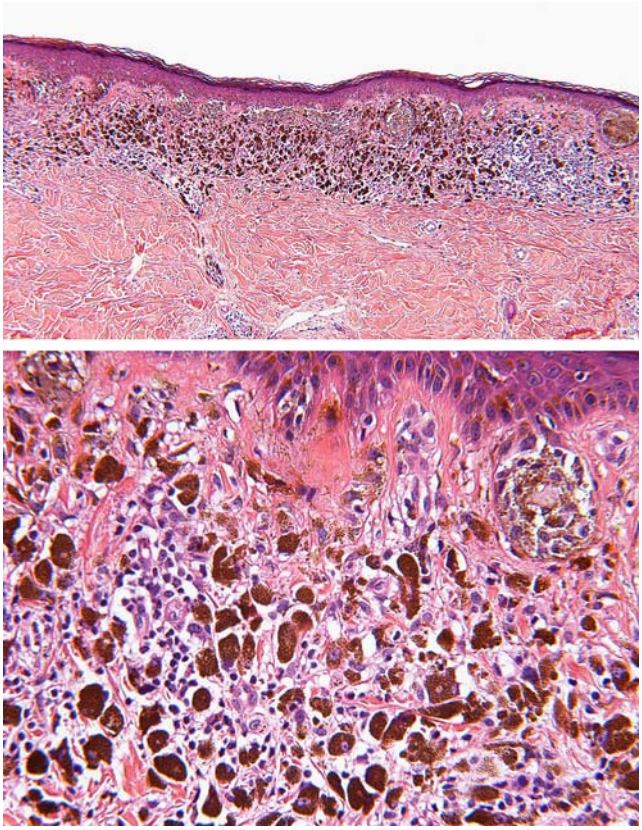

Fig. 6 At first glance, this heavily pigmented melanocytic nevus can be misinterpreted as a form of regressing melanoma. The small size of the lesion, the absence of atypia and the presence of small regular nests at the junction will confirm its benign nature

tumour is present, it consists of clustered atypical cells in the dermis and, occasionally, of epithelioid atypical junctional melanocytes in a lentiginous array.
– Rete ridges are preserved or even elongated in the nevus, annihilated in the regressing melanoma.

Serial sections in both entities usually reveal further evident details indicating the nature of the lesion, like expansive nodules in the melanoma and regular junctional nests in the nevus.

When rich in dendritic cells, the Reed nevus can be misdiagnosed as a melanoma in severely sun-damaged skin. The clue for the correct diagnosis is indeed the presence of signs of sun damage, mostly represented by abundant fibroelastosis. Such indications of chronic and severe solar damage rule out the Reed nevus. Moreover, a melanoma of this type, at the shoulders of the lesion, has lentiginous proliferation of melanocytes at the junction and above it.

In mature forms of Reed nevi, cells are arranged in elegant elongated fascicles parallel to the epidermis [8, 9, 114]. Cells are mostly spindle and rich in pigment, which is also present in the epidermis in the keratinocytes and in the dermis inside numerous melanophages. A dermal inflammatory infiltrate is also frequent. A few melanocytes are scattered above the junction, and epithelioid cells are regularly found among the spindle ones. With this morphology, the Reed nevus has the tendency of being confused with a spindle cell melanoma [78].

The similarities between the Reed nevus and spindle cell melanoma are indeed numerous, but a few details will lead to the correct diagnosis:

– Reed nevus has a peculiar clinical setting. It develops in youngsters usually on the lower part of the body, below the waist. A ‘Reed nevus’ on the face or on severely sun-damaged skin is most probably a form of spindle cell melanoma.
– The elongated cells, which compose the nevus, are always remarkably typical, while hyperchromatic nuclei or prominent nucleoli are consonant with a spindle cell melanoma.
– In Reed nevus, the pigment is overwhelmingly abundant but regularly and symmetrically distributed. Uneven distribution of the pigment or nodules of melanophages restricted in one focus belongs to a melanoma.
– Reed nevus is restricted to the papillary dermis, whereas infiltration of the reticular dermis is indicative of a melanoma.
– Large nodules of epithelioid cells are absent in the Reed nevus; hence, they always must be considered as diagnostic of melanoma.
– As said above, the presence in the skin of signs of severe sun damage (mostly represented by solar elastosis) rules out the Reed nevus.
– In Reeds nevi, horizontally oriented fascicles of melanocytes are found in the papillary dermis, whereas the junctional/intra-epidermal component consists of vertically oriented nests with spindle-shaped cells arranged in the fashion of hanging bananas. This regular architectural pattern is absent or distorted in melanoma-simulating Reed nevus.
– Melanoma with features of Reeds nevus often presents with skip areas, whereas the cells of Reeds nevus are evenly distributed.

Cellular atypical blue nevus vs melanoma on a blue nevus

Among the many forms of cellular blue nevus, a few may be confused with a melanoma developed on a blue nevus or with other forms of melanoma [25]. The most frequently misdiagnosed form of cellular blue nevus is the so-called atypical cellular blue nevus (an unfortunate but entrenched

term). The atypical cellular blue nevus [143] is characterized by large size and by deep infiltration of the subcutaneous fat. Cells show random cytological atypia with large hyperchromatic or vesicular nuclei (giant or bizarre cells are also possible), mild pleomorphism and scattered mitoses. Despite its worrying cytological details, the atypical cellular blue nevus retains a constant benign conduct and must not be diagnosed as a melanoma developed on a cellular blue nevus [52, 97, 141, 160].

In the distinction between these two entities, one must consider:

- A melanoma on a cellular blue nevus is exceedingly rare, whereas cytological and architectural atypia in a large cellular blue nevus is much more common.
- A melanoma on a blue nevus usually consists in large hypopigmented nodules of atypical epithelioid cells, which are indistinguishable from a common form of melanoma [76]. In these nodules, necrosis en masse can supervene, and cytology is obviously malignant. In other cases, melanoma develops in blue nevus as large sheets of sarcomatous spindle cells with marked nuclear pleomorphism and numerous mitoses. A third morphologic aspect of melanoma on a blue nevus is represented by masses of highly hyperchromatic branching dendritic elements, which are rich in melanin [50]. In summary, melanoma on a blue nevus always betrays itself with marked cytological atypia and a growth pattern in large solid sheets, elongated fascicles or nodules, destructive of the surrounding nevus or the dermal structures.
- The atypical blue nevus is characterized by the preservation of the structure of a cellular blue nevus. In this benign-looking background, a few large melanocytes with hyperchromatic nuclei are randomly scattered. These cells have nuclei with evenly dispersed chromatin, reminding alteration induced by senescence. On occasion, however, nuclei are vesicular with a prominent nucleolus. These atypical cells never aggregate in sheets or nodules and are neither associated with mitoses in number nor with large areas of necrosis.
- Mitoses are possible in both entities, but they are more numerous in a melanoma. Atypical mitoses are indicative of melanoma.

Another variant of cellular blue nevus, which may be confused with a melanoma (or with clear cell sarcoma), is the recently reported form named by Mihm known as amelanotic cellular blue nevus [19, 159]. A variation on the theme is probably the entity described by Deyrup et al. [39] as paraganglioma-like melanocytic tumour because of its peculiar nested architecture and solid pattern of growth (Fig. 7). In these tumours, cells are very large, epithelioid, with pale or clear cytoplasm. Cells aggregate in nests or cords, which are separated by mature, occasionally sclerotic, collagen fibres. Melanin is absent or very scarce. Mitotic figures are possible in these lesions, as in all forms of cellular blue nevus, even in the deep portion of the tumour. Cells can be very large and nuclei hyperchromatic (but nucleoli are inconspicuous). In cases like this, the diagnosis of cellular blue nevus (or of a variation on the theme) is based on the presence of recognizable areas of cellular or common blue nevus (serial sections may be necessary). Moreover, the masses of clear cells show a monotonous cytology, while a solid growth pattern is absent. Necrosis and pleomorphism are also absent. Finally, in this entity (at variance with melanoma), collagen fibres among the nests are undisturbed and sclerotic. The lesion is divided in lobules, cords and alveolar structures and has a sort of organoid or paraganglioma-like architecture.

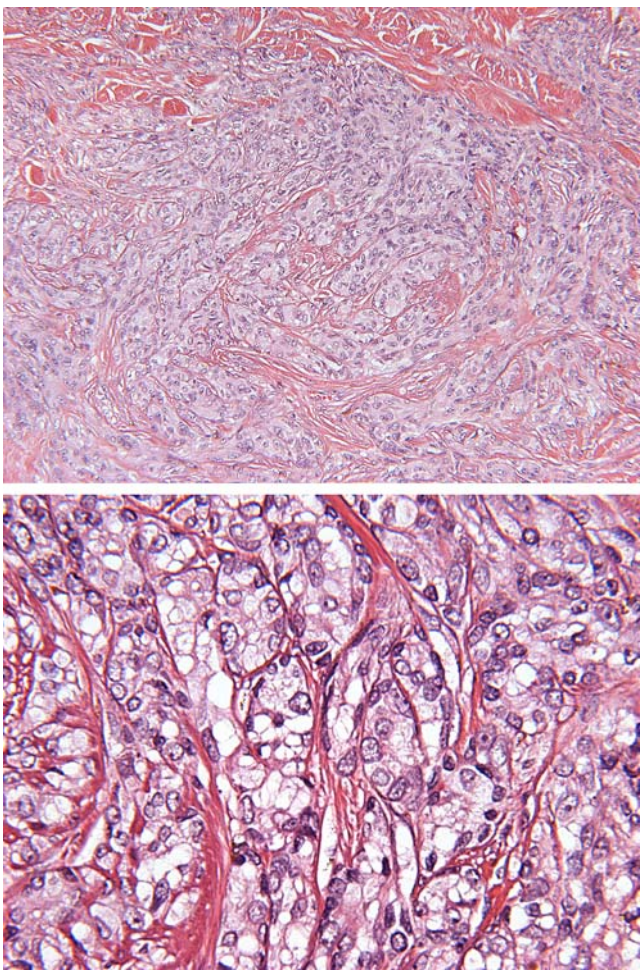

Fig. 7 In other parts of this large lesion, the features were that of a cellular blue nevus. In these images, we illustrate a more bizarre architecture: Cells gather in small anastomotic nests and cords and are utterly devoid of melanin. The differential diagnosis with a melanoma on blue nevus, intradermal melanoma and clear cell sarcoma is based on the absence of pleomorphism, of large solid nodules, and atypical cells with many mitotic figures

Other cases in which an innocent cellular blue nevus can be misdiagnosed as a melanoma are those in which the cellular density is very high [26] or in which the lesion is scattered with densely packed alveolar structures (the so-called microalveolar cellular blue nevus) [58, 94]. In these cases, however, the high cellular density is the only worrying sign; cells are typical, and mitoses are low in number.

Acral nevi vs acral melanoma

Nevi on palms and soles (volar or acral skin) have a tendency to be confused with melanoma [44]. The two most important sources of confusion are the so-called acral lentiginous nevus and the Spitz nevus on volar skin.

In acral lentiginous nevus [33], cells are organized at the junction in small nests, alternated with melanocytes in single units. The cells, especially the lentiginous ones, have dendrites. A scattering of the typical elements above the junction is the rule. Occasionally, this aspect is so overwhelming that the acronym MANIAC (melanocytic acral nevi with intra-epidermal ascent of cells) is ironically suggested. The epidermis is hyperplastic with elongated rete ridges. In the dermis, melanocytes are arranged in small nests or cords or also in single units scattered among undisturbed collagen fibres.

Occasionally, the acral lentiginous nevus is so similar to the so-called acral lentiginous melanoma that a distinction between these two entities is almost impossible. This happens because this form of melanoma has a junctional pattern in nests and single dendritic units similar to that seen in the acral lentiginous nevus. Moreover, this form of melanoma occasionally develops an intra-dermal growth of small, loosely aggregated melanocytes that is deceptively similar to that of a nevus. Furthermore, the epidermal alterations (elongation of rete ridges and thickened cornified layer) are similar in both entities as is the poor lateral circumscription of the lesions.

The following observations could be of help to the diagnostic pathway:

- Being that the histological similarity between acral nevi and acral melanoma is so great, it would be wiser to base the diagnosis mostly on clinical grounds [75, 106]. With due caution and acknowledging exceptions, one could say that a lesion with dendritic melanocytes on volar skin less than 6–8 mm in lateral diameter in a young patient is most probably a nevus. On the contrary, a melanocytic neoplasm bigger than 6–8 mm in a patient older than 50 is almost certainly a melanoma with the only exception being the congenital nevus.
- Histologically, the depth of the lesion is another useful indication for the diagnosis, the only exception being the congenital nevus (and the Spitz nevus, as discussed below); benign lesions on volar skin do not infiltrate deep dermis. Any other widely invasive form of melanocytic neoplasm is to be considered a melanoma unless the contrary is convincingly and exhaustively proved. Invasion of the sub-cutis is highly indicative of melanoma, even if the cytological features of the neoplasm are bland and mitotic activity is undetectable.
- At the junction, in a nevus, nests are prevalent in relation to single cells aligned in a lentiginous array, while the exact opposite is the rule in a melanoma [22, 77]. In a nevus, the cells gather in nests quite soon when the lesion is still small, while melanomas form discrete nests only after having reached a large lateral extension.
- In an acral lentiginous nevus, there is a scattering of melanocytes above the junction as in a melanoma. In melanoma, however, this aspect is much more evident and involves the lateral shoulders of the lesion. Most importantly in melanoma, pagetoid melanocytes have large and hyperchromatic nuclei, with a clear halo and possess prominent dendrites.
- Both in nevi and in melanoma, cells are frequently dendritic at the junction, and dendrites contain melanin [129]. However, in melanoma, dendrites are much thicker and elongated up to the highest part of the spinous layer and bizarrely oriented in all directions. Usually, in melanoma, dendrites are heavier pigmented than in nevus.
- In melanoma, a striking involvement of eccrine ducts is present in most cases [71]. The infiltration of the ducts is in single units, usually the melanocytes are highly hyperchromatic with scant or no detectable cytoplasm. These melanoma cells aligned in a lentiginous array displace the myoepithelial cells around the eccrine intra-dermal ducts. This peculiar eccrine involvement interests the ducts to their deepest reaches. In nevi, eccrine ducts can also be involved by melanocytic proliferation, but benign melanocytes in the eccrine ducts are usually gathered in discrete oval nests and not aligned in single units, and the involvement is restricted to the uppermost portion of the ducts.
- In melanoma, cells are atypical and enlarged at the dermoepidermal junction [116, 131] and above it and can be stellate or spindle, with finely granular cytoplasm. Nevus cells are usually less conspicuous, and atypia is less evident. These aspects are, however, difficult to evaluate, and one must remember that atypia can be slight in some cases of melanoma.
- The dermal component in the nevus is usually typical. Cells are small and symmetrically distributed in the dermis. In many melanomas, the intra-dermal compo-

nent is atypical, but cases in which the intra-dermal component in melanoma is nevoid can occur [137]. We have seen a few cases in which the intra-dermal component of melanoma was barely distinguishable from a nevus. In these cases, the presence of mitoses in the deepest portion of the lesion is always an indication of melanoma (but their absence does not rule it out). Furhtermore, hyperchromatic nuclei and their pleomorphism are indication of melanoma.

– Although not decisive for the final diagnosis, ancillary techniques can also be useful. HMB45 often may stain cells in the deepest portion of acral melanoma, which is rarely the case in acral nevi [69]. As for other techniques, Bastian noted a set of genomic alterations in acral melanoma, aspects that could be decisive in the near future [140].

Another source of error in the diagnosis of acral melanocytic neoplasms is the Spitz nevus. The entity is rare on acral skin, but the similarity with melanoma is striking. In fact, the Spitz nevus frequently has a centrally sited invasive and nodular component in the acral location. In the Spitz nevus, a pagetoid spread of melanocytes is present in the centre of the lesion, frequently accompanied by transepidermal elimination of entire well-circumscribed nests. In the nodule, the cells are large and with vesicular nuclei, and they are very similar to melanoma.

In this differential diagnosis between Spitz nevus and melanoma on volar skin, the most important clues for the diagnosis of a Spitz nevus are on the two lateral shoulders (that is, the two lateral borders beyond the centrally sited intra-dermal mass) of the lesion, where more clear-cut histological features of the Spitz nevus are present. Cells are epithelioid or spindle but monomorphous here. Moreover, they are gathered in comfortingly discrete regular nests, and a clear crescent-shaped cleft (‘capping’) is frequently present between the nests and the epidermis. Mitotic activity is scant or nil, both at the junction and—most importantly—in the dermis. Finally, Spitz nevus involves youngsters, whereas melanoma on volar skin is a neoplasm of old patients.

At the end of this section dedicated to acral nevi, it should be stressed one more time that a great care should always be used in the diagnosis of a melanocytic lesion in this area, and an overdiagnosis of melanoma must be avoided. In fact, an erroneous diagnosis of melanoma can cause an undue and debilitating surgical procedure, especially in weight-bearing areas. In my opinion, a consultation should be sought in all lesions on volar skin where the diagnosis is not immediately obvious. Moreover, clinic pathological correlation in this field is a mandatory procedure: The combination of the age of the patient, the lateral and vertical diameters of the lesion and the extension of the lentiginous and pagetoid spread are together the most important indications for the diagnosis [124].

Dysplastic nevus vs superficial spreading melanoma

The dysplastic nevus, first popularized by Clark, is a peculiar form of nevus, which has never found a clear-cut set of diagnostic criteria, this despite (or because of) the hundreds of articles dedicated to the subject. In general [15, 34, 42, 43, 123], the dysplastic nevus is considered a lesion with irregularly shaped and confluent nests at the junction, where nests are unevenly mingled with melanocytes in single units (so-called lentiginous array). Rete ridges are unevenly spaced and sized but always present. In the dermis, the melanocytes are restricted to the most central area of the lesion. Peculiar host response alterations, such as lamellar fibroplasia and mild inflammatory infiltrate are also present. Clark’s dysplastic nevus (also called atypical nevus) is only rarely a forerunner of malignant melanoma, but per se, before the actual degeneration in melanoma occurs, there is a general consensus that it is a benign lesion unable to metastasize. Clark’s dysplastic nevus can be morphologically very similar to some sub-types of superficial spreading melanoma, especially the form recently labelled by Mihm as *lentiginous melanoma* [70]. Similar lesions have been also presented as dysplastic nevus-like lentigo maligna and nevoid lentigo maligna [45, 74]. In this form of melanoma, melanocytes are only mildly atypical, and the epidermal rete ridges are mostly preserved.These two entities, the dysplastic nevus and the so-called lentiginous melanoma, are indeed so similar that most probably, in the past, an unpredictable number of diagnosed dysplastic nevi were in fact superficial spreading melanoma, lentiginous melanoma variant. We recently saw two cases of this form of melanoma that had been diagnosed as dysplastic nevi years ago. Both were later associated with metastatic disease. Melanoma misdiagnosed as dysplastic nevus range high in the list of medicolegal claims [144, 145].

Although our knowledge on the matter is still insufficient, we can propose the following criteria for the diagnosis:

– Patients with this peculiar form of superficial spreading melanoma simulating the Clark’s nevus (lentiginous melanoma) are usually older than those bearing a real Clark’s nevus. The clinical picture is always worrying, and frequently, areas of regression can be seen.
– Histologically, the Clark nevus has only few melanocytes above the junction. Indeed, unless located on special sites like the genitalia or the mammary line, it would be better that no significant pagetoid spread were present. In any case, these aspects should be closely restricted on the central portion of the lesion and on the lowermost part of

the epidermis. In a melanoma simulating a dysplastic nevus, the pagetoid spread is prominent with cells reaching the granular layer. Most importantly, melanocytes above the junction are also found in the 'shoulders' of melanoma (beyond the intra-dermal component of the lesion). The presence of hyperchromatic nuclei, cellular necrosis or mitoses in the pagetoid cells is also indicative of melanoma.

- A crucial element in the lentiginous melanoma is the presence of numerous slightly atypical elements. Occasional atypical melanocytes are actually necessary for a diagnosis of dysplastic nevus (so-called discontinuous or discontiguous cytological atypia), but a large prevalence of these atypical cells is a clear indication of melanoma. The cells have enlarged vesicular nuclei, irregularly thickened nuclear membranes, plump asymmetrically marginated chromatin and prominent nucleoli. Moreover, nuclei are also pleomorph. Many cells are epithelioid, and the cytoplasm/nuclear ratio is altered, and the cytoplasm contains dusty melanin. In other cases of melanoma with the architectural aspect of the dysplastic nevus, the melanocytes on the contrary are small, lymphocytic like, highly hyperchromatic with barely distinguishable cytoplasm, and nucleoli are not seen.
- Although in Clark's dysplastic nevus, a lentiginous component is present, in this lesion, most of the cells are gathered in bizarrely elongated nests. On the contrary, a large prevalence of the lentiginous organization throughout the lesion is indicative of melanoma.
- In melanoma, cells involve the adnexa: In an appropriate setting (that is, with most of the criteria being present), a pagetoid scattering of cells in the infundibular epithelium is indeed diagnostic of melanoma.
- Melanoma presents itself as a large lesion: Most cases are larger than 0.8–1 cm. All the 'dysplastic nevi' of that size should be closely scrutinized.
- Although the architectural features of Clark's nevus are not always regular, nests are mostly at the tips of rete ridges in a dysplastic nevus, whereas they are much more chaotically scattered in melanoma. Indeed, in melanoma, the nests are widely confluent to each other and seem to form one single aggregate of cells at the junction. This pattern brings to mind the acral lentiginous melanoma of the volar skin and of the mucous membranes or the lentigo maligna.
- The epidermal rete ridges are preserved or elongated both in the dysplastic nevus and in the superficial spreading melanoma that simulates it (lentiginous melanoma). However, the rete ridges are more irregularly shaped and outlined in melanoma. Effacement of rete ridges in large tracts and focal epidermal atrophy both indicate melanoma.
- The presence in the dermis of well-structured, widely represented, concentric or lamellar fibroplasia suggests a benign lesion. The pattern of the inflammatory infiltrate is similar in dysplastic nevus and melanoma that simulates it.
- A warning should be issued regarding the intra-dermal component. In the subset of melanoma prone to be misdiagnosed as Clark's nevus, the melanoma cells in the dermis can be only slightly atypical and thus easily misinterpreted as benign. Mitoses are not usually found, and cells seem to mature. Furthermore, from an architectural point of view, the dermal component simulates a nevus: Cells are gathered in regular nests and cords distributed among undisturbed collagen fibres.
- So far, immunohistochemistry and molecular genetic techniques provided only minor contribution to the routine diagnosis of these entities. In general, Ki67-positive cells are said to be less numerous in dysplastic nevus than in melanoma. This notwithstanding, it is wise not to rule out a melanoma upon Ki67-negative results. The same applies to other immunostains.

Indeed, Clark's dysplastic nevus and the sub-set of superficial spreading melanoma that most simulates it are very similar. The main detail indicating a melanoma is mild, but widespread, nuclear atypia, lentiginous-prevalent architecture at the junction and pagetoid spread above it. Whether these morphologically similar neoplasms are also biologically related (that is, one being the precursor of the other) is a matter of speculation [63, 68] and beyond the aim of this paper.

Desmoplastic nevi vs desmoplastic melanoma

Melanocytic nevi can have a large collagen component. The most important entities of this group of collagen-burdened lesions are the desmoplastic Spitz nevus [86], the desmoplastic common nevus [56] and the sclerotic blue nevus [93]. All of the above and particularly the desmoplastic Spitz nevus are frequently confused with desmoplastic melanoma.

Desmoplastic Spitz nevus (Fig. 8) is an entity that usually develops in adults but is occasionally seen in elderly patients, usually on the limbs [85]. The lesion is mostly intra-dermal, but a junctional component is frequently present. Cells are those usually found in a Spitz nevus namely, spindle and epithelioid melanocytes with abundant eosinophilic cytoplasm. Abundant mature hyper-eosinophilic collagen fibres surround the cells. On rare occasions, the entire dermal span is occupied by the neoplasm, which reaches the sub-cutis. The Desmoplastic Spitz nevus is frequently confused with a melanoma with desmoplasia [24, 29, 142, 149], mostly because of its cytological

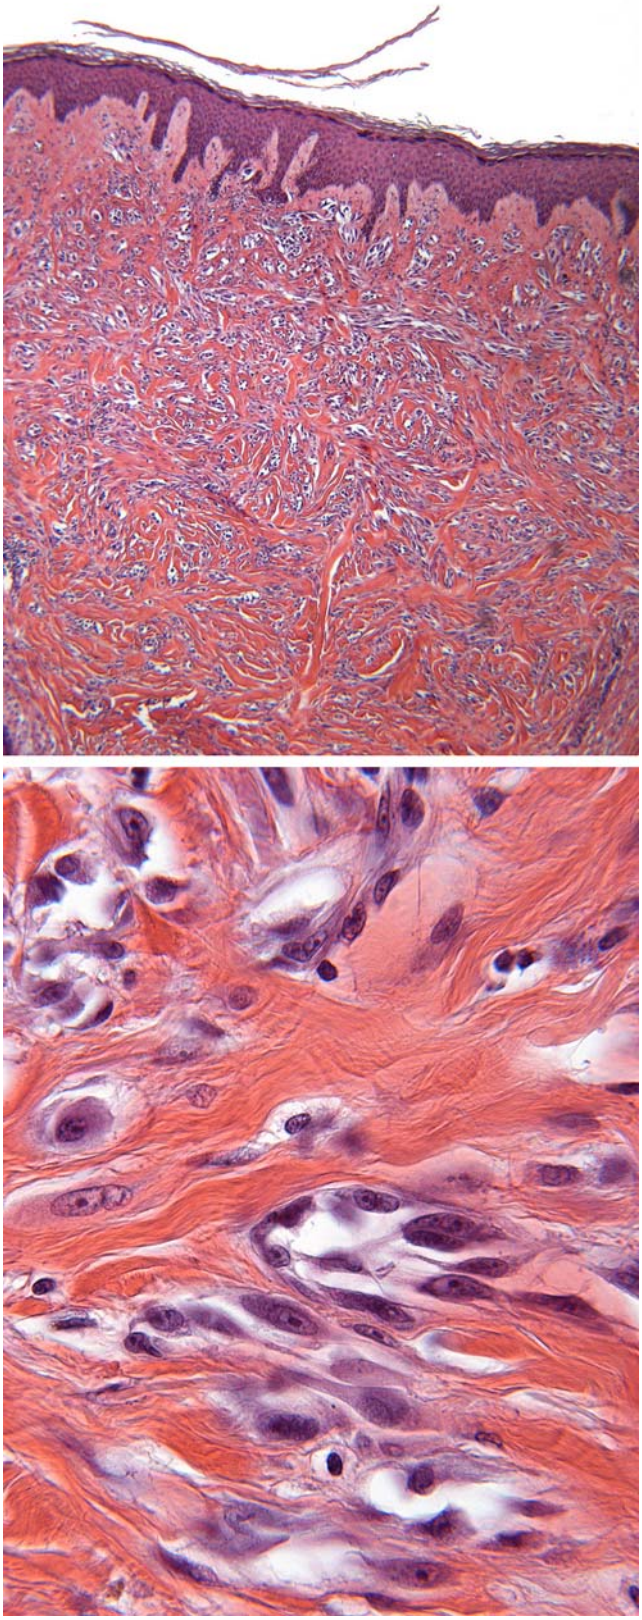

Fig. 8 Desmoplastic Spitz nevus closely simulates a desmoplastic melanoma. The large epithelioid cells with abundant cytoplasm of this lesion are the most important clue for the diagnosis. Note also the hyperplasia of the epidermis, a feature frequent in all forms of Spitz nevus

atypical features. Other misleading aspects could be neurotropism and poor circumscription. The following criteria for a distinction between desmoplastic Spitz nevus and desmoplastic melanoma could be suggested:

- Desmoplastic melanoma is exceedingly rare outside the classic sites namely, head, hands, feet and mucous membranes.
- Desmoplastic melanoma usually derives either from a lentigo maligna on sun-exposed areas or from a lentiginous melanoma on acral skin or on mucous membranes. Remnants (even scant) of these lesions are found at the junction in most of the desmoplastic melanomas. On the contrary, in some cases of Spitz nevus, there are at least a few well-circumscribed, round nests of epithelioid cells at the junction, which are very similar to those of an ordinary non-desmoplastic Spitz nevus. These epithelioid cells and discrete nests are also present in the papillary dermis, where these features indicating a Spitz nevus can indeed be found. However, one must remember that many desmoplastic Spitz nevi are entirely intra-dermal, so that junctional nests may be altogether absent.
- The size of the lesion is crucial for the diagnosis. A desmoplastic melanoma entirely removed at the first attempt of excision is rare: Strands of the neoplasia almost always infiltrate the margins. The opposite is true for the Spitz nevus, which an excisional biopsy almost always successfully removes in toto. This depends on the melanoma's large dimension and also on the fact that clinically, the Spitz nevus (even in its desmoplastic variant) is always much better circumscribed than the desmoplastic melanoma.
- In the cases sited on the head, masses of solar elastosis are usually present in desmoplastic melanoma. Tangles of elastotic fibres are above, inside and all around the neoplasm: features not to be found in any form of Spitz nevus.
- If the lesion has a junctional component, the epidermis is thinned in melanoma (on cases not sited on acral skin) and thickened in Spitz nevus.
- Paradoxically, the presence of isolated, large atypical cells with abundant sharply delineated cytoplasm in the lesion is an indication of its benign nature. In fact, the elongated melanocytes of desmoplastic melanoma most frequently seem like plump innocent-looking fibroblasts with scant or barely discernible cytoplasm. The presence of large triangular or polygonally shaped melanocytes (either multi-nucleate) with ground glass cytoplasm indicate a Spitz nevus.
- Both in Spitz nevus and in melanoma, the desmoplasia is accompanied by lymphocytic infiltrate. However, in melanoma, the lymphocytes are characteristically ag-

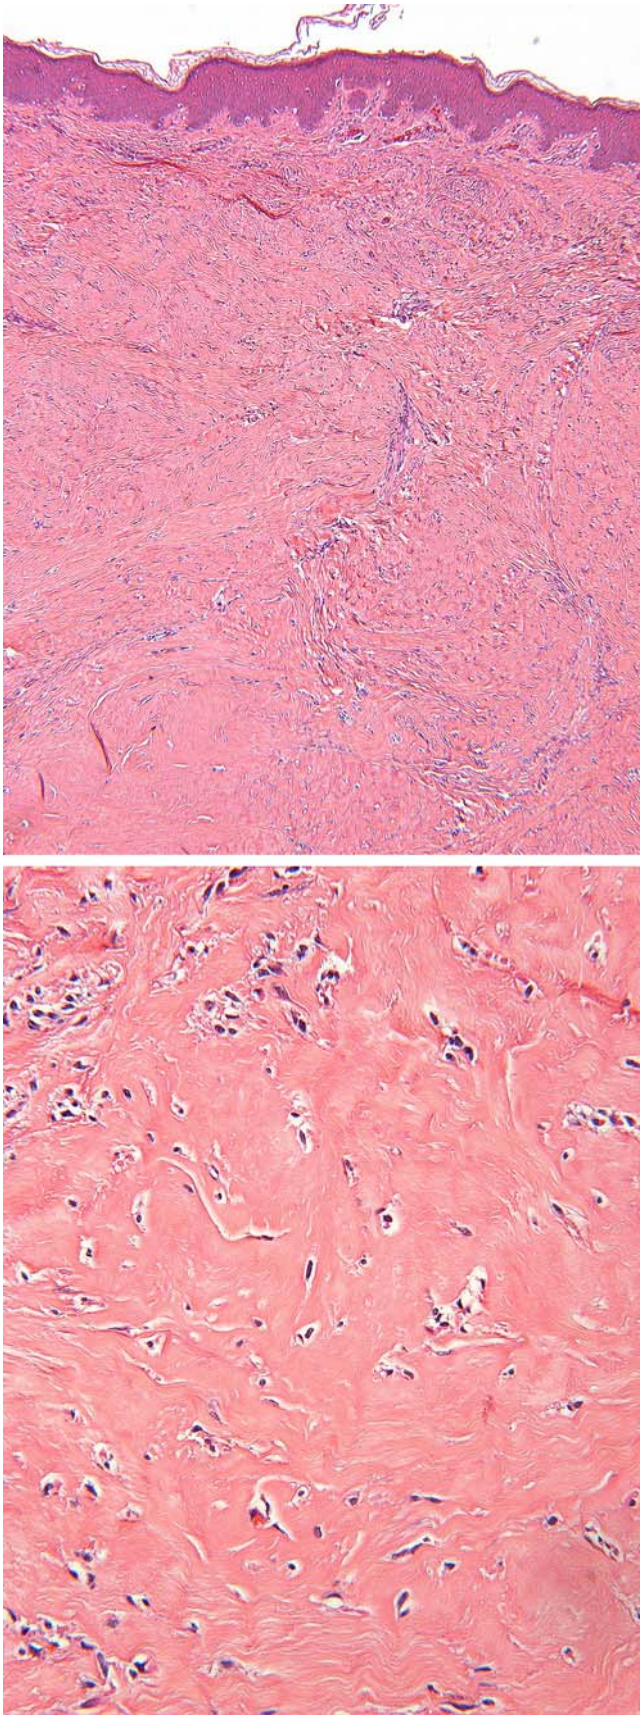

Fig. 9 This fibrous variant of blue nevus seem almost undistinguishable from a desmoplastic melanoma. However, at the periphery of the lesion, a clear pattern of blue nevus was present. Moreover, cells are delicately dendritic and pigmented, aspects not to be found in desmoplastic melanoma. Immunostain for HMB45 will contribute to the diagnosis

gregated in round follicles scattered all around the neoplasia, even at the bottom. Moreover, in melanoma, the lymphocytes aggregates are present not only inside and at the periphery of the tumour but also in the dermis and sub-cutis at a distance from the neoplasm.

– In melanoma, collagen fibres are fibrillary or dense and are inter-woven chaotically with the fibroblast-like melanocytes. The overall aspect is that of a mesenchymal neoplasia, with a whorled or storiform pattern or a scar (with which desmoplastic melanoma is, in fact, frequently confused). In desmoplastic Spitz nevus, fibres are thick and uniform, hyper-eosinophilic and oriented parallel to the cells in a quite regular fashion.
– Mitoses are usually rare in both entities, when present in number, they indicate a melanoma. In a few cases, in melanoma, there are small areas of conventional nodular melanoma, which can be found through serial sections.
– In the differential diagnosis of these entities, immunohistochemistry [30] can be useful but never decisive: Desmoplastic melanoma is usually HMB45 negative, whereas desmoplastic Spitz nevus is positive especially in the uppermost portion of the neoplasm [83, 152]. However, one must keep in mind that areas of more conventional melanoma (epithelioid or spindle) are possible in desmoplastic melanoma, and the cells in these areas are HMB45 positive. In one third of desmoplastic melanoma, a significant number of smooth actin-positive cells are found, a finding not reported in any desmoplastic nevus.

A second less frequent type of nevus with desmoplasia is a common ordinary nevus with an overwhelming production of collagen fibres. This entity, however, is rarely confused with melanoma because a plain nevus tissue is always present at the periphery of the lesion.

The distinction with a sclerotic blue nevus (Fig. 9) is more complex, especially if this neoplasm has been only partially removed. Indeed, despite their deeply different biological nature, desmoplastic melanoma and sclerotic blue nevus share numerous clinico-pathological characteristics. Patient's age and the site of the lesion (head and extremities) are, in fact, the same. Both can be very large and are composed of elongated fibroblast-like melanocytes embedded in collagen fibres. The distinction is occasionally problematic and is mainly based on the following:

- Although the blue nevus can be mostly sclerotic and achromic, a few spindle and dendritic melanocytes containing melanin can be found (with serial sections) at the periphery of the tumour. If these cells are along few melanophages, the picture is characteristic of an ordinary common blue nevus.
- Blue nevus, especially when sclerotic, does not have a junctional component but only melanocytic hyperplasia in the epidermal basal layer. Most desmoplastic melanomas have a melanoma in situ-like proliferation at the junction, or at least, a few nests are recognizable (an aspect not to be found in a common or cellular blue nevus).
- A useful clue to sclerotic blue nevus is a stromal hyalinosis with sharp circumscription and often a wedge-shaped silhouette.
- In blue nevus, the lymphocytic follicles that are scattered inside and all around the desmoplastic melanoma are absent.
- Neurotropism is not a feature of sclerotic blue nevus as it is of desmoplastic melanoma. The same applies to invasion of follicular adventitia, more consonant with melanoma.
- Blue nevus is HMB45 positive, whereas, with few exceptions, desmoplastic melanoma is negative or with only few positive cells.

Proliferative nodules on nevus vs melanoma on congenital nevus
