Abstract This study analyzes the occurrence of epithelial atypia in 2,833 serially sectioned surgical breast biopsies (SB) performed for microcalcifications (median number of blocks per SB:26) and the occurrence of subsequent cancer after an initial diagnosis of epithelial atypia (median follow-up 160 months). Epithelial atypia (flat epithelial atypia, atypical ductal hyperplasia, and lobular neoplasia) were found in 971 SB, with and without a concomitant cancer in 301 (31%) and 670 (69%) SB, respectively. Thus, isolated epithelial atypia were found in 670 out of the 2,833 SB (23%). Concomitant cancers corresponded to ductal carcinomas in situ and micro-invasive (77%), invasive ductal carcinomas not otherwise specified (15%), invasive lobular carcinomas (4%), and tubular carcinomas (4%). Fifteen out of the 443 patients with isolated epithelial atypia developed a subsequent ipsilateral (n=14) and contralateral (n=1) invasive cancer. The high slide rating might explain the high percentages of epithelial atypia and concomitant cancers and the low percentage of subsequent cancer after a diagnosis of epithelial atypia as a single lesion. Epithelial atypia could be more a risk marker of concomitant than subsequent cancer.

Introduction

Breast biopsies for infraclinical lesions are more frequent with mammographic screening programs, but the distribution of the corresponding histological lesions and their associations are still imprecise. Difficulties encountered in following up patients without cancer account for the fact that the clinical significance of certain non-malignant lesions and the management of patients are still debated. Moreover, the problem of surgical biopsy sampling has never been fully investigated and has added additional confusion in appreciating the distribution and clinical significance of such lesions. In 1981, breast epithelial atypia were hardly mentioned and not clearly defined in the World Health Organization/International Union Against Cancer (WHO/UICC) histologic classification of breast tumors [73]. The histologic classification of noncancerous lesions has been mainly based on studies analyzing for each lesion the associated risk of subsequent cancer. These studies were initiated by the survival studies of Dupont and

Page [15, 46] based on lesions discovered by palpation before the era of mammography. Thereafter, further studies [6, 9, 17, 24, 31, 51, 62, 67] substantiated these results, which were ratified in 2003 by the new American Joint Committee on Cancer (AJCC)/UICC classification of breast tumors [70]. Schematically, this classification differentiates benign epithelial lesions (usual ductal hyperplasia and other lesions) from atypical lesions of ductal or lobular type. Although this historical classification is challenged by a new classification [68], it remains the most widely used in practice. Interestingly, the occurrence of epithelial atypia was low in Page's study [46] and has increased with mammographic screening programs [60, 66] and with the development of percutaneous large core needle biopsy (CNB) methods using stereotactic mammography or ultrasound guidance. At present, CNB is frequently used for the initial evaluation of clinically occult breast lesions, thus generating dilemma for the subsequent management of certain noncancerous lesions. At our institution, surgical biopsies (SB) have always been managed in the same way, and most patients with atypical and malignant lesions have been followed. The objectives of our work were to analyze the occurrence of epithelial atypia and their association with a concomitant cancer in a large series of SB performed for microcalcifications without a palpable tumor and to assess the subsequent cancer probability in the group of patients with an initial diagnosis of epithelial atypia. Finally, we provide some practical considerations for the management of patients with epithelial atypia in this era of mammographic screening and CNB.

Materials and methods

Selection of patients

At Institut Bergonié, from January 1975 to December 2002, 3,166 breast biopsies for diagnostic purposes, 2,833 SB and 333 CNB, were performed for microcalcifications without any palpable mass in 2,708 patients (mean age 51.8 years, range 19.7–81 years). Among them, 248 (9%) had several biopsies in the same or contralateral breast. Since 1998, microcalcifications have been classified according to the classifications of the American College of Radiology [2]. SB for diagnostic purposes were defined before 1998 by the absence of a preoperative diagnosis based on the clinical–mammographic–cytologic triplet and by the absence of a positive frozen section and, since 1998, by the presence of epithelial atypia on CNB. Excluded from this study were 132 cancers and 139 non-atypical benign lesions diagnosed on CNB as well as 49 re-excisions performed elsewhere than in our center. Thus, 2,833 SB in 2,375 patients were available for analysis, among which 13 corresponded to re-excision after a CNB with epithelial atypia. Since 1989, needle localization, intraoperative specimen radiography, and post-excisional biopsy mammography have been performed in most cases.

Surgical biopsies and tissue sampling: serial macroscopic sectioning

SB was removed in one fragment and measured more than 3 cm in 94% of the cases (mean size 60 mm, 5–250 mm). For SB margin assessment, either the surface of the specimen was inked or the surgeon during the same operation removed additional tissue in the remaining cavity after excision of the specimen (surgical margins). After fixation in Holland Bouin, SB and margin specimens were serially sectioned in their entirety into numbered slices every 2 mm [12]. In most cases (89%), careful macroscopic examination of the specimen failed to reveal any lesion. Each numbered slice was put in as many numbered separate cassettes as necessary and paraffin-embedded in sequence. The median number of blocks per SB was 26 (from 2 to 180) and 8 (from 1 to 44) for surgical margins. Each block was examined on one hematoxylin–eosin–safran stained slide.

Classification of lesions and review of slides

Since 1975, all patients have been prospectively included in our clinical, histologic, and biologic database by senior pathologists (IM, GMG, IS, JMC). For each SB and each lesion, we prospectively entered in our pathologic database morphological descriptive criteria by using 65 pathological items for noncancerous lesions and 181 for cancers. Definitions and terminologies given in the literature were used to report columnar cell lesions (CCL), non-atypical ductal hyperplasia, atypical ductal hyperplasia, ductal carcinoma in situ (DCIS), and lobular carcinoma in situ (LCIS) [1, 4, 7, 10, 17, 19, 21–28, 38, 43–45, 47, 49, 50, 56, 59, 61, 69, 72, 74, 75]. The interest of our database was to collect morphological descriptive criteria of nearly all the breast lesions without labeling them. In fact, labels and definitions of breast lesions have varied throughout the past 30 years, while neither lesions nor their corresponding descriptive criteria (i.e., size, type, architecture, cellular and nuclear features, etc...) have changed. The only changes during this period were the definitions and/or the names given to these lesions. As we have listed for each lesion all the corresponding descriptive criteria among the 236 available items, we have been able to reclassify each lesion according to the "new" criteria recommended by referent authorities for a new definition, by selecting in our database the "new" correspondent descriptive criteria corresponding to this new definition. Consequently, this provided a

homogeneous approach to the pathological lesions at the time of our study. For example, low-grade DCIS≤2 mm have been reclassified as atypical ductal hyperplasia/ductal intraepithelial neoplasia (ADH/DIN) 1B (n=30) according to the new AJCC/UICC classification of breast tumors [70], and lesions that we used to term before 1997 [71] as clinging carcinoma of the monomorphic type [4] have been reclassified as flat epithelial atypia (FEA)/DIN 1A or columnar cell change (CCC) with atypia (n=84) [61]. About half of these 114 cases have been systematically reviewed by one (IM) or two senior pathologists (IM and GMG or IS), and there was a complete concordance between the second review and the initial descriptive criteria listed in the database. Similarly, lesions that we used to name LCIS before 1997 have been renamed lobular neoplasia (LN) since 1997, corresponding either to atypical lobular hyperplasia (ALH) or to LCIS. On the contrary, all the cases with micropapillary lesions were reviewed (n=155) because there was no item corresponding to precise descriptive criteria of micropapillations (number, topography around the duct, type).

Atypical ductal hyperplasia: definition and sizing

Among the group of ADH/DIN 1B, we individualized two morphologic types of ADH. Neither had any high-grade cytological atypia or necrosis.

ADH "mimicking DCIS" (Fig. 1). In this type, architectural atypia were qualitatively insufficient to allow a diagnosis of DCIS, therefore this "mimicking" DCIS lesion was classified as ADH whatever its size. Tufts and short micropapillations formed by cells had a broad base and were cohesive. There was no polarization of cells, i.e., no true cribriform spaces. Pseudo-cribriform patterns comprised irregular or relatively round microlumina with incomplete polarization of surrounding epithelial cells. Cellular bridges were wavy without any cellular polarization. Cells corresponded either to columnar cells with uniform ovoid to elongated nuclei or to cells with a slight increase in the nuclear/cytoplasmic ratio with more or less distinct cell borders and round or ovoid nuclei. These cells were sometimes admixed in the same lesion displaying a morphological gradient, but there was no regular arrangeent. Nuclear chromatin was evenly dispersed, homogeneous, or slightly marginated, and nucleoli were inconspicuous. Apical snouts, intraluminal secretions, and psammoma-type calcifications were frequently present.

ADH corresponding to "mini DCIS" (Fig. 2). In this type, architectural and cytologic atypia corresponded to a low-grade DCIS but were quantitatively insufficient to allow a diagnosis of DCIS, therefore this "mini" DCIS lesion was classified as ADH when ≤2 mm. Tufts and short micropapillations had a tight base, were present on over all the periphery of the duct, and were non-cohesive with small

free papillary tufts in the lumen. There were true cribriform patterns with a polar organization of cells around glandular spaces and/or variants of cribriform patterns (i.e., trabecular bars, cartwheel formations, and Roman bridges, Fig. 3) with polarized cells arranged perpendicular to the axes. Some solid areas with regular arrangement of cells were also present. Cells were often small, monomorphous, sometimes without a columnar change, with a distinct cytoplasmic membrane and a spaced regular round nucleus with uniformly dispersed chromatin without prominent nucleoli. Intraluminal secretions and calcifications (amorphous or psammoma-type) were also frequently present (Fig. 4). When one mini DCIS focus was found in one partially or completely involved duct/ductular cross-sections in one terminal ductal lobular unit (TDLU), it was classified as ADH when it measured ≤2 mm and as DCIS when it measured >2 mm. When there were several foci of "mini" DCIS in close duct/ductular cross-sections in the same TDLU or in TDLUs located in the same field at low power magnification (2.5), the lesion was classified as ADH when its size, i.e., its largest diameter, was ≤2 mm and as DCIS when >2 mm. When there were several foci of "mini" DCIS in distant duct/ductular cross-sections in the same TDLU or in close TDLUs, the size of each focus was assessed separately. FEA, rare and scattered single micropapillations, and cribriform variants

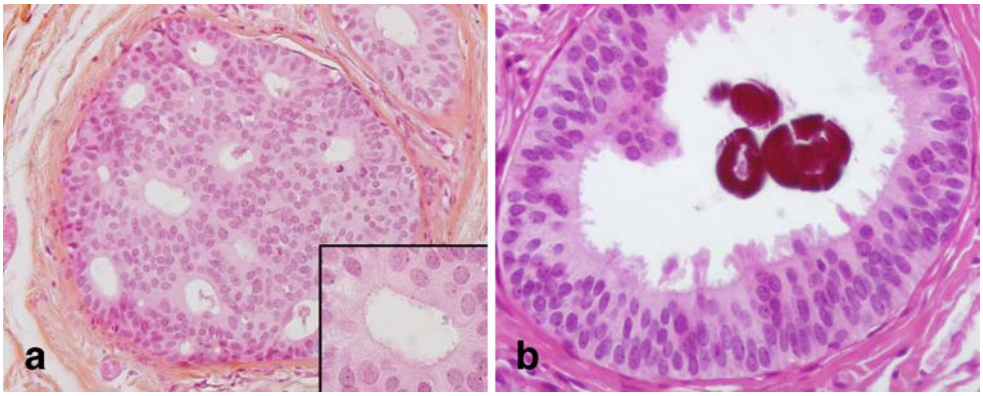

Fig. 4 **a** and **b**. **a** Mild cytologic atypia. **b** Columnar cells with uniform ovoid nuclei, intraluminal calcifications

were not taken into consideration for sizing, even if located in the same TDLU.

FEA were present either as a single lesion or in association with ADH in the same TDLU and since 1997 have been included in the ADH group. The distinction of FEA from columnar change without atypia was based on the criteria given by the WHO for the definition of FEA. Furthermore, columnar change without atypia was characterized by one or two layers of columnar cells without nuclear atypia, i.e., no increase in the nuclear/cytoplasmic ratio, no prominent nucleoli. Nevertheless, some cases of columnar change with progesterone impregnation, especially in the second part of the cycle, might display a lobular distension with a secretory material and large nuclei with prominent nucleoli. In such cases, myoepithelial cells displayed the same alterations with clarified cytoplasms, thus facilitating the diagnosis. The distinction of ADH mimicking DCIS from usual hyperplasia (UDH) was based on morphological criteria. Architectural pattern and cytologic criteria of usual ductal hyperplasia were easy to identify in most cases. UDH corresponded to a proliferation of epithelial cells in solid or fenestrated areas without any polarization of surrounding cells. Cells were haphazardly arranged with overlapping nuclei or were parallel with characteristic streamings. They were elongated or pseudo epithelioid, but there was no columnar metaplasia. Cytoplasms were more or less abundant with indistinct borders. Nuclei had irregular size and shape and sometimes contained a prominent eosinophilic inclusion. In some rare cases, immunohistochemical staining with cytokeratin 5/6 [41] was used and was negative in ADH mimicking DCIS and strongly positive in UDH. In some lesions, differential diagnosis between ADH and low-grade DCIS was all the more difficult because there were intermediate and intricated morphological aspects in the same TDLU. In practice, diagnosis of micropapillary lesions was often difficult. Extensive micropapillary lesions were classified as DCIS when quantitative and qualitative criteria were simultaneously present, i.e., lesion sizing more than 2 mm corresponding to micropapillations with a tight base over the entire periphery of the ducts. Additional sections could be useful for demonstrating more or less qualitative or quantitative diagnostic criteria. When malignancy remained equivocal, the case was classified as ADH. When a concomitant cancer was diagnosed, histologic size was assessed, and in DCIS, the percentage of blocks with cancer ("positive blocks") was specified [13]. Presence and topography of microcalcifications were also assessed. Lastly, when FEA and/or "mimicking" DCIS foci were found on excision margins of a SB with DCIS, a further surgical resection was not performed.

Follow-up of patients with epithelial atypia as a single lesion

There were 443 patients with epithelial atypia in one or several SB, without any previous or synchronous carcinoma in the same or contralateral breast and treated by biopsy alone (median follow-up 160 months, 7 to 315). Only 28/443 (6%) were lost to follow-up. Among the 415 other patients, 180 were monitored at our institute and 235 outside by correspondent specialists working in close relationship with our institute. All patients received a clinical examination and mammography once a year. When a new biopsy was necessary, it was performed at our institute.

Statistical analyses

Comparison of clinical and histologic characteristics was conducted by using the chi-square test. For women with epithelial atypia, the probability of developing in situ or invasive cancer was calculated from the date of the first biopsy to the earliest event: breast cancer (ipsi- or contralateral), death, or last contact (last consultation for the group monitored at our institute and checkpoint date, i.e., 1 March 2004, for the others). Probabilities were calculated according to the Kaplan–Meier method (SPSSv11).

Results

Occurrence of epithelial atypia in the 2,833 surgical biopsies

Epithelial atypia were recorded in 971/2,833 SB (34%). They were found with and without a concomitant cancer in 301/971 (31%) and 670/971 (69%) of the cases, respectively. Thus, isolated epithelial atypia were found in 23% of the cases (670 out of the 2,833 SB). Calcifications were present at histologic examination in 98.6% of SB with cancer and were located in benign, cancerous, and both lesions in 10, 39, and 51% of the cases, respectively. In several cases, cancerous foci without any microcalcifications were located at points distant from those with calcifications detected by needle localization.

Types of epithelial atypia

Among the 971 SB with epithelial atypia, there were 101 SB with FEA as a single lesion (11%), 342 (35%) with ADH, 223 (23%) with LN, and 305 (31%) with ADH and LN. Thus, ADH was encountered in 647/971 SB (66%).

Types of cancers associated with epithelial atypia

Cancers associated with epithelial atypia corresponded to DCIS and micro-invasive carcinoma (DCIS-MI) in 233 cases (77%). Among invasive carcinomas (n=68), there were 13 (9%) lobular and 11 (6%) tubular carcinomas (Table 1). Cancers were small (≤5 mm in 46% of invasive carcinomas, fewer than half of the blocks positive in 76% of DCIS). They were non-high grade in 78 and 67% of DCIS and invasive carcinoma, respectively. In most cases, ADH and cancer were situated close to each other. FEA alone were less frequently associated with a concomitant cancer than ADH and/or LN ($p=5\times10^{-4}$).

Cancers without epithelial atypia (malignancy alone)

There were 821 malignant SB without epithelial atypia [590 micro-invasive carcinomas, 206 infiltrating ductal carcinomas (IDC), and 25 infiltrating lobular carcinomas (ILC)].

Subsequent cancer in patients with an initial diagnosis of epithelial atypia as a single lesion

At 5 and 10 years, the probabilities of developing invasive breast cancer in the group of 443 patients with epithelial atypia were 2.8% [95%CI=1.4 to 5.5] and 5.5% [95%CI= 3.3 to 9.9], respectively (Fig. 5). Among the 18 subsequent carcinomas, 15 were invasive (11 IDC and 4 ILC), and 3 corresponded to DCIS. Most subsequent carcinomas were encountered in the homolateral breast (n=14) and before 10 years (n=16). Seven carcinomas occurred in the group of patients with an initial diagnosis of LN, in the same (n= 5) or contralateral (n=2) breast. They corresponded to infiltrating ductal (n=6) or lobular (n=1) carcinomas. The interval of development was 4, 5, 6 (n=2), 9, and 12 (n=2) years. Seven carcinomas occurred in the group of patients with an initial diagnosis of ADH, in the same (n=3) or contralateral (n=4) breast. They corresponded to DCIS (n= 2) and to infiltrating ductal (n=4) or lobular (n=1) carcinomas. The interval of development was 1, 2, 3 (n=3), 9, and 12 years. Four carcinomas occurred in the group of patients with an initial diagnosis of ADH associated with LN, in the same (n=3) or contralateral (n=1) breast. They corresponded to DCIS (n=1) and to infiltrating ductal (n=2) or lobular (n=1) carcinomas. In the four cases, the interval of development was 4 years. There was no subsequent carcinoma in the group of patients with FEA.

Table 1 Types of concomitant cancers (n=301) in the 971 surgical biopsies with epithelial atypia

Epithelial atypia	FEA (n=101)		ADH (n=342)		LN (n=223)		ADH+LN (n=305)	
	No. of cases (%)		No. of cases (%)		No. of cases (%)		No. of cases (%)	
Without cancer	84	83	220	64	139	62	227	74
With cancer	17	17	122	36	84	38	78	26

Discussion

Application of the WHO classification: practical considerations

For a long time, DCIS was diagnosed even if the characteristic features were found in only one ductal space [6]. Thereafter, some authors introduced quantitative criteria for distinguishing between ADH and DCIS [46, 67], while others [23] rejected them. More recently, Rosen [57–59] and Schnitt and Vincent-Salomon [61] described CCL comprising CCC and columnar cell hyperplasia (CCH) with and without atypia. Nasser [40] challenged this classification based on columnar shape and limited the group of lesions to proliferations characterized by a low-grade atypicality, "atypical columnar cell lesions," (ACCL) rather by a columnar cell configuration. In the WHO classification, ADH includes various not clearly defined types of lesions (Table 2). On one hand, there are lesions with arcades, moundings, and micropapillary formations, but without any true cribriform/complex architectural patterns [34]. This type of ADH corresponds to the CCH with atypia of Schnitt and Vincent-Salomon [61] termed category 3 in Simpson's study [51], to the definition of ADH by Koerner [34] and to ADH "mimicking" DCIS in our study. On the other hand, there are lesions displaying architectural and cytologic atypia. This type of ADH corresponds to the complex architectural pattern with cytologic and architectural atypia of Schnitt and Vincent-Salomon [61] termed category 5 in Simpson's study [64], to the definition of "microfocus of DCIS" by Koerner [34] and to "mini DCIS" in our study. In Simpson's study, the ADH/category 5 contained chromosomal changes and the same total mean number of changes to that observed in DCIS/DIN IC, unlike the other CCL. Lastly, because there is still no consensus for measuring ADH, there is no clear-cut distinction between ADH and DCIS, and the cut-off at 2 or 3 [52] mm or at two completely involved spaces [70] seems arbitrary. While awaiting a definitive molecular classification, the simplest attitude could be recommended in routine

Table 2 Terminologies used for intraductal proliferative lesions with low-grade cytologic atypia, so-called atypical columnar cell lesions

Spectrum of lesions	1, 3–5 Layers	No polarization*	With polarization	
	Occasional mounding	Mounding, arcades	Cribriform spaces and their variants	
	No or rare arcades and micropapillary formations	Cohesive micropapillary tufts with a broad base	Non-cohesive micropapillary tufts with a tight base	
[70]	Flat epithelial atypia/DIN 1A	ADH/DIN 1B≤2 mm; or in two spaces		DCIS/DIN 1C
[59, 61]	Columnar cell hyperplasia with atypia		ADH if not extensive	DCIS if extensive
			=	
	Columnar cell change (CCC) with cytologic atypia		Complex structures with architectural and cytologic atypia	
[34]	Columnar cell lesions + ADH		Microscopic focus of DCIS	DCIS
Institut Bergonié	Ex-clinging carcinoma of monomorphic type	ADH "mimicking" DCIS	ADH corresponding to "mini" DCIS≤2 mm	DCIS
[64]	CCC with cytologic atypia Or CCH with cytologic atypia	CCH with architectural atypia	CCH with architectural atypia And Cytologic atypia	DCIS
Regrouping?	DIN 1A	ADH/DIN 1B Not measured	ADH/DIN 1C Measured: ≤3 mm	DCIS/DIN 1C >3 mm

*Or incomplete polarization

practice. Only mini foci of ADH obviously similar to low-grade DCIS foci could be measured and classified as ADH when equal to or less than 2–3 mm [52] and as DCIS when more than 3 mm. Although the mode of measurement in our study is not under consensus, it is simple and can been routinely applied.

Occurrence of epithelial atypia and their association with a concomitant cancer: practical considerations

In our study, the proportion of epithelial atypia is high (23%), a result difficult to compare to others in the literature, as the methodologies used by teams are different. In the Page and Dupont case-control studies [15, 46], ADH and ALH were found in 2.1 and 1.6% of the cases, respectively. In mammographic screening programs, epithelial atypia and cancers increase as the number of biopsies performed for microcalcifications increases, especially as ACR4/ACR5 lesions are more often excised than ACR3. However, as underlined by Page [46], "the most direct relationship of epithelial atypia incidence is to slide rating." The number of slides per SB in our study (median 26) was higher than in the other studies on benign breast lesions: 1–5 in 93% of the cases in the study of Page et al. [46] (n=283), 3 (range 1–25, n=674) in the study of Shaaban et al. [62], and a mean of 1.6 slides per cm of tissue (n=199) in the study of Tavassoli and Norris [67]. In a recent study conducted in the south west of France in women aged between 50 and 75 with mammographically detected non-palpable breast lesions, a similar proportion of atypical lesions were found when biopsies were serially sectioned [39]. Furthermore, this high slide rating allowed the detection of small concomitant cancers in the vicinity of epithelial atypia in 31% of our cases, with a skew towards low-grade lesions (high proportions of DCIS and low-grade invasive carcinomas, especially tubular carcinomas). Our results strengthen the hypothesis that FEA and ADH are risk markers of low-grade cancers. This has been confirmed by the study of Simpson et al. [64] on molecular genetic profiles of CCL. In some of them, there are both a morphological and a molecular continuum in the degree of proliferation and atypia, supporting the hypothesis that "CCL are a non-obligate, intermediary step in the development of some forms of low grade in situ and invasive carcinoma." The association of epithelial atypia with a concomitant cancer in nearly one third of the cases in our study parallels previous findings concerning the frequency of cancers found in SB performed for atypia in CNB. Thus, approximately 30% [20, 29] and 15 to 21% [5, 8, 14, 18, 35, 45, 53, 63, 76] of excisions after CNB with ADH and LN, respectively, were proven to have cancer. Consequently, excision is recommended [45] for all patients in whom ADH is identified on CNB and may be justified in patients with FEA, as they are included in the spectrum of ACCL. Excision remains a controversial issue in patients with LN. Some authors have advocated it [3, 18, 33, 63], while others have rebutted it [55], especially when LN is an incidental non-extensive finding [48] with no radiologic–pathologic discordance [18] and without any synchronous mass lesion [37]. SB corresponding to re-excision should be processed in its entirety by serial macroscopic sectioning [32, 65]. When pathologic examination is exclusively focused on mammographic calcifications, the risk is to underestimate the DCIS size/extension because cancerous foci without any calcification (10% in our study vs 6% in Owing'study) [42] may be located at points distant from those with benign breast tissue containing calcifications.

Subsequent cancer after an initial diagnostic of epithelial atypia as a single lesion: practical considerations

In the literature, 4 to 22% (average interval 8.3 years follow-up) [6, 42, 67] and 15 to 20% [16, 30, 56] of patients developed invasive carcinomas after a diagnosis of ADH and LN, respectively. The risk of developing cancer increases with extended follow-up, but many cancers after a diagnosis of LN have a good prognosis and a low mortality [36]. These results are difficult to compare to ours because the methodologies are different. The low probabilities of subsequent invasive cancer in our study could be due to the high slide rating, allowing the detection of small concomitant cancer that might have been missed with a low slide rating and inadequate patient management [11, 54].

In conclusion, when epithelial atypia are present, they are associated in nearly one third of the cases with a concomitant close cancer and are found as isolated lesions in nearly 23% of SB performed for microcalcifications. In practice, ADH should be more clearly defined with simple guidelines for measuring lesions. When malignancy remains equivocal and/or when sizing is difficult, it is better to classify the lesion as ADH. Epithelial atypia could be more a "risk factor" of a concomitant geographically small close cancer than a risk marker for a subsequent cancer, as they form part of a spectrum of lesions [64].

Ki-67 expression in primary breast carcinomas and their axillary lymph node metastases: clinical implications

Daehoon Park · Rolf Kåresen · Tove Noren · Torill Sauer

Received: 11 January 2007 / Revised: 20 April 2007 / Accepted: 13 May 2007 / Published online: 7 June 2007

Abstract Proliferative activity of tumour cells assessed by immunohistochemical Ki-67 expression is one of several prognostic indicators in breast cancer. The major objective of this study was to investigate the prognostic impact of Ki-67 proliferative activity in the axillary lymph node metastases and in the matched primary breast carcinoma from 194 patients. There was a statistically significant up-regulation of Ki-67 protein in the metastatic deposit compared to where the primary tumour was found (p=0.001). A low Ki-67 index in both the primary and the metastatic tumours was a favorable prognostic factor. A high index in both primary and metastatic lesion and an up-regulation from a low index in the primary tumour to a high index in the metastatic deposit represented an unfavorable prognostic factor. Multivariate analysis showed that Ki-67 expression in the metastases was a superior independent prognostic factor of clinical outcomes compared to that in the primary tumours. Ki-67 expression in ≥10% of carcinoma cells in the primary tumours and ≥15% in the nodal metastases seems to be optimal cut-off levels. Ki-67 is of value as an independent prognostic factor in breast cancer.

Introduction

The proliferative capacity of breast cancer is an important prognostic factor and can be evaluated by a variety of methods such as number of mitoses per 10 high power field (HPF), thymidine labeling index, bromodeoxyuridine labeling, S-phase fraction, and Ki-67 /MIB-1 antigen, Ki-S1 antigen, and proliferating cell nuclear antigen proliferative index [4, 11, 17, 24]. Determination of the proliferative index by means of immunohistochemistry (IHC) represents an easy and reliable method of assessing tumour cell proliferation in breast cancer [1, 23].

Ki-67 is a labile, nonhistone nuclear protein that is tightly linked to the cell cycle and is expressed in all continuously cycling cells of mid-G_1, S, and G_2 phase and in mitosis, but not in quiescent or resting cells in the G_0 and early G_1 phase [12]. As this protein is present in all proliferating cells (normal and tumour), it may serve as a marker to evaluate the growth fraction of a given cell population [7]. The functional significance of Ki-67 protein in cell cycle regulation still remains unknown [23]. Previous studies have shown controversial results concerning Ki-67 as an independent prognostic factor [18, 19, 25, 31]. To our knowledge, no study has investigated the relationship of Ki-67 expression in the metastatic lesions with clinical outcomes in breast cancer.

We have assessed the associations between Ki-67 immunoreactivity and other established clinicohistopathological parameters and the prognostic significance of Ki-67 both in primary breast carcinomas and in their corresponding axillary lymph node metastases (ALNM). We have also compared Ki-67 immunoreactivity in the primary tumours with the corresponding metastases and discuss the clinical implications of our findings.

Materials and methods

Patients

The study comprised 194 consecutive breast cancer cases that, from May 2000 to August 2004, underwent mastectomy or breast conserving surgery with complete axillary dissection at Ullevaal University Hospital for primary breast carcinomas with ALNM. Patients, 191, received postoperative adjuvant therapy according to national adjuvant treatment guidelines (http://www.nbcg.net/filer/79.ppt). Follow-up included clinical examination at 6–12 months intervals with annual mammography. Paraffin sections from the primary tumours and their corresponding metastases were retrieved from the archives. Data registered included age, tumour size, histological subtype, and grade, estrogen/progesterone receptor (ER/PgR) status, size of the largest metastatic focus and number of lymph nodes with metastasis. The characteristics of the study population and their specimens are summarized in Table 1. The median number of lymph nodes with metastasis was one (range : 1–27). The histological subtype and grade of the primary tumours had been evaluated according to the criteria of the World Health Organization [28] and the Elston and Ellis system [10].

Immunohistochemistry

Paraffin sections were immersed in Tris/ethylenediaminetetraacetic acid (EDTA) pH9 (HIER) in microwave oven (2.5 min at 750 W and 15 min at 160 W) for antigen retrieval. The IHC staining of Ki-67 was performed with the Ventana ES automated immunostaining system (Ventana Medical Systems, Inc., Tucson Arizona, USA), using mouse monoclonal antibodies with Ki-67 (Clone MIB-1; dilution 1:75; DAKO Norden A/S, Glostrup, Denmark).

The histological sections were reviewed to ensure representative tumour tissue for IHC from both primary tumour and its corresponding metastatic deposit. IHC analysis was carried out simultaneously on the primary mammary tumours and their corresponding metastases. The number of positively stained nuclei of all cases was assessed by one observer (DP). Another 35 randomly chosen cases were examined by TS to assess the inter-observer variation. Ki-67 positive nuclei were counted in several random areas including the periphery. At least 100 nuclei were counted in each area using a ×40 objective magnification. The results were expressed as percentages of positively stained nuclei over the total number of nuclei counted. The mean of the percentages of positively stained nuclei obtained in all areas was used for defining high/low Ki-67 index. A cell was considered positive if there was a clearly detectable brown colour in the nucleus. Cytoplasmic staining was considered nonspecific and was interpreted as negative. For high/low Ki-67 indices, four different cut-off values, 5, 10, 15 and 20%, were set and tested.

Statistical analysis

The results were analyzed using the statistical software SPSS 14.0 for Windows (SPSS Inc., Chicago, IL, USA). The comparison between the percentage of cells expressing Ki-67 in the primary tumour and ALNM was evaluated for statistical significance using Student's *t* test. The correlation between Ki-67 protein at the four different cut-off points and histopathological parameters was assessed using the χ^2 test and linear-by-linear test. For the interobserver agreement, the kappa (κ) statistic [15] was used. (Value of κ; poor to fair agreement: <0.4, moderate: 0.4–0.6, substantial: 0.6–0.8, almost perfect: >0.8). The clinical end points in the survival analysis were: disease/relapse free survival (DFS),

Table 1 Summary of the characteristics of the study population (N=194) and their specimens

Characteristics	Values
Age (years)	
Median (range)	54 (22–82)
Primary tumour type	
Invasive ductal carcinoma	172 (88.7%)
Invasive lobular carcinoma	22 (11.3%)
Primary tumour grade	
1	42 (21.6%)
2	112 (57.7%)
3	40 (20.6%)

Total number of relapse (local/systemic)	28 (4/24)

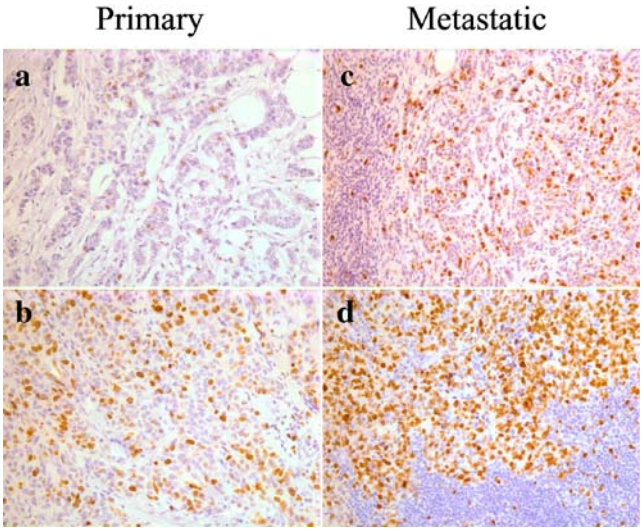

Fig. 1 Expression of Ki-67 protein in two primary tumours and their corresponding axillary lymph node metastases. (IHC, magnification ×200). Tumour 1 reveals a low number of positively stained nuclei (Ki-67 negativity) in the primary tumour (**a**), whereas the number of positively Ki-67 stained nuclei in the axillary lymph nodal metastases is significantly increased (**c**) (up-regulation). In tumour 2, both the primary (**b**) and metastatic carcinoma cells (**d**) show Ki-67 positivity, but the metastatic lesion reveals a higher number of Ki-67 positive cells than the primary tumour

distant disease free survival (DDFS), and breast cancer specific survival (BCSS). Kaplan–Meier survival curves were constructed, and the survival rates were compared using the log-rank test. Uni- and multivariate analyses of the independent prognostic factors were performed using the Cox proportional hazards regression model (stepwise backward elimination). A p-value of <0.05 was considered statistically significant.

Results

Method validation

The interobserver reproducibility was tested in 35 randomly chosen patients according to Ki-67 cut-off values and the tumour sites (i.e., in the primary tumours and in the ALNM). The agreements between the two observers were in the sufficient or good agreement range, irrespective of Ki-67 cut-off values and the tumour sites (k>0.6).

Expression of ki-67 in the primary tumours and their corresponding ALNM

There was a significant difference in the number of positively stained cells between the primary tumours and the corresponding ALNM (p=0.001) for Ki-67 immunoreactivity (Fig. 1). The mean percentage of positively cells was 11.4% in the primary breast tumours and 18.1% in the metastases (11.4±17.9 and 18.1±20.7%, respectively).

Correlation of ki-67 expression in primary and metastatic tumour with other histopathological parameters

Ki-67 expression in the primary tumours and the metastases correlated with a high histological grade (all Ki-67 cut-off values, p<0.001) and with a negative ER/PgR status (p=0.05~p<0.001). No correlation was found with age, cancer type, tumour size or number of lymph nodes involved. All cut-off values for Ki-67 expression in the ALNM correlated with the size of the metastases. The relationships between Ki-67 IHC staining and histopathological parameters are detailed in Table 2.

Prognostic value of ki-67 in primary and metastatic tumours

All 194 patients were included in the analyses for DFS, DDFS and BCSS. Twenty-eight patients had been diagnosed with recurrence within a median observation time of 40 months after primary surgery (range 8–73 months). A local relapse without distant metastasis was observed in 4 of 28 patients, while distant metastases occurred in 24. Nine had died of breast cancer.

Uni- and multivariate analyses

Age, cancer type, hormone status, histology grade, primary tumour size, size of largest metastatic focus and Ki-67 expression were all tested as prognostic factors in uni- and multivariate analyses. Hormone status, histology grade, primary tumour size and Ki-67 with 10 and 20% cut-off points both in the primary breast tumours and the nodal metastases were significantly correlated with both DFS and DDFS in univariate analyses. Ki-67 with 5 and 15% cut-off points in the primary tumours did not reveal association with DDFS. Multivariate Cox regression analyses based on four different Ki-67 cut-off values (Table 3) showed that primary tumour size and Ki-67 for all cut-off points in ALNM were significant prognostic factors for DFS. The same prognostic factors were found for DFS with exception of Ki-67 with 5% cut-off point where only histological grade and primary tumour size were independent prognostic factors. No independent prognostic factor was found for BCSS in uni- or multivariate analysis.

Survival analyses according to different cut-off values

Kaplan–Meier survival analyses based on four different Ki-67 cut-off points showed significantly reduced DFS and DDFS in patients with high Ki-67 index in the ALNM and in the primary tumours compared to those with low Ki-67 index ($p=0.036 \sim p<0.001$). In the primary tumours, the survival curves for Ki-67 with 5% and 15% cut-off points showed no significant difference in DDFS. The DDFS curves for Ki-67 with all four cut-off points are shown in Fig. 2. A high Ki-67 expression with cut-off points of 15 and 20% in the metastases was significantly associated with a shorter BCSS ($p=0.048$ and 0.037, respectively), whereas Ki-67 expression with the other cut-off values showed no difference in survival.

Survival analyses according to the combined results of both Ki-67 expressions in primary and in metastatic tumours

Most cases had a similar Ki-67 expression in the primary tumour (10% cut-off) and its corresponding metastasis

Table 3 The prognostic factors (multivariate analyses, stepwise backward elimination)

Variables	HR	DFS 95% CI	*p*-value	HR	DDFS 95% CI	*p*-value	HR	BCSS 95% CI	*p*-value
Ki67 with 5% cut-off value									
Age (<55 vs ≥55)		NS			NS			NS	
Cancer type (IDC vs ILC)		NS			NS			NS	
Hormone receptor status[a] (− vs +)	0.4	0.2–0.9	0.025		NS			NS	
Histology grade ($G_{1–2}$ vs G_3)		NS		2.5	1.1–5.7	0.034		NS	
Tumour size (T_1 vs $T_{2–3}$)	3.5	1.6–7.6	0.001	4.0	1.7–9.5	0.002		NS	
Size of largest metastatic focus (0.2–2 mm vs > 2 mm)		NS			NS			NS	
Ki67 in primary tumours (− vs +)		NS			NS			NS	
Ki67 in metastatic tumours (− vs +)	4.0	1.2–13.5	0.026		NS			NS	
Ki67 with 10% cut-off value									
Tumour size (T_1 vs $T_{2–3}$)	3.7	1.7–8.1	0.001	4.8	2.0–11.5	<0.001		NS	
Ki67 in metastatic tumours (− vs +)	5.9	2.0–17.4	0.001	5.8	2.0–17.2	0.001		NS	
Ki67 with 15% cut-off value									
Tumour size (T_1 vs $T_{2–3}$)	3.6	1.7–7.8	0.001	4.7	2.0–11.0	<0.001		NS	
Ki67 in metastatic tumours (− vs +)	4.1	1.6–10.3	0.003	5.1	1.9–13.6	0.001		NS

Tumour size (T_1 vs $T_{2–3}$)	3.2	1.5–6.9	0.003	4.2	1.8–10.0	0.001		NS	
Ki67 in metastatic tumours (− vs +)	4.4	2.0–9.8	<0.001	5.1	2.1–12.5	<0.001		NS	

From Ki-67 with 10% cut-off value, the significant prognostic factor(s) were simply enrolled in the table.

DFS Disease free survival, *DDFS* distant disease free survival, *BCSS* breast cancer specific survival, *HR* hazard ratio, *CI* confidence interval, *IDC* invasive ductal carcinoma, *ILC* invasive lobular carcinoma, *NS* nonsignificant

[a] Hormone receptor status: positive—ER and/or PgR positive; negative—ER and PgR negative

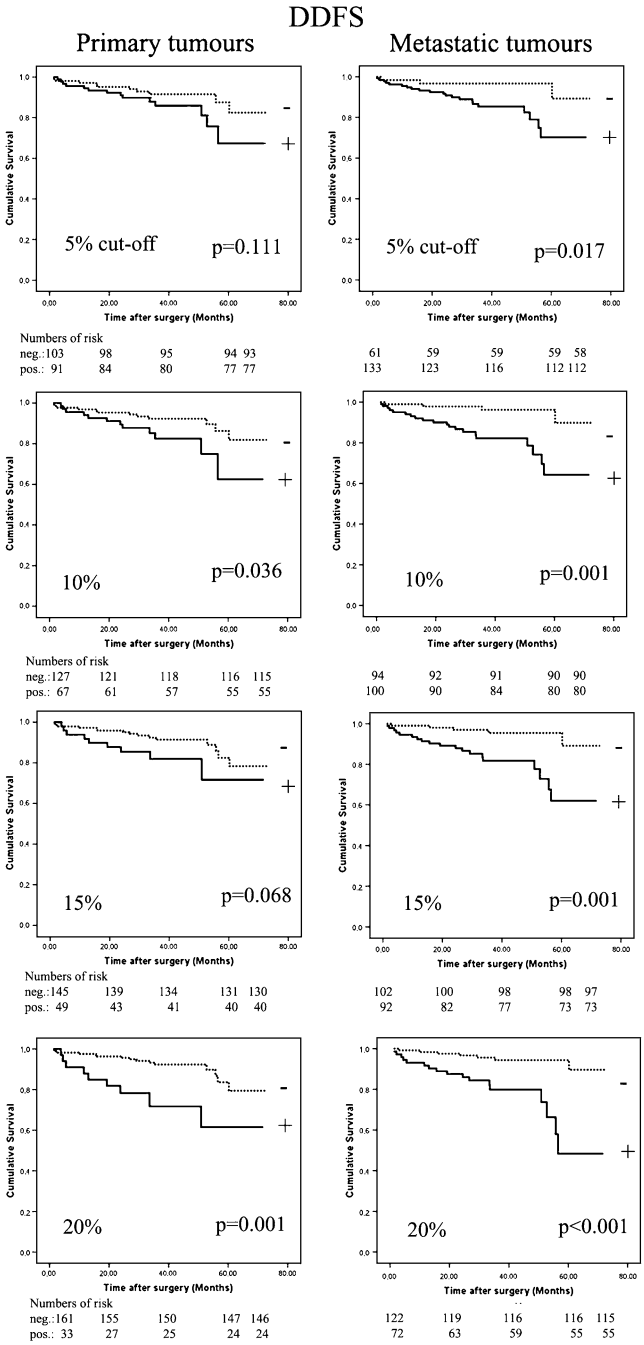

Fig. 2 Kaplan–Meier survival analyses based on four different Ki67 cut-off values show significantly shorter distant disease-free survival (DDFS) in patients with high Ki67 index in the nodal metastases and in the primary tumours compared to those with a low Ki67 index. No difference was found in 5 and 15% cut-off points in the primary tumours

(15% cut-off), either low (P−/M−: n=86, 44.3%) or high (P+/M+: n=53, 27.3%). A different Ki-67 expression between primary lesion and corresponding metastasis was detected in 55 cases (P+/M−: n=14, 7.2% and P−/M+: n=41, 21.1%, respectively). The correlation between the four groups and clinical outcome is detailed in Table 4. There was a highly significant difference in DFS and DDFS between P−/M- and the other groups; DFS: P−/M− vs P+/M− (p=0.002), P−/M− vs P−/M+ (p<0.001) and P−/M− vs P+/M+ (p<0,001), DDFS: P−/M− vs P+/M− (p=0.02), P−/M− vs P−/M+ (p=0.001) and P−/M− vs P+/M+(p=0,001). There was no difference among the three groups that had a high Ki-67 index either in the primary tumour or in the metastasis (i.e., P+/M−, P−/M+, and P+/M+), whereas a significant difference in BCSS was found between P−/M− and P−/M+ (p=0.006). The survival curves are shown in Fig. 3.

Survival analyses according to the presence of high Ki-67 expressions either in the primary or in the metastatic lesion compared to histological grade

The distribution of the four groups (i.e., P−/M−, P+/M−, P−/M+, and P+/M+) according to histological grade is shown in Table 4. Two groups were created according to the presence or absence of high Ki-67 index irrespective of the tumour sites (i.e., P−/M− vs the other group with P+ or/and M+: P+/M−, P−/M+ and P+/M+ were regarded as one group) and analyzed for the survival rates. Grade 2 P−/M− cases had a significantly better DFS than the other group. No significant differences in DDFS and BCSS were shown, but the difference in DDFS showed a borderline significance (p=0.057). No statistics were computed for grade 1 and grade 3 cases because they were all censored.

Discussion

Cell proliferation rate is a major determinant of the biologic behaviour of invasive breast carcinoma [25]. Ki-67 protein expression is strictly correlated to cell proliferation and to the active phases of the cell cycle [23]. Assessment of Ki-67 index represents an easy and reliable method for evaluating cell proliferative activity in breast cancer [1]. In the present study, we have assessed Ki-67 expression and compared the proliferative activity of cells in the primary breast carcinoma and their corresponding ALNM. We have detected significantly higher Ki-67 activity in the ALNM compared to the primary tumours (p=0.001). The finding corresponds with the result of Buxant et al. [5] who reported that Ki-67 expression was significantly increased in the ALNM. There was a significant difference in clinical outcome (DFS, DDFS and BCSS) between the groups with similar Ki-67 expression levels in primary and metastatic tumours and the groups with different expression levels. The group with similar expression was composed mainly of cases with P−/M− (73%, 72/98). As expected, this turned out to be a group with favorable prognosis (Fig. 3). Cases showing different Ki-67 expression in the primary tumour and the corresponding metastasis and cases with a high

Table 4 The high (+) or low (−) Ki-67 expression in primary (P) and metastatic tumours (M) and correlation to histological grade and clinical outcome

Groups	Number of patients (%)	Number of patients within histological grade			Number of any relapse (%)	Number of systemic relapse (%)	Number of breast cancer death (%)
		1	2	3			
P−/M−	86 (44.3)	35	48	3	3 (10.7)	3 (12.5)	1 (11.1)
P+/M−	14 (7.2)	2	10	2	2 (7.1)	2 (8.3)	1 (11.1)
P−/M+	41 (21.1)	2	28	11	10 (35.7)	9 (37.5)	5 (55.6)
P+/M+	53 (27.3)	3	26	24	13 (46.5)	10 (41.7)	2 (22.2)

expression in both lesions had an unfavorable prognosis. This finding supports Buxant et al.'s supposition [5] that a primary tumour is composed of multiple cell populations and that only those with the most aggressive potential (like a high proliferative index) are the most likely to escape from the primary tumour and establish itself as a lymph node metastasis.

Previous studies have reported significant associations between high Ki-67 index and clinicohistopathological parameters, such as age [18, 22], tumour size [18, 30, 32], histologic grade [2, 3, 18, 27, 32], ER/PgR status [6, 8, 18, 27, 30, 32] and lymph node status [32]. We found a statistically significant correlation of high Ki-67 expression in metastatic breast cancer with increasing histologic grade, negative ER/PgR status, size of largest metastatic focus, but not with age, cancer type, tumour size and the number of nodes involved. The high correlation between Ki-67 and grade is not surprising, as Ki-67 expression and mitotic rate are strongly interrelated [9, 18, 27]. In agreement with our findings, Ding et al. [9] reported that most ERα positive tumours were negative for the proliferation marker, Ki67. They suggested that such an inverse association between ERα expression and Ki-67 expression might be due to their different tumourigenic features; i.e., ERα positive tumours are more likely to be well differentiated, while Ki-67 positive breast tumours are frequently poorly differentiated [9].

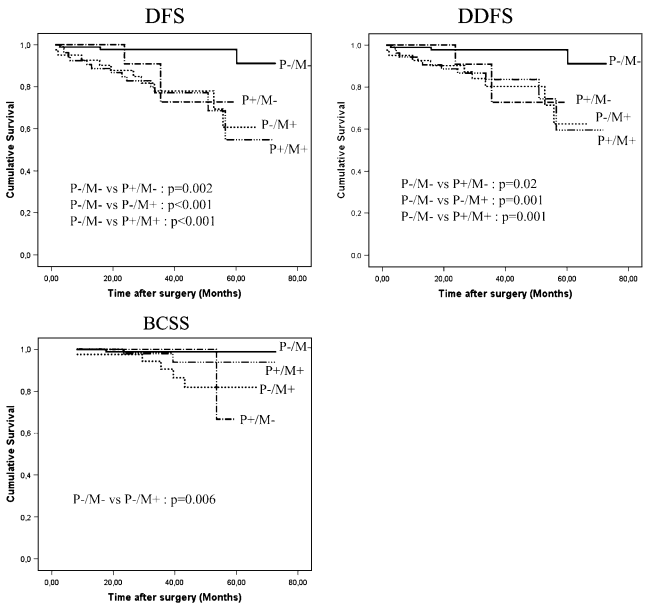

Fig. 3 The survival analyses (DFS, DDFS and BCSS) of all patients (n=194) according to the combined Ki67 status [high index (+) or low index (−)] in the primary tumours (P) and their nodal metastases (M). A significant difference in DFS and DDFS between P−/M− and the other groups was shown. No significant difference in DFS and DDFS among the combined groups (P+/M−, P−/M+ and P+/M+) was detected. In BCSS, the only survival difference between P−/M− and P−/M+ groups was significant

As there is no universally established standard Ki-67 cut-off value, we decided to treat Ki-67 expression as categorical variables by using four different Ki-67 cut-off points between 5 and 20% in 5% steps to be able to define a cut-off point for high/low proliferation rate in relation to clinical outcome.

Previous studies [3, 13, 14, 16, 21, 29] have shown statistically significant associations between Ki-67 immunoreactivity and clinical outcomes/survival. In our study, the associations between Ki-67 cut-off values and the predictabilities of DFS and DDFS were highly significant in all Ki-67 cut-off values both in the primary tumours and the metastases, except for Ki-67 expression of 5 and 15% cut-off in the primary tumours in predicting DDFS. The lack of significance in the two latter is probably due to too few cases in the group. BCSS correlated with Ki-67 expression at cut-off points of 15 and 20% in the ALNM. Ki-67 expression in more than 15% of tumour cells in the metastatic tumours pinpoint patients with a worse survival. Thus, it seems biologically "correct" to set the optimal "lower limit" of Ki-67 cut-off point to distinguish between a clinically relevant high and low proliferative activity at 15% in ALNM. In multivariate analysis, the Ki-67 expression in the metastatic tumours was a potential independent prognostic factor in predicting shorter DFS and DDFS. No association was found in BCSS, but the number of events with breast specific death (9/194) in the median follow-up of 40 months was low. A longer follow-up is probably required to see an eventual relation to BCSS.

Based on the statistical analysis, a cut-off of 10% seems to be optimal for Ki-67 expression in primary tumours. Ki-67 cut-off values have varied from one study to another. Some have used median values [14, 26], while others have chosen an arbitrary value (e.g., 10, 20% and so on) [9, 20, 25, 33]. Intriguingly, all the studies [14, 20, 26, 33] have shown a statistical correlation with clinical outcome irrespective of cut-off points. The reason might be explained by the fact that they all had chosen cut-off values that were found to be within the optimal range for evaluation of Ki-67 in the primary tumours.

On the basis of our results, we suggest that Ki-67 expression in ≥10% of carcinoma cells in the primary tumours and ≥15% in the ALNM should be used as cut-off levels for a clinically relevant prognostic difference. Evaluation of the Ki-67 index in the ALNM would pick up P−/M+ in addition to P+ cases. This would be in agreement with the finding that the level of Ki-67 expression in ALNM is a superior independent prognostic factor of clinical outcomes in metastatic breast cancer compared to that of Ki-67 expression in primary tumour.

The group with low Ki-67 index in both primary and metastatic tumour cells (P−/M−) is a favourable prognostic group albeit node-positive. Histological grade 2, P−/M− cases revealed significantly better survival than the other groups. The number of histological grade 1 P−/M− was probably too small to reach statistical significance. Histological grade 2 (and probably grade 1) tumours with a low Ki-67 expression in both the primary lesion and the corresponding metastasis (P−/M−) could be regarded as a low-risk group despite their ALNM and possibly with less need of adjuvant chemotherapy. However, further studies are necessary to confirm the association between low Ki-67 index (P−/M−) within grade 1 and 2 tumours and a good clinical outcome before such a conclusion might be drawn.

In conclusion, Ki-67 index has a potential to be used as an additional marker in metastatic breast cancer to select a high-risk (P+/M+, P−/M+ and P+/M−) and low-risk group (P−/M−) for distant metastasis that again might have consequences for adjuvant therapy strategies. Our results indicate that evaluation of Ki-67 expression in the axillary lymph node metastases is superior to evaluation of Ki-67 expression in primary breast carcinomas for predicting survival.

Abstract HER2 is an important tumour marker in breast cancer. However, there is controversy regarding which method reliably measures HER2 status. This study evaluates the concordance between *HER2* gene amplification in invasive breast cancer determined by fluorescence in situ hybridisation (FISH) and a new silver enhanced in situ hybridisation (SISH) technique. Ninety-nine cases were analysed by direct-labelled manual FISH (PathVysion®, Abbott/Vysis) and bright field automated SISH (INFORM®, Ventana). For comparison, all specimens were stained by immunohistochemistry (Dako-HercepTest™ and Ventana-PATHWAY®4B5). Evaluation was performed by five pathologists following the algorithms of the manufacturers and the American Society of Clinical Oncology/College of American Pathologists (ASCO/CAP) guidelines. Concordance was calculated and the value of κ statistics estimated. Overall concordance between FISH and SISH was 96.0% (κ=0.754, 95%CI). Discrepancies were mostly seen in tumours with intra-tumoural heterogeneity of HER2 amplification. In conclusion, *HER2* gene copy status can be reliably determined by SISH. The 96% concordance with FISH fulfils the ASCO/CAP requirement of greater than 95% concordance for amplified vs non-amplified cases. There was a low inter-observer variability in the interpretation of SISH, suggesting that SISH is equally reliable in determining *HER2* amplification as FISH. Because SISH combines bright field microscopy with molecular analysis and full automation, it appears to be particularly suited for routine application in surgical pathology.

Introduction

Identifying tumours which over-express the human epidermal growth receptor 2 gene (ERBB2; also referred to as HER2/neu) has become an established guide for treating breast cancer with targeted therapeutics [3, 15, 23], e.g. the humanised anti-HER2 monoclonal antibody trastuzumab (Herceptin® Genentech, South San Francisco, CA) [4, 20]. It may be equally important in the selection of patients responsive to a small molecule dual HER1/HER2 tyrosine kinase inhibitor lapatinib (Tykerb, GlaxoSmithKline, Philadelphia, PA), which in combination with capecitabine improves clinical outcome in advanced disease [10]. Without doubt, the therapeutic relevance of the ERBB2 status mandates highly reliable and robust assays. However, prospective sub-studies from 2 adjuvant randomised trastuzumab trials have shown that approximately 20% of HER2/neu protein assays proved incorrect when the same specimens were re-evaluated in a high volume, central laboratory [13, 19]. More recently, a consensus statement has labelled the high rate of inaccuracy of ERBB2 testing unacceptable [22]. Clearly, a reliable, reproducible and easy to perform procedure for assessing the ERBB2 status is of utmost importance because any specific antibody-based therapy can be effective only with the target present on the cancer cells to be attacked.

Amplification of the *ERBB2* gene appears to be the primary mechanism underlying over-expression of its gene product [2]. Basically, there exist two approaches to determine the ERBB2 status: detection of the protein and/or of the genomic status as provided by immunohistochemistry (IHC) and in situ hybridisation (ISH), respectively. Both have advantages and disadvantages; quantification or semi-quantification of IHC reactions is generally difficult and suffers from a great inter-observer and inter-laboratory variability whereas ISH enables the pathologist to perform a more robust quantification of the genomic alteration. However, the most widely used technology of fluorescence in situ hybridisation (FISH) requires specialised microscopic equipment and suffers from fading of fluorochromes, which comprises long-term stability. In addition, the inter-observer variability is comparably high due to the possibility of misinterpretation of signal vs noise. This means that FISH requires a learning curve and only persons experienced in FISH interpretation should read the slides [7]. Despite many attempts by the international pathology community to improve the accuracy of HER2 testing in routine practice, high inter-observer and inter-laboratory variability remains an issue with both IHC and FISH [1, 8, 11, 24].

A newly introduced fully automated method—silver enhanced in situ hybridisation (SISH)—may overcome some of the disadvantages mentioned above since it allows the quantification of the number of centromeric chromosome 17 and HER2-specific signals by conventional bright field light microscopy [1].

In the present study, the *HER2* gene amplification status of 100 consecutive breast cancer cases was examined in parallel by FISH and SISH. For validation and comparison of the genetic assays (FISH vs SISH) and to determine inter-observer variability, a panel of five pathologists (MD, IE, HH, HK, HM) read and scored the slides following the guidelines of the American Society of Clinical Oncology and the College of American Pathologists [22]. The results of two HER2/neu IHC assays were used for discrepancy analyses.

Materials and methods

Clinical material Diagnoses and tumour characteristics are listed in Table 1.

Slide preparations One hundred consecutive breast cancer cases diagnosed and treated surgically during the years 2005 and 2006 at the Interdisciplinary Breast Cancer Centre of the Charité-University Hospital Berlin were selected for the study. All cases were formalin-fixed, paraffin-embedded and processed in the routine diagnostic laboratory of the institute according to standardised protocols. The time of fixation in 4% neutral buffered formalin ranged between 6 and 24 h. All specimens were excisional biopsies with an extended part of invasive breast carcinoma.

The slides were prepared from archived paraffin blocks and were processed in parallel for H&E, FISH (PathVysion® HER-2 DNA Probe Kit, Abbott/Vysis), SISH (INFORM® *HER2* DNA Probe and ultraView™ SISH Detection Kit, Ventana) and IHC (HercepTest™, Dako and PATHWAY® anti-HER2/neu (4B5) Rabbit Monoclonal Antibody, Ventana). Before ISH and IHC staining, each case was checked to confirm the presence of invasive tumour tissue by three pathologists (MD, GL, AD). All procedures were performed at room temperature.

Staining procedures

Silver enhanced in situ hybridisation

Automated SISH of consecutive slides from the same paraffin blocks as for H&E were stained according to the manufacturer's protocols for the INFORM HER2 DNA and chromosome 17 probes. Both probes were labelled with dinitrophenol (DNP) and optimally formulated for use with the ultraView SISH Detection Kit and accessory reagents on Ventana's Benchmark® series of automated slide stainers. The *HER2* DNA probe was denatured at 95°C for 12 min and hybridisation was performed at 52°C for 2 h. After hybridisation, appropriate stringency washes (3 times at 72°C) were performed. The chromosome 17 probe was denatured at 95°C for 12 min and hybridisation was performed at 44°C for 2 h. After hybridisation, appropriate stringency washes (3 times at 59°C) were performed. The HER2 and chromosome 17 DNP-labelled probes were visualised using the rabbit anti-DNP primary antibody and the ultraView SISH Detection Kit. The detection kit contains a goat anti-rabbit antibody conjugated to horseradish peroxidase (HRP) utilised as the chromogenic enzyme. The chemistry of the SISH reaction, briefly described, is driven by the sequential addition of silver A (silver acetate), silver B (hydroquinone) and silver C (H_2O_2). Here, the silver ions (Ag+) are reduced by hydroquinone to metallic silver atoms (Ag). This reaction is fueled by the substrate for HRP, hydrogen peroxide (silver C). The silver precipitation is deposited in the nuclei and a single copy of the *HER2* gene is visualised as a black dot. The specimen is then counterstained with Ventana Hematoxilin II for interpretation by light microscopy.

Fluorescence in situ hybridisation

For FISH, consecutive sections from the same blocks used for SISH and IHC were cut at 6 μm thickness and mounted on SuperFrost +/+ slides. Deparaffinising, pre-treatment and protease digestion procedures followed the ABBOTT/Vysis PathVysion HER-2 DNA Probe Kit protocol (PathVysion CE Package Insert, Revision I, 2002) with additional monitoring of the progress of proteinase digestion by propidium iodide staining. Probe mixes were hybridised at 37°C between 14 and 18 h. After hybridisations, slides were washed in 2X SSC/0.3% NP-40 at 72°C for 30 min, air dried and counterstained with DAPI. A minimum of 20 nuclei of invasive tumour cells were scored using LEICA epifluorescence microscopes equipped with ×100 oil immersion objective and DAPI/Spectrum Green/Orange single and triple bandpass filters (AHF).

Immunohistochemistry

IHC was performed following routine procedures as described in detail by Fritzsche et al. [9]. For automated staining, Ventana's Benchmark® XT was used.

Teaching and evaluation

A 1-h consensus meeting was conducted to teach the elements and characteristics observed with the SISH assay and the algorithm for the assessment of *HER2* gene amplification status. The scoring algorithm and morphological details defined therein were clearly described and accepted by the panelists. A teaching set of 10 specially selected cases were read together using a multi-head microscope. The teaching set contained specimens that were negative, equivocal and positive for *HER2* gene amplification and examples of polysomy and inadequate staining. After this introduction, a blinded test set of six cases was given to the participants and evaluated independently. The results were compiled and then discussed in the group.

After achieving consensus, all 100 cases were independently examined in a blinded fashion by 5 pathologists (MD, IE, HH, HK, HM) during a 2-day meeting; each participant read 500 slides (100 cases by H&E, chromosome 17 SISH, *HER2* SISH, Herceptest IHC and PATHWAY 4B5 IHC). In detail, each participant first read the H&E and SISH slides together and recorded the results. In a second independent review, the IHC slides were read in a blinded fashion. The FISH reaction was determined separately and independently by MD and KK.

Scoring criteria and algorithms

SISH Per American Society of Clinical Oncology/College of American Pathologists (ASCO/CAP) guidelines, *HER2* gene amplification status was classified applying the following criteria:

- Negative for *HER2* gene amplification was defined as a *HER2*/Chr17 ratio less than 1.8.
- Equivocal for *HER2* gene amplification was defined as a *HER2*/Chr17 ratio between 1.8 and 2.2.

– Positive for *HER2* gene amplification was defined as a *HER2*/Chr17 ratio greater than 2.2.

The detailed evaluation was performed following the instructions provided by the manufacturer (Ventana INFORM *HER2* DNA Probe CE Package Insert 16034EN Revision 1 [2007], for more details see http://www.her2sish.com).

FISH Per ASCO/CAP guidelines, *HER2* gene amplification status was classified applying the following criteria:

– Negative for *HER2* gene amplification was defined as less than 4.0 *HER2* gene copies per nucleus or a *HER2*/Chr17 ratio less than 1.8: no staining or weak, incomplete membrane staining in any proportion of tumour cells.
– Equivocal for *HER2* gene amplification was defined as a *HER2*/Chr17 ratio between 1.8 and 2.2.
– Positive for *HER2* gene amplification was defined as more than 6 *HER2* gene copies per nucleus or as a *HER2*/Chr17 ratio greater than 2.2 in on average of 60 cells.

The detailed evaluation was performed following the instructions provided by the manufacturer (ABBOTT/Vysis PathVysion CE Package Insert Revision I (2002), for more details see http://www.vysis.com/PathVysionHER2DNAProbeKit_35793.asp).

IHC Per ASCO/CAP guidelines, HER2 protein expression status was classified applying the following criteria:

– Negative for HER2 protein is an IHC staining of 0 or 1+: no staining or weak, incomplete membrane staining in any proportion of tumour cells.
– Equivocal for HER2 protein is an IHC staining of 2+: complete membrane staining that is either non-uniform or weak in intensity but with obvious circumferential distribution in at least 10% of cells.
– Positive for HER2 protein is an IHC staining of 3+: uniform intense membrane staining of >30% of invasive tumour cells.

The protein analysis was performed to assist discrepancy resolution.

Statistics

Consensus among the panelists was defined as the agreement among three or more members representing either a simple or greater majority. Only samples that yielded informative results at both techniques were included in the concordance analyses. Consensus FISH results reported by MD and KK were used for the comparison of FISH to SISH.

Concordance data (or agreement) between consensus FISH and SISH methods and between consensus FISH and individual observers were determined and the κ statistics calculated using Cohen's κ [12].

Results

Case evaluation

From the 100 cases entering the study, 99 were dual-evaluable (informative) for SISH and FISH (details see Table 2). One case was excluded due to an unusually high polysomy of chromosome 17 (will be described separately). Typical examples of the SISH and FISH staining are shown in Figs. 1 and 2.

Comparison of SISH vs FISH *HER2* gene amplification status

There was agreement in 95 of 99 cases representing a concordance of 96.0% (κ=0.754, 95%CI; 0.518–0.993). Representative concordant cases are illustrated in Figs. 1 and 2.

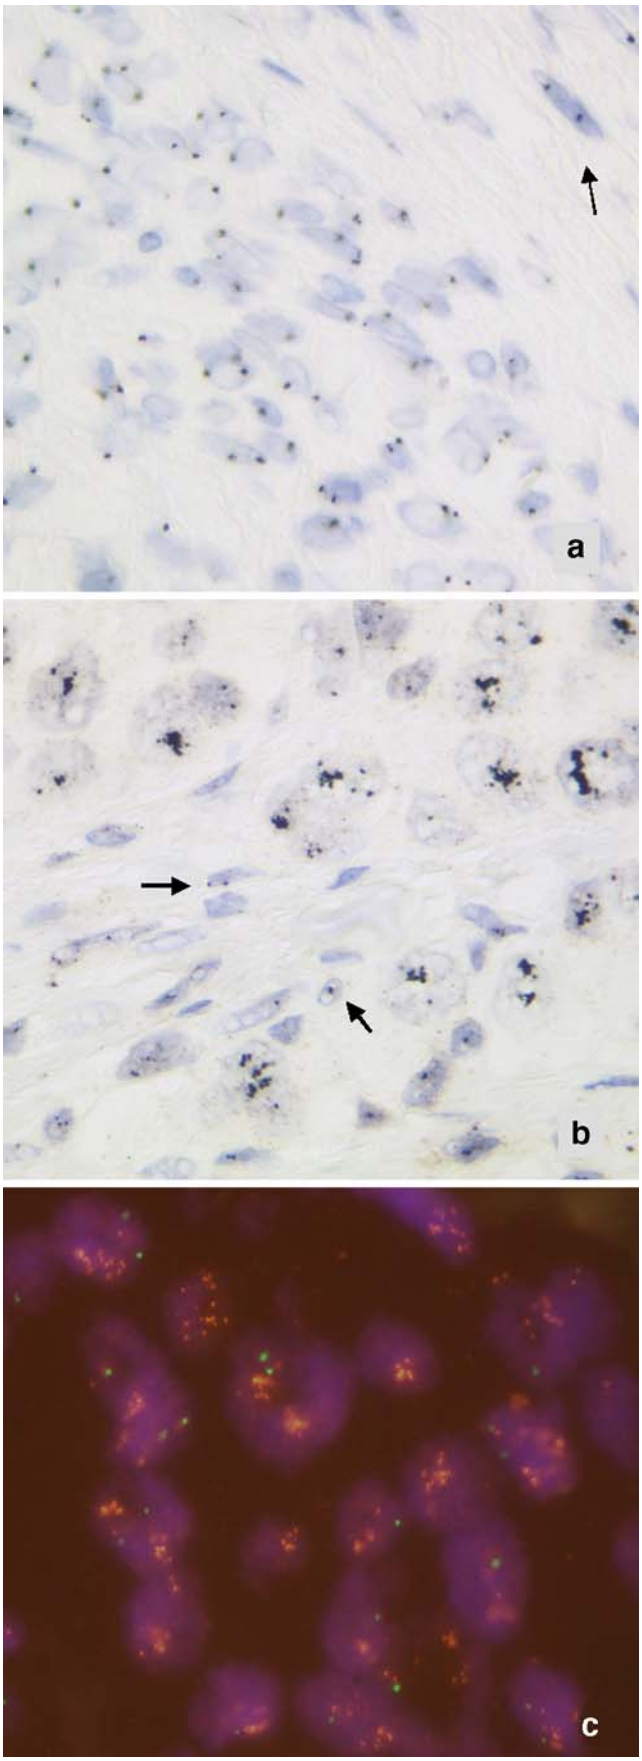
Concordance with consensus among the pathologists regarding amplified vs non-amplified cases: As per ASCO/CAP guidelines, the *HER2* gene amplification status judged by each individual relative to the consensus SISH results gave the following: among the pathologists a high overall agreement was achieved where 3 were nearly equivalent (concordance with consensus 94.4–95.2%, κ=0.767, 95% CI; 0.568–0.965), 1 tended to underscore (concordance of 92.6%, κ=0.630, 95%CI; 0.345–0.915) and 1 tended to over-score (concordance of 92.8%, κ=0.770, 95%CI; 0.592–0.947, respectively).

There were four discrepant cases, two of them representing FISH positive, SISH negative and two the converse. A case by case analysis revealed the following:

Case 1. The SISH consensus ratio of 2.25 gave a positive result for *HER2* gene amplification. The FISH analysis yielded a ratio of 2.0 forcing the

Table 2 Detailed demonstration of FISH vs SISH *HER2* gene amplification status obtained from 99 consecutively examined invasive breast cancer cases

HER2 gene amplification status		FISH			
		Positive	Equivocal	Negative	Total
Consensus SISH	Positive	9	0	2	11
	Equivocal	0	3	0	3
	Negative	2	0	83	85
	Total	11	3	85	99



◀ **Fig. 1** Typical example of an amplified case as demonstrated by SISH. **a** Chr17—2 signals in fibroblasts (*arrow*) and max. 3 signals in tumours cells, **b** same case HER2—clusters of HER2 signals in tumour cells. Note the fibroblasts (*arrows*) as internal control, i.e. 2 HER2 signals. **c** FISH Chr17 shown as 2 or 1 *green* signal and >6 HER2 signals

mathematical decision of equivocal for *HER2* gene amplification due to definition but was called negative by the observer. The consensus HER2 protein expression staining analysis was 1+. Thus, the final diagnosis reported in the pathology report would be negative for *HER2* gene amplification.

Case 2. The SISH consensus ratio of 2.56 gave a positive result for *HER2* gene amplification. The FISH analysis yielded a ratio of 1.0 giving a negative result for *HER2* gene amplification. Re-reading of the SISH slides revealed heterogeneity in the signal distribution and explains the discrepancy. The consensus HER2 protein expression staining analysis was 1+. Thus, the final diagnosis reported in the pathology report would be negative for *HER2* gene amplification.

Case 3. The SISH consensus ratio of 1.44 gave a negative result for *HER2* gene amplification. The FISH analysis yielded a ratio of 3.0 giving a positive result for *HER2* gene amplification. Re-reading of FISH revealed some areas of signal heterogeneity and areas difficult to interpret explaining the discrepancy. The consensus HER2 protein expression staining analysis was 1+. Thus, the final diagnosis reported in the pathology report would be *HER2* negative.

Case 4. The SISH consensus ratio of 1.06 gave a negative result for *HER2* gene amplification. During re-reading of the case, it became obvious that there was a discrepant interpretation of what is a single signal or a cluster (should be counted as six signals due to the manufacturer's instruction). The FISH analysis yielded a ratio of 2.2 giving a positive result for *HER2* gene amplification. Re-reading of FISH revealed some areas of signal heterogeneity explaining the discrepancy. The consensus HER2 protein expression staining analysis was 2+. Thus, the final diagnosis reported in the pathology report would be equivocal for *HER2* gene amplification. Regarding therapy, these cases may well be handled as amplified.

Discussion

Pathomorphological detection of tissue-based biomarkers identified as target molecules for humanised antibodies

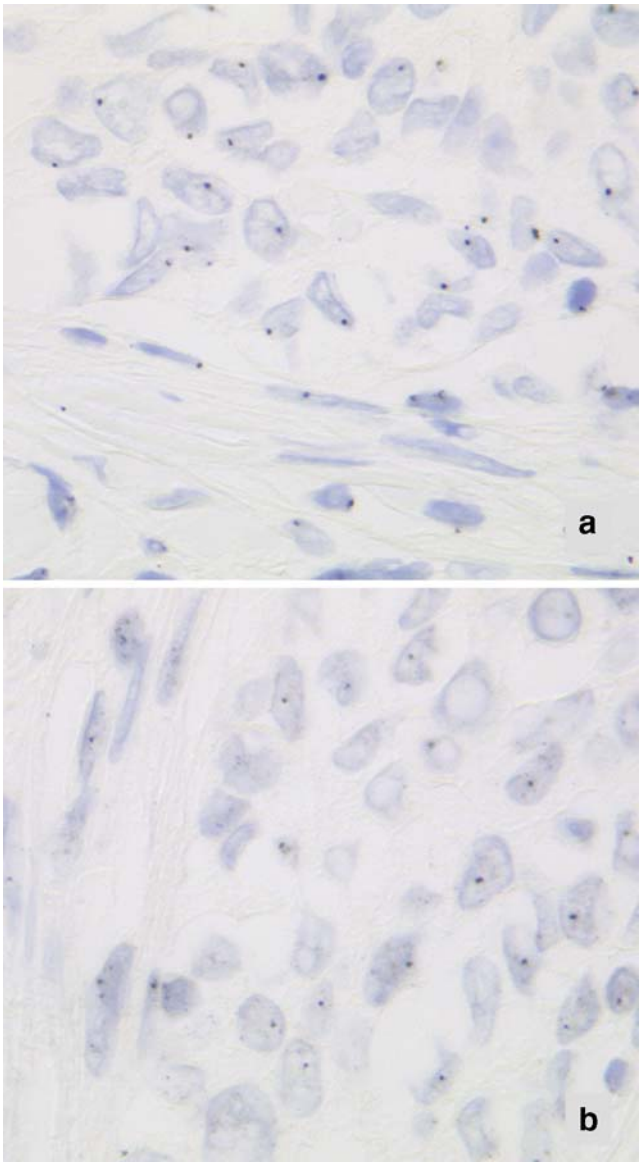


Fig. 2 Typical example of a non-amplified case as demonstrated by SISH. **a** Chr17—2 signals, **b** same cells HER2—2 signals. Note the fibroblasts as internal control, i.e. 2 HER2 signals

such as trastuzumab or cetuximab represents an essential tool in medical progress towards more personalised cancer therapies [5, 6]. The ideal procedure of target detection apart from being reliable and reproducible should lend itself to automated processing. This study compares a novel methodology, the SISH, fulfilling these requirements with a high concordance with the current imperfect gold standard, FISH.

The ASCO/CAP guidelines recommend the ERBB2/HER2 status to be optionally determined by IHC or FISH/CISH [22]. In most laboratories, IHC is done first. In case the primary immunohistochemical result is equivocal on the protein level, such as an IHC score of 2+, faint staining or other artefacts, an additional test is strongly recommended to clarify the HER2 status on the genomic level diagnosing amplification or non-amplification. Most often, this additional genomic testing is accomplished by FISH. However, this approach is not optimal because it is time-consuming, laborious, non-automated and expensive. Further exclusive use of FISH as the primary method for determining *ERBB2*/*HER2* gene status may also be problematic due to specialised instrumentation, special training, high costs and other disadvantages in the diagnostic workflow [14]. Previous methods of bright field in situ hybridisation have not found wide acceptance in routine pathology laboratories because they require manual processing and overnight hybridisation.

An alternative may be the newly developed SISH technology because it consists of a 6-h automated protocol and yields a stable and discrete chromogenic reaction product. Without the need for specialised microscope equipments, the pathologist can integrate this testing within the "normal" workflow. Due to the stable chromogenic signal, a cell-by-cell discussion using a screen or a multi-head microscope is facilitated. This possibility is of great advantage because it enables a continuous educational process and, in difficult cases, consensus can be reached more easily. Thus, SISH could readily be integrated into the surgical pathology workflow for routine assessment of ERBB2/HER2 status in breast carcinoma.

A major prerequisite for the acceptance of SISH is that it has to yield a high concordance with the current imperfect gold standard (FISH) and should exhibit low inter-observer variability. The current study proved that this is the case; the rate of cases that were negative vs equivocal vs positive for *HER2* gene amplification were very similar when detected by SISH or FISH (concordance 96.0%). This concordance then is compliant with the ASCO/CAP requirements of greater than 95% concordance among amplified/non-amplified cases. Only 4 out of 99 cases proved discordant among the panelists. Also the inter-observer concordance of 5 pathologists was unexpectedly high (concordance with consensus between 92.8% and 95.2%). This high percentage of scoring reproducibility was surprising because four of the five panelists did SISH interpretation for the first time. This clearly illustrates that the SISH signals are relatively straightforward to interpret.

Image analysis can be an effective tool for achieving consistent interpretation [16, 21]. The constant black signal of SISH will help to develop computer-based tools for automated signal detection and, by this, may contribute to a better reproducibility of *HER2* evaluation and a reduction of interpretive variation. However, image analysis procedures would need further validation before implementation.

Further independent international external quality assurance studies to demonstrate accuracy of SISH-HER2 testing should be initiated. To standardise inter-laboratory tests,

cell cultures with defined protein and gene alterations may be included [17, 18]. This would facilitate proficiency testing as made mandatory by the ASCO/CAP guideline [22] before the introduction of new assays.

In summary, the challenge to standardise, facilitate and speed up the diagnostic process above the gold standard of today is met by the newly introduced SISH technology. Thereby it appears to contribute to the progress of diagnostic pathology.

Abstract Recently, oncogenic potential of the WT1 gene has been proposed in some human solid tumors and leukemias. Although previous studies have shown the frequent expression of the WT1 protein in ovarian serous adenocarcinomas (OSAs), its clinicopathologic significance is still unclear. We immunohistochemically examined the expression status of WT1 in 119 OSAs and analyzed the correlation of the intensity of WT1 immunoreactivity with the level of WT1 mRNA expression by quantitative real-time polymerase chain reaction, clinicopathologic variables, expression of p53, Bcl-2, and Ki-67 labeling index (LI). Of 119 OSAs, nuclear WT1 immunoreactivity was positive in 99 (83%), of which 44 (44%) and 55 (56%) exhibited high and low WT1 immunoreactivities, respectively. The quantitative WT1 mRNA levels were significantly correlated with the intensity of WT1 immunoreactivity ($P<0.05$). In comparison with WT1-negative OSAs, the WT1-positive OSAs showed a higher grade ($P=0.007$), advanced stage ($P=0.018$), and higher Ki-67 LI ($P<0.001$). Additionally, high WT1 immunoreactivity was correlated with a higher grade ($P=0.003$), Ki-67 LI ($P=0.012$), Bcl-2 expression ($P=0.003$), and poorer patient outcome (5-year survival, 36.5 vs 63.8%, $P=0.008$ by log-rank test). The WT1 protein may be an accelerator of the progression of OSA.

Introduction

The WT1, located on chromosome 11p13, was at first identified as a gene responsible for the development of Wilms' tumor [10]. Although the role of the product of the WT1 gene was initially described as transcriptional regulation, recent researchers have demonstrated its multifunctional roles sometimes with contradictory features, including being an activator vs a repressor of transcription, transcription in the nucleus vs RNA metabolism and

translational regulation in the cytoplasm, and even being an oncogene vs a tumor supressor gene [12].

Although the *WT1* gene was primarily considered to be a tumor-suppressor gene, recent studies have demonstrated an overexpression of the wild-type *WT1* gene in leukemias [15] and various solid neoplasms such as those of the breast [16, 19], lung, digestive tract [25, 26], pancreas [23], bone, and soft tissues [33, 37]. Moreover, several reports indicating an oncogenic, rather than a tumor-supressor, role of the wild-type *WT1* gene have been accumulated. For example, high expression levels of WT1 messenger ribonucleic acid (mRNA) are correlated with poor prognosis in leukemias [15], breast cancer [19], and soft tissue sarcomas [33]. Treatment with WT1 antisense oligomers specifically causes growth inhibition in leukemic blast cells [2, 39] and in cell lines derived from cancers of the lung, stomach, colon, and breast [24, 41]. These findings indicate that the *WT1* gene product is a potent target of immunotherapy because *WT1* gene expression is restricted to a limited set of normal tissues including the gonad, uterus, kidney, and mesothelium [4, 27].

Ovarian carcinoma behaves more aggressively and has a worse prognosis than any other cancer involving the female genital tract [28]. Because of the paucity of specific early symptoms, up to 70% of patients present with advanced disease [28]. Of the various histological subtypes of ovarian carcinoma, ovarian serous adenocarcinoma (OSA) is the most common and usually shows aggressive behavior and secondary resistance to current adjuvant chemotherapies.

It is a generally accepted idea that the expression of a single or multiple specific oncogenes and subsequent activation of cell proliferation contribute to neoplastic transformation of cells, tumorigenicity, and tumor progression. Such oncogenes and oncogene products may be of a clinical utility as predictive or prognostic factors and as therapeutic targets. So far, it has been shown that the incidence of WT1-positive tumors was highest in OSA among the various histological types of ovarian carcinoma [1, 13]. However, there is limited evidence for the clinicopathologic significance of WT1 in ovarian carcinomas [13, 21].

In the present study, to evaluate the clinicopathologic significance of the WT1 expression in OSA, we analyzed WT1 protein expression status by immunohistochemistry (IHC) applied to a tissue microarray (TMA) containing 119 specimens of OSA. Tumors showing a distinctly intense immunoreaction were further tested for their expression levels of WT1 mRNA by real-time, quantitative, reverse transcriptase polymerase chain reaction (RT-PCR) analysis. We demonstrated that these features of OSA were correlated with clinicopathologic parameters, expression of other molecular markers, and patient outcome.

Materials and methods

Patients and tissue samples

This study was performed with the approval of the Internal Review Board on ethical issues. All patients involved gave their informed consent to participate. We reviewed the clinicopathologic records of 119 patients who underwent initial surgery followed by platinum-based chemotherapies for primary ovarian OSA at the Department of Obstetrics and Gynecology, National Defense Medical College Hospital, Tokorozawa, Japan, between 1987 and 2004. All 119 patients underwent surgical staging according to the International Federation of Gynecology and Obstetrics (FIGO) system. Radical cytoreductive surgery was performed for patients with advanced disease. The chemotherapeutic regimens comprised cyclophosphamide, doxorubicin, and cisplatin for 74 patients, paclitaxel and carboplatin for 32, docetaxel and carboplatin for 10, cyclophosphamide and cisplatin for one, cyclophosphamide and carboplatin for one, and irinotecan and cisplatin for one. All pathology specimens were reviewed at our institution, and the tumors were classified histologically as OSAs according to the World Health Organization criteria [34]. The clinicopathologic details, such as patient age, FIGO clinical stage, tumor histologic grade, residual tumor after initial surgery, and overall patient survival were assessed for all 119 patients.

Histologic grading was performed by reference to the system proposed by Shimizu et al. [31] and Silverberg [32] (Table 1). Clinical response to chemotherapy was evaluated by ultrasonography or computed tomography and classified as complete response (CR), partial response (PR), stable disease, or progressive disease in accordance with the new Response Evaluation Criteria for Solid Tumours [35].

Table 1 Scoring system used for grading

Score	Criteria
A. Predominant architectural pattern	
1	Tubular and/or cystic
2	Papillary
3	Solid
B. Cytologic atypia	
1	Slight
2	Moderate
3	Marked
C. Mitotic Figures/10 high-power fields[a]	
1	0–9
2	10–24
3	≥25

Sum of the scores for A, B and C: 3–5=Grade 1; 6, 7=Grade 2; 8, 9=Grade 3

[a] Counted in the most active region at 10× 40× using an Olympus Optiphot microscope (field area 0.345 mm^2)

Tumor size was determined as the product of the maximum diameter and the length perpendicular to the maximum diameter. Clinical response to chemotherapies was assessed for the 63 patients who had residual tumors 2 cm in size or larger, after initial surgery.Tumors that showed CR or PR to first-line chemotherapies were considered to be chemosensitive.

Follow-up was calculated from the date of initial definitive surgery to the date of either last follow-up or death. The average follow-up period after initial surgery was 46.4 months, ranging between 2 and 227 months. Forty-two of the 119 patients died because of OSA spread, and two patients died of other causes.

Tissue microarray and immunohistochemistry

To construct TMA blocks, we selected formalin-fixed paraffin-embedded tissue blocks containing the areas where histologic grading had been performed, from the 119 OSA cases. Two core specimens 2.0 mm in diameter were taken from a tissue block of each case and transferred to recipient blocks using a Tissue Microarrayer (Beecher Instruments, Silver Spring, MD).

These TMA blocks were cut into 4-μm-thick sections, mounted on silane-coated glass slides, and subjected to IHC using the following primary monoclonal antibodies and dilutions: anti-WT1 (clone 6F-H2, 1:50, Dako, Grostrup, Denmark), anti-p53 (clone DO7, 1:100, Dako), anti-Bcl-2 (clone 124, 1:50, Dako), and anti-Ki-67 (clone MIB-1, 1:50, Dako).

These tissue sections were deparaffinized, subjected to antigen retrieval by digestion with proteinase K (ready to use, Dako) for 10 min for WT1, or by autoclaving in sodium citrate buffer (pH 6.0) for 15 min at 121°C for p53, Bcl-2, and Ki-67, then being allowed to cool at room temperature. Endogenous peroxidase was blocked using 5% hydrogen peroxide. Nonspecific staining was blocked in 2% normal swine serum. The slides were incubated with primary antibodies at 4°C overnight and then reacted with a dextran polymer reagent combined with secondary antibodies and peroxidase (Envision Plus; Dako) for 1 h at room temperature. Specific antigen–antibody reactions were visualized with 0.2% diaminobenzidine tetrahydrochloride and hydrogen peroxide. Counterstaining was performed using Mayer's hematoxylin. As positive controls, we used leukemic cell line K562 for WT1, a breast cancer with nuclear p53 immunoreactivity, and a lymph node showing reactive hyperplasia positive for Bcl-2 and Ki-67. As negative controls, the primary antibodies were omitted from each reaction process.

A case showing any degree of nuclear immunoreactivity for WT1 in more than 10% of the core tissue was considered to be the WT1-positive case. The intensity of WT1 expression was classified as 0 (nonstaining), 1+ (weak), 2+ (moderate), or 3+ (intensive; Fig. 1). Cases showing heterogeneous intensity of WT1 immunoreactivity were classified according to the highest degree of immunoreactivity of the WT1-positive cells in each core when the area with such immunoreactivity occupied more than 10% of the core tissues. If the part with the highest degree of immunoreactivity occupied less than 10% of area, the intensity of the largest area was adopted. Tumors scored as 1+ were defined as a low-level immunoreactivity group and those with a score of 2+ or 3+ as a high-level immunoreactivity group. Based on the literature, p53 and Bcl-2 were regarded as positive if more than 10% of tumor cells showed nuclear immunoreactivity for p53 and cytoplasmic immunoreactivity for Bcl-2 [3, 29, 36]. The Ki-67 labeling index (LI) was determined using the formula: Ki-67 LI (%)=100× number of tumor cells with nuclear Ki-67 immunoreactivity/ number of tumor cells with and without nuclear Ki-67 immunoreactivity. In total, 400 cell nuclei were counted twice independently, and both sets of data were combined.

RNA extraction and reverse transcription

To compare the intensity of WT1 immunoreactivity with its level of messenger ribonucleic acid (mRNA) expression, we selected a total of 21 OSA samples based on the pattern of their WT1 immunoreactivity—seven different samples each with negative, low-level, and high-level immunoreactivity—and prepared them for mRNA expression analysis. As controls for WT1 mRNA expression, the K562 leukemic cell line and five samples of non-neoplastic ovarian tissue obtained from separate patients who had undergone radical surgery for uterine cancers confined to the uterus were used [15]. All these non-neoplastic ovarian

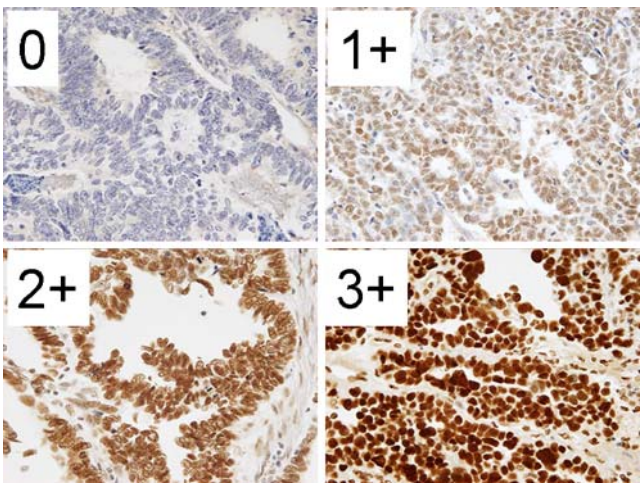

Fig. 1 Nuclear immunoreactivity of WT1 in ovarian serous adenocarcinomas (OSAs). OSA with negative WT1 (*0*), OSA with low-level WT1 immunoreactivity (*1+*), OSA with high-level WT1 immunoreactivity (*2+*), and OSA with high-level WT1 immunoreactivity (*3+*). Original magnification, ×400

tissues contained the ovarian surface epithelia, which are reportedly immunoreactive for the WT1 [30], on their peritoneal surface. All tissue samples were snap-frozen immediately after resection and stored until use in liquid nitrogen.

Total RNA was isolated from the tissues and cell line using RNeasy Mini (Qiagen, Hilden, Germany) in accordance with the manufacturer's instructions. Real-time PCR amplification of synthesized complementary deoxyribonucleic acid (cDNA) was performed in a total volume of 50 μl of reaction mixture containing 2 μl cDNA, corresponding to 100 ng of total RNA, 0.4 pmol/μl of each primer, and 1× TaqMan Universal PCR Master Mix (Applied Biosystems, Foster City, CA) using an ABI Prism 7700 Sequence Detection System (Applied Biosystems). We used TaqMan, a set of primers, and a probe (assay ID: Hs01103751_m1) for WT1 cDNA amplification. Cycling conditions were 95°C for 10 min, followed by 40 repeats of 95°C for 0.5 min and 63°C for 1 min. Standard curves for quantification of WT1 and β-actin (TaqMan β-actin Control Reagents: no. 401846) were constructed from the results of simultaneous amplification of serial dilutions of the cDNA from K562 cells, in which the expression level of WT1 mRNA was defined as 1.0, as described previously [15]. WT1 mRNA expression levels in the 21 samples of OSA and five non-neoplastic ovaries were determined according to the standard curves. To normalize the difference in RNA degeneration and in RNA loading for RT-PCR in individual samples, the level of *WT1* gene expression divided by the level of β-actin gene expression were defined as the relative WT1 mRNA expression level in each sample.

Statistical analysis

Statistical analyses were performed using the StatMate III software (ATMS, Tokyo, Japan). Comparisons between parameters were computed by the Chi-squared test or by the Student's *t* test or the Mann–Whitney test for unpaired data. For survival analysis, Kaplan–Meier curves were drawn, and differences between the curves were calculated by the log-rank test. Independent prognostic significance was computed by the Cox proportional hazards general linear model for disease-specific survival. Differences at $P<0.05$ were considered to be statistically significant.

Results

Correlation of nuclear WT1 immunoreaction with the corresponding mRNA expression level

Of the 119 OSAs, 99 (83.2%) were found to be WT1 positive and the remaining 20 (16.8%) were considered to be WT1 negative. Of the 99 WT1-positive cases, 55 (55.6%) were classified as having low-level immunoreactivity (1+) and 44 (44.4%) as having high-level immunoreactivity (2+, 24 cases; 3+, 20 cases).

The relative WT1 mRNA expression levels in the groups showing different intensities of immunoreactivity were quantified using real-time PCR assay and represented relative to the level in the human leukemia cell line K562 (defined as 1.0; Fig. 2). The median levels of mRNA expression in the WT1-negative, low-level, and high-level immunoreactivity groups were 0.66, 3.15, and 8.17, respectively. The WT1 mRNA expression level in the WT1-immunonegative group was statistically different both from that in the group with low-level WT1 immunoreactivity ($P=0.009$; Mann–Whitney *U* test) and from the group with high-level WT1 immunoreactivity ($P=0.0027$; Mann–Whitney *U* test). The mRNA expression levels were also significantly different between the low-level and high-level immunoreactivity groups ($P=0.017$; Welch's *t* test) and between the non-neoplastic ovarian tissues and the WT1 high-level immunoreactivity group ($P=0.028$; Mann–Whitney *U* test). WT1 mRNA expression in the immunohistochemically WT1-negative group was significantly lower than that in the non-neoplastic ovarian tissues (median, 0.66 vs 3.21, $P=0.028$; Mann–Whitney *U* test). There was no significant difference between non-neoplastic

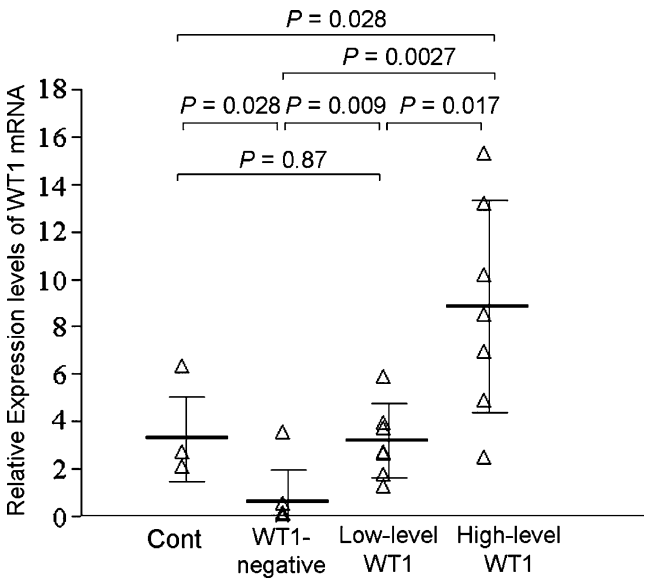

Fig. 2 Relative levels of WT1 mRNA expression in ovarian serous adenocarcinomas (OSAs) with distinct levels of immunoreactivity and in normal ovarian tissues. WT1 mRNA expression levels were calculated by comparison with the WT1 expression level in the K562 cell line. There was a significant difference in the mean relative expression level of WT1 mRNA between control ovarian tissues and WT1-negative OSAs ($P=0.028$), between the WT1-immunonegative group and the group with low-level WT1 immunoreactivity ($P=0.0088$), between the WT1-immunonegative group and the group with high-level WT1 immunoreactivity ($P=0.0027$), between the low-level and the high-level immunoreactivity groups ($P=0.017$), and between control ovarian tissues and the high-level immunoreactivity group ($P=0.028$). *Cont* Normal ovarian tissue samples

ovarian tissues and the low-level WT1 immunoreactivity group (median, 3.21 vs 3.15, P=0.871; Mann–Whitney U test).

Correlation of nuclear WT1 immunoreactivity with clinicopathologic factors

Eight (40%) of the 20 cases in the WT1-negative group were in FIGO stage I to II, compared with only 13 (13.1%) of the 99 WT1-positive cases (P=0.019; Table 2). Moreover, the WT1-positive group showed a higher proportion of histologically high-grade tumors (P=0.0072) and a higher Ki-67 LI (mean, 51.0 vs 29.3, P<0.0001) than the WT1-negative group. With regard to patient age, residual tumors (2 cm in size or more), the proportion of chemosensitive tumors, and expression of Bcl-2 and p53, there were no significant differences between the WT1-negative and WT1-positive groups. Although not statistically significant, patient outcome in the WT1-negative group tended to be better than that in the WT1-positive group (5-year survival, 73.6 vs 52.0%, P=0.387; log-rank test; Fig. 3).

As well as the comparison between the WT1-negative and WT1-positive groups, the group showing a high level of WT1 immunoreactivity had a higher histological grade (P=0.0032) and a higher Ki-67 LI (mean, 57.3 vs 46.0, P=0.0121) than the low-level immunoreactivity group (Table 3). Moreover, the high-level immunoreactivity group showed a higher frequency of Bcl-2 expression than the low-level immunoreactivity group (52.3 vs 23.6%, P=0.0032). There was no significant difference in age, FIGO stage distribution, residual tumors (2 cm in size or more), proportion of chemosensitive tumors, or p53 expression status between these two groups. Patient outcome was significantly poorer in the high-level WT1 immunoreactivity group than in the low-level WT1 immunoreactivity group (5-year survival, 36.5 vs 63.8%, P=0.0082; log-rank test; Fig. 3).

Univariate and multivariate analyses of disease-specific survival

The results of univariate analysis for disease-specific survival according to various clinicopathologic factors, including the intensity of WT1 immunoreactivity, are summarized in Table 4, a. Among the clinicopathologic factors, residual tumor (2 cm in size or more; P=0.007) was

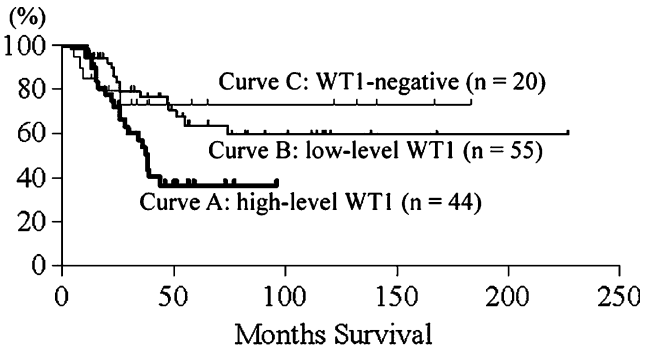

Fig. 3 Overall survival curves for 119 patients with ovarian serous adenocarcinoma (OSA), stratified by WT1 immunoreactivity status. *Curve A* for 44 OSA patients with high-level WT1 immunoreactivity, *Curve B* for 55 OSA patients with low-level WT1 immunoreactivity, and *Curve C* for 20 OSA patients with negative WT1 immunoreactivity. Significant differences were evident between the high-level WT1 immunoreactivity group (*Curve A*) and the low-level immunoreactivity group (*Curve B*; P=0.0082, log-rank test)

significantly correlated with worse patient outcome. Higher histological grade (grade 3/2/1) and the intensity of WT1 immunoreactivity (high-level immunoreactivity or others) showed only marginal significance (P=0.052 and 0.083, respectively). Patient age greater than or equal to 57 years (median; P=0.801), advanced FIGO clinical stage (stage III or IV; P=0.113), Ki-67 LI greater than or equal to 47.4 (median; P=0.563), p53 positivity (P=0.244), and Bcl-2 positivity (P=0.649) were not correlated with disease-specific survival in the present analysis.

We also performed a multivariate analysis using the Cox proportional hazards model including residual tumor size (≥2 vs <2 cm), histologic grade (3/2/1), and the intensity of WT1 immunoreactivity (high-level immunoreactivity vs others) as parameters (Table 4, b). The residual tumor size was identified as an independent prognostic value for overall survival (P=0.0052). The high-level WT1 immunoreactivity also showed nearly significant prognostic value (P=0.054).

Discussion

In the present, real-time PCR analysis clearly demonstrated that the intensity of WT1 immunoreactivity in OSAs was associated with the mRNA expression level, indicating that the intensity of WT1 immunoreactivity is a good indicator of the level of true WT1 protein expression. Taken together with clinicopathologic features, it appears that WT1 could assist the progression of OSAs in proportion to the level of expression of both its mRNA and protein.

The frequency of immunohistochemical detection of WT1 protein expression in OSA was 83.2% (99 of 119

cases), which was compatible with the range reported in previous studies (50.5–97%) [1, 13]. The introduction of TMA technology allowed a large number of specimens to be processed and was especially useful for comparative scoring of WT1 protein expression with specimens subjected to IHC under identical conditions.

Principally, the clinicopathologic significance of the *WT1* gene and its gene product in tumor tissues has been discussed from the viewpoints of (1) diagnostic utility, (2) functional roles in tumor progression, and (3) potential as a target for antigen-specific immunotherapy. From the viewpoint of diagnostic utility, a high level of WT1 protein expression could be a marker of the clinical aggressiveness of OSA. In relation to clinicopathologic parameters, the WT1-positive group showed a more advanced stage and higher histological grade than the WT1-negative group. Moreover, compared with the low-level WT1 immunoreactivity group, the group with a high immunoreactivity level showed a higher histological grade and a poorer patient outcome. Hylander et al. [13] demonstrated that WT1-positive OSAs tended to have a higher grade and more advanced stage than WT1-negative tumors. Netinatsunthorn et al. [21] divided WT1-positive OSAs into subgroups by the intensity of their immunostaining, as we did in the present study, and demonstrated that a high intensity of WT1 immunoreactivity had an independent prognostic value. In our multivariate analysis, the prognostic value of the high-level WT1 immunoreactivity was also nearly significant (P=0.054).

Some reports have advocated the practical utility of IHC for detecting the WT1 protein in differentiating OSA from other histological subtypes of ovarian carcinoma or from adenocarcinomas of other primary sites such as the endometrium or the pancreatobiliary system [8, 9]. However, its application to differential diagnosis in surgical pathology is currently limited and controversial, as a recent study by Nakatsuka et al. [20] demonstrated WT1 immunoreactivity in carcinomas of various primary sites such as the stomach, prostate, biliary tract, and urinary tract, and even in malignant melanomas.

The functional role of the *WT1* gene and its product in ovarian carcinomas is largely unknown, and few studies have investigated the issue. Shimizu et al. [30] hypothesized that the *WT1* gene is related to cell differentiation in OSAs, based on the detection of WT1 expression in normal female genital tissues such as the ovarian surface epithelium, the lining of inclusion cysts, and the tubal epithelium, but not in the cervical or endometrial epithelium.

The *WT1* gene encodes a zinc-finger transcription factor that represses the transcription of growth factor genes such as the platelet-derived growth factor A chain [7], colony-stimulating factor 1 [11], insulin-like growth factor (IGF)-II [5], and growth factor receptor genes such as the IGF-I receptor (IGF-IR) [38] and epidermal growth factor receptor [6]. Because the transcription of these growth factors and growth factor receptors can be regulated by WT1 via its interaction with wild-type p53, it has been recognized that WT1 functions as a transactivator in the absence of wild-type p53 [14, 17]. In OSAs, especially those with a histologically high grade, p53 mutation, which commonly contributes to nuclear p53 immunoreactivity, is associated with tumor progression [3, 29, 36]. Genetic or molecular interaction between WT1 and mutant p53 may be related to tumor progression and aggressive biological activity of OSA cells.

The different subcellular distribution of the WT1 protein among tumor types is of interest. In the reports by Nakatsuka et al. [20], a majority of WT1-positive tumors showed diffuse or granular immunoreactivity in the cytoplasm, whereas ovarian tumors and desmoplastic small round cell tumors frequently showed nuclear immunoreactivity. To date, the pathological significance of such contrasting distribution (nucleus vs cytoplasm) is unclear. Although the WT1 protein is principally a DNA-binding transcription factor distributed in the nucleus, recent reports have demonstrated that phospholylation in the DNA-binding domain alters the affinity for DNA and subcellular distribution of the WT1 [40]. Moreover, nucleus-cytoplasmic shuttling of WT1 and the association between WT1 and actively translating polysomes were reported [22]. Therefore, distinct subcellular localization of WT1 might alter the properties of tumor cells through the regulation of variable genes and/or proteins.

The WT1-positive group showed a higher Ki-67 LI than the WT1-negative group. Moreover, compared with the low-level WT1 immunoreactivity group, the group showing high immunoreactivity had a higher Ki-67 LI. Interestingly, expression of Bcl-2, an apoptosis regulator, was more frequent in the high-level than in the low-level WT1 immunoreaction group. WT1 can also directly activate the transcription of several apoptosis-related genes including Bcl-2 [18]. The present study demonstrated that a high level of WT1 immunoreactivity was significantly associated with both Ki-67 LI and Bcl-2 expression. These findings suggest transcriptional interaction of WT1 with cell cycle accelerators and apoptosis inhibitors.

It is intriguing that WT1-negative OSAs showed lower mRNA expression than non-neoplastic ovarian tissues. Moreover, the mRNA expression level of OSAs with low WT1 immunoreactivity was similar with that of non-neoplastic ovarian tissues. We additionally studied the WT1 immunoreactivity in the ovarian surface epithelium and/or the lining of inclusion cysts in seven unremarkable ovaries and the tumor cells of seven cases of serous tumor of borderline malignancy, which is thought to be a precursor of OSAs. Consequently, all the ovarian surface

epithelia, linings of inclusion cysts, and tumor cells of serous borderline tumors studied showed a weak WT1 immunoreactivity (data not shown), corresponding to the low-level immunoreactivity demonstrated in the present study. These findings suggest that low-level expression of WT1 may be associated with cell differentiation rather than an accelerator of tumor progression, and moreover, the low-level WT1 positivity might be a native characteristic of ovarian serous neoplasms. However, at present, it is unknown what kind of molecular mechanisms give rise to the different WT1 expression pattern, i.e., high-level immunoreactivity and the negativity, in OSAs.

Comprehension of WT1 expression in ovarian carcinomas should aid its utility for diagnosis or prognostication and might also help to clarify whether the *WT1* gene product could be an attractive tumor antigen for immunotherapy. Recent evidence that the presence of intratumoral T cells in advanced ovarian carcinomas is correlated with better clinical outcome has prompted a search for a well-characterized tumor antigen [42]. Generally, the ideal tumor antigen for immunotherapy should demonstrate a high level of expression in tumors, limited expression in normal tissues, and a functional role in tumor progression. Therefore, WT1-positive OSAs, especially those with a high level of WT1 immunoreactivity, could be a prime target for antigen-specific immunotherapy.

In conclusion, the results of the present study suggest that WT1 can be an accelerator of tumor progression in OSAs, possibly with a dose-dependent manner. A high level of WT1 immunoreactivity in high-grade and advanced-stage OSA may have not only a diagnostic and prognostic value but also a potential for application of antigen-specific immunotherapy against this highly lethal malignancy.

Human pheochromocytomas show reduced p27Kip1 expression that is not associated with somatic gene mutations and rarely with deletions

Abstract Pheochromocytomas are neuroendocrine tumors arising in the neural crest-derived chromaffin cells of the adrenal gland or in extra-adrenal sympathetic ganglia (paragangliomas). In a rat model of multiple endocrine neoplasia (MEN), absence of functional p27Kip1 protein predisposes to pheochromocytoma and paraganglioma development. As no data is available regarding the involvement of p27Kip1 in human pheochromocytoma and/or paraganglioma, we set out to determine the expression pattern of p27Kip1 in those tumor types. A panel of 25 pheochromocytomas and 23 paragangliomas was collected. Two pheochromocytomas were from MEN2 patients. The paragangliomas included 15 tumors that developed at the carotid bifurcation, three in the jugulo–tympanic area, and five at other sites. Except for the MEN2 cases, all others were apparently sporadic. Immunohistochemistry for p27Kip1 and the proliferation marker Ki67 was performed. We found that p27Kip1 expression is reduced/lost in 56% of pheochromocytomas, but only in 18.1% of paragangliomas. Downregulation of p27Kip1 was not associated with increased proliferation. Cases showing reduced/lost p27Kip1 expression were screened for the presence of somatic mutations in *CDKN1B* (p27Kip1) and for allelic imbalance at the p27Kip1 locus. Three cases had allelic imbalance but none had mutations. In conclusion, pheochromocytomas display extreme reduction/loss of p27Kip1 expression at high frequency.

Introduction

Pheochromocytomas are neuroendocrine tumors that arise from neural crest-derived chromaffin cells of the adrenal gland and extra-adrenal sympathetic ganglia (referred to as paragangliomas). About 25% of patients with pheochromocytoma and/or paraganglioma present with a family history of von Hippel–Lindau disease (VHL), multiple endocrine neoplasia type 2 (MEN2), one of the three familial paraganglioma syndromes (PGL1, PGL3, PGL4), or, more rarely, neurofibromatosis type 1 (NF1). The causative germline mutations in these syndromic cancers have been identified in *VHL*, rearranged during transfection (*RET*), succinate dehydrogenase (*SDH*) subunits B, C, D, and *NF1*, respectively [14]. Approximately 10–15% of pheochromocytomas/paragangliomas are malignant and present very challenging problems for therapy. Currently, the malignant

status of pheochromocytomas/paragangliomas is established primarily by the presence of metastases at non-chromaffin sites [18], and although several markers have been proposed to predict malignancy in those tumors, there is no consensus as to the existence of histological, clinical, or molecular indicators of worse prognosis.

We have identified a MEN-like syndrome in the rat (named MENX) that shows phenotypic overlap with both MEN1 and MEN2 human syndromes [21]. Affected rats develop bilateral pheochromocytoma and parathyroid adenoma, multifocal anterior pituitary adenoma, and thyroid C-cell hyperplasia, as well as paraganglioma [21]. The histopathology of the rat lesions resembles that of their human counterpart [21]. Noteworthy, pheochromocytoma has complete penetrance in MENX rats: Adrenal medullary hyperplasia is already evident at 2 months of age and progresses to pheochromocytoma with age. We recently mapped the *MenX* locus [35] and identified the genetic mutation that causes MENX. Affected rats harbor a germline loss-of-function mutation of *Cdkn1b*, a gene in which germline mutations predisposing to cancer had not been previously reported [34]. Noteworthy, we also identified a mutation-negative, suspected MEN1 patient who carries a germline heterozygous nonsense mutation in the human *CDKN1B* gene [34]. *Cdkn1b* encodes the cyclin-dependent kinase (Cdk) inhibitor p27Kip1, an important cell-cycle regulatory protein that controls the progression from G1 to the S phase by interacting with cyclinE/Cdk2 and cyclinD1/Cdk4 complexes [36, 39]. Emerging evidence suggests that p27Kip1 can regulate cellular functions other than cell-cycle progression, such as cell differentiation and migration [6, 8]. Due to its central role in many important cellular processes, p27Kip1 has been analyzed in several human malignancies. The *CDKN1B* gene, encoding p27Kip1, usually is not somatically mutated in human cancers and is inactivated through epigenetic mechanisms only in a small subset of tumors including lymphoid malignancies and hepatocellular carcinoma [27, 31]. In contrast, p27Kip1 expression level is frequently reduced or absent in human tumors, and the downregulation of p27Kip1 is a statistically significant predictor of survival and tumor behavior in a variety of cancers, including prostate, breast, hepatocellular, and gastrointestinal cancers (reviewed in [28]). In the tissues of MENX-affected rats, the level of p27Kip1 protein is extremely reduced or absent compared to wild-type animals [34], and likely, this inactivation triggers tumor development in neuroendocrine tissues. Due to the tumor spectrum of MENX rats with inactivation of p27Kip1, we decided to study the expression pattern of p27Kip1 in human pheochromocytoma and paraganglioma. In this paper, we report that p27Kip1 expression is frequently reduced/lost in pheochromocytoma (56%) but less so in paraganglioma (18.1%; P=0.0151, phaeochromocytoma versus paraganglioma). This suggests that, despite their histopathological similarities, those two tumor types follow distinct molecular pathways. The downregulation of p27Kip1 represents the single most-frequent molecular alteration so far reported in pheochromocytoma, implicating p27Kip1 in the pathogenesis of this tumor type.

Materials and methods

Samples

Formalin-fixed, paraffin-embedded tissues from 25 pheochromocytomas and 22 paragangliomas were retrieved from the archives of the Institute of Pathology, Technical University of Munich. The histological classification of the cases was reviewed and is reported in Tables 1 and 2. Of the pheochromocytoma cases, two belonged to MEN2A patients (PC21 and PC22) and were both bilateral and associated with medullary thyroid carcinoma (MTC); one case (PC20) was associated with a renal cell carcinoma (RCC; Table 1), but the patient was negative for *VHL* gene mutations. The paragangliomas included 13 tumors that developed at the carotid bifurcation, three in the jugulo–tympanic area, and 6 in other sites (Table 2). All cases, except PC21 and PC22, were apparently sporadic.

Immunohistochemistry

Conventional sections of the tissue samples mentioned above were used for immunohistochemistry. Immunohistochemistry was performed using monoclonal antibodies against p27Kip1 (clone 57, 1:1,000, BD Transduction Laboratories, San Jose, CA, USA) and the proliferation marker antigen Ki-67 (MIB-1, 1:500, DAKO, Carpinteria, CA, USA). Sections were cut at 3 μM and stained immunohistochemically using an automated immunostainer (Ventana Medical System, Tucson, AZ, USA) according to previously published procedures [37]. Positive controls (tonsils) were included in each staining run to confirm the adequacy of the staining. The degree of staining was evaluated using a semi-quantitative scoring system at ×200 magnification. To score the p27Kip1 staining, both the intensity of the staining and the percentage of positive tumor cells were taken into consideration. Three positive signs indicate >80% of tumor cells showing strong nuclear staining for p27Kip1, two positive signs indicate >80% of tumor cells showing very weak nuclear positivity, one positive sign indicate very weak to moderate positivity in <20% of tumor cells, and the negative sign indicate that tumor cells have negative staining. Only distinct nuclear staining of tumor cells was used for scoring the Ki67 immunoreactivity, which was determined semiquantitatively and is indicated as the percent of positive cells on the entire

tumor represented in the section. The immunohistochemistry of the clinical data in all cases was reviewed blindly by two pathologists (LQ-M and FF). Images were recorded using a Hitachi camera HW/C20 installed in a Zeiss Axioplan microscope with Intellicam software (Zeiss MicroImaging, Thornwood, NY, USA). Adobe PhotoShop (San Jose, CA, USA) was used for image processing.

Molecular analyses

Normal and tumor tissue areas were grossly macrodissected from five 5-μm sections of formalin-fixed, paraffin-embedded tissue blocks to obtain homogeneous cell populations. The tumor tissue samples contained >80% tumor cells. DNA was extracted from both cell populations as follows. Briefly, tissues were deparaffinized using xylene and ethanol, centrifuged, and dried. Pellets were resuspended in 200 μl of lysis buffer (0.05 M/l Tris–HCl at pH 7.5, 1 mM/l ethylenediaminetetraacetic acid (EDTA), 0.5% Tween-20) with 1 mg/ml proteinase K. After overnight digestion at 55°C, samples were boiled for 10 min to inactivate the proteinase K and used for polymerase chain reaction (PCR) amplification. Sequencing of the complete coding region and 140 bp of the 5′ untranslated region of the *CDKN1B* gene was performed with the Big-Dye terminator kit (Applied Biosystems), and sequences were run on an ABI377 sequencer. Primers for sequencing the 5′ region and exon 1 were: p27Kip1_1a FW GTCGGGGTCT GTGTCTTTTG, p27Kip1_1a Rev CCATGTCTCTG CAGTGCTTC; p27Kip1_1b FW TGTCTAACGG GAGCCCTAGC, p27Kip1_1b Rev AGTAGAACTCGGG CAAGCTG; p27Kip1_1c Fw AGTTAACCCGGGACTTG GAG, p27Kip1_1c Rev GTCCGACGGATCAGTCTTTG; p27Kip1_1d Fw AGGAGAGCCAGGATGTCAGC, p27Kip1_1d Rev GCCAGGTAGCACTGAACACC. Primers for exon 2 were: p27Kip1_2 Fw CTGACTATGGGGCCAA CTTC, p27Kip1_2 REV GCCAGCAACCAGTAAGATCAG. Sequencing of the *VHL* gene was performed using previously

reported primers and conditions [40]. Allelic imbalance (AI) analysis at the *CDKN1B* locus was performed using the chromosome 12 p markers D12S391, D12S358, and D12S1580 in cases showing abnormal p27Kip1 staining. PCR products were loaded onto a 377XL sequencer (PE Biosystems). Allele size and fluorescent intensity were determined by Genescan and Genotyper software (PE Biosystems). AI was established by determining the fluorescent intensity of each allele and calculating their ratio in both normal (*N*) and tumor (*T*) DNA using the formula (allele1−*N*/allele2−*N*)/(allele1−*T*/allele2−*T*). Samples were scored as showing AI if an allelic ratio of <0.67 or >1.5 was obtained [10].

Statistical analyses

The number of patients with a reduced expression level of p27Kip1 and that of patients showing the typical high expression was compared between the two tumor types (pheochromocytoma versus paraganglioma cases) using the Fisher's exact test. Two sided P value<0.05 was considered statistically significant.

Results

Expression patterns of p27Kip1 and Ki-67 in pheochromocytoma

Normal adrenal medulla typically shows strong nuclear positivity for p27Kip1 in virtually all cells and low percentage of Ki67-positive cells (below 5%), indicating low proliferative activity (data not shown). From the 25 analyzed pheochromocytomas, 11 cases (44%) showed strong nuclear p27Kip1 staining in >80% of the tumor cells (classified as '+++,' Fig. 1a, b; Table 1), while 14 cases (56%) showed a very weak (Fig. 1c–f) to negative nuclear staining for p27Kip1 (Fig. 1h). The case illustrated in Fig. 1g, showed complete loss of p27Kip1 staining except for one small nodular area of the tumor, which had very strong nuclear expression of the protein. In the negative cases, infiltrating lymphocytes and residual normal adrenal gland were strongly stained with p27Kip1 and, thus, served as internal positive controls for the adequacy of staining. The immunohistochemical staining was mainly nuclear also in the cases with reduced p27Kip1 protein

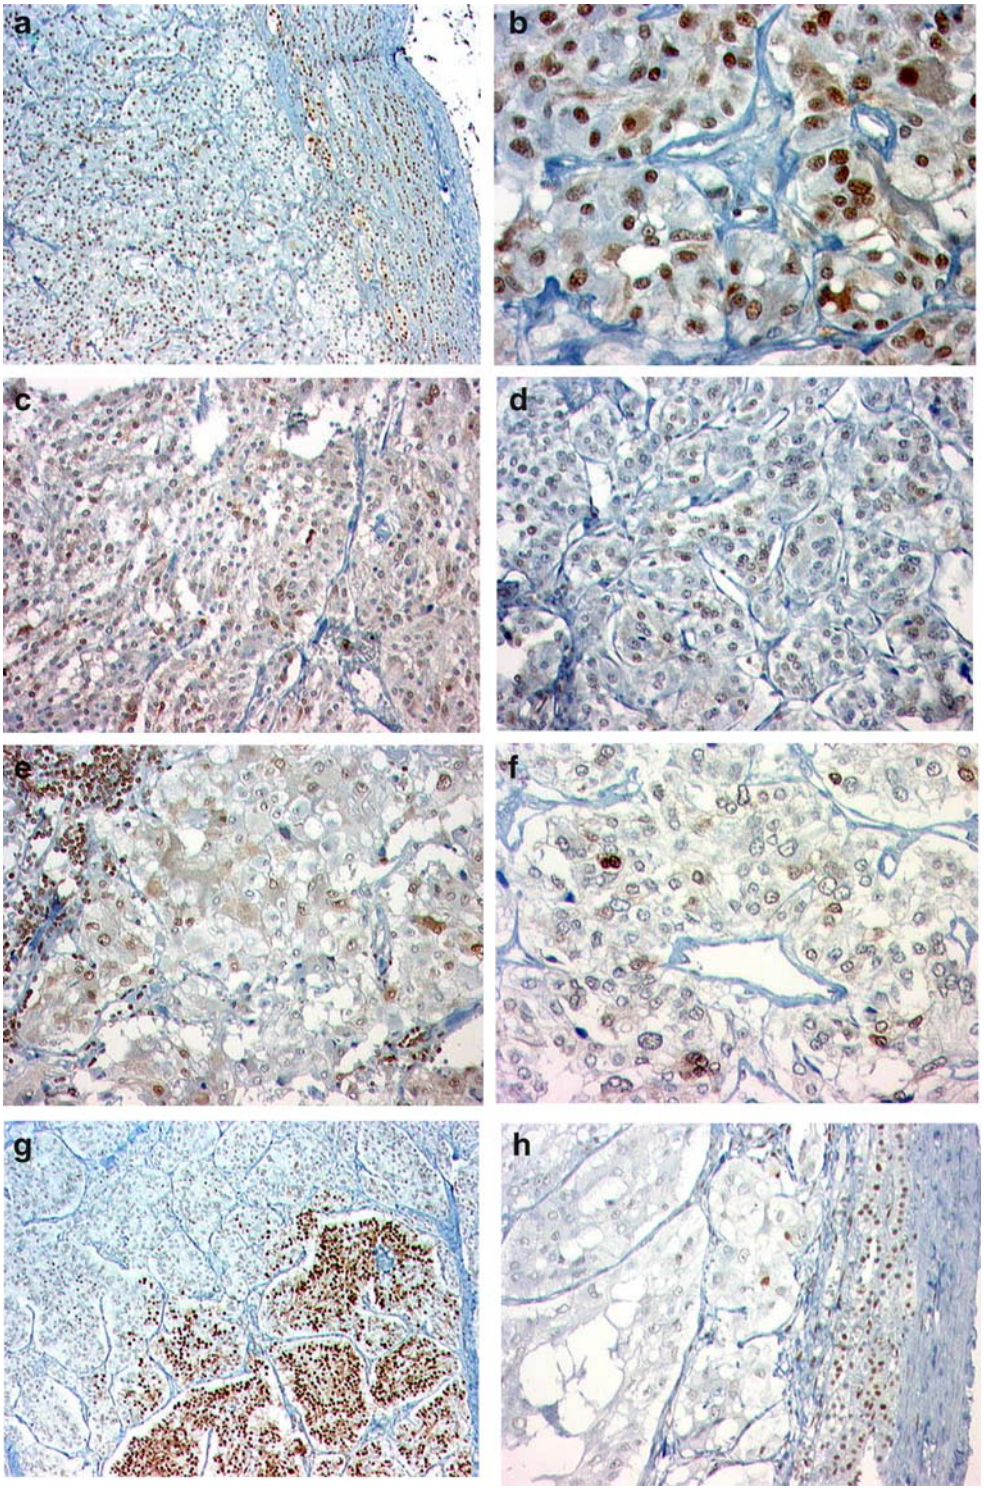

Fig. 1 Immunohistochemical analysis of pheochromocytoma. Sections were scored for the p27Kip1 staining intensity, and the percentage of stained cells in the tumor (see "Materials and methods"). **a**, **b** Strong p27Kip1 staining (+++). **a** Note on the right side that the residual normal adrenal cells are strongly positive for p27Kip1 (100×). **b** Higher magnification demonstrates that the vast majority of the tumor cells have a strong, nuclear positivity for p27Kip1 (400×). **c**–**f** Cases with reduced expression of p27Kip1. **c**, **d** Weak diffused expression of p27Kip1 in the majority of the cells (++; 200×). **e**, **f** Very weak or moderate expression of p27Kip1 in <20% of the cells (+; **e** 200×, **f** 320×). Note that in case **e**, in addition to the reduced expression of p27Kip1, there is also cytoplasmic staining. On the upper-left side of **e**, there are numerous lymphocytes with strong nuclear positivity used as internal control. **g**–**h** Cases of pheochromocytoma with lost p27Kip1 expression or negative for p27Kip1 (−). **g** Only one nodule within the tumor showed nuclear positivity for p27Kip1; the rest of the tumor was negative (100×). **h** Pheochromocytoma negative for p27Kip1. On the right side, there are residual normal adrenal cells strongly positive for p27Kip1 used as internal control (200×)

expression. Four cases (PC5, PC6, PC22, PC24) showed in addition some cytoplasmic reactivity (as an example, see Fig. 1e). The extent and distribution of the cytoplasmic p27Kip1 staining mirrored the nuclear staining in each sample; i.e., when the nuclear staining was very faint and present in only a few cells, the same also held true for the cytoplasmic staining. All pheochromocytomas showed immunoreactivity for Ki-67 in <5% of the cells (Table 1) irrespective of p27Kip1 status.

Expression pattern of p27Kip1 and Ki-67 in paraganglioma

Of the 22 paraganglioma cases, 18 (77.3%) showed strong nuclear immunoreactivity in >80% of the tumor cells

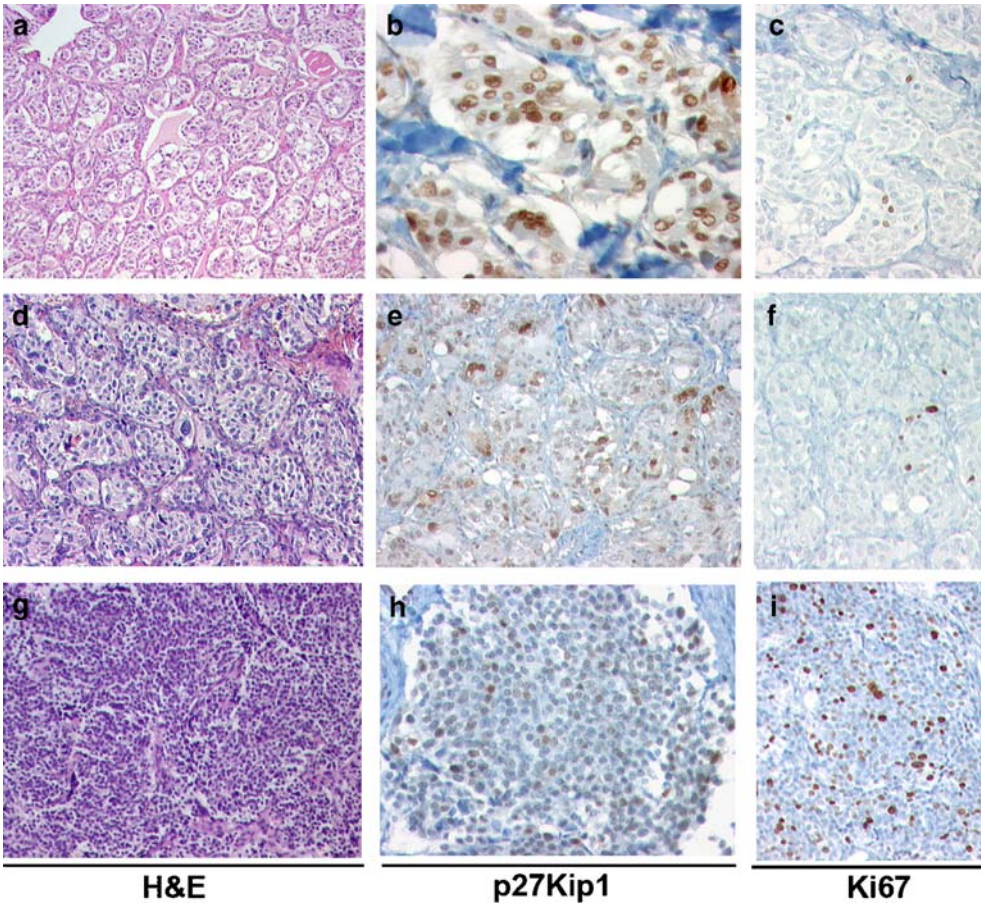

Fig. 2 Histological and immunohistochemical analysis of paraganglioma. **a**–**c** H&E stain of a paraganglioma (**a** 100×) with strong p27Kip1 nuclear positivity (+++) in virtually all tumor cells (**b** 400×) and very low proliferation rate as demonstrated by the Ki67 immunoreactivity (**c** 200×). **d**–**f** H&E stain of a paraganglioma (**d** 160×) with weak to moderate p27Kip1 staining in >80% (++) of the tumor cells (**e** 100×) and very low proliferation rate (**f** 200×). **g**–**i** H&E stain of the aggressive paraganglioma case PG1 (**g** 100×) with p27Kip1 staining in less than 20% (+) of the tumor cells (**h** 400×) and high proliferation rate (**i** 200×)

(Fig. 2b), while 4 cases (18.1%) had weak (Fig. 2e and h) or negative p27Kip1 staining (Table 2). The staining was mainly nuclear also in the cases with reduced p27Kip1 positivity. Only two cases (PG3 and PG17) showed some cytoplasmic reactivity for p27Kip1, and the extent and distribution of the cytoplasmic p27Kip1 staining mirrored the nuclear staining in each sample (as described above for the PC cases). Paraganglioma cases with abnormal p27Kip1 staining included tumors at different locations throughout the body (Table 2). All paraganglioma cases showed immunoreactivity for Ki-67 in <5% of the cells, except one (PG1) that showed positivity in more than 20% of the cells (Fig. 2i). PG1 was classified as an aggressive paraganglioma, as it was a tumor in the nasal cavity associated with infiltration into the base of the skull, both frontal sinuses, and both orbitae.

Genetic analyses of the samples showing abnormal p27Kip1 immunoreactivity

The reduction in the level of expression of p27Kip1 in these tumors (both phaeochromocytoma and paraganglioma cases) could be due to loss of the chromosomal region harboring the gene. Therefore, we searched for allelic imbalance (AI) at the p27Kip1 locus using three highly polymorphic microsatellite markers (D12S391, D12S358, D12S1580) flanking the p27Kip1 locus on chromosome 12p13 (Fig. 3). These markers present a centromere-to-telomere orientation, covering 890 Kb of chromosome 12 that include the *CDKN1B* gene (encoding p27Kip1). The 5′ end of the *CDKN1B* gene is approximately 230 kb downstream of D12S358 and the 3′ end 472 kb upstream of D12S1580. For ten (out of 14) pheochromocytomas and 3 paragangliomas with reduced/lost p27Kip1 expression (see Tables 1 and 2), normal tissue was available for AI analyses. Two samples were non-informative for D12S391, four were non-informative for D12S358, and two for D12S1580. The remaining samples were informative for at least one marker in the region (Fig. 3a). One pheochromocytoma showed AI for D12S391 (PC5; Fig. 3b), another showed AI for D12S1580 (PC7), and the aggressive paraganglioma (PG1) showed AI for all three markers (not shown). Overall, the AI frequency calculated as the ratio of samples showing AI versus the total number of informative cases for each marker is quite low, ranging from 11% (D12S358) to 18% (D12S391, D12S1580).

Nine cases showing a decreased expression of p27Kip1 were analyzed for the presence of somatic mutations in the coding region of the *CDKN1B* gene (Tables 1 and 2). Control DNA from the adjacent normal tissues was also

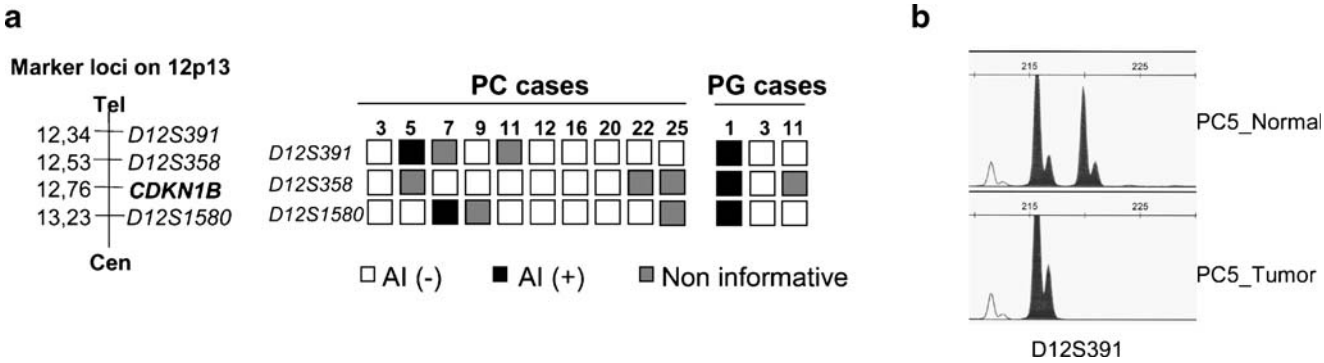

Fig. 3 Allelic imbalance analysis for markers at 12p13. **a** The panel summarizes the status of thirteen cases having abnormal p27Kip1 immunohistochemical staining. Cases described as retaining heterozygosity; having AI and non-informative cases are indicated by *open*, *close*, and *gray* squares, respectively. On the left is reported the position of the markers along chromosome 12 in megabases [according to the National Center for Biotechnology Information (NCBI) genome browser], as well as the position of the *CDKN1B* gene encoding p27Kip1. PG1 was the only sample showing AI for all the markers tested. PC5 and PC7 showed AI for one marker each. **b** Example of AI for marker D12S391 in sample PC5. The normal DNA shows two alleles, while the tumor DNA retains the smaller allele but has lost the larger one

sequenced. PCR amplification of the 5′ region and the two coding exons was performed followed by direct automated sequencing of the PCR products. Although potential pathogenic mutations in *CDKN1B* were not found, known polymorphisms in the 5′ untranslated region of exon1 (SNP rs34330) and at codon 109 (Val109Gly, SNP rs2066827) were identified (Tables 1 and 2).

Patient PC20 could be affected by VHL disease, as the tumor spectrum of this syndrome includes RCC and pheochromocytoma. Therefore, we sequenced the *VHL* gene in the DNA from the normal tissue of case PC20 but we found no mutations. Furthermore, no mutations were identified in *MEN1* and *RET* in this patient (data not shown).

Statistical analysis

The number of patients with a reduced expression level of p27Kip1 (scored −, +, or ++) or showing the high p27Kip1 expression typical of normal tissues (scored +++) was compared between the two tumor types (pheochromocytoma versus paraganglioma) using the Fisher's exact test. The results showed that the number of pheochromocytoma samples having reduced p27Kip1 expression is significantly higher than that of paraganglioma cases showing reduced p27Kip1 positivity (P=0.0151). Age at presentation, malignant potential, and tumor location (for the paragangliomas) were not found to be significantly associated with downregulation of p27Kip1 in both tumor types.

Discussion

In this study, we examined the expression of the cyclin-dependent kinase inhibitor p27Kip1 in a panel of apparently sporadic pheochromocytoma and paraganglioma cases. Two syndromic pheochromocytomas (MEN2) were among the cases analyzed. A striking decrease/loss of p27Kip1 expression was observed at a high frequency in pheochromocytoma (56% of cases), as demonstrated by the low immunostaining and decreased number of cells/field stained with the anti-p27Kip1 antibody. In the remaining cases, the typical strong nuclear expression was observed. In contrast to the high frequency of decreased p27Kip1 expression observed in pheochromocytoma, only 18.1% of the paragangliomas showed reduction of p27Kip1 immunoreactivity. These two tumor types share many similarities: They both arise from chromaffin cells derived from the embryonal neural crest, they are histologically very similar, and they both can be caused by germline mutations in the same susceptibility genes (*VHL*, *SDHD*, *SDHB*). However, our data points to a different genetic etiology of those tumor types with a significantly higher percentage of downregulation of p27Kip1 in pheochromocytomas compared to the paragangliomas (P=0.0151). This finding strongly implicates reduction of p27Kip1 in adrenal but less so in extra-adrenal pheochromocytoma development. These observations are in agreement with our studies on the MENX rat model system. Indeed, affected rats (homozygous for a loss-of-function mutation in p27Kip1 [34]) develop pheochromocytoma with complete penetrance at young age (<6 months), while paragangliomas occur later in life (>10 months), and their incidence is only about 10% (Pellegata, unpublished observation).

In contrast to what is observed by immunohistochemistry for many antigens, we did not find a continuum of p27Kip1 immunoreactivity in our samples, but instead a discontinuous expression pattern. Indeed, we observed samples with virtually all tumor cells highly positive for p27Kip1 (as seen in normal adrenal chromaffin cells), while the others had a dramatic reduction of positivity in either the number of stained tumor cells and/or the intensity of staining.

The molecular mechanism underlying the reduction/loss of p27Kip1 expression is as yet uncertain. We have examined allelic status of chromosome 12p, where the *CDKN1B* gene is located, but changes occur at a low incidence in these tumors: One aggressive paraganglioma showed loss of p27Kip1 through allelic imbalance (AI), and two pheochromocytomas showed AI at markers in the vicinity of p27Kip1. The overall incidence of AI at the analyzed loci (D12S391, D12S358, D12S1580) was 11–18% (calculated as the ratio of AI/informative cases for each marker). Although microdeletions are a formal possibility, it is likely that AI is not the most important mechanism for loss of protein expression. In addition, we did not find mutations in the coding sequence of the *CDKN1B* gene. Both these results are in agreement with the reported low incidence of AI at the p27Kip1 locus and the scarcity of somatic mutations in *CDKN1B* in other solid tumors [24, 25, 30, 38]. It has been shown that the intracellular level of the p27Kip1 protein is mainly regulated at the post-translational level via proteasome-mediated degradation [33]. Indeed, in most cases of decreased p27Kip1 concentrations, increased proteolytic activity toward the protein has been observed [12, 19, 29]. In contrast, no changes in the level of *CDKN1B* messenger RNA (mRNA) have been found in tumors that show downregulation of the p27Kip1 protein [11, 23, 29]. Our studies on the p27Kip1-negative tissues of MENX rats [34] have also failed to detect changes in the level of p27Kip1 mRNA. Thus, the mechanism causing loss of p27Kip1 expression in human pheochromocytomas and paragangliomas might be post-translational.

Cytoplasmic relocation due to phosphorylation or sequestration by partner proteins plays an important role in regulating p27Kip1 functions. It has been proposed that, while p27Kip1 in the nucleus acts primarily as a tumor suppressor by modulating cyclin-cdk complexes, cytoplasmic p27Kip1 has oncogenic properties. Indeed, expression of a p27Kip1 protein that can only localize in the cytoplasm was recently found to increase motility, survival, and Akt levels in MCF7 breast cancer cells [42]. Cytoplasmic p27Kip1 staining has been observed in several tumor types and is in general associated with more aggressive behavior and poorer prognosis [3]. Among the samples analyzed, six showed cytoplasmic staining for p27Kip1 in addition to nuclear staining (see tables). Four of these cases (PC5, PC6, PC24, PG3) had an overall downregulation of p27Kip1 expression (three classified as "+" and one as "++"), indicating that, in those samples, cytoplasmic relocation could contribute to the loss of p27Kip1 tumor suppressor function.

PC21 and PC22 are MEN2A-associated tumors arising in patients who carry a germline mutation in the *RET* protooncogene. It has been reported that younger age of onset, multifocality of the tumors, and the presence of extra-adrenal tumors is parameters usually associated with a genetic predisposition to pheochromocytoma [32]. Thus, cases PC3 (32 years of age) and PC11 (41 years) could also be syndromic pheochromocytomas. Interestingly, three of the above cases (PC3, PC11, PC22) showed reduction/loss of p27Kip1. This observation warrants further studies in a larger cohort of syndromic pheochromocytomas to determine whether p27Kip1 inactivation may occur at a higher incidence in hereditary cases.

The biological consequences of the downregulation of p27Kip1 in pheochromocytoma are not yet known. Except one, all the tumors we analyzed have relatively low proliferative activity (Ki67 immunoreactivity, <5%) irrespective of the p27Kip1 expression level. The fact that downregulation of p27 does not cause massive increase in cell proliferation is in agreement with the phenotype of MENX-affected rats. These animals display increase in overall body size and weight compared to their normal littermates and show a remarkable increase in the size of some organs [34], but the proliferative activity of most tissues (including neuroendocrine tissues) is similar to that observed in unaffected animals (Pellegata, unpublished). It is, therefore, likely that impaired p27Kip1 function may affect not only proliferation but additional cellular processes required to maintain tissue homeostasis (such as differentiation and senescence).

Our observation that reduction of p27Kip1 expression in pheochromocytoma does not increase tumor cell proliferation is in contrast to what has been reported for other tumor types (including medulloblastomas, endocrine tumors of the pancreas, and gastrointestinal tract and most lymphoma subtypes) in which immunoreactivities for p27Kip1 and Ki67 are inversely correlated [1, 9, 13]. When an inverse relationship exists, it is not easy to discern whether the low p27Kip1 expression is the pathological cause or the physiological consequence of increased proliferative activity. In our cases, the decreased p27Kip1 concentration is not the result of an increased proliferation of the tumor cells, but it is due to an altered regulation of the protein's expression. Studies performed in mice have shown that neuroendocrine cells are especially sensitive to defects in cell-cycle regulatory proteins affecting the Rb pathway. In fact, mice heterozygous for Rb [22, 26], chimeric for Rb −/− [41], and deficient for the Cdk-inhibitors p18Ink4c and p27Kip1 develop tumors with high penetrance in the pituitary gland, pancreatic islets, and thyroid [20]. Hyperplasia of the adrenal medulla also develops in mice chimeric for Rb −/− [41]. Our results on the frequent reduction of p27Kip1 in human adrenal medullary tumors further support the hypothesis that this protein plays a role in regulating endocrine tissue homeostasis, not necessarily via controlling cell proliferation.

While the molecular mechanisms underlying the development of hereditary pheochromocytoma and paraganglioma

have been largely elucidated, advances in understanding the molecular pathogenesis of their sporadic counterparts has lagged behind. Somatic mutations in the six known pheochromocytoma/paraganglioma susceptibility genes occur at relatively low incidence (10–25%) in sporadic tumors [5, 7]. Candidate gene approaches have identified tumor suppressor genes inactivated in pheochromocytomas, such as the RAS-association domain family 1, isoform A (*RASSF1A*), and the p16 tumor suppressor genes. *RASSF1A* [2, 4] and p16 [17] were found to be down regulated through promoter region hypermethylation in 22–48% and in 24% of pheochromocytomas, respectively. Interestingly, the incidence of p16 and of *RASSF1A* inactivation was higher in hereditary pheochromocytomas compared to sporadic cases [2, 4, 17]. Recently, genome-wide approaches have been used to identify molecular pathways involved in sporadic and hereditary pheochromocytomas and paragangliomas development [15, 16, 18]. These studies have not yet provided us with individual candidate genes to further analyze. The limited knowledge of the molecular pathogenesis of sporadic pheochromocytomas and paragangliomas has hampered the identification of predictors of malignancy and the development of novel therapeutic approaches to target specific dysregulated pathways. In view of the newly established role of p27Kip1 downregulation in pheochromocytomas, cell cycle regulatory pathways can now be further explored in this tumor type, as well as new therapeutic modalities able to restore p27Kip1 expression (function) in adrenal medullary tumor cells.

ORIGINAL ARTICLE

Submucosal connective tissue-type mast cells contribute to the production of lysophosphatidic acid (LPA) in the gastrointestinal tract through the secretion of autotaxin (ATX)/lysophospholipase D (lysoPLD)

Abstract Lysophosphatidic acid (LPA) is involved in a broad spectrum of biological activities, including wound healing and cancer metastasis. Autotaxin (ATX), originally isolated from a melanoma supernatant as a tumor cell motility-stimulating factor, has been shown to be molecularly identical to lysophospholipase D (lysoPLD), which is the main enzyme in the production of LPA. Although ATX/lysoPLD is known to be widely expressed in normal human tissues, the exact distribution of ATX-producing cells has not been fully investigated. In this study, we evaluated ATX/lysoPLD expression by immunohistochemical staining using a rat anti-ATX mAb in the human gastrointestinal tract and found that submucosal mast cells (MC) highly expressed this enzyme. This was confirmed by immunofluo rescent double staining using mAbs to tryptase and chymase. Then, we isolated MC from human gastric tissue by an immunomagnetic method using CD117-microbeads and showed that a subpopulation of CD203c-positive MC showed positive staining for intracellular ATX/lysoPLD on flowcytometry. This was confirmed by Western blotting of the isolated cells. Moreover, a significant level of ATX/lysoPLD release could be detected in the culture supernatants of human MC by Western blot analysis. Our data suggest that submucosal MC play significant roles in various aspects of pathophysiology in the gastrointestinal tract by locally providing bioactive LPA through the production of ATX/lysoPLD.

Keywords Autotaxin · Lysophpsphatidic acid · Mast cell · Gastrointestinal tract

Abbreviations

ATX	autotaxin
lysoPLD	lysophospholipase D
LPA	lysophosphatidic acid
MC	mast cell
NPP	ecto-nucleotide pyrophosphatase / phosphodiesterase

Introduction

Autotaxin (ATX) was originally isolated from a melanoma cell supernatant as a 125-kD glycoprotein that stimulates tumor cell motility in a pertussis toxin-sensitive manner [55, 57]. Thereafter, more evidence for a positive role of ATX in tumor metastasis has been demonstrated by both in vivo and in vitro studies [36–38, 56, 70]. ATX is strongly detected in the culture media of various cancer cells, and its mRNA is overexpressed in various human malignancies, such as lung, breast, and renal cell carcinoma [53, 70, 71]. These findings support that ATX functions as an autocrine motility factor in the step of tumor progression. ATX was initially identified as a member of the ecto-nucleotide

pyrophosphatase/phosphodiesterase (NPP) family and was termed NPP2 [56]. The NPP family is composed of three ecto-enzymes that hydrolyze phosphodiester and pyrophosphate bonds in nucleotides [9, 18]; however, its molecular structure relating to stimulation of cell motility is an enigma. On the other hand, lysophospholipase D (lysoPLD), which converts lysophosphatidylcoline (LPC) to lysophosphatidic acid (LPA, 1- or 2-acyl-*sn*-glycero-3-phosphate), was found to be abundant in plasma and serum [3, 62]. LPA is a lipid mediator of a broad range of cellular responses, including smooth muscle contraction, platelet aggregation, neurite retraction/cell rounding, regulation of proliferation, protection from apoptosis, and modulation of chemotaxis and transcellular migration [19, 35]. LPA elicits most of its cellular responses via transduction cascades downstream of its specific G protein-coupled receptors, LPA1/Edg-2, LPA2/Edg-4, and LPA3/Ede-7, which belong to the endothelial cell differentiation gene (Edg) family [2, 4, 11, 24]. Some of these cellular responses implicate LPA as a mediator of tumor progression [31, 34, 50–52]. Recently, molecular cloning of lysoPLD revealed that this enzyme was identical to ATX [63, 66]. As LPC is abundantly present in plasma and tissues (exceeding 100 μM), ATX/LysoPLD is considered to be a key enzyme in the production of LPA in vivo [3, 12, 61]. Therefore, it is generally accepted that the effects of ATX/LysoPLD in cancer progression (including proliferation, migration, and angiogenesis) are mostly attributable to the production of LPA from LPC or more complex lysophospholipids [66, 67]. Although the mechanism of catalysis of ATX/lysoPLD is well characterized, its post-translational processing, regulation of expression, and mechanism of release from cells are not well understood. ATX is widely expressed, with highest mRNA levels detected in brain, placenta, intestine, and ovary [36]. However, the cellular expression of ATX/lysoPLD in each tissue remains unclear. Herein, by immunohistochemical study using a specific monoclonal antibody, we assessed the cellular distribution of ATX/LysoPLD in the human gastrointestinal tract, and found that submucosal mast cells (MC) constitutively express ATX/lysoPLD.

Materials and methods

Reagents and human samples

Rat anti-ATX/lysoPLD monoclonal antibodies (2A12, 4F1) were generated by the immunization of rat with a polypeptide (amino acids 58–182 of human autotaxin) at the Graduate School of Pharmaceutical Sciences, The University of Tokyo, Tokyo, Japan. The specificity [60] and immunoreactivity for tissue section of these mAbs were evaluated previously [5, 46]. Antihuman tryptase mAb (AA1) and antihuman chymase mAb (CC1) were purchased from Dako (Carpinteria, CA) and Serotic (Oxford, UK), respectively, and both of their subclasses were IgG1.

Surgical specimens were obtained from seven patients with primary gastric carcinoma treated by total gastrectomy and seven patients with primary colon cancer treated by right hemicolectomy in the University of Tokyo, with written informed consent. Normal parts of the stomach or colon in those specimens, more than 5 cm from the tumor edge, were used for staining experiments. The ileum of the oral margin of right hemicolectomy specimens and the jejunal margin used for reconstruction after gastrectomy was used for evaluation of the small intestine.

Immunohistochemical study

Paraffin-embedded sections, 5 μm thick, were deparaffinized in xylene, hydrated through a graded series of ethanol, then immersed in 3% hydrogen peroxide in 100% methanol for 30 min to inhibit endogenous peroxidase activity. To activate the antigens, the sections were boiled in 10 mM citrate buffer pH 6.0 for 15 min. After being rinsed in phosphate-buffered saline (PBS), the sections were incubated with normal rabbit serum for 30 min and incubated overnight at 4°C in humid chambers with primary antibodies to tryptase (AA1, dilution 1:100), chymase (CC1, dilution 1:100), or ATX/lysoPLD (2A12, dilution 1:50). After washing with PBS, the sections were incubated with biotinylated rabbit anti-mouse immunoglobulin (Nichirei, Tokyo, Japan) for 20 min. After washing again with PBS, the slides were treated with peroxidase-conjugated streptavidin for 10 min and developed by immersion in 0.01% H_2O_2 and 0.05% diaminobenzidine tetrahydrochloride. Light counterstaining with Mayer's hematoxylin was performed. All cases had a negative control that was run simultaneously with the test slide, in which control rat IgG was used as the primary antibody. Tryptase-, chymase-, and ATX/LysoPLD-positive cells were counted in five different fields selected at random, using a microscope (and expressed as number per ×200 field).

Immunofluorescent double staining

To identify the two molecules in the same specimen, immunofluorescent double staining was performed on frozen sections. The surgically removed specimen was immediately fixed with acetone for 10 min and immersed in 3% hydrogen peroxide in 100% methanol for 30 min. Then, sections were incubated with normal rabbit serum for 30 min and incubated overnight at 4°C in shaded humid chambers with primary antibodies to tryptase or chymase. After washing with PBS, sections were incubated for 2 h with rhodamine-conjugated rabbit anti-mouse IgG (Chemicon International, Temecula, CA). Then, sections were incubated overnight with rat anti-

ATX antibody chemically conjugated with fluorescein isothiocyanate (FITC) (FITC-conjugated 4F1, dilution 1:10). The sections were observed with a confocal laser microscope (Fluoview, Olympus, Tokyo, Japan).

Buffer for cell preparation

Tris–ethylenediaminetetraacetic acid (EDTA) (TE) buffer is Eagle's minimum essential medium (MEM, Gibco, Berlin, Germany) containing 2 mM EDTA. TGMD buffer is TE buffer supplemented with 1 mg/ml gelatin, 1.23 mM $MgCl_2$, and 15 μg/ml DNAse. Hepes buffer contains 20 mM Hepes, 125 mM NaCl, 5 mM KCl, and 0.5 mM glucose. HA buffer is Hepes buffer plus 0.25 mg/ml bovine serum albumin (BSA).

Cell preparation

The normal parts of the gastric wall were resected, and tissues containing the mucosal and submucosal layers were separated from the muscularis propria layer using scissors and used for cell separation. MC were isolated by a four-step enzymatic tissue dispersion method as described previously with some modifications [7, 8, 49]. The tissues were cut into fragments with scissors and incubated in TE buffer containing 1 mg/ml acetylcysteine for 10 min at room temperature to remove mucus and then in TE buffer containing 5 mM EDTA for 15 min at 37°C to detach epithelial cells. After washing in TE buffer, the tissue was incubated in TE buffer containing 3 mg/ml pronase and 0.75 mg/ml chymopapain at room temperature. Pronase and chymopapain were purchased from Roche (Mannheim, Germany). During this first digestion step, the tissue was cut into smaller pieces using scalpels. After 30 min, the free cells (fraction 1) were separated from tissue fragments by filtration through a polyamide Nybolt filter (pore size 300 μm). The remaining tissue fragments were washed in TE buffer, and the first digestion step was repeated at 37°C (fraction 2). The tissue fragments were then washed in TGMD buffer and incubated twice for 30 min at 37°C in TGMD buffer containing 1.5 mg/ml collagenase D (Roche, Mannheim, Germany) and 0.15 mg/ml elastase (Roche, Mannheim, Germany). The freed cells were separated from the digested tissue by filtration (fraction 3 and 4). Fraction 3 and 4 were filtered through a Nyblot filter (pore size 100 μm) again and resuspended in HA buffer. Cell viability was measured using trypan blue staining, and MC counts were performed using Alcian blue at each step.

Mast cell purification

Dispersed cells containing approximately 1% MC were purified as described previously with some modifications [7, 39, 49]. In brief, the dispersed cells were incubated with anti-CD117 mAb-conjugated microbeads (Miltenyi Biotec, Bergisch Gladbach, Germany) for 15 min at 4°C. Then, CD117-positive cells were enriched by passing through a magnetic column twice at 1 ml/min using the "POSSEL DS" program of the AutoMACS system which enables the fast and efficient positive selection of rare population with low immunogenic epitope (Miltenyi Biotec, Bergisch Gladbach, Germany). "POSSEL DS" means "double sensitive positive selection".

The purified MC were dispersed on slides by centrifugation for 10 min (×500 rpm) and fixed with acetone. Then, the slide samples were incubated with biotinylated anti-tryptase (AA1) or anti-chymase (CC1) mAbs followed by incubation with peroxidase-conjugated streptavidin and development by diaminobenzidine tetrahydrochloride as described above. Under the microscope, 100 cells were randomly selected in five to seven different fields, and cells positive for tryptase or chymase in those cell populations were calculated (per ×200 field).

Detection of ATX/lysoPLD by flow cytometry

Dispersed cells obtained after the four enzymatic steps were washed twice with PBS and fixed with acetone for 10 min at 4°C. Then they were permeabilized with 4% paraformaldehyde (PFA) for 10 min at 4°C. For two-color staining, cells were incubated with FITC-conjugated anti-ATX mAb and PE-conjugated anti-CD203c antibody (Immunotech, Marseille, France). Data were collected in a fluorescent activated cell sorting (FACS) Calibur (Becton Dickinson, Mountain View, CA) and analyzed using CellQuest software (Becton Dickinson).

Detection of ATX/lysoPLD by Western blot analysis

Immunoselected MC (2×10^6), which contained more than 70% Alcian blue-stained cells, were cultured in 8 ml Roswell Park Memorial Institute (RPMI) supplemented with 0.1% BSA, 100 U/ml penicillin, and 100 μg/ml streptomycin (Life Technologies, Inc., Grand Island, NY). As a control, the same numbers of negatively selected cells were also cultured in the same medium. After culture for 48 h, the proteins of the culture supernatants were extracted as described previously [66]. Then, 8 ml culture supernatant was concentrated to 100 μl by a Centricon Plus-20 (Millipore, Bedford, MA), and electrophoresed in sodium dodecyl sulfate (sodium dodecyl sulfate (SDS)) 7.5% polyacrylamide gel for 45 min at 200 V. Then, the protein was transferred onto an Immobilon transfer membrane (Millipore, Bedford, MA) for sequential incubation with 5% reconstituted nonfat milk powder to block nonspecific sites, dilutions of anti-ATX antibody, and horseradish peroxidase-labeled rabbit polyclonal anti-rat IgG, before development with a standard enhanced chemiluminenscence kit (Amersham, Inc., Buckinghamshire, United Kingdom).

Results

Immunostaining of MC in the gastrointestinal tract

MC were clearly identified in the stomach, small intestine, and colon by immunostaining with anti-tryptase antibody (AA1), as reported previously [27, 69]. Granules in the MC cytoplasm were stained brown. In the stomach, tryptase-positive MC were diffusely present from the mucosal to the muscular layer, but the number of MC in the submucosal layer was significantly greater than that in the mucosal or muscular layer (Fig. 1b). MC were also diffusely present in the small intestinal and colonic tissues (Fig. 1d).

Immunodetection of ATX/lysoPLD in the gastrointestinal tract

As shown in Fig. 1, there were many large oval cells whose cytoplasm was clearly stained by anti-ATX/lysoPLD antibody (2A12). The positive cells were detected in the mesenchymal area in the submucosal layer of the gastrointestinal tract, while they were rarely observed in the mesenchymal area of the mucosal or muscular layers (Table 1). Interestingly, in serial sections, most of the ATX-positive cells were morphologically similar to MC detected by anti-tryptase antibody (Fig. 1e,f).

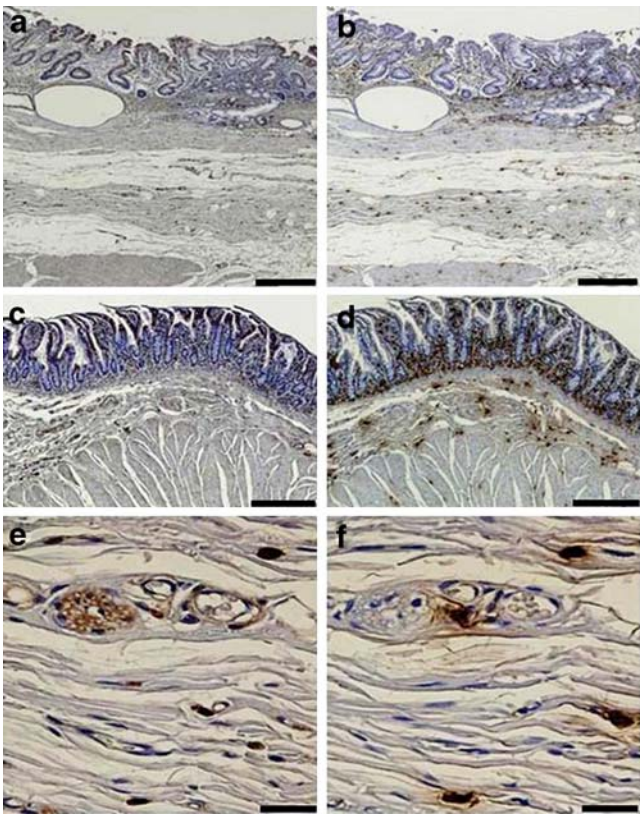

Fig. 1 Immunohistochemical staining of the stomach (**a**, **b**, **e**, **f**) or terminal ileum (**c**, **d**) with anti-ATX/lysoPLD mAb (2A12) (**a**, **c**, **e**) or anti-tryptase mAb (AA1) (**b**, **d**, **f**). Serial sections of submucosal area of the stomach with high magnification (**e**, **f**). *Bar* indicates 1,000 μm (**a**, **b**), 500 μm (**c**, **d**), and 50 μm (**e**, **f**). Immunoreactivity for ATX/lysoPLD was clearly detected in a subpopulation of tryptase positive cells

ATX/lysoPLD-positive cells were identified as a subtype of MC

To confirm that ATX/lysoPLD-positive cells are identical to MC, we performed immunofluorescent double staining in surgically removed gastric tissue. As shown in Fig. 2, when tryptase-positive MC were stained red and ATX/LysoPLD-positive MC green, ATX/LysoPLD-positive cells were detected with yellow fluorescence in merged views (Fig. 2c). On the other hand, some MC were detected as red in merged views, suggesting that some MC did not express ATX/LysoPLD (Fig. 2f). No cells were stained green in these frozen sections. This clearly indicates that the cells expressing ATX/LysoPLD in merged views are confined to a subpopulation of MC in the gastrointestinal tract.

Then, we performed double immunofluorescent staining with anti-chymase antibody (CC1). Most of the ATX/lysoPLD-positive MC were stained yellow in the merged view (Fig. 2i). When the number of ATX/lysoPLD-positive MC in tryptase- or chymase-positive MC was counted in 20 fields selected at random, 92% (82–96%) of chymase-positive cells expressed ATX/lysoPLD, whereas 68% (61–86%) of tryptase-positive cells expressed ATX/LysoPLD (Table 2). A previous study on human intestine showed that tryptase-positive MC exist in both the mucosal and submucosal layers, while most chymase-positive MC exist in the submucosal layer [27]. This appears to be consistent with our result that most of the MC in submucosal, but not mucosal layers, highly expressed ATX/lysoPLD.

Proportion of ATX/lysoPLD-positive MC in the gastrointestinal tracts

The proportion of ATX/lysoPLD-positive cells in tryptase-positive MC was comparatively evaluated in the stomach, intestine, and colon. As shown in Table 1, more than 50% of MC in the submucosal layer expressed ATX/lysoPLD in all organs examined (stomach: 52%, small intestine: 63%, colon: 56%). In contrast, only a small proportion of MC in the mucosal or muscular layer expressed ATX/lysoPLD (stomach: 7.1%, 8%, small intestine: 6.7%, 8%, colon: 14%, 4.1%).

Detection of intracellular ATX/lysoPLD in MC isolated from gut tissue

Enzymatic isolation provided at least 2×10^8 single cells containing about 1% MC, and their viability was at least 90%. After positive selection using magnetic affinity purification with anti-CD117, the majority of the cells were

Table 1 Distribution of tryptase and autotaxin (ATX/lysoPLD)-positive cells in each layer of gastrointestinal tract

Tryptase- and ATX/LysoPLD-positive cells were counted in five different fields using a microscope (×200 field), and the mean (min–max) of seven different samples were expressed.

Parts of the gastrointestinal tract	Layer	Tryptase(+)	ATX(+)	ATX(+)/Tryptase(+)
Stomach	m	16 (13–27)	1 (0–5)	7.1% (0–27%)
	sm	40 (17–77)	20 (3–35)	52% (18–69%)
	mp	56 (6–94)	4 (0–6)	8% (0–17%)
Small intestine	m	33 (10–54)	2 (1–4)	6.7% (2.7–10%)
	sm	41 (16–48)	26 (10–30)	63% (32–95%)
	mp	18 (3–35)	2 (0–6)	8% (0–50%)
Colon	m	20 (18–45)	3 (1–5)	14% (4–18%)
	sm	27 (18–29)	16 (14–36)	56% (47–90%)
	mp	15 (2–28)	1 (0–4)	4.1% (0–27%)

stained blue by Alcian blue (Fig. 3a) and anti-tryptase mAb (Fig. 3b). In contrast, cells stained with anti-chymase mAb were fewer than tryptase-positive cells (Fig. 3b). Then, to detect intracellular expression of ATX/lysoPLD, we performed double staining of the dispersed cells with anti-ATX/lysoPLD and anti-CD203c, which was determined as a specific cell surface antigen of human MC and basophils [17]. FACS analysis showed that more than 70% of the cell population positively expressed CD203c (Fig. 3c). When the CD203c-positive population was gated, 22% (13–27%) of CD-203c positive cells were clearly positive for intracellular ATX/lysoPLD, whereas the CD203c-negative population lacked expression of ATX/lysoPLD (Fig. 3d).

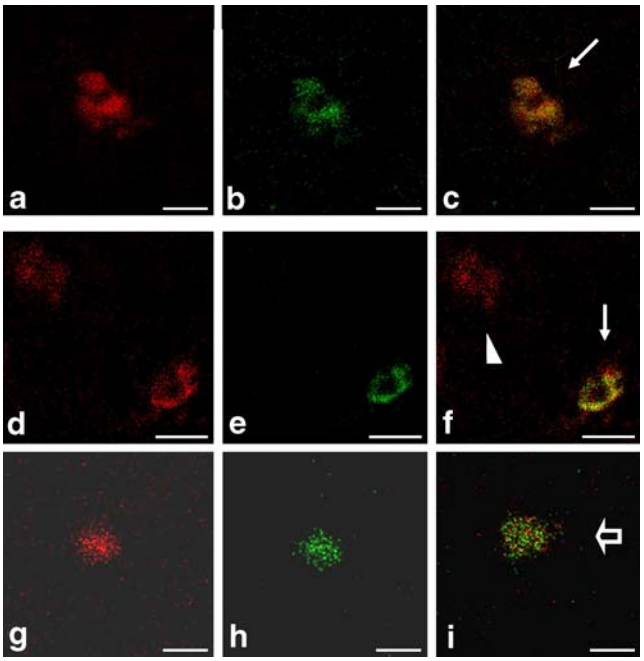

Fig. 2 Immunofluorescent double staining with anti-tryptase (AA1), anti-chymase (CC1), and anti-ATX/lysoPLD (4F1) mAbs. A frozen section of normal gastric tissue was stained as described in the Materials and Methods section. The section was observed with a confocal laser microscope (Fluoview, Olympus, Tokyo, Japan). The *bar* indicates 10 μm **(a–f)**. Double staining for tryptase in *red* (**a**, **d**) and ATX/lysoPLD (**b**, **e**) in *green*. In the merged view, a double-positive cell is stained *yellow*, indicating that the cell expresses ATX/lysoPLD and tryptase (*white arrows* in **c**, **f**). In contrast, a cell stained *red* in the merged view expresses tryptase but not ATX/lysoPLD (*white arrow head* in **f**). No cells are stained green in the merged view, indicating that ATX/lysoPLD-producing cells are restricted to a subtype of MC. **(g–i)** Double staining for chymase in *red* (**g**) and ATX/lysoPLD (**h**) in *green*. In the merged view, most of the cells are stained *yellow* [*open arrow* in (**i**)], indicating that most chymase-positive MC coexpress ATX/lysoPLD

Expression of tryptase or chymase in cell population isolated from gut tissue

As shown in Fig. 3b, 82% of the cells were positive for tryptase, while only 17% MC were positive for chymase (Table 3). This result is consistent with Gebhardt's report, showing that about 20% of purified MC expressed both tryptase and chymase [16]. From these results, it is supposed that the cell isolates from gut tissue by this method contain relatively more mucosal MC than submucosal MC.

Detection of the release of ATX/lysoPLD from MC by Western blot analysis

Finally, we examined the protein expression of ATX/lysoPLD and tryptase and chymase in MC-rich population.

Table 2 Proportion of ATX/lysoPLD-positive cells in tryptase- or chymase-positive cells

Cells	ATX/lysoPLD-positive cells	ATX/lysoPLD-negative cell	Percentage of ATX/lysoPLD-positive cells
Tryptase-positive cells	30 (27–44)	16 (5–19)	68% (61–86%)
Chymase-positive cells	26 (23–38)	2 (1–5)	92% (82–96%)

Frozen section of normal gastric or intestinal tissues were immunostained red by anti-tryptase or anti-chymase mAbs and green, by anti-ATX/lysoPLD mAbs. Positive cells were counted in 20 different fields, and the mean (min–max) in five different samples were expressed.

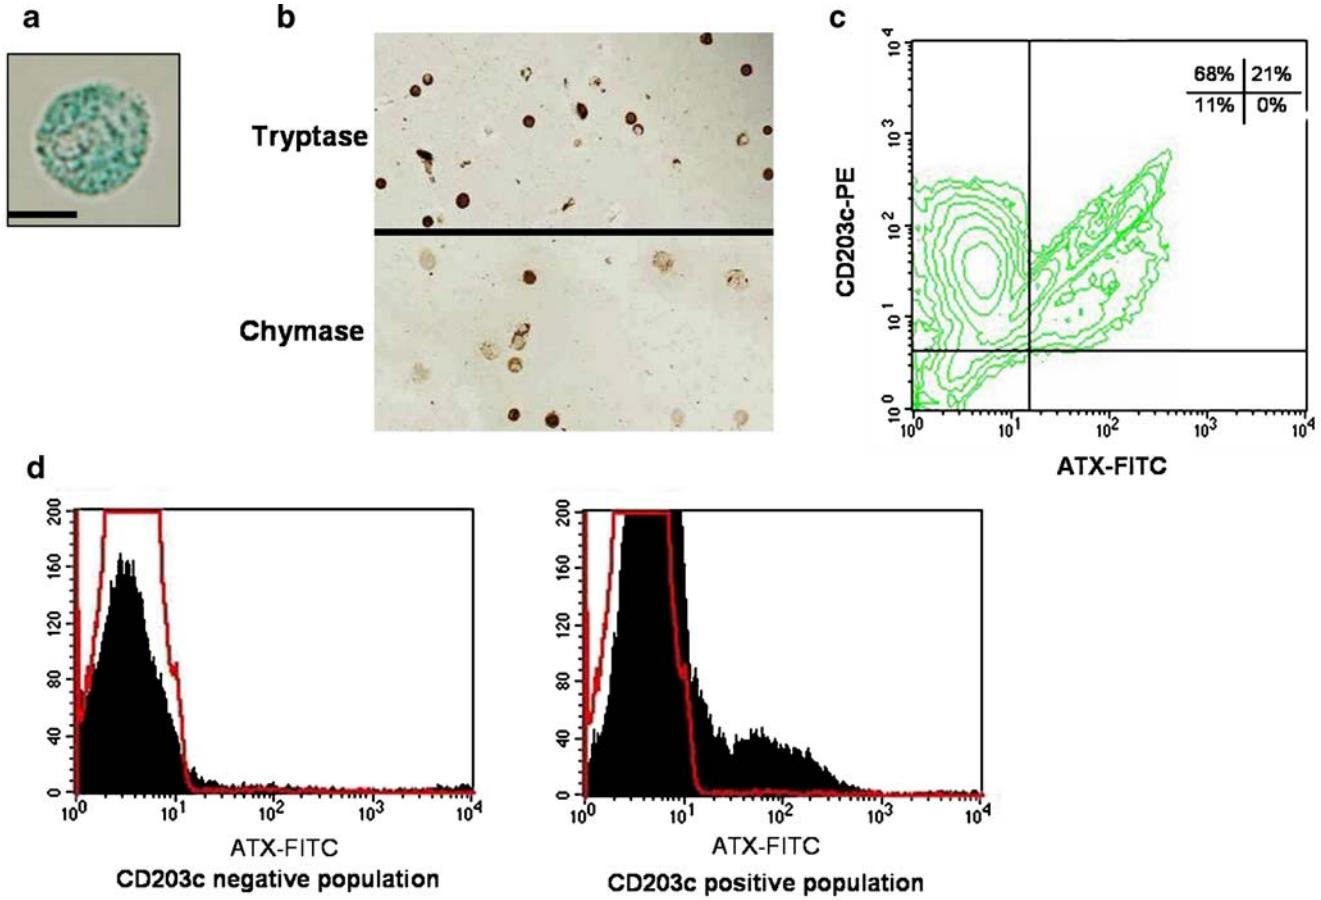

Fig. 3 Characterization of MC isolated from gastrointestinal tissue. The cells recovered after enzymatic digestion of gastrointestinal mucosal tissue were positively selected using anti-CD117 mAb. **a** A representative MC stained by Alcian blue (**b**); Immunochemical staining with anti-tryptase (*upper*) and anti-chymase (*lower*). The majority of cells are positive for tryptase, but not for chymase. **b** Flowcytometric profile of double staining by CD203c and ATX/lysoPLD. The MC-enriched fraction was fixed, permeabilized, and double stained with PE-conjugated anti-CD203c mAb and FITC-conjugated anti-ATX/lysoPLD mAb (**c**). The CD203c-negative (*left*) and -positive (*right*) areas were gated, and the FITC level was examined in each gated fraction. The *red line* represents negative control. The figure shows the representative data from four different experiments (Table 4)

Positively selected cells expressed ATX/lysoPLD, whereas negatively selected cells did not (Fig. 4a). As shown in Fig. 4a, tryptase and chymase were also detectable in cell lysates of MC-rich population.

Then, we evaluated whether MC extracellularly secrete ATX/lysoPLD. As shown in Fig. 4b, ATX/lysoPLD protein was detected in the concentrated culture supernatant of MC-enriched population cells isolated from gastric tissue, but not in the supernatant of negatively selected cell populations. This finding indicates that a subpopulation of the human MC in gastric tissue release soluble ATX/lysoPLD into the culture medium.

Discussion

LPA is involved in the etiology of a variety of diseases such as atherosclerosis, obesity, and cancer and in physiological responses such as wound healing, vascular tone, vascular integrity, and reproduction [34, 48]. However, the molecular mechanism of the production of this bioactive phospholipid is poorly understood, although a large amount of LPA is known to be produced by activated platelets or stimulated fibroblasts in pathological conditions. Recently, it has been postulated that at least two pathways exist for LPA production, intracellular synthesis from phosphatidic acid and

Table 3 Distribution of tryptase- and chymase-positive MC in the immunomagnetically purified population

Tryptase (+)	Chymase (+)	Chymase (+)/Tryptase(+)
82 (79–90)	17 (12–25)	21% (13–29%)

The purified MC were stained with avidin–biotin peroxidase method using biotinylated anti-tryptase or anti-chymase mAbs. Under the microscope, a hundred cells were randomly selected in five to seven different fields and positive cells for tryptase or chymase in those cell populations were calculated. Mean (min–max) in five different samples were expressed (Fig. 3b).

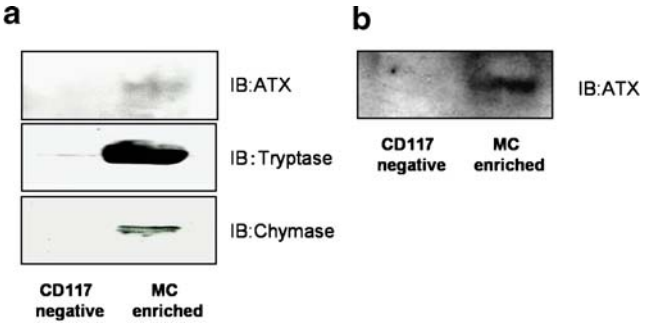

Fig. 4 **a** Western blotting of lysates of MC-enriched cell population from gastrointestinal tract for ATX/lysoPLD, tryptase, and chymase. **b** Detection of release of ATX/lysoPLD from MC-enriched population. MC-enriched cells (2×10^6) were cultured. Then, the supernatant was concentrated and the protein expression of ATX/lysoPLD was evaluated by Western blotting. For negative control, negatively selected cells with anti-CD117 mAb were cultured in the same conditions, and the culture supernatant was assessed for the presence of ATX/lysoPLD. The figure shows representative data from three different experiments

extracellular conversion from other lysophospholipids. In the latter pathway, ATX/lysoPLD is shown to be a key enzyme in the production of LPA by the catalysis of LPC, which is known to be abundantly present in plasma and tissue fluids [3, 64, 66]. In this study, we found a subtype of MC in the human gastrointestinal tract that showed strong staining for ATX/lysoPLD. This reports characterized the cellular producer of ATX/lysoPLD in normal tissue, while a recent study has demonstrated that ATX/LysoPLD is overexpressed in Epstein–Barr virus-infected Hodgkin's lymphoma cells [5]. That study used the same antibody as us and showed similar cytosolic staining of ATX/LysoPLD in lymphoma cells, suggesting that ATX/lysoPLD is stored in the cytosol in contrast to the other NPP family proteins, which are predominantly distributed in the plasma membrane [54]. By Western blotting of culture supernatants, we confirmed the secretion of ATX/lysoPLD from the MC-enriched fraction. These data clearly indicate that those MC undergo membrane-proximal cleavage to yield soluble ATX/lysoPLD, and thus, have important physiological roles through the local supply of a high concentration of LPA in gastrointestinal mucosal tissue.

Tissue MC are known to derive from specific bone marrow progenitor cells and migrate into tissues, where they mature depending on the microenvironment and acquire the capability to produce a wide range of mediators including histamine, heparin, prostaglandins, leukotrienes, and many inflammatory cytokines such as interleukin-8, vascular endothelial cell growth factor (VEGF), and platelet-derived growth factor (PDGF), and exert their biological effects by releasing such mediators [6, 15, 21, 26, 30]. In rodents, MC are phenotypically divided into two subtypes, mucosal-type MC (MMC) and connective tissue-type MC (CTMC), that produce distinct types of mediators. MC in the human gastrointestinal tract are also subdivided by immunohistochemical detection of two proteases; CTMC that contain tryptase and chymase, and MMC containing tryptase but not chymase [1, 27–29]. Those studies have shown that MMC are preferentially located in the mucosal surface, while CTMC are detected mainly in submucosal tissue in the gut. Our immunostaining results revealed that MC in the submucosal layer highly expressed ATX/lysoPLD, but MC located in the mucosal and muscular layers did not. Moreover, double staining experiments showed that most of the chymase-positive MC also expressed ATX/lysoPLD, while about half of the tryptase-positive cells lacked the expression of ATX/lysoPLD. This is consistent with previous findings and indicates that ATX/lysoPLD is constitutively produced mainly by submucosal CTMC in the gastrointestinal tract.

Using flowcytometry, we confirmed that intracellular staining of ATX/lysoPLD was detected by CD203c-positive MC isolated from gut tissue. In FACS analysis, however, only 10–20% CD203c-positive MC are positive for ATX / lysoPLD, which does not agree with the immunostaining data indicating that most of the submucosal MC are positive for ATX /lysoPLD (Table 4). In fact, cells separated by this immunomagnetic method contained many tryptase-positive MC but fewer chymase-positive MC. This suggests that submucosal MC are collected less efficiently than mucosal MC by this isolation process, which may contribute to the discrepancy between FACS analysis and immunohistochemistry.

Table 4 Percentages of each quadrant for different four FACS plots

Quadrant	Ex.1 (%)	Ex.2 (%)	Ex.3 (%)	Ex.4 (%)	Mean (%)	(Max–min) (%)
Left upper	68	66	60	55	62	(55–68)
Right upper	21	10	22	17	18	(10–22)
Left lower	11	24	18	28	20	(11–28)
Right lower	0	0	0	0	0	0

The MC-enriched fraction was fixed, permeabilized and double stained with PE-conjugated anti-CD203c mAb and FITC-conjugated anti-ATX/lysoPLD mAb. Percentages of each quadrant for different four FACS plots were shown.

The expression of ATX/lysoPLD in submucosal MC is considered to have physiological relevance. MC are essential for allergic and late phase reactions and T-cell-mediated immunity [14, 33, 42]. LPA has been reported to lead to overexpression of adhesion molecules and chemokines in endothelial cells, and thus, induces the recruitment of mononuclear phagocytic cells [40, 45]. For helper T cells, LPA has been shown to induce chemotactic migration of naïve CD4(+) T cells expressing the specific receptor Edg4 (LPA2), while enhancing proliferation and IL-2 production in activated CD4(+) T cells expressing Edg2 (LPA1) predominantly, but rather, inhibit the migration of these activated CD4 (+) T cells [20, 73]. This strongly suggests that the production of ATX/lysoPLD in submucosal MC has an important role in preparation of CD4(+) helper T cells' repertoire to respond to a variety of antigens in gastrointestinal mucosal tissue. Once T cells are stimulated with certain antigens, ATX/lysoPLD can augment T cell-mediated responses in mucosal tissue through the production of LPA.

On the other hand, LPA is considered to have suppressive effects on neutrophil-induced inflammation in vivo. LPA reduces IL-8-induced migration of human neutrophils in patients with pneumonia and inhibits the production of oxygen species in human neutrophils in response to stimulation with PMA [10, 43]. In the gastrointestinal tract, LPA reduces the degree of colonic inflammation induced by ethanol and trinitrobenzene sulfonic acid in a rat colitis model in vivo [59]. These findings suggest the possibility that ATX/lysoPLD released from submucosal MC plays a protective role against acute phase inflammatory bowel disease (IBD) [23]. Because the number of MC is markedly increased in IBD, it would be intriguing to examine the production of ATX/lysoPLD in MC in the intestinal mucosa in patients with IBD. In addition, recent studies have demonstrated that LPA also activates enteric glia cells, which are considered to play critical immunoregulatory roles in gut tissue [47, 68]. Taken together, these findings suggest that MC-derived ATX/lysoPLD has pivotal effects on mucosal immunity in the gastrointestinal tract.

LPA is also essential in wound healing. When superficial mucosal injury occurs, the mucosal defect is rapidly closed through a process termed epithelial restitution in physiological conditions [25, 58]. LPA is considered to play major roles in this step, as it strongly promotes epithelial cell migration and proliferation in vitro [41]. In fact, rectally applied LPA stimulates wound healing of the intestinal epithelium and reduces the size of ulcers in the rat [58]. Therefore, the production of ATX/lysoPLD in gastrointestinal CTMC is considered to be necessary for the maintenance of mucosal barrier function, as they can constitutively provide a considerable amount of LPA in the submucosal area, and thus, epithelial cells can rapidly respond to repair the mucosal injury.

Finally, ATX/lysoPLD has an essential role in the progression of malignant diseases in the gastrointestinal tract. Many studies have provided evidence for positive roles of LPA in the initiation or progression of malignancy, including melanoma, ovary, prostate, breast, head and neck, colon, and stomach cancer [13, 22, 72]. This is reasonable, because LPA can function as a growth factor for cancer cells and also stimulates angiogenesis [34]. More than 40 years ago, it has been reported that a large number of MC accumulate around solid tumors and a large number of tumor-associated MC were significantly correlated with high vascular density and poor outcome [32, 44, 65]. In those studies, MC-derived secretalogues, such as histamine, heparin, or VEGF are considered to be responsible for the new vessel formation. However, our results strongly support additional mechanisms of MC to promote the malignant potential of cancer through the production of ATX/lysoPLD.

In summary, we discovered that a subpopulation of submucosal CTMC constitutively secrete ATX/lysoPLD. MC are considered to play important roles in the pathophysiology of gastrointestinal diseases, such as allergic enteritis, inflammatory bowel disease and malignancy. The effects of MC may be partly attributable to ATX/lysoPLD by providing LPA in gastrointestinal mucosal tissue, although circulating ATX/lysoPLD synthesized in different locales may also modulate LPA levels. As ATX/lysoPLD is a relatively stable protein compared to the bioactive phospholipid product, further research on this enzyme may be useful for the evaluation of functional role.

Acknowledgements This work was supported partly by a Grant-in-Aid for Scientific Research from the Ministry of Education, Culture, Sports, Science and Technology of Japan and partly by a grant from the Ministry of Health, Labor and Welfare of Japan. We thank Dr. M. Uchikawa for his kind help to conjugate FITC to anti-ATX mAb, and Ms. C. Uchikawa and Ms. K. Amitani for their excellent technical assistance.

Received: 1 February 2007 / Revised: 2 May 2007 / Accepted: 6 May 2007 / Published online: 7 June 2007

Abstract We report here four cases of pediatric patients in whom the diagnosis of cystic fibrosis was made only after the histological examination of a liver specimen obtained by biopsy (three cases) or at autopsy (one case). There were two boys and two girls, aged 13 months to 7.5 years. None had a personal or familial history suggestive of cystic fibrosis. One patient, presenting with myocardial lesion and hepatomegaly, died of heart failure; at autopsy, the liver showed a typical aspect of focal biliary cirrhosis. In the three other cases, liver disease was the only manifestation of cystic fibrosis at the time of diagnosis. Liver biopsy examination showed focal biliary cirrhosis in one case and massive steatosis in two. In all four cases, the diagnosis was confirmed by the existence of known pathogenic mutations in the *CFTR* gene. The evolution was variable; one patient had progressive liver disease with severe portal hypertension after 7 years; another one had lung complications after 1 year. In conclusion, our experience recalls that the diagnosis of cystic fibrosis must be considered in children presenting with unexplained liver disease; its confirmation by molecular techniques makes it possible to set up an appropriate follow-up.

Introduction

Cystic fibrosis (CF), with a prevalence of 1/2,500 newborns, is the most frequent lethal genetic disease among whites [9, 26]. The disease is caused by mutations in the *CTFR* gene, which maps on chromosome 7 (7q31) [39]. About 1,000 disease-causing mutations have been identified [43], among which, the most common is ΔF508 [9]. Pathogenic mutations result in the synthesis of an abnormal CFTR protein. CFTR is a glycoprotein located at the apical pole of most secretory epithelial cells including those of airways, intestine, pancreatic ducts, and bile ducts. It forms a cAMP-mediated low-conductance channel by which chloride ions pass from the cell into the lumen [9].

The large tissue distribution of CFTR protein explains why cystic fibrosis may affect multiple organs. The most common targets are the respiratory tract, the pancreas, and the digestive tract [9]; their involvement may be responsible for life-threatening complications which are the main determinants of the natural history of the disease and of its prognosis. Among the various other manifestations

which may be encountered in cystic fibrosis, hepatobiliary complications are frequent but are often overlooked because of their insidious development, usually mild course and slow progression [3, 6, 20, 22, 27, 30, 42, 49]. It is usually assumed that only 20% of cystic fibrosis patients would present clinical liver disease during their evolution; however, because of the increased duration of survival in patients with cystic fibrosis, the apparent incidence and the severity of hepatobiliary disease have recently increased [12]. In two recent large prospective studies including respectively, 177 [5] and 241 [27] patients with previously diagnosed cystic fibrosis, the prevalence of liver disease was 27 and 35%, and the median age at diagnosis was 7 and 3 years, respectively.

Despite their high incidence during the course of cystic fibrosis, it is highly unusual for hepatobiliary complications to reveal the disease. Only a few cases of patients presenting with end-stage liver disease as the only manifestation of cystic fibrosis have been described in children or even in adults. Even more rarely, severe liver disease may reveal some unusual forms of cystic fibrosis, such as the rare cases of cystic fibrosis masquerading as neonatal hepatitis or neonatal cholestasis mimicking extrahepatic biliary atresia [31, 46] or the cases of adult [15] or pediatric [40] patients presenting as sclerosing cholangitis.

It is, therefore, very much unusual to raise the diagnosis of cystic fibrosis at the histological examination of a liver biopsy taken during the evaluation of a pediatric patient without any prior history or any other symptom suggestive of the disease and presenting only with alterations in liver blood tests and/or hepatomegaly. We report four such cases to discuss the difficulties encountered in the diagnosis and management of these unusual patients, to underline the criteria necessary for a definitive diagnosis, and to point out the limits of routine screening for the early diagnosis of cystic fibrosis in asymptomatic patients.

Materials and methods

Study group

The files of our departments have been searched for identifying all the patients fulfilling the following criteria: (a) patients referred between 1990 and 2005 to the gastroenterology unit of the Department of Pediatrics, Hôpital Edouard Herriot, Lyon, (b) for the evaluation of abnormal liver tests and/or hepatomegaly, and (c) in whom the diagnosis of liver disease associated with cystic fibrosis was made after the histological examination of a liver biopsy (d) in the absence of known personal or familial history of the disease. Four patients fulfilled these criteria and are the subjects of the present report.

Clinical data

In each case, complete clinical charts were available. The following clinical data were recorded: mode of presentation, clinical course, and outcome. Biochemical tests of liver function included serum measurements of free and conjugated bilirubin, transaminases (aspartate transferase and alanine transferase), and gamma-glutamyl transpeptidase. Sweat test was performed in all patients; it was considered positive when chloride value was >60 mmol/l in at least two examinations as recommended [10]. Molecular genetic screening for the most common mutations of *CFTR* gene was performed in all cases by PCR (Elucigene CF30, Tepnel, Abingdon, UK). After diagnosis, standard protocols for the follow-up of cystic fibrosis patients were applied; in particular, complete chest and abdominal explorations were done at least once a year.

Histological data

Liver tissue samples were obtained by percutaneous transthoracic biopsy (in three cases) or at autopsy (in one case). They were fixed in Bouin's fluid or formalin and embedded in paraffin. Three micrometer thick sections were stained with hematoxylin–eosin–saffron, Perls reaction, periodic acid Schiff (PAS) reaction with diastase digestion and chromotrope. All the available tissue material was reviewed. The following histological variables were assessed: overall architecture, presence and extent of fibrosis, presence and extent of ductular proliferation, presence of cholangitis, presence, pattern, extent and distribution of steatosis, occurrence of giant cell transformation, cholestasis, iron deposition, and hemopoiesis.

Results

Clinical data are summarized in Table 1 and histological features in Table 2.

Clinical features

There were two boys and two girls, all born at term. Pregnancies were uneventful in all cases. There was no previous family history of cystic fibrosis. The median age at presentation was 47 months (range, 13 to 90 months).

The clinical presentation was variable. One case presented with growth retardation since birth and progressive heart failure of unknown cause associated with hepatomegaly and a fourfold increase in serum transaminase activities. A sweat test was performed at 7 months of age, but was in the normal range. The child died of heart failure at the age of 13 months. The histological examination of autopsy

Table 1 Clinical features

Patients	1	2	3	4
Age at clinical presentation	43 months	13 months	42 months	7 1/2 years
Sex	Male	Female	Male	Female
Mode of presentation	Abdominal pain Chronic diarrhea	Growth retardation Heart failure causing death	No symptom	Abdominal pain Chronic constipation
Clinical examination	Hepatomegaly	Hepatomegaly	Hepatomegaly	Hepatomegaly
Liver blood tests	↑ Transaminases	↑ Transaminases	↑ Transaminases	No abnormality
Ultrasound findings	Heterogeneous pseudotumoral hepatomegaly	Hepatomegaly	Hepatomegaly	Heterogeneous pseudotumoral hepatomegaly
Sweat test highest chloride value (mmol/l) and age of realization	102 (at 43 months, after liver biopsy)	27 (at 7 months)	135 (at 42 months, after liver biopsy)	102 (at 7 1/2 years, after liver biopsy)
CFTR mutations	ΔF508 N1303K	ΔF508 ΔF508	1717-1 (G-A) 1303 (N-K)	585 (E-X) 1066 (R-C)
Clinical outcome	Alive No sign of pancreatic insufficiency or bronchitis	Dead of heart failure due to myocardial necrosis and fibrosis	Alive First bronchitis at 5 years	Alive Portal hypertension (splenomegaly and esophagus varicoses) at 15 years
Duration of follow-up	6 months	–	11 years	14 years

samples showed the existence of scattered myocardial necrosis and fibrosis and of severe liver alterations; hepatic lesions were not in keeping with a diagnosis of chronic cardiac liver disease, but suggested a diagnosis of cystic fibrosis.

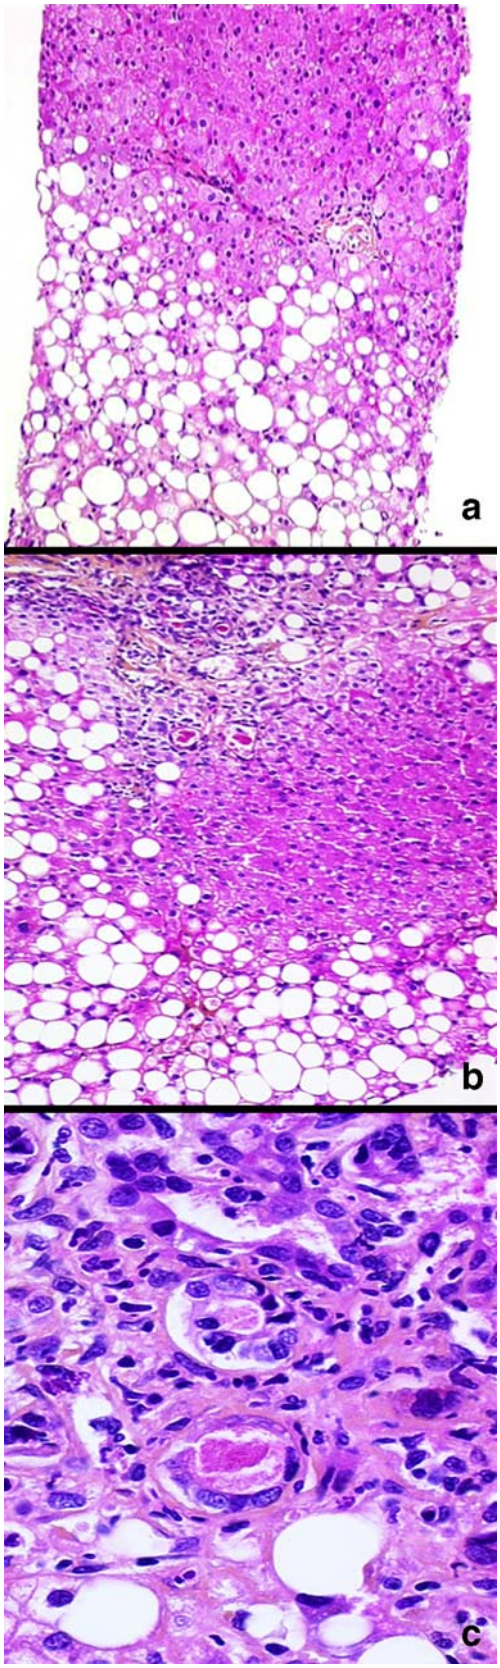
In the three other patients, clinical symptoms were mild. Chronic abdominal pain with intestinal transit dysfunction was the only symptom in two cases. One child was asymptomatic. Hepatomegaly was present in all three cases; in two cases, ultrasound examination showed an enlarged liver with steatosis and a heterogeneous pseudotumoral appearance. Liver blood tests showed increased transaminase serum levels in two cases; they were normal in one case. There was no evidence of viral infection or autoimmune disease; metabolic diseases (including alpha1-antitrypsin deficiency and Wilson's disease) were ruled out by biochemical and molecular tests. In all cases, the decision of liver biopsy was taken because of persistent abnormal liver blood tests and/or dysmorphic liver at imaging studies.

Histological findings

Typical histological features of focal biliary cirrhosis were observed in two cases (cases no. 1 and no. 2; Fig. 1). Focal periportal fibrosis was associated with ductular proliferation

Table 2 Histological findings

	1	2	3	4
Tissue sample	Liver biopsy	Autopsy	Liver biopsy	Liver biopsy
Number of portal spaces	24		12	25
Steatosis and % hepatocytes	80	80	90	80
Giant cell transformation	−	−	−	−
Expansion of portal tracts	+	+	−	+
Fibrosis	Extensive bridging Focal cirrhosis	Extensive bridging Focal cirrhosis	−	Focal, periportal
Cholangiolitis	+	+	−	−
Ductular proliferation	+	+	−	−
Cholestasis	−	−	−	−
Mucous plugs PAS +	+	+	−	−
Iron deposition	−	−	−	−
Extramedullary hemopoiesis	−	−	−	−



◀ **Fig. 1** Typical focal biliary cirrhosis (case no. 1). In this case, the histological picture is typical of focal biliary cirrhosis. At low magnification (**a**), periportal fibrosis and steatosis are readily visible. At higher magnifications (**b** and **c**), the periportal neoductular proliferation is obvious; numerous bile ducts contain large plugs made of amorphous proteinaceous material. Hematoxylin–eosin–saffron; original magnifications: **a** ×120; **b** ×240; **c** ×380

and pericholangitis, defined by the presence of a rim of inflammatory cells, including polymorphonuclear leukocytes and lymphocytes around the bile ducts. Amorphous pink deposits were present in dilated ductules; this material stained with PAS and resisted diastase digestion. There was no evidence of cholestasis. In both cases, macrovesicular steatosis occurred in 80% of hepatocytes without preferential distribution in the acini. The combination of portal fibrosis, ductular proliferation, PAS+ diastase resistant bile plugs and steatosis was highly suggestive of cystic-fibrosis-associated focal biliary cirrhosis. This hypothesis was therefore raised, and it was suggested to confirm the diagnosis by biochemical and molecular techniques.

In the two other cases, the only lesion was massive macrovesicular steatosis present in 80% of hepatocytes (cases no. 3 and no. 4; Fig. 2). It was panacinar in distribution. There was no evidence of steatohepatitis; portal spaces were not enlarged; there was no ductular proliferation or cholestasis; no bile plug was visible; there was no iron deposition. There was no clinical evidence for the more common causes of steatosis or steatohepatitis in children, including obesity, chronic hepatitis C, and drug-induced injury. Metabolic diseases associated with steatosis, such as Wilson's disease and mitochondrial diseases, have been ruled out. The hypothesis of massive steatosis associated with cystic fibrosis was therefore considered, and it was suggested to confirm the diagnosis by biochemical and molecular techniques.

Final diagnosis

After the results of the liver biopsy, a sweat test was performed in the three children in whom it has not been performed before. In all cases, the result was positive. Molecular screening revealed the presence of known pathogenic *CFTR* mutations in all four cases. The ΔF 508 mutation was present in two cases (cases no. 1 and no. 2); it was homozygous in one case, heterozygous and associated with a N1303K mutation in the other. In the two other cases, different combinations of heterozygous mutations were observed (Table 1).

Evolution and follow-up

Three patients were alive after the diagnosis. They presented no clinical, radiological, and/or biological sign

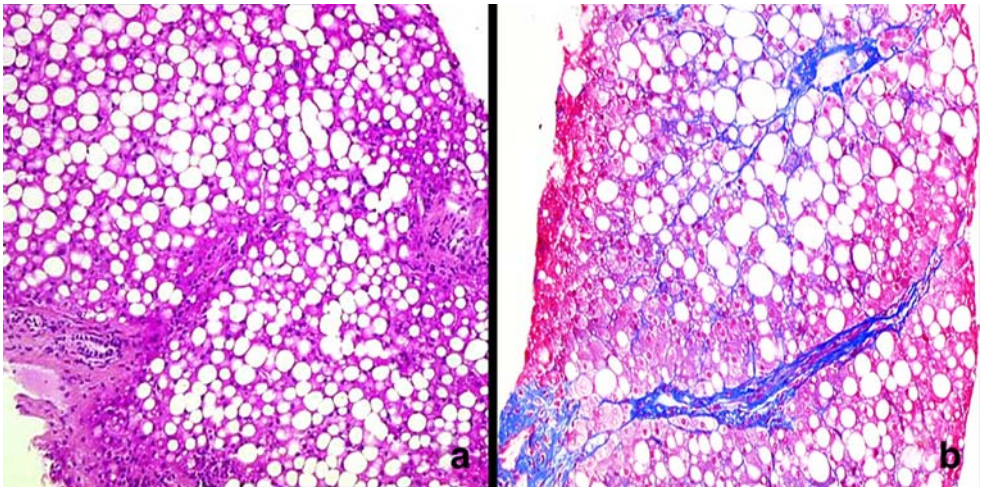


Fig. 2 Massive steatosis (case no. 3). In this case, macrovesicular steatosis is present in most hepatocytes, with a pancinar distribution (**a**); chromotrope staining confirms the presence of an extensive periportal fibrosis. **a** hematoxylin–eosin–saffron, **b** chromotrope; original magnifications ×260

suggestive of pancreatic insufficiency or lung involvement. Treatment consisted in fat soluble vitamin supplements, ursodeoxycholic acid, and pancreatic enzymes.

During further evolution, liver disease was progressive in only one case: Portal hypertension, with splenomegaly and esophageal varices, appeared after 7 years of follow-up. Imaging studies confirmed the existence of a dysmorphic liver; there was no biological sign of hepatocellular insufficiency, and no additional liver biopsy was taken during the course of the disease. In the other two cases, liver disease was stable; no complication was apparent. In one of these cases, lung disease appeared after 1 year of follow-up. At the time of submission of the manuscript, all three children were alive after, respectively, 6 months, 11 years, and 14 years of follow-up.

Discussion

The four patients included in this report are characterized by a much unusual mode of presentation. In all four cases, there was no known prior personal or familial history of cystic fibrosis. In three cases, liver disease was the only manifestation of cystic fibrosis at the time of diagnosis; in the remaining case, liver disease was present early in the course of the disease, but its correct interpretation was delayed because of its association with progressive heart failure due to myocardial lesion. In all four cases, the diagnosis of cystic fibrosis was first suggested only after the histological examination of liver tissue obtained either at biopsy or at autopsy. In two cases, the histological pattern, with a typical aspect of so-called focal biliary cirrhosis, was highly suggestive of cystic fibrosis; in the other two patients, presenting only with massive steatosis, the diagnosis of cystic fibrosis was considered in the absence of clinical, biochemical, or histological argument for another etiology. The presentation of the four cases included in our study is therefore in sharp contrast with the usual clinical pattern of the hepatobiliary manifestations of cystic fibrosis, which preferentially occur in patients with a known history of the disease.

Apart from their mode of presentation, the hepatobiliary manifestations observed in our patients were typical in their clinical, biological, and histological features. Two cases corresponded to typical examples of focal biliary cirrhosis. It is usually assumed that focal biliary cirrhosis results from bile duct injury secondary to the accumulation of an abnormal bile secretion in the lumen of bile ducts [19]; this results in the obstruction of bile ducts and in a reactive ductular proliferation usually associated with pericholangitis, which, in turn, promotes the development of periportal fibrosis in injured areas. It is likely that the abnormal bile secretion which triggers this sequence of events is related to the expression of an abnormal CFTR protein by biliary epithelial cells [13, 44]. However, the absence of genotype–phenotype correlations explaining the development of hepatobiliary manifestations in cystic fibrosis [18] suggests the existence of "modifier" genes [7, 8, 16], which remain, however, to be identified with certainty, even if several gene candidates have been proposed, including alpha1-antitrypsin, defensins, glutathione S transferase P1, mannose-binding lectin, and TGFbeta1 [2, 14, 21, 23, 43].

Focal biliary cirrhosis occurs in 10 to 70% of patients according to the series [1]: Such important differences may be explained by differences in the composition of the series reported so far as well as in the diagnostic procedures employed and in the criteria retained for the diagnosis [12]. In most cases, as in the two patients reported here, the clinical and biological abnormalities associated with focal biliary cirrhosis are mild [38]. Hepatomegaly, as observed in the two cases reported here, is present in only 30 to 43% of patients at diagnosis [1]. There is usually no sign of portal hypertension or hepatocellular insufficiency until late

in the course of the disease. Liver blood tests are normal in 70 to 80% of patients [1]. In contrast, the two patients reported here presented with alterations in liver blood tests: Both had a persistent increase in serum transaminase levels. In contrast to its clinical expression, the histological picture of focal biliary cirrhosis is highly suggestive [24]; it results from the variable combination of the following lesions: focal portal and periportal fibrosis, reactive ductular proliferation, presence of amorphous, proteinaceous PAS+ diastase-resistant material in dilated bile ducts, periductular inflammation, and steatosis. In the two cases reported here, all the histological features were present, and the resulting picture was therefore a strong argument supporting the unexpected diagnosis of cystic fibrosis.

The main risk of focal biliary cirrhosis is the evolution toward multilobular cirrhosis, which occurs in 5 to 15% of patients with cystic fibrosis [5, 27, 30]; the prevalence increases with age and duration of follow-up [27]. In some cases, multilobular cirrhosis results in end-stage liver disease, dominated by portal hypertension and its complications [11, 17], which may require liver transplantation [34]. We could not evaluate the pattern of evolution in our two patients: One died at diagnosis of heart failure due to scattered myocardial necrosis and fibrosis, a rare but known complication of cystic fibrosis [35, 48], and the other one has a follow-up of only 6 months.

In the two other cases included in this report, the clinical and histological picture was that of a massive steatosis of the liver in an asymptomatic child. Hepatomegaly and/or mild alterations of liver blood tests were present. The only histological lesion observed at liver biopsy was massive macrovesicular steatosis without preferential zonal distribution. Cystic fibrosis is known to be one of the possible etiologies of fatty liver disease in children [41]. Indeed, steatosis is a frequent manifestation of cystic fibrosis: It occurs in 20 to 60% of patients (23% in an autopsy series [33]), but is massive in less than 5% of cases [12]. Its pathogenesis is not fully understood. As hepatocytes do not express CTFR [25, 44], steatosis has been usually assumed to be of secondary, toxic, or nutritional origin [3]. In particular, it has been associated with dietary factors such as essential fatty acid deficiency [30]. However, this pathogenetic mechanism is unlikely in asymptomatic patients like those included in our study. In addition, our data show that steatosis associated with cystic fibrosis may precede the onset of severe hepatobiliary complications. In one of our cases, steatosis was the first sign of progressive liver disease, culminating with the development of severe portal hypertension after 7 years of follow-up. This lends support to the concept that in cystic fibrosis as in other liver diseases, steatosis may contribute to the promotion of liver fibrosis. Taken as a whole, our data therefore show that the pathogenesis of steatosis in cystic fibrosis needs to be reevaluated and that its role in the progression of liver disease must not be underestimated.

The very unusual presentation of the patients included in our study made it necessary to enforce and confirm the diagnosis of cystic fibrosis by specific arguments. The classical diagnostic and screening test for the identification of cystic fibrosis remains the sweat test, even if other screening tests have been recently proposed, such as the trypsin test which is gaining large acceptance [47]. The principle of the sweat test is simple: In the presence of an abnormal CFTR protein, the chloride concentration of the sweat is increased; a value >60 mmol/l is considered positive [28]. However, the results of a negative sweat test must be interpreted with caution, especially when the clinical context is suggestive. False negative results are possible because of unreliable methods, technical errors, and errors in interpretation [28, 29]. Moreover, sweat tests may be normal in atypical cases of cystic fibrosis, as shown by our own experience and by previous reports [4, 36, 45]; indeed, some recent series have shown that 1 to 2% of patients with cystic fibrosis may have sweat chloride concentrations of less than 60 mmol/l, likely as a result of heterozygous mutations preserving some biological activity for the residual CFTR protein [32, 36, 37]. This was observed in one of our patients (case no. 2) in whom the sweat test performed at 7 months was negative. In our experience, it is important to control such negative results after some months of evolution, as delayed positivity of the sweat test may be observed in a few instances.

Currently, molecular techniques are necessary to confirm the diagnosis of cystic fibrosis. They have to show the presence of pathogenic mutations in the *CFTR* gene. In our series, such mutations were detected in all four cases. One patient was homozygous for ΔF508. The other patients were heterozygous. The variety of mutations found in this small group of patients confirms the absence of genotype–phenotype correlation underlying the development of hepatobiliary manifestations in cystic fibrosis. We have no information regarding the expression of possible modifier genes involved in the pathogenesis of liver disease [2, 14, 43] in our patients, except for α1-antitrypsin, which had a normal phenotype in all four cases.

In conclusion, we report here four unusual pediatric cases to underline the variety of clinical presentations which may be associated with cystic fibrosis. They recall that this diagnosis has to be considered in children presenting with unexplained liver disease. The confirmation of the diagnosis by molecular techniques makes it possible to set up an appropriate follow-up to detect the possible complications of liver disease and the late involvement of other target organs.

Angiogenic switch during tumor progression of carcinoma ex-pleomorphic adenoma

Received: 15 December 2006 / Revised: 17 May 2007 / Accepted: 3 June 2007 / Published online: 26 June 2007

Abstract We analyzed the tumor vascularization in carcinomas ex-pleomorphic adenoma (CXPA) to investigate the angiogenic switch during the malignant transformation of pleomorphic adenoma (PA) to carcinoma and during tumor progression. In eight cases of early CXPA (intracapsular and minimally invasive tumors), eight of advanced CXPA (widely invasive tumors), and ten of PA without malignant transformation, tumor vascularization was assessed in histological samples by measuring total microvascular area (TVA) and microvessel density (MVD) using CD34 and CD105 antibodies. MVD for CD105 increased significantly during tumor progression, whereas this was not the case for CD34 MVD. Comparing widely invasive CXPA with and without myoepithelial differentiation, CXPA with myoepithelial differentiation showed a significantly lower number of CD105 positive vessels but revealed higher TVA values. In these tumors, the neoplastic cells usually formed larger hypovascularized aggregates that were often surrounded by large-sized vessels. In conclusion, the antibody CD105 reveals an angiogenic switch during the progression from adenoma to carcinoma in salivary glands. The degree of angiogenesis and the total vascular area have distinctive patterns in CXPA with and without myoepithelial differentiation. Low angiogenesis associated with high TVA value is more characteristic of CXPA with myoepithelial differentiation.

Introduction

Angiogenesis, the formation of new blood vessels from preexisting ones, has been considered a critical process for tumor growth, invasion, and metastasis [20, 24]. The ability to induce and sustain angiogenesis occurs during tumor development via an angiogenic switch from vascular quiescence [12]. Besides that, blood can be supplied by a non-angiogenic process, the so-called co-option mechanism, well-documented in some human cancers, where the neoplastic cells use the existing blood vessels without eliciting an angiogenic response [9, 22, 28].

Tumor vascularization has rarely been studied in salivary gland tumors [5, 30].

In humans, the most common salivary gland tumor, the pleomorphic adenoma (PA), usually shows a poorly vascularized myxoid and chondroid stroma [26]. Carcinoma ex-pleomorphic adenoma (CXPA) is the principal form of malignancy arising in PA and accounts for 4.5–15% of all cancers of the salivary glands [7, 10, 18]. They are usually high-grade carcinomas, with frequent metastases and a poor clinical outcome [7, 10, 11, 17, 18].

In salivary carcinoma spontaneously arising in HER-2/neu transgenic mice, it has recently been suggested that the

richly vascularized preexisting salivary tissue is able to support tumor onset and progression with no need for an angiogenic switch [4].

Taking these results into consideration, we investigated the question whether an angiogenic switch would take place during the malignant transformation of PA into carcinoma and during tumor progression.

In a series of CXPAs, which represent the different phases of the adenoma–carcinoma sequence, i.e., in situ (intracapsular), minimally invasive and invasive carcinoma, tumor vascularization was assessed in histological samples by measuring the total microvascular area (TVA) and microvessel density (MVD) using CD34 and CD105 antibodies. PA without malignant transformation was used as control. CD34 has been reported as an optimal pan-endothelial marker [9] that stains not only "newly forming" vessels but also normal ones trapped within tumor tissues. In contrast, CD105 (endoglin), a proliferation-associated and hypoxia-inducible protein expressed in angiogenic endothelial cells, has been considered as a marker of neoangiogenesis [9, 24, 27, 29].

Materials and methods

The study was performed in 16 cases of CXPA which were retrieved from the files of the Department of Pathology of the University of Campinas. All diagnoses were reviewed by two pathologists (AA and VCA) using 50-μm sections obtained from formalin-fixed paraffin-embedded samples and routinely stained with hematoxylin–eosin. CXPA was defined as a malignant epithelial neoplasm arising in association with a primary or recurrent PA. The tumors were classified according to extension of invasion beyond the capsule of the previous PA as intracapsular (without invasion)—4 cases, minimally invasive (≤1.5 mm of invasion)—4 cases, and widely invasive—8 cases. Demographic and clinical information was obtained from the patients' medical records.

Immunohistochemistry

One paraffin block from each case was chosen for the immunohistochemical study [23], and the following antibodies were used (Table 1): CD34 and CD105 for detection of blood vessels and α-smooth-muscle actin (α-SMA), vimentin; cytokeratins 7 (CK7) and 14 (CK14) for the detection of epithelial and myoepithelial cells. The 5-μm sections were deparaffinized and hydrated, and endogenous peroxidase activity was quenched by immersion of the slides in 3% hydrogen peroxide. For all antibodies, except for α-SMA and anti-CD105, antigen retrieval (AR) was achieved by boiling in a steamer immersed in citrate buffer (pH 6.0, for 30 min). For CD105, AR was performed using 0.4% pepsin for 30 min (Table 1). Only the sections for CD105 were incubated at 37°C with protein block serum-free (code x0909, Dako, SA, Denmark) for 30 min. Subsequently, for all antibodies, the sections were incubated overnight at 4°C with the primary antibody and afterwards with the EnVision polymer HRP and Envision+ (code K1491, DAKO, SA, Denmark) for 1 h at 37°C. Sections were stained for 5 min at 37°C with 3.3′-diaminobenzidine tetrahydrochloride (DAB) and counter-stained with hematoxylin. Negative controls were run by omitting primary antibodies.

Microvessel density and microvessel area assessments

Immunohistochemical reactions for CD34 and CD105 were interpreted by two authors (AA and AS) using a double-headed microscope, and the most vascularized areas at low power magnification (hotspots) within each tumor were chosen for further analysis. For quantitative study, ten digital images per case were obtained using a charge-coupled device camera adapted to an Olympus CX30 microscope (X40 objective, 0.44 mm field diameter) and analyzed with Imagelab analysis software (version 2.4), which allows manual segmentation of target areas (vessels). Microvascular density for CD34 as well as for CD105 was considered the mean number of microvessel count, and

Table 1 Details of the antibodies used for immunohistochemistry

Specificity	Clone	Isotype	Dilution	Source	Buffer (AR)
CD34	QBEnd 10	IgG_1	1:50	Dako[a]	Citrate
CK7	OV-TL 12/30	IgG_1	1:100	Dako[a]	Citrate
CK14	LL002	IgG_3	1:1000	Neomarkers[b]	Citrate
Vimentin	V9	IgG_1	1:100	Dako[a]	Citrate
α-SMA	1A4	IgG_{2a}	1:200	Dako[a]	None
CD105	SNG	IgG_1	1:10	Dako[a]	Pepsin

total vascular area the mean area occupied by microvessels per unit area of the tumor, i.e., that correspondent to one tumor field using the ×40 objective—0.152 mm^2. Vessels with muscular walls were excluded.

Statistical analysis

For comparison of the variables between the different tumor types, we used the Kruskal–Wallis test. To assess changes during the tumor progression, we codified adenomas as 0, minimally invasive carcinomas as 1, and widely invasive carcinomas as 2 and followed the changes of the variables with a Sperman rank order correlation. Results with $p<0.05$ were considered significant

Results

The CXPA group included 11 women and 5 men, and the tumors were located in the parotid glands in nine cases, in the submandibular glands in five, and in the minor salivary glands in two. The average age of the intracapsular CXPA group was 47, in the minimally invasive 67, and in frankly invasive 65. The CXPAs were classified into two main groups according to the extent of invasion beyond the capsule of the previous PA: early tumors—eight cases (four intracapsular and four minimally invasive carcinomas) and advanced tumors—eight cases (eight widely invasive carcinomas).

The PA group without malignant transformation included five women and five men, the average age was 41, and the tumors were located in the parotid glands in eight cases and in the submandibular glands in two.

Microvascular density (MVD) for CD34 and CD105

Figures 1, 2, 3, and 4 illustrate positive vessels and MVD for CD105 and CD34 in all groups. The mean vessel density of CD105 stained vessels was significantly different between the groups ($p<0.0001$; Kruskal–Wallis test). During the adenoma carcinoma sequence, the MVD of CD105 gradually increased (Fig. 3) with a highly significant strong positive correlation ($R=0.793$; $p<0.0001$). In PA without malignant transformation (Figs. 1 and 3), a low number of small CD105 positive vessels were detected (mean 3.33). However, in the early CXPA (intracapsular and minimally invasive carcinomas), these vessels were more numerous (mean 9.0; Figs. 1 and 3). The greatest increment in CD105 MVD was seen in the widely invasive CXPA (mean 33.6), with carcinomas without myoepithelial differentiation revealing higher values (mean 46.5) than those with such cellular differentiation (mean 16.33; Figs. 2 and 3).

In relation to MVD for CD34, no significant differences ($p=0.15$) were observed in the subgroups that represent the adenoma–carcinoma sequence (Fig. 4; adenoma mean 10.49, early CXPA 7.66, advanced CXPA 8.71, CXPA without myoepithelial differentiation 9.35, and CXPA with myoepithelial differentiation 7.87).

Total vascular area (TVA)

Total vascular area was significantly different among the tumors ($p=0.005$); Kruskal–Wallis test.

Figure 5 illustrates TVA in all groups of adenoma–carcinoma sequence. In widely invasive CXPAs, the TVA value was higher (mean 179.4) than in intracapsular and minimally invasive CXPAs (mean 63.8). In widely invasive CXPA, comparing tumors with and without myoepithelial differentiation, TVA value was higher in the former (mean 260.2 and 118.9, respectively). In widely invasive tumors with myoepithelial differentiation, the carcinoma cells often formed large hypovascularized cellular aggregates that were surrounded by large vessels (Fig. 2c), whereas in those without such cellular differentiation, the carcinomatous aggregates usually contained a smaller quantity of cells, and the vessels around them were thinner (Fig. 2d).

Discussion

Studies over the last decade have assumed that quantification of microvessel density may reveal the degree of angiogenic activity in a tumor [13]. However, a crucial question in angiogenesis is what proportion of the tumor vascular network is due to preexisting normal host vessels or newly formed tumor vessels that truly represent tumor angiogenesis [24]. Therefore, it has been suggested that markers that are preferentially expressed in angiogenic vessels, such as CD105, would be more appropriate to quantify angiogenesis [6, 8]. In this context, in recent works a distinctive pattern of expression of pan-endothelial markers (CD34 and CD31) and CD105 was found in benign and malignant lesions, where MVD for CD105 was more indicative of tumor angiogenesis [3, 19].

In the current study, a series of CXPAs that represent the lesion in the different carcinogenesis phases was analyzed in relation to MVD for CD34 and CD105 as well as total vascular area, thus allowing the characterization of tumor vascularization and the assessment of angiogenic activity during tumor progression.

In our series, when the different subgroups that represent the adenoma–carcinoma sequence (adenoma–intracapsular/minimally invasive CXPA–widely invasive CXPA) were compared, MVD for CD105 showed a strongly significant

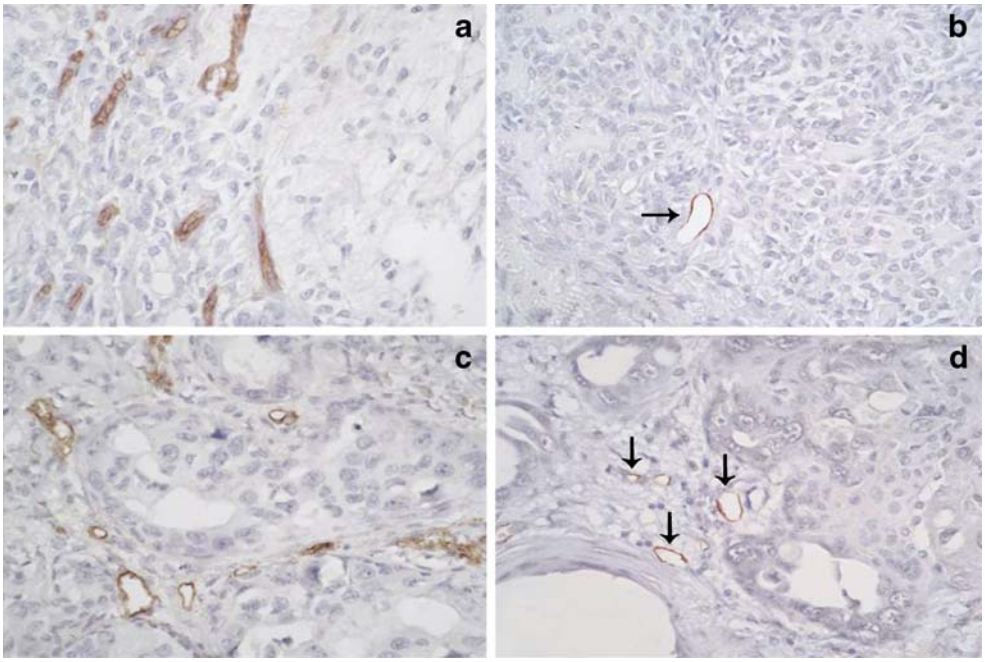

Fig. 1 CD34 (*at left*) and CD105 (*at right*) positive vessels: in pleomorphic adenoma without malignant transformation (**a**, **b**) and in intracapsular CXPA (**c**, **d**)

positive correlation with tumor progression, whereas MVD for CD34 revealed no difference. These results suggest that an angiogenic switch was required during the process of malignant transformation of PA into carcinoma and also reinforce the idea that MVD for CD105 may give a more accurate measure of the tumor angiogenic activity than a pan-endothelial marker [1]. Furthermore, our findings in salivary adenoma–carcinoma sequence were similar to those reported in the process of human colorectal cancer development where CD105, but not CD34, gradually increased in adenoma–carcinoma sequence [1]. Nevertheless, CXPA differs markedly from salivary carcinoma sponta-

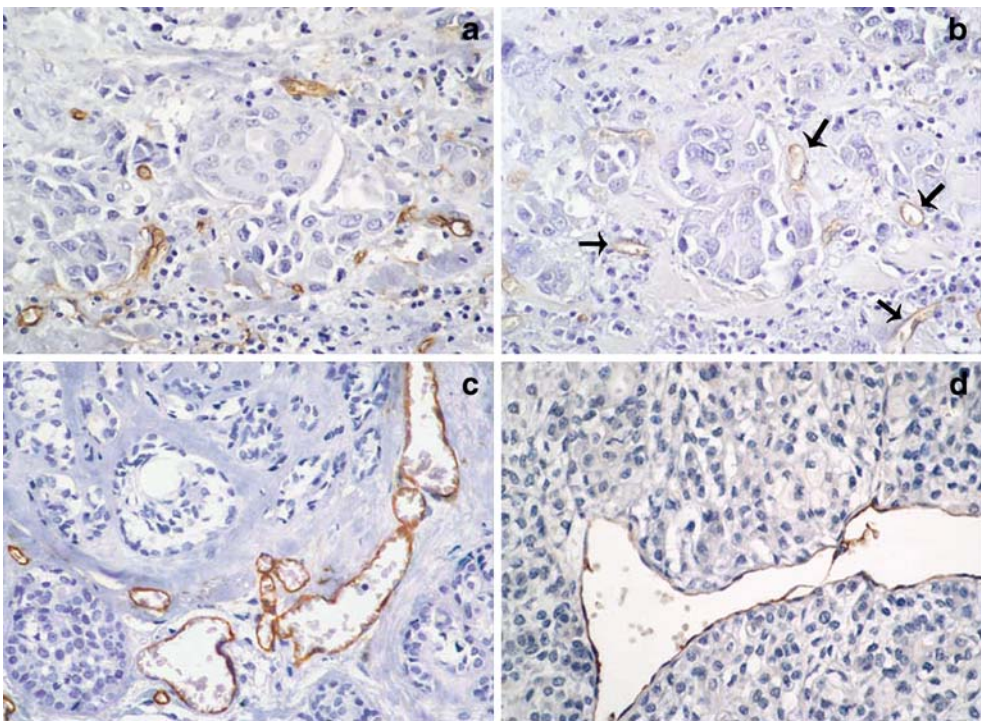

Fig. 2 CD34 (*at left*) and CD105 (*at right*) positive vessels: in widely invasive CXPA with myoepithelial component (**c**, **d**) large hypovascularized carcinomatous aggregates are surrounded by larger vessels than seen in widely invasive CXPA without myoepithelial differentiation (**a**, **b**); carcinomatous aggregates contain fewer cells, and the vessels around them are thinner

neously arising in HER-2/neu transgenic mice, as in this animal model an angiogenic switch was not detected in any phase of carcinogenesis. However, it should be noted that CXPAs are usually high-grade carcinomas with frequent metastases, whereas the salivary carcinoma in the murine model is a slow-growing tumor with low metastatic capability, and therefore, there are probably differences in terms of oxygen and nutrient consumption rates of the tumor cells.

The onset of angiogenesis has been considered a hallmark of neoplastic transformation [13]. In benign lesions, the expression of CD105 in the microvessels has been described as barely visible, contrasting with that in carcinoma where it is marked [3, 19]. In our series, in PA without malignant transformation, CD105-positive vessels were rare and usually small. Nevertheless, in PA harboring intracapsular or minimally invasive carcinoma, they were more numerous, suggesting that angiogenesis was activated in these early malignant lesions. These findings are in agreement with those reported in multistep tumorigenesis models. In these models, angiogenesis was found to be activated in midstage lesions before the appearance of full-blown tumors suggesting that neovascularization is a prerequisite for the rapid clonal expansion associated with the formation of macroscopic tumors [12]. However, in macroscopic tumors, the major factor contributing to vessel density is metabolic demand, which frequently increases during tumor progression to accommodate an increased metabolic need of cancer cells [13, 24]. In this sense, in our salivary adenoma–carcinoma sequence, the most significant increment regarding MVD for CD105 was observed in the widely invasive CXPA group, suggesting that a marked modification in metabolic burden occurred when the carcinoma cells infiltrate the tissues outside the confines of the original PA.

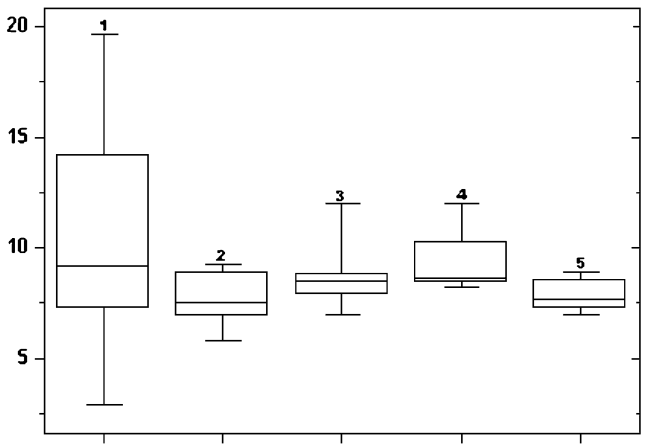

Fig. 4 Box and whisker plot of the microvascular density (MVD) for CD34: *1* pleomorphic adenoma without malignant transformation, *2* intracapsular and minimally invasive CXPA, *3* widely invasive CXPA, *4* CXPA without myoepithelial differentiation, *5* CXPA with myoepithelial differentiation. The *limits of the box* represent the 25 and 75% percentiles and the *center bar* the median. The *whiskers* are equivalent to the 5 and 95% percentiles

However, it is known that MVD varies widely with tumor type. Carcinomas arising in PA encompass a wide spectrum of histological tumor types [2]. In our series, comparing widely invasive CXPA with and without myoepithelial differentiation, a marked difference in terms of MVD for CD105 (neoangiogenesis) was detected. CXPA with myoepithelial differentiation showed a lower number of CD105-positive vessels. Angiogenesis is influenced by the net balance between angiogenic factors that stimulate

and those that inhibit vessel growth [12], and it has been suggested that myoepithelial cells may inhibit angiogenesis [25]. Therefore, this non-angiogenic property of the myoepithelial cell could be an explanation for the lower MVD for CD105 found in CXPA with such cellular differentiation. In our laboratory, studies are being carried out to investigate if other types of salivary carcinomas (non-ex-pleomorphic adenoma) with and without myoepithelial differentiation also show difference regarding degree of angiogenesis.

Total vascular area (TVA) has been less studied than MVD, but recent studies have emphasized its prognostic value [14–16, 24]. Our series showed significant findings in relation to TVA. Although widely invasive CXPA with or without myoepithelial component presented a MVD for CD34 without significant difference, the total vascular area assessed by this antibody revealed a marked difference among them. Widely invasive CXPA with myoepithelial component showed the highest TVA mean value. In these tumors, the neoplastic cells usually formed larger hypovascularized aggregates that were often surrounded by large-sized vessels. In contrast, in CXPA without myoepithelial differentiation, the carcinomatous aggregates usually contained a smaller quantity of cells with several small-sized vessels among them. These differences in vessel shape, size, and distribution between the two types of carcinomas could also be explained by some properties of myoepithelial cells. These may produce an abundant extracellular matrix devoid of vessels and containing bound angiogenic inhibitors [21]. It is likely that large-sized blood vessels are needed for cellular nutrition in carcinomas with myoepithelial component to compensate for the low angiogenesis inside the large cellular aggregates. Regarding benefit from antiangiogenic therapies and measuring the response to such a therapy, it has been suggested that localization of CD105 to angiogenic tissue could have potential when selecting patients [6]. Whether these differences appointed in our study could be relevant in terms of antiangiogenic treatment is only a topic of speculation at the present moment.

In conclusion, the antibody CD105 reflects more clearly the angiogenic changes during the progression from adenoma to carcinoma in salivary glands than CD34, revealing an angiogenic switch during this process. The degree of angiogenesis and the total vascular area have distinctive patterns in CXPA with and without myoepithelial differentiation. Low angiogenesis associated with high TVA value is more characteristic of CXPA with myoepithelial differentiation.

Received: 13 February 2007 / Accepted: 16 April 2007 / Published online: 10 May 2007

Abstract Sclerosing angiomatoid nodular transformation (SANT) is a splenic lesion composed of angiomatoid/vascular nodules surrounded by hyalinized/sclerotic stroma, fibroblasts, myofibroblasts, and inflammatory cells. The endothelium within the nodules has a phenotype resembling splenic sinusoids, capillaries, and small veins. Martel et al. (Am J Surg Pathol 28:1268–1279, 2004) suggested that SANT may represent the final pathway of a variety of splenic lesions including inflammatory pseudotumors (IPTs). Epstein–Barr virus (EBV) has a role in the genesis of some splenic IPTs, but its presence in SANT has not been investigated. Six cases of SANT are reported. All were stained for CD31, CD34, CD8, CD68, smooth muscle actin, muscle-specific actin, and CD30 and were tested for EBV by in situ hybridization (EBER). All cases showed angiomatoid nodules with complex expression of CD31, CD34, and CD8, with focal CD68. Expression of CD30 by endothelial cells was also seen. One case had small diffuse areas lacking nodules resembling an IPT and was positive for EBV. The inflammatory cells and the normal spleen were negative for CD30 and EBER. In conclusion, SANT shows upregulation of CD30 with respect to normal spleen. The presence of EBV in the stromal cells of a case supports the notion that a subset of SANT may be related to IPT.

Introduction

Sclerosing angiomatoid nodular transformation (SANT) is a recently recognized splenic vascular lesion characterized by multiple well-circumscribed individual and confluent vascular/angiomatoid nodules with interstitial hemorrhage set in a heterogeneous fibrocollagenous stroma admixed with inflammatory cells [5, 14, 16]. The nodules contain a complex mixture of endothelial phenotypes resembling splenic sinusoids (CD34−/CD31+/CD8+), capillaries (CD34+/CD31+/CD8−), and small veins (CD34−/CD31+/CD8−). Focal expression of CD68 can also be seen [5, 14]. The internodular stroma of SANT is composed of variable numbers of fibroblasts, myofibroblasts, plasma cells, lymphocytes, macrophages, and hemosiderin-laden macrophages. SANT appears to be a benign process, and splenectomy has been curative in all cases reported to date. Martel et al. [16] hypothesized that SANT may represent a peculiar sclerotic process with transformation of splenic red pulp in response to an exaggerated stromal proliferation. These authors also suggested that some SANTs might have started off as inflammatory pseudotumors (IPTs) due to the

appearance of the internodular stroma and the fact that some patients had fever or elevated erythrocyte sedimentation rate (ESR) at presentation, features often seen in splenic IPTs.

Herewith, we describe six examples of SANT. One case was prospectively identified as SANT on core biopsy, a diagnosis confirmed in a subsequent splenectomy. A second patient had an original diagnosis of IPT on core biopsy and was managed conservatively without splenectomy. The role of core biopsy in the diagnosis and management of SANT has not been previously addressed. One case had small diffuse non-nodular areas closely resembling an IPT. Epstein–Barr virus (EBV) was detected in this lesion. This is the first reported example of SANT associated with EBV supporting the notion that a subset of SANTs may be related to IPTs. CD30 is an activation marker expressed in the endothelial cells of approximately one third of non-splenic vascular lesions [7] but has not been studied in SANT. All six cases described herein expressed CD30 in endothelial cells.

Materials and methods

The material studied consists of eight specimens originating from six patients and includes five splenectomies and three core biopsies of splenic masses. One patient had two core biopsies followed by a splenectomy. Hematoxylin and eosin, Gomori methenamine silver (GMS), and Ziehl–Nielsen (ZN) stains were performed on 3- to 4-μm thick sections of formalin-fixed paraffin-embedded tissue on all cases. Immunohistochemical stains were performed in sections from one or more representative paraffin blocks from each case using the ultrastreptavidin–HRP detection system (ID Labs Biotechnology, London, ON, Canada). Color development was performed using the NovaRed® substrate kit (Vector Labs, Burlingame, CA). The antibodies employed are listed in Table 1. All the immunohistochemical studies were performed in an automated Ventana BenchMark® instrument (Ventana Systems, Tucson, AZ). In situ hybridization for the presence of EBV-encoded small RNAs (EBER) was performed on all cases using a pre-diluted probe (Ventana Systems) following standard protocols [3]. Polymerase chain reaction (PCR) analysis for EBV was performed on a single case in the mass and adjacent uninvolved spleen from formalin-fixed paraffin-embedded tissue using standard methods with appropriate positive and negative controls [18].

Table 1 Immunohistochemical antibodies employed

Antibody	Source	Dilution
CD31	Dako	1/100
CD34	Ventana	Pre-diluted
CD8	Novacastra	1/50
CD68	Dako	1/50
CD21	Dako	1/50
CD23	Novocastra	1/100
CD30	Dako	1/50
SMA	Ventana	Pre-diluted
MSA	Dako	1/100
ALK-1	Ventana	Pre-diluted
EBER	Ventana	Pre-diluted

SMA Smooth muscle actin; *MSA* muscle-specific actin; *EBER* Epstein–Barr virus encoded RNA.

Results

Clinical features

Clinical features are summarized in Table 2. There were six patients, two men and four women with an average age of 57.8 years and range of 41–73 years. The masses ranged in size from 1.9 to 12.0 cm with an average of 5.8 cm. Clinical and follow-up information was available in five patients. One patient was lost to follow-up. In three patients, SANT was an incidental imaging finding: one in a lung cancer patient undergoing staging CT scan (case 1), one during investigation for chronic cough (case 3), and another undergoing yearly serial ultrasounds for persistent hydronephrosis due to a neurogenic bladder secondary to myelomeningocele (case 5). The latter patient underwent two core biopsies with a tentative diagnosis of SANT but due to rapid change in the mass size, underwent splenectomy for definitive diagnosis and treatment. Case 4 presented with a 4-year history of persistent anemia of unknown cause and an elevated ESR and C-reactive protein. A full hematological workup including bone marrow biopsy revealed no additional abnormalities. Case 6 had a remote history of periampullary carcinoma treated with a Whipple's procedure 20 years earlier. This patient presented with epigastric pain and anemia and was found on CT scan to have an anastomotic bowel "mass" and multiple small splenic nodules. The splenic lesions had hyper-dense central zones suggestive of vascular structures. The bowel lesion was biopsied numerous times and revealed only an inflammatory fibroblastic lesion, which has remained clinically stable. A core biopsy of the largest splenic mass was undertaken 4 years after initial presentation due to growth of the lesion. This was the only material available for review in this patient. A year after biopsy, the splenic lesions have remained stable, and the patient has been discharged from our hospital. No splenectomy was performed.

Follow-up information was available on four of the five splenectomized patients and the patient with a core biopsy only. All five patients are alive and well with either stable disease or no recurrence. Case 4 had normalization of all blood counts after splenectomy.

Table 2 Clinicopathological features

Case	Age	Sex	Spleen weight (gm)	Mass size (cm)	Presentation	Original Dx	Follow-up
1	58	F	110	1.9	Lung ca staging	SANT	12 months, NER
2	65	M	320	6.5	Not available	Hamartoma	Lost to follow-up
3	73	F	324	6.0	Hypertension, hyperlipidemia, remote lung abscess, chronic cough	hemangioendothelioma	16 months, NER
4	51	M	2,720	12.0	Anemia NYD	IPT	5 months, NER
5	41	F	256	6.5	Growing mass on two serial ultrasounds	SANT	1 month, NER
6	59	F	Unknown	2.1[a]	Multiple splenic lesions 20 years post Whipple's procedure for periampullary carcinoma	IPT	12 months, NEP

Dx Diagnosis; *IPT* inflammatory pseudotumor; *SANT* sclerosing angiomatoid nodular transformation; *NER* no evidence of recurrence; *NEP* no evidence of progression of unresected splenic mass.
[a] Size for the splenic mass in case # 6 is based on radiological estimates as only a core biopsy has been performed to date in this case.

Macroscopic findings

Of the five splenectomies, three cases were multinodular and had well-demarcated red-brown nodules ranging individually from 0.1 to 1.0 cm with intervening white fibrotic areas (Fig. 1a). One case was mostly red-brown, and one case was tan-white, with both showing only vague nodularity giving the masses a variegated appearance (Fig. 1b). The surrounding splenic tissue appeared normal.

Microscopic findings

All cases exhibited a multinodular vascular proliferation admixed with a variable inflammatory infiltrate and fibrosis (Figs. 2a,b and 3a,b). A partial pseudocapsule was seen in five cases. The coalescing "angiomatoid" nodules were made up of thin walled veins, small capillary-like or slit-like vessels, and plump spindle cells with extravasated red blood cells (Figs. 2a,b and 3b). The nodules also contained inflammatory cells comprised of lymphocytes, plasma cells, and smaller numbers of neutrophils. The nodules were well circumscribed, of varying sizes and shapes, and many had serpiginous borders with a surrounding rim of either sclerotic tissue or fibrinous material (Figs. 2b and 3a,b). Two cases had the entire internodular stroma replaced by dense hypocellular fibrocollagenous tissue (Fig. 3b), while four others had a dense chronic lymphoplasmacytic infiltrate (Figs. 2b, 3a) and a fibroblastic proliferation in between nodules, with only focal collagen or myxoid matrix deposition. There were varying numbers of hemosiderin-laden macrophages in the internodular stroma (Fig. 3b).

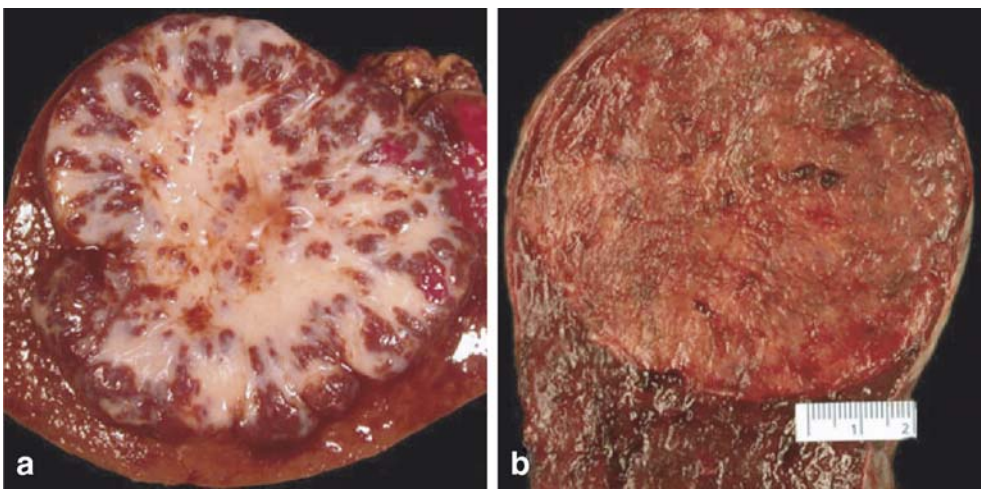

Fig. 1 Case 5 showing red-brown nodules of varying size surrounded by stellate white fibrous tissue (**a**). Case 4 showed a well-defined tan mass with poorly defined nodules (**b**)

Occasional entrapped lymphoid follicles with germinal centers were also seen.

In case 4, in addition to the multinodular vascular proliferation, there were focal areas completely devoid of angiomatoid nodules. These regions represented approximately 5% or less of the total surface area of the mass and contained dense chronic inflammation, consisting predominantly of plasma cells with smaller numbers of lymphocytes, and neutrophils (Fig. 3c). Merging imperceptibly with these cells were larger spindled and ovoid cells, some with irregular nuclear contours, which had vesicular chromatin and eosinophilic nucleoli. Some of these cells were seen in small clusters.

There was no mitotic activity, and no necrosis was identified in any of the cases. No evidence of carcinoma or lymphoma was seen, and ZN and GMS stains revealed no fungal or mycobacterial organisms. The normal surrounding spleen contained lipogranulomas in the white pulp in one case and another had abundant extra-medullary hematopoiesis (case 4). In the remaining cases, the surrounding splenic parenchyma was unremarkable.

Immunohistochemical findings

All cases demonstrated similar immunohistochemical findings. The angiomatoid nodules showed diffuse CD31 (Fig. 2c) staining of all the vascular spaces. CD34 demonstrated a smaller degree of staining with intense expression in capillaries only (Fig. 2d). CD8 was seen lining a smaller number of channels and showed the weakest staining of all

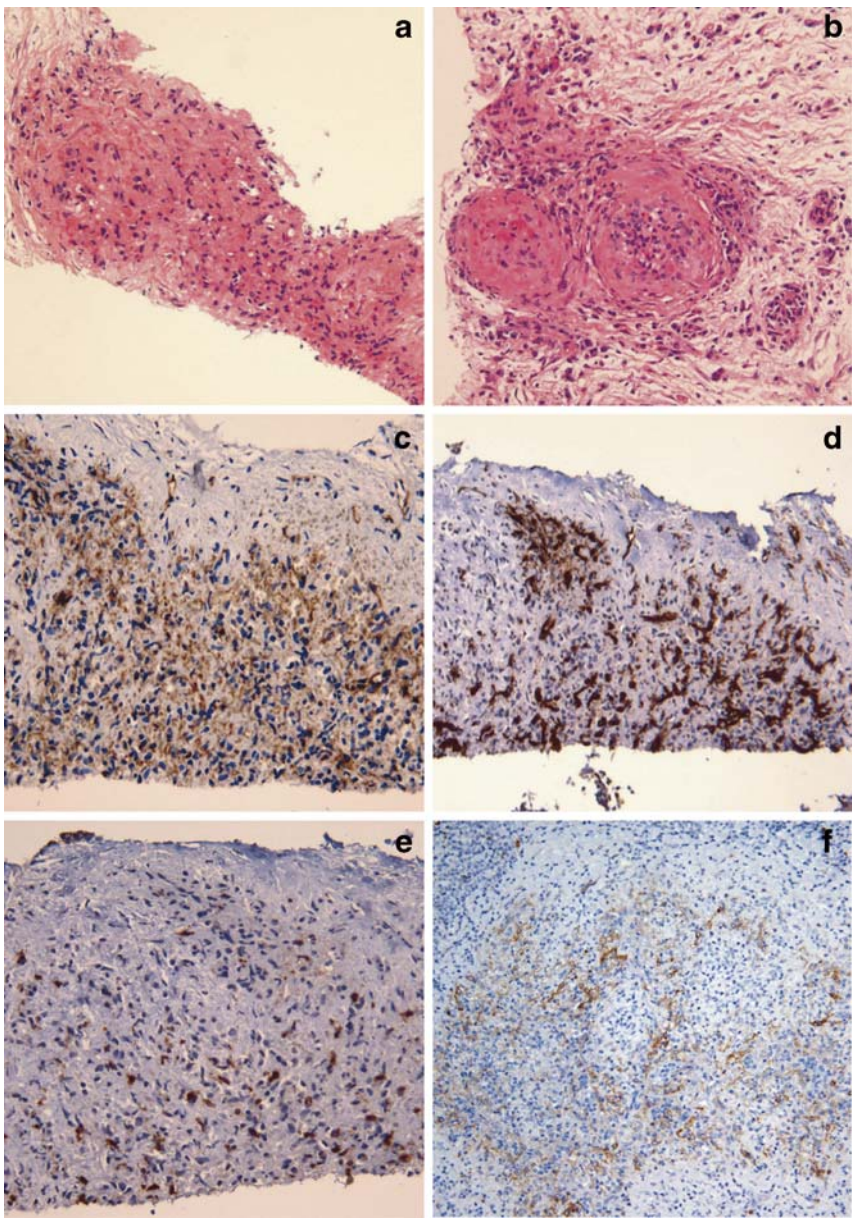

Fig. 2 Core biopsy of SANT demonstrating well-defined angiomatoid nodule composed of endothelial cells, inflammatory cells, and extravasated red cells (**a**); nodule with a fibrinoid ring with interstitial hemorrhage surrounded by lymphocytes, plasma cells, and eosinophils (**b**); and variable expression for CD31 (**c**), CD34 (**d**), CD8 (**e**), and CD30 (**f**)

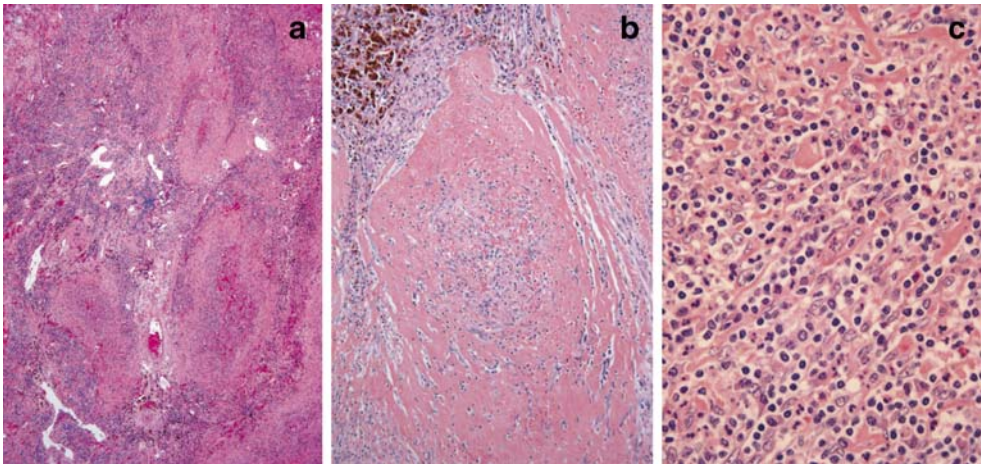

Fig. 3 Low-power magnification of Case 4 showing multiple nodules with interstitial hemorrhage surrounded by sclerotic stroma and inflammatory cells (**a**). Case 4 showing angiomatoid nodule with prominent interstitial hemorrhage surrounded by a sclerotic rim and inflammatory cells with hemosiderin-laden macrophages (**b**). High-power magnification of Case 4 showing internodular IPT-like areas with spindle cells admixed with numerous inflammatory cells (**c**)

vascular markers (Fig. 2e), with some nodules lacking reactivity altogether. CD68 stained isolated cells within the nodules in all cases, whereas CD21 and CD23 were negative. Three cases tested for ALK-1 exhibited no staining. CD30 was strongly and diffusely expressed by the endothelial cells of the angiomatoid nodules in all cases (Fig. 2f). The expression was stronger than endothelial markers in most cases. The distribution of CD30 positive cells was somewhat similar to the pattern seen with CD31. No CD30 staining was seen in between the nodules or in normal splenic parenchyma. Smooth muscle actin (SMA) and muscle-specific actin (MSA) were strongly expressed by spindle cells within and between the nodules. In case 4, the areas devoid of angiomatoid nodules demonstrated MSA and SMA staining only (Fig. 4a).

In situ hybridization

Strong nuclear expression for EBER was noted in case 4. The positivity was present in the spindle cells within and between angiomatoid nodules (Fig. 4c), with no staining in inflammatory cells and complete absence in normal spleen.

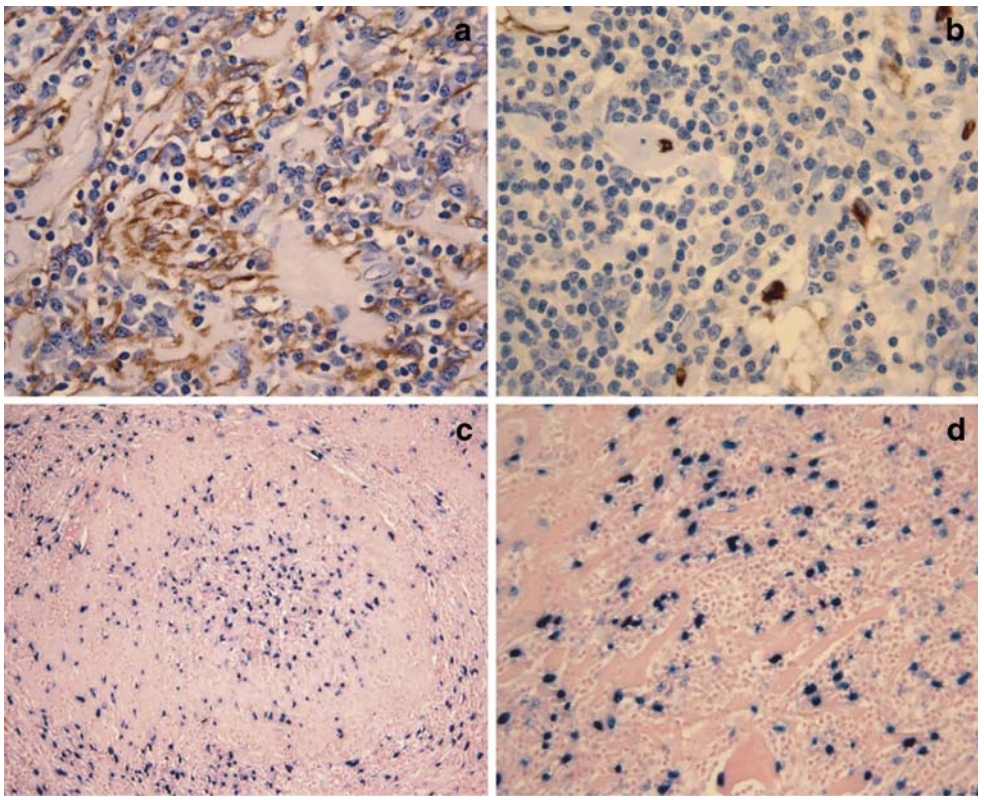

Fig. 4 Case 4 demonstrating MSA staining in IPT-like area staining spindle cells (**a**). Same area stained with CD34 demonstrating only a few isolated endothelial cells (**b**). The spindle cells are negative. Strong nuclear staining with EBER in angiomatoid nodules (**c**) and IPT-like area (**d**)

EBER was also noted in the areas devoid of angiomatoid nodules (Fig. 4d) suggesting that the expression was limited to fibroblasts and myofibroblasts. Double staining for EBER and CD31 was attempted, but the results were technically unsatisfactory; therefore, the presence of EBV in endothelial cells could not be completely excluded. EBER was negative in the remaining five cases.

Molecular analysis

A strong PCR band was present in the splenic mass in case 4 consistent with the presence of EBV DNA. There was no evidence of EBV in the normal spleen.

Discussion

Since its first description by Martel et al. [16] in 2004 and including the cases described herein, there have been approximately 33 reported cases of SANT [5, 14, 16]. Additional cases have been reported as splenic hamartoma and hemangioendothelioma [9, 10, 21]. The usual clinical presentation is of a middle-aged adult with abdominal discomfort, splenomegaly, raised ESR, or an incidental finding on routine cancer staging/medical imaging. Women are affected twice as often as men. SANT can be separated from other vascular lesions by its unique nodular angiomatoid proliferation with distinctive immunohistochemical profile, namely, a mixture of CD31+/CD8+/CD34− red pulp sinusoid-type endothelial cells, CD31+/CD34+/CD8− capillary-like endothelial cells, and CD34−/CD31+/CD8− small vein-type endothelium [16]. Focal CD68 staining has also been described in the nodules [14]. The internodular stroma and nodules themselves contain SMA and MSA positive fibroblasts/myofibroblasts and mixed inflammatory infiltrate [16]. SANT is considered a benign reactive process, and there have been no recurrences after splenectomy [5, 14, 16].

Martel et al. [16] noted that most SANTs often have an internodular stroma indistinguishable from IPT and suggested that SANT could represent the end stage or a final common pathway of a variety of splenic lesions, including IPT [16]. Like IPT, SANT has been found in association with extrasplenic malignancies [8, 17], is more common in women, and some patients have fever or elevated ESR at presentation. All the cases in our series had internodular areas resembling IPT, and one patient who presented with persistent anemia of unknown cause and elevated serum ESR and C-reactive protein also had small diffuse IPT-like areas. The presence of EBV was demonstrated in the spindle cells of the angiomatoid nodules, internodular stroma, and diffuse IPT-like areas of this case. This is the first description of EBV associated with SANT. None of the previously described cases was tested for EBV [5, 14, 16]. IPT of spleen is associated with the presence of EBV in tumor cells in a significant number of cases [1, 11, 17]. The presence of EBV in this case supports the suggestion that at least a subset of SANTs may represent transformation of an EBV-associated IPT. EBV has been shown to be associated with two types of mesenchymal tumors in the spleen, IPT, and "IPT-like" follicular dendritic cell tumor (FDCT) [1, 2, 4, 13, 17, 19, 22]. The relationship between IPT and "IPT-like" FDCT is not entirely understood, but recently, Lewis et al. [13] postulated that EBV positive mesenchymal tumors of the spleen may represent a group of related lesions arising from an EBV infected mesenchymal stem cell. This cell of origin could proceed to differentiate down a myofibroblastic pathway with actin positivity, a follicular dendritic cell pathway with CD21 or CD35 positivity, or an IPT with no specific differentiation. Some IPTs contain clonal EBV genomes strongly suggesting that they are true neoplasms [4, 13]. Additional studies investigating the morphologic spectrum and the presence and clonal status of EBV in SANT are necessary to gain further insight into the nature and pathogenesis of SANT.

In the six cases described herein—in addition to the usual immunoprofile of SANT—there was strong CD30 expression in the angiomatoid nodules. CD30 is an activation marker inconsistently expressed in vitro by endothelial cells [7]. It has been hypothesized that CD30 acts as a receptor for a number of as yet unidentified growth factors thereby regulating cytokine-mediated cell growth [6, 20]. The expression of CD30 suggests that the angiomatoid transformation of splenic red pulp in SANT is a cytokine-mediated process. A single study looking at CD30 staining in other non-splenic vascular lesions demonstrated moderate CD30 expression in 17 of 52 benign vascular tumors, 1 of 6 hemangioendotheliomas, 3 of 8 angiosarcomas, 0 of 8 Kaposi sarcomas, and 0 of 8 telangiectatic granulomas [20]. CD30 may prove to be a useful marker in supporting a diagnosis of SANT; however, additional studies of CD30 expression in littoral cell angioma, hemangioma, and hemangioendothelioma of spleen are needed.

Core biopsy of spleen appears to be a useful and noninvasive procedure in the recognition of SANT. In our series, two cases of SANT were diagnosed by core biopsies. One patient was initially called an IPT and chose to be followed with no additional treatment. The diagnosis in this patient was made before the description of SANT as a pathologic entity. The second patient had a presumptive diagnosis of SANT and was initially managed conservatively with repeat imaging but proceeded to surgery as the size of the lesion tripled over the course of a few months. Given the excellent prognosis of SANT, it is possible that some patients may be managed conservatively by "watchful" waiting and follow-up imaging studies. Splenic core biopsies are typically employed in the diagnosis of splenic

masses with a view to triage patients in need of splenectomy. Core biopsy of spleen is considered sensitive and specific for both hematological and non-hematological diagnoses—including vascular lesions—and they correlate well with final splenectomy diagnoses [12, 15]. Littoral cell angioma, hemangioma, hemangioendothelioma, and angiosarcoma are on the differential diagnosis of SANT on core biopsy; however, the nodular pattern, lack of atypia, and distinct immunohistochemical profile of SANT make this distinction possible. Potential indications for splenectomy in patients with a core biopsy diagnosis of SANT may include increase in mass size, marked splenomegaly, blood count abnormalities, or suspicion of malignancy.

ORIGINAL ARTICLE

Human brain tumors: multidrug-resistance *P*-glycoprotein expression in tumor cells and intratumoral capillary endothelial cells

Silvia Fattori · Francesca Becherini · Maurizio Cianfriglia · Giuliano Parenti · Antonella Romanini · Maura Castagna

Received: 18 January 2007 / Revised: 20 February 2007 / Accepted: 2 March 2007 / Published online: 26 June 2007

Abstract Malignant brain tumor is a lethal disease with currently available treatment options having a limited impact on outcome. Nevertheless, novel therapeutic approaches combined with genetic prediction of chemosensitivity have, in the last decade, significantly improved clinical benefit for the treated patients. The fine characterization of the MDR1 gene encoding for *P*-glycoprotein (MDR1–Pgp) in brain tumors may be a crucial determinant for evaluating the long-term efficiency of specific anticancer compounds. By using a very high specific monoclonal antibody, the MDR1–Pgp was immunodetected in 34 out of 43 grade IV, 6 out of 10 grade III, 4 out of 7 grade II, and 1 out 3 grade I brain tumors. MDR1–Pgp resulted hyper-expressed, both in vessels and in neoplastic cells from the majority of tumors examined, compared to normal parenchyma. This study demonstrates that the MDR1 gene can be detected in all grade tumor brain malignancies and in endothelial cells of newly formed capillaries, thus, impairing drug access at the tumor cell level. Although the role of MDR1–Pgp in tumor blood vessels needs to be further examined and more clearly defined, drug resistance in malignant brain tumors may result from characteristics not only of tumor vasculature but also of neoplastic cells.

Background

The unresponsiveness of solid tumours to chemotherapy is a multifactorial phenomenon, which may include the overexpression of drug transporter mechanisms conferring the simultaneous resistance to a large array of anticancer compounds [19].

MDR1 gene encoding for *P*-glycoprotein (MDR1-Pgp), which is physiologically expressed in several human tissues by acting as an active (ATP-dependent) transporter, is capable of reducing drug bioavailability to target cells [10]. The presence of this drug efflux system on the cell membrane of tumor cells may play a significant role in the intrinsic or acquired resistance to chemotherapy [9].

Although a clear relationship between the expression level of MDR1–Pgp and the outcome of some pediatric tumors, including acute myelogenous leukaemia (AML), has been demonstrated, the role of MDR1–Pgp in the failure of chemotherapy of solid tumors is still a matter of discussion [20]. Drug resistance in brain tumors may

involve multiple mechanisms. For commonly used drugs, such as vinca alkaloids and epipodophyllotoxins, Pgp appears to be the major feature in the unresponsiveness of tumors to chemotherapy [11]. However, because of contradictory results on the expression of the MDR1–Pgp, its clinical significance on brain tumors requires further investigations. In fact, it is not rare that controversial indications about the presence or the expression level of MDR1–Pgp come out from different laboratories upon examination of identical tumor specimens.

Distinct aspects, including the use of weakly discriminating monoclonal antibodies (MAbs) and/or unsuitable techniques and procedures, contribute in generating differences in the multidrug resistance (MDR) phenotype evaluation of cancer cells [2]. In this context, several authors suggest that immunoreactivity detected with MAbs JSB1 [17], C494 [16], and C219 [21] extensively used for MDR1–Pgp typing of glioblastoma and other brain tumors could, therefore, reflect an artifact rather than a specific Pgp staining. As an example, it has been reported that MAbs JSB1 and C494 cross-react with a widely distributed cytoplasmic antigen, pyruvate carboxylase, which is present in abundance in normal astrocytes [1]. Thus, because the unexpectedly poor specificities of many of the antibodies thought to be specific for MDR1–Pgp, the role of Pgp in producing drug resistance in malignant astrocytoma is questionable [1]. Further, the MAb C219 is utilized worldwide for immunohistochemistry and biochemical characterizations of mammalian MDR cells, cross-reacting with non-*P*-glycoprotein molecules [4]. Hence, the use of MAbs JSB-1, C494, and C219 for the detection of MDR1–Pgp expression should be approached with caution [2].

For the evaluation of MDR1–Pgp expression in brain tumors, we have used the well-characterized MAb MM4.17 for the following reasons: (1) The MAb reacts with an external human-specific epitope that is mapped in the fourth external loop at a single amino acid level (TRIDDPET) [5]; (2) the MAb binds with very high affinity and specificity to MDR1–Pgp expressed in human tumoral MDR cells [3]; (3) it allows to detect even the very small level or variation of MDR1–Pgp, such as that usually expressed in circulating human lymphocytes [15]; (4) the MAb binding to target cells is abrogated by specific MM4.17 phagotopes mimicking external *P*-glycoprotein conformation [14].

The use of MAb MM4.17 can eliminate misleading interpretations of the presence and expression level of MDR1–Pgp in brain tumors. The results we obtained and reported in this article might well contribute in routine clinical determinations of MDR in tumor specimens, thus, contributing to our understanding of the basis of the mechanisms of brain tumors' resistance to anticancer compounds.

Materials and methods

This study analyzes formalin-fixed and paraffin-embedded tissue blocks from 83 patients with brain tumors between 2003 and 2006, from the Surgery Pathologic Anatomy Department III of the University of Study in Pisa. All these patients were treated with neurosurgical abscission of the brain tumor. Furthermore, the study also includes formalin-fixed and paraffin-embedded brain tissue from ten different regions of a normal adult brain autopsy and from ten fetal autopsy. Clinical and pathological information were obtained from medical records and surgical pathology reports.

Histopathology

Brain tumors are classified according to the World Health Organization (WHO) classification of the central nervous system tumors. This study analyzes 62 tumors of neuroepithelial tissue (39 malignant glioblastomas, grade IV; 2 gliosarcomas, grade IV; 1 ganglioneuroblastoma, grade IV; 8 anaplastic astrocytomas, grade III; 1 choroid plexus carcinoma, grade III; 1 anaplastic oligoastrocytoma, grade III; 5 oligodendrogliomas, grade II; 1 oligoastrocytoma, grade II; 1 ependymoma, grade II; 3 pilocytic astrocytomas, grade I), 1 embryonal tumor (1 medulloblastoma), and 20 tumors of meningothelials cells (10 meningothelial meningiomas and 10 transitional meningiomas).

Treatment

None of the 83 patients had received chemotherapy or radiotherapy before surgery.

Immunohistochemistry

Immunohistochemistry was performed on 5-mm thick formalin-fixed and paraffin-embedded sections mounted on slides. After conventional deparaffinization and rehydratation, endogenous peroxidase activity was quenched by incubation in 0.3% H_2O_2 (10 min) at room temperature. The following procedure was to unmask the antigen. Next, samples were washed in phosphate-buffered saline (PBS; pH 7.2 for 10 min) and were incubated (10–15 min) in normal bovine serum albumin. After that, the sample were incubated with the optimally diluted (5 ug/ml) specific antibody MM4.17 (30 min) at room temperature and then with the secondary antibody. As positive control, kidney tissue samples were used for MDR1–Pgp immunodetection.

Monoclonal antibody

For specific MDR1–Pgp immunodetection, a purified form of the MAb MM4.17 (IgG2a,k) directed to the fourth loop of Mdr1–Pgp extracellular domain was used [5]. Several studies including (1) the recognition of the mdr1 gene expressed in various human MDR cells [15], (2) the epitope mapping at the amino acid level using a PIN-synthesized mdr1 peptide library [5], (3) the abrogation of MAb staining to human tissues and MDR cell lines by an MDR1 phagotope [14], and (4) the specific staining of human tumors expressing MDR1–Pgp [3] have demonstrated that this rodent MAb utilized in a purified form react exclusively with Mdr1–Pgp. No cross-reactivity with other mammalian *P*-glycoprotein have been observed.

Immunoreactivity scoring

Three observers without knowledge of the clinical data independently assessed the expression of Pgp. The distribution of the Pgp expression was assessed by estimating the percentage of positively stained cells. Four staining categories were established: − (0–5% staining), +/− (6–25% staining), + (26–50% staining), ++ (51–75% staining), and ++ (76–100% staining).

Results and discussion

The poor prognosis of brain malignancies is partly based on the minor success obtained from chemotherapeutic treatments. Resistance mechanisms at the tumor cell level may be in addition to the blood–brain barrier involved in the intrinsic drug unresponsiveness of brain tumors [9, 10, 18, 19]. To determine the expression level of MDR1–Pgp in brain tumors, we have used the MAb MM4.17 that has been shown to react with unique specificity and affinity with a well-defined human epitope located on the fourth loop of the external domain of MDR1–Pgp.

Astrocytic tumors are the most common human brain tumors. They originate from astrocytic cell lineages and are classified, according to the WHO guidelines, into four categories of increasing malignancies: pilocytic astrocytomas (grade I), astrocytomas (grade II), anaplastic astrocytomas (grade III), and glioblastomas (grade IV).

In grade IV glioblastoma (n=39), we found that a considerable expression of MDR1–Pgp was observed in the majority of tumor samples (32 out of 39; 82%; Table 1). The MDR1–Pgp is mainly localized in the membrane and cytoplasm compartments of positive cells (Fig. 1), while its distribution was heterogeneous within the tumors. In MDR1–Pgp-positive glioblastomas, the specimens are arbitrarily classified as 7.5%+/−, 20.5%+, 18%++, and 36%++, according with the intensity of MAb MM4.17 immunostaining (Table 1).

Our findings seems in contrast with previous published data reporting different percentage of MDR1–Pgp positivity in neuroblastomas and gliomas [7].

However, these previously reported investigations have been conducted with non-MDR1–Pgp specific MAbs, such as JSB1 and C219 [22], or using non-histologically well-defined tumor samples [7].

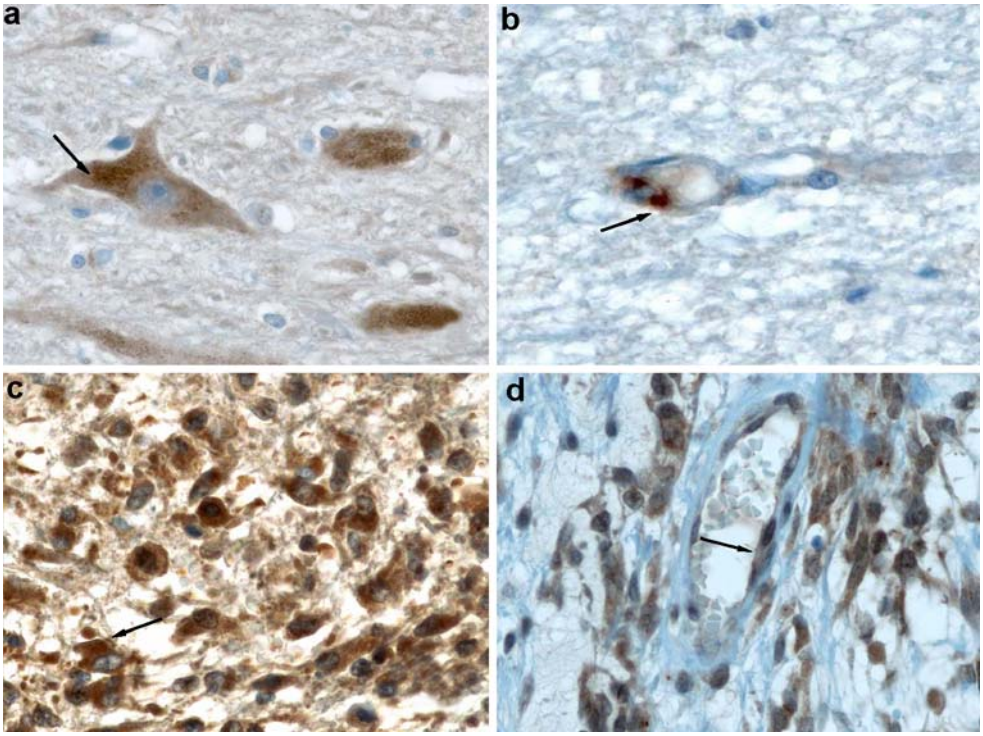

Fig. 1 MDR1–Pgp expression in normal and tumoral brain tissues. In the *upper part* of the panel, the *arrow* indicates the expression of MDR1–Pgp immunodetected by MAb MM4.17 in the cytoplasm of neuronal (**a**) and endothelial (**b**) cells of the mesencephalic nuclei. In the *lower part* of the panel, the *arrow* indicates the MDR1–Pgp expression in the cytoplasm of glioblastoma (**c**) and in the cytoplasm of endothelial cells of newly formed tumor vessels (**d**)

In 24 brain tumors showing various histological defined malignancies (Table 2), the MDR1–Pgp presents an identical cellular localization of the glioblastoma cells (Fig. 2). In these samples, MDR1–Pgp was detected in 2 out of 4 high grade IV tumors, 6 out of 10 grade III, 4 out of 7 grade II, and 1 out 3 grade I brain tumors.

The immunohistochemical investigation of 10 meningothelial and 10 transitional meningiomas, (both grade I in the WHO classification) shows that 19 out of 20 of these tumor samples express the MDR1–Pgp (Fig. 3). The intensity of the MAb MM4.17 staining was found etherogenous in cells of both meningioma histotypes: MDR1–Pgp-positive meningothelial meningiomas were classified as 30%++, 60%+, and 10%−, and MDR1–Pgp positive transitional meningiomas were classified as 10%++, 30%++, and 60%+ (Table 3). Differently from a previous report [22] where transitional meningioma were found to be more MDR1–Pgp positive in comparison to meningothelial meningioma, we found no clear relationship between meningioma histotype and MDR1–Pgp expression. Because none of the patients with meningiomas had received chemotherapy or radiotherapy before surgery, the high MDR1–Pgp levels in these tumors were not induced by any treatment. Meningiomas represent approximately 20% of the brain tumors [13]. WHO has subdivided meningiomas into 11 histological subtypes and classified them based on the cytological features of anaplasia as benign, atypical, or malignant. The molecular pathogenesis is poorly characterized, and only a few molecular markers have been associated with meningiomas [12].

To confirm and extend previously published observations on the expression of human MDR1–Pgp in the capillary endothelial cells of the central nervous system [6], ten adult and ten fetal autoptical samples from different brain sites of different gestational age were immunohistochemically investigated. The MDR1–Pgp expression was found in the endothelial and meningeal cells, in the choroid plexus epithelium of both the fetal and the adult autoptic brain tissues (data not shown). MDR1–Pgp positivity was also observed in the pyramidal neurons of different cortical areas, including hyppocampi Ammon's horn in the adult autoptic brain and in the neuronal cells of ponto-mesencephalic nuclei in fetal brain (data not shown). These results confirm that MDR1–Pgp may play an important role in the endothelial cells of the brain, pumping out xenobiotics from endothelial cells into the lumen of capillaries for the protection of the brain parenchyma and protecting fetal brain against toxic agents or maternal metabolic products during the intrauterine development.

To examine whether the endothelial cells of the newly formed capillaries during neoangiogenesis within malignant human brain tumors express MDR1–Pgp, 83 tumor specimens were investigated for MDR1–Pgp expression (Tables 1, 2, and 3).

The endothelial cells of the newly formed capillaries in 16 of 39 glioblastomas (41%) and in 2 of 24 other brain tumors (8%), including gliosarcomas, a medulloblastoma, a ganglioneuroblastoma, anaplastic astrocytomas, a choroid plexus carcinoma, an anaplastic oligoastrocytoma, oligodendrogliomas, an oligoastrocytoma, an ependymoma, and

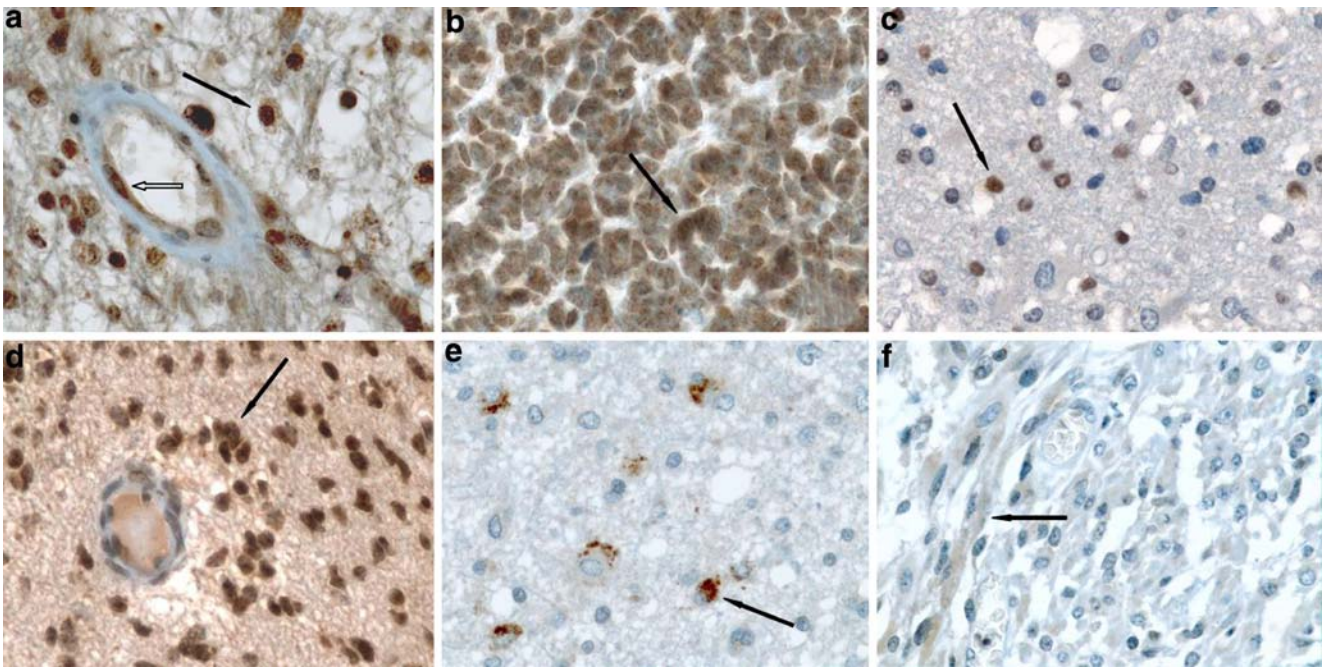

Fig. 2 MDR1–Pgp expression in brain tumors. The *arrows* (in *bold*) show that MDR1–Pgp is immunodetected in the cytoplasm of gliosarcoma (**a**), medulloblastoma (**b**), anaplastic astrocytoma (**c**), anaplastic oligoastrocytoma (**d**), oligodendroglioma (**e**), and pilocytic astrocytoma (**f**). MDR1–Pgp expression was also observed in the newly formed endothelial cells (*empty arrow*) of gliosarcoma (**a**)

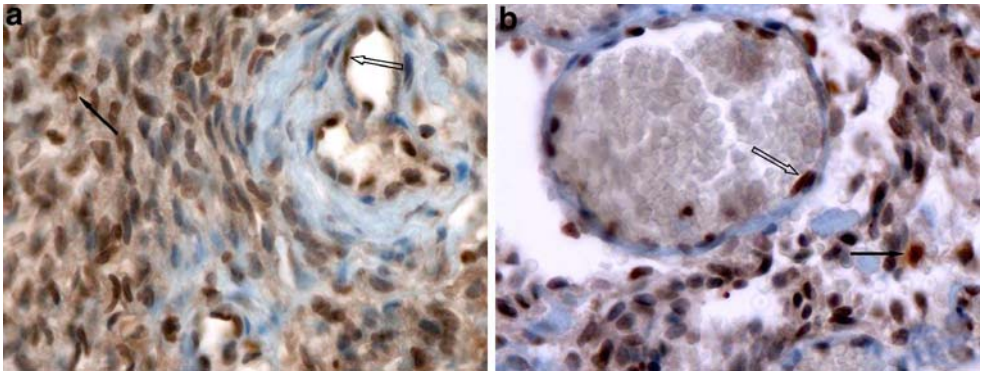

Fig. 3 MDR1–Pgp expression in meningioma. The *arrows* in *bold* show that MDR1–Pgp is immunodetected in the cytoplasm of transitional (**a**) and meningothelial (**b**) meningiomas. The *empty arrows* show that MDR1–Pgp is immunodetected in the endothelial cells of newly formed vessel in both tumors

pilocytic astrocytomas, immunostained positive for MDR1–Pgp. These results demonstrated that MDR1–Pgp is expressed not only in the capillaries of normal brain [6] but also in the majority of the newly formed capillaries of brain tumors. Our data are in good agreement with previous published data, in which MDR1–Pgp was biochemically identified by MAb C219 [8]. Similar percentage of MDR1–Pgp positivity was also observed by Toth et al. [22]. In this study, while the authors found 25 out of 29 cases of gliomas positive for MDR1–Pgp expression at the endothelial cell level, they found tumor cells in only 7 of 35 cases also positive for MDR1–Pgp. In contrast, we found that in glioblastomas and meningiomas (Tables 1 and 3), the MDR1–Pgp positivity of capillary endothelial cells of neo-vasculature correlates with that observed in cells of brain tumors. These putative differences in MDR1–Pgp detection may be due to the different discriminating ability of MAbs JSB1, C219, and MM4.17. However, it cannot be ruled out that unsuitable techniques and procedures or the use of nonhomogeneous histological classification may contribute in generating differences in the MDR–Pgp evaluation in brain tumors.

Summing up, our data indicate that the MDR of brain tumors may result not only from the expression of resistance markers in endothelial cells of tumor capillaries but also from the MDR1–Pgp expression in neoplastic cells. MDR1–Pgp in this special localization can remove anticancer compounds from tumor cells located around the capillaries. These observations suggest that, after careful evaluation in well designed preclinical studies, combined chemotherapy consisting of MDR1–Pgp reversing agents and specific anticancer compounds may represent a novel and promising clinical approach for the treatment of malignant brain tumors.

ORIGINAL ARTICLE

The spectrum of persistence of testicular blastema and ectopic testicular parenchyma: a possible result of focal delay in gonadal development

Mariana M. Cajaiba · Eugenia García-Fernández · Miguel Reyes-Múgica · Manuel Nistal

Received: 9 January 2007 / Revised: 7 March 2007 / Accepted: 11 March 2007 / Published online: 4 April 2007

Abstract Sex-cord formation and organization are important steps in testicular development and depend on adequate interactions between mesenchymal cells, pre-Sertoli cells, and germ cells. These elements form the testicular blastema, the precursor of the testicular parenchyma, morphologically characterized by poorly organized sex cords and mesenchymal components. Here, we study two uncommon testicular lesions, unrelated to other gonadal anomalies. In the first group, we describe the features of persistence of testicular blastema in three fetal autopsy cases, discussing its possible pathogenesis and clinical importance. In the second, we analyze 11 cases of ectopic testicular parenchyma in the tunica albuginea, an uncommon benign condition of uncertain clinical significance, whose main differential diagnosis is gonadal dysgenesis. Based on their similar topography within the testis, and on their possibly shared embryological origin, we propose that both lesions may represent the two extremes of a maldevelopmental spectrum resulting from a focal delay in testicular development.

Introduction

Testicular blastema can be defined as the primitive tissue that gives rise to testicular parenchyma, characterized by immature sex cords, germ cells, and mesenchymal components. Persistence of blastematous tissue is described in many organs, such as lung, kidney, adrenal gland, and the rete testis, the latter three sharing similar embryonal origins.

Normal testicular development in mammals has been fully reviewed [5, 11, 12, 20]. Testis development in humans begins around week 4 of embryonal age, and should be complete by week 10, when one can clearly recognize its architecture [11, 17, 23]. Although there are few studies on testicular development in humans, the morphologic steps parallel those observed in murine models.

The fully developed testis is composed of germ cells and somatic cells. The somatic elements include Sertoli and interstitial cells (Leydig cells, endothelium and peritubular myoid cells). Normal gonadal development initiates through proliferation of the celomic epithelium adjacent to the mesonephros. This results in thickening of the epithelium, forming two protuberances on the ventro-lateral surfaces of each mesonephros, morphologically identical in both sexes, the gonadal ridges.

In males, somatic cells begin to condense into clusters, initiate basement membrane deposition forming cords, and polarize, acquiring epithelial characteristics. The primordial

sex cords form as a consequence of molecular interactions between the celomic epithelium and the mesonephros, and germ cells that migrated from the yolk sac colonize them, giving rise to the seminiferous cords. The tunica albuginea, a thick collagenized layer that separates the surface celomic epithelium from the cortical testicular parenchyma, forms after parenchyma differentiation is complete.

Testicular blastema is not expected to be present in testes after their complete development. We describe the persistence of testicular blastema (PTB) in three fetal cases, a finding not previously reported in the literature. We also describe 11 cases of ectopic testicular parenchyma (ETP) in the tunica albuginea, a rare condition. Although both lesions have an unexplored clinical significance, we believe it is important to distinguish them from features of testicular dysgenesis. Furthermore, we propose that in between the two lesions there exists a continuum in testicular maldevelopment, in which PTB represents the early stage of a series of changes that result in ETP. Here, we discuss their possible relationship and the biological mechanisms underlying this type of testicular abnormality.

Materials and methods

Fourteen cases were retrieved from the Pathology Department files at Hospital La Paz, corresponding to either autopsy examples (nine cases), orchiectomies (three cases), or testicular biopsies (two cases). Age ranged from 17 weeks of gestation to 53 years. Clinical data were reviewed, and information on age, laterality, and testicular location (intra-abdominal, inguinal canal, or scrotal testes) is summarized in Table 1.

Table 1 Clinical information of all PTB and ETP cases

13	46 years	ETP	Right	SC
14	29 years	ETP	Right	IA

WGA weeks of gestational age, *IA* intra-abdominal, *IC* inguinal canal, *SC* scrotal, *NA* nonavailable

Both autopsy and surgical cases were routinely fixed, paraffin-embedded, cut, and H&E-stained. Histological specimens were reviewed and slides containing lesions of interest were selected. Immunohistochemistry was performed in selected paraffin blocks using the streptavidin–biotin–peroxidase technique with antibodies against high-/low-molecular-weight cytokeratin AE1/AE3 (Signet™), collagen IV (DAKO™), placental alkaline phosphatase (PLAP) (DAKO™), inhibin (DAKO™), calretinin (DAKO™), and vimentin (Progen™). Appropriate quality control and quality assurance procedures were implemented, including positive and negative tissue controls with each assay. Histological and morphometric analyses were performed in the adjacent normal parenchyma (data not shown).

Results

Persistence of testicular blastema

In all three cases, the testicular lesions were incidental findings of fetal autopsies. In case 1, the patient was the product of a spontaneous abortion at 20 weeks of gestation due to severe chorioamnionitis, and showed no developmental abnormalities. Case 2 was the product of an elective abortion at 17 weeks of gestation due to a neural tube defect (lumbosacral rachischisis with associated myelomeningocele), associated with an abdominal wall defect (omphalocele) and skeletal abnormalities (asymmetrical arthrogryposis of lower limbs and ribs). No cytogenetic studies were performed, and a specific syndrome could not be diagnosed based on these findings. Case 3 had a cytogenetically proven trisomy 18 (Edwards syndrome), presenting with classical facial features, cardiac malformations, esophageal atresia with tracheoesophageal fistula, and skeletal abnormalities.

Light microscopy studies in cases 1, 2, and 3 showed well-defined foci of poorly differentiated testicular parenchyma located immediately beneath the celomic epithelium (Fig. 1a). In all cases, the lesions were bilateral and contiguous to the celomic epithelium, with no visible tunica albuginea formed in the involved areas (Fig. 1b). This poorly differentiated parenchyma resembled testicular blastema and consisted of ill-organized cords composed by polygonal to oval-shaped cells with scanty cytoplasm and prominent nucleoli. Another population of cells, characterized by cells with large, round, pale nuclei and abundant clear cytoplasm, resembling germ cells, was less frequently seen, sparsely distributed among the cords (Fig. 1c). The remaining testicular parenchyma, tunica albuginea, and epididymis were normal for the age.

Immunohistochemistry for AE1/AE3 antibody showed intense staining of the celomic epithelium and also of the

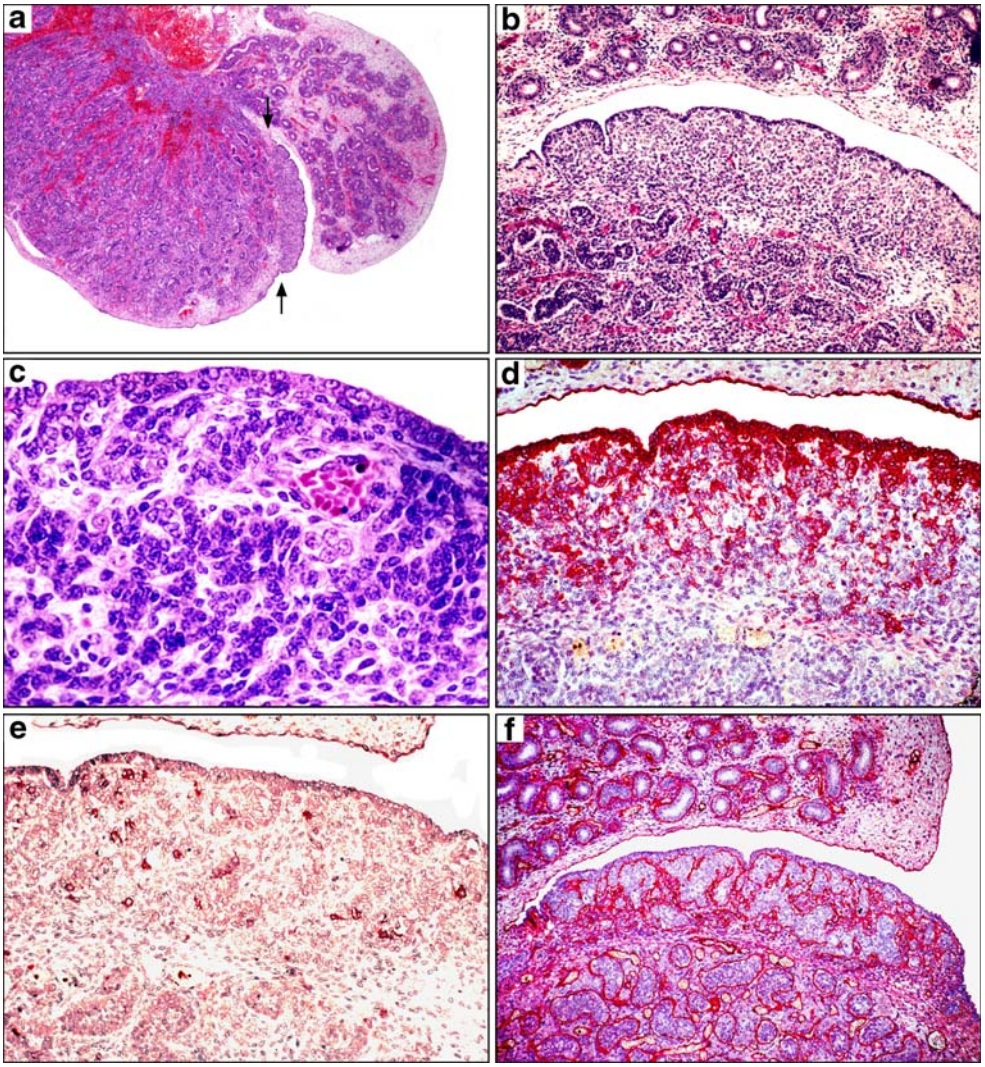

Fig. 1 **a**–**c** Microscopic appearance of PTB (H&E). **a** Focal and well-defined aspect of the lesion (*arrows*) (40×). **b** Poorly differentiated parenchyma adjacent to celomic epithelium, with absence of tunica albuginea (100×). **c** Ill-organized cords containing scattered germ cells (400×). **d**–**f** Immunohistochemical features. **d** Cytokeratin AE1/AE3 staining in celomic epithelium and superficial blastemal cells (200×). **e** PLAP staining of scattered gonocytes within the blastema (200×). **f** Collagen IV stain, highlighting the presence of a contiguous basement membrane between the blastemal cords and the celomic epithelium (100×)

adjacent polygonal cells observed in the testicular blastema (Fig. 1d). Immunoreactivity was less frequent in cells more deeply located below the celomic epithelium, and no staining was observed in the normal Sertoli cells of the well-formed seminiferous cords present in the rest of the testes. Strongly reactive cells in the epididymis and rete testis served as internal controls. In an opposite pattern, vimentin stained Sertoli cells in normal cords but was absent in both the persistent blastema and the celomic epithelium. Cells resembling germ cells were negative for AE1/AE3 and vimentin in all sections, and all were positive for PLAP (Fig. 1e). No PLAP immunoreactivity was observed in other cell populations.

Stains for collagen IV highlighted normal basement membrane deposition around the well-formed seminiferous cords, and also underneath the celomic epithelium layer. Collagen IV was present in a similar linear pattern within the nodules of persistent blastema, delineating irregular, large cords of cells in obvious continuity with the celomic epithelium basement layer (Fig. 1f).

Testicular parenchyma ectopy

Among the 11 cases, six were incidental autopsy findings with grossly and otherwise histologically normal testes (three children and three adults). There were two biopsy specimens; one biopsy was performed for evaluation of a small testis associated with hydrocele, and in the other, no clinical information was available. Of three orchiectomy specimens, two were due to cryptorchidism (one child and one adult) and one was due to a Leydig cell tumor.

Lesions observed histologically in cases 4 to 14 consisted of a variable number of seminiferous tubules, and testicular stroma containing Leydig cells, located inside the tunica albuginea. In all the cases, the tunica albuginea was well formed and collagenized, with normal thickness. Collagen fibers were always parallel to the surface, and there was no resemblance to ovarian-type stroma. The morphology of tubules, distribution of germ cells, and presence of Leydig cells inside the lesions were variable among the cases (Fig. 2a–c); however, all of them displayed

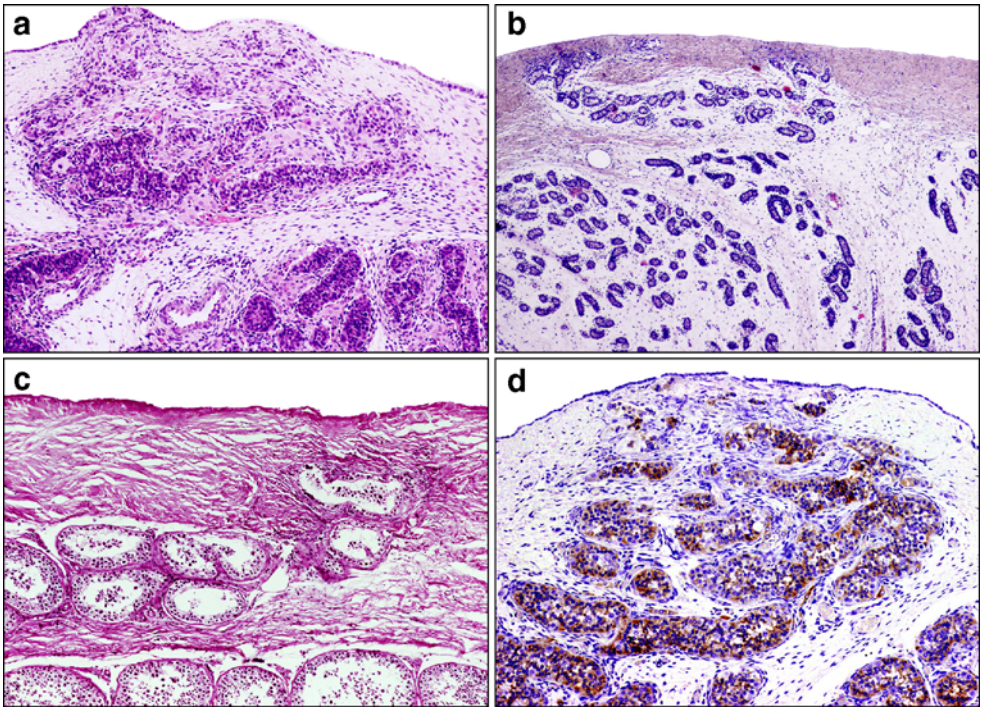

Fig. 2 **a**–**c** Histological aspect of ETP (H&E). **a** A childhood case, with the presence of infantile seminiferous tubules and Leydig cells within a normal tunica albuginea (200×). **b** ETP in a child with cryptorchidism (200×). **c** An adult case of ETP, with mature seminiferous tubules and Leydig cells inside a well-collagenized tunica albuginea (100×). **d** Immunohistochemistry for inhibin, showing both Sertoli and Leydig cells within the ectopic parenchyma (200×)

morphology features similar to the observed in the adjacent testicular parenchyma, including the morphological alterations observed in the cryptorchidism cases (*vide infra*).

Immunohistochemical studies were compatible with the pattern observed in normal, well-developed testicular parenchyma. Cytokeratin AE1/AE3 was positive in the celomic epithelium and negative throughout the parenchyma, including Sertoli cells. Inhibin and calretinin stains highlighted the presence of Leydig cells in both ectopic and adjacent normal parenchyma (Fig. 2d), while isolated gonocytes distributed within and outside the lesion stained strongly for PLAP.

Histological evaluation of the adjacent parenchyma revealed both normal histology and morphometric parameters (mean tubular diameter, tubular fertility index, and germ cell and Sertoli cell numbers) [13] in all childhood cases except in case 12, which showed the alterations commonly observed in cryptorchidism. The nonlesional parenchyma in adult cases showed slight alterations compatible with obstructive changes (cases 7 and 11), changes secondary to chronic disease/systemic therapy (cases 8 and 9), and features observed in cryptorchidism (case 14) [13]. All the observed changes were compatible with the clinical histories.

Discussion

PTB beyond the embryonal period has never been reported in the literature. In the three cases described here, the lesions were focal, well defined, and bilateral, contrasting with the well-developed adjacent parenchyma. The histological aspect was identical to the previously described findings in testes of less than 7 weeks of embryonal-age fetuses (corresponding to 9 weeks of gestational age) [17], with polygonal to oval-shaped cells with scanty cytoplasm resembling pre-Sertoli cells, poorly organized in primitive sex cords, and cells with clear cytoplasm, large nuclei, and prominent nucleoli resembling germ cells.

The more likely explanation for the PTB would be a localized delay in testicular parenchyma development because the remaining testicular components show normal maturation. Primordial sex cords are rudimentary, poorly formed tubular structures composed of pre-Sertoli cells and germ cells, and together with the adjacent gonadal stroma characterize the testicular blastema. Further tubular organization occurs as a consequence of interactions with the gonadal stroma [4, 5, 12, 19], and it happens in parallel with Sertoli cell differentiation, first at the central portion of the testis and later within the periphery [12]. The testicular stroma arises from mesonephric precursors that migrate into the gonad and further differentiate into endothelial and peritubular myoid cells. The processes of mesonephric cell migration, sex cord formation, and Sertoli cell differentiation all depend on the expression of the *Sry* gene and its downstream targets, mainly *Sox9*, at the gonadal ridge and mesonephros [5, 19]. Other proteins shown to be involved in sex-cord organization are adhesion molecules, such as integrins and cadherins [7, 10].

Vascular development is the earliest morphological feature of male gonadal differentiation, and developing testicular vessels play an important role in sex cord

development [2, 3, 16, 22]. Knockout animals for *Pdgfr-α*, a growth factor receptor responsible for sex-specific vessel development in the male gonad, fail to develop a normal vascular pattern and show delayed testicular development [16, 22]. The morphological pattern observed in *Pdgfr-α* −/− mice is very similar to that observed in the focal lesions of PTB, showing large and irregular primitive cords lacking Sertoli cell differentiation and an organized stroma. We could hypothesize that the pathogenesis of PTB might be a defective segmental branching of the developing celomic vessels, leading to a focal lack of interactions between testicular vessels and parenchyma.

The pattern of immunohistochemical staining observed in these lesions is interesting. The presence of AE1/AE3 cytokeratin staining in epithelial-type blastemal cells adjacent to the celomic epithelium, with loss of immunoreactivity in deeper cells, could indicate that these cells are arising from the superficial celomic epithelium and further maturating into Sertoli cells that lack cytokeratin expression, which is consistent with the normally observed pattern of cytokeratin expression in the developing testis [1]. The hypothesis of an origin in the celomic epithelium for epithelial blastemal [9] cells is reinforced by the presence of a continuous basement membrane between the celomic epithelium and the blastemal cords, as shown by collagen IV stains.

The clinical significance of PTB is unclear. The lesions in all three cases were incidental findings of postmortem examinations in previable fetuses and were probably unrelated to the cause of death. Although in two of the cases (cases 2 and 3, *vide supra*) there were associated malformations in other organ systems, the limited number of cases and lack of published data make it difficult to establish a relationship between the testicular lesion and the other phenotypic findings. We could not find in the literature any description of a similar testicular histology among other trisomy 18 (Edwards syndrome) cases. One can speculate whether these lesions could have a potential for malignant transformation in childhood, as occurs in neoplasms related to blastemal persistence in other organs, such as Wilms tumor in the kidney or pleuropulmonary blastoma in the lung. Further studies for genetic profiling of these lesions could identify molecular alterations and help to establish a possible relationship with malignant transformation.

The finding of ETP in the tunica albuginea, unrelated to other testicular lesions, has only been reported twice in the literature [14, 18]. Cases were described in both children (five cases) and adults (one case), ranging from 1 to 51 years of age. In four out of the five cases reported in children (ages ranging from 1 to 13 years), the testicular lesions were incidental findings of autopsy with grossly normal, descended testes; the fifth case was of a 6-year-old boy who underwent orchiectomy due to cryptorchidism [14]. The adult case was also an incidental finding following orchiectomy due to persistent pain secondary to a granulomatous epididymitis [18]. All reported lesions were unilateral, and their gross appearance characteristically showed small cysts measuring less than 1 mm at the testis surface. Histologically, the lesions were described as the presence of normally developed seminiferous tubules, some of them containing germ cells and stroma with Leydig cells, inside a well-collagenized, morphologically normal tunica albuginea, sometimes splitting it into two layers. Testicular histology outside the lesions was normal in all reported cases. In our series, none of the surgical specimens had a clinical suspicion of a lesion in tunica albuginea. ETP represented an incidental finding in both autopsy cases and surgical specimens obtained due to other clinical indications. Among our adult cases, slight alterations in the morphology were present in the adjacent parenchyma, such as changes secondary to obstruction, chronic disease, and cryptorchidism [13], but no causal relationship can be established between them and ETP due to the limited number of cases. As the lesions contain both testicular stroma and seminiferous tubules inside, we prefer to call them ETP rather than ectopic seminiferous tubules.

The focal character of the lesions, in addition to the presence of a normal tunica albuginea in all cases (displaying normal collagenization and absence of features of an ovarian-like stroma), absence of müllerian structures, and no clinical history of intersexual state, rules out the diagnosis of gonadal dysgenesis (GD) [6, 8]. This entity represents the main differential diagnosis in both ETP and PTB. Other clinical differential diagnoses for ETP include two lesions that result in cystic appearance of the tunica albuginea, mainly if the ectopic tubules present cystic dilatation: tunica albuginea cysts, a benign condition of probable mesothelial origin [15], and cystic teratomas. However, the histopathological aspect of both is very characteristic. Regarding PTB, another important differential diagnosis would be gonadoblastoma, which can also present with an aspect of disorganized tubules in the testicular peripheral portion, but shows other characteristic features, such as atypical gonocytes, Call–Exner bodies, and a nodular architecture. Furthermore, almost all gonadoblastomas are associated with an underlying dysgenetic testis [21].

We could speculate that ETP is the natural evolution of progressive development of PTB into mature parenchyma occurring inside the tunica albuginea. According to this notion, the ectopic parenchyma would have become “entrapped” in the tunica albuginea as a result of its delayed maturation, which probably occurred simultaneously with or after the formation of the tunica albuginea, which occurs under the influence of the anti-Müllerian hormone, secreted by differentiating Sertoli cells [12, 14]. In fact, it arises after the organization of sex cords is complete and

Sertoli cells already show some degree of maturation [23], possibly around the same time the primordial sex cords lose their connection with the celomic epithelium [9]. Another explanation for the pathogenesis of ETP could be a focal delay in tunica albuginea formation, allowing "penetration" of testicular parenchyma within it. However, one important difference between the two lesions described here is that all of our PTB cases showed bilateral involvement, whereas cases of ETP in both the reported cases and our series were unilateral. Nevertheless, as most of the cases of ETP were seen in orchiectomy or biopsy specimens, the contralateral testes were not studied to rule out bilateral lesions.

In conclusion, both PTB and ETP represent uncommon findings in testicular pathology, associated with a developmentally normal adjacent parenchyma. Although it is not clear whether these lesions may carry a potential for malignant transformation, their current clinical importance lies in their differential diagnosis with GD and also with other cystic lesions of the tunica albuginea, mainly in testicular biopsies, thus preventing these patients from unnecessary orchiectomy. Understanding of these findings may also shed light on our knowledge regarding biological mechanisms involved in testis development.

CASE REPORT

Hepatoportal venopathy due to disseminated *Mycobacterium avium* complex infection in a child with IFN-γ receptor 2 deficiency

Amy V. Rapkiewicz · Smita Y. Patel · Steven M. Holland · David E. Kleiner

Received: 8 December 2006 / Revised: 14 February 2007 / Accepted: 25 April 2007 / Published online: 7 June 2007

Abstract The control of intracellular microorganisms such as mycobacteria is largely dependent on the adaptive immune response, specifically the interaction of T helper cells and antigen presenting cells such as macrophages. The interferon gamma (IFN-γ) pathway activation is crucial for containment and killing of mycobacteria, as evidenced by the fact that defects in this pathway often result in profound infections with both tuberculous and non-tuberculous mycobacteria. We herein report a case of a child with autosomal recessive IFN-γ receptor 2 (IFN-γR2) deficiency who developed hepatic venopathy secondary to disseminated *Mycobacterium avium* complex (MAC) infection.

Introduction

Interferon gamma (IFN-γ) is a cytokine critical for the management of intracellular organisms. Normally produced by T lymphocytes and natural killer (NK) cells, IFN-γ stimulates macrophages to elaborate IL-12 and TNF-α, which in turn stimulate helper T cells and NK cells. Infection with mycobacteria also stimulates macrophage production of IL-12. The IFN-γ receptor (IFN-γR) complex is composed of ligand binding IFN-γ receptor 1 chains and signal transducing IFN-γ receptor 2 (IFN-γR2) chains. Upon binding of IFN-γ, IFN-γR1 dimerizes and engages two chains of IFN-γR2, the limiting moiety. Aggregation of these chains apposes the constitutively associated Jak1 and Jak2 molecules, leading to their phosphorylation and activation of STAT1. This signal transduction pathway upregulates a multitude of genes involved in both the innate and adaptive immune systems, including TNF-α and IL-12. These actions culminate in macrophage activation and bactericidal activity [6]. Genetic defects found at multiple points along the IFN-γ/Jak/STAT pathway result in susceptibility to non-tuberculous mycobacterial infection [4, 9]. IFN-γR2 deficiencies have been described due to mutations in the extracellular and transmembrane domains [18].

Clinically, patients with IFN-γR2 deficiency present with non-tuberculous mycobacterial infections predominately due to *Mycobacterium avium* complex (MAC) infection. *Mycobacterium fortuitum*, cytomegalovirus, and herpes simplex virus (HSV) infections have also been reported [18]. However, only a few cases have been reported so far, thereby preventing a comprehensive description of the disease.

Disseminated MAC infections have been reported in patients with IFN-γR1 deficiency [14]. MAC peritonitis in the setting of disseminated MAC infection in an AIDS patient has been described [11]. Hepatic vein obliteration with subsequent portal hypertension has not been described in MAC infection. Liver findings in patients with disseminated MAC infection include ill-formed non-caseating portal granulomas formed by Kupffer cells. These macrophages are often distended by large numbers of MAC [13]. Liver involvement by systemic conditions and resultant portal hypertension can occur in association with a variety of conditions such as Gaucher's disease, sarcoidosis, Wilson's disease, and infections such as schistosomiasis [7, 17]. Clinically, patients can present with portal hypertension, congestive splenomegaly, esophageal varices, pancytopenias, and gastrointestinal bleeding. The underlying histopathogenesis of these conditions is generally agreed to be an obliterative venopathy of the portal system, with collapse, thrombosis, or occlusion of the portal veins. Suffocation and obliteration of the venous system occurs secondary to involvement of macrophages by storage products, as in Gaucher's disease, or through the formation of granulomas and fibrosis, as in schistosomiasis and sarcoidosis.

We report a child with autosomal recessive IFN-γR2 deficiency who developed hepatoportal venopathy due to disseminated MAC infection.

Clinical history

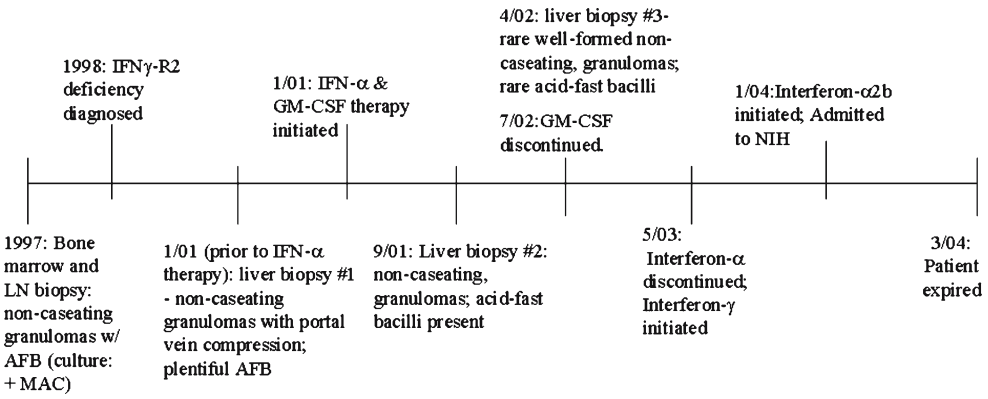
The patient was an HIV-negative 9-year-old boy born to unrelated American parents at 26 weeks. He did not receive the *Bacille Calmette-Guérin* immunization but did receive the usual childhood immunizations. At age 20 months, he presented with cough, cold symptoms, and pulmonary infiltrates. At 2 years, he developed lymphadenopathy, hepatosplenomegaly, and fevers; bone marrow and lymph node biopsies showed non-caseating granulomas containing acid-fast bacilli. Culture of the lymph node biopsy grew *M. fortuitum* and MAC. Despite improvement on antimycobacterial therapy including rifabutin, azithromycin, ciprofloxacin, ethambutol, and amikacin, the patient continued to have lymphadenopathy. He was referred to the NIH Clinical Center where complete autosomal recessive IFN-γR2 deficiency due to a two-base deletion in the extracellular domain leading to a frame shift and premature stop was identified [3]. The patient was managed for 4 years with antibiotics. A liver biopsy (1) was performed in January 2001 for elevation of liver enzymes. HSV1 esophagitis responded to acyclovir. Recurrent mild HSV1 of the thumb was suppressed by chronic administration of acyclovir. Splenomegaly was complicated by infarction leading to splenectomy. Recurrent ampullary stenosis due to mycobacterial infiltration required biliary stenting with frequent revisions. Chronic protein-losing enteropathy and malabsorption were ascribed to small bowel lymphangectasia. Between January 2001 (after biopsy 1) and May 2003, the patient received IFN-α and granulocyte macrophage-colony stimulation factor (GM-CSF) injections in an effort to induce macrophage antimycobacterial activity through activation of Jak/STAT pathways other than through the IFN-γ receptor. GM-CSF (100 mcg) was administered subcutaneously three times a week from January 2001 until July 2002. Liver biopsy 2 was performed in September 2001, after the patient had been receiving IFN-α and GM-CSF along with anti-mycobacterial therapy for 8 months. Liver biopsy 3 was performed in April 2002. Due to diffuse musculoskeletal pain, and sclerotic bony lesions in May 2003, IFN-α was discontinued, and IFN-γ was initiated.

The patient was readmitted in January 2004 for ascites, multiple ill-defined low-density liver lesions and painful, generalized lymphadenopathy. IFN-γ therapy was discontinued, and IFN-α 2B was restarted. Anti-mycobacterial therapy continued. His laboratory studies showed white blood cells $11.7\times10^3/\mu l$, hemoglobin 6.3 g/dl, hematocrit 21%, platelet count $58{,}000\times10^3/\mu l$, prothrombin time 13 s, partial prothrombin time 32.9 s, total protein 4 g/dl, albumin 2.1 g/dl, aspartate aminotransferase 63 U/l, alanine aminotransferase 28 U/l, alkaline phosphatase 1,082 U/l, total bilirubin 1.5 mg/dl, hepatitis B and C serology negative. Despite treatment, the patient died in March 2004. The patient's clinical course is summarized in Table 1.

Materials and methods

The patient underwent three liver biopsies at various time points as part of his clinical care while enrolled in the NIH protocol 93-I-0119. A full, unrestricted consented autopsy was performed on March 5, 2004. After formalin fixation, paraffin-embedded tissue sections were processed for hematoxylin and eosin (H and E) and Masson trichrome stained sections, as well as stained for acid-fast bacilli with Ziehl–Nielsen staining.

Table 1 Clinical summary timeline



Results

Liver biopsy 1 showed a moderate portal lymphohistiocytic infiltrate consisting of non-caseating granulomas with proliferation of bile ductules in the portal areas involving most of the portal areas in the biopsy. Early fibrosis, as determined by Masson trichrome stain, was present within the portal tract without evidence of bridging. The granulomas were ill formed and compressed the adjacent portal veins. Plentiful mycobacteria were demonstrated in the cytoplasm of the histiocytes (Fig. 1a and inset).

Liver biopsy 2 showed a mild granulomatous hepatitis involving isolated portal triads (Fig. 1b). Similar to biopsy 1, the granulomas were ill formed with inflammation spilling into the lobules. The portal tracts showed portal fibrotic expansion without bridging. Sinusoidal dilatation was present; however, the central veins were uninvolved.

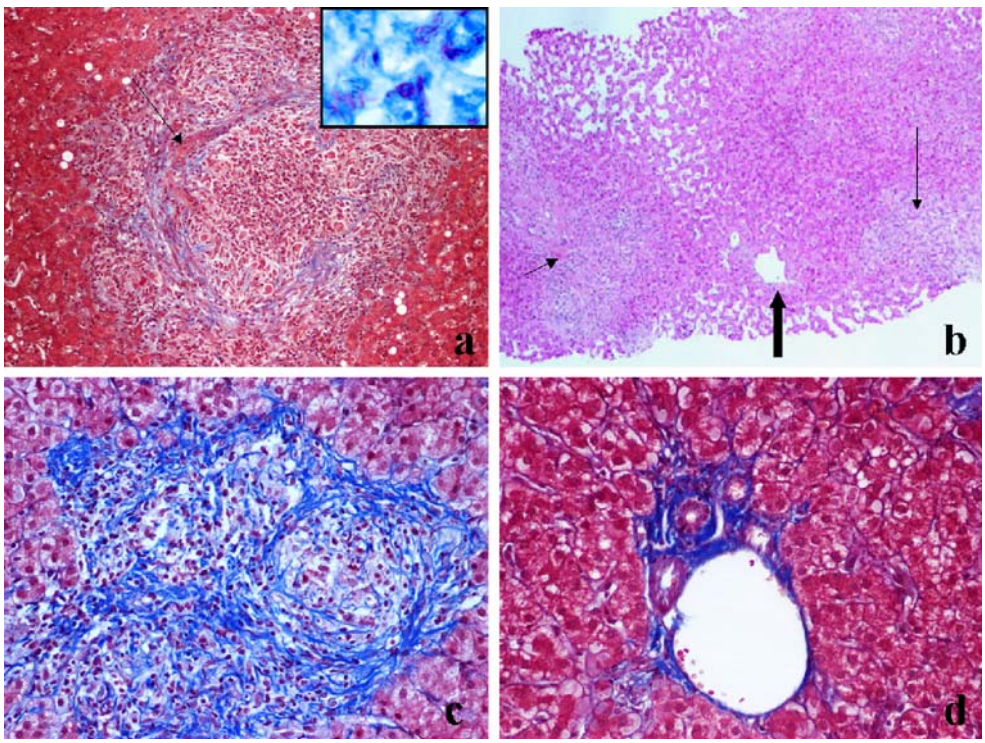


Fig. 1 **a** Liver biopsy 1, granulomatous portal inflammation with compression of the portal vein. This portal area shows a moderate mixed lymphocytic and histiocytic infiltrate that obliterates the central vein. Only a remnant portion of the collagen fibers (*blue*) and smooth muscle of the central vein is seen (*red*, *arrow*) (Masson trichrome, ×400). *Inset*, liver biopsy 1, numerous acid-fast bacilli (*arrow*) are present in the cytoplasm of the histiocytes (modified Ziehl–Nielsen, ×600) **b** Liver biopsy 2, isolated portal granulomatous infiltrates. Two portal areas are infiltrated by histiocytes and small lymphocytes (*thin arrow*). Fibrosis is seen extending out from the portal area (*short arrow*). The central vein is unremarkable (*thick arrow*). The sinusoids show dilatation. (H and E, ×40) **c** Liver biopsy 3, portal area with a well-formed granuloma and brisk chronic inflammatory infiltrate surrounded by early collagen formation (*blue*). The portal vein is compressed. (Masson trichrome, ×400). **d** Liver biopsy 3, an unremarkable portal triad with a patent portal artery and vein. (Masson trichrome, ×400)

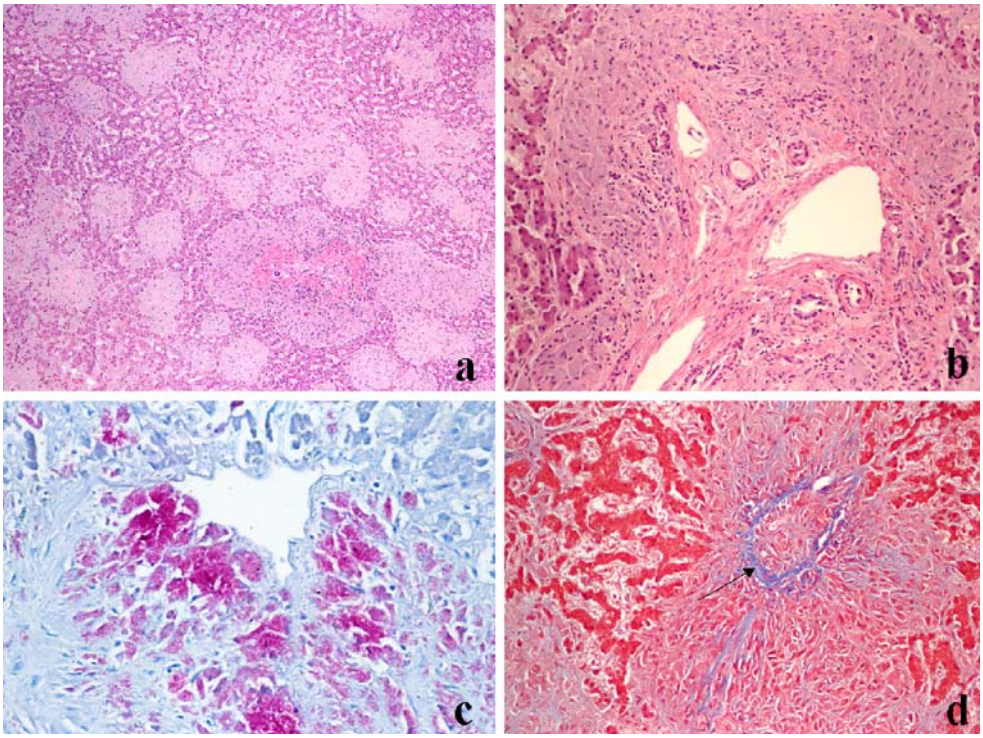

Fig. 2 **a** Autopsy liver section, multifocal well-formed non-caseating granulomas (H and E, ×40). **b** Autopsy liver section, a portal area expanded by histiocytes compressing the venous lumina (H and E, ×400). **c** Autopsy liver section, histiocytes distended by acid-fast bacilli compressing a central vein (Ziehl–Nielsen, ×400). **d** Autopsy liver section, fibrous obliteration of a central vein (*arrow*), the remnant collagen fibers are identified by *pale blue staining* (Masson trichrome, ×400)

Liver biopsy 3 was performed in April 2002 while the patient was still on IFN-α and GM-CSF therapy and showed a dramatic decrease in the number of granulomas. Most portal areas were unremarkable, and only a rare isolated well-formed non-necrotizing, granuloma was seen. A small number of acid-fast bacilli were found with special staining. This well-formed granuloma was associated with a brisk lymphocytic infiltrate (Fig. 1c). The majority of the portal areas appeared normal and were uninvolved by inflammation or fibrosis (Fig. 1d). As compared to the liver biopsies 1 and 2, the granulomas, which were seen during IFN-α treatment in biopsy 3, were rare, smaller, better formed, and had more lymphocytic infiltrate.

Autopsy findings

A full, unrestricted autopsy found that the peritoneal cavity contained 750 ml of serous ascites. The liver was 2,100 g (normal 560 g), with bile staining but without gross nodules. The cut surface of the liver showed diffuse stellate-shaped lesions, some with central degeneration, measuring from 1 to 2 cm in maximum dimension.

A diffuse, granulomatous infiltrate was present in all portal areas and also involved the lobules and central veins. The granulomas consisted of aggregates of pale-staining histiocytes distended by large numbers of acid-fast bacilli (Fig. 2a and c). Very few lymphocytes were present. The portal and central veins were either compressed or frankly obliterated by these non-caseating granulomas, which were associated with mild fibrosis (Fig. 2b). The hepatocytes showed atrophic changes with an increase in the nuclear/cytoplasmic ratio. Sinusoidal congestion was seen. The remnant of collagen around central veins could be demonstrated with trichrome staining (Fig. 2d).

In summary, all three pre-mortem liver biopsies showed the central veins to be relatively uninvolved by the granulomatous inflammation. The vascular blockage was predominately pre-hepatic involving the portal areas. At autopsy, there was a combination of pre- and posthepatic obstruction such that the hepatocytes in the lobule showed atrophic changes, but frank ischemic changes and/or necrosis was not seen.

Discussion

Veno-occlusive disease and hepatoportal venopathy have been described in patients with central and portal hepatic vein involvement due to storage diseases, sarcoidosis, primary biliary cirrhosis, primary sclerosing cholangitis, mastocytosis, cystinosis, schistosomiasis, and graft-vs-host disease [5, 7, 15]. Granulomatous disease associated with non-cirrhotic portal hypertension is rarely reported; primary biliary cirrhosis and sarcoidosis are the most frequent causes [12, 16]. Ascites is infrequently reported in portal venopathy and, in this case, may have been a complication of either the hepatoportal venopathy, the small bowel lymphangectasia/mesenteric lymphadenitis, or both. Non-

tuberculous mycobacterial infection has not been reported to cause portal venous obliteration in either HIV or non-HIV infected patients.

Patients with complete autosomal recessive IFN-γ2R deficiency show a total loss of normal IFN-γ signal activation and do not clinically respond to either endogenous or exogenous IFN-γ therapy. IFN-α shares with IFN-γ activation of the common downstream effector molecule, STAT-1, that served as the rationale for its use and may explain the clinical and histopathologic changes during IFN-α treatment. A similar use of IFN-α has recently been reported, and this also appeared to facilitate mycobacterial control [19]. IFN-γ has been used to treat patients with defects in the IL-12/IFN/Jak/STAT pathway with non-tuberculous mycobacterial infections who have residual IFN-γR activity [9].

The causes of the obliteration of the intrahepatic portal and central veins in the current case may be twofold. Firstly, the diffuse MAC infection with granulomatous inflammation may have compressed the venous lumina, mostly portal but both central and portal, as seen at autopsy (Figs. 1a and 2b and c). Secondly, the intermittent resolution of the granulomas seen during treatment may have spurred a reactive fibrotic response with resulting phlebosclerosis and fibrous obliteration, as observed at autopsy (Fig. 2d). Both processes would result in resistance to portal venous flow and portal hypertension. Clinically, we observed worsening of granulomatous inflammation when the patient was not undergoing treatment with IFN-α, contrasting with more well-defined granulomatous inflammation and clinical improvement during IFN-α therapy. The partial resolution and quality of the granulomas and MAC organism burden correlated with the duration of IFN-α and antibiotic treatment. This improvement was seen most dramatically in liver biopsy 3 (Fig. 1c,d), taken when the patient had been treated for 16 months with IFN-α and anti-mycobacterials. There was markedly decreased granulomatous inflammation and decreased MAC burden in biopsy 3 as compared to liver biopsy 1, taken before IFN-α therapy was initiated. The granulomas, which were seen during IFN-α treatment in biopsy 3, were smaller, better formed, and had more lymphocytic infiltrate than in liver biopsies 1 and 2. Acid-fast bacilli were rare and difficult to identify in biopsy 3 as well, in contrast to 1. Liver pathology from times of nontreatment showed ineffective granulomatous inflammation with abundant mycobacteria that involved the portal and central regions of the liver. These granulomas impinged on the venous lumina and obliterated some vessels. At autopsy, the patient had been receiving IFN-α for the second course for only 3 months and, before that, had received IFN-γ therapy for 7 months; anti-mycobacterials had been administered throughout. Although the granulomas were starting to appear well formed at autopsy, the MAC burden was quite high, and venous obliteration was observed. At autopsy, the vascular obstruction was both pre- and posthepatic, with atrophy of the hepatocytes and sinusoidal congestion.

Responding to IFN-γ stimulation is necessary for the containment of mycobacteria [10]. The IFN-γ response may also control the pro-fibrogenic milieu created by granulomatous inflammation. The anti-fibrogenic property of IFN-γ has been described in hepatitis C virus-infected patients [2]. IFN-γ and IFN-α have been used in other clinical settings for the prevention of fibrosis, such as in idiopathic pulmonary fibrosis [1]. The inability to respond to IFN-γ, as seen in patients with IFN-γR2 deficiency, may have contributed to the development of fibrosis after an inflammatory insult, as was seen in the current case.

Hepatoportal venopathy is an uncommon cause of non-cirrhotic portal hypertension in the Western world. Our case developed hepatoportal venopathy and veno-occlusive disease presumably secondary to disseminated MAC infection. The partial resolution of the granulomatous inflammation and MAC in response to IFN-α therapy reinforces the integral role that this cytokine pathway may play in controlling mycobacterial infections. This unusual clinical presentation may help better define the phenotype of patients with IFN-γR2 deficiencies as well as the importance of the IFN-α and IFN-γ pathways in controlling intracellular infection.

Acknowledgements The authors would like to express thanks to Dr. K. Carr for her involvement with this case.

CASE REPORT

Hodgkin's lymphoma in a patient with Jo-1 syndrome

Alexander C. Adam · Christian Grohé · Sebastian Stier · Stefan Gattenlöhner · Zeynep Balta · Reinhard Büttner · Ines Gütgemann

Received: 5 January 2007 / Revised: 5 April 2007 / Accepted: 30 April 2007 / Published online: 24 May 2007

Abstract Jo-1 syndrome is an autoimmune disease with autoantibodies against the histidyl tRNA synthetase. Characteristic clinical findings include inflammatory myopathy and interstitial lung disease. We present the first case of a patient with Jo-1 syndrome (positive Jo-1 autoantibodies, myositis, interstitial alveolitis) who developed Hodgkin's lymphoma of nodular-sclerosing type. Thus, patients with Jo-1 syndrome and immunosuppressive therapy similar to other patients with autoimmune disease are at risk to develop lymphomas and should therefore be monitored carefully.

Introduction

Patients with autoimmune disease have been suspected to develop malignancies with increased frequency. In particular, an association of non-Hodgkin lymphoma in patients with systemic lupus erythematosus, rheumatoid arthritis and primary Sjögren syndrome has been demonstrated. Reports about malignancies associated with anti-tRNA-synthetase autoimmune diseases are very rare. In Jo-1 syndrome, patients present with myopathy, interstitial pulmonary fibrosis and arthritis. Antibodies against the histidyl tRNA synthetase are diagnostic. In this paper, we report the first case of a patient with Jo-1 syndrome who developed Hodgkin's lymphoma.

Clinical history

A 47-year-old male patient presented with myalgia, exertional dyspnea (pO_2 40 mmHg), fatigue and a generalised erythema, predominantly affecting the proximal lower limbs and the face. Electromyography was normal, and biochemical myositis markers such as LDH [max. 565 U/l (104–248 U/l)] and creatine kinase [max. 334 U/l (<80 U/l)] were elevated. A myocardial source for CK elevation was excluded by isotyping and coronary angiography. Computed tomography (CT) scans revealed ground glass pattern opacity of both entire lungs compatible with interstitial lung disease (Fig. 1). Due to respiratory impairment, open lung biopsy was not attempted. Bronchioalveolar fluid analysis revealed a mixed neutrophilic and eosinophilic granulocytosis. Serologic detection of Jo-1- and SS-A-antibodies was finally sufficient to confirm the clinical diagnosis of Jo-1 antisynthetase syndrome. On treatment with corticosteroids and azathioprin, the respiratory symptoms improved. Three years

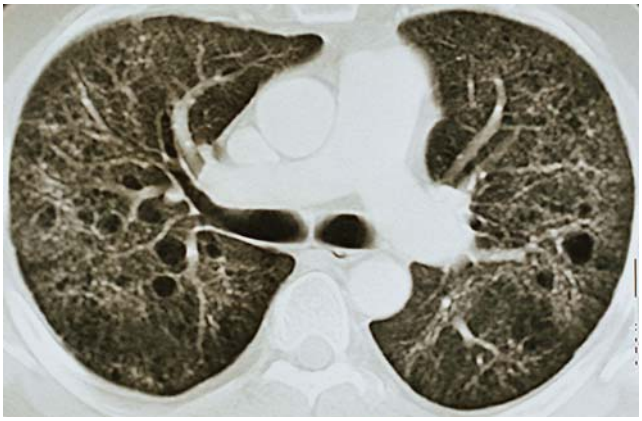

Fig. 1 CT scan of the chest. Both lungs show ground glass pattern opacity, interstitial scaring and bronchiectasis

later, fatigue and dyspnea began to worsen again. Treatment with methotrexate (MTX) failed to improve the clinical symptoms. During the following year, a severe respiratory insufficiency developed, necessitating the regimen to be changed to continuous cyclophosphamide and corticosteroids in a modified Fauci protocol. In addition, 15 courses of plasma apheresis were performed, and the endothelin receptor antagonist bosentan was added to the regimen. The course remained uneventful for the next 14 months. Subsequently, mediastinal lymphadenopathy was discovered by CT scan, and bilateral axillar and supraclavicular enlarged lymph nodes were noted on palpation. Right supraclavicular lymph nodes were removed for histological analysis.

Materials and methods

The study was performed in accordance with the guidelines of the local ethics commission. Histological material was fixed in 4% formalin and embedded in paraffin according to standard procedures. One to two micrometre sections were used for conventional and immunohistochemical staining procedures. The following antibodies were used: CD15 (1:50; Hölzel, Köln, Germany), CD20 (1:1,000; Dako, Hamburg, Germany), CD30 (1:10; Dako), CD3 (1:25; Menarini, Neuss, Germany), Ki67 (1:2,000; Dako), LMP-1 (1:200; Novocastra Laboratories, Newcastle Upon Tyne, UK), PAX5 (1:50; BD Biosciences, Heidelberg, Germany). For antigen retrieval, deparaffinised sections were heated in 10 mM citrate buffer pH 6.0 either for 5 min (LMP1, PAX5), respectively, 10 min (CD15, CD30) at 2 bar using a pressure cooker or for 30 min at boiling temperature in a microwave oven (CD20, CD3, Ki67). Immunohistochemistry was performed with diaminobenzidine as substrate. Epstein–Barr virus (EBV)-encoded RNA (EBER) in situ hybridisation was performed according to the previously published protocol (EBER probe Y-5200, PNA-ISH-detection kit K-5201, Dako) [7]. Slides were counterstained with hematoxylin. For T cell clonality analysis, the receptor gamma-chain was amplified following the standard procedures [5] and analysed using capillary electrophoresis.

Results

Morphology

The lymph node section showed an almost completely destroyed lymph node architecture and a mixed infiltrate consisting of spindle cells, plasma cells, eosinophilic granulocytes and lymphocytes. Classical Hodgkin and Reed–Sternberg cells (HRS) were detected besides sparse lacunar cells. Isolated mitotic figures were visible. The infiltrate was separated by broad bands of fibrosis and extended into the surrounding adipose tissue (Fig. 2a).

Immunohistochemistry and in situ hybridisation

Immunohistochemical staining demonstrated scattered single atypical cells with large prominent bilobed nuclei and nucleoli of the Hodgkin and Reed–Sternberg cell type which were positive for CD15 and CD30 (Fig. 2b, c), as well as for BSAP (PAX5; Fig. 2f) with the typical weaker staining of the HRS cells compared to reactive B cells [9]. CD20 staining was negative. Tumour cells were positive for EBV-related antigens as shown by LMP1 (Fig. 2e) [3]. Likewise, EBER in situ hybridisation (Fig. 2e) indicated prior EBV infection. Anti-CD3 showed diffusely scattered small bland T lymphocytes (not shown). There was up to 30% proliferative activity as detected by anti-Ki-67 staining (not shown).

T cell receptor gamma-chain PCR

The oligoclonal rearrangement pattern of the T cell receptor γ-chain was consistent with Hodgkin lymphoma, thus, confirming the diagnosis of Hodgkin's disease of nodular-sclerosing type.

EBV-specific antibodies

Antibodies directed against the Epstein–Barr viral capsid antigen (VCA) were detected in the serum at the time of diagnosis. Positive IgG and negativ IgM anti-EBV-VCA antibodies indicated a past, not acute, EBV infection.

Discussion

The Jo-1 syndrome belongs to the group of anti-tRNA-synthetase autoimmune diseases. These syndromes are

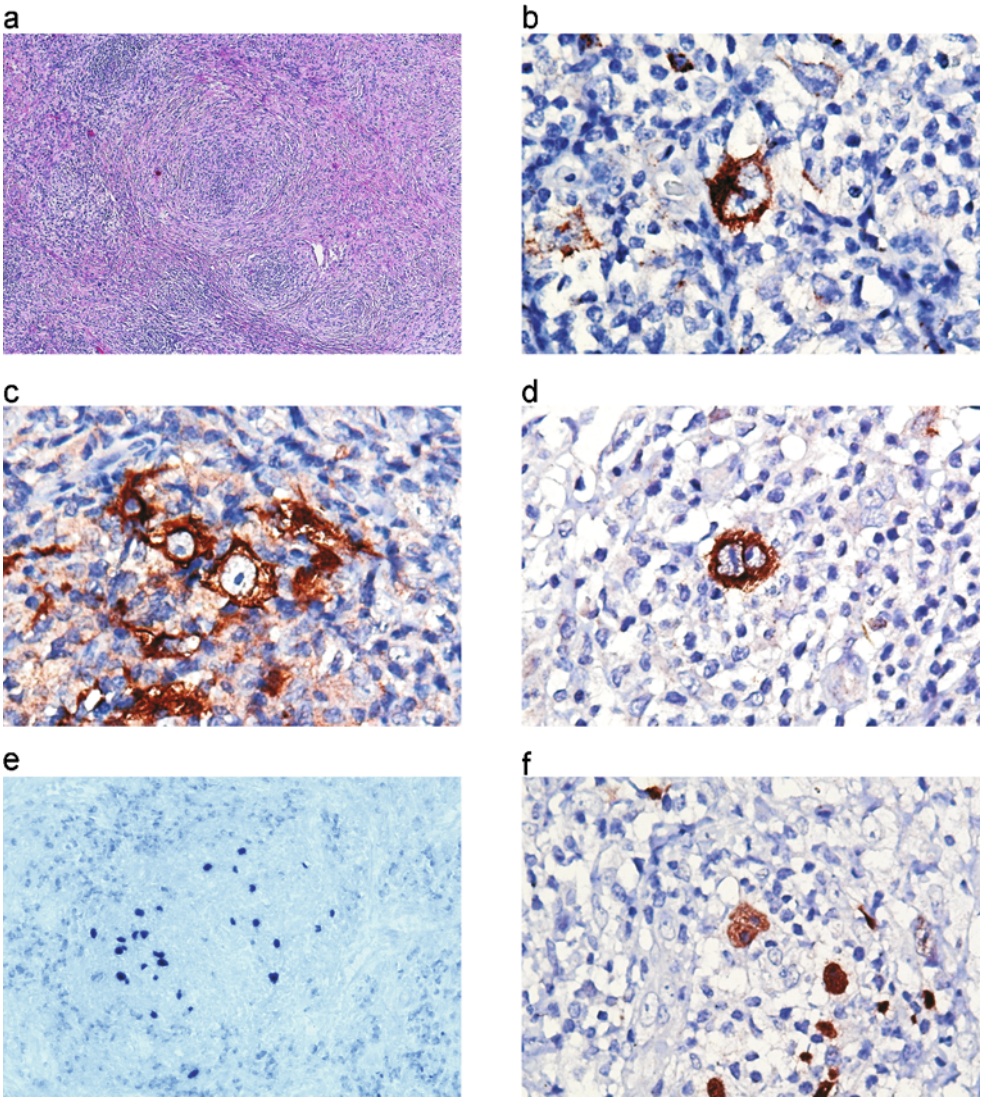

Fig. 2 **a** Hodgkin's disease, nodular-sclerosing type, with effaced lymph node architecture caused by a mixed inflammatory infiltrate consisting of eosinophilic granulocytes, lymphocytes, plasma cells and fibroblasts (HE, 50×). **b** Classical Reed–Sternberg cells expressing CD15 and **c** CD30 in a Golgi-like pattern (DAB, 400×). **d** EBV-associated LMP-1 expression in a RS cell (DAB, 400×). **e** EBER in situ hybridisation (100×). **f** BSAP (PAX5) expression of EBV-infected RS cells (weak staining) and reactive B cells (strong staining; DAB, 400×)

characterised by the presence of antibodies against different types of cytosolic aminoacyl–tRNA synthetases. In Jo-1 syndrome, antibodies against the histidyl tRNA synthetase are present in the serum. Inflammatory myopathy is found in nearly all cases, whereas other frequent clinical signs are interstitial pulmonary fibrosis, arthritis and elevated inflammation parameters [6, 8]. Fever, Raynaud phenomenon, mechanic's hands and carpal canal syndrome can be found in a subset of cases.

We report the first case of Hodgkin's lymphoma occurring in a patient with Jo-1 syndrome.

A linkage between autoimmune myositis and malignancies has frequently been observed. Dermatomyositis seems to be the most often linked entity [1], whereby the cause of this association is still unclear. Association of Jo-1 syndrome and malignancies is very rare. Watkins et al. [10] reported a case of poorly differentiated adenocarcinoma in a patient with Jo-1 antibody syndrome. Iwasaki et al. [4] presented a patient with polymyositis, interstitial pneumonitis and a positive Jo-1 antibody test in association with renal cell carcinoma. In this paper, we report a case of Jo-1 syndrome (Jo-1 autoantibodies, myalgia, interstitial lung disease, erythema) associated with Hodgkin's lymphoma. In our case, Hodgkin's disease was observed 3 years after onset of Jo-1 syndrome, first treated with MTX, and 14 months after intensified immunosuppressive therapy with cyclophosphamide.

Hodgkin's lymphoma in immunocompromised patients is rare and less frequent than B cell lymphomas [11]. But still, there is an elevated prevalence of Hodgkin's disease in immunosuppressed patients, including HIV patients, recipients of solid organ or bone marrow transplantation or patients with autoimmune disease treated with immunosuppressive drugs.

In our patient, Hodgkin's disease might be associated with the long-lasting immunosuppressive therapy rather than caused by the Jo-1 syndrome itself. However, a contribution to the pathogenesis by the underlying autoim-

mune disease is possible. One reason for the coincidence of the autoimmune disease and/or immunosuppressive treatment with lymphoma may be a deviation of the host's immune response leading to a defective immune surveillance to oncogenic viruses like EBV [2]. Interestingly, in our case, prior EBV infection could be demonstrated serologically by anti-EBV-VCA IgG type antibodies by positive LMP-1 immunostaining and EBER in situ hybridisation in the lymphoma cells.

Clearly, additional examples of occurrence of Jo-1 syndrome and malignant lymphomas need to be analysed to prove a significant association and study of mechanisms.

Acknowledgments We thank Prof. Hans H. Schild, director of the Department of Radiology, University of Bonn, for providing the CT scan image.

LETTER TO THE EDITOR

Over-estimation of radiation-induced malignancy after the Chernobyl accident

Sergei V. Jargin

Received: 11 April 2007 / Accepted: 25 April 2007 / Published online: 11 May 2007

Dear Editor,

The article by Romanenko et al. published in Virchows Archiv [6] is based on the study of renal tumours from the Chernobyl area and Kiev. Alterations of extracellular matrix (ECM) in renal cell carcinoma are reported. The main conclusion is that long-term low-dose ionising radiation (IR) "can promote malignant tumour progression" through the following mechanism: "significantly disrupted ECM with a lack of orchestrated communication between cells and between cells and ECM that leads to loss of cellular differentiation". It should be noted that the term "low-dose IR" would be relevant if radioactivity were counted from zero, but in fact it is a question of a minor increase of doses obtained due to the natural radiation background. Patients from contaminated areas around Chernobyl and Kiev are united in one group, although radioactivity in Kiev was elevated insignificantly [1], which can give rise to reasoning about radiation-induced malignancy in Kiev.

On the basis of limited material (contaminated area plus Kiev, 41 patients; control, 37 patients), statistically significant differences were found for 4 parameters: immunohistochemical expression of fibronectin, laminin, β-catenin and TGF-β1 (P values are 0.05, 0.008, 0.003 and 0.01, respectively); the integral level of statistical significance being very high for a medical study. At the same time, majority if not all tumours should have been spontaneous because cancer incidence (except for thyroid carcinoma) remained in the contaminated area within statistical error in agreement with the increase rate for Russia in general [2, 5]. The male/female ratio=27/14, approximately the same as for renal cell carcinoma in the general population, provides additional evidence in favour of spontaneous origin. The main features of spontaneous tumours must be on average the same as in the control group. Besides, comparison between the group from the contaminated zone plus Kiev and the control is performed without standardisation after the tumour grade: more than 50% of cases in the first group belong to poorly differentiated carcinoma (G3–G4), whereas in the control there is only 1 G3 case, all others being G1–G2. Without representative statistics about tumour grading, reported data can be misleading, making an impression that renal carcinoma in the contaminated areas and Kiev is on average less differentiated than in the general population. Reported differences between the groups could have been caused by differences in differentiation grade, which in its turn could have resulted from non-random case selection. In previous publications [3, 4], we criticised other studies by Romanenko et al. For further details, visit http://www.freewebs.com/ruspat1/

LETTER TO THE EDITOR

Response from authors of "Extracellular matrix alterations in conventional renal cell carcinomas by tissue microarray profiling influenced by the persistent, long-term, low-dose ionizing radiation exposure in humans"

Alina Romanenko · Luisa Morell-Quadreny · David Ramos · Valentin Nepomnyaschiy · Alexander Vozianov · Antonio Llombart-Bosch

Received: 13 May 2007 / Accepted: 1 June 2007 / Published online: 28 June 2007

The Chernobyl accident introduced for the first time the problem of chronic, persistent, long-term, low-dose exposure to ionizing radiation (IR) in humans. Currently, 21 years after the accident at the Chernobyl Power Plant in Ukraine (70 Km from Kiev), approximately 17 million people live in the radiocontaminated area and have been exposed to low-dose IR. Information regarding irradiation of the Ukrainian population is based on the official reports provided by the Ukrainian Government and the Ukrainian Academy of Medical Sciences. Morbidity of malignant renal tumors in adults during the period 1986–2006 increased from 4.7 to 9.9 per 100,000 of total population (from 6.0 to 12.6 per 100,000 of the male population and from 3.6 to 7.5 per 100,000 of the female population in Ukraine) [4].

The scientific collaboration between the Institute of Urology, the Academy of Medical Sciences in Kiev (Ukraine) and the Department of Pathology of the Valencia University in Spain has been in operation for approximately 9 years already. Recent studies by our group have shown that during the period subsequent to the Chernobyl accident, increases in morbidity, aggressivity, and proliferative activity of renal-cell carcinomas (RCCs) in Ukrainian patients were recognized [2]. At the beginning of our study, we did separate patients with RCCs from the city of Kiev and patients with RCCs from radiocontaminated areas. Our recent studies have shown that RCCs (their histological and molecular biological features) of both these groups were identical (it is therefore not necessary to distinguish them); however, they significantly differ from the analogous tumors from clean (without radio-contamination) areas of Ukraine as well as the Spanish RCCs.

It must be noted that the tumors (RCCs) were randomly selected (successive cases) from the laboratories of Kiev and Valencia. No one doubts the spontaneous origin of these RCCs in both geographical areas. The main differences are not in reference to their origin but to their biological, histological, and clinical behavior, which is clearly more aggressive in the Ukrainian population in comparison with the Valencian cases. Furthermore, "chronic low-dose irradiation toxicity" (CLDIT) exerts its effect as a cocarcinogen or within a pluri-carcinogenetic context. We have never proposed that CLDIT was the only cause of this cancer.

The development of "radiation sclerosing proliferative atypical nephropathy" in the peritumoral kidney tissue then followed and demonstrated a good correlation with the duration of radiation exposure [3]. In addition, the influence of chronic, regular, and sustained low-dose IR on renal carcinogenesis in the population living in Cesium 137-contaminated areas of Ukraine has been confirmed [2].

There is no dose–response relationship in the range 2–12 Gy, suggesting that an unstable phenotype may be induced by quite low radiation doses [1]. Moreover, the "bystander" or nontargeted effects of very low doses of IR were recently described as important genetic consequences of IR, which may arise in cells that in themselves received no direct nuclear exposure [1]. Thus, the actual target for radiation effect in a cell population may be much larger than the irradiated cell itself [5].

Research during the last decade has focused on cellular and molecular mechanisms for the effects of low-level IR in mammalian cells as well as in mammalian carcinogenesis. Our group follows the same scientific direction.

LETTER TO THE EDITOR

TTF-1 staining in glioblastoma multiforme

Malcolm Galloway · Rosalind Sim

Received: 1 March 2007 / Revised: 30 April 2007 / Accepted: 5 May 2007 / Published online: 12 June 2007

Dear Editor,

Agaimy and Wunsch recently reported potentially misleading thyroid transcription factor 1 (TTF-1) immunoreactivity in a primary ovarian malignant mullerian mixed tumour [1]. This is one of several recent papers highlighting the danger of relying on TTF-1 expression in isolation as a marker of either lung or thyroid origin for a malignant tumour. Comperat et al. reported that 5% of primary colorectal adenocarcinomas expressed TTF-1 when assessed with Novocastra's SPT24 clone [2]. Penman et al. also found that the SPT24 but not the 8G7G1 TTF-1 clone showed nuclear positivity in some colorectal adenocarcinomas [3].

We would like to highlight the observation that immunocytochemical TTF-1 positivity may be found in glioblastoma multiforme, which to our knowledge has not previously been reported. Usually, the distinction between glioblastoma multiforme and metastatic carcinoma is relatively easy to make on morphological grounds; however, there are some cases in which the tumour is poorly differentiated, and for such cases, immunocytochemistry may be of value in making this distinction.

Following our observation in routine diagnostic practice of two cases of glioblastoma which showed positivity with antibodies to the SPT24 clone of TTF-1 (Fig. 1), a further 26 cases of glioblastoma multiforme and one case of gliosarcoma were assessed. In all cases, there were morphological, immunocytochemical, radiological and clinical features supporting the diagnosis of glioblastoma, and none had any evidence of metastatic disease or of any pre-existing lower grade cerebral neoplasm.

Immunocytochemical staining for the SPT24 (Novocastra) and 8G7G3/1 (Dako) TTF-1 clones, MNF116, CK7, CK20 and glial fibrillary acidic protein (GFAP) was performed in all cases. Staining for the TTF-1 clone SPT24 (Novocastra) was performed with 2 min of pressure cooking pretreatment in 2 l of 10 mM citrate buffer at pH 6.0. The primary antibody was diluted at 1:100 and incubated for one hour at room temperature. Standard ABC method was performed using Vector's RTU Universal Elite ABC kit PKY200. The staining was developed for 10 min in diaminobenzidine. The technique for TTF-1 clone 8G7G3/1 (Dako) immunocytochemistry was identical, other than that the primary antibody was diluted at 1:50. To calculate percentages of positive cells, at least 500 presumed neoplastic nuclei per case were counted from the areas in which staining appeared most abundant.

In total, fourteen glioblastomas (50%) showed some degree of nuclear positivity when stained with the SPT24 TTF-1 clone. This staining was patchy and variable between cases (ranging from 0.1 to 62.2% of nuclei). Nuclear positivity was seen in under 2% of cells in seven cases, between 2 and 10% of cells in three cases, and over 30% of cells in the other four cases. Positive neoplastic nuclei were not detected in the other fourteen cases of glioblastoma or in the gliosarcoma. All cases were negative when stained with the 8G7G3/1 TTF-1 clone. Staining for GFAP was positive in the cytoplasm of at least a proportion of the neoplastic cells in all cases. MNF-116 and cytokeratin 20 staining was negative in all cases. Cytokeratin 7 staining was negative in all cases of glioblastoma, but showed focal positivity in the spindle cell element of the gliosarcoma.

M. Galloway (✉) · R. Sim
Department of Histopathology, Royal Free Hospital,
London, UK
e-mail: malcolm.galloway@royalfree.nhs.uk

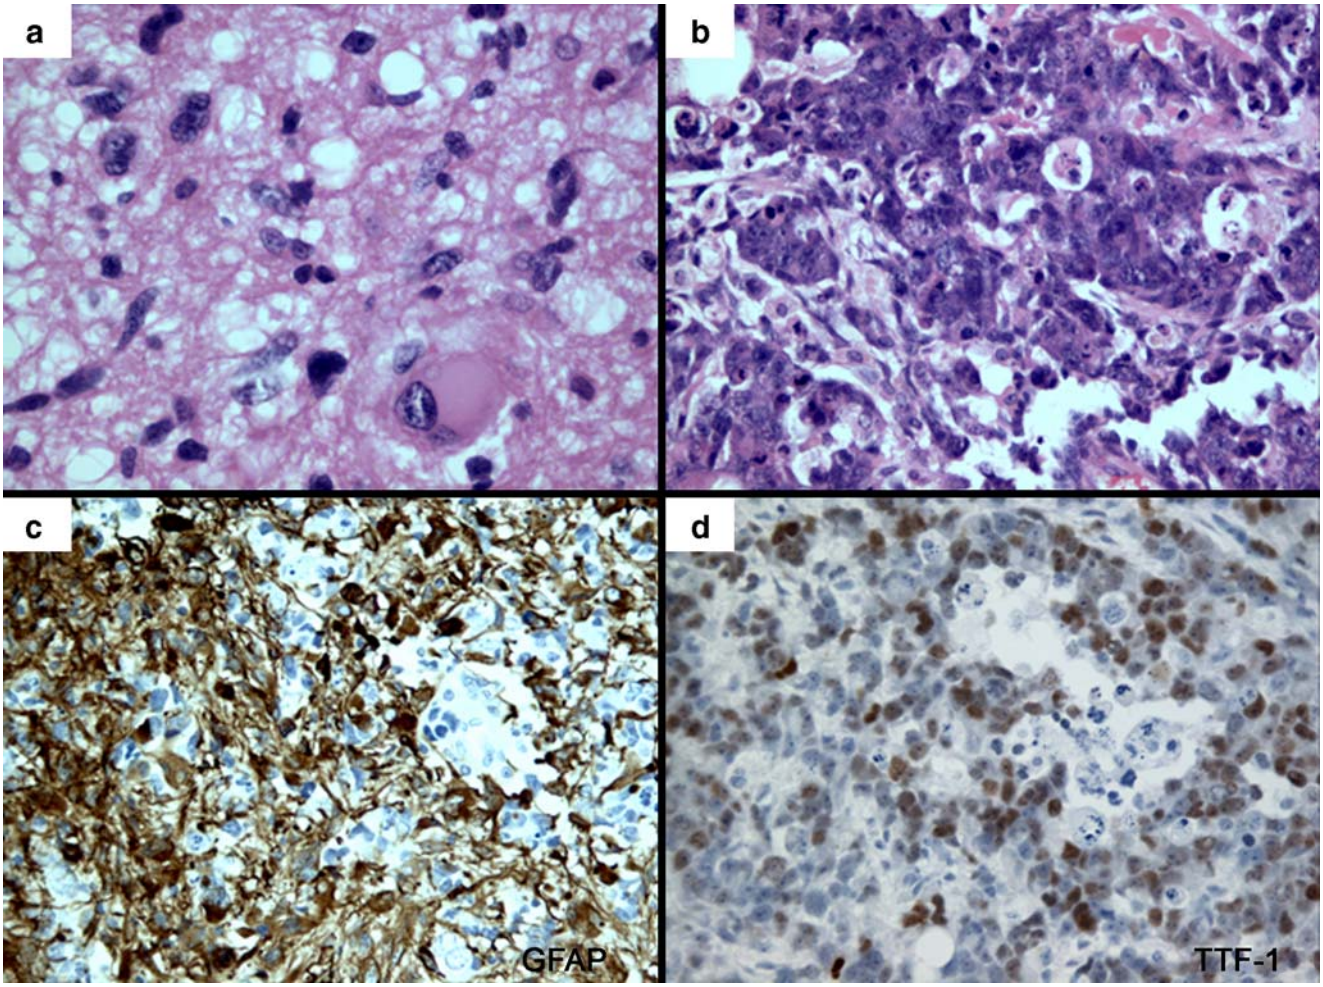

Fig. 1 Photomicrographs of the tumour from the first patient in whom we had noted TTF-1 positivity. The patient is an elderly man with glioblastoma multiforme (WHO grade IV) involving the temporal lobe. Mitotic activity, necrosis and vascular endothelial hyperplasia were present. **a** An area of tumour with typical glioblastoma multiforme morphology. **b** In this area the neoplastic cells are cohesive, poorly differentiated, and resemble metastatic carcinoma. **c** Many of the neoplastic cells are GFAP-positive. **d** There is widespread nuclear positivity with SPT-24 clone of TTF-1

It is unclear whether the TTF-1 positivity with Novocastra's SPT24 TTF-1 clone seen in a high proportion of cases of glioblastoma reflects cross-reactivity or whether this clone is detecting genuine expression of TTF-1 of uncertain significance. It is known that TTF-1 is expressed during development in areas of the basal forebrain; however, a previous study that examined TTF-1 expression in 73 primary brain tumours (including astrocytomas, glioblastomaa, ependymomas, oligodendrogliomas, medulloblastomas, and gangliogliomas) with clone 8G7G3/1 only showed positivity in two ependymomas of the third ventricle [4]. It is of interest that a recent study assessing the value of TTF-1 staining in identifying brain metastases of pulmonary origin using the 8G7G3/1 TTF-1 antibody found no positivity in 50 glioblastomas, but the SPT24 clone was not assessed in this study [5] (the antibody clone used has been confirmed via personal communication with Dr. Prayson).

These cases highlight the danger of misleading results when using TTF-1 clone SPT24 in the diagnosis of brain tumours. Although TTF-1 nuclear positivity in metastatic carcinoma of the lung is usually more widespread than was seen in our cases of glioblastoma, it should be noted that some cases of carcinoma of the lung express TTF-1 in only a minority of the neoplastic nuclei [5]. Focal nuclear positivity was seen in 50% of our series of glioblastomas, and to avoid the risk of diagnostic confusion, we suggest that the 8G7G3/1 clone may be more suitable than the SPT24 clone for use in diagnostic neuropathological practice.

THE ACCURACY OF IMPRINT CYTOLOGY OF SENTINEL LYMPH NODE IN BREAST CANCER: AN ANALYSIS OF CAUSES OF DISCREPANCIES

Peir-In Liang[1], Ming-Yuan Lee[1], Ben-Long Yu[2], Chii-Ming Chen[2], Dong-Ling You[3], Christopher K-J Lin[4]
[1] Department of Pathology and Laboratory Services, Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan
[2] Department of General Surgery, Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan
[3] Department of Nuclear Medicine, Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan
[4] Department of Radiology, Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan

Background: Axillary lymph node status in breast cancer provides important information for staging, prognosis, and decision making for adjuvant therapy. However, less than half of the patients are likely to derive therapeutic benefit from complete axillary lymph node dissection (ALND), and most of them may suffer from chronic morbidity after the procedure. Intraoperative evaluation of axillary sentinel lymph node (SLN) provides information of status of regional lymph nodes, and may prevent ALND if SLN is negative. Touch imprint cytology (TIC) is a rapid and effective method without sacrifying valuable tissue. The aim of this study is to clarify the possible causes of the discrepancy between TIC and histopathology results. Method: A total of 1455 SLNs from 574 patients with breast cancer during the period of May 2002 to July 2006 were reviewed. The SLNs were detected either by isotope or blue dye method. The fresh lymph nodes were rapidly stained with Hematoxylin and Eosin (H&E) and examined immediately. The specimen then underwent standard histopathological processing. At least 3 levels of routine H&E-stained sections and one level for pankeratin immunostaining were obtained. Intraoperative TIC results were correlated with final histopathology results. Cases with discrepancy between TIC and permanent sections were reviewed by experienced cytopathologist. Results: The sensitivity, specificity, negative predictive value and accuracy were 57.1%, 98.7%, 94.6%, and 93.8%, respectively. Among 17 false positive cases, 9 were interpretation errors and 4 were due to tumor cells exhausted in processing. Four cases were contaminated during the process. Sampling error was the major cause in false negative cases (54/73; 74%). The remaining 19 cases were interpretation error. The median size of metastatic focus in false negative cases with interpretation error and with sampling error was 2.30mm and 1.05mm, respectively (p=0.0004). Conclusion: Sampling error is the major cause of discrepancy in false negative cases and their metastatic foci are smaller compared with those with interpretation error. Contamination may cause false positive in benign lymph nodes, and patients will undergo unnecessary ALND. More caution should be paid in order to prevent interpretation error and contamination.

THE VALUE OF FLUORESCENCE IN SITU HYBRIDISATION (FISH) IN THE DIAGNOSIS AND FOLLOW UP OF THE TRANSITIONAL CELL CARCINOMA

Ignat Schwartz, Eddie Fridman, Sylvie Polack-Sharcon, Jury Kopolovic
Departement of Pathology, Sheba Medical Center, Tel-Hashomer, Israel

Introduction: Transitional cell carcinoma (TCC) comprises about 90% of the urinary bladder tumors with about 50% recurrences. All of the nowadays diagnostic techniques are limited by low sensitivity. Therefore, it's very important to find highly sensitive diagnostic clues for early detection of TCC. Fluorescence In Situ Hybridisation (FISH) is a high sensitive technique, providing rapid examination of cytogenetic abnormalities in urothelial cells even in the early stage of their neoplastic transformation. Since February 2005 the UroVysiov Kit was FDA approved for using as for diagnostic purpose for primary tumors, as well as for follow up of the patients with TCC . The kit is multicolor and multitarget, providing visualization of the cytogenetic rearrangements in the chromosomes 17, 3 and 7 and in the Locus-Specific Gene 9P21 (Tumor Suppressor Gene). The aim of the study is to check correlation between the results of FISH for both diagnostic and follow up purposes of TCC patients, with the results of conventional urine cytology and urinary bladder biopsies. Results: 67 urine samples from the patients with primary TCC or suspected for recurrence were examined using FISH UroVysiov Kit. The distribution of the cases according to cytological findings and the results of FISH are represented in the table 1 (The distribution of the cases according the results of cytology and FISH). Cystoscopic diagnostic biopsies were also performed in about of 40 cases and the results are represented in the table 2 (The correlation between suspected and/or malignant cases by cytology and FISH with histological findings). It's important to emphasize that in all 17 cases which were diagnosed as malignant by cytology, correlation with results of FISH was 100%. In the cases which were diagnosed as malignant by the biopsy, the correlation with FISH was 94%. Conclusion: UroVysion FISH assay is an easy and rapid technique, providing more specify and sensitivity for the conventional urine cytology for the diagnosis and follow up of the patients with TCC with high correlation rate with cytology and histology (94%). So, in the borderline cases by cytology, use of UroVysion FISH assay is recommended.

OP1-3

CYTOPATHOLOGIC DIFFERENTIAL DIAGNOSIS OF MALIGNANT MESOTHELIOMA, ADENOCARCINOMA AND REACTIVE MESOTHELIAL CELLS: A LOGISTIC REGRESSION ANALYSIS

Ebru Cakir[1], Funda Demirag[1], Mehtap Aydin[1], Ebru Unsal[2]
[1] Ankara Ataturk Chest Disease and Chest Surgery Education and Research Hospital Department of Pathology, Turkey
[2] Ankara Ataturk Chest Disease and Chest Surgery Education and Research Hospital Department of Chest Disease, Turkey

Background: Distinguishing malignant mesothelioma, adenocarcinoma and reactive mesothelial proliferation in both cytologic and surgical pathologic specimens is diffucult despite the application of new diagnostic techniques. Traditional cytomorphologic criteria are still important in the differential diagnosis of these entities. Method: The pleural effusion cytologies from 40 cases of malignant mesothelioma, 40 cases of adenocarcinoma and 30 cases of reactive mesothelial proliferation diagnosed at Ankara Ataturk Chest Disease and Chest Surgery Education and Research Hospital during 1997-2007 were reviewed. 27 cytologic features which are regarded as useful in the differential diagnosis of mesothelioma, adenocarcinoma and benign mesothelial proliferation were assessed. These cytologic features were subjected to a stepwise logistic regression analysis. Results: Three features were selected to distinguish malignant mesothelioma from adenocarcinoma: giant atypical mesothelial cell, nuclear pleomorphism and acinary structures, the latter two being characteristics of adenocarcinoma. The other variables selected to differentiate malignant mesothelioma from reactive mesothelial cells were: cell ball formation, cell in cell engulfment and monolayer cell groups, the latter being a feature of benign proliferations. When these selected variables were used the logistic model correctly predicted %90 of cases of benign mesothelial proliferation versus %97.5 of malignant mesothelioma and %92.5 of malignant mesothelioma versus %92.5 of adenocarcinoma. Conclusion: Conventional cytomorphologic assessment is the first step to establish an accurate diagnosis in pleural effusions. Several cytologic features are of predictive value in seperating malignant mesothelioma from adenocarcinoma and reactive mesothelial proliferations.

OP1-4

PULMONARY BRONCHIOLOALVEOLAR CARCINOMA. REVIEW OF 43 CASES OF CYTOLOGICAL DIAGNOSIS

M. Carme Dinares, Vicente Peg, M. Teresa Salcedo, Nieves Medina, Carmela Iglesias, Montse Ochoa, Marta Serra, Santiago Ramon Y Cajal, Natalia Tallada
Pathology Department. Hospital Vall d'Hebron. Barcelona, Spain

Background: Bronchioloalveolar carcinoma (BAC) represents a clinic, radiological and pathologic entity of malignant pulmonary carcinomas. It has got a well known biologic behaviour, an established treatment and a good prognosis, compared with other subtypes of non-small-cell lung carcinoma. Cytological study is an useful and an invasive method in the diagnostic practice. We propose a cytological review and immunohistochemical (IHC) analysis of these tumours. Material And Methods: We collected 43 cases from 1983 until 2007, diagnosed by cytological analysis. Samples were obtained from fine needle aspiration (FNA), sputum, bronchial washing and bronchoalveolar lavage. We evaluated 13 morphologic parameters. We performed IHC techniques (p53, MUC 1, MUC-5 and CK20) on 15 of 30 cases with available cell block, or histological samples, evaluating intensity of staining and percentage of positive cells. Results: 57% of cases presented high cellularity and 43% mucinous and haematic background. Cells were arranged in flat sheets or 3-dimensional clusters. Nuclei were eccentric with nucleoli and grooves (62%) and inclusions (45%). We observed neither mitosis figures (10%) nor high grade atypia. Cytoplasm were cylindrical and clear in mucinous BACs and polygonal and dense in non mucinous BACs. Psammoma bodies were found in 24% of cases. As IHC study is concerned, 67% showed weak staining of p53, 67% of cases expressed MUC-1, MUC-5 was not valuable. CK20 was only positive in the 2 mucinous BAC cases. Discussion: BAC represents 4% of pulmonary tumours, with predilection for non-smokers women. These tumours grow along the alveolar septae without evidence of stromal invasion. Two histological subtypes exist: mucinous and non-mucinous. The differential diagnosis must be made with bronchial hyperplasia, conventional adenocarcinoma or metastasis. Cytological characteristics (highly mucinous material and mucosecretor cells) allow to identify mucinous type (31% of cases in our series). Non mucinous type was diagnosed as well differentiated adenocarcinoma because the absence of specific features. The IHC profile obtained was according with the literature data and could be useful for the diagnosis of this entity.

OP1-5

ENTROPY OF THE CHROMATIN TEXTURE IN ROUTINELY STAINED CYTOLOGY IS A PROGNOSTIC FACTOR IN ACUTE LYMPHOBLASTIC LEUKEMIA

Konradin Metze[1], Mariana R B De Mello[2], Randall L Adam[3], Neucimar J Leite[3], Irene G H Lorand-Metze[4]
[1] Department of Pathology, Faculty of Medicine, State University of Campinas (UNICAMP), Campinas, Brazil
[2] HEMOPE Foundation, Recife, Brazil
[3] Institute of Computing, State University of Campinas (UNICAMP), Campinas, Brazil
[4] Department of Medicine, Faculty of Medicine, State University of Campinas (UNICAMP), Campinas, Brazil

Background: Age, peripheral leukocyte number at diagnosis, and specific cytogenetic abnormalities are well known risk factors in acute lymphoblastic leukemia (ALL). Recently it has been shown that nuclear texture in Giemsa-stained smears reflects the DNA methylation pattern. Entropy derived from the gray level co-occurrence matrix is a measure of heterogeneity of an image and therefore may be used for the objective description of the chromatin texture of nuclei in cytologic smears. The aim of this study was to evaluate the prognostic value of the gray-level histogram entropy measured in cytologic smears of patients with B-ALL. Material and Methods: In newly diagnosed patients with B- ALL of two institutions, clinical and laboratory data, as well as those of quantitative flow cytometric analysis were obtained. Routinely May-Grünwald -Giemsa stained smears from diagnostic bone marrow aspirates were digitalized (100 objective magnification), and 100 randomly selected nuclei analyzed. Shannon´s entropy of the gray level histogram was calculated for each nucleus. Overall survival was evaluated using uni- and multivariate Cox proportional hazard models stratified for therapy. Results: 66 patients entered the study with a mean age of 32.3 years (range 2 - 74 years) and a mean peripheral blood leukocyte count of 50.0 billion /l (range 0.6 billion/l – 300.0 billion/l). There were no significant correlations between the entropy values of the chromatin texture and age or leukocyte count of the patients. In the univariate analyses, higher entropy values were an unfavorable prognostic factor ($p=0.0045$) as well as age ($p=0.001$) and the logarithmated peripheral leukocyte count ($p=0.028$). In the multivariate Cox analysis all three variables remained independent prognostic factors. Conclusions: The present study demonstrates that subtle alterations of the chromatin structure, not detectable by an observer, but measured objectively by the entropy values of the gray level histogram of routinely stained bone marrow smears provide important additional prognostic information. Increased heterogeneity of the chromatin structure is associated with higher risk and may reflect a different methylation pattern as well as genetic modifications.

OP1-6

IMMUNOHISTOCHEMICAL EXPRESSION OF GALECTIN-3, CYTOKERATIN 19 AND P27 IN CYTOHISTOLOGICAL DIAGNOSIS OF THE THYROID NODULES

Ruth Orellana Fernández, MR Bella, N Combalia, S Fernández, G Giménez, A Casalots, MR Escoda, M Rey
Pathology Dep UDIAT-CD and Endocrinology Dep. Corporació Parc Taulí, Sabadell, Barcelona, Spain

Introduction: Fine-needle aspiration(FNA) is a well established diagnostic technique for the preoperative approach of the solitary or dominant thyroid nodule. The different thyroid lesions can be displayed like nodules, representing different entities with different antigen expression. Aim: To evaluate the diagnostic value of the immunohistochemical markers: cytokeratin-19(CK19), Galectin-3(Gal-3) and p27, we correlate their expression in the material of cell block with respect to surgical specimen and to validate their preoperative value. We investigate whether the differences in antigen expression could be improve the accuracy of conventional FNA and provide the histological diagnosis Material and method: Immunohistochemical analysis was performed on 91 thyroid specimens (24 nodular hyperplasias-NH-, 28 follicular adenomas-FA-, 16 follicular carcinomas-FC- and 23 papillary carcinomas-PC-) from selected patients with thyroid nodules and their preoperative cytological samples. We analysed CK19(b170), Gal-3(9C4) and p27(1B4) expressions in both cell block and their histological counterparts, using semi quantitative valuation. Results: The immunohistochemical expression was: in 24 NH: Gal-3 in 12,5% histological samples (hs)/4,16% cytological samples (cs); CK19 in 16,66% hs/4,16% cs; p27 in 58,33% hs/50% cs; in 28 FA: Gal-3 in 7,14% hs/3,57% cs; CK19 in 17,85% hs/3,57% cs; p27 in 64,28% hs/50% cs; in 16 FC: Gal-3 in 25% hs/18,75% cs; CK19 in 18,75% hs/31,25% cs; p27 in 43,75% hs/43,75% cs; in 23 PC: Gal-3 in 82,6% hs/78,26% cs; CK19 in 91,30% hs/78,26% cs; p27 in 21,73% hs/4,34% cs. Conclusions: Our findings show that Gal-3($p<0.001$) and CK19($p<0.001$) are useful to differentiate follicular variant of classic CP from other thyroid lesions, in both cell block and surgical specimen. A tendency to express p27 was observed in benign thyroid lesions. However, heterogeneous positive pattern expression is not useful for preoperative diagnosis of conventional cytology. Gal-3 does not discriminate between benign follicular lesions (FA) and their malignant counterpart (FC). The data presented indicate that Gal-3 and CK19 are reliable presurgical molecular markers allowing a better selection of patients requiring surgery.

OP1-7

A COMPARISON OF FINE NEEDLE ASPIRATION CYTOLOGY AND CORE BIOPSY IN THE DIAGNOSIS OF BREAST MASSES

Rengin Ahiskali[1], Zeynep Tosuner[1], Burcu Tuzuner[1], Handan Kaya[1], Bahadir Gulluoglu[2], Erkin Aribal[3]
[1] Marmara University School of Medicine, Department of Pathology, Istanbul, Turkey
[2] Marmara University School of Medicine, Department of Surgery, Istanbul, Turkey
[3] Marmara University School of Medicine, Department of Radiology, Istanbul, Turkey

BACKGROUND: Fine needle aspiration cytology (FNAC) is a fast, cost-effective and reliable method of diagnosing clinically suspicious breast masses. In the recent years, some studies reported that core biopsy (CB) has a higher rate of adequacy and a higher accuracy compared to FNAC and proposed CB as the first step of evaluating breast lesions. METHOD: We reviewed a total of 522 FNAC and 331 CB samples performed in our institution from the years 2000-2006. Either FNAC or CB were obtained from patients. Material adequacy was evaluated on site with modified toluidine blue stained wet films during fine needle aspiration procedure and aspiration was repeated if the sample was found to be inadequate. Although samples obtained with both methods had specific diagnoses in the original reports, for sake of comparison, diagnoses were classified into malignant, benign, suspicious, inadequate, less than optimal but benign categories. FNAC and CB diagnoses were compared with those of the corresponding resection materials, if available. RESULTS:Invasive carcinoma was reported in 153(29%) of FNAC and in 67(20%) of CB samples. FNAC had a high inadequacy rate (12%), while CB had none. All of the acellular/hypocellular FNAC samples were found to be inadequate during on-site evaluation. The majority of these were cyst contents with no or sparse epithelial cells, a minor group was fibrotic/schirrous lesions that did not yield enough diagnostic cells. Cystic lesions were not sampled by CB. Suspicious category was remarkably low (<1%) when compared to other reported series of FNAC. When the FNAC and CB diagnoses were compared to those of corresponding excision materials, the sensitivity of FNAC was 92%, and that of CB was 97%. Both methods had a specificity of 100%. CONCLUSION: FNAC is a highly accurate method for the diagnosis of suspicious breast lesions. On-site evaluation is important to guarantee material adequacy. When cysts are excluded, FNAC has a comparable adequacy rate to CB, with the exception of fibrotic lesions. Regarding its reliability, ease and speed of use, we suggest FNAC as the first step of evaluating the majority of suspicious breast masses. CB should be the preferred method for the diagnosis of fibrotic/schirrous lesions.

OP1-8

URINE CYTOLOGY FOR THE IDENTIFICATION OF INCLUSION BEARING "DECOY CELLS": THE INCREASED SHEDDING OF CLUMPED DECOY CELL VARIANTS IDENTIFIES PATIENTS AT VERY HIGH RISK FOR POLYOMAVIRUS ALLOGRAFT NEPHROPATHY

S. Singh, R. Detwiler, K. Andreoni, V. Nickeleit
The University of North Carolina at Chapel Hill, Dep. of Pathology, USA

BACKGROUND: The risk assessment of renal allograft recipients for the development of polyomavirus allograft nephropathy (PVN) includes the detection and quantitation of polyomavirus intranuclear inclusion bearing decoy cells (DC) by urine cytology. Greater than 10 decoy cells per ThinPrep slide have a positive predictive value for PVN of 27%. Different DC phenotypes can be recognized at the light and electron microscopic level: Type 1 (classic variant with ground glass type inclusions) and Types 2-4 (cells with various irregular and clumped intranuclear inclusions). AIMS: 1) to evaluate potential differences in the shedding of different DC phenotypes in patients with biopsy proven PVN versus patients with no diagnosis of PVN (i.e. non-diseased viral activators); 2) to study changes in the shedding of different DC phenotypes over time in patients with persistent PVN; 3) to correlate differences in the shedding of various DC phenotypes with the histologic stages of PVN (A-early; B-florid; C-sclerosing). DESIGN: 102 urine samples from 14 patients with biopsy proven PVN and 57 urine samples from 34 patients with asymptomatic viral activation and no PVN were retrospectively reviewed (ThinPrep slides, Papanicolaou stain, count of DC types 1-4 per slide). Per definition, all urine samples showed a total of ≥10 decoy cells/ThinPrep slide with no significant differences in the total DC numbers between patients with PVN (median: 36; range: 10-318) and without PVN (median: 31; range:10-150). RESULTS: Shedding of DC phenotypes 2-4 was significantly increased in the PVN patient group at time of initial diagnosis versus asymptomatic viral activators without PVN (DC phenotypes 2-4: PVN group = 5 cells (median), 31% of total DC count per slide, range = 3-70%; group with viral activation and no PVN= 0 cells (median), 3% of total DC count per slide, range = 0-32%; $p<0.002$). Shedding of DC phenotypes 2-4 remained increased over time during persistent PVN. It was already detected in 28 urine samples from 10 patients with PVN up to 8 weeks prior to the initial biopsy diagnosis. The shedding of increased numbers of DC phenotypes 2-4 did not correlate with the histologic disease stages of PVN (stage A: n = 8 patients; stage B: n=5 patients; stage C: n=1 patient). CONCLUSION: increased numbers of DC phenotypes 2-4 (accounting for ≥25% of the total DC number per slide) in voided urine specimens from renal allograft recipients indicate a high risk level for PVN (= "presumptive PVN"; positive predictive diagnostic value for PVN of > 75%).

OP1-9

FNA CYTOLOGY OF PRIMITIVE NEUROECTODERMAL TUMORS

Yuri Batoroev
Irkutsk Oncology Hospital, Russia

OBJECTIVE: Primitive neuroectodermal tumors/extraskeletal Ewing's sarcoma is a round/small-cell tumor that manifests most commonly in the paravertebral and pelvic regions/ It occurs predominantly in adolescents and young adults, and follows an aggressive course with a high recurrence. Fine-needle aspiration (FNA) is a diagnostic technique, especially effective with the help of immunocytochemical (ICC) and ultrastructural studies on the FNA material. MATERIAL&METHODS: Fine-needle aspiration biopsy specimens from 11 histologically proven cases of extraskeletal Ewing's sarcoma were studied by both light microscopy, immunocyto/histochemistry and electron microscopy (EM). RESULTS: All cases had cellular smears. The cells occur mostly as loose sheets, but also dispersed as single cells, with rare mitoses and few apoptotic bodies. The small tumor cells have round (or molded) nuclei with somewhat coarse granular chromatin, and inconspicuous nucleoli. Six cases had rosette-like structure. The rosette-like structures lack the typical fibrillar material at their centre, as seen in cases of neuroblastoma. Numerous naked nuclei and focal crush artifacts were seen. Mitosis were rare. All eleven tumors with abundant glycogen vacuoles. Ultrastructural studies shows characteristic features, such as: intracytoplasmic glycogen, lipid droplets and primitive cell junctions. CONCLUSIONS: Primitive neuroectodermal tumors/extraskeletal Ewing's sarcoma shows cytologic features similar to Ewing's sarcoma of bone. We would like to emphasize high diagnostic value presence of so-called 'punched-out clear spaces' in the cytoplasm in primitive neuroectodermal tumors/extraskeletal Ewing's sarcoma smears and CD99/O13 immunocytostaining showed strong membranous reactivity. We also comment the role of EM and ICC as ancillary technique in cytologic diagnosis of these tumors.

OP2-1
THE AMAZON TELEMEDICINE PROJECT: AN AFFORDABLE TELEPATHOLOGY SYSTEM FOR REMOTE ACCESS AREAS
Vinicius Duval Da Silva, Eder Huttner, Ricardo Cardoso, Thais Russomano, Adolfo Sparenberg, Lucas Michaelsen, Vinicius Michaelsen, Maria Helena Itaqui Lopes
Pontificia Universidade Catolica do Rio Grande do Sul, Porto Alegre, Brazil

BACKGROUND: Telemedicine can provide support for healthcare in extremely remote areas of the planet through the use of satellites, low and wide-band internet transmission. But there are some key points of utmost importance to establish a reliable and continuing telemedicine system such as the development of software with user-friendly interface and short learning curves and adequate training of non-skilled communitarian staff, reference hospitals and attending physicians in the remote area. This project aims to develop and implement an efficient and cost-effective system for the Amazon Indian native population and extremely impoverished migrants of other Brazilian regions. The areas of teledermatology, telecardiology, teledentistry, teleradiology and telepathology and videoconferences for continuing education of these populations. Telepathology and teledermatology were the first to be implemented in January, 2007. METHOD: 181 patients consulted during a one week period in January, 2007 in the city of Tabatinga, close to the border of the Amazon Brazilian State with Colombia and Peru. The Internet was used as the primary telemedicine tool. A second visit is scheduled for October, 2007. RESULTS: Of all patients, 37 were Indians and the remaining were migrants from various areas of Brazil. Seventy patients had their diagnosis made by teledermatology and received medical treatment by a physician on site. Twenty two patients had skin or oral mucosal biopsies sent to the Hospital Sao Lucas of Pontifica Universidade Catolica do Rio Grande do Sul in Porto Alegre, Southern Brazil. The onsite attending physician received the final diagnostic reports encrypted by e-mail. Of these biopsies, 9 were dignosed as dematoses, one as deep mycosis, 4 epidermoid carcinomas and 8 basocellular carcinomas. Most neoplastic lesions had maximum diameters over 4 cm, demonstrating a population without access to health assistance. CONCLUSIONS: This ongoing project is feasible, cost-effective and extremely relevant for non-assisted populations in remote areas in the world. The main problems that need further studies and tests are related to adequate training of onsite healthcare assistants, permanent involvement of the staff at the reference institutions and the development of teleconference material for continued education of these populations adapted for their cultures. Several endpoints such as epidemiologic measures like infant mortality rates among others need to be evaluated to assess the impact of telemedicine in these situations.

OP2-2
UTILIZATION OF COLLEGE OF AMERICAN PATHOLOGISTS CHECKLIST AS A QUALITY IMPROVEMENT TOOL FOR ACCREDITATION
Alp Usubutun, Ozay Ozkaya, Pinar Firat, Arzu Sungur
Hacettepe University Department of Pathology, Ankara, Turkey

Background: Accreditation of Pathology Departments is a process which requires meticulous quality improvement efforts. We utilized College of American Pathologists (CAP) Checklist for benchmarking during this process in our department. Initially a Quality Improvement Committee (QC) was established to guide and monitor the whole process. QC met every three months for evaluation. Here we present the goals established and the unresolved issues at the end of a year. Methods: QC started its activities by reviewing the 94 criteria on the CAP Checklist and decided that 48 of these criteria were already met in the department. In the second phase QC analyzed the reasons of failure in the remaining 42 criteria to initiate quality improvement activities. Priorities were determined by the QC. A physician satisfaction survey took place and the medical staff was encouraged to contribute to the quality improvement activities by filling a problem record book. Most of the activities were dedicated to improve the surgical pathology reporting turnover times. Results: At the end of the first year a reevaluation disclosed that 87.2% of the CAP criteria were met. When priority activates were analyzed it was seen that the average turnover time for pathology reports which was 6.8 days was reduced to 5 days at the end of the year. One of the QC strategies was to establish a new frozen section unit within the floor of operating theaters since the original one was located in another building within our department. Before this unit the yearly number of frozen sections was 876 and it increased to 1171/year afterwards. This measure reduced the frozen section turnover time to less than 20 minutes in 63% of cases. Problem record book enabled the staff to express their ideas for improvement freely and the problems reported increased in a linear fashion. QC decided that two major topics remaining for further quality improvement are; an efficient consultation system within the pathology department and a system for consulting specimens referred from other institutions. Discussion: This process proved that CAP Checklist can be successfully utilized for benchmarking during the preparation period before an external accreditation. These criteria can be used as a reference to find solutions for both intra and extradepartmental obstacles for improvement in a pathology department. Personal support and reconciliation of the staff, as well as a consensus proposal between the hospital directory and the pathology department is critical for the enhancement of the achievement.

OP2-3
TISSUE PATHWAYS AND CANCER DATASETS; AN OVERVIEW OF THE PROGRAMME OF THE ROYAL COLLEGE OF PATHOLOGISTS
Tim Helliwell
Royal College of Pathologists, United Kingdom

The cancer dataset programme of the UK Royal College of Pathologists was initiated in 1996-7 with the publication, of datasets for the histopathology reporting of breast and colorectal cancers. By the end of 2007, over 30 datasets will be available to view on, and download from, the College website [www.rcpath.org.uk]. The cancer datasets are being supplemented by a series of Tissue Pathways Guidelines for the handling and report of non-cancer specimens. The aims of the dataset programme include education, through providing a succinct literature review of current acceptable practice, improving clinical management by providing consistent prognostic information, providing information to assist Cancer Registries, and providing a set of data to allow national audits of practice. The tissue pathways aim to provide a succinct evidence-based description of the optimal macroscopic description, trimming, staining and reporting of non-cancer specimens. Achieving these aims presents significant challenges to the College as a commissioning organisation, to the authors of datasets and to the users. The authority of the datasets relies on a robust consultation process with clinical stakeholders and the College membership before the datasets are published, and the promise of regular revision. This has been reinforced by clearer guidelines for authors, a standard format for the datasets, and an internal audit process according to international standards. The datasets describe core data that are regarded as those data that are most important for clinical management based on published evidence; these are incorporated into the national cancer dataset and are used for national cancer audits. Tissue pathways have been constructed in a similar manner to the cancer datasets with clear guidelines on format and content. The challenges for users are to adapt to the continually increasing amount of information required for optimal clinical management and the need to use the datasets flexibly in conjunction with free text reports when

assessing complex specimens. Future challenges include the widespread incorporation of the datasets into laboratory IT systems, facilitating access to the datasets through improvements in the College website and in decision support software within the laboratory, and the continuing engagement with specialist pathology groups to incorporate new prognostic data for the management of patients with non-malignant diseases and cancers.

OP2-4
IS DIGITAL SLIDE MICROSCOPY LIMITED TO SPECIFIED MORPHOLOGICAL APPLICATIONS?

Gombás Péter[1], Illyés Gyorgy[2]
[1] Central Hospital, Division of Pathology, Budapest, Hungary
[2] II. Department of Pathology, Semmelweis University, Budapest, Hungary

BACKGROUND: Digital slide microscopy is enabled by amazing rapidity of hardware and software development after the millennium. Following some skepticism of whole slide imaging (WSI), growing expectations can be detected among surgical pathologists. Disappointment of earlier applications have been followed by WSI systems, which enables many specified examination in quantitative morphometry, image processing for signal detection, etc. While these progress on high way, question of routine surgical pathology, how digital microscopy supports pathology reporting, is open. METHODS: In a 6-month period in 2006, we have selected randomly 60 cases of various diagnostic entities. All type of specimens has been included. We have scanned routine case slides using Mirax Scan Desk scanner (Zeiss) than stored them on local network connected to Windows server. We have examined the 'digital cases' on two way: 1.) via local area network, 2.) via Internet. E-slides were uploaded on slide server, Pathonet (3DHISTECH) on Internet, so reachable for remote consultant. After remote evaluation we have discussed some cases using VoIP phone system, some in personal conversation as well. RESULTS: Experiences could be classified be more aspects, as technical and human parameters. Considerable diversity could be discovered between LAN and Internet based consultation, caused by bandwidth limitation at case upload on slide server. However, no such differences could be detected et remote case evaluation using e.g. ADSL line of 3 MB/sec transfer rate. Whole slide (although not 'all slide' of the entire case yet) consultation including immunohistochemical slides, special staining, TMA specimens may satisfy clinical expectations of the routine reporting in average hospitals as well. Appling on line VoIP phone in helped to an approximately 99% consensus diagnostic concordance. We found that WSI tele-reporting enables proper judgment of 'digital case': remote consultant may adjudicate all expected diagnostic factors as tumor grade, stage, free excision margins, immunohistochemical and lymph node status, morphological multiplicity, etc. CONCLUSIONS: Although the digital histology microscope technology is spreading worldwide it seems to support two main area: teaching and morphometric investigations: technology remains clinically separated, closed in specified labs for specified applications. Extensive studies are required how can we integrate routine laboratories in this progress to support daily decision via cyber corps specialists' collaboration.

OP2-5
HONEY AS A SUBSTITUTE FOR FORMALIN?

Naziye Ozkan[1], Fulya Cakalagaoglu[1], Burcu Tuzuner[2], Emine Salva[3]
[1] Marmara University Medical Faculty, Pathology Depart., Istanbul; Marmara University Vocational School of Health Related Professions, Pathology Laboratory Depart. Istanbul,Turkey
[2] Marmara University Medical Faculty, Pathology Depart. Istanbul, Turkey
[3] Marmara University Vocational School of Health Related Professions, Pathology Laboratory Depart., Istanbul, Turkey

Background. In cellular pathology, fixation preserves tissues by preventing autolysis and putrefaction. Formalin is the most widely used tissue fixative,as the result of increasing concerns about its effect as a potential carcinogen,attempts have been made to find safer alternatives.Alcoholic formalin is useful as a fixative on the tissue processors,because in addition to fixation,the dehydration process is also begun. For centuries, honey has been shown to be a successful antibacterial agent,having the potential to preserve compounds without any harmful effects on users.In addition,studies have shown that honey has acidic and dehydrative properties.Pine honey is a particular type of that the honey bees produce,not on the basis of nectar or pollen,as is the case for other types of honey,but by using the honeydew excreted by an insect, an aphid named Marchalina hellenica, which lives by sucking on the sap of certain pine species, and leaves the honeydew on the trunks of these trees.Pine honey is produced in western (mainly southwestern) Turkey,in a number of Greek islands and in in New Zealand. The aim of this study is to determine honey properties that influence tissue fixation and compare the other routine fixative in histopathology. Method. In this study,different fresh tissues were obtained from the Department of Pathology at Marmara University Hospital Same tissue pieces were dissected into small segment using normal laboratory protocol and immediately placed into numbered universal tree containers.First containers was 10% honey diluted with distilled water,second container had 10% neutral buffered formalin (NBF) and last container was alcoholic formalin.All tissues were fixed 24h and processed to paraffin wax, sectioned and stained by hematoxylin-eosin and Gomori One Step Trichrome.Ki-67 and Vimentin were stained by streptavidin-biotin peroxidase immunohistochemical method.All slides were examined by light microscopically. Results. The histomorphology of tissue sections were rated according to cellular outline, cytoplasmic and nuclear detail,erythrocyte integrity, overall morphology and staining based on a 1-4 grading system.Tissues fixed in alcoholic formalin and NBF have similar histomorphology.Honey fixative has minor histomorphologic difference, however,in no way interfere with establishing the correct diagnostic conclusion.In three groups, among the expressions of Vimentin and Ki-67 was not a significantly difference ($p>0,05$). Conclusion: Low concentrations of honey can be a safe alternative fixative to formalin in histopathology laboratories.

OP3-1
EURO-FISH: A CONCERTED ACTION TOWARDS STANDARDIZED TRANSLOCATION DETECTION IN PATHOLOGY

Anke Van Rijk[1], David Mason[2], Lorenzo Leoncini[3], José Cabecadas[4], Martin Hansmann[5], Christiane Chriscopie Bergman[6], Juan Cruz Cigudosa[7], Dimitra Anagnostou[8], Stephen Stehamilton Dutoit[9], Tim Svenstrup Poulsen[10], Steen Hauge Matthiesen[10], Han Van Krieken[1]
[1] University Medical Hospital Nijmegen, Department of Pathology, Nijmegen, The Netherlands
[2] Haematology Department, John Radcliffe Hospital, University of Oxford, United Kingdom
[3] Department of Human Pathology and Oncology, University of Siena, Italy
[4] Servico de Anatomia Patológica, Instituto Português de Oncologia, Lisboa, Portugal
[5] Department of Pathology, University of Frankfurt, Frankfurt, Germany
[6] Département de Pathologie, Hôpital Henri Mondor, Créteil, France
[7] Cytogenetics Unit, Spanish National Cancer Centre, Madrid, Spain
[8] Hematopathology Dept. Evaggelismos Hospital, Athens, Greece
[9] Institute of Pathology, Aarhus University Hospital, Aarhus, Denmark
[10] Dako, Glostrup, Denmark

Background: Lymphomas are cancers originating from the lymphatic system. This specific group of cancers can be divided into two major categories; Hodgkin versus non-Hodgkin lymphomas. Their definition is based on clinical, morphological, immunophenotypic and genetic features and is generally considered difficult and prone to mistakes. Since non-random chromosomal translocations are specifically involved in the different lymphoma types, the detection of these aberrations will be an increasingly important step in the correct identification. For that reason, the Euro-FISH program aimed at a validation of a robust, standardized FISH protocol. When implemented this procedure will be an aid in discriminating the most difficult to diagnose cases. Method: The Euro-FISH protocol is a useful tool in discerning the different types of lymphoma and available treatment options. The Euro-FISH project, organized in three stages therefore has established a robust standardized FISH protocol, to be used in routine laboratories for diagnostically difficult lymphoma cases. For the evaluation of the protocol 16 split-signal FISH probes were tested on 10 different lymphoma categories (MCL, splenic MZL, gastric MALT, CLL/SLL, DLBCL, FCL, LPL, BL, ALCL, T-LBL) supplemented with reactive tissues. The chromosomal localization of every probe was confirmed by using metaphase slides of healthy donors, before the probes were tested on the selected entities. Results and conclusions: Based on a shared protocol FISH testing was standardized (Stage 1) in all eight participating laboratories. The initial stage (Stage 0), testing on metaphase slides, confirmed that all 16 available probes were correctly localized. Stage 1, testing of laboratory specific TMA's, made with the laboratories own samples, indicated that a laboratory specific digestion might be recuired to obtain obtimum FISH results. However, Stage 1 resulted in general digestion time appropriate for more than 90% of the samples, which thereby allowed the exact same procedure to be used in Stage 2 in all participating laboratories In Stage 2, 4 TMA's of 36 cones each were prepared with 10 entities and reactive tissue orriginating from the eight laboratories. The results show that TMA's are usable in this setting and that standardization is feasible in the great majority of cases. From our results we conclude that the split-signal FISH technique provides reliable results in at least 90% of the cases tested and can in principal be implemented for routine use in every pathology laboratory with access to a fluorescence microscope.

OP3-2

TOPOISOMERASE IIα EXPRESSION IS AN INDEPENDENT PROGNOSTIC FACTOR IN HODGKIN'S LYMPHOMA

Ipatia Doussis-Anagnostopoulou[1], Theodoros Vassilakopoulos[2], Irini Thymara[3], Loukas Kaklamanis[1], Penelope Korkolopoulou[3], Athina Androulaki[3], Efstratios Patsouris[3], Christos Kittas[1], Gerassimos Pangalis[2]

[1] Laboratory of Histology and Embryology, Greece

[2] First Department of Internal Medicine and Department of Haematology, Greece

[3] Department of Pathology, National and Kapodistrian University of Athens, Medical School, Greece

Background: Topoisomerases are enzymes involved in the formation of transient single or double-stranded DNA breaks, relaxing DNA supercoiling. The isophorm IIα (topoIIα) is a target for several cytotoxic agents used in the treatment of hematologic malignancies. These agents appear to stabilize the DNA-topoIIα complex and inhibit DNA relegation, resulting in an accumulation of lethal double-strand DNA breaks, leading the cells to apoptosis. Furthermore, topoIIα is mainly expressed in proliferating cells, being identical to the proliferation-associated antigen KiS1 and can be used as a proliferation marker in normal and neoplastic cells. Reports in the litterature are conflicting and it is not clear whether high levels of topoIIα are beneficial, increasing tumor sensitivity to topoIIα inhibitors, or they are associated with worse prognosis reflecting increased proliferative activity. In order to elucidate this issue, we correlated the immunohistochemical expression of topoisomerase IIα (topoIIα) with clinicopathological parameters, the expression of Ki-67 and the outcome in a large series of Hodgkin's lymphoma (HL) patients, who had been homogenously treated with ABVD or equivalent regimens. Method: Immunohistochemistry using the monoclonal antibodies Ki-S1 (topoIIα) and MiB1 (Ki-67) was performed in 238 HL patients and their expression was evaluated in approximately 100 neoplastic Hodgkin Reed-Sternberg (HRS) cells. Results: The mean±SD percentage of topoIIα- and Ki-67-positive HRS cells was 64±19% (5%-98%) and 73±19% (8%-99%), respectively. The median percentage of topoIIα-positive HRS cells was 64% (interquartile range, 51-78%). There was no correlation between topoIIα expression and patient characteristics. TopoIIα and Ki-67 expression were correlated (Spearman's Rho 0.255, $p<0.001$). TopoII expression within the highest quartile of this patient population was predictive of failure free survival (FFS) (10-year rates 82±3% vs 68±7%, $p=0.02$ for patients falling into the quartiles 1-3 and 4 respectively). In multivariate analysis topoIIα expression was independently predictive of FFS and HL-specific survival. Conclusion: TopoIIα was expressed in all cases of HL showing a correlation with Ki-67 expression. Under current standard therapy including drugs inhibiting its activity, topoIIα was an independent adverse predictor of FFS and HL-specific survival with no statistically significant correlation with other established prognostic factors.

OP3-3

REDISTRIBUTION OF CD4 AND FOXP-3 POSITIVE TREG CELLS FROM LYMPHOID TISSUES TO PERIPHERAL BLOOD IN EARLY STAGE HIV INFECTED PATIENTS.

Alba Diaz[1], Ana Mozos[1], Marta Garrido[2], Joaquim Carreras[1], Montse Planas[3], Llucia Alos[1], Elias Campo[1], Felipe Garcia[4], Antonio Martinez[1]

[4] Department of Infectious Diseases, Hospital Clinic, Barcelona, Spain

Background: The suppression of immune responses by CD4 regulatory T-cells (Treg) may play a role in the spreading of viral chronic infectious diseases. Tregs are involved in suppression of immune cells.The purpose of this study is to analyze the distribution of Tregs in HIV infection, before and after HAART. Methods: Paired samples from lymphoid tissues (LT) and peripheral blood lymphocytes (PBL) were simultaneously obtained from 27 patients with chronic asymptomatic HIV-1 infection, before and after HAART. Six HIV- individuals were used as controls. Fresh tissue was divided in two pieces, one was immediately snap frozen and used to determine the LT viral load and to extract mRNA. A formalin-fixed-paraffin-embedded tissue block was obtained in each case for immunoarchitecture analysis and immunohistochemical studies. We analyzed FOXP3 expression by RT-PCR in LT and PBL. We studied the number and distribution of FOXP3+ Treg in LT by immunohistochemistry/computer image analysis and in PBL by flow cytometry. Clinical data, CD4 counts and viral load were obtained from each patient. Results: We observed a reduction in FOXP3 expression in LT of HIV patients, both before and after treatment compared to healthy donors at mRNA ($p<0.001$) and protein ($p=0.018$) levels. The expression of FOXP3 was even lower after treatment (mRNA,$p=0.041$; protein,$p=0.041$). These changes were positively correlated to the changes in LT viral load ($r=0.671$;$p=0.009$). To the contrary, a high number of FOXP3 positive cells was observed in PBL from HIV patients, both before ($p=0.014$) and after treatment ($p=0.002$). FOXP3 mRNA levels in PBL were not influenced by therapy and they remained

constant after HAART although still higher than controls.The patients treated with NNRTI showed a lower FOXP3 mRNA expression when compared to the group treated with PI in both compartments analyzed, PBL (p=0.008) and LT (p=0.015). Conclusion: HIV patients had low number of FOXP3 Treg cells in lymphoid tissues compared to HIV- individuals due to a redistribution of these cells from LT to peripheral blood compartment in chronic HIV infected patients. This finding correlated with the immunological recovery observed after treatment. For the first time, we associate a particular HAART regimen with alteration in Tregs, showing an increased FOXP3 gene expression in the group of patients treated with PI compared to other modalities of HAART.

OP3-4

GCET1 EXPRESSION IN ENDEMIC BURKITT LYMPHOMA. CORRELATION WITH EBV STATUS AND IGH MUTATION PATTERN

Cristiana Bellan[1], Stefano Lazzi[1], Giovanna Roncador[2], Teresa Amato[1], Giulia De Falco[1], Eleonora Leucci[1], Mario Cocco[1], Nazzareno Palummo[1], Susanna Mannucci[1], Piero Tosi[1], Miguel Piris[2], Leoncini Lorenzo[1]
[1] Department of Human Pathology and Oncology, University of Siena, Italy
[2] Spanish National Cancer Centre (CNIO), Lymphoma Group, Madrid, Spain

BACKGROUND: Gcet1 (centerin, serpin A9), a gene that belongs to the serpin family of proteins, is located on chromosome 14q32. It is induced when B cells are stimulated with CD40L and it may play an important role in GC-B cell physiology and survival. Previous studies have shown that the expression of GCET1 is primarily restricted to GC B-cells (centroblasts and large centrocytes but not small centrocytes) and also to lymphoid malignancies with GC B-cell maturation. The BL exhibit a heterogeneous staining for Gcet1 that probably reflects the heterogeneity of cell of origin of this lymphoma. The normal counterpart of the neoplastic B cells in Burkitt lymphoma (BL) is still unclear. Based on immunoglobulin gene rearrangement studies, some authors suggest an origin from germinal center cells and others from memory B cells. METHOD: To better clarify the origin of BL we analysed the GCET1 expression on 38 endemic BL, and we correlated the GCET1 expression with the EBV status and with the immunoglobulin mutation pattern of these cases. For that purpose we have performed immunohistochemical analysis using a newly generated monoclonal antibody reactive in paraffin embedded tissues and EBV RNA in situ hybridization (ISH) using. A semi nested polymerase chain reaction (PCR) to amplify the VDJ rearrangements of the immunoglobulin heavy chain (VH) genes was performed and the resultant amplificates were sequenced for comparison with known germline VH segments RESULTS AND DISCUSSION: We found that GCET1 expression was significantly correlated with EBV status (Table 1). Table 1 EBV+ EBV- A9+ 2/31 5/7 A9- 29/31 2/7 Interestingly the mutation pattern of Ig genes differed between EBV-/A9+ cases and EBV+/A9- cases as EBV-/A9+ cases had a significantly lower average mutation frequency that EBV+/A9- cases. All together these results again suggested that EBV-positive and EBV-negative BL may originate from distinct subsets of B cells, pointing to a particular role for the germinal center reaction in the pathogenesis of these tumors. The immunoglobulin gene mutation patterns of single GC A9 + and A9- cells in the GC will be analysed and compared to that of BL.

OP3-5

ALTERED EXPRESSION OF MIRNAS IN C-MYC NEGATIVE BURKITT LYMPHOMA CASES

Eleonora Leucci[1], Mario Cocco[1], Patricia Van Cleef[2], Cristiana Bellan[1], Anke Van Rijk[2], Giulia De Falco[1], Anna Onnis[1], Joshua Nyagol[1], Bessie Byakika[3], Stefano Lazzi[1], Piero Tosi[1], Han Van Krieken[2], Lorenzo Leoncini[1]
[1] Department of Human Pathology and Oncology, University of Siena, Italy
[2] Department of Pathology, Radboud University Nijmegen Medical Center, Nijmegen, The Netherlands
[3] The Nairobi Hospital, Nairobi, Kenya

Background: The hallmark of Burkitt lymphoma (BL) is the translocation t(8;14) that place c-Myc under the control of immunoglobulin gene regulatory elements, resulting in the over-expression of this gene. Variant translocations also occur into either ? or ? light chain locus on chromosome 2 and 22 respectively. From the EUROFISH (www.euro-fish.org) project, aiming at the standardization of FISH procedures in lymphoma diagnosis, emerged that 5 cases out of 26 classic endemic BLs were negative for c-Myc translocation with split signal probes. These results were also confirmed by the lack of alternative translocations as demonstrated by means of either IgH and IgL split signal probes as well as a t(8;14) specific fusion probe. These findings suggest that a different pathogenetic mechanism, other than c-Myc translocation, may be involved in malignant transformation in those cases. We aim therefore to investigate alternative oncogenic pathway. Several studies have reported miRNAs involvement in cancer and their association with fragile sites in the genome. MicroRNAs are a class of small non-coding RNAs that are able, in their mature form (?22nt), to regulate gene expression by mRNAs cleavage or translational inhibition. Methods: By using web available softwares, we searched for miRNAs directed against the key regulators of B cell proliferation and differentiation. Expression of these miRNAs was then analyzed by Real-time PCR in BLs both positive and negative for traslocation. Results and Discussion: We selected hsa-mir125a, Hsa-mir125b, Hsa-mir9, Hsa -mir127 and has-mir34b. We found a different pattern of expression between c-Myc negative and c-Myc positive cases for Hsa-mir9, Hsa-mir127 and has-mir34b. The specific effect of these miRNAs are under investigation by transfection of synthetic miRNAs and their inhibitors in a human lymphoblastoid cell line immortalized by EBV.

OP3-6

EXPRESSION OF BTK IN NORMAL AND NEOPLASTIC LYMPHOID TISSUES

Sermin Ozkal[1], Johan Hjm Van Krieken[2], Sara Tedoldi[1], Jennifer C Paterson[1], Martin-Leo Hansmann[3], Aydanur Kargi[4], Teresa Marafioti[1]
[1]LRF Immunodiagnostics Unit, Nuffield Department of Clinical Laboratory Sciences, University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom
[2]Department of Pathology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands
[3]Senckenberg Pathology Institute, University Clinic Frankfurt am Main, Germany
[4]Department of Pathology, School of Medicine, Dokuz Eylul University, Izmir, Turkey

Background: Non-receptor protein tyrosine kinases (PTKs) are important for many signal transduction such as T-cell receptor and B-cell receptor signals. They also play an important role in the cellular growth and differentiation. Tec family are protein tyrosine kinases and comprises Tec, Bruton's Tyrosine Kinase (BTK), Itk, Bmx and Txk proteins. BTK is crucial for the development and differentiation of B-cells. Mutations occurring in BTK gene are responsible for X-linked agammaglobulinemia (XLA) which is the most common disorder among primary immunodeficiency diseases. The purpose of the present study was

to examine the expression of BTK protein in normal and neoplastic lymphoid tissues since no previous stusies have been reported. Method: Expression of the Btk protein was assessed by immunohistochemistry in paraffin-embedded tissue sections of various normal tissues, and in several types of tumor cell lines. The material investigated consisted of paraffin-embedded sections of normal and neoplastic lymphoid tissues, cytospin preparations of lymphoma-derived cell lines and normal non-lymphoid samples (e.g. heart muscle, breast, thyroid, liver, stomach, pancreas, kidney, adrenal gland, endometrium, placenta, ovary, prostate, and testis). The diagnosis of lymphoma was made following the criteria of WHO classification. Double immunoenzimatic staining was also performed on some tissue sections of human tonsil. Results: In human tonsil, BTK was expressed strongly in germinal centre and mantle zone B-cells, marginal zone cells of the spleen and monocytoid B cells (in a case of lymph node infected by Toxoplasmosis) were also BTK-positive. In bone marrow, BTK was detected in some of the lymphoid cells, granulocytes and megakaryocytes. Among lymphomas, BTK was found in the majority of non-Hodgkin's B cell lymphomas, (T–cell lymphomas were negative) and in many cases of lymphocyte predominant Hodgkin lymphoma (in the investigated cases of classical Hodgkin lymphoma the tumour cells were BTK-negative). In normal non lymphoid tissues, glandular epithelial cells of stomach, acinar cells of pancreas and tubular cells of kidney were BTK-positive. Conclusions: Our results suggest that BTK can be considered as a new marker for marginal zone B cells, a molecule to be added to the panel of B cell markers for study of B cell lymphomas and another useful marker to distinguis the two forms of Hodgkin lymphomas.

OP3-7

ANALYSIS OF LYMPHOCYTE SUBPOPULATIONS, BONE MARROW HEMATOPOIESIS AND HISTOPATHOLOGY IN RITUXIMAB-TREATED LYMPHOMA PATIENTS WITH LATE-ONSET NEUTROPENIA

Kostas Stamatopoulos[1], Theodora Papadaki[2], Charalambos Pontikoglou[3], Ioanna Athanasiadou[1], Niki Stavroyianni[1], Juergen Bux[4], Ioannis Batsis[1], Katerina Pyrovolaki[3], George Paterakis[5], Dimitra Anagnostou[2], Achilles Anagnostopoulos[1], Helen Papadaki[3]

[2] Evangelismos Hospital, Greece
[3] University of Crete School of Medicine, Greece
[4] Blood Service West of the German Red Cross, Hage Germany
[5] G. Gennimatas Hospital, Greece

Late-onset neutropenia (LON) is a complication of Rituximab of yet unknown pathophysiology. We investigated potential underlying mechanisms in 12 patients with lymphoma who developed LON after completion of the intended treatment with Rituximab±chemotherapy. Ten of 12 patients developed B-cell depletion and inverted CD4/CD8 cell ratios; absolute CD8+ lymphocytosis and T-large granular lymphocyte (T-LGL) proliferation were identified in 8/12 and 7/12 cases, respectively. TCR Vβ repertoire flow cytometric analysis revealed expanded Vβ subsets in three cases, who displayed significantly increased proportions of Vβ3 or Vβ22 or Vβ16 expressing T8 cells. Multiplex PCR analysis in all patients with expanded T-LGL populations did not detect monoclonal TCRβ or TCRgamma gene rearrangements. Bone marrow (BM) biopsy samples from 10/12 patients of the present study were examined morphologically and immunohistochemically at onset of neutropenia. Mild (5-10%) to moderate (10-15%; one case: 30%) lymphocytic infiltration with predominantly nodular and/or interstitial growth was observed in all cases. Immunohistochemical analysis showed that the lymphoid aggregates lacked CD20+ and CD79a+ B-cells and were composed entirely of CD3+, CD45RO+ (CD3>>CD45RO) and CD43+ T-cells. Moderate-to-significant reduction of the granulocytic series and pronounced shift to the left in the form of abnormal localization of immature precursors (ALIP) with concomitant dysplastic changes of mature forms, mimicking MDS, was observed in 7/10 cases. The remaining cases (3/10) showed hyperplasic granulocytic series with ALIP-like lesions as well as dysplastic changes of mature forms, also mimicking MDS. All cases were either negative or had <2% CD34+ immature precursors. Hyperplasia of the erythroid and megakaryocytic series with abnormal paratrabecular localization as well as concomitant dysplastic changes was identified in all cases. Patients also displayed: (i) low reserves of granulocytic progenitors associated with increased apoptosis and increased proportion of Fas-expressing cells within the CD34+/CD33+ cell compartment; (ii) Fas-Ligand and Interferon-gamma mRNA expression within BM CD3+ cells; (iii) accelerated apoptosis in all stages of BM granulocytic development. All patients were negative for granulocyte-reactive antibodies. We conclude that T-cell mediated immune myelopathy associated with MDS-like changes and suppression of myeloid progenitor cell growth is critically implicated in the pathophysiology of LON in a number of Rituximab-treated patients.

OP3-8

EVALUATION OF ANGIOGENESIS IN THE BONE MARROW OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA BY A NOVEL MORPHOMETRIC METHOD

Lida Kalmanti, Konstantina Dambaki, Vrettos Haniotis, Helen Dimitriou, Eftihia Stiakaki, Efstathios Stathopoulos, George Delides
University of Crete, Greece

Background: Although it is well known that angiogenesis plays a key role in the growth and metastasis of solid tumors, its role in hematological malignancies is still unclear. The use of anti-angiogenic factors in the therapeutic strategy of such diseases is promising, making mandatory the investigation of angiogenesis contribution in disease evolution and prognosis. The aim of this study was to estimate morphometrically, by a novel method, angiogenesis in childhood B-Acute Lymphoblastic Leukemia at the onset of the disease. Method: Tissue sections from formalin-fixed, paraffin-embedded trephine bone marrow biopsies from newly diagnosed, untreated, children with B-Acute Lymphoblastic Leukemia (n=25) were stained immunohistochemically with anti-Factor VIII antibody. Angiogenesis was estimated by two morphometric methods. In the one method it was expressed as microvessel density by evaluating "hot spots", a widely used method of microvessel density, and in the other method -that has been applied previously in breast carcinomas-it was expressed as volume corrected angiogenesis index (VCAI), by taking into account the bone marrow cellularity; thus providing a more accurate, although time consuming, method. The formula [V1/(NBMC1/Tot1) + V2 / (NBMC2/Tot2) + Vn / (NBMCn/Totn)]/N was applied; where V is the number of vessels per optical field, NBMC is the number of nucleated bone marrow cells coinciding with the knots of the grid, Tot is the total number of grid points projected in one viewing optical field coinciding with NBMC and fat cells, and N is the number of optical fields scored. Control group comprised free of disease bone marrow biopsies obtained for staging of children with solid tumors (n=26). Results: Leukemic bone marrows samples were found to have increased vascularity (microvessel density: 2.32 + 0.3 vs. 1.47 + 0.16 for the controls, p = 0.025) and increased but not statistically significant different VCAI (1.009 + 0.19 vs. 0.77 + 0.19 for the controls, p=0.29). Conclusion: These findings suggest that for the evaluation of angiogenesis in B-cell lineage Acute Lymphoblastic Leukemia of childhood, the parameter of bone marrow cellularity has to be taken into consideration, using the volume corrected angiogenesis index. Patients with increased angiogenesis, as studied with this novel method, may prove candidates for anti-angiogenic treatment, and should be followed for the outcome of their disease.

OP3-9
INVOLVEMENT OF THE BREAST BY HEMATOLOGICAL MALIGNANCIES: A STUDY OF PRIMARY AND SECONDARY INVOLVEMENT
Arzu Saglam, Aysegul Uner
Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: Involvement of the breast by hematological malignancies is rare, in spite of the fact that secondary lymphomas represent the most common metastatic lesions of the breast. Non-Hodgkin Lymphomas (NHLs) make up the majority of these malignancies. Methods: We reviewed the clinical features and morphology of 21 cases of hematological breast malignancies diagnosed in our department over the past 15 years. The cases were reclassified according to the WHO 2001 classification after examination of H&E slides and available immunohistochemical stains. Additional immunohistochemical stains were performed when necessary. Results: The age of the patients ranged between 17 and 78 (mean 48), 20 were female, 1 was male. The presenting complaint was generally the presence of a breast mass, although most patients were seen to have accompanying multiple lymphadenopathies. Several of the patients were misdiagnosed during their initial evaluation at another institute. Histomorphological analysis revealed 2 cases of granulocytic lymphoma, both patients had a history of acute myeloid leukemia. There were 16 cases of Non-Hodgkin Lymphoma (NHL), 6 of which were primary. Of the 6 primary lymphoma cases 4 were diffuse large B-cell lymphoma and the other 2 Marginal zone lymphomas. The clinical data of 2 patients was not accessible and hence we could not evaluate the primary versus secondary nature of these cases, both were diffuse large B-cell lymphomas. The distribution of the remaining 8 cases of NHL representing secondary involvement were as follows: 2 cases of Diffuse large B-cell lymphoma , 2 cases of chronic lymphocytic lymphoma/leukemia, one with Richter transformation, 2 cases of lymphoblastic lymphoma and 1 case each of Burkitt lymphoma and mantle cell lymphoma. There were 3 cases of secondary breast involvement by classical Hodgkin lymphoma, an exceedingly rare finding to our knowledge. Conclusion: Keeping in mind that several of our cases were misdiagnosed, either as inflammatory lesions or nonhematological malignancies, hematological malignancies should be considered in the differential diagnosis of breast lesions, especially in incisional biopsy specimens, to avoid unnecessary operations or delays in treatment.

OP3-10
EXPRESSION AND ACTIVATION STATUS OF THE GENOTOXIC STRESS-INDUCED 53BP1 PROTEIN IN NON HODGKIN AND HODGKIN LYMPHOMAS
Elias Drakos[1], L. Jeffrey Medeiros[1], Julio Morales[2],
Vasiliki Leventaki[1], Phillip Carpenter[1], George Rassidakis[1]
[1] The University of Texas M. D. Anderson Cancer Center, USA
[2] The University of Texas Health Sciences Center, USA

Background: The tumor protein p53 binding protein 1 (53BP1) is involved in DNA damage response after induction of DNA double-strand breaks (DSB). Recent studies in 53BP1 and p53 double knockout mice show that 53BP1 and p53 synergize to suppress genomic instability and lymphomagenesis suggesting o potential role of 53BP1 loss in lymphoma pathogenesis. However, expression and activation status of 53BP1 in reactive lymph nodes and lymphomas are unknown. Methods: The specificity of 53BP1 antibodies used in this study was previously tested in our laboratory by immunoprecipitation and Western blot analysis in lymphoma cell lines. Using immunohistochemical methods, we assessed for total 53BP1 protein expression in reactive lymph nodes and in 167 B-cell or T-cell non-Hodgkin lymphomas of various types, as well as in 48 Hodgkin lymphomas. In a subset of 130 53BP1-positive lymphomas activation (phosphorylation) of 53BP1 (p-53BP1) was also assessed. Results: 53BP1 immunoreactivity was primarily nuclear in normal or tumor cells. In normal reactive lymph nodes, 53BP1 was predominantly expressed in centroblasts and centrocytes of reactive germinal centers and less frequently in lymphocytes of the mantle and marginal zones or interfollicular areas. Using a 10% cutoff for positivity, 53BP1 was expressed in 9 of 10 (90%) Burkitt lymphomas, 15 of 19 (76%) chronic lymphocytic leukemias/small lymphocytic lymphomas, 36 of 40 mantle cell lymphomas (MCL) (90%), 20 of 20 (100%) follicular lymphomas (FL), 42 of 43 (98%) diffuse large B-cell lymphomas (DLBCL), 30 of 35 (86%) anaplastic large cell lymphomas (ALCL), and 42 of 48 (87%) Hodgkin lymphomas (HL). Using the same cutoff, p-53BP1 was expressed with variable staining intensity in 27 of 29 (93%) DLBCL, 25 of 26 (96%) FL, 24 of 24 (100%) MCL, 26of 28 (93%) ALCL and 20 of 23 (86%) HL. Conclusion: Loss of 53BP1 expression is found only in a small subset of Hodgkin and non-Hodgkin lymphomas. When expressed, 53BP1 is frequently phosphorylated (activated) indicating activation of DNA damage response pathways in lymphomas.

OP3-11
DIFFERENTIAL EXPRESSION OF ACTIVATED (PHOSPHORYLATED) C-JUN N-TERMINAL KINASE (JNK) IN B-CELL NON-HODGKIN LYMPHOMAS
Vasiliki Leventaki, Elias Drakos, Ellen Schlette, Pei Lin,
L. Jeffrey Medeiros, George Rassidakis
The University of Texas M. D. Anderson Cancer Center, USA

Backround: c-Jun N-terminal Kinase (JNK), member of the mitogen activated protein kinase (MAPK) superfamily, has been shown to play a role in cell transformation, proliferation and apoptosis. JNK is activated through phosphorylation by upstream MAPK kinases (MKK), MKK4 and MKK7, in response to cytokines, growth factors or ultraviolet (UV) radiation. In addition, JNK is positively regulated by c-myc oncoprotein. The activation status of JNK in B-cell non-Hodgkin lymphomas (B-NHL) is unknown to date. Methods: Using tissue microarrays, immunohistochemistry and an antibody highly specific for phosphorylated JNK (p-JNK), JNK activation was assessed in 144 B-NHL tumors including 12 Burkitt lymphoma (BL), 39 diffuse large B-cell lymphoma (DLBCL), 21 follicular lymphoma (FL), 48 chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), 18 multiple myeloma (MM), and 6 marginal zone lymphoma of MALT type (MZL-MALT). Nuclear staining of p-JNK present in stromal and endothelial cells in all tissue specimens served as an internal positive control. Results: Using a 10% cutoff, p-JNK was expressed 10 of12 (83%) BL, 9 of 39 (23%) DLBCL, 4 of 21 (19%) FL, and 1 of 6 (18%) MZL-MALT. By contrast, none of the 48 CLL/SLL and 18 MM cases included in the study group expressed p-JNK ($p<0.001$, Kruskal Wallis test). Staining intensity and number of positive tumor cells reflecting the expression level of pJNK varied considerably among the positive cases; 5 of 10 (50%) BL, 3 of 9 (33%), and 1 of 4 (25%) of FL expressed p-JNK strongly in a high proportion (>50%) of tumor cells. Conclusion: p-JNK is differentially expressed among B-NHL subtypes. BL tumors, which are characterized by c-myc over-expression, show the highest level of JNK activation suggesting a potential role of JNK in myc-induced tumor cell proliferation and apoptosis of these tumors.

OP4-1
HISTOPATHOLOGICAL CHARACTERISTICS OF PRIMARIES AND PELVIC LYMPH NODE METASTASES PREDICTING SURVIVAL IN SURGICALLY TREATED NODAL POSITIVE PROSTATE CANCER PATIENTS
Achim Fleischmann[1], Sylviane Schobinger[1],
Regula Markwalder[1], Martin Schumacher[2], Fiona Burkhard[2],
George N. Thalmann[2], Urs E. Studer[2]
[1] Department of Pathology, University of Bern, Switzerland
[2] Department of Urology, University of Bern, Switzerland

Background: The current TNM classification has only one category for nodal positive prostate carcinomas implying similar outcome for these patients. However, there is accumulating evidence that surgically treated nodal positive prostate carcinoma patients have a variable clinical course. This encourages identification of tumor characteristics predicting survival. Methods: We evaluated the prognostic potential of various histopathological features in primaries (volume, stage, Gleason score) and nodal metastases (quantity of tumor burden, Gleason score, extranodal extension) of 102 prostate carcinoma patients (median age: 65 years, range: 45–75; median follow-up 7.7 years, range: 1.0–15.9 years). All had clinically non-metastasizing cancer, underwent radical prostatectomy and standardized extended lymphadenectomy and had nodal metastases upon histological examination. They had no immediate androgen deprivation. Results: A median of 21 nodes (range: 9-68) and 2 positive nodes (range: 1–24) per patient were detected. A significant stratification was possible with the Gleason score of the primary and virtually all nodal parameters favoring patients with better differentiated primaries and metastases, lower nodal tumor burden, and without extranodal extension of metastases. In multivariate analyses diameter of the largest metastasis (≤1 cm vs. >1 cm) was the strongest independent predictor for biochemical recurrence free (bRFS; P<0.001), disease specific (DSS; P<0.001) and overall (OS; P<0.001) survival with a more than quadrupled relative risk of cancer related deaths for patients with larger metastases (HR: 4.2, CI: 2.0–8.9; 5 year bRFS/DSS/OS: 18%/57%/54%). The highest 5 year survival probabilities had patients with exclusively micrometastases (bRFS/DSS/OS: 47%/94%/94%). Conclusion: The TNM classification with only one category for nodal metastases for prostate carcinomas is unsatisfactory since subgroups with significantly different prognoses can be identified. The diameter of the largest metastasis per patient (≤1 cm vs. >1 cm) should be used for substaging because of its independent prognostic value. Extranodal extension of metastases provides further prognostic potential which is particularly important in case of limited lymphadenectomy without adequate estimation of nodal tumor burden. Finally, survival probabilities of patients with only micrometastases indicate a chance of cure by surgery alone for some of them.

OP4-2
ABERRANT PROTEIN EXPRESSION IN MICROPAPILLARY BLADDER CARCINOMA

Eva Maria Comperat[1], Armelle Bardier-Dupas[1], Emmanuel Chartier-Kastler[2], Marc-Olivier Bitker[2], Francois Richard[2], Olivier Cussenot[3], Frederique Capron[1], Philippe Camparo[4]
[1] Service d'Anatomie Pathologique, Hôpital La Pitié, France
[2] Service d'Urologie, Hôpital La Pitié, France
[3] Service d'Urologie, Hôpital Tenon, France
[4] Service d'Anatomie Pathologique, Hôpital Val de Grace, France

Introduction: Bladder cancer affects approximatively 10000 patients in France each year. More than 90% are conventional urothelial carcinomas. Several histological variants exist. One rare variant, micropapillary carcinoma (MPC), with male predominance is from great clinical importance, because of its aggressiveness. The exact incidence is unknown, as these tumors are not always exclusively pure forms. We explored, whether MPC display special protein expression, such as overexpression of markers known to be predictive for unfavourable clinical outcome. M&M: We chose p53, MIB-1, Aurora-A and survivin. Immunoexpression of micropapillary carcinomas was evaluated by two experienced pathologists. Normal urothelial tissue never expressed any of these markers. Results: 13 patients, all male, aged between 46-85 years were included in this retrospective study. Staging, according to the WHO classification 2004, showed 1Cis, 2 pT1, 2pT2, 3pT3 and 5pT4 tumors. The micropapillary contingent in tumor specimen was between 30-100%. Ten patients were treated by cystoprostatectomy, 3 underwent transurethral resection. Nine patients died of disease, one patient was lost, 3 patients are alive with follow-up between 8 -26 months. All micropapillary carcinomas overexpressed p53 and MIB-1 in 39% weakly and in 61% in a strong way respectively. Aurora-A was strongly overexpressed by all micropapillary carcinomas. Survivin displayed weak staining in 46% and strong staining in 54%. Conclusion: p53 is a prognostic factor of bad clinical outcome. Studies have shown a sensitive reduction of overall survival or/and progression free interval for p53-positive tumors. MIB-1 protein is strictly associated with cell proliferation. Urothelial carcinomas with overexpression of MIB-1 have a less favourable outcome, a higher risk of progression and significant association with distant metastasis. Aurora-A plays a role in cell division and in maintaining genomic integrity. Increased expression of Aurora-A is linked to clinical aggressiveness and poor overall survival of the patients. Major implication of survivin in bladder cancer development has been demonstrated. Survivin inhibits apoptosis and acts in downstream signaling pathways. Elevated urinary levels of survivin are associated with cancer presence, higher tumor grade and advanced pathological stage. Our study clearly shows overexpression in all MPC of markers of bad clinical outcome. These cancers seem to act in several pathways of genetic deregulation, which might explain their clinical aggressiveness.

OP4-3
EFFECT OF TAMOXIFEN ON GROWTH OF BLADDER CANCER CELLS IS INDEPENDENT OF ESTROGEN RECEPTORS BUT INVOLVES UPREGULATION OF BAX AND CYCLIN D1 EXPRESSION

Paul Smith, Elwin Morgan, Sheng Yao, Joseph Philip, Carol Beesley, Alix Bee, Youqiang Ke, Brian Lane, Christine Gosden, Christopher Foster
Division of Cellular and Molecular Pathology, School of Cancer Studies, University of Liverpool, United Kingdom

Introduction:- Tamoxifen is an estrogen receptor alpha (ERα) antagonist widely used in the therapy of breast cancer. However, it can inhibit growth of neoplastic cells other than breast including transitional cell carcinoma (TCC) of bladder. Many TCC cells express ERα and/or ERβ hence it is likely that tamoxifen may prove to be an effective therapeutic agent for selected bladder cancers. This study was performed to detect any relationship between expression of individual ER isoforms and effects of estrogen and tamoxifen on proliferation of bladder cancer cell lines, and to identify genes modulated by these agents. Materials and Methods:- Growth curves were prepared for 10 bladder cancer cell lines exposed to 10-fold increments of concentration (0.001-10.0 μmol) of β-estradiol either alone or in conjunction with tamoxifen (0.01-10.0 μmol). Total RNA was extracted from all cell lines during linear growth and reverse transcribed for PCR using primers specific for the two isoforms of ER. Messenger RNA prepared from total RNA was amplified, labelled, and hybridised to custom-designed DNA oligonucleotide arrays (MetriGenix, Gaithersburg,USA). Results:- ERα was present in 8 bladder cancer cell lines but ER βwas identified in only 6. One cell line contained neither isoform. B- estradiol at an optimum dose of 1.0 μmol significantly increased growth in 6 cell lines, especially TCCSUP. Tamoxifen at 10.0 μmol was lethal to all cell lines but at lower doses (optimum 1.0 μmol) it stimulated growth in two including TCCSUP. In two cell lines, tamoxifen had little effect, and in 6 it inhibited growth. Inhibition was greater than that due simply to antagonising estradiol, especially in line HT1197, and was not related to ER status. For example, TCCSUP and HT1197 both contained ERα but not ERβ. Analysis of data from the arrays showed heterogeneity of gene expression between cell lines with no apparent relationship to ER status. Of the 80 genes on the array, 14 were highly expressed when related to control genes and, of these, 3 were significantly upregulated by tamoxifen but

not estradiol. Two of these,Bax and CCND1 (cyclin D1), are involved in promoting apoptosis and the cell cycle respectively. Conclusion:- Modulation of Bax and Cyclin D1 expression may explain, in part, how tamoxifen influences cell growth. It also provides objective evidence that tamoxifen could be successfully employed in treatment of TCC with fewer side effects than current regimes.

OP4-4
POSSIBLE ROLE OF CYCLOOXYGENASE-2 IN SCHISTOSOMA-AND NON-SCHISTOSOMA ASSOCIATED BLADDER CANCER

Olfat Hammam, Ahmed Aziz, Tarek Abou Shousha, Mamdouh Roshdy, Ahmed Abdel Hady
Pathology and Urology Departments , Theodor Bilharz Research Institute, Warrak El-Hadar, Imbaba, Egypt

Background and purpose: Cyclo-oxygenase (COX) is an angiogenic factor, which is strongly related to inflammatory diseases and the development of cancer and metastasis in several cancers. It is overexpressed in a variety of premalignant and malignant conditions, including urinary bladder cancer. Our aim is to investigate and compare the expression of cyclooxygenase-2 (COX-2) enzyme in patients with bladder cancer, chronic cystitis and normal bladder. The results were correlated to the classical prognostic factors, mainly tumor stage and grade in a trial to determine the prognostic significance of COX-2 marker. Materials and methods: Seventy-five bladder samples, including 50 cases with bladder cancer (31 were bilharzial associated and 19 non bilharzial associated), 20 samples from cases with chronic cystitis (7 were non specific and 13 were bilharzial cystitis) as well as 5 samples from normal bladder tissue taken as control.The specimens were stained by streptavidin biotin immunohistochemistry protocol, with COX-2 monoclonal antibody. Results: Although no notable expression of COX-2 was observed in the normal bladder, it was slightly expressed in chronic cystitis notably in areas of dysplasia and squamous metaplasia, whereas there was a significant increase in COX-2 ($P < 0.001$) with moderate to strong granular cytoplasmic expression in all malignant histological types. The COX-2 reactivity was higher in transitional cell carcinoma (TCC) than in squamous cell carcinoma (SQCC) ($P < 0.001$). As well as COX-2 expression was significantly higher in schistosomal TCCs than in non schistosomal TCC ($P < 0.05$). There was a statistically significant positive correlation between COX-2 expression and tumor grade ($P = 0.0052$). COX-2 expression was significantly higher in Grade 3 bladder transitional cell carcinoma than in Grades 1 and 2 ($P < 0.05$, $P < 0.01$). Also the correlation between COX-2 expression and progression of bladder transitional cell carcinoma was observed ($P = 0.001$), there was significant difference in COX-2 expression level between the bladder transitional cell carcinomas at different clinical stages ($P < 0.01$). Conclusion: COX-2 is over-expressed in schistosoma-associated bladder cancer. COX-2 might be of significance to the development and proliferation of bladder transitional cell carcinoma, consistent with a potential role for COX-2 inhibitors in the prevention and management of this disease.

OP4-5
DIFFERENTIAL DIAGNOSTIC OF RENAL CLEAR CELL CARCINOMA USING PLOIDOMETRY

Tatiana Fedorina, Michael Pleshivcev
Samara State Medical University, Russia

Background. The problem of differential diagnostics of renal clear cell carcinoma in various stages of disdifferentiation is particularly important in the light of patient's prognosis determination. Aim: to use ploidometry research for studying the epithelial cell clones in the clear cell renal tumors to determine objective criteria of different stages of cancerogenesis. Methods. Computer ploidometry test was carried out for nuclei of epithelial cells in renal operative specimens, taken from 50 patients with clear cell carcinomas in different grades. Renal epithelium nuclei taken from 10 healthy individuals operated in the case of traumas were used as control. Histological preparations of 8 micron thickness, stained by Feulgen's technique, were subject of the research. Nuclei's ploidy was defined by means of the computer image analyzer "Imager-CH" ("Avtan-San" software version). The "tissue ploidy standart" (2c) was used for obtaining the data of 3024 renal epithelium nuclei. Inter-phase cell nuclei of clones of normal renal epithelium, clear cell carcinomas in different grades were the subjects of investigation. Results: In comparison with the average ploidy value of the normal renal epithelial cells nuclei, the average ploidy index increases 1,8 times in well differentiated clear cell carcinomas (1 grade), 2,1 and 2,4 times in middle differentiated (2,3 grade) and 2,8 times in poorly differentiated clear cell carcinomas (4 grade). The study results showed that tumor cells proliferative activity and nuclei ploidy increase in parallel with the increased disdifferentiation of clear cell carcinomas. Retrospective analysis of 45 cases of renal clear cell carcinomas was provide in routine diagnostics and using ploidometry, the mistake in carcinomas grade was fined in 24%. The average ploidy of nuclei significantly differs between various grades of cancers (4,6 c versus > 6,8 c) which makes the ploidy index a useful differential diagnostic criteria. Conclusions: Computer ploidometry may be used in differential diagnostics of clear cell renal carcinomas. Use of ploidometry data in morphological diagnostics of renal tumors can be an objective tool for taking justified clinical decisions.

OP4-6
INVASION FRONT PHENOMENA IN PROSTATIC CANCER

Peter Stoemmer[1], Ingrid Bayer[2]
[1]Forschungslabor Prof. Dr. Stoemmer und Gemeinschaftspraxis für Pathologie Dr. Langer Prof. Dr. Stoemmer Augsburg, Germany
[2]Forschungslabor Prof. Dr. Stoemmer und Gemeinschaftspraxis für Pathologie Augsburg, Germany

Background: Intratumoral heterogenitiy is a common phenomenon in prostatic cancer, leading to different architectural and cytological classifications (Gleason, Mostofi, AK-Uropath).In most studies however, no correlation was made with the intratumoral distribution of these markers in respect to centrally located carcinoma cells and tumor-cells in the invasion front (which are probably more important for the biological behaviour of the tumor). We therefore analysed various markers in the epithelial-mesenchymal transition zone (EMT) of prostatic carcinomas. Materials and Methods: Tumor cells of the EMT-Zone of 40 intermediate grade prostatic carcinomas were analysed in respect of their expression of chromosome 7 aneuploidy (Zytolight CEN 7 Probe; FISH), E-Cadherin (Biologo, Dr.Schultheiss, Kronshagen, Klon 5H9, IgG1, IHC), N-Cadherin (Biozol, Eching GeneTex.Inc; IgG, polyclonal, IHC) and hepsin (Cayman Chemical, via Biozol Eching; affinity puified IgG, Rabbit; IHC) in comparision to adjacent non-tumor epithelia and carcinoma- cells in well-defined patterns. Results: E-Cadherin: Good expression in basal and secretory cells of non-neoplastic gland and basal cells of PIN. Low expresssion in the tumor-cell-membranes of Gleason Pattern 3 and 4 ; good expression in peripherial parts of cribriform areas and in small tubular and solid parts of the tumor. Loss of E-Cadherin-expression in ETMs adjacent to prostatic stromal cells. N-Cadherin: No N-cadherin in non-neoplastic glands; high cytoplasmic and membranous expression in tumorcells of EMTs. Hepsin.Low expression in non-tumor glands; medium intracytoplasmatic expression in PINs and cancer cells of well defined patterns; very high expresssion in epithelias of small-glandular areas and in most EMTs; Some (regressing?) EMTs show low levels of hepsin, corresponding to their loss of E-Cadherin. Aneuploidy of chromosome 7: (high grade PIN and cancer cells adjoinig ton the EMT showed three to five chromosom 7 centromers by CEN7 analysis. Conclusions:

Tumorcells in EMTs show extensive remodelling of shape and function. Especially the loss of intercellular connections (cadherins) and the abundance of a serin-protease (hepsin), fostering invasion by dissolving collagens and dissolving tight cell-adhesions in the invasion front might influence the tumor's biology more than architectural tumor patterns alone.

OP4-7

TMPRSS2:ERG GENE FUSION EXPRESSION AND PROSTATE CANCER PROGRESSION

Gabriella Nesi[1], Lorella Bonaccorsi[1], Milena Paglierani[1], Csilla Krausz[1], Lorenzo Masieri[1], Sergio Serni[1], Laura Proietti-Pannunzi[2], Marco Carini[1], Gianni Forti[1], Elisabetta Baldi[1], Lucio Luzzatto[3]
[1] University of Florence, Italy
[2] University of Rome "La Sapienza", Italy
[3] Istituto Toscano Tumori, Florence, Italy

Background. Recent studies have reported functional fusion of the TMPRSS2 and ERG genes with consequent ERG overexpression in a large proportion of prostate cancers. Some data suggest that ERG expression is higher in less aggressive prostate carcinomas while others show an association between TMPRSS2:ERG gene fusion and more aggressive disease. Materials and Methods. The TMPRSS2:ERG fusion status was assessed in tumour samples from 84 patients undergoing radical prostatectomy between 1998 and 2000. Sixty patients (group A) had surgery alone, while 24 patients (group B) received androgen ablation therapy for 3 months before surgery. Results. The fusion of TMPRSS2 and ERG was demonstrated by reverse transcription polymerase chain reaction (PCR) in 84% of patients in group A and in 54% of patients in group B (p=0.01). The levels of TMPRSS2:ERG and ERG, measured by real-time quantitative PCR, did not show significant association with clinical and pathological characteristics of the tumours, except for a negative correlation of ERG overexpression with Gleason score (R=0.457; p=0.0001), only observed in group A. The lower proportion of patients harbouring TMPRSS2:ERG fusion in group B suggests that androgen ablation inhibits the expression of TMPRSS2:ERG, underscoring the key role of androgen-mediated transcription control of the gene fusion. Biochemical (PSA) recurrence-free survival was not significantly different in group A patients both with and without TMPRSS2:ERG expression. Conclusions. In this specimen set, we observed that the presence of a TMPRSS2:ERG fusion expression did not correlate with recurrence-free survival following radical prostatectomy. Further studies in larger cohorts of tissue are under way to confirm these observations.

OP4-8

THE EFFECT OF CHRONIC ARSENIC EXPOSURE FROM DRINKING WATER ON THE PATHOLOGIC CHARACTERISTICS OF UROTHELIAL TUMORS IN A NON-SELECTED PATIENT POPULATION WITH BLADDER CANCER

Alan Schned[1], Angeline Andrew[1], Carmen Marsit[2], Steven Morris[3], Scot Zens[1], Karl Kelsey[2], Margaret Karagas[1]
[1] Dartmouth Medical School, USA
[2] Harvard School of Public Health, USA
[3] University of Missouri, USA

Background: In the United States, among the highest incidence and mortality rates for bladder cancer are found in northern New England. Several lines of evidence suggest a possible environmental explanation for this excess. Arsenic, a known cause of bladder cancer in parts of Taiwan, Bangladesh, and other countries where drinking water concentrations are markedly elevated, was considered a plausible explanation in northern New England because of known elevations of arsenic in the ground water and the fact that over 33% of residents obtain their drinking water from drilled wells. We reported in a large, population-based case-control study (Karagas MR, et al. Cancer Cause Cont 2004;15:465) that there is an elevated odds ratio for bladder cancer among patients in the uppermost category of arsenic exposure only in smokers. The current study explores whether there are differences in the pathologic characteristics of bladder cancers in patients with the highest and lowest chronic arsenic exposures. Method: All residents of the state of New Hampshire with bladder cancer newly diagnosed from July 1, 1994, to June 30, 2000, were identified through the state cancer registry. Individual exposure to arsenic was determined in toenail clippings using instrumental neutron activation analysis. All slides were reviewed by a single pathologist. Tumors were classified according to both WHO (1973) and WHO/ISUP (1998) criteria. From a total of 690 patients with pathologically confirmed cancer and toenail arsenic results, tumor classification, grade, and stage were compared between patients with the highest decile (>0.205 μg/g) and the lowest quartile (<0.061 μg/g) of toenail arsenic levels. Results: Tumors from individuals with high arsenic concentration tended to have lower grade, non-invasive tumors, as well as a higher proportion of stage T.i.s. (carcinoma-in-situ) tumors. There was no difference in the proportion of non-urothelial tumors between individuals with high versus low arsenic exposure; non-urothelial tumors comprised a minority of cases in both groups. Conclusion: In this preliminary analysis of a population-based study from the United States, we noted some histopathologic differences between those with higher and lower arsenic exposures. Further investigation of these differences is underway.

OP4-9

TISSUE MICROARRAY STUDY OF THE RELATIONSHIP BETWEEN CLUSTERIN EXPRESSION AND HORMONE THERAPY EFFECT IN PROSTATIC ADENOCARCINOMA

Nuria Juanpere[1], Jose Antonio Lorente[2], Andreas Doll[3], Marina Rigau[3], Miguel Abal[3], Teresa Baro[1], Pilar Garcia[1], Carlos Allepuz[4], Luis Plaza[4], Asunta Munne[1], Luis Angel Rioja[4], Jaume Reventos[3], Sergio Serrano[1], Antoni Gelabert[2], Jose Lloreta[5]
[1] Pathology, Hospital del Mar, UAB, Barcelona, Spain
[2] Urology, Hospital del Mar, UAB, Barcelona, Spain
[3] Biomedical Research Unit, Hospital Vall de Hebron, UAB, Barcelona, Spain
[4] Urology, Hospital Miguel Servet, Zaragoza, Spain
[5] Pathology, Hospital del Mar, UPF, Barcelona, Spain

Background: Clusterin is a secretory glycoprotein that is present in many tissues. It has been identified as one of the main prostasomal proteins. It has dual functional properties related to both apoptotic and antiapoptotic signals. Clusterin expression is upregulated in prostatic tumor tissue after neoadjuvant hormone therapy (NHT). On the other hand, increased expression of clusterin has been associated with shorter biochemical recurrence-free survival. We conducted the present tissue microarray (TMA) study to further elucidate the relationship of clusterin expression with the effect of NHT in tumor cells, as well as with several clinico-pathological variables. Design: For this study, two TMA blocks with 233 prostatic adenocarcinoma samples selected from radical prostatectomy specimens were constructed. They included 175 cases with and 58 without previous NHT. Sections were stained with an antibody for Clusterin. Intensity of Clusterin staining was recorded (0-3), as well as the severity of the hormone blockade-induced changes in tumor cells (also scored 0 to 3). ANOVA tests were performed to study relationship of Clusterin expression with treatment, with treatment-induced changes, pathologic stage and biochemical recurrence-free survival. Result: The intensity of Clusterin expression was significantly related to previous NHT (Chi-square 34.042, p=0.0001). There was no statistically significant relationship between Clusterin expression and pathologic stage or biochemical recurrence-free survival, regardless of previous NHT. Conclusion: The strong association between intensity of

Clusterin expression and the presence and effect of NHT in tumor cells suggests that Clusterin may be involved in the mechanisms that are responsible for this effect. Alternatively, Clusterin expression could be the consequence of such changes. The biological role of Clusterin in prostatic adenocarcinoma needs to be further elucidated, because of the potential therapeutic implications of the availability of Clusterin antisense oligonucleotides.

OP4-10
FISH ANALYSIS OF PTEN GENOMIC DELETION IN PATIENTS WITH RENAL CELL CARCINOMA

Isabela Cunha[1], Eurico Campos[2], Stenio Zequi[2], Gustavo Guimaraes[2], Maisa Yoshimoto[3], Jeremy Squire[3], Ademar Lopes[2], Fernando Soares[1]
[1] Department of Pathology of A. C. Camargo Hospital, São Paulo, Brazil
[2] Department of Pelvic Surgery of A. C. Camargo Hospital, São Paulo, Brazil
[3] Ontario Cancer Institute, University of Toronto, Canada

Introduction: Recent advances in the understanding of the molecular biology of renal cell carcinoma (RCC) have identified new prognostic factors. The PTEN (phosphatase with tensin homology deleted in chromosome 10) is a tumor suppressor gene which deletions and/or mutations have been reported in several solid tumors and associated with poor prognosis. Material And Methods: 110 patients were analyzed from 1980 up to 2005. Clinic-pathological features were reviewed according the WHO/TNM criteria. FISH analysis for PTEN was performed in a TMA block. PTEN genetic abnormalities were correlated to overall survival and disease free survival, and to the established RCC prognostic factors. Results: There were 68 men (61.8%) and 42 women (38.2%), and 55 years-old in median. The average follow-up was 42.3 months. The Fuhrman's grade 1 was observed in 18 patients (16.4%),G2 in 47 patients (42.3%), G3 in 27 (24.5%), and G4 in 18 patients (16.4%). According the 2002 TNM, the following distribution was observed: 54 patients (49.1%) EC I, 14 patients (12.7%) EC II, 26 patients (23.6%) EC III and 16 patients (14.5%) EC IV. There were 71 patients (64.5%) with clear cell subtype, 12 patients (10.9%) with papillary subtype, 14 chromophobe subtype (12.7%), 10 (9.1%) unclassified renal cell tumor, 2 two patients with TTE3 gene subtype and one collecting duct carcinoma. FISH was available in 47 cases. Eighteen of them (40%) had PTEN hemizygous deletion, 3 PTEN homozygous deletion, and in 16 patients (32%) there was no PTEN deletion. Monossomy of chromosome 10 was found in 9 (8%) and trissomy in 2 patient (1.8%). The overall survival (OS) and cancer specific survival (CSS) for the 110 patients were 70.3% and 71.8%, respectively. There were no statistically significant differences in OS (p=0.182) and CS (p=0.273) when patients with or without deletion were compared. There was no differences when compared PTEN status and Fuhrman grade (p=0.109), TNM staging (p=0.220) and tumor subtype (p=0.132). CONCLUSION: The PTEN deletion detected by FISH was not associated with OS, although a trend was observed. Also, there is no association to the traditional prognostics factors for RCC.

OP4-11
CLINICAL SIGNIFICANCE OF NF-κB LEVELS IN UROTHELIAL CARCINOMA

Polyanthi Papanastasiou, Georgia Levidou, Angelica A Saetta, Penelope Korkolopoulou, Irene Thymara, Petros Pavlopoulos, Eupthemia Thomas-Tsagli, Efstratios Patsouris
National and Kapodistrian University of Athens, Department of Pathology, Athens, Greece

Background: Nuclear transcription factor (NF)-κB is a family of proteins which regulate the expression of immune genes that mediate cellular apoptosis, proliferation, invasion and angiogenesis. NFκB has been reported to be constitutively activated in various neoplasms and its immunoexpression has been regarded as a marker of poor prognosis in several carcinomas. However, its clinical significance in urothelial carcinoma remains an unresolved issue. We therefore conducted a retrospective investigation in order to address the role of NFκB in urothelial carcinoma and to explore its potential prognostic significance. Method: The levels of p65/RelA protein expression were quantified immunohistochemically in paraffin-embedded tissue from 116 patients with urothelial carcinoma, using a polyclonal rabbit antibody against the p65 subunit. Nuclear and cytoplasmic immunoreactivity was assessed separately. Basic statistical analysis was performed using appropriate non parametric tests, whereas survival analysis by plotting survival curves according to the Kaplan-Meier method and comparing groups using the log-rank test, as well as by using multivariate analysis (Cox's model). Results: Positive nuclear p65/RelA staining was detected in 92/116 cases (79.3%) and cytoplasmic staining in 95/116 cases (81.89%). Concurrent nuclear and cytoplasmic expression of NFκB was seen in 96.7% (89/92 cases). Nuclear p65/RelA expression was associated with tumour grade and stage in the entire cohort as well as in invasive carcinomas ($p<0.0001$ in the former, $p=0.0019$ and $p=0.0196$ in the latter relationships). Also, cytoplasmic p65/RelA expression was lower in advanced stage (T2/T3 versus T1, $p=0.0197$) and high grade tumours (I/II versus III), although the latter was significant only when analysis was restricted to invasive carcinomas. p65/RelA expression adversely affected survival in both univariate and multivariate analysis in invasive ($p<0.0001$ and $p=0.001$ respectively) as well as in muscle invasive carcinomas ($p=<0.0001$ and $p=0.01$ respectively). Conclusion: The results of our investigation demonstrate that NF-κB activation is correlated with tumour histologic grade and invasive potential in urothelial carcinomas, probably supporting the crucial role of this molecule in tumour agressiveness. Moreover, our study, directly implicates NF-κB nuclear expression as an independent prognostic marker of adverse significance, conveying information beyond that obtained by standard clinicopathological prognosticators.

OP5-1
LEFT VENTRICULAR MECHANICAL SUPPORT IN CONGESTIVE HEART FAILURE: CHANGES OF PLOIDY STATUS, NUMBER OF BINUCLEATED CARDIOMYOCYTES AND CELL-CYCLE REGULATORY PROTEINS

Jeremias Wohlschlaeger
Institute of Pathology University Hospital of Essen, Germany

Aims: In chronic heart failure (CHF) left ventricular assist devices (LVAD) lead to cardiomyocyte hypertrophy regression and numerous molecular changes. Besides hypertrophy, cardiomyocyte nuclei undergo polyploidy in CHF. Given the significant decrease of cardiomyocyte diameter after LVAD treatment, we investigated the cardiomyocyte ploidy status after left ventricular unloading. Methods: In 24 paired myocardial samples the Feulgen stain was applied and computed DNA cytometry both before LVAD and after unloading was performed. Moreover, the number of binucleated cardiomyocytes and cardiomyocyte diameters were determined. The expression of cell cycle regulatory proteins was immunohistochemically demonstrated and morphometrically quantified. Results: There is a significant reduction of the cardiomyocyte ploidy status with a significant increase of di- and tetraploid cardiomyocytes after LVAD. Moreover, a significant correlation between the ploidy status reduction and hypertrophy regression was outlined. The number of bi- and multinucleated cardiomyocytes was significantly increased, whereas expression of cyclin D1 was significantly decreased after LVAD. Conclusions: There is a significant reduction of the cardiomyocyte ploidy status after ventricular unloading, that significantly correlates with

hypertrophy regression, suggesting that cardiomyocytes shift from polyploidy to di- and tetraploidy upon volume- and pressure unloading by LVAD, which might be regulated by cell cycle regulatory proteins.

OP5-2
IMMUNE INFLAMMATION PECULIARITIES IN ATHEROSCLEROSIS

Zota Ieremia, Melnic Eugen, Foca Ecaterina
The State Medicine and Pharmacy, Moldavia

Introduction: The aim of this study was to evaluate the role of immune inflammation in human atherosclerosis. Immunomorphological investigation was directed on CD-4, CD-8, TNF-α,HSP- 60 and CRP level in atherosclerotic lesions. Material and methods: This study has been performed on the human aorta, coronary heart vessels and cerebral arteries collected from 86 early performed autopsies. The patients with cardiovascular insufficiency on atherosclerosis background from 30 to 69 years of age were taken into study group. CD-4, CD-8, TNF-α, HSP- 60,CRP implication was studied trough immunohistochemical reaction using monoclonal antibodies. This material was fixed in 4% phormaldechyde solution. Results: T-cells are believed to act as orchestrator of atherogenesis. The increase of CD-4, CD-8 lymphocytes-T and HLA–DR mononuclears' count in intima and adventitia of the vessels was releved in humans aged 31-59. CRP is an important component of the plasma proteins that insudates the arterial wall preceding the so called initial atherosclerotic lesions. Among the inflammation mediators TNF-α have been detected in increased quantity, being localized on the surface and in depth of atherosclerotic plaque. Identification of HSP-60 cross-reactive T-lymphocytes within atherosclerotic tissue indicates that cell-mediated responses are also involved. Because human HSP-60 have been detected on the surface of endothelial cells in the arterial wall, it could be a putative autoantigen involved in eliciting cell-mediated and humoral immune responses against the vessel wall causing its injury and that leads to atherosclerosis development. The most quantity of the inflammation's markers has been detected at the early stages of atherogenesis, in young persons. In advanced lesions and in old persons their incidence decrease. Conclusions: Our outcomes demonstrate the toxic and immune factors' existence which are considered to be decisive in atherosclerosis pathogenesis. These data give us the reason to elaborate other diagnosis and treatment strategy.

OP5-3
SUDDEN CARDIAC DEATH – A VIEW OF FORENSIC PATHOLOGIST

Katarzyna Michaud[1], Hugues Abriel[2], Vincent Castella[1], Patrice Mangin[1]
[1] Institut universitaire de médecine légale, Lausanne, Switzerland
[2] Département de pharmacologie et de toxicologie, Lausanne, Switzerland

In Switzerland the cases of sudden unexpected death and especially of relatively young people are reported to the judge who orders a forensic autopsy. In some cases, the cause of death remains however unexplained after a classical autopsy and toxicological analyses. In these cases, the cause of death may be related to potentially inherited arrhythmias. According to the literature, the cases of unexpected arrhythmogenic death are estimated to represent 5-10 % of all sudden deaths. The advances in molecular biology have opened new diagnostic perspectives in forensic pathology. In fact, with the appearance of molecular autopsy, it becomes possible to detect the cause of death related to genetic origin and without morphological substrate diagnosed at autopsy as for example cardiac channelopathies. To illustrate this concept, two cases with no evident cause of death found at classical autopsy are presented, one of a 6-month-baby and a second one of a 24-year-old woman. For both victims SCN5A mutations have been detected. One of these mutations has been already described in the literature, whereas the pathogenicity of the second one was determined by analysis of the mutation-induced alteration in cardiac sodium current. However, the molecular diagnosis concerns not only cardiac diseases. Indeed, since the apparition of pharmacogenetics it is considered that both drug disposition and response are individually variable and some genetically vulnerable victims may die with extremely low drug levels found at toxicological analyses. It is also evident that chronic drug abusers may have increased tolerance for high levels of substances detected in their body. Thus, the autopsy findings as well as the results of toxicological and genetic analyses need to be interpreted together in order to decide which case could be really considered as a sudden cardiac death. The molecular diagnosis is important to clarify a case, especially in cases without morphological substrate and makes also possible the detection of the genetic predisposition to sudden deaths of relatives. In this respect, the information provided by genetic analysis places the forensic pathologist in an interdisciplinary collaboration. At the University of Lausanne a multicenter team has been created between departments of forensic pathology, cardiology, and genetics in order to diagnose and prevent the cardiovascular diseases in relatives. The role of the forensic pathologist in this team as well as the legal aspects of post-mortem genetic analyses will be discussed.

OP5-4
ENDOMYOCARDIAL BIOPSY GUIDED BY ELECTROANATOMIC VOLTAGE MAP IN ARRHYTHMOGENIC RIGHT VENTRICULAR CARDIOMYOPATHY

Paola Francesca Silenzi[1], Andrea Avella[2], Augusto Pappalardo[2], Claudio Tondo[2], Cira Rosaria Tiziana Di Gioia[1], Giulia D'Amati[1]
[1] Department of Experimental Medicine, Sapienza University, Rome, Italy
[2] Cardiovascular Department St. Camillo-Forlanini Hospital, Rome, Italy

Objective: To evaluate the sensitivity of right ventricle (RV) electroanatomic (EA) mapping with CARTO system (Biosense-Webster) for arrhythmogenic right ventricular cardiomyopathy (ARVC) diagnosis. Background: Despite currently used standardized criteria represent a useful clinical tool, the diagnosis of ARVC remains a clinical challenge, particularly in its early stages. Endomyocardial biopsy (EMB) may be used for a definitive in vivo histopathological demonstration of the typical fibrofatty infiltration of RV myocardium but its sensitivity is low. Recent data support CARTO system as an innovative approach to identify low-voltage regions reflecting fibrofatty myocardial replacement. Methods: Twenty patients (pts) (9 males, 33.2 + 18.4 years) with frequent symptomatic drug refractory ventricular ectopies or sustained/unsustained ventricular tachycardia of right ventricular origin were enrolled for the study. Noninvasive standardized ARVC criteria were fulfilled in 10 pts (50%). An EA reconstruction of RV was performed in all pts, sampling multiple endocardial sites (202 + 61) during sinus rhythm. Bipolar voltage map analysis, documented low-voltage areas (< 0.5 mV) in 17 pts (85%). In 14 pts (70%) with pathological EA map (6 males, 31.9 + 17.7 years) an EMB focused on low-voltage areas was attempted (study group). For each patient, up to 6 specimens were picked up from low-voltage regions. Endomyocardial biopsies were fixed in 10% phosphate-buffered formalin and embedded in paraffin. A minimum of 15 sections were obtained from each sample and stained with Hematoxylin & Eosin and Masson Trichrome. Immunohistochemical stains for CD3, CD20 and CD68 were also performed to eventually characterize inflammatory infiltrates. Slides were examined under light microscopy by two observers, unaware of voltage mapping results. Results: EMB guided by RV voltage map was diagnostic for ARVC in 11 pts (79%), while only non specific findings (mild hypertrophy and interstitial fibrosis) were documented in

the remaining 3 pts (21%). Among pts with bioptic evidence of ARVC, 9 pts (82%) did not fulfill standardized noninvasive criteria and 7 pts (64%) presented only minor RV morpho-functional alterations. Conclusions: EMB guided by bipolar RV voltage mapping seems to have a high diagnostic sensitivity for ARVC, particularly in patients presenting in the early stages of the disease. Nevertheless, the real clinical impact of this innovative approach needs to be confirmed in a greater patient population.

[5] Department of Histology, Embryology and Applied Biology, Policlinico S. Orsola, University of Bologna, Italy

Background.Rapid revascularization of ischemic organs is essential to restore tissue function. In experimental models,bone marrow derived-endothelial progenitor cells are able to mobilize to ischemic sites and complement neo-angiogenesis in vivo; however, their clinical use is yet hampered by difficulties in obtaining an adeguate number of healthy and functional progenitors.Recently vasculogenic progenitors were demonstrated in the vascular wall of human muscular arteries; this study aimed to establish whether human thoracic aortas from healthy multiorgan donors contain mesenchymal stem cells (MSC) with angiogenic property. Methods.Fresh thoracic aortas from 10 heart beating multi-organ donors were processed for IHC staining (c-kit,CD-34,ASMA,vWF,ki-67,CD-45,CD-68) and used to isolate putative progenitor cells. Cells taken at passages 3-5 were characterized with flow citometry (CD133-PE, CD117-FITC, CD34-PE, CD44-FITC, CD90-PC5, CD105-PE, CD166-PE, CD45-APC, CD146-PE, HLA class I-FITC,HLA-DR-FITC). IF studies on cells plated in collagen biocoated slide chambers were done in parallel. Total RNA was extracted from cells and the expression of the following mRNAs was investigated:OCT4,BMI-1,BCRP-1,IL-6, c-kit, CD-133, KDR. For the in vitro angiogenesis assay, cells were cultured for 7 days in DMEM plus 2% FBS with and without 50 ng/ml VEGF. The expression of endothelial cell markers (vWF, KDR) was performed using flow cytometry, IF and RT-PCR."Capillary formation was investigated on Matrigel; cell seeded on Matrigel were also processed for TEM."Results.IHC studies of human thoracic aortas showed distinct CD34+ and c-kit+ cell populations in between the media and adventitia;"ki-67+ cells were found in corresponding areas."Cells expanded from thoracic aortas had characteristics of MSC:CD44+,"CD90+, CD105+, CD166+, CD45-; they showed a transcript expression of stem cell markers: OCT4, c-kit, BCRP-1,"IL6, and BMI-1.Cells cultured in the presence of VEGF acquired characteristics of endothelial cells, i.e., increased expression of KDR, vWF expression as documented by flow cytometry, IF and TEM. The matrigel assay revealed that cells were able to form capillary-like structures within 6 hours of seeding. Conclusions:This study demonstrates that thoracic aortas from multi-organ donors yield MSC with the ability to differentiate in vitro into endothelial cells.These cells can be expanded rapidly, providing numbers which are adequate for therapeutic neovascularization; again, being recovered from young and healthy donors, they can be cryostored in appropriate cell banking facilities for later use.

OP5-6

LYMPHATIC VESSELS, LYMPHATIC VASCULAR ENDOTHELIAL GROWTH FACTORS AND THEIR RECEPTORS IN HUMAN HEART VALVES

Ivana Kholová[1], Svetlana Laidinen[2], Galina Dragneva[2], Petra Hájková[3], Ivo Steiner[3], Veli-Matti Kosma[1], Seppo Ylä-Herttuala[2]
[1] Pathology Unit, Institute of Clinical Medicine, University of Kuopio and University Hospital, Kuopio, Finland
[2] Department of Biotechnology and Molecular Medicine, A. I. Virtanen Institute for Molecular Medicine, University of Kuopio, Kuopio, Finland
[3] Fingerland Department of Pathology, Charles University Faculty of Medicine and University Hospital, Hradec Králové, Czech Republic

Background: Despite the importance of myocardial vasculature in many pathological conditions very little information is available about cardiac lymphatic vessels in normal and pathological conditions. Recent generation of lymphatic specific antibodies enables accurate studies of lymphatic vasculature. Additionally we studied the expression of lymphatic vascular endothelial growth factors and their receptors in valves. Methods: We evaluated bioptic samples of 6 aortal and 3 mitral valves from 8 patients (age range 50-77 years, 7 males, 1 female). The histopathological diagnosis was as follows: infective endocarditis, postrheumatic fibrohyalinosis, myxoid degeneration and calcified stenosis. Vasculature was assessed by immunohistochemical staining with the panel of antibodies: CD31, LYVE-1, D2-40. The expression profiles of vascular endothelial growth factors VEGF-C and VEGF-D and their receptors VEGFR-2 and VEGFR-3 were additionally evaluated. Results and conclusions: Highest amount of lymphatics was found in infective endocarditis (up to 70 per section) and they formed up to 100% of all vessels. The increase was found also in degenerative calcified stenosis. The myxoid degeneration was accompanied by lowest increase. The majority of vessels in fibrotic areas were CD31-positive blood vessels. Lymphangiogenesis was accompanied by an increase in the lymphatic vascular growth factors expression. The profound knowledge of cardiac lymphatic system has an impact on further therapeutic vascular growth studies and improvement of new therapeutic approaches.

OP5-7

MORPHOLOGICAL AND IMMUNOHISTOCHEMICAL ANALYSIS OF A SERIES OF 33 CONGENITAL VASCULAR MALFORMATIONS – A SINGLE CENTRE EXPERIENCE

Nonica Maftei[1], Nigel J Standfield[1], Amanda Forsyth[1], Michelle Farrar[1], Louise C Brown[2], Ann Sandison[1]
[1] Charing Cross Hospital, London, United Kingdom
[2] Imperial College, London, United Kingdom

Background: Congenital vascular malformations (CVMs) are the result of abnormal blood vessel development. Whilst some lesions are self-limiting, the sub-class arteriovenous malformations (AVMs) persist and in many instances with potential implications for disfigurement, functional disability, morbidity and rarely mortality. Different clinical categories of CVMs are not distinguishable histologically and features described in the literature are largely non-specific. This is partly responsible for the current lack of understanding and subsequent sub-optimal management of CVMs, especially of AVMs. We have analysed the histological morphology in comparison with control tissues in 33 patients with CVMs (including 9 AVMs). The significant findings were related to clinical confounding parameters (sex, high or low flow categorisation, location of the CVM, previous embolisation / sclerotherapy and associated surface ulceration. This study was performed to elucidate the histology of these uncommon but often locally aggressive lesions and to gain insight into possible mechanisms involved in their

aetio-pathogenesis. Methods: 33 consecutive CVM lesions excised from patients presenting between 1992 - 2006 were analysed morphologically using routine techniques, histochemical (H&E, Masson Trichrome, Elasic Von Gieson and Toluidine blue) and immunohistochemical (CD68, CD3, CD20, Factor VIII, actin 1-alpha, Ki67 and S100). 10 control specimens were similarly analysed. As 10 outcomes have been analysed on the same small dataset, a Bonferroni correction was applied such that $p<0.005$ indicates significance. Results: Macrophages ($p<0.0001$), mast cells ($p<0.0001$), vessel number ($p=0.0004$) and vessel diameters ($p=0.0005$) were significantly higher in the CVM group compared to controls. There was no correlation between the statistically significant morphological parameters resulted in this study, and any of the clinical parameters. Discussion: Macrophages and mast cells have recognised roles in angiogenesis. Our findings suggest that the inflammatory cellular infiltrate may be implicated in the development of CVMs. Increased vessel diameter may be the result of abnormal local concentrations of angiogenesis mediators. Further insight into the role of inflammatory and angiogenic cytokines in the aetio-pathology of these lesions may provide novel criteria for more clinically appropriate classification and accurate diagnosis of CVMs. This enhanced clinico-pathological correlation should improve therapeutic options and efficacy.

OP6-1

MORPHOLOGIC, PHENOTYPIC AND CYTOGENETIC CHARACTERIZATION OF THREE ESTABLISHED EWING/PNET CELL LINES

Rosa Noguera, Isidro Machado, Samuel Navarro, Empar Mayordomo, Marta Piqueras, Antonio Pellin, Antonio Llombart-Bosch
Department of Pathology, Medical School, University of Valencia, Spain

Background: Cell lines are of great importance in the study of the genetic changes in tumors, and some reveal several aspects of tumor oncogenesis. Several Ewing/PNET cell lines are available, usually isolated from the original tumors and only on few occasions from the xenotransplanted tumors. Method: The aim of this report is to characterize and describe the evolution of three Ewing/PNET cell lines, primarily isolated and cultured (in vivo and in vitro cell lines) from the original tumor. Subsequently, xenotransplanted cell lines were cultured in vitro, and analyzed and characterized by morphologic (phase contrast microscopy), immunohistochemical (CD99, FLI-1, Vimentin, HNK-1, NF, c-kit, EPO, EPO-R and SCF), cytogenetic (EWSR1 break apart, p16 and p53 status) and molecular biology (gene fusion type) studies. Subsequently, in vivo re-inoculation of these cell lines in nude mice was performed and all studies including the ki-67 index, p53 and p16 immunohistochemical analysis were made; the results were then compared with the initial in vivo xenotransplanted tumors. Results: CD99 was the most-expressed immunohistochemical marker in the three xenotransplanted cell lines, the original tumors and the nude mice tumors. The FISH breakapart (EWSR1) studies showed positive translocation of the EWS gene in all the material studied, as well as the molecular biology studies which revealed the fusion gene EWS/FLI1 in the three xenotransplanted cell lines. The growth of the tumors in nude mice was more accelerated when the inoculation was performed from the in vitro xenotransplanted cell lines; in these cases, the proliferation index measured by the value of ki67, increased progressively in the passages. This could be related or associated with the genetic changes that occur in cells lines; p16 deletions and/or p53 mutation can immortalize the cells lines and promote a high proliferation rate of the cells in vitro and in vivo. Conclusions: There was heterogeneity in the results of the p16, p53 and ki67 in the three cell lines, the original tumors as well as in the nude mice tumors. * Performed with support of EUROBONET VI FW.EU Contract Nº 018814 and FISS Madrid: PI 04/0882 and RD 06/0020/0102

OP6-2

POTENTIAL PROGNOSTIC IMPORTANCE OF CHOSEN MORPHOMETRIC CHARACTERISTICS OF THE CELLS OF WILMS' TUMOR AND NEUROBLASTOMA IN CHILDREN

Jozef Kobos, Piotr Dembski
Department of Pathology of the Age of Development Medical University of Lodz, Poland

Currently new technologies based on the computer image analysis are used in the histopathological evaluation. Application of these technologies make possible more detailed and precise morphological diagnosis. The aim of the study was the evaluation of the MVf (morphometric discriminat of the function MV) and its potential prognostic importance in the group of children with Wilms' tumor and neuroblastoma. The MVf value was calculated on the basis of the age of the patients and also on the basis of surface area, circumference and diameter of the neoplastic cells. Our material consisted of 51 cases of Wilms'tumors and 19 cases of neuroblastomas from the files of the Department of Pathology of the Age of Development Medical University of Lodz. The MultiScanBase CSS Ltd. Company system was used for scoring the morphometric characteristics (surface area, circumference, diameter and maximum and minimum Feret diameter) of the neoplastic cells. According to the article "Nuclear Morphometry and Prognosis in Favorable Histology Wilms' Tumor. A Prospective Reevaluation" the MVf value > - 0.35 was related to unfavorable prognosis. Our date showed that the higher MVf value were observed in neuroblastomas than in Wilms' tumors. We also proved that the lower MVf value was related to favorable prognosis in children with nephroblastomas. We noted that the higher value of this parameter in children with neuroblastomas characterized tumors with benign clinical course. In conclusion we believe that the MVf value is an independent useful prognostic marker in the group of Wilms' tumor and neuroblastomas in children.

OP6-3

GENETIC ALTERATIONS IN NEPHROBLASTOMAS AND CORRESPONDING NEPHROGENIC RESTS

Christine Grill[1], Ivo Leuschner[2], Otto Dietze[1], Cornelia Hauser-Kronberger[1], Barabara Guertl[1]
[1] Department of Pathology, General Hospital and Paracelsus Medical University Salzburg, Austria
[2] Department of Paidopathology, University of Kiel, Germany

Background and Aims: Nephroblastomas are thought to develop from nephrogenic rests (NR) by accumulating genetic alterations. All subtypes of nephrogenic rests can potentially develop into nephroblastoma. In a few single studies identical genetic changes have been identified at chromosome 11p15, 11p13 and 16q. In this project we want to establish the molecular relationship between NR and nephroblastomas. Methods: For our study we have selected several different tumor suppressor candidate genes (nm23, p63 and PTEN), which also either play a role in nephrogenesis like WT1 gene or in the development of renal cancer. Expression analysis of these genes was performed by routine immunohistochemistry in combination with the DAKO ENVISION detection system. Nephrogenic rests, nephroblastomas and the corresponding normal tissue were manually microdissected under the microscope followed by routine extraction of genomic DNA in order to evaluate loss of heterozygosity (LOH) of our candidate genes. We investigated polymorphic gene loci by different PCR-based methods. Results: 30 cases of nephroblastomas with associated NR from the paediatric tumor registry, Kiel, will be included in the study. So far samples of 11 cases of perilobar NR, 5 cases of intralobar NR and one case showing a perilobar and an intralobar NR have been investigated. p63 protein expression showed predominant negative staining except for some tubular structures and squamous elements within the tumour. The expression pattern of

metastasis suppressor gene nm23 was only cytoplasmatic. It was strongly expressed within the tumour and NR in seven cases. The remaining cases showed predominant partial positive staining of tumour and NR. The cases so far investigated with antibodies against PTEN showed expression in normal renal tissue and weak expression in the blastemal part of the tumour. Analysis of LOH of the PTEN gene has revealed so far non-informative cases. Conclusions: In order to interpret our results of the PTEN gene we need to investigate the yet remaining cases. The mixed staining pattern of nm23 needs to be clarified in connection with clinical data and outcome. So far we have been able to exclude a possible role of p63 in the pathogenesis of nephroblastomas.

OP6-4

LUNG DEVELOPMENT IN PATIENTS WITH SEVERE HYPOPHOSPHATASIA (HPP): SEVERE EFFECTS DUE TO POOR MECHANICAL FUNCTION

Cirilo Sotelo-Avila[1], Richard A. Cahill[1], Daphne Demello[2], Deborah Wenkert[3], Michael P. Whyte[4]
[1] SSM Cardinal Glennon Childrens Medical Center/Saint Louis University, USA
[2] Phoenix Childrens Hospital, USA
[3] Shriners Hospital for Children, St. Louis, USA
[4] Washington University School of Medicine, USA

Background: A better understanding of the mechanisms of lung morphogenesis and lung plasticity will improve our ability to treat and or prevent a variety of neonatal and adult lung diseases. Growth and maturation of fetal lungs are regulated by both humoral and physical factors. But most of the studies on lung development have been done in animal models. “Experiments in nature” will help us to better understand the molecular, biochemical and biophysical events involved in producing normal human lung. Mechanical stretch that stimulates fetal lung proliferation is inhibited by mechanical forces (i.e. congenital diaphragmatic hernia), or a lack of amniotic fluid (oligohydramnios); all lead to a reduction in airway number in fetuses. The critical period for alveolarization begins during the canalicular period (16–26 weeks post conception [pc]) of lung development. But alveolarization continues on with impressive growth during the post natal period (38 weeks pc–2 years postnatally). Hypophosphatasia (HPP) is a rare inborn error of metabolism which features deficient activity of “tissue non-specific” alkaline phosphatase. Patients with the perinatal (p-HPP) form die in utero or shortly after birth. Patients with infantile HPP (i-HPP) present before 6 months of age with rickets, failure to thrive, or vitamin B6-dependent seizures. Approximately 50% succumb to respiratory failure. Radiographs of both p-HPP and i-HPP reveal a generalized demineralization of all bones with narrowing of the rib cage and fractures. Collagen and the extracellular matrix are normal in HPP. Reports on the pathogenesis of respiratory failure in these patients and others with severe and fatal skeletal abnormalities are deficient. Methods and Results: We examine four children with HPP including two with i-HPP who lived beyond 6 months. A lung biopsy at 14 months, revealed a decreased number of alveolar ducts, marked medial hypertrophy, intimal proliferation and fibrosis in pre-acinar and intra-acinar pulmonary arteries with luminal narrowing. Alveoli were lined with Type II pneumocytes with absent tubular myelin. No Type I cells were identified. Patients with p-HPP who died at birth had normal radial alveolar counts but a paucity of blood vessels (alveolar:arterial ratio > 20) Conclusion: Despite postnatal survival, mechanical factors must be corrected in the critical period of alveolarization before these changes become irreversible. Delays in the current strategies to correct the mineralization defect in the skeleton after birth may not be sufficient.

OP6-5

FOCAL ADHESION KINASE EXPRESSION IN MOST COMMON PEDIATRIC SOLID TUMORS

Stamatios Theocharis[1], Jerzy Klijanienko[1], Maria Papaefthymiou[2], Paul Freneaux[1], Jean Michon[1], Jerome Couturier[1], Herve Brisse[1], Philippe Vielh[1], Xavier Sastre[1]
[1] Department of Tumor Biology, Pediatrics and Radiology, Institut Curie, Paris, France
[2] Department of Forensic Medicine and Toxicology, National and Kapodistrian University of Athens, Athens, Greece

Background: Focal Adhesion Kinase (FAK) is a nonreceptor protein kinase widely expressed in various tissues and cell types, playing important role in integrin signaling. In vitro studies showed that tumor cells present increased FAK signaling, inducing uninhibited proliferation, protection from apoptosis, invasion, migration, adhesion, spreading and tumor angiogenesis. Several in vivo studies supported the above observations and further correlated FAK expression with clinicopathological parameters in several types of human malignancies. The aim of our study was to characterize FAK expression in the most common solid pediatric tumors (neuroblastoma, nephroblastoma and rhabdomyosarcoma) and estimate clinical significance. Method: Ultrasound-guided Fine-Needle Aspiration (FNA) aspirates from 30 patients with neuroblastoma, 15 with nephroblastoma and 10 with rhabdomyosarcoma were obtained at initial diagnosis and maintained as ThinPrep preparations. Tumor cells were immunostained with the streptavidin-biotin immunoperoxidase technique to evaluate FAK expression. FAK positivity, overexpression (positivity in more than the mean percentage value) and intensity of immunostaining (mild, moderate, intense) were correlated with the clinical stage of disease and tumor cells´ proliferative capacity (Ki-67 labeling index). Results: FAK positivity was noted in 20 out of 28 (71,4%) neuroblastoma, in 10 out of 16 (62,5%) nephroblastoma and in 7 out of 8 (87,5%) rhabdomyosarcoma cases, while FAK overexpression in 8 out of 20 (40%) positive neuroblastoma, in 4 out of 10 (40%) positive nephroblastoma and in 3 out of 7 (42,8%) rhabdomyosarcoma positive cases. The intensity of FAK immunostaining was mild, moderate and intense in 65%, 30% and in 5% of neuroblastoma, in 80%, 10% and 10% of nephroblastoma and in 14,3%, 71,4% and 14,3% of rhabdomyosarcoma positive cases, respectively. FAK positivity, overexpression and intensity of immunostaining were not correlated with patients' clinical stage and tumor cells' proliferative capacity. Conclusion: FAK expression was prominent in the most common pediatric solid tumors, nevertheless no correlation was found with clinicopathological parameters important for patients’ outcome, suggesting an uncertain involvement of FAK in either diagnosis or management of patients with neuroblastoma, nephroblastoma or rhabdomyosarcoma.

OP6-6

HTERT EXPRESSION IN MALIGNANT PERIPHERAL NERVE SHEATH TUMORS (MPNST) OF PEDIATRIC AGE: CORRELATION WITH TUMOR GRADE AND PROGNOSIS.

Sara Pizzi[1], Patrizia Dall'Igna[2], Emanuele S. G. D'Amore[3], Claudio Gambini[4], Paolo Nozza[4], Angela Rita Sementa[4], Vito Ninfo[1], Gianni Bisogno[2], Rita Alaggio[1]
[1] University of Padova, Pathology Department, Padova, Italy
[2] University of Padova Pediatric Oncology and Surgery Departments, Padova, Italy
[3] Ospedale S. Bortolo, Pathology Department, Vicenza, Italy
[4] Istituto G. Gaslini, Pathology Department, Genova, Italy

Telomerase is a complex ribonucleoprotein enzyme that extends telomeric repeats on the ends of chromosomes, preventing the progressive shortening in each cell division that would lead to replicative senescence of cells. hTERT is the catalytic subunit

that provides the function to replicate the ends of chromosomes. In epithelial neoplasms hTERT is frequently increased, but in sarcomas it is less well characterized. We have investigated the expression of hTERT in a series of pediatric MPNST and its correlation with grading and prognosis Methods and results 19 MPNST enrolled in the Italian protocol for soft tissue tumors (RMS 88, RMS 96) were reviewed and graded according to the French FNCLCC system. Immunohistochemical staining for hTERT was performed, and the results were scored as follows: 0, negative; +1, weak positivity in rare cells; +2, strong and diffuse positivity. The age range of patients was 1-17 yrs; 7 suffered from NF1, 8 did not show any syndrome; for 4 patients the status was unknown. The mean follow-up was 4.8 yrs (range 1-9 yrs). 8 patients died (1 for toxicity), 1 had local relapse, 1 is alive with disease. hTERT expression was detected in 12 cases (63%), with +1 in 6 and +2 in other 6 tumors. NF1-associated MPNST were positive in 4/7, with +2 in only one case; conversely, 7/8 non NF1-associated MPNST were positive, with +2 in 4 cases; MPNST with unknown NF1 status were positive in 1/4 cases. The relationship of tumor grade and hTERT expression was the following: G1: hTERT 0 in 1/5, +1 in 3/5 and +2 in 1/5; G2: hTERT 0 in 2/4, +1 in 1/4 and +2 in 1/4; G3: hTERT 0 in 4/10, +1 in 2/10 and +2 in 4/10. Death occurred in 1/6 patients with hTERT 0, in 3/6 with hTERT +1 and in 4/6 with hTERT +2; follow-up was not available for 2 patients (1 hTERT 0 and 1 hTERT +2). Conclusions Pediatric MPNST express hTERT in 63% of the cases, with strong immunoreactivity in 31.5% of cases, and +2 positivity is more frequent in tumors not associated with NF1. In addition expression of hTERT seems to be related to an unfavorable prognosis.

OP6-7
ACTIVATION OF THE PI3K/AKT PATHWAY IN NEUROBLASTOMA

Herve Sartelet[1], Marine Castaing[2], Monique Fabre[3], Jacques Bosq[2], Anne-Laure Rougemont[1], Stefan Michiels[2], Gilles Vassal[2]
[1] CHU Sainte Justine, Montreal, Canada
[2] Institut Gustave Roussy, Villejuif, France
[3] CHU Kremlin Bicêtre, le Kremlin Bicêtre, France

Background: Neuroblastoma is a pediatric malignant neurorectodermal tumor with still a poor survival in children over 1 year of age. In cancer, the PI3K/Akt pathway contributes to tumor aggressiveness (proliferation, metastasis). It is a major target for novel anti-cancer therapies. The objective was to study the activation of the PI3K/Akt pathway in NB. Methods: 101 patients (median age 2.5 years, range: 0-13) with a resected neuroblastoma (16 stage I; 7, II ; 22 ,III; 48, IV and 8, IVS) were included. Tissue microarrays were constructed containing 101 primary tumors, 39 paired metastases and 56 paired normal tissues. Immunohistochemical staining was performed on sections using antibodies against PI3K, Akt and phosphoAkt (S-473). The expression of membrane receptors (EGFR, HER-2, VEGFR1, VEGFR2, PDGFRα, PDGFRβ, IGF1Rβ, TrkB), proteins directly interfering with AKT (PTEN, mTOR) and downstream proteins (phospho-p70S6 kinase, 4eBP1) was studied. The intensity was evaluated by a semi-quantitative score based on the percentage of positive cells. The Wilcoxon signed rank test was applied for the comparison of paired data and adjusted for multiple testing using the False Discovery Rate criterion. Spearman correlation values (rho) were used to compare the expression between genes in the primary tumors. Results: 60% of the tumors expressed PI3K, 80% AKT and 73% pAKT. In addition, phospho-p70S6 kinase and 4eBP1p were expressed in 95% and 85%. All these proteins had a higher expression in tumors as compared with paired normal tissues (fdr-adjusted $p<0.001$). Akt and pAkt showed a tendency for higher expression in metastases as compared to paired primary tumors (raw $p<0.05$ for both, but fdr-p=0.11 and fdr-p=0.17 respectively). While EGFR, IGF1Rβ, TrkB, PDGFRα and PDGFRα were significantly more expressed in primary tumors as compared to normal tissues (fdr-$p<0.05$), only IGF1Rβ seemed more expressed in metastases (fdr-p=0.09). A significant positive correlation was found between pAkt and the following: VEGFR1, VEGFR2 and IGF1Rβ (rho>0.34, $p<0.001$), phospho-p70S6 kinase and mTOR(rho>0.26, $p<0.01$). Conclusions: The PI3K/Akt pathway is activated in neuroblastoma and could be an attractive target for novel therapies. In addition, the data suggested that VEGFR and IGF1R are preferentially committed to this pathway activation.

OP6-8
MORPHOLOGICAL AND IMMUNOHISTOCHEMICAL CHANGES OF PLACENTA OF WOMEN WITH MULTIFETAL PREGNANCIES REDUCED TO TWINS

Tamara Zadorozhna[1], Larisa Tumanova[1], Olena Ryabenko[2]
[1] Institute of Pediatrics, Obstetrics and Gynaecology, Ukraine
[2] Clinic of Reproductive Medicine 'Nadija', Ukraine

Introduction: Multifetal pregnancies are known to be associated with a higher risk in maternal, perinatal complications when compared to singletons or twins. Materials and methods: We made a retrospective study of placenta of 38 high multiple pregnancies following assisted reproduction that were reduced to twins (group 1). They were compared with nonreduced twins pregnancies (group 2) and control group (natural pregnancy). The study of structural and functional features of the placenta included morphological, morphometrical and immunohistochemical methods (expression of the antigen tumor necrosis factor (TNF) and proliferative cellular nuclear antigen (PCNA) by streptavidin-peroxidase method). The Results of the immunohistochemical detection were assessed by traditional approaches using the score to reflect the degree of the expression of detected antigens and the apoptosic index (AI). Results: Chronic placenta insufficiency was detected in the group 1 in 71.5% compare to 28.5% in the group 2 according to the results of histological examination. Destructive changes and chronic placenta insufficiency mild (28.58%) were detected together with sever (71.42%) compensatory changes including angiomatosis of the vessels, increased number of syncytial inserts and sinusoidal transformation of capillary. Described compensatory changes were further supported by the detection of the regeneration markers such as PCNA expressed in the nuclei of the cells. Increased expression of PCNA (relevant to the score of 3 to 4) in the cyto- and syncytiotrophoblast cells of the women from IVF and embryo reduction group compared to group 2 was detected by immunohistochemical methods. The Expression was lower in stroma fibroblasts (mostly score 2, in some cells 3), compared to group2. The level of apoptosis (AI) in placenta barrier was increased in the patients with embryo reduction almost by 2 fold in the villies sincitii (12.0+-0.42% and 7+-0.21 % in control group). AI in stroma cell was lower than in the group 2. Significant number of TNF-positive cells with mild and high TNF expression (score 2-3) was detected in placentas of patients from the group 2 (patients who had IVF) compared to the control group. Conclusions: Chronic placenta insufficiency, increased expression of TNF (especially in epithelial cells), inreased AI in epithelium, stroma and decidual cells and elevated PCNA in epithelial cell of the villies were characteristic findings in the placentas of the women after IVF and embryo reduction.

OP6-9
ESTIMATION OF APOPTOSIS IN PLACENTAS WITH INTRAUTERINE GROWTH RETARDATION

Nikolaos Kavantzas, George Agrogiannis, Emmanuel Agapitos, Sofia Tseleni, Efstratios Patsouris
National and Kapodistrian University of Athens, School of Medicine, 1st Dept of Pathology, Greece

Background: Intrauterine growth retardation (IUGR) and preterm delivery remain the most important risk factors of perinatal

morbidity and mortality. However, the underlying pathophysiological mechanism of IUGR still remains the subject of extended studies. This immunohistochemical study aims to analyze the incidence of apoptosis in placenta tissue with IUGR due to uteroplacental insufficiency, to compare its incidence to uncomplicated gestation and to interpret its possible role in case of IUGR. Method: Placental tissue samples were obtained from 15 normal pregnancies (control group) and 20 pregnancies complicated with IUGR (study group). All the samples were examined with fluorescence microscopy using fluorescence TUNEL staining and the number of apoptotic nuclei was measured using an image analysis system. Results In general, few apoptotic cells were seen in term placental tissue of uncomplicated pregnancies. By contrast, a significant increase in the incidence of apoptosis was identified in placental tissue of IUGR pregnancies at term, with the highest apoptotic index in the syncytiotrophoblast layer ($p<0.0001$). Conclusion: Whether the observed increase in the incidence of apoptosis is a result of IUGR or is a part of the pathophysiological process leading to these complications is yet not clearly identified. Placenta may respond to hypoxic stress by enhancing the number of apoptotic cells. This could be interpreted as an attempt from the placenta to compensate for this relative ischemia and so increase the nutritional transport and gas exchange.

OP7-1

E-CADHERIN/CATENIN COMPLEX AND THE RECENTLY IDENTIFIED DYSADHERIN ARE DIFFERENTIALLY EXPRESSED IN PRIMARY LIVER TUMOURS

Alexander Charalabopoulos[1], Anna Batistatou[2], Konstantinos Charalabopoulos[3], Yukihiro Nakanishi[4], Setsuo Hirohashi[4], Angelos Kappas[5], Niki Agnantis[2]
[1] Department of Surgery, Ioannina University Medical School, Ioannina, Greece and Department of Surgery, Peterborough and Stamford Hospitals, Cambridgeshire, United Kingdom
[2] Department of Pathology, Ioannina University Medical School, Ioannina, Greece
[3] Department of Physiology, Ioannina University Medical School, Ioannina, Greece
[4] Pathology Division, National Cancer Center Research Institute, Tokyo, Japan
[5] Department of Surgery, Ioannina University Medical School, Ioannina, Greece

Background: The aim of the present study is to examine the expression and localization of the E-cadherin cell-cell adhesion molecule and its associated undercoated catenins (α-, β-, and γ-catenin), as well as the recently identified by members of our research team, anti-adhesive protein termed dysadherin, in primary endo-hepatic carcinomas. Method: Fifty-six (56) formalin-fixed, paraffin-embedded tissue specimens of primary liver tumours (39 hepatocellular carcinomas and 17 cholangiocarcinomas) were examined immunohistochemically. The EnVision system (DAKO, Netherlands) and the monoclonal antibodies CM170B (Biocare Medical, Menarini Hellas) against E-cadherin, anti- α-, β-, and γ-catenin (Menarini, Hellas), as well as NCC-M53 against dysadherin, were used. The staining was evaluated by a semiquantitative method. Results: In the vast majority of hepatocellular carcinomas there was decrease in the membranous immunostaining for E-cadherin and increase in immunostaining for α-, β-, and γ-catenin. The expression of E-cadherin was inversely correlated with the grade of hepatocellular carcinomas, while that of α-, β-, and γ-catenin was directly correlated. Furthermore, in high grade hepatocellular carcinomas, nuclear localization of β-catenin was noted. Dysadherin was not expressed in non-neoplastic hepatocytes. Membranous dysadherin immunostaining was noted only in 3 (7.6%) hepatocellular carcinomas, all of which exhibited decrease in E-cadherin expression. In non-neoplastic bile ducts there was membranous immunostaining for E-cadherin and α-, β, and γ-catenin, but not for dysadherin. In cholangiocarcinomas reduction in the expression of E-cadherin, α-, β-, and γ-catenin, and positive membranous staining for dysadherin (10/17, 59%) were noted. There was no statistically significant correlation between dysadherin and E-cadherin expression. Conclusion: Hepatocytes and intrahepatic bile duct cells, although situated in the same area, differ in the signal transduction pathways that are implicated in carcinogenesis, at least regarding the role of molecules involved in cell adhesion and dysadhesion processes.

OP7-2

HEPATOCELLULAR CARCINOMA IN ALPHA-1-ANTITRYPSIN DEFICIENCY: A GENOTYPE STUDY IN SINGLE NEOPLASTIC AND NON-NEOPLASTIC HEPATOCYTES.

Simona Saccani[1], Paola Francalanci[2], Filippo Maria Santorelli[3], Francesca Minnei[2], Pierpaolo Coni[1], Gavino Faa[1], Francesco Callea[2]
[1] Department of Pathology, University of Cagliari, Cagliari, Italy
[2] Department of Pathology, "Bambino Gesù" Children's Hospital, Rome, Italy
[3] Unit of Molecular Medicine, "Bambino Gesù" Children's Hospital, Rome, Italy

Background. Alpha-1-antitrypsin (AAT) deficiency is associated with mutation in the SERPINA 1 gene and represents the most common cause of metabolic liver disease in children. Around 10-15% of adults develop hepatocellular carcinoma (HCC). Hepatocellular damage is due to toxicity of the mutant alpha-1-antitrypsin molecule retained within hepatocytes. The histological hallmark of the disease is the intracellular periodic acid-Schiff diastase (PASD) resistant positive globules in hepatocytes with heterogeneous distribution within liver tissue. Moreover, aging processes enhance the relative number of globule-devoid cells, which ultimately might result in neoplastic transformation. Methods. We attempted to correlate the AAT genotype with globule-devoid hepatocytes in single cells from two patients who had developed HCC. The first was a 56 year-old woman whose ultrasound examination had revealed a 3 cm nodule in the left hepatic lobe, while the second one, a 65 year-old man, was submitted to hepatectomy due to a 3.7 cm liver mass. Paraffin-embedded liver sections from both patients were evaluated on hematoxylin and eosin (HE) and PASD stains. Immunohistochemistry used polyclonal and monoclonal antibody anti-AAT. To assess the AAT genotype, DNA was extracted from paraffin-embedded liver sections and the 5 exons of the SERPINA 1 gene were PCR-amplified and directly sequenced. To test whether globule-devoid hepatocytes were the result of a self-induced correction of the genetic defect, laser-assisted microdissection on a HE-stained slide was used to collect separately cells from neoplastic liver as well as non-neoplastic hepatocytes. Results. The non-neoplastic liver cells were found to contain PASD globules, while the tumours hepatocytes were globule-devoid. The globules were positive for polyclonal AAT-antibody in both cases, whereas monoclonal AAT-antibody was positive in the first case and negative in the second one. DNA analysis revealed a PiSZ genotype in the first case and PiMM-Cagliari in the second patient. An identical genotype was observed in cells obtained with micro-dissection in both cases. Conclusions. This study presented the following considerations. First, not only Z but also M-Cagliari AAT deficiency might lead to HCC. Second, both conditions are associated with a heterogeneous morphological phenotype in liver tissue. Third, the presence of the same genotype in both cell population suggests that phenotype change is not a result of a retro-mutation during neoplastic transformation and that other mechanisms are responsible for the phenomenon.

OP7-3
CLUSTERIN EXPRESSION IN CHOLESTASIS AND LIVER FIBROSIS

Aigelsreiter Ariane[1], Janig Elke[2], Halasz Judit[3], Lackner Carolin[1], Sostaric Julia[1], Pichler Martin[1], Stumptner Cornelia[1], Unterthor Daniela[1], Kufferath Iris[1], Zatloukal Kurt[1], Denk Helmut[1]
[1] Institute of Pathology, Medical University Graz, Austria
[2] Department of Dermatology and Venereology, Medical University Graz, Austria
[3] 2nd Department of Pathology, Semmelweis University Budapest, Hungary

Background: Clusterin is a chaperone which shares functional properties with small heat shock proteins (sHSP), but its physiological function is restricted to the extracellular space. Cytoplasmic clusterin overexpression was found to be associated with poorer prognosis in hepatocellular carcinomas (HCCs). Furthermore, clusterin may play a role in HCC metastasis and the serum clusterin level was found to correlate with patient survival. Method: A tissue microarray was used to evaluate the expression of clusterin in 116 HCCs and 103 matched non-neoplastic livers (including fibrosis and cirrhosis) by immunhistochemistry (IHC). Additionally, in several cholestatic liver diseases, including primary sclerosing cholangitis (10 samples), primary biliary cirrhosis (18 samples), mechanical cholestasis (9 samples) and drug-induced cholestasis (12 samples) the presence and distribution of clusterin was explored. The distribution pattern of clusterin in portal tracts was correlated with staining of elastic fibers (Elastica-VanGieson stain). To examine the presence of clusterin in human bile western blotting was performed in three bile samples from autopsy cases. Results: Clusterin was found to be associated with fibrotic areas of the liver, with colocalization with elastic fibers. Furthermore, clusterin was detected immunohistochemically in bile plugs in all investigated cholestatic liver diseases. Additionally, 44 of 116 cases of HCC showed pseudoglandular features with clusterin staining of their content. Clusterin was also demonstrated in bile by western blotting. Conclusion: In liver fibrosis and cirrhosis clusterin was associated with elastic fibers but not with hepatocytes or bile duct epithelia. Moreover, clusterin was present in bile as revealed by western blotting and IHC. The biologic significance of the association of clusterin with elastic fibers is unclear. It may act as chaperone either protecting and stabilizing elastic tissue or shielding abnormal elastic material. In bile, clusterin may protect bile duct epithelium against aggressive bile components or inhibit precipitation of biliary proteins.

OP7-4
PROTEIN PROFILING OF CHOLANGIOCARCINOMA: ARE HILAR AND INTRAHEPATIC CHOLANGIOCARCINOMAS DIFFERENT MOLECULAR ENTITIES?

Guedj Nathalie, Perigny Martine, Degos Francoise, Belghiti Jacques, Farges Olivier, Bedossa Pierre, Paradis Valérie
Beaujon, Clichy, France

Background: cholangiocarcinoma is a devastating malignancy diagnosed lately and associated with a high mortality. The tumour arises from the ductular epithelium of the biliary tree and two main forms are recognised: hilar and intrahepatic cholangiocarcinomas. In addition to different clinical patterns, they also differ in terms of etiopathogenesis and potential risk factors. However, up to now there are no data regarding their molecular signatures. The aim of the study was to investigate the protein profile of a large series of hilar and intrahepatic cholangiocarcinoma in order to better characterize their phenotype. Method: we reviewed the major morphological features including size, tumor differentiation, mucus secretion, perineural invasion of cholangiocarcinoma from 112 patients who underwent surgical resection at Beaujon hospital from 1996 to 2006. We compared the expression profiles between hilar (n=59) and intrahepatic cholangiocarcinomas (n=53) using a tissue microarray technology. Immunohistochemical staining of paraffin embedded tissue sections was performed for a total of 32 antibodies against a panel of keratins (CK), apomucins, cell cycle proteins, growth factors and cell signalization proteins. Two pathologists independently scored the protein expression. Results: Comparison of morphological features showed that hilar cholangiocarcinomas were smaller in size (mean: 2.9cm vs 7.8cm, $p<0.0001$), were more differentiated adenocarcinomas (62% vs 38% well_differentiated, $p<0.05$), secreted more mucus (91% vs 68%, $p<0.01$) and realized more perineural invasion (80% vs 45%, $p<0.001$) than intrahepatic cholangiocarcinomas. Regarding protein expression, 93% and 98% of cholangiocarcinomas were positive for CK7 and CK19, respectively. Among all proteins markers tested, a significantly different expression was observed only for three molecules. Hilar cholangiocarcinomas expressed more often MUC 5AC (60% vs 22%, $p<0.0001$) and Akt2 (53% vs 27% $p<0.001$). At the opposite, VEGF expression was more frequently encountered in intrahepatic cholangiocarcinomas (76% vs 53%, $p<0.05$). Conclusion: Our study shows that hilar and intrahepatic cholangiocarcinomas display a specific phenotype regarding their protein expression. These results suggest that different molecular pathways are involved in the carcinogenetic process of cholangiocarcinoma and that new therapeutic targets may be efficient.

OP7-5
TRANSCRIPTION FACTORS FBP-1 AND FBP-3 AND THEIR REPRESSOR FIR ARE PRO-TUMORIGENIC FACTORS IN HEPATO-CARCINOGENESIS

Weber Achim[1], Malz Mona[2], Ehemann Volker[2], Schirmacher Peter[2], Breuhahn Kai[2]
[1] Department of Pathology, Institute of Clinical Pathology, University Zurich, Switzerland
[2] Institute of Pathology, University Heidelberg, Germany

Background: The single-stranded DNA binding transcription factors FBP-1 (far upstream element (FUSE)-binding protein) and FBP-3 as well as their transcriptional repressor FIR (FBP interacting repressor) bind to DNA by recognizing dynamic changes of DNA-conformation and influence the general transcription factor TFIIH. This system has been shown to suppress the intrinsic noise of transcription and to ensure a steady transcriptional output of genes like c-myc, which is necessary for cellular homeostasis. These data suggest a potential pro-tumorigenic function for these factors. So far, little is known about the functional relevance in carcinogenesis, especially in the case of hepatocellular carcinomas (HCC). Methods: Measuring transcription by real-time PCR, FBP-1 and FBP-3 as well as FIR are found to be over-expressed in human HCCs (70% for FBP-1 and FBP-3 [19/27] and 33% for FIR [9/27]), and their expression levels significantly correlate among each other. Determing protein levels by immunohistochemistry using tissue-micro arrays (215 tumors), a highly significant correlation is found between the nuclear expression of FBP-1, FBP-3 and the cytoplasmic enrichment of FIR with tumor progression (Spearman correlation: $r=0.355$ (FBP-1), $r=0.454$ (FBP-3), and $r=0.335$ (FIR); $p<10\text{-}6$). Furthermore, the expression of both FBPs and FIR significantly correlates among each other but not with the nuclear expression of c-myc in HCCs. However, this over-expression does not correlate with elevated c-myc transcript levels. Using RNAinterference, the transient inhibition of FBP-1, FBP-3 and FIR in different HCC cell lines does not influence the c-myc expression but significantly reduces tumor cell viability due to diminished proliferation and G0/G1-cell cycle arrest (for FIR) or moderate G2/M-cell cycle arrest (for FBP-1/-3). Interestingly, western-blot analyses shows that inhibition of FIR reduces the expression of FBP-1 but not the expression of the FBP-3 in different HCC cell lines. Results and Conclusions: The transcription factors FBP-1, FBP-3 and FIR are over-expressed

and co-regulated in the course of human hepatocarcinogensis. In this context, FIR seems to be an inducer of FBP-1, but not FBP-3 expression. Since in the case of HCC, FBP and FIR obviously do not influence the expression of c-myc, they probably exert their oncogenic properties through the activation of other tumorigenic factors, which we currently aim to identify.

OP7-6

SIGNIFICANCE OF THE E-CADHERIN REPRESSOR SNAIL IN PANCREATIC, AMPULLARY, AND SMALL BOWEL CARCINOMAS

Yesim Gurbuz[1], Karl-Friedrich Becker[2]
[1] Kocaeli University, Medical Faculty-Department of Pathology, Turkey
[2] Technical University of Munich-Institute of Pathology, Germany

Pancreatic, ampullary and duodenal carcinomas are tumors originating in related anatomical structures that have the same embryogenetic origin. Alterations of the cell adhesion molecule E-cadherin have been commonly found and directly related to dedifferentiation, aggressive behavior, and lymph node or liver metastasis of pancreatic carcinomas. Recently, it was reported that the transcription factor Snail, a master regulator of epithelial-mesenchymal-transition (EMT) and E-cadherin inhibitor, plays a role in tumor-stroma interactions. The aim of our study was to examine Snail and E-cadherin immunoreactivities in pancreatic, ampullary and duodenal carcinomas in order to better understand their biological behaviour. A series of 104 cases, including 42 pancreatic, 45 ampulla, and 17 duodenal adenocarcinomas were analysed from the archive of the Institute of Pathology at the Technical University of Munich. One representative block from each case was selected and the intensity and localization (epithelial, stromal, mixed) of the Snail expression and the intensity and localization (membranous/cytoplasmic/mixed) of E-cadherin expression were evaluated. Chi square test was used to assess a possible correlation between expression levels for Snail and E-cadherin and the tumor localization. We found a statistically significant difference between tumor localization and desmoplasia: 42 (100%) of the pancreas cases have desmoplasia compared with 15 (88%) of the duodenum tumors ($p<0.0001$). Snail expression was observed in 38 (90%), 33 (73%), and 10 (58.8%) of the pancreas, ampulla, and duodenum cases, respectively ($p<0.012$). There was a significant relation between desmoplasia and Snail intensity ($p<0.003$). The most common localization of stromal Snail expression was in pancreas (n=31 or 73%), followed by 6 (55.3%) duodenal cases and 20 (47.6%) ampullary cases. There was a significant inverse correlation between E-cadherin and Snail immunoreactivities ($p<0.005$). In summary, we found a correlation between tumor localization, desmoplasia, intensity and localization of Snail immunoreactivity in the 3 types of cancer, most likely related to the stromal Snail expression in pancreatic adenocarcinoma. Our study demonstrates Snail-associated communication between tumor and stroma and suggests involvement of EMT in these tumors.

OP8-1

HUMAN SPERMATID CENTRIOLE ABNORMALITIES ARE CAUSATIVE FOR INTRACYTOPLASMIC SPERM INJECTION (ICSI) FERTILIZATION FAILURE.

Josef Schroeder[1], Ferdinand Hofstaedter[1], Monika Bals-Pratsch[2], Bernd Paulmann[2], Dagmar Seifert[2], Bernd Seifert[2]
[1] Pathology Department, University Hospital Regensburg, Germany
[2] Center for Gynaecologic Endocrinology, Reproductive Medicine and Human Genetic, Regensburg, Germany

Background: A low birth rate for a number of European countries is predicted (Germany = 1.4 children per woman), the difference between the birth and death indices will rise over the next several decades, which would have an adverse social and economical impact. The infertility prevalence rate for all couples of reproductive age is estimated to be 15%, in 1/3 of them male infertility is causative and can be overcome by innovative therapeutic options. Fertilization failure in human after assisted reproduction technique with ICSI (Intracytoplasmic Sperm Injection) may be due to different dysfunctions affecting the spermatozoon. Because the mature oocyte is devoid of centrioles, an impaired capacity to promote the growth of microtubule (MT) arrays from the sperm centrosome may preclude pronuclear opposition required for syngamy resulting in developmental arrest of the embryo. Method: Native ejaculate with motile sperm evidence (50%) from an 40-years old healthy man with a history of 2 unsuccessful homologous ICSI cycles (woman= intact mature oocyte function evidenced by polar body ”spindle-view”; one embryo transfer with one irregular embryo) resulting in pronuclear stage arrest of the zygotes, was Karnovsky-fixed, processed for electron microscopy examination, and evaluated for potential ultrastructural abnormalities. Results: A significant number (80% of examined) of abnormal spermatozoa with an aberrant acrosomal complex (agenesia, dysgenesia, crater-deformation, vacuoles/membranous inclusions), head deformations (round-shaped, tapered-shaped, binuclear, uncompacted chromatin), and multiple centrosome lesions was observed. In eight spermatozoa out of 11 with optimally visible centrosomes (73%), the transversal centriole sections revealed a distinct loss of the MT-triplets or their reduction to a MT-doublet, and a coupled additional smaller centriole structure was evidenced. In the longitudinal centrosome sections overlong MT protruding laterally the spermatid neck were displayed. Conclusion: The spectrum and relatively high incidence of the observed centriolar aberrations suggest the causative sperm defect responsible for the early embryo development failure. At present no help could be offered to couples affected by totally impaired centrosome function, first heterologous trials to restore human sperm centrosomal function using cytoskeletal stabilizers were reported. In our experience, electron microscopic sperm examination could reveal crucial findings for decision making in male infertility therapy.

OP8-3

DIFFERENTIAL DIAGNOSIS OF CLINICALLY NONFUNCTIONING PITUITARY ADENOMAS WITH IMMUNOHISTOCHEMICAL AND ELECTRON-MICROSCOPY METHODS

Maria Maksymowicz[1], Wlodzimierz T. Olszewski[1], Grzegorz Zielinski[2], Jan K. Podgorski[2]
[1] Department of Pathology, M. Sklodowska-Curie Memorial Cancer Center, Warsaw, Poland
[2] Department of Neurosurgery, Medical Military Institute, Warsaw, Poland

In the current WHO classification of pituitary adenomas immunohistochemical evaluation represents the “gold diagnostic standard”. However, immunohistochemical profiles may overlap, but ultrastructural features of these tumors are essential to reach a correct diagnosis of adenomas with specific biologic behavior, invasiveness, aggressive growth potential and recurrences. The aim of this study was evaluation of usefulness of immunohistochemical and ultrastructural methods in prognostic evaluations of pituitary adenomas. Material and methods: Among 1032 pituitary tumors diagnosed between 1998 and 2007 at the Department of Pathology of Cancer Center in Warsaw there were 889 pituitary adenomas. About of 35% of all cases were clinically nonfunctioning pituitary adenomas. All cases were studied by review of clinical features, light and electron microscopy and immunohistochemistry. Selected cases were examined using a postembedding immunogold technique. The proliferative index was determined by MIB-1 immunohistochemistry. Results: Among 285 clinically nonfunctioning pituitary adenomas 18 cases of silent corticotroph adenomas (I, II and Crooke’s type), 6 of silent thyreotroph, 17 of silent lactotroph and 8 cases of silent somatotroph adenomas were revealed by electron microscopy.

All tumors were diagnosed as aggressive macroadenomas with invasion of the surrounding structures. The proliferative index had low values (0–3%). Conclusions: Immunohistochemical evaluation permits the diagnosis of silent adenomas associated with a poor prognosis. In the cases of overlapping immunohistochemical profiles ultrastructural analysis is valuable to provide useful information. Currently, there are no accepted means of predicting an adenoma's invasiveness and long-term aggressiveness, but morphologic separation of some subtypes of pituitary adenomas by electron microscopy provided fundamental knowledge to classify and management. Proliferative markers, as MIB-1 may be helpful in diagnosis.

OP8-4

WHEN DOES THE CORNEA DIE?

Jon Klokk Slettedal[1], Magnus Roger[1], Kahsai Beraki[1], Torstein Lyberg[2], Bjorn Nicolaissen[3]
[1] Department of Pathology, Ullevaal University Hospital, Oslo, Norway
[2] Center for Clinical Research, Ullevaal University Hospital, Oslo, Norway
[3] Center for Eye Research, Department of Ophthalmology, Ullevaal University Hospital, Oslo, Norway

Background: The cornea is a unique tissue, being non-vascularized and dependent on diffusion of oxygen from the anterior chamber and the air. Even though the cornea is the body's most transplanted tissue, little is known about cell changes and cell survival post-mortem. Method: 28 corneas (14 pairs) were obtained during autopsies at Department of Pathology, Ullevaal University Hospital, Oslo, Norway. A corneoscleral disc with a diameter of 14 mm was removed with a trephine and curved scissors and placed in Hank's balanced salts solution for transport to the laboratory. The transport time did not exceed 20 minutes. The post-mortem time (interval between recorded death and fixation or cultivation) ranged from 14 to 163 hours and donor age from 24 to 91 years. The cause of death ranged from acute deaths to chronic disease. All donors died in the hospital and were on the same day as death brought to a cool storage room with a temperature of 4ºC. One cornea of a pair was examined for post-mortem changes and the second was placed in culture medium containing 8% serum for 3 or 6 days as a viability test. Examination was performed with scanning (SEM) and transmission electron microscopy (TEM), light microscopy, and immunohistochemistry with antibodies against n- and e-cadherin, PCNA, cytokeratin 3 and 12, vimentin and P63. Results: In the post-mortem epithelium, first the superficial cells detached in a sheet-like fashion, after 4 to 7 days the basal cells detached and the denuded basement membrane became visible in large areas. The endothelial cells lost the posterior membrane. When examined by TEM, cytoplasmic vacuolization was observed. Stromal keratocytes showed shrinkage. In specimens with very high post-mortem time (5 to 7 days) few epithelial cells remained in the peripheral cornea, and few endothelial cells remained structurally intact. Cultivation demonstrated rapid regeneration of the epithelium and endothelium. The endothelial cells became electron-dense with abundant organelles and the keratocytes increased in size and became electron dense when examined with TEM. Conclusion: With increasing post-mortem time, gradually more pronounced cellular changes and cell loss occurred in the human cornea. All three cell types (epithelial, endothelial and keratocytes) survive up to seven days post-mortem. Regeneration during cultivation restores the cell layers and the corneal architecture. Important factors for cell survival post-mortem are supposedly hypothermal donor storage and diffusion of oxygen to the externally situated and non-vascularized cornea

OP8-5

DETECTION OF SILICA PARTICLES IN LUNG TISSUE BY ENVIROMENTAL SCANNING ELECTRON MICROSCOPY

Matteo Corradin[1], Davide Zardo[1], Claudio Furlan[2], Bruno Murer[3], Massimo Montisci[4], Laura Ventura[5], Ambrogio Fassina[1]
[1] Department of Pathology, University of Padova, Italy
[2] CUGAS, University of Padova, Italy
[3] Department of Pathology,Mestre Hospital, Italy
[4] Department of Forensic Medicine, University of Padova, Italy
[5] Department of Statistics, University of Padova, Italy

Background: In lung pathology the role of silica is still debated at various levels of experimental, epidemiological, clinical and forensic evidence. To physicians and other health professionals it could be of relevance to know silica levels in lung tissue in order to better define cut-off limits of exposure. In this investigation, our objective was to apply Environmental Scanning Electron Microscopy (ESEM) in lung tissue microanalysis and to compare silica levels between subject with and without lung cancer. Methods: ESEM technology was employed to measure silica particles in tissues obtained from twenty-five patients with non-small cell lung cancer (Group A) and twenty patients without lung cancer deceased for extra-pulmonary diseases (Group B). Silica levels were quantified considering the number of spots (NS), (silica particles) and the number of positive zones (NPZ) in which there was at least one spot. Levels of NS and NPZ were assessed with Poisson-type regression models, and two patients with suspected workplace exposures were used to evaluate the performance of fitted models (Group C). Results. In Group A, 12 subjects were silica positive with a medium NS of 4.6 and a medium NPZ of 2.8. Three subjects were silica positive in Group B, with a medium NS of 1.3 and a medium NPZ of 0.8. In Group C, a medium NS of 210 and a medium NPZ of 27.5 were detected. Patients with lung cancer displayed significantly higher levels of silica relative to non-cancer controls, and smoking, age and gender had no significant effect on this relationship. While only evaluated in two patients, measured values of NS and NPZ for the workers in Group C were in agreement with model estimates. Conclusions: Higher silica levels were observed in lung cancer tissue in comparison non-cancer controls, and, if demonstrated effective in a larger number of patients, the fitted model between NS and NPZ might be useful in evaluating new observations and in the development of threshold limit values for silica in biological tissues. In this investigation, ESEM was a rapid, simple and valid tool for the determination of silica levels in lung tissues.

OP8-6

ULTRASTRUCTURAL AND STEREOMETRICAL PARAMETERS OF THE PLACENTAL BARRIER UNDER HYPOXIA CONDITIONS

Ganna Mylovydova[1], Olga Reshetnikova[2], Igor Nalcha[1], Yuriy Avdosyev[1]
[1] Laboratory of Pathomorphology, Institute of General and Urgent Surgery of Academy of Medical Sciences of Ukraine, Ukraine
[2] Department of Pathologic Anatomy, Lugansk State Medical University, Ukraine

The electron microscopic investigation of placenta under hypoxia condition caused by maternal iron-deficiency anaemia and EPH-gestosis was carried. Electronograms from 30 placentas, including 10 cases of EPH-gestosis, 10-maternal anaemia and 10-uncomplicated pregnancy (controls) were studied stereometrically by point count method at magnification X 5600. Pathological ultrastructure's alterations of a placental barrier, including a damage of microvilli, thickening of basal membranes both of epithelium and endothelium, a stromal fibrosis were found. Compensatory proliferations of cytotrophoblast in cases of EPH-gestosis and in anaemia group; as well as hyperaemia of foetal vessels in EPH-gestosis group were seen too. The increase

of the syncytiotrophoblast volume fraction (VF) in anaemia group (35,71±0,66 vs. 32,19± 0,26 % in controls), as well as cytotrophoblast, epithelium and endothelium basal membranes VF's both in anaemia (A) and gestosis(G) groups had registered (correspondingly: A – 2,76±0,04; 3,52±0,02; 0,57±0,06; G – 1,05±0,03; 4,76±0,03; 0,74±0,04 vs. 0,76±0,04; 3,04±0,01; 0,38±0,12% in controls, P<0,05). The capillary lumen increased to 14,70±0,26% in gestosis group (13,5±0,21% VF in controls, P<0,05). Pathological changes of a placental barrier could be a structural basis of a placental insufficiency. It was suggested that the process of ultrastructural remodelling of the placental membrane may compensate for different pathologies at the terminal parts of the villous chorion, which is essential base of the morphological correction of a placental insufficiency.

OP9-2

DIFFERENT PROGNOSTIC ROLE OF MUTATIONS IN THE HELICAL AND KINASE DOMAINS OF THE PIK3CA GENE IN BREAST CARCINOMAS.

Mattia Barbareschi[1], Fiamma Buttitta[2], Lara Felicioni[2], Sabrina Cotrupi[1], Fabio Barassi[2], Maela Del Grammastro[2], Antonella Ferro[3], Paolo Dalla Palma[4], Enzo Galligioni[3], Antonio Marchetti[2]
[1] Unit of Surgical Pathology, Laboratory of Molecular Pathology, S. Chiara Hospital, Trento, Italy
[2] Clinical Research Center, Center of Excellence on Aging, University-Foundation, Chieti, Italy
[3] Unit of Medical Oncology, S. Chiara Hospital, Trento, Italy
[4] Unit of Surgical Pathology, Laboratory of Molecular Pathology, S. Chiara Hospital, Trento, Italy

In breast cancer, the PIK3CA gene is frequently mutated at "hot spots" in exons 9 and 20, corresponding to the helical and kinase domain respectively. We investigate the association of PIK3CA mutations with pathological features and clinical outcome in a large series of breast cancer patients. Experimental Design: frozen samples from 163 consecutive patients were analyzed for PIK3CA mutations using PCR-SSCP and sequence analysis. Results: we identified 46 missense mutations, 24 (53%) in exon 9 and 21 (47%) in exon 20. Twelve (50%) of the 24 mutations in exon 9 were of the E542K type and 11 (46%) were of the E545K type. Twenty (95%) of the 21 mutations in exon 20 were H1047R substitutions. Mutations in exon 9 were more frequent in lobular carcinomas (42% of cases) than in ductal carcinoma (11% of cases) (p=0.002). At univariate survival analysis PIK3CA exon 20 mutations were associated with prolonged overall (OS) and disease free survival (DFS) while mutations in exon 9 were associated with significantly worse prognosis. At multivariate analysis exon 9 PIK3CA mutations were the strongest independent factor to predict poor prognosis for DFS (P = 0.0003) and OS (P = 0.001). Conclusion: Our data show that exon 9 PIK3CA mutations are typical of infiltrating lobular carcinomas. In addition, they indicate that PIK3CA mutations in different exons are of different prognostic value: exon 9 mutations are independently associated with early recurrence and death, while exon 20 PIK3CA mutations are associated with optimal prognosis.

OP9-3

INTRATUMORAL T LYMPHOCYTES ARE A PREDICTIVE MARKER OF RESPONSE TO NEOADJUVANT CHEMOTHERAPY IN BREAST CARCINOMA

Helena Hornychova[1], Bohuslav Melichar[2], Marketa Tomsova[1], Ales Ryska[1]
[1] Department of Pathology, Charles University Faculty of Medicine & Faculty Hospital, Hradec Králové, Czech Republic
[2] Departments of Oncology & Radiotherapy and of Medicine, Charles University Faculty of Medicine & Faculty Hospital, Hradec Králové, Czech Republic

Background: The antitumor immune response plays a crucial role in development and spread of many malignancies. Cellular immunity represents an important factor in the antitumoral defense, however, certain immune reactions can have an adverse effect and support the growth of tumor, e.g. by induction of angiogenesis. Tumor infiltrating T lymphocytes (TIL) (CD8+ cytotoxic and TH1 subset of CD4+ T lymphocytes, NK cells) seem to play an essential role in antitumor response. Aims Investigation of the relationship between CD3+ TIL and the effect of neoadjuvant chemotherapy in breast carcinoma. Method: We have examined 73 cases of breast carcinoma treated by neoadjuvant chemotherapy with paclitaxel and doxorubicin during 1998-2003. In each patient, the core needle biopsy taken before the treatment and the resection specimen were available. In addition to routine histology, the tissue was examined immunohistochemically (CD3, ER, PR, Ki67, p53, HER2/neu). CD3+ intratumoral lymphocytes were quantified by counting in three high-power fields (400x) and recorded as average and maximal values. The values of TIL were correlated with results of examinations of hormonal receptors (ER, PR), proliferative activity (Ki67) and selected oncoproteins (p53, HER2/neu). The results in core biopsy and resection specimen were compared by Mann-Whitney and Wilcoxon paired tests. Results The age of patients was 22-75 years (median 56 years). There were 53 ductal, 13 lobular and 7 other type carcinomas; 3 cases were grade 1, 36 grade 2 and 34 grade 3, respectively. A complete pathologic response (pCR), i.e. absence of tumor in resection specimen - was observed in 10 patients (16%). There were statistically significant differences between maximal (14 ± 14 vs. 5 ± 7; p=0.004) and average (7 ± 8 vs. 2 ± 3; p=0.05) values of TIL in the groups with and without pCR. Maximal values of tumor infiltrating lymphocytes (7 ± 8 vs. 10 ± 16; p=0.05) and associated lymphocytes (220 ± 176 vs. 359 ± 370; p=0.004) significantly increased during chemotherapy. Conclusion: Our results indicate that besides the well known prognostic role of intratumoral lymphocytes, values of CD3+ TIL in core needle biopsy specimens can also serve as a predictive marker of response to neoadjuvant chemotherapy. The increase of maximal values of TIL after chemotherapy indicates that they play an important role in destruction and elimination of tumor cells during this treatment. Supported by a grant of Internal Grant Agency of the Ministry of Health of the Czech Republic NR 8392-3.

OP9-4

HER2 OVER-EXPRESSION QUANTITATIVELY ACT ON LEVEL OF PROLIFERATION IN BREAST CANCER

Semyon Petrov, Gregory Raskin, Roustem Khasanov
Kazan Cancer Center, Russia

Introduction: Over-expression of HER should lead to high level of proliferation in breast cancer via homo- and hetero dimmerization. However, we have some investigations which contradict to these terms and authors claim that over-expression of HER2 may lead to low level of proliferation. The aim: to analyze influence of HER2 over-expression on proliferation of breast cancer's cells and pathways via which this influence is exist. Material and methods: We studied 414 breast cancer cases in which level of proliferation (Ki-67), expressions of HER2, progesterone and estrogen receptors were analyzed via immunohistochemistry and 23 samples of breast cancer with known positive immunohistochemical reaction of HER2 ("++", "+++") where analysis of HER2 gene amplification (FISH or CISH), morphometric comparative immunohistochemical analysis of Ki-67, P21/waf1, topoisomerase-II-a, E-cadherin, CD44v6 were performed. Exact calculation of percent of cancer cells expressed markers (among 2000 cancer cells by station LeicaCTR5000 and program LeicaQwinPlus) in each tumor with further their comparison allows us to make conclusions about activity of p21/waf1, level of expression of topoisomerase-II-a, allocation of cancer cells in the cell cycle. Results: Difference between proliferations of HER2 positive and negative groups was

statistically inauthentic (p>0,05). Thus HER2 positive cases don't have higher proliferated level than HER2 negative ones. Analysis of HER2 gene amplification has shown that over-expression of HER2 generally caused by gene amplification (87% of cases), but in 13% investigated samples the cause of over-expression was polysomia of 17 chromosome. Analysis of p21/waf1 protein showed that over-expression of HER2 is accompanied by active condition of p21/waf1 (17% of cases), inactive (13% of samples), mixed (43% of cases in which some cancers cells with active p21, others – with inactive), loss of p21/waf1 expression (27% of samples). Analysis of topoisomerase-II-a showed that normal and over-expression of this marker observe in 39% of cases. Hypo-expression was found in 61% of samples. Analysis of adhesion molecules (E-cadherin, CD44v6) also showed much differed conditions from low level of expression to high one with invert correlation of model expression of these two molecules. Conclusion: Over-expression of HER2 accompanies opposite conditions of pathways which quantitatively act on level of proliferation.

OP9-5

MAY THE QUANTIFICATION OF ESTROGEN RECEPTOR MRNA SERVE AS THE BASIS FOR MOLECULAR PROFILING OF BREAST CARCINOMAS?

Piotr Potemski, Renata Kusinska, Andrzej Bednarek, Elzbieta Pluciennik, Grazyna Pasz-Walczak, Dorota Jesionek-Kupnicka, Robert Kubiak, Radzislaw Kordek
Department of Oncology, Medical University in Lodz, Poland

Background: A cDNA microarray technology has allowed to make molecular profiling of breast carcinomas by monitoring expression levels of many genes simultaneously. Clustering of microarray data indicates that expression of estrogen receptor (ER) plays a fundamental role in such molecular division. Cancers with high expression of ER are numbered among luminal phenotypes characterized by better clinical outcome. Tumors with low expression of ER form basal-like and HER2 subtypes associated with the shortest survival times. The aim of the present study was to compare ER-mRNA level and ER status assessed by immunohistochemistry. We also tried to validate which method of assessing ER status may be more reliable for molecular subtyping in relation with basal keratins (5 and 17) and HER2 genes expression. Patients and Methods: This retrospective study was conducted on 97 patients with operable invasive ductal breast carcinomas not otherwise specified. A median median follow-up period was 60 months. mRNA levels for ER, HER2, keratin 5 (KRT5), and keratin 17 (KRT17) genes were measured by real-time RT-PCR in fresh tumor specimens frozen immediately after excision at -800C. ER status was also assessed by routine immunohistochemistry. Results: In 45 cases (46.4%) identified immunohistochemically as being ER-negative, mean ER-mRNA level was 8.51±15.71, whereas in 52 (53.6%) cases classified by immunostaining as being ER-positive it was 17.35±31.66 (p=0.013). However, a significant discordance between real-time RT-PCR and immunohistochemistry in assessing ER status has been found. In a group of 27 tumors with low level of ER-mRNA (<1.00), there were 8 ER-positive cases as assessed by immunostaining, and among 70 cases with high level of ER-mRNA (≥1.00), 26 were ER-negative by immunohistochemistry (p=0.003). Regardless of the method of dichotomization of real-time RT-PCR data, lack of prognostic relevance of ER-mRNA level has been demonstrated, whereas ER-positive patients as assessed by immunostaining had a relative risk of cancer-related death lower by 65% when comparing with ER-negative ones (p=0.020). ER-mRNA level did not correlate significantly with HER2-mRNA (τ=0.14, p=0.061), KTR5-mRNA (τ=0.01, p=0.873) or KRT17-mRNA (τ=-0.13, p=0.071). Conclusions: Our observations may question the rationale for the assessment of ER-mRNA in a molecular division of breast tumors and indicate that results of cDNA microarray experiments should be interpreted cautiously.

OP9-6

PSEUDOANGIOMATOUS STROMAL HYPERPLASIA (PASH) TUMORS ON CORE NEEDLE BIOPSY (CNB): IS EXCISION NECESSARY?

Marco Ferreira[1], Nilesh Gupta[2], Erika Resetkova[2]
[1] Servico de Anatomia Patológica, Instituto Português de Oncologia de Lisboa Francisco Gentil, E. P. E. , Lisboa, Portugal
[2] The Department of Pathology, The University of Texas M. D. Anderson Cancer Center, Houston, Texas, USA

Background: Tumor formed by PASH (PASH-TU) is rare, with only a few reported case series in literature. Clinical management of PASH-TU diagnosed by CNB is still controversial. The aims of our study were: 1) to evaluate clinical, radiologic, and histologic features of PASH-TU; 2) to correlate CNB findings of PASH-TU with subsequent excision and/or clinical follow-up. Methods: PASH-TU cases were retrieved from the Department of Pathology database at UT M. D. Anderson Cancer Center and retrospectively studied. PASH was histologically classified as simple/classic or fascicular/proliferative. Associated pathologic findings, including epithelial and stromal atypia, location of the PASH [intralobular (IL), perilobular (PL)], and the presence of hamartomatous changes were correlated with patients´ clinical data, hormonal use, imaging study results, and follow-up data. Statistical analysis was performed using Fisher's exact test. Results: Twenty-six cases were found. Patient ages ranged from 19 to 70 years (mean, 47±13 years), 62% of patients were premenopausal, and 13 had a long-standing history of oral contraceptive use or hormone replacement therapy (6). Nine patients (35%) presented with a palpable mass; in the others, tumor was detected by mammography mostly as a hyperdense mass with irregular margins and/or by sonography as a hypoechoic mass. Lesion size ranged from 0.8 cm to 11 cm (mean, 4.2±4.3 cm). PASH was simple/classic in 18 patients (69%) and fascicular/proliferative in 8. PL involvement was noted in 5 patients, and PL and IL involvements, in 21. The associated pathologic findings were invasive ductal carcinoma in 1 patient (4%), gynecomastia-like change (GLC) in 17 (65%), and other benign findings in 8 patients (31%). In 5 patients, GLC was originally read as columnar cell change. The presence of GLC was significantly associated with IL PASH (p=0.00085). Hamartomatous change was noted in 54% of patients. Among 15 patients with clinical follow-up ≤27±17 months after surgical excision (7) or radiologic surveillance (8), none demonstrated additional pathology or significant change in lesion characteristics on imaging. Conclusion: PASH-TUs occur more frequently in premenopausal women and are associated with hormonal therapy use in the majority of patients. The GLC frequently occurs in PASH-TUs and its presence is strongly associated with IL involvement by PASH. CNB-diagnosed PASH-TUs not subsequently excised remained clinically and radiologically stable, thus offering the option of close clinical surveillance instead of surgery in those patients.

OP9-7

NEAR TILING MICROARRAY-BASED CGH IDENTIFIES CCNE1 AMPLIFICATION IN BASAL-LIKE BREAST CANCER

Rachael Natrajan[1], Socorro Maria RodríGuez Pinilla[2], Caterina Marchio[1], Radost Vatcheva[1], Kay Savage[1], Alan Mackay[1], Kerry Fenwick[1], Narinder Tamber[1], Jose Palacios[2], Alan Ashworth[1], Jorge Sergio Reis-Filho[1]
[1] The Breakthrough Breast Cancer Research Centre, Institute of Cancer Research, London, United Kingdom
[2] Breast and Gynaecological Cancer Group, Molecular Pathology Programme, Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid, Spain

Background: Basal-like breast cancers (BLBC) constitute a heterogeneous group of aggressive neoplasms, accounting for around 15% of invasive breast carcinomas. BLBCs are characterised at the molecular level by lack of oestrogen receptor

(ER) and HER2 expression, and expression of genes consistently expressed in normal basal/ myoepithelial cells. Current tailored therapies are not amenable for the management of these tumours, given that they lack hormone receptors and HER2 expression. The aims of this study were to characterise the molecular genetic profiles of BLBCs using a high resolution microarray-based CGH (aCGH) platform and to novel amplifications in BLBCs. Methods: A series of 20 fresh frozen grade 3 BLBCs were subjected to aCGH analysis using whole genome 16K near tiling bacterial artificial chromosome (BAC) arrays. Specific amplifications were confirmed by means of chromogenic in situ hybridisation (CISH) analysis using in-house generated probes and immunohistochemistry was used to investigate the expression of oncogene candidates. Furthermore, we investigated the prevalence of CCNE1 amplifications with CISH on a tissue microarray containing 97 grade III tumours. Results: 20%, 50% and 30% of cases exhibited the recently described "simplex", 'sawtooth' and "firestorm" patterns of genomic alterations, respectively. The most common regions of gain (>25% of cases), included 1q, 6p, 8q, 10p and 17q, and the most common regions of loss (>25% of cases), encompassed 3p, 6q, 8p, 13q and 17p. Common amplifications observed in greater than 10% of cases included 1p12-q25.3, 7q11.21, 8q24.21, 11q13.3, 12p13.33-p13.31, and a novel amplification on 19q12. Further delineation of this novel amplicon identified CCNE1 (cyclin E1) as a possible amplicon driver. CCNE1 amplification was confirmed by means of CISH in all samples identified as CCNE1 amplified by aCGH. In the TMA, CCNE1 gene amplification was found in 7% of cases and was significantly associated with basal-like phenotype (p=0.0082, Fisher's exact test), with CCNE1 protein expression as determined by immunohistochemistry (p=0.008, Fisher's exact test) and lack of CCND1 amplification (p<0.001, Fishers exact test) as defined by CISH. Conclusion: These results demonstrate that CCNE1 amplification may be one of the mechanisms driving cyclin E1 protein expression in basal-like breast cancers. These results also suggest that CCNE1 and CCND1 amplification act in a mutually exclusive manner.

OP9-8

BASAL-LIKE PHENOTYPE IS FREQUENT IN INVASIVE BREAST CARCINOMA FROM UGANDAN AFRICANS AND IS STRONGLY ASSOCIATED WITH A HIGH EXPRESSION OF EGFR/C-KIT AND FEATURES OF AGGRESSIVE TUMORS

Hawa Nalwoga[1], Jarle Arnes[2], Henry Wabinga[3], Lars Andreas Akslen[2]

[2] Department of Pathology, The Gade Institute, Haukeland University Hospital, University of Bergen, Bergen, Norway

[3] Department of Pathology, Faculty of Medicine, Makerere University, Kampala, Uganda

Breast cancer is the most common neoplasm-affecting women and a leading cause of death from cancer in women worldwide. Therapeutic targets are needed to improve clinical outcomes, which are still poor in Africa, although incidence is increasing rapidly. Basal-like breast carcinoma has been recognized as a subtype with poor prognostic features and specific therapeutic implications. It frequently expresses epidermal growth factor receptor (EGFR) and c-Kit. The prognostic significance of c-Kit in breast cancer is still controversial. EGFR has emerged as an important prognostic parameter and a promising strategy in tumor specific therapies. There is a paucity of reports about basal-like breast carcinoma and expression of EGFR/c-Kit in Africa. The aim of this study was to explore invasive breast carcinoma from Ugandan African women in association with basal-like phenotype, EGFR/c-Kit expression and other prognostic factor. We studied 65 archival paraffin blocks of invasive breast carcinoma from female patients in the archives of the Pathology Department, Makerere University. Five μm-thick sections were stained with antibodies against Cytokeratin 5/6, P-cadherin EGFR, c-Kit, oestrogen receptor (ER), progesterone receptor (PR), HER-2 and Ki-67. Sections were scored according to recommended criteria. Tumors that expressed Cytokeratin 5/6 and/or P-cadherin were considered have a basal-like phenotype (BLP). Basal-like phenotype was expressed in 34% of cases and in 52% of ER negative tumors. Forty-five percent of basal-like tumors expressed EFGR, while 23% expressed c-Kit. Fifty-five percent of basal-like tumors expressed EGFR and/or c-Kit. BLP was expressed in 71% of the EGFR and/or c-Kit positive tumors (P = 0.000). The BLP positive tumors were more likely to express EGFR and/or c-Kit than non basal-like type (OR 9.1; 95% CI 2.6-32; P = 0.000). BLP was strongly associated with EFGR expression (P = 0.002), c-Kit positivity (P = 0.003), high histological grade (P = 0.001), high mitotic counts (P = 0.002), and marked nuclear pleomorphism (P = 0.002). All basal-like tumors were ER negative (P < 0.0001) and PR negative (P = 0.002). No association with HER2 expression (P = 0.410) and Ki-67 proliferative rate (P = 0.114) was found. Basal-like phenotype is frequent in invasive breast carcinoma from Uganda and is strongly associated with high expression of EGFR/c-Kit and features of aggressive tumors. Ugandan patients with BLP could benefit from EGFR-targeted therapies. More studies are required to validate this.

OP9-9

VASCULAR PROLIFERATION IS A STRONG AND INDEPENDENT PROGNOSTIC FACTOR IN BREAST CANCER

Background: In 1971, Folkman et al. proposed that the growth of malignant tumors is dependent on angiogenesis, and can be inhibited by targeting its blood supply. Various measures of angiogenesis have been reported as prognostic factors, although no available marker can predict treatment response. Microvessel density (MVD) is a widely used indicator of angiogenesis, but clinical use is not currently recommended. Improved measures of angiogenesis are required, and we recently found that vascular proliferation might be superior to MVD. We have now studied vascular proliferation with regards to prognosis in a well characterized series of breast carcinomas. Methods: The study was restricted to 292 cases of first primary invasive breast cancer diagnosed in Ashkenazi Jewish women between 1980-95. Ki-67 and Factor VIII double immunostaining was performed on 239 cases with sufficient material, including 24 BRCA1 and 6 BRCA2 carriers. Microvessels in 10 consecutive 250x fields within vascular hot spots were registered, simultaneously counting microvessels with Ki-67 positive endothelial cells. Results: Vascular Proliferation Index (VPI): Median 1.3%.There were significant associations with higher histologic grade (p=0.05), higher mitotic rate (p= 0.020), positive expression of CK 5/6 (p=0.017), P-cadherin (p<0.0005), EGFR (p=0.004), p53 (p=0.031), negative ER-expression (p= 0.001), and the presence of glomeruloid microvascular proliferation (GMP) (p<0.0005). Survival analysis: Univariate survival analysis showed no significant effect of MVD. VPI was highly significant, with 10 year survival 78.6% in negatives versus 57.4% in positives (Log Rank test: p<0.0005; HR 2.47). By multivariate analysis, tumor size (p=0.001, HR 2.839), GMP (p= 0.043, HR 1.918) and VPI (p=0.007; HR 2.247) were significant and independent prognostic factors. Conclusions: Vascular Proliferation Index (VPI) is a novel prognostic factor in breast carcinoma, and is superior to microvessel density (MVD). We suggest that VPI should be evaluated further in studies of prognosis and response to adjuvant treatment.

[4] Department of Pathology, Ambroise Paré Hospital, Boulogne, France

The WHO classification of thyroid tumors has recently described and introduced borderline lesions called « well –differentiated tumor of uncertain malignant potential » (WDT-UMP) and « follicular tumor of uncertain malignant potential » (FT-UMP). Although histologic definition of these lesions is readily available, application of the diagnosis criteria and personal experience may lead to disagreement among pathologists. FT-UMP designate tumors that show either questionable capsular invasion without vascular invasion or minor nuclear changes of papillary carcinoma. WDT-UMP designate tumors having questionable papillary thyroid carcinoma-type nuclear changes, and if capsular invasion is questionable or absent. Although as rarely as possible, the term « uncertain malignant potential tumor of the thyroid » (UMPTT) must be employed. However, the different categories of lesions described under this terminology should not be an easy option to avoid the intellectual commitment involved in making a clear diagnosis of malignancy or benignity. The aims of this study were i) to investigate interobserver variation in assessment of different UMPTT diagnosed from 2004 to 2007 in a single institution (CHU of Nice, France); ii) to see for UMPTT if ancillary molecular techniques assist one in defining more precisely benign from malignant tumors. For each case, the entire capsule was examined by 5 pathologists. Twenty four UMPTT (14 FT-UMP and 10 WDT-UMP) were diagnosed independently by each pathologist from a unique institution. All these diagnosis were reviewed by all the pathologists from the 2 different institutions. Surprisingly, in more than 95% of the cases, there was complete agreement for the diagnosis of FT-UMP and WDT-UMP. None of the 24 UMPTT were BRAF positive. Detection of PAX8-PPAR gamma rearrangements was performed in all cases and these rearrangements were found in most of the FT-UMP. RET/PTC (RET/PTC1 and RET/PTC2) alteration was found in some WDT-UMP. RAS alteration was detected in both some WDT-UMP and FT-UMP. In conclusion this work showed first that diagnosis of UMPTT (both WDT-UMP and FT-UMP) can be reproductive among pathologists, but the observer variation is considerably reduced when the entire lesion, and particularly the entire capsule, is examined. Secondarly, it seems that further study performed in a larger series must be done to see if gene analysis can contribute to the prognosis of these lesions, but to our opinion it is doubtful whether even this tool will provide reliable separation of the clinical behaviour of the UMPTT.

BACKGROUND: The distinction of benign from malignant follicular thyroid lesions is difficult. There is controversial evidence for the significance of Ki67 and p53 and very few studies refer to the expression of prothymosin-a (Pro-Ta) with evidence of gradual increase from normal to hyperplastic, benign neoplastic and malignant thyroid epithelium. The fact that Pro-Ta, an immunoregulator, plays a role in cell proliferation, made us study its expression in normal and diseased thyroid, and its probable relationship to Ki67 and p53. METHODS: 105 sections were selected from 51 thyroidectomy specimens: normal follicles (23), hyperplasia nodular (NH,) 30, diffuse (DH) 2, adenomatous (AH) 4, adenoma, follicular (FA) 4, oncocytic (OA) 1, 3 cases of follicular tumour of uncertain malignant potential (FTUMP) and 31 carcinomas. Papillary (PTC) 27: classical 10, follicular 13, tall cell 4 , oncocytic carcinoma(OC) 1, anaplastic 1 and myeloid 2. Pro-Ta, Ki67 and p53 were immunohistochemically studied. The percentage of positive nuclei was measured using digital morphometry and the p53 intensity was arbitrarily assessed as +,++,+++.For statistical analysis of Pro-Ta the SPSS v13.0 was used.RESULTS: Pro-Ta nuclear positivity in 4 categories(1,2,3,4), 0-20,21-40,41-60 and >60% respectively. Normal follicles showed <20% positivity (19/23) and none exceeded 40%. Only the microfollicles of NH and DH were in categories 1 and 2 (17/25) but follicles of Hashimoto thyroiditis , AH and adenomas reached category 3. 1/3 FTUMP showed >60% positivity. 12/27 PTC and the 2 myeloid increased to category 3 while 12/27 reached category 4. The anaplastic Ca showed 100% positive and totally negative areas. The oncocytic Ca was <20%. Pearson's correlation index showed statistically significant increase of Pro-Ta in malignancy compared to normal and benign follicular cells (p0.086). Ki67 % categories 1,2,3,4. <0.5, 0.6-2.9, 3-6 and 6.1-30 accordingly. Normal thyroid follicles were almost negative (22/23). Hyperplastic, neoplastic benign and malignant epithelial cells in category 2, with exception of 8/27 PTC in category 3 and only the myeloid and anaplastic Ca showed >6% positivity. p53 ranged between 0-6% with negative normal follicles, weak focal positivity in all hyperplasias and FTUMP (categories 1-2) and only the microfollicles of Hashimoto in category 3.There was marked increase in intensity and grade for 15/27 PTCs (+++) and 22/27 (category 3).CONCLUSIONS: Increased Pro-Ta and intense albeit low p53 characterise thyroid malignancy. Pro-Ta overexpression needs further investigation.

[2] Department of Biomedical Sciences and Human Oncology, University of Turin, Italy
[3] Pathology Unit, San Luigi Hospital, Italy

Background: The molecular mechanisms leading to adrenocortical carcinoma (ACC) development, as well as clear-cut diagnostic parameters in the differential diagnosis with adrenocortical adenoma (ACA), are currently poorly defined. Reports exist on the de-regulation of cellular to extracellular matrix interactions in ACC, with the identification of putative novel diagnostic markers. Methods: PCR-based array profiling of 86 molecules involved in cell to cell and cell to matrix interactions was performed in 6 frozen ACC and 4 control ACA samples. Statistical significance in transcript expression fold changes of target genes was evaluated by Student's T test. A large series of 55 ACC and 25 ACA paraffin embedded control cases was also available for histochemical and immunohistochemical analysis. Complete pathological and

clinical information, including follow up, were available for all cases. Results. By array analysis, most genes were generally down-regulated in ACC as compared to ACA samples. Four of them had a significantly ($p<0.05$) altered expression in ACC, including laminin alpha 3 and hyaluronan synthase 1 (both 4-fold up-regulation), osteopontin (OPN) (20-fold up-regulation), and laminin alpha 2 which was down-regulated. Based on such findings, OPN protein expression was evaluated in archival paraffin specimens and found to be absent in all 25 ACA and specifically expressed with a typical paranuclear dot-like pattern in 22/55ACC ($p<0.0001$). However, OPN protein expression did not correlate with any of the clinico-pathological parameters considered (presence of necrosis, mitotic index, presence of capsular/vascular invasion, overall Weiss score, clinical course). With regard to laminins, since the alpha 2 type is a major basal membrane component of human adrenal cortex (as opposed to the alpha 3 isoform), we speculated that its down-regulation could be associated to a disruption of the reticular network. By means of reticulin histochemical stain, all ACC cases had a disruption of the reticulin framework, as opposed to ACA that maintained a fine reticulin network, thus providing a simple and useful additional morphological parameter in the differential diagnosis between ACA and ACC. Conclusions: Some molecules involved in cell to matrix interactions have specifically altered expression in ACC: by selective cDNA array screening, we provide novel data on OPN expression as well as constitutive alterations of the reticular framework in ACC, which may be useful to better understand its pathogenesis and also support ACC morphological diagnosis.

OP10-4
DUODENAL AND PANCREATIC SOMATOSTATIN-PRODUCING NEUROENDOCRINE TUMORS: INCIDENCE, TYPES, BIOLOGICAL BEHAVIOR, ASSOCIATION WITH INHERITED SYNDROMES, AND FUNCTIONAL ACTIVITY

Nele Garbrecht[1], Martin Anlauf[1], Anja Schmitt[2], Tobias Henopp[1], Holger Moch[2], Phillip U. Heitz[2], Paul Komminoth[2], Aurel Perren[3], Guenter Kloppel[1]

[3]Department of Pathology, Technical University, Munich,Germany

Background: The somatostatin-producing neuroendocrine tumors (SOM-NETs) of the duodenum and pancreas are very rare and a heterogeneous group of neoplasms. Therefore, we determined their clinicopathological profiles. Methods: Clinical and pathological data of a series of 82 duodenal and 541 pancreatic NETs were screened. In addition, the clinical records of 821 patients with duodenal or pancreatic NETs were reviewed for evidence of a somatostatinoma syndrome. Results: Predominant or exclusive expression of somatostatin was found in 27% (n=22) of duodenal and 4% (n=22) of pancreatic NETs. They were classified as sporadic (n=31) or neurofibromatosis type 1 (NF1)-associated duodenal NETs (n=3), gangliocytic paragangliomas (GCPGs) (n=7), poorly differentiated neuroendocrine carcinomas (pdNECs; n=2), or mixed acinar endocrine carcinoma (MAEC; n=1). In addition, 5 duodenal and 4 pancreatic SOM-NETs were found in 5 patients with multiple endocrine neoplasia type 1 (MEN1). Metastases occured in 42% of the sporadic and NF1-associated SOM-NETs, but in none of the duodenal MEN1-associated SOM-NETs or GCPGs. Sporadic advanced (stage IV) SOM-NETs were more commonly detected in the pancreas than in the duodenum. None of the patients (including the 808 patients for whom only the clinical records were reviewed) fulfilled the criteria for a somatostatinoma syndrome. Conclusion: Somatostatin expression is not only seen in sporadic NETs, but may also occur in GCPGs, pdNECs and hereditary NETs. Surgical treatment is effective in most duodenal and many pancreatic SOM-NETs. Benign behavior is seen in MEN1-associated SOM-NETs and GCPGs, whereas highly malignant somatostatin-producing pdNECs/MAECs have a poor prognosis. The so-called somatostatinoma syndrome seems to be an extreme rarity.

OP10-5
HUMAN ASH1 TRANSCRIPTION FACTOR EXPRESSION IN PROSTATE CANCER WITH NEUROENDOCRINE DIFFERENTIATION

Marco Volante[1], Ida Rapa[1], Paolo Ceppi[1], Enrico Bollito[2], Rosj Rosas[1], Elisa Bacillo[1], Susanna Cappia[2], Giorgio Scagliotti[1], Alfredo Berruti[1], Mauro Papotti[1]

[2] Pathology Unit, San Luigi Hospital, Orbassano, Turin, Italy

Background: Prostate cancer (PC) is a leading malignancy in the aging male population, with a heterogeneous clinical course. The occurrence of neuroendocrine (NE) phenotype in PC correlates with overall prognosis and prostate cancer progression after androgen-deprivation therapy. The mechanisms leading to NE differentiation in PC are currently poorly understood. A role of Notch pathway has been reported in determining NE phenotype of normal and neoplastic tissues. Aim of this study is to analyse whether this pathway might affect NE differentiation in prostate cancer. Methods: Human achaete-scute homolog 1 (hASH1), a pivotal member of the Notch signalling pathway, was investigated in 80 PC selected and grouped according to chromogranin A (CgA) immunohistochemistry, as follows: PC without NE differentiation, untreated (group PCNE-, 25 cases); PC with NE differentiation, untreated (group PCNE+, 40 cases); PC with previous androgen deprivation therapy, all having NE differentiation (group PCNE+Ther, 15 cases). Three cases of prostatic pure large cell NE carcinomas were also analyzed. hASH1 protein was analyzed by immunohistochemistry, whereas the presence of hASH1 mRNA transcripts was investigated on representative microdissected tumor areas from serial paraffin sections by Real Time PCR. Results. By immunohistochemistry, hASH1 was co-localized with CgA in NE cells of the normal prostate. It was strongly expressed in pure NE prostate cancers, absent in all but one PCNE- cases, whereas it was positive in 25% of PCNE+ cases, with a strong correlation with the extent of NE differentiation ($p=0.02$). Moreover, comparing PCNE+ and PCNE+Ther cases, a strong positive association with androgen deprivation therapy was observed ($p=0.01$). In PC with NE differentiation, RNA analysis confirmed the association of higher transcript levels in androgen deprivation-treated (PCNE+Ther) versus untreated (PCNE+) patients ($p=0.01$). In addition, hASH1 mRNA analysis in microdissected CgA positive and negative areas within the same tumor demonstrated heterogeneous upregulation of hASH1 mRNA expression, with a 2 to 7 fold increase in the CgA positive tumor cell population. Conlusions: hASH1 mRNA and protein expression correlates with the presence and extent of NE phenotype in PC, especially in cases undergoing preoperative androgen deprivation therapy, and our data identify hASH1 as a likely critical factor in PC to drive NE differentiation, which represents an independent poor prognostic indicator and is a major responsible for hormonal refractory disease.

OP10-6
CYTOKERATINS 8 AND 18 IN SILENT PITUITARY ADENOMAS: FROM IMMUNOHISTOCHEMISTRY TO PROGNOSIS

Chiara Villa, Patrizia Morbini, Solcia Enrico
Policlinico S. Matteo/Università di Pavia, Italy

Background: Cytokeratin 8/18 expression is recognized in some subtypes of clinically functioning and nonfunctioning pituitary adenomas. In nonfunctioning lesions, when pituitary hormones and cytokeratins are identified with immunohistochemical

reaction, the profile of expression resembles that of respective functioning adenomas. Cytokeratin 8/18 immunoreactivity characterizes different pituitary adenomas with difficult clinical management: sparsely granulated somatotroph and acidophil stem cell adenomas, characterized by fibrous bodies, which respond poorly to therapy and show invasive growth, and silent corticotroph adenomas particularly prone to invasion and recurrences. In the present work, we studied 36 clinically nonfunctioning adenomas exclusively immunoreactive for gonadotroph and thyrotroph hormones (silent gonadotroph and thyrotroph adenomas), normally negative for cytokeratin 8/18 and representing the largest group of silent adenomas in several series. Immunohistochemical expression of CAM5.2 was investigated and related to biological behaviour. Methods: All 36 specimens were immunostained for the full panel of pituitary hormones and for MIB1/ki67 and CAM 5.2 antibodies. The patterns of CAM 5.2 immunoreactivity were classified in 3 subtypes according to cellular expression, intensity and distribution: cytoplasmic/intense/diffuse (CID), dot-like/intense/patchy(DIP) and dot-like/mild/patchy(DMP). Age, sex, endocrine function, tumour size and disease status were obtained from patient charts. The mean follow-up was 57 months (range 18-96). Results: 13 (36%) cases were variably immunoreactive for CAM5.2; 23 (64%) were completely negative. 7 (54%) CAM5.2+ patients recurred, while only 2 (9%) of CAM5.2- patients had recurrent disease. According to CAM5.2 expression patterns: 4 CID cases were identified; all were females with aggressive behaviour (recurrences, invasive growth and 1 exitus for disease). In DIP subgroup (7 patients, 5 males) we observed 4 recurrences, 1 death for other disease and 2 negative follow-ups. Finally, the 2 DSP adenomas did not recur. Conclusion: CID and, to a lesser extent, DIP pattern of immunoreactivity for CAM5.2 in nonfunctioning gonadotroph and thyrotroph adenomas may help to identify a recurrent/aggressive phenotype. The control group confirmed that CAM5.2- cases rarely show an aggressive behaviour. These results suggest that cytokeratin 8/18 expression is associated with aggressive behaviour of pituitary adenomas independently of tumor functional status. The biological bases of this phenomenon need to be further clarified.

OP10-7

DNA COPY NUMBER STATUS IS A POWERFUL PREDICTOR OF POOR SURVIVAL IN ENDOCRINE PANCREATIC TUMOR PATIENTS

Background: The clinical behavior of endocrine pancreatic tumors (EPTs) is difficult to predict in the absence of metastases or invasion to adjacent organs. Several markers have been indicated as potential predictors of metastatic disease, such as tumor size ≥2 cm, Ki67 proliferative index ≥2%, cytokeratin (CK) 19 status, and recently in insulinomas, chromosomal instability (CIN). The goal of this study was to evaluate the value of these markers, and in particular of CIN, to predict tumor relapse and / or tumor-specific death, using a series of insulinomas and non-insulinoma EPTs. Method: From seventy-one EPT cases, including 47 insulinomas, a genomic profile could be generated and follow-up data could be obtained. The proliferative index could be determined in 68 tumors and a CK19 expression pattern in 50 tumors. Results were statistically analyzed using Kaplan-Meier plots and the log-rank statistic. Results General CIN, as well as specific chromosomal alterations such as 3p and 6q loss and 12q gain, turned out to be the most powerful indicators for poor tumor-free survival ($p \leq 0.0004$) and tumor-specific death ($p \leq 0.0113$) in insulinomas. CIN, chromosome 7q gain, and a proliferative index ≥2% were reliable in predicting a poor tumor-free survival in non-insulinoma EPTs ($p \leq 0.0181$), whereas CK19 expression was the most optimal predictor of tumor-specific death in these tumors. Conclusion: DNA copy number status is the most sensitive and efficient marker of adverse clinical outcome in insulinomas and of potential interest in non-insulinoma EPTs. As a consequence, this marker should be implemented as a prognosticator to improve clinical diagnosis. THE COEXISTENCE OF PRIMARY HYPERPARATHYROIDISM AND PAPILLARY THYROID CARCINOMA

Ahmet Korkut Belli[1], Yusuf Bukey[1], Figen Aksoy[2]

[1] Cerrahpasa Med. School Department of General Surgery Endocrine Division, Turkey

[2] Cerrahpasa Med. School Department of Pathology Endocrine Division, Turkey

Background: The coexistence of primary hyperparathyroidism and nonmedullary thyroid carcinoma has been reported by several authors. The incidence was reported between %2.6 and %17.4. Some authors believe that this is fortitious on the contrary some of them believe this is more than fortitious and accepting an underlying aetiology. Methods: The records of Cerrahpasa Medical School Department of General Surgery reviewed between January 2002 and December 2006 for the patients who underwent surgery for primary hyperparathyroidism. Results: There were 147 patients underwent to surgery due to primary hyperparathyroidism and 46 patients had coexistent thyroid pathology. 13 patients had total thyroidectomy , 11 patients had near totoal thyroidectomy and 15 patients had subtotal thyroidectomy. We found 8 patients of parathyroid adenoma coexistent with papillary thyroid carcinoma . The mean age of these patients is 58.2(29-64) and male:female ratio is 1:7. Conclusion: The prevalence of minimal thyroid carcinoma in Turkish Community was reported 1.3%. The incidence of parathyroid adenoma and papillary thyroid carcinoma in our patients is 5.4 %.We believe that this is more than coincidental. Three factors considered to be responsible in the aetiology. These are external irradiation to the head and neck, goitrogenic effect of Ca and genetics.Our patients had no history of external head and neck irradiation . We are performing further studies to find an underlying aetiology. While performing a parathyroid surgery especially mininal access parathyroid surgery, surgeons should be careful in detecting the patients preoperatively. We recommend US-FNAB if any thyroid nodule is found with parathyroid adenoma before parathyroid surgery.

[3] Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Branch Gliwice, Tumor Pathology Departament, Poland

BACKGROUND: Papillary thyroid carcinoma (PTC) is the most common type of endocrine malignancy. PTC is diagnosed by defined morphological features, which include optically clear nuclei, irregular nuclear profile, pseudoinclusions and grooves. These features probably are driven by specific molecular mechanisms in PTC cells. In this study we analyze the relationship between gene expression profile and the microscopic futures of PTC. MATERIAL AND METHODS: Thyroid post-operative samples were studied. 41 cases with histologically verified diagnosis were analyzed. Light microscopy with morphometry was performed with the help of a semiautomatic computer image analyzer. One hundred thyroid nuclei were assessed in each sample. RESULTS Karyometric, densytometric and textural parameters were assessed for PTC and normal thyroid (NT) tissue. Obtained information was related to gene expression profiles obtained from DNA microarrays. Difference between normal thyroid tissue (NT) and PTC tissue was noted using complex of morphometrical parameters: circular rate (NT – 0.68; PTC – 0.57), diameter equivalent circle (NT – 51.0; PTC – 63.09), coefficient of variation of nuclear area (NT – 30.65; PTC – 19.36) and others. In the next step we assessed the relationship between morphometrical parameters and gene expression profile of papillary thyroid tumors, looking for genes with expression correlated with analyzed features. Genes, highly correlated with morphometrical parameters were discovered and discussed. CONCLUSIONS: Histomorphometry of PTC is reflected in its gene expression profile.

OP11-1
HER2/ TOP2A AMPLICON IN BREAST: A MICROARRAY-BASED AND CHROMOGENIC IN SITU HYBRIDISATION ANALYSIS

Edurne Arriola[1], Maryou Lambros[1], Caterina Marchio[1], David Tan[1], Rachael Natrajan[1], Socorro Maria Rodriguez-Pinilla[2], Narinder Tamber[1], Kerry Fenwick[1], Alan Mackay[1], Chris Jones[3], Alan Ashworth[1], Jorge S Reis-Filho[1]
[1] The Breakthrough Breast Cancer Research Centre, Institute of Cancer Research, London, United Kingdom
[2] CNIO, Madrid, Spain
[3] Section of Paediatric Oncology, Institute of Cancer Research, Sutton, United Kingdom

Background: Although the HER2 amplicon has been subjected to extensive molecular genetic analysis, the characteristics of the 17q12 amplicon in cases harbouring HER2/ TOP2A amplification are not well known. The aims of this study were 1) to provide a detailed molecular genetic analysis of the 17q12 amplicon in breast cancers harbouring HER2/ TOP2A co-amplification and 2) to describe additional recurrent coamplifications in cases with HER2/ TOP2A amplification. Methods: A tissue microarray containing replicate cores of 245 breast carcinomas were subjected to chromogenic in situ hybridisation analysis (CISH) using Zymed SpotLight probes for HER2, TOP2A and chromosome 17 (CEP17) centromere. Amplification was defined according to the manufacturer's guidelines. All cases harbouring HER2/ TOP2A co-amplification and 5 cases with HER2 but not TOP2A amplification by CISH were microdissected and subjected to microarray-based CGH (aCGH) using the Breakthrough Breast Cancer 16K bacterial artificial chromosome (BAC) array platform. Results: HER2 and TOP2A amplification was found in 37 and 20 samples, respectively. All cases harbouring TOP2A amplification were also HER2 amplified. Out of 25 microdissected cases, 13 rendered optimal results with microarray-based CGH analysis – 9 HER2/TOP2A amplified and 4 HER2 amplified. Cases displaying HER2/ TOP2A high level amplification by CISH were confirmed by aCGH analysis. The smallest region of amplification on 17q12 in the whole series extended from 34719.9 to 35454.8Kbs, and encompassed HER2 but not TOP2A. In TOP2A/ HER2 co-amplified samples, the smallest region of overlap was extended from 34719 to 36537kb, comprising a region of 1817kb. This region comprised several other genes that are reported to be overexpressed when amplified, such as GRB7, THRA, CASC3, RARA, CDC6, SMARCE1 and KRT10. HER2 amplified cases displayed recurrent co-amplifications mapping to 8p12, 13q34, 17q23, 18q21.1 and 20q13. Conclusion: HER2/ TOP2A amplified breast cancers characteristically display the so-called 'firestorm' molecular genetic pattern, being characterised by multiple, focal, high level amplifications. The 17q12 amplicon is complex and harbours multiple genes that may be associated with breast cancer development and progression.

OP11-2
ANALYSIS OF BREAST NORMAL AND TUMOR TISSUES BY USING MICROIMAGING FOURIER TRANSFORM INFRARED (FT-IR) SPECTROSCOPY

Christos Valavanis[1], Evridiki Boukaki[1], Stefanos Konstadoudakis[1], Petroula Arapantoni-Dadioti[1], Joanna Anastasopoulou[2], Theophillos Theophanides[2], C Conti[3], P Ferrari[3], E Giorgini[3], C Rubini[3], S Sabbatini[3], G Tosi[3]

BACKGROUND AND OBJECTIVE : Fourier Transform Infrared Spectroscopy (FT-IR) has received great attention from various fields because it can provide information about the molecular structure and the chemical composition of biological materials. Recently, infrared spectroscopy has been considered as an early diagnostic tool for the detection of tumours in synergy with traditional methods such as histopathological analysis, ultrasound, X-rays, etc. Micro imaging FT-IR is a powerful technique applied in tissue analysis, because it allows to detect biochemical changes that can be extremely subtle and located in a small area of tissue . Recently, micro-FT-IR imaging of normal and tumor breast cells has been carried out on breast tissues and cell lines showing certain spectral features, which could distinguish different breast neoplastic lesions and normal tissue. MATERIALS AND METHODS: In this study we have investigated 19 breast tumors (4 invasive lobular carcinomas with LCIS component, 13 invasive ductal carcinomas with DCIS component, 1 mixed type carcinoma and 1 osteosarcoma). The carcinomas were of variant histologic grade of malignancy. Thin paraffin sections of 5μm were obtained and spectral analysis of their solid state spectra was performed by using a Perkin-Elmer Spectrum One FT-IR equipped with a Perkin-Elmer Auto-image microscope. RESULTS AND CONCLUSIONS: By analysing these spectra, we have found characteristic bands in the infrared region, where the main components of these signature bands are located. For example, characteristic DNA band near 1680-1660

cm-1, Amide I, II, III protein bands and phospholipid band near 1140-1170 cm-1. These characteristic bands have been monitored as a function of the degree of cancer progression, and displayed spectral differences between normal breast tissue and different types of breast tumors. The results have been obtained with chemometric methods, such as cluster analysis, principal component analysis and custom analysis.

OP11-3
ANALYSIS OF THE EFFECTS OF A HIGH CORN OIL AND A HIGH OLIVE OIL DIET ON THE HISTOPATHOLOGIC CHARACTERISTICS AND ON P21RAS EXPRESSION IN DMBA-INDUCED RAT MAMMARY ADENOCARCINOMAS

Background: Breast cancer is associated with lifestyle and environmental factors. Animal studies have shown that dietary lipids influence mammary carcinogenesis, mainly at promotion stage. c-Ha-ras is involved in proliferation pathways in normal and tumoral cells and can be activated by point mutations and overexpression mechanisms. Methods: We investigated the effects of a high corn oil and a high olive oil diet on the histopathologic characteristics and on p21ras expression in rat dimethylbenz(a)anthracene (DMBA)-induced mammary adenocarcinomas in comparison with those of a control low-fat diet. We analyzed nine histologic parameters and we applied a grading method adapted to rat tumors, described previously by us, on 227 carcinomas from three dietary groups of an experimental series: C (n=69), fed a normolipidic diet; M (n=91), fed a high corn oil diet and O (n=67), fed a high olive oil diet after the DMBA induction. An immunohistochemical study with an antip21ras monoclonal antibody (Ab-1 Oncogene Research) was performed on 209 carcinomas (65 C, 83 M and 61 O) and we evaluated the results using the image analysis software VISILOG 5.1 (NOESIS). Results: More than 50% of carcinomas from M exhibited architectural or nuclear grade 2 or 3 and > 3 mitosis/10HPF compared to the prevailing grade 1 and a lower mitotic count on control and high olive oil groups. An unequivocal stromal desmoplasia and tumoral necrosis were more prominent than tumors from O and a prevailing cribriform pattern was observed. High olive oil diet adenocarcinomas exhibited a predominantly low histologic grade, similar to the control, few necrotic and invasive areas and the highest percentage of papillary areas. Lymphoplasmacytic and mast cell infiltration were also influenced by diet. The different degrees of morphological malignancy, evident when analyzing the isolated parameters, was highlighted when we applied the adapted grading method: 72% and 64% of carcinomas from C and O, respectively, were well differentiated whereas only 50% of the tumors from M displayed a grade I. Regarding the expression of p21ras, we found no significant differences on the expression between the three groups: mean positivity of 49,66% in C; 56,43% in M and 54,26% in O. Conclusions: Our study demonstrates that dietary lipids affect the degree of morphological aggressiveness of the experimental mammary tumors according to their clinical behavior, which provides more arguments in favor of their relationship with breast cancer, and an unlikely role of p21ras overexpression in rat mammary carcinogenesis.

OP11-4
NESTIN POSITIVE MYOEPITHELIAL / PROGENITOR CELLS IN THE BREAST

Zdenek Kolar[1], Jiri Ehrmann Jr. [1], Gulisa Turashvili[1], Jan Bouchal[1], Josef Skarda[1], Jaroslav Mokry[2]
[1] Department of Pathology and Laboratory of Molecular Pathology, Faculty of Medicine and Dentistry, Palacky University, Hnevotinska 3, CZ-77515 Olomouc, Czech Republic
[2] Department of Histology and Embryology, Faculty of Medicine, Charles University, Hradec Kralove, Czech Republic

Nestin (neuroepithelial stem cell protein) is an intermediate filament (IF) protein considered to be a marker of neural stem cells. Nestin expression has been confirmed in stem/progenitor cells of the dermis, hair follicles, intestine, pancreas, bone marrow as well as in neural, muscle and other tissues. Nestin expression has also been detected in the endothelium and we have noted the activation of nestin expression in newly formed human blood vessels. The myoepithelial cells of the breast form an outer layer of the terminal duct lobular unit. Several markers have been reported for the immunohistochemical detection of breast myoepithelial cells, however, the specificity and sensitivity of these markers vary widely. We analysed the expression of nestin by an indirect immunohistochemical method in 300 archival formalin-fixed and paraffin-embedded tissue samples of breast cancer and surrounding mammary tissue as well as in tissue microarrays consisting of 109 cases. Nestin expression of various intensities was found in the cytoplasm of myoepithelial cells of almost all normal ducts and lobular acines found in the vicinity of tumours. The intensity of expression varied from strong /marked (32 cases, ~10%), to moderate/clearly visible (91 cases, ~29%) to low/visible (113 cases, ~38%) and to very low/visible in less than 50% cells only (64 cases, ~21%). Pathological lesions like adenosis with atypical hyperplasia and in situ carcinoma exhibited very strong positivity and the detection of nestin could be also used for the diagnosis of pseudoinvasion in some controversial cases. In invasive carcinomas we found nestin positivity in a portion of epithelial cells in a minority of cases. The positivity in the epithelial component was confirmed by simultaneous AE1AE3 cytokeratin immunostaining and was significantly higher in hormone receptor and c-erbB-2/HER2/neu negative cases which likely corresponded to basal cell phenotype cancer ($p \leq 0.003$). Beside the epithelial component, nestin positivity in carcinomatous samples was also confirmed in some stromal elements and endothelium of the capillary network (confirmed by simultaneous CD34 immunostaining). In summary, we have described the potential utility of nestin immunostaining in breast pathology for the detection of myoepithelial/progenitor cells and suggest its potential involvement in the processes of tumour development and neoangiogenesis. Acknowledgement: This work was supported in part by grants MSM 6198959216 and 0021620820.

OP11-5
TPL2/COT AS A NEW PROGNOSTIC AND PREDICTIVE FACTOR IN BREAST CANCER?

Zuzana Krcova[1], Jiri Ehrmann Jr. [1], Aristides Eliopoulos[2], Gulisa Turashvili[1], Jiri Klein[3], Josef Skarda[1], Eddie Fridman[4], Veronika Krejci[1], Jana Zapletalova[5], Zdenek Kolar[1]

[4] Department of Pathology, Sheba Medical Centre, Tel-Hashomer, Israel
[5] Department of Medical Biometry, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

Inhibition of protooncogene Tpl2/Cot (serin/threonin kinase) lead to its inability to activate signalling pathway ERK-MAPK, which, among others, regulates synthesis of cytokines TNF-alpha and IL-1 and expression of cyclo-oxygenase 2 (COX-2). Moreover there is a change in signalling pathway mediated by NF-kappaB. These molecules are also affected by the STAT protein family. STAT mediated signalling pathways participate not only in the modulation of immune response but also in the development of several types of malignant umours. Therefore, we can hypothesise that there is a relation between expression f STAT and Tpl2/Cot which has not been studied to date. The latest studies show Tpl2/Cot over-expression in about 40% of breast carcinomas. Experimental increase in expression of Tpl2 in breast carcinoma cell lines leads to activation of COX-2 expression. Over-expression of COX-2 detected in approximately 40% of breast carcinomas seems to play an important role especially in regulating angiogenesis, cell proliferation, cell differentiation and apoptosis. The aim of this pilot study was immunohistochemical detection of expression of TPL-2, COX-2 and STAT1,3,5 proteins in tissue microarrays (TMA) of 32 cases of invasive ductal carcinomas and analysis of its expression in relation to hormonal status and c-erbB-2 status. The results showed significant increase in Tpl2/Cot expression in c-erbB-2 negative carcinomas (p=0,001). This increase correlated with enhanced nuclear expression of STAT3 in the same group of tumours (p=0,014). In contrast to these findings, multivariate analysis showed significantly lower values of STAT1 expression in tumours characterized by ER+/PR+/cerb2- immunophenotype in comparison to other tumour types (p=0,001). COX-2 expression was increased in all studied types of tumour. No significant correlation was observed for other proteins. These results indicate that increased Tpl2/Cot and STAT3 expression together with decreased STAT1 expression in c-erB-2 negative breast cancer tumours could by an other important prognostic and predictive factor. Supported by grants VZ MSM 6198959216 and 6FP LSHC-CT-2006-037344.

OP11-6

MORPHOLOGICAL AND MOLECULAR EVOLUTIONARY PATHWAYS OF LOW AND HIGH GRADE BREAST CANCERS AND THEIR PUTATIVE PRECURSOR LESIONS

Tarek Abdel-Fatah[1], Desmond Powe[1], Zsolt Hodi[1], Jorge Reis-Filho[2], Andrew Lee[1], Ian Ellis[1]
[1] Division of Pathology, School of Molecular Medical Sciences and Nottingham University Hospitals Trust, University of Nottingham, Nottingham, United Kingdom
[2] The Breakthrough Breast Cancer Research Centre, Institute of Cancer Research, London, United Kingdom

BACKGROUND: In this study, further support to our proposed histogenetic pathways concerning low and high grade breast cancer (LGBC and HGBC) and their putative precursors was provided. MATERIALS & METHODS: 495 successive cases of invasive tubular (TC), cribriform (ICC), lobular (ILC), tubulolobular (TLC), low and high grade ductal carcinomas (IDC) and tubular/classic lobular mixed tumours were reviewed for the frequency of pre-invasive lesions. Tissue microarrays containing 790 representative areas of the putative precursors, co-existing terminal lobular units and carcinomas were immunoprofiled for putative tumour suppressor genes, cell cycle regulators, and proliferation and differentiation markers. RESULTS: More than 85% low grade IDC, ICC, TC, TLC, and ILC had associated CCLs, predominantly flat epithelial atypia (FEA). FEA, ADH, LN, and low grade DCIS was rare in high grade IDC; instead, high grade DCIS were the common precursor lesions (43%). The epithelial cells in FEA, ADH, LN, DCIS lesions and their co-existing LGBC/ILC were negative for basal and myoepithelial markers, but positive for CK19/18/8, ER-α, Bcl-2, and cyclin D1. The ER-α/ER-β expression ratio increased during carcinogenesis, as did cyclin D1 expression. Bcl-2 was expressed in almost all epithelial cells lining CCLs, ADH, LN, low grade DCIS and LGBC but was reduced, or absent, in high grade IDC. FHIT expression was reduced in hyperplastic CCLs, ADH/DCIS, LN and the associated invasive lesions. In LGBC/ILC, p53 immunopositivity was very rare (3%) while ATM expression was reduced in only 22% of LGBC cases. Positive expression of p53 was detected in 35% of high grade IDC. CONCLUSION: Our findings support the concept that FEA is the committed precursor cell lesions of LGBC/ILC. These may represent a family of precursor, in situ and invasive neoplastic lesions belonging to the luminal 'A' subclass of breast cancer. Our results suggest that the committed progenitor cells (PCs) for low grade breast neoplasia are CK19/18/8 positive and exhibit ER-α mediated CCND1 and BCL2 gene expression. Alternatively, breast cancer (PCs) regardless of their original phenotype may acquire stochastic genetic and epigenetic hits that lead to the activation of separate histogenetic pathways for LGBC and HGBC, and that these events determine the phenotype of the pre-invasive and invasive lesions. Furthermore, these hits may be an early event in the progression of 'luminal A' tumours and once committed to this 'molecular pathway', progression to a 'high grade' (basal-like or HER2+) phenotype would be unlikely.

OP12-1

IS BACTERIAL TRANSLOCATION IN CROHN'S DISEASE DEPENDENT ON CARD15 GENOTYPE?

Gert De Hertogh[1], Jeroen Aerssens[2], Peter Van Eyken[1], Paul Rutgeerts[3], Karel Geboes[1]
[1] Department of Pathology, UZ KUL, Leuven, Belgium
[2] Johnson & Johnson Pharmaceutical Research & Development, Beerse, Belgium
[3] Department of Gastroenterology, UZ KUL, Leuven, Belgium

Background: The intestinal bacterial flora is involved in the pathogenesis of Crohn's disease (CD). Bacterial translocation may be required for the development of chronic transmural inflammation. Three single nucleotide polymorphisms (SNPs) of the CARD15 gene are associated with an increased susceptibility to develop CD and a decreased expression of alpha-defensins in ileal Paneth cells. We questioned whether the CARD15 gene status influences the type and ultimate distribution in the bowel wall of translocating bacteria in CD patients. Methods: 4 CD patients were selected on the basis of their status for the Arg702Trp, Gly908Arg, and Leu1007fsinsC SNPs of the CARD15 gene (1 wild type; 1 heterozygous and 1 homozygous for Arg702Trp; 1 compound heterozygous for Arg702Trp and Gly908Arg). Normal and pathological mucosa, myenteric plexus and mesenterial lymph node tissue were microdissected from snap-frozen ileal biopsies taken from the surgical bowel specimens. Extracted DNA was used as template in a 2-round PCR using universal primers for the 16S rDNA gene. Purified PCR products were subcloned, sequenced and subjected to a BLAST-search against the GenBank-, EMBL- and RDPII-databases. Results: PCR and cloning of 16S rDNA was successful in all samples. Sequence analysis revealed the presence of typical bowel bacteria (Enterobacteriaceae; Clostridia; Bacteroidetes) at all levels of the bowel wall, but there was no relation between the CARD15 gene status and the type of translocating bacteria. There was also no difference between the types of bacteria detected at the mucosal level and deeper in the bowel wall. Interestingly, 2 samples of the myenteric plexus in macroscopically involved bowel segments contained DNA derived from Legionella species. Conclusions: The majority of translocating bacteria in CD belong to the typical bowel microflora. The status of the CARD15 gene for the Arg702Trp, Gly908Arg, and Leu1007fsinsC SNPs does not influence the type and ultimate distribution in the bowel wall of these bacteria. Interestingly, this is the first report that demonstrates the presence of Legionella species deep in the bowel wall in CD patients. Further exploration of additional biopsy samples will be needed to confirm this finding.

OP12-2
HEDGEHOG PATHWAY IN COLONIC LESIONS
Alinger Beate, Aberger Fritz, Strasser Felix, Dietze Otto, Hauser-Kronberger Cornelia
Department of Pathology, General Hospital and Paracelsus Medical University Salzburg, Salzburg, Austria

Hedgehog signaling is a main regulation cascade in embryonic differentiation of the whole gastrointestinal tract and mutations of some components have been associated with birth defects like gut malrotation. Unusual expression of Hedgehog components has been associated with malignancies of the GI-tract. Methods Immunohistochemistry was performed on FFPE non-pathological (n=10) and pathological (n=45) tissue from human colon. The benign colonic lesions (n=23) comprise tubular/villous adenomas and hyperplastic polyps, malignant lesions (n=22) include adenocarcinomas and neuroendocrine carcinomas. Additionally Tissue array with 274 samples of colon cancer and normal tissue sections were used. Antibodies for Gli1, Gli2, Gli3, Shh, Ihh, Dhh, Ptch, Smo, β-Catenin and monoclonal antibodies for CK20 and Ki67 were used. For real time PCR tissue specimens were obtained from coloscopy. Colon cancer cell lines, including HCT 15, HT 29, DLD-1, C 201, C 205 and C 320 were investigated by real time PCR and BrdU assay. Functional assays were performed using cyclopamine as a pathway inhibitor and retroviral Gli1 and Gli2 constructs as promoters of Hedgehog signaling. Results Hedgehog signaling components are expressed in normal tissue samples as well as in benign and malignant lesions of the colon . In normal colon tissue the ligands Sonic Hedgehog (Shh) and Desert Hedgehog (Dhh) are expressed exclusively in the lining epithelium. Strong and focally distributed Shh and Dhh expression was detected in all malignant cases, although the expression of Hedgehog ligands is reduced in adenocarcinomas. Shh/Dhh expression was inversely correlated with proliferation using Ki67. Possible regulation of differentiation was proven with CK20. Corresponding tissue samples were analyzed by real time PCR. Cell culture experiments were performed to verify correlation of active Hedgehog signaling and proliferation or differentiation, respectively. The colon cancer cell lines investigated did not show significant changes neither on treatment with pathway inhibitor cyclopamine, nor by ectopic Hedgehog expression. BrdU incorporation assay also confirmed immunohistochemical findings. Conclusion The Hedgehog signaling pathway seems to play an essential role rather in maintaining normal colonic tissue than promoting cancer formation or even accelerating cancer growth. Relating to cancer dedifferentiation and proliferation loss of Hedgehog function may be associated not with regulation of well differentiated cancer cells but with cancer stem cells.

OP12-3
HEDGEHOG SIGNALING IN THE PANCREATIC NEUROENDOCRINE SYSTEM AND MALIGNANT TUMORS
Alinger Beate, Mayrhauser Ursula, Lechner Berta, Dietze Otto, Hauser-Kronberger Cornelia
Department of Pathology, General Hospital and Paracelsus Medical University Salzburg, Salzburg, Austria

The Hedgehog (Hh) pathway is one of the most fundamental signal transduction pathways in pancreatic embryonic differentiation. The presence in mature tissue is still to be investigated. Three mammalian Hh ligands Sonic (Shh), Indian (Ihh) and Desert Hedgehog (Dhh) are all able to bind to the receptor Patched (Ptch) on target cells at the same extent. Binding of the ligand at Patched receptor looses its inhibitory effect on the protein Smoothened (Smo), activating an intracellular signaling cascade which leads to the release of the transcription factors Gli1, Gli2 and Gli3 and therefore expression of downstream target genes. Hh signaling in developing pancreas determines boundaries, as inhibition by cyclopamine results in expansion of pancreatic tissue and expression of pancreatic hormones. Indian Hedgehog and Patched seem to promote correct development of the pancreas as targeted mutation of one of them results in pancreatic defects. Patched especially affects organization of endocrine cells, as seen by a reduction of islet size and pancreas specific gene expression and impaired glucose homeostasis in the absence of the receptor. The expression of Hh pathway members (Gli 1, 2, 3, Shh, Dhh, Ihh, Ptch, Smo, Hip) in normal human and murine pancreatic tissue and neuroendocrine tumors (n=30), including e.g. insulinoma, glucagonoma and gastrinoma was analyzed. For immunohistochemistry a standard S-ABC detection system (Dako) and a double immunofluorescence technique on FFPE tissue was performed. Interaction of Hh activity with Wnt and Notch signaling has been analyzed. For mRNA detection and quantification real time PCR was performed on a Corbett RotorGene 6000. The insulinoma cell lines TGP52 and Beta TC-6 were used for in vitro experiments. Therefore the pathway has been inhibited by cyclopamine to show changes in gene expression and correlation with hormone secretion. By adding glucose the impact of Hh signaling on hormone secretion and release was investigated. Immunohistochemical results showed an active Hh pathway in the β- and δ-cells of normal mature pancreas. We detected a specific expression pattern of the Hh components and members of other pathways like Notch and β-Catenin. Activity of the Hh signaling cascade is also demonstrated in neuroendocrine tumors. These findings are confirmed by real time PCR. Our results indicate an involvement of Hh signaling in formation of pancreatic neuroendocrine tumors. Hh pathway may be associated with neuroendocrine cell differentiation and stem cell determination in pancreatic Langerhans islets.

OP12-4
QUANTITATIVE MONITORING OF THE MRNA LEVELS OF CYCLIN D1 AND PROLIFERATION MARKERS (Ki-67, TOPOISOMERASE IIα, AND TPX2) ASSOCIATED WITH UNFAVORABLE PROGNOSIS IN PATIENTS WITH MANTLE CELL LYMPHOMA
Helena Brizova, Marcela Mrhalova, Roman Kodet
Department of Pathology and Molecular Medicine, 2nd Medical School, Charles University in Prague, Czech Republic

Background: Mantle cell lymphoma (MCL) is an aggressive neoplasm with a poor long-term outcome. The median overall survival is usually 3–4 years. However, the clinical behavior may be variable. Some patients suffer from an aggressive disease with survival less than a year, while other patients have a relatively slow clinical evolution and survive more than 10 years. It is therefore of a great importance to recognize MCL at initial diagnosis and to establish routinely applicable prognostic markers. Cyclin D1 is described as a molecular hallmark of MCLs. Expression of proliferation markers (Ki-67, topoisomerase IIα and/or TPX2) is shown to be the most effective prognostic factor for the clinical outcome. The aim of the study was to analyze the cyclin D1 expression and to design a methodology allowing a precise quantitative assessment of the proliferation markers. Method: We developed a real-time quantitative (RT-RQ-PCR) measurement of the cyclin D1, Ki-67, topoisomerase IIα, and TPX2 transcripts. We studied 113 fresh frozen or formalin fixed, paraffin embedded biopsy specimens of non-Hodgkin's lymphomas, of which 77 were diagnosed as MCL. Results: We detected the cyclin D1 overexpression in all MCL specimens including bone marrow aspirates infiltrated by MCL. We designed and approved a novel quantitative assessment of the proliferation markers. We demonstrated RT-RQ-PCR as a highly reliable, specific, objective and routinely applicable technique to examine the proliferation activity. The proliferation activity varied from one tumor to another reflecting the heterogeneity between individual patients, which is described to be of a clinical relevance. Generally, we observed the highest proliferation activity in Burkitt lymphomas and the lowest in reactive lymph

nodes. The proliferation activity assessed by the quantitative measurement of topoisomerase IIα and TPX2 correlated with the cyclin D1 level indicating the quantitative regulation of the cell cycle rather than an on/off switch control. Conclusion: RT-RQ-PCR is a reliable method for molecular monitoring of patients with MCL. A quantitative detection of cyclin D1 mRNA is a useful tool to recognize MCL and also a tool for monitoring the bone marrow during the disease course. The quantitative assessment of the proliferation markers provides a potent tool to predict the survival of MCL patients. This work was supported by the Internal grant of Faculty Hospital in Motol No. 9756, Grant of Charles University GAUK 200055, 46/2006/C/2.LF, and the Research project of the Ministry of Health No. 00064203/6704

OP12-5

MINIMAL DISSEMINATED DISEASE IN ALVEOLAR RHABDOMYOSARCOMA USING PAX3/FKHR AND PAX7/FKHR FUSION GENES.

Lenka Krsková[1], Marketa Kalinova[1], Alenla Augustinakova[1], Irena Hilska[1], Eva Drahokoupilova[2], Roman Kodet[1]
[1] Department of Pathology and Molecular Medicine, 2nd Medical School, Charles University in Prague, Czech Republic
[2] Department of Pediatric Hematology and Oncology, 2nd Medical School, Charles University in Prague, Czech Republic

Background: Rhabdomyosarcoma (RMS) has 2 major histological subtypes: alveolar (ARMS) and embryonal (ERMS). ARMS is more aggressive and prone to distant dissemination, whereas ERMS tends to expand and recur locally. The aim of the study was to monitor minimal disseminated disease (MDD) using real-time quantitative reverse-transcription PCR (RQ-RT-PCR) of the PAX3-FKHR or PAX7-FKHR fusion gene. Design: We prepared an assay using RQ-RT-PCR for the quantitative assessment of MDD in ARMS by using hydrolysis probe for quantification of PAX3-FKHR or PAX7-FKHR genes and beta-2-microglobulin housekeeping gene, which was used as an internal cDNA quality and quantity control. We constructed plasmid standards with either PAX3/7-FKHR fusion genes or beta-2-microglobulin gene. Normalized expression of PAX3/7-FKHR was determined as a ratio between PAX3-FKHR or PAX7-FKHR and beta-2-microglobulin levels assessed by RQ-RT-PCR. We determined the sensitivity and specificity of PAX3/7-FKHR transcripts as markers for detection of MDD. Primary tumor samples (18), local recurrent samples (16), bone marrow samples (91), peripheral blood progenitor cell samples (24), peripheral blood samples (16) or bone marrow grafts (3) in 27 patients with ARMS were examined by the RT-PCR and RQ-RT-PCR techniques. Results: PAX3/7-FKHR transcripts are specific and sensitive tool for detection of MDD in ARMS. We were able to identify 13/25 patients with BM involvement using RQ-RT-PCR and 15/25 using nested RT-PCR method. Nine of eighteen BM samples were positive for the fusion transcript at the time of diagnosis. We analyzed PAX3-FKHR or PAX7-FKHR expression during the course of the disease in 133 sequential BM, PB or PBPC (93, 24, 16) samples. The RQ-RT-PCR results correlated well with nested RT-PCR results ($p<0.0001$). Conclusion: The presence of metastases is the most adverse prognostic factor in RMS, and bone marrow is a frequent site of the tumor dissemination in ARMS. Our results detecting the fusion transcripts typical of ARMS in the BM or peripheral blood suggest that patients with positive findings are at a high risk of the tumor progression. Of the 9 patients in whom we were able to identify bone marrow involvement by the tumor cells at the time of presentation, four died of progressive disease and two live with the tumor progression. In three patients the follow-up is too short to make a conclusion. The project was supported by grant GACR 304/07/0532, by research project FNM MZO 00064203 and by MSM 0021620813.

CD44 (H-CAM) EXPRESSION IN BREAST CARCINOMA. AN EXPERIENCE OF 314 CONSECUTIVE CASES IN VERONA

Marta Gobbato, Erminia Manfrin, Andrea Remo, Daniela Reghellin, Daniela Dalfior, Claudia Canizzaro, Rosanna Loss, Maria Paola Rapagnani, Marco Vergine, Marco Chilosi, Fabio Menestrina, Franco Bonetti
Department of Pathology, University of Verona, Italy

Background: CD44 is a family of plasma membrane glycoproteins encoded by a single gene in chromosome 11. This adhesion molecule has been recently reported in breast carcinoma, but the role and the prognostic impact is not clear. CD44v7-v8 expression is associated with poor long term prognosis. CD44s expression is associated with increased diseased free survival in node negative patients. Our aim is to study CD44 (H-cam) expression in breast carcinoma and the correlation with other molecular markers. Methods: We studied CD44 (H-CAM) immunoexpression in 314 consecutive breast carcinomas consisted of 310 primary neoplasm and four metastasis. All cases were also submitted to routinely immunohistochemical evaluation for Estrogen Receptor (ER), Progesteron Receptor (PgR), E-caderin, Ki-67 and Hercep-test (HcT). To evaluate CD44 expression, the cases have been stratified into three different categories according to the pattern of cell positivity. High-positive: diffuse membrane expression in all neoplastic cells; low-positive: low rate of neoplastic cells positive in a context of highly heterogeneous expression; negative: lack of staining in neoplastic cells. Results: 141 (45%) cases were CD44 high-positive and consisted of 71 ductal invasive carcinoma, 26 ductal carcinoma in situ, 2 microinvasive carcinoma,19 lobular invasive carcinoma, 9 mixed carcinoma ductal and lobular, 3 colloid carcinoma, 2 papillary carcinoma, 2 metaplastic carcinoma, 1 lobular carcinoma in situ, 1 tubular carcinoma, 1 inflammatory carcinoma, 4 metastasis of breast carcinoma (liver, pleura, nodal and bone), 51 (16%) cases were low-positive, 122 (39%) cases were negative . In our analysis, CD44 was not correlated to histotype, ER (P=0,50), PgR (P=0,88), ki67 (P=0,9) E-caderin (P=0,47), HcT (P=0,78) and nodal metastasis (P=0,88). Conclusion: In preliminar data CD44 is not correlated to histotype and other immunohistochemical markers. [3] University of Nottingham, Nottingham, United Kingdom
[4] University of Torino, Torino, Italy

Background: Micropapillary carcinoma (MPC) is a special type of breast cancer with a distinctive histological growth pattern, high prevalence of lymph-node metastasis and aggressive clinical behaviour. Methods: We studied 28 MPCs, 14 pure (PMPCs) and 14 mixed carcinomas (MMPCs). A tissue microarray was constructed and immunohistochemistry for ER, PR, HER2, p53, basal markers (CK5/6, CK14, CK17, CAV-1, EGFR) and adhesion proteins (E-cadherin, beta-catenin) was performed. Eleven primary PMPCs and 2 matched lymph-node metastases

were microdissected and studied by microarray-based comparative genomic hybridisation (aCGH) using the Breakthrough Breast Cancer Research Centre aCGH platform containing 16K bacterial artificial chromosomes clones arranged at ~100Kb intervals throughout the genome. Validation of genetic alterations was performed with chromogenic in situ hybridization (CISH). Results: The vast majority of MPCs showed luminal (93% of PMPCs, 71% of MMPCs) or HER2+ (7% of PMPCs, 29% of MMPCs) immunophenotype. Neither positivity for any of the basal markers studied nor EGFR amplification was found. E-cadherin expression was seen in both PMPCs and MMPCs, beta-catenin showed only membranous and cytoplasmic staining in all cases but one pure carcinoma which also displayed nuclear positivity. p53 was positive in 21% of PMPCs and in 42% of MMPCs. aCGH analysis revealed recurrent (> 30% of cases) copy number gains on 1q, 6p, 7p, 8p, 16p, 17p, 17q, 20q, 20q; losses at 3q, 6q, 6q, 8p, 9p, 13q, 13q, 16q, 16q, 17p, 18p, 18q, 18q and 22q. Recurrent amplifications mapping to 1q23.3, 1q31.3-q32.1, 8p12-p11.21 (FGFR1), 8q21.12-q24.3 (MYC), 11q13.3 (CCND1), 16p13.3, and 17q21 (HER2) were also found. CISH analysis of the whole series revealed HER2 amplification in 7% of PMPCs and 29% of MMPCs. TOP2A amplification was found in 2 HER2 amplified MMPCs. MYC amplification was found in 21% of PMPCs and 28% of MMPCs. FGFR1 amplification was found in 14% of both PMPCs and MMPCs. CCND1 amplification was only found in 7% and 14% of PMPCs and MMPCs respectively. 7% of PMPCs harboured co-amplification of HER2 and TOPO2A and of MYC and CCND1. The 14 MMPCs showed coamplification of HER2 and TOPO2A in 2 cases, coamplification of HER2, TOPO2A and CCND1 in 1 case, and HER2, MYC, FGFR1 in 1 case. Conclusions: MPCs do not display a basal-like immunophenotype and are predominantly of luminal phenotyope. At the molecular genetic level they show varying patterns of genomic aberrations and frequent coamplification of key oncogenes that may account for their aggressive clinical behavior.

OP13-3
MAMMAGLOBIN, A USEFUL ADDITION TO THE CURRENTLY AVAILABLE IMMUNOHISTOCHEMICAL MARKERS FOR THE DETECTION OF METASTATIC BREAST CARCINOMA

Gitte Nielsen, Betsy Spaulding
Dako North America, USA

Background: Gross cystic disease fluid protein (GCDFP-15) and estrogen receptor alpha (ER α) are immunohistochemical markers routinely used in antibody panels for the diagnosis of metastatic breast cancer. These markers are valuable diagnostic tools, but there is a need to improve the sensitivity and specificity of the existing panel of breast markers. Mammaglobin is a member of the secretoglobin-uteroglobin family and its expression is largely restricted to normal and neoplastic breast. Mammaglobin protein expression has been demonstrated in the majority of well, moderately, and poorly differentiated invasive ductal carcinomas and in metastatic breast cancers by immunohistochemistry (IHC). In this study, we compared the expression of monoclonal antibodies to Mammaglobin, GCDFP-15 and ER α on metastatic breast cancers to evaluate whether mammaglobin improves the sensitivity of the antibody panel in detecting metastatic breast carcinoma. Method Formalin-fixed, paraffin-embedded (FFPE) tissue specimens from metastases of breast cancer, renal cell carcinoma, melanoma, and large cell carcinoma were obtained. Immunostaining was performed using mouse monoclonal antibodies to human mammaglobin (clone 304-1A5), GCDFP-15 (clone 23A3) and ER α (clone 1D5) on tissue pretreated with Tris/EDTA target retrieval solution. Bound antibody was visualized with the Dako EnVision+ Dual Link Detection System. Results: Mammaglobin, GCDFP-15 and ER α were found to be expressed in the majority of metastatic breast carcinomas tested. The highest positivity rate was found with anti-mammaglobin, followed by anti-ER α and finally anti-GCDFP-15. While expression of all three markers was observed in the majority of cases tested, the percentage of positively stained tumor cells varied significantly. Both GCDFP-15 and mammaglobin exhibited focal positivity in a subset of tumors, however their expression was complementary in that cases that were only very focally positive for GCDFP-15 exhibited significant mammaglobin expression and vice versa. Additionally, cases with significant mammaglobin and GCDFP-15 expression frequently labeled different cell populations within a tumor, further demonstrating the complementarity of the two markers. Conclusions: In this study we have demonstrated that mammaglobin is a sensitive marker for the identification of metastatic breast cancer. Furthermore, our findings suggest that the addition of mammaglobin to the panel of currently available breast markers improves the sensitivity when establishing breast as the site of origin.

OP13-4
IMMUNOHISTOCHEMICAL ANALYSIS OF TOPOISOMERASEIIα EXPRESSION IN SPORADIC INVASIVE BREAST ADENOCARCINOMAS

Christos Valavanis[1], Katerina Koutsoubi[2], Theofani Gavresea[1], Maria Terzi[1], Amalia Patereli[2], Nikiforos Apostolikas[2], Petroula Arapantoni-Dadioti[1]

[2] Department of Pathology, St. Savvas Cancer Hospital, Athens, Greece

BACKGROUND-OBJECTIVE: TopoisomeraseIIα gene is located at chromosome band 17q12-q21 and encodes a 170 kDa protein which alters the topological state of DNA through DNA strand cleavage, strand passage and religation, actions vital to cell division. Anti-cancer drugs called topoIIα inhibitors target this protein and induce tumor cell death via stabilization of DNA-TopoIIα complexes and double-stranded DNA breaks. The oncogene HER2 is located close to TopoIIα chromosomal locus and is overexpressed or amplified in 14-34% of breast carcinomas. Patients who respond to targeted therapy with monoclonal antibodies against HER2 often benefit from the parallel administration of TopoIIa inhibitors. In vitro studies with cell lines have demonstrated that TopoIIa gene amplification leads to TopoIIa protein overexpression and increased sensitivity to TopoIIa inhibitors. On the other hand loss of TopoIIa gene or decreased protein expression leads to chemoresistance against those drugs. Therefore, information on the expression levels of TopoIIa could be a significant predictive factor for therapeutic response in breast cancer treatment. In this context we investigated the expression of TopoIIα in sporadic invasive breast carcinomas and correlated its expression with tumor type, histological grade, lymph nodes status and HER2 receptor's expression. MATERIALS AND METHODS:Retrospective study of 368 cases of sporadic invasive breast carcinoma, from total and partial breast resections. Immunohistochemical detection of TopoIIa and HER2 protein expression using monoclonal antibodies. Semiquantitative protein expression assessement according to the accepted guidelines. RESULTS AND CONCLUSIONS: A. Overall and independently of tumor type 54.07% of breast carcinomas showed intense nuclear expression of TopoIIα B. Correlation of TopoIIa expression with tumor type, revealed high levels in 61.92% of ductal type, 41.82% of lobular, 25% of mixed and 33.3% of other types. C. Correlation of TopoIIa expression with histological grade showed high expression in Ductal: Grade I 23.8%, II 51.8%, III 69.7%, Lobular: Grade I 50%, II 38.46%, III 33.4%, Mixed: Grade I 20%, II 20.4%, III 30%.D. There was not statistically significant association between TopoIIα expression levels and lymph node status.E. Correlation of TopoIIα expression status with HER2 expression levels revealed : 72.3% of HER2 (3+) and 81.4% of HER2 (2+) carcinomas had high TopoIIα expression levels, while 39.6% of HER2 negative tumors showed increased TopoIIα expression.

[7]Department of Pathology, A. Fleming General Hospital, Athens, Greece

OBJECTIVES: To evaluate the expression of HER2 in infiltrating breast carcinomas by IHC, to compare the reactivity against HER2 of three different antibodies, to correlate HER2 expression levels with its gene amplification by CISH, tumor type, grade, lymph node status and ERα, PgR, p53 and ki-67 expression levels.MATERIALS AND METHODS: Prospective analysis of 1020 specimens of infiltrating breast carcinomas (680 ductal, 117 lobular, 69 mixed, 154 others) by IHC, using AO485, CB11, TAB-250 antibodies against HER2. Immunostaining was evaluated according to accepted guidelines.Cases scored 1+ and 2+ were further analysed by CISH. Gene amplification was graded as negative (1-2 gene copies/nucleus), putative Chr 17 polysomy (3-5 gene copies/nucleus), low amplification (6-10 gene copies/nucleus) and high amplification (>10 gene copies/nucleus). The same specimens were assessed IHC for ERα, PgR, p53 and Ki-67 expression status.RESULTS AND CONCLUSIONS: 1. AO485 IHC showed 24.80% of the tumors had 3+, 16.57% 2+, 26.47% 1+ and 32.16 % negative HER2 reactivity 2. There was concordance in evaluating HER2 expression levels among the antibodies used (AO485 vs CB11 92.8%, $p < 0.0001$ and AO485 vs TAB250 95.1%, $p<0.0001$) especially in 3+ cases. 3. Concerning CISH, among 1+ IHC analysed cases (249/270), 47.8% had no gene amplification, 45.8% showed putative chromosome 17 polysomy (not evaluated by Chr. 17 centromeric probe), 4.4% displayed low gene amplification and 2.0% high gene amplification. Cases scored 2+ (160/169) showed low gene amplification in 13.8%, high gene amplification in 8.8%, putative chromosome 17 polysomy 33.8% and no amplification in 43.8%. In conclusion CISH is a highly accurate method in evaluating HER2 gene copy status, more sensitive than IHC and should be used not only in 2+ IHC cases but also in 1+ IHC ones 4. HER2 expression levels were correlated with tumor type showing lower levels in lobular carcinomas ($p=0.0006$) and with tumor grade displaying higher expression in higher grade ($p<0.0001$). There was not statistically significant association between HER2 expression levels and lymph node status ($p=0.2744$) 5. Correlation of HER2 expression status with ER/PgR expression revealed higher HER2 levels in negative hormone receptors tumors and lower levels in positive ones ($p<0.0001$) 6. Higher HER2 levels have found in tumors with high p53 and Ki-67 expression ($p<0.0001$) 7. Stratified analysis revealed that tumor grade is more important than type in determining the expression status of HER2 (tumor grade $p<0.0001$ tumor type $p=0.7827$)

OP13-6

ANALYSIS OF THE CONCORDANCE BETWEEN THE BI-RADS CLASSIFICATION WITH USNCB AND BETWEEN USNCB WITH DEFINITIVE HISTOLOGICAL DIAGNOSIS IN 595 PATIENTS (601 CONSECUTIVE CASES)

Manuela Lacerda[1], Belmiro Duarte[2], Idílio Gomes[1]

[1] I. P. O. Coimbra F. G. , E. P. E., Portugal

[2] GEPSI-IEQPF-DEQ-FCTUC and ISEC , Portugal

Introduction: Preoperative ultra-sound guided needle core biopsy (USNCB) in breast cancer is becoming the standard of care and is used as the initial sampling method for non palpable, breast lesions detected by radiology. Objective: The aim of this study is to analyze the correlation between the breast imaging reporting and data system (BI-RADS) and the histological classification B categories for NCB of the European Working Group on Breast Pathology (EWGBP). We further analysed the pre-operatory histological diagnosis of the NCB with the definitive histological diagnosis after the definitive surgery was performed. Material and Methods: 601 consecutive USNCB from 595 patients with suspicious breast lesions (23% =0-9mm; 57%=10-19mm) were carried out from March 2003 to June 2006. Biopsies were performed using US equipment with a 7.0 -12 MHz multi frequency transducer; a minimum of three cores from each lesion were obtained using disposable automatic needles 14-G. The biopsies were formalin-fixed, paraffin-embedded, three-micro-thick sectioned and haematoxylin and eosin stained. Results: The data revealed 99% agreement of the 5 category BI-RADS with B5 category of the EWGBP classification, 71% of the category 4 BI-RADS with B5 category of the EWGBP classification. In case categories 5 and 4 BI-RADS are considered together the agreement is 80% with B5 category of the EWGBP classification. Furthermore, one found 57% agreement of 3 category BI-RADS with B3 category of the EWGBP classification (33% were B1; 4% were B5 and 5% were B3).The analysis of the concordance of the pre-operative histological diagnostic of the NCB with the definitive histological diagnosis after the definitive surgery was performed revealed 100% agreement for B5 category of the EWGBP classification with the definitive histological diagnosis (95% invasive carcinoma; 5% in-situ). For B3 category of the EWGBP classification we found 59% benign lesions, 22% borderline lesions (phyllodes tumour), 7.4% in-situ malignant lesions (intra- papillary carcinomas) and 11% invasive carcinomas (invasive papillary carcinomas). Discussion and conclusions: Ultra-sound guided needle core biopsy (USNCB) is an effective diagnostic method for a pre-operatory histological diagnosis; when definitive surgery was performed the definitive diagnosis with the histological diagnosis in NCB was 100% of the agreement for B5 categories which allowed that women to be submitted to one surgery only.

OP13-7

BASAL DIFFERENTIATION WITH CK5/6 IN INVASIVE DUCTAL CARCINOMAS OF BREAST AND PROGNOSTIC FACTORS

Eda Yilmaz Akcay, Isin Pak

Ankara Oncology Hospital, Turkey

Aim: Currently human breast carcinomas are classified according to 2002-WHO histological classification. This system doesn't take into account prognostic factors. Recent studies on breast tumors have identified distinct subtypes of breast carcinomas that are associated with different outcomes. These subtypes are: ER+/ luminal, normal breast-like, HER-2 over expressing and basal-like groups. The latter two are associated with poor prognosis, and basal-like tumor group express basal cytokeratins like CK5/6. Our study aimed to asses basal phenotype in invasive ductal carcinomas of breast by the expression of CK5/6 and examine the relationship between their expression and other pathological and immunohistological factors that have clinical significancy.

Material- methods: Expression of CK5/6 (basal marker), SMA (myoepithelial marker) and CK8/18 (luminal marker) was analyzed by immunohistochemistry in 93 invasive ductal carcinoma (NOS) of breast diagnosed between December 2004-November 2006 in Ankara Oncology Hospital, pathology department. CK5/6 positive and negative groups are identified and these groups are compared according to known prognostic and immunohistological factors which are; patient age, tumor size, histological grade, mitosis count, lymphovascular tumor invasion, necrosis, lymph node status (metastatic node number, extracapsular tumor extension, conglomeration of metastatic nodes) and ER, PR status, cerbB2 expression. Results: Of 93 tumor samples 16 expressed basal marker CK5/6 (%17.2). All of the cases expressed CK8/18 but just one case was SMA positive. Between CK5/6 positive and negative groups 4 parameters showed statistically significant difference; histological tumor grade, conglomerated metastatic lymph nodes, ER and PR status. Most of the CK5/6 positive basal group tumors was grade 3 (%75), %54.5 had conglomerated metastatic lymph nodes. Twelve of 16 CK5/6 positive cases were ER negative (%75), eight of them were PR negative (%50) whereas in CK5/6 negative group results were respectively %9,1 and %5.2. Conclusion:Our results are correlated with the literature. Immunohistochemically basal like phenotype of breast carcinomas are identified and CK5/6 positive tumors are associated with poor prognostic factors; conglomerated metastatic lymph nodes, higher histological grade and negative steroid hormone receptors.

OP13-8
SELECTIVE FROZEN SECTION IN SENTINEL NODE BIOPSY: A RELIABLE APPROACH

Thomas Decker[1], Joke Tio[2], Daniela Hungermann[1], Christian Kersting[1], Stefanie Weigel[3], Werner Bocker[1]
[1] University of Muenster, Dpt. of Pathology, Germany
[2] University of Muenster, Dpt. of Gyecology and Obstetrics, Germany
[3] University of Muenster, Dpt. of Clinical Radiology, Germany

Background: Independently of existing guidelines the role of frozen section (FS) as obligate constituent of intraoperative pathological examination in axillary sentinel biopsy (SLNB) is still under debate. However, frozen sectioning can lead to significant tissue loss with the risk of missing metastases at all, or failing to determine their largest diameter. To avoid this, our multidisciplinary protocol includes exclusively selective FS. That means that FS examination is done only when standardized pathological gross exploration provides findings suspicious for metastasis. Aim of this study was to estimate reliability of selected FS in SLNB for breast cancer. Methods: In 145 consecutive patients with unifocal invasive breast cancers of two to 24 mm in diameter (median 14 mm) SLNB procedure detected 272 lymph nodes (LN). Pathology protocol: Slicing of LNs parallel to the length axis in 2 mm slices; macroscopic inspection and palpation of any slice; FS in case of suspicious finding only; embedding of all slices; step sectioning (500 µm levels) throughout the LN; in all H&E-negative cases cytokeratin immunohistochemistry from each level. Interpretation of microscopic findings was accomplished according to recommendations of the European Working Group on Breast Screening Pathology; the findings were documented according to the UICC-TNM-classification. We determined the rates of positive LNs with macrometastases (MaMet), micrometastases (MiMet), as the rate of LNs with isolated tumor cells (ITC), the false-classification-rate (FCR), and the rate of secondary axillary dissection in a separate operation (SAD). We analysed sensitivity and specificity of the standardised macroscopical examination of SLNB referred to final complete work-up results, separately per LN and per patient. Results: 29/145 patients showed one ore more positive LN (20 MaMet, 7 MiMet, 2 ITC). The FNR was 0.13% per LN and 0.17% per patient. The rate of SADs accounted to 6/145 (4.1 %). Sensitivity and specificity measured solely for standardised macroscopical examination was by 87% and 98%, respectively per LN, and by 82% and 98%, respectively per patient. (Two macroscopically suspicious LN proved to be negative by FS which enhanced the specificity of the SLNB procedure up to 100%.) The negative predictive value of the SLNB procedure including selective FS examination was 96%, the FCR was 0.04%. Conclusion: A selective FS only in case of suspicious finding after macroscopical examination of LNs by the pathologist is a reliable approach to intraoperative decision making for axillary dissection.

OP13-9
PROGNOSTIC SIGNIFICANCE OF SKI PROTEIN IN BREAST CANCER PATIENTS

Dimitra Koumoundourou[1], Theodoros Kassimatis[1], Maria Repanti[2], Panagiota Ravazoula[3], John Varakis[1]
[1] Department of Anatomy-Histology-Embryology, Medical School, University of Patras, Greece
[2] Department of Pathology, "Agios Andreas" General Hospital, Patras, Greece
[3] Department of Pathology, Rio University Hospital, Patras, Greece

Introduction: Ski protein has recently been identified as a co-repressor of TGF beta signaling pathway through interaction with Smad family proteins. The activation of the signaling cascade begins by activation of TGF-beta receptor II (TbRII) after the ligand's binding. The purpose of the present study was to investigate the potential role of TbRII and Ski proteins in breast carcinogenesis and their correlation with several clinicopathological parameters. Materials and methods: TbRII and Ski expression was studied by immunohistochemical methods in 154 cases of breast lesions (8 cases of atypical hyperplasias, 22 cases of in situ carcinomas and 124 cases of invasive breast carcinomas). There was a median follow up time of 70 months (4-150) during which 47 developed blood borne metastases and 31 finally died of metastatic cancer. The statistical analysis of the results was performed using SPSS 13 for Windows. The statistical significance was set at 0.05. Results: Ski immunostaining exhibited a granular and mainly cytoplasmic pattern, though both nuclear and cytoplasmic immunostaining was observed in a few cases. TbRII showed a solely cytoplasmic expression. Ski protein was detected in 3 cases (37,5%) of atypical hyperplasias, 10 cases (45%) of in situ and 86 cases (69,4%) of invasive carcinomas. TbRII was positive in 2 cases (25%) of hyperplasias, 6 cases (27%) of in situ and 30 cases (24,1%) of invasive carcinomas. Kaplan Meier survival analysis showed that Ski protein's expression indicated a worse outcome (Spearman's Rho=0,290, p=0.001). Ski protein's expression was associated with TbRII expression ($p<0.001$), while a similar association existed between Ski proteins' expression and the presence of invasive carcinomas (p=0.006). No association was found between TbRII expression and patients' survival or the presence of invasive component. Conclusions: Ski protein may play a pivotal role in several steps of breast tumorigenesis and is probably correlated with a more aggressive phenotype.

OP13-10
HER2 DIAGNOSIS PROGRAMME IN ARGENTINA: MAIN RESULTS

Isabel Frahm[1], Gabriela Acosta[2], Sandra Saranconne[3], Grupo Cooperativo Her[4], Valeria Cáceres[5]
[1] Sanatorio Mater Dei, Argentina
[2] Hospital Maria Curie, Argentina
[3] Laboratorio Quantum, Argentina
[4] Nacional, Argentina
[5] Productos Roche, Argentina

Background: Early HER2 status determination becomes essential for primary and metastatic disease management. Identifying HER2 positive patients enables offering specific therapy leading

to a significant change in treatment and prognosis. Technique standardization is a key to success in identifying HER 2 over-expression in an accurate, precise and truthful way. Objectives: Implement a program enabling access to replicable and standardized HER2 diagnosis country-wide. Develop a team of pathologists trained in IHC to meet demands, for fast and truthful detection of HER2 over-expression. Material and methods: In August 2003, 13 pathologists formed a cooperative group and created a national framework to train and set HER2 diagnostic centres in each country region. A coordinator responsible for coaching and evaluating centres and two technical consultants in charge of quality control and technique standardization were designated. In February 2004, the program was launched. Tumors were received from 82 oncologists and breast surgeons, using a private courier created "ad hoc". HER2 over-expression was analyzed by Inmuno-Histo-Chemical (IHC) test between February 2004 and March 2006. HER-2 analysis was performed using policlonal antibody anti Her 2 (DAKO), microwave antigenic recovery, detection system EnVision (Dako) and developed with diaminobenzidine. Results were interpreted as hercepTest® guideline's. Results: 7011 HER 2 tests were completed; HER 2+ prevalence in our sample is 16.4%. Internal quality control, executed by the Advisory Board,as well as independent and external quality control, carried out by the American College of Pathologists have assured accurate results Conclusions: HER2 National Program enabled country-wide HER2 testing. A clear and defined strategy within the regulated and controlled framework, with a standardized and replicable technique, renders excellent results. HER2+ prevalence in our sample (16.4%) is in line with previously published ones. We presented guides of performance, interpretation, and technical issues for HER2 testing based on our experience endorsed by Argentinean Society of Pathology

OP13-11
HER2 IN INVASIVE BREAST CARCINOMA: ASSOCIATION WITH PROGNOSTIC AND PREDICTIVE FACTORS

Snježana Frković Grazio, Primož Drev, Matej Bračko
Institute of Oncology Ljubljana, Slovenia

Background: Since its discovery HER2 has been linked with poor prognosis in node positive and negative primary invasive breast carcinoma (IBC). Association between HER2 status and various prognostic and predictive factors has been analyzed in numerous studies; however, multivariate analysis has only rarely been used and HER2 status was rarely assessed by both IHC and FISH. Methods: HER2 status was assessed by IHC (HercepTest™) and FISH (PathVysion™) in 1519 consecutive primary IBC. Strong protein expression (3+) and/or gene amplification indicated positive HER2 status (HER2+). Correlations between HER2 status and patient age, tumor size, histologic type and grade, lymph node involvement, number of involved lymph nodes, lymphovascular invasion, estrogen (ER) and progesterone receptor (PR) were analyzed univariately by Chi-square test or Spearman's correlation and multivariately by logistic regression. Results: 14.5% of tumors were HER2+. In univariate analysis, HER2 positivity was strongly associated with younger age ($p<0.001$), higher histologic grade ($p<0.001$) as well as each of its components (gland formation, nuclear pleomorphism, mitotic count; all $p<0.001$), ductal type ($p<0.001$), presence of vascular invasion ($p<0.0001$), lymph node involvement ($p=0.003$) and number of involved lymph nodes ($p=0.004$). There was no significant association with tumor size. HER2 positivity was inversely associated with ER ($p<0.0001$) and PR ($p<0.0001$) expression. In multivariate analysis, ER status, histologic grade and lymphovascular invasion were the only independent predictors of HER2 status. Among ER+ tumors, HER2 positivity was independently associated with increasing grade and decreasing age, whereas among ER- tumors the only feature significantly related to HER2 positivity was lymphovascular invasion. Conclusions: The results of the present study are in line with findings from previous studies, which have shown that HER2 positive tumors usually exhibit other adverse features, such as ER/PR negativity and higher histologic grade. In addition, our study also reveals a strong and independent association between HER2 positivity and presence of lymphovascular invasion, which, to our knowledge has not been reported before.

OP14-1
MYXOID SOFT TISSUE TUMOURS HAVE A HETEROGENEOUS COMPOSITION OF THEIR EXTRACELLULAR MATRIX: A STUDY ON MYXOFIBROSARCOMA, INTRAMUSCULAR MYXOMA AND EXTRASKELETAL MYXOID CHONDROSARCOMA

Stefan Willems[1], Yvonne Schrage[1], Hans Baelde[1], Alex Mohseny[1], Raf Sciot[2], Judith Bovée[1], Pancras Hogendoorn[1]
[1] Department of Pathology, Leiden University Medical Center, Leiden, The Netherlands
[2] Department of Morphology and Molecular Pathology, University Hospitals, Catholic University of Leuven, Leuven, Belgium

Intramuscular myxoma, myxofibrosarcoma and extraskeletal myxoid chondrosarcoma are soft tissue tumors characterized by their abundant, so-called myxoid extracellular matrix. We studied the biochemical composition of this extracellular matrix to unravel its constitution and functional consequences for tumor growth, which are still poorly understood. Using Alcian blue staining we showed that intramuscular myxoma and grade I myxofibrosarcoma contained heparan sulphate, hyaluronan, keratan sulphate, chondroitin-4 and –6 sulphate in comparable amounts; Myxofibrosarcoma showed a significant increase in heparan sulphate with increasing histological grade; In contrast, chondroitin-4 and -6 sulphates were the major glycosaminoglycans of the extracellular matrix of extraskeletal myxoid chondrosarcoma. Using Western Blot, we identified albumin as a major protein in tumor lysates of all three tumors. We showed its presence in the extracellular matrix of all tumors and in the cytoplasm of the majority of the tumor cells by immunohistochemistry. We confirmed that the tumor cells produced albumin using qPCR. However, we demonstrated the expression of albumin in the extracellular matrix and cytoplasm of many other tumors using a tissue microarray containing 28 unrelated mesenchymal tumors. This was therefore not specific for any tumor type. In conclusion, we showed that the composition of the extracellular matrix of myxoid soft tissue tumors is heterogeneous and dependent on the type and histological grade of the tumor. Based on these results we propose an active, interacting role of glycosaminoglycans and albumin in the morphogenesis of these tumors.

OP14-2
GENE EXPRESSION IN PERIPROSTHETIC MEMBRANES FROM ENDOPROSTHESIS LOOSENING - CHITINASE ACTIVITY FOR EARLY DIAGNOSIS?

Lars Morawietz[1], Andreas Weimann[2], Joerg Schroeder[3], Ralf-Juergen Kuban[4], Ute Ungethuem[4], Veit Krein[5]
[1] Institute for Pathology, Charite University Medicine Berlin, Germany
[2] Institute for Laboratory Medicine, Charite University Medicine Berlin, Germany
[3] Hospital for Orthopaedic Surgery, Charite University Medicine Berlin, Germany
[4] Laboratory for Functional Genomic Research, Charite University Medicine Berlin, Germany
[5] Institute for Pathology Trier, Germany

Aim: The identification of markers for the early diagnosis of hip and knee endoprosthesis loosening, for the differentiation between wear-particle induced and septic loosening and of new

insights into the pathogenesis of endoprosthesis loosening. Methods: Gene expression profiles were generated from 5 periprosthetic membranes of wear-particle induced and 5 of infectious (septic) type using Affymetrix HG U133A oligonucleotide microarrays. The results of selected differentially expressed genes were validated by RT-PCR (n=30 periprosthetic membranes). The enzyme activity and the genotype of chitinase-1 were assessed in serum samples from 313 consecutive patients hospitalized for endoprosthesis loosening (n=54) or for other reasons, serving as control subjects (n=259). Results: 824 genes were differentially expressed with a fold change greater than 2 (data sets on http://www.ncbi.nlm.nih.gov/geo/ GSE 7103). Among these were chitinase 1, CD52, calpain 3, apolipoprotein, CD18, lysyl oxidase, cathepsin D, E-cadherin, VE-cadherin, nidogen, angiopoietin 1 and thrombospondin 2. Their differential expression levels were validated by RT-PCR. The chitinase activity was significantly higher in the blood from patients with wear-particle induced prosthesis loosening (p=0.001). However, using chitinase activity as a marker for early diagnosis, it has a specificity of 83% and a sensitivity of 52%, due to a high variability both in the disease and in the control group. Discussion: This study shows that gene expression analyses from histopathologically defined tissue samples deliver valid and interesting results when applied to non-tumor tissue like periprosthetic membranes, but that only a portion of the differentially expressed genes is worth further clinical examination and that only a minor portion will be beneficial for the clinical routine work.

OP14-3
BIOLOGICAL AND PROGNOSTIC ROLE OF CCN3 PROTEIN IN EWING'S SARCOMA TUMORS

Antonio Llombart-Bosch[1], Noureddine Lazar[2], Samuel Navarro[1], Patricia Bacchini[3], Franco Bertoni[3], Jose Antonio Lopez-Guerrero[4], Isidro Machado[1], Nikita Savelov[5], Katia Scotlandi[6], Bernard Perbal[1]

[2] Laboratoire d?Oncologie Virale et Moléculaire, Université Paris 7 D. Diderot, France
[3] Department of Pathology, Istituti Ortopedici Rizzoli, Bologna, Italy
[4] Unit of Molecular Biology, Fundación Instituto Valenciano de Oncología, Spain
[5] Department of Pathology, Blockin Cancer Center, Moscow, Russia
[6] Laboratorio di Recerca Oncologica, Instituti Ortopedici Rizzoli, Bologna, Italy

Background: CCN3 belongs to the family of CCN proteins which participate in fundamental biological functions. Deregulation of their expression has been associated with tumorigenesis. Structurally, CCN proteins share a common multimodular organisation with 4 structural modules resembling Insulin-like growth factor binding proteins, Von Willebrand factor, thrombospondin 1, and a series of matricellular proteins and growth factors that contain a cystin-knot motif, (IGFBP, VWC, TSP1 and CT). Expression of the full-length CCN3 protein is associated with differentiation in rhabdomyosarcomas, neuroblastomas, Wilms? tumors and chondrosarcomas, as well as with the inhibition of the growth of cell lines derived from Ewing's sarcoma (ES). The aim of this study was to evaluate the biological and the prognostic significance of CCN3 isoforms using a panel of antibodies that recognize different modules of the protein. Method: Paraffin-embedded material from 226 ES subtyped: 66% classic, 10% large cell, 10% PNET, 3% clear cell, 3% atypical, 6% spindle cell and 1% hemangioendothelial. Seven tissue arrays (TA) of these cases were performed and immunohistochemical expression of CCN3 was evaluated with five different antibodies recognizing different parts of the protein: anti-NH2 (IGFBP), anti-NH3 (VWC), anti-NH4 (TSP1), anti-NH5 and K19m (CT). Results: Follow-up was available from 132 patients with a median of 49 months (range: 1-306 months). CCN3 expression was variable in all cases depending on the antibodies tested. We observed that 36% of cases expressed a full-length CCN3 protein (immunoreactive for the 5 antibodies analyzed) and no differences between histological ES subtypes were found. Interestingly, expression of full-length CCN3 was correlated with the progression of ES, its expression being higher in recurrence and in metastasis than in primary tumors (70-60% vs. 40%, p=0.033). Univariate analysis for progression-free (PFS) survival and overall (OS) showed a trend towards prognostic significance of the expression of different CCN3 isoforms, especially those isoforms detected with the NH3 (p=0.111 for PFS and p=0.118 for OS) and NH4 (p=0.039 for OS) antibodies. Conclusion: Full-length CCN3 protein is expressed in a third of ES cases being more frequent in recurrences and metastasis than in primary tumors. The isoforms detected with NH3 and NH4 have a prognostic value, the biological significance of which needs to be better understood. * Supported with grants FIS P1040822, Spain and PROTHETS Contract number: 503036 FP6 from the EC.

OP14-4
EXPRESSION OF ALPHA-B-CRYSTALLIN IN NEOPLASMS DERIVED FROM MESENCHYMAL PERIVASCULAR EPITHELIOID CELLS (PECOMAS)

Angel Panizo, Jesus Javier Sola, Gregorio Aisa, Maria Dolores Lozano, Miguel Angel Idoate, Javier Pardo
Clinica Universitaria de Navarra. Universidad de Navara, Spain

Background: Alpha-B-crystallin (ABCryst) is a major protein component of the eye lens with chaperone-like functions and is a member of the small heat-shock protein HSP20. ABCryst expression has been demonstrated to varying extent in epithelial neoplasms, but not in mesenchymal tumors. Abnormal expression of ABCryst in hamartomas of tuberous sclerosis has been reported. The family of tumors derived from mesenchymal perivascular epithelioid cells (PEComas) includes angiomyolipoma (AML), lymphangioleiomiomatosis (LAM), "sugar" tumor of the lung, and abdominopelvic tumor/sarcoma of perivascular epithelioid cells. The aim of the study is to examine ABCryst expression in PEComas and to assess the value of this protein as a new tumor marker. Methods: All tumors derived from mesenchymal perivascular epithelioid cells were retrieved from our files (n=43). We performed immunohistochemistry using the monoclonal antibody for ABCryst (clone G2JF, Novocastra) in formalin-fixed, paraffin-embedded tumors. Tissue microarray containing a wide variety of neoplasms and normal tissues was also stained with ABCryst antibody. ABCryst cytoplasmic immunoreactivity was scored based on intensity (0-3+) and distribution (% of positively tumor cells). Cases showing 2+ or 3+ in >75 % of tumor cells were considered as positive. Results: There were 32 renal AML, 1 hepatic AML, 1 lung LAM, 2 lymph node LAM, 1 sugar tumor of the lung, and 6 PEComas. Twelve patients were male (27.9%) and 31 female (72.1%), with an average age of 55.6 yr (range 30-83 yr). All cases studied showed granular immunostaining in the tumor cell cytoplasm with the anti-ABCryst Ab. Cytoplasmic reactivity was noted in the spindle cells, adipocytes, and perivascular epithelioid cells. All cases showed strong (3+) or moderate (2+) cytoplasmic labelling, in a diffuse pattern (75-100% cells). Endothelial cells of the blood vessels were negative in all cases. No correlation was found between ABCryst score and age, sex, tumor size, nuclear atypia, necrosis, and mitotic rate. In all cases, appropriate positive internal control (Schwann cells) was assessed. Other tumors that demonstrated diffuse (> 75 %) and intense immunoreactivity included alveolar soft part sarcomas, astrocytomas, schwannomas, and TFE3 renal cell carcinomas. Conclusions: We have demonstrated ABCryst positivity in all tumors derived from mesenchymal perivascular epithelioid cells. ABCryst may be a useful ancillary marker for the diagnosis of these neoplasms when used in a panel with other melanocytic markers and SMA.

OP14-5

PATTERN OF EXPRESSION OF CELL CYCLE/APOPTOSIS REGULATORS REFLECT LOCATION, MUTATION AND PROGRESSION FREE SURVIVAL (PFS) OF GASTROINTESTINAL STROMAL TUMOUR (GIST) TREATED WITH IMATINIB FROM RANDOMIZED PHASE III TRIAL 62005 EORTC/STBSG

Salvatore Romeo[1], Heidi Van Paassen[1], Martine Van Glabbeke[2], Paola Comite[1], Jan Oosting[1], Ole S Nielsen[3], Jaap Verweij[4], Raf Sciot[5], Maria Debiec-Rychter[6], Pancras CW Hogendoorn[1]
[1] Department of Pathology, Leiden University Medical Center, Leiden, The Netherlands
[2] EORTC Data Center, Brussels, Belgium
[3] Department of Oncology, Aarhus University Hospital, Aarhus, Denmark
[4] Department of Medical Oncology, Erasmus University Medical Center, Rotterdam, The Netherlands
[5] Department of Pathology, University of Leuven and University Hospital Gasthuisberg, Leuven, Belgium
[6] Department of Human Genetics, University of Leuven and University Hospital Gasthuisberg, Leuven, Belgium

Background: A randomized phase III trial reported PFS in advanced GIST treated with imatinib to be dependent amongst others on drug-dose and mutational status. Impaired expression of key-regulators of cell cycle/apoptosis such as p53, p16, p21, chek2, ccnd1, bcl2, cdk4 and mdm2 is crucial for tumour progression, might reflect secondary genetic/epigenetic events and impair the response to therapy. We studied how pattern of expression of these molecules might correlate with: 1. clinico-pathological parameters at the start of therapy, 2. mutation status and 3. ultimately PFS upon treatment with imatinib. Method: A tissue array made up of 4 cores of tumour tissue per each of 353 GIST patients enrolled in the phase III trial was built. All were histologically validated. Immunohistochemistry was performed to assess expression of the above-mentioned molecules. Results were correlated with clinico-pathological data and mutation status. Expression patterns were analysed with hierarchical clustering. Results: The site of origin was: stomach,118 patients, other parts of the gastro-intestinal tract, 175 patients (94 small bowel, 27duodenum). High expression was found for bcl2, p53, cdk4, mdm2, and ccnd1 in 78%, 47%, 31%, 13% and 8% of the cases, respectively; while low expression of p21, chek2, and p16 was found in 73%, 50% and 43% of the cases, respectively. High bcl2 expression was found in GIST originating from small bowel and duodenum and low expression in gastric ones. GISTs of gastric origin are also associated with low expression of p21, p16 and ccnd1. 268 (76%) GISTs disclosed mutations in KIT: 198 (56%) harboured exon 11, 58 (16.4%) exon 9, six (1.7%) exon 13 and three exon 17. Eight (2.3%) tumors carried PDGFRA mutations, while 36 (10.2%) cases were wild type.High bcl2 expression was associtated witjh KIT-exon 9 mutation. Low bcl2 and high cdk4 expression was more frequent in KIT-exon 11 ones. High level of p53 and low level of p16 expression were associated with shorter PFS in a multivariate model including already identified prognostic factors ($p<0.05$). Hierarchical clustering showed 4 different clusters characterized by different PFS ($p<0.05$). Conclusions: Advanced GISTs show a heterogenous pattern of expression of the studied molecules which reflects the accumulation of distinctive secondary events in tumour progression. A distinct pattern of expression correlates with location and tumor genotype. Maintenance of cell cycles/apoptosis regulation in GISTs is relevant for the optimal response to imatinib.

OP14-6

THE IMPACT OF HISTOLOGICAL GRADING IN PREDICTING OUTCOME OF HIV-ASSOCIATED KAPOSI'S SARCOMA

Gieri Cathomas[1], Emmanuel Boffi El Amari[2], Laurence Toutous-Trellu[2], Michele Baumann[1], Peter Erb[3], Ingrid Steffen[4], Nicolas Muller[3], Bernard Hirschel[2]
[1] Laboratory for Pathology of Infectious Diseases, Cantonal Institute for Pathology, Liestal, Switzerland
[2] Division of Infectious Diseases, Geneva University Hospital, Geneva, Switzerland
[3] Institute for Medical Microbiology, University of Basel, Basel, Switzerland
[4] Division of Infectious Diseases, Zurich University Hospital, Zurich, Switzerland

Background: Although the incidence of Kaposi's sarcoma has decreased in the era of HAART, clinical outcome varies and a considerable subgroup of patients experiences a bad outcome. Little is known, however, about the impact of histological grading of Kaposi's sarcoma in predicting outcome. Aim of the present study was to analyze histological grading parameters in respect to clinical outcome. Method: Index biopsies of 89 patients with Kaposi's sarcoma prospectively included in the Swiss HIV Cohort Study from January 1996 to December 2004 were analyzed using the grading parameters defined by the French Federation of Cancer Centers Sarcoma Group (FNCLCC) grading system, including tumor differentiation, mitosis count per 10 high power fields and tumor necrosis. Based on the summing score, tumors were graded in G1 (2 or 3), G2 (4 or 5) and G3 (6, 7 or 8). Survival and outcome (use of chemotherapy and/or death) were correlated with the histological data. Results: Based on the summing score, G1, G2 and G3 tumors were observed in 73.0%, 22.5% and 4.5%, respectively. Of the total 34 (38.2%) of 89 patients with clinically bad outcome, 13 (38.2%) had Grade 2 and 3 tumor compared to 11 (20.0%) of 55 patients with favourable outcome ($p=0.085$) and Grade 2 and 3 tumors were significantly associated with a bad clinical outcome ($p<0.02$). Analyzing individual histological parameters revealed that the presence of necrosis and the cytomorphology of tumor cells were not significantly associated with outcome. In contrast, mitosis count of ≥ 3 was seen in 16 (47.1%) of patients with bad and in 13 (23.6%) of 55 patients with good outcome ($p<0.05$) and increased mitotic activity was significantly associated with a clinical inverse outcome (Hazard ratio 2.65) (95 % CI 1.35-5.23). Conclusion: The FNCLCC scoring system for soft tissue tumors can be applied to Kaposi's sarcoma. However, due to the low incidence of tumor necrosis and the often minor cytomorphological differences of the tumor cells, only the mitotic activity shows a significant correlation with prognosis. Mitosis count of ≥ 3 is strongly associated with bad clinical outcome and should therefore be included in the histopathological report of Kaposi's sarcoma.

OP14-7

PRIMARY MALIGNANT VASCULAR TUMOURS OF BONE: IMMUNOHISTOCHEMICAL INVESTIGATION ON ENDOTHELIAL PHENOTYPE AND HISTOPATHOLOGICAL CORRELATION.

Sofie L. J. Verbeke[1], Franco Bertoni[2], Patrizia Bacchini[2], Herman M. H. Kroon[3], Pancras C. W. Hogendoorn[1], Judith V. M. G. Bovée[1]
[1] Department of Pathology, Leiden University Medical Center, Leiden, Netherlands
[2] Department of Pathology, Rizzoli Institute, Bologna, Italy
[3] Department of Radiology, Leiden University Medical Center, Leiden, Netherlands

Background : Primary malignant vascular tumours of bone (PMVTB) are rare and represent less than 1% of the primary malignant bone tumours. Because of their rareness little is known. Clinically they are extremely aggressive. Due to the lack

of uniform terminology and accepted histological criteria, terminology and classification of PMVTB has been highly controversial. Today, angiosarcoma is the most accepted term for high-grade PMVTB, as recognized by the 2002 WHO Classification. However, the classification of intermediate and low-grade vascular tumours is still controversial and not well-defined. Method: We collected 66 cases of paraffin embedded PMVTB diagnosed between 1967 and 2006. All clinical, radiological, and pathological data were reviewed and different histological criteria were assessed. A tissue micro-array was constructed containing the 66 cases with the addition of 6 malignant vascular tumours of soft tissue, 3 benign vascular lesions of bone and, 2 haemangiopericytomas of bone as controls. To confirm the vascular origin of all lesions, and to investigate the diagnostic value of commonly used markers, immunochemistry was performed for CD31, CD34, Factor VIII, and keratin AE1/AE3. Staining was evaluated as positive or negative. Result: The PMVTB show positive staining for CD31 in 62/66 (94%), CD34 in 36/66 (55%), Factor VIII in 53/66 (80%), and keratin in 47/66 (71%). Of the 47 keratin positive angiosarcomas, only 18 tumours (27%) showed an epithelioid phenotype at classical morphology. All tumours with an epithelioid phenotype are keratin positive. Conclusion: CD31 and Factor VIII are the best diagnostic markers in PMVTB, which is comparable to its soft tissue counterpart. A combination of these markers should therefore be used to diagnose these lesions. While CD34 is valuable in vascular lesions of soft tissue, in PMVTB its diagnostic value seems limited. It is striking that keratin positivity is seen in the majority of PMVTB and is independent of epithelioid morphology. Because, in addition, PMVTB is often multifocal, one should be aware not to misinterpret this clinically, radiological, and histological as metastatic carcinoma.

OP14-8

CLINICOMORPHOLOGICAL AND IMMUNOHISTOCHEMICAL FEATURES OF MALIGNANT VASCULAR TUMORS: GLUT1 AND FKBP12 EXPRESSION IN MALIGNANT VASCULAR TUMORS

Kemal Kosemehmetoglu, Gokhan Gedikoglu
Hacettepe University Faculty of Medicine, Department of Pathology, Ankara, Turkey

Introduction: Recently, many new immunohistochemical markers, for instance FKBP12 and GLUT1, have been introduced to exhibit vascular differentiation in assistance to CD34 and CD31. In this study, besides a detailed clinicopathologic assessment, we evaluated expression profile of FKBP12 and GLUT1 among low and high grade malignant vascular tumors. Methods: We collected 13 angiosarcoma and 16 hemangioendothelioma cases from the archives of Hacettepe University, Department of Pathology. Slides were reviewed by two pathologists. Clinicomorphological analysis and immunohistochemical panel including CD34, CD31, GLUT1, FKBP12, MDM2, p53, CD99 and c-kit were performed. Expression pattern of each antibody is assessed regarding location, intensity and extent. Results: Age at diagnosis ranged between 6-77 years (median, 49 yrs). Mass and pain were the two common presenting symptoms. The preoperative duration ranged from 1 month to 2 years. Extremities were the most common primary site, following spine and head&neck. Tumor size, varied 1 cm up to 20 cm in diameter (median, 6 cm), was >3 cm in 20 cases, 12 of which were high grade. Liver and lungs were the commonest metastatic sites. Follow up information were available for 19 of 29 patients with a duration ranging from 1 month to 120 years (median, 36 mos). Five patients, 4 of which had low grade tumor, were alive for at least 5 years whereas 9 cases, 6 of which with high grade tumor, were dead of disease. Lymphedema, vascular stent, radiation and chemical exposure (dye) are investigated as etiologic factors in five patients. Twenty-five cases were available for immunohistochemical study. Immune expression pattern did not varied significantly between low and high grade tumors. Ninety-two percent and %80 of cases expressed CD34 and CD31, respectively. Only 35% of cases expressed GLUT-1 and expression was stronger in epithelioid cells, while hobnail cells were GLUT-1 negative. All cases expressed FKBP12 strongly except one low grade hemangioendothelioma, in which expression was weak. In 34.6% of cases, either MDM2 or p53 was positive, suggesting that p53/MDM2 pathway may be included in pathogenesis. CD99 and c-kit were both negative in all cases. None of studied markers has correlated with survival. Conclusions: FKBP12 may take a role in the diagnostic panel of malignant vascular tumors. GLUT1, although expressed only in one third of cases, reveals the epithelioid character of tumor, which is likely to suggest worse prognosis. p53/MDM2 pathway, at least in some cases, may take place in the pathogenesis.

OP14-9

EGFR SIGNALING IN GIANT CELL TUMOR OF BONE (GCTB): AN IMMUNOMORPHOLOGICAL TISSUE MICROARRAY (TMA) STUDY USING DIGITAL SLIDES AND DATABASE MANAGEMENT

Linda Moskovszky[1], Miklos Szendroi[2], Zoltan Sapi[3], Laszlo Kopper[1], Vivien Angeli[4], Bela Molnar[5], Tibor Krenacs[6]
[1] 1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary

[4] 3DHISTECH Ltd. , Budapest, Hungary
[5] 2nd Department of Internal Medicine, Semmelweis University, Budapest, Hungary
[6] 1st Department of Pathology and Experimental Cancer Research, Budapest, Hungary

Background. Giant cell tumor of bone (GCTB) is a relatively rare tumor, which is considered “an aggressive, potentially malignant lesion” by the WHO classification. Local recurrence may occur in 20-50% of cases, with 10% undergoing malignant transformation and 1-4% giving metastasis mainly to the lung. GCTB is characterized by osteoclast accumulation causing lytic bone lesions, surrounded by reactive monocytic-histiocytic cells and potentially malignant fibro-osteoclat-like stromal cells. The pathogenesis and the factors behing GCTB progression are still largely unknown. Method. In this work, EGFR receptor expression of 138 primary GCTB cases, 56 recurrent tumors, and 6 GCTB transformed into osteosarcoma were studied. 210 pieces of 2 mm tissue cores were collected into tissue microarrays (TMA) using Mirax TMA engeneer (3DHISTECH, Budapest, Hungary). For EGFR immunostaining, sections were treated with Ventana Confirm (Tucson, AZ, USA; clone: 3C6) mouse monoclonal antibody and Novolink detection kit (Vision-Biosystems, Newcastle Upon Tyne, UK) following heat induced epitope retrieval using Tris-EDTA. Immunostained slides were digitalized using Mirax Scan (Zeiss, Gottingen, Germany) analysed and linked to database using the Mirax TMA software. Results. 47% of studied GCTB cases were either moderately (2+), or strongly (3+) positive for EGFR, further 25% were weekly positive and only 28% were fully negative. Immunopositive cells were usually adjacent to osteoclasts, and most were elongated consistent with the potentially malignant stromal cells. Recurrence and tranformation into osteosarcoma were significantly more frequent in strongly EGFR positive cases. Conclusion. About half of the studied GCTB cases are possibly under the influence of EGFR signalling, which may facilitate tumor growth and recurrence, and/or osteosarcoma transformation. Further studies of mutation hot-spots in EGFR gene, and phosphorylated downstream signalling elements are under way to dissect the possible role of EGFR in GCTB. (Supported by EuroBoNet)

OP14-10
CANONICAL AND NON-CANONICAL PATHWAYS OF OSTEOCLAST FORMATION IN GIANT CELL TUMOUR OF BONE
Richard Taylor, Francesca Jones, Helen Knowles,
Nick Athanasou
University of Oxford, United Kingdom

Background: Giant Cell Tumour of bone (GCTB) is tumour that contains numerous scattered osteoclast-like giant cells and a mononuclear cell component of fibroblast/osteoblast-like spindle-shaped cells and macrophages. The cellular mechanisms underlying the accumulation of osteoclast-like giant cells in these tumours is not clear. The canonical pathway of osteoclast formation involves differentiation of mononuclear (macrophage-like) precursors into osteoclasts in the presence of receptor activator of nuclear factor kappa B ligand (RANKL) and macrophage-colony stimulating factor (M-CSF). Abundant RANKL and M-CSF-producing cells have been noted in GCTB. Other growth factors are known to be present in abundance in GCTB, notably vascular endothelial growth factor (VEGF), and hepatocyte growth factor (HGF). In this study we determined whether these growth factors might play a role in osteoclast formation in GCTB. Method: The (CD14-positive) monocyte/macrophage-like fraction of peripheral blood mononuclear cells (PBMCs) was isolated and cultured in the presence of RANKL +/- M-CSF, VEGF or HGF. Osteoclast formation was assessed by noting the formation of multinucleated cells which expressed osteoclast-specific markers including tartrate-resistant acid phosphatase (TRAP), vitonectin receptor (VNR), F-actin rings and formation of resorption lacunae on dentine slices. Results: It was found that numerous TRAP+/VNR+/F-actin ring- forming multinucleated cells capable of lacunar resorption formed in PBMC cultures where HGF and VEGF was substituted for M-CSF. The presence of these growth factors and their receptors was noted immunohistochemically in GCTB. Conclusion: Our findings indicate that VEGF and HGF may play a role in the extensive osteoclast formation that occurs in GCTB and that these factors may provide a therapeutic target to inhibit the extensive osteoclast formation and osteolysis that is associated with these tumours .

OP15-1
DEFICIENCY OF COMPLEMENT FACTOR D RESULTS IN MESANGIAL IMMUNE COMPLEX GLOMERULONEPHRITIS
Maria Abrera-Abeleda[1], Yuan Yuan Xu[2], Matthew Pickering[3], Richard Smith[1], Sanjeev Sethi[4]

[4] Mayo Clinic, Rochester, MN, USA

Factor D, a serine protease essential for the activation of the complement alternative pathway, is expressed in adipocytes, macrophages and the kidney. Mice mutants with a targeted deletion of the Factor D gene were used to characterize the role of Factor D in complement and immune complex mediated glomerulonephritis. We show that mice with targeted deletion of the factor D gene (Cfd-/-) spontaneously developed mesangial immune complex glomerulonephritis. In Cfd-/- mice, mesangial deposits that stained predominantly for C3 and IgM were detectable in 8-month-old animals. The mesangial deposits results in mesangial expansion and cellularity, the mesangial hypercellularity is due to increase in mesangial cells and not infiltrating leukocytes. The Cfd-/- mice also showed impaired renal function evidenced by the development of albuminuria and reduced creatinine clearance. In contrast to the mesangial location of the immune deposits in the Cfd-/- animals, age-matched mice lacking the alternative pathway inhibitory protein factor H (Cfh-/) developed immune deposits along the capillary wall. These observations suggest that factor D or alternative pathway activation is required to prevent the spontaneous accumulation of C3 and IgM within the mesangium. Cfd-/- mice represent a novel model of spontaneous mesangial immune complex glomerulonephritis.

OP15-2
COMPARISON BETWEEN WHO AND ISN/RPS CLASSIFICATION OF LUPUS NEPHRITIS, IS ANYONE BETTER THAN THE OTHER?. ANALYSIS OF DISCORDANT CASES.
Angel Fomperoza-Torres, David Olvera-Castillo,
Harold Ayala-Palma, Luis Eduardo Morales,
Ricardo Correa-Rotter, Norma Ofelia Uribe-Uribe
Instituto Nacional de Nutricion Salvador Zubiran,
Mexico City, Mexico

Introduction: Lupus nephritis (LN) is one of the most common and serious complication of systemic lupus erythematosus (SLE). Given the diversity of morphologic alterations grouped and named as LN, it has been challenging to create a morphologic classification with good clinical correlation. Several attempts have been done, the latest one by the ISN and RPS. Objectives: to compare the previous WHO histological diagnosis and classification of lupus nephritis kidney biopsies with that established with the new ISN/RPS classification, to identify discordant histological cases between the two classifications,and to establish if clinical outcome differences were present in those histologically discordant cases. Methodology: Cases with adequate histological material, and complete clinical and laboratory data were included. Eighty three renal biopsies were reviewed and reclassified according to the ISN/RPS. Renal survival, considered as patients free of renal replacement therapy, was compared in discordant cases only. Kaplan-Meier survival curves were used. Results: Eighteen discordant cases (21%) were detected, all women, mean age 33.7 years.When Renal survival curves are shown, class III cases of both, the WHO and the ISN/RPS classifications are compared, it is noted that in the former, the renal survival rapidly drops and patiens show a worse prognosis than with the ISN/RPS. If class IV cases in the WHO classification are compared, with the ISN/RPS, they have a longer survival than with the latter classification. The class IV cases in the ISN/RPS classification has a worse prognosis than that with the WHO classification. Conclusion: Approximately one fifth of the initial cases with LN had discordant results. Reclassified cases with the ISN/RPS have a better clinical correlation, according to renal survival, displaying a worse outcome for class IV cases and improved outcome in class III cases.

OP15-3
PROGNOSTIC UTILITY OF CYCLIN D3, CYCLIN E, P27, MUC1 IN RENAL CELL CARCINOMA (RCC)
Saba Kiremitci[1], Ozden Tulunay[1], Sumer Baltaci[2], Orhan Gogus[2]
[1] Medical School of Ankara University, Pathology Department, Turkey
[2] Medical School of Ankara University, Urology Department, Turkey

Background: Renal epithelial neoplasms are a heterogeneous group of tumors with different prognosis. RCC has an unpredictable behavior and tendency to recur and metastasize, and there can be major differences in clinical outcome even within the same tumor stage. Clear cell type (CRCC) is the most common histologic variant of RCC. The prognosis of the patients with CRCC is significantly worse than that of the patients with other histologic subtypes. Although there are clinicopathological parameters have proven their prognostic significance in primary RCCs, there is an utmost need of biological predictors for individual tumor behavior with respect to response to treatment,

survival rate and progression to metastasis. If the potential for early metastatic spread of RCC or tumor aggressiveness can be predicted reliably, additional novel treatment alternatives could be studied. Design: Immunohistochemistry was performed on tissue microarray sections of 83 cases of RCC; 62 CRCC, 6 chromophobe RCC, 13 papillary RCC, 2 unclassified RCC, using antibodies against CyclinD3, CyclinE, p27, MUC1. Clear and non-clear variants were differentiated by CK7 expression. Results: CK7 expression patern was significantly different between clear and non-clear variants. Prognostic factors identified in this study were high nuclear grade, regional lymph node (RLN) involvement, distant metastasis (DM), advanced clinical stage (cT), histological tumor necrosis, renal capsule invasion, severe inflammation, lymphovascular invasion (LVI) and multifocality (M). cT and LVI were independent prognostic factors in RCCs. M of the tumor and high MUC1 expression were correlated and both were associated with DM. CyclinE overexpression was correlated with LVI and DM and so with poor prognosis. A significant correlation was found between high CyclinD3 protein expression and DM which leads to poor survival. p27 expression was significantly correlated with tumor size and RLN involvement. Conclusions: Negativity of CK7 helps to differentiate CRCCs from non-clear RCCs. cT and LVI are strongly related to increased metastatic potential and biological aggresiveness, and reduced survival. p27 expression is correlated with tumor size and RLN involvement. The association of MUC1 overexpression with DM indicates a potential therapeutic target in RCC. CyclinE overexpression indicates the risk of DM with regard to LVI potential. For the first time it is shown that CyclinD3 protein is an independent prognostic factor in RCC; patients with high CyclinD3 expression have worse clinical outcome and short survival.

OP15-4

BOSENTAN AND LOSARTAN AMELIORATE ACUTE RENAL FAILURE ASSOCIATED WITH MILD BUT NOT STRONG NITRIC OXIDE BLOCKADE INDUCED BY L-NAME

Zoran Miloradović[1], Mirjana Jerkić[2], Ica Jovović[1], Nevena Mihailović-Stanojević[1], Jelica Grujić-Milanović[1], Gordana Stošić[3], Jasmina Marković-Lipkovski[4]

[2] Hospital for Sick Children, Cancer and Blood Program, Toronto, Canada
[3] Clinical Center of Serbia, Institute of Neurology, Belgrade, Serbia
[4] Medical School, Institute of Pathology, University of Belgrade, Serbia

Background. Acute renal failure (ARF) is a devastating illness, especially when it occurs in various conditions with impaired nitric oxide (NO) synthesis. We have directed our investigations to effects of both angiotensin II (AII) and endothelin (ET) receptor blockade associated with mild or strong NO deficiency on haemodynamic, biochemical and morphological parameters in experimental postischaemic ARF. Methods. In this study, we used bosentan (dual, ETA/ETB-receptor antagonist), losartan (nonpeptide, competitive antagonist of type I angiotensin II receptor), and NG-nitro-L-arginine methyl ester (L-NAME, inhibitor of NO synthesis). Experiments were performed in anesthetized, adult male Wistar rats. The right kidney was removed and the renal ischaemia was performed by clamping the left renal artery for 45 minutes. Experimental groups received receptor antagonists (bosentan or losartan) or vehicle (saline) in the femoral vein 20 minutes before, during, and 20 minutes after the period of ischemia. Investigation was designed in two separately performed setups, with high (10 mg/kg b.m.) and with low (3 mg/kg b.m.) dosage of L-NAME given as i.v. bolus before each antagonist infusion. Haemodynamic (mean arterial pressure, heart rate, cardiac output, total vascular resistance and renal vascular resistance) and biochemical (urinary and plasma creatinine, Na+, K+, protein concentrations and creatinine clearance) parameters were measured 24 hours after reperfusion and compared with histological findings. Results. Our results showed that strong NO blockade overcame effects of both ET and AII receptor blockade in experimental postischemic ARF. In addition, the AII receptor blockade had harmful effect in this condition, probably due to disturbed autoregulatory renal function. On the other hand, ET and AII receptor blockade in mild NO blockade associated with reperfusion injury, improves the most haemodynamic, biochemical and morphological parameters: tubular necrosis was less widespread and predominantly focal, proximal tubular dilatation was slightly prominent, and casts formation was very rarely present. The loss of brush border of proximal tubular epithelium was less evident. Conclusion. We concluded that experimental postishemic ARF is neither AII nor ET mediated in case of strong NO blockade, but, in more realistic conditions of mild NO deficiency, these peptides represent significant players whose receptor blockade expresses relevant therapeutic potential.

OP15-5

NONINVASIVE DIAGNOSIS OF POLYOMAVIRUS ALLOGRAFT NEPHROPATHY BY ELECTRON MICROSCOPY ON VOIDED URINE SAMPLES

S. Singh, V. Madden, R. Detwiler, K. Andreoni, V. Nickeleit
Department of Pathology, The University of North Carolina at Chapel Hill, USA

BACKGROUND: Polyomavirus Nephropathy (PVN) is a serious complication after renal transplantation. Noninvasive screening tools currently in use for identifying patients at increased risk for PVN include quantitation of decoy cells and quantitative urine and/or plasma PCR analyses for BK DNA load levels. These tests, however, lack specificity for accurately separating patients with PVN from asymptomatic viral activators. Negative staining electron microscopy (nsEM) is a well established but largely forgotten noninvasive tool that has been routinely used for decades to search for viruses in various body fluids. The aim of our retrospective analysis was to determine whether the detection of cast-like, three dimensional polyomavirus clusters (named “Haufen”) in voided urine samples by nsEM could serve as a noninvasive strategy to accurately diagnose PVN. DESIGN: 89 urines from 14 patients with biopsy proven PVN (2-15 samples/patient over 18 months followup; study group) and 48 urines from 25 control patients with signs of polyomavirus activation but no PVN (1-5 samples/patient over 14 months followup; control group) were analyzed (urine samples by nsEM and cytology for decoy cell sheding; plasma and urine samples by quantitative PCR for BK virus DNA). RESULTS: A) PVN Study Group: At time of initial biopsy diagnosis, 100% of patients showed shedding of Haufen in the urine by nsEM, decoy cells (median: 50, range = 10-150), and positive urine and plasma PCR readings for BK virus. During followup (median=9 months; range=3-18 months), 7 patients overcame disease over 3-30 weeks with clearance of Haufen and decoy cells along with negative or markedly decreased urine and plasma viral load levels; 1 patient had a repeat kidney biopsy negative for PVN. 4 patients had persistent PVN with continuous shedding of Haufen, urine decoy cells, and positive urine and plasma viral load levels. B) Control Group (no PVN): No urine samples (n=48) showed Haufen by nsEM. All urine samples showed decoy cells (median= 30; range =10-100). 19 serum samples from 5 control patients showed persistent positive PCR readings for BK virus. Renal biopsies were performed in these 5 patients and did not show histologic evidence of PVN. CONCLUSION: nsEM of voided urine samples to search for cast-like polyomavirus aggregates, i.e. “Haufen”, is a highly specific, noninvasive diagnostic tool for identifying PVN (positive and negative predictive values of “Haufen” for PVN: >95%). nsEM is a fast, easily performed, and cost effective method that can be used to optimize patient management.

OP15-7
INFECTION BY BK POLYOMA VIRUS IN RENAL TRANSPLANT PATIENTS: CONTRIBUTIONS OF MOLECULAR BIOLOGY, URINE CYTOLOGY AND ELECTRON MICROSCOPY

Sharon Bauer, Grant Johnson, Mark Moreland, Serge Jothy
Department of Laboratory Medicine, St. Michael's Hospital and University of Toronto, Canada

BK virus can become activated and cause nephropathy after kidney transplantation. The clinical goal is to detect and treat patients early enough to limit the amount of damage to the transplanted kidney. The aim of our study was to compare the relative contribution of molecular and morphological approaches in the diagnosis of BK virus associated nephropathy. Thirty seven plasma specimens from 28 renal transplant patients were tested by PCR for the presence of a BK genomic sequence, a test which has the advantage of giving technically unambiguous results. The results were compared with 56 urine cytology specimens obtained from the same patients, searching for decoy cells. Ten urine specimens from 8 patients had a positive urine cytology and 1 of these 10 had a positive BK plasma test. Twenty eight out of the 56 urine cytology specimens (50%) were reported as indeterminate. The plasma of 7 patients was positive by PCR. The result of the PCR tests was confirmed by restriction enzyme digestion. One out 7 of these patients had a positive urine cytology; the other 6 were reported as having an indeterminate or negative cytology. Electron microscopy of patients who had a renal allograft biopsy showed typical viral particles but was less sensitive than PCR testing. We conclude that molecular testing of viremia for the documentation of BK virus replication in renal transplant patients is more specific than the demonstration of decoy cells in urine cytology specimens, or electron microscopy of renal allograft biopsies. Urine cytology for decoy cells leads to a large number of indeterminate and false positive results.

OP16-1
DERMATOFIBROSARCOMA PROTUBERANS (DFSP): CLINICAL, MORPHOLOGICAL AND IMMUNOHISTOCHEMICAL STUDY OF 83 CASES.

Mameri Saâdia
CHU Béni-Messous, Algeria

Background: The DFSP is a sub- cutaneous tumor characterized by a strong tendency to recur,rarely metastasizant, which may present under several morphological aspects. These are named variants: sclerosing, schwanian, myxoïd, with giant cells, pigmented, atrophic, myofibroblastic, and fibrosarcomatous. Method: Our series is composed by 83 cases of DFSP observed during 7 years coming from Surgical, Plastician and Orthopaedics units. A clinical list is elaborated containing some elements: age-sex-evolution- trauma-anterior biopsy –number of recurrences. Multiple sections of the tumor and their margins are realized. The microscopic study with haematoxylin-eosin staining evaluates some parameters: classical storiform pattern-presence of variants-quantification of these variants-vascular component-inflammation- necrosis- mitotic index- cellular density-cellular atypia. Secondary, an immunohistochemical study using a panel of antibodies with CD34 is achieved. Results: They show that DFSP affects young adults and also children. Physical and clinical aspects are preserved during a long time even with very evoluated tumors.The classical storiform pattern is the most often found, diffusely and intensively CD34 positive. It's followed by sclerosing, neuroïd, myxoïd which express sometimes CD 34 but less diffusely and less intensively. Rarely (6 cases among the 83), a fibrosarcomatous form of poorer prognosis and CD34 negative is found in variable proportions near typical areas. Conclusion: Although it may grow very slowly during several years, DFSP is an authentic sarcoma but often without malignant cytological criteria. Its habitual microscopic pattern is that knowed by storiform cartwheel pattern. Some of the variants which may be associated and sometimes be predominant have no influence on the prognosis but the fibrosarcomatous form will be searched by the analysis of multiple specimens. The study of these 83 cases aims to show the clinical , morphological and immunohistochemical particularities in an Algerian population.

OP16-2
COLLAGEN V NASAL TOLERANCE IN EXPERIMENTAL MODEL OF SYSTEMIC SCLEROSIS

Ana Velosa, Walcy Teodoro, Cristiane De Oliveira, Antonio Filho, Rodnei Moutinho, Angela Santos, Margarete Vendramini, Cleonice Bueno, Edwin Parra, Vera Capelozzi, Natalino Yoshinari
University of São Paulo Medical School, Discipline of Rheumatology and Department of Pathology, Brazil

Objective: Our aim was to study skin remodeling and autoantibody production in an experimental model of Scleroderma (Ssc), following nasal tolerance with human type V collagen (Col V). Methods: Female New Zealand rabbits (N=12) were immunized with two doses of 1mg/ml of Col V in complete Freund's adjuvant and additional two boosters in incomplete Freund's adjuvant to induce Ssc. After 150 days, half of from these immunized rabbits were submitted to type V collagen-induced tolerance receiving a daily nasal administration of 25μg of Col V. Control animals (N=6) were only submitted to type V collagen-induced tolerance. Serial skin biopsies were performed at 0, 150 and 210 days, and stained with H&E, Masson's trichrome and Picrosirius for morphological and morphometric analysis. Types I, III and V collagen, TGF-β and PDGF were identified by immunofluorescence. The animals serum samples were collected to determine anti types I, III, IV and V collagen and antinuclear antibodies (ANA). Results: Skin biopsies from immunized animals confirmed Ssc morphology as previously described, such as progressive decrease of papillary dermis, appendages atrophy, increased type I, III and V collagen deposition and augmented expression of TGF-β and PDGF. Rabbits with Col V-induced nasal tolerance showed reduction of skin involvement, with significant decrease of collagen amount and lower TGF-βand PDGF expressions. Humoral immune response did not change with nasal tolerance. Conclusions: Col V nasal tolerance promotes regression of skin remodeling process in an experimental model of Ssc. We suggest that nasal tolerance with type V collagen can be a promising therapeutic option to treat Scleroderma patients.Financial Support: FAPESP,CNPq.

OP16-3
HHV8 IN KAPOSI'S SARCOMA AND OTHER VASCULAR LESIONS: COMPARISON OF IMMUNOHISTOCHEMISTRY AND CHROMOGENIC IN-SITU HYBRIDIZATION METHODS

Ebru Karayigit, Nesimi Buyukbabani
Istanbul University, Istanbul Medical Faculty, Pathology Department, Istanbul, Turkey

BACKGROUND: Kaposi's sarcoma (KS) is an angioproliferative disease occurring in several clinical and epidemiological subsets: classical (Mediterranean), endemic (African), post-transplant or iatrogenic immunosuppression associated and AIDS-related. Kaposi sarcoma associated herpes virus or human herpes virus 8 (HHV8) discovered in 1994, has been implicated as the most important etiological agent and its presence had been demonstrated in all types and stages of lesions. The aim of this study was to assess by two different methods, immunohistochemistry and chromogenic in-situ hybridization, the presence of HHV8 in KS and a group of vascular lesions that can be included in the differential diagnosis. The main purpose was to compare the sensitivity and specificity of the two methods. METHOD: Paraffin embedded archival tissue of 45 KS patients were included in the working group. Four patients had two lesions in different stages. A total of 49 KS lesions, 4 patch, 13

plaque and 32 nodules were analyzed. Control group consisted of 42 various benign and malignant vascular lesions and 3 cases of non-involved skin of KS patients. Monoclonal anti-HHV8 LNA (clone 13B10) and polymer detection system was used in immunohistochemistry. In-situ hybridization was performed using an oligonucleotide probe directed to T1.1 mRNA transcript. Visualization was achieved using nitro blue tetrazolium and 5-bromo-4-chloro-3-indolylphosphate as chromogens. RESULTS: All cases of KS were positive for HHV8 LNA with immunolocalization in the nuclei of spindle cells and cells lining vascular channels, whereas all vascular lesions and non-involved skin of KS patients were negative. Sensitivity and specificity was 100%. Positive reaction was detected in only 29 KS cases by in-situ hybridization and percentage of labeled cells was very low, around 1%. No reactivity was detected on the control group, except one case. Sensitivity and specificity for this method were 64.4% and 97.8% respectively. CONCLUSION: We concluded that immunohistochemistry for HHV8 LNA is a highly sensitive, specific and simple technique compared to chromogenic in-situ hybridization and can be a reliable adjunct to conventional histopathology for the diagnosis of Kaposi's sarcoma.

OP16-4
P63 EXPRESSION AS A NEW PROGNOSTIC MARKER IN MERKEL CELL CARCINOMA.

Sofia Asioli[1], Alberto Righi[2], Marco Volante[1], Vincenzo Eusebi[2], Gianni Bussolati[1]
[1] Department of Biomedical Sciences and Human Oncology, University of Turin, Italy
[2] Section of Anatomic Pathology M. Malpighi, University of Bologna, Italy

BACKGROUND: Merkel cell carcinoma (MCC) is an aggressive neuroendocrine skin tumor, mostly affecting elderly individuals. Histogenesis of this rare tumor as well as prognostic criteria are a matter of dispute. Several prognostic indicators have been proposed for MCC. Gender (male), tumour size >5 cm or > 2 cm, location in the buttock, thigh, trunk or head & neck, advanced clinical stage, small cell size, high mitotic index, diffuse pattern as well as mutation of TP53 gene family, have all been reported as indicators of poor prognosis. The p63 protein is a member of the p53 family, and it can be frequently amplified and/or overexpressed in human tumours including carcinoma of head & neck, lung, skin, esophagus, mammary glands, urothelia, cervix, prostate glands, oral squamous cell carcinomas and in odontogenic tumours. Although p63 per se is not general indicator of poor prognosis, nevertheless it is often associated to poorly differentiated basaloid carcinoma. Recently Fukushima et al. suggested that p63 expression is a disadvantageous factor for prognosis in a subgroups of B-cell lymphomas. Our study will show that the same statement can be made in MCC. METHODS: An immunohistochemical analysis of markers of proliferation (Ki67/MIB1), neuroendocrine differentiation (chromogranin A and synaptophisin) and basal cell differentiation (p63) was performed in a series of 47 cases of MCC. Significance of pathological data and of immunoreactivity with different markers was evaluated by chi-squared test. Survival curves were calculated by Kaplan-Meyer method. The difference of survival was estimated using Wilcoxon or Mantel-Cox test. RESULTS: Immunohistochemical evidence of neuroendocrine differentiation and immunopositivity for cytokeratin 20 were observed in all cases, while p63 positivity (≥10 of neoplastic cell) was detected in approximately half (25/47; 53.2%) of the cases. Cases positive for p63 showed a more aggressive clinical course than the negative ones (Z =2.93; P=.0003; HR=22.22). CONCLUSIONS: Our data indicate that p63 expression is associated with a worse prognosis in MCC and it represents a new independent marker of clinical evolution with a better predictive power than the other prognostic parameters.

OP16-5
MELANOCYTIC TUMOURS IN CHILDREN AND ADULTS ARE GENETICALLY DIFFERENT

Suzanne Mol[1], Marcory Van Dijk[2], Annelies Klaasen[1], Marjolein Ligtenberg[1], Wolter Mooi[3], Dirk Ruiter[1], Willeke Blokx[1]
[1] University Medical Centre Nijmegen, The Netherlands
[2] University Medical Centre Groningen, The Netherlands
[3] VU Medical Centre Amsterdam, The Netherlands

Background: Childhood melanomas, although very rare, do occur and even expert pathologists can not always arrive at an unequivocal diagnosis. The reason is its similarity to the, in this age group more common, Spitz nevus. The etiology of melanomas at childhood is unclear. In adults, the majority of cutaneous melanoma and common nevi harbour BRAF and NRAS mutations, whereas HRAS mutations occur in Spitz nevi. The purpose of this study is to evaluate the use of mutation analysis of BRAF, NRAS, and HRAS genes in the differential diagnosis of melanocytic tumours in children. Method: We reviewed histology of 67 cutaneous melanocytic lesions from children younger than 16 years. DNA was isolated from formalin-fixed paraffin-embedded blocks. We sequenced BRAF (exon 15), NRAS (exons 2 and 3), and HRAS (exon 3) genes to detect hotspot mutations. Results: Lesions were grouped into seven different diagnostic categories: common melanocytic nevus (15), Spitz nevus (13), Spitzoid tumour of uncertain malignant potential (STUMP) (22), Spitzoid melanoma (6), non-Spitzoid melanoma (7), melanoma metastasis (2), and combined nevus (common nevus with an atypical Spitzoid component) (2). We detected a BRAF or NRAS mutation in all common nevi. No HRAS mutations were found in common nevi. In the other diagnostic groups, only sporadic mutations were found. In the (Spitzoid and non-Spitzoid) melanomas and melanoma metastasis no mutations were found, except for one NRAS exon 3 mutation in a non-Spitzoid melanoma, which had an adjacent nevus component. No mutations were detected in Spitz nevi. Only one STUMP had an HRAS mutation. Furthermore, one of the two combined nevi harboured a BRAF mutation. --Conclusion-- In contrast to melanocytic lesions in adults, melanomas in childhood do not (or only sporadic) have BRAF mutations and Spitz nevi less frequently have HRAS mutations. Therefore, mutation analysis is not useful in the differential diagnosis of Spitz nevus and (Spitzoid) melanoma in childhood, in contrast to adults. Other, undiscovered, gene abnormalities must be responsible for the development of melanoma and Spitz nevus in children. Remarkably, the only BRAF and NRAS mutations detected, outside the common nevi, are in lesions adjacent to a nevus component. One hypothesis is that only childhood melanomas that develop from a congenital or common nevus have NRAS or BRAF mutations and that this is an infrequent event in children; we speculate that most childhood melanomas, different from adults, probably arise via a different pathway (de-novo).

OP16-6
MELK IS A NOVEL TUMOUR PROGRESSION MARKER IN MELANOMA

Cristina Manieli[1], Véronique Winnepenninckx[2], Joost J. Van Den Oord[3]
[1] Department of Cytomorphology, Section of Pathology, University of Cagliari, Italy
[2] University Hospital, University of Maastricht, The Netherlands
[3] University Hospitals, Katholieke Universiteit Leuven, Belgium

Background: MELK (Maternal Embryonic Leucine Zipper Kinase) is a member of the snf1/AMPK family of serine-threonine kinases; its specific targets in the normal cell have not been identified yet, and its role is therefore still elusive. However, several studies report an increased expression of MELK in various tumours (colon, breast, paediatric brain tumours) compared to normal tissues. The role of MELK in melanoma has

not been explored yet; in a previous gene expression profiling study , we found a significant difference in MELK expression between patient with and patients without distant metastasis within four years after diagnosis (J Natl Cancer Inst 2006; 98: 472-482); moreover, besides its prognostic significance, MELK mRNA-levels increased with increasing thickness of the primary melanoma. The aim of the present study was to assess the expression of MELK by immunohistochemistry (IHC) comparing normal skin, nevi, primary melanomas and metastasis of melanomas. Method. Immunohistochemical studies were performed either on frozen sections from 124 cases using a goat polyclonal antibody or on paraffin embedded material using a mouse monoclonal antibody against Melk. The 31 benign cases included 7 congenital and 15 acquired common nevi, 2 acral nevi, 2 common blue nevi, 1 cellular blue nevus and 4 Spitz nevi. The 84 malignant lesions included 57 primary and 27 metastatic melanomas. Nine cases of normal skin were also studied. The results were confronted with clinical data and mRNA levels. Results: MELK was not expressed in normal melanocytes and was only focally expressed in common acquired nevi; on the other hand, 2 acral , 3 Spitz , 4 congenital and 1 cellular blue nevus showed immunoreactivity. 33/57 primary melanomas and 15/27 metastases were positive for MELK. The percentage of positive melanoma cells increased with tumor thickness and was highest in the metastases. Surprisingly, MELK was expressed by endothelial cells lining intact vessels in 16/29 melanomas and in 7/11 melanoma metastases. Conclusion: Our data showed that MELK is a tumour progression marker in melanoma. Whether it is of prognostic significance at the protein level needs further study. In line with other members of the AMPK family, MELK expression in endothelial cells may suggest a role in tumour angiogenesis .

OP17-1
GENE EXPRESSION PROFILING OF TFE/MITF RENAL CELL TRANSLOCATION CARCINOMAS

Camparo Philippe[1], Dykema Carl[2], Furge Kyle[2], Comperat Eva[3], Denoux Yves[4], Molinie Vincent[5], Sibony Mathilde[6], Vasiliu Viorel[7], Vieillefond Annick[8], Teh Bin[2]

[4] Hopital Foch, Suresnes, France
[5] Hopital Saint Joseph, Paris, France
[6] Hopital Tenon, Paris, France
[7] Hopital Necker, Paris, France
[8] Hopital Cochin, Paris, France

Objective : In order to determine the gene expression profiling of TFE translocation renal cell carcinomas (RCC). Patients and methods : Frozen samples of 4 primary tumor specimens with a histological diagnosis of TFE-translocation RCC were obtained. Diagnosis was made according strong and specific nuclear immunohistohemical expression of TFE3 (3 cases) or TFEB (1 case). Institutional Review Board approval was obtained from each participating institution. 48 cases of renal carcinomas that were representative of their respective subtypes based on both histology and gene expression were selected to enable comparison of the gene expression of the TFE translocation RCC with other renal tumors. The reference set included 11 cases of clear cell, 7 cases of chromophobe, 11 cases of papillary type 1, 6 cases of papillary type 2, and 13 cases of urothelial RCC. In addition, we included 7 cases of Oncytoma and 13 samples of normal kidney. Total RNA extraction, RNA quality and oligonucleotide expression profiling were assessed as previously described. All statistical analyses were performed using the R statistical environment utilizing Bioconductor project version 1.9. Unsupervised clustering was performed based on the Euclidean distance between each case in terms of gene expression. Genes that were differentially expressed between the samples of TFE translocation RCC and our reference samples were identified using the Limma package from the Bioconductor project. Results: From our clustering analysis against 6 other subtypes of kidney tumors and normal kidney, we demonstrated that the three TFE3 translocation and the TFEB translocation cluster each closer to each other than to others renal tumors suggesting that this group of tumors could be further divided based on their molecular signatures. The main genes over expressed were TRIM63 (tripartite motif-containing 63, average fold change 107,54), Cytochrome p450 17A1, hyaluronan binding protein 2, integrin beta 1 binding protein 3, and synaptic vesicle glycoprotein 2B (over expressed). Zinc finger protein 204 cytochrome p450 2B6, MUC1 and CAXII (average fold change 0,04) were under expressed. Conclusion : Based on gene expression profiling, we confirmed that TFE3 and TFEB translocation RCC should be considered as one distinct group of RCC. The genes we identified as distinct from other subgroups of RCC represent potentially novel diagnostic makers, although further validation studies are warranted.

OP17-2
CELL SURFACE PEPTIDASES CD13 AND CD10 IN RENAL CELL NEOPLASMS.

Matteo Brunelli, Stefano Gobbo, Albino Eccher, Alice Parisi, Marta Gobbato, Daniela Dalfior, Marco Chilosi, Fabio Menestrina, Guido Martignoni
Department of Pathology, University of Verona, Italy

Background: the immunoexpression of cell surface peptidases, such as the metallopeptidase/CD10 in renal cell neoplasms have been found to be of diagnostic value among renal cell neoplasms. The aminopeptidase N/CD13 has been reported in some renal cell neoplasms, however little is know about its immunoexpression according to different histotypes of renal cell neoplasms. The current study attempts to evaluate and compare the CD13 and CD10 immunohistochemical staining in a large series of renal cell neoplasms. Method: we investigated 100 renal cell neoplasms, including 38 clear cell, 16 papillary, 17 chromophobe renal cell carcinomas (RCCs) and 14 renal onocytomas by CD13 (38C12, Novocastra) and CD10 (56C6, Novocastra) immunohistochemical expression. Results: a membranous staining pattern for CD13 was observed in 31/38 (81%) (19/38, 50% in >50% of neoplastic cells), and 11/16 (68%) (9/11, 81% in >50% of neoplastic cells) papillary RCCs. No staining was observed in all chromophobe RCCs and renal oncocytomas. CD10 was observed in 36/38 (94%) clear cell and 14/16 (87%) papillary RCCs; CD10 was also detected in 9/17 (52%) of chromophobe RCCs and in 7/14 (50%) (with patchy positive staining in 4/14, 28% and in 3/14, 21% with a microluminal and single cells stain) renal oncocytomas. Conclusion: we concluded that: 1) CD13 is a relatively sensitive and specific marker for clear cell and papillary RCCs; 2) CD13 is always absent in chromophobe RCCs and renal oncocytomas, whereas CD10 can be immunoexpressed in both chromophobe RCCs and renal oncoytomas; 3) CD13 should be included in a panel of antibodies to distinguish clear cell (most CD10+, CD13+) from chromophobe RCCs (most CD13-, CD10+/-).

OP17-3
MOLECULAR MORPHOLOGY IN RENAL ONCOCYTOMA: EVALUATION OF CYCLIN D1 IMMUNOEXPRESSION AND 11q13 INTERPHASE CYTOGENETIC REARRANGEMENTS.

Matteo Brunelli[1], Stefano Gobbo[2], Albino Eccher[2], Paolo Cossu-Rocca[3], Vincenzo Ficarra[4], Fabio Menestrina[5], Mihaela Mina[5], Guido Martignoni[5]

[4] Department of Urology, University of Padua, Italy
[5] University of Verona, Italy

INTRODUCTION: cyclin D1 has been immunohistochemically demonstrated in approximately one-half of renal oncocytomas and CCND1 gene maps near to chromosome 11q13. Cytogenetically renal oncocytomas fall into three categories, namely characterized by normal karyotype, numerical or structural abnormalities on chromosome 1 and or 14, often with Y chromosome loss, and structural abnormalities of 11q13. We south to identify any correlation between cyclin D1 immunoexpression and different 11q13 structural rearrangements in renal oncocytoma. MATERIAL AND METHODS: we evaluated the cyclin D1 immunoexpression in 13 renal oncocytoma (11 with a solid-acinar and 2 with a tubulo-cystic pattern) and performed an interphase cytogenetic fluorescence in situ hybridization study, using a SpectrumGreen locus specific probe spanning to 11q13 on fomalin-fixed-paraffin embedded tissue. Fluorescence signal count was scored on 150 neoplastic nuclei. RESULTS: cyclin D1 was immunoexpressed in 10/13 (76%) renal oncocytomas (8/11 with solid/acinar and 2/2 with ubulo-cystic). Fluorescence in situ hybridization showed three cases (23%) with a 11q13 rearrangements, showing more than two signals for 11q13 probe (from three to eight signals) in most of neoplastic cells (>55%), and two of them immunoexpressed cyclin D1. Seven renal oncocytomas (70%) with cyclin D1 immunoexpression did not show any 11q13 genetic rearrangements. CONCLUSION: our study shows that 1) cyclin D1 is immunoexpressed in most renal oncocytomas without any difference between solid/microcystic patterns; 2) there is no correlation between cases with 11q13 genetic rearrangement with those with cyclin D1 immunoexpression; 3) different breakpoints near the CCND1 gene locus could explain different cyclin D1 immunoexpresion in renal oncocytoma.

OP17-4
PROSTATE ADENOCARCINOMA: IMMUNOHISTOCHEMICAL EVALUATION AFTER HIFU TREATMENT.

Alice Parise[1], Daniela Reghellin[1], Marta Gobbato[1], Stefano Gobbo[1], Albino Eccher[1], Matteo Brunelli[1], Fabio Menestrina[1], Marco Chilosi[1], Vincenzo Ficarra[2], Guido Martignoni[1]
[1] Department of Pathology, University of Verona, Italy
[2] Department of Urology, University of Padua, Italy

Background: High Intensity Focused Ultrasound (HIFU) is a minimally invasive alternative treatment for prostate adenocarcinoma. High energy converging ultrasound waves induce a rise in temperature and subsequent destruction of target tissue. Necrosis and fibro-sclerosis are histological findings after HIFU treatment. Little is known about the evaluation of residual neoplasia in patients who received HIFU treatment. Residual prostate neoplasia is the most important point in the pathologist-report. We performed an immunohistochemical analysis to detect the presence of residual foci of prostate adenocarcinoma after HIFU treatement. Method: We tested 11 cases (7 from agobiopsies and 4 from chips obtained by trans-urethral resection) with morphologically residual neoplastic foci of prostate adenocarcinoma after HIFU treatment, using immunohistochemically the following antibodies: racemase, p63, cytokeratin 34βE12, PSAP, cromogranine, PSA and CD56. Cytokeratin 8-18 was performed to test material quality. Racemase expression was scored as "0" when negative, "+" when weakly or focally positive (in less than 10% of the cells), "++" when diffuse or strongly positive (in more than 10% of the cells). Results: Cytokeratin 8-18, PSAP and PSA where positive in almost all cases in both neoplastic foci and in normal tissue. p63 and cytokeratin 34βE12 marked the basal layer in normal prostatic glands tissue, while where absent in neoplastic glands. We found rare cells with staining for CD56 and cromogranine in four cases. Racemase was expressed in seven cases (in 3 "++" and in 4 "+") and negative in two cases. Two cases showed too small residual foci for a good quality evaluation. Conclusion: Immunohistochemistry is a useful tool to detect prostate neoplastic residual foci on biopsy or chips after HIFU treatment. A panel including neoplastic positive markers such as racemase and negative markers such as p63 and cytokeratin 34βE12 may confirm the presence of neoplastic glands.

OP17-5
LOSS OF EXPRESSION OF CARCINOEMBRYONIC ANTIGEN-RELATED CELL ADHESION MOLECULE-1 (CEACAM1) IN PROSTATE INTRAEPITHELIAL NEOPLASIA (PIN) AND INVASIVE PROSTATE CANCER INDUCES ANGIOGENESIS

Ergin Kilic[1], Derya Tilki[2], Leticia Oliveira-Ferrer[3], Hartwig Huland[3], Suleyman Ergun[4]
[1] University Hospital Basel, Institute of Pathology, Basel-Stadt, Switzerland
[2] University Hospital Grosshadern, Department of Urology, Munich, Germany
[3] University Hospital Eppendorf, Department of Urology, Hamburg, Germany
[4] University Hospital of Essen, Institute of Anatomy, Essen, Germany

Background: Tumor growth and metastasis essentially depend on a sufficient neovascularization via angiogenesis, which is regulated by angiogenic activators and inhibitors. We previously showed that soluble human CEACAM1 exhibits angiogenic properties. It has been known, that mRNA of CEACAM1 is downregulated in several tumors, so a tumor-suppressive role of CEACAM1 has been postulated. Methods: prostates specimen were fixed in formalin or Bouin's solution (for electron microscopy) and embedded in paraffin. Human prostate cancer cell line DU-145 were cultured until 70% confluence. The cDNA encoding human full-length CEACAM1 was ligated into the plasmid pcDNA3.1/Hygro(-) (Clontech) and used for CEACAM1-overexpression studies. For CEACAM1 silencing, we used the siRNA technique. From the cell lysates, proteins were extracted and used in SDS-Page. From extracted RNA, qRT-PCR were performed on LightCycler Instrument (Roche) using the fluorescent SYBR-Green. Immunhistochemical stainings on prostate specimen were performed and on serial-sections, the CD34-positive and CEACAM1-positive blood vessels adjacent to the normal prostate gland and to tumor (PIN and invasive cancer) were counted separately. HDMEC's (human endothelial cells) treated with VEGF alone, with conditioned media of CEACAM1-verexpressing or CEACAM1-silenced DU 145 cells alone or the latter both together with VEGF were used to perform in vitro wound assay. Conditioned media of empty vector transfected and of luciferase-silenced DU-145 cells alone or in combination with VEGF were used as control. Results: We demonstrate here that epithelial CEACAM1 down-regulation in high-grade PIN and in invasive prostate cancer is inversely correlated with its up-regulation in adjacent blood vessels. CEACAM1 silencing in prostate cancer cell line DU-145 via siRNA increased but its overexpression suppressed the expression of angiogenic/lymphangiogenic factors such as VEGF-A, -C and –D, and the angiogenesis inhibitor collagen 18/endostatin. Furthermore, CEACAM1 overexpression in DU-145 cells increased but CEACAM1 silencing reduced angiopoietin-1 expression. Inverse relation was found for angiopoietin-2. Supernatant of CEACAM1-overexpressing DU-145 suppressed but that of CEACAM1-silenced increased the VEGF-induced endothelial tube formation. Electron microscopically, the majority of tumor-associated blood vessels were structurally destabilized, exhibiting endothelial fenestrations, trans- and inter-endothelial gaps. In some areas invasion of single tumor cells into the destabilized blood vessels were observed. Conclusions: These data show that disappearance of epithelial CEACAM1 in PIN and invasive prostate cancer is accompanied by its up-regulation in adjacent vasculature, which apparently correlates with vascular destabilization and increased vascularization of prostate cancer. Strategies to either conserve the epithelial CEACAM1 or to target endothelial CEACAM1 might be useful for anti-angiogenic therapy of prostate cancer.

OP18-1
MATRIX METALLOPROTEINASES AND THEIR TISSUE INHIBITORS EXPRESSIONS IN INVASIVE CUTANEOUS MELANOMAS

Mustafa Gureli, Ozlem Erdem, Cigdem Vural
Gazi University Department of Pathology, Turkey

Background: Primary cutaneous melanomas are characterized by their tendency to metastasize. Essential steps in this process involve the degradation of basement membranes and remodelling of the extracellular matrix by proteolytic enzymes such as matrix metalloproteinases and their tissue inhibitors. In this study; we investigated the relationship between histopathological parameters and immunhistochemical expressions of the matrix metalloproteinases and their tissue inhibitors in primary invasive cutaneous melanomas. Materials and Methods: Seventy primary cutaneous invasive melanoma cases were re-evaluated for histopathological parameters including Breslow thickness, Clark level of invasion, ulceration, histological subtypes, mitotic rate, tumor-infiltrating lymphocytes (TIL), vertical and radial growth phases. Furthermore; immunohistochemical expressions of MMP-2, MMP-9, TIMP-1 and TIMP-2 have been evaluated by using staining intensity and percentage. Results: There was a statistically significant relationship between Breslow thickness, Clark level, mitotic rate, ulceration. However, there was no correlation between histologic subtypes and other histopathologic parameters. MMP-2 expression was correlated with Breslow thickness and tumor ulceration. There was also significant relation between MMP-9 expression and Breslow thickness. Although TIMP-1 was not correlated with any known histopathologic parameters, TIMP-2 was significantly correlated with mitotic rate and TIL. Although there was a statistically correlation between TIMP's, there had not been determined any statistical expressive correlation between MMP's and TIMP's. Conclusion: MMP-2 and MMP-9 expressions were correlated with Breslow thickness in primary invasive melanomas; which is support the relation with invasion.

OP18-2
OVER-EXPRESSION OF THE HEMIDESMOSOMAL ADHESION PROTEIN COLLAGEN XVII IN MALIGNANT MELANOMA

Tibor Krenacs[1], Eva Stelkovics[2], Elizabeth Raso[3], Irma Korom[4], Ilona Marczinovits[5], Laszlo Kopper[1], Josef Timar[3]
[1] 1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary

[3] Department of Tumor Progression, National Institute of Oncology, Budapest, Hungary
[4] Department of Dermatology and Allergology, University of Szeged, Hungary
[5] Department of Anatomy, University of Szeged, Hungary

Background: Collagen XVII (BP180, BPAGII) is a transmembrane protein anchoring proliferating basal keratinocytes to the underlying basal lamina in normal stratified epithelia. Collagen XVII is lost during normal keratinocyte maturation, however, it is still expressed in precancerous and cancerous epithelial lesions primarily of squamous cell origin as a sign of dedifferentiation. In this study we tested the potential neo-expression of collagen XVII in melanocytic tumors. Method: We produced mouse monoclonal antibody clones against the synthetic oligopeptide sequence aa542-564 of collagen XVII. Archived tissue blocks of 9 normal skins, 22 dysplastic- and 20 Spitz nevi, 83 primary melanomas (35 surface spreading, 33 nodular, 12 acrolentiginous and 3 lentigo maligna type) and 18 metastatic melanomas were tested for collagen XVII immunostaining using a non-biotin polymer detection EnVision+. Human melanoma mouse xenografts and melanoma cell lines in culture were also studied. Immunostains were analysed on digital slides scanned using Mirax Scan and the HistoQuant software(3DHITECH, Budapest & Zeiss, Gottingen, Germany). Results: Antibody clones 6D1 and 9G2 were selected out of 300 based on collagen XVII antigen specificity confirmed with ELISA and Western immunoblotting, and detectability of this antigen both in native frozen and routinely archived paraffin tissue sections following heat induced epitope retrieval. The presence of collagen mRNA in melanoma cell lines A2058, HT168M1, WM35 and WM983A was confirmed with RT-PCR technique. Substantial amount of collagen XVII protein was detected in paraffin sections of normal basal keratinocytes and primary and metastatic melanomas either in human tissue or in human melanoma mouse xenografts. When positive staining was defined by over 40% of tumor cell staining, the tested antibodies showed the following efficiency: 1) Collagen XVII 85% in melanomas; 6% in nevi; Melan A 87% in melanomas; 92% in nevi; S-100 94% in melanomas and 90% of nevi; HMB-45 72% in melanomas and 68% of nevi. In many instances collagen XVII staining was elevated on the tumor front in both primary and metastatic cases, and stained melanomas which were negative for HMB-45. Conclusion: This is the first study to show that immunodetection of collagen XVII protein, which is not associated to melanosomes or melanin production, 1) can be an efficient marker of malignant melanomas; 2) may be a useful adjunct in differentiating benign and malignant melanocytic lesions; and 3)may be positively linked to metastatic melanoma progression. Supported by OTKA K62758

OP18-3
THE ELASTIC TISSUE CHANGES IN GRANULOMA ANNULARE: A STUDY OF THIRTY CASES

Pembegul Gunes[1], Fatih Goktay[2], A. Tulin Mansur[2], Filiz Koker[1], Gamze Erfan[1]
[1] Department of Pathology, Haydarpasa Numune Education and Research Hospital, Istanbul, Turkey
[2] Department of Dermatology, Haydarpasa Numune Education and Research Hospital, Istanbul, Turkey

Background: Granuloma annulare (GA) is a common skin disorder, characterized by mainly two types of inflammation patterns which are interstitial and granulomatous. In the past; focal degeneration of dermal collagen fibers had been reported for this disease. However; recent studies also have been emphasized degeneration and fragmentation in elastic tissue, Objective: In this study we aimed to examine histopathologic characteristics and elastic tissue changes in GA. Material and methods: The hematoxylin and eosin-stained slides of the thirty patients which are diagnosed as GA between 1994-2007 were re-examined. The new serial sections of formalin fixed paraffin embedded blocks were stained with Verhoeff-van Gieson and Alcian Blue. All slides were examined by an experienced pathologist. Results: In the study population, 17 patients were female (70.8 %), 7 were male (29.2%). Their ages ranged from 4-72 years with a mean of 39.5. The biopsied lesions were localized on the leg (8/24), hand (6/24), arm (5/24), foot (1/24), shoulder (1/24), nape (1/24), trunk (1/24), arm and leg (1/24). Out of 30 patients, we were not able to reach 6 patients age, gender and biopsied lesion localizations. In hematoxylin and eosin slides, we observed 21 interstitial, 8 granulomatous and 1 both granulomatous and interstitial inflammation patterns. In 26 of 30 (86.7%) biopsy specimens, mucin was detected with Alcian-Blue staining. We observed elastophagocytosis in only 1 (3.3%, n=30) specimen, whereas giant cells were in 11 (36.7%, n=30). Elastic and collagen fiber fragmentation were seen in 28 (93.3) biopsy specimen. There was no remarkable changes in both elastic and collagen fibers in case 24 and 25. Additional histologic findings included vasculitis (8/30, 26.7 %) and necrosis (7/30, 23.3 %). Conclusion: Sunlight exposure has been considered as an etiologic factor in the pathogenesis of granuloma annulare. Furthermore, some authors concluded that degenerating elastic fibers may promote the granulomatous reaction seeing in GA. In

this study, on microscopy, elastic fiber degeneration was seen in almost all cases. All cases showed degenerated elastic fibers were surrounded by intact collagen fibers. These findings showed that the main alteration in GA is elastic fiber degeneration and strongly suggest that development of this disorder was injury to the elastic tissue.

OP18-4
THE NOTCH SIGNALING IN HUMAN SKIN CANCER

Ioannis Panelos[1], Francesca Tarantini[2], Milena Paglierani[3], Claudia Di Serio[2], Vincenza Maio[3], Silvia Pellerito[2], Nicola Pimpinelli[4], Marco Santucci[3], Daniela Massi[3]
[1]Department of Pathology, University of Ioannina, Greece
[2]Department of Critical Care Medicine and Surgery, University of Florence, Italy
[3]Department of Human Pathology and Oncology, University of Florence, Italy
[4]Department of Dermatological Sciences,University of Florence, Italy

BACKGROUND: The Notch pathway acts through the regulation of cell proliferation, migration, and apoptosis, with opposing outcomes that may result in oncosuppression or protumoral effects, depending on the cellular and tissue context. In the mouse skin, Notch-1 coordinates differentiation of squamous epithelia and deletion of Notch 1 results in hyper-proliferation of the basal epidermal layer, and development of skin tumors. However, little information is available on the level of expression of Notch-1 and its ligands, in precancerous lesions and invasive carcinomas in human skin. METHOD: The expression of Notch 1, Jagged 1, Jagged 2 and Delta-like 1 proteins was investigated by immunohistochemistry in a series of premalignant and invasive cutaneous carcinomas: 2 solar keratoses (SK); 4 Bowen's disease (BD), 4 squamous cell carcinomas (SCC) on sun-exposed skin, 6 SCC on sun-protected genital skin, and 14 basal cell carcinoma (BCC) of different histotypes (nodular, superficial type, sclerodermiform and baso-squamous). RESULTS: Expression of Notch 1 was decreased in solar keratoses and invasive SCC localized in sun-exposed sites. In contrast, marked Notch-1 staining was observed in extragenital Bowen disease as well as in genital HPV-related in situ and invasive SCC. Notch-1 was diffusely expressed in nodular and superficial BCC while sclerodermiform and baso-squamous BCC showed a low to absent Notch 1 expression. Jagged 1, Jagged 2 and Delta-like 1 proteins were expressed in all the tissues examined. CONCLUSION: Present findings suggest divergent expression of Notch-1 in cutaneous SCC depending on anatomical site: In UV-related squamous cell photocarcinogenesis Notch functions as tumor suppressor; in contrast, in sun-protected HPV-related SCC, Notch-1 is upregulated. Finally, Notch 1 expression is downregulated in BCC subtypes correlated with risk of recurrence (sclerodermiform and baso-squamous) in comparison with more common nodular and superficial-type subtypes.

OP18-5
THE RELIABILTY OF MULTIPLEX PCR AND HETERODUBLEX ANALYSIS USING BIOMED-2 PRIMERS ON MYCOSIS FUNGOIDES DIAGNOSIS

Aylin Okcu Heper[1], Yasemin Sahin[1], Nisa Akay[2], Hatice Germen Unverdi[1], Hatice Sanli[2], Isinsu Kuzu[1]
[1] Ankara University, School of Medicine, Department of Pathology, Ankara, Turkey
[2] Ankara University, School of Medicine, Department of Dermatology, Ankara, Turkey

Background: Mycosis Fungoides(MF) is the most frequently seen cutaneus T cell lymphoma. The morphological and clinical variability in the presentation of the disease can create diagnostic difficulties. The early phases of the disease can mimick inflammatory lesions both with their morphology and immunophenotype. Although demonstrating the clonal T cell proliferation does not always imply the neoplastic nature of the lesions, the previously performed molecular methods were less sensitive in detection of T cell clonality. Our aim in this study is to examine the efficiency of T cell clonality on differentiation of the inflammatory skin lesions from MF cases showing different morphological features and monitorisation of the therapy response. Method: We examined 15 MF (mean 53 years of age, 11 male, 4 female) cases showing characteristic morphological and immunophenotypic features, 8 suspicous MF (mean 61 years of age, 6 male, 2 female) cases. Post therapy control biopsies of 7 of 15 MF cases were also examined. Ten skin biopsies of licken planus lesions were included for polyclonal negative control. BIOMED 2 primers were used for detection of clonal TCR beta, gamma and delta rearrangements. Multiplex PCR with heterodublex (HD) analysis was performed for the molecular detection of T cell clonality. Results: Clonal TCR gene rearrangement were not demonstrated on licken planus. All of the MF lesions and 50% of the suspicious MF lesions showed clonal TCR gene rearrangements. 2 of 7 suspicious lesions were mimicking MF by their morphology but composed of predominantly CD8 positive lymphoid infiltration were within the clonal group. Conclusion: Multiplex PCR and HD analysis by using Biomed 2 primers are highly sensitive methods for detecting the monoclonal T cell proliferations in skin lymphoproliferative diseases. Molecular results were not enough for differential diagnosis of neoplastic and reactive lymphoid lesions. Combination of the molecular results with morphological, immunophenotypic and clinical features are essential in the interpretation of the behaviour of these lesions.

OP19-1
REGENERATIVE POTENTIAL OF CIRRHOTIC LIVER FOLLOWING VASCULAR LIGATION IN EXPERIMENTAL ANIMALS

Mona Nosseir, Mohammed Abbas, Youssef Farouk, Ayman Nafeh, Maged Nasr, Mona Zoheiry
Theodor Bilharz Research Institute, Egypt

Preoperative occlusion of hepatic inflow vessels increased the volume and function of the contralateral lobe. We aimed to compare, biochemically and histopathologically, the effects of selective ligation of portal vein branch (PVL) alone or with hepatic artery branches (HAL) in cirrhotic liver on liver functions and regeneration. This study was carried out in the experimental unit of TBRI on 40 adult male dogs. Preoperative liver cirrhosis was induced in all animals.They were divided into 4 groups: Group1, in which laparotomy was done without any surgical manipulation; Group2, in which occlusion of portal vein branch only was done; and Group3, in which occlusion of portal vein and hepatic artery branches were done simultaneously (at the same time) & Group 4, in which occlusion of hepatic artery was done 48 hours after portal vein ligation. Blood samples for liver profile and wedge liver biopsies were taken from all animals . Hepatic regeneration and portal angiogenesis were determined. Also, tissue expression of TGF-β1 was established by immunohistochemistry. No significant biochemical differences could be detected between Groups 2,3 & 4 except for AST. By histology, significant regeneration was observed in group 4 ($p < 0.05$) which was more prominent than groups 2 & 3. There was significant portal angiogenesis in the non ligated lobes of all groups and significant decreased expression of TGF-β1 ($p < 0.001$) with no statistical difference between all groups. Extra-hepatic vascular exclusion with a little preference for PVL plus HAL in a heterchronous manner (Group 4) in induced cirrhotic liver is safe and efficacious. This improve survival rate and outcome of hepatic resection for liver diseases.

OP19-2
CLAUDIN 1, 3, 4, 5 AND 7 IN ESOPHAGEAL CANCER: LOSS OF CLAUDIN 3 AND 4 EXPRESSION IS ASSOCIATED WITH METASTATIC BEHAVIOR

Juha Saarnio[1], Heikki Wiik[1], Ylermi Soini[2]
[1] Department of Surgery, University Hospital of Oulu, Finland
[2] Institute of Clinical Medicine, Pathology and Forensic Medicine, University of Kuopio, Finland

Background: Claudins are tight junctional proteins known to play a role in normal tissues and cancers.To elucidate their significance in esophageal cancer we analysed their expression in cases of surgically treated esophageal carcinoma. Methods: The expression of claudin 1, 3, 4, 5 and 7 was studied by immunohistochemistry. Tumor proliferation was assessed with Ki67 immunostaining and apoptosis by the TUNEL method and immunostaining of fragmented caspase 3. Results: Adenocarcinomas showed significantly more cases with moderate or strong claudin 3 ($p<0.001$) and claudin 5 positivity ($p=0.031$) than squamous cell carcinomas. Loss of claudin 3 expression was associated with the presence of distant metastases ($p=0.039$). Claudins 3, 4 and 7 had a significant association with either a high apoptotic index or a high number of caspase 3 positive cells, while claudin 5 was associated with increased proliferation. Conclusion: In esophageal carcinoma, claudin expression may vary along with the histology of the tumor. Claudin expression may also associate with apoptosis or proliferation, suggesting that they may contribute to tumor behavior and growth.

OP19-3
PROGNOSTIC IMPACT OF CLASS I HISTONE DEACETYLASES IN COLORECTAL CANCER: SPECIFIC ROLE OF HDAC2

Weichert Wilko[1], Roske Annika[1], Niesporek Silvia[1], Noske Aurelia[1], Buckendahl Ann-Christin[1], Dietel Manfred[1], Gekeler Volker[2], Boehm Markus[2], Beckers Thomas[2], Denkert Carsten[1]
[1] Institut für Pathologie, Charité Universitätsmedizin,Berlin,Germany
[2] Altana Pharma AG, Konstanz, Germany

Post-translational acetylation of core histones by histone deacetylases (HDACs) play an important role in the regulation of activity and expression of a large number of genes intimately involved in the initiation and progression of cancer. Consequently, a variety of HDAC inhibitors have recently been validated as promising anticancer agents and are now entering clinical trials. However, the tumor specific function and expression of specific HDAC isoforms is still incompletely understood. In this study, we determined class I HDAC isoform expression in 140 colorectal carcinomas by immunohistochemistry and correlated our findings with clinicopathological parameters and patient survival. In addition, effects of unspecific HDAC inhibition by valproic acid (VPA) and suberoylanilide hydroxamic acid (SAHA) as well as specific HDAC isoform knockdown by short interfering RNA (RNAi) on cell number and cell cycle were investigated in the colon adenocarcinoma cell line CX-2. We found Class I HDAC isoforms to be highly expressed in a subset of colorectal carcinomas (HDAC1:36.4%, HDAC2:57.9%, HDAC3:72.9%). High expression of HDAC isoforms was pronounced in strongly proliferating dedifferentiated tumors and implicated reduced patient survival, with HDAC2 being an independent survival prognosticator. Unselective inhibition of HDACs by both, VPA and SAHA as well as selective inhibition of HDAC2 and to a lesser extend HDAC1 but not HDAC3 depleted growth of CX-2 tumor cells in vitro, partly by initiating specific cell cycle alterations. In conclusion, we showed that long known in vivo effects of HDACs on differentiation and proliferation could be confirmed in human cancer tissue. Furthermore, we proved that class I HDAC isoforms are differentially expressed and highly prognostic in colorectal cancer. This may influence response to HDI treatment, which should be taken into account when clinical trials are being planned and carried out.

OP19-4
GASTROINTESTINAL STROMAL TUMORS: RECENT RESULTS OF A NATIONWIDE DATABASE INCLUDING 1008 CASES WITH HISTOPATHOLOGICAL AND IMMUNOPHENOTYPICAL FEATURES

Gulen Bulbul Dogusoy
GIST Working Group Turkish Society of Pathology, Turkey

Background:Gastrointestinal stromal tumors (GIST) which are the most common mesenchymal tumors arising from the gastrointestinal tract, omentum, and retroperitoneum, are known for their wide variability in biologic behavior and for the difficulty in determining their malignant condition. In this multicenter study, 1008 Turkish patients with GIST, were reviewed in order to determine their histopathological features and immunohistochemical profiles. Design: Working Group of GIST in Turkey, developed a nationwide database, including the standardized gross and microscopic features as well as the results of immune antibody panel including CD117, CD34, Desmin, Smooth Muscle Actin (SMA), S-100 protein, and Ki67. The risk of aggressive behavior of the tumors was calculated according to the NIH consensus statement of 2001. Statistical analysis was performed in 1008 cases after the elimination of cases with incomplete data. Pearson correlation analysis was used for describing the linear association between each pathologic features and immunohistochemical expressions. Kruskal Wallis, Mann Whitney U and Spearman tests were performed for nonparametric values. Results:1014 GIST cases were registered into the database by 29 centers from Turkey. In 1008 cases, male to female ratio was 1.24, mean age was 56.45 and 79.14% of them were more than the age of 50 years. The most common location was stomach (42.4%) followed by small intestine, omentum-peritoneum, large intestine, and esophagus (31.1%, 13.1%, 9.5%, 1%, respectively). The risk groups consisted of 5.9% very low, 20.5% low, 18.9% intermediate and 52.2% high risk cases. There were significant relationships ($p=0.01$) between each of the mean size, number of mitoses and Ki67 index. Many other histopathologic features like location, cell type, cellularity, cytologic atypia, infiltrative growth pattern, necrosis, hemorrhage, ulcer and distant metastasis were positively correlated with increasing risk ($p<0.001$). CD117 was positive in 94.7% of GISTs but no significant relation was found between CD117 expression and tumour location and risk groups. CD34, SMA and Ki67 expressions significantly varied in different locations ($p<0.001$). A similar difference was observed in CD34, SMA, Desmin, Ki67 expressions in relation to risk groups: SMA and Ki67 expressions increased in parallel with the risk while CD34 and Desmin decreased. Conclusion: The results of this study demonstrated that features other than tumor size and mitosis, and other immune markers besides Ki67 also seem to be useful predicting factors.

OP19-5
THE SIGNIFICANCE OF APC/BETA-CATENIN PATHWAY AND TGF-BETA/SMAD PATHWAY IN ASSOCIATION WITH MATRIX METALLOPROTEINASES AND THEIR TISSUE INHIBITORS IN THE NEOPLASTIC PROGRESSION OF THE COLORECTAL MUCOSA

Hilal Erinanc[1], Berna Savas[1], Arzu Ensari[1], Sibel Percinel[1], Isinsu Kuzu[1], Mehmet Ayhan Kuzu[2], Mehmet Bektas[3], Hulya Cetinkaya[3], Nazmiye Kursun[4]

[2]Ankara University Medical Faculty,Department of Surgery,Turkey
[3]Ankara University Medical Faculty, Department of Gastroenterology, Turkey
[4] Ankara University Medical Faculty, Department of Biostatistics, Turkey

Background: The classic genetic pathway for the pathogenesis of colorectal cancer (CRC) is based upon the concept of an adenoma-carcinoma sequence. However, in recent years, a "serrated pathway" involving hyperplastic polyp-serrated adenoma-carcinoma sequence has been proposed as an alternative. In the present study, the neoplastic continuum of colorectal mucosa was evaluated in terms of molecules responsible for the initiating events (APC/Beta-catenin pathway) as well as molecules involved in the progression to invasive carcinoma (TGF-beta/Smad pathway together with matrix metalloproteinases and their tissue inhibitors) in a large series of cases represented by tissue array. Method: Core tissue biopsies of 4mm in diameter were prepared from paraffin-embedded tissue blocks of 252 cases, including 11 hyperplasic polyps, 8 serrated adenomas, 98 colorectal adenomas (24 tubular; 24 tubulovillous, 26 villous adenomas, and 24 FAP polyps), 22 adenomas with intramucosal carcinoma, 48 conventional CRC, 24 mucinous CRC, 17 FAP-associated CRC and 24 normal colon mucosae. Sixty two percent of adenomas showed low grade while 38% presented with high grade dysplasia. Immunohistochemistry was performed using monoclonal antibodies to beta-catenin, MMP-2, MMP-7, TIMP-2, TGF-beta1 and Smad4. Distribution of positivity was assessed using percentage expression while an arbitrary grading scale was used for staining intensity. Results: Our results showed that, 24,4% of adenomas and 30% of adenocarcinomas had nuclear beta-catenin expression which was significantly highly expressed in cases with high grade dysplasia ($p<0,001$). MMP-7 expression was significantly higher ($p<0,05$) in adenomas than in normal mucosae and carcinomas while carcinomas at later stages showed stronger MMP-7 expression compared to early stage tumours. MMP-2 expression demonstrated a significant increase ($p<0,01$) in parallel with neoplastic progression. TIMP-2 expression, on the other hand, decreased significantly ($p<0,001$) from normal mucosae to carcinomas in a similar manner as Smad4 expression which also showed a significant decrease through the sequence. Adenomas and carcinomas showed increased TGF-beta1 expression compared to normal mucosae. Expressions of TGF-beta1 and MMP-2 were significantly ($p<0.001$) correlated with the neoplastic sequence. Conclusion: Our results suggest that, MMP-2, MMP-7 and TGF-beta1 seem to take place in early stages of carcinogenesis while beta-catenin and Smad-4 seem to have a role at both early and later stages of the neoplastic sequence of the colorectum.

OP19-6

HER-2 OVEREXPRESSION/AMPLIFICATION IN ESOPHAGEAL DYSPLASIA PREDICTS EARLY TRANSITION TO ADENOCARCINOMA: A CLINICO-PATHOLOGIC STUDY.

Elisa Rossi[1], Vincenzo Villanacci[1], Salvatore Grisanti[2], Domenico Della Casa[3], Guido Missale[3], Luigi Minelli[3], Gabrio Bassotti[4], Piergiovanni Grigolato[1], Renzo Cestari[3]
[1] 2nd Department of Pathology - University of Brescia, Spedali Civili - Brescia, Italy
[2] Department of Medical Oncology, University of Brescia, Spedali Civili - Brescia, Italy
[3] Digestive Endoscopy, Department of General Surgery, University of Brescia, Spedali Civili - Brescia, Italy
[4] Gastroenterology & Hepatology Section, Department of Clinical & Experimental Medicine, University of Perugia, Italy

Background: Barrett's esophagus (BE) is the primary preneoplastic lesion to esophageal adenocarcinoma (ADC). The natural history of metaplasia-dysplasia-carcinoma sequence remains largely not known. The HER2/neu oncogene results to be overexpressed/amplified in preneoplastic lesions and in ADC of the esophagus and it has been associated with poor prognosis. Our aim is to evaluate the value of HER2 overexpression / amplification and other clinical variables in predicting the conversion from preneoplastic lesion to ADC. Methods: We retrospectively analysed clinical records and histological specimens of 14 patients with a confirmed diagnosis of BE or esophageal dysplasia. All patients performed surveillance endoscopic controls at regular intervals or when clinically indicated. Clinical variables included age (≤65/>65), gender, alcohol and smoking intake, presence of symptoms (pirosis, disphagia) and endoscopic features (length). The HER2 status was studied by immunohistochemistry (IHC) and Fluorescence In Situ Hybridization (FISH), on paraffin-embedded tissue. Numerical alterations of chromosome 17 (CEP17) were also evaluated by FISH. The endpoint was the time-to-progression (TTP) from the initial histologic lesion to the worst histologic diagnosis. Univariate analysis of single variables was performed using the Log Rank test and a level of significance of $p<0.05$ was established. Results: Median age at diagnosis was 60 years, 10 patients were male and 4 female. BE median length was 5.2 cm. HER2 was overexpressed/amplified in 8/14 (57%) patients. Median time-to-progression was 39 months. At univariate analysis, age older than 65 years and HER2 overexpression/amplification were the only variables associated with a shorter TTP although, due to the small size of this series, a statistically significant association was not reached. Conclusion: This study provides evidence for a pathogenetic role of HER2 in the transition from low grade to high grade dysplasia and to ADC of the esophagus. HER2-positive cases showed a trend toward an early progression of their initial lesion to a higher grade lesion. This result should be confirmed in a larger study and could help in identification of patients at high risk of malignant transformation.

OP19-7

INTRAHEPATIC MACROPHAGE MIGRATION INHIBITORY FACTOR EXPRESSION AND MIF GENE-173G/C POLYMORPHISM IN NON ALCOHOLIC FATTY LIVER DISEASE

Murat Akyildiz[1], Fulya Gunsar[1], Deniz Nart[2], Osman Sahin[1], Galip Ersoz[1], Zeki Karasu[1], Yucel Batur[1], Funda Yilmaz[2], Ulus Akarca[1]
[1] Ege University Medical School, Department of Gastroenterology, Turkey
[2] Ege University Medical School, Department of Pathology, Turkey

Background: Macrophage migration inhibitory factor (MIF) is a cytokine which plays an important role in the innate immunity. Increased expression of MIF at liver tissue and serum levels had been reported in alcoholic liver disease and chronic hepatitis B infection. In-vitro studies revealed that anti-MIF monoclonal antibodies decreased MIF expression and prevent liver damage by reducing inflammatory response. Aim: to investigate role of the MIF expression and 173G/C polymorphism of the MIF gene in non alcoholic fatty liver disease (NAFLD). Method: 91 patients with diagnosis of NAFLD were included in the study. After informed consent, blood was collected and DNA was obtained from patients and 104 healthy controls. MIF 173 C/G polymorphism was detected using the PCR-RFLP based method. NAFLD were stratified as non alcoholic steatohepatitis (NASH), probable NASH and steatosis, respectively group 1, group 2 and group 3, according to NAFLD study group definitions by a blinded pathologist. Intrahepatic expression of MIF was detected by immunhistochemistry staining. Results: Mean age of patients with NAFLD was 50.1±9.6 (19-69) years, and 54 were male. There were 37/44/10 patients in group 1/group 2/group 3, respectively and demographic features (sex, age, BMI) were similar in all three groups. ALT and AST were found as 50/83, 42/63 and 31/32, respectively in group 1, 2 and 3, ($p<0.05$). MIF expression of hepatocytes were similar in all groups, on the other hand, MIF expression of mononuclear cells was significantly more prominent in both group 1 and group 2 than group 3. There was not any significant correlation between MIF expression of hepatocytes and fibrosis stage. On the other hand, MIF expression of mononuclear cells significantly increased according

to fibrosis stage ($p<0.05$, R:0.2). There was not any significant correlation between MIF genotype and MIF expression in the liver ($p>0.05$). MIF-173 C allele frequency and genotype were similar in all three groups and control group ($p>0.05$). Conclusion: MIF-173 C allele and genotype of MIF gene have no effect on NAFLD subgroups and on expression of MIF in liver tissue in patients with NAFLD. Our results suggest that MIF expression is significantly increased especially by mononuclear cells in liver tissue of patients with NASH secondary to inflammation. Thus, it should be considered as a consequence not a causal factor.

OP19-8
HEPATOCYTE DIFFERENTIATION IN CHOLANGIOCARCINOMA, SUGGESTING HEPATIC PROGENITOR CELL ORIGIN

Mina Komuta, Sara Vander Borght, Raymond Aerts, Baki Topal, Werner Van Steenbergen, Frederik Nevens, Tania Roskams
K. U. Leuven, Belgium

BACKGROUND/AIMS: Cholangiocarcinoma (CC) is a primary malignant liver tumour which is known to have a poor prognosis and the incidence and mortality is increasing worldwide. Recent studies showed that hepatic progenitor cells (HPCs) play a role in the carcinogenesis of hepatocellular carcinoma. The relationship between cholangiocarcinoma (CC) and HPCs have not yet been reported. Since HPCs can differentiate into both hepatocytes and cholangiocytes, we evaluated the hepatocyte differentiation and presence of HPCs in CC. MATERIAL AND METHODS: We studied 93 cases of CC by immunohistochemistry for hepatocellular differentiation markers (Hepar, canalicular polyclonal carcinoembryonic antigen (pCEA), CD10), biliary/progenitor cell markers (cytokeratin (CK) 7, CK19 and neural cell adhesion molecule (NCAM)) and the ATP-binding cassette (ABC) superfamily of membrane transporters (MDR1, MRP1, MRP3 and BCRP). RESULTS: Thirty-seven (39.8%) cases of CC showed hepatocyte differentiation. The morphological features of hepatocyte differentiation was classified into two patterns: (i) a trabecular pattern which show thick trabecular with little stroma consisting of tumour cells with abundant eosinophilic cytoplasm and mild atypia; and (ii) a cord pattern which show atrophic trabecular and/or cord structure of small uniform cells. A trabecular pattern was observed in 17 /37 cases (45.9%), a cord pattern in 16/37 (43.3%) cases, and both patterns in 4/37 cases (10.8%). In these areas, CK7 positive intermediate-sized cells which showed a submembranous staining pattern was observed in all cases, a canalicular staining pattern of pCEA in 30/32 cases (93.8%), CD10 in 21/29 cases (72.4%) and Hepar in 5/24 cases (20.8%). In addition, cytoplasmic CK7 and/or CK19 positive small round oval cells resembling HPCs were present in all cases and also positive to NCAM in 19/24 (79.2%) cases. These immunoshitochemical staining pattern were same in both pattern. BCRP, MRP3 and MRP1 staining showed a basolateral staining pattern and MDR1 showed canalicular staining pattern in both pattern, but the expression was down-regulated in comparison with surrounding normal hepatocyte. CONCLUSION: In our study, about 40% cases of CC showed hepatocyte differentiated features. According to both morphological and immunohistochemical features, these findings strongly suggest a possible HPCs origin of a subset of CC and the fact that MRP1, MRP3 and BCRP are up-regulated, can be responsible for chemoresistance of CC.

OP20-1
MICROMETASTASES IN PELVIC LYMPH NODES IN SURGICALLY TREATED PATIENTS WITH CARCINOMA OF THE CERVIX UTERI ARE OF PROGNOSTIC VALUE

Horn Lars-Christian[1], Galle Dana[1], Hentschel Bettina[2], Bilek Karl[3]
[1] Institute of Pathology, Division of Gynecologic Pathology University of Leipzig, Germany
[2] Institute for Medical Informatics, Statistics and Epidemiology, University of Leipzig, Germany
[3] Department of Obstetrics and Gynecology, University of Leipzig, Germany

Background: Althought, metastatic disease in pelvic lymph nodes is the strongest prognostic factor in carcinomas of the uterine cervix (CX), limited information exist about the prognostic impact of micrometastatic disease (i.e. metastatic deposits < 0.2cm = pN1mic). Methods: Pelvic nodes of 894 surgically treated CX FIGO-stage IB to IIB were histologically re-examined regarding metastatic disease. In cases with lymph node involvement, the metastatic deposits were measured using ocular micrometer. Pelvic lymph node status (pN0 vs. pN1mic vs. pN1 = metastasis > 0.2cm) was correlated to recurrence free and overall survival. Results: 29.7% (266/894) patients represented with pelvic lymph node involvement. 22.1% of these patients showed micrometastases (pN1mic). Patients with macrometasases (pN1) and those with micrometastatic disease (pN1mic) represented significant reduced recurrence free survival (RFS) time (112.6+6.8 and 122.5+9.6 months), when compared to patients without metastatic disease (pN0: 190.9+3.0 months; $p<0.0001$). The 5-year-overall survival (OS) was decreased in patients with metastatic disease (pN0: 86.6%, pN1mic: 63.8%, pN1: 48.2%; $p<0.0001$). Conclusions: The results suggest that micrometastases in pelvic lymph nodes represent an important risk factor for reduced RFS and OS in cervical cancer patients, and all lymph nodes, especially resulting from sentinel lymph node procedure, should be examined very careful histologically.

OP20-2
GENE EXPRESSION IN ENDOMETRIAL CANCER CELLS (ISHIKAWA) AFTER SHORT TIME HIGH DOSE EXPOSURE TO PROGESTINS

Ruth Hracky Paulssen[1], Bjørn Moe[2], Halvor Grønaas[3], Anne Ørbo[4]
[1] Laboratory of Molecular Medical Research, Institute of Clinical Medicine, University of Tromsø, N-9037 Tromsø, Norway
[2] Department of Pathology, University Hospital of North-Norway, Norway
[3] Department of Medical Genetics, University Hospital of North-Norway, Tromsø, Norway
[4] Department of Pathology, Institute of Medical Biology, University of Tromsø, Tromsø, Norway

Background: The potent antiproliferative effect of progesterone and the mimic progestin has been utilized in clinical regimens in the treatment of endometrial disorders. The treatment of endometrial hyperplasia with progestin infiltrated intrauterine device yields in a hundred-fold increase of local progestin concentration in the endometrium compared to per oral treatment. The genetic basis for the complex effects of high dose progestins and the details of the different signalling pathways regulated by these genes has never been accurately surveyed. Therefore, the aim of the present study was to reveal gene expression in highly differentiated endometrial cancer cells (Ishikawa) after short time high dose exposure to progestins. Method: In eight independent experiments cells were treated with progestin (30 mg/ml) for four hours. Cells not treated with progestin served as control groups. Analysis of progestin-treated cells with microarrays representing 24,650 genes identified 939 genes with changed gene expression levels ($p<0.01$). The False Discovery Rate (FDR) was estimated

to be 25%. Genes present on [GTEQ] seven microarrays and with a fold changed expression level threshold set to 1.3 were used for further analysis. Results: Analysis revealed 247 differentially expressed genes of which 126 were up- regulated and 121 were down- regulated. Of these, 135 genes are known to be involved in biological processes like cell cycle, cell proliferation and differentiation, developmental processes, immune responses, intracellular protein traffic and transport. Our study shows that microarray analysis can detect relevant gene expression changes in endometrial cells treated with progestin, and that several alternative transcriptional factors and signalling pathways are involved. In addition, many genes are identified that were not previously known to be affected by progestin or that have unknown biological functions. Conclusion: Characterization of the roles of the differentially expressed genes may give new insights into molecular responses to treatment with high dose of progestins. Alternative signalling pathways for progestin different from the classical steroid receptors are suggested.

OP20-3

EXTRANUCLEAR STEROID-INITIATED SIGNALING BY PROGESTIN AND MIFEPRISTONE: CONCENTRATION DEPENDENT INHIBITION OF ISHIKAWA CELL PROLIFERATION AND INDUCTION OF APOPTOSIS

Bjorn Thorvald Moe[1], Anne Beate Vereide[2], Anne Orbo[1], Georg Sager[3]
[1] Department of Pathology, Univeristy Hospital of Tromsø, Tromsø, Norway
[2] Department of Obstetrics and Gynecology, Univeristy Hospital of Tromsø, Tromsø, Norway
[3] Department of Pharmacology, Institute of Medical Biology, Faculty of Medicine, Univeristy of Tromø, Tromsø,Norway

Background: The anti-proliferative effect of progestins on the human endometrium in vivo and in vitro is well known. Previous studies suggest that at least 60 % of patients with endometrial hyperplasia respond to progestin therapy. In the present study Ishikawa cells(endometrial adenocarcinoma) were used to mimic the in vivo situation. A pharmacological analysis of the effects of progesterone, levonorgestrel and medroxyprogesterone acetate during cell culture was performed to determine sensitivity and the order of potency of these progestins/antiprogestins. Method: Progesterone,levonorgestrel,medroxyprogesterone acetate and mifepristone were added to Ishikawa cell cultures . Cell cycle analysis, detection of early apoptosis by Annexin V-FITC binding, late apoptosis detection by DNA fragmentation and detection of mitochondrial transmembrane potential were performed by flow cytometry employing a FACScan flow cytometer equipped with an argon-ion laser (488 nm). Results: Cells exposed to progesterone (0.32–95mikroM) caused a concentration-dependent reduction in cell densities. Progesterone (95mikroM) caused a reduction of 57±18% (dialyzed FCS),60 (range60-59) % (FCS) and 41±5% (stripped FCS). The respective IC50-values were 53.8±6.7mikroM, 61.5mikroM (range 53.3-69.7) and 50.6±1.0mikroM. Different progestins exhibited differing potencies for inhibition of cell growth: Levonorgestrel (IC50 = 3.9±0.4 mikroM)> medroxyprogesterone acetate (IC50=30.4±3.4mikroM)>progesterone (IC50=60.3±6.2mikroM). Surprisingly, the progesterone inhibitor, Mifepristone (0.2–23mikroM) did not antagonize the antiproliferative effect of progesterone, but had a progesterone-mimicking effect with an IC50value of 19.0±1.7mikroM. High concentrations of mifepristone (23mikroM) and progesterone (32 mikroM) had an additive effect. Both progesterone and mifepristone caused cell cycle arrest in the G1/G0 phase and induced apoptosis. Conclusion: The present study shows that pharmacological concentrations of both progesterone and mifepristone lead to cell cycle retardation and induction of apoptosis. In combination, mifepristone caused an additive effect rather than antagonizing the action of progesterone. Among the progestins tested for their anti-proliferative effect, levonorgestrel was markedly more potent than medroxyprogesterone acetate and progesterone. The present results also suggest that progesterone and mifepristone, in high concentrations, interact with non-classical molecular targets and that the antiproliferative effect is conveyed by signals having an extranuclear initiation.

OP20-4

SEX CORD-LIKE TUMOURS OF THE FEMALE GENITAL TRACT: PATTERN ANALYSIS IN 31 CONSULTATION CASES

Gonzalez-Rocha Talina[1], Stolnicu Simona[2], Aneiros Fernandez Jose[3], Nogales Francisco F. [1]
[1] University of Granada, Spain
[2] University of Medicine Targu Mures, Romania
[3] Fundacion Jimenez Diaz Madrid, Spain

INTRODUCTION: Uterine tumours resembling ovarian sex cord tumours are an unusual group of stromal neoplasms that share a similar appearance with ovarian sex cord tumours. METHODS: We analyzed their clinico- and immunopathologic patterns in an extensive material (31 consultation cases). RESULTS AND CONCLUSIONS: Uterine tumours resembling ovarian sex cord tumours develop in premenopausal patients and their most frequent symptom is vaginal bleeding. Macroscopically, most tumors are intramural nodule (17 cases) or polypoid (10 cases). Some of them can be incidental findings (tumorlets) (2 cases) or may be present in ectopic endometrial tissue (2 adenomyosis, 2 endometriosis). Microscopically, tumours were evaluated for approximate proportions of sex cord, endometrial stromal and other components. Tumours with predominant (over 50%) sex cord differentiation were diagnosed as UTROSCT (22 cases) and tumours with minor sex cord differentiation (less than 50%) were diagnosed as ESTSCLE (4 cases). Four were present in ectopic endometrial tissue (2 adenomyosis. 2 endometriosis). Architecturally, the tumour cells may form trabeculae (87.09 %), nests (35,4 %) solid appearance (32,2 %), retiform pattern (19,3 %) or may be associated with luteinised cells (19,3%). Rare, the tumour cells may form pseudoglandular structures (6,4%). Pseudoglandular or trabecular patterns are usually misdiagnosed in endometrial biopsy. In some tumours, smooth muscle (1 case) or chondroid component (1 case) may be encountered. Immunohistochemically, the tumour cells of the sex cord component are usually positive for Inhibin, CD 10, CAM5.2, Vimentin and Calponin. In two cases where an endometrial biopsy was performed, an erroneous diagnosis of carcinoma was made. Although there is a marked morphologic similarity between sex-cord patterns found in tumours and the corresponding ovarian patterns (granulosa, Sertoli, retiform, etc), there are not immunopathologically identical. The microscopic aspect together with the immunohistochemical features helped us to correct diagnose these tumours and to distinguish them from other malignant epithelial tumours, mixed mullerian malignant tumours which is essential in patient's management.

OP20-5

DISCRIMINATION OF COMPLETE HYDATIDIFORM MOLE FROM PARTIAL HYDATIDIFORM MOLE AND HYDROPIC ABORTION BY IMMUNOHISTOCHEMICAL STUDY OF THE PATERNALLY IMPRINTED GENE PRODUCT P57KIP2:A STUDY OF 120 CASES OF EARLY MOLAR AND NON MOLAR ABORTIONS IN TUNISIA

Landolsi Hanène[1], Yacoubi Mohamed Tahar[1], Gribaa Moez[2], Missaoui Nabiha[1], Hidar Samir[3], Trabelsi Amel[1], Korbi Sadok[1]
[1] Department of Pathology F. Hached Hospital Sousse, Tunisia
[2] Department of Cytogenetics, Tunisia
[3] Department of Gynaecology-Obstetrics, Tunisia

Introduction: Classification of molar gestations into complete (CHM) and partial (PHM) and their differentiation from hydropic abortions (HA) traditionally are accomplished by morphology alone. The process sometimes may be inaccurate of inconclusive

especially in early diagnosed cases. With the availability of p57kip2 immunostaining (the product of a strongly paternally imprinted gene), it may be possible to objectively classify these lesions. Aims: to assess the value of p57kip2 immunohistochemistry in the diagnosis of molar and non molar gestations. Material and method: the immunohistochemical expression of p57kip2 protein was investigated using monoclonal antibody on paraffin embedded, formalin fixed tissue sections of 120 first trimester abortus conceptions. Samples included 95 histologically confirmed molar gestations (65 CHM and 30 PHM), and 25 HA. Results: p57kip2 was strongly expressed in cytotrophoblast and villous mesenchyme in 24/25 HA, 23/30 PHM and 2/65 CHM. Immunostaining of extravillous trophoblast cells, trophoblastic cells within cell columns or islands, and interstitial trophoblast at maternofetal junctional zones was observed as internal positive controls. Syncytiotrophoblastic cells were used as negative controls in all cases. Based on the pattern of p57 staining the cases were reclassified into 25 HA (initial diagnosis (ID): 24 HA and 1 CHM), 24 PHM (ID: 23 PHM and 1 CHM) and 71 CHM (ID: 63 CHM, 7 PHM and 1 HA). Conclusion: differential expression of p57kip2 in CHM and PHM supports the evidence of misexpression of the maternally expressed, paternally imprinted gene in CHM. Therefore immunohistochemical staining with p57kip2 can be a very useful diagnostic adjunct for the differential diagnosis of CHM and PHM or HA in difficult cases. This differentiation is clinically relevant since patients with hydropic abortions do not need to be followed while patients with molar gestations do.

OP20-6

COMPARATIVE CHARACTERISTICS OF EXPRESSION OF MMPS, TIMPS, MARKERS OF PROLIFERATION AND APOPTOSIS, ESTROGEN AND PROGESTERONE RECEPTORS IN EUTOPIC AND ECTOPIC ENDOMETRIUM IN WOMEN WITH ADENOMYOSIS.

Evguenija Kogan[1], Olga Gretchukhina[1], Ara Unanjan[1], Irina Sidorova[1], Vsevolod Kiselev[2]
[1] Moscow Setchenov Medical Academy, Russia
[2] Scientific Research Institute of Molecular Medicine, Russia

Endometriosis is one of the most common diseases of reproductive system in women aged between 20 and 40, adenomyosis is the most frequent type of endometriosis and is found in 70 -90% of all cases. The aim of our study was to investigate the expressions of matrix metalloproteinase 1, 2, 7, 9 (MMP 1, 2, 7, 9) and tissue inhibitors of metalloproteinase 1, 3, 4 (TIMP 1, 3, 4), collagen IV, laminin, fibronectin, proliferating cell nuclear antigen (PCNA), marker of apoptosis (Apo), adhesive molecule (E-cadherin), epidermal growth factor receptor (EGFR), estrogen and progesterone receptors (ER/PR) in foci of adenomyosis and eutopic endometrium. Materials and Methods. The study was performed on biopsy samples of uterus taken from 19 women with adenomyosis. Immunohistochemical staining of tissues was performed with antibodies to MMP-1, MMP-2, MMP-7, MMP-9, TIMP-1, TIMP-4, E-cadherin (Lab Vision), PCNA, collagen IV, laminin, fibronectin (DAKO), Apo, EGFR, ER, PR (Novocastra). Reaction results were evaluated with the help of quantitative and semiquantitative methods and statistic analysis. RESULTS: Stroma in foci of adenomyosis showed higher levels of MMP1, 2, 9, TIMP1, whilst epithelium was more active in expressing MMP7, TIMP4, E-cadherin, EGFR and PR. Stroma in ectopic endometrium have similar levels of expression of MMP 1, 2, 9, TIMP-4, EGFR, PR with those in the basal layer stroma of eutopic hyperplastic endometrium. Active foci of adenomyosis with cytogenic stroma differed from silent areas with fibrotic stroma by the higher expression of MMP2, TIMP1 and e-cadherin in epithelium and MMP2 and TIMP1 in fibroblasts. CONCLUSION: The obtained data suggests that adenomyosis may result from the invasion of endometrium into the myomertium occurs due to the activity of MMPs in stromal elements and increased angiogenesis rather than the activity of glandular epithelial cells. This hypothesis may be proved by similarity of stroma in ectopic and basal layer in eutopic endometrium. Foci of adenomyosis according to their morphology and MMPs, TIMPs and E-cadherin expression may be classified as active and silent.

OP20-7

SERUM AMYLOID A: EXPRESSION AND POSSIBLE ROLE IN OVARIAN CANCER

Diana Prus, Inbar Ben-Shachar, Dalia Galinski, Mark Levin, Simcha Urieli-Shoval
Hadassah-Hebrew University Medical Center, Mount Scopus, Jerusalem, Israel

Background: Serum amyloid A (SAA) is an acute phase protein, whose levels in the blood are elevated in response to trauma, infection, inflammation and neoplasia. Elevated levels of SAA in the serum of cancer patients were suggested to be of liver origin rather than being produced locally in the tumor tissue. The role of SAA in human malignancies has not been elucidated. We investigated the expression and localization of SAA in ovarian serous epithelial tumors and measured the serum concentrations of SAA in patients with ovarian pathology in comparison to CA-125 and C-reactive protein (CRP). Methods: The expression of SAA mRNA was investigated by non-radioactive in situ hybridization using digoxigenin–labeled probes applied on formalin-fixed paraffin-embedded tissue sections from ovarian serous tumors of 23 patients. Sections included 10 serous carcinomas, 5 serous borderline tumors (tumors of low malignant potential) and 8 serous cystadenomas. Protein expression was studied in selected cases using immunohistochemistry. SAA levels were measured in sera of 80 patients with different ovarian pathologies using specific ELISA. Results: SAA mRNA was expressed in all the ovarian tumors, however, its intensity and pattern of expression varied with tumor type. Strong to moderate expression was observed in tumor cells of most ovarian carcinomas (90%). The staining pattern was diffuse in 60% of the carcinomas. Moderate-strong and mainly focal expression was observed in epithelial cells of all 5 borderline ovarian tumors. Weak and focal or negative staining of epithelial cells was observed in 66% of cystadenomas, and focal strong expression was found in the remaining third. Immunohistochemical staining revealed SAA protein expression that co-localized with mRNA expression. CA-125 serum levels were divided into three groups; normal, moderately elevated and highly elevated. The mean values of CA-125 within each of these groups strongly correlated with both SAA and CRP levels. Furthermore, in sera of patients with ovarian malignancies, where CA-125 values were normal SAA levels, although low, were higher than the normal values. Conclusions: Our data demonstrates enhanced expression of SAA in serous ovarian carcinomas, suggesting a role in ovarian tumorigenesis. Furthermore, SAA may serve as an additional serum tumor marker more sensitive than CA-125. Recent studies in our laboratory indicate that SAA plays a role in tumor cell migration, invasion and activity of matrix-degrading enzymes. Our findings may have diagnostic and therapeutic applications.

OP20-8

PROGNOSTIC VALUE OF THE SILVERBERG GRADING IN THE PRIMITIVE MALIGNANT EPITHELIAL TUMORS OF THE OVARY: A STUDY OF 47 CASES

Ben Abdelkader Atef[1], Yacoubi Mohamed Tahar[1], Trabelsi Amel[1], Hidar Samir[2], Abid Lilia[1], Kabir Fatma Zahra[1], Korbi Sadok[1]
[1] Department of pathologyF. Hached Hospital Sousse, Tunisia
[2] Department of gynecology and obstetrics F. Hached Hospital Sousse 4000, Tunisia

Background : Ovarian cancer impose great problems in diagnosis and prognosis. Until now, only the age, the histological type and the clinical stage have a true prognostic value. The aim of our

study is to evaluate the place of Silverberg grade in the prognosis of the ovarian carcinoma. Materiel and Methods: Our study concerned 47 cases of ovarian tumor managed between 1994 and 1998. We determined retrospectively the Silverberg grade based on architectural score, atypia and mitotic index. We defined the grade I when the score is between 3 and 5, grade between 5 and 6 and grade III between 8and 9.We made a correlation between this grade, others prognostic parameters and the survival rate (kappa test). Results: 53% of our patients were aged between 50 and 70 year with an average of 54,8. The predominant histological type was the serous type followed by the mucinous type. 81% of the tumors were diagnosed in FIGO III and IV stage. 23% were Silverberg Grade I , 23% Grade II and 32% grade III. Mucinous and endometroid tumor were respectively in 89% and 100% Silverberg Grade I-II while the clear cell carcinoma was Grade III .The tumors diagnosed in FIGO I-II were Silverberg I-II. The survival rate at 3 years was significantly correlated to Silverberg Grade. Conclusion: Silverberg Grade should be considered in the evaluation of the prognostic and the management of the ovarian tumor. This grade is easily reproducible but it is subjective in the grade II. It should be simplified in two grades; high and low grade .Studies based on large samples should be done in order to evaluate this grade by multivariate analysis.

OP21-1
MICRO-RNA IN HUMAN LUNG CANCER AND HUMAN LUNG EMBRYOGENESIS

Angels Quera, Alfons Navarro, Ramon Marrades, Bernat Gel, Rosa Artells, Sonia Jansa, Josep M Gimferrer, Nuria ViñOlas, Josep Ramirez, Mario Serrano, Antoni Torres, Mariano Monzo
Anatomia Patológica, Neumología, Anatomía Humana, Cirugía Torácica, Oncología. Hospital Clínic. IDIBAPS. Universitat de Barcelona, Spain

INTRODUCTION: Mature microRNAs (miRNAs) are small RNA molecules that act as negative regulators of genes and participate in cell regulation, embryogenesis and cancer. AIM: To analyze if the miRNAs present in lung embryogenesis are also active in lung tumors and which are differentially expressed between tumor and normal lung tissue. METHODS: We studied by Real Time-PCR 18 mature miRNAs (let-7a family, cluster 17-92, mir-155, RNU6B, RNU66) in lung tissue from twelve 7-12-week human embryos and 36 human lung samples (18 tumor and 18 normal). Data were analyzed with BRB Array tools and TIGR M-Viewer. RESULTS: The hierarchical clustering showed four groups: E7-8 embryos, E9-12 embryos, tumor and normal samples. Embryonic samples were closer to tumor samples. To determine common miRNAs during tumor and embryonic development, we analyzed the miRNAs differentially expressed between tumor and embryonic tissues versus normal. miRNAs mir-17-5p, mir-106a, mir-19a, mir-25, mir-93 and mir-98 were overexpressed in tumor and embryos samples and miRNAs let-7a, let-7b, let-7c and let-7g were underexpressed compared to normal samples. We analyzed the miRNAs differentially expressed between tumor and normal samples and we found that mir-106a, 93, 17-5p, 25, mir-98 and mir-19a were significantlly overexpressed and let7-a, let-7c, let-7g and let-7b were significantlly underexpressed. These miRNAs allows to classify a sample as tumoral or normal. CONCLUSION: Due to their similar expression miRNAs of cluster-17-92 and members of let-7 family play a role during the normal lung and tumor development. These miRNAs may be a good targets for new therapeutics strategies. FIS060087, SEPAR06.

OP21-3
IMMUNE-PHENOTYPING OF INFLAMMATORY CELLS IN BRONCHIOLAR INTERSTITIUM OF IDIOPATHIC INTERSTITIAL PNEUMONIAS: PRELIMINARY STUDY

Edwin Parra, Luisa Tinoco, Vera Capelozzi
University of São Paulo Medical School,Department of Pathology, Brazil

Background: Several studies have implicated the role of inflammation in the pathogenesis of lung damage in idiopathic interstitial pneumonias (IIPs). Investigations of inflammatory cells in IIP have show that eosinophils, neutrophils and T cells may be associated with a poorer prognosis. The aim of our study was to map, by quantitative analysis, the number of inflammatory cells in bronchiolar interstitium of patients with non-specific interstitial pneumonia/non-specific interstitial pneumonia (NSIP/NSIP), acute interstitial pneumonia/diffuse alveolar damage (AIP/DAD), and idiopathic pulmonary fibrosis/usual interstitial pneumonia (IPF/UIP). Methods and results: Inflammatory cells [macrophages, neutrophils (Elastase+), CD20 and CD3, CD4, CD8 TLs] were quantified in 8 NSIP, 18 DAD and 24 UIP surgical lung biopsies. The total density of inflammatory cells was significantly increased in DAD and NSIP when compared to UIP (p=0.04). Lymphocytes (CD3 and CD20) were increased in UIP when compared to DAD lungs (p=0.04). The other individual inflammatory cells were not significant differences between groups. Conclusion: Total density of inflammatory cells and lymphocytes present a different distribution within the pulmonary bronchiolar interstitium in AIP/DAD, NSIP/NSIP and IPF/UIP indicate evolutionary adapted responses to active parenchymal injury. Our findings not provide evidence of the participation of inflammation in the bronchiolar interstitum remodeling of IIPs.Financial Support: FAPESP, CNPq

OP21-4
ROLE OF THE MATRIX METALLOPROTEINASES IN THE PATHOGENESIS AND MORPHOGENESIS OF THE CHRONIC CAVITARY PULMONARY TUBERCULOSIS OF THE PERSONS WHO HAS BEEN LIVING IN RADIOACTIVE-CONTAMINATED ZONES OF THE SEMIPALATINSK REGION OF KAZAKHSTAN

Gulmira Sagindikova, Evguenija Kogan
Moscow Medical Academy, Russia

Aim. The object of the work is studying the role of the matrix metalloproteinases in the pathogenesis and morphogenesis of the chronic cavitary pulmonary tuberculosis of the persons who has been living in radioactive-contaminated zones of the Semipalatinsk region of Kazakhstan. Methods. 75 cases of patients with the fibrotic- cavernous tuberculosis of the lung were selected for study. 54 patients living in Kazakhstan regions with high radiation level (group I). 21 patients had been living in Kazakhstan regions (6) and Moscow (15) with normal radiation level (group II). There were 63 males and 12 females with the mean age from 17 to 74 years.. The surgical and endoscopic bronchobiopsy material was studied with light and immunohistochemistry. Paraffin-embedded microwave pretreated sections were stained immunohistichemically to detect the presence of chromogranin A (DAKO), ÌÌĞ-1; ÌÌĞ-2; ÌÌĞ-9, TIMP-1 (LabVision, USA), VEGF, CD34, CD68, Ki-67, TGF-b (DAKO). Results and conclusion. the chronic cavitary pulmonary tuberculosis in patients from Semipalatinsk region of Kazakhstan with high radiation level is characterized by accumulation of MMPs and prominent angiogenesis could be applied for the development of new and pathogenetically grounded trends in therapy.

OP21-5
MMPS AND TIMP- 4 IN REMODELING OF EXTRACELLULAR MATRIX, FIBROSIS, CELL PROLIFERATION IN DIFFERENT VARIANTS OF IDIOPATHIC CHRONIC INTERSTITIAL PNEUMONIAS (ICIP)

Evguenija Kogan, Vuong Tuong, Sophija Demoura
Moscow Medical Academy, Russia

The aim of this study was to evaluate the role of MMPs in pulmonary remodeling and progression of ICIP. Biopsies from 149 patients with ICIP were studied (116 with usual interstitial

pneumonia-UIP, 15 - desquamating interstitial pneumonia-DIP, 11 - nonspecific interstitial pneumonia -NSIP and 7 - bronchiolitis obliterans organizing pneumonia -BOOP). Immunohistochemistry on paraffin section was done with antibodies to MMP1, 2, 7, tissue inhibitor of metalloproteinase 4 (TIMP-4) (Lab Vision), and CD34 (Novocastra). Expression of MMPs and TIMP4 has been analyzed separately in each type of cells (epithelial cells, myofibroblast, fibroblast, macrophages and endothelial cells). Particularity of different variants of ICIP has been established with help of semiquantitative score, ranging from 0-6. Positive and negative controls were used. Results. UIP was characterized by the highest expression of all studied markers, especially MMP-2 in alveolar and interstitial macrophages (3,81± 1,28; P<0,05) as well as fibroblasts (4,50 ± 1,55; P<0,05) and endothelial cells (4,50 ± 1,37; P<0,05). Myofibroblasts, forming subepithelial foci, were positive only for MMP-2 (3,69 ± 1,54 ;P<0,05). In addition, hyperplastic alveolar and bronchiolar epithelial cells contained MMP1, 2, 7 and TIMP-4. Cells in foci of angiogenesis expressed MMP-2. BOOP differed from UIP by the highest MMP-7 expression in bronchiolar epithelial cells (4,50 ± 1,37; P<0,05). Alveolocytes of the II type covered Masson bodies were positive for MMP1, 2, 7 and TIMP-4. MMP-2 was also seen in stroma, especially in foci of angiogenesis (3,98 ± 1,80; P<0,05) . DIP cases showed predominant moderate activity of MMP-2 in alveolar macrophages (3,00 ± 1,41; P<0,05), in fibroblasts (2,00 ± 0,00; P<0,05) and endothelial cells (3,00 ± 1,41;P<0,05); MMP-7 was expressed moderately in alveolar epithelial cells (3,00 ± 1,41; P<0,05) and alveolar macrophages (3,00 ± 1,41; P<0,05) , while MMP-1 and TIMP-4 were at low level. In NSIP we registered low levels of all studied markers. Conclusion. Remodeling of lung interstitial tissue, resulting in interstitial fibrosis, develops through distinct mechanisms with activation of definite cells and production of MMPs are different in UIP, BOOP, DIP and NSIP. High activity of MMP-2 in stromal cells, the presence of hyperplastic epithelial cells and myofibroblasts as the source of MMP1, 2, 7 and TIMP-4 result in most severe reconstruction of lung tissue in UIP. The expression levels of MMPs and TIMP may relate to the differential diagnosis and distinct prognostic features of ICIP.

OP21-6
LATENCY PERIODS AND PATHOGENESIS IN ASBESTOS-RELATED MESOTHELIOMA OF THE PLEURA

Claudio Bianchi, Tommaso Bianchi
Center for the Study of Environmental Cancer - Italian League against Cancer - Monfalcone, Italy

BACKGROUND Latency periods in asbestos-related mesothelioma are defined as time intervals elapsing between first exposure to asbestos and diagnosis of the tumor. The duration of the latency period is a key-point for understanding the sequence of events, that eventually result in mesothelioma. While figures of 20-40 years are generally reported in the literature, some studies indicate far longer periods. METHODS We reviewed a series of 164 malignant mesotheliomas of the pleura, diagnosed in the Trieste-Monfalcone district, northeastern Italy, in the period 2001-2006. This district (total population about 300,000) has been identified as an area with very high incidence of mesothelioma. The diagnosis was confirmed by necropsy in 91 cases. Lifetime occupational histories were obtained from the patients themselves or from their relatives by personal interviews. In 19 cases asbestos bodies were isolated from the lung after the Smith-Naylor method. Latency periods were calculated in 138 cases, in which sufficiently detailed chronological data were available. RESULTS The group, in which latency periods were calculated, included 129 men and 9 women, aged between 43 and 89 years (mean 68.8, median 69.0). A majority of patients (86 people) had been exposed to asbestos in shipbuilding industry. Other sources of exposure included various industries (16 cases), port work (11), maritime trades (9), insulation (4), various (12). Asbestos body burdens, evaluated in 15 cases, ranged between 900 and 230,000 bodies per gram of dried tissue, with nine people showing more than 10,000 bodies per gram, and five people showing more than 50,000 bodies per gram. In 109 cases (79%) latency periods were longer than 40 years. In about 20% of the cases latency periods were longer than 60 years. Mean latency periods differed in the various occupational groups, being 38.5 among insulators, 41.9 among port workers, 42.1 in the various industries workers, 46.0 in the group classified as various, 51.3 among shipyard workers, and 53.7 in maritime trades. Latent periods longer than 40 years were observed even in four patients with very high amounts of lung asbestos bodies (more than 50,000 bodies per gram). CONCLUSIONS The present findings are at variance with those currently reported. The latency periods observed in the present as well as in other series suggest that the presence of asbestos fibers might be for a longtime well tolerated. It is probable that new events (recurrent inflammatory processes? impairment in immune mechanisms?) have to occur before malignant transformation starts.

OP21-7
THE INACTIVATION OF RBM5 TUMOR SUPRESSOR GENE AT 3P21 IS A MOLECULAR PATHWAY ASSOCIATED WITH ADVANCED NON-SMALL-CELL LUNG CANCER.

Julian Sanzortega, Susana HernáNdez, Jose Antonio Lopezasenjo, Elena Sierra, Ana Gomez, Florentino Trancho, Olga Rodriguez, Julian Sanzesponera
Hospital Clinico San Carlos, Spain

Background: 3p21 is a chromosomal region with frequent somatic genetic alterations in Non-small-cell lung cancer (NSCLC). Those changes appear to be more specific in lung cancer than in other malignancies. For many years, different putative tumor suppressor genes (TSG) at this locus has been proposed to play a major role in NSCLC. Recent studies show that RBM5 (LUCA15) located at 3p21 acts as a TSG regulating cell growth and apoptosis and inducing cell proliferation in cell lines. Materials and methods: ARN was extracted from 28 NSCLC frozen tissue samples and hybridized with the CNIO Oncochip 2001 (9216 spots anlyzing 6386 genes): 14 SCC and 14 adenocarcinomas, Stage I –II (n=18) y III-IV (n=10) . A different series of 112 NSCLC paraffin embedded cases: stage I-II (n=95) y III-IV (n=17). Median follow-up 76 months. A tissue microarray was constructed with 0.6-mm cylinders. Immunostaining for VEGF, EGFR, Her2/neu, Cox-2, p21, p27, p16, p53, rb, p120, survivin, caspase3, bcl2, ki67, TopoisomeraseIIa, ECadherin, G-catenin, Mdm2, CDK1, CDK2, Ciclins D1, D3, A, E, MLH1,MSH2, Timidilate sintase, MMP1, MMP9 and in situ hybridization with APOPTAG were performed. Results: Analysis of cDNA microarrays with POMELO tool showed that advanced stages overexpressed cytochrome p450, ubiquitins, TNF. The first genes with differential loss of expression between advanced and early stages were RBM5, nucleoplasmin 3, phosphatase DVSP22, ARF6 and AKT2. Smoker patients showed loss of MFTC and EPB41 expression and FLJ10211 overexpression. Cytokeratin10 differentiates SCC and adenocarcinomas. The immunohistochemical study of a different series of NSCLC showed that the only markers associated with overall survival and tumor progression were CyclinE and CDK2. Discussion: We previously demonstrated LOH at 3p21 in 48% of NSCLC. RBM5 is located at 3p21. RBM5 functions as a TSG downregulating the CyclinE and CDK2 complex that is crucial at the end of G1 phase in cell cycle. Conclusions: Inactivation of RBM5 by deletion and/or other types of mutations as shown by mARN analysis may originate over-expression of both CyclinE and CDK2 stimulating cell proliferation. Our study suggests that this molecular pathway is more frequent in advanced stages of NSCLC.

BACKGROUND: Gastrointestinal stromal tumors (GISTs) are considered to be the most common gastrointestinal mesenchymal tumor.It is generally agreed that the most powerful prognostic factors are size and mitotic counts. GISTs are classified as very low, low, intermediate and high risk groups for their estimated potential for aggressive clinical behavior. DNA aneuplody has been claimed to be discriminative between benign and malignant tumors of gastrointestinal tract, but conflicting results are also existing. The aim of this study was to examine the type of DNA content in risk groups of GISTs. METHOD: We analysed the DNA content of the parafin-embedded tumor specimens of 195 patients selected from the database of GIST working group of Turkey. Tumors were representing four different risk groups. We divided the tumors into two groups as high risk (high risk) and low risk (very low, low, intermediate risk). RESULTS: 88 cases were in low risk group and 107 cases were in high risk group. DNA aneuploidy was detected in 126 cases (67 in high risk, 59 in low risk). There was no significant relationship between DNA content and risk groups ($p>0.05$) We compared the patterns of aneuploidy of high and low risk groups. Hyperdiploidy was detected in 57 cases of the high risk group and 39 cases of the low risk group. Hyperdiploidy was associated with the high risk group ($p<0.05$). Hyperdiploid aneuploidy was also associated with spindle and mixed cellular group. CONCLUSION: The results suggest that DNA aneuploidy presents no difference between the risk groups, whereas aneuploidy patterns (hypo or hyperdiplody) may differ within the risk groups.

OP22-2
TWO PATHWAYS OF CARCINOGENESIS IN PATIENTS WITH COLORECTAL CANCER LESS THAN 45 YEARS OLD

[2] President of Research Center for Gastrointestinal and Liver Disese, Taleghani Hospital, Shahid Beheshti University of Medical Science , Tehran, Iran

Background: Colorectal cancer (CRC) arising from a complex series of molecular changes that involve at least in two different pathways. These include microsatellite instability (MSI) pathway and chromosomal instability (CIN) pathway. The aim of this study was the determination of predominant pathway involved in carcinogenesis of patients with CRC less than 45 years old with and without family history (FH) of CRC. Method: In our study surgical pathology specimens of 108 patients with CRC less than 45 years old were immunostained for DNA mismatch repair proteins (MMRP) including hMLH1, hMSH2, hMSH6 and PMS2. Beta-catenin and P53 were also examined for CIN pathway. Results: Totally 108 patients with median age of 40(20 to 45) were evaluated. Fifty seven patients were male and 51 were female. The site of tumor in 84 patients was colon and in 14 were rectum. Among 96 patients with known family history, 33(34.4%) had positive FH. The overall rate of abnormal immunostaining were MLH1 8.3%, MSH2 18.5%, MSH6 8.3%, PMS2 11.1%, P53 74.1% and beta catenin 35.2%. Meanwhile abnormal staining for hMSH2 and hMSH6 were significantly more seen in patients with positive family history ($p=0.008$ and $p= 0.032$ respectively). Patients with positive FH for CRC had significantly more abnormal MMRP (54.5% vs. 20.6%, $p=0.001$) and less positive p53 (54.5%vs. 81%, $p=0.006$) than patients with negative FH. Patients with early T, N stage tumor had at least one more abnormal MMRP than advance T, N stage ($P=0.050$ for T and $P=0.030$ for N stage). Among different factors abnormal hMSH2 had significant association with lower cancer related death ($P=0.060$). Patients with rectal cancer had more abnormal MMRP than patients with colon cancer but not significantly (35.7% vs. 29.8%, $p=0.655$) and positive p53 staining for rectal and colon cancer were 71.4%and 72.6% respectively. Both in colon and rectal cancer patients with negative family history had more prevalent positive p53 (80.4% vs. 56.7%, $p=0.022$ for colon and 81.8% vs. 33.3%, $p=0.099$ for rectal cancer). Conclusion: Our study indicate that even in CRC less than 45 years old, the main pathway for carcinogenesis in patients with negative family history is CIN, but in positive family history MSI is as effective as CIN.However main pathway in both colon and rectal cancer is CIN .

OP22-3
ADAM17 AND TIMP3 ARE DIFFERENTIALLY REGULATED IN INFLAMED INTESTINAL EPITHELIUM: ROLE NEUTROPHIL TRANSEPITHELIAL MIGRATION

Background: Inflammatory bowel diseases (ulcerative colitis and Crohn's disease)(IBD) in humans are chronic disorders inducing intestinal inflammation. These inflammatory diseases are mainly characterized by a large afflux of PMNL into the mucosa causing the release of several cytokines such as TNF alpha. This latter cytokine requires cleavage of a transmembrane precursor protein to release the biologically active form. The protease responsible for this cleavage is the TNF alpha-converting enzyme (TACE, ADAM17) which is mainly regulated by TIMP3. Aims: to determine the status of ADAM17 in intestinal epithelium during the transepithelial migration of PMNL and in inflamed mucosa of patients with Crohn’s disease and then to elucidate the molecular mechanism (s) of such modulation. Methods: we used both an in vitro model of human neutrophils migration (T84 model) and an ex vivo approach from a collection of human digestive tissues.

ADAM17 expression was checked by RT-PCR, Western blotting and immunohistochemistry. Results: ADAM17 was up-regulated during PMNL transepithelial migration and in digestive biopsies associated with acute phase of IBD showing strong afflux of PMNL and crypt abcesses, independently of NOD2 mutations. Timp3 expression into the intestinal cells was decreased after 4 h of migration, but decreased or increased in digestive biopsies, depending of the disease activity (presence or not of afflux of PMNL and of crypt abcesses). In the absence of acute phase of inflammation, digestive biopsies showed a weakly expression of ADAM17. Finally, proinflammatory cytokines induced ADAM17 upregulation in T84 cells. Conclusion: Taken together, these results strongly suggest an early upregulation of ADAM17 in intestinal epithelial cells during PMNL transepithelial migration linked to proinflammatory cytokines production, whereas Timp3 is down regulated during the early phase of neutrophil migration.

OP22-4

CARDIAC RATHER THAN INTESTINAL-TYPE BACKGROUND IN ENDOSCOPIC MUCOSAL RESECTION SPECIMENS OF PRIMARY ESOPHAGEAL ADENOCARCINOMA

Kaiyo Takubo[1], Junko Aida[1], Tomio Arai[1], Manfred Stolte[2], Michael Vieth[2]

[2] Institute of Pathology Bayreuth Klinikum, Bayreuth, Germany

Background: The most important complication of Barrett's esophagus is adenocarcinoma, and recently the incidence of Barrett's adenocarcinoma has been increasing very rapidly, especially in male Caucasians in Western countries. It is widely accepted that intestinal-type mucosa in the columnar-lined esophagus (CLE) is the probable common precursor of adenocarcinoma. Many publications focusing on the background or original mucosa of Barrett's adenocarcinoma have maintained that adenocarcinoma arises in intestinal-type mucosa with goblet cells in the CLE, and this has become a central dogma. Materials and Methods: The mucosa on each side of a series of 151 small esophageal adenocarcinomas endoscopically resected was recorded as the background mucosa. The mucosae were classified as squamous, fundic-type, cardiac-type, and intestinal-type on the basis of routine histopathology, mucin staining (alcian blue, pH 2.5) and immunohistochemical staining (MUC-2, human gastric mucin, MUC-6, CD10). Histologic evaluation was performed by five Japanese and German pathologists. The type of mucosa on both sides, immediately adjacent to the adenocarcinoma, was recorded. The 151 adenocarcinomas were classified on the basis of Japanese criteria, according to the Japanese Classification of Gastric Carcinoma, 2nd English edition. Results and Discussion: The present joint pathologic examination of the background mucosa of Barrett's adenocarcinoma conducted by Japanese and German pathologists found that about 70% of primary early and small adenocarcinomas of the esophagus were adjacent to cardiac-type rather than intestinal-type mucosa. In other words, there was no evidence to support the previously held view that Barrett's adenocarcinoma is nearly always accompanied and preceded by intestinal-type mucosa. Conclusion: Follow-up is recommended irrespective of whether intestinal-type or cardiac-type mucosa is found in biopsy specimens from CLE. Also, it seems better to define Barrett's esophagus as metaplastic CLE alone, without requiring the presence of goblet cells.

OP22-5

CONFLUENT BASAL APOPTOSIS IN COLONIC ADENOMAS: MORPHOLOGY, POTENTIAL FUNCTIONAL SIGNIFICANCE, AND PRELIMINARY REVERSE PHASE MICROARRAY FINDINGS FOR APOPTOSIS-RELATED PROTEINS

BACKGROUND: Apoptosis extent and pattern differs among colonic adenomas,and may correlate with progressive alterations in cell proliferation,growth,and increasing genomic instability.We(Brodie et al 2004)have reported that the confluent basal pattern of apoptosis very significantly correlates with small([LTEQ]5mm)adenoma size,whereas the crypt luminal apoptosis pattern correlates with larger adenomas and high grade dysplasia,and is the typical apoptosis pattern of adenocarcinoma. In this study we extend observations on confluent apoptosis and present preliminary tissue proteomics results for apoptosis/cell proliferation proteins in colonic tumourigenesis. METHODS: Fifty sequential colorectal biopsies of tubular adenomas with low grade dysplasia ([LTEQ]5m) were assessed as previously described by Brodie et al (2004). The definition of confluent basal apoptosis was expanded to include those crypts in which clusters of basal apoptotic bodies were discontinuous but overall measured at least the equivalent of the crypt diameter.Fresh tissue from separately processed colonic tissue samples (normal colonic mucosa,adenomas, and colonic adenocarcinomas) was subjected to laser capture microdissection and processed for reverse phase protein microarrays(Paweletz, 2001).Lysates were probed for 17 apoptosis related proteins,including those of the MAPK cell proliferation and differentiation pathway. RESULTS: All small adenomas had basal apoptosis. Twenty-one (42%) small tubular adenomas had confluent basal apoptosis, and 29 (58%) had scattered basal apoptosis.Confluent basal apoptosis was conspicuous but focal in each adenoma section, often sparing crypts.It was most prominent at crypt convolutions and branching points.Preliminary tissue proteomics results: There was differential expression of several probed proteins e.g. pAkt,pFAK,MEK,pMEK in adenocarcinomas.In 2 large adenomas there was differential expression of EGFR and pAKT. However,there were no consistent alterations in small adenomas. CONCLUSION: Variations in tumour morphology often reflect specific molecular or pathogenetic mechanisms, some of which may become the basis of new therapies.Confluent basal apoptosis may be considered a typical but very distinctive feature of early tubular adenomas and tubulovillous adenomas. Because it is prominent in convolutions and branch-points we will investigate whether it represents anoikis(apoptosis due to cell-cell or cell-matrix detachment),using reverse phase arrays to probe integrins and other proteins on lysates prepared from paraffin sections and confocal microscopy.

OP22-6
PROGNOSTIC AND PREDICTIVE VALUE OF THYMIDYLATE SYNTHASE EXPRESSION IN COLON CANCER

Background: Surgery is the primary treatment of colon cancer, resulting in cure in approximately 50% of patients, while recurrence following surgery remains the major problem. Treatment with 5-fluorouracil (5-FU) significantly improves patients' survival rate. The antitumor effect of 5-FU has been ascribed to a number of mechanisms including a competitive inhibition of thymidylate synthase (TS, EC 2.1.1.45), an enzyme responsible for DNA synthesis. Aim of our study was to examine the clinical importance of TS expression in colon cancer, and to correlate it with various clinicopathological parameters and patients´ outcome. TS expression was also correlated with tumor cells' proliferative capacity and the expression of cell cycle related molecules (cyclin D1, cyclin E, pRb, p16 and p21). Methods: TS expression was examined immunohistochemically on paraffin-embedded tissue sections obtained from 71 patients, who underwent surgical resection due to colon cancer without preoperatively administration of chemo- or radiotherapy. TS positivity, was correlated with patients' age and gender; tumor location, Dukes' stage, histological grade, and proliferative capacity (Ki-67 immunohistochemical expression); as well as with patients' final outcome. Additionally, TS expression was correlated with that of cyclin D1, cyclin E, pRb and p21, detected immunohistochemically. Result: Positivity for TS was found in 51 out of 71 (71.83%) colon cancer cases, being statistically significantly correlated with patients´ gender (P=0.012) and tumor histological grade (P=0.032). TS expression was also positively correlated with the expression of pRb and p16, (P=0.001 and P=0.001, respectively), while a positive trend for cyclin E (P=0.042) was noted. The overall five years survival rate was 40% for TS positive patients and 68.6% for TS negative ones (P=0.0134). In patients aged more than 70 years, the five years survival rate was 30% for TS positive and 77.8% for TS negative ones (P=0.0008). In multivariate analysis of survival (9 variables, including TS), TS expression proved of prognostic significance (P=0.0174). Conclusion: TS was expressed in the majority of colon cancer cases examined, being statistically significantly correlated with clinicopathological parameters and the expression of cell cycle-related molecules. The prognosis of TS positive patients was worse than that of TS negative, especially in patients older than 70 years. Multivariate analysis confirmed that TS expression can be used as an independent prognostic risk factor for colon cancer patients.

OP23-1
HUMAN PAPILLOMAVIRUS (HPV) PROFILES OF VULVAR LESIONS: POSSIBLE IMPLICATIONS FOR THE CLASSIFICATION OF VULVAR SQUAMOUS CELL CARCINOMA PRECURSORS AND FOR THE EFFICACY OF PROPHYLACTIC HPV VACCINATION

Petr Skapa[1], Josef Zamecnik[1], Eva Hamsikova[2], Martina Salakova[2], Jana Smahelova[2], Kristyna Jandova[3], Helena Robova[3], Lukas Rob[3], Ruth Tachezy[2]
[1] Department of Pathology and Molecular Medicine, Charles University, 2nd Medical School, Faculty Hospital Motol, Prague, Czech Republic
[2] Department of Experimental Virology, National Reference Laboratory for Papillomaviruses, Institute of Hematology and Blood Transfusion, Prague, Czech Republic
[3] Department of Obstetrics and Gynecology, Charles University, 2nd Medical School, Faculty Hospital Motol, Prague, Czech Republic

Background: The term vulvar intraepithelial neoplasia (VIN) was introduced by the International Society for the Study of Vulvovaginal Disease (ISSVD) in 1986 and incorporates three grades of usual VIN (u-VIN I-III) and the differentiated VIN (d-VIN). While u-VIN is associated with the human papillomavirus (HPV) infection, d-VIN belongs to the HPV negative pathway of vulvar carcinogenesis. In the revised ISSVD 2004 classification, the u VIN I category was abandoned and u-VIN II and III were merged. Further, an alternative Bethesda-like terminology presenting the term vulvar intraepithelial lesion (VIL) was proposed. To analyze the validity of the newly introduced classifications of vulvar precancerous lesions and to assess the presumable efficacy of the prophylactic HPV vaccination, we correlated histopathological features and HPV profiles of various vulvar non-neoplastic, precancerous and neoplastic lesions. Method: The total of 269 vulvar excisions representing lichen sclerosus (n=35), lichen simplex chronicus (n=14), condylomata acuminata (CoA; n=57), d-VIN (n=12), all grades of u-VIN (n=82) and squamous cell carcinomas (SCC; n=69) were subjected to the HPV typing by use of GP5+/6+ PCR and reverse line blot hybridization. Detected HPV types were stratified into low-risk (LR), high-risk (HR), probably high-risk and undetermined-risk groups. Histopathological categorization of vulvar lesions was correlated with their HPV profiles. Results: High prevalence of HPV DNA was found in CoA (94.7%) and u-VIN (98.8%) being lower in SCCs (42%). While LR-HPV types prevailed in the HPV positive CoA (96.3%), HR-HPV types (especially HPV 16, 33 and 45) were detected in the majority of the HPV positive u-VIN (97.6%) and SCCs (93.1%). A tendency to the multiple-type HPV infection was observed in CoA (17.5%) and u-VIN II (41.7%). Importantly, our results showed differing HPV profiles, as well as the frequency of multiple-type HPV infection and the age structure in patients with u-VIN II and III. The biological heterogeneity within the u-VIN II group was also demonstrated. U-VIN I was distinguished as a rare disorder associated with HR-HPV. Conclusion: The ISSVD 1986 terminology seems to be optimal for the classification of vulvar precancerous lesions. The spectrum of HPV types found in vulvar SCCs indicates that the efficacy of HPV vaccination in the prevention of vulvar cancer might be decreased in the studied population, because prophylactic vaccines are targeted against a limited number of HPV types. OP23-2
FASCIN IMMUNOHISTOCHEMICAL INVESTIGATION IN ENDOMETRIAL STROMAL SARCOMAS AND PRIMARY UTERINE LEIOMYOSARCOMAS

Mattheos Bobos[1], Evangelia Athanasiou[2], Dimitrios Hatziboughias[1], Georgia Rapti[1], Athanasios Papanikolaou[3], Anastasios Hatzitolios[3], Ioannis Efstratiou[4], Eleni Nenopoulou[1]
[1] Department of Pathology, Aristotle University Medical School, Thessaloniki, Greece
[2] Department of Pathology, Faculty of Health and Care, Alexandrian Technological Institute, Thessaloniki, Greece
[3] Department of Pathology, "Hippokration" General Hospital, Thessaloniki, Greece
[4] Department of Pathology, "Papageorgiou" Hospital, Thessaloniki, Greece

Background: Endometrial stromal sarcoma (ESS) of the uterus is a rare uterine neoplasm. It accounts for approximately 10-13% of uterine sarcomas and 0.2% of all uterine malignancies. There are two types of ESS: low-grade ESS (LGESS), and high-grade ESS (HGESS). Primary uterine leiomyosarcomas (LM) comprise approximately 1% of uterine malignancies. Often issues of differential diagnosis arise when a pathologist encounters a tumor (especially in endometrial biopsy material) with high cellularity, increased mitotic index and areas of necrosis. Recent reports indicate that immunohistochemistry can be useful in affording a

distinction. In the present study we assessed the usefulness of fascin in distinguishing these two neoplasms Methods: 17 ESS and 11 LM cases were collected from 4 different Institutes for the period 1998-2006. Representative sections from FFPE tissue blocks of the tumors were re-cut and stained in automated staining system using the mAb NCL-Fascin. Results: The mean age of the patients with ESS was 52 years (range 25-71), while for LM was 63 years (48-89). 12/17 ESS was of low histologic grade. Fascin expression was detected in 16/17 ESS (12/12 LGESS; 5/6 HGESS) and in 8/11 LM. Conclusions: As our data indicates fascin is widely expressed in both investigated groups of sarcomas (94% for ESS vs 73% for LM). Given what is currently known about fascin, the widespread immunoexpression of fascin in primary uterine sarcomas of stromal and smooth muscle differentiation may indicate a potential factor in tumor cell infiltration and a risk factor of pelvic recurrence.

OP23-3

COXSACKIEVIRUS ADENOVIRUS RECEPTOR (CAR) EXPRESSION IN ENDOMETRIAL ADENOCARCINOMA

Stamatios Theocharis[1], Constantinos Giaginis[1], Maria Papaefthymiou[1], Ekaterini Papadopouli[1], Ioannis Sfiniadakis[2]
[1] Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Greece
[2] Department of Pathology, Naval Hospital, Athens, Greece

Background: Coxsackievirus adenovirus receptor (CAR) functions as the primary receptor for both coxsackie B viruses and adenoviruses, playing a crucial role for their entry into host cells. CAR expression on target tumoral cells is correlated with their sensitivity to adenoviral infection. Tumoral cells lacking or expressing low CAR levels are resistant to adenovirus infection and to efficient oncolysis by recombinant adenoviruses. The aim of our study was to examine CAR expression on clinical material of endometrial adenocarcinoma and to correlate it with clinicopathological parameters, tumors' proliferative capacity and patients' survival. Methods: CAR expression was detected immunohistochemically on paraffin-embedded tissue sections of 41 endometrial adenocarcinoma cases. CAR positivity, overexpression (expression in more than the mean percentage value), and intensity of immunostaining were correlated with patients' age and FIGO stage; tumors' histopathological type (adenocarcinoma with or without squamous elements) and grade of differentiation, proliferative capacity (Ki-67 immunohistochemical expression); and patients' survival. Results: CAR positivity was noted in 23 out of 41 (56%) endometrial adenocarcinoma cases and CAR overexpression in 8 out of 23 (35%) positive cases. CAR intensity of immunostaining was classified as mild in 11 (48%), moderate in 10 (43%) and intense in 2 (9%) out of the 23 positive cases. CAR positivity was statistically significantly correlated with tumors' histopathological grade of differentiation (p=0.036). CAR intensity of immunostaining was statistically significantly correlated with tumors' histological type (p=0.016), as cases possessing squamous elements presented more frequently intense CAR immunostaining. CAR overexpression also presented a trend of correlation with tumors presenting increased proliferative capacity (p=0.057). CAR positivity, overexpression and intensity of immunostaining were not statistically significantly correlated with the other clinicopathological parameters examined and patients' survival. Conclusion: Our data reveal, for the first time, the expression of CAR protein in clinical material obtained from patients with endometrial adenocarcinoma in correlation with clinicopathological parameters. As CAR appears to modulate the proliferation and characteristics of cancer cells, playing a crucial role in malignant transformation, its expression is considered of possible clinical importance in the future.

OP23-4

EXPRESSION AND PROGNOSTIC SIGNIFICANCE OF CYCLIN D3 IN OVARIAN ADENOCARCINOMAS

Georgia Levidou, Penelope Korkolopoulou, Irene Thymara, Angelica A Saetta, Ioannis Vassilopoulos, Hariclia Gakiopoulou, Anastasia Konstantinidou, Evi Kairi-Vassilatou, Kitty Pavlakis, Efstratios Patsouris
National and Kapodistrian University of Athens, Department of Pathology, Athens, Greece

Background: Abnormal expression of cell cycle regulators may contribute to malignant transformation. Cyclins are prime cell cycle regulators which play a key role in the control of major checkpoints of cell cycle progression. Recently, experimental data have been published implying that the relationship between D-type cyclins and oncogenesis may not be as simple as initially thought, given the emerging dual role of cyclin D1 and D3 as regulators of both cell cycle progression and arrest. For example, cyclin D1 overexpression is associated with unfavourable prognosis in pancreatic carcinoma and serous ovarian adenocarcinoma, but with a better survival in breast, hepatocellular and lung carcinoma Moreover, the clinical significance of the expression of cyclin D3 in ovarian cancer remains undefined. We therefore conducted a retrospective investigation to address the role of this cell-cycle protein in this tumour. Methods: In our study, paraffin-embedded tissue from 109 non-benign epithelial ovarian tumours, including 17 tumours of low malignant potential and 92 primary adenocarcinomas, was stained immunohistochemically for cyclin D3 by using a mouse monoclonal anti-cyclin D3-antibody and a sensitive polymer-based system. Most of the cases had previously been stained for pRb, p21Cip1, p27Kip1, p53, and Ki-67 antigen. Expression of cyclin D3 was correlated with clinicopathological features, the expression of other cell cycle regulators, and postoperative survival of patients. Results: Cyclin D3 levels were significantly higher in tumours of low malignant potential than in adenocarcinomas (P = 0.0002). In the latter group, cyclin D3 expression decreased with increasing grade (P = 0.0004) and advancing stage (P = 0.0315). Cyclin D3 expression positively correlated with pRb, p21Cip1, and p27Kip1 levels (P = 0.0021; P = 0.0036; P G 0.0001, respectively) and negatively with p53 and Ki-67 (P = 0.0003; P G 0.0001). Absent cyclin D3 expression was an important indicator of poor survival in univariate analysis in the entire cohort (P 9 0.00010) and in the platinum-treated patients (P = 0.001) and in multivariate analysis (P = 0.044). Conclusions: Our results demonstrate that absent or decreased cyclin D3 expression is adversely related to several clinicopathological indicators of aggressiveness in ovarian adenocarcinomas and is combined with a better prognosis, suggesting that cyclin D3 may have a biological role distinct from that of other G1 cyclins which is possibly regulated through interaction with other cell cycle genes.

OP23-5

EXPRESSION OF AMP-ACTIVATED PROTEIN KINASE (AMPK) IN OVARIAN CARCINOMA: CORRELATION WITH TUMOR GRADING AND PROGNOSIS

Ann-Christin Buckendahl, Wilko Weichert, Silvia Niesporek, Aurelia Noske, Manfred Dietel, Carsten Denkert
Institut of Pathology, Charité Universitätsmedizin Berlin, Germany

Background: Adenosine monophosphate (AMP)-activated protein kinase (AMPK) plays a central role in regulating the energy metabolism in cells. In addition, activated AMPK is known to inhibit the mTOR pathway in cancer cell lines, which leads to an attenuation of cell growth and proliferation. The recently identified upstream kinase of AMPK is LKB1, a known tumor suppressor in Peutz-Jeghers syndrome. However, little is known on AMPK expression in human malignant tumors. Method: To address this apparent lack of translational information, we

investigated AMPK expression in normal ovaries (n=5) and in tissue microarrays (TMA) of ovarian tumors (n=84) by immunohistochemistry. We correlated our findings with clinicopathological patient characteristics and progression free as well as overall patient survival. Results: We observed loss of cytoplasmic AMPK expression in 44.3% of ovarian carcinomas. A decrease in AMPK expression correlated with higher tumor grade (p=0.009). High expression of AMPK was significantly associated with prolonged overall survival time in patients with advanced tumor stages (p=0.016) as well as in patients with serous ovarian tumors (p=0.037). Conclusion: Our study shows that loss of AMPK is more prevalent in poorly differentiated ovarian carcinomas and might serve for an important and large subgroup of ovarian cancer patients as a predictor of poor survival, which underscores its biological significance. This hints on AMPK as an attractive target for novel antineoplastic treatment strategies.

OP23-6

FALLOPIAN TUBE EPITHELIUM: THE IGNORED HYPOTHETIC ORIGIN OF GYNECOLOGIC SEROUS CARCINOMAS

Isil Yildiz[1], Alp Usubutun[1], Ali Ayhan[2], Turkan Kucukali[1]
[1] Hacettepe University, Faculty of Medicine, Department of Pathology, Ankara, Turkey
[2] Hacettepe University, Faculty of Medicine, Department of Gynecology, Ankara, Turkey

BACKGROUND: Tubal inner surface epithelium, due to its histological resemblance to the neoplasm, has been suggested as one of the possible tissues of origin for serous female tumors for a long time. We aimed to make an immunohistochemical and morphological comparison between normal and abnormal looking tubal epithelium of two different serous tumor groups (ovarian and peritoneal) . METHOD: Fallopian tube samples from 26 cases of ovarian, 28 cases of peritoneal serous carcinomas were included.Tissue array blocks containing 2 to 4 samples, from each case were prepared. For immunohistochemical study p16, p53, WT1, CD24, calretinin and Ep-CAM antibodies were used. For all antibodies, cases were evaluated for staining rate, intensity and pattern seperately. Cytoplasmic and membranous staining for CD24, membranous staining for Ep-CAM, nuclear and/or cytoplasmic staining for p16, p53 and WT1 were taken into evaluation. RESULTS: The intensity of p16 staining was strong in ovarian (57,7%) and the peritoneal group (60,7). Peritoneal carcinoma group had the highest number of diffusely positive cases for p16 (35,7%-10/28). It was noted that strong and diffuse p16 and p53 positivity always accompanied the obvious atypical changes in the tubal epithelium.Two peritoneal cases were found to display p16 and p53 positive atypical changes in the tubal epithelium. CD24 showed strong and diffuse positivity in both groups. CD24 showed cytoplasmic staining in 15,4% of ovarian and 21,4% of peritoneal cases. Ep-CAM displayed similar staining intensity and rate with CD24. Over 57,1% of the tubal epithelium of the ovarian and peritoneal cases showed strong and diffuse positivity with WT1.Calretinin was mostly negative and weak in intensity in both groups. CONCLUSION: Existence of atypical changes associated with strong and diffuse expression of p16 and p53 in the tubal epithelium of both the ovarian and peritoneal serous carcinomas and variable expression of these markers in normal-looking tubal epithelium is an important finding. Also, in a few areas, the cytoplasmic expression of CD24 was noted instead of the expected membranous staining. These observations may support the hypothesis of common tubal origin for ovarian and peritoneal serous carcinomas. Prospective studies in which the whole fallopian tube is sectioned are required for further support.

[5] Laboratory of Clinical and Experimental Pathology, INSERM ERI-21, Human Tissue Biobank, University of Nice, Nice, France

An important problem in the diagnosis of lung bacterial infection is the evaluation of microbiological results. Moreover, histological approach of bacterial pneumonia does not allow to make an etiological diagnosis, since a precise identification of bacilli and cocci is impossible in paraffin sections, most of the time. In situ hybridization is gaining popularity and with the development of automated and more standardized methods, it is becoming more widely available and more cost effective. This method has been used to detect the presence of a variety of microorganisms in tissue sections. Although it is most commonly used to detect viral targets, in situ hybridization can also been used to detect bacteria. The aim of this work was to identify different bacteria species in lung tissues using FISH method and to compare the signal obtained in different specimens fixed in formalin and in alternative preservation methods (RCL2, Excell plus, Glyofix, Finefix solutions). We used a series of 10 patients with bacterial pneumonia and the following probes: the oligonucleotide probe EUB338, which binds to the 16S RNAs of all eubacteria, Spn pB-00350 (Streptococcus peumoniae), PseaerA pB 00384 (Peudomonas aeruginosa), Sau pB 00349 (Staphylococcus aureus), and EC01167-ECO 45A pb-00115 (Escherichia coli). The results obtained by fluorescence microscopy can be summarized as follows: i) hybridization with the positive control (EUB338) revealed that all eubacterial cells are visualized by this technique without any difference according to the fixative, ii) 5 cases showed different associated bacteria species (S. pneumoniae and P. aeruginosa: 3 cases; S. pneumoniae and E. coli: 2 cases), iii) 2 cases revealed the presence of S. aureus, and iv) 3 cases were negative with the specific probes used in this study. In conclusion, FISH method using probes against bacteria can be performed after formalin fixation and different alternative preservation methods. This method increases the specificity and in some instances may increase the sensitivity of histopathologic tests. FISH method may be particularly useful when bacteria are present in low numbers, stain poorly, are uncultivable, or exhibit an atypical morphology.

OP24-2

MOST LUNG CARCINOMAS ASSOCIATED WITH IDIOPATHIC PULMONARY FIBROSIS SHOW FEATURES OF BRONCHIOLAR DERIVATION

Marco Chilosi[1], Venerino Poletti[2], Daniela Reghellin[1], Sara Tomassetti[2], Alberto Cavazza[3], Giulio Rossi[4], Marianne Kambouchner[5], Alessandra Cancellieri[6], Alessandra Dubini[7], Mattia Barbareschi[8], Licia Montagna[1], Serena Pedron[1], Paola Piccoli[1], Giuseppe Pelosi[9], Bruno Murer[10]

[10] Department of Pathology, Mestre Hospital, Italy

The association of lung cancer and idiopathic pulmonary fibrosis (IPF) is a well known event, but the pathogenesis of this association is poorly understood. According to recent data, the pathogenesis of IPF is not inflammatory, but related to abnormal tissue remodelling following chronic damage. In previous studies we proposed that abnormal bronchiolar proliferation is a major event in IPF, triggered by molecular abnormalities (wnt/beta-catenin, p53/p21waf1 pathways) involving progenitor basal cells at the bronchiolo-alveolar junction. In this study we have investigated the morphologic and immunophenotypic features in a series of lung carcinomas developed in patients with IPF. Material and Methods. Paraffin blocks of 17 cases of lung cancer arising in patients with IPF were retrieved from the files of our Institutions and analyzed using a panel of markers useful for characterising different epithelial cells and airway (basal cells) and alveolar (pneumocyte type II) precursor cells. Results. Overall there were 6 peripheral squamous carcinomas, 8 adenocarcinomas, 2 large-cell carcinomas and 1 small-cell carcinoma. Among adenocarcinomas 3/8 exhibited a peculiar and rare immunophenotype consistent with metaplastic-enteric type carcinoma as defined by the expression of the intestinal markers cdx-2, MUC2, and villin. 2 cases were classified as mucinous-BAC, and expressed at high level MUC5, a mucin expressed by goblet bronchiolar cells. Other 2 were conventional adenocarcinomas lacking surfactant protein-A (SPA). Only two cases (one adenocarcinoma and one large-cell carcinoma) showed focal expression of the Clara-cell CC10 antigen and SPA. A single large-cell carcinoma showed lymphoepithelioma-like features with focal expression of squamous markers such as CK5 and DN-p63. Abnormal p53 expression (>50% positive cells, with concomitant low/absent p21waf1) was demonstrated in 4/6 squamous carcinomas, both large-cell carcinomas, and 2/8 adenocarcinomas. Conclusions. Striking divergence from carcinoma cases observed in non-IPF patients, including the prevalence of rare entities, is shown. The peculiar features of our series suggest that most cases have a “bronchiolar” derivation, in line with the proposed model of IPF pathogenesis. In particular, the expression of pneumocyte-related markers was rare, whereas the expression of an enteric-type “metaplastic” phenotype was exceedingly represented (37,5%). It is possible to speculate that also the peripheral squamous carcinomas can be considered as “metaplastic”, arising from transformed bronchiolar basal cells.

OP24-3

INFLAMMATORY MYOFIBROBLASTIC TUMOUR OF THE LUNG – MORPHOLOGY DECEIVES HISTOGENESIS

Lina Carvalho[1], Conceicao Moura[2], Rosete Nogueira[3], Ana Paula Martins[4], Eugenia Pinto[5], Ana Gomes[1], Maria Joao Falcao[1], Maria Silva[1]
[1] Pathology Institute, Medical Faculty, University of Coimbra, Portugal
[2] Hospital São João, Porto, Portugal
[3] Hospital Vila Nova Gaia, Gaia, Portugal
[4] Hospital Sta Cruz, Carnaxide, Portugal
[5] Hospital Santa Marta, Lisboa, Portugal

Inflammatory myofibroblastic tumours (IMT) are represented by spindle cells, lymphocytes, plasma cells, macrophages and variable collagen deposition. Children and adults present this tumour that arises mainly in lung and also in mesentery and retroperitoneum. Being a rare tumour, 19 cases were collected from the archives of five Departments of Pathology to be studied under an immunohistochemical and genetic point of view to follow the pass of histogenesis. The patients had been submitted to lobectomy (14 cases) or pulmonary resection (5), there were 10 females and 9 men with ages ranging from 19 to 65 years. The immunohistochemical panel was chosen in order to determine the properties of the tumour spindle cells and also to allow differential diagnosis with the other spindle cell tumours of the lung; vimentin was demonstrated in all cases indicating the validity of this study based in formalin-fixed paraffin-embedded tissue; actin and calponin were revealed in 18 cases; CD68 was a constant marker in spindle cells. The antibodies directed to search dendritic cell differentiation (CD35; CK8 and CK18) were weakly positive in 4 cases. The ALK antibody applied (ALK1, DAKO) was revealed in 5 cases. FISH analysis was performed in all cases, corresponding to paraffin-embedded tissue, by the application of the Vysis LSI ALK probe assay. Only 6 cases showed till 5% of cells with the split signal indicating a translocation of the ALK gene. In these cases it was not possible to reveal the ALK antibody by immonohistochemistry. In this study it was clear an immunohistochemical macrophagic differentiation of the spindle cells in all the 19 cases of IMT of the lung classified according with the criteria defined in WHO 1999/2004 classification. It indicates that the histogenesis of this particular tumour is related with the concept of the histiocyte as a tissue macrophage that sometimes and somewhere acquires genetic alterations not yet demonstrated. Being the lung an organ of antigen contact and defence and according with the results of this study, IMT is a tumour of the monocytic – macrophagic system (related to the classical reticulum – endothelial system as complementary auto-immune defence). IMTs may be understood as a predominantly low grade tumour of monocytic – macrophagic origin (in parallel with the clinical behaviour of MALT lymphoma).

OP24-4

PROGNOSTIC IMPACT OF INTRATUMORAL AND STROMAL LYMPHOCYTIC INFILTRATE IN NON-SMALL-CELL LUNG CANCER

Khalid Al-Shibli[1], Tom Donnem[2], Samer Al-Saad[3], Marit Delghandi[4], Magnus Persson[5], Marit Nilsen[5], Roy Bremnes[2], Lill-Tove Busund[3]
[1] Department of Pathology, Nordland Central Hospital, Norway
[2] Department of Oncology, University Hospital of Northern, Norway
[3] Department of Pathology, University Hospital of Northern, Norway
[4] Institute of Clinical Medicine, University of Tromso, Norway
[5] Institute of Medical Biology, University of Tromso, Norway

Background: Lung carcinoma is the most common cancer in the world (12.6% of all new cancer, 17.8% of cancer deaths), with an overall 5 years survival of 15%. The identification of events that are predictive of the rate of progression towards metastatic cancer, and of new treatment modules, including immunotherapy,

remains a big challenge. The immune system has a paradoxical role during cancer development; activation of the adoptive immune system can eradicate malignant cells, whereas activation of various types of innate immune cells might promote tumor development. However, the significance of tumor infiltrating lymphocytes, especially in the stroma, as a prognostic factor in non-small cell lung carcinoma (NSCLC) is controversial and not well studied. The aim of this study is to elucidate the prognostic significance of intratumoral and stromal lymphocytes in NSCLC. Methods: Tumor samples from 335 resected NSCLC, stages I to IIIA were obtained and tissue microarrays were constructed from duplicate cores of viable tumor tissue and surrounding stroma. Immunohistochemistry was used to evaluate the infiltrate of CD20, CD4, CD8 lymphocytes. The disease-free survival curves were calculated by the Kaplan-Meier method and compared using the Log-rank test. Multivariate analysis was carried out by Cox's proportional hazard method, and Chi-Square test for correlation with the clinicopathological variables. Results: In univariate analyses, a high number of CD8 T lymphocytes in the tumor (P = .023) and in the stroma (P=.002) was significant positive prognostic indicators for a better disease-specific survival (DSS). No such relation was noted with CD4 and CD20. The most significant correlation between stromal CD8 lymphocytic infiltration and DSS was observed in patients with T2 stage and with squamous cell carcinoma. Furthermore, a low level of stromal CD8 lymphocytes is associated with an increased incidence of angiolymphatic invasion (P=.032). In multivariate analyses, high CD8 cells in the stroma (P = .003) was an independent positive prognostic factor for DSS. Conclusion: A high number of CD8 positive lymphocytes in the stroma of NSCLC is a favorable independent prognostic factor; its significance is higher than that of tumor grade and angiolymphatic invasion. It is also associated with a lower incidence of angiolymphatic invasion.

OP24-5

CATHEPSIN-K IMMUNOHISTOCHEMISTRY IN THE SENSITIVE AND SPECIFIC DETECTION OF MICRO-GRANULOMAS IN HYPERSENSITIVITY PNEUMONITIS

Daniela Reghellin[1], Bruno Murer[2], Venerino Poletti[3], Sara Tomassetti[3], Alberto Cavazza[4], Giulio Rossi[5], Giuseppe Pelosi[6], Serena Pedron[1], Licia Montagna[1], Paola Piccoli[1], Marco Chilosi[1]
[1] Department of Pathology, Verona University, Italy
[2] Department of Pathology, Mestre Hospital, Italy
[3] Department of Pneumology, Forlì Hospital, Italy
[4] Department of Pathology, Reggio Emilia Hospital, Italy
[5] Department of Pathology, Modena and Reggio Emilia University, Italy
[6] Department of Pathology, IEO, Milan, Italy

Background: Cathepsin-K (Cath-K) is a cysteine protease with high matrix-degrading activity that plays an important role in osteoclast function. Its expression is regulated by Mitf transcriptional factor family. Cath-K is expressed also in epithelioid cells and in multinucleated giant cells but not in resident macrophages, suggesting that it could be a marker of macrophage activation and differentiation. Hypersensitivity Pneumonitis (HP), also known as Extrinsic Allergic Alveolitis, is a diffuse interstitial granulomatous lung disease that represents an immunologic reaction to inhaled organic antigens or to chemicals. Histologically, small noncaseating granulomas and mononuclear cell infiltrates are diagnostic criteria of HP, but detection of small aggregates of epithelioid cells and distinction from alveolar macrophages is at times difficult. Different macrophage markers can be used to detect and quantify granulomas and epithelioid cells (CD68, CD45RO, CD16 and others) but none of these allows a specific and sensitive evaluation. In this work we aimed to study expression of Cath-K in interstitial lung diseases and its utility in diagnosis of HP. Method: We studied Cath-K expression in 20 HP cases and in control cases: 3 normal lung tissue samples, 7 pulmonary Wegener Granulomatosis, 3 Sarcoidosis, 3 Airway-Centred Interstitial Fibrosis (ACIF) and 25 cases of other interstitial lung diseases. Granulomas were quantitatively evaluated scoring Cath-K expression as follows: negative: no immunoreactivity; 1+: scattered small granulomas; 2+: scattered large granulomas; 3+: numerous large granulomas. Results: 16/20 HP (80%) contained Cath-K-positive granulomas: in 4/20 cases (20%) score was 3+; in 4/20 (20%) 2+ and in 8/20 (40%) 1+. In 4 cases (20%) granulomas were absent. In control cases, Cath-K was strongly expressed in granulomas of Wegener Granulomatosis and Sarcoidosis but was negative in alveolar macrophages of normal lung tissue and in all interstitial lung diseases, including cases with large collections of macrophages (RB-ILD, DIP, alveolar haemorrhage). No granulomas were detected in the 3 cases of ACIF. Conclusion: In our study Cath-K was strongly expressed in epithelioid and giant cells of granulomas (80% of HP had Cath-K-expressing granulomas) but was negative in intraluminal alveolar macrophages, confirming Cath-K as a good marker for sensitive and specific detection of small interstitial granulomas in Hypersensitivity Pneumonitis and as a useful tool in diagnostic routine of interstitial lung diseases.

OP25-1

TUMOURS WITH PERITONEAL METASTASIS OF COLORECTAL OR APPENDICEAL ORIGIN ARE A SPECIFIC SUBGROUP

Sjoerd Bruin, Andrew Vincent, Vic Verwaal, Frans Zoetmulder, Laura Van Het Veer, Marie-Louise Van Velthuysen
Netherlands Cancer Institute, Amsterdam, The Netherlands

BACKGROUND: A specific subgroup of colorectal and appendiceal neoplasms progress with widespread peritoneal metastasis rather than the more common metastatic spread to the liver. A histologic classification of peritoneal metastasis in the clinical context of pseudomyxoma peritonei (PMP) according to Ronnett et al. has been shown to predict survival. This study investigates if a similar classification is useful for all cases with peritoneal metastasis of colorectal or appendiceal origin. And if these cases represent a specific subtype of colorectal and appendiceal tumours. METHODS: In the Netherlands Cancer Institute patients with peritoneal metastasis from primary colorectal or appendiceal origin are treated with Hypertermic Intraperitoneal Chemotherapy (HIPEC). Distant metastasis are an exclusion criterion for this treatment. Histology of peritoneal metastasis of all patients (n=269) treated with HIPEC in this institute between 1995 and 2006 was evaluated using a semi quantitative analysis of mitotic activity, atypia, cellularity, and the mucinous component. Using these criteria peritoneal metastasis were classified according to Ronett in DPAM (Diffuse Peritoneal Adeno Mucinosis), PMCA (Peritoneal Mucinous Carcinomatosis) and an intermediate subtype (PMCA-i). Metastasis consisting for less than 50% of mucin were classified as PCA (Peritoneal Carcinomatosis). Furthermore, tumour type was described according to WHO standards. RESULTS: Peritoneal metastasis classified as DPAM (n=101) had a significant better outcome, originated in 97% from the appendix and were more common in women (F:M = 64%:36%). The other peritoneal metastasis were mucinous in 44% (PMCA or PMCA-i). Of PCA, 26% was partly mucinous. These partly mucinous PCA seemed more common in men. PMCA and PMCA-i originated from the appendix in 41%, whereas PCA was only in 14% of appendiceal origin. Of all primary colorectal tumours 37% had mucinous peritoneal metastasis, whereas 16% were partly mucinous. Of all cases 15% were of a non-intestinal tumour type (signet-ring or goblet) CONCLUSION: DPAM seems to be a separate disease with a specific clinical outcome that should be recognised within the group of patients with peritoneal metastasis of colorectal or appendiceal origin. Peritoneal metastasis of the non-DPAM type are mucinous relatively often in contrast to what is known of the incidence of mucinous tumours of colorectum and appendix. This suggests a specific genetic pathway for the development of peritoneal metastasis.

OP25-2
IMMUNO-EXPRESSION OF PRO- AND ANTI-APOPTOTIC PROTEINS IN H. PYLORI INFECTION ASSOCIATED WITH GASTRITIS AND DUODENAL ULCER

Christiane Cartelle, Cláudia Mendes, Celso Oliveira, Mônica Demas, Ana Nogueira
Federal University of Minas Gerais, Brazil

Background: H. pylori infection induces apoptosis in the gastric epithelium, which might be related to atrophy development. There are no data about apoptosis in H. pylori gastritis associated with duodenal ulcer (DU). Most data on record point to involvement of the intrinsic pathway, but over-expression of Fas and Fas-ligand (Fas-L) proteins was reported. The aims of this study were to evaluate the expression of proteins of the intrinsic and extrinsic apoptotic pathways in patients with H. pylori gastritis and in relationship to DU and atrophy development. Method: The expression of bcl2 family proteins, FAS and FAS-L was studied by immunohistochemistry (LSAB) in the antral mucosa of 57 H. pylori infected patients, 18 with DU and in 14 non-infected patients with normal mucosa. The immuno-expression was scored considering the intensity (0-negative; 1-weak; 2- moderate; 3- strong) and extension (1:<10%); 2:10-25%; 3:25-50%; 4:50-75%; 5:>75%) of the reaction in the superficial epithelium and foveolae; the final result in each region and in each case was the sum of these scores. Results: Bax was significantly over-expressed in H. pylori gastritis, both in the superficial epithelium and foveolae and considering the reaction intensity and the percentage of stained epithelium, in comparison to cases with DU ($p \leq 0.03$) and non-infected patients ($p \leq 0.2$). Bak was over-expressed in the superficial epithelium of non-infected and in DU patients in comparison to those with gastritis ($p=0.04$, $p=0.048$, respectively). However, in the final evaluation of the antral mucosa, the reaction intensity was significantly higher in gastritis than in DU. Bcl-x was significantly over-expressed in patients with gastritis compared to non-infected ones ($p \leq 0.04$) and to those with DU ($p=0.03$). Fas expression was negative or weak in most of the cases and the expression of Fas-L was higher in non-infected mucosae than in gastritis ($p=0.05$). Bax, Bak and Bcl-x were over-expressed in the foveolae of cases with atrophy compared to non-atrophic ones ($p \leq 0.05$) and the percentage of superficial epithelium expressing Bcl2 was higher among atrophic gastritis ($p=0.03$). On the other hand, Fas-L was significantly over-expressed in non-atrophic cases ($p=0.05$). Conclusion: Apoptosis in H. pylori infection was mainly related to the intrinsic pathway. The expression of pro-apoptotic proteins (Bax/Bak) was significantly higher in patients with gastritis than in those with DU, which might be related to atrophy development in the former group. Financial support: CNPq, CAPES.

OP25-3
LYMPH NODE ANALYSIS IN COLORETAL CANCER: THE IMPACT OF THE USE OF CLEARING FAT SOLUTION

Rair Xavier, Túlio Pereira, Ana Nogueira
Federal University of Minas Gerais, Brazil

Background: Lymph node (LN) involvement is one of the most important criteria for staging colorectal cancer (CRC). Special procedures have been recommended in order to improve LN analysis and metastasis detection. The aims of this study were to evaluate the impact of using a fat clearing solution in LN dissection. Method: We analysed prospectively 74 CRC (35 men, median age 62.9 years-old). After routine (conventional - CM) LN dissection, the fat was emerged in a mixture containing 65% alcohol, 20% ether, 5% acetic acid and 10% formalin (at 10%) for 24 hours (2 changes). A new LN search was performed. LN diameters were measured using a computerized system (KS400, Karl Zeiss, Germany). The number of positive and negative LN with <4mm was determined. The number and measures of the LN obtained by both methods were compared and analysed in respect to patients and tumour characteristics. Results: All CRC were adenocarcinomas, 81% moderately differentiated and 69% pT3; 3167 LN (42.8/case) were dissected: 1814 (24.5/case) by the CM and 1355 (18.3/case) after the use of the clearing solution (CS). Metastasis were detected in 196 LN: 170 (86.7%) by the CM and 26 (13.2%) after CS; 59% of the LN dissected conventionally had <4mm (n=1068, 14.4/case; range 0.4-23mm); 93% of the LN dissected after CS had <4mm (n=1261, 17/case; range 0.2-11mm). Among the 170 positive LN (LN+) conventionally dissected, 39 (22.9%) had <4mm; 73% of the LN+ dissected after CS measured <4mm ($p=0.000$). The use of the CS increased the LN number in 74.7% ($p=0.000$), the detection of small LN in 118% ($p=0.000$), and metastasis in 15.3% of the cases ($p=0.003$). The number of LN dissected in both groups was correlated ($r=0.3$; $p=0.004$) and the number of LN+ after CS was higher when at least one metastasis was previously detected ($p=0.007$); pN changed in 5 cases ($p=0.03$); 90% of the LN+ cases were detected only after the dissection of 40 LN. Patient's age ($r=-0,2$; $p=0.04$), LN diameter (smallest: $r=-0.3$;$p=0.01$; biggest: $r=0.3$;$p=0.004$) and the number of <4mm LN ($r=0.9$; $p=000$) were significantly associated with LN number. The number of LN was independently predicted by the pT, the number of <4mm LN and the diameter of the biggest LN. Conclusion: A large number of small LN must be dissected to adequately stage CRC. Fat clearing solutions simple to apply and neither expensive nor time consuming, might be useful for this propose. Financial support: CNPq

OP25-4
ALTERATIONS OF MDR1 AND MRP1 FUNCTIONAL ACTIVITY OF COLORECTAL MALIGNANCIES

Tamas Micsik[1], Tamas Mersich[2], Zsolt Baranyai[2], Ferenc Jakab[2], Eva Karaszi[2], Andras Lorincz[2], Richard Schwab[2], Gyorgy Keri[2], Istvan Petak[2]
[1] Rational Drug Design Laboratory of Cooperation Research Center, Semmelweis University, Budapest, Hungary
[2] Department of Surgery, Uzsoki Teaching Hospital, Budapest, Hungary

BACKGROUND: The ABC-transporter MDR1 and MRP1 are expressed in the normal mucosa of gastrointestinal tract and early studies assumed elevated expression of these proteins during the colorectal carcinogenesis. Other studies found decreased expression of these proteins in the majority of colorectal cancer cells. Since these transporters are able to pump out various drugs from cells and thus can alter the chemosensitivity of tumor cells, the role of ABC-transporters in the moderate chemoterapeutic response of colorectal carcinoma cells has been investigated by several groups by immunohystchemistry or real-time PCR. Posttranslational modifications influence the functional activity (MDR Activity Factor: MAF) of MDR proteins, so the determination of functional activity could bring new insights in understanding the controversial data and connection between colorectal cancer and MDR. Furthermore, in case of the upcoming treatment modalities which brought better survival in CRC (like irinotecan and oxaliplatin) and which are substrates of the MDR-transporters, MAF might also have impact on treatment and survival. METHOD: Our aim was to determine and compare the functional activity of MDR1 and MRP1 transporters in surgical samples from normal mucosa and primary and metastatic colorectal cancers. Cancer tissue and blood samples were taken after informed consent (98 primary colorectal cancers, 38 hepatic metastases and 23 healthy mucosae) and brought into one-cell suspension with collagenase treatment. MDR1/MRP1 functional activity (MAF) of viable epithelial cells were determined according to the modified protocol of the calcein-assay (MDQuant). MAF-values of blood leukocytes were determined according the original calcein-assay protocol. RESULTS: The mean MDR1 functional activity of primary CRC was significantly lower than in normal mucosa. MDR1-MAF significantly increased in metastases altought didn't reach the activity of normal mucosa. MRP1 activity was similarly low in

healthy mucosa and in primary CRCs and only slightly elevated in metastatic tumors. The elevation of MAF in metastatic cases was also found on peripheral blood leukocytes. CONCLUSION: In contrast to the common dogma of the majority of the scientific litterature, our results showed that primary CRCs have lower mean MDR1 functional activity than normal mucosa cells. The relative increase in MDR activity in metastases may be induced by the applied chemotherapy which took place after the resection of primary tumors. This finding is further supported by the increase of MAF-values of the PBLs.

OP25-5

PROGESTERON INDUCED BLOCKING FACTOR – PIBF AS A POTENTIAL TUMORMARKER

Tamas Micsik[1], Beata Polgar[2], Klara Rasky[3], Ferenc Péterfy[3], Eszter Schafer[4], Tibor Krenacs[5], Katalin Jakab[6], Zsolt Holló[6], Julia Szekeres-Bartho[2], Richard Schwab[7], Istvan Petak[1]

[6] Solvo Ltd. , Budaőrs, Hungary
[7] Drug Design Laboratories, Cooperative Research Center, Semmelweis University, Budapest, Hungary

BACKGROUND: PIBF was first described in the blood and urine of pregnant women. It is secreted by lymphocytes and cells of placenta upon progesterone stimulation and causes a Th1>Th2 shift, which leads to decrease in cell mediated activity of the immune system. This creates a favorable condition for the embryo and in healthy pregnancy PIBF urine levels continuously increase from the first trimester until the end of pregnancy. The elevation of PIBF in the urine samples correlated to the outcome of the pregnancy: higher levels of PIBF predicted normal delivery, while lower PIBF levels predicted preterm delivery. Other investigations showed that PIBF production is also elevated in rapidly proliferating cells and might be in connection with tumor progression, since decreased NK-cell-activity is favorable also for tumor growths. METHOD: Our aim was to investigate PIBF expression in different malignancies. Clinical samples have been obtained from patients with colorectal and pancreatic cancer and a smaller number of other malignancies: mamma, lung, stomach, bile duct cancers, lymphomas, etc. PIBF-levels in the urine samples were determined by one-plate competitive ELISA and statistical analysis of the collected 80 tumor samples, and the 19 normal control and 15 samples from inflammatory diseases confirmed the potential use of PIBF as a tumor marker. RESULTS: The PIBF level in the urine sample of cancer patients was significantly higher than in healthy individuals. In case of colorectal and pancreatic cancers (25 samples each) the significant difference in PIBF levels compared to control samples was confirmed also separately respectively. Patients with inflammatory diseases had higher PIBF levels than in healthy people, but still much lower than in tumor patients. The protein expression of PIBF was simultaneously investigated with more polyclonal and monoclonal antibodies by immunohistochemistry in the tissue blocks of surgical samples of tumor patients. Specific strong positive cytoplasmic-staining was found in cancer cells. CONCLUSION: The investigated surgical samples and clinical urine samples of different malignant diseases showed strong positivity with PIBF-antibodies by ELISA and IHC and strengthened the possibility of applying PIBF as a tumor marker. Further studies are in progress with other malignancies and for the evaluation of PIBF as a tumor progression and monitoring marker.

OP25-6

THE CRUCIAL ROLE OF PATHOLOGIST IN DETERMINING THE PROGNOSIS OF COLORECTAL CARCINOMA CASES: AN ANALYSIS OF 502 CASES WITH COLORECTAL CARCINOMA BY TURKISH NATIONAL WORKING GROUP OF GASTROINTESTINAL PATHOLOGY

BACKGROUND: Lymph Node evaluation is an important prognostic factor in colorectal cancer (CRC). An accurate gross and microscopic examination of the surgical specimen is very important for the correct assesment of the lymph node (LN) status and other pathological parameters of tumor. We performed a retrospective analysis to determine the clinicopathological parameters associated with poor prognosis in CRCs. METHOD: A total of 502 CRC patients diagnosed and treated with surgery in 14 different hospital located in different cities in Turkey, were reviewed. The clinical and pathological parameters considered in statistical analysis were age, gender, tumor size and location, depth of invasion (AJCC,TNM-2002), histological grade, the number of examined LN, LN metastasis, lymphatic vessel invasion (LVI), blood vessel invasion (BVI), perineural invasion (PNI). Patients were divided in three groups depending on the number of examined LNs; group I (n=190) patients had <9; group II (n=117) had 10-14 and group III (n=195) had ≥15. RESULTS: Patients in our study group were constituted by 294 men, 208 women had a mean age of 61,8 and mean follow-up of 42,7 months (24-122) . The mean number of examined lymph node was 13,8 (range 1-57). Two hundred eight (41,2%) of the patients had LN metastases with mean number 4,1 (range 1-31). Depth of invasion was T1 in 9 (1,8%); T2 in 61 (12,1%); T3 in 275 (54,5) and T4 in 143(28,3%) of cases. There was strong correlation between depth of invasion and lymph node metastasis (p<0,001). Cox regression analysis revealed that BVI had the most significant prognostic effect in disease-free survival (p=0,001); LN involvement (p=0,007) and depth of invasion (p=0,028) had the highest prognostic effect in overall survival in our study group. In Kaplan-Meier analysis, mean survival time(month±SD) was significantly lower in group I (45,44±2,9) than in both groups II (59,6±5,8) and III (75±4,79), (p=0,018). The patients with 4 or more LN metastasis (36,1± 3,7) had poorer prognosis than for those with ≤3 LN metastasis (40,6 ±3,1) and with no metastasis (66,20±3,79), respectively (p<0,001). CONCLUSION: LN metastasis is associated with poor outcome in CRC cases in whom accuracy of staging and survival can be improved with increasing the number of LN examined by pathologists. A standardization of harvesting and reporting in lymph nodes is extremely necessary.

OP25-7

MUCINOUS TUMOURS OF THE COLORECTUM: RIGHT VERSUS LEFT IN TERMS OF MOLECULAR MECHANISMS

Berna Savas[1], Astrid Hirschmann[2], Andreas Jung[2], Arzu Ensari[1], Thomas Kirchner[2], Nazmiye Kursun[3]

[3] Ankara University, Medical Faculty, Department of Biostatistics, Turkey

Background: The majority of colorectal cancer cases arise in a background of chromosomal instability, a mechanism associated with loss of heterozygosity leading to tumour suppressor gene inactivation. A small proportion of CRC, however, progress through microsatellite instability (MSI) – "serrated" pathway and these tumours are often right-sided and present a mucinous phenotype. The molecular characteristics of right and left sided mucinous adenocarcinomas (MAC) and conventional adenocarcinomas (CA) in terms of MSI status, KRAS and APC mutations were determined in the present study. Method: A total of 37 MAC (17 left, 20 right sided) and 37 sex and age-matched CA (19 left, 18 right sided) were studied. Mutation analysis was performed using PCR and sequencing exon 2, exon 3 of KRAS and mutation cluster region of APC (part 1-5). Microsatellite instability status was determined using primers for BAT25, BAT26, D5S346, Mfd15, D2S123 BAT40, Mycl, D18S58, D10S197 and D13S153. MSI-high (MSI-H) cases showed mutation in two of five markers whereas in MSI-low (MSI-L) phenotype only one of five markers was unstable and in microsatellite stable (MSS) cases none was mutated. "MSI tumours" were defined as those that showed MSI-H. Immunohistochemical detection of mismatch repair gene proteins was performed using antibodies to hMLH1, hMSH2, hMSH6 and PMS2. Tumour cells without nuclear staining, in the presence of positively stained stromal cells were considered to have an abnormal pattern of expression. Chi-square and Mann-Whitney U tests were used for statistical analysis. Results: Our results revealed that, MSI tumours were significantly more frequent in MAC (43,2%) then in CA (18.9%) ($p<0.05$). In MAC, MSI-H tumors were significantly ($p<0.05$) more frequent in the proximal colon (55%) than in distal colon (29.4%). Compared to CA, more MAC presented with expansive margins (45 vs 0%, $p<0.001$), tumour "serration" (37,8 vs 5.4%, $p<0.01$) and hyperchromatic nucleus (56.8 vs 24,3%, $p<0.01$). APC mutation was significantly higher in CA when compared to MAC (55,9% vs 32,4%, $p<0,05$). No significant difference was found for KRAS mutation between tumour types. Immunohistochemically hMLH1, hMLH2, hMSH6 and PMS2 yielded a sensitivity of %32, %11, %4 and %4 respectively, for the detection of MSI-H tumours. Conclusions: In accordance with the morphologic characteristics of MAC which are suggestive of "serrated pathway" in their neoplastic progression, they showed higher MSI in right colon tumours, in particular, and fewer APC and KRAS mutations compared to CA.

OP25-8

THE RELEVANCE OF MULTIPLEX PCR AND HETERODUBLEX ANALYSIS ON DIFFERENTIATING THE REACTIVE VERSUS NEOPLASTIC T CELLS IN THE SPECTRUM OF GLUTEN SENSITIVE ENTEROPATHY – ENTEROPATHY ASSOCIATED T CELL LYMPHOMA.

Isinsu Kuzu[1], Yasemin Sahin[1], Irfan Soykan[2], Hulya Cetinkaya[2], Arzu Ensari[1], Mitat Bozdayi[3], Oner Dogan[4], Mine Hekimgil[5]

[5] Ege University, School of Medicine, Department of Pathology, Izmir Turkey.

Enteropathy associated T cell lymphoma (EATCL) is a rare agressive lymphoid neoplasm of intestine. Gluten sensitive enteropathy (GSE) and EATCL are at the two ends of one spectrum. Some of the cases which are refractory to gluten free diet may represent the early phase of neoplastic transformation to EATCL. Multiplex PCR (MPCR) by Biomed-2 primer sets for T cell clonality analysis are very sensitive. The aim of this study is to examine the diagnostic value of MPCR and hetereodublex analysis (HD) by using Biomed-2 primers for differentiation of the entities within the GSE-EATCL spectrum. Intestinal biopsies of 23 GSE patiens diagnosed by clinical and histopathological parameters, 8 cases of EATCL were studied in the disease group. Nine duodenal biopsies with normal histology were studied as the disease free negative control group. The immunophenotypic characteristics of the samples of the disease group were recorded. The control biopsies of 8 patients in GSE group with no or partial response to gluten free diet were and the non-tumoral segments of EATCL were studied. Multiplex PCR and HD analysis for examination of the clonal rearrangement of T cell receptor beta, gamma and delta genes were performed for every sample. Clonal TCR rearrangement was present in the tumoral area of all EATCL cases whereas the the non tumoral mucosa were found clonal in 75% of the cases. In the negative control group 7 cases were clonal for TCR gamma gene whereas 2 for beta gene. TCR gamma clonality was present in 46% of the responders. Only 6% had clonal TCR beta rearrangement. Except one case the immunophenotype of intraepithelial T lymphocytes (IETL) were CD8 positive in the refractory group. TCR gamma gene was clonal in 65%, TCR beta was 25% in non responders. Only one case was composed of CD8 and CD4 negative IETL and clonal rearrangement in TCR beta and gamma in this group. Conclusion: MPCR and HD with Biomed-2 primers is a sensitve method for detecting the clonal T cell population in the lesions of GSE-EATCL. The value of TCR gamma for clonality analysis are not enough for the decision of the neoplastic T cells. Examination of TCR beta gene rearrangement together with gamma decrease the rate false positivity. Relying on molecular methods alone for the cases in this disease spectrum may cause overdiagnosis if not combined with the immunophenotypic and clinical data.

[9] Sisli-Etfal Research and Training Hospital, Department of Pathology, Istanbul, Turkey
[10] Karadeniz Technical University, Department of Pathology, Trabzon, Turkey

Background: GEPNETs are relatively rare tumors with heterogeneous histological, clinical and biological properties. In this preliminary multicentric study, a large series of GEPNETs were evaluated according to the WHO classification along with some other macroscopical and histopathological features. Method: A national database network was developed and ten different centers registered a total of 191 cases of GEPNETs. Only surgically resected pure endocrine tumors immunostained with at least two neuroendocrine markers were included in the study. All tumors were classified according to the 2000 WHO criteria. Results: Our series consisted of 72 well-differentiated benign GEPNETs (37,7%), 32 well-differentiated GEPNETs with uncertain behavior (16,8%), 61 well-differentiated malignant GEPNETs (31,9%) and 26 poorly-differentiated endocrine carcinomas (13,6%). There were 102 female (53,4%) and 89 male (46,6%) patients. The most common tumor location was pancreas (32,5%), followed by appendix, stomach, ileum, duodenum, rectum, jejunum, cecum and colon (23%, 17,3%, 8,3%, 6,8%, 4,1%, 3,1%, 2%, 2%, respectively). Benign GEPNETs were more frequent in women and younger patients while poorly-differentiated carcinomas were more frequent in men and older patients (p=0,001). Multicentricity was a common finding in well-differentiated tumors (19%), but not in poorly differentiated ones (3,8%). Necrosis when found grossly or microscopically was a strong indicator of malignancy (benign vs malignant, p=0,001) though there was no statistically significant difference between benign and uncertain group. Parameters such as tumor size, mitotic index, and Ki-67 index were all statistically significant between benign-uncertain, benign-malignant and well differentiated-poorly differentiated malignant tumors (p=0,001). Conclusion: The 2000 WHO classification provides a standard evaluation of GEPNETs which will improve our understanding of biology and natural history of these rare tumors.

Background: It is important to make the differential diagnosis of gastrointestinal (GI) stromal tumors (GIST) from other GI mesenchymal tumors (GIMT) because of the opportunity of molecular-targeted therapy for GISTs. This study was designed to describe the pathologic, immunohistochemical (IHC) and molecular features of cases with a possible diagnosis of GIST and to identify KIT immunostaining profile by using two different antibodies. Method: Cases of GIMTs, identified from the database of 14 diagnostic centers in Turkey between 1986-2007, were analyzed. A total of 523 cases were represented on seven tissue microarray (TMA) parafin blocks by using manual arrayer. Immunohistochemistry was performed using CD117, CD34, SMA, Desmin, S100, and h-caldesmon. Two different antibodies for CD117 were used. RNA in situ hybridization (ISH) was performed to identify KIT and platelet-derived growth factor receptor alpha (PDGFRA) m-RNA. Mutation testing for KIT and PDGFRA genes will be performed. Results: Tumors were located in the stomach (41%), small intestine (32%), colorectum (10%), abdominal cavity (16%), and esophagus (1%). Histologically, the tumors had spindle cell (61%), epithelioid (12%), and mixed type (27%) of morphology. Immunohistochemically, 78% of cases were positive for monoclonal CD117 antibody (T595, Novocastra) whereas 77% of cases were stained with polyclonal CD117 antibody (polyclonal, A4502, DAKO). There was statistically moderate to good agreement on CD117 0,001). CD117 staining<0,037, p±=0,743κstaining with two different antibodies (by IHC and by ISH was not comparable because of the preparation differences of parafin blocks from different centers. Mutation testing for KIT and PDGFRA will be performed for 95 KIT negative cases either by IHC or by ISH. Conclusion: The accurate diagnosis of GIST is dependent on clinicopathological and immunohistochemical criteria. It is

important to perform appropriate antibody optimization and validation, and to interpret KIT immunostaining in the clinical decisions of treating with Imatinib. This study has an importance of being the review of the largest series of Turkish GIST cases with pathological, phenotypic and molecular characteristics

OP25-11
GASTROINTESTINAL EPITHELIAL DYSPLASIA/NEOPLASIA: WHERE DO TURKISH PATHOLOGISTS STAND - EAST OR WEST?

Background: Interpretation of gastrointestinal biopsies for epithelial neoplasia/dysplasia is one of the most difficult tasks of pathologists since there is no objective method. Despite two international consensus meetings there are still discrepancies between east and west in the interpretation of dysplastic lesions. Pathologists with special interest in gastrointestinal cancer precursors have proposed different nomenclatures to identify such lesions, both in western countries and in Japan. Vienna classification has largely resolved this problem by adopting both architectural and cytologic criteria. However, this classification scheme has not gained much interest from the practising pathologists despite its clinical considerations. We, therefore, decided to evaluate the approach of a group of pathologists to gastrointestinal epithelial lesions in terms of diagnostic criteria and also to assess interobserver agreement on the diagnosis of preneoplastic lesions of the gastrointestinal tract. Method: Twenty four Turkish pathologists and four Japanese pathologists, all experienced in gastrointestinal pathology, reviewed 20 gastric and 8 colonic lesions (11 endoscopic biopsies, 6 polypectomy, and 10 operation specimens). The specimens were evaluated according to Japanese classification and Vienna classification using both architectural and cytologic criteria. The extent of diagnostic agreement between the observers with Western and Japanese viewpoints was assessed by kappa statistics. Results: Turkish pathologists gave a diagnosis of cancer in 32.1% of cases while Japanese pathologists gave a diagnosis of cancer in 71.4% of the cases. The agreement between Turkish and Japanese pathologists had a kappa value of 0.597 for Japanese classification while kappa was 0.508 for Vienna classification between the two groups of pathologists. Overall interobserver agreement did not differ between Japanese and Vienna classification (kappa: 0.357, kappa: 0.332, respectively). The disagreement between biopsy diagnosis and EMR or resection was 59.5% for Turkish pathologists, and 45.8% for Japanese pathologists. Conclusion: Turkish pathologists seem to be more conservative in their interpretation of dysplasia. The concept of noninvasive carcinoma does not seem to be widely accepted by Turkish pathologists who stand closer to the West in their approach to gastrointestinal epithelial dysplasia-neoplasia. There is stil much to be done to improve our diagnostic skills and to standardize our criteria in the diagnosis of gastrointestinal epithelial dysplasia.

OP26-1
THE VEGF-SIGNALLING PATHWAY IN PULMONARY SMALL AND NON-SMALL CELL CARCINOMAS – AN IMMUNOHISTOCHEMICAL COMPARATIVE STUDY

Elvira Stacher[1], Franz Quehenberger[2], Iris Halbwedl[1], Margit Gogg-Kamerer[1], Elisabeth Grygar[1], Helmut Popper[1]
[1] Institute of Pathology, Medical University Graz, Austria
[2] Institute of Medical Statistics and Documentation, Medical University Graz, Austria

Context: Angiogenesis is pivotal for the survival of tumor cells. VEGF (Vascular Endothelial Growth Factor) is understood to be a major stimulator of angiogenesis. Recently VEGF-targeted therapies have been identified as a promising therapeutic approach in solid tumors, including lung tumors. Our study aims to analyze the differences and similarities of factors of the VEGF-pathway (Tie2, VEGF, VEGFR2, VEGFR3, PI3K) in different types of Small and Non-Small Cell Lung Cancers. Design: We used tissue microarrays consisting of 32 Small Cell Carcinomas (SCLC), 27 Large Cell Neuroendocrine Carcinomas (LCNEC), 75 Adenocarcinomas (AC), 67 Squamous Cell Carcinomas (SQCC) and 53 Large Cell Carcinomas (LC), respectively (each represented by an average of 5 punches and 1 punch of normal adjacent lung parenchyma). Immunohistochemistry was performed according to standard protocols. The mean value for percentage and intensity and a composite score (percentage multiplied by intensity) of stained tumour cells were evaluated statistically using the Goeman`s Global Test. Results: Whereas factors of the VEGF-pathway are frequently expressed in LC, AC, SQCC and LCNEC (in descending order), they reveal a positivity in only a small amount of cases in SCLC. We found striking differences regarding the expression of VEGFR2 and VEGFR3: VEGFR2 was frequently and strongly expressed in LC and AC, whereas it was negative or weak in SCLC, LCNEC and SQCC. In AC and LC we observed an intense nuclar positivity of VEGFR3, and also SCLC and LCNEC revealed a nuclear positivity of VEGFR3, but to a much lesser extent. VEGFR3 was negative in SQCC. Conclusion: Our results suggest that the inhibition of angiogenesis by blocking of VEGF- VEGFR- pathway might lead to a better outcome in the group of Non-Small Cell Lung Carcinomas. In contrast angiogenesis might be mediated by another pathway than the VEGF-pathway in Small Cell Lung Carcinomas. The frequently observed event of nuclear staining of VEGFR3 might point towards another, hithertho unknown function.

OP26-2
SUPEROXIDE DISMUTASE POLYMORPHISMS AND EXPRESSION IN IDIOPATHIC PULMONARY FIBROSIS

Patrizia Morbini[1], Simona Inghilleri[1], Ilaria Campo[2], Chiara Villa[1], Tiberio Oggionni[2], Maurizio Luisetti[1]
[1] Policlinico S. Matteo/Università di Pavia, Italy
[2] Policlinico S. Matteo, Italy

Background The inflammatory theory in the pathogenesis in idiopathic pulmonary fibrosis (IPF) has been largely confuted. However, markers of oxidative stress have been consistently

reported in lavage samples form IPF patients, and are responsible of fibrogenic TGFb activation. Increased reactive species of oxygen and nitrogen could depend from reduced scavenger activity of enzymes such as superoxide dismutases (SOD). Two enzyme isoforms are mainly implied in antioxidant activity: intracellular MnSOD and extracellular (Ec)SOD. Both proteins show genetic variants that influence the activity and/or stability of the enzyme. Methods We investigated by means of PCR amplification the Arg213Gly polymorphism in EcSOD and the Ala16Val polymorphism in MnSOD in 70 patients with clinical and instrumental diagnosis of IPF, in 38 different patients with confirmed histopathological and clinical diagnosis of usual interstitial pneumonia (UIP) according to ATS/ERS 2000 criteria, and in 295 normal subjects. Ec and MnSOD expression was also assessed immunohistochemically in UIP samples Results MnSOD Ala16Val polymorphism was significantly more frequent in histologically confirmed UIPs (heterozygous 39%, homozygous 44%) than in control cases (heterozygous 51%, homozygous 25%, p<0.05%). No difference was found between controls and clinical IPF series. The distribution of ARG213Gly EcSOD polymorphism was not significantly different in the 3 groups. Both Mn and EcSOD were moderately expressed in type 1 pneumocytes, in airway epithelia, macrophages, endothelia and vessel miocytes. No immunoreactivity was observed for both enzymes in fibroblastic foci, while overlying reactive pneumocytes were intensely positive for EcSOD. No difference in staining was observed in cases with or without polymorphisms. Conclusion Molecular investigations documented the significantly higher frequency in UIP patients of an MnSOD genetic variant associated with reduced antioxidant activity. Interestingly, the significant association was only observed in a series of histologically confirmed UIP cases, but not in a series of clinically diagnosed IPF. This result stresses the importance of basing molecular association studies on carefully selected patient series, in particular in the complex field of pulmonary fibrosis, and underlines the relevance of histological classification of fibrosis. Negative antioxidant activity in fibroblastic foci, together with the molecular results, suggest that foci can be the site of increased oxidative stress.

OP26-3

PDGFR BETA, A POTENTIAL TARGET FOR MOLECULAR CHEMOTHERAPY, IS EXPRESSED IN MESOTHELIOMA

Patrizia Morbini[1], Chiara Villa[1], Simona Inghilleri[1], Camillo Porta[2]
[1] Policlinico S. Matteo/Università di Pavia, Italy
[2] Policlinico S. Matteo, Italy

Background In the search for drugs effective in controlling malignant mesothelioma (MM) clinical trials have recently been performed employing tyrosine kinase (TK) inhibitor imatinib mesylate, as single drug or in combination with other molecules. While monotherapy did not show appreciable advantage, the synergistic combination with gemcitabine or pemetrexed seems to be more promising, both in experimental and in as yet unpublished clinical settings. Imatinib blocks a family of TK associated receptors including c-kit/CD117 and PDGFRβ by inhibiting kinase binding with ATP and activation. PDGF autocrine production seems to play a relevant role in mesothelioma cell growth, and its receptors are differentially expressed in normal mesothelium (expressing PDGFRβ) and in MM cell lines (expressing PDGFRβ). Furthermore, one of the most common genetic abnormalities observed in MMs involves chromosome 22q13, where PDGFRβ gene is mapped. CD117 has been reported to be expressed in 1/3 of MM, while PDGFRβ was documented in MM cell coltures but it has never been investigated in MM sample series. Methods We investigated with immunohistochemistry the expression of PDGFRβ (Rb-1692, Labvision, Freemont CA) and CD117 (A4502, Dako Cytomation, Carpinteria, CA) in a series of 138 MMs and correlated the results with clinical and tumor data (histological type, patient survival, type of exposure to asbestos). Results 105 cases (76%) were moderately or intensely reactive for PDGFRβ; 33 (24%) showed weak or absent immunoreactivity. Consistent expression of CD117 was observed in 16 cases (11,5%). All 16 cases were also reactive for PDGFRβ. CD117 expression was significantly associated with epithelioid histology (p<0,01). No association with histological type was observed for PDGFRβ. TK receptor expression was not associated with survival. Interestingly, PDGFRβ expression was significantly associated with professional exposure to asbestos (subjects working in cement factory, railways, naval industry), as compared to ambiental exposure (subjects living in neighbourhood of cement factories) or to undetermined exposure. Conclusion The present study confirms for the first time in vivo in a large series of MM cases the expression of PDGFRβ, further supporting the promising therapeutic strategy combining TK inhibitor imatinib mesylate with antifolates or gemcitabine.

OP26-4

EXPRESSION AND PROGNOSTIC SIGNIFICANCE OF PTEN, P27, CKS1 AND SKP2 IN NON-SMALL CELL LUNG CANCER

Vassiliki Zolota[1], Vassiliki Tzelepi[1], Paraskevi Zyli[1], Michalis Leotsinidis[2], Nikolaos Panagopoulos[3], Demetrios Dougenis[3], Chrisoula Scopa[1]
[1] Department of Pathology, Medical school, University of Patras, Greece
[2] Laboratory of Public Health, Medical School, University of Patras, Greece
[3] Department of Cardiothoracic Surgery, Medical School, University of Patras, Greece

Background: p27 inhibits cell cycle progression and is frequently down-regulated in various neoplasms. p27 levels are regulated by degradation from a SCF complex. Cks1 and Skp2 are important components of the SCF complex and they are upregulated in various neoplasms. PTEN increases p27 levels, due to inhibition of Skp2-mediated degradation. This study investigates the expression of PTEN, p27, Cks1 and Skp2 in human non-small cell lung carcinomas (NSCLC) and correlates them with clinicopathologic factors and survival. Method: 128 surgically resected, formalin-fixed, paraffin-embedded NSCLC specimens were subjected to immunohistochemistry for PTEN, p27, Cks1 and Skp2 proteins. Adjacent non-neoplastic lung parenchyma was also evaluated. For each case, a % value for each marker was obtained (labeling index-LI), by dividing the positive stained (epithelial) nuclei by the total number of cells. Specimens containing <50% stained cells were considered as having downregulated PTEN and p27. The cut-off level used for Cks1 and Skp2 was 10%. Follow-up data was available for 91 patients (follow-up time 1-78 months, mean: 19). Results: The median LIs of PTEN, p27, Cks1 and Skp2 were 75%, 60%, 15% and 12%, respectively. PTEN and p27 were always highly expressed in non-neoplastic lung (median LI:95%) whereas Cks1 and Skp2 were never expressed in normal tissue. PTEN and p27 were downregulated in 30.4 and 39.1% of the cases, respectively. Induced expression of Cks1 and Skp2 was noted in 58,5 and 57% of the cases. Statistical analysis revealed a significant reduction of PTEN and p27 expression in neoplastic compared to normal lung tissue (p<0.0001). Additionally, PTEN and p27 were more frequently expressed in T1 compared to T3-T4 neoplasms (p=0.033 and 0.028, respectively). A positive correlation between PTEN expression and prolonged survival was noted for T1 tumors (p=0.034) and albeit not reaching statistical significance, PTEN tended to be an independent prognostic factor for overall survival in T1 tumors (p=0.095). Cox regression analysis revealed stage, age and gender as independent prognostic factors for overall survival(p=0.011, 0.013, 0.014, respectively). Cks1 and Skp2 expression levels correlated to each other but not with p27, stage or survival. Conclusion: PTEN and p27 seem to be

involved in the progression of lung neoplasia. PTEN emerges as an important prognostic factor in T1 neoplasms, albeit its prognostic value needs further investigation. Finally, Cks1 and Skp2, despite their parallel expression, do not seem to account for p27 loss in lung neoplasms.

OP26-5
DECREASED FOXP3 EXPRESSION IN COPD PATIENTS

Sergejs Isajevs, Immanuels Taivans, Aina Kratovska, Gunta Strazda, Uldis Kopeika, Valentina Gordjushina
Department of Pathology, Faculty of Medicine, University of Latvia, Latvia

Background. Chronic obstructive pulmonary disease (COPD) is a frequent disorder characterized by mostly irreversible airway obstruction that develops predominantly in susceptible smokers and is characterized by persistent airway inflammation and remodelling. CD4+CD25+ FOXP3 positive T regulatory cells have been shown to play an important role in controlling immune and inflammatory reactions. We hypothesize that these cells can be involved in the pathogenesis of COPD. The aim of our study was to characterise the expression of FOXP3 in large and small airways of nonsmokers, smokers with normal lung function and COPD patients. Methods. 19 nonsmokers, 20 smokers with normal lung function and 16 smokers with moderate COPD were enrolled in the study. Immunohistochemical methods were used to evaluate FOXP3 expression in airways. Results. Obtained results have shown that patients with COPD have decreased number of FOXP3 cells in small airways compared to nonsmokers (10 ± 7 versus 21 ± 10 cells/ mm2, p=0.001). Furthermore, the positive correlation between FOXP3 T cell density and airways obstruction was observed (r=0.35; p=0.02). However, our results have shown that the total number of FOXP3 immunoreactive cells in large airways did not significantly differ between nonsmokers, smokers with normal lung ventilation function (137 ± 14 versus 74 ± 12 cells, p>0.05) and COPD patients (304 ± 51 versus 74 ± 12 cells, p>0.05). Conclusion. To conclude, COPD is characterized by downregulation of FOXP3 positive Tregulatory cells in small airways that correlates with airways obstruction.These results highlight a novel, potentially relevant, pathogenic mechanism of chronic obstructive pulmonary disease

OP26-6
LUNG INJURY AFTER SURFACTANT TREATMENT – EXPERIMENTAL STUDIES

Andrzej Marszalek[1], Monika Seget[2], Elzbieta Kaczmarek[2], Wieslawa Biczysko[2]
[1] Department of Pathomorphology Collegium Medicum Nicolaus Copernicus University, Bydgoszcz, Poland and Department of Clinical Pathomorphology Poznan University of Medical Sciences, Poland
[2] Department of Clinical Pathomorphology Poznan University of Medical Sciences , Poland

Background. The use of exogenous pulmonary surfactants formulas was accepted with very good results in treatment of respiratory distress syndrome in newborns. Several attempts were also done for acute respiratory insufficiencies treatment in adults. Unfortunately results of such efforts remain still unsatisfactory. The aim of the present study was the evaluation of effects of therapeutic dose of semi-natural surfactant on the morphology of lung in an experimental model. Method. Pathogen-free rats under anesthesia were given a single dose (150mg of lipids/kg of b.w.) of commercially available surfactant (Curosurf). After 1, 6, 24 hours, 5, 10, 21 and 42 days animals were sacrificed (at least 5 in each group) and lungs were taken and prepared in standard way for paraffin and epoxy resin blocks. Tissue slides were examined by light and transmission electron microscopy as well morphometric studies on aeration of the lung were performed. All results were statistically evaluated. Results. In controls average air-less areas (AALA; corresponding to lung parenchyma) oscillated between 13.86 and 21.73%. In experimental lungs AALA were fluctuating during observations, but in all groups they were larger than in controls ($p<0.0001$). In lungs taken short after treatment we found a progressive raise of AALA from 28.15% (at 1h) to 35.31% (at 24h; $p < 0.001$) and than a decrease. At first time intervals in experimental lungs there were collapsed alveoli with parenchymal and intraalveolar edema. At 1h observations in some samples only about 10% of area was aerated (vs controls 82%; $p<0.0001$). Since 24h observations enormous, inflow of pulmonary macrophages into areas with abundance of exogenous surfactant was found. Moreover in such areas we found proliferation of type II pneumocytes. At 21 and 42 days of observations alveolar septa were widened by the proliferation of fibroblasts as well as deposits of extracellular components (mainly collagen). At 10th day of experiment average area occupied by lung parenchyma was the lowest in experimental groups (28.41% vs 17.61% in controls; $p<0.002$) and than it raised again. Although the maximum AALA at 24h in experimental animals decreased during observations it never became same as for controls. In experimental lungs at 42nd day of observations AALA was 30.57% vs 21.73% in controls ($p<0.001$). Conclusion. Our results suggest that surfactant use has possible destructive effects while reacting with healthy lung. It could cause a rapidly developing changes which are partially reversible. Unfortunately it might lead to lung fibrosis.

OP26-7
EVALUATION OF TKTL1 EXPRESSION IN PRIMARY NON-SMALL CELL LUNG CANCER IN RELATION TO CLINICO-PATHOLOGICAL DATA: WHAT DO AUTOMATED ANALYSES ADD TO HUMAN PERFORMANCE?

Gian Kayser[1], Britta Kubitz[1], Wulf Sienel[2], Dominic Mattern[1], E. Stickeler[3], Johannes Coy[4], Bernward Passlick[2], Martin Werner[1], Axel Zur Hausen[1]
[1] Institute of Pathology, University Hospital Freiburg, Germany
[2] Department of Thoracic Surgery, University Hospital Freiburg, Germany
[3] Universitatsfrauenklinik Freiburg, Germany
[4] R-Biopharm AG, Darmstadt, Germany

Introduction: Malignant tumours are able to degrade glucose to lactose even in the presence of oxygen. This so called Warburg effect is controlled by transketolases converting ribose-5-phosphate, which is usually utilized for nucleic acid synthesis, into C5- and C3-carbohydrates. These can now be degraded into lactate for energy generation. Transketolase like Protein 1 (TKTL1) is supposed to be one of the key-molecules in this shunt from the pentose-5-phosphate pathway to the Embden-Meyerhoff pathway. Material and Methods: Upon this theoretic background we investigated the expression of TKTL1 in 201 primary non small cell lung carcinomas operated with curative intent especially in regard to clinico-pathological data and patients' over all survival by immunohistochemistry using a monoclonal TKTL1 antibody. Results: 90 tumours (44.7%) showed no or mild TKTL1 expression, whereas in 111 tumours (55.3%) it was overexpressed. TKTL1 overexpression correlated with tumour-type ($p= 0.02$) and histological grading (G2: 61% vs. G3: 76%; $p= 0.034$). Overexpression of TKTL1 was significantly associated with poor survival ($p= 0.0077$). This prognostic effect remained significant in multivariate analysis with overexpression of TKTL1 being the second most important marker for patients' survival in our study ($p< 0.0223$). Furthermore, patients with favourable clinicopathologic stages (i. e. $G < 3$, N0, adeno- or squamous cell carcinoma) showed a poorer outcome if the tumours were overexpressing TKTL1 ($p < 0,039$). Conclusion: The data suggest that TKTL1 overexpression relative to the corresponding benign epithelial cells is a new predictor of patient survival in primary non small lung cancer especially for patients with a favourable prognosis. Since inhibition of transketolase enzyme reactions has recently been shown to effectively suppress tumour growth TKTL1 may represent pharmaceutical target.

OP26-8
SEQUENCING OF THE MITOCHONDRIAL D-LOOP REGION AS A TOOL TO DISCRIMINATE BETWEEN SYNCHRONOUS OR METACHRONOUS PRIMARY LUNG TUMOURS AND INTRAPULMONARY METASTATIC SPREAD

Giacomo Caprara[1], Luca Morandi[1], Maurizio Boaron[2], Alessandra Cancellieri[3], Kenji Kawamuka[2], Annalisa Pession[1], Giovanni Tallini[1], Stefania Damiani[1]
[1] Division of Anatomic Pathology University of Bologna, Italy
[2] Division of Thoracic Surgery AUSL di Bologna, Italy
[3] Division of Anatomic Pathology AUSL di Bologna, Italy

Four to 10 percent of patients with non small cell lung carcinoma (NSCLC) present with two nodules or develop a second nodule after the initial diagnosis. Tumor stage is the most important prognostic factor in lung cancer and, therefore, the differential diagnosis between synchronous or metachronous primary lung neoplasms (pT1m) and intrapulmonary metastasis of (NSCLC) (pT4 or pM1 according to their location) is crucial for patient management. The large number of mitochondrial mitochonodrial DNA (mtDNA) copies present in each tumour cell and the high frequency of mtDNA mutation rate in tumours suggest that sequencing of the highly polymorphic D-loop mtDNA region may be useful to discriminate synchronous/metachronous primary tumours from intrapulmonary metastases (1). We studied a retrospective series of 20 patients underwent to surgery for synchronous and metachronous NSCLC. The charts from each patient were reviewed and the tumours were staged according the current WHO and classified as multiple primary or metastases according Martini and Melamed (2). Direct DNA sequencing of the mitochondrial D-loop region was performed in all samples and the genetic distance between the multiple tumours was evaluated. Our results show that in 72% of the casess the tumours were genetically unrelated and thus should be considered as independent multiple primary cancers. It is noteworthy that in this group, in up to 65 per cent of patients, the histological type was the same in all nodules analyzed (most frequently adenocarcinoma, acinar type). In the remaining 28% of cases the mtDNA sequencing revealed the same mutation pattern, compatible with origin from a single neoplastic cell clone. Thus, our study indicates that the present clinicopathologic criteria (site, histological type, etc) for staging patients with multiple nodules of NSCLC may not be fully reliable and that molecular analysis may represent a very useful tool to discriminate multiple primary tumours from intrapulmonary metastases.

OP27-1
INVERTED PAPILLOMA AND RESPIRATORY EPITHELIAL ADENOMATOID HAMARTOMA; CONFUSING TERMINOLOGY AND OVERLAPPING FEATURES

Sulen Sarioglu[1], Ugur Pabuccuoglu[1], Mehtat Unlu[1], Cenk Ecevit[2]
[1] Dokuz Eylul University Faculty of Medicine Department of Pathology Izmir, Turkey
[2] Dokuz Eylul University Faculty of Medicine Department of Otorhinolaryngology and Head and Neck Surgery Izmir, Turkey

Background: At least some of the inverted papillomas (IP) and respiratory epithelial adenomatoid hamartomas (REAH) have overlapping histopathological features. Cases with a diagnosis of IP or REAH, along with a number of sinonasal polyps and nasopharyngeal biopsies were morphologically evaluated in order to describe the overlapping and differential histological features of these cases. Methods: The REAH and/or IP cases included 36 biopsies from 24 patients. All slides were reevaluated according to the pertinent literature by three pathologists in order to classify as IP, REAH or with features of both REAH and IP. Also 55 nasal biopsies from 30 patients and 26 nasopharyngeal biopsies from 10 patients were evaluated for invagination of the surface epithelium with or without branching as well as squamous metaplasia. Results: Twenty eight (% 77.7) biopsies from 17 (70,8%) patients were IP, 4 (16,6%) biopsies from 4(% 11.1) patients were REAH, 4 (16,6%) biopsies from 3 (% 12,5) patients demonstrated a mixture of the microscopic features of IP and REAH. Six patients had recurrent disease. Of these 4 were IP, 1 was REAH and 1 case had features of both IP and REAH. Invagination of the surface epithelium was identified at 45 (82%) of the 55 nasal polyps and 17(65,4) of the nasopharyngeal biopsies, but squamous metaplasia was not identified. Conclusions: We found that only squamous metaplasia was a feature of IP but not of REAH. The invagination of the surface epithelium was a very common feature of the sinonasal region that mimics REAH in many biopsies of the sinonasal region, but smaller. So herein we propose that hamartoma term should be reserved for only cases with components other than epithelial. And IP cases might be grouped as glandular (respiratory epithelial) IP, glandular and solid IP, solid (squamous metaplastic) IP. Probably in this setting the solid (squamous metaplastic) IP will be the group most frequently associated with neoplastic transformation.

OP27-2
THE DIAGNOSTIC ACCURACY OF REVERSE TRANSCRIPTION-PCR QUANTIFICATION OF

Raynaud Pierre[1], Garrel Renaud[2], Rigau Valerie[1], Dromard Mathilde[3], Boulle Nathalie[3], Rousset Thérèse[1], Costes Valerie[1]
[1] CHU Montpellier, Department of Pathology, Gui de Chauliac Hospital, Montpellier, F-34000 France
[2] CHU Montpellier, Department of Head and Neck Surgery, Gui de Chauliac Hospital, Montpellier, F-34000 France
[3] CHU Montpellier, Department of Cellular Biology, Arnaud de Villeneuve Hospital, Montpellier, F-34000 France

PURPOSE: The main goal of sentinel lymph node (SLN) detection in head and neck squamous cell carcinomas is to limit neck dissections to pN+ cases only. However, intraoperative + diagnosis cannot be routinely done using the current gold standard, serial step sectioning with immunohistochemistry. Real-time quantitative reverse transcription-PCR (RT-PCR) is potentially compatible with intraoperative use, proving highly sensitive in detecting molecular markers. This study postoperatively assessed the accuracy of quantitative RT-PCR in staging patients from their SLN. EXPERIMENTAL DESIGN: A combined analysis on the same SLN by serial step sectioning with immunohistochemistry and quantitative RT-PCR targeting cytokeratins 5, 14, and 17 was done in 18 consecutive patients with oral or oropharyngeal squamous cell carcinoma and 10 control subjects. RESULTS: From 71 lymph nodes examined, mRNA levels (KRT) were linked to metastasis size for the three cytokeratins studied (Pearson correlation coefficient, $r = 0.89$, 0.73, and 0.77 for KRT 5, 14, and 17 respectively; $P < 0.05$). Histopathology-positive SLNs (macro- and micrometastases) showed higher mRNA values than negative SLNs for KRT 17 ($P < 10(-4)$) and KRT 14 ($P < 10(-2)$). KRT 5 showed nonsignificant results. KRT 17 seemed to be the most accurate marker for the diagnosis of micrometastases of a size >450 mum. Smaller micrometastases and isolated tumor cells did not provide results above the background level. Receiver operating characteristic curve analysis for KRT 17 identified a cutoff value where patient staging reached 100% specificity and sensitivity for macro- and micrometastases. CONCLUSION: Quantitative RT-PCR for SLN staging in cN(0) patients with oral and oropharyngeal squamous cell carcinoma seems to be a promising approach.

OP27-3
HYPOXIA INDUCIBLE FACTORS HIF1A AND HIF2A ARE LINKED TO POOR RESPONSE OF HEAD-NECK CANCER TO RADIOTHERAPY

Michael Koukourakis[1], Alexandra Giatromanolaki[2], Harilaos Stamos[2], Vassilios Danielidis[3], Efthimios Sivridis[2]
[1] Department of Radiotherapy/Oncology, Democritus University

of Thrace, Alexandroupolis, Greece
[2] Department of Pathology, Democritus University of Thrace, Alexandroupolis, Greece
[3] Department of Otorhinolaryngology, Democritus University of Thrace, Alexandroupolis, Greece

Background: Hypoxia is a major factor defining resistance of cancer cells to ionizing radiation. HIF1α and HIF2α are key transcription factors that are accumulated intracellularly under hypoxic stress, triggering the transcription of more than 50 genes involved in angiogenesis, glycolysis and apoptosis. Materials and Methods: In this study, we assessed the expression of HIF1α and HIF2α in formalin-fixed paraffin-embedded tissues from 37 patients with locally advanced inoperable head-neck cancer (HNC) treated with radical radiotherapy combined with platinum chemotherapy. Radiotherapy was given with hypofractionation (3.5Gy/day). Results: HIF1α and HIF2α were consistently expressed in the nuclei and cytoplasm of cancer cells, but only occasionally in the tumor associated stroma. Using a grading scale that combined the subcellular patterns, the extent and the intensity of staining, we identified groups of low and high HIF reactivity. High expression of HIF1α and HIF2α was noted in 20/37 (54%) and 17/37 (46%), respectively. HIF1α was significantly associated with poor LRFS (p=0.01), whilst HIF2α was not related to local relapse. Cases with low HIF1α expression had a 24month local progression free survival of 73% vs. 46% of patients with high HIF1α reactivity. Conclusion: The expression of HIF1α in HNC predicts resistance to platinum to hypofractionated raditoherapy. Whether HIF2α expressing tumors are more sensitive to larger radiotherapy fractions, compared to standard radiotherapy fractionation, should be further investigated. Molecular inhibition of HIF function appears as a promising therapeutic approach aiming to improve the efficacy of radiotherapy.

OP27-4

OVEREXPRESSION OF CORTACTIN IN HEAD AND NECK SQUAMOUS CELL CARCINOMA IS ASSOCIATED WITH POOR PROGNOSIS AND HIGHER LOCAL RECURRENCE RATES

Van Obberghen-Schilling Ellen[1], Butori Catherine[2], Havet Katia[3], Hofman Véronique[2], Guevara Nicolas[4], Santini José[4], Hofman Paul[2]
[1] UMR CNRS 6543, University of Nice, Nice, France
[2] Laboratory of Clinical and Experimental Pathology, INSERM ERI-21, Human Tissue Biobank, University of Nice, Nice, France
[3] Laboratory of Clinical and Experimental Pathology, University of Nice, Nice, France
[4] Department of Oto-Rhino-Laryngology, University of Nice, Nice, France

Background : Despite recent advances in cancer treatment, the overall-5-year survival rate for patients with squamous cell carcinoma of the head and neck (HNSCC) has not improved over the last 30 years. Thus identifying a biological marker that correlates with recurrence would provide more accurate information on prognosis. Cortactin is a ubiquitously expressed Src substrate that engages in several protein-protein interactions that may be functionally relevant to tumoral progression. Aim : We have investigated expression of cortactin in a large series of HNSCC using tissue microarray (TMA) technology and have correlated this expression to the outcome of these patients. EGF receptor (EGFR) staining was performed to investigate the potential linkage between cortactin and EGFR receptor overexpression. Methods: Cortactin and EGFR expression was retrospectively evaluated by immunohistochemistry in a TMA composed of 176 HNSCC with a mean follow-up time of 5 years. Results: Cortactin immunoreactivity was weak to absent in normal epithelial tissue. Overexpression of the protein in 77 of 176 tumors (44%) was associated with more advanced Tumor-Node-Metastasis stage and higher histologic grade. Cortactin overexpression was associated with increased 5-year local recurrence rates (49 versus 36 %), decreased 5-year disease-free survival (11 versus 48%) and decreased overall survival (24 versus 51%), independently of the EGFR status. In multivariate analysis, cortactin expression status remained an independent prognostic factor for local recurrence, disease-free survival, and overall survival. A subset of patients with cortactin-overexpressing tumors that displayed low EGFR levels had a survival rate that equalled that of patients with tumoral overexpression of both EGFR and cortactin. Conclusion: In patients with HNSCC, overexpression of cortactin as determined by immunohistochemistry is associated with significantly poor prognosis and higher local recurrence rates.

OP27-5

CELL CYCLE PROTEIN EXPRESSION PATTERNS IN HPV-CONTAINING AND –LACKING TONSILLAR SQUAMOUS CELL CARCINOMAS AND ASSOCIATION WITH PROGNOSIS: A ROLE FOR P21?

Jeroen Mooren[1], Johannes Manni[2], Harriet Hafkamp[2], Boris Klingenberg[1], Adri Voogd[3], Fredrik Bot[4], Sandra Claessen[1], Anton Hopman[1], Frans Ramaekers[1], Bernd Kremer[2], Ernst-Jan Speel[1]

[3] Department of Epidemiology, University of Maastricht, The Netherlands
[4] Department of Pathology, Academic Hospital Maastricht, The Netherlands

Background. Tonsillar squamous cell carcinoma (TSCC) may be induced by chemical carcinogens as a result of, e.g., tobacco and alcohol consumption, or by oncogenic human papillomavirus (HPV). HPV presence has been reported to be associated with a favorable patient survival. This study was undertaken because controversial data exist on the expression of key cell cycle proteins in the retinoblastoma (pRb) and p53 pathways in HPV-containing and –lacking TSCC and their impact on patient survival. Method. Formalin-fixed, paraffin-embedded tissue sections (4 µm thick) of 77 TSCC were analyzed for ki-67-, p16INK4A-, cyclinD1-, pRb-, p14ARF-, MDM2-, p53-, p21CIP1/WAF1- and p27KIP1 expression by immunohistochemistry. The presence of biologically associated HPV16 was determined by HPV-specific fluorescence in situ hybridization. Results were correlated with each other and with patient survival. Results. 75 of 77 (97%) TSCC showed strong, nuclear Ki67 expression in 30-90% of tumor cells. 32 (42%) TSCC were HPV16-positive. The presence of HPV was significantly associated with overexpression of p16INK4A ($p<0.0001$), p14ARF ($p<0.0001$) and p21CIP1/WAF1 ($p=0.001$), and downregulation of pRb ($p<0.0001$). p53 and MDM2 accumulation tended to be associated with absence of HPV ($P<0.082$). Accumulation of nuclear cyclinD1 and p27KIP1 was detected in 43% and 28% of the tumors, respectively, irrespective of HPV-status. Univariate Cox regression analysis revealed a favorable survival rate for non-smokers ($p=0.006$), as well as for patients with TSCC, which are classified as T1-2 ($p<0.0001$) or show either low/no expression of cyclinD1 ($p=0.028$), HPV presence ($p=0.024$) or overexpression of p16INK4A ($p=0.029$), p14ARF ($p=0.02$) or p21CIP1/WAF1 ($p=0.004$). Conclusion. HPV 16-associated TSCC exhibit overexpression of p16INK4A, p14ARF and p21CIP1/WAF1 and downregulation of pRb. Tumor size and p21CIP1/WAF1 immunostaining are the most optimal indicators for favorable prognosis in TSCC. This study was supported by the Research Foundation of the University Hospital Maastricht.

OP27-6

ASSOCIATION OF INTERLEUKIN-6 (IL-6) EXPRESSION WITH PROGRESSION OF SQUAMOUS CELL CARCINOMA OF THE HEAD AND NECK IS NOT DEPENDENT ON IL-6 -174 G>C POLYMORPHISM

Metka Volavšek, Mojca Stražišar, Damjan Glavač
Institute of Pathology, Faculty of Medicine, Ljubljana, Slovenia

Background: Recent studies showed increased levels of interleukin-6 (IL-6) and IL-6 receptor (IL-6R) playing a role in development/progression of different cancers including oral carcinoma where oncogenesis was associated with IL-6-174 G>C promoter polymorphism. We wanted to determine whether IL-6 polymorphism affects IL-6 and IL-6R expression in squamous cell carcinomas of the head and neck (HNSCC) and how these factors are interrelated. Methods: DNA was isolated from tumor and adjacent normal tissue from 67 HNSCC patients using standard procedure. The allelic discrimination was performed with TaqMan™ technology on ABIPrism® 7900 HT (Applied Biosystems, USA). Formalin fixed tissue samples were stained immunohistochemically with antibodies against proteins IL-6 and IL-6R. Percentage of positive tumor and adjacent non-cancerous squamous epithelial cells was determined. Correlation with disease parameters and survival analysis was performed with SPSS ver. 14. Results: HNSCC patients were mostly male (60; 89,6%) with moderately differentiated (43; 64,2%) laryngeal cancers (37; 55,2%). Homozygosity for normal IL-6 promoter allele (GG) was found in 21 (31,3%), heterozygosity (GC) in 34 (50,8%) and CC homozygosity in 12 (17,9%) cases. Allele frequency in 67 HNSCC patients didn't differ from control population of 93 healthy persons. It correlated significantly with IL-6 expression in adjacent mucosa (p=0,004) but not tumor cells. Significant correlation was present between IL-6/IL-6R expression in tumor cells (p=0,025) and IL-6 expression/disease progression (N stage p=0,002; stage grouping p=0,044; recidivant disease p=0,043). Survival analysis attested prevalent prognostic value of tumor based prognostic markers, since for other variables only non-significant trends were noted. Conclusions: Our results proved coordinated expression of IL-6 and IL-6R in HNSCC cells. Irrespective of no statistical significance between IL-6 promoter polymorphism and protein expression in tumor cells there was positive correlation to IL-6 expression in adjacent mucosa. This finding suggests that promoter polymorphism may play a role in activation of autocrine/paracrine activating loop mediated by IL-6 and other cytokines appearing in the area of field cancerisation, leading to HNSCC as an ultimate result. Moreover, significant association of IL-6 expression to disease progression not only confirms its significance in tumor proliferative and immune suppresive activity but suggests a possible role of immunohistochemistry in research and different diagnostic or treatment procedures.

OP27-7

PREVALENCE AND TYPING OF HUMAN PAPILLOMAVIRUS IN OROPHARYNGEAL SQUAMOUS CELL CARCINOMAS IN GREECE

Christos Valavanis[1], Prokopis Vogiatzis[1], Mircea Corneliu Romanitan[2], Anders Nasman[2], Torbjorn Ramqvist[2], Konstantinos Banis[3], Petroula Arapantoni-Dadioti[1], Tina Dalianis[2]
[1] Molecular Pathology Unit, METAXA Cancer Hospital, Piraeus, Greece
[2] Oncology-Pathology Dept, Cancer Center Karolinska, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden
[3] Oto-Rhino-Laryngology Dept. , METAXA Cancer Hospital, Piraeus, Greece

BACKGROUND AND OBJECTIVE: The incidence of head and neck squamous cell carcinoma (HNSCC), varies between geographic regions, and tobacco usage and alcohol consumption are the main risk factors. Over the past twenty years however, it has been shown that high-risk types of HPV may be a risk factor for developing HNSCC, and particularly for tonsillar cancer, where HPV is most commonly found and where HPV-16 is by far the most frequently identified subtype. Moreover, recently in the Stockholm area, we have shown that between the years 1970-2002, there has been a 3-fold increase both in the proportion of HPV positive tonsillar cancer (from 23-68%) and the incidence of tonsillar cancer. The increase in tonsillar cancer incidence has been observed in spite of a decreased incidence in smoking, suggesting that HPV is an independent causative factor for tonsillar cancer. Furthermore, patients with HPV positive tonsillar cancer were with regard to median age 10 years younger that patients with HPV negative cancer. The incidence of smoking in Greece is much higher than in Sweden, and for this reason we decided to examine for the presence of HPV in head and neck cancer and particularly in tonsillar cancer in a Greek material for comparison. MATERIALS AND METHODS: Ninety-three squamous cell carcinoma samples (18 tonsillar, 38 tongue, 41 oral cavity tumours) collected between 1986-2006 were analysed by PCR. DNA was extracted from paraffin embedded biopsies. To confirm the presence of PCR amplifiable DNA a PCR for the house-keeping gene S14 was run. For the detection of HPV, PCR with HPV consensus primers GP5+/6+ and CPI/IIG were used. For detection of HPV 16, a PCR with HPV 16 type specific primers was used. RESULTS AND CONCLUSIONS: In total 9/93 tumours were HPV positive. Eight of the 18 tonsillar cancer samples (44%) were HPV positive and notably, within the same material, 7/12 (58%) of the tonsillar cancer samples obtained between years 2000-2006 were HPV positive. Seven (88%) out of the eight HPV positive tonsillar tumours were HPV 16 positive. Of the tongue cancer samples 1/38 (3%) were HPV positive, while none of the 41 oral cavity cancer samples were HPV positive. In addition, patients with HPV positive tonsillar cancer were with regard to median age 5 years younger than patients with HPV negative tonsillar cancer. In summary, almost half of all the Greek tonsillar cancer patients had presence of HPV in their tumours, and HPV-16 was the dominant type. In addition, patients with HPV positive tumours were also younger than patients with HPV negative ones

OP27-8

DEVELOPING HUMAN MINOR SALIVARY GLANDS: MORPHOLOGICAL RELATIONSHIP BETWEEN THE EXPRESSION OF TGF-BETA ISOFORMS AND CYTOSKELETAL MARKERS OF DIFFERENTIATION

Silvia Vanessa Lourenco[1], Dirce Mary Correia Lima[2], Sabrina Hitomi Uyekita[3], Cláudia Malheiros Coutinho Camillo[4], Marcilei Eliza Cavicchioli Buim[4], Fernando Augusto Soares[5]

[3]Department of Dermatology, Medical School, University of São Paulo, São Paulo, Brazil
[4]Department of Pathology,Hospital A.C.Camargo,São Paulo,Brazil
[5]Department of General Pathology, Dental School, University of São Paulo; Department of Pathology, Hospital A. C. Camargo, São Paulo, Brazil

Background: Development and complete differentiation of salivary glands is a complex process that involves a large number of coordinated events. Synchronization between cell proliferation, polarisation and differentiation, which are dependent on epithelial-mesenchymal interactions and on the microenvironment are a requirement. Hormones and growth factors mediate many of these highly orchestrated biological processes and transforming growth factor-beta (TGF-beta) appear to be relevant. TGF-beta is a multifunctional growth factor that has several biological effects, including control of cell growth and differentiation, cell migration, lineage determination, motility, adhesion, apoptosis, synthesis and degradation of

extracellular matrix. Method: Using immunohistochemistry and immunofluorescence we have mapped the distribution of TGF-beta 1, 2 and 3 and compared it with the expression of differentiation markers in human salivary glands obtained from foetuses ranging from weeks 4 to 24 of gestation. Results: TGF-beta 1 first appeared during canalisation stage in the surrounding mesenchyme, and, in the more differentiated stages was expressed in the cytoplasm of acinar mucous cells throughout adult gland. TGF-beta 2 was detected since the bud stage of salivary gland differentiation and its expression was observed in epithelial ductal cell, which increased along gland differentiation, TGF-beta 3 was detected from canalisation stage of salivary gland differentiation being weakly expressed on epithelial ductal cells and it was the only factor detected on myoepithelial cells. Conclusion: The data suggest that TGF-beta have a role to play in salivary gland development and differentiation.

OP28-1

PRIMARY CULTURES FOR PROTEOMIC STUDY IN COLORECTAL CARCINOMA: DO CELLS SURVIVE?

Stefano Pozzi Mucelli[1], Alberto Cescato[2], Enrico Cian[3], Antonio Paniccià Bonifazi[2], Renzo Barbazza[2], Giorgio Stanta[1]

[3] Operative Unit of General Surgery, City Hospital, Feltre, Italy

A novel approach in the proteomic study of tumours, breast cancer in particular, was developed to identify proteins present in fluid collected from primary cultures. A possible aim is to compare the secreted proteomic profile with the plasma proteome, to highlight candidate markers for the diagnosis. In our study we cultured samples of tissue from healthy colon and from colorectal cancer and we evaluate the different expression between proteins derived from the lysis of cells, obtained from traditional tissue homogenization, and those secreted from vital cells in primary culture. Surgery samples were brought in ice to the department of pathology within 20 minutes from resection; they were accurately washed in water and sample from neoplastic and healthy tissue limited to the mucosa far from the zone of necrosis were collected. Tissue samples were posed in sterile Petri dishes, fragmented with sterile knifes, then cultured for 1 to 4 hours in sterile physiologic solution into a CO2 humidified incubator at 5% CO2 and 37 °C. Supernatant collected by centrifugation underwent Western-Blot analysis against Ku80, a nuclear protein involved in DNA repair, and HSC70, involved in secretive pathway. Supernatants were also analyzed to deeper investigate possible modifications in the protein expression profiles. Results achieved show an actual enrichment of the secreted protein within the primary colture media, with a parallel decrease of the amount of the nuclear protein, both for healthy and neoplastic tissues, compared to whole tissue lysates. We can conclude from these preliminary data that cells maintain their secretory activity at least for 4 hours after the resection; the minor alterations observed in the protein profiles point out small modification in cell activity, but suggest also to limit the colture time.

OP28-2

IMPACT OF CELL SENESCENCE AND RAS PATHWAYS IN BREAST CANCER PROGRESSION

Serena Bonin[1], Davide Brunetti[2], Elena Benedetti[3], Nader Gorji[4], Giorgio Stanta[1]

[3]International Centre for Genetic Engineering and Biotechnology, Italy
[4] Surgical Pathology Unit, S. Andrea Hospital, La Spezia, Italy

Background: Breast cancer is the major cause of death among women. Many studies on gene expression have identified, by microarrays, expression profiles and gene sets that are prognostic, predictive or both for breast cancer patients. The major concern related to the use of microarrays platform is the requirement of high-quality RNA, generally derived from frozen samples. Such tumor sets are often small and lack clinical information, whereas formalin-fixed paraffin-embedded (FFPE) materials are abundant and gave the possibility to select samples related to patients with long follow-up periods. Although RT-PCR-based methods from FFPE samples are achieving clinical application, genome-wide microarray analysis has proven difficult. Methods: By using quantitative RT-PCR, we explored the mRNA expression level of 23 genes belonging to RAS pathway (EGFr1, Her2, k-RAS, RAF-1, ERK1, PI3K, AKT), cell cycle regulation/senescence (Cyclin A, D1 and E1, CDK2, CDK4, CDK6, p16, p130-RB2, Retinoblastoma, CDC25a), telomerase complex (mRNA coding for catalytic component and RNA component) and differentiation/metastasis suppression genes (NM23, SEL-1L, cytokeratin 8) by quantitative RT-PCR in 80 patients with breast cancer and 19 metastic lymph nodes. Patients submitted to this study were diagnosed between 1971 and 1989 and were only treated with Halsted radical mastectomy. Our main goal was to investigate whether the gene expression profiles of the reported molecular markers in the primary tumor is predictive of its metastatic potential. Results: The prognostic contribution of the analysed molecular makers in conjunction to age, tumor stage and grade were submitted to Cox proportional hazard regression analysis. Our results showed that PI3K/AKT signalling is related to patients' survival via HER2. Patients with higher expression level of HER2 and/or PI3K, but lower expression level of AKT seem to have worst outcome. Moreover, RAF-1 and CDK2 higher expression seem to have a worst influence on patients' outcome. Among the analysed markers Cytokeratin 8 and Retinoblastoma seem to have a protective effect, in fact higher expression level were associated to better prognosis. Conclusions: In this study we identified a panel of 7 genes that seems to have an influence on patients' survival. The final phase of these markers evaluation would include a prospectively conducted randomised case study to show that the use of these assays yields better clinical outcome than current decision making without molecular tests.

OP28-3

POTENTIAL OF MICRORNA PROFILING FOR THE DIAGNOSIS OF PAPILLARY THYROID CARCINOMA

MicroRNAs (miRNAs) are a new class of non-protein-coding, endogenous small RNAs. They are important regulatory molecules and plants. miRNA regulates gene expression by translational repression, mRNA cleavage, and mRNA decay initiated by miRNA-guided rapid deadenylation. Previous studies showed that some miRNAs regulate cell proliferation and apoptosis processes that are important in cancer formation. So, a current challenge is to elucidate the function of miRNAs in normal physiologic processes and in disease states, since several clues have recently pointed to the potential role of miRNAs in

cancer and suggest that aberrations in miRNAs may be crucial in tumor progression. Thyroid cancer poses a significant clinical change, and our understanding of its pathogenesis is still incomplete. Papillary thyroid carcinoma (PTC) is the most common malignancy in thyroid tissue accouting for around 80% of all thyroid cancers. Apart from alterations in the BRAF-RAS-RET/PTC pathway, little is known about he genetics of PTC. The aim of our study was to determine the regulation of miRNAs in different thyroid tumors, including PTC, by using an home-made miRNA microarray. For this purpose, 8 follicular adenomas, 10 PTC, and 3 follicular carcinomas were included. Total RNA was extracted with TRIzol solution and the integrity of RNA was assessed by using an Agilent Bioanalyzer 2100. Following extraction, hybridization of miRNAs was then carried out on our miRNA microarray chip, which contained more than 500 mature miRNA probes spotted in quadruplicate. Obtained results were the more significative in PTC tumors. Analysis showed that eight miRNA genes were significantly overexpressed in PTC with fold changes superior to 2.5 in all patients. Among these miRNAs the following were strongly upregulated: miRNA-146, miR-221, miR-21, miR-155, and miR181. Interestingly, the expression of miR-221 was also detectable in normal thyroid tissue adjacent to PTC tumors from all patients. Overexpression of miR-221 in PTC tumors and in normal thyroid tissue adjacent to PTC tumors was confirmed by both semiquantitative RT-PCR and Northern blot. In conclusion, these data indicated that the upregulation of miRNAs in PTC tumors may represent a distinct miRNA signature. Moreover, increased expression of miR-221 in normal tissue might be also an early genetic event in PTC carcinogenesis. Altogether, these datas showed that RNA-based regulatory mechanisms involving miRNAs characterise PTC.

OP28-4

GENE EXPRESSION ANALYSIS IDENTIFIES NOVEL RBL2/P130 TARGET GENES IN ENDEMIC BURKITT'S LYMPHOMA CELL LINES AND PRIMARY TUMORS

Giulia De Falco[1], Eleonora Leucci[1], Dido Lenze[2], Pier Paolo Piccaluga[3], Anna Onnis[1], Giovanna Cerino[1], Joshua Nyagol[1], Anna Luzzi[1], Cristiana Bellan[1], Michael Hummel[2], Stefano Pileri[3], Piero Tosi[4], Harald Stein[2], Antonio Giordano[5], Lorenzo Leoncini[1]

Background: Burkitt lymphoma (BL) is a B-cell tumor whose characteristic gene aberration is the translocation t(8;14), which determines c-myc over expression. Several genetic and epigenetic alterations, other than c-myc over expression, have also been described in BL. It has been demonstrated that the RBL2/p130 gene, a member of the retinoblastoma family (pRbs), is mutated in BL cell lines and primary tumors. Methods: The aim of this study was to investigate the biological effect of RBL2/p130 in BL cells and its possible role in lymphomagenesis, as we previously observed that this gene is often mutated in BL. Therefore, we reintroduced a functional RBL2/p130 in BL cell lines. Results and conclusions: Our results demonstrated that RBL2/p130-transfected cells regain growth control, suggesting that RBL2/p130 may control the expression of several genes, which may be important for cell growth and viability. Gene expression analysis revealed a modulation of several genes, including CGRRF1, RGS1, BTG1, TIA1 and PCDHA2, upon RBL2/p130 reintroduction. We then monitored their expression in primary tumors of endemic BL as well, demonstrating that their expression resembled those of the BL cell lines. These data suggest that, as RBL2/p130 modulates the expression of target genes, which are important for cell growth and viability, its inactivation may be relevant for the occurrence of BL. Therefore we checked whether it could represent the second hit, together with c-myc over expression, for the onset of BL. To check whether these two events were sufficient per se to confer the cells a transformed phenotype and to mimic a BL, we engineered a human non-transformed lymphoblastoid B cell line to over express c-myc and we then silenced RBL2/p130 by RNAi. Our preliminary results indicate that RBL2/p130 silencing strengthens the growth advantage due to c-myc over expression, suggesting that its inactivation may concur to Burkitt lymphomagenesis.

OP28-5

VEGF AS AN AUTOCRINE STIMULATOR OF PROLIFERATION AND MOTILITY IN ASTROGLIAL CELL LINES

Petra Knizetova, Alice Hlobilkova, Zdenek Kolar, Jiri Ehrmann
Laboratory of Molecular Pathology, Institute of Pathology, Palacky University, Hnevotinska 3, 775 15 Olomouc, Czech Republic

Background: Glioblastoma multiforme is characterized by exuberant angiogenesis, a key event in tumor growth and progression. Of all solid tumors, those of the brain show the highest degree of vascular proliferation. The neovascularization in glial tumors correlates directly with their biological aggressiveness, degree of malignancy and inversely with post-operative survival. Inducibility of Vascular Endothelial Growth Factor (VEGF) through growth factors such as epidermal growth factor, platelet derived growth factor and basic fibroblast growth factor in vitro has been demonstrated in astroglial cell lines. Paracrine effect of VEGF secreted by glioma cells on tumor vasculature was supported by several lines of evidence, but lesser is known about its autocrine function in glioma progression and invasivity. Method: RT-PCR and immunohistochemistry were used to confirm co-expression of VEGF and VEGF receptors (Flt-1 and KDR) in astroglial cell lines (A172, U87MG, T98G, U118MG, SPF126, U251G, Gli-6 and U373MG). MTT proliferation test and F-actin staining were performed to investigate effect of VEGF on cell proliferation and motility. Following stimulation with exogenous VEGF, cells were washed and incubated for 24 hours to detect exogenously induced VEGF secretion using VEGF ELISA Kit (R&D Systems). Protein extracts from VEGF-treated cell lines were used for Western blotting to detect phosphorylation levels of key members of Ras/MAPK and PI3K signalling pathways. Results: VEGF and VEGF receptors were found to be co-expressed in all cell lines tested, both on RNA and protein level. Stimulation of these cell lines with exogenous VEGF lead to significant increase in proliferation, as well as massive re-organization of F-actin and stress fibers formation implicating enhanced cell motility. These cellular effects were based on preferential activation of Ras/MAPK in co-operation with PI3K signalling pathway. ELISA testing of VEGF-treated astroglial cell lines confirmed autocrine loop between VEGF ligand and VEGF receptor, since exogenous VEGF was capable of enhancing VEGF secretion comparing to VEGF-untreated control. Conclusion: Our results indicate indispensable role of VEGF not only as paracrine stimulator of tumor angiogenesis, but also as important autocrine factor stimulating glioma growth and migration. Because diffusely infiltrating gliomas are mostly resistant to current chemo- and radiotherapies, the research of angiogenesis as well as autocrine role of VEGF is of special interest. This work was supported by grants VZMSM6198959216 & IGAMZCR & NR/8370-3/2005.

[4] Obstetrics and Gynecology Department, Principe de Asturias Hospital, Spain

BACKGROUND: Ductal carcinoma in situ (DCIS), responsible for 25% of newly diagnosed breast carcinomas, is considered an early step in the progression to invasive cancer. The rationale for treating DCIS is to prevent progression into an invasive disease. Vasoactive intestinal peptide (VIP) may function as autocrine/paracrine growth factor in breast cancer tissue. Recently, it has been hypothesized that VIP receptors ($VPAC_1$ and $VPAC_2$) may constitute a dynamic element in plasma and nuclear membranes. The aim of this work was to detect the different compartmentalization of VPAC receptors supporting the role for both exogenous and endogenous VIP. METHOD: Tissue samples were obtained by total or partial mastectomy and embedded in paraffin. They included benign proliferative diseases, and in situ and infiltrative carcinomas. The expression of the mRNAs for both VPAC receptors was detected in normal and pathological situations by means of quantitative RT-PCR assays. In order to evaluate VIP expression, quantitative RT-PCR and enzyme immuno-analysis assays were performed. RESULTS: All the specimens studied showed $VPAC_1$ immnunoreactivity mainly located at nuclear level and showing a differential expression. $VPAC_2$-immunoreactivity was absent. We observed overexpression of VIP mRNA, and two to four-fold higher VIP levels in DCIS samples as compared to normal tissue. CONCLUSION: This is the first demonstration of nuclear location of $VPAC_1$ receptor in human breast tissue. It suggests another role, which is still unclear, for this receptor in cell signalling involved in malignant transformation processes. In addition, these findings contribute to previous observations of our group on the intracrine mode of action of VIP on the genomic regulation of target genes such a vascular entothelial growth factor. Furthermore, these features support further studies on the potential therapeutic usefulness of available VIP receptor antagonists for breast cancer.

OP28-7

LOSS OF HETEROZYGOSITY (LOH) FOR THE 17Q22-24 LOCUS, PRKAR1A GENE MUTATIONS AND MICROSATELLITE INSTABILITY (MSI) IN BASAL CELL CARCINOMA (BCC)

Angeliki Stamatelli[1], Thaleia. A Bei[2], Angelika. A Saetta[1], Sotirios Stergiopoulos[2], Sosipatros Boikos[2], Efstratios Patsouris[1], Kiriaki Aroni[1], Constantine A Stratakis[2]
[1] 1st Department of Pathology, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece
[2] Section of Endocrinology & Genetics, DEB, National Institutes of Child Health and Human Development, NIH, Bethesda, MD, USA

Background: Basal cell carcinoma (BCC) is the most common malignant human neoplasm; it is characterized by slow growth, virtual absence of metastases and strong stroma-dependency. It is estimated that the incidence of cutaneous basal cell carcinoma is increasing worldwide. Microsatellite instability (MSI) constitutes an alternative -to the chromosomal instability- pathway of carcinogenesis for certain tumor types with prognostic and therapeutic significance for the respective patients. Protein kinase A regulatory subunit type 1α (R1α) is encoded by the PRKAR1A gene located on chromosome 17q22-24. PRKAR1A is mutated in more than half of Carney complex (CNC) patients; loss of heterozygosity (LOH) can be demonstrated in tumors from CNC patients. Molecular studies also revealed R1α down-regulation, PRKAR1A-inactivating mutations and/or 17q22-24 LOH in certain sporadic tumors. In this study, we investigated whether changes in the PRKAR1A gene and the expression of the R1α protein are related to the MSI status of BCCs and involved in the pathogenesis of BCC. Methods: The presence of MSI was investigated in 75 BCCs using mononucleotide microsatellite markers, BAT-25, BAT-26 and the repetitive sequences within the target genes TGF-beta-RII, IGFIIR, hMSH3, hMSH6 and Caspase5. Additionally, 3 dinucleotide markers were analyzed on 20 cases of BCC with matched normal tissue. DNA analyses for the 17q22-24 locus (LOH) and the PRKAR1A gene mutations were also performed on 20 cases of BCCs with matched normal tissue. For LOH studies, 12 microsatellite markers (MM) were examined around the 17q22-24 locus. The coding PRKAR1A gene sequence was checked in all samples. Results: MSI was detected in 16% of the cases exhibiting alterations only in the mononucleotide markers. The rate of High-MSI (H-MSI) was <5%: two cases, 1 multifocal superficial and 1 nodular BCC showed H-MSI at three markers (BAT-25, BAT-26 and hMSH3) and at two markers (BAT-25 and TGF-beta-RII) respectively. The rate of LOH for 17q22-24 was 15%; 3 of the 20 matched BCC cases showed extensive 17q22-24 LOH. The analysis of the PRKAR1A gene is pending. Conclusion: No association could be elicited between LOH for the 17q22-24 locus and the MSI status of the BCCs. Results of immunohistochemistry (IHC) with R1a antibody as well as the results of PRKAR1A mutations will elucidate the contribution of PRKAR1A in the pathogenesis of BCC.

OP28-8

THE FUSE/FBP/FIR/TFIIH-SYSTEM IS A MOLECULAR MACHINERY EQUIPPED TO CONTROL THE EXPRESSION OF THE C-MYC PROTO-ONCOGENE BY SENSING DNA-CONFORMATION OF THE PROMOTER AND FINE-TUNING TRANSCRIPTIONAL OUTPUT

[2] Gene Regulation Section, Laboratory of Pathology, NCI, NIH, Bethesda, MD 20892, USA

Background: De-Regulation of the c-myc proto-oncogene can be carcinogenic. A continuous stream of activating and repressing signals is processed by the transcription complex at the promoter of the c-myc gene. The general transcription factor IIH (TFIIH) is held at promoters prior to promoter escape, and targeted by the single-stranded DNA-binding transcription factors FarUpStream element (FUSE) binding protein (FBP) and FBP-interacting repressor (FIR). Since transcpritionally generated torsion melts FUSE, FBP and FIR bind dependent on FUSE melting, and both regulate transcription through TFIIH, the FUSE/FBP/FIR/TFIIH-system is well situated to modulate the input of activators and repressors of the c-myc gene. Methods: Chromatin immunoprecipitation (ChIP) reveals that FBP and FIR establish a dynamically remodelled loop with TFIIH, which is lost in cells from xeroderma pigmentosum B, a cancer-prone syndrome caused by mutations of p89, the largest subunit of TFIIH (XPB). Using in vivo-footprinting and nuclear run on-experiments, structural, compositional, and functional differences are demonstrated in transcription complexes at the native c-myc promoter between XPB cells, and cells complemented with wild-type p89 (XPB/wt-89). Remarkably, although the mean levels of c-Myc are only modestly elevated in XPB cells compared to XPB/wt-p89 cells (determined by RNase protection assay, western blot, and FACS analysis), the range of expression and the cell-to-cell variation of c-Myc are shown to be markedly increased. Results and Conclusions: Our data indicate that TFIIH integrates inputs from multiple signals, regulating transcription at multiple steps between initiation and promoter escape. By utilizing dynamic changes of DNA-conformation, the FUSE/FBP/FIR/TFIIH system helps to suppress the intrinsic

noise of transcription and to ensure a steady transcriptional output of c-myc, which is necessary for cellular homeostasis.

OP29-1

E -CADHERIN LOSS AND DELTA-NP73L EXPRESSION IN ORAL SQUAMOUS CELL CARCINOMAS

Alberto Righi[1], Roberto Cocchi[2], Luca Morandi[1], Gianluca Marucci[1], Maria G. Pennesi[2], Annalisa Tosi[1], Dario De Biase[1], Annalisa Pession[1], Lucio Montebugnoli[3], Maria Pia Foschini[1]

[2] Department of Maxillo-Facial Surgery, Bellaria Hospital, Bologna, Italy

[3] Department of Dental Sciences, University of Bologna, Bologna, Italy

BACKGROUND: During the last years studies based on DNA array have evidenced that oral squamous cell carcinoma (OSCC) with metastases has a gene expression profile different from OSCC devoid of metastases. This lead to the formulation of the "metastatic gene expression profile" hypothesis. Accordingly primary OSCC harboring metastases carry genetic alterations favoring the metastatic process. Purpose of the present study is to investigate parameters useful to predict lymph node metastases. METHOD: Fifty-eight cases of surgically resected OSCC were studied with an immunohistochemical method for the adhesion molecule E-Cadherin and the truncated dominant-negative isoform of p63 (delta-Np63). In addition p63 gene expression profile was evaluated by Real Time-PCR to disclose the presence of the truncated variant delta-Np73L. Data obtained were correlated with lymph node metastases detected at presentation and during follow-up. RESULTS: E-Cadherin expression is the most powerful parameter related to the presence of lymph node metastases at presentation. Twenty four cases out of 38 (63%) showing low E-Cadherin expression developed lymph node metastases as compared to 5 out of 20 (25%) cases($P<0.01$) showing high E-Cadherin expression. The predictive value increases when low expression of E- cadherin is associated to immunohistochemical expression of delta Np63. When this occurs, lymph node metastases are seen in 21 out of 28 (75%) of the cases, as opposed to 17 out of 30 (57%) of the remaining cases. The association between E-Cadherin low expression and delta-Np73L is highly predictive for developing lymph node metastases even in small sized tumours (T1\T2). When this association occurs, metastases develop in 5 out of 8 (62.5%) cases as compared to 5 out of 31 (16.1%) that don't show this association. CONCLUSION: the present study shows that low E-Ccadherin expression is useful to predict lymph node metastases in cases of OSCC. The predictive value is enhanced when low E-Cadherin positivity is associated to delta-Np63 and delta-Np73L expression.

OP29-2

HTERC TELOMERASE GENE AMPLIFICATION AT 3Q DEMONSTRATED WITH FISH ANALYSIS STRATIFIES LARYNGEAL PRECURSOR LESIONS

Kay Hertel, Regine Dahse, Birgit John, Hartwig Kosmehl

Institute of Pathology, HELIOS Klinikum Erfurt GmbH, Germany

Background: HPV DNA is detectable in 25 to 43% of laryngeal carcinomas. HPV-associated invasive cervical carcinomas invariably carry extra copies of chromosome arm 3q. The demonstration of this specific genomic imbalance using FISH analysis is considered as a valuable tool to identify precursor lesions with potential to progress to invasive carcinoma. FISH analysis includes a series of six BAC clones that cover the human telomerase gene (hTERC) which maps to chromosome 3q. We analysed the gain at 3q in HPV-positive or negative laryngeal precursor lesions using FISH technique in order to stratify the potential to progress. Method: Buffered formalin-fixed routine samples of laryngeal precursor lesions were classified according to the Ljubljana criteria (WHO 2005). 11 laryngeal precursor lesions (4 atypical hyperplasias and 7 carcinomas in situ) were analysed for HPV by PCR technique. PCR primers GP5 and GP6 detecting the HPV L1 open reading frame were used for general HPV detection. Typing was performed using type-specific primers for HPV 6, 11, 16 und 18. Additionally, all samples were analysed concerning gains at 3q using FISH technique and the CERVIxCYTE kit following manufacture's protocol (Cancer Genetics, USA). Results: None of the 4 atypical hyperplasias were positive for HPV, but 3 out of 4 cases demonstrated a 3q amplification in FISH analysis. In 3 out of 7 carcinomas in situ HPV DNA was detected and typed as HPV 16. The 3 HPV 16-positive cases carried multiple signals of the telomerase gene. Conclusions: The increase of telomerase gene signals in the HPV-positive laryngeal carcinoma in situ is in accordance with reports of cervical intraepithelial neoplasia (CIN) 2/3. Consequently, it can be assumed that the telomerase gene amplification visualised via FISH technique is suitable to stratify HPV-associated laryngeal precursor lesions concerning the potential risk to progress. An increase of telomerase activity and protein expression in laryngeal precursor lesions is well documented. The significance of increased telomerase FISH signals in the HPV-negative atypical hyperplasias may be discussed in this relation.

OP29-3

CHROMOSOME INSTABILITY AS DETECTED BY FISH PREDICTS PROGRESSION OF PREMALIGNANT LESIONS OF THE LARYNX

Ewa Bergshoeff[l], Annick Haesevoets[2], Fredrik Bot[3], Adri Voogd[4], Anton Hopman[2], Frans Ramaekers[2], Johannes Manni[1], Ernst-Jan Speel[2]

[3] Department of Pathology, Academic Hospital Maastricht, The Netherlands

[4] Department of Epidemiology, University of Maastricht, The Netherlands

Background: The dilemma in managing patients with precursor lesions of the head and neck mucosa is of deciding which lesions or mucosal areas are potentially malignant and will progress to carcinoma. In a previous study on a small series of laryngeal precursor lesions we showed that chromosomal instability (CIN), indicated by the presence of chromosome imbalances and/or polyploidization using single-target brightfield in situ hybridization (ISH) for chromosome centromeres 1 and 7, strongly predicted its malignant progression (J. Clin. Oncol. 2000, 1644-1651). To further substantiate these data for clinical application, we have examined retrospectively a new series of 69 patient specimens by a double-target fluorescence ISH (FISH) approach using both centromere probes. Method: Paraffin-embedded tissue sections of laryngeal precursor lesions with dysplastic features of 69 patients were used for histopathological reclassification and FISH analysis. Medical records were screened for patient follow-up data (development of carcinoma (in situ)), and results were statistically evaluated. Twenty cases, which received radiotherapeutic treatment directly after the histopathological diagnosis of carcinoma in situ, were omitted in Kaplan Meier analysis. Results: FISH analysis showed an increasing level of CIN with increasing histopathological grade. The disease-free survival in lesions with CIN was significantly worse than in lesions without CIN ($P=0.0014$). Routine histopathology was unable to predict malignant progression in precursor lesions of the larynx ($P=0.13$). Its value, however, strongly improved after reclassification of the specimens by an experienced pathologist ($P=0.0007$). In the group of low grade lesions (hyperplasia, mild and moderate dysplasia) only CIN

strongly predicted malignant progression (P=0.0004 versus P=0.1134 for histopathological diagnosis). Conclusion: Laryngeal tumorigenesis is associated with the development of CIN, which can be used for reliable identification of lesions at risk for progression. This study was supported by the Research Foundation of the University Hospital Maastricht and the Dutch Cancer Society.

OP29-5
HIGH PREVALENCE OF HPV INFECTION IN HEAD AND NECK SQUAMOUS CELL LESIONS.

Patrizia Morbini[1], Paola Alberizzi[2], Giulia Bertino[2], Patrizia Gatti[2], Chiara Villa[1], Marco Benazzo[1]
[1] Policlinico S. Matteo/Università di Pavia, Italy
[2] Policlinico S. Matteo, Italy

Background: Cytopathic modifications due to human papillomavirus (HPV) infection are difficult to recognize from artefactual changes in small, crushed or electrocoagulated samples and from cytologic atypia of neoplastic cells. Having noticed the presence of simil-cytopathic modifications in nearly all squamous cell lesions of the head and neck, we collected a small consecutive series of hyperplastic, preneoplastic and neoplastic lesions and investigated the prevalence and the genotype of HPV infection. Materials: 30 samples were examined including 5 reactive hyperplasias, 16 squamous cell papillomas, 3 dysplasias and 6 squamous cell carcers. HPV infection was assessed with the INNO-Lipa HPV-Genotyping V2 kit (Innogenetics NV, Ghent, B) that recognizes 10 low-grade (LG) and 15 high-grade (HG) viral types. P16 expression was immunohistochemically determined to document viral genome integration. Results: All samples tested but one papilloma harboured HPV DNA. HG-HPV was detected in 3 (60%) hyperplasias, 6 (37,5%) papillomas, 2 (66%) dysplasias and 5 (83,3%) neoplasias. 27 different HG-HPV infections were observed in 16 samples. HPV 16 was the most frequent (26%), followed by less common types 31, 51 and 52 (18.5% each), 18 (7,4%), and 33, 39,68 (3,7% each). According to disease site, oral, oropharyngeal and nasal lesions showed an equal number of HG and LG type infections; laryngeal lesions harboured in 7 cases HG and in one case LG HPV. One reactive hyperplasia with HG-HPV infection recurred repeatedly with cancer development; 1 of 9 papillomas with LG infection and 3 of six with HG recurred repeatedly. Follow-up of dysplastic lesions was too short to assess recurrences. P16 expression was observed in 75% of samples with HG infection, including those recurring, and in none of those with LG infection. One heavy smoker and 2 drinkers were present in the series, all harbouring HG HPV infection. Conclusions: The high prevalence of HPV infection in a small series of squamous cell lesions of the head and neck with suspected cytopathic changes suggests that in our geographic area HPV diffusely infects high airways. Molecular tests recognizing a wide spectrum of viral types are probably in part responsible for the higher prevalence observed in the present study with respect to literature data, most focusing on types 16 and 18. HG infection in benign lesions seems to increase the risk of recurrence/progression. Further tests to assess prevalence of HPV in normal subjects and the association with heavy smoke/drink are in progress.

OP29-6
CO-EXPRESSION OF EGFR AND CYCLIN-D1 PREDICTS RADIOCURABILITY OF T2N0 SQUAMOUS CARCINOMA OF THE LARYNX

Mark Rafferty[1], Andrew Jones[1], Terry Jones[1], David Husband[2], Tim Helliwell[1]
[1] University of Liverpool, United Kingdom
[2] Clatterbridge Centre for Oncology, United Kingdom

Modulators of the cell cycle are considered important in carcinogenesis and may influence the response to radiotherapy. Many previous studies of potential interactions between tumour biomarkers in head and neck cancers have produced inconsistent results due to a mixture of primary sites, stages and treatment modalities. This study has examined the immunocytochemical expression of Ki-67, epidermal growth factor receptor (EGFR), cyclin D1 and retinoblastoma protein in diagnostic biopsy material, in relation to primary site recurrence rates of T2N0 laryngeal carcinomas in 50 patients treated with curative intent using a standard radical radiotherapeutic protocol. Five carcinomas showed loss of retinoblastoma protein expression and the median indices of immunocytochemical markers were 50% for Ki-67, 21% for cyclin D1 and 47% for EGFR. There was a positive correlation between the expression of EGFR and that of cyclin D1 (p=0.03). On univariate analysis, relatively low Ki-67 expression (<50%) showed a trend for association with tumour recurrence but this association was not statistically significant. When interactions were examined using median values for a cut off between high and low expression and multiple logistic regression analysis with categorical modelling, it was found that a combination of high EGFR expression and high cyclin-D1 expression was associated with a high risk of tumour recurrence at the primary site (odds ratio 5.32, 95% CI +/- 0.41). This study illustrates the value of examining molecular interactions in a group of clinically well-defined cancers treated with a uniform protocol. If confirmed, the results may provide assistance in deciding between appropriate treatment options for patients with squamous cell carcinomas of the larynx.

MOLECULAR H&E

Ali Can, Harvey E. Cline, Xiaodong Tao, Musodiq O. Bello, Maximilian L. Seel, Michael J. Gerdes, Fiona Ginty, Michael Montalto.
Molecular Imaging and Diagnostics Advanced Technology Program, General Electric, Global Research Center, Niskayuna, NY, USA

Traditional quantitation techniques for anatomical or molecular pathology applications involve either processing Hematoxylin-Eosin (H&E) bright field microscopy color images (containing red, green, and blue image channels), or multiple channel molecular images taken by a fluorescence microscopy. Simultaneous imaging of both microscopy modalities has been difficult due to optical and chemical effects of the H&E dyes. We propose a new sequential imaging and registration technique that overlays the molecular image information from fluorescence microscopy with the color H&E images, hence increasing the number of data channels. First the tissue is labeled with molecular biomarkers, and imaged through a fluorescence microscope, and then the tissue is re-labeled with H&E dyes, and imaged again. We present robust image registration techniques to overcome the sparse distribution of small cell nuclei across different modalities. Once the images are registered then image analysis and quantitation techniques can benefit from the extra information channels. Multi-dimensional clustering and segmentation algorithms can detect different cell compartments from the registered multi-channel images. By merging transmitted brightfield channels with monochromatic fluorescence channels, we can utilize the advantages of each imaging modalitiy such as, high signal-to-noise ratio, and specificity in fluorescence images, and unscattered light in bright-field images. For diagnosis, the pathologist can easily superimpose the molecular biomarker images on the digital H&E images. We demonstrate superimposition of ER, AR, Her2 and

p53 marker images of immunohistochemically stained breast tissue micro arrays on the H&E image of the same tissue.

OP30-2

AUTOMATED IMAGE ANALYSIS FOR HIGH-THROUGHPUT QUANTITATIVE DETECTION OF ER AND PGR EXPRESSION LEVELS IN LARGE-SCALE CLINICAL STUDIES: THE TEAM TRIAL EXPERIENCE

Dana Faratian[1], Charlene Kay[1], Fiona Campbell[1], Tammy Robson[1], Margaret Grant[2], Daniel Rea[2], John Bartlett[1]
[1] Endocrine Cancer Group, Edinburgh Cancer Research Centre, University of Edinburgh, Crewe Road South, Edinburgh, EH4 2XR, United Kingdom
[2] Institute for Cancer Studies, University of Birmingham, Edgbaston, Birmingham, B15 2TT, United Kingdom

BACKGROUND: Automated image analysis is an attractive solution to rapid, accurate, and reproducible evaluation of tissue biomarkers in large clinical trials, which to date has not been validated for standard immunohistochemical (IHC) stains in large numbers of samples due to perceived difficulties in complex tissue analysis. By taking a pathology-based approach to cell and compartment discrimination we have validated the Ariol Image Analaysis platform for nuclear ER and PgR histoscore analysis against manually-scored samples. METHODS: 397 cases of breast cancer (UK TEAM trial, part of the multinational TEAM pathology study) were arrayed on two tissue microarrays (TMAs), in six replicates. 56 full sections of corresponding tumours were cut for comparison with TMAs. Slides were stained for ER and PgR by standard IHC techniques. All cores were scored to produce a semi-quantitative histoscore (0-300). One half of the cohort was used as a training set and the other as an independent test set. Slides were scanned on the Ariol SL-50 Image Analysis System, tumour epithelium marked for analysis, and marked areas quality assured by a pathologist. The system was trained on the basis of the cellular characteristics of epithelial, stromal, and infiltrating non-tumourous cells to produce a trained classifier applicable to all nuclear stains. Correlations were assessed using Pearson's correlation coefficient (PCC) and inter-class correlation coefficient (ICCC) for continuous variables. RESULTS:The PCCs for full section and TMA PgR manual histoscores were equal for both three and six cores (0.94). PCCs and ICCCs for automated and manual scores for PgR training TMAs were 0.96-0.97 and 0.88-0.93 when <3 cores were analysed and 0.97-0.98 and 0.94-0.96 when >3 cores were analysed. The PCC and ICC for the PgR test set was 0.98 and 0.96, respectively. PCCs and ICCCs for ER training sets were 0.95 and 0.82 while for the ER test set were 0.98 and 0.84. CONCLUSIONS:Full section and TMA scoring shows excellent concordance for both ER, and the more heterogeneously staining PgR. There is no significant improvement in correlation when more than 3 cores are analysed. The PCCs and ICCCs for PgR are always excellent (>0.93, >2 cores), while the ICCCs for ER show good concordance (0.8-0.9). The lower ICCC values for ER reflect better discrimination of darkly stained nuclei, and an improvement over manual scoring. Automated image analysis can replace manual scoring for ER and PgR performed on TMAs in clinical trials.

OP30-3

MOLECULAR PROFILING OF SIGNAL PATHWAYS IN FORMALIN FIXED CANCER TISSUES USING PROTEIN LYSATE MICROARRAYS

Karl-Friedrich Becker, Hildegard Mack, Susanne Hipp, Christina Schott, Heinz Hofler
Technical University of Munich - Institute of Pathology, Germany

Histopathological diagnosis in most hospitals around the world is based upon formalin fixed and paraffin embedded (FFPE) tissues. Recently, we established a very efficient and easy-to-use technique for extraction of high amounts of full length, non-degraded and immunoreactive proteins from routinely processed FFPE tissues for Western blot and protein lysate microarray analysis. As defective, hyperactive or dominating signal pathways may drive cancer growth, survival, invasion, and metastasis, we evaluated in this study whether phosphorylated proteins can be detected and quantified in routine clinical tissues. Monitoring the total and phosphorylated proteins in a diseased tissue may allow us to infer the activity levels of the proteins in a particular pathway as starting point for the design of individual therapy regimens. We first compared the extraction efficiency of phosphorylated proteins between formalin fixed and unfixed cells in culture. Epidermal growth factor (EGF) receptor-positive cell lines were stimulated with EGF for various time points and either fixed with formalin or left unfixed. Subsequently, proteins were extracted and analysed by Western blot. We were able to extract and identify all phosphorylated proteins analysed, including phospho-EGFR, phospho-ERK, and phospho-Akt. There were no differences between formalin fixed and unfixed cells. In a first proof-of-principle study we analysed 31 formalin fixed primary human cancers (20 breast and 11 endometrial cancers) and quantified 6 pairs of phosphorylated and non-phosphorylated proteins (EGFR/pEGFR, p38MAPK/pp38MAPK, Akt/pAkt, HER2/pHER2, ERK/pERK, GSK3beta/pGSK3beta). Proteins were extracted from formalin fixed histological tumour sections and printed on nitrocellulose coated glass slides. The resultant protein lysate microarrays were probed with 12 antibodies against the total or the phosphorylated proteins, respectively. We were able to identify all proteins of interest; thus, quantitation of protein phosphorylation in formalin-fixed tissues is possible. The first result of our analysis is the striking degree of patient heterogeneity in the activity of the signalling molecules within each breast cancer patient. In contrast, the endometrial cancer patients did not show this marked heterogeneity. Our study demonstrates the utility of protein lysate microarrays from formalin fixed tissues for the multiplexed analysis of critical phospho-specific endpoints and suggest that pathway activation profiles in breast cancer may be patient-specific.

OP30-4

MOLECULAR EVALUATION AND CLINICAL CORRELATION OF T(14;18)(BCL-2/IGH) IN 26 CASES OF FOLLICULAR LYMPHOMA: THE IMPACT OF DIFFERENT MOLECULAR APPROACHES

Nur Selvi[1], Buket Kosova[2], Mine Hekimgil[3], Cumhur Gunduz[2], Burcin Tezcanli[2], Emin Karaca[4], Guray Saydam[5], Yesim Ertan[3], Nejat Topcuoglu[2]

[3] Ege Universit, Faculty of Medicine, Departments of Pathology, Izmir, Turkey
[4] Ege University, Faculty of of Medicine, Deparments of Medical Genetics, Izmir, Turkey
[5] Ege University, Faculty of Medicine, Departments of Haemotology, Izmir, Turkey

Follicular lymphomas (FL) are among the most common lymphomas, characterized t(14;18) (q32;q21) in more than 80% of patients. As a result bcl-2/IgH rearrangement occurs leading to overexpression of bcl-2. Detection of this translocation is essential either for the diagnosis or the follow-up of the minimal residual disease. The aim of this study was to determine the positivity of t(14;18) by detection of mbr or mcr in 32 paraffin-embedded tissue samples and four peripheral blood samples of consecutive FL patients who were diagnosed and followed-up between 1999-2006 and compare the results with clinical outcomes. After extracting the DNA, t(14;18) bcl-2/IgH rearrangements were detected via different PCR methods. In order to detect the mbr breakpoint real-time PCR with the LightCycler t(14;18) Quantification Kit, multiplex PCR, and

semi-nested PCR was performed. For the determination of the mcr breakpoint, real-time PCR was performed with specific primers and the LightCycler-Fast Start DNA Master SYBR Green I Kit. For the detection of t(14;18) by fluorescence in situ hybridization (FISH), nuclei from paraffin-embedded tissue sections were extracted and used together with LSI IGH Green/BCL2 Orange probes. The success rates for DNA and nuclei isolation of 12 B5-formalin-fixed tissues was 42% and 33%, respectively. More successful isolation rates were obtained on 20 tissues fixed in formalin only, 95% and 60%, respectively. The DNA of blood samples was isolated in all four, but a 50% success rate was obtained in nuclei isolation. In DNA of 24 tissues and four blood samples, mbr positivity was detected 82.14% with semi nested PCR, 53.57% with multiplex PCR, and 28.57% by real-time PCR. mcr rearrangement could not be detected in any of the samples. Of 19 patients whose nuclei were isolated, all but one were t(14,18) positive with FISH. Fourteen of 18 patients with Grade I FL, the only one case of Grade II FL, and four of five patients with Grade III FL were mbr-positive. Kaplan-Meier curves demonstrated that the mean estimated overall survival in mbr (+) and (-) patients were 59.0 and 91.5 months, respectively. As a result, semi-nested PCR has been found to be superior for the detection of mbr positivity, compared to all the other methods used in this study. In addition it has been shown that mbr positivity has an important impact on survival and is essential for the follow-up of minimal residual disease even in the status of clinical remission.

OP30-5
OPTIMISATION OF DNA EXTRACTION AND AMPLIFICATION FROM LASER MICRODISSECTED PARAFFIN EMBEDDED BREAST CARCINOMA FOR ARRAY COMPARATIVE GENOMIC HYBRIDIZATION (ACGH): PROBLEMS AND SOLUTIONS

Tarek Abdel-Fatah[1], Desmond Powe[1], Maryou Lambros[2], Jorge Reis-Filho[2], Ian Ellis[1]
[1] Division of Pathology, School of Molecular Medical Sciences and Nottingham University Hospitals Trust, University of Nottingham, Nottingham, United Kingdom
[2] The Breakthrough Breast Cancer Research Centre, Institute of Cancer Research, London, United Kingdom

Background: Array comparative genomic hybridization (aCGH) is a powerful cytogenetic technique for assessing unbalanced genomic alterations and has successfully been used in determining putative oncogenes and tumour suppressor genes in breast cancer. There is a need to apply aCGH to small quantities of DNA obtained from laser capture microdissected (LCM) archival formalin-fixed paraffin-embedded (FFPE) tissue. Our objective was to develop a DNA extraction and amplification protocol compatible with aCGH for investigating small foci of FFPE putative preinvasive breast cancer lesions. Material and Methods: A number of DNA extraction and amplification techniques were compared using whole FFPE and frozen tissue sections, including degenerate oligonucleotide-primed (DOP) PCR, Phi29 (GenomiPhi), restriction and circularization aided rolling circle amplification (RCA-RCA), GenomePlex whole genome & single cell amplification (WGA-2 & WGA-4) techniques. Following amplification, three proprietary kits were compared for their ability to retain high molecular weight DNA. The DNA quality was assessed using a multiplex PCR-based technique. Subsequently, an optimised technique was employed to investigate DNA derived from LMD FFPE tissue with aCGH, utilizing the Breakthrough Breast Cancer Research Centre 16K BAC array platform. Results: We found that incubation of FFPE sections in NaSCN at 37oC overnight prior to DNA extraction was associated with improved DNA quality. Although DOP-PCR and GenomiPhi amplification gave high DNA yield, we found that a modified GenomePlex amplification (WGA-4) technique was more robust in producing higher molecular weight DNA fragments as assessed by the multiplex PCR QC assay, in conjunction with the use of the MinElute kit. Prediction of successful PCR QC was found to be independent of the FFPE sample age. Successful aCGH was achieved only in the cases that had passed the multiplex PCR QC assay. Conclusion: We present a protocol for DNA extraction and amplification of archived LMD-FFPE tissue compatible with aCGH. Using our technique, successful aCGH can be accomplished from as little as 10ng of FFPE-derived DNA; further work is needed to assess amplification fidelity. This technique facilitates the investigation of small/microscopic lesions, including breast pre-invasive lesions, breast cancer precursors and micrometastases.

OP31-1
NEURONAL ALTERATIONS IN RAT HYPOTHALAMIC TYPE HYPOTHYROIDISM

George Stoica
TAMU, USA

Background: Thyroid hormones (THs) are important in the development and maturation of the central nervous system (CNS). The significant actions of THs during CNS development occur at the time when TH levels are lower than those in the mother and the hypothalamic-thyroid (HPT) axis is not fully functional. In the developing rat nervous system, primarily cerebellum the first three postnatal weeks represents a period of significant sensitivity to thyroid hormones. Method: Hypothyroid Sprague-Dawley rats were obtained from a colony maintained at Texas A&M University, USA. Thyroid hormones (T3, T4, and TSH) were analyzed from blood serum samples by a radioimmunoassay procedure. Frozen brain sections were saved at -80C for western blot and RT-PCR assays. Rats were perfused with 4% paraformaldehyde via the left ventricle and tissues were saved for routine histology, immunohistochemistry and electron microscopy studies. Results: This study presents a spontaneous, inherited recessive hypothyroidism in Sprague Dawley rats with devastating functional consequences to the development of the CNS. The clinical signs develop around 14 day?s postnatal (dpn) and are characterized by ataxia, spasticity, weight loss and hypercholesterolemia. The afflicted rats died at 30 days due to severe neurological deficits. The deterioration affects the entire CNS and is characterized by progressive neuronal morphological and biochemical changes, demyelination and astrogliosis. The cerebellum, brain stem, neocortex, hippocampus and adrenal gland medulla appear to be most affected. Thyroid Stimulating Hormone (TSH), T3 and T4 levels are significantly lower in hypothyroid rats than control. Immunohistochemistry and RT-PCR demonstrated a reduction of Thyrotropin Releasing Hormone (TRH) in the hypothalamus of hypothyroid rats. Western blots demonstrated elevation of ERK1/2, pro- NGF and GFAP. The HPLC analysis of brain samples from hypothyroid rats showed elevation of glutamate and decrease in GABA. The weight of both thyroid and pituitary glands are significantly less in hypothyroid rats than the corresponding normal littermate controls. Transmission electron microscopy demonstrates consistent postsynaptic dendritic, synaptic and spine alterative changes in the brain of hypothyroid rats. Conclusions: This data suggests that we discovered a tertiary form of inherited hypothyroidism involving the hypothalamus. In this neonatal inherited tertiary hypothyroidism rat animal model there are widespread CNS changes with fatal consequences to the host.

OP31-2
THE IMPACT OF IGF-1 AND VEGF ON CELLULAR PROLIFERATION AND INVASIVENESS OF PITUITARY ADENOMAS

Aydin Sav[1], Sertac Akpulat[2]
[1] Marmara University Hospital, Department of Pathology, Altunizade, Istanbul, Turkey
[2] Pathology Laboratory, Acibadem Health Group, Altunizade, Istanbul , Turkey

Introduction: Pituitary tumors comprise 10 to 15% of all intracranial tumors. The factors related to tumor progression, proliferation and invasiveness in pituitary tumors have not been fully explained. In the recent studies it was shown apparently that proliferative, antiapoptotic and mitogenic effects of IGF-1 in epithelial and mesenchymal tumors. VEGF is a specific mitogen of vascular endothelium what is more is its well documented role in angiogenesis of diabetic retinopathy. Additionally, it is a fact that tumors those of capable of secreting VEGF behave more aggressive clinically. Methods: In this study, formalin fixed-paraffin embedded tissue blocs were specifically stained. Endocrine active (GH, PRL and mammosomatotrop) and endocrine inactive (null cell) and invasive pituitary adenomas were grouped according to their expressivity of IGF-1, IGF-1 receptor, VEFG and MIB-1 LI's. Tumors were classified according to demographic (age, gender, site) and hormonal immunoreactivities. Proliferative capacities of each individual tumor were assessed by MIB-1 in addition to other factors, i.e., IGF-1, IGF-1 receptor, VEFG. Results: In almost all groups it was apparent that IGF-1 receptor reactivity decreased and VEFG expressivity increased. Besides, it was apparent that statistically significant correlation between IGF-1 and VEGF existed. In contrary, although there was a trivial increase in MIB-1 LI in comparison with control group, but no significant correlation between histological subtypes. Conclusion: It seemed that no correlation between VEGF and tumor cell proliferation was existent. However, proliferating elements of vascular infrastructure for pituitary tissue could be suppressed by IGF-1 so that these neoplastic lesions could have been kept under control without necessitating surplus therapeutic irradiation. Also, the use medical IGF-1 treatment relentlessly decrease incidence of post radiotherapy pituitary failure syndrome. Hitherto, invasive pituitary adenoma group shared similar immunophenotypical properties with that of non invasive group. These findings were most likely demonstrating that some additional factors controlling not only invasion but also migration might have been action. So, this emphasizes the uncertainty in this field necessitating further compelling and meticulous studies. Abbreviations: LI: Labeling index / IGF-1: insulin-like growth factor / IGF-1 receptor: insulin-like growth factor / MIB-1 (anti-Ki-67) /

Aim: Studies investigating the proliferation markers and outcome of patients with glioblastoma multiforme (GBM) have generated controversial results. In this study, we aimed to assess the prognostic significance of Ki-67 proliferation index (PI) in a cohort of 85 GBM patients treated with surgery and radiotherapy. Material and Methods: Patients were treated in a single institution between 1997 and 2004. Median age was 59 years (range 22-79) and male/female ratio 55/30. Type of surgery was gross total resection in 43%, subtotal resection in 29% and stereotactic biopsy in 28%. All patients received median dose of 60 Gy radiotherapy (range 10-72 Gy). MIB-1 (MS-123-R7, Neomarkers) against the Ki-67 antigen in paraffin-embedded tissue sections was used to determine Ki-67 PI. Results: Median overall survival (OS) was 9 months, and 1 year OS rate was 37% for all patients. Ki-67 PI ranged between 0 and 96 (median=13, mean=17.86). In univariate analysis, age<50(p=0.02), male gender (p=0.039), KPS score >/=70 (p=0.037), symptom duration >/= 2 months (p=0.035), multicentricity (p=0.034) and surgical resection (p=0.0003) were favourable prognostic factors for improved survival. Patients with Ki-67 PI >/= 13 showed a trend for better prognosis (p=0.07). In multivariate analysis, age (p=0.006), Ki-67 PI (p=0.008) and surgical resection (p=0.008) were observed to be predictive for survival. Conclusion: In our GBM patients series younger age, surgical resection and Ki-67 PI proved to be independent prognostic factors for survival. Since all patients received radiotherapy, we suggest that tumors with a high proliferation rate were more responsive to treatment.

OP31-4
VASCULOGENESIS IN HUMAN GLIOMAS

Johan Kros, Pingpin Zheng
Department of Pathology Erasmus Medical Center, Rotterdam, The Netherlands

Neovascularization is a prerequisite for the growth and invasion of a malignant tumor mass. Traditionally vasculogenesis, a process defined as the recruitment and differentiation of circulating bone marrow-derived endothelial progenitor cells (EPCs) into mature endothelium, was thought as solely occuring in the embryo, but it appears that postnatal vasculogenesis under specific circumstances may also occur in adults. EPCs largely reside in the adult bone marrow and the fraction of circulating EPCs in the peripheral blood of healthy people is very low. Upon triggering by cytokines or the release of angiogenic growth factors this fraction increases. Subsequently, the EPCs may enter extravascular tissues where they promote de novo vessel formation by integrating into existing blood vessels and by growth factor signalling. So far vasculogenesis, as a hypothesized mechanism of tumor neovascularization in glioma, has only been investigated in animal models by injection of exogenous bone marrow-derived stem cells followed by tracking these cells in an artificially induced tumor. Whether such data truthfully mirror the situation in human tumors like gliomas is questionable. It is well known that gliomas are among the highest vascularized tumor types. We hypothesized that EPCs are present in glioma tissues and also that patients with gliomas have raised levels of circulating EPCs due to increased release of these cells from bone marrow. We quantified the fraction of circulating EPCs by FACS-analysis using anti-CD34, -CD133 and -KDR-monoclonal antibodies in unselected peripheral blood samples of 32 glioma patients. As control groups served 39 patients with other CNS tumors or diseases; 10 patients with recent ischemic strokes and 19 healthy blood donors. The presence of the EPCs in blood samples and the gliomas was confirmed by mmunophenotyping of cells in cytosmears of the blood buffy-coat and glioma tissue sections. We found that the percentage of CD34+CD133+KDR+ EPCs in the blood of glioma patients is significantly higher than that in the blood of patients with other CNS tumors or diseases (p=0.002), stroke patients (p=0.005) or healthy donors (p=0.013). The presence of identical cells in the cytosmears and in the tumor tissue of the same patients further supports the notion that the EPCs significantly contribute to glioma vasculogenesis. Further investigations on the diagnostic value of these elevated blood levels of EPCs in glioma patients is indicated.

OP31-5
IDENTIFICATION OF GLIOMA NEOVASCULARISATION-RELATED PROTEINS BY USING MALDI-FTMS AND NANO-LC FRACTIONATION TO MICRODISSECTED TUMOR VESSELS

Dana Mustafa, Johan Kros
Dept. of Pathology, Erasmus Medical Center, Rotterdam, The Netherlands

The identification of angiogenesis-related proteins is important for the development of new anti-angiogenetic therapies, and such proteins are potential new biomarkers for gliomas. The aim of this study was to identify proteins which are exclusively present in glioma neovasculature and not in the vasculature of normal brain. We combined advanced proteomic techniques to compare the expression profiles of microdissected blood vessels from glioma with blood vessels of normal control brain samples. We measured the enzymatic generated peptide profiles from these microdissected samples by matrix-assisted laser desorption\ionization Fourier transform mass spectrometry (MALDI-FTMS). Subsequently, the samples were fractionated by nano-LC prior to matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF/TOF). This combined approach enabled us to identify four proteins which appeared to be exclusively expressed in the glioma blood vessels. Two of these proteins, fibronectin and colligin 2, were validated on tissue sections using specific antibodies. We found that both proteins are present in active angiogenesis in glioma, other neoplasms and reactive conditions in which neo-angiogenesis takes place. This work proves that gel-free mass spectrometric techniques can be used on relatively small numbers of cells generated by microdissection procedures to successfully identify differentially expressed proteins.

[9] Department of Pathology, Metropolitan Hospital, Athens, Greece

Background: Interleukin-8 is a member of the chemokine family which plays a critical role to the progression of various malignancies, including those that arise in the CNS. Accumulating evidence highlights IL-8 mRNA and protein expression in grade II, III, and IV astrocytomas and the potent mediative role of IL-8 in angiogenesis. Nevertheless, the accurate mechanisms by which IL-8 exerts its angiogenic properties are still under investigation. The aim of the present study was to examine the expression levels of IL-8 in astrocytomas and to explore any possible associations with microvessel morphometry. Method: 98 patients with astrocytomas were enrolled in our study. We determined the expression levels of IL-8 using immunohistochemistry in formalin-fixed paraffin-embedded tissue sections of 65 glioblastomas (WHO grade IV), 10 anaplastic astrocytomas (WHO grade III), and 23 diffuse astrocytomas (WHO grade II). Tumour specimens were categorized in three levels according to the presence of necrosis (absent, focal, extensive). Microvessels, highlighted by means of anti-CD34 immunohistochemistry, were enumerated with computer-assisted image analysis. A spectrum of microvascular parameters was estimated: major and minor axis length, total vascular area (TVA), microvessel density (MVD), perimeter, area, shape factor. Results: IL-8 expression was noted in the cytoplasm of neoplastic astrocytes in 89 cases. Positive neoplastic cells represented 1% to 40% of the neoplastic population. IL-8 expression was highest in cells around areas of pseudopalisading necrosis, within glioblastomas. IL-8 was also detectable in endothelial cells within glomeruloid vascular structures of glioblastomas as well as in inflammatory cells usually around the areas of necrosis. IL-8 expression increased significantly with the presence of necrosis and with tumour grade ($p<0,001$, respectively). We observed a significant positive correlation among IL-8 expression levels and: MVD ($p<0,001$), major axis length ($p=0,008$), minor axis length ($p=0,032$), area ($p=0,016$), perimeter ($p=0,016$), shape factor ($p=0,003$). Conclusion: To the best of our knowledge, this is the first study presenting a fundamental relationship between IL-8 expression and various microvascular parameters within astrocytomas, using immunohistochemistry. Our experimental results testify the proangiogenic capacity of IL-8 confirming its central role in the malignant transformation of astrocytes. Further studies are needed to shed light upon the prognostic significance of IL-8 expression within the heterogeneous group of astrocytomas.

[4] Laboratory of Physiology, Aristotle University Of Thessaloniki, Greece

Background: Neural stem cell (NSC) transplantation has been proposed as a means of cell replacement therapy for various diseases of the Central Nervous System (CNS). Transplanted NSCs improved the clinical outcome in experimental models of stroke and spinal cord trauma Although transplanted myelin-forming cells have remarkable remyelinating properties the exact mechanisms by which they react are not clear yet. In multiple sclerosis (MS), as well as in experimental allergic encephalomyelitis (EAE) which is the most reliable experimental model of MS, demyelination and inflammation-related axonal pathology lead to chronic neurological disability. Method: EAE was induced in C57Black/6 mice with myelin oligodendrocyte glycoprotein (MOG). NSCs were isolated and cultured from newborn green fluorescent protein (GFP) transgenic mice, with the same genetic background and transplanted into the lateral ventricles of mice at day 7 after induction of EAE. The control group received only the medium without NSCs. The mice were clinically evaluated daily. Brain and spinal cord immunohistochemistry was performed for glial and neuronal differentiation of transplanted cells and the sections were evaluated under light and confocal microscope. Evaluation for inflammation, demyelination and axonal injury, was also performed under standard histological protocols. Results: Transplanted cells attenuated the clinical course of the disease,

migrated into the white matter and were differentiaied mainly into glial cells. NSC transplantation down-regulated the CNS inflammatory process as indicated by a reduction in the number of perivascular infiltrates. In addition, transplanted cells reduced demyelination and axonal injury and induced the remyelination of demyelinated axons. However, remyelination was attributed to an increased production of myelin of host oligodendrocytes since there was no indication of myelin derived directly from the transplanted cells. Conclusion:Demyelination and acute axonal injury in this model result mainly from the acute inflammatory process and correlate well with the chronic neurological residua. We suggest that the beneficial effect of transplanted NSCs in chronic EAE may at least in part, be due to a down-regulation of brain inflammation and the concomitant reduced axonal injury, leading therefore to improvement of the clinical outcome.

Glioblastoma multiforme (GBM) is the most common malignant primary brain tumor in adults and remains extremely lethal despite the continuous technical improvements and recent therapeutic advances. High-throughput analyses of gene expression can identify new key genes, networks and pathways which may be clinically rellevant in patients with this highly malignant tumor. We investigated the pattern of gene expression in 20 primary GBMs using cDNA microarrays containing 27,454 cDNA clones, including 9,900 known genes and uncharacterized tumorigenesis-related ESTs. Differentially expressed genes detected by cDNA array analysis were further evaluated by RT-PCR, tissue microarray (TMA) immunohistochemistry, FISH, and Western blot techniques. Statistical analysis revealed 345 deregulated genes (159 upregulated and 186 downregulated). A gene ontology-based study showed that the most strongly deregulated pathways in our series were those of MAPK and actin cytoskeleton, followed by cell cycle, GnRH and calcium signaling pathways. Several genes of the PI3K pathway were also included in the signature of our GBM series. Microarray analyses showed strong upregulation of ANXA1 in 90% (18/20) of GBMs. Immunohistochemical analysis of protein expression demonstrated strong expression of ANXA1 in 86% (102/118) of the GBM in our TMA, and in 70% (129/182) of the astrocytomas (all grades), 5% (1/20) of oligodendrogliomas, and 17% (3/17) of oligoastrocytomas included in a separated TMA (ANOVA, $P < 0.05$). Distinct molecular subsets of GBM showing different gene expression patterns were detected. Survival analysis using functional clusters of genes revealed an association between the PI3K-signaling pathway and clinical outcome. TIAF1, BAX, RPS6KB2 (p70s6k) and BAD were among the genes whose expression was significantly associated with survival. Some candidate target genes, including ANXA1, BAX, USP7 (HAUSP) and STIM2 were further evaluated in GBM tumors by TMA immunohistochemistry and quantification of the expression levels of STIM2 and USP7 was tested by RT-PCR. We also analyzed the activation status of Akt and GSK3ß and demonstrated that PI3K/Akt pathway is activated in our series of GBM. Our high-throughput studies of gene expression patterns, complemented by immunohistochemistry, RT-PCR, and other validation studies confirm the distinctive expression profile of some PI3K pathway survival-related genes, which may play a significant role as prognostic markers in GBM.

OP31-9

MEDULLOBLASTOMA: CLINICOPATHOLOGIC EVALUATION OF 51 CASES.

Yesim Ertan[1], Murat Sezak[1], Bengu Demirag[2], Mehmet Kantar[2], Nazan Cetingul[3], Yusuf Ersahin[3], Saffet Mutluer[3], Taner Akalin[1]

[3] Ege University School of Medicine, Department of Neurosurgery, Izmir, Turkey

Medulloblastoma, which accounts for 20-25% of all childhood brain tumors, is defined as a primitive neuroectodermal tumor located in cerebellum. In this retrospective study, we reevaluated medulloblastoma cases diagnosed within the last 10 years in our pathology department. The aim of this study was to assess the histological variants and demographic findings of medulloblastomas in our region, and the prognostic value of MIB-1 in our medulloblastoma cases. There were 51 medulloblastoma cases at the period of January 1997 to December 2006. Of the 51 cases, 42 (82%) were children (aged 17 and younger), 9 (18%) adult, 30 (59%) male , 21(41%) female. The mean age of children was 9± 3 and adult 36± 10. Histologically 39 (76%) cases were classical, 11 (22%) desmoplastic (6 of them were adult) and 1(2%) large cell medulloblastoma. Immunohistochemically all of the tumors were immunoreactive for synaptophysine, 11(21%) of 51 were focally immunoreactive for GFAP. P53 immunoreactivity was found in 8 (15%) cases. The immunoreactivity of MIB-1 ranged from 10 to 95% (mean 35%). Follow-up was available for 37 patients in children group. Thirty four patients received a combination of chemotherapy (Cisplatin, Etoposid, Cyclophospamid and Vincristine) and craniospinal radiotherapy, 1 chemotherapy alone. Two patients died at the early phase of postoperative duration. Follow up period ranged from 5 to 64 months (mean 27,1 ±18,8 months). Of the 35 patients, 21 were alive without any evidence of recurrent disease, three were alive with evidence of recurrent disease and 11 died of disease during follow-up. The mean life time for these 11 patients was 21,9±10,4 months. Of the 35 cases with follow-up, 16 have 25% or least MIB-1 value, 19 have 26% or more. Of the 16 cases with a low MIB-1 value, 6 were dead of disease; of the 19 cases with high MIB-1 value, 5 were dead of disease. The statistical difference ($p=0,51$) was not significant.

FINE NEEDLE ASPIRATION CYTOLOGY OF BENIGN FIBROEPITHELIAL TUMORS OF THE BREAST

Mehrdad Herbert[1], Judith Sandbank[1], Sonia Mendlovic[1], Pavel Liokumovich[2], Michael Segal[1], Sergei Zahavi[1], Lea Rath-Wolfson[3]
[1] Department of Pathology, Assaf Harofeh Medical Center, Israel
[2] Megalab Institute of Pathology, Israel
[3] Department of Pathology, Rabin Medical Center, Israel

BACKGROUND: Benign fibroepithelial lesions of the breast, including hamartoma, fibroadenoma, and benign phyllodes tumor show proliferation of both epithelial and stromal elements. The aim of the present study was to look at common and dissimilar features in order to enable differentiation between these lesions, if possible.
METHOD: Nine fine needle aspiration cytology slides of each entity (hamartoma, fibroadenoma, phyllodes tumor), which were histopathologically confirmed, were reviewed for smear cellularity, epithelial and stromal fragments, epithelial/stromal area ratio, intact lobular units, naked bipolar stromal nuclei, adipose tissue, smooth muscle and multinucleated giant cells. We also reviewed the literature regarding the cytologic picture of adenomyoepithelioma, sclerosing lobular hyperplasia and other lesions with epithelial and stromal components.
RESULTS: Cytologic characteristics were retrospectively evaluated in a semiquantitive manner.
CONCLUSION: The finding of intact lobular units with various amounts of adipose tissue may favor the diagnosis of hamartoma over that of fibroadenoma. Cytologic diagnosis of phyllodes tumor remains difficult. The presence of a low epithelial/stromal ratio favors the diagnosis of phyllodes tumor over fibroadenoma.

PP1-2
PHYLLODES TUMOUR: LINICOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL STUDIES OF 45 CASES

Judith Sandbank[1], Mehrdad Herbert[1], Gratina Hermann[1], Sonia Mendlovic[1], Pavel Liokumovich[2], Itzhak Pappo[3], Tami Karni[4]
[1] Department of Pathology, Assaf Harofeh Medical Center, Israel
[2] Megalab Institute of Pathology, Israel
[3] Department of Surgery A, Assaf Harofeh Medical Center, Israel
[4] Department of Surgery B, Assaf Harofeh Medical Center, Israel

BACKGROUND: The aim of our study was to investigate the clinical, pathological and immunohistochemical features of phyllodes tumors, in order to obtain a detailed profile of this lesion. METHOD: This study presents a clinical, pathological and immunohistochemical analysis of 45 phyllodes tumors, 11 high grade and 34 low grade. Three cases of fibrocystic breast changes were used as a control group. The immunohistochemical panel included, Ki67, p53, Bcl2, CD34, CNA42, Her-2/neu, telomerase, ER, and PR. The following detailed clinical data were collected: age; weight; height; family history of breast tumors; smoking; nicotine intake; and coffee intake). RESULTS: All patients presented with a palpable unilateral mass. Tumors ranged from 25–55 mm in diameter. Typical macroscopic and microscopic features were noted. Immunohistochemical studies showed higher immunoreactivity for CNA42, Ki67, and p53 in high grade phyllodes tumors. CD34 immunoreactivity was greater in low grade phyllodes tumors. No differences were seen between the high and low grade tumors relating to the other markers used. The detailed clinical data collected revealed no significant differences between the low and high grade phyllodes tumors. CONCLUSION: The immunohistochemical profile adds another aspect and may aid in the differential diagnosis of low and high grade phyllodes tumors.

PP1-3
IS ESTROGEN RECEPTOR NEGATIVITY USEFUL AS A MARKER FOR HIGH-GRADE DUCTAL CARCINOMA IN SITU OF THE BREAST?

Nasrin Shayanfar, Kambiz Movaghar
Iran University of Medical Science, Tehran, Iran

BACKGROUND: Ductal carcinoma in situ (DCIS) of the breast is a heterogenous group of non-invasive cancers which if left untreated thought to have the ability to transform to invasive carcinoma in around 30% of cases. There is a substantial difference in the frequency with which this phenomenon occurs depending on the type and grading of DCIS.There has been a sharp increase in the detection of DCIS during the last two decades,largely due to the widespread use of mammography.The aim of this study is to compare the morphological and immunohistochemical characteristics of estrogen receptor(ER) negative and ER positive DCIS of the breast in an attempt to establish a more objective criteria for detecting cases at higher risk to progress to invasive carcinoma. METHOD:60 cases of ductal carcinoma of breast which had a prominent DCIS component in the surrounding tissue and were surgically excised included in this study.All archival hematoxylin and eosin-stained sections were reviewed to confirm the diagnosis and to classifing and grading the in situ lesions.Additional sections of 60 cases were stained for ER,progestrone receptors(PR) and p53 using the immunoperoxidase technique.DCIS was graded according to nuclear morphology as outlined by the National Health Service Breast Screening Programe and Europian Economic Community(NHSBSP/EEC) into three grades.The lesions also classified according to predominent component into comedo,solid,cribriform and micropapillary types.For all markers ,a positive score was given if>10% of tumor cells a dark brown nuclear staining.Statistical analyses were carried out using the X^2 test. RESULTS:60 DCIS cases included 30(50%) high-grade,25(42%) intermediate-grade and 5(8%) low-grade cases.Twenty-two cases were ER-negative(37%) and 38(63%) were ER-positive.The ER-negative cases included 20(91%) high-grade and two(9%) intermediate-grade DCIS.All five low-grade cases were ER-positive.All ER-negative cases were PR-negative,but 16(73%) of ER-negative cases were p53 positive.The 38 ER-positive cases included 10(26%) high-grade,23(61%) intermediate-grade and all five low-grade cases(13%).Of the ER-positive cases 10(26%) were PR-negative and 4(11%) were p53 positive.ER negativity & p53 positivity were significantly associated with high nuclear grade in DCIS. CONCLUSION: There is a significant relationship between ER negativity and high nuclear grade, PR negativity and p53 positivity.Immunohistochemical evaluation of ER status may be of great help in classification of DCIS as well as in planning the management of the disease.

PP1-4
EVALUATION OF THE INCIDENCE OF ANDROGEN RECEPTOR EXPRESSION IN INVASIVE DUCTAL CARCINOMA OF BREAST

Nasrin Shayanfar, Behrang Kazeminejad
Department of Pathology, Iran University of Medical Science, Tehran, Iran

BACKGROUND: To evaluate the frequency of androgen receptor (AR) expression in invasive ductal carcinoma of breast.
METHODS:Sections of 55 cases of invasive ductal breast carcinoma were examined using a monoclonal antibody against AR on formalin-fixed paraffin-embedded archival material.AR was considered positive when at least 10% of tumoral cell nuclei were immunoreactive.The results also were correlated with the results of estrogen and progestrone receptors(ER & PR) previously done immunohistochemically on the specimens. RESULTS: AR were positive in 24 cases(43.6%).From 55 cases,9(16%) were grade 1,33(60%) grade 2 and 13(24%) cases

were grade 3.AR were positive in 33%(3) of grade 1,45%(16) of grade 2 and 38%(15) of grade 3 tumors.ER and PR were done on 34 cases previously including 5 grade 1,18 grade 2 and 11 grade 3 carcinomas.Among the grade 1 cases 2 were AR positive which also were ER and PR positive but 2(11%) of grade 2 and 3(27%) of grade 3 tumors were AR positive and ER negative.Also 5(28%) of grade 2 and 3(27%) of grade 3 tumors were AR positive but PR negative.
CONCLUSION: Androgen receptor expression is common in invasive breast carcinomas.Some high grade carcinomas are ER and PR negative but AR positive.We suggest that immunohistochemical evaluation of AR may help in providing more information about steroid receptors in breast carcinomas and could be helpful in diagnosis of origin in metastatic high grade breast carcinomas.

PP1-5
BCL-2 ONCOGENE AND Ki-67 ANTIGEN EXPRESSION: A CORRELATION BETWEEN ESTROGEN-RECEPTOR POSITIVE AND NEGATIVE BREAST CARCINOMA

Lina Gomes Dos Santos[1], Benedito Borges Da Silva[1], Aracy Carstens Cunha[2], Celio Marcos Oliveira[3]
[1] Federal University of Piauí, Brazil
[2] Diagnose Cunha Lab, Brazil
[3] Biocelula Lab, Brazil

BACKGROUND: The aim of this study was to evaluate Bcl-2 oncogene and Ki-67 antigen expression in estrogen receptor (ER) and progesterone receptor (PR) positive and negative breast carcinoma. METHOD: A retrospective study was conducted in 72 cases of infiltrating ductal carcinoma of the breast in postmenopausal women, between 1999 and 2004, divided into two groups: Group A (ER and PR positive, n=37) and Group B (ER and PR negative, n=35). Immunohistochemical analysis of Bcl-2 expression was carried out semi quantitatively based on the percentage of stained tumoral cells and the intensity of staining, while Ki-67 analysis was performed by counting the stained nuclei of 500 tumor cells in each sample. Student t-test and chi-square test were used in the statistical analysis of the data and significance was established at p [LTEQ] 0.05. RESULTS: Bcl-2 oncogene expression was statistically greater in tumors of Group A (59,5%) compared to those of Group B (8,6%), ($p<0.001$). There was no significant difference in Ki-67 antigen expression between the two groups (p=0,200). CONCLUSION: Of the markers studied, only Bcl-2 had a significantly greater expression in the estrogen and progesterone receptor-positive breast tumors compared to the negative tumors.

PP1-6
ASSESSMENT OF SKIN INVOLVEMENT IN MASTECTOMY SPECIMENS DUE TO BREAST CANCER REFERRED TO BAQIYATALLAH HOSPITAL PATHOLOGY PART - TEHRAN – IRAN DURING 2004-2006

Hassan Mohammadhoseiniakbari[1], Morteza Movahhed[1], Morteza Musavinaini[2], Zahra Tofigh[3]
[1] Department of Pathology, School of Medical Science, University of Baqiatallah, Tehran, Iran
[2] Department of Surgery, School of Medical Science, University of Shahed, Tehran, Iran
[3] Department of Pathology, School of Medical Science, University of Baqiatallah, Tehran, Iran

Objective: The goal of this retrospective, descriptive & cross-sectional study was to assess the rate of skin involvement by the invasive malignant tumoral cells in breast cancer patients who underwent mastectomy operations & thus to evaluate the feasibility & adequacy of skin- sparing operations in these patients. Materials & methods: There were 130 mastectomy specimens referred to this lab. during 1382-84. After gross examination the specimens were sampled using routine sampling procedure, including at least three sites of the nipple, areola & the closest portion of the skin to the tumoral mass as well as any grossly abnormal area, if present. Results: The peak of age incidence of breast cancer was the range of 40-49 years. From 130 received specimens, data about skin involvement & tumor type included in 126 & 124 available reports, respectively. Invasive ductal carcinoma was present in 120 specimens (97%) & invasive lobular carcinoma in 2 specimens (1.5%), while two specimens showed mixed invasive ductal & lobular carcinoma. The overall tumoral involvement of the skin, nipple & areola was seen in 12 patients (9.5%) as the following: skin: 4% (5 cases); nipple: 8% (10 patients); areola: 0.8% (one patient). Paget's disease was present in two patients whereas three other patients showed concomitant nipple & skin involvement by the ordinary tumoral cells. The areolar involvement was seen along with nipple involvement in only one patient. All of the surgical skin margins were free from the tumors. Conclusion: There was only a significant (statistical) relationship between skin involvement & nipple involvement & also between skin involvement & perineurial invasion. Regarding the lower age of peak incidence of breast cancer compared to other populations & also the overall low rate of skin, including resected margins, nipple & areola involvement in our patients, skin- sparing mastectomy operations seem to be the adequate procedures for the patients with the aim of performing reconstructive surgery at the time of mastectomy. Furthermore, nipple& areola- sparing mastectomies are also to be considered in these cancer patients. It is suggested that this study also to be performed in other pathology centers.

PP1-7
EVALUATION OF NUCLEAR GRADE IN LOBULAR CARCINOMA IN SITU (LCIS): CORRELATION WITH IMAGE CYTOMETRY

Deepa Patil, Carol Schiller, Marina Ivanovic, Barbara Susnik
Northwestern University Feinberg School of Medicine, United States

Background: The LCIS lesions are a heterogeneous group of lesions that need further characterization and classification. Although in ductal lesions the correlation between nuclear grade and aggressive behavior is well accepted, this aspect has been disregarded in lobular lesions. The aim of this study was to demonstrate the heterogeneity of LCIS in their nuclear grade and confirm these findings by nuclear morphometry. Design: Consecutive cases of LCIS were retrieved from files; non-classic lesions were confirmed by immunohistochemical staining for E-cadherin and HMW-CK. The following histologic features were evaluated: cell type (A or B), necrosis, degree of distention of units and nuclear grading. Nuclear grading was based on nuclear size and pleomorphism, similar to that used for grading DCIS (CAP recommendations). We used a two-tiered grading scheme: low grade included grade 1 lesions and high grade included grade 2 and 3 lesions. Measurements of nuclear features were performed using the research prototype of quantitative pathology system ClearPathTM (Perceptronix, Vancouver, Canada). Nuclear grade was correlated with histopathologic features and quantitative nuclear features. Result: Of the total 33 cases, 73% were associated with invasive carcinoma (55% lobular, 18% ductal). Based on our grading system, 52% cases of LCIS were low grade and 48% were high grade. Low grade lesions exhibited classic LCIS phenotype; small cells with regular small nuclei without nucleoli, while high grade lesions showed larger nuclei, cytologic atypia, or both. Quantitative morphometry supported the grading system with significant differences observed in mean nuclear area (p=0.001) and standard deviation of area (p=0.005) between the grades. High nuclear grade was significantly associated with the presence of necrosis (p=0.04), but not with cell type, degree of distension of units, or presence of invasion.
Conclusion: We have shown that nuclear grading of LCIS is feasible and the differences in nuclear grade correlate with quantitative nuclear features measured by image cytometry.

Grading LCIS may be important to better characterize this heterogeneous group of lesions. Outcome based studies are needed to explore the prognostic significance of nuclear grade in LCIS in order to define treatment strategies needed for lesions with different levels of risk or malignant potential.

PP1-8
THE STATUS OF MDM2 GENE EXPRESSION IN PRIMARY BREAST CANCER AND IT'S RELATIONSHIP WITH PROGNOSTIC FACTORS

Mohammad Reza Jalali Nadoushan, ShahabBagherzadeh, Ali Davati
Shahed University, Iran

Introduction: The breast cancer is the most common malignancy in women. MDM2 expression is determined in some carcinomas, sarcomas, leukemias,and breast cancer. The purpose of this study is to determine the expression of MDM2 gene in primary breast cancer and its relationship with grade, stage and axillary lymph node involvement. Material and Methods: the study is the cross-sectional one that was performed on 75 samples of patients with breast cancer admitted in Mostafa Khomeini hospital (2000-2005). After preparing the samples, a tissue section from each sample was obtained. One of the tumoral sections and one of the lymph node sections were stained by H&E. We determined the type of the tumor, the number of lymph nodes, the stage and the grade of the tumor.We studied MDM2 with polycholonal antibody by IHC. Result: Our study showed that 69.3% of patients had lymphoid involvement. 32% of samples were positive for MDM2, 58.7% of samples were in stage II and the most of patients (42.7%) were in grade III. In this study, we didn't find any relationship between MDM2 & grade. We found a relationship between MDM2 & stage ($p<0.002$), a relationship with lymph node involvement ($p<0.002$) that the incidence of MDM2 is increased with lymph node involvement. Conclusion: According to the results of previous studies and our study, it seems that MDM2 is a prognostic factor in breast cancer. But a further investigation with more specimens and long-time follow-up is required to clarify the exact role of MDM2 in prognosis of breast cancer.

PP1-9
PRIMARY BREAST MALT LYMPHOMA – DIAGNOSED BY LYMPHOEPITHELIAL LESION- CASE REPORT

L. Tadic Latinovic
Department of Pathology Clinical Center Banja Luka, Bosnia and Herzegowina

Background: Primary breast lymphoma, particularly primary mucosa- associated lymphoid tissue (MALT) lymphoma is rare disease. Methods: An 78 year- old woman presented with large firm 10,5x7,8 cm mass into the central part of the right breast with extension to outer lateral quadrant. Ipsilateral axillary lymph nodes were enlarged. The rest of the physical examination findings were normal. Patient underwent mastectomy with axillary lymph node dissection. Results: Pathologically the tumor tissue was composed of small to large lymphoid cells. The large cells contained considerable number of centroblasts and immunoblasts. Small cleaved centrocites were predominant in small cell population. Predominant tumor cell populations in lymph nodes were centroblasts and imunoblasts with high mitotic activity. Using a panel of immunohistochemical stains, tumor cells expressed B cell phenotype CD20+, CD 79α +, CD3-, CD5-, CD23-, bcl 2+, bcl 6-, CD43-, CD10+/-, CD38+, CD 138+/-, Ki-67+. The tumor cells infiltrated the ductal epithelial cells, distording the duct structures, to form, lymphoepithelial lesions for the diagnosis of MALT lymphoma of the breast. Conclusions: Patient post- operatively was given chemotherapy. We emphasize the importance of lymphoepithelial lesions for the diagnosis of MALT lymphoma of the breast.

PP1-10
A PEROPERATIVE EXAMINATION OF A SENTINEL LYMPH NODE IN BREAST CANCER : ...TO BE OR NOT TO BE...

Martin Čegan[1], Jana Dvořáčková[1], Lenka Čeganová[1], Jiřina Heroková[2], Jaroslav Štěrba[1], Dusan Žiak[1]
[1] CGB laboratory Corp. , Ostrava, Czech Republic
[2] Mammologic Centre, Vitkovice Hospital Corp. , Ostrava, Czech Republic

A peroperative examination of a sentinel lymph node in breast cancer has not been considered yet as a standard in the surgical therapy and being de facto rejected by pathologists in the Czech Republic. It is an examination demanding for both a surgeon and pathologist. Methods: A sentinel lymph node is identified by a surgeon by the patent blue and radio colloid. Individual lymph nodes are prepared, measured and divided in halves in a longitudinal direction. From each half of the node, impression cytological preparations are made, and, simultaneously, a cryostat cut is made from one half of suspecting node. Cytological specimens are stained by May Grünwald-Giemsa in a shortened regime, histological sections by haematoxylin-eosin in a shortened regime, too. A time interval between the material supply and result announcement varies depending on a number of examined nodes in a range of 5 to 20 minutes. Then the material is fixed in a solution intended to fixation of the lymphatic tissue. The fixation is followed by a histological examination from a paraffin sections. From each half of the sentinel node, 10 cuts are made (haematoxylin eosin) in 30 μm levels, each third and eighth cut are stained immunohistochemicaly against pancytokeratins. We considered compliance between a result of the peroperation and definitive histological examination to be a completely negative result and occurrence of a macro and micro metastasis in case of a positive result of a peroperation examination. A presence of the isolated cell cluster was considered to be a negative result in both examinations. Results: In the period of January 2006 to February 2007, we at our workplace made peroperative examinations of 338 nodes from 113 patients in the age of 36 to 83 years (the age median being 60 years) with breast malignity followed by classical histopathological techniques, while the sensitiveness of the peroperation examination against paraffin techniques was 87.6 % (99 cases in compliance with the peroperation finding). False positive findings occurred in two cases (1.8 %). Conclusion: A peroperative examination of a sentinel node can be made while taking into account false negativity (in this file 12.4 %), or false positivity (in this file 1.8 %). In order to eliminate mistakes, it is suitable to use a combination of an impression cytology and cryostat section which, however, puts great demands for technical and personal equipment of a biopsy executing laboratory.

PP1-11
THE CORRELATION OF CYCLIN EXPRESSION TO HISTOLOGICAL GRADE IN BREAST CANCER

Pia Boström[1], Mirva Söderström[1], Heikki Hiekkanen[2], Mia Kero[3], Yrjö Collan[4], Pirkko Hirsimäki[4]
[1] Turku University Central Hospital, Dept of Pathology, Turku, Finland
[2] University of Turku, Dept of Biostatistics, Turku, Finland
[3] HUSLAB, Dept of Pathology, Helsinki, Finland
[4] Turku University Central Hospital, Dept of Pathology, BioCity, Turku, Finland

Background Cyclins are proteins which control the cell cycle. They are associated with and activated by cyclin dependent kinases at different stages of cell cycle. A-type cyclins are expressed during late G1 and S phase. Cyclin B1 controls the G2-M transition of the cell cycle. The D-type and E-type cyclins control the G (1) to S phase transition during normal cell cycle progression. Loss of normal cell cycle control is a key event in tumorigenesis. The aim was to investigate the protein expression

and gene amplification of cyclins A, B1, D1 and E in breast carcinomas and to correlate the results with traditional prognostic factors. Design Immunohistochemistry and Tissue microarray (TMA) technique were used to analyse cyclin A, B1, D1 and E protein expression in 50 tumours. The results were compared with clinical variables. In addition, real time quantitative PCR (RT-PCR) was used to determine gene amplification of cyclins in 13 tumours. The results were compared with immunohistochemical cyclin protein expression. Statistical analyses Statistical analyses were carried out using Kruskal-Wallis -test. Non-parametric test was applied because of non-normal distribution of responses. In pair wise comparisons Bonferroni-adjustment was applied. P-value less than 0.05 were considered as significant. Results: The immunohistochemical expression of especially cyclin A and also cyclin E showed a significant relationship with histological grade. Cyclin A index seemed to present well the cyclin-associated prognostic power. The results estimated from TMA were not as clear as from tumour sections. RT-PCR revealed that cyclin protein expression occurred in both the presence and absence of gene amplification. Conclusion: The prognostic value of cyclin A and to a certain extent also cyclin E had significant relationship with histological grade. Cyclin A was the most suitable single cyclin to characterize the cell fraction in the proliferation cycle. The results indicate that strong Cyclin A expression correlates to high breast cancer grade and poor prognosis. In the literature there are contradictory results concerning the prognostic value of cyclin A. However in several studies Cyclin A is associated with poor prognosis in breast cancer patients. The finding that expression occurred in both the presence and absence of gene amplification supports previous studies that protein expression is not necessarily caused by gene amplification, and emphasizes the need for further studies with RT-PCR samples.

PP1-12
INTEGRIN LINKED KINASE EXPRESSION IN BREAST CANCER PATIENTS AND RELATION TO LYMPH NODE METASTASIS

Yusuf Ozer[1], Binnur Onal[1], Aysegul Uner[2]
[1] S. B. Diskapi Yildirim Beyazit E. A. Hospital, Turkey
[2] Hacettepe University Hospital, Turkey

Background: Integrin linked kinase (ILK) over-expression results in anchorage-independent cell survival, oncogenic transformation, increased tumorigenicity and invasiveness. A correlation between ILK expression and tumor grade and survival has been shown in some tumor types. Previous molecular studies in breast tissue have demonstrated that ILK over-expression in mammary epithelial cells results in hyperplasia and tumor development. Method: This study was undertaken to investigate whether the expression of ILK correlates with the number of lymph nodes involved by metastasis. Seventy five cases with a diagnosis of infiltrative ductal carcinoma (not otherwise specified) were included in this study. 3-5 m thick sections were taken from tumor blocks of patients representing pN0, pN2 or pN3 in the TNM classification. ILK expression was evaluated immunohistochemically by a mouse monoclonal antibody raised against full-length recombinant ILK (Santa Cruz Biotechnology). ILK expression levels were graded according to the percentage of cells showing staining. The grades were as follows; no expression (0), less than 10% (1+), 11-50% (2+) and greater than 50% (3+) expression. Results and Conclusion: Seventy five patients with an age range of 32-78 were included. In 37 cases there was no lymph node involvement (pN0), in 13 cases there was 4-9 metastatic lymph nodes (pN2) and 25 cases had more than 10 lymph nodes involved (pN3). The number of tumor samples with strong (3+) ILK expression was significantly higher in the pN3 group (p= 0.03) compared to the other two groups.

PP1-13
MODIFICATION OF GRID REFERENCE DEVICE FOR BREAST SPECIMEN RADIOGRAPHY

Alan Mills
Dorevitch Pathology, Australia

Specimen radiography is mandatory for image localized excision biopsies of mammographically detected impalpable breast lesions, usually focal stellate spiculations, or microcalcifications. It is essential that a radiologist report the specimen radiograph, to correlate radiological and pathological features; and to indicate to both surgeon and pathologist, whether or not, the lesion has been excised. Ideally, in-house radiographic examination, with an attendant radiologist,will examine and report radiographs of measured, thin serial slices of the specimen. In the absence of such facilities, use of a grid localization device,such as a Dubin TranSpec is acceptable. These devices can accurately detect the defined lesion. However, the downside is that they tend to distort the specimen. They retain the specimen, by restraining it with a ratcheted perforated compression plate marked with radio-opaque grid references, to identify the co-ordinates of the lesion.This compression causes attenuation of excision margins, the width of which is an important prognostic feature. In extreme cases, the specimen becomes as flat as a pancake.To overcome compression artefact; we have modified the Dubin system, by placing the specimen above, rather than below, the perforated plate. Which rests on a polystyrene base in the bottom of the container. The specimen is restrained by transfixing it with four or five 21 gauge needles, which can easily be manipulated through underlying perforations, and pinned into the polystyrene base. The polystyrene inserts are 10mm thick, and can be readily made in most workshops.They are attached to the bottom of the container with a thin rim of glue. Using a separate compression plate as a template, lightly held above the specimen, the lesion can be accurately located, by inserting a slender skewer into the appropriate co-ordinates

PP1-14
THE IMPORTANCE OF APPLICABILITY OF THE SENTINEL LYMPH NODE BIOPSY IN ADVANCED INVASIVE BREAST CANCER

Stolnicu Simona[1], Coros Marius Florin[1], Radulescu Doinita[2], Jung Janos[1], Podeanu Daniela[1], Musca Simona[3], Gurzu Simona[1], Mezei Tibor[1], Pricop Zenovia[4], Pricop Mihai[3]
[1] University of Medicine Targu Mures Romania
[2] University of Medicine Iasi Romania
[3] "Cuza Voda" Hospital Iasi Romania
[4] "Elena Doamna" Hospital Iasi Romania

Introduction: Breast cancer is the most frequent malignant tumour in female patients. 4200 new breast tumors are diagnosed every year in Romania and from this, 2/3 in an advanced stage. In such cases, radical mastectomies followed by axillary lymph node resection are performed. The aim of this study is to establish whether it is necessary to perform axillary dissection in all patients with advances stage breast cancer. Material and results: We studied 250 cases of invasive breast cancer (2004-2005) in patients with mean age of 55 years. Maximum diameter of the tumor was 2-7 cm. Axillary's lymph node dissection done in 222 cases (89 %) and microscopic examination revealed that the metastases were absent in 88 cases (39,6%). In 15 of these cases, the maximum diameter of the tumor was 5 cm. Discussion: It was demonstrated that the axillary's lymph node status is the most important prognostic factor for breast cancer patients, TNM staging, therapeutic management, but also patient's survival, depending on the presence or absence of axillary's lymph node metastases. Systematic studies in breast cancer have shown that the tumour spreads to one or a few lymph nodes (the sentinel lymph node(s)), before it spreads to other axillary nodes and that these nodes can be identified by using vital blue dye, a radiolabeled colloid or both and the biopsy can be performed in selected patients avoiding the associated morbidity. Recent

recommendations indicate that sentinel lymph node biopsy should not be performed for large or locally advanced invasive breast cancer. We demonstrated in this study that even in advanced cases metastases could be absent in axillary lymph node. Thus, the indication of intraoperative lymphatic mapping and performing the selective biopsy of the sentinel lymph node could be applied also in advanced stages of the disease.

PP1-15
EXPRESSION OF P27 IN INVASIVE DUCTAL CARCINOMAS OF THE BREAST WITH TISSUE MICROARRAY

M. A. Siti Aishah, M. A. Munirah, M. Mastura, M. Z. Reena-Rahayu, M. I. Nurismah, M. Rohaizak, A. Norlia, I. Naqiyah, N. A. Sharifah
University Kebangsaan, Malaysia

Background: Breast carcinoma is the most common malignancy among women worldwide including Malaysia. Protein p27 is one of the cyclin-dependent kinase inhibitory proteins, and plays an important role in cell cycle regulation. The aim of this study was to investigate the relationship between the expressions of p27and MIB1 and their clinico-pathologic parameters in invasive breast carcinomas. Methods: The immunohistochemical expression of p27 protein was evaluated and correlated with MIB1 and clinico-pathological parameters by tissue microarray in 112 invasive ductal carcinomas of the breast. The patients consisted of 109 females and 3 males and the ages ranged from 26 to 85 years (median, 63: mean, 56) and the histological types were mainly invasive ductal carcinomas (84%; 94/112). Results: Over expression of p27 and MIB1 proteins was found in 56% (54/96) and 45% (41/91) of breast carcinomas respectively. P27 protein was statistically significant with ER whereas MIB1 was statistically significant with c-erbB-2 ($p<0.05$) and p53 proteins. Positive staining of both ER and p27 was exhibited significantly in patients who were than older than 50 years ($p<0.05$). The expressions of p27 and MIB1 in breast carcinomas were not correlated with race, size, histological types, grade and nodal metastases. Conclusion: These findings showed that this protein, p27 expressed at relatively high levels, was correlated with positive estrogen receptor compared to MIB1 expression, was associated with c-erbB-2 and p53 proteins.

PP1-16
VIMENTIN, P-CADHERIN AND BASAL TYPE CYTOKERATINS EXPRESSION IN INVASIVE DUCTAL BREAST CARCINOMA

Renata Kusinska[1], Piotr Potemski[2], Dorota Kupnicka[1], Grazyna Pasz-Walczak[1], Radzislaw Kordek[1]
[1] Department of Pathology, Medical University of Lodz, Copernicus Memorial Hospital, Lodz, Poland
[2] Department of Chemotherapy, Medical University of Lodz, Copernicus Memorial Hospital, Lodz, Poland

Background: Basal-type breast carcinomas defined by the CK5/6, CK14 and CK17 expression and ER and HER2 negativity are related with poorer outcome. There were suggestions that these tumours more often present vimentin and p-cadherin expression and these antigens characterize high grade and ER-negative tumours. Method: We investigated the expression of vimentin, p-cadherin, cytokeratins: 5/6, 14, 17 and ER, PGR, HER2, Cyclin E and Ki67 in 193 invasive ductal breast cancer by immunohistochemistry, to find out the relationship among vimentin and p-cadherin expression and basal cell phenotype. We check also association of analyzed antigens with clinical and morphological factors. Results: Forty one (21,2%) cases expressed vimentin, whereas 111 (57.5%) tumours were p-cadherin-positive. Expression of CK5/6 showed 66 (34.2%) tumours, 48 (24.9%) were CK17-positive and 48 (24.9%) CK14-positive. Expression of vimentin showed 32 (45.7%) cases from the group of 'CK 5/6 or CK 14 or CK17'- positive tumours and 9 (7.4%) remaining tumours ($p<0.001$). P-cadherin was positive in 73.2% and 48.4% ($p<0.001$) cases accordingly. Conclusion: P-cadherin and vimentin expression are more often present in the group of basal cytokeratin positive tumours, but can not be regarded as sensitive markers of basal-type tumours.

PP1-17
RADIOFREQUENCY ABLATION OF INVASIVE BREAST CARCINOMAS. RESULTS AND PROBLEMATIC OF HISTOLOGICAL STUDY

De Miguel Concepcion, Apesteguía Luis, Reparaz Begoña, Fernandez Pilar, Azagra Ana, Sanz Miguel Angel
Hospital Virgen Del Camino Pamplona, Spain

Purpose: To evaluate the safety and accuracy of office-based radiofrequency ablation (RFA), under local anesthesia and US guidance, as local therapy for primary invasive breast carcinomas (PIBC). Problematic of histological study of tumour treated and assessment of residual enzymatic activity using the nicotine amide adenine dinucleotide-diaphorase (NADH-D) technique on frozen material. Methods and materials: Prospective study of 20 PIBC smaller 20 mms. previously diagnosed by needle core biopsy (NCB) and then, treated by RFA. All patients underwent conservative surgical therapy 2-4 weeks after RFA. Complete lymphadenectomy was done if axillary node metastasis were demonstrated. Sentinel biopsy in the remaining cases. Protocol for pathological study: Prior NCB to determine histological type, degree, hormonal receptors and Her-2. Study of the surgical specimen: Intraoperation study of surgical borders, photograph, freezing of the sample for NADH-D tecniche, conventional study with H-E, to assessment size, residual tumour, extension of coagulative necrosis and final state of surgical borders. Evaluation of NADH-D: positive: blue, negative: colourless. Results: Surgical specimen: Tumour size: 4-20 mm (X: 10). Complete coagulative necrosis: 19 cases, incomplete: 1 case. NADH-D: Negative: 12 cases, partial positivity: 2 cases, (one case showed slightly positive and, other, an intraductal component was found out side the effet ring), not done: 4, not assessed (the sample frozen didn't include a tumour): 2 cases. In 16 cases the surgical borders were negative. In all cases no significant complications were observed. Conclusions: RF ablation is a safe procedure which permits the oncologically correct treatment of malignant breast tumours. The histological study of the tumour treated should be similar to any malignant breast tumours. The specimen treated presents a concentric image: a central ablation, with destructured, necrotic tissue, with the residual tumour; a red halo 1 cm. beyond the tumour (the halo marks the limit of the necrotic effect) and tissue of normal appearance outside the hyperemic ring. The assessment of enzymatic activity with NADH-D technique is problematic. It is easy to carry out and assess: Positive (blue) and negative (colourless). The problems are technical: 1: To obtain good histological sections in frozen and bad tissue (frequently adipose, necrotic and friable). 2: how much material to freeze, as the tumours are very small, and 3: what zone to freeze as, at times, it is difficult to recognize the residual tumour.

PP1-18
IMPORTANT CLINICOPATHOLOGICAL PARAMETERS ON THE HER 2 POSITIVE BREAST CARCINOMA

Bratislav Stojiljkovic
Institute of Oncology Vojvodina, Sremska Kamenica, Serbia

Introduction Treatment of breast carcinoma as a category of hormone-dependent tumors requires the evaluation of receptor status (ER, PR, and HER 2), which is fundamental for planning and application of adequate therapy. Information on HER2 status is particularly important because it selects the patients suitable for the application of Herceptin. Aim: The aim was to analyze receptor status in case of 200 breast carcinoma patients and to select all HER2 3+ findings. These findings were compared to main clinicopathological parameters: age of patients, histological type and grade of the carcinoma, TNM status, and receptor

status). Material and Methods: Samples for IH analysis of receptor status were examined by means of ER, PR, and HER2 antibodies N and M series. LSAB2 kit was used for visualization. Estrogen and progesterone were ranged with 1, 2, and 3 and HER2 was ranged according to reference ranges (DAKO) 1+, 2+, and 3+. Results HER2 3+ results were found in case of 16.58% of patients. Those were mainly patients younger than 54 years (40.55%) with ductal (53.57%) or lobular invasive carcinoma (17.86%), stage pT1c (18.18%) or pT2 (45.45%) with positive nodal status. The results showed that HER2 3+ were most frequently associated with ER-0 (57.57%) and PR-0 (65.62%). Conclusion: The analysis of obtained results showed that HER2 3+is correlates most often to loco regional advanced ductal invasive carcinoma of the breast with negative ER and PR, which suggests that HER 2 status predicts more aggressiveness of the tumor.

PP1-19

INTRAOPERATIVE HISTOLOGICAL EVALUATION OF SENTINEL NODES IN BREAST CANCER BY USING IMMUNOHISTOCHEMISTRY

Bratislav Stojiljkovic, Andrija Golubovic, Zoran Radovanovic, Aleksandar Plzak, Zeljko Pozega
Institute of Oncology Vojvodina, Sremska Kamenica, Serbia

Background: Histological methods that are usually used for determination of metastatic status of SN in breast cancer have a postoperative character; that is why subsequent extirpation of fat tissue must be performed in some patients. Therefore, the authors suggest the application of intraoperative histological evaluation of SN by means of the method of serial ex tempore analysis with immunohistochemistry Purpose of the study: The specimen consisted of 100 patients with breast cancer pT1 classification (£ 2 cm) who underwent surgical treatment involving sentinel concept. Material and methods: Sentinel lymph nodes found in one half of investigated patients were analyzed by routine (postoperative) histological technique; the other half of the sentinel nodes was analyzed by the suggested intraoperative serial extempore analysis with immunohistochemistry. The control histological method identical for both groups of patients was used to record the cases with the conversion of initial histological finding (false negative), which made possible to establish the sensitivity of used methods and their mutual comparison. Results: The main result was to find metastatic status of sentinel lymph nodes in both investigated groups of patients, which the authors obtained by using the suggested and its competitive methods. After the verification of the results obtained in both groups of patients by means of control (extensive) histological method the number of false-negative sentinel lymph nodes was established and used to calculate the sensitivity of applied methods. Finally, the results were compared and it was noted that the most effective histological method was the suggested serial extempore analysis with immunohistochemistry. Conclusion: By the analysis, conclusions were made related to positive and negative performances of the suggested histological method; it was also noted that the control serial section of paraffin blocks with immunohistochemistry did not significantly increase the number (percent) of conversed histological findings in sentinel lymph nodes in relation to suggested method.

FIBROADENOMA ARISING IN ECTOPIC BREAST TISSUE OF THE PUBIC REGION. A CASE REPORT

Abdelfatteh Zeddini[1], Nour Salhab[2], Jean-Michel Coindre[3], Angela Fior[2]
[1] Service d'anatomie pathologique - CHC de Cayenne - Guyane
[2] Service de chirugie B - CHC de Cayenne - Guyane
[3] Service d'anatomie pathologique - CHU de Bordeaux

BACKGROUND: Ectopic breast tissue is usually found within the milk lineextendind from the axilla to the pubic region, and can develop any disease that affects the normal breast, including fibroadenoma. MATERIALS AND METHODS: We report a new case in 50-year-old woman occurring at the pubic evolving more than ten years without pain. A surgical resection was performed and the pathological study concludede at a fibroadenoma arising in ectopic breast tissue CONCLUSION: Through this observation we try to recall the clinical particalities, the diagnosis, differential diagnosis and treatment of this rare entity.

PP1-21

IMMUNOPHENOTYPE OF ESTROGEN RECEPTOR (ER), PROGESTERONE RECEPTOR (PR) AND HER-2 NEGATIVE BREAST CARCINOMAS

Natalia Vladika, Doxakis Anestakis, Persefoni Xirou, Fotios Chatzinikolaou, Kalliopi Gianna, Frideriki Patakiouta
Department of Pathology, Theagenion Cancer Hospital, Thessaloniki, Greece

Background: Gene expression analysis has identified several breast cancer subtypes that are associated with different clinical outcomes. The ER/PR/HER-2 negative (triple negative) phenotype represents an aggressive subtype of breast cancer that is unresponsive to therapeutic agents used to treat other type carcinomas. The aim of this study is to characterize the histological and immunohistochemical features and to identify potential prognostic markers of these tumours. Method: We retrospectively evaluated 70 triple negative breast tumours for different histological features, including tumour type, grade, architectural growth pattern, circumscription and presence of necrosis and inflammatory infiltrate. Formalin-fixed paraffin-embedded tissue sections were immunostained for CK5/6, EGFR, E-Cadherin and COX-2. Results: Morphologically the 70 triple negative tumours included 55 grade 3 ductal (NOS), 7 metaplastic, 6 medullary, 1 papillary and 1 lobular carcinomas, that frequently showed geographic necrosis, a pushing border of invasion and a stromal lymphoplasmatocytic infiltration. Marker of basal-like differentiation (CK5/6) was weakly to strongly positive in 21/70 (30%) cases. EGFR and COX-2 positivity was observed in 19/70 (26%) and 15/70 (21%) cases, respectively. Nine (47%) of EGFR and three (7%) of COX-2 positive tumours were also CK5/6 positive. COX-2 expression was observed in 6/19 (30%) of EGFR positive tumours. Loss of E-Cadherin immunoreactivity was seen in 32/70 (46%) tumours. Conclusion: Triple negative carcinomas of the breast are a distinct clinical and pathological entity, characterized by predominately high nuclear grade and lack of hormone receptor and HER-2 expression. Our study indicates that approximately 30% of these tumours express a basal-like phenotype and show positivity for EGFR and COX-2; about half cases display loss of E-Cadherin immunoreactivity. Therefore, the use of these markers in a standard immunohistochemical panel may assist in sub classification and search of new therapeutic approaches in triple negative cancer.

PP1-22

CLINICAL-PATHOLOGICAL FACTORS ASSOCIATED WITH NODAL INVOLVEMENT IN T1A-B BREAST CANCER. A RETROSPECTIVE ANALYSIS ON A MONO-INSTITUTIONAL SERIES

Antonella Ferro[1], Mattia Barbareschi[2], Rocco Micciolo[3], Renza Triolo[1], Sabino Walter Della Sala[4], Michela Frisinghelli[1], Viviana Murgia[1], Barbara Soini[1], Elena Leonardi[2], Daniela Cazzolli[5], Nino Natale[5], Salvatore Mussari[6], Bruno Zani[5], Enzo Galligioni[1]
[1] Medical Oncology; S. Chiara Hospital; Trento, Italy
[2] Unit of Surgical Pathology, Laboratory of Molecular Pathology, S. Chiara Hospital, Trento, Italy
[3] University of Trento, Italy
[4] Unit of Mammography; S. Chiara Hospital, Trento, Italy

[5] Unit of Surgery, S. Chiara Hospital; Trento; Italy
[6] Unit of Radiotherapy; S. Chiara Hospital; Trento, Italy

BACKGROUND: The proportion of T1a and T1b breast cancers is progressively increasing due to early diagnosis and mammographic screening. In these patients the incidence of axillary node metastasis (ANM) is relatively low (6-31%). However it remains the most important prognostic factor. Few information are available on the correlation between clinical and histological features and the frequency of lymph node involvement in small invasive breast cancer (ibc). Our retrospective analysis was designed to determine if it is possible to identify any clinical and/or pathological predictor of ANM metastasis in T1a and T1b ibc. PATIENTS AND METHODs: A series of 818 patients with T1a and T1b ibc, treated at our institution from 1990 to 2005 with primary tumor resection and axillary lymph node clearance was investigated. Univariate and multivariate analyses were used to evaluate the relationship between axillary node status and clinical-pathological factors (age, tumor size, histologic type and grade, ER and PgR status and immunohistochemical expression of MIB-1, HER-2 and p53). RESULTS: Of 818 tumors, 222(27%) were T1a and 596 (73%) T1b. The incidence of ANM was 16,5% (135/818) with 30 detected in T1a (3,7%) and 105 (12,8%) in T1b tumors. In univariate analysis we found a significant correlation between ANM and younger people (OR= 1,85; p=0.01); further, poorer histologic grade was also associated with an increased risk of ANM (OR = 2,45; p=0.01). No statistically significant correlation was observed between node status and tumour size (T1a vs T1b), histologic type (ductal, lobular, medullar, mucinous), hormone receptor status, MIB-1, p53 and HER-2 expression. Then, we divided the positive node group in [LTEQ] 3 (109/135) and > 3 (26/135) positive nodes patients. In N [LTEQ]3 group 27 patients presented T1a and 82 presented T1b, while in other group (N > 3) 3 patients were T1a and 23 T1b. This subgroup analysis revealed a statistically significant relationship between more severe nodal involvement and younger age (p= 0.03), ductal histological type (p=0.02), high histological grade(p=0.003) and > 20% MIB-1 (p=0.02). In multivariate analysis, the risk of ANM was related to increasing histologic grade and to larger size, but was independent from age. CONCLUSIONS: In our series, the incidence of nodal metastases in pts with very small ([LTEQ]1cm) breast cancer is not negligible, particularly in pts with worse histological grade. Therefore, it remains important to investigate axillary nodes with sentinel node biopsy technique or radical dissection.

PP1-23
TELECONSULTATION OF BREAST PATHOLOGY DATA: THE BELGIAN-LUXEMBURG TRIAL

Daniel Faverly
CMP Laboratory, Belgium

Virtual slide generators offer new opportunities in teleconsultations of pathology cases. Nevertheless, the validity of virtual slides as a routine diagnostic tool is not yet confirmed. A clinically valuable diagnosis is not only requiering high quality virtual slide (VS) images but also a securized network between refering centers, the opportunity of sending reports and consultation of medical imaging. The one year Bel-Lux trial, started January 2007, proposes to evaluate the efficiency of virtual needle core and surgical breast specimens slides teleconsultation between the Laboratoire National de Santé of Luxemburg and pathology laboratory CMP in Brussel. VS are compared to standard glass slides sent by post. Delays in responding are monitored and compared in an economical model. VS are generated by Mirax Zeiss and information exchanged via the Kisano Euromedim platform. Early results confirms the quality of VS images allowing routine diagnosis in clinical settings. This trial is supported by IRSIB granting (Brussel).

MITOTIC INDEX OF EPITHELIAL CELLS IN FIBROEPITHELIAL BREAST TUMOURS – DIAGNOSTIC SIGNIFICANCE

Vitomir Govedarović[1], Dragan Mitrović[1], Jasmina Marković-Lipkovski[1], Danica Jovanović[2]
[1] Institute of Pathology, School of Medicine, University of Belgrade, Serbia
[2] National Cancer Research Institute, Belgrade, Serbia

BACKGROUND: Human breast fibroadenomas (FA) and phyllodes tumours (PT) have almost identical morphology of epithelial components, but different kinetic potential of these cells. In the present study we investigate mitotic index of epithelial cells in different histological and biological types of these tumours with regard to diagnostic significance. METHOD: 100 FA and 102 PT were analyzed in the National Cancer Research Institute of Serbia. In 10 PT (1 border line and 9 malignant tumours) epithelial component were absent ("stromal overgrowth"). On H&E semi-thin histological slides of each tumour, epithelial mitotic figures were detected on 50 (malignant PT), 100 (benign PT) and 600 (FA) microscopic fields, with size 0.0962 mm2. Mitotic index was expressed as mitotic count per 100 epithelial cells. Statistical analyses were performed by ANOVA test. RESULTS: Epithelial mitotic index (mean±SD, 10-3%) in 100 FA and 92 PT was 1.45±4.02 vs. 2.92±3.72 ($p<0.001$), in 53 intracanalicular FA and 73 benign PT was 1.51±4.86 vs. 2.67±3.41 ($p<0.001$). Epithelial mitotic index 4.82±5.15 was the highest in 13 border line PT among all analyzed tumour types, and it was significantly higher in comparison to the intracanalicular FA ($p<0.01$). CONCLUSION: Epithelial component of the breast phyllodes tumours have significant higher growth potential than fibroadenomas. Benign intracanalicular fibroepithelial breast tumours (intracanalicular fibroadenomas versus benign phyllodes tumour) may be distinguished by mitotic count of epithelial tumour cells.

PP1-25
POTENTIAL DOUBLING TIME OF TUMOUR CELL NUMBER IN HUMAN FIBROEPITHELIAL BREAST TUMOURS – A MORPHOMETRIC APPROACH

Dragan Mitrović[1], Vitomir Govedarović[1], Jasmina Marković-Lipkovski[1], Danica Jovanović[2]
[1] Institute of Pathology, School of Medicine, University of Belgrade, Serbia
[2] National Cancer Research Institute, Belgrade, Serbia

BACKGROUND: Kinetic cells proliferation parameters of human solid tumours are still poorly investigated. Potential doubling time of total tumour cell number (PDT) is the time for which the total number of tumour cells will be doubled, under the supposition that losing cell number is equal to zero. PURPOSE: Calculate PDT by mitotic and nuclear numerical density determination of mesenchymal and epithelial tumour cells in H&E semi-thin histological slides of human breast fibroepithelial tumours after tumourectomy. MATERIAL AND METHODS: 100 fibroadenomas (FA) and 102 phyllodes tumours (PT) were analyzed on the National Cancer Research Institute of Serbia. Epithelial and mesenchymal mitotic figures were detected in 50 (malignant PT), 100 (benign PT) and 600 (FA) microscopic fields with size 0.0962 mm2. Number of nuclei was determinated in Weibel testing system M42 by area 0.0576 mm2. Nuclear numerical density (Nv) was calculated by formula of Weibel and Gomez. PDT in hours was calculated by originally adapted formula $PDT=(Nv/Nvm)\cdot\ln 2\cdot 0.5$ in which Nvm is the numerical density of mitotic figures. RESULTS: PDT (mean±SD, years) was 60.47±97.42 in 100 fibroadenomas, 9.40±21.38 in 73 benign FT, 0.61±0.76 in 14 border line FT and 0.06±0.06 in 15 malignant FT (ANOVA, $p<0.001$). CONCLUSION: PDT in human fibroepithelial breast tumours largely varies from 22 days in malignant phylodes tumour to 60 years in fibroadenomas.

PP1-26

ASYMMETRY OF TUMOUR VOLUME LOGNORMAL DISTRIBUTION – AN INDICATOR OF MALIGNANCY

Dragan Mitrović[1], Vitomir Govedarović[1], Danica Jovanović[2], Aleksander Lipkovski[3]
[1] Institute of Pathology, School of Medicine, University of Belgrade, Serbia
[2] National Cancer Research Institute, Belgrade, Serbia
[3] Faculty of Mathematics, University of Belgrade, Serbia

BACKGROUND: Kinetic growth parameters of human solid tumours are still poorly investigated. Tumour volume is a prognostic indicator for many human tumours. PURPOSE: To calculate skew ness for the volume frequency distribution with regard to the biological behaviour of different intra-canalicular fibroepithelial human breast tumours. MATERIAL AND METHODS: Three diameters of first extirpated 1702 intracanalicular fibroadenomas (IFA) and 348 phyllodes tumours (PT) were measured in the National Cancer Research Institute of Serbia. Tumour volumes were calculated by ovoid volume formula. Skewness of logarithmic tumour volumes for different growing and non-growing tumour groups were calculated by StatPlus 2006 Professional software. RESULTS: Skew±SE were in 27 non-growing hyalinized IFA 0.209±0.431, in 1438 normocellular IFA 0.366±0.065, in 237 hypercellular IFA 0.438±0.157, in 264 benign TP 0.288±0.149, in 21 border malignant TP −0.176±0.477 and in 63 malignant TP −0.224±0.297. Normalized volume frequency distribution of analyzed benign tumours and benign non-growing tumours are skewed to the right (positive skewness), but of malignant ones are skewed to the left (negative skew ness). CONCLUSION: Negative asymmetry of tumour volume lognormal distribution may be an indicator of tumour malignancy.

PP1-27

NODULAR FASCIITIS OF THE MALE BREAST : A CASE REPORT

Amal Kouchkar[1], Leila Cherfaoui[2], Nadjiba Debabech[2], Meriem Benahmed[1], Nadjia Terki[1]
[1] Department of pathology ,Centre Pierre et Marie Curie Algiers, Algeria
[2] Department of pathology ,Centre Pierre et Marie Curie Algiers
Department of pathology ,Centre Pierre et Marie Curie Algiers, Algeria

Introduction: Nodular fasciitis is a rare benign soft tissue lesion, interesting a fibroblastic proliferative condition of unknown aetiology .It can clinically and radiologically mimic a malignant tumour. To our knowledge, there was only one case reported of a lesion of this type in the male breast. Methods and results: We describe a case of nodular fasciitis of the breast that involved the breast parenchyma of a 81-year-old man. The patient complained of a slowly growing mass in his left breast. There was no evidence of axillary lymphadenopathy. The patient underwent a total excision of a lesion measuring (7cm x 6cm) Histologically the appearances included short interweaving fascicles of spindle cells in a loosely textured mucoid matrix. There was also present an extravasated red blood cells and a focal lymphocytic infiltration. Discussion : Spindle cell lesions of the breast constitute a wide spectrum of benign and malignant proliferations. The differential diagnosis of nodular fasciitis in the male breast mainly includes fibromatosis and myofibroblastoma. The histologic features and a review of the literature are presented.

PP1-28

C-KIT EXPRESSION IN COLUMNAR CELL LESIONS OF THE BREAST ACCOMPANIED TO BENIGN AND MALIGNANT BREAST DISEASES

Ayse Polat
Mersin University Faculty of Medicine, Turkey

Columnar cell lesions (CCLs) of the breast are being increasing frequency reported in pathology specimens. However the significance and treatment approach of these lesions are unknown. The proto-oncogene c-KIT is believed to play an important role in growth control and differentiation of normal breast epithelium, but it is shown to decreased expression in invasive carcinoma. In this study we aimed to evaluate c-KIT expression in CCLs accompanied to benign and malignant breast diseases. Of 65 patients with CCLs, 18 were coexisted benign breast diseases, 8 of them were coexisted DCI and 39 of them were coexisted invasive carcinomas. C-KIT was found to be expressed intensively in normal breast epithelium. Staining intensity (SI) in normal epithelium was 3±0.0, whereas SI in CCLs (All cases were CCLs without atypia) accompanied to benign diseases was 1.45 ±0.52. Whereas SI in CCLs with or without atypia accompanied to DCI were 1.25 ±0.50 and 1.38 ±0.52 respectively. Finally SI in CCLs with and without atypia accompanied to invasive carcinoma was 0.77 ±0.73 and 1.21 ±0.42 respectively. However c-KIT expression was detected in 10.4% of invasive carcinomas. No significant association was observed between c-KIT expression and tumour histological grade and nodal status. Reduction of c-KIT expression with malign transformation of breast epithelium is believed to be c-KIT has a role of breast carcinogenesis. Additionally similar c-KIT expression pattern in CCLs to malignant breast diseases suggest that at least some CCLs could be a premalign status of breast carcinoma. But implication of c-KIT in CCLs and relation to breast Carcinogenesis should be evaluated in follow up studies in larger series.

PP1-29

REPORT OF A CASE OF BREAST CARCINOMA WITH CARTILAGINOUS AND OSSEOUS METAPLASIA

Vazquez Navarrete Sofia, Diaz Lagama Ana, Jimenez Peña Raquel
Hospital del SAS. La Linea. Cadiz, Spain

The reported frequency of invasive breast cancer with cartilaginous and/or osseous metaplasia (mixed epithelial / mesenchymal metaplasic carcinoma. WHO Classification) is 0’03 – 0’2 % of all breast cancer.There is a paucity of information on clinically relevant pathologic and clinical outcomes for these rare tumors. CASE REPORT A 72 year-old spanish woman presented to the external consultation of our hospital, with a tumor of the right breast, palpable, as numerous adenopaties in the right axillary area. After mammography and ultrasonography were performed two continuous nodular masses with greater tissue density than the adjacent parenchyma with irregular-shaped grouped calcification within the tumor area, were revealed. A core needle biopsy was done and a report of invasive ductal carcinoma provided. No distant metastasis or elevations of tumor markers were detected.With this diagnosis a modified radical mastectomy of the right breast and dissection of the axillary lymph nodes was practised.Gross examination showed two more or less well circumscribed tumors of 2´5 x 1´7 x 1 cms. and 2´6 x 2´4 x 0´75 cms., white with yellow areas. Necrosis and hemorrhage was seen.Histologically the tumor showed invasive ductal carcinoma with pushing margins, and moderate lymphocytic infiltrate and necrosis. Numerous areas of osseous and cartilaginous metaplasia,with osteoclastic giant cells, were observed. In some fields the bone trabeculae were found adjacent to the epithelial cancer cells, in others in necrosis foci, and in some places related to cartilaginous plates and a bland looking area of fusiform cells. The ductal cancer was classified as Grade II (Bloom- Richardson). Twenty one of the twenty six lymph nodes encountered, were found to be metastasic.Immunohistochemical studies were positive in the invasive ductal cancer for estrogen and progesterone receptors and negative for HER2 (CB11 clone) overexpression. The behaviour of metaplastic carcinoma seems to be more aggresive than of ordinary invasive ductal-type carcinoma, although some

authors stated that the presence of metaplasia in human breast cancer did not alter the behavior of the tumor in comparison with similar tumors.In a case reported recently by Kisima and cols the patient died of rapidly progressive pulmonary metastasis despite no lymph node involvement at the time of the diagnosis. Those authors recommended a large number of studies to examine the predictive value of known prognostic variables in patients this type of breast carcinoma, that justifies the report of our case.

PP1-30

METAPLASTIC CARCINOMA OF THE BREAST WITH OSSEOUS DIFFERENTIATION AND PRIMARY OSTEOGENIC SARCOMA OF THE BREAST - REPORT OF TWO UNUSUAL CASES OF BREAST NEOPLASMS

Vanja Filipovski, Saso Banev, Milco Ristovski, Blagica Dukova, Lolita Andonovska
Institute of Pathology, Medical Faculty, University "St. Cyril and Methodius" Skopje, Macedonia

AIM: The aim of this paper is to present two rare cases of breast neoplasms characterized with development of bony structures but with different etiology. MATERIALS AND METHODS: Samples from the breast lesions, formalin fixed and paraffin embedded were stained with Hematoxyllin Eosin, and additionally immunohistochemical analyses were performed using antibodies for Cytokeratin, Cytokeratin high molecular weight, Cytokeratin 18, Cytokeratin 19, Epithelial specific antigen (ESA), S-100 protein and Vimentin. RESULTS: Case1. Female with a clinical diagnosis of mammary cancer presented with a breast nodule confirmed by fine needle aspiration cytology as a malignant lesion. Partial resection of the breast with minimal axillary lymphadenectomy was performed. The nodule measured 18 mm, and was presented as a star shaped, hard grey-white lesion. Histology showed malignant infiltrative neoplastic lesion arranged in solid nests or sheaths and partly tubular structures. One focus showed a desmoplastic reaction with a differentiation of a hyaline collagenous stroma toward cartilage and bony structures with a calcium deposition. Case2. A 71 year old female presented a well defined breast mass that was clinically diagnosed as a benign breast lesion. Due to the large size (85 mm) quadrantectomy was performed. Morphological analysis revealed hard calcified well circumscribed nodule that was additionally treated with a decalcination procedure. Histology showed malignant lesion composed of spindle shaped cells placed in a collagenous stroma with foci of myxomatous differentiation. Toward the center of the lesion the cells differentiate in bony elements: bone trabeculae, calcium deposits and cartilaginous elements. Immunohistochemical analysis differentiated this lesion into primary osteogenic sarcoma. Eight months later a recidivant lesion emerged with identical histological characteristics. CONCLUSION: These rare breast neoplasms can often present a differential diagnostic challenge. First they are rarely present in everyday pathological practice, second they can have almost identical histology, and most importantly even though immunohistochemistry helps in their differentiation sometimes these results are inconclusive.

PP1-31

DISTRIBUTION AND SIGNIFICANCE OF CAVEOLIN 2 EXPRESSION IN NORMAL BREAST AND BREAST CANCER: AN IMMUNOFLUORESCENCE AND IMMUNOHISTOCHEMICAL ANALYSIS

Kay Savage, David Robertson, Michelle James, Suzanne Parry, Robin Jones, Jorge Sergio Reis-Filho
The Breakthrough Breast Cancer Research Centre, Institute of Cancer Research, London, United Kingdom

Backround: The distribution and significance of caveolin 2 (CAV2) in normal breast and breast cancers remain poorly understood. The aims of this study were to define the distribution of caveolin 2 in frozen and formalin fixed, paraffin embedded (FFPE) normal breast samples and the significance of CAV2 expression in breast cancer. Methods: Caveolin 2 distribution in frozen and paraffin-embedded whole tissue sections of normal breast was evaluated using immunohistochemistry and immunofluorescence, in conjunction with antibodies to define luminal epithelial cells (oestrogen receptor and cytokeratin 8/18) and myoepithelial/ basal cells (cytokeratins 14 and 5/6, p63 and smooth muscle actin). CAV2 expression was also immunohistochemically analyzed in a cohort of 245 invasive breast carcinomas from patients treated with surgery followed by anthracycline-based chemotherapy. Results: In normal breast, CAV2 was expressed in myoepithelial cells, endothelial cells, fibroblasts and adipocytes. Luminal epithelial cells showed no or only negligible staining. CAV2 expression was observed in 6.2% of all breast cancers and was strongly correlated with lack of oestrogen and progesterone receptor expression and cyclin D1, and positivity for epidermal growth factor receptor, cytokeratins 5/6, 14 and 17 and p53, and high proliferation index. Furthermore, CAV2 expression was significantly associated with basal-like immunophenotype and proved to be a prognostic factor for overall survival independent of tumour size and grade. Conclusion: Our results demonstrate that CAV2 is preferentially expressed in basal-like cancers and is associated with poor prognosis. Further in vitro studies are required to determine whether CAV2 has oncogenic properties or is only a surrogate marker of basal-like carcinomas.

PP1-32

EFFECT OF HORMONE RECEPTOR POSITIVITY IN c-erbB-2 POSITIVE BREAST CARCINOMAS

H. Elif Pestereli[1], Taner Colak[2], Gulgun Erdogan[1], F. Seyda Karaveli[1]
[1] Akdeniz University, School of Medicine, Department of Pathology, Turkey
[2] Akdeniz University, School of Medicine, Department of General Surgery, Turkey

AIM: C-erbB-2 overexpression occurs in 10-30 % of breast carcinomas. This oncogene encodes a transmembrane tyrosine kinase receptor belonging to the epidermal growth factor family. Its overexpression in breast carcinomas associates with poorer prognosis. Generally it's inversely correlated with estrogen and progesterone receptors (ER,PR). However some of the c-erbB-2 positive breast carcinomas also express estrogen and progesterone receptors. We investigate the difference between the clinicopathologic characteristics (menstrual status, histologic grade, lymph node metastasis, stage) of hormone receptor positive and hormone receptor negative but c-erbB-2 positive carcinomas and also compare the outcome of these patients. MATERIAL and METHODS: We analysed the tumors of 370 patients, operated at the General Surgery Department and diagnosed as invasive ductal carcinoma at the Pathology Department of Akdeniz University between 2003 and 2006. Immunohistochemical method was used to determine the hormonal status and c-erbB-2 overexpression. Flouresence in situ hybridization method (FISH) to confirm the Her2/neu overexpression was performed only in randomly selected 20 carcinomas. Statistical analysis was done by using Chi-square test and survival analysis by Kaplan Meier. RESULTS: Among 370 invasive ductal carcinomas 146 revealed c-erbB-2 immunopositivity. Seventyfour of 146 positive carcinomas showed both ER and PR positivity where 42 were ER (-) and PR (-). There were 22 (52 %) grade 3 carcinomas in the ER-/PR- and c-erbB-2 + group but only 18 out of 74 ER+/PR+/c-erbB-2+ group (p= 0.001). Lymph node positivity was seen in 69 % of ER-/PR-/c-erbB-2+ and 44.6 % of ER+/PR+/c-erbB-2+ carcinomas (p=0.009). Twentytwo of 42 (57.1 %) ER-/PR-/c-erbB-2+ carcinomas were stage II A, in the ER+/PR+/c-erbB-2+ group 44 (59.5 %) out of 74 were stage I (p= 0.063). ER-/PR-/c-erbB-2+ carcinomas were associated with a higher likelihood of recurrence. In 36 months, 7 of ER-/PR-/c-erbB-2+ carcinomas showed local recurrences but none of the hormone and c-erbB-2

positive carcinomas had recurrence (p=0.0012). CONCLUSION: There was a statistically significant difference between the histologic grade, lymph node metastasis of hormone receptor and c-erbB-2 positive and hormone receptor negative but c-erbB-2 positive carcinomas. Disease free survival of hormone receptor positive and c-erbB-2 positive carcinomas was also better so we concluded that even in the c-erbB-2 positive carcinomas, hormone receptor expression improve the prognosis.

PP1-33
IMMUNOEXPRESSION OF HER FAMILY IN INVASIVE DUCTAL CARSINOMAS OF THE BREAST
Ipek Erbarut, Handan Kaya, Naziye Ozkan, Nural Bekiroglu, Semiha Sen, Ufuk Soylemezoglu, Bahadir Gulluoglu
Marmara University, Turkey

Background: The purpose of the study was to investigate the frequency of expression of erbB/HER family of growth factor receptors, in invasive ductal carcinomas of the breast. The frequency of expression of the antibodies, their coexpressions and their correlations with the histopathological prognostic parameters as tumor stage, grade, lymph node status, hormonal status, and patients clinical follow-up has been searched. Material Method: 59 invasive ductal carcinomas of the breast has been studied for EGFR, c-erbB-2, c-erbB-3, c-erbB-4, by streptavidin-biotin horseradish method. EGFR, c-erbB-3, c-erbB-4 were all evelatuated as; ›20% of tumor cells with moderate 2+ and strong membranous 3+ staining were regarded as positive immunoexpression or overexpression and ›10% of the tumor cells strong, complete membranous staining for c-erbB-2. Statistical analysis was based on associations between categorical variables were assessed by means of ^{2} and coefficient of associations with Somers'd tests. P-value of less than 0.05 was considered to indicate a statistically significant difference. Results: Of the 59 tumours, 44 (75%) were ER+, 37 (63%) PR+, 4 (7%) EGFR+, 7 (12%), c-erbB-2+, 7 (12%) c-erbB-3+, 14 (24%) c-erbB-4+. Results of the immunohistochemistry revealed statistically significant correlation with PR negativity and EGFR overexpression (p‹0.05). There were also statistically significant correlation between c-erbB-2 and c-erbB-3 overexpression, c-erbB-3 and c-erbB-4 overexpression (p‹0.05). Although there were a tendency of coexpression found to be between c-erbB-2 and c-erbB-4 (p=0.062) and between c-erbB-2 and EGFR (p=0.066). According to the clinical follow-up results of the patients the only statistically significant correlation found to be between c-erbB-4 overexpression and good prognosis (p‹0.05). Conclusion: The results of our study demonstrates a subgroup of invasive ductal carcinomas of the breast which are PR negative. PR negative breast carcinomas show different molecular characteristics as, EGFR and c-erbB-2 overexpression. Expression and co-expression profile of receptor throsine kinase growth factors are usually not characterized in pathological diagnosis. However targeting multiple erbB-receptors may provide an exceptional strategy for an effective cancer therapy.

PP1-34
IMMUNOHISTOCHEMICAL EXPRESSION OF C-MET / HGF REGULATORY SYSTEM IN N0 BREAST CANCER
Ceausu Mihai, Terzea Dana, Iosif Cristina, Vasilescu Florina, Andrei Florin, Mihai Mihaela, Dobrea Camelia, Ceausu Zenaida, Ene Diana, Neagu Maria, Butur Georgeta, Ardeleanu Carmen
"Victor Babes" National Institute of Pathology, Bucharest, Romania

Background: Breast cancer is on the top of tumor morbidity in women, with an estimated incidence of 1 from 8 in the next decade. C-met is a proto-oncogene encoding a protein tyrozin-kinase (HGFR) – the receptor for scatter factor / HGF, involved in invasion and metastasis of tumor cells. Material and method: 40 archived formalin fixed parrafin embedded samples with breast cancer (invasive ductal carcinoma – IDC), with negative lymph nodes have been assessed, using an ABC peroxidase immunohistochemical method, by mean of 5 monoclonal antibodies: c-met, HGF alpha, HGF beta, c-erbB2, EGFR. All cases were graded according to the revised Bloom Richardson system. Therefore, in the study batch have been recorded: 10 cases with G1 IDC, 25 cases with G2 IDC and 5 cases with G3 IDC. Results and discussions: The HGF alpha reaction was diffusely positive (99% of cases), with various intensity and the HGF beta stained focally in IDC, specially in solid pattern types or with high nuclear pleomorphism (67,5% of cases); 70% of cases were positive to c-met intracytoplasmic, while EGFR was positive in 10% of tumors; 37,5% of cases have shown a 2+ and 3+ positivity for c-erbB2. Between HGF alfa and HGF beta have been recorded the following data: a negative correlation (r = -0.47) in G1N0 IDC, a direct positive correlation, statistically significant (r = 0.36, p = 0.01) in G2N0 IDC, and no correlation in G3N0 IDC. There was no correlation between c-met or HGF alpha/beta (independent parameters) in our study. A slightly positive correlation statistically significant between HGF beta and c-erbB2 has been noticed (r = 0.31, p = 0.05) in all investigated cases. Also, a resonable correlation between HGF alpha and microvascular density (assessed with EGFR) was recorded in G2N0 cases (r = 0.35, p < 0.001). Conclusion: c-met expression is independent of HGF alpha and beta activation, but the similar high percentage of c-met and HGF beta suggests their potential as predicting factors for invasion and metastasis in N0 breast tumors; the receptor seems to be activated only when both HGF alpha / beta subunits are present, the IHC expression decreasing with the tumoral grade.

PP1-35
IMMUNOEXPRESSION OF HER-2, NEUREGULIN, MAPK, AKT IN BREAST CARCINOMAS
Handan Kaya, Ipek Erbarut, Naziye Ozkan, Nural Bekiroglu
Marmara University, Turkey

Background: The purpose of this study was to investigate the frequency of expression of Her-2/neu, neuregulin, mitogen activated protein kinase (MAPK) and serine/threonine kinase (Akt), their co-expressions and their correlations with the histopathological prognostic parameters as tumor stage, grade, lymph node status, hormonal status, and patients clinical follow-up, in invasive ductal carcinomas of the breast. Material Method: 59 invasive ductal carcinomas of the breast has been studied for c-erbB-2, Neuregulin Ab-3, Phospho-Akt, and Phospho-p44/42 Map Kinase by streptavidin- biotin horseradish method. While strong and complete membranous staining of more than 10% of the tumor cells was scored as positive for c-erbB-2, strong cytoplasmic and/or nuclear staining pattern ›20% of tumor cells with moderate 2+ and strong 3+ staining were regarded as positive immunoexpression for Neuregulin Ab-3, Phospho-Akt. Moderate or strong (2 +and 3+) nuclear immunoexpression of ›20% of the tumor cells was scored as positive for phospho-p44/42 Map Kinase. Statistical analysis was based on associations between categorical variables were assessed by means of ^{2} and coefficient of associations with Somers'd tests. P-value of less than 0.05 was considered to indicate a statistically significant difference. Results: Of the 59 tumours , 44 (75%) were ER+, 37 (63%) PR+. Strong complete membranous staining revealed with 7 (12%) c-erbB-2 and cytoplasmic + nuclear immunoexpression with 17 (29%) neuregulin and 13 (22%) pAkt. Nuclear immunoexpression with pMAPK found to be 17 (29%) of the cases. While 4 (7%) of the cases were positive with both c-erbB-2 and neuregulin, there were only 3 (5%) cases co-expressing neuregulin+pMAPK+pAkt. Results of the immunohistochemistry revealed statistically significant correlation between PR negativity and both pAkt, and pMAPK overexpression (p‹0.05).There were a stastistically tendency of correlation between lymph node metastases and pAkt overexpression (p=0.067). According to the clinical follow-up results of the patients the only statistically tendency of correlation found to be between pAkt overexpression and patients poor

prognosis (p=0.059). Conclusion: PR negative breast carcinomas seems to be activated by receptor thyrosine kinase growth factors which leads to phosphorilation of the Akt and MAPK. This pathway known to be as inducing resistance to endocrine therapy. Information about tumorigenesis in the diagnostic pathology reports may lead an exceptional strategy for an effective cancer therapy.

PP1-36

EXPRESSION OF CYCLOOXYGENASE-2 AND ITS RELATION TO HISTOLOGICAL GRADE, INOS, MMP-2, CD-34, CASP-3 AND CD8 IN INVASIVE DUCTAL CARCINOMA OF BREAST

Esin Atik[1], Bulent Akanasu[1], Sevgi Bakaris[2], Nedim Aban[3]
[1] Department of Pathology, Faculty of Medicine, Mustafa Kemal University, Antakya-Hatay, Turkey
[2] Department of Pathology, Faculty of Medicine, Sutcu Imam University, Kahraman Maras, Turkey
[3] Department of General Surgery, Faculty of Medicine, Mustafa Kemal University, Antakya-Hatay, Turkey

Background: Breast cancer is the most common cancer in women and is second only to lung cancer as a cause of cancer related mortality. Interest in chemoprevention in oncology using suppressants of prostaglandin (PG) synthesis has been stimulated by epidemiological observations that the use of non-steroidal anti-inflammatory drugs (NSAIDs) is associated with reduced incidence of some cancers such as breast carcinoma. The main target of NSAID activity is the cyclooxygenase (COX) enzyme. The aim of our study was to assess by immunohistochemistry COX2 expression in invasive ductal carcinoma and its possible correlation with histological grade, iNOS, MMP-2 and other common immunohistochemical parameters (CD-34, CASP-3 and CD8). The mean value of positive stained cells were independently calculated by three pathologists and the results were averaged. Method: This study included 50 patients with invasive ductal carcinom with a mean age of 54.9±12.0 years. These cases were graded according to a modified form of the Bloom Richardson Histological Grading Index. The routine hematoxylin-eosin staining and COX2, iNOS, MMP-2, CD-34, CASP-3 and CD8 immunoperoxidase techniques were performed on paraffin–embedded tissues. Immunohistochemical antigen staining was performed with Ultra Vision Polyvalent, HRP-AEC kit (Lab Vision, Neomarker-Biogen USA). Results and Conclusion: The mean COX2 and MMP-2 values were found to be 274.02±54.4 and 263.42±54.30 respectively, whereas the mean iNOS values were found to be 258.10±56.05. CD-34 staining also yielded positive results as 26.18±8.00. The mean values of CASP-3 and CD8 were 284.06±41.2 and 164.17±69.5 respectively. This reveals an inverse correlation between CASP-3 reactivity and CD8 (Spearman correlation r = -0.33, p= 0.01). There was also an inverse correlation between iNOS reactivity and patients age (Spearman correlation r = -0.29, p= 0.03) There was a positive correlation with COX2 and MMP-2 (p=0.00) but there was not any relation with COX2 and other parameters. While there was a positive correlation with lymph node positivity and histological grade (p=0.007), a positive correlation was found between lymph node positivity and CD-34 reactivity and patients age (p=0.007, p=0.01 respectively)

PP1-37

DUCTAL CARCINOMA IN SITU (DCIS) OF THE MALE BREAST

Anastasia Nikolaidou[1], Michael Katsamakas[2], Christos Tsalikidis[3], Elisavet Pazarli[1], Athena Kriaka[4]
[1] Department of Pathology, General Hospital of Kilkis, Greece
[2] Department of Surgery, General Hospital of Kilkis, Greece
[3] 2nd Department of Surgery, University Hospital of Alexandroupoli.
[4] Department of Pathology, General Hospital ‘’G. Gennimatas’’, Thessaloniki, Greece

BACKGROUND: According to the World Health Organization the ductal carcinoma in situ (DCIS) of the male breast is a rare disease. Both DCIS and the invasive occur at a ratio of 1:25. The histological features are similar to those in the female breast, with the predominant architectural pattern being papillary and the comedo DCIS occurring rarely. METHODS AND RESULTS: We report a case of DCIS in a 74-year-old patient displaying the clinical features of gynaecomastia, with retroareolar enlagement of the breast tissue but without nipple discharge. The patient underwent excision of this mass, under local anaesthesia. The mass weighed 31 grs, its size was 4X3X2 cm and it was firm and grey white on the cut surface. The microscopic findings showed gynaecomastia lesions with multiple foci of prominent atypical epithelial intraductal hyperplasia, which, in rare locations, had the appearance of ductal carcinoma in situ of cribriform and solid type. The patient underwent simple mastectomy without axilla dissection four weeks following the original procedure. The DCIS expressis the estrogen (ER) and progesterone (PR) receptors and the oncogene c-erB-2 CONCLUSION: Although a review of literature suggests that most DCIS in men is of the papillary type, this case was of the rare cribriform and solid type. More cut sections should be taken from the macroscopically suspicious areas when we observe sites of atypical epitheliosis. It should be noted that there must be high clinical suspectability for DCIS of the male breast, especially in unilateral gynaecomastia in middle aged males.

PP1-38

RET FINGER PROTEIN EXPRESSION IN INVASIVE BREAST CARCINOMA: RFP CORRELATES WITH ErbB2 EXPRESSION

Gaye Guler Tezel[1], Aysegul Uner[1], Isil Yildiz[1], Gulnur Guler[1], Masahide Takahashi[2]
[1] Hacettepe University Faculty of Medicine, Department of Pathology, Ankara, Turkey
[2] Nagoya University Graduate School of Medicine, Department of Pathology, Nagoya, Japan

Background: RET finger protein (RFP), which belongs to the large B-box RING finger protein family, has been reported to be expressed in breast carcinoma cell lines. To examine the role of RFP in breast cancer tumorigenesis, the expression of RFP was assessed by immunohistochemistry. Methods: Tissue microarrays were constructed from one hundred thirty three cases of breast carcinomas. Two punches, one from central and another from peripheral part of the tumor were put in the arrays. Sections obtained from tissue arrays and whole sections of ten nonneoplastic breast tissue were stained for ER, PR, ErbB2 and RFP by immunohistochemistry and ErbB2 gene status was evaluated by FISH. The correlation between various immunohistochemical markers were determined. Results: We found nuclear RFP expression in 41.4% of carcinomas and none of the nonneoplastic breast tissues. In statistical analysis, there was a significant positive association between RFP and ErbB2 status at protein level (P = 0.002) as well as at the gene level (P = 0.049). There was no statistically significant association between the expression of RFP and ER, PR and nuclear grade (p>0.05). Conclusion:The expression of RFP in breast carcinomas together with a highly significant positive association between RFP and ErbB2 suggested that RFP could play a role in breast carcinogenesis.

PP1-39
EXPRESSION LEVELS OF FHIT AND WWOX CORRELATE WITH HER-2 PROTEIN OVEREXPRESSION AND GENE AMPLIFICATION IN BREAST CANCER

Gulnur Guler[1], Gaye Guler Tezel[1], Isil Yildiz[1], Aysegul Uner[1], Kay Huebner[2]
[1] Hacettepe University Faculty of Medicine Department of Pathology Ankara Turkey
[2] The Ohio State University Comprehensive Cancer Center, Columbus, OH, USA

BACKGROUND: We noticed borderline association of Fhit and Wwox expression with Her-2 in ductal carcinoma in situ of the breast in our previous study. The purpose of this study was to compare expression levels of Fhit and Wwox with Her-2 in invasive breast cancer. MATERIALS AND METHODS: Tissue microarrays were constructed from 130 invasive breast cancer cases. Two punches, one from central and another from peripheral part of the tumor were placed in the arrays. The expression levels of Fhit, Wwox, ER, PR and Her-2 were determined by immunohistochemistry and Her-2 gene amplification status was assessed by FISH. Correlations between various immunohistochemical markers and their relation with Her-2 gene amplification status were determined. RESULTS: Her-2 gene amplification determined by FISH was observed in 2.1% of Her-2 negative, 59.5% of Her-2 2(+) and 86.2% of Her-2 3(+) cases. There was a significant association of loss of Fhit and Wwox expression with Her-2 protein expression ($p<0.001$, $p=0.001$; respectively) and gene amplification ($p=0.002$, $p=0.001$; respectively). We divided our cases into four groups according to their ER (ER(+) means >10% nuclear staining) , PR (PR(+) means >10% nuclear staining) and Her-2 status (Her-2 (+) means existence of gene amplification detected by FISH): (group1, ER and/or PR (+), Her-2 (-) ; group 2: ER and/or PR (+), Her-2 (+); group 3: ER (-) PR (-), Her-2 (-); group 4: ER (-) PR (-) Her-2 (+). Reduced or lost Fhit staining was seen in 53.7% of group 1, 79.2% of group 2, 75% of group 3 and 93.8% of group 4 cases. Reduced or lost Wwox was detected in 50% of group 1, 66.7% of group 2, 42.9% of group 3, 76.5% of group 4 cases. Reduced Fhit and Wwox expression in these four groups were significantly different from each other ($p=0.026$, $p=0.023$, respectively).
CONCLUSION: Our results show that reduced Fhit and/or Wwox expression is more common in Her-2-positive invasive breast tumors.

PP1-40
FASCIN EXPRESSION IN INVASIVE DUCTAL CARCINOMA OF BREAST

Gulgun Erdogan[1], H. Elif Pestereli[1], Taner Colak[2], F. Seyda Karaveli[1]
[1] Akdeniz University, School of Medicine, Department of Pathology, Antalya, Turkey
[2] Akdeniz University, School of Medicine, Department of General Surgery, Antalya, Turkey

BACKGROUND: Malignant transformation is usually characterised by decreased cell–cell and cell–matrix adhesion and invasion to surrounding tissue. Tumor cells have many phenotypical alterations that include changes in cell shape, cell rounding, increased cell motility, loss of anchorage dependency and loss of cell–cell contacts. These changes are due to the rearrangement of cytoskeletal actin microfilaments. Fascin is an actin-binding protein that regulates the rearrangement of cytoskeletal elements and their interactions with the cell membrane and induces cell membrane protrusions and increases the motility of cells. In fact fascin is normally expressed by cells characterized by different types of membrane protrusions, such as neurons, glial and dendritic cells. In addition it is markedly up regulated in several types of carcinomas.
MATERIAL AND METHOD: We examined the expression of fascin in the invasive ductal carcinomas (IDC) with lymph node negative (IDC+LN-)(n=16), lymph node positive (IDC+LN+)(n=16) and in their metastatic lymph nodes (n=16),microinvasive + infiltrating ductal carcinoma with extensive insitu component (IDC with EIC)(n=9) by immunohistochemical method using monoclonal antifascin antibody. RESULTS: Fascin immunoreactivity was detected in 4 (44.4 %) microinvasive+IDC with EIC, 7 (43.7 %) IDC+LN-, 13 (81 %) IDC+LN+ tumors and 10 (62.5 %) metastatic LN. There was a significant difference for fascin immunoreactivity in these groups (p=0,044). Though the expression of fascin was not different between IDC+LN- and microinvasive+IDC with EIC but fascin immunoreactivity were significantly higher in IDC+LN+ than IDC+LN- group (p=0,033). No statistically significant difference was seen between IDC+LN+ group and their metastasis in the lymph nodes. The tumors with high fascin immunoreacivity tended to show more frequently lymphovascular invasion (p= 0.002). Advanced stage and high grade correlated significantly with higher fascin immunostainining (p=.0.036, p= 0.01).There were no significant association between fascin expression and tumor size, ER/PR and cerb-B2 overexpression. CONCLUSION: We evaluated the expression of fascin by performing immunohistochemistry to determine its role in the progression of invasive ductal carcinomas, invasive phenotype and metastatic potential. Our findings suggest that fascin expression plays a role in metastatic potential of invasive ductal carcinomas.

PP1-41
OCCULT CARCINOMA OF THE BREAST - CASE REPORT

Vanja Filipovski, Saso Banev, Blagica Dukova, Lolita Andonovska
Institute of Pathology, Medical Faculty, University "St. Cyril and Methodius" Skopje Macedonia

BACKGROUND: Occult carcinoma is defined as an axillary lymph node metastasis as a first clinical manifestation of a breast carcinoma. AIM: To present an unusual case of metastatic carcinoma in the axillary lymph nodes thought to origin from the breast even though the primary lesion was not identified. MATERIAL AND METHODS: Tissue sections were standard formalin fixed, paraffin embedded, and stained with Hematoxyllin Eosin. Additionally sections were immunohistochemically processed using antibodies for Cytokeratin wide spectrum (CKHMW), Cytokeratin 18 (CK18), cytokeratin 19 (CK19), HMB45, LCA, CD3, CD20, CD43, CD30, CD79a and MAC387. RESULTS: Female patient age 60 presented with axillary lymphadenopathy. Fine needle aspiration cytology revealed malignant cell population in a punctate from a lymph node, suggestive of a ductal invasive metastatic cancer, but mammography did not reveal a suspected malignant lesion. However radical mastectomy was performed based on the cytology finding. After a thorough macroscopic examination of the breast tissue suspected lesion was not detected. From the axillary fat tissue 13 lymph nodes were extracted, and two of them measuring 7 and 3 cm in diameter, contained timorous infiltrates. Microscopic results, from random tissue samples of the breast parenchyma, did not reveal malignant lesion. Samples from lymph nodes showed presence of a metastatic adenocarcinoma in 3 of 13 lymph nodes. The tumor cells formed solid nests and tubular structures, partly with necrotic areas. This morphology was highly suggestive of ductal breast carcinoma. Immunohistochemical analysis gave the following results: CK18, CK19 positive staining, CKHMW negative staining, HMB45 negative staining, and negative staining for lymphoid markers (LCA, CD3, CD20, CD43, CD30, CD79a and MAC387). CONCLUSION: The lesion was diagnosed as metastatic adenocarcinoma. Morphology suggests metastasis from ductal invasive breast cancer. We recommended exclusion of subtotal

resection of the breast, contralateral breast carcinoma, carcinoma arising in extra mammary breast parenchyma or aberrant breast tissue. These possibilities were excluded, so in this case the literature suggests existence of occult carcinoma of the breast.

PP1-42
"COMPLEX APOCRINE METAPLASIA" AND "ATYPICAL COLUMNAR CELL LESION" ARE THEY REALLY SO DISTANT?
Kemal Kosemehmetoglu, Gulnur Guler
Hacettepe University Faculty of Medicine, Department of Pathology, Ankara, Turkey

BACKGROUND: Both complex apocrine metaplasia (CAM) and atypical columnar cell lesion (ACL) are considered as candidates of early premalignant breast lesions. However, because of their distinct immunophenotypical features, it is thought that these two lesions might be involved in different breast carcinogenesis pathways. As we noticed their histological coexistence and proximity in our daily practice, we decided to investigate their relation at the morphological level, systematically. METHODS: We selected cases who received both a diagnosis of CAM and ACL. We found 93 cases, meeting these criteria, 38 of which was non-neoplastic and the rest neoplastic, among 197 non-neoplastic and 280 neoplastic (a total of 477 cases) breast specimens. We reevaluated sections and measured the distance between these lesions. Five groups were described: "Zero" for lesions with direct continuity, "<1mm" for lesions in adjacent lobules, "1-2mm", "2-5mm" and ">5mm". In case of multiple lesions the closest one was chosen for analysis. All excision materials were examined totally and mastectomy materials were sampled using a topographical map. RESULTS: Ninety-three of 477 (19.4%) breast specimens contained both CAM and ACL and in 73.1% of them, the two lesions were in continuity or adjacent to each other. Two main groups were formed: "zero" and "<1mm" groups were considered together as "adherent lesions" and the rest was grouped as "distant lesions". When neoplastic and non-neoplastic specimens were compared, a significant difference (p=0.006) was found between adherent ("zero" + "<1mm") and distant (">1mm") lesions, that is the CAM and ACL were much closer in the neoplastic group. During the detailed investigation of continuing lesions, some hybrid lesions were also encountered. CONCLUSION: CAM and ACL, when found in the same breast tissue, tend to appear in close contact, especially in neoplastic breasts. This result implies, CAM and ACL may be included in the same pathogenetic pathway, despite of their distinct immunophenotypical properties.

PP1-43
IMMUNOHISTOCHEMICAL DETECTION OF BRCA1 MUTATION AND cerbB-2 AMPLIFICATION IN BREAST CANCER PATIENTS WITH POSITIVE HISTORY
Panagiota Ravazoula, Maria Gkermpesi, Paraskeyi Zyli, Anna Liava, Christina Aletra
University Hospital of Patras, Greece

Aim: It is believed that BRCA1 mutations account for the majority of hereditary breast carcinomas. Women who carry BRCA1 mutations have a high probability for developing ovarian, colon and stomach cancer. On the other hand cerbB-2 amplification has been identified in 25%-30% of breast carcinomas. The aim of our study is to detect immunohistochemicaly the BRCA1 mutations and the cerbB-2 amplification in breast cancer patients with positive history. Materials and Method: Forty patients diagnosed with breast carcinoma (3/40 lobular and 37/40 ductal carcinomas) in University Hospital of Patras between January 2000 to December 2005. Five out of 40 had a family history, 15/40 had a second breast carcinoma and 20/40 had a second primary cancer in other organs (8/20 had endometrial cancer, 4/20 lymphoma/leukemia, 3/20 colon cancer, 1/20 vaginal cancer, 1/20 astocytoma, 1/20 renal cell carcinoma, 1/20 ovarian carcinoma and 1/20 skin carcinoma). Tissue sections from breast cancer were immunohistochemicaly examined by using polyclonal antibodies against BRCA1 (Biogenex) and cerbB-2 (Dako). Results: Reduced staining or loss of staining for BRCA1 was not detected in any case. Expression of cerbB-2 was evident in 26/40 (65%) cases (in 3/5 women with breast cancer and family history, 10/15 cases with second breast cancer and in 13/20 cases with second primary cancer in other organ). Conclusions: Our findings suggest that immunohistochemical detection of BRCA1 mutation is not an effective method. High percentage of cerbB-2 expression in patients with breast cancer and positive history indicate that this gene play a substantial role in carcinogenesis in these patients.

PP1-44
ANALYSIS OF THE LOSS OF HETEROZYGOSITY AT THE SHORT ARM OF CHROMOSOME 3 IN SPORADIC BREAST CANCER AMONG TUNISIANS
Mounir Trimeche, Sameh Charef, Sonia Ziadi, Mohamed Hachana, Khaled Amara, Badreddine Sriha, Moncef Mokni, Sadok Korbi
Laboratory of Pathology, CHU Farhat Hached, Sousse 4000, Tunisia

Background: Studies of allelic imbalance and suppression of tumorigenicity have consistently suggested that several regions on the short arm of chromosome three (3p) are commonly affected in different epithelial tumors, including breast cancer. However, several discrepancies between the frequencies of loss of heterozygosity (LOH) have been reported. Further, molecular genetic events associated with sporadic breast cancer in North Africa, area with low incidence but early onset, are lacking. Method: Here we investigated 3p for allelic imbalances, including LOH, homozygous deletion and microsatellite instability in 45 sporadic breast tumors of Tunisian patients using six highly polymorphic microsatellite markers spanning the most frequently affected regions. Results: Allelic loss at one or more loci was observed in 17 (37.8%) of these tumors. The marker D3S1228 at 3p14.1-14.2 showed the highest frequency of LOH (28%), followed by D3S1568 at 3p21.3 (19.5%), D3S1038 at 3p25.2-26.1 (15%), D3S659 at 3p13 (13%), D3S1067 (11.5%) at 3p14.3-21.1, and D3S1076 at 3p21.1-21.2 (7.5%). A low frequency of microsatellite instability (6.6%) was identified. Conclusion: These finding suggest that LOH at 3p, in particular at the region of D3S1228, may play a role in sporadic breast tumorigenesis among Tunisian women.

PP1-45
EXPRESSION OF CD 10 IN 7 MAMMARIAN METAPLASTIC CARCINOMAS
Seyran Yigit, Fatma Seher Pehlivan, Gozde Evcim
Ataturk Training and Research Hospital Izmir, Turkey

Background: Metaplastic carcinomas of the breast that have unknown histogenesis are biphasic neoplasms composed of carcinomatous component contiguous or admixed with a pleomorphic mesenchymal component. They are rare neoplasms and there is somewhat confusing terminology related with this group of tumors in the literature. In this study, 7 metaplastic carcinomas were evaluated for CD 10 expression which is a reliable marker for myoepithelial cells, with respect to different cellular components. Method: All of the metaplastic carcinomas were assessed for CD 10 and conventional epithelial and mesenchymal markers of pancytokeratin, vimentin, smooth muscle actin and steroid receptors by immunohistochemistry. Results: All different categories of metaplastic carcinomas showed similar clinico-pathological features (age, tumour size, nuclear grade, mitotic activity, lymph node metastasis and hormonal receptor status). Out of 7 case, 1 was adenosquamous carcinoma and the others were biphasic tumors with sarcomatous

and carcinomatous components. In metaplastic carcinoma with epitehelial component only, CD 10 was not expressed. Sarcomatoid component was positive for CD 10 in 3 of 6 cases. Smooth muscle actin was also positive in these 5 cases. Remaining 1 case did not expressed smooth muscle actin. Conclusion: CD 10 expression with smooth muscle actin may be used as an adjunct marker in the diagnosis of metaplastic carcinomas.

PP1-46

BLINDED RETROSPECTIVE STUDY EVALUATING THE DIAGNOSTIC ACCURACY IN THE INTERPRETATION OF BENIGN AND PRECANCEROUS LESIONS OF THE BREAST

Olympia Tzaida, Helen Siatra, Helen Trihia, Theofani Gavresea, Petroula Arapantoni-Dadioti
Pathology Department, METAXA Cancer Hospital, Piraeus, Greece

BACKGROUND-OBJECTIVE: Quality assurance of diagnostic accuracy in surgical pathology is an important part of a pathologist's total quality management program. Blinded retrospective review is a highly sensitive and effective method to detect errors and/or disagreements. Breast biopsies were reviewed in order to assess the rate of diagnostic discrepancy. MATERIAL–METHODS: Blinded retrospective review of 257 cases of benign, pre-cancerous and pre-invasive lesions of the breast was performed, by three independent observers, with special interest in breast pathology. The diagnostic discrepancies between the two observers were correlated with the diagnosis of a third observer, the opinion of which was estimated as the gold standard. The results of the pathology reports were also correlated with the gold standard diagnosis. RESULTS: A. Review of the three observers: • Agreement of all three reviewers on 231 cases (89,88%) • Disagreements on 26 cases (10,12%), as follows: a. ADH:atypical ductal hyperplasia(DIN1b)versus lowDCIS(DIN1c) 1(0,39%) (hypoestimation) b. UH: usual hyperplasia versus ADH(DIN1b): 21(8.17%) (19 hypo-& 2hypest) c. ALH: atypical lobular hyperplasia versus LCIS:1 (0,39%) (hyper-estimation) d. UH: usual hyperplasia versus ALH: 3 (1,17%) (2 hypo-& 1hyperest) In total, 23 hypo-estimations (8,95%) were detected, 21 of which (8,17%) of the b group and 3 hyper-estimations (1,17%). B. Correlation between the initial and the gold standard diagnosis : • Agreement on 221cases (86 %) • Diagnostic discrepancies on 36 cases (14%) subdivided as follows: 1 error (0,39%) concerning hypo-estimation (UH instead of DIN1c) and 35 disagreements (13,65%) (16 common among the three observers), as follows: α. ADH(DIN1b) versus DIN1c:2 (0,78%) (1 hypo-& 1hyper-estimation) b. UH versus ADH: 27(10,5 %) (18 hypo-& 9 hyper-estimations) c. ALH versus LCIS: 1 (0,39%) (1 hypo-estimation) d. UH versus ALH: 5 (1,95%) (4 hypo-& 1 hyper-estimations) In total, we detected 25 hypo-estimations (9,75%), 18 (7,02%) of which concerned the b group and 11 hyper-estimations (4,24%). CONCLUSION: A low rate of diagnostic discrepancy was detected between the initial and the gold standard diagnosis, as well as between the three reviewers (14% and 10,12%, respectively), with an error rate of 0,39%. The majority of the detected diagnostic discrepancies concerned hypo-estimations of the subgroup b, a group with diagnostic difficulties even for expert breast pathologists.

PP1-47

BLINDED RETROSPECTIVE EVALUATION STUDY OF THE DIAGNOSTIC ACCURACY IN THE INTERPRETATION OF CARCINOMAS OF THE BREAST

Helen Trihia, Theofani Gavresea, Olympia Tzaida, Helen Siatra, Petroula Arapantoni-Dadioti
Pathology Department METAXA Cancer Hospital, Piraeus, Greece

BACKGROUND-OBJECTIVE: Medicine is currently challenged by society to substantially improve patient safety and to significantly reduce medical errors. Oncologists and radiotherapists still look to the pathologists for assistance in tumor diagnosis. It is of crucial importance that the pathologic diagnosis be accurate. 'Blinded' retrospective review is a highly sensitive and effective method to detect errors or/and disagreements in diagnosis of histopathologic material. MATERIAL-METHODS: 'Blinded' retrospective review of 283 cases of breast carcinomas was performed by three independent observers with a special interest in breast pathology. The diagnostic discrepancies between the two observers (A: T.O. & B: T.H.) were correlated with the diagnosis of a third observer (C: AD.P.), the opinion of which was estimated as the 'gold standard'. The result of pathology report was also assessed in regard to the 'gold standard' opinion. RESULTS: A. Review of the three observers: - Agreement between the three observers on 236 cases (83,39%) - Disagreements between A/B: 47 cases (16,6%) - Disagreements between A/C: 33 cases (11,6%) - Disagreements between B/C: 24 cases (8,48%) As to the observer A, the disagreements concerned 16 cases of histological grade, 8 cases of histological type and 9 cases of both. Of the total 25 cases (grade), 19 cases were hyper-estimated and 6 cases were hypo-estimated. As to the observer B, the disagreements concerned 13 cases of histological grade, 8 cases of histological type and 3 cases of both. Of the total 16 cases (grade), 14 cases were hyper-estimated and 2 cases were hypo-estimated. B. Correlation between the pathology report and the 'gold standard' diagnosis: - Agreement on 219 cases (77,38%) - Disagreement on 64 cases (22,61%) Of the total 64 cases, 34 concerned grading, 26 the histological type and 4 both. Of the total 38 cases (grade), 23 were hypo-estimated (10,5%) and 15 (6,8%) were hyper-estimated. CONCLUSION: a low rate of diagnostic discrepancy was detected between the pathology report result and the 'gold standard' diagnosis, as well as between the three reviewers (22,61% versus 8,48%/11,6% respectively). No errors were detected. The diagnostic disagreements concerned misinterpretation of tumor type or hyper- or hypo-estimation of tumor grading. The clinical impact of the diagnostic discrepancies is not easy to assess, although decisions on therapeutic management could have been adversely influenced.

BREAST LESIONS OF UNCERTAIN MALIGNANT POTENTIAL IN THE SCREENING PROGRAM. AN AUDIT FOR QUALITY ASSURANCE

Erminia Manfrin[1], Renata Mariotto[2], Andrea Remo[1], Paola Bricolo[3], Francesca Falsirollo[3], Daniela Reghellin[1], Daniela Dalfior[1], Giovanni Paolo Pollini[4], Francesca Pellini[4], Franco Bonetti[1]
[1] Department of Pathology, University of Verona, Italy
[2] Radiology, "C. Poma" Hospital, Mantova, Italy
[3] Screening Mammografico, ULSS20 Verona, Italy
[4] Department of Surgery, University of Verona, Italy

Background: The low ratio for benign to malignant open biopsy is an audit for the quality of breast cancer screening programs. Screen-detected benign breast lesions are a wide spectrum that also includes lesions at risk of cancer. Nevertheless, the open biopsies carried out because of these lesions are included in the rate of useless benign breast surgery. We evaluated the impact of screen-detected benign lesions at risk of cancer in the open biopsy rate. Methods: We subdivided open biopsies into 6 groups: Histo1-normal histology; Histo2-"pure" benign lesions; Histo3-low risk proliferative lesions; Histo4-high risk proliferative lesions; Histo5- breast carcinoma; Histo6-other, non epithelial malignant neoplasms. Results: In the Verona Breast Cancer Screening Program the benign to malignant ratio was 1:5 and standards for cancer detection rate were high. Of the 510 open biopsies performed, 83 were benign. Among the benign lesions, Histo1 were 4.8% of the benign biopsies. Histo2 made up

37.7%. Histo3 made up 31.3% (10 radial scars, 1 mucocele-like lesion, 10 papillomas, 4 multiple papillomatosis, 1 phyllodes). Histo4 were 26.5% (1 atypical columnar cell hyperplasia, 22 atypical ductal hyperplasia, 1 atypical lobular hyperplasia). The benign to malignant ratio changed from 1:5 to 1:12 when biopsies due to lesions at risk of cancer were excluded. Conclusions: In screening programs lesions at risk should not be included in the benign rate. Only Histo1 and Histo2 open biopsies should be considered the real quota of false positive results. A detection rate for lesions at risk of cancer should represent an audit for high screening performance. This work was supported by: Fondazione Cassa di Risparmio di Verona Vicenza Belluno e Ancona. PP1-49

EVALUATION OF EXPRESSION OF PHOSPHORYLATED AKT AT THREONINE 308 [PAKT(THR308)] AND MEMBRANE TYROSINE KINASE RECEPTORS (HER-2 AND FLT-4) IN INVASIVE BREAST CANCER

Christina Magkou[1], Evanthia Karamitopoulou[2], Irene Theohari[1], Eleni Mylona[1], Ioanna Giannopoulou[1], Eleni Papanikolaou[3], Kleio Papaparaskeva[2], Sophia Markaki[4], Lydia Nakopoulou[1]
[1] 1st Department of Pathology, Medical School, University of Athens, Greece
[2] 2nd Department of Pathology, Attikon University Hospital, Athens, Greece
[3] Cell and Gene Therapy Laboratory, Institute of Biomedical Research of the Academy of Athens, Athens, Greece
[4] Department of Pathology, Alexandra Hospital, Athens, Greece

BACKGROUND: The PI3K-Akt signaling pathway plays a pivotal role in tumorigenesis. Akt is a serine/threonine kinase which, when full activated [phosphorylated Akt (pAkt)], promotes cell survival by inhibition of apoptosis. In addition, pAkt promotes angiogenesis and contributes to tumor invasion and metastasis. Previous studies regarding PI3K-Akt pathway in breast cancer, have mainly investigated the role of the phosphorylated Akt at Serine 473 [pAkt (Ser473)]. Our purpose was to investigate the expression pattern of the phosphorylated Akt at Threonine 308 [pAkt (Thr308)] and its possible role in invasive breast carcinomas. METHOD: Immunohistochemistry was performed on paraffin-embedded tissue specimens from 152 invasive breast carcinomas to detect the pAkt (Thr308) protein. pAkt was assessed in combination with clinicopathological parameters, ER and PR receptor status, p53, Ki67, c-erbB-2, caspase-3, Flt-4, VEGF-C, VEGF-D and MMP-14. RESULTS: pAkt (Thr308) protein was immunodetected in the cytoplasm and the nuclei of the malignant cells, as well as in in situ carcinoma and normal epithelium. Of the classical clinicopathologic parameters, cytoplasmic pAkt was found to positively correlate with the lobular histologic type, while it was found to exert no impact on patients survival. Cytoplasmic pAkt (Thr308) immunopositivity was inversely correlated with Ki-67 and p53 ($p=0.013$ and $p=0.020$ respectively), while positive was found to be the association between pAkt (Thr308) and c-erbB-2 ($p=0.005$), caspase-3 ($p=0.031$), Flt-4 ($p=0.023$) and MMP-14 ($p=0.014$). Nuclear expression of pAkt (Thr308) was positively correlated with VEGF-C ($p=0.025$) and VEGF-D ($p=0.009$). CONCLUSION: This is the first study to mention a more frequent detection of pAkt(Thr308) in the lobular breast carcinomas and to correlate pAkt(Thr308) with some of the membrane tyrosine kinase receptors in invasive breast carcinomas. Membrane tyrosine kinase receptors, like HER-2 and Flt-4, activation enhances Akt activity and contributes to the transduction of mitogenic and angiogenetic signals, a fact that is reflected in the positive correlations with MMPs and VEGFs.

PP1-50

THE DIFFERENCES BETWEEN CENTRAL AND LOCAL LABORATORIES IN HER2 TESTING: IHC AND FISH STUDY WITHIN 2+ IHC GROUP

Anna Mrozkowiak, Wlodzimierz T Olszewski
Department of Pathology, The Maria Sklodowska-Curie Memorial Cancer Centre, Warsaw, Poland

Background: Proper HER2 testing is an essential issue in breast cancer management. There are two established methods of HER2 status evaluation: immunohistochemistry (IHC) and fluorescence in situ hybridisation (FISH). According to the wide-accepted algorithm of diagnostic procedure, all cases immunohistochemically described as "2+" should be re-tested with more reliable method – FISH. Although IHC has got clear interpretation criteria, the reproducibility of this method differs significantly between local and central laboratories, especially in "borderline" group (2+ according to DAKO). Aim: The aim of the study was the comparison of differences in HER2 assessment between central and local laboratories within 2+ group. Materials and methods: The material consisted of 944 breast cancer cases from 2+ group. In all cases HER2 status was determined by IHC in central (n=732 cases) and local (n=212) laboratories. There were four local laboratories: A, B, C and D, which differ with the experience and the quantity of IHC tests performed yearly (A is the most experienced laboratory, D – the less one). All FISH tests were performed in central laboratory. Results: In the analyzed 2+ cases, the lowest percentage of HER2-positive tumours (FISH) was observed in the central laboratory material (15%). In the material obtained from A laboratory, the percentage of HER2-positive cases was similar to the result of the central lab (15,1%). Lab B had 26%, lab C – 34,9% and lab D – 36,8% of HER2-positive cases within 2+ group. The less experienced hospital, the more HER2-positive cases in 2+ group. According to the statistical analysis, the dependence was linear ($p<0,001$). Conclusion: The experience of the pathologist plays an important role in HER2 assessment in breast cancer. The IHC borderline group (2+) should be re-tested by FISH not only in the central laboratory, but especially in the small local labs.

PP1-51

USE OF LASER SCANNING CYTOMETRY (LSC) IN DETERMINING S-PHASE FRACTION AND DNA CONTENT IN BREAST CANCER PATIENTS

Kuliffay Peter, Galbavy Stefan, Macak Dusan
St. Elizabeth University of Health and Social Sciences, Slovakia

Introduction: High proliferation rate in surgicaly removed breast tumours is an unfavourable prognostic factor. In node negative cases it can help distinguish patients with higher risk for distant metastases from those with a lower risk. Patients and Methods: In a prospective study we investigated 97 breast tumours, of which 81 were invasive ductal carcinomas, 8 were invasive lobular carcinomas, and 9 tumours were of other histological types. Cells for LSC investigations were prepared from fresh, surgicaly removed tumours by mechanical disintegration and the suspensions were cytocentrifuged onto miscroscopical slides. After fixation the cells were stained with FITC conujgated anti-cytokeratin (CK-FITC) to distinguish tumour CK positive tumour cells from CK negative stroma, and with propidium iodide to stain DNA. Results: In our group of patients, we identified three S-phase fraction (SPF) groups (<5 %, 5 to 10 %, and >10 %). As to aneuploidy, 53.8 % of the tumours were aneuploid, 36.3 % were diploid, and 9.9 % had a bimodal distribution of DNA content. Aneuploid DNA content and higher SPF values tended to be associated with larger tumour size, lymph node involvement, and higher histological grade. An attempt was made to correlate DNA content and SPF to tumour marker values (CEA, TPS, CA 15-3). Conclusions: Our results showed that the measurement of DNA content and S-phase fraction of tumours by laser scanning cytometry completed by and correlated with the

investigation of tumour markers and other biological properties of the tumour cells may be a useful tool in assessing prognosis and clinical outcome of patients with breast cancer.

EVALUATION OF HER2 STATUS IN BREAST CARCINOMA BY CISH AND FISH; COMPARISON OF THE RESULTS IN IHC 2+ GROUP OF 257 CASES

Wojciech P Olszewski[1], Anna Mrozkowiak[1], Katarzyna Suszylo[1], Jan Sir[2], Robert Kubiak[3], Wlodzimierz T Olszewski[1]
[1] Department of Pathology, The Maria Sklodowska-Curie Memorial Cancer Centre, Warsaw, Poland
[2] Department of Pathology, Centre of Oncology, Bydgoszcz, Poland
[3] Department of Pathomorphology, SYNEVO, Lodz, Poland

Determining the HER2 status in breast carcinoma management has become crucial for introducing proper therapy (chemo- and hormonotherapy). Therefore reliable methods for HER2 status evaluation, even at time of primary diagnosis are necessary. In Poland IHC is employed as a basic method for HER2 status evaluation. Interpretation of IHC stains according to four-tier DAKO system generates three groups HER2 positive, HER2 negative and "borderline" (2+ cases according to DAKO method). The cases from the last category need to be additionally evaluated. In Poland FISH (Fluorescents in situ Hybridization) method is used in these cases. Costs of the method and necessity of fluorescent microscopy make this method "unfriendly" for smaller laboratories. The alternative for FISH method is CISH (Chromogenic in situ Hybridization). The CISH method is cheaper and there is no need for fluorescent microscopy. Still, FISH method is considered as golden standard in HER2 status evaluation. Aim: The aim of the study was comparison of FISH and CISH results in the group of 257 cases labeled as "borderline" by IHC method (2+ according to DAKO). Narrowing the study group on this category only in our opinion should had result in more practical answer to question of value of CISH method in determine HER2 status. Methods: Two methods of HER2 status evaluation were applied to all 257 cases: CISH and FISH. Results: The overall concordance between these two methods was 78,6% (202 out of 257). In 21,4% of cases (55 out of 257) the discordant results were found. In the discordant group of 55 cases, 40% (22 cases) of them presented with chromosome 17 aneuploidy (by FISH). In this specific group alone, as many as 55% tumors (22 out of 40) presented discordance between CISH and FISH results. Conclusions: In the group selected for the study (IHC 2+) a significant (21,4%) discordance between CISH and FISH results was observed. The discordance is the highest (55%) in the subgroup with chromosome 17 aneuploidy.

PP1-53
USE OF LASER SCANNING CYTOMETRY (LSC) IN DETERMINING S-PHASE FRACTION AND DNA CONTENT IN BREAST CANCER PATIENTS

Kuliffay Peter, Galbavy Stefan, Macak Dusan
St. Elizabeth University of Health and Social Sciences, Slovakia

Introduction: High proliferation rate in surgicaly removed breast tumours is an unfavourable prognostic factor. In node negative cases it can help distinguish patients with higher risk for distant metastases from those with a lower risk.
Patients and Methods: In a prospective study we investigated 97 breast tumours, of which 81 were invasive ductal carcinomas, 8 were invasive lobular carcinomas, and 9 tumours were of other histological types. Cells for LSC investigations were prepared from fresh, surgicaly removed tumours by mechanical disintegration and the suspensions were cytocentrifuged onto miscroscopical slides. After fixation the cells were stained with FITC conjugated anti-cytokeratin (CK-FITC) to distinguish tumour CK positive tumour cells from CK negative stroma, and with propidium iodide to stain DNA.
Results: In our group of patients, we identified three S-phase fraction (SPF) groups (<5 %, 5 to 10 %, and >10 %). As to aneuploidy, 53.8 % of the tumours were aneuploid, 36.3 % were diploid, and 9.9 % had a bimodal distribution of DNA content. Aneuploid DNA content and higher SPF values tended to be associated with larger tumour size, lymph node involvement, and higher histological grade. An attempt was made to correlate DNA content and SPF to tumour marker values (CEA, TPS, CA 15-3).
Conclusions: Our results showed that the measurement of DNA content and S-phase fraction of tumours by laser scanning cytometry completed by and correlated with the investigation of tumour markers and other biological properties of the tumour cells may be a useful tool in assessing prognosis and clinical outcome of patients with breast cancer.

PP1-54
CYTOLOGIC NUCLEAR GRADE OF MALIGNANT BREAST ASPIRATES AS A PREDICTOR OF NOTTINGHAM PROGNOSTIC INDEX, ESTROGEN RECEPTOR, PROGESTERON RECEPTOR, cerb B2 AND p53 EXPRESSIONS

Binnur Onal, Ozgur Ilhan, Ataturker Arikok, Fulya Koybasioglu, Unsal Han
SB Diskapi YB Training&Research HospitalDepartment of Pathology 1, Turkey

BACKGROUND: Nuclear grade is one of the key prognostic factors of breast carcinomas since 1990's. The aim is to compare the nuclear Grade (NG) in cytological material (cNG) obtained from breast fine needle aspiration cytologies (FNACs) with the Nottingham Prognostic Index (NPI), Estrogen Receptor (ER), Progesteron Receptor (PR),cerb B2, and p53 expressions, observed in surgical materials(SM) of the same tumors. METHOD: From Jan.2000 to Dec.2006, 835 consecutive cytologic breast FNACs were performed at Pathology Dept. Of these cases 702 were benign, 133 were malignant, on MGG stain. The study group consisted of 63 carcinomas (21 low NG (LcNG) -42 high NG (HcNG) cases, according to simplified Black; F=60, M=3; age range=23-85) with both FNAC and SM which were reviewed by two pathologists. Most of them (95 %) were invasive ductal carcinomas (IDC); 2 were mucinous and 1 was lobular ca. Corresponding tissues of IDC were independently evaluated with modified Bloom-Richardson and NPI systemsNPI scores were grouped into good (score 1-3.3, n=12), moderate (score 3.4-5.4, n=26) and bad prognostic groups (score 5.4, n=18). Then was modified (mNPI) into low (good & moderate) and high (bad) prognostic groups. All of the SM were stained with ER, PR, cerbB2 and p53 and the immunohistochemical staining was categorized as negative and positive . Chi-square test is used for statistical evaluation. RESULTS: There was overall aggrement between cNG and mNPI in 91.7% of tumors with LcNG and low prognostic group. The percentage coincidence was greater (100%) for HcNG and MBR Grade 3 and MBR Grade 3 cases.Most of the LcNG group was ER(+), cerbB2(-) and p53(-). However in HcNG group, most were cerbB2(+), p53(+) and ER (-). In patients younger than 50 year-old, ER was lower, cerbB2 was higher and p53 was higher expressed than the older patients. PR expressions were not statistically significant ($p>0,05$). All of the results, (except PR) were statistically significant ($p<0,05$). Therefore it seems to be important and significant to distinguish LcNG from HcNG in breast aspirates of ductal carcinomas. CONCLUSION: Assigning a NG in breast carcinoma aspirates is done with little effort, is reproducible and correlates with NPI, ER, cerbB2, and p53 expressions, while grading, nuclear pleomorphism, presence of nucleoli in aspiration material retained their statistical significance. The lack of correlation may have been due to sample limitations, tumor heterogenity and observer subjectivity. The cNG should appear in FNAC reports of breast carcinomas.

PP1-55
EGF AND HGF/SF REGULATE THE DIFFERENT STAGES OF BREAST CANCER PROGRESSION

Olga Popova[1], Tamara Danilova[1], Larisa Zavalishina[2], Alla Kuznetsova[1], Alexei Ivanov[1], Georgy Frank[2]
[1] Moscow Medical Academy, Russia
[2] Moscow Research Institute of Oncology, Russia

BACKGROUND: Numerous studies have shown an indirect regulation of steroid action by growth factors. Growth factor signaling could selectively be activated in different stages of cancer progression and stimulate the steroid responsiveness as well as become a cause for hormone-independent growth. In our study we evaluated the relationship between epidermal growth factor (EGF) and hepatocyte growth factor/scatter factor (HGF/SF) production and steroid receptor status, oncoprotein expression and the basic clinicopathological factors in breast cancer. METHODS: Estrogen receptor (ER), progesterone receptor (PR) and Her2/neu expression in paraffin sections and in primary cultures of breast cancer from the same tissue specimens of 40 patients was demonstrated by immunohistochemistry. Production of HGF/SF and EGF in culture media was examined by enzyme-linked immunosorbent assay. RESULTS: EGF content in supernatant of breast cancer primary cultures demonstrated an association with ER expression (p=0,05) and a tendency for correlation with Her2/neu oncoprotein expression (p=0,07). The median value was higher in ER-positive tumors (527,44±132,16 pg/ml) when compared to those without ER protein expression (283,09±119,40 pg/ml). Correlation analysis between HGF/SF concentration and clinicopathological factors showed that the HGF/SF level exhibited an independence of ER status but it was positively correlated with nodal status (p = 0,01). The average of HGF concentration in primary culture media from the patient with node metastasis was 1369,47±594,87 pg/ml (range, 756,9 – 3009 pg/ml) versus 293,48±169,08 (range 102,0 – 674,1) in patients without lymph node involvement. On the contrary the association of EGF concentrations with nodal status had no statistical significance. Neither HGF/SF nor EGF content correlated with histological type, histological grade and PR expression. CONCLUSION: The present findings suggest that up-regulation of several growth factors and the appearance of autocrine pathways in malignant breast epithelial cells could occur during alternating periods as cancer progresses. Enhanced EGF having a close connection with ER expression might trigger Her2/neu and the growth of mammary cells expressing ER at the beginning of cancer development. Such critical steps as adhesion and migration are elicited by increasing of HGF/SF but not by EGF in advanced cancer stage. An independence of HGF/SF of steroid receptor status could be a principal factor of hormone resistance development in breast cancer.

PP1-56
HER-1 (EGFR) IN INFLAMMATORY BREAST CANCER: A NEW PROGNOSTIC FACTOR AND A POTENTIAL PREDICTIVE MARKER

Andrea Remo, Erminia Manfrin, Daniela Reghellin, Marta Gobbato, Claudia Canizzaro, Rosanna Loss, Maria Paola Rapagnani, Marco Vergine, Daniela Dalfior, Marco Chilosi, Fabio Menestrina, Franco Bonetti
Department of Pathology, University of Verona, Italy

Background: Inflammatory Breast Cancer (IBC) is an highly invasive manifestation of Breast Carcinoma characterized by clinical inflammatory signs and/or dermal lymphatic carcinomatosis. HER-1 (EGFR) in breast carcinoma has been reported with different expression rate ranging from 14% to 91%. Few papers described EGFR expression in IBC with a rate ranging from 19% to 31%. Methods: We collected 65 cases of IBC referred to Department of Pathology at "G.B. Rossi" Hospital of Verona (Italy) between January 1989 and December 2005. We studied, by tissue micro array technique, EGFR immunohistochemical expression as prognostic factor on overall (OS) and disease free (DFS) survival time. Results: In our series, HER-1 positive cases were 13% (8/65 cases) and were associated with poor prognosis (OS: P=0,00025), with a mean overall survival time of 29 months. This result confirm the published data on the influence of HER-1 as a prognostic factor on overall survival time. Nevertheless, this marker cannot predict a neoplastic recurrence of IBC (DFS: P=0,0543). In our experience HER-1 positive carcinomas didn't show HER-2 expression. The publication of clinical trials of patients suffering from breast carcinoma treated with HER-1 inhibitor candidates this marker as a predictive factor and the patients who can't benefit of the anti-HER-2 neoadjuvant therapy, could be treated with an HER-1 inhibitor. Conclusion: EGFR is a good prognostic factor of overall survival time in IBC and it could represent an important predictive marker for therapy. This work was supported by: Fondazione Cassa di Risparmio di Verona Vicenza Belluno e Ancona. HER-2/neu STATUS IN BREAST CARCINOMA: CORRELATION OF GENE AMPLIFICATION BY FISH WITH IMMUNOHISTOCHEMISTRY

Burak Bahadir, Banu Dogan Gun, Sibel Bektas, Sacide Colak, Gurkan Kertis, Sukru Oguz Ozdamar
Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey

Background: Numerous biologic markers have been proposed to assist in deciding treatment modality in breast carcinoma. Assessment of HER2/neu protein expression by immunohistochemistry (IHC) or HER2/neu gene amplification by fluorescence in situ hybridization (FISH) have been suggested to provide valuable prognostic information, particularly in selection of patients for treatment with trastuzumab. Patients with gene amplification by FISH are expected to have poor prognosis but respond better to trastuzumab therapy. We evaluate HER2/neu status in mammary ductal carcinomas by using both methods. Method: Formalin-fixed paraffin embedded archival tissues of mastectomy specimens from 44 patients with invasive ductal carcinoma between February 2002 and October 2006 were evaluated. Immunohistochemistry for HER2/neu expression and FISH for HER2/neu gene amplification were performed for all cases. Immunohistochemically, only membrane staining was considered and scored on a scale of 0+ to 3+. Cases with negative or 1+ immunostaining were considered negative for HER2/neu, while cases with 2+ and 3+ were classified as positive. Results: Overall, 12 of 44 (27.3%) cases showed amplification by FISH, while 35 cases (79.6%) were either 2+ or 3+ by immunohistochemistry. Two of nine cases (22.2%) with negative IHC staining (either 0+ or 1+) were amplified; the both amplifications were from seven cases (28.6%) with 1+ immunostaining; two cases with clear-cut negative IHC staining (0+) were also negative by FISH. Four of 23 cases (17.4%) with 2+ positivity showed amplification. Amplification was observed in six of 12 cases (50%) with 3+ staining. Conclusion: The unexpected finding of 50% discordance rate between 3+ IHC and FISH may be associated with high overall IHC positivity rate in the current study exceeding recommended IHC rate. However, compared to previous studies, relatively higher gene amplification in 1+ (28.6%) and 2+ (17.4%) cases seems more conflicting, particularly if these expressions are misleading due to high IHC rate and may in fact represent lower (ie. 0+) scores.

PROTECTIVE EFFECT OF ISCHEMIC PRECONDITIONING AGAINST HEPATIC ISCHEMIC INJURY DURING THE COURSE OF LIVER RESECTION IN A RAT MODEL

Hesham Abdeldayem, Ahmad Ahmad-El-Refaie, Ashraf Bassiouny
National Liver Institute, Egypt

Background: Ischemic preconditioning (IP) is a process by which a brief ischemic episode confers a state of protection against subsequent sustained long-term ischemia-reperfusion injury. The purpose of this study was to evaluate the protective effect of ischemic preconditioning on ischemic injury of the liver during the course of hepatic resection in a rat model. Material and Method: Three groups of 6 Wistar rats were examined; Group A: subjected to sham-operation, Group B (ischemia/reperfusion group I/R): animals subjected to left-lobe hepatic ischemia for 30 min followed by reperfusion and right lobe resection and Group C (ischemic preconditioning group IPC): subjected to 10 minutes to left-lobe hepatic ischemia followed by 10 minutes of reperfusion followed by the prolonged ischemia for 30 min followed by reperfusion and right lobe resection. After 10 days the animals were killed and the livers were excised for histopathological assessment of the degree of liver damage. Serum concentrations of lactate dehydrogenase (LDH), aspartate aminotransferase (AST), alanine aminotransferase (ALT), were measured as markers of hepatocyte injury at completion of the first laparotomy and at relaparotomy after 10 days. Results: There were significantly higher levels of AST ,ALT and LDH in ischemia/reperfusion group as compared to ischemic preconditioning group ,($p < 0.05$). Furthermore, histopathological evidence of liver damage was more pronounced in ischemia/reperfusion group as compared to ischemic preconditioning group, ($p < 0.05$). Conclusion: Ischemic preconditioning exerts a protective effect on hepatic ischemia-reperfusion injury in rat model. Such a manoeuvre may be useful for hepatic resection in the clinical setting.

PP1-59
OBSTRUCTIVE JAUNDICE PROMOTES INTESTINAL BARRIER DYSFUNCTION AND BACTERIAL TRANSLOCATION: EXPERIMENTAL STUDY

Hesham Abdeldayem, Enas Ghoneim, Ahmad Ahmad-El Refae, Ashraf Abou Gabal
National Liver Institute, Egypt

Background: Clinical and experimental studies have demonstrated a correlation between obstructive jaundice and sepsis.The aim of this study was to investigate the influence of biliary obstruction on bacterial translocation as a possible source of infection in cases of obstructive jaundice. Material and Methods: Two groups of 12 Wistar rats were examined: rats subjected to common bile duct (CBD) ligation (group A) and rats subjected to a sham operation (group B). After 7 days blood samples were taken and liver, spleen, and mesenteric lymph nodes (MLN) from the ileocaecal area were removed, divided into small pieces and cultured. Quantitative culture results were determined by the number of colony-forming units (CFU) per ml homogenate. Bacterial translocation was defined as the presence of a positive culture of mesenteric lymph nodes, blood, liver and/or spleen. Samples for histopathological examination were taken from the mucosa of the ileum and the colon and evaluated for inflammatory and destructive changes. Results: There was no evidence of bacterial translocation to MLN, blood, spleen or liver detected in any of the 12 sham-operated control rats. In contrast, bacterial translocation was demonstrated in 8 of the 12 CBD ligated rats ($P < 0.01$). In all 8 cases in which translocation occurred, Escherichia coli was cultured from the mesenteric lymph nodes. There were no histological changes in the mucosal samples of the control animals. In the CBD ligated rats hyperemia, vacuolization, reduction of goblet cells, decreased mitotic activity and infiltration by lymphocytes and PMNLs were detected. Cases in which translocation occurred were significantly associated with decreased mitotic activity in the colon ($r = -0.5$, $p < 0.01$) and higher infiltration by PMNLs in the ileum ($r = -0.62$, $p < 0.05$). Conclusion: Obstructive jaundice predisposes to bacterial to bacterial translocation.

PP1-60
MUTANT p53 PROTEIN AS A BIOMARKER OF HISTOPATHOLOGICAL FEATURES AND PROGNOSIS OF HEPATOCELLULAR CARCINOMA AFTER SURGICAL RESECTION

Hesham Abdeldayem[1], Maissa El Raziky[2], Mohammed Badr[1]
[1] National Liver Institute, Egypt
[2] Cairo University, Egypt

Background and Aim: Prognosis after hepatectomy for hepatocellular carcinoma (HCC) has been improved by early diagnosis, progress in the surgical techniques and perioperative management. However, even when curative resection is performed at a relatively early stage, a considerable number of patients develop early intrahepatic and/or extrahepatic recurrence postoperatively. .This study analysed the correlation between the p53 mutations and the clinical, pathological features, tumor recurrence and patient survival after surgical resection of HCC. Patients and methods: Specimens from 20 HCCs and surrounding liver tissues from patients who underwent surgical resection were examined histopathologically and by immunohistochemisty for detection of p53 gene mutation. The association between p53 mutation and histopathological features of HCCs, as well as tumor recurrences and patient survival were evaluated. Results: p53 mutation was found in 9 out of 20 HCCs. p53 mutations were frequent in large, and poorly differentiated HCCs. Five out of 9 with p53 mutation showed microvascular invasions in contrast to none out of 11 without mutation. Hepatocellular carcinoma recurred in 6 out of 9 with p53 mutation, in contrast to only 2 out of 11 without mutation. The 1-year survival rate in patients with p53 mutation was significantly lower than those without. Conclusion: The detection of p53 mutation in HCC may provide additional and independent prognostic information for HCC and may serve as an indicator of high-risk patients for whom closer follow-up and aggressive adjuvant therapy may be required.

PP1-61
ANGIOGENESIS IN COLON CANCER

Nourieh Sharifi
Mashhad Medical University, Ghaem Hospital Department of Pathology, Iran

Abstract Introduction: The basic pathogenic step in the process of tumor growth, invasion and metastasis, is tumor – induced angiogenesis, the aim of this study was to evaluate the angiogenesis in colorectal carcinoma by microvascular density (MVD) determination with IHC method and to determine if and how angiogenesis correlates with clinicopathologic parameters.
Material and Methods : Seventy cases, archival, paraffin embedded tissue of colorectal carcinoma of Omid hospital (Mashad, Iran) were selected. Microvesseles were identified immunohistochemically, using monoclanal CD34 antibodies. CD34 positive staining was obtained in 62 out of 70 cases, and observed mainly in the cytoplasm of endothelial alls. Counting was performed at the invasive foci of tumor and not in granulation tissue or necrotic area. Two investigators examined the microvessel density by counting immunoreactive cells in the three hot spot area of tumor using a 400 X field in a blind fashion, then the median and mean value of MVD was determine and correlate with clinicopathologic parameters.

Results : Tumor – induced angiogenesis of colorectal carcinoma statistically correlated with histologic tumor grade (P=0.000). there was no significant correlation between intratumoral microvessel density and sex and age of patients, localization, stage and histologic tumor type. (P>0.1) Conclusions: Intratumoral microvessel density quantification in histologic specimens of colorectal carcinoma reflects the biological malignant potential of tumors and may be a useful additional prognostic factor. Microvessel density in tumor specimens may be valuable in stratifying patients in planning appropriate adjuvant and antiangiogenic therapy after surgery.

PP1-62
TUMORS OF THE DIGESTIVE SYSTEM BY FINDINGS OF POST-MORTEM EXAMINATIONS
Alexander Zubritsky
Municipal Institution "Taldom Central Regional Hospital, Russia

The current study was designed to retrospectively determine the incidence rate of neoplasms of the digestive system on pathoanatomical material of the Municipal Institution "Taldom Central Regional Hospital" over the period from 1995 to 2004. Of 495 postmortem examinations of adults, we revealed a total of 36 cases (21 males and 15 females, mean age 68 years) with stage 4 tumours diseases of the digestive system, which turned out to have been the primary cause of death, with the majority of cases accounting for cancer of various portions of the colon (8 cases), sigmoid colon cancer (6 subjects)and pancreatic cancer (5 cases) with the histological form, as a rule, of adenocarcinoma of various degree of differentiation. Diffuse peritonitis was registered as the most frequent cause of death (10 cases). Mention should be made that in 13 cases we revealed discrepancies between the clinical and pathoanatomical diagnoses by the primary disease, these discrepancies were primarily caused by insufficient examination of the patient (neither diagnostic laparotomy, nor ultrasound examination of the abdominal organs performed), the severity of the state and a short hospital stay of the patient, overestimation of the diagnosis and erroneous interpretation of the obtained findings by the surgeon, and difficulty of making the accurate diagnosis due to comissural process during to operative intervention. Further analysis showed that amongst the adult patients having died of neoplasms, first came tumours of the digestive system, to be followed by tumours of the genitourinary system (8 cases), ranking third were tumours of the respiratory system (4 cases), and place 4 being shared by tumours of the central nervous system and haemopoietic and lymphoid tissues - 2 cases each, respectively. Hence the incidence rate of neoplasms of the digestive system amounts to 7.27% amongst the 495 postmortem examinations of adult patients of our general somatic hospital over the decade under investigation. In the majority of cases, the immediate cause of death was diffuse peritonitic resulting from ingrowing of the tumour of all the membranes with decomposition, to be followed by perforation of the wall of the intestine, or stomach.

PP1-63
CYCLOOXYGENASE-2 AND TRANSFORMING GROWTH FACTOR-B1 EXPRESSION IN HEPATOCELLULAR CARCINOMA FOLLOWING HEPATITIS C VIRUS INFECTION AND CIRRHOTIC LIVER DISEASE
Azza El-Bassiouny, Mona Zoheiry, Mona Nosseir,
Eman El-Ahwany, Raafat Atta, Noura El-Bassiouni
Theodor Bilharz Research Institute, Egypt

It is unknown whether COX-2 or TGF-β1 contribute to the malignant growth in HCC. Their expression were investigated in 30 cases of post-HCV, HCC whose corresponding non-tumorous tissues were hepatitis C virus-related chronic hepatitis (n=50) and post-hepatitis C liver cirrhosis (LC) (n=30). Samples of ten histologically normal livers were also analyzed. Serum alpha fetoprotein level (α-FP), histopathological diagnosis and immunohistochemistry were done for all cases. Histologically, normal livers were weakly positive for COX-2 (<10%) & TGF-β1 (<50%). The intensity of tissue expression of COX-2 increased from normal liver to chronic hepatitis to cirrhosis. In HCC, 36.7% (11/30) of samples displayed a high COX-2 expression with a significant correlation with differentiated carcinomas. No significant relation was found with the level of α-FP. TGF-β1 was expressed in all cases of LC& HCH at different staining intensities; which was mostly marked being in 93.3% & 52% of cases respectively. It was also expressed in 60% of HCC cases because it serves as either an epithelial cell growth inhibitor or a tumor promoter, depending on the cellular context. However, no correlation could be detected between TGF-β1 expression and grade of HCC differentiation or serum level of α-FP. ver-expression of COX-2 in HCV, LC and well-differentiated HCC suggest that it is a potential marker for hepatocarcinogenesis particularly in its early stages. Meanwhile, HCV & LC regulate TGF-β1-induced signal transduction pathway. Interruption of TGF-β1 signaling improves liver fibrosis and stimulates liver regeneration.

PP1-64
Bcl-2 POSITIVITY IN B AND C HEPATITIS AND HEPATOCELLULAR CARCINOMAS
Levent Yildiz, Sancar Baris, Oguz Aydin, Mehmet Kefeli,
Bedri Kandemir
19 Mayis University, Department of Pathology, Turkey

Background Hepatocellular carcinoma (HCC) is a widespread disease and constitutes up to 1/4th of all adult malignancies in Asia and Saharan Africa. Worldwide HCC is the 7th and 6th most common cancer in males and females, respectively. Predictive value of bcl-2 expression in the development of HCC is unknown and results of the studies so far have been contradictory. In the present study bcl-2 expression in chronic hepatitis B and C cases, as well as in neoplastic and non-neoplastic peritumoral tissue in HCC have been immunohistochemically investigated and bcl-2's possible role in the development of hepatocellular malignancy has been discussed. Method In this study, 23 chronic hepatitis C, 17 chronic hepatitis B and 29 hepatocellular carcinoma cases, which were obtained from the archives of the Department of Pathology, Faculty of Medicine, Ondokuz Mayis University, between years 1992 and 2004 in the were examined. They have been immunohistochemically stained for the expression of bcl-2. Positive staining was semi-quantitatively graded from + to +++. Results Two out of 23 hepatitis C cases and 3 out of 17 hepatitis B cases were found to express bcl-2, staining was more intense in areas adjacent to active inflammatory process. Of the 29 hepatocellular carcinoma cases 6 stained positively for bcl-2; 9 biopsies in this group had also non-neoplastic liver tissue, and, of these 6 stained positively for bcl-2. Of the latter 6 bcl-2 positive biopsies 3 also showed tumoral staining while in the remaining 3, neoplastic elements were bcl-2 negative. Conclusion As the present study is a cross-sectional study, no causative relation between bcl-2 positivity and hepatocellular carcinoma can be implied, however high incidence of bcl-2 activity in the non-neoplastic liver parenchyma of the HCC cases suggest that bcl-2 activation may be involved in the development of at least some cases of hepatocellular carcinoma. Case control and/or prospective studies are needed to show whether bcl-2 positivity in a chronic hepatitis case has a predictive value for the development of hepatocellular carcinoma.

PP1-65
GASTROINTESTINAL STROMAL TUMORS RECOGNIZED AS OVARIAN NEOPLASMS BEFORE SURGICAL OPERATION

Wanda Michej, Zzbigniew Nowecki, Piotr Rutkowski, Włodzimierz Olszewski, Włodzimierz Ruka
Cancer Centre, Poland

Introduction: Gastrointestinal stromal tumors (GISTs) are the most common neoplasms of mesenchymal origin of stomach and small bowel. They derive from precursors of Cajal's cells and express positive reaction with CD117 antibody. This immunohistochemical examination is currently a base of recognition them and allows to treat with imatinib. Aim: The histopathologic analysis of tumors diagnosed preoperatively as ovarian neoplams in women, whereas postoperative pathologic recognition revealed, that they were gastrointestinal stromal tumors (GISTs). Materials and methods: Among 240 women with GIST , 12% were operated due to ovarian neoplasm. These tumors were diagnosed as GISTs in Department of Pathology at Cancer Center in Warsaw. A part of postoperative material came from Cancer Center, whereas a large amount were provided as consult examinations. Results: Grossly the tumor's diameter ranged from 10 to 15cm, cream - coloured, sometimes with many haemorrhages. Most of them were attached to small bowel. A few of them were connected to large intestine. In two cases they looked like big leiomyomas of uterus. Microscopically: the spindle cells were seen mostly mixed with epitheliod and signet – ring ones. There were no big atypia.. There were skenoid fibers in a few tumors. Mitotic figures were counted in 50 high power fields. They ranged from 5 to 20. Most of neoplams expressed a positive reaction with CD 117 antibody. The most of them were no resected within healthy limits, so they demanded postoperative treatment. Conclusions: GISTs in females, very often are clinically similar to ovarian neoplams. The fundamental aim is good histopathologic recognition and finally – treatment with imatinib.

HEPATIC STELLATE CELL/MYOFIBROBLAST SUBPOPULATIONS IN CHRONIC HEPATITIS C AND NONALCOHOLIC STEATOHEPATITIS

Dina Tiniakos[1], George Papatheodoridis[2], Emmanuel Manesis[2], Olga Aggelopoulou[2], Georgia Kafiri[3], Christos Kittas[1], Athanassios Archimandritis[2]
[1] Lab. of Histology & Embryology, Medical School, Univ.of Athens, Greece
[2] Academic Dept. of Medicine, Hippokration General Hospital, Athens, Greece
[3] Dept. of Pathology, Hippokration General Hospital,Athens,Greece

Background: In human fibrotic liver, activated HSC, interface myofibroblasts (MF) and portal/septal MF, which represent the source of collagen production, differentially express mesenchymal (α-smooth muscle actin-SMA) and neural/neuroendocrine markers (glial fibrillary acidic protein, GFAP; neural cell adhesion molecule, N-CAM; synaptophysin, SYN). We evaluated the distribution and quantity of HSC/MF subpopulations in chronic hepatitis C (CHC) and nonalcoholic steatohepatitis (NASH) and correlated these with disease grade and stage. Methods: Needle liver biopsies from 21 CHC and 14 NASH patients were immunostained for αSMA, GFAP, N-CAM, SYN and semi-quantitatively evaluated in zones 1,2,3 and portal/septal areas using a 12-point scoring system (Feldstein et al, 2005). Histological lesions of CHC and NASH were evaluated according to Ishak's and Brunt's classifications respectively. Results: In CHC and NASH, portal/septal and interface MF were positive for αSMA, GFAP and N-CAM but not SYN, while activated HSC were positive for all markers. Immunohistochemistry for αSMA identified the highest number of activated HSC, while SYN the lowest. In CHC, αSMA and SYN HSC scores correlated with grade (p=0.036 and p=0.035), but not with stage or steatosis' severity. In NASH, portal/septal MF αSMA score was related to stage (p=0.049), while there was no correlation of any other marker's score with global grade, stage or steatosis' grade. The total scores for all markers were no significantly different between CHC and NASH. However, in zone 2 the quantity of GFAP+, N-CAM+ and SYN+ HSC was higher in NASH compared to CHC (p=0.036, p=0.012 and p=0.003). Furthermore, in the subgroup of cases with minimal/mild fibrosis, αSMA and GFAP HSC scores and aSMA and N-CAM portal MF scores were higher in CHC (p=0.05, p=0.007, p=0.026 and p=0.05). Conclusions: a) Portal/septal MF, in contrast to previous reports, express N-CAM in addition to αSMA and GFAP; b) αSMA is the best marker for identification of activated HSC, while GFAP, N-CAM and SYN identify only a subpopulation of HSC; c) In CHC, αSMA and SYN HSC scores are related to necroinflammation grade, while in NASH, αSMA portal/septal MF score is related to fibrosis stage; d) There are no significant quantitative differences in total activated HSC between CHC and NASH. However, there may be quantitative differences in the zonal distribution of neural/neuroendocrine marker-expressing HSC; in the subgroup of cases with minimal/mild fibrosis the number of HSC and portal MF is higher in CHC.

PP1-67
EFFECT OF SPLENECTOMY ON LIVER FIBROGENICITY IN PORTAL HYPERTENSION PATIENTS

Omran Zeinab[1], Elbatanouny Mohamed[3], Elbee Abdel Rahman[2], Ezzat Hussein[3], Abbas Mohamed[3], Nosseir Mona[1], Khaled Iman[4]
[1]Pathology Department, Theodor Bilharz Research Institute, Egypt
[2]General Surgery Department of Kasr El-Aini, Cairo University, Egypt
[3]General Surgery Department,Theodor Bilharz Research Institute, Egypt
[4]Hematology Department, Theodor Bilharz Research Institute, Egypt

This study was designed to assess the role of the spleen on the presence and localization of liver fibronectin, to measure the amount of hepatic collagen and serum level of fibronectin and procollagen III in cases of portal hypertension. The study was performed on 40 patients divided into two groups: Portal hypertension group (20 patients) included one pure schistosomal hepatic fibrosis, three mixed schistsomal and virus C cirrhosis, ten virus C hepatic cirrhosis, two virus B hepatic cirrhosis and four mixed B&C infections. Control group (20 patients) presented with different splenic insults without hepatic affection. In the first group, through clinical examinations and sonographic findings revealed hepatosplenomegaly and grade III & IV varices with history of injection sclerotherapy in 65% of cases. Preoperatively, marked hepatic fibronectin deposition in portal tracts and around blood vessels raised the stage of fibrosis. This was accompanied by decrease in plasma level of fibronectin and increase of serum level of procollagen III in relation to the control group. Six months post-operatively, tissue fibronectin, collagen content and serum procollagen III were insignificantly decreased. However, plasma level of fibronectin was increased significantly. These results denoted that fibronectin is one of the predominant early fibrogenic components in chronic liver diseases, stimulating further collagen deposition. It is concluded that the role of the spleen in the development of hepatic fibrosis seems ancillary. Multifactorial influences, including etiology, timing of splenectomy, hepatic vascular adjustment, and factors associated with the biology of extracellular matrix of the liver, probably play a more significant role. Further studies were recommended to assess the role of splenectomy on liver fibrogensis at different stages of fibrosis. Intervention with splenectomy could improve or reverse fibrogenic activity at early stages. Key words: Splenectomy, fibrogenicity, fibronectin, procollagen III, liver fibrosis, portal hypertension.

[2] Theodor Bilharz Research Institute Department of Pharmacology, Egypt
[3] Department of Pharmacology and Toxicology, Faculty of Pharmacy, Cairo University, Egypt

We have proved previously that Nigella Sativa oil reduced Schistosoma mansoni (S. mansoni) induced hepatic fibrosis, the total worm burden, egg load and granuloma formation. Therefore, we aimed here to study the possible antischistosomal effect of one of its active constituent's thymoquinone (TQ). The drug was given to S. mansoni infected mice in two dose levels (5 and 10 mg/kg, p.o.) for two weeks, and its effect was compared to that of the standard antischistosomal drug, praziquantel (PZQ). Two weeks later, the following parameters were estimated, viz., worm load and distribution, oogram changes, egg load in liver and intestine, granuloma diameter, collagen deposition and intercellular adhesion molecule-1 (ICAM-1) expression. Moreover, serum levels of L-alanine aminotransferase (ALT) and nitric oxide (NO), as well as NO hepatic level were estimated. Mice treated with TQ showed a significant reduction in total number of worm burden, both in liver and portomesentric blood vessels. The oogram pattern recorded a decrease in immature and mature ova, and an elevation in dead ova. Tissue egg load was reduced in both liver and intestine. In infected mice treated with TQ, the elevated serum ALT activity leveled off. However, neither serum NO level was altered, nor in the infected group nor in those treated with TQ or PZQ. In liver homogenate, infection decreased NO level, which was not corrected with PZQ, but in-groups treated with TQ, a further reduction was reported. TQ caused shrinkage in granuloma diameter, and a diminution in collagen deposition. On the other hand, PZQ failed to reduce collagen deposition. Both TQ and PZQ decreased ICAM-1 expression in Kupffer and inflammatory cells. However, neither TQ nor PZQ affected its expression in endothelial cells. These results point to a possible antischistosomal role of TQ, which may be correlated with modulation in the immune system. Key words: schistosomiasis mansoni; nitric oxide; granuloma; intercellular adhesion molecule-l (ICAM-l), collagen; thymoquinone; praziquantel.

OSTEOPONTIN AND CD44 PROTEIN AND mRNA EXPRESSION IN COLORECTAL ADENOCARCINOMA

Jung Yeon Kim[1], Eunah Shin[1], Hyun-Jung Kim[1], Kyeongmee Park[1], Byung-Noe Bae[2], Kyoung-Soo Kim[3]
[1] Pathology, Inje University Sanggye Paik Hospital, Korea
[2] Surgery, Inje University Sanggye Paik Hospital, Korea
[3] Bone and Joint Research Center, East-West Neomedical Center, Kyung Hee University, Korea

PURPOSE: B (NFkB) and mediatesκOsteopontin (OPN) binds to CD44 and nuclear factor kappa tumorigenesis, invasion, and metastasis. This study evaluated the relationship between the expressions of OPN, CD44, and NFkB in untreated colorectal adenocarcinoma. METHODS: One hundred and two patients with colorectal adenocarcinoma were included between 2001 and 2003. We constructed tissue microarray blocks that were immunostained with primary OPN, CD44, CD44v6, CD44v3, and NFkB monoclonal antibodies. Real-time RT-PCR with OPN was performed with fresh frozen tissue. RESULTS: OPN and CD44 protein expressions were noted in 76.5% and 34.0% of the adenocarcinoma tissue compared to 23.2% and 5.9% of the paired normal colonic mucosa, respectively, and the protein expressions were correlated in the adenocarcinoma tissue ($p<0.05$). The expressions of OPN and CD44 proteins, however, were not correlated with any of the clinicopathological factors including age, sex, location, stage, lymph node metastasis, lymphatic, angioinvasion, and perineural invasion separately. The CD44v3, CD44v6, and NFkB protein expression rates were 0.9%, 8.9%, and 97.0% in tumorous tissue. No correlation was detected between the OPN, CD44, CD44v3, CD44v6, and NFkB protein expressions. The OPN mRNA expression was higher in tumor tissue than in paired normal mucosa, but the difference was not statistically significant. The lymph node status was the only independent prognostic factor of survival in Cox's regression analysis. CONCLUSIONS: OPN and CD44 may participate in colorectal tumorigenesis, but their roles are relatively minor in the progression of human colorectal adenocarcinoma.

PP1-70

CORRELATION BETWEEN LIVER BIOPSY FINDINGS AND DIFFERENT SERUM BIOCHEMICAL TESTS IN STAGING FIBROSIS IN EGYPTIAN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION

Mohamed Tawfik Badr, Nermine Ahmed Ehsan, Gamal Badra, Ahmed Abbass Raouf
National Liver Institute, Menoufiya University, Egypt

Hepatitis C virus (HCV) infection is characterized by silent onset in most infected individuals, a high rate of viral persistence, and the potential for the development of chronic hepatitis, liver fibrosis that eventually may progress to cirrhosis or hepatocellular carcinoma. Liver biopsy is still the gold standard for liver fibrosis assessment. Recent studies strongly suggest that due to limitations and risk of biopsy, as well as the improvement of the diagnostic accuracy of biochemical markers, the requirement for liver biopsy in clinical practice should be reduced. Fibro test, several simple laboratory tests, scores and indices have been proposed for non invasive prediction of hepatic fibrosis in patients with chronic hepatitis. Therefore, the aim of this study was to assess the value of different non invasive routine serum biochemical tests of hepatic fibrosis in the prediction of advanced fibrosis in patients with HCV infection. One hundred and sixteen patients with chronic HCV infection selected from the outpatient clinic of the National Liver Institute, Menoufiya University, Egypt, were subjected to the following tests: serum ALT, AST, albumin and total bilirubin; prothrombin time and concentration; complete blood count; Hepatitis B surface antigen (HBsAg); Hepatitis C virus antibody (anti-HCV); HCV- RNA by quantitative PCR and liver biopsy. The following ratios, scores and indices were calculated and compared with the grade of necroinflammation activity and the stage of fibrosis. AST/ALT ratio (AAR), Cirrhosis discriminating score (CDS), Age platelet index, AST to platelet ratio index (APRI), Pohl score, Goteborg University Cirrhosis Index (GUCI) and Hepatitis C Antiviral Long -term Treatment against Cirrhosis (HALT-C). Results from our study revealed that CDS, APRI, GUCI and HALT-C had good diagnostic accuracy, moderate sensitivity, high specificity and significant correlation between both the grade of activity and the stage of fibrosis. Whereas, AAR and Pohl score demonstrated significant correlation with advanced stages of fibrosis. In conclusion, the combination of simple biochemical serum tests may replace the requirement to liver biopsy in staging advanced fibrosis and cirrhosis in chronic hepatitis C patients.

PP1-71

CARDIAC MUCOSA: CONGENITAL OR ACQUIRED? A MORPHOLOGICAL STUDY IN CHILDREN AND ADULTS

Gert De Hertogh, Celine Van Hooland, Peter Van Eyken, Karel Geboes
Dpt of Pathology, UZ KUL, Leuven, Belgium

BACKGROUND & AIM The incidence of gastric cardiac adenocarcinoma has increased dramatically. Adequate prevention is hampered by limited knowledge on precursor lesions and controversy about the origin of cardiac mucosa (CM). Some investigators consider CM as a normal structure present from birth, while others propose that it is always acquired by metaplasia of oesophageal squamous epithelium in a setting of reflux. To solve this question, we investigated the presence and structure of CM in children and adults. METHODS We studied fixed endoscopic gastro-oesophageal junction biopsies of 46 children and 56 adults. Detailed clinical information was available for all subjects. The following stains were applied: haematoxylin-eosin (HE), mucin stains (AB/PAS, AB/HID) and immunohistochemical stains for Ki-67, CK7 and CK20, MUCs 2, 5AC and 6 and CDX2. CM was defined by the presence of mucous glands without parietal cells. RESULTS Cardiac mucosa was present immediately distal to the Z-line in 79% of children and 87% of adults. Its length varied between 0,15 and 0,90 mm, being only slightly larger in patients with reflux signs. Acid mucins were predominantly present in the foveolae of CM. The epithelial proliferative compartment was more often superficially localized and discontinuous in CM than in the more distal mucosae. CK7 was expressed both superficial and deep in CM's foveolae, while CK20 was present only superficially. MUC 5AC was present in the foveolar and MUC 6 in the glandular epithelium of CM. We observed several transformations in CM related to patient age and the presence of reflux signs or active inflammation. Increasing age correlated with CDX2 and MUC2 positivity, indicating a trend to develop intestinal metaplasia. Deep foveolar CK7 expression was seen more commonly in patients with reflux signs. In case of active inflammation, more acid mucins (especially sulfomucins) were produced in CM. CONCLUSIONS The near universal presence of CM and the absence of conspicuous lengthening in case of reflux argue against the hypothesis that CM is always acquired by metaplasia. Native CM undergoes age-related changes which may be accelerated in a setting of reflux with active inflammation.

USE OF ALPHA METHYLACYL-COA RACEMASE FOR DISTINCTION OF REACTIVE VERSUS DYSPLASTIC LESIONS IN COLONIC EPITHELIUM

Nadia Kourda, Houda Dhouib, Awatef Ferchich, Ahlem Blel, Sarrah Baltagi Ben Jilani, Rachida Zermani
Charle Nicolle's Hospital Department of Pathology, Tunisia

Background: Alpha methylacyl-CoA racemase (AMACR) catalyses the racemization of alpha-methyl branched carboxylic coenzyme A thioesters and is overexpressed in a variety of neoplasms, such as prostate and colon cancer. The aim of this study was to evaluate AMACR expression in adenoma of the colon and regenerative lesion in inflammatory bowel disease (IBD) and to determine if its expression can be used to distinguish regenerative changes from dysplastic epithelium in these conditions. Design: 34 routinely processed biopsy and/or resection specimens from 34 patients with regenerative lesion in IBD [11with crohn s disease (CD);15 with RCH ; 8 with adenomas] were immunostained with a monoclonal AMACR antibody (p504S). Results: there were highly significant differences between the percentages of AMACR immunopositive cells in adenomas compared with regenerative epithelium. AMACR staining was uniformly positive in the adenomas group (75%).only 2 (25%) of 8 specimens with adenomas showed negative. Of 26 specimens, 21(80%) showed negative staining for AMCAR in regenerative group [crohn's disease and RCH] The p values were fisher bilateral test was considered to be significant 0.007<0.05 Conclusions: The high degree of specificity is of AMACR but moderately sensitive for distinguishing dysplasia from regeneration in IBD suggests that it may be useful to distinguish reactive from neoplastic epithelium.

EPSTEIN-BARR VIRUS ASSOCIATED GASTRIC CARCINOMA: A STUDY IN ONE REFERRAL CENTER IN IRAN IN THE LAST FOUR DECADES

Afshin Abdirad[1], Siavash Ghaderi-Sohi[1], Karem Shuyama[2], Chihaya Koriyama[2], Hosain Nadimi-Barforoush[1], Sara Emami[1], Suminori Akiba[2], Azin Nahvijou[1], Alireza Mosavi-Jarrahi[1]
[1] The Cancer Institute Research Center, the Cancer Institute, Tehran University of Medical Sciences, Iran
[2] Department of Epidemiology and Preventive Medicine, Kagoshima University Graduate School of Medical and Dental Sciences, Japan

Background: Epstein-Barr virus has been proved to be associated with many of the human malignancy including gastric carcinoma, one of the most important human malignancies in the world. There has been no study about the presence of EBV in gastric adenocarcinoma in Iran. Method: We examined the presence of EBV in 273 formalin fixed paraffin-embedded cases of gastric carcinoma from Cancer institutes of Tehran University, from 1962 to 2004. In situ hybridization of EBV-encoded small RNA-1 (EBER-1) was conducted. The strain of positive cases was examined by means of polymerase chain reaction and/or restriction fragment length polymorphism analysis. Results: We found 9 (3%; 95% CI=1-5%) EBV positive cases. The gender difference was not statistically significant. The proportion of EBV-GC cases in diffuse type was higher than intestinal type (OR=0.08; 95% CI=0.002-0.64). EBV-GC cases had no relation with age, location and invasion. Six out of 9 EBV-GC cases were born during the period between 1928 and 1930. All 9 cases were Type A. Prototype F was seen in 6 out of 8 cases. Type "i" was found in 8 cases and type I in 1 case. XhoI+ and XhoI- polymorphism accounted 6 and 3 of the cases, respectively. Conclusion: Our study is the first to describe the frequency of EBV-GC in Iran and the Middle East, highlighting a very low prevalence with specific clinicopathologic features. The predominance of EBV-GC birth year in a fixed period, suggests that EBV infection or other events at early childhood may be related to the development of EBV-GC later in the life. The predominance of the type "i" and XhoI+ cases are contradictory to other studies in Asia and is similar to what is reported from Latin American countries.

PP1-74

ROLE OF bcl2 ONCOPROTEIN IN CARCINOGENESIS OF COLORECTAL NEOPLASIA AND CORRELATION WITH HISTOPATHOLOGIC AND PROGNOSTIC PARAMETERS

Mohammad Hossein Sanei, Maryam Razi
Isfahan University of Medical Sciences, Iran

Background: Tumor progression is a multistep process and consist, loss of regulation and balance between cell death and cell proliferation. The bcl2 oncoprotein plays an important role in carcinogenesis by inhibiting cell death (apoptosis). It was initially discovered in follicular B cell Lymphoma with t (14, 18) and subsequently in other malignant lesion. The aim of this study was to (1) investigate role of bcl2 immunostaining expression in colonic adenoma and carcinoma. (2) Identify any relationship between bcl2 marker and several histopathologic parameters. Materials and Methods – surgical specimen colorectal carcinoma (50) and adenoma (50) have been studied. Sections of paraffin block are used for Immunostaining according to the avidine - biotin - peroxidase complex method. Then correlation of bcl2 expression in colon adenoma and carcinoma and relationship between bcl2 and several histopathologic parameters is identified. Results: bcl2 was consistently higher in adenoma than in carcinoma. There were 92% in adenoma and 40% in carcinoma. (P values = 0 .001) bcl2 oncoprotein expression in carcinoma was significantly higher in well differentiated than moderately differentiated carcinoma. But there is not any correlation between

bcl2 expressions with others histopathologic parameters. There was only statistically significant relation between bcl2 expressions with size of adenoma. Discussion: Correlation of bcl2 expression in colon adenoma and carcinoma and with Tumor differentiation is similar to the results obtained in most previous study in this field. This result confirms that expression of bcl2 is valuable in diagnosis and predicting the clinical course of the patients.

PP1-75
IMMUNOHISTOCHEMICAL CHARACTERIZATION OF HUMAN FETAL PANCREAS AND PANCREATIC DUCTAL ADENOCARCINOMA. A STUDY OF SOMATOSTATIN ANTIBODY NCL-SOMATOP

Demetrio Tamiolakis, Maria Lambropoulou, George Alexiadis, John Venizelos, Theodoros Jivannakis, Akrivi Costopoulou, Christos Gaitanidis, Helias Papadopoulos, Nikolas Papadopoulos
Department of Histology - Embryology, Medical School, Democritus University of Thrace, Greece

Purpose: Somatostatin is a gastrointestinal peptide hormone that inhibits growth of pancreatic cancer as reported by an increasing body of evidence. Yet this is not always the case. To clarify the controversy we aimed to identify the expression of somatostatin in developing human embryonic pancreatic tissue and pancreatic adenocarcinoma given that somatostatin positive cells were shown either into primitive pancreatic ductal epithelium or into pancreatic carcinoma. Methods: Tissue sections representing pancreatic fetal specimens (n=15) and ductal pancreatic adenocarcinoma specimens (n=15) were assessed using immunohistochemical methods for somatostatin expression. Results: Normal primitive exocrine ductal epithelium and endocrine epithelium showed a definite, statistically significant, higher expression of somatostatin over neoplastic pancreatic tissue of mixed (ductalendocrine) and pure ductal type ($p1=0.021$, $p2=0.001$, $p3<0.0001$, and $p4=0.003$ respectively) during the 8th to the 10th week. No statistically significant differential expression of somatostatin in the mantle zone of the islets over neoplastic tissue of mixed ($p5=0.16$) and pure ductal type ($p6=0.65$), from the 13th to the 24th week was demonstrated. Conclusion: Pancreatic cancer cells can express somatostatin in a model that reproduces the normal expression of the peptide by δ-cells during embryonal organogenesis. Therapy aimed at pancreatic cancer must be targeted to somatostatin and analogues as potential adjuvant novel option.

PP1-76
GASTROINTESTINAL MESENCHYMAL TUMOURS ARE NOT ALL STROMAL: REPORT OF TWO RECTAL LEIOMYOSARCOMAS

J. Kourda[1], Nadia Kourda[1], F Farah[1], S. Sayari[2], M Ferchiou[1], B Tahayi[1], O Elamine[1], Aj. Zaouch[2], Sarrah Baltagi Ben Jilani [1], Rachida Zermani[1]
[1] Department of Pathology, Charles Nicolle's Hospital Tunisia
[2] Department of Surgery, Charles Nicolle's Hospital, Tunisia

INTRODUCTION: Leiomyosarcoma (LS) is considered as a malignant gastrointestinal smooth muscle tumour that occurs most frequently in oesophagus and rectum. Rectal leiomyosarcoma is an uncommon malignancy; it accounts for less than 0,5% for all malignancies of the colon and rectum. This rarity makes the choice of suitable associated treatment after surgery difficult and requires long-term follow-up to determine their behaviour. We report two cases of rectal LS. We will discuss clinical and histological findings allowing us to distinguish this entity from gastrointestinal stromal tumour (GISTs). OBSERVATIONS: We report tow new cases of rectal leiomyosarcoma. A 77-year-old and a 65-year-old men, were admitted for gastrointestinal bleeding, abdominal pain, and the first patient had a loss of weight. Rectal examination revealed for the first, a firm polypoid mass at 2 cm from anal sphincter. The latter, presented an indurate circumferential ulcerative mass in the rectal ampullae. On abdominal ultra-sonography and CT scan appeared a circumferential inhomogeneous mass in continuity with rectal wall, showing intramural necrotic area in one case; in the other case, there was a second little mass having the same characteristics. No metastases were disclosed. Abdomino-perineal resection was performed for the two patients. Grossly, the tumours were fungated and polypoid and measured 3 cm for the first patient and 9cm for the second with surface ulcerations. On the cut surface, necrotic and hemorrhagic foci were occasionally recognized. Microscopically, in the rectal tumour, there were areas of broad necrosis and haemorrhage, and viable tumour cells occupied about 50% of the tumour. There were no metastases in the resected lymph nodes. The tumour consisted on a proliferation of spindle cells arranged in fascicles. with epithelioid features. The cytoplasm of the tumour cells was eosinophilic or clear. The cellular and nuclear atypia was high, characterized by marked mitotic activity (more than 20 mitosis/10HPF), supporting the diagnosis of high grade LS. Mucosal involvement occurred in only one patient. Surgical margins were microscopically negative. For confirmation, an immunohistochemical study was performed. The tumour cells were negative for cytokeratin and epithelial membrane antigen, but positive for vimentin, indicating that the tumour was a sarcoma. The tumour cells were positive for á-smooth muscle actin, desmin and PS100. However, they were negative to CD 117 (C-kit). The tumour cells showed high proliferate activity as evidenced by Ki-67 immunostaining. The disease free interval for the two patients was 1 and 4 months. No regional recurrences were detected; however in one case, there was a pulmonary metastasis. The evolution was fatal in both cases. CONCLUSION: Leiomyosarcoma (LS) of the rectum is a rare tumour associated to a poor prognosis. GISTs are the main differential diagnosis. Morphological and immunohistochemical findings allows to separate theses two entities, so long time confused. The treatment of LS is primarily surgical, where possible, and should guarantee complete clearance of the tumour, which often requires an aggressive approach. Histopathological characteristics predictive of poor prognosis include high mitotic activity, intra-tumoral necrosis and tumour differentiation. Non-curative resection, high tumour grade and size > 10 cm, are considered unfavourable prognostic factors. Further trials are needed to establish the exact role of adjuvant therapy.

PP1-77
PROGNOSIS OF THE HIRSCHSPRUNG'S DISEASE ALLIED DISORDER (HAD) OR NEURONAL DYSPLASIA: THE VALUE OF GANGLIA/NERVE FIBERS RATIO

Dražen Kovač[1], Iva Gašparović[1], Mladen Peršić[2], Irena Slavić[2], Harry Nikolić[3], Nives Jonjić[1]
[1] Department of Pathology, University School of Medicine, Rijeka, Croatia
[2] Department of Paediatrics, University School of Medicine, Rijeka, Croatia
[3] Department of Paediatric Surgery, University School of Medicine, Rijeka, Croatia

BACKGROUND: The Hirschsprung's disease allied disorder (HAD) pathohistological findings of abnormal myenteric nervous plexus vary depending of the quantity of ganglia, therefore, the complete absence of ganglia (the real Hirschprung), hypoganglionosis, and hyperganglionosis which is considered as the colonic neuronal dysplasia.1 The lack of ganglia cells and increased and abnormal proliferation of mucosal nerve fibers follow the congenital dismotility problems of the GIT. The aim of our study was to determine a possible connection between ganglia/nerve fibers ratio and the clinical outcome in HAD predicting possible recovery of patients even before treatment. METHOD: We have followed the recovery of 15 patients treated and compared the clinical outcome with the histopathological

findings of ganglia and nerve fibers. Sections of the full thickness bowel specimens, obtained from 15 patients with HAD, were treated with antibodies against neurofilament protein (NF), marking ganglia, S-100, marking nerve fibers. RESULTS: 5 patients undergoing surgery were found to have low ganglia/nerve fibers ratio while 9 out of 10 patients not showing the need for surgery had higher ganglia/nerve fibers ratio. CONCLUSION: We propose that the ganglia/nerve fibers ratio can be used to predict the clinical outcome and long term prognosis as well as the need for invasive procedures in patients diagnosed with HAD. High ganglia/nerve fibers ratio correlates with good clinical outcome and decreased need for surgery, while lower ganglia/nerve fibers ratio shows poorer prognosis and increases the need for surgical treatment in our patients.

[4] Department of Pathology, Zagreb University School of Medicine, Zagreb, Croatia
[5] Department of Pathology, Trieste University School of Medicine, Trieste, Italy

BACKGROUND: Gastrointestinal stromal tumors (GIST) are rare neoplasm of unknown etiology and pathogenesis. Clinical behaviour is very unpredictable and a reliable prognostic factor is lacking. The aim of this study is to analyze some prognostic factors and estimate which one is the most reliable. METHOD: 38 biopsy specimens of GIST were immunolabeled with PC –10 for PCNA, for CD-34, vimentin, NSE and actin. Greatest diameter, histological grading, mitotic count, DNA-indeks and S-phase were estimated for each case. All patients were followed-up for at least 24 months or to death. Data were analysed by univariate and multivariate statistical analysis using computer program. RESULTS AND CONCLUSION: Results showed that greatest diameter, tumor grade, mitotic count and PCNA-index are prognostic factors in univariate analysis. In multivariate analysis only greatest diameter are useful prognostic factor for planning further therapy. Tumors with diameter less than 6.3 cm have better prognosis and they are benign, without reccurence and distant metastasis. Prognostic parameters (PCNA-index, mitotic count and tumor grade) could be useful as an auxiliary methods in cases of GIST with greatest diameter within a range 5 – 9 cm.

PP1-79
LIVER PATHOLOGY IN CHRONIC HEPATITIS C AND NORMAL ALT LEVELS

Farhod Kamilrov, Bahrom Aliev, Jasur Ahmadhodjaev
Advanced Institute for Doctors, Tashkent, Uzbekistan

Introduction: Hepatitis C virus (HCV) is a major cause of chronic liver disease, affecting 175 million people globally. Over 80% of acutely infected patients go on to develop chronicity. To date, there are no accurate noninvasive markers of hepatitis C activity and fibrosis. Liver biopsy is indicated to establish the stage and character of liver disease. In this work the role of liver biopsy in the patients with chronic hepatitis C (CHC) and persistently normal serum alanine aminotransferase (ALT) levels was evaluated (PNALT) Methods: Sections of formalin fixed, paraffin-embedded liver biopsies from 20 patients with CHC and PNALT were stained by Haemotoxylin and Eosin. Diagnosis was made on the basis of histological findings, clinical and virological information. Results: As showed results of our investigation, in the liver of the patients with CHC and PNALT histologically was observed chronic mild hepatitis. It was characterized by appearance of lymphoid follicules and/or aggregates and liver fat infiltration in 3 cases. Conclusion: There is no absolute correlation between serum ALT levels and liver disease activity in the patients with CHC and PNALT. Liver biopsy is an important implication on staging of the liver diseases, prognosis and management of therapy. Treatment decisions of these patients should be based on global evaluation of the patients rather than the results of laboratory test. (This work is supported by Grant A – 9-400 RUz).

[2] Department of Radiotherapy/Oncology, Democritus University of Thrace, Alexandroupolis, Greece
[3] Imperial Cancer Research Fund, Molecular Oncology Laboratories, Institute of Molecular Medicine, John Radcliffe Hospital, Oxford OX3 9DS, United Kingdom

Background: Phosphorylation of specific tyrosine kinase receptors of the VEGF on endothelial cell membrane promotes angiogenesis. Using a specific monoclonal antibody recognizing the phosphorylated form of VEGFR2/KDR receptor (pVEGFR2/KDR), we investigated the activation status of VEGF pathway in normal colon and in colorectal adenocarcinomas. Materials and Methods: Immunohistochemistry was performed on 128 paraffin-embedded sections of colorectal adenocarcinomas and 30 normal colonic specimens. The 34a monoclonal antibody recognizing the p VEGFR2/KDR (University of Oxford) was used. Results: Normal colon showed a weak expression of pVEGFR2/KDR. In contrast, pVEGFR2/KDR was strongly expressed in the cytoplasm and nuclei of cancer cells and the tumor-associated vasculature, mainly at the invading tumor edge. pVEGFR2/KDR expression in cancer cells was significantly associated with tumor size >6cm ($p=0.04$) and poor histological differentiation ($p=0.004$). Tumor-associated vessels expressing high pVEGFR2/KDR density was significantly related with high VEGF expression in cancer cells ($p=0.02$). This was also related significantly to high pVEGFR2/KDR expression in cancer cells. Conclusion: VEGFR2/KDR is not simply a vasculature restricted receptor, but has an additional role in cancer cell biology itself. It is suggested that VEGF released by cancer cells induce auto-activation of cancer cell VEGF receptors. This autocrine loop may function as a stimulus for cancer cell proliferation or resistance to apoptotic stimuli. Novel drugs inhibiting VEGF receptor phosphorylation may, therefore, have a direct activity on colorectal cancer cells, in addition to their function as inhibitors of neo-vascularization.

PRIMARY SQUAMOUS CELL CARCINOMA OF THE STOMACH: A CASE REPORT

Ioannis Efstratiou[1], Marketta Hakala – Bletsa[1], Stavroula Pervana[1], Anastasia Fotiadou[1], Asterios Samaras[2]
[1] Papageorgiou General Hospital Institute of Pathology, Greece
[2] Papageorgiou General Hospital Second Surgical Department, Greece

Primary squamous cell carcinoma (SCC) of the stomach is a very rare tumor, probably arising from ectopic or metaplastic squamous epithelium. We report a case of SCC of the stomach in

a 73-year-old woman, who was admitted to our hospital because of weight loss, anemia, epigastric pain and melena. Gastroscopy and CT of abdomen showed a big exophytic tumor of the anterior wall between corpus and antrum. A biopsy taken from the tumor revealed a SCC. The patient underwent a total gastrectomy. A 9cm in diameter cauliflower-like tumor was observed macroscopically. A total of 25 tissue blocks from the tumor showed a pure moderately differentiated keratinizing SCC. No foci of squamous metaplasia or component of adenocarcinoma were present. Immunohistochemically, the tumor cells were positive for HMW cytokeratin and negative for cytokeratin 7,20 and CEA. The tumor infiltrated the whole thickness of the wall without penetrating the serosa. All regional lymph nodes (31 in number) and the resection margins were free of tumor involvement. The TNM – staging was pT2pNoG2. 18 months after the diagnosis was established the patient is free of recurrence. SCC and adenosquamous carcinoma constitute less than 1% of all gastric carcinomas. The majority of them is localized in the distal half of the stomach. 80% of the reported patients were male with a peak incidence in the sixth decade of life. Our case fulfills the criteria proposed by Parks et al. Prognosis of SCC cannot be clearly assessed since the number of reported cases is low and many patients present with locally advanced disease.

PP1-82
RUSSELL BODY POLYP OF STOMACH

Yuji Kimula, Takashi Tanaka, Toshihiko Okuyama
Kurashiki Medical Center, Okayama, Japan

A plasma cell tumor of the stomach with many Russell bodies is reported. A gastric polyp of 57 year-old woman was found by annual health check. Due to the low level of pepsinogen, she was recommended to take an examination of upper gastrointestinal endoscope. A 7mm in diameter sized polyp of gastric antrum was found and biopsy revealed Russell body gastritis. Polypectomy was done and the tumor of the stomach was diagnosed as Russell body polyp of the stomach. Russell bodies were stained positive for CD21, CD79α, and right-chain kappa. She is infected by Helicobacter pylori as well. CD21 is reported to be an activator of B-cell and CD21 proliferates B-cells, resulting in a round polyp of gastric mucosa. Seven cases of Russell body gastritis were reported in literatures, however, no report is about the Russell body polyp of stomach. This is the first case of Russell body polyp of stomach in the world.

PP1-83
MOLECULAR EVIDENCE OF INVOLVEMENT OF COX-2 AND NF- κB IN TRIGGERING CELL CYCLE ALTERATION IN BARRETT'S ESOPHAGUS

Massimo Milione[1], Emilio Di Giulio[1], Ludovica Feigusch[1], Antonella Carnuccio[1], Cristina Colarossi[1], Stefania Scarpino[1], Antonella Stoppacciaro[1], Emidio Luciani[1], Gabriele Capurso[1], Francesco Panzuto[1], Elisabetta Froio[2], Cesare Bordi[2], Luigi Ruco[1], Gianfranco Delle Fave[1]
[1] University of Rome La Sapienza, Ospedale Sant'Andrea, Italy
[2] University of Parma, Italy

Background: The reflux of gastric content, bile and acid , in esophagus , is able to induce first Esophagitis (ES) and then Barrett's Esophagus (BE). Nuclear factor kappa B (NF-kB) is a ubiquitous transcription factor that regulates the activation of genes involved in pro-inflammatory response. NF-kB and Cyclooxygenase (Cox-2) activation are increased in BE. p27 expression increases in accord to inflammation. CDX2, a transcription factor associated with intestinal differentiation, is related to cell cycle regulators cdk-2 and p27Kip1. The targeted degradation of cdk-2 is the mechanism through which CDX2 activity can be regulated in coordination with the cell cycle machinery.. Aim: To investigate the molecular pattern of inflammation metaplasia sequence in ES and EB. Matherials and methods: In order to investigate the molecular pattern of inflammation -metaplasia sequence in ES and EB, immunohistochemestry (IHC) with antiCDX-2, anti-p27Kip1, anti-cdk-2, anti NF-kB, and anti COX-2 monoclonal commercial antibodies was performed on paraffin embedded tissue sections of 60 BE , of 64 endoscopic (A,B,C los Angeles scale) and histologic esophagitis (ES), and of 30 non inflammed gastro-esophageal junction (GEJ) as control. Multiple (four) biopsies for each patient were obtained during endoscopy. Western blot (WB) was performed on proteins extracted from samples from each group Results: WB and IHC showed super imposable data. In GEJ is preferentially expressed cdk-2, instead NF-kB, COX-2, p27 and , CDX2 are absent. ES is associated with an high rate of NF-kB, COX-2 and p27, and with an iportant decrease of cdk-2 respect to the GEJ value.EB presented obviously high level of CDX2, NF- kB, and COX-2 , but a decrease of p27. Conclusions: Normal esophageal mucosa is characterized by the expression of cdk-2 and no inflammatory proteins, when both COX-2 and NF-kB increase esophagitis is present that fact may be able to bring an increase of p27. p27 determine selective inhibition of cdk-2. Low levels of cdk-2 are associated with BE and are the molecular prerequisite for the CDX2 expression. Then the high rate of inflammation regulators such as NF-kB and COX-2 are the trigger for CDX2 activation. But the coexistence on BE of high level CDX2, NF- kB, and COX-2 suggest that CDX-2 isn't directly influenced by inflammation.

PP1-84
WHICH APPENDICEAL NEOPLASMS LEAD TO PSEUDOMYXOMA PERITONEI AND HOW OFTEN: A POPULATION BASED STUDY

Robert Smeenk, Marie-Louise Van Velthuysen, Vic Verwaal, Frans Zoetmulder
Netherlands Cancer Institute, The Netherlands

Background: Pseudomyxoma peritonei (PMP) is a rare disease with an estimated incidence of 1 per million per year, and is thought to originate usually from an appendiceal mucinous epithelial neoplasm. However it is not known exactly how often these neoplasms lead to PMP. The aim of this study is to investigate the incidence of both lesions and their relation. Methods: The nationwide pathology database of the Netherlands (PALGA) was searched for the incidence of all appendectomies, the incidence of primary epithelial appendiceal neoplasms and the incidence and pathology history of patients with PMP. All regarded the 10-year period of 1995-2005. Results: In the 10-year period 167,744 appendectomies were performed in the Netherlands. An appendiceal lesion was found in 1482 appendiceal specimens (0.9%). Nine percent of these patients developed PMP. Coincidentally, an additional epithelial colonic lesion was found in 13% of patients with an appendiceal epithelial neoplasm. A mucinous epithelial neoplasm was identified in 0.3% (73% benign, 27% malignant) of appendiceal specimens and 20% of these patients developed PMP. For mucocele and non-mucinous neoplasm the association with PMP was only 2% and 3%, respectively. From the nationwide database 267 patients (62 men and 205 women) with PMP were identified, which demonstrates an incidence of PMP in the Netherlands approaching 2 per million per year. The primary site was identified in 68% and dominated by the appendix (82%). Conclusions: Primary epithelial neoplasms of the appendix occur in 0,9% of appendectomies. One third of these lesions is mucinous. In 20% of patients with a mucinous lesion of the appendix PMP develops. The incidence of PMP seems to be higher than thought before. Furthermore there is a considerable risk of an additional colonic epithelial neoplasm in patients with an epithelial neoplasm at appendectomy

PP1-85
HISTOCHEMICAL AND IMMUNOHISTOCHEMICAL STUDY OF EPITHELIAL MUCINS IN CAP POLYPOSIS
Katarina Katic[1], Vesna Zivkovic[2], Miljan Krstic[2],
Ivana Stankovic[1], Aleksandra Radicevic[1], Vuka Katic[2]
[1] Institute of Pathology, Clinical Center Nis, Yugoslavia
[2] Institute of Pathology, Medical Faculty Nis, Yugoslavia

Background - Cap polyposis is rare disease characterised by mucoid and bloody diarrhea, with polyps that contain an overlying 'cap' of necroinflammatory debris and granulation tissue.The pathogenesis is not known. Aims – To pour some light on cap polypsis pathogenesis, we have examined the epithelial mucins of 30 polyps, taken from a patient with cap polyposis in whom has been done right hemicolectomy. Material and methods – The study was performed on biopsy specimens taken from 30 polyps of various size, sessile or with stalk.Fixation has been done in 10%formaldehyde.Paraffine sections were stained with:H&E, HID-AB at pH 2.5 with exclusive expression of sialo- and sulfomucins and LSAB2 immunohistochemical method, by using antibodies to MUC2, MUC3, MUC4 and MUC5A.The intensity of the expression was scored semiquantitatively by two independent observer as: -, absent, + weak, ++ moderate, and +++ strong; normal sygmorectal mucosa servs as control. Results – The diagnosis of cap polyposis was established on the basis of the appearance of the polyps, which formed from hypertrophic colonic mucosa with dilated glands containing mucus and granulocytes, covered by a cap formed from mucus,fibrin and leucocytes. In contrast to numerous small sessile inflammatory polyps found 15 cm from the anal margin, 24 filiform villous polyps('giant inflammatory polyps') with stalks, were discovered 6cm from the proximal colon margin. Comparative histochemical and immunohistochemical examination showed that the mucus of cap polyposis differed in two aspects from that of normal colon: predominance of non-sulfated mucins in the goblet cells and abnormal expression of the MUC4, MUC3 and MUC5AC genes. The intensity of the MUC5AC expression was strong (+++) in filiform polyps, moderate (++) in small sessile polyps, but it was not detected in normal colonic mucosa.We suggest that the mucin abnormality detected, which reflect deregulation of the expression of the apomucin genes, abnormal glycosylation and abnormalities of the secretion process, are also probably involved in the clinical manifestations of cap polyposis.

PP1-86
STATISTICAL CORRELATION BETWEEN SOME MOLECULAR MARKERS IN COLORECTAL CANCER
Camelia Doina Vrabie, Mihai Ceausu, Angela Petrescu,
Maria Waller
National Institute of Pathology "Victor Babes", Romania

Background Colorectal cancer (CRC) is one of the major cancer diseases in the world. For surgical resected malignancies, the pathologic stage is widely recognized as the most accurate predictor of survival and it determines the appropriateness of adjuvant treatment as well. In the same time, molecular tumor markers are often studied in CRC using immunohistochemistry to determine their prognostic or predictive value. Protein expression is typically assigned a positive score based on a predetermined cutoff. The aim of our study was to find out the statistical correlations between different molecular markers and tumor grade and stage. Methods. We investigate histopathological and immunohistochemical 40 patients who undergone surgery for colorectal cancer. The study included 19 female and 21 males. We analyzed using ABC method for immunohistochemistry the following markers for 10 selected cases: vascular endothelial growth factor (VEGF), CD44, carcinoembrionic antigen (CEA), transforming growth factor beta (TGFβ), cytokeratin 20 (CK20), epidermal growth factor receptor (EGFR) and oncoprotein p53. Then, we analyzed statistical the results using Student-t test. Results The 40 patients with CRC presented in 6 cases perforation (15%), lymph nodes invasion (85%). 23 cases (57.5%) were moderate differentiated, 6 cases had distant metastasis, and only 9 cases were mucinous cancers. We noticed positive correlation between VEGF1 and CK20 (r=0.4, p=0.05), and between VEGF1 and CEA (r=0.88, p=0.001). Also, our results demonstrated a positive correlation between tumor grade and CEA (r=0.43, p=0.009), and no relation among the other markers. Conclusions. Our present study show no correlation between EGFR protein status and the grade and stage of CRC, but direct proportional relation in VEGF expression and CEA, and CEA and tumor grade.

PP1-87
PNEUMATOSIS INTESTINALIS IN A CASE OF SIGMOID VOLVULUS
Alex Casalots, Maria-Rosa Escoda, Ruth Orellana,
Sara Fernandez, Tamara Parra, Maria-Rosa Bella, Mercè Rey
Corporació Sanitaria Parc Tauli-UDIAT-C. D., Spain

BACKGROUND Pneumatosis intestinalis (PI) is a rare condition characterized by the presence of multiple gas filled cysts within the bowel wall. PI might occur as a primary idiopathic disorder, but a secondary form of the disease has been described in association with a variety of underlying conditions including traumatic or mechanical disorders, inflammatory, autoimmune, infectious and pulmonary pathologies. We report a case of PI associated to sigmoid volvulus. METHOD A 70-year-old man presented with a 48-hour history of abdominal pain and constipation. Clinical examination showed generalized gaseous distention of the abdomen and tympanism without signs of peritoneal irritation. Abdominal X-ray and computed tomography showed a grossly dilated large bowel segment consistent with sigmoid volvulus. After failured of non-operative management, the sigmoid colon was resected. Pathological examination of the resected loop showed numerous subserosal and submucosal gas cysts which histologically were lined by flattened cuboidal cells, macrophages and multinucleated giant cells. RESULTS AND CONCLUSION PI is a secondary finding caused by an underlying disease. The significance and the prognosis of PI depends on the nature and severity of the underlying condition. The pathogenesis of PI has been debated for decades and multiple explanations have been suggested. The breath of pathologic conditions associated with PI formation suggests that its development is a multifaced phenomenon in which mucosal integrity, intraluminal pressure, bacterial flora and intraluminal gas have an interactive role in formation of the pneumocysts.

PP1-88
ADENOCARCINOMA (AC) AND INTRAEPITHELIAL NEOPLASIA OF THE ESOPHAGUS (EIN), BARRETT'S ESOPHAGUS (BE): MOLECULAR AND MORPHOLOGICAL MARKERS p53, ki67, CK8, CK10/13 AND APOPTOSIS
Tatiana Demura, Svetlana Kardasheva, Eugenia Kogan,
Olga Sklyanskaya, Vladimir Ivashkin, Michael Paltcev
Moscow Medical Academy, Russia

Risk of AC development increases from 30 to 125 times in patients with BE. Thus, it is of the essence to diagnose EIN in BE at early stages with the help of molecular markers. The aim of our study was to estimate malignancy potential in BE with the help of several immunohistochemical (IHC) markers of differentiation, proliferation and apoptosis. Materials and Methods. The study was performed on 4-quadrant biopsy of the lower esophagus. The specimens were embedded in formalin and fixed in paraffin. From each specimen several slices were made and fixed on the slides. 362 slides were made and selected into 6 groups: 1 - squamous epithelium, control group, 2 - squamous epithelium in BE, 3 - gastric metaplasia (GM), 4 - intestinal metaplasia (IM), 5 - EIN in BE (1 –low grade, 4 – high grade), 6 - AC in patients with BE. Slides were treated with standard IHC with following monoclonal antibodies: P-53, Ki-67, CK10/13, CK8 (Dako

Cytomation). Apoptosis was studied with the help of Tunnel test in situ labeling (Enzo Diagnostic). Reaction results were evaluated with the help of quantative and semi quantitative methods and statistic analysis. Results. Tunnel test showed apoptosis level increasing from GM to IM and EIN, where it was maximum, and comparative decreasing in AC. P-53 expression was moderate in GM, increased in IM and EIN and maximum in AC. The study revealed expression of Ki-67 to be moderate in IM, increased in EIN and maximum in AC. CK8 - glandular differentiation marker - showed moderate expression in each epithelial type. However, CK10/13 - squamous differentiation marker - showed high expression in squamous epithelium, it was detected in GM, IM, EIN and AC as well. Conclusion. GM in BE is characterized by moderate level of apoptosis, ki-67, P-53. IM is characterized by increased apoptosis and P-53 and Ki-67 expression. EIN develops only in BE with large IM and is characterized by high levels of apoptosis, P-53 and Ki-67 and AC has maximum P-53 and Ki-67 expression and decreased level of apoptosis comparing with EIN and IM. Obtained results showed that BE is a precancer condition and its malignancy potential depends on the prevalence of apoptosis and proliferation and altered differentiation.

PP1-89

PARTICULARITIES OF ANAL CANAL CARCINOMAS COMPARED TO COLORECTAL CARCINOMAS

Simona Gurzu, Ioan Jung, Tibor Mezei
University of Medicine and Pharmacy Tg. Mures, Romania

Background: Carcinomas of the anal canal represent 4% of all carcinomas of the digestive tract. According to data from the literature, predominates squamous carcinoma followed by adenocarcinoma. Method: We studied 507 colorectal carcinoma (CRC) specimens, following their classical clinical and pathologic parameters (sex, age, localization, gross and microscopic aspect, stadialisation and their association with polyps) as well as immunohistochemical parameters related to prognosis and angiogenesis. We studied the anal carcinomas and compared them with the colorectal carcinomas. For the immunohistochemical assays we used antibodies provided by DAKO and LabVision, with the immunoperoxidase method. We used the following antibodies: CEA, Chromogranin A, p53, Cathepsin D, Cadherin E, oncoproteins c-erb-B2 and bcl-2, CD31, CD105 and VGEF. For statistical analysis we used GraphPad InStat 3 software. We considered the association significant when $p<0.05$. Results: From the 507 cases with CRC, 12 (2.37%) were anal canal carcinomas, 2 of these were synchronous tumours. The average age was 63.17±10.87 and in the anal canal carcinoma group was 57.9±10.05 ($p<0.0001$). Compared with CRC the anal canal carcinomas occur more frequently at the women (58%). The polypoid-ulcerated tumours predominated. In our cases the incidence of adenocarcinoma is higher (83%) then of squamous carcinomas (17%). 70% of the cases were diagnosed in the T3N0 stage. Polyps were associated in 8% of the cases, whereas in the CRC group an association of 24% was observed ($p=0.003$). The expression of CEA, chromogranin A, Cathepsin D and Cadherin E was simmilar in the two groups. Oncoproteins (c-erb-B2 and bcl-2) and p53 were observed more rarely than in CRC. Angiogenesis (marked with CD31, CD105) was expressed in all the cases, although VEGF does not correlate with the expression of the former markers. In the anal canal the incidence of synchronous tumours was higher (16.66%) than in the other segments of the colon (1.58%). Conclusions: The performed assessments have showed a higher incidence of anal canal carcinomas at women and at younger ages, the predominance of polypoid-ulcerated forms and the higher proportion of synchronous tumours, compared to CRC. Immunohistochemically we observed differences between the expression of p53, c-erb-B2, bcl-2. The angiogenesis was marked in all cases, and it seems that the role of tumour cells is not significant in this process.

PP1-90

MISMATCH REPAIR PROTEINS AND CLINICOPATHOLOGIC FACTORS IN COLORECTAL CANCER

Mahsa Molaei, Babak Noorinayer, Ali Ghanbarimotlagh, Reza Mashayekhi, Mohamadreza Zali
Research Center for Gastroenterology and Liver Disease, Iran

Mismatch repair proteins and clinicopathologic factors in colorectal cancer Background: Microsatellite instability due to defective mismatch repair proteins(MMRP) is one of the major pathways for carcinogenesis in colorectal cancer (CRC).The impact of these proteins in prognosis is not well defined.The aim of this study were the evaluation of abnormal MMRP prevalence and its relationship with some clinical and pathologic factors. Methods: In our study 350 patients with CRC were immunostained for DNA mismatch repair proteins (MMRP) including hMLH1, hMSH2, hMSH6 and PMS2.Patients with at least one abnormal above factors considered in abnormal MMRP group. Clinical factors such as sex, tumor site(colon or rectum),family history of CRC and vital status(alive or dead) is considerd.Pathologic factors including grade, T and N stage in tumor specimen were examined. Results: Totally 350 patients with median age of 51(20 to 94) were evaluated. One hundred ninety five patients were male and 151 were female. The site of tumor in 270 patients was colon and in 68 were rectum. Among 329 patients with known family history, 132(40.1%) had positive FH.The overall rate of abnormal immunostaining for hMLH1, hMSH2, hMSH6 and PMS2 were 4.4%, 7.2%, 3.5%and 4.9% respectively. Overall 44 patients (12.7%) had at least one abnormal MMRP staining. Abnormal MMRP were not significantly associated with histopathologic factors including T stage, N stage and grade. There was no difference in MMRP staining as a result of whether patients were male or female except PMS2 that was significantly more abnormal in male ($p=0.083$).Abnormal staining of MMRP were seen further in colon than in rectum that was significant for hMLH1 ($p=0.044$).Patients with family history of CRC had more abnormal staining that was significant for hMSH2 ($p=0.061$). There was no difference in MMRP staining according to vital status. Conclusion: Our results suggest that abnormal MMRP is associated with clinical factors such as family history of CRC but not with pathologic factors. Abnormal MMRP is more important pathway for carcinogenesis in colon than rectal cancer.

PP1-91

PLEOMORPHIC LIPOSARCOMA OF THE STOMACH

Lora Manolia[1], Eleni Mahaira[2], Anna Fillipidou[1], Nikolaos Tamvakis[1], Maria Demonakou[1]
[1] Sismanoglio General Hospital-Athens, Greece
[2] KAT General Hospital-Athens, Greece

Background: Liposarcoma is the most common soft tissue sarcoma. It may develop anywhere, but predominantly in the retroperitoneum and the soft tissues of the thigh. Liposarcoma of the stomach is very rare and only 7 cases have been described in the English literature. Case report: A 66 years old woman with hemorrhage of the upper GI tract was admitted to hospital. From laboratory exams anemia was found (Ht:36).Radiology showed a large ecogenic neoplasm in the frontal wall of the stomach. The patient was led to surgery and had a partial gastrectomy. MACROSCOPY: In the anterior wall of the stomach a neoplasm measured up to 8cm was detected. It was elastic with solid, lipomatous and necrotic areas. It also caused a central ulceration in the mucosa. MICROSCOPY: The solid areas had the morphology of vascular spindle cell sarcoma of high malignancy with multiple mitosis. In the lipomatous areas multinucleated cells were seen and lipoblasts were detected. It was positive for Vimentin ,CD34 and S-100 and negative for a-SMA, Desmin, CD117 and HHF35. The diagnosis of pleomorphic liposarcoma was made. Discussion: Liposarcomas of the GI appear at any age with a male to female ratio of 3:1.Clinical signs and symptoms

are not specific and include an increasing growth palpable mass, anemia, hemorrhage, obstruction and intessuception or symptoms related to increased intra-abdominal pressure. They are neoplasms that rise from the adipose tissue of the submucosa and rarely from the adipose tissue of the serosa. One of the most characteristic findings is the presence of adipose cells.The main histological subtypes are: Adipocytic (lipoma like), Sclerosing, Inflammatory and Spindle cell. The terms "atypical lipoma" and "atypical lipomatous tumor" have been suggested by different authors for tumors that may reccur but are uncapable of distant metastasis. Conclusion: Gastric liposarcomas are very rare neoplasms that affect both sexes at any age. Their histology is similar to this of the soft tissue tumors and the diagnosis is based on the presence of lipoblasts. The differential diagnosis is from inflammated lipomas of the gastrointestinal tract.

PP1-92

DLK: A POTENTIAL NEW IMMUNOHISTOCHEMICAL MARKER FOR HEPATOBLASTOMA

Nagy Peter[1], Halász Judit[2], Dezső Katalin[1], Paku Sándor[1], László Viktória[1], Bisgaard Hanne Cathrine[3], Schaff Zsuzsa[2]
[1] Semmelweis University, 1st Department of Pathology and Experimental Cancer Research, Budapest, Hungary
[2] Semmelweis University, 2nd Department of Pathology, Budapest, Hungary
[3] The Panum Institute, University of Copenhagen, Dept. of Medical Biochemistry and Genetics, Copenhagen, Denmark

Background: Delta-like protein (DLK) also referred to as pG2 (human adrenal specific mRNA), Pref-1 (preadipocyte factor 1), SCP-1, ZOG, as well as the soluble product FA1 (fetal antigen 1) is encoded by the gene DLK1. It belongs to the EGF-like homeotic protein family. The function of DLK is not known but the protein is highly expressed in human and rodent fetal hepatocytes and in transit-amplifying oval cells in stem cell-mediated liver regeneration in rat. We investigated in the present study if this protein is expressed in human hepatoblastomas. Method: Paraffin blocks of 30 hepatoblastomas were selected from our archives and DLK expression was studied by standard ABC based immunohistochemistry using DAB as chromophobe. The primary antibody was purchased from R& D (cat.: AF 1144). DLK expression was also investigated in other alpha-fetoprotein producing tumors: hepatocellular carcinomas (10), germ cell tumors (6) and in undifferentiated childhood tumors: Wilms tumor (5), neuroblastoma (7), meduloblastoma (5), kidney rhabdoid tumor (1). Results: All the hepatoblastomas were positive for DLK. The staining was mostly focal covering 5-30% of the areas of tumors, the surrounding liver tissue remained negative. The reaction was present always in the epithelial component of the tumors but there was no preferential staining over the fetal or embryonic parts. The staining pattern was membranous and cytoplasmic. The differentiating cells of two ganglioneuroblastomas stained positively, no reaction was observed in any other tumors. Conclusion: DLK immunostaining seems to be a highly sensitive and specific marker for hepatoblastomas. If this primary observation can be confirmed DLK can be used as an immunohistochemical marker for hepatoblastomas. The biological function of DLK in hepatoblastomas requires further studies. However since DLK is a membrane receptor it can be considered a molecular target for therapeutical approaches.

PP1-93

HEMORRHAGIC GIST WITH NEURAL DIFFERENTIATION IN AN INFLAMED MECKEL DIVERTICULUM – CASE REPORT

Ceausu Mihai[1], Ichim Paul[2], Ceausu Maria[2], Andrei Florin[3], Ceausu Zenaida[4], Ene Diana[3], Florescu Simona[3], Ardeleanu Carmen[5]
[1] "Victor Babes" National Institute of Pathology, Bucharest, Romania ,"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania
[2] "St. Andrew" Clinical Hospital, Galati, Romania
[3] "Victor Babes" National Institute of Pathology, Bucharest, Romania
[4] "St. Pantelimon" Emergency Clinical Hospital, Bucharest, Romania
[5] "Victor Babes" National Institute of Pathology, Bucharest, Romania ,– "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background: The Meckel's diverticulum tumors are observed in approx. 2% of cases and about 12% of these tumors are GIST; according to Pubmed / Medline database there are 5 such tumors described in the last 5 years. Material and methods: We report a 67 years old women admitted with abdominal pain at the hospital for surgical intervention, for a bleeding tumor developed in an inflamed Meckel's diverticulum, discovered at CT scan. A six centimeters, 150 gr., yellowish – white, firmly, encapsulated tumor was removed. Standard HE stain and the immunohistochemical indirect tristadial ABC-peroxidase technique for 9 antibodies (vimentin, CD117, PDGFR, CD34, S-100, NSE, actin, Ki-67, p53) have been done. DNA extraction was performed using the Qiagen kit- QiaAmp (Austria). PCR for mutations in exons 9 and 11 of c-kit proto-oncogene, with agarose gel electrophoresis has been carried out. Results and discussions: Microscopic, a proliferation with elongated eosinophilic tumor cells with fibril cytoplasm and with nuclear atypia, growing in palisades, dissecting the muscularis propria has been noticed; no mitotic activity was recorded. IHC reactions showed CD117 focally positive, PDGFR diffusely positive, CD34 positive in scattered tumoral cells, vimentin diffusely positive, S-100 focally positive, NSE diffusely positive, actin weakly positive in scattered cells, p53 positive in ~ 5-10% of tumor cells nuclei, Ki-67 negative. PCR has not revealed mutations such as deletions or insertions bigger than 6bp in the exons 9 and 11 of c-kit gene, thus the study requires investigations for point mutations. Conclusion: We considered this case as a GIST with neural differentiation developed in a Meckel's diverticulum, being the 3rd case recorded in the last 5 years in our institution. Further molecular investigations for point mutatins in exons 9 and 11 will be performed by SSCP (Single Stranded Conformation Polymorphism).

PP1-94

GASTROINTESTINAL DYSMOTILITY IN MITOCHONDRIAL NEURO-GASTROINTESTINAL ENCEPHALOMYOPATHY IS CAUSED BY MITOCHONDRIAL DNA DEPLETION

Carla Giordano[1], Roberto De Giorgio[2], Claudia Travaglini[1], Mariangela Sebastiani[1], Maria Lucia Valentino[3], Michio Hirano[4], Valerio Carelli[3], Giulia D'Amati[1]
[1] Dipartimento di Medicina Sperimentale, Sapienza, Università di Roma, Rome, Italy
[2] Department of Internal Medicine & Gastroenterology, University of Bologna, Italy
[3] Department of Neurological Sciences, University of Bologna, Bologna, Italy
[4] College of Physicians and Surgeons, Columbia University, New York, USA

Objective: To investigate the pathophysiology of gastrointestinal (GI) dysmotility in mitochondrial neurogastrointestinal encephalomyopathy (MNGIE). Background: MNGIE, an autosomal recessive neuromuscular disorder clinically dominated by severe GI dysmotility, is due to loss-of-function mutations in the thymidine phosphorylase (TP) gene, which induce pathologic accumulations of thymidine and deoxyuridine, and generate mtDNA defects (depletion, multiple deletions and point mutations). Methods: Using laser capture microdissection and quantitative Real Time PCR techniques, we correlated histologic features with mtDNA abnormalities in different tissue components of the GI wall in 5 patients (4 M, 1 F; mean age 32, range 34-41) with genetically defined MNGIE and 10 age-

matched controls. Results: The external longitudinal layer of muscularis propria from stomach, small intestine and colon showed marked atrophy and cytoplasmic vacuolization of smooth muscle cells. These features were more prominent in the small intestine where ultrastructural analyses revealed marked mitochondrial proliferation. In contrast, the internal layer of muscularis propria and the myenteric plexus were unremarkable. Microdissection analysis revealed marked mtDNA depletion confined to the longitudinal layer of muscularis propria from stomach, small intestine and colon. Intriguingly, analyses from ten controls showed that the longitudinal layer of muscularis propria had a lower amount of mtDNA compared to the internal layer and the myenteric plexus (1:2). Multiple deletions were detected only in skeletal muscle cells from cricopharyngeal muscle. Site-specific somatic point mutations were detected at very low abundance both in the muscle and nervous tissue of the GI tract. Conclusions: Our results showed that GI dysmotility in MNGIE is associated with marked mtDNA depletion limited to the longitudinal layer of muscularis propria of stomach, small intestine and colon. The constitutive low abundance of mtDNA at this site may significantly predispose MNGIE patients to mtDNA depletion and visceral myopathy. Multiple mtDNA deletions accumulate only in skeletal muscle cells from cricopharyngeal muscle. The selective occurrence of mtDNA deletions in the cricopharyngeal muscle suggests post-mitotic skeletal muscle cells accumulation, whereas negative selection may decrease the load of deleted mtDNA molecule during turnover of smooth muscle cells.

PP1-95
GENDER AND LIVER FIBROSIS IN CHRONIC HEPATITIS C: ROLE OF THE TGF-BETA1

Jurijs Markovs[1], Sergejs Isajevs[2], Baiba Rozentale[3], Gundega Knipshe[1], Darja Svirina[1]
[1] Faculty of Medicine, University of Latvia, Latvia
[2] Faculty of Medicine, University of Latvia and Center of Pathology, Latvia
[3] Infectology Center of Latvia, Latvia

Background. It is known that during chronic hepatitis C liver fibrosis progression is faster in males than in females. Experimental data also suggest that estrogens may have an antifibrotic effect. TGF-β1 is a key cytokine that is involved in the pathogenesis of hepatic fibrosis by activating of epithelial-mesenchymal transition (EMT). In this study we investigated whether gender affects the progression of TGF-β1 dependent EMT in the liver of patients with chronic active hepatitis C. Methods. Liver biopsies performed before antiviral therapy was analyzed using METAVIR scoring system. Ten men (age range 21-46 years) and nine women (age range 31-45 years) were enrolled in the study. Immunohistochemical methods were used to analyze TGF-β1, α smooth muscle actin (SMA), pan cytokeratin, desmin and CD8 expression in liver tissue. Results. Hepatic fibrosis (stages 2-4) was identified in 18.4 % of men and 5.9 % of women. TGF-β1 and desmin could be immunolocalized in the majority of limiting plate hepatocytes. A variable pattern of TGF-β1 expression in intralobular hepatocytes (e.g. TGF-β1 positive and negative hepatocytes) was observed. TGF-β1 immunoreactivity was inversely proportional to the size of the hepatocyte. About 57.8% of TGF-β1 positive hepatocytes was found in male patients and only 42.2% in female patients. Cellular morphology of some limiting plate hepatocytes changes to a more fibroblastic appearance with desintegration of cell-cell contacts. At the same time these cells remain pan cytokeratin and desmin positive. Meanwhile there was an increase in the CD8 positive T cells and α SMA-positive myofibroblasts in the close vicinity of a limiting plate with the appearance of the piecemeal necroses. These events take place more frequently in HCV-infected men, than in women. It is likely that during the disruption of limiting plate some hepatocytes of this plate under the influence of TGF-β1 undergo EMT-like phenotypic changes with the subsequent overproduction of matrix components of fibrotic liver. Conclusion. In conclusion, our results suggest that fibrosis progression is slower in females as compared to males with hepatitis C. It may be due to estrogen action on liver cells which preserve hepatocytes from TGF- β1 overexpression.

PP1-96
EXPRESSIONS OF C-erbB-2 AND p53 PROTEINS IN GASTRIC CARCINOMA: CORRELATION WITH PROGNOSTIC PARAMETERS

Ozlem Ton, Serife Basaran, Saime Gul Barut
Haseki Education and Research Hospital Pathology Department, Turkey

Background: Expressions of c-erbB-2 and mutant p53 proteins have been observed in some gastric carcinomas but reports of their prognostic value are conflictual. The aim of this study was to investigate c-erbB-2 and p53 protein expressions and their relation to the clinicopathological factors in gastric carcinomas. Materials and Methods: Fifty-four cases with gastric carcinomas who had undergone gastrectomy at Haseki Hospital between the years of 2005 and 2006 were reevaluated. Formalin-fixed, parafin-embedded tissue sections were analyzed immunhistochemically for the expression of c-erbB-2 and p53. Correlation between c-erbB-2, p53 expressions and histopathologic parameters was evaluated. Results: Positive membranous staining for c-erbB-2 was detected in 6 of 54 gastric carcinomas (11,1%) and no positive reaction was evident in noncancerous tissue. All of c-erbB-2 positive tumors were intestinal type according to Lauren classification. There was no statistically significant association between c-erbB-2 expression and age, sex, histopathologic type, depth of invasion, the tumor size, growth pattern, lymph node involvement, lymphatic vessel invasion or perineural invasion. p53 expression was detected in 40 of 54 gastric carcinomas (74,1%), with strong inter- and intratumor heterogenity. Statistically, no significant correlation between p53 overexpression and age, sex, the tumor size, histopathologic type, growth pattern, depth of invasion, lymphatic vessel invasion, perineural invasion or lymph node involvement. Additionally, no correlation was found between c-erbB-2 and p53 expressions. Conclusions: The results suggest that expression of c-erbB-2 protein may occur selectively in intestinal type of gastric carcinomas. However, c-erbB-2 and p53 expressions are not related to the pathological characteristics of gastric carcinomas.

PP1-97
TRANSFORMING GROWTH FACTOR-BETA RECEPTOR-1 (TGFßR-1) EXPRESSION IN LIVER INJURY AND HEPATOCELLULAR CARCINOMA

Pelin Bagci, Gulsen Ozbay
Istanbul University, Cerrahpasa school of medicine, Department of pathology, Turkey

BACKGROUND: Hepatocellular carcinoma (HCC) is a tumor with fatal outcome and resistant to therapy. Leading etiologic factors of HCC include chronic hepatitis and cirrhosis with any etiology. Hepatic stellate cells (HSC) is the key fibrogenic cell type in liver. TGFß generated by the activated HSC is the most significant fibrogenic molecule of cirrhosis. The inflammatory, portal cells and hepatocytes of liver express different kinds of TGFß receptors (TGFßRs). We planned this study to observe the expressions of TGFßR-1 in different steps of liver injury. METHOD: A study group composed of 65 viral hepatitis, 58 cirrhosis and 21 HCC cases was chosen. Immunohistochemical technique was used for TGFßR-1 antibody and the slides were scored for the intensity and the distribution of staining. The correlations between TGFßR-1 expressions and the clinical and histological features including age, sex, etiology, histologic activity index, fibrosis score, tumor diameter and differentiation, vascular invasion, multifocality and presence of cirrhosis were analyzed. RESULTS: We observed staining with TGFßR-1 in

endothelial cells of central veins, sinusoids and portal veins, portal and sinusoidal macrophages, portal fibroblasts, few bile duct epithelial cells and lymphocytes. In hepatitis group, the only significant correlation was the one between fibrosis score and the intensity of TGFßR-1 staining. The intensity was positively correlated with the increasing fibrosis score ($p<0,05$). TGFßR-1 expression was sustained in active but decreased in inactive cirrhosis. The only significant finding in HCC group was the inverse correlation between tumor diameter and TGFßR-1 expression. The expression was significant in the smaller tumors (<3 cm), whereas it is less noticeable in the greater ones (>3 cm). But it was stable over 3 cm, even if the diameter gets bigger. CONCLUSION: TGFßR-1 expression increases in inflammation in correlation with fibrosis, sustains in active cirrhosis, decreases in inactive cirrhosis and during carcinogenesis, and almost disappears in HCC which is greater than 3 cm. These results support the idea that receptor down-regulation or mutation occur in the late stages of hepatocarcinogenesis.

PP1-98

COMPARING THE CLINICAL HISTOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL PROPERTIES OF 40 GASTROINTESTINAL STROMAL TUMOR CASES WITH EACH OTHER AND ACCORDING TO PROGNOSTIC FACTORS

Tugce Guzel Cay, Kemal Behzatoglu, Nevra Dursun, Erol Rustu Bozkurt, Bilgin Aksoy
The Ministry of Health Istanbul Training and Research Hospital, Turkey

AIMS: Gastrointestinal stromal tumors (GIST), which are originated from intestinal pacemaker cells (interstitial cells of Cajal , ICC) , which are normally found in bowell wall or originated from the neoplastic transformation of these cells' precursors, are the most common mesenchymal tumors of the gastrointestinal tract. In this study our purpose is to evaluate GISTs morphologically and immunohistochemically and compare their features with each other and according to the GIST risk table of Fletcher et. al. (20) and find the parameters that are important in GIST diagnosis and prognosis. MATERIAL AND METHODS: 40 GIST and extragastrointestinal GIST cases , which were diagnosed in Ministry of Health Istanbul Education and Training Hospital Pathology Department between 2000-2006 were retrospectively studied. Cases were gouped acording to location of the tumor, gender and age of the patient. Paraphine blocks of the cases were sectioned again as 4mm thicknes, stained with hematoxylen-Eosin and evaluated with light microscopy according to their mitosis, necrosis, tumor number, tumor diameter, cell type, cellularity, nuclear pleomorphism, ulceration, hemorrhage, lymphocytic cell infiltration, myxoid stroma, signet ring cell, skenoid fiber, mucosal invasion, collusion tumor. Immunohistochemicaly CD117, CD34, vimentin, smooth muscle actin (SMA), S100, desmin and ki-67 were studied. RESULTS: GıST cases were equally seen in both sexes and the median age was between 5.-6. decades. They were located in stomach (18 cases), small bowell (11 cases) , large bowell (4 cases) and extra-gastrointestinal tract location (7 cases). 100% of cases were positive for CD117, 90% were positive for CD34, 100% were positive for vimentin, 50% were positive for SMA, 20% were positive for S100 and 7,5% were positive for desmin. Ki-67 ratio was found >10% only in high risk group GIST cases. CONCLUSION: GISTs were mostly located in stomach and high risk GISTs were found in extra-gastric location in high proportion. (+++) cellularity, and (+++) nuclear pleomorphism were mostly found in extragastrointestinal system location GISTs; mucosal invasion, tumor necrosis, hemorrhage, signet ring cell, myxoid stroma, ulceration were mostly found in high risk GISTs. Lymphocytic cell infiltration parameter was not different between risk groups. In 4 cases which were operated for adenocarcinoma, GIST were found insidentally and these tumors were named as collusion tumors.

PP1-99

CLINICOPATHOLOGICAL VARIABLES AND THEIR CORRELATION WITH COX-2 EXPRESSION IN GASTROINTESTINAL STROMAL TUMORS

Ilhami Alkan, Huseyin Kemal Turkoz, Deniz Ozcan
Okmeydani Training and Research Hospital, Turkey

BACKGROUND: Tissue cyclooxygenase-2 (COX-2) plays important roles in carcinogenesis and tumor progression. Evaluation of COX-2 expression in malignincies has been performed mostly on tumors of epithelial origin and little is known about its presence in mesenchymal tumors, including gastrointestinal stromal tumors (GIST). COX-2 expression has been reported in GISTs and suggested as a potential diagnostic marker in a few articles. METHODS: We reexamined surgically resected 41 cases of GISTs in our hospital in last nine years. We evaluated COX-2 protein expression and immunohistochemical markers like CD34, CD117, desmin, smooth muscle actin and S-100 in GISTs and analyzed correlation of COX-2 expression with other clinicopathological markers. RESULTS: Mean age of the patients was 57, tumor size were between 1 and 26 cm. All cases were positive for CD117 and/or CD 34. COX-2 was expressed in 19 (%46) of all 41 tumors. Extent of expression was greater in tumors with higher mitotic index, coagulative necrosis and infiltrative pattern of growth. CONCLUSIONS: Overall COX-2 expression was not so high to make it a diagnostic tool in GISTs. Observation of greater COX-2 expression in GISTs with unfavorable histopathologic factors is against previous reports and consistent with reported roles of COX-2 in carcinogenesis and tumor progression of epithelial malignancies

PP1-100

EVALUATION OF BARRETT'S MUCOSA IN TERMS OF CK7, CK20, Ki67, p53, AND COX2 EXPRESSIONS USING CHROMOENDOSCOPIC OESOPHAGEAL BIOPSIES

Berna Savas[1], Arzu Ensari[1], Necati Ormeci[2], Isinsu Kuzu[1], Murat Palabiyikoglu[2], Sahin Coban[2], Nazmiye Kursun[3]
[1] Ankara University Medical School, Department of Pathology, Turkey
[2] Ankara University Medical School, Department of Gastroenterology, Turkey
[3] Ankara University Medical School, Department of Biostatistics, Turkey

Background: Barrett's mucosa (BM) is a complication of chronic gastroesophageal reflux disease and can be diagnosed when there is an endoscopically irregular Z line and intestinal metaplasia (IM) in a lower oesophageal biopsy. It is still not clear whether IM in the gastric cardia or columnar mucosa without IM in the lower oesophagus have any significance as BM which is considered as preneoplastic. Aims: To determine the immunohistochemical features of BM and columnar mucosa in the distal oesophagus and also to evaluate the value of chromoendoscopy in the diagnosis of BM in a prospective manner. Material & Method: A total of 18 chromoendoscopic biopsies (6 from normal looking unstained oesophagus, 6 from oesophageal mucosa stained with methyl blue-suspicious of BM, 2 from fundic mucosa, 2 from corpus mucosa and 2 from antral mucosa) were taken from 111 cases who underwent endoscopy because of a variety of upper gastrointestinal symptoms. Immunohistochemical analysis was performed using CK7, CK20, p53, Ki67, and COX2. Results: Of the 111 cases 19 cases with carcinoma (9 adeno, 5 squamous, 4 undifferentiated carcinomas) and 17 cases with normal squamous epithelium were excluded while 75 cases showing columnar epithelium including 46 (% 61.3) with IM and 29 (%38,7) without IM were further evaluated immunohistochemically. Chromoendoscopy yielded a sensitivity and specificity of 76% and 69%, respectively, while conventional endoscopy had a sensitivity and specificity of 54% and 77%, respectively, for the detection of BM. CK7 was observed in surface, crypt, and glandular epithelium whereas CK20 was expressed in surface and superficial crypt epithelium. No

significant difference was observed between the Barrett and non-Barrett type of CK7/20 staining pattern (p>0,05). Expression of p53 did not show any difference between BM and columnar mucosa without IM whereas Cox2 expression was significantly increased in BM (p<0.05) in comparison to columnar mucosa without IM. Ki67 expression was significiantly higher both in upper and lower crypts in BM (p<0.05). No significant difference was observed for the presence of gastric IM and H. pylori infection between BM (47.8%, 4.3%, respectively) and non-BM (24.1%, 13.8%, respectively). Conclusions: The present study showed that a Barrett pattern does not seem to exist however, there seems to be a CK pattern for the lower oesophageal mucosa different form gastric IM. Expression of Ki67 in the upper half of the crypts together with COX2 seems to be additional features of BM.

[2] University of Istanbul, Cerrahpasa Medical Faculty, Department of Gastroenterology, Istanbul, Turkey

Background: Gastrointestinal tuberculosis (TB) currently represents an uncommon disease in Western world; however it remains as an important cause of morbidity and mortality in developing countries and immunodeficiency patients. As the diagnosis in endoscopic biopsies is often very difficult, the aim of this study is to pay attention to the possibility of TB colitis and to avoid more invasive diagnostic procedures. Design: Clinical manifestations, pathological findings and diagnostic methods in endoscopically biopsied colonic tuberculosis patients were evaluated. Gastroenterology archives of the last five years were reviewed to find cases with tuberculous colitis. 10 cases which were diagnosed as tuberculosis according to clinical and microbiologic findings were found and their colonoscopic biopsy materials were reexamined in Pathology Department. Clinical and histopathologic features of these cases were analyzed and compared with the results of other diagnostic methods. Results: All of the 10 cases had chronic diarrhea and investigated by colonoscopy and microbiologic analysis to differentiate especially inflammatory bowel disease and infectious colitis. Ulcers and erosions were common endoscopic findings. In the colonoscopic biopsies, granulomas were observed in colonic mucosa or submucosa of all cases, with suppuration of granulomas in 9, caseous necrosis in 4, and ulceration in 8 cases. Ziehl-Neelsen (ZN) stain revealed presence of acid fast bacilli in 5 cases however tissue culture and PCR studies for mycobacterium were found positive in all cases. Conclusion: The results of this study demonstrated that in colonoscopic biopsies of tuberculous patients, granulomatous colitis is the common diagnosis mostly with suppuration and ulceration; however EZN stain is less sensitive than PCR results.

[3] Digestive Endoscopy, Department of General Surgery, University of Brescia, Spedali Civili - Brescia, Italy

Background: HER2/neu protooncogene results to be overexpressed/amplified in preneoplastic lesions and in adenocarcinoma (ADC) of the esophagus. Thus, HER2 could be considered a target for both chemoprevention and treatment of esophagus dysplasia/ADC. Our aim is to evaluate the therapeutic role of the anti-HER2 monoclonal antibody, trastuzumab, in the management of ADC derived from HER2-positive Barrett's esophagus (BE). Methods: We selected two patients after esophageal mucosectomy with a histological diagnosis of HGD and ADC of the esophagus without distant metastases. Patients were considered not eligible for radical surgery or chemo-radiotherapy because of age and comorbidities. The treatment was administered after ethical institutional approvation and patients' written informed consent was obtained, and consisted of four cycles of monotherapy with trastuzumab every 3 weeks. Patient #1 received four cycles at a dose of 6 mg/kg, and patient #2 received trastuzumab at a loading dose of 4 mg/kg and 2 mg/kg as maintenance dose. The different doses were chosen on the basis of cardio-vascular conditions of the patients. Trastuzumab was administered as an iv infusion according to the manifacturer's instructions. HER2 status was studied by IHC and FISH. Additional immunohistochemical analyses were performed. The whole panel was analysed at baseline, after treatment and then at scheduled follow-up controls. Results: At baseline, the two patients showed HER-2 overexpression/amplification in all areas of dysplasia and ADC but not in BE. Trastuzumab treatment was well tolerated without any acute or delayed toxicity. Early evaluation after treatment revealed no significant differences in terms of endoscopical and immunohistochemical patterns of the disease. However, in the patient who received the higher doses of trastuzumab, a downregulation of HER2 overexpression and an increase of the apoptotic index was observed six months after treatment. Conclusion: This study demonstrates that this treatment is feasible. No clear evidence of dysplasia regression was observed. However, the observation that HER2 downregulation and induction of apoptosis occurred 6 months after treatment, suggests that a dose-intensified regimen with trastuzumab alone should be investigated in a phase I-II dose-finding study.

PP1-103

EXPRESSION OF BONE MORPHOGENETIC PROTEINS AND THEIR RECEPTORS IN GASTRIC ADENOCARCINOMAS AND THEIR NODAL METASTASES

Angeliki Cheva, Prodromos Hytiroglou, Vassiliki Kotoula, Georgios Karkavelas

Department of Pathology, Aristotle University, Medical School, Thessaloniki, Greece

Background: Bone morphogenetic proteins (BMPs) are multifunctional cytokines, which belong to the transforming growth factor-β (TGF-β) superfamily. So far, more than 20 mammalian BMPs have been identified and they are divided into several subtypes based on their structure. BMPs play an important role in the differentiation, proliferation, apoptosis and survival of different cell types. They are also involved in a variety of biological effects which are related to homeostasis and chemotaxis, like the migration of cells, or their activation in emergency situations. There is evidence that the BMPs are implicated in several aspects of embryonic development, from the establishment of the basic embryonic body plan to the morphogenesis of several organs, but also in the regular functions of normal cells during adulthood. Recent studies have demonstrated the involvement of BMPs and their receptors in the development of a variety of pathologic conditions, including several human tumors, such as carcinomas. Method: In this study, we have investigated the expression of BMPs and their receptors in gastric adenocarcinomas (12 gastric adenocarcinomas were of the diffuse, and 17 of the intestinal type). Immunohistochemical stains were performed by a standard streptavidin-biotin method

and we used commercially available goat polyclonal antibodies for BMPs (-2, -4, -6 and -7) and for their receptors (BMPRIa, BMPRIb). Results: BMPs and their receptors were expressed both in diffuse and in the intestinal type of gastric adenocarcinomas. BMP-6 was expressed in larger quantities in the intestinal type of gastric adenocarcinoma than in the diffuse type. In addition, there were statistically significant differences in the expression of BMP-6 between the neoplastic cells of the primary tumors and those of the nodal metastases of gastric adenocarcinomas.

PP1-104
HISTOLOGICAL EVALUATION OF LIVER OF CHILDREN WITH AUTOIMMUNE HEPATITIS AT INITIAL DIAGNOSIS AND FOLLOW-UP MANAGEMENT BIOPSY

Nermine Ehsan[1], Menen Salem[2], Behairy Behairy[2], Mohsen Hussein[2], El-Sayed Salama[2]
[1] Department of Pathology, National Liver Institute, Menoufiya University, Egypt
[2] Department of Pediatrics, National Liver Institute, Menoufiya University, Egypt

Autoimmune hepatitis (AIH) is a chronic liver disease characterized histologically by interface hepatitis, portal plasmalymphocytic infiltrate and parenchymal inflammation. Hepatic fibrosis and cirrhosis occur in many types of chronic liver injury including AIH. Recent studies have reported that hepatic fibrosis and cirrhosis may be reversible in some patients with AIH that respond to treatment. Therefore the objectives of this study were to compare between histological assessment of liver tissues of children with AIH at initial diagnosis and follow-up management biopsies regarding histological activity index (HAI), nature of inflammatory infiltrate and the stage of liver fibrosis. Nineteen patients with AIH who responded to medical therapy and had follow-up liver biopsy were included in this study. Paraffin embedded liver tissues were used for assessment of histological activity and stage of fibrosis according to Ishak et al (1996). Results revealed that the median HAI decreased from 11.8 to 3.2 ($p=0.003$) and the median fibrosis score decreased from 3.6 to 1.9 ($p=0.09$). The nature of the inflammatory infiltrate was predominantly plasma cell with few eosinophils at initial diagnosis biopsy whereas it was predominantly eosinophils with occasional plasma cells at follow-up biopsies. A significant number of biopsies at initial diagnosis revealed sclerosing cholangitis that was not present at follow-up biopsies. Data from this study demonstrate a significant improvement in follow-up management liver biopsies from initial diagnosis biopsies, in patients who responded to medical treatment, regarding histological activity and stage of fibrosis.

PP1-105
RETINOL BINDING PROTEIN 4 (RBP4) EXPRESSION IN NONALCOHOLIC FATTY LIVER DISEASE (NAFLD)

Dina Tiniakos[1], Maria Schina[2], John Koskinas[2], Despina Karandrea[1], Emmanuel Manesis[2], Emilia Hadziyannis[2], Savvas Savvas[2], Vassilios Karamanos[2], Athanassios Archimandritis[2], Christos Kittas[1]
[1] Laboratory of Histology & Embryology, Medical School, University of Athens, Greece
[2] 2nd Department of Internal Medicine, Medical School, University of Athens, Hippokration General Hospital, Athens, Greece

Background: RBP4 is a novel adipokine mediating systemic insulin resistance. Insulin resistance plays a central role in the pathogenesis of NAFLD. We aimed to evaluate for the first time RBP4 liver tissue expression in NAFLD. Method: We used immunohistochemistry with a polyclonal antiserum to RBP4 (Phoenix Pharmaceuticals, Belmont, CA) on needle liver biopsies from 30 NAFLD patients (mean age 51 y, range 18-76, M/F: 3/2, mean BMI 29 range 22.1-40.9, normal oral glucose tolerance test-OGTT 17, impaired OGTT 13, mean serum ALT 80 IU/L range 22-308, simple steatosis 13, NASH 17: global grade 1 n=7, 2 n=8, 3 n=2, fibrosis stage 1 n=10, 2 n=4, 3 n=1, 4 n=2) and on normal liver tissue from 10 adults. NAFLD biopsies were assessed histologically according to Brunt et al, 1999 and Kleiner et al, 2005. RBP4 immunohistochemical expression was semiquantitatively evaluated (0-3) in each acinar zone and a summative RBP4 total score (RBP4 score, range 0-9) was issued for each case. Results: Anti-RBP4 produced mild cytoplasmic hepatocellular immunostaining, which in normal liver was mostly evident in zone 3 (RBP4 score range 1-3). In most NAFLD cases, RBP4 immunopositivity was more intense in zone 3 and milder in zones 2 and 1 or periseptal areas (RBP4 score 4-8). Inverse or no zonation was observed in high grade or high stage NASH. RBP4 score was significantly higher in NAFLD compared to normal liver and was correlated with male sex ($p<0.01$) and grade of steatosis ($p<0.01$). In the subgroup of NASH, RBP4 score was positively correlated with grade of activity ($p<0.01$) and stage of fibrosis ($p<0.05$). There was no correlation of RBP4 score with age, serum ALT, BMI or OGTT. Conclusions: In normal human liver, RBP4 is mildly expressed by zone 3 hepatocytes. In NAFLD, zonal RBP4 hepatocellular expression is increased. In NASH, elevated RBP4 expression is related to increased disease severity and high fibrosis stage.

PP1-106
CLINICOPATHOLOGICAL STUDY ON CHOLANGIOLOCELLULAR CARCINOMA SUGGESTING HEPATIC PROGENITOR CELL ORIGIN

Mina Komuta[1], Sara Vander Borght[1], Masamichi Kojiro[2], Raymond Aerts[2], Tania Roskams[2]
[1] K. U. Leuven, Belgium
[2] Kurume University, Belgium

BACKGROUND AND AIMS: Cholangiolocellular carcinoma (CLC), a subtype of cholangiocarcinoma (CC), is thought to originate from Hering's canal, where hepatic progenitor cells (HPCs) are located. Since HPCs can differentiate into both cholangiocellular and hepatocellular direction, we studied these phenotypes in CLC. MATERIALS AND METHODS: We clinicopathologically studied 30 CLC cases. Immunohistochemical analysis was performed using hepatocytic markers (Hepar, canalicular polyclonal carcinoembryonic antigen (pCEA), CD10), biliary/hepatic progenitor cell markers (cytokeratin (CK) 7, CK19 and Neural cell adhesion molecule (NCAM)) and the ATP binding cassette (ABC) superfamily of membrane transporters, (MDR1, MRP1, MRP3, and BCRP). RESULTS: 29/30 (96.7%) CLC were associated with chronic hepatitis and/or cirrhosis. Gross findings were similar to CC: whitish color, solid, not encapsulated. CLCs formed small monotonous anastomosing glands and cords and sometimes small trabeculae with abundant fibrous stroma. The tumor cells varied from small cuboidal in the glandular areas to larger, with larger eosinophilic cytoplasm in the trabeculae areas. At the tumour boundary, all cases had replacing growth pattern like HCC. CLC, HCC-like and CC areas coexisted in various degrees in the tumors and these three different histological pattern showed transitional formation with each other. The tumor mainly consisted of CLC area, and the HCC like and CC like-areas occupied less than 10% of tumour area. On CK7 and CK 19 stains, surrounding liver showed HPCs activation. In the glandular areas tumour cells were reactive for CK19 and CK7 in a strong cytoplasmic pattern, 19/30 (63.3%) cases had focal mucin production and pCEA showed cytoplasmic reactivity. 100% of tumours showed hepatocellular differentiation in the trabecular area, characterized by submembranous CK7 expression and canalicular staining patterns for CD10 and pCEA. In CLC area, 26/30 cases (86.7%) were positive for NCAM. MDR1 showed a diffuse apical staining pattern and the expression IN CLC areas was up-regulated in comparison with

surrounding normal cholangiocytes. MRP1, MRP3 and BCRP showed a diffuse basolateral staining pattern. CONCLUSIONS: 100% of CLC show hepatocellular differentiation in part of the tumour and more than 80% of cases showed expression of HPCs markers. These findings highly suggests a progenitor cell origin of this subtype of CC. The MRP1, MRP3, MDR1 and BCRP up-regulation in CLC area is similar to what is seen in non-tumoral HPCs and provides these cells with a multidrug resistant phenotype.

[3] Cytology Dpt Volos General Hospital, Greece
[4] Radiology Dpt Volos General Hospital, Greece
[5] Surgery Dpt Volos General Hospital , Greece

Medullary carcinoma or carcinoma with lymphoid stroma is an unusual gastric neoplasm, subclassified as a separate entity and consisting of 3.5-4% of gastric carcinomas, according to the literature. We report the case of a 79 year old woman, who presented with dyspepsia and anaemia. CT examination revealed a polypoid mass measuring 5x6 cm, at the greater curve of the gastric body and ulcerated according to endoscopy. Cytological examination of imprints was suggestive of carcinoma with a heavy inflammatory component. Biopsy material consisted of necrobiotic and malignant neoplastic tissue. The cells of the latter where of medium or large size, with scanty cytoplasm and hyperchromatic nuclei, showing slightly increased mitotic activity. They formed irregular, mostly small nests or lined pseudoglandular and slit-like spaces. Immunohistochemistry substantiated the epithelial nature of the neoplasm (strongly positive for pankeratin and focal positivity for CEA). The stroma was desmoplastic and highly vascularized, with an extensive lymphocytic infiltration mainly composed of T-cells (CD3+). Histological diagnosis was strongly suggestive of medullary carcinoma and the patient underwent surgery (partial gastrectomy). Microscopical findings of the surgical specimen were similar to bioptic ones. It was a moderately differentiated carcinoma with lymphoid stroma and early infiltration of the muscularis mucosa (less than 1/3), while lymph node metastases were not detected. The special stain for Helicobacter pylori was negative.The immunophenotype of the carcinoma was: pankeratin (+), CEA (+focally), CA19-9 (+), CA15-3 (+), CK8 (+), CK18(+), CK19(+), CK4,7,10/13,14,20(-), and the majority of the T-population were CD8+. The patient received no adjuvant chemotherapy. She presented with reccurrence and fatal haemorrhage six months later.

PP1-108
ALTERED EXPRESSION OF E-CADHERIN IN PRECANCEROUS LESIONS AND GASTRIC CANCER CAN SERVE AS A DIAGNOSTIC MARKER

Maria Demonakou-Vatopoulou, Ekaterini Pierrakou, Lora Manolia, Anastasia Sakka, Nikolaos Tamvakis
Sismanoglion General Hospital Maroussi Athens Hellas , Greece

BACKGROUND: E-cadherin is important for cell-cell adhesion of epithelial cells. Decreased expression has been observed in gastric cancer by immunohistochemical method. Studies also along the Correa's cascade showed that the membranous pattern alters gradually in normal gastric epithelium, in chronic atrophic gastritis, intestinal metaplasia, and dysplasia and eventually in adenocarcinoma. AIM: We study the expression of E-cadherin in gastric Dysplasia/Intraepithelial Neoplasia (IEN), indefinite dysplasia, Reactive hyperplasia and Gastric Cancer to search for a marker which could be used in guiding the pathological diagnosis of these lesions. METHODS: The E-cadherin expression (DAKO: 1/10) evaluated in gastric tissues of 52 patients (34 men and 18 women), by immunochemistry with a standard Envision technique in formalin-fixed and paraffin-embedded specimens. E-cadherin expression was evaluated as Membranous, Cytoplasmic, Cytoplasmic/Membranous in samples from 18 Indefinite dysplasia/Reactive hyperplasia (Vienna Group 2) (34, 6%), 17 gastric Dysplasia/IEN (Vienna Group 3 & 4) (32, 7%) and 17 Gastric Cancers (Vienna Group 5) (32, 7%) In addition Pearson's Chi-square test with continuity correction and t-test was used to investigate the correlation of E-cadherin expression type with Vienna groups (G2, G3/4, and G5) RESULTS: The membranous type identified in 16 cases: 14 RH/IDys(G 2) and 2 cases of IEN (G 3/ 4). Cytoplasmic / membranous type diagnosed in 12 cases: 4 RH/IDys(G2), 7 IEN(G3/4) and 1 GC.(G5).Cytoplasmic staining was found in 24 cases: 16 GC(G5) and 8 IEN(G3/4) In G2 membranous type was found in 14(77.8%) cytoplasmic/membranous in 4 In G3/4 membranous type was found in 2 (11.7%), cytoplasmic / membranous in 7(41.1%) and cytoplasmic in 8 (47.05) .In G5 cytoplasmic staining was found in 16 (94.1%) and cytoplasmic / membranous in 1 Normal cytoplasmic staining decreased gradually between Vienna Groups (G2: 77, 8%, G3/4:11, 7%, G5:0%) Abnormal cytoplasmic expression of E-cadherin increased gradually between Vienna Groups (G2:0%, G3 /G4:47.05%, G5:94.1%) had a significant difference, ($p<0.05$) and ($p<0.01$) CONCLUSION: There is altered expression of E-cadherin in gastric IEN and gastric carcinoma. Cytoplasmic expression of E-cadherin can be used as a marker to differentiate gastric IEN from reactive epithelial lesions.

PP1-109
THE RELATIONS BETWEEN CLINICOPATHOLOGIC/PROGNOSTIC FACTORS AND CD44S EXPRESSIONS OF OESOPHAGEAL SQUAMOUS CELL CARCINOMA

Serkan Senol[1], Mustafa Izmirli[2], Irfan Bayram[1], Mahmut Ilhan[3]
[1] Yuzuncu Yil University, Faculty of Medicine, Department of Pathology, Turkey
[2] Yuzuncu Yil University, Faculty of Medicine, Department of Radiation Oncology, Turkey
[3] Yuzuncu Yil University, Faculty of Medicine, Department of Medical Oncology , Turkey

AIM: CD44 is an adhesion molecule which is a member of the cell adhesion molecules family hyaladherins. CD44 has some effects including tumor-endothel interaction, cell motility and migration, cell adhesion and tumor invasion, tumor progression, and metastasing. In this study, we aimed to evaluate the relationship between survival rates and CD44 expressions in patients with ESCC. MATERIAL AND METHODS: Between 1999 to 2004, pathologic specimens belonging to 35 patients were examined by the Yuzuncu Yil University (YYU) Medical Faculty's Department of Pathology. In addition, clinical and laboratory findings were collected from medical records. The relations between clinical, laboratuary, histopathologic findings and survival rate, prognosis, and the status of CD44s expressions were examined. RESULTS: 13 patients were well-differentiated, 18 were moderately differentiated, and 4 were poorly differentiated. Inflamatory reactions were observed in 23 cases. The ratios of stained CD44 were positive in 32 patients and negative in 3 patients. The concentration of stained CD44 was positive in 30 and negative in 5 patients. The median survival periods were 5.2 months and the one year and two year survival rates were %34.4 and %11.3, respectively. We did not detect any correlation between CD44 expressions to survival and prognosis. The treatment options, response to chemotherapy, clinical stage and tumor size influenced the survival outcome in univariant analysis. In contrast, only tumor size at time of diagnosis was significant in multivariant analysis. ($P=0.045$). CONCLUSION: Tumor size at the time of diagnosis was found to be a valuable

factor on the survival and evaluation of the prognosis. CD44 expressions and its variants were absent as prognostic factors. We concluded that CD44 may act as a valuable parameter on metastatic and local advanced tumour cases because most of our patients have positive CD44 expressions.

PP1-110
ENDOSCOPIC ULTRASOUND GUIDED BIOPSY IN ROUTINE-DIAGNOSTICS

Knolle Jurgen[1], Hubner Georg[2], Häder Andreas[2], Marcy Tobias[3], Schutte Wolfgang[4], Hölsken Antje[1]
[1] Institute of Pathology, City Clinic Dessau, Germany
[2] Clinic of Internal Medicine II, Regional Hospital Koethen, Denmark
[3] Clinic of Abdominal Surgery, Regional Hospital Koethen, Denmark
[4] Clinic of Internal Medicine II, Martha-Maria Hospital, Halle-Doelau, Denmark

Background: Endosonography will be used more and more as a diagnostic tool for solid tumors of the upper gastrointestinal tract. Among a random sample of patients the efficiency of the method according to gained tissue samples for histological and cytological examination and their clinical validity was examined prospektive. So far little data is available on the efficiency of endosonographical punctions outside specialized centres. There are no standards for the processing of endosonographically gained tissue samples. There is only little data available on the gained tissue samples for histological serial sections with the 22-G-needle at endosonographical punctions. Patients and methods: On 40 patients (median 67 years, 17 female) endosonographical punctions of the upper gastro-intestinal-system (22 mediastine, 7 esophagus- and stomach-wall, 6 pancreas and 5 retroperitoneum) were conducted with a longitudinal ultrasoundendoscope (HITACHI EG-3830UT) and a 22-G-needle (Sono Tip II, HITACHI Medical Systems GmbH). The acquired material was completely fixed in formaline 4% and only in the pathology separated for histology (embedded in paraffine for a minimum of 8 serial sections and the zytology (cell-block-cytology using the cyto-zentrifuge at 1500 rpm (rounds per minute) universal16A zentrifuge). The reference procedures to assess the clinical validity were an independent histological diagnosis through surgery or biopsy (n=10) or the results of other clinical imaging procedures and further clinical observations. Results: With 24 out of 40 patients a histological examination of the tissue sample could be conducted (17 as immuno-histochemical test) and in 21 cases a histological diagnosis was stated. Among the remaining 16 cases a diagnosis was found via cytological examination for 14 patients. Using histological and cytological examination the sensitivity was 78%, the specificity was 100%, the accuracy was 82% and a positive predictive value of 100% and a negative predictive value of 50% was reached. Conclusion: The embedding of the whole tissue sample acquired through endosonographical punction in formaline simplifies its postinterventional processing and allows both histological and cytological testing. Using both histological and cytological examinations on each tissue sample probably guarantees the most accurate diagnosis.

PP1-111
THE EFFECT OF MMP-26 GENE EXPRESSION IN TUMORIGENESIS AND INVASIVENESS OF GASTRIC CARCINOMA

Talha Karabiyik[1], Gulen Bulbul Dogusoy[2], Melih Paksoy[3], Ahmet Korkut Belli[3], Fatih Aydogan[3], Sibel Erdamar Cetin[2], Suha Goksel[2], Nuray Kepil[2], Meliha Burcu Irmak Yazicioglu[1]

[3] Istanbul University, Cerrahpasa Medical Faculty, Department of Surgery, Istanbul, Turkey

Background: The matrix metalloproteinases (MMPs) contribute to the invasive and metastatic abilities of a variety of malignant tumors. Among these MMPs, MMP-26 has been described to take role in invasion and metastasis of cancers of epithelial origin including choriocarcinoma, breast and prostate carcinoma. Moreover, MMP-26 gene, as well as MMP-7 gene, is a target of Wnt-signaling pathway, being regulated by β-catenin. There is a striking relation between Wnt pathway and gastric carcinogenesis. Alterations of genes in this pathway, such as mutations of β-catenin and E-cadherin, have been illustrated in gastric carcinoma cases, indicating deregulation of this pathway during gastric carcinogenesis. Design: In this study, the involvement of MMP-26 gene in invasion and metastasis of gastric tumors was analyzed, and the roles of MMP-7 and β-catenin were also studied. Twenty gastric tumor samples were studied. The expression levels of MMP-26, MMP-7, and β-catenin were investigated by semiquantitative RT-PCR. Results: MMP-26 expression was observed neither in normal nor in tumor biopsy specimens. MMP-7 expression was seen in almost half of the gastric tumor samples. β-catenin expression was detected in some tumor tissues as well as in some normal tissues. No biopsy specimen showed MMP-26 expression. MMP-7 expression was observed in 9 of 20 gastric tumor biopsies. β-catenin expression was detected in both normal and tumor tissues. 9 out of 20 samples showed β-catenin expression in tumor biopsies. Among those only 3 samples expressed only β-catenin while the rest had expression in also normal biopsy samples. Among 9 β-catenin positive samples, 3 also had MMP-7 expression. Conclusion: MMP-26 was not expressed in gastric carcinomas, however MMP-7 was positive. Our reults are preliminary and this project is continuing until significant results will be found. This project is supported by the Scientific Research Fund of Fatih University under the project number P50030503 and by TUBITAK under the project number 105S352 (SBAG-K-110).

SINONASAL LEIOMYOMA. REPORT OF A NEW CASE.

Farah-Klibi Faten, El Amine Olfa, Kourda Nadia, Tayahi Basma, Ferchiou Malek, Kouda Jihen, Sarrah Baltagi Ben Jilani, Zermani Rachida
Charle Nicolle's Hospital Department of Pathology, Tunisia

Most of the sinonasal tumours are of epithelial origin. Leiomyomas are benign smooth-muscle tumours that are common in the alimentary tract, uterus, skin and subcutaneous tissue. They are very uncommon in the upper respiratory tract and extremely rare in the nasal cavity and paranasal sinuses. They account for less than 2.5% of the mesenchymal neoplasms of the sinonasal tract and the nasopharynx. To the best of our knowledge, only 23 cases of primary leiomyogenic tumours have been reported in the sinonasal tract with almost an equal frequency of benign and malignant types. We report a case of 48-year-old woman presenting a leiomyoma of the sinonasal cavity. The clinical and pathological characteristics of this tumour will be discussed.

PP1-113
SIGNET-RING CELL CARCINOMA OF THE SMALL INTESTINE AROUND CROHN DISEASE : ANALYSE OF BRAF MUTATION

Nese Calli-Demirkan, Lale Satiroglu-Tufan, Cigdem Berna Ege, Aysen Cetin
Department of Pathology, School of Medicine, Pamukkale University, Denizli ,Turkey

It has been recently identified a clinically distinct subgroup of colon adenocarcinomas having high incidence of BRAF mutation. We have observed a signet-ring cell carcinoma of the small intestine in an old patient with long- standing chronic inflammatory disease. The aim of this case report is to emphasize the importance of the BRAF gene mutation in the carcinogenesis

occurring in chronic inflammatory disease. BRAF is a member of the MAP kinase pathway, which mediates cellular response to growth signals. T1796A transversion mutation of BRAF gene identified in melanomas and colon carcinomas causes missense coding of glutamic acid rather than valin amino acid at position 599. BRAF mutations appear to be a later event in ulcerative colitis-related carcinogenesis and do not occur in corresponding nondysplastic mucosa of patients with UC-related cancer. In our case, BRAF V599E mutation has been investigated by the amplification of DNA segment including 1796 nucleotide region with polymerase chain reaction and direct DNA sequencing. We did not detect any mutation of BRAF gene neither in tumoral lesion nor in the adjacent inflammatory mucosa. Studies are underway to analyze BRAF mutations including G-to-T transversion at nucleotide 1382, T-to-G transversion at nucleotide 1385, and G-to-A transition at nucleotide 1388.

PP1-114
TUMOR-ASSOCIATED TISSUE EOSINOPHILIA IN COLORECTAL ADENOCARCINOMAS

Charalampos Charalampidis[1], Ch. Tsobanidou[2], Ch. Charalampidis[3], A. Chatzitolios[3], I. Moschos[4]
[1] General Hospital Of Drama, Greece
[2] Histopathology Department, Medical Center, Veria, Greece
[3] Pathology Department, General Hospital of Drama, Greece
[4] Gastroenterology Department, Medical Center, Thessaloniki , Greece

Background Tumor-associated tissue eosinophilia has been described in many sites, including colorectal region. The exact role of tumor-associated tissue eosinophilia in tumors has not yet been defined, and its presence has been related to a good and to a poor prognosis or even having no influence on patients outcome. The aim of this study was to examine the presence of tumor-associated tissue eosinophilia in colorectal carcinomas and their relationship with clinicopathologic parameters such as tumor size, histological grade, histological stage and age of the patients. Material and Methods 132 patients (78 males and 54 females) with colorectal carcinomas who have been treated surgically were examined retrospectively. The tumor specimens have been examined for tumor-associated tissue eosinophilia and reviewed by two pathologists. The carcinomas were 62 well differentiated, 48 moderate differentiated and 22 poorly differentiated neoplasms. According to the modified Dukes classification the carcinomas were A:13 , B:54, C:35, D:30 respectively. The diameter of the tumors was 1,1 to 6 cm (mean size 3,2 cm). The age of the patients ranged from 32 to 80 years (mean age 58 years). Eosinophil infiltration was classified as “marked”, “moderate” and “mild” according to density of the stromal infiltrate. These indicate eosinophil infiltration over 200 in a high power field (hpf) (x400), that ranged from 100 to 200, or with less than 100 eosinophils, respectively. Results Marked to moderate eosinophilic infiltration was found in 51 (82,2%) of poorly differentiated, 30 (62,5%) moderately differentiated and 13 (59%) of well differantiated adenocarcinomas. Marked to moderate eosinophilic infiltration was observed in 4 cases (30,7%) of adenocarcinomas stage A, in 23 cases (42,5%) stage B, in 25 (71,4%) stage C and 28 (93,3%) stage D. There was no correlation between marked to moderate eosinophilic infiltration and size of the tumors. An association of marked to moderate eosinophilic infiltration with advanced age was noticed. Conclusions Our data have shown that high rates of tumor-associated tissue eosinophilia could represent a favourable prognostic factor in colorectal adenocarcinomas. These findings could help to elaborate a therapeutic strategy in specific subgroups of patients.

TH1/TH2 SERUM CYTOKINES IMBALANCE AND THEIR RELEVANCE TO SEVERITY OF DISEASE IN HCV- RELATED LIVER CIRRHOSIS

Afaf Ahmed Abdel Hadi, Abulla El Desoki, Mervat El Damrawi, Olfat Hammam, Ahmed Sadek, Ahmed Abel Hady
Theodor Bilharz Research Institute, Egypt

Objective: Hepatitis C virus is a RNA virus responsible for the majority of post transfusion non-A, non-B hepatitis worldwide. T lymphocytes and immunoregulatory cytokines may be important in the host response to hepatitis C virus (HCV) infection. T helper type one (Th1) cytokines (interleukin [IL]-2, interferon gamma [IFN-γ] and tumor necrosing factor alpha [TNF-α]) are required for host antiviral immune responses, including cytotoxic T-cell generation and natural killer cell activation, while T-helper type 2 [Th2] cytokines (IL-4, IL-6 and IL-10) can inhibit the development of these effector mechanisms. Cytokines’ pattern was suggested to play an important role in the development of liver fibrosis and cirrhotic transformation in chronic viral infection. Aim of this study is to clarify the relationship between the balance of Th1 and Th2 cytokines production and liver damage in HCV infection. Materials and methods: The study was conducted on 62 patients with chronic HCV infection and 20 apparently healthy subjects as a control group. Patients were classified according to histopathological examination and staging of liver fibrosis into three groups [S2 (22 patients), S3 (18 patients) and S4 (22 patients)]. Circulating Th1 and Th2 cytokines were measured by enzyme linked immunoassay (ELISA) in all subjects. Collagen I and III reflecting stage of liver fibrosis, were evaluated by using indirect immuno-histochemical technique in all patients. Results: Serum Th1 cytokines (TNF-a, IL-2, IFN-g) are significantly elevated in all patient groups versus control group. Regarding IL2 level, it shows non significant changes in all studied groups. Levels of serum Th2 cytokines are dramatically elevated in all patient groups compared to normal group. Serum cytokine levels are correlated directly with progression of hepatic fibrosis stage and parameters of liver injury (ALT & bilirubin levels) but inversely with hepatic synthetic parameters (Prothrombin concentration & albumin level). Conclusion: A continued balance between Th1 and Th2 cytokine levels must be critical for normal immunoregulation. Consequently, further extensive studies on the imbalance of the cytokines network are required to improve the therapeutical approach in patients with chronic HCV infection.

PP1-116
STUDY OF DNA PATTERN CHANGES UNDER THE USE OF 5% ETHANOL AMINE OLEATE AND HISTOACRYL DURING ERADICATION OF ESOPHAGEAL AND GASTRIC VARICES

Ahmed Abdel Hadi[1], Olfat Hammam[1], Alaa Noh[2]
[1] Theodor Bilharz Research Institute, Egypt
[2] Monofya University, Egypt

Esophageal varices are one the most health emergencies in Egypt. Although bleeding from gastric varies is not as common as esophageal varices, it is always a serious and difficult problem. Aim of the work : to evaluate the use of the hypertonic glucose water as a sclerosing material in esophageal, esophageogastric and gastric varices with studying the DNA pattern of the mucosa , and its effect on the outcome of sclerotherapy and the proliferating index present in correlation with S phase fraction of cell cycle. Material and Methods: This study was carried out on 75 patients , they were grouped into:Group I: esophageal varices :Subgroup 20 patients treated with injection of glucose 50%.Subgroup IB: 20 patients treated with injection of Ethanol amine oliate. Group II: Fundal varices:Subgroup IIA: 10 patients treated with injection of glucose 50%.Subgroup IIB: 10 patients treated with injection of Histoacryle. Group III: 15 patients are control. Endoscopic biopsies taken. Sections were stained by

haematoxyline and eosin for routine examination, feulgen stain for DNA evaluation using Cell Image analyser and indirect imuonohistocheistry for proliferating cell nuclear (PCN). Results: Esophageal varices cases, the S phase fraction showed significant increase in both subgroup IA and IB compared to control group ($p<0.01$) on the expense of cells at 2C. PCNA nuclei increased in both subgroups IA+IB and subgroups IIA+IIB compared to control cases $p<0.01$. In esophageal varieces patients injected by 50% glucose (subgroup IA), showed the majority of histogram are diploid histogram with marked increase in S phase (60%), while patients treated by injection of ethanolamine oliate, elaborated aneuploid histogram in (30%). In fundal varieces cases treated by injection of 50% glucose elaborated aneuploid histogram in 50% of the cases, while patients treated by injection of histoacryle, elaborated aneuploid histogram in 70% of cases. Conclusion: Glucose 50% and ethanolamine oliate were coparable to each other as regard the cessation of bleeding but Glucose 50%had less hazardous effect on the mucosa of the esophagus as regards histopathological study, did not cause any marked lesions of the mucosa whether acute or chronic and had lesser damage on the DNA content of mucosal cells than ethanolamine oliate as regards the cell image analysis.

PP1-117

DNA PLOIDY AND P53 OVEREXPRESSION IN PAPILLA OF VATER IN CASES WITH OBSTRUCTIVE JAUNDICE: IMMUNOHISTOCHEMICAL STUDY

Ahmed Abdel Hadi[1], Olfat Hammam[1], Alaa Noh[2]
[1] Theodor Bilharz Research Institute, Egypt
[2] Monofya University, Egypt

Carcinoma of the papilla of Vater has a relatively good prognosis when compared with the case of other biliary tract neoplasm such as pancreatic carcinoma or bile duct carcinoma. Our aim is to evaluate the clinicopathologic features and the alteration of the p53 tumor suppressor gene using p53 and the DNA ploidy of papilla of Vater epithelium. Patients and methods: The study included 70 patients had obstructive jaundice due to papillary lesions. The patient's were 40 adenocarcinoma, 10 cases pure adenoma of the papilla of Vater and 15 chronic papillitis as well as 5 patients had normal papilla as a control. We used imunohistochemistry technique for detection of p53 suppressor gene and Cell image analyzer to detect the DNA content of the epithelium through staining the tissue by feulgen stain. Results: The patients were 34 to 76 years, 42 male and 28 female. The papillary adenocarcinoma was well differentiated in 10 cases, moderately differentiated in 22 cases, and poorly differentiated in 8 cases. Positive staining for p53 protein was found only in the nuclei of tumor cells .Positive reaction for p53 were 0% on papillitis and in normal mucosal tissue , 20%(2/10) in adenomas , 50% (20/40) in adenocarcinoma. The percentage of p53 overexpression in adenocarcinoma was 48% (7/15) for early carcinomas and 51.8% (13/25) for advanced carcinomas. All cases of papillitis and adenoma exhibit DNA diploid histogram, while 16/40 (40%) of adenocarcinoma cases exhibit diploid histogram and the rest of cases 60% (24/40) exhibit aneuploid histogram. There was increase in the number of cells at the proliferative S phase in the chronic papillitis, adenoma and adenocarcinoma compared to control cases $p<0.01$and $p<0.05$ respectively.In conclusion; The p53 may be useful in the diagnosis of carcinoma of the ampulla of Vater.The DNA ploidy can help in diagnosis and outcome of papillary neoplasms. Our results confirm that this group of tumors are heterogeneous and underline the need for earlier markers of an aggressive behavior.

PP1-118

THE ROLE OF EPIDERMAL AND TRANSFORMATING GROWTH FACTOR β IN GENESIS OF CHRONIC H.PYLORI - ASSOCIATED GASTRITIS IN CHILDREN

Eugene Kazachkov, Angela Kazimirova, Polina Tselischeva
State Medical Academy, Chelyabinsk, Russia

Aim – to study the role of epidermal growth factor (EGF) and transformating grow factor-β (TGF-β) in the development of chronic HP-associated gastritis in children. Material and methods. The gastrobioptats of 45 children of school age with chronic HP-associated gastritis were examined. Comparing group gastrobioptats of 15 pupils with functional dyspepsy. To assess the proliferative stomach epithelium activity, intensiveness of expression of marker Ki-67 were counted, calculating the proliferative index (PI). Primary antibodies to EGF and TGF-β ("Novocastra", UK) were used. Morphologic researches were made with the help of computer system of colour picture analyses "Diamorph-cito" (Russia). Results. While HP- associated gastritis Ki-67 a small amount of stomach epitheliocytes were found in nucleus, although PI increased in 1.5 times in comparison with homonamed index of functional dyspepsia. Besides, Ki-67 were registred in pericytes of vessels of mucous membrane stroma. EGF were found in membranes and cytoplasm of external epithelium, stomach glandulocytes, pericytes and endoteliocytes, besides in 1.3times more often than while functional dyspepsy. TGF-β was found in same cells (macrophages, fibroblasts) of inflammatory infiltrate. TGF-β assortment in cytoplasm and nucleus of epitheliocytes of gastrit pits and glands was unhomogeneous, but reliable did not reach the level of this parameter in bioptats of people from comparing group. Conclusion. Conducting research showed homodizected representation in the structures of stomach mucous membrane chronic HP-associated children gastritis Ki-67 and EGF. The localization of the last one (vessels endothelium, pericytes) points at the role of this cytokine in stimulating angiogenesis processes during the development of chronic inflammation. The decreasing of TGF-β, taking into account functional load of this growing factor, also promoted the increasing of proliferative epithelium activity and cells of stroma of stomach walls, oppression of monocyte migration to the focus of inflammation, phagocyte macrophage activity, supporting the chronic development of inflammatory process.

PP1-119

ROLE OF NK RECEPTORS IN CELIAC DISEASE COMPLICATIONS

Vincenzo Canzonieri[1], Laura Caggiari[2], Tiziana Perin[1], Mariangela De Zorzi[2], Tiziana Salviato[1], Lorenzo Memeo[3], Alessandro Da Ponte[4], Michele Spina[5], Renato Cannizzaro[6], Valli De Re[2]

[2] Experimental and Clinical Pharmacology Aviano Cancer Center - IRCCS, Italy
[3] Division of Pathology Mediterranean Institute of Oncology Catania, Italy
[4] Blood Bank and Transfusion Medicine Unit, Aviano Cancer Center - IRCCS, Italy
[5] Medical Oncology A, Aviano Cancer Center - IRCCS, Italy
[6] Gastroenterology, Aviano Cancer Center - IRCCS, Italy

Background: Celiac disease (CD) has an increased risk of non-Hodgkin's lymphoma (NHL). Although CD was initially associated with enteropathy- associated T-NHL, patients with CD are also at increased risk for other NHLs, B and T cells. Long-standing CD in adult patients or gluten-free diet (GFD) non-responsive CD, clonal γ/δ T-cells, severe mucosal inflammation, are predisposing conditions for NHL. The diagnosis of CD-associated-NHL may be difficult and the prognosis is usually poor. Therefore, there is a need of markers for the early diagnosis and prognosis of NHL in CD. KIRs (Natural Killer cell immunoglobulin-like receptors) are specific receptors involved in the functional T/NK cell regulation contributing to the mucosal damage and possibly to the lymphoma development. Methods 33 patients with suspected or ascertained diagnosis of CD, and 50 blood donors, were enrolled. Oberhuber-modified Marsh criteria, ranging from Marsh type 0 to type 4, were used. KIRs were analyzed by DNA genotyping and KIR/HLA-I ligand matching

with the addition of HLA-I typing. Results 28 pts were at first evaluation. 5 had 8 or more months GFD, and 4/5 developed complication (1 intestinal carcinoma, 1 intestinal DLBCL, 1 bone marrow DLBCL, 1 refractory CD). At first diagnosis, we found 12 Marsh 0, and 16 Marsh 1-3 (3 type 1, 2 type 2, 11 type 3). When 16 CD Marsh 1-3 and 5 CD-GFD were compared with 50 donors, KIR2DS1 was more frequent in CD (14/21 vs 15/50, p=0,004), while in donors and CD Marsh 0 (6/12) was similar. When, at the first visit, CD Marsh 0 were compared to CD Marsh 3, KIR2DL5 was more frequent (10/12) in Marsh 0, than in Marsh 3 (4/11), p=0,021. In all CD with GFD, KIR2DS1 and KIR2DL5 were both present. However, KIR2DS1/HLA-C2 match was present in the 4/4 CD with complications, while it was existent in 11/29 of suspected or ascertained diagnosis of CD, including GFD-responsive patients, p=0,019. Conclusion KIR2DS1 is associated with overall symptomatic CD in comparison to donors. The highest match frequency of KIR2DS1/HLA-C2 in the CD patients with complications suggests the hypothesis that a functional KIR2DS1 receptor is associated with tumor development. Instead, KIR2DL5, is present in almost all Marsh 0, where it may have a protective effect against inflammation, and in all CD with complications. Since inflammatory response could also be involved in the immune control of the neoplastic process, KIR2DL5 might favor directly or indirectly the immuno-escape of neoplastic cells.

PP1-120
LOOP AMPLIFICATION OF THE INFLAMMATORY PROCESS INDUCED BY P2X7 ACTIVATION IN INTESTINAL EPITHELIAL CELLS THROUGH NEUTROPHIL TRANSEPITHELIAL MIGRATION

Cesaro Annabelle[1], Wildman Scott[2], Hebuterne Xavier[3], Unwin Robert[2], Mograbi Baharia[1], Hofman Paul[4]
[1] INSERM ERI-21, University of Nice, Nice, France
[2] Department of Physiology, Royal Free and University College Medical School, London, United Kingdom
[3] INSERM ERI-21, Department of Gastroenterology, University of Nice, Nice, France
[4] Laboratory of Clinical and Experimental Pathology, INSERM ERI-21, Human Tissue Biobank, University of Nice, Nice, France

Inflammatory bowel diseases (ulcerative colitis and Crohn's disease) in humans are chronic disorders inducing intestinal inflammation. These inflammatory diseases are mainly characterized by a large afflux of neutrophils into the mucosa causing the release of several cytokines. Moreover, during neutrophil transepithelial migration, large amounts of extracellular ATP are released both by neutrophils and epithelia. The P2X7 receptor is a ligand-gated cation channel activated by extracellular ATP and highly expressed on monocytes, macrophages and lymphocytes. P2X7 activation leads to release and maturation of IL1 beta. Moreover, extracellular ATP causes apoptosis and/or necrosis of the hematopoietic lineage through the activation of P2X7 receptors. There is strong evidence from P2X7 gene-deleted mice suggesting that the P2X7 receptor amplifies the inflammatory response, but little is known of the mechanism. Expression of P2X7 on intestinal epithelial cells is not well determinated as well as its putative function during the cross talk with the neutrophils. The aim of this study was to identify the presence of P2X7 in intestinal epithelial cells, to look for the level of P2X7 expression during the neutrophil transepithelial migration, and to see if P2X7 stimulation may induce release of cytokines by epithelial cells. For this purpose we used the T84 model which allow in vitro a human neutrophil transepithelial migration in a physiological direction. P2X7 expression was studied by confocal microscopy, Western blotting and qPCR. Release of cytokines by the T84 monolayers was looked by Elisa method. Results: P2X7 is strongly expressed in T84 cells and the signal is observed both at the apical side and at the basolateral side. Transepithelial migration of neutrophil induces an upregulation of P2X7 at the mRNA and protein levels. Incubation of T84 cells by extracellular ATP in T84 cells induces activation of caspase 1 and IL1 beta as well as different cytokines synthesis (in particular, TNF alpha and TGF beta). Finally, altogether these data showed that activation of P2X7 receptor in intestinal epithelial cells by extracellular ATP can provoked release of proinflammatory cytokines at the basolateral side of the T84 monolayers. We can speculate that amount of extracellular ATP produced during the neutrophil transepithelial migration may activate the P2X7 receptor and thus may amplify the inflammatory response.

PP1-121
MICROVESSEL DENSITY IS AN INDEPENDENT PROGNOSTIC FACTOR OF GASTRIC CANCER

Filip Vukmirovic[1], Dragutin Savjak[1], Slavica Usaj[2], Zivka Eri[3], Istvan Klem[3], Ljiljana Vuckovic[1], Mileta Golubovic[1]

[3] Department of Pathology, Institute for Lung Disease, Sremska Kamenica, Serbia

BACKGROUND: Tumor induced generation of new blood vessels is an important process in growth, prognosis and metastasis of tumors. We have done some research works to find out the relationship between the microvascular density and clinicopathologic features related with prognosis in gastric cancer patients. METHODS: To asses tumor angiogenesis, microvascular density (MVD) were analyzed immunohistochemically in 83 primary gastric cancers. Any single brown-stained cell with Factor VIII, that indicates an endothelial cell, was counted as a single vessel. Branching structures were counted as a single vessel unless there was a discontinuity in the structure. Vessels were counted in 4 regions, with the highest vascular density, at 200-magnification, and the average number of microvessels was recorded. RESULTS: The microvascular density for 83 tumor speciment ranged from 17,5-51,5 with a mean MVD of 33,17±7,95. Mean microvascular density was chosen as the cut-off point, 38 patients were categorized as a low MVD and 45 patients as a high MVD. There was no significant relationship between MVD and age, sex, and histological type of gastric cancer. A significant correlation was found between the MVD in early and advanced gastric cancer, and between gastric cancer with and without regional lymph node metastasis. High MVD was significantly associated with poor survival. Multivariate survival analysis showed that stage of dissease and MVD were independent prognostic factors. CONCLUSION: MVD is one of the most important prognostic factors for gastric cancer patients. Generally, poor prognosis of gastric cancer patients may be enhanced by therapeutic inhibition of angiogenesis.

PP1-122
PROGNOSTIC IMPORTANCE OF VASCULAR ENDOTHELIAL GROWTH FACTOR EXPRESSION IN GASTRIC CANCER

Filip Vukmirovic[1], Dragutin Savjak[1], Zivka Eri[2], Slavica Usaj[3], Istvan Klem[2], Mileta Golubovic[1], Ljiljana Vuckovic[1]
[1] Department of Pathology, Clinical Center of Montenegro
[2] Department of Pathology, Institute for Lung Disease, Sremska Kamenica, Serbia
[3] Department of Pathology, Institute for Oncology, Sremska Kamenica, Serbia

BACKGROUND: Angiogenesis plays a central role in cancer growth, survival and development of distant metastasis. One of the most important regulator of the angiogenic process is vascular endothelial growth factor (VEGF), which induce endothelial cell proliferation, migration and invasion. VEGF also has been demonstrated to increase vascular permeability. METHOD:

VEGF was investigated by using immunohistochemical staining in 83 formalin-fixed paraffin embedded tissue sample patients with gastric carcinoma who underwent surgical resection between 2000. and 2003. at the Clinical Center of Montenegro. The relationship among VEGF expression and clinicopathological parameters was analyzed. RESULTS: Positive staining was obtained in 59 out of 83 cases (71,1%). VEGF immunoreactivity was observed mainly in the cytoplasm of tumor cells, and also frequently in stromal cells. No significant correlation between VEGF expression and age, sex, localization of tumors, and Lauren histological type of gastric carcinoma. Positive expression of VEGF correlated significantly with lymph node metastasis ($\chi2=4,27$; $p<0,05$). VEGF expression was more intense in poorly differentiated adenocarcinoma in comparison with other tumors ($\chi2=3,95$; $p<0,05$). According to prognosis, patients with VEGF-positive tumors had significantly worse survival and lowest 5-year survival rate than those with VEGF-negative tumors ($\chi2=11,22$; $p<0,01$). In multivariate analysis, status of VEGF were not an independent prognostic factor. CONCLUSION: VEGF may be a useful marker for predicting metastasis in gastric cancer, and inhibition of VEGF activity may have an important therapeutic benefit in the control of gastric cancer.

PP1-123

VALIDATION OF AUTOMATED IMAGE ANALYSIS (HISTOQUANT) IN COLON CANCER USING DIGITAL SLIDES OF EGFR, COX-2, BETA-CATENIN, AND CYCLIN D1 IMMUNOSTAININGS

Levente Ficsor[1], Viktor Varga[1], Viktor Jonas[2], Tamas Micsik[3], Laszlo Fonyad[3], Istvan Petak[3], Laszlo Kopper[3], Bela Molnar[1], Tibor Krenacs[3]

[2] 3DHISTECH Ltd. Budapest; Hungary

[3] 1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest; Hungary

Background: Colon cancer is one of the leading causes of tumour mortality in developed countries. Recent efforts in diagnostic and clinical research of colon cancer have resulted in potential marker molecules, which may be associated with disease progression, prognosis and/or clinical response to therapy. However, evaluating of these markers in situ using immunohistochemistry, frequently suffers from lack of consistency, preventing intra- and inter-laboratory standardization of the diagnostic procedure and proper patient selection for treatment. Method: In this work we tested 68 cases of primary and metastatic colon cancers included in tissue microarrays (TMAs) for prognostic and predictive biomarkers localized to different compartments of tumour cells, including EGFR, beta-Catenin, Cox-2 and Cyclin D1. Immunostaining results were parallel evaluated by 2 independent assessors using both an empirical scoring based on negative, weak, moderate and strongly positive categories and an image-segmentation based automated analysis software, HistoQuant® (3DHISTECH, Budapest, Hungary). Altogether 116 representative areas of 58 colon cancers including all markers and score groups were analysed and measured along 56 parameters including color/intensity segmentation, absolute and relative values of positive and negative areas and cell numbers withing tumors. Discriminant analysis (Statistica®, Statsoft, USA) was used to find out if there was a correlation between the human classification and measured data. Results: From the examined areas 110 were classified correctly using HistoQuant program(overall 95%; EGFR 97%, beta-Catenin 79%, Cox-2 100%, Cyclin D1 100%). Negative cases were revealed in 100% agreement between the analyses. At disagreement, some cases were ranked only to adjacent classes, e.g. some weak positive areas were upgraded to be moderate using the automated measurement, but there was no transition between the weak and strong positive cases. The most discriminative parameters were the positive area within selected area and the intensity values, resulting in very similar differences between groups compared to empirical assessment. Conclusion: Based on this study, we suggest, that that quantitative measurements on digital slides may correlate very well with properly set up empirical scoring in colon cancer. The HistoQuant software can be a reliable tool of accurate marker assessment for diagnostic, prognostic and/or therapeutic utilization.

PP1-124

4 CASES OF UNUSUAL METASTASIS TO DUODENUM

Nese Ekinci, Arzu Avci Ucarsoy, Fatos S Pehlivan, Gozde Evcim, Murat Ermete

Ataturk Training And Research Hospital, Izmir-Turkey

Background: Small bowel involvement by metastatic tumors is very rare and the most common primaries known are malignant melanoma, lung cell carcinoma, renal cell carcinoma, testicular germ cell tumor, hepatocellular carcinoma, cervical carcinoma, thyroid carcinoma and Merkel cell carcinoma. We found 4 cases of metastatic tumor in the duodenum in the archives of Izmir Ataturk Training and Research Hospital between 2000 and 2006. Case 1: A 54-year old man who had undergone right nephrectomy for a renal mass 9 months before, presented with severe weight loss and vomiting. Upper endoscopy showed a submucosal mass 5 cm in diameter. Duodenal biopsy was consistent with metastatic renal cell carcinoma similar in morphology with the tumor diagnosed in his nephrectomy material. Case 2: A 69-year old man presented with a pigmented lesion on his left cheek and also with hematemesis and melena at the same time. Biopsy of the pigmented lesion showed a malignant melanoma of the superficial spreading type. Upper endoscopy revealed multipl pigmented lesions in gastric and duodenal mucosal surfaces. Duodenal biopsy was a metastatic melanoma with typical melanoma cell groups in the lamina propria. Case 3: A 42-year old man with a diagnosis of testicular tumor had melana in the postoperative period. Ultrasonography showed multipl metastatic tumors in liver, the largest being 6 cm in diameter and the patient underwent surgery. Choriocarcinoma metastasis to duodenum was confirmed from the surgical specimen which was similar to the testicular tumor diagnosed as mixed germ cell tumor with choriocarcinomatous component. Case 4: A 76-year old man who was a heavy smoker for more than 50 years, presented with severe weight loss and jaundice. Endoscopic retrograd cholangiopancreatography showed a tumor in the second part of the duodenum narrowing the lumen. Duodenal biopsy was a squamous cell carcinoma growing in a polypoid fashion. No other diagnostic procedure could be performed as the patient detoriated rapidly and died. Autopsy was not done. It was thought that the primary site of the squamous cell carcinoma might be of lung origin but could not be proved pathologically. Conclusion: Those patients having severe gastrointestinal symptoms with any prior malignancy should be completely evaluated by the help of endoscopic examination followed by biopsy in order to exclude the possibility of duodenal metastasis.

PP1-125

REVIEW OF 24 APPENDICEAL CARCINOID TUMORS:A CONSECUTIVE SERIES FROM 4848 APPENDECTOMIES IN 13 YEARS

Nese Ekinci, Arzu Avci Ucarsoy, Fatma S. Pehlivan, Gozde Evcim

Ataturk Training And Research Hospital, Izmir-Turkey

Background: Primary appendiceal carcinoid tumor is a rare disease but carcinoid tumors are the most common type of neoplasms seen in appendix that is rarely suspected before the pathologic examination. Clinical presentation of the appendiceal carcinoid is usually that of an acute appendicitis and in the majority of cases the diagnosis is incidental. Method: The medical records of patients who underwent appendectomy at

Izmir Ataturk Training and Research Hospital between January 1994 to December 2006 were reviewed retrospectively. Age, gender of the patients, location of the tumor and diameter, depth of invasion, histopathologic type of tumor and also incidence of other pathologic lesions in the appendix were recorded. Immunohistochemically neuron specific enolase (NSE), chromogranin A and synaptophysin were performed in 20 cases, since paraffin blocks were not available in 4. Results: During the study period 4848 appendicectomies were performed and out of these, 24 cases of carcinoid tumor were diagnosed (0.49%). There were 9 female, 15 male patients, mean age 29.73 years (range:15-65). Mean tumor diameter was 9.1 mm (range:1 mm-2 cm) and in 14 patients the tumour was localised at the appendix apex, 10 at the mid portion. Acute appendicitis was the clinical presentation in 9 patients (37.5%), but it was an incidental finding in 15 (62.5%). Goblet cell carcinoid was seen in 2 patients and all 22 patient had classical type carcinoid. Serosal infiltration was seen in 14 cases (58.3%). Immunohistochemical study performed in 20 patients revealed NSE positivity in 20 cases (100%), synapthophsin in 18 (90%) and chromogranin A in 15 (75%) cases. Most of the patients underwent only appendectomy and no adjuvant therapy was performed. Only two patients who were brothers, had a right hemicolectomy due to a synchronous carcinoma located in the ceacum at the same time. 15 patients were alive and disease free during a follow up period of 8 years. 7 patients were lost to follow-up. 1 patient died because of colonic adenocarcinoma. Conclusion: Carcinoid tumors of the appendix are extremely rare lesions with no specific clinical symptom but some may present with acute appendicitis. The treatment of choice may be appendectomy especially if the tumor diameter is <1 cm.

PP1-126
COX-2 EXPRESSION IN INTESTINAL AND DIFFUSE TYPE GASTRIC ADENOCARCINOMA

Hulya Ozel, Selda Seckin, Gulusan Ergul
Ankara Numune Training and Research Hospital, Department Of Pathology, Turkey

Cyclooxygenase (COX) is an enzyme that catalyzes the conversion of arachidonic acid into prostaglandin. It has 2 isoforms: constitutive (COX-1) and inducible (COX-2). It is reported that COX-2 expression has a role in inflammation and carcinogenesis. The expression of COX-2 in gastric adenocarcinomas and precancerous lesions proposes its role in gastric carcinogenesis. In this study, 2 different types (intestinal, diffuse) of gastric adenocarcinomas have been compared in respect of COX-2 expression with regard to possible different carcinogenetic pathways. Immunohistochemically COX-2 has been performed on tissue sections of 20 intestinal type and 20 diffuse type gastric adenocarcinomas. COX-2 expression has been scored as; staining intensity (weak:1, moderate:2, strong: 3) and staining extension (no staining:0, <10 %:1, 10-50 %:2, >50 %:3). The staining is (+) in case the total score is over 4 and (-) in case the total score is 4 or less than 4. Statistically chi-square test and Mann Whitney U test have been used. Results for $p<0.05$ are statistically signicant. Staining is observed in 42,5% cases of the total gastric adenocarcinomas while in 53,5% no staining was observed. In 55% of intestinal type and in 30% of diffuse type adenocarcinomas cytoplasmic staining was detected. Considering the total score, a higher level of positivity was observed in intestinal type tumors compared to the diffuse type. Yet, the difference was not statistically significant (p: 0142). COX-2 might play an important role in the evaluation of carcinogenesis in stomach and might be related to carcinogenesis pathway of intestinal type. COX-2 inhibitors might be important in the prevention of carcinoma development in patients with precancerous lesions and in the treatment of patients with gastric adenocarcinoma. However, further studies are needed to detect this fact.

PP1-127
HEPATOCYTE ANTIGEN EXPRESSION IN SUBTYPES OF INTESTINAL METAPLASIA OF THE STOMACH

Guzide Ayse Gokhan, Gokben Yildirim Kupesiz, Gulsum Ozlem Elpek
Akdeniz University School of Medicine, Department of Pathology, Turkey

Background: Intestinal metaplasia (IM) is generally regarded as a premalignant lesion that is classified by mucin modifications confirmed by histochemical and immunohistochemical methods. Recently, hepatocyte antigen (Hep) introduced as a sensitive and reliable marker of IM. However, the distribution of Hep expression in subtypes of IM are not described. Method: We examined the expression of Hep in 58 cases of chronic gastritis (CG) associated with IM by immunohistochemical staining. According to the mucin expression patterns cases were classified as; 19 cases of IM type I, 16 cases of type II and 23 cases of type III. The distribution of Hep expression were classified into four groups according to the rate of Hep expressing metaplastic cells: negative, low (between 1% and <30%), moderate (between 30% and <60%), high (over 60%). We also compared expression of Hep with that of MUC-1, MUC 2 and MUC 5AC. Results: Hep expression showed a granular cytoplasmic staining and specifically identified in columnar cells, but not in goblet cells. There was no significant difference between Hep expression and subtypes of IM ($p>0.05$). However, the difference between the distribution of Hep expression among three subtypes of IM was significant ($p<0.001$). In type I IM most of the cases expressed Hep in >60% (high) of columnar cells. In contrast in type II IM, the expression was moderate in a grate majority of cases with only 4 cases with high expression. In both group low expression was not observed. In contrast in type III IM low expression was observed in 17 of the 19 positive cases. In the same group moderate expression was noted in two cases and any case displayed a high Hep expression. A strong correlation between the distribution of Hep expression and subtypes of IM was also noted ($r = -0.844$). Any relationship was observed among the expression of Hep, MUC-1, MUC 2 and MUC 5AC. Conclusion: Results of the present study revealed that the distribution of Hep expression is higher in the complete type (type I) of IM and gradually decreases in the incomplete types (type II and type III) and suggest that besides its role as a sensitive marker in IM, the evaluation of the distribution of Hep expression might be useful in the classification of IM.

PP1-128
POLYP SIZE DETERMINES THE PATHOLOGIC FEATURES THAT DISTINGUISH SESSILE SERRATED ADENOMAS AND HYPERPLASTIC POLYPS.

Athanassios Tsamandas, Konstantinos Thomopoulos, Vassilis Margaritis, Christos Triantos, Vassiliki Tzelepi, Anna Liava, Evangelos Katsakoulis, Vassiliki Nikolopoulou, Chrisoula Scopa University of Patras, Greece

Background: Large sessile serrated adenomas (SSAs) and hyperplastic polyps (HPs) are morphologically distinctive, whereas small polyps often lack these distinctive features and are often difficult to classify. This study correlates polyp size with pathologic features of serrated polyps in order to establish diagnostic criteria to separate small SSAs and HPs. Methods: The study included 1162 SSAs and HPs were retrieved from our file and grouped by mm size (2mm, 3mm, 4mm, 5mm, 6mm, 7mm, 8mm; N=75, 267, 270,246,186, 87, 31, respectively). In each mm group, the number of right colon polyps was matched to those of left colon. The number of normal, mildly-, and moderately (mod)-dilated, and flask-shaped crypts was recorded. For each crypt shape, the number with basilar, mid and superficial upwards extension of immature cells, mitoses, serration, and type of cytoplasmic differentiation was recorded. Polyps were blindly re-reviewed at a later date and diagnosed as SSA, HP, Indeterminate (Ind). Results: The percentages of normal crypt bases/ polyp were

86% and 28% in 2 mm and 8 mm polyps, respectively, whereas the percentage of crypts with mod-dilated or flask shaped bases increased from 4% and 2% respectively in 2 mm polyps to 44% and 21% in 8 mm polyps. The percentage of polyp crypts with mid-level immature cells and mitoses was <10% in all 2 and 3 mm and most 4 mm polyps to >50% in >5 mm polyps. There was uniform cytoplasmic maturation in all 2 and 3 mm, whereas almost all >5mm polyps had small clusters of crypts with similar cytoplasmic maturational features that were different from the features of adjacent crypts. The percentage of 2mm, 3mm, 4mm, and 5mm polyps diagnosed as HP, Ind, SSA were (94%,6%,0), (55%,42%,3%), (31%,46%,23%), and (10%,25%, 65%), respectively. Conclusions: There was progressive increase in the extent of changes with increasing polyp size beginning with basilar crypt dilation, followed by upwards expansion of immature epithelial cells and mitoses, and ending with flask-shaped serrated crypt bases and full-thickness immature epithelial cells. Small polyps were singularly HP-like. 46% of 4 mm polyps had indeterminate features, whereas whereas 65% of 5mm polyps had predominantly SSA features. Polyp size may be an marker of the extent of underlying molecular alterations. SSAs and HPs may be related entities and derive from a common pool of lesions. SSAs emerge from this pool due to greater levels of cell cycle control slippage and cell signaling pathway perturbations.

PP1-129

EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) EXPRESSION IN LATE STAGE METASTATIC COLORECTAL CANCER. COMPARATIVE IMMUNOHISTOCHEMICAL STUDY USING TWO COMMERCIALLY AVAILABLE ANTIBODIES

Christos Valavanis, Mersini Karampola, Athanasios Simoulis, Gino Vecchini, Joanna Iakovidou, Petroula Arapantoni-Dadioti
Molecular Pathology Unit, METAXA Cancer Hospital, Piraeus, Greece

BACKGROUND AND OBJECTIVE : Colorectal carcinoma is one of the most common malignancies worldwide and manifests a high mortality, especially at late stages of the disease. Currently available therapeutic strategies have a modest effect on overall survival of patients with advanced and/or metastatic disease. Recently, targeted therapy drugs, such as EGFR inhibitors, are in use for the management of advanced-stage colorectal cancer. It is well known that the dysregulation of the epidermal growth factor receptor (EGFR) signal transduction pathway is involved in colon cancer development and progression, and overexpression of the receptor confers a poor prognosis. Thus targeting the EGFR has become a rational approach for the treatment of colorectal carcinoma. In this context we investigated the expression of EGFR in advanced/metastatic colorectal cancer using two different antibodies against EGFR and compared the incidence, the cellular distribution and the intensity of its expression as given by the two antibodies. We also correlated the EGFR expression with differentiation grade, Dukes' stage at primary site, age and gender. MATERIALS AND METHODS: In this study, 121 archival specimens of metastatic colorectal cancer were analysed immunohistochemically, using two different antibodies against EGFR , the mouse monoclonal anti-human EGFR clone 2-18C9 of the EGFR pharmDx kit (DAKO) and clone 31G7 (Zymed). Immunostaining was evaluated as membranous, and the intensity of the immunostaining was graded 0 (negative), 1+ (weak), 2+ (moderate) and 3+ (strong). RESULTS AND CONCLUSIONS: Overall, 34.7% of the adenocarcinoma cases had membranous EGFR reactivity; 9.1% of the tumors had 3+ reactivity in 3-30% of the neoplastic cells, 17.4% of them displayed 2+ reactivity and 8.3% exhibited 1+ in the same tumor cell percentage. EGFR expression in colorectal carcinomas correlated with differentiation grade showing higher levels in high grade tumors ($p < 0.0001$). However, there were not statistically significant association with Dukes' stage, site, patient age or gender. There was high concordance (92%, $p < 0.0001$) in evaluating EGFR expression between the two antibodies used in this study, with no difference in the incidence, the cellular distribution and the intensity of EGFR expression.

PP1-130

PRELIMINARY STUDY OF INFILTRATIVE COLON CANCER BY USING MICROIMAGING FOURIER TRANSFORM INFRARED (FT-IR) SPECTROSCOPY

Christos Valavanis[1], Stefanos Konstadoudakis[1], Evridiki Boukaki[1], Petroula Arapantoni-Dadioti[1], Joanna Anastasopoulou[2], Theophillos Theophanides[2], C Conti[3], P Ferrari[3], E Giorgini[3], C Rubini[3], S Sabbatini[3], G Tosi[3]
[1] Molecular Pathology Unit, METAXA Cancer Hospital, Piraeus, Greece
[2] Radiation Chemistry and Biospectroscopy Laboratory, Chemical Engineering Department, National Technical University of Athens, Greece
[3] Dip. di Scienze e Tecnologie Chimiche - Dip. di Neuroscienze, Università Politecnica delle Marche, Ancona, Italy

BACKGROUND AND OBJECTIVE: Fourier Transform infrared (FT-IR) spectroscopy represents a reliable method for the resolution of the molecular structure and determination of chemical composition of biologic materials. There is evidence that this technique could be used in the early diagnosis of several neoplasms in combination with the conventional histopathologic diagnosis because of the possibility to provide information on the molecular changes in limited areas of lesions. MATERIALS AND METHODS: In this context we examined using FT-IR spectroscopy a limited number of infiltrative colon adenocarcinomas , of variant histologic grade of malignancy, along with adjacent normal colon tissue. Thin paraffin sections of 5μm were obtained and spectral data were collected by a Perkin-Elmer Spectrum One FT-IR equipped with a Perkin-Elmer Auto-image microscope. RESULTS AND CONCLUSIONS: The analysis and the comparison between the spectra obtained from neoplastic and normal tissue zones indicated that there were significant differences of the spectral absorption signatures in the infrared region: i) in the Amide I band, the spectra of normal tissues if compared with the ones of malignant zone, were sharper and were found at higher frequencies with a maximum at 1661 cm-1), ii) in the Amide II band, the normal region was broader and red shifted 5 cm-1 with two maxima around 1658 and 1635 cm-1, differences that could arise from a change of the secondary structure of proteins during carcinogenesis, iii)differences in the CH2 and CH3 modes at 1400, 1466, 2849 and 2920 cm-1 (hypomethylation process in neoplastic cells), iv) small blue shift of the C-OH mode from 1164 cm-1 to 1172 cm-1 indicating an increased phosphorylation induced by carcinogenesis v) in PO^2 modes of nucleic acid and carbohydrates in the region 1100-1000 cm-1 in which the bands of the neoplastic tissue were convoluted with only two maxima at 1080 cm-1 (vsPO^2) and 1117 cm-1 (mucin), while in the normal tissue, the peaks at 1048, 1080 and the one of mucin at 1121 cm-1 were easily discernible (reduction of mucin production in cancer). Specific spectral signatures were also obtained from the connective tissue and from necrotic and inflammation areas.

PP1-131

KIT EXON 11 CODON 557/558 MUTATIONS DEFINES A SUBSET OF MALIGNANT CLINICAL BEHAVIOR IN GASTROINTESTINAL STROMAL TUMORS

Katerina Kontogianni-Katsarou[1], Euthimios Dimitriadis[2], Konstantina Lariou[2], Evi Kairi-Vassilatou[1], Nikolaos Pandis[2], Agatha Konti-Paphiti[1]
[1] Athens Medical School, Areteion University Hospital, Department of Pathology, Greece
[2] Saint Savas Hospital , Department of Genetics, Greece
[3] Evngelismos General Hospital, Department of Pathology, Greece

Aim: Most gastrointestinal stromal tumors (GISTs) express activated mutant isoforms of KIT or PDFFRA genes that are potential therapeutic targets. The significance of these mutations for the prediction of GISTs biological and clinical behavior is still under consideration. In this study we have analysed the frequency and pattern of KIT and PDFFRA mutations in a group of patients with GISTs and the association of these mutations with other clinicopathological factors. Materials and methods : Thirty patients with GISTs were examined. DNA were extracted from paraffin sections. Exons 9, 11, 13, and 17 of the KIT-gene and exons 12 and 18 of the PDGFRA-gene were evaluated for the presence of mutations by PCR amplification and direct sequencing. Results : Overall KIT or PDGFRA mutations (MT) were detected in 21 of the 30 patients (70%). Sixteen patients had MT within KIT exon 11, three patients within KIT exon 9 and two patients within PDGFRA exon 18. The detected MT within KIT exon 11were heterogeneous and consisted of 10 deletions, 4 point mutations and 2 insertions. Codons 557 and 558 were involved in 8 cases (50%) of the KIT exon 11 mutations. KIT-MT exon 9 were almost detected in GISTs located in small intestine, showing spindle cells phenotype and they were classified as uncertain malignant potential or malignant. KIT-MT exon 11 were largely confined located in small and large intestine, showing spindle cells phenotype ($p<0.05$) and they were classified as malignant potential. KIT-MT exon 11 codon 557/558 were associated with malignant clinical behavior ($p=0.032$). PDGFRA mutations were all detected in GISTs located in stomach, showing mixed type phenotype and they were classified as uncertain malignant potential. Conclusion: Integration of histological features and determination of KIT and PDGFRA mutations should be additional parameters for the better prediction of GISTs clinical behavior. Tumors with mutations affecting codons 557/558 of the KIT gene seems to represent a distinct subset of malignant GISTs.

PP1-132
EXPRESSION OF RETINOBLASTOMA PROTEIN AND CYCLIN D1 IN GASTRIC CARCINOMA

D. Sema Arici[1], Gulay Simsek[1], Ersin Tuncer[1], Hatice Ozer[1], Ayhan Koyuncu[2]
[1] Cumhuriyet University Faculty of Medicine Department of Pathology, Turkey
[2] Cumhuriyet University faculty of Medicine Department of General Surgery, Turkey

BACKGROUND: Abnormal regulation of the cell cycle is a feature of many neoplasms. Regulation of the G1/S checkpoint, which is controlled by the retinoblastoma protein (pRb), is critical event and cyclin D1 plays a positive regulation of the cell cycle. The role of cell cycle regulators in oncogenesis has been investigated in many human tumors. Alteration of the pRb and cyclin D1 disrupt the Rb pathway and occur in many carcinomas. However the expression of the pRb and cyclin D1 in intestinal type gastric carcinoma, is unclear. In this study, our aim was to investigate the expression of pRb and cyclinD1 in resected gastric carcinoma, their adjacent nonneoplastic mucosa and normal gastric mucosa. Also relationship with histopathological features were analyzed. METHOD: The study consisted of 43 patients (32 men, 11 women; mean age: 64) who underwent surgery for primary gastric adenocarcinoma at our institute between 2004–2006. Immunohistochemistry was performed by streptavidin biotin peroxidase method. Using immunohistochemical methods, the expression of pRb and cyclinD1 was investigated in 43 resected intestinal type gastric carcinoma specimens, adjacent noneoplastic mucosa and normal gastric mucosa. Adjacent nonneoplastic mucosa consisted of atrophy, dyplasia, intestinal metaplasia and gastritis. RESULTS: Adjacent nonneoplastic mucosa showed atrophy, dysplasia and intestinal metaplasia in 33(76.7%), 31(72%) and 34(77.2%) of the cases, respectively. Gastritis was detected in all cases. Expression of pRb was detected in 30 (69.7%) of gastric carcinoma, 18 (41.8%) of the adjacent nonneoplastic mucosa. Expression of cyclinD1 protein was detected in 31 (72%) of gastric carcinoma, 24 (55.8%) of adjacent nonneoplastic mucosa. Expression of pRb and cyclinD1 was not detected in normal gastric mucosa. The positive rate of pRb and cyclin D1 expression in gastric carcinoma was significantly higher than that adjacent noneoplastic mucosa ($p<0.05$). pRb and cyclinD1 expression were not significantly associated with histopathological features ($p>0.05$). CONCLUSION: There were significant trends for increased expression of pRb and cyclinD1 from normal mucosa to precursor lesions, detected adjacent noneoplastic mucosa, and carcinoma. These results suggested that positive expression of pRb and cyclinD1 might be an early event in gastric carcinoma and it tended to begin at precursor lesions and maintain throughout the progression of infiltration.

PP1-133
COLORECTAL CARCINOMAS: CLINICOPATHOLOGIC INVESTIGATION, CORRELATION WITH EXPRESSION OF ESTROGEN AND PROGESTERONE RECEPTORS

Tulu Emre Ekem, Burak Bahadir, Banu Dogan Gun, Sibel Bektas, Gurkan Kertis, Gamze Yurdakan, Sukru Oguz Ozdamar
Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey

Background: Colorectal adenocarcinoma is the forth most frequently diagnosed visceral and the second leading cause of cancer mortality in both genders. The correlation in mortality data between breast cancer and colonic cancer, and the increased incidence of colonic cancer in individual women with breast cancer suggest common factors in their etiology. The protective effect of increasing parity from colonic cancer, similar to breast cancer and relatively better prognosis in women may also imply a common role for sex steroid hormones. Method: In this study, clinicopathologic parameters and estrogen and progesterone receptor expressions of 60 cases previously diagnosed as colorectal adenocarcinoma in the Department of Pathology in Zonguldak Karaelmas University Faculty of Medicine from November 2001 to March 2006 were investigated. Results: 31 cases were men and 29 were women with an age distribution ranging from 33 to 90 (average 65.8; SD: ± 13.55). 18 (30%) cases were from rectosigmoid area, followed in decreasing order by tumors limited in rectum, and sigmoid; ascending colon; descending colon; transverse colon; tumors with multiple sites at presentation and cecum. Histologic grading for well, moderately and poorly differentiated tumors were consecutively found 17 (28.3%), 37 (61.7%) and 6 (10.0%). Most cases were classified either in B2 or C2 according to the Astler Coller staging. Immunohistochemistry was carried out by using antibodies against estrogen and progesterone receptors; tumors with more than 5% nuclear staining were considered positive. Six cases displayed cytoplasmic reaction for estrogen receptor; no nuclear staining was demonstrated for estrogen or progesterone receptors. Conclusion: Epidemiologic parameters and sites of involvement in this study were almost akin to previous reports, except lower incidence of ceacal tumors. Nuclear staining for neither estrogen nor progesterone receptors had been demonstrated in the current study. It is vague whether to exclude cytoplasmic staining. Moreover, although potential importance of estrogen and progesterone receptors has been emphasized by certain reports, its importance is still controversial in terms of both prognosis and management. Therefore, there remains much to do to estimate the significance of these receptors in colorectal carcinoma.

PP1-134
HELICOBACTER PYLORI PREVALENCE IN GASTRIC ADENOCARCINOMA

Burak Bahadir, Banu Dogan Gun, Gurkan Kertis, Gamze Yurdakan, Figen Barut, Sibel Bektas, Sukru Oguz Ozdamar
Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey

Background: Helicobacter pylori colonizes in the gastric mucosa, and may cause various degrees of epithelial damage contributing to the pathogenesis of not only chronic inflammatory changes but also malignancies including gastric lymphoma and carcinoma. Considering its high incidence, approximately more than 50% of asymptomatic the population in most countries (exceeding 80% in developing countries), medical eradication of this organism may trim down inflammatory changes, and thus prevent carcinogenic cascade. In this study, we aimed to determine the prevalence and the value of Helicobacter pylori in gastric adenocarcinomas. Method: Gastrectomy specimens of 45 patients with gastric adenocarcinoma between July 2001 and December 2006 in Karaelmas University Faculty of Medicine were retrospectively re-evaluated. Histological classification of adenocarcinoma and Helicobacter pylori assessment were accomplished by applying Lauren classification and Sydney system, respectively. Results: The study group consisted of 32 males and 13 females with an average age of 61.84, ranging from 35 to 84. Intestinal type adenocarcinoma was detected in 40 cases while the rest five were diffuse type. Helicobacter pylori was present in 20 (44.4%) cases regardless of histologic type; when considered in 18 of 40 (45%) intestinal type, and in 2 of 5 (40%) diffuse adenocarcinoma. Conclusion: The overall Helicobacter pylori incidence in gastric carcinoma patients was generically consistent with literature. Although conflicting results have been reported, in contrast to most previous studies suggesting a closer association with intestinal type carcinoma than diffuse type, no such relation was determined in this study, probably because of the limited number of cases.

PP1-135
INCREASED NUMBER OF NEUROENDOCRINE CELLS IN METASTATIC COLORECTAL ADENOCARCINOMA FOLLOWING CHEMO/RADIOTHERAPY

Snezana Andrejevic-Blant[1], Marco Tampellini[2], Luisella Righi[2], Irene Alabiso[2], Veronica Tavaglione[2], Marco Volante[2], Luigi Dogliotti[2], Mauro Papotti[2], Valerio Marci[2]
[1] University Institute of Pathology, CHUV Hospital, Lausanne, Italy
[2] Department of Clinical and Biological Sciences at San Luigi Hospital, University of Turin, Orbassano, Turin, Italy

Background. Previous reports demonstrated a positive modulation of neuroendocrine (NE) phenotype in rectal adenocarcinomas receiving neoadjuvant therapy prior to radical surgery. However, to our knowledge no data are available on the role of post surgical adjuvant therapy in determining NE differentiation in recurrent/metastatising colo-rectal carcinoma (CRC). Methods. We analysed 15 randomly selected cases of primary CRC (9 cases from colon and 6 from rectum) and the corresponding metastases (8 liver, 4 peritoneal and 3 lung) developed during tumor progression. These were resected 1 to 3 years following adjuvant chemotherapy (all cases) and radiotherapy (5 cases, all from the rectum). The presence of NE cells was evaluated by means of Chromogranin A (CgA) immunohistochemistry, which was scored on the basis on the percentage of neoplastic cells as follows: 0 (no cell staining), 1+ (1-20% positive tumor cells) and 2+ (more than 20% positive tumor cells). Results. In primary tumor samples, focal NE differentiation (CgA score 1+) was evident in 3/15 cases (2 colonic and 1 rectal). Two of these cases had predominant mucinous features. Metastatic tumors resected after adjuvant chemotherapy were stained in parallel, and found to contain CgA positive cells in 8/15 cases (1 of the three CgA positive primary CRC, and 7 additional cases that were negative in the primary tumor (4 from the colon and 3 from the rectum). Radiotherapy treated cases were not significantly correlated with an increased number of NE cells. The presence of NE phenotype was not correlated to clinical outcome, although the two patients with the highest number of endocrine cells in metastatic tissue (score 2) were both died of the disease. Conclusion. Our data support the hypothesis that adjuvant therapy might modulate the NE phenotype in CRC, possibly selecting a cell population less responsive to current therapeutic regimens for CRC with possible biological and prognostic implications.

PP1-301
IMMUNOHISTOCHEMICAL STUDY OF E-CADHERIN AND BETA-CATENIN EXPRESSION IN COLORECTAL CARCINOMAS

Banu Yilmaz Ozguven[1], Tugba Taskin[1], Senay Yener[1], Didem Karacetin[2], Fevziye Kabukcuoglu[1]
[1] Sisli Etfal Training and Research Hospital, Pathology Laboratory, Istanbul, Turkey
[2] Sisli Etfal Training and Research Hospital, Radiation Oncology Department, Istanbul, Turkey

AIM: Parameters as histologic type, differentiation, lymph node metastasis and stages defining the prognosis of colorectal carcinomas have been observed. This study was executed observe E-Cadherin and beta-catenin expressions of tumor cells and using these parameters and the results to define life expectancy, response to the treatment, metastatic illness and recurrence of tumor. MATERIAL AND METHOD: 60 cases diagnosed as colorectal adenocarcinoma between 2004-2005 were selected to study retrospectively. 5 of these cases were left out because of technical reasons. H&E stained preparates were examined and the differentiation and the prognostic parameters of the tumors were evaluated. Along with the tumor, a block which has normal tissue was selected. Immunohistochemistry was performed using E-cadherin (36B5 clone, Neomarkers) and beta-catenin (Cat-a.1. clone, Immunovision) primary antibodies and avidin-biotin-peroxidase. RESULTS: 53 of 60 adenocarcinoma tissues were evaluated as classical type adenocarcinoma and 7 of them as mucinous carcinoma . 48 classical type adenocarcinoma tissues showed membranous staining for E-Cadherin, 13 tissues showed cytoplasmic staining and no staining was observed in 5 tissues 4 of Mucinous carsinoma tissues showed membranous type staining. Three of them showed no staining. All 53 adenocarcinoma tissues expressed nuclear or membranous type beta-catenin in different intensities. In all of 7 mucinous carcinoma tissues nuclear or membranous staining was observed. CONCLUSION: E-cadherin and beta-catenin showed membranous, beta-catenin nuclear, and E-cadherin cytoplasmic expressions. The staining intensity of E cadherin and Beta catenin were compared separately with prognostic parameters (tumor type: mucinous or classical adenocarcinoma, degree of differentation, vascular invasion, existence of lymph node metastasis, metastatic illness and recurrence of tumor) When E-cadherin and beta-catenin expressions were compared, no significant difference was observed. On the other hand, there was a significant difference between the tumor stage and the existence of lymph node metastasis.

Neuropathology

PP1-136
CEREBROVASCULAR DISEASES: A REPORT OF 175 AUTOPSY CASES
Alexander Zubritsky
Municipal Institution "Taldom Central Regional Hospital", Russia

The aim of this study was to determine the incidence of cerebrovascular diseases (CVD) on pathoanatomical material of the Municipal Institution "Taldom Central Regional Hospital" over the period from 1989 to 2006. The obtained findings revealed 175 cases of CVD (91 females and 84 males, mean age 63 years) from a total of 1,071 postmortem examinations of adults. In the majority of cases, the primary disease had been diagnosed as intracerebral haemorrhage (121 subjects) and intracerebral infarction (54 cases), with all the CVD having been registered on the background of arterial hypertension and/or progressing diffuse atherosclerosis, however, not all the patients had even been on ambulatory medical records. Besides these risk factors, obesity(59 cases)and diabetes mellitus (12 cases)were revealed as concomitant diseases. The direct causes of death were the following complications of the combined primary disease: haemorrhage into the cerebral ventricles (102 cases), compression and dislocation of the truncus cerebri due to oedema or swelling of the substantia medullaris (39), thromboembolism of the pulmonary artery (18), pneumonia (14), rupture of the ascending aortic wall followed by haemorrhage into the pericardial cavity (1 case), and renal insufficiency (1 observation). Hence, CVD on the background of arterial hypertension and disseminated progressing atherosclerosis amounted to 16% amongst the 1,071 postmortem examinations of adult subjects of the general somatic hospital over the above-mentioned eighteen-year period. In order to decrease and prevent CVD morbidity, it is necessary to systematically and thoroughly meticulously follow-up the health status of patients with cardiovascular diseases, to improve the organization of preventive measures, and to remove the risk factors amongst the adult population of the Taldom region by means of cardiological screening to be followed by ambulatory registration of the cohort revealed.

ALVEOLAR SOFT PART SARCOMA METASTASIS TO CEREBELLUM: REPORT OF AN UNUSUAL CASE
Nasrin Shayanfar, Mehrnoush Attar, Yalda Nilipour
Iran University of Medical Science, Iran

Background: Alveolar soft part sarcoma is a malignant soft tissue tumor which it;s metastasis to other organs like lung and brain as primary presenting symptom is not unusual.In the review of literatures there are reports of metastasis to different parts of brain,but to our knowledge cerebellar metastasis is not reported.We present an extremely rare case of metastatic alveolar soft part sarcoma to cerebrum and cerebellum at the same time as primary manifestation of the tumor. Case report:A 18 year old lady admitted due to nausea,vertigo,severe headache and blurred vision.MRI shows multiple lesions in cerebral hemispheres and cerebellum.Craniotomy was done.Pathologic diagnosis was metastatic alveolar soft part sarcoma which was confirmed immunohistochemically. Metastasis of this type of sarcoma to cerebellum is extremely unusual.

PP1-138
METHANOL TOXICITY: GFAP AND CD34 EXPRESSIONS IN HUMAN OPTIC NERVE AND BRAIN
Bulent Eren[1], Nursel Turkmen[1], Recep Fedakar[1], Semra Akgoz[2], Nil Comunoglu[3]
[1] Uludag University Medical Faculty, Forensic Medicine Department, Council of Forensic Medicine of Turkey, Turkey
[2] Uludag University Medical Faculty, Department of Biostatistics, Turkey
[3] Yeditepe University Medical Faculty,Pathology Department,Turkey

Methanol is used in variety of commercial products and production of illegal alcoholic beverages. The toxicity of methanol is due to its metabolites, which are formaldehyde and formic acid. The optic nerve consists mainly of ganglion cell axons, glial cells blood vessels and mesodermic tissue. Astrocytes are particularly important, they contribute to the blood-optic nevre, blood-brain barrier and participate in the scarring and repair of the nervous system GFAP immunostaining is the most commonly used method for examining astrocyte proliferation and hypertrophy after various central nervous system (CNS) injuries. The antigen CD34 is expressed widely on vascular endothelium, including that of the central nervous system (CNS) and high endothelial venules. The aim of the present study was to investigate the effects of methanol exposure on GFAP positive astrocytes in brain and optic nerve, and to show changes in CD34 expression in endothelial cells. 12 cases (all male; individual ages, mean 47.6±15.6 median 46 range 20–76 years) and 12 controls were identified and included in the study. According to toxicological results, the blood methanol concentration ranges widely from 14 to 202 mg per 100 ml. There were 6 cases (50%) with the methanol concentration over mean (98.35 mg per 100 ml). In the 10 of 12 cases (83.3%) also ethyl alcohol was detected in their blood samples. The ethyl alcohol concentrations ranged from 75 to 230 mg per 100 ml. Of these cases, six died before admittance to hospital. In the case group there was positive significant correlation between GFAP and CD34 intensity scores, furthermore there was positive statistically significant correlation between brain and optic nerve GFAP extent of expression (Spearman's correlation coefficient = 0.711, p=0.010, and Spearman's correlation coefficient = 0.720, p=0.008). Intensity and extent for every one of the two markers and groups were evaluated according after dividing score groups in 0-2 and 3-4 scores. There was no statistically significant differences between cases and controls brain GFAP and CD34 intensity and extent scores (p= 0.05).

PP1-139
CEREBRAL ASPERGILLOSIS PRESENTING AS A MASS LESION IN AN IMMUNOCOMPETENT HOST
Negar Azarpira[1], Ali Esfandiary[2], Mohammad Rakei[3], Hadi Bagheri[4]
[1] Transplant Research Center, Iran
[2] Pathology Department, Iran
[3] Neurosurgery Department, Iran
[4] Radiology Department, Iran

Fungal infections of the central nervous system (CNS) are almost always surprising findings. Their presentation is subtle, often without any diagnostic characteristics, and they are frequently mistaken for pyogenic abscess, or brain tumor.Aspergillosis of the central nervous system is an uncommon infection, mainly occurring in immunocompromised patients. It may be presented in several forms: meningitis, mycotic aneurysms, infarcts and the tumoral form. In this case, we reported an intracranial granuloma caused by Aspergillus fumigatus involving the anterior cranial fossa and the frontal lobe. In this case, clinical symptoms developed since 1 year before. The final diagnosis made after craniotomy. The patient treated with an extensive excision and medical antifungal therapy, but finally he failed to respond to these treatments.

PP1-140
EGFR STATUS IN PEDIATRIC EPENDYMOMAS USING IMMUNOHISTOCHEMISTRY (IHC) AND CHROMOGENIC IN SITU HYBRIDIZATION (CISH)
Martha Quezado[1], Mariarita Santi[2], Elisabeth Rushing[3], Maria Begnami[1]
[1] NCI/NIH/USA
[2] Children's Hospital, Washington DC/USA
[3] AFIP/Washington DC/USA

Background: The epidermal growth factor receptor (EGFR), a member of the family of receptor tyrosine kinases, plays an important role in a wide variety of pathophysiological disorders including cancer. Studies have shown that EGFR amplification correlate with shorter survival in glioma patients receiving adjuvant therapies. In ependymomas, EGFR status remains unclear. Different EGFR targeted therapies using agents directed toward the intracellular tyrosine kinase domains are currently in phase III clinical trials. The optimal assay to evaluate EGFR status in possible candidates for possible anti-EGFR therapy remains to be determined. In this study, we evaluated nine pediatric ependymomas for both EGFR gene amplification and protein expression by CISH and IHC. Design: Nine pediatric ependymomas were evaluated. CISH and IHC were performed using paraffin-embedded tissue. High EGFR expression was detected when total membranous staining was seen in more than 10% of the cells. CISH amplification was seen when 10 or more copies or larger clusters were seen in more than 50% of the nuclei; low amplification was seen in the cases with 6-10 copies in more than 50% of the nuclei. Result: EGFR amplification was not detected in any case. Protein EGFR eoverexpression was present in a single ependymoma. Conclusion: EGFR amplification/protein overexpression is a rare phenomenon in pediatric ependymomas. These findings suggest that EGFR abnormalities are not associated with pediatric ependymomas tumorigenesis; therefore, it is unlikely that patients with these tumors will benefit from EGFR targeted therapy.

PP1-141
EVALUATION OF THE RELATIONSHIP BETWEEN UNDESCENDED TESTES AND NEUROMUSCULAR DISORDERS

Gulden Diniz, Mustafa Barutcuoglu, Safiye Aktas, Nedret Uran, Hursit Apa, Ragip Ortac, Aycan Unalp, Saniye Gulle, Aysel Aydogan
Izmir Dr. Behcet Uz Children's Hospital, Turkey

Background/aim: Because of striated muscle origin; the cremaster muscle may be possibly affected by neuromuscular disease and may cause the increased incidence of undescended testes and other urogenital malformations. Therefore we aim to determine the frequency of undescended testes in children with muscle disease. Material and methods: Seventy boys as having neuromuscular disorders confirmed with muscle biopsy were included in this study. Fresh striated muscle samples of all cases were frozen in liquid nitrogen and frozen sections were evaluated with several histochemical, enzyme and immune histochemical stains. Detailed clinical information, physical and laboratory examination findings were obtained from patients files. Clinical relevance of undescended testes was evaluated. All findings were searched statistically. Results: The mean age of the boys was 6.73 (± 3.71). Muscular dystrophies were the most common disease (57.2 %). Other diseases determined in the cases were 17 primary myopathies, 6 inflammatory myopathies, 4 neuropathies, and 3 have metabolic/ mitochondrial myopathies. Sixteen patients (22.9 %) had similarly affected family members. Consanguinity rate was 28.6 % (n= 20). Sixty two patients (88.6 %) presented at least one of the muscle serum enzymes altered. Forty four patients (62.6 %) had pathological EMG findings. Fourteen cases (20 %) had fiber type disproportion. Urogenital malformations were determined in 7 patients (10 %). In Spearman's Correlation Analysis, there were statistical significances between the types of neuromuscular disease and the presence of undescended testes (p= 0.040) and urogenital malformations (p= 0.017). In Chi Square test, no statistical significance was found (p= 0.284). The odds ratios for undescended testes and urogenital pathologies were computed and they were found 4.03 and 4.51 respectively. These results supported that urogenital abnormalities were more common in children with neuromuscular disorders than population. Conclusion: We thought that congenital muscle disease may create a disturbance of testicular descend possibly with influence of cremaster muscle or other inguinal tissues. Therefore children with muscle diseases must be more carefully physical examined for presence of urogenital pathologies and paradoxically children with urogenital pathologies must be neurologically examined for presence of neuromuscular disorders.

PP1-142
CYCLOOXYGENASE-2 (COX-2) EXPRESSION AND ANGIOGENESIS IN GLIOBLASTOMA

Onder Onguru[1], Mehmet Gamsizkan[2], Cuneyt Ulutin[3], Omer Gunhan[1]
[1] GATA, Department of Pathology, Turkey
[2] Ankara Military Hospital, Department of Pathology, Turkey
[3] GATA, Department of Radiation Oncology, Turkey

Background: Cyclooxygenase-2 (Cox-2) (the key enzyme that catalyzes the first steps in the biosynthesis of the prostaglandins from arachidonic acid) appears to play a role in the regulation of progression, invasiveness and angiogenesis of various neoplasms. Method: We analyzed the imunohistochemical expression of Cox-2 and angiogenic parameters (microvessel density and vascular patterns) in 54 glioblastomas. We also examined their relation with prognosis. Results: Cox-2 immunohistochemical expression was observed in 48 tumors (89%). There was no staining in six tumors (11%). On univariate analysis, MVD was correlated with a poor outcome (MVD>70, hazard ratio:0.441, 95% confidence interval: 0.200-0.975, p=0.041). But MVD showed no prognostic impact on multivariate analysis. Neither Cox-2 expression nor vascular pattern showed prognostic value. The difference in Cox-2 expression between the classical and bizarre vascular pattern in glioblastomas was statistically significant (p=0.047). But, no correlation was found between Cox-2 expression and MVD. Conclusion: These findings suggest that Cox-2 is heterogeneously expressed in glioblastomas without a significant association with microvessel density. However, Cox-2 expression may be related with vascular pattern in glioblastomas.

PP1-143
BRAIN PARENCHYMA CLEAR CELL EPENDYMOMA

Thouraya Achach, Soumaya Rammeh, Amel Trabelsi, Wided Stita, Ines Kalamoun, Sonia Ziadi, Lilia Jaidane, Mohamed Tahar Yaacoubi, Sadok Korbi
Department of Pathology, Farhat Hached Hospital, Sousse, Tunisia

Background Ependymoma is a slow growing glial tumor originating from the ventricular or central canal lining and composed of neoplastic ependymal cells. In children, it usually arises in the posterior fossa. Exceptionally, it may occur in brain parenchyma, without any connection to the ventricular lining. Clear cell ependymoma is an uncommon and diagnostically challenging variant. Method We report a rare case of brain parenchyma clear cell ependymoma arising outside the ventricular system and occurring in a 12-year-old-boy and we describe the epidemiologic, clinicoradiologic and pathologic features of clear cell ependymoma. The differential diagnosis is discussed and similar published cases are reviewed. Results The patient was presented with 4-months history of symptoms related to intracranial hypertension. MRI brain demonstrated a heterogenous lobulated solid and cystic parietal mass, which measured 7 cm at high diameter. Tumor was partially excised. Histology, showed variable density of tumor cells. Many of these cells had a clear perinuclear halo. Perivascular pseudorosettes were obvious in most of the sections. Immunohistochemistry revealed positivity for GFAP, S-100. EMA showed granular cytoplamic positivity. Conclusion Two particularities are highlighted in this case: first the localization on brain parenchyma without connection to ventricular system, second the predominance of clear cells in this tumor.

PP1-144
ANTI-INFLAMMATORY AND ANTI-APOPTOTIC ACTION OF ATYPICAL 1,4-DIHYDROPYRIDINE COMPOUNDS IN NEUROTOXICITY MODELS

Vija Klusa[1], Sergejs Isajevs[1], Linda Klimaviciusa[1], Jolanta Pupure[1], Juris Rumaks[1], Simons Svirskis[1], Gunars Duburs[2]
[1] University of Latvia, Latvia
[2] Latvian Institute of Organic Synthesis, Latvia

Background. Our concept suggests that atypical (non-calcium antagonistic) 1,4-dihydropyridine (DHP) compounds which previously demonstrated anti-neurodeficiency activities in vivo models, may open new possibilities of neuroprotection provided by targeting mitochondrial and oxidative stress processes. These DHPs are: cerebrocrast (comprizing classical bi-cyclic DHP structure), glutapyrone and tauropyrone (glutamate- and taurine-containing monocyclic DHP structures). The present studies investigated ability of these drugs to protect neuropathologic changes in cultured nerve cells and cerebral cortex (ex vivo) caused by different neurotoxic agents which induce mitochondrial dysfunctions. Methods. 1.Assessment of cell death, free radical production and mitochondrial membrane potential in neurotoxicity model in cerebellar granule cells by use of neurotoxins: a) MPP+, b) oxygen-glucose deprivation (OGD), and c) glutamate; 2. Immunohistochemical assessment of apoptosis and astrocyte proliferation in cerebral cortex: caspase-3 and GFAP, a glial fibrillary acidic protein, expression in mice brain tissue after repeated i.p. administration (for two weeks) of DHP drugs per se, and DHP + anti-HIV drug azidothymidine (AZT), a well-known mitochondria-compromizing drug. Results. In MPP+ model, only cerebrocrast acted as neuroprotective agent by complete prevention of cell death, free radical production and drop in mitochondrial membrane potential. Amino acid-containing DHPs lacked these activities, however they showed neuroprotection in OGD (ischemia) and glutamate models. In the mice cerebral cortex, AZT induced major histopathological changes (pericellular and perivascular oedema, perivascular inflammatory infiltration), increased caspase-3 expression and caused an upregulation of astrocytes. Cerebrocrast considerably decreased these changes and reduced caspase-3 expression in AZT-induced neurotoxicity model (9 ± 1 vs.16 ± 2 cells/mm2, $P<0.004$), whereas glutapyrone and tauropyrone lacked this effect. Besides, tauropyrone demonstrated pro-apoptotic activity. Conclusion. The data obtained clearly demonstrate a beneficial neuroprotective - anti-apoptotic and anti-neuroinflammatory - action of cerebrocrast, a representative drug of atypical DHP series, opening new vistas in novel mitochondria-targeted drug design for the treatment of neurodegenerative disease related to mitochondrial and apoptotic damages (e.g. Parkinson's disease, Alzheimer's disease).

PP1-145
CD44, MEMBRANE TYPE 1- MATRIX METALLOPROTEINASE (MT1-MMP) AND KI–67 EXPRESSION IN ASTROCYTIC TUMORS

Fugen Kivanc[1], H. Reyhan Egilmez[2], Ersin Tuncer[2], Hatice Ozer[2], Ozen Karadag[3], O. Fahrettin Goze[2]
[1] Yozgat State Hospital Pathology Laboratory - Yozgat, Turkey
[2] Cumhuriyet University Faculty of Medicine Pathology Department - Sivas, Turkey
[3] Cumhuriyet University Faculty of Medicine Neurosurgery Department - Sivas, Turkey

BACKGROUND: Astrocytic tumors are the most common primary tumors of the brain. Astrocytic tumors include astrocytoma (Grade II), anaplastic astrocytoma (Grade III), and glioblastoma multiforme (Grade IV). Astrocytomas and glioblastomas are known to have high capacity of local invasiveness with uncommon extracranial metastatic ability. CD44's expression shows poor prognosis in breast and colon carcinomas and proposed to be an invasion marker in glioblastomas. Matrix Metalloproteinase (MT1-MMP) is an important factor promoting the cerebral invasion and neovascularisation of the gliomas. METHOD: H&E slides obtained from Cumhuriyet University Faculty of Medicine Pathology Department archieve belonging to 70 patients who were diagnosed as having astyrocytic tumor between years 1993 to 2005 were reevaluated according to the criterias of WHO classification accepted in 1993. Slides obtained from paraffin blocks of the cases were stained with CD44, MT1-MMP and Ki-67 immunohistochemically. RESULTS: Nine of the cases were pilocytic astrocytoma, 14 were diffuse astrocytoma three were anaplastic astrocytoma and 44 were glioblastoma multiforme. Statistical analysis of the study were performed between Low Grade Astrocytic Tumors (LGAT) (Grade I + Grade II) and High Grade Astrocytic Tumors (HGAT) (Grade III + Grade IV). CD44 and MT1-MMP expressions showed weak cytoplasmic and membranous staining in LGATs whereas they showed strong cytoplasmic and membranous staining in HGATs. There was a significant difference in cytoplasmic staining ratios and membranous staining intensities in MT1-MMP and CD44 expressions between LGATs and HGATs ($p<0.05$). Ki-67 proliferation index was found to be 4.54 ± 7.81 in LGATs and 18.31 ± 9.51 in HGATs ($p<0.05$). CONCLUSION: Ki-67 proliferation index was found to be directly correlated with increased tumor grade. As a result it is concluded that, CD44 and MT1-MMP may be useful as an invasion marker in astrocytic tumors and they are related with malign progression of gliomas.

PP1-146
FATAL FAMILIAL INSOMNIA (FFI): CLINICAL AND NEUROPATHOLOGICAL STUDY OF ANOTHER SPANISH FAMILY

Garcia-Bragado Federico[1], Caballero Cristina[2], Tuñon Teresa[2], Ayuso Teresa[3], La Cruz Francisco[3]
[1] Pathology Department Virgen del Camino Hospital, Pamplona, Spain
[2] Navarra Brain Bank, Pamplona, Spain
[3] Neurology Department Navarra Hospital, Pamplona, Spain

Fatal familial insomnia (FFI) is a transmissible prion disease linked to a mutation in codon 178 of the prion protein gene (PRNP) on chromosome 20. It is characterized by disturbed sleep-wake cycle, resulting in daily vigilance perturbations and a variety of other neurological symptoms. We present the clinical and neuropathological findings, and genotyping of three relatives of a Spanish family affected with fatal familial insomnia. The patients were maternal cousins, (43, 49 and 53 years old) and the mother of two of them was previously diagnosed of Gerstmann–Straüssler–Scheinker disease (GSS) in another institution based exclusively on neuropathologic study. The patients developed a rapidly evolving disease with alterations of sleep-wake cycle and behavioural disorders as the initial symptoms and died between 4 and 12 months after the onset of the illness. A full neuropathological examination done at the Navarre Neurological Tissue Bank showed thalamic and olivary degeneration with isolated and mildfocal cortical spongiosis. In the genetic examination all the patients harboured the prion protein (PrP) D178N (ASP178ASN) mutation and were homozygous Met/Met in codon 129. Based on the cases presented here, we discuss typical clinical symptoms and neuropathological findings. In particular, we outline how genetic testing is mandatory in the diagnosis and may lead to the identification of a risk of a genetic prion disease.

THE STATUS OF MGMT METHYLATION AND TP53 MUTATIONS IN PATIENTS WITH GLIOBLASTOMA

Dorota Jesionek-Kupnicka[1], Izabela Zawlik[2], Emilia Jesień-Lewandowicz[3], Małgorzata Szybka[1], Dominika Kulczycka[1], Reneta Kusińska[1], Grażyna. Pasz-Walczak[1], Radzisław Kordek[1]
[1] Department of Tumor Pathology, Chair of Oncology, Medical University of Lodz, Poland
[2] Department of Molecular Pathology and Neuropathology, Chair of Oncology, Medical University of Lodz, Poland
[3] Department of Radiation Oncology, Copernicus Memorial Hospital, Lodz, Poland

Background: MGMT (O – 6 – methylguanine – DNA - methyltransferase) is a DNA-repair enzyme that specifically removes promutagenic alkyl groups from the O-6 position of guanine and protects cells from cytotoxic and mutagenic effects. Epigenetic silencing of O (6) – methylguanine - DNA methyltransferase (MGMT) by promoter methylation can leads to lack of DNA-repair, increased sensitivity to alkylating chemotherapeutic agents and a higher susceptibility to TP53 transition mutations, especially G:C/ A:T transitions. The aim of our study was to assess the correlation of promoter methylation of the MGMT gene with TP53 mutations and the clinical characteristics of glioblastomas. . Methods : Tumor samples were obtained from 32 patients with primary glioblastoma (15 males and 17 females, aged from 40 to 75 years). The methylation-specific PCR (MSP) was performed in a two-step approach .The PCR products were separated on 3% agarose gel containing ethidium bromide and documented using the Gel Doc1000 Bio Rad Image System. For each PCR reaction, methylated and unmethylated DNA were included as positive and negative control. Results : Methylation of the MGMT promoter was detected in 72% (23 of 32) of tumors. 31% (10 of 32) of all tumors presented TP53 mutations. 90 % of TP53 mutations were detected in tumors that also presented MGMT methylation. We further correlated the results with survival. Conclusions: Methylation of the MGMT promoter gene is a freguent molecular event in glioblastoma.There was no statistical correlation between TP53 mutations MGMT methylation (Fisher exact test p=0.223). Coexistence of MGMT methylation and TP53 mutations in patients with glioblastoma was not associated with the best prognosis.

PP1-148

ANGIOLIPOMA OF SUPRASELLAR AND SELLAR REGION – CASE REPORT

Danijela Kolenc[1], Kamelija Žarković[1], Hrvoje Jednačak[2], Josip Paladino[2]
[1] Division of Neuropathology, Department of Pathology, University Hospital Zagreb, Croatia
[2] Department of Neurosurgery, University Hospital Zagreb, Croatia

INTRODUCTION Angiolipomas are benign mesenchymal neoplasms. The forearm is the most common site, followed by the trunk and upper arm. Within the craniospinal axis, angiolipomas are extremely rare, and almost all have been found in the spinal extradural space. Here we present two patients with suprasellar and sellar angiolipoma. CLINICAL SUMMARY Patient 1 – A 53-year old man presented to neurologist six months before initial neurological evaluation with sudden intensive headache, vertigo and deficit in lower part of visual field. Magnetic resonance imaging disclosed an expansive process in pituitary gland that was isointense compared to brain tissue on T1-weighted images, whereas T2-weighted images and the gadolinium enhanced T1-weighted images showed a strongly hyperintense, homogeneous lesion. Patient 2 – A 49-year old woman was admitted to hospital because of intensive headache, fatigue, vertigo and visual deficit. Magnetic resonance showed a expansive process within sellar region extending to the adjacent cavernous sinus. T1 and T2-weighted and the gadolinum enhanced images were identical to Patient's 1. METHODS AND RESULTS Paraffin embedded tumors of both patients were examined by staining section with hematoxylin and eosin and with Mallory, and immunohistochemistry method with vimentin and actin. Light microscopy revealed a very vascular tumor composed of dilated capillaries and mature adipose tissue. Vessels were composed somewhere of only flattened single layer of endothelial cells and others showed a few layers of smooth muscle cells. Interstitium consisted of mature adipose tissue with mast cells and collagenous stroma. CONCLUSION Angiolipomas represent mesenchymal hamartomas composed of abnormal blood vessels and mature adipose tissue. These tumors are extremely rare within craniospinal axis. According to the literature, only four patients have been reported with angiolipoma in suprasellar and sellar region.

PP1-149

USEFULNESS OF IN SITU DEMONSTRATION OF 1P LOSS AND P53 OVEREXPRESSION IN PATHOLOGIC DIAGNOSIS OF OLIGODENDROGLIAL TUMORS

Takanori Hirose, Keisuke Ishizawa
Department of Pathology, Saitama Medical School, Japan

BACKGROUND: Recent development of adjuvant chemotherapy effective to oligodendroglial tumor increases the requirement of an accurate pathologic diagnosis of this tumor. However, the differentiation between astrocytic and oligodendroglial tumors is not always straightforward. To improve the diagnostic accuracy of diffuse gliomas, we intended to compare pathologic findings to chromosome 1p status and overexpression of p53. DESIGN: The cases studied included 12 oligodendrogliomas (6 grade II, 6 grade III), 6 oligoastrocytomas (1 grade II, 5 grade III), 1 pilocytic astrocytoma, 9 astrocytomas (4 grade II, 5 grade III), and 10 glioblastomas. On the paraffin sections, 1p loss was analyzed using the fluorescence in situ hybridization (FISH) method. When the ratio of nuclei containing a single 1p signal and two centromere 1 signals is more than 50%, the case was evaluated to be positive for 1p loss. Immunohistochemically, the expression of p53, GFAP and Olig2 was studied. In addition, double immunostaining for GFAP and Olig2 was carried out. RESULTS: FISH analyses demonstrated the 1p loss in 83% of oligodendrogliomas and 50% of oligoastrocytomas, but not in any astrocytic tumors except for 1 grade II astrocytoma and 1 glioblastoma. No detectable microscopic differences were noticed between 1p loss-positive and negative cases in oligodendroglial tumors. Overexpression of p53 was detected in 5 oligodendroglial tumors, all of which corresponded to 1p loss-negative cases, as well as in 40% of astrocytic tumors including glioblastoma. Olig2 expression was seen in all gliomas studied and GFAP was also commonly expressed in most oligodendroglial (78%) and all astrocytic tumors. Double immunostaining for Olig2 and GFAP demonstrated that the expression of these antigens was mutually exclusive in most cases and that the coexistence in a single cell was noted in only 30% of glioblastomas. CONCLUSION: The present study confirmed that 1p loss was almost specific to oligodendroglial tumors and demonstrated that the overexpression of p53 in oligodendroglial tumors was restricted to those without 1p loss. Although it seems hard to predict the 1p status microscopically, p53 immunohistochemistry may provide useful information about the chromosomal abnormality. Olig2 and GFAP were frequently expressed in both gliomas, indicating a limited role for the differential diagnosis. Considering the mutually exclusive localization of these antigens in low and moderate grade gliomas, the coexistence may indicate the severe disruption of cell differentiation in glioblastoma.

FASCIN EXPRESSION IN GLIAL TUMORS AND PROGNOSTIC VALUE
Armagan Gunal[1], Mukerrem Safali[1], Onder Onguru[1], Murat Beyzadeoglu[2]
[1] Gulhane Military Medical Academy, Department of Pathology, Turkey
[2] Gulhane Military Medical Academy, Department of Radiation Oncology , Turkey

Backround: Glial tumors, especially high grade forms are known as aggressive malignancies, with generally short survival time. So, determination of prognostic parameters is always important. But prognostic parameters of glial tumors are quite limited and histologic grade of the tumor is accepted as the most important prognostic factor. While tumor histologic grade increases, mean survival time remarkably shortens. In addition to tumor histologic grade, to detect new prognostic parameters, especially molecular and genetic alterations are interesting study subjects. Fascin, an actin-bundling protein, is one of those molecules and its contribution to prognosis investigated in many tumors. Method: In this study, fascin expression of glial tumors correlated with histologic grade and investigated prognostic value. 76 glial tumors (44 glioblastomas with known survival time, 18 anaplastic astocytomas, 6 diffuse astrocytomas, 8 pilocytic astrocytomas) were examined immunohistochemically for fascin expression. Results: As results for this study, significant correlations have been found between "distribution and intensity of fascin expression" and tumor histologic grade. In glioblastoma group; survival rates were statistically higher for cases that ≤ 50 year-old and express weak fascin intensity ($p< 0.05$). In addition, age and "distribution-intensity score of fascin expression" found as independent prognostic factors in glioblastomas ($p< 0.05$). Conclusion: In conclusion, fascin expression levels are correlated with tumor grade and fascin overexpression may play an important role in the biologic behavior of glial astrocytic tumors and in their prognosis

FASCIN EXPRESSION IN ASTROCYTIC NEOPLASMS
Levent Yildiz, Mehmet Kefeli, Oguz Aydin, Bedri Kandemir
Ondokuz Mayis University, Faculty of Medicine, Department of Pathology, Turkey

BACKGROUND: Fascin is a 55-kd actin-bundling protein encoded by the human homolog for sn (hsn) gene. It is found in cell membranes and promoting cellular motility. Fascin has been linked to the malignant biological behavior of some tumors. We investigated immunohistochemically fascin expression in astrocytomas and in gliosis cases. METHOD: Immunohistochemical study was performed in 28 astrocytic tumors and in 6 gliosis. Fascin positivity of tumor cells was graded as follows: no staining or less than 5% as 0, 5% to 25% as (1+), 26% to 50% as (2+), 51% to 75% as (3+), more than 75% as (4+). RESULTS: There were 18 males and 10 females (mean age, 47.6 years) in astrocytoma group. Eighteen of 28 cases showed positive fascin staining (64%). Two of seven WHO grade I cases showed positive fascin staining (28.5%). Four of six WHO grade II cases showed positive fascin staining (66%). Four of eight anaplastic astrocytomas cases showed positive fascin staining (50%). All of GBM cases (7 cases) were positive (100%). All of gliosis cases (3 males, 3 females) were positive. Immunohistochemically fascin staining was intracytoplasmic in tumor cells whereas paranuclear staining was seen in astrocytic cells in gliosis cases. Fifteen tumors showed more than 75% positive staining tumor cells, 3 tumors had 50% to 75% staining. In comparison, 6 of 13 WHO grade I and grade II astrocytomas had fascin positivity (46%), 12 of 15 WHO grade III and IV astrocytomas had fascin staining (80%). CONCLUSION: Higher grade astrocytic tumors generally expressed a greater degree of fascin staining. But for it shows reactivity in gliosis too, it is not helpfull in distinguishing tumor and gliosis. Fascin expression may play a role in malignant biological behavior of astrocytic neoplasms.

PP1-152
HDAC, MGMT, P53 AND ACTIVATED AKT/PKB PROFILES IN ASTROCYTIC GLIOMAS
Despoina Televantou, Triantafyllia Koletsa, Athanasios Fassas, Georgios Karkavelas, Vassiliki Kotoula
Aristotle University, Greece

BACKGROUND/AIM: Response to alkylating and methylating agents currently in use for astrocytic glioma treatment is considered to depend on p53 status or MGMT (O6-methylguanine DNA methyltransferase) expression. MGMT silencing, usually a result of promoter methylation, can also be achieved by HDACs (histone deacetylases), which, in addition, promote survival by keeping AKT/PKB in the phosphorylated and p53 in the deacetylated status. The aim of this study was to identify immunophenotypic/functional profiles of astrocytic gliomas in regard to proteins targeted by newly developed anticancer drugs. METHODS: Eleven protein markers (acetylated histones H2A, H2B, H3, H4, lysine specific histone demethylase-1 [LSD1], HDAC1, 3 and 5, MGMT, p53, and phosphorylated / activated AKT/PKB [pAkt-Ser473]) were investigated in 42 astrocytomas (28 grade IV, 7 grade III and 7 grade II). Immunostaining evaluation cut-offs were set at 10% strong staining in tumor cells for all markers except acetylated histones and LSD1. RESULTS: Acetylated histones and LSD1 were ubiquitously expressed in all categories of tissues tested, benign and malignant, whereby strong positivity for H2B was predominantly found in grades II and III ($p=.013$). Aberrant expression of HDACs, MGMT, p53 and pAkt was collectively observed in 39/42 (92.9%) astrocytic gliomas. HDAC1 and/or HDAC5 expression were observed in 29/42 (69.1%) cases, wherefrom in 5/14 (35.7%) grade II/III and in 24/28 (85.7%) grade IV tumors ($p=.001$). HDAC1 positive tumors were exclusively grade IV (12/28 [42.9%], $p=.004$), while coexpression of both HDACs occurred in 9 cases. MGMT and p53 expression (19/42 [45.2%] for both, different cases) were unrelated to tumor grade but showed inverse correlation to each other ($p=.025$), justifying the reported need of wild-type p53 for MGMT expression. The same incidence (45.2%) was observed for strong cytoplasmic pAkt-Ser473 positivity, which was associated with grade IV tumors ($p<.001$). HDAC expressing tumors with phosphorylated AKT/PKB (15/42 [35.7%]) were either MGMT or p53 positive ($p<.0001$ and $p<.001$, respectively). CONCLUSIONS: This study shows that the majority of astrocytic gliomas, mainly those of grade IV, express HDACs 1 and/or 5, and that half of these tumors have activated AKT/PKB while simultaneously expressing MGMT or p53. The above profiles may explain the commonly observed failure in classic and recently established astrocytic glioma treatment and, if validated in larger studies, they seem to justify the need for therapeutic interventions with HDAC activity in this group of tumors.

PP1-153
ANGIODYSGENETIC NECROTIZING MYELOPATHY (FOIX – ALAJOUANINE SYNDROME): REPORT OF TWO AUTOPSY CASES
Mario Alfonso Reséndiz-Morán, Alva Martínez-Angoa, Laura Graciela Chávez-Macías, Juan Eligio Olvera-Rabiela
Hospital General de México, México

In 1926 Foix and Alajouanine described for the first time two postmortem cases with spinal arteriovenous malformations. These occur in adult males, clinically they often involve low thoracic and lumbosacral spinal segments, are manifested with paraparesis, gradual sensory disturbances in the lower limbs, sphincters disfunction and impotence (Foix-Alajouanine syndrome or angiodysgenetic necrotizing myelopathy). Two

postmortem cases are reported in which the clinical manifestations and the arteriovenous malformations were present. Both patients died of pulmonary embolism. There are around 50 case reports in the world literature about this entity. Two cases with the clinical features above described and in which a spinal arteriovenous malformation was documented by autopsy, are presented here. The first was that of a 60 year old man with severe pain and inability to stand up. Later on had weakness of the lower limbs, alterations of sensation and difficulty to urinate. Died 23 days after admission from pulmonary emboli. The spinal cord had a large number of dilated and tortuous subarachnoid veins on its dorsal surface. The second case was that of a 46 year old male with motor deficit of the left lower limb which evolved to paralysis of both pelvic extremities, sensitivity disturbances and urinary retention. Died on day 13 of his hospitalization from pulmonary emboli. An extensive intraspinal haemorrhage was found. In both cases abnormal intraspinal and subarachnoid vessels were identified. They showed tortuosity, dilatation and collagenization of their walls. Changes of hypoxic myelopathy were present. It has been proposed that there is a direct communication between arterial and venous systems throughout abnormal vessels ("dilated" veins) without passing through capillaries as is seen in normal conditions. The blood flows from arteries to veins, so the blood pressure of venous system increases and an ischemic damage is produced in the spinal cord because of degeneration of the walls of vessels that are not designed to support elevated pressure, besides there is a progressive occlusion. Venous hypertension per se predisposes to stasis and thrombosis, so there is spinal necrosis and irreversible neurological damage. In conclusion it should be emphasized angiodysgenetic necrotizing myelopathy is an entity with a prognosis that depends of a correct and early diagnosis, so it is very important to use imaging techniques as myelography and spinal angiography in those patients that present a spinal cord syndrome, and to establish timely surgical management.

PP1-154
GIANT ARTERIOVENOUS MALFORMATION IN THE BRAIN. REPORT OF SEVEN AUTOPSY CASES

Mario Alfonso Reséndiz-Morán,
David Eduardo Aguirre-Quezada, Alva Martínez-Angoa,
Laura Graciela Chávez Macías, Juan Eligio Olvera-Rabiela
Hospital General de México, México

Arteriovenous malformation (AVM) is an abnormal communication between arteries and veins without an intermediate capillary network. They are usually seen in the fourth and fifth decades of life and more commonly in males. They cause approximately 5% of the parenchymatous hemorrhages in the brain. They can cause ischemic damage by the "steal phenomenon" which results from the arteriovenous shunt. Classically they have been divided in capillary telangiectasias, cavernous angiomas and arteriovenous malformations, but now the are all considered in one group and behave like pseudotumoral lesions. The usual sequence in the formation of the AVMs is first dilatation of the veins with compression of the neighboring tissue, then replacement of the muscular wall by collagen which confers to the cut surface a sand paper texture. Seven cases of giant arteriovenous malformations of the brain are presented. Four were in males and three in females. In all of them chronic headache was present. Three manifested with haemorrhage, one with multiple infarcts due to "steal phenomenon" and one with hydrocephalus due to compression of the aqueduct. Five were clinically diagnosed and treated and two were autopsy findings. About 1% of parenchymal hemorrhages are due to AVMs. Clinically they manifest by parenchymal bleeding in 50% of cases, with seizures in 20% to 25%, headache in 15% and focal deficits in <5%. In children of less than 2 years of age heart failure is not uncommon. The "steal phenomenon" is rare at any age. Nowadays the diagnosis is made by CT, MRI and arteriography both carotid and vertebral. The size and topography of the AVM are essential to institute the correct treatment. In 1986 Spetzler and Martin proposed a system of grading based on the size, location and pattern of venous drainage. The scale has 5 grades and is used to evaluate the relative risk and the selection of the appropriate therapy. Four modalities of treatment exist, namely monitorized follow up, microsurgery, endovascular surgery and radiosurgery. Deterioration due to treatment has been observed in 19% in patients with grades I and II, in 25% in those with grades III and in 42% of patients with grades IV and V. Therefore, surgical treatment is not recommended in high grade cases. The cases presented here show that the size of the lesion is the most important factor in the outcome, which can be hemorrhage, "steal phenomenon" and massive dilatation of the vein of Galen.

PP1-155
THE DETECTION OF DIFFUSE AXONAL INJURY IN HEAD TRAUMAS, THE ROLE OF BETA AMYLOID PRECURSOR PROTEIN IN DIAGNOSIS

Ferah Karayel[1], Aydin Sav[2], Nadir Arican[3]
[1] Council of Forensic Medicine, Turkey
[2] Marmara University Marmara Medical Faculty Department of Pathology, Turkey
[3] Istanbul University Istanbul Medical Faculty Department of Forensic Medicine, Turkey

One of the most important factors affecting mortality and morbidity in head trauma cases is diffuse axonal injury (DAI). The aim of this study is to prospectively study DAI both macroscopically and microscopically in brain samples obtained from head trauma cases whose autopsies were carried out in Mortuary department of the Council of Forensic Medicine. We also aimed to analyze the relationships between the DAI, survival time and other traumatic findings in autopsy. Of the 70 cases involved in this study, 64 (91,4 %) were male and 6 (8,6 %) were female and those having 3-24 hours survival time after the trauma constituted the most crowded group (28,6 %). Traffic accidents were found to be the major trauma type with a frequency of 54,4 %. While DAI was detected in 22 cases (31,4 %) by microscopic examination of Hematoxyline- Eosin (HE) sections, it was detected in 33 cases (47,1 %) by evaluation of the immunohistochemical Beta-Amyloid Precursor Protein (β-APP) treated sections. When the regions of the brain were taken into consideration in DAI cases, axonal bulbs as a finding of the axonal injury were detected to be in corpus callosum in all cases (100%), rostral brainstem in 77,2 %, internal capsule in 63,6 % and parasagittal white matter in 9 % of the cases. In evaluation of the relation of the morphological findings of axonal injury to the survival time after the trauma, the early morphological findings of the injury was demonstrated to be present at about 12 hours by an examination with HE but at 4-5 hours by an examination using β-APP. In none of the cases with a survival time of 3 hours or less, axonal injury was detected by using the both techniques. There seemed an increase of the density and degree of widespread in relation to survival time after the trauma and the most intensive β-APP positivity was detected in the cases with a survival time of over 8 days. The relationship between the development of axonal injury in the brain and type of head trauma, post-mortem interval, scalp lesions detected at autopsy and other parameters such as skull fracture, bleeding and contusion was insignificant. In conclusion, in all head trauma cases, regardless of the type of the trauma, DAI must be taken into consideration and the brain must be thoroughly examined both macroscopically and microscopically.

PP1-156
CORRELATION OF PROLIFERATIVE CAPACITY (MIB-1) AND ANGIOGENESIS (VEFG AND BFGF) IN HISTOLOGICAL SUBTYPES OF MENINGOTHELIAL TUMORS

Aydin Sav[1], Idil Almaata[2]
[1] Marmara University Hospital, Department of Pathology, Altunizade, Istanbul, Turkey
[2] Gaziosmanpasa Clinic, Pathology Laboratory, Gaziosmanpasa, Istanbul, Turkey

Introduction: Tumors of the central nervous system show highly complex growth capacity that is end result of interaction between cellular proliferation and growth factors controlling angiogenesis. By and large, growth factors of controlling vasculogenesis have crucial importance in neurooncology. Methods: In a cohort of 37 cases containing typical (n=20) [grade I]; atypical (n=11) [grade II and malignant (n=6) [grade III] meningiomas classified according to demographic (age, gender, site) and histological subtypes. Proliferative capacities of each individual tumor were assessed by MIB-1 whereas angiogenetic markers bFGF and VEFG for their growth manipulation and angiogenesis, respectively. Results: WHO 2000 classification was used not only for grading but for subtyping in meningothelial tumors. Higher the grade of tumors, more apparent hypercellularity, necrosis, mitosis, sheeting and brain invasion were. By and large, vascular, nuclear and cytoplasmic immunoreactivity of bFGF correlated as higher the grade, more prominent the expressivity. It should be emphasized intratumoral vascular bFGF correlated with tumor grade ($p<0.05$). Furthermore, MIB-1 LI correlated with vascular bFGF immunoreactivity positively and it appeared to be statistically significant ($r=0,543$, $p<0,001$). Neither nuclear bFGF nor cytoplasmic bFGF immunoreactivity correlated with different grades ($p>0,05$). VEFG immunoreactivity was found to be highest expressivity in malignant meningioma group, particularly in papillary subtype. Conclusion: MIB-1 LI is a precise marker for cell kinetics that directly proportional between grade I vs. grade II, but not useful for differentiating grade III from the former two. There was no significant correlation between cytoplasmic VEGF with that of cytoplasmic and nuclear bFGF immunoreactivity suggesting the meager interaction between these two molecules. Moreover, tumors profoundly proliferating showed a proportional and selectively higher vascular bFGF proposing close correlation between proliferating tumor cell and its vascular supply (angiogenesis). Atypical and malignant meningiomas those bearing microvascular rich matrix were under control of not only high cell kinetics but also vascular growth factor, i.e., bFGF and VEGF. Abbreviations: LI: Labeling index / WHO: World Health Organization / VEGF: vascular endothelial growth factor / bFGF: basic fibroblast growth factor /

PP1-157
LOH ON 1P/19Q AND 10Q AND Ki-67 LABELLING INDEX IN GLIAL TUMORS

Inanc Elif Gurer[1], Sezin Yakut[2], Sibel Berker Karauzum[2], Ethem Coksu[3], Guzide Gokhan[1]
[1] Akdeniz University, School of Medicine, Department of Pathology, Antalya, Turkey
[2] Akdeniz University, School of Medicine, Department of Medical Biology and Genetics, Antalya, Turkey
[3] Akdeniz University, School of Medicine, Department of Neurosurgery, Antalya, Turkey

Backgrounds: Many studies have shown that molecular and cytogenetic findings offer a more encouraging view of the behavior of glial tumors. The loss of special genes can be related to tumor progression. LOH of the oligodendroglioma-associated tumour suppressor genes suspected on 1p and 19q have been shown in mostly oligodendrogliomas and closely correlated with the oligodendroglioma phenotype and the survival of patients with these aberrations considered more favorable. Same chromosomal aberrations can also occur in some astrocytomas as well.. Also loss of chromosome 10 is common in glioblastoma multiforme (GBM) and pivotal events as the lesion passes from grade III to IV . About Ki-67 labelling index (LI), various percentages are being reported in various studies depending on the grade of glial tumors. In this study, LOH of chr 1p/19q and 10q , their relation with survival and Ki-67 LI in GBMs have been investigated Also a few oligodendroglioma cases included to compare . Method: To study allelic deletions at chromosomes 1p,19q and 10q, we obtained DNA from peripheral blood and also tumor samples of 19 patients. 8 microsatellite markers were used for PCR-LOH analysis. LOH analysis were performed by ABI 31O Genotype. Data were collected automatically and analysed by Gene- Scan programme. Results: There were 13 GBMs, 3 anaplastic astrocytomas and 3 oligodendrogliomas. In 2 oligodendrogliomas, neither 1p/19q LOH nor 10qLOH were found but LOH 1p was seen only in one oligodendroglioma.Ki-67 LI was found 1% in two of them, interestingly 10% in one who has no LOH of these chromosomes. Among anaplastic astrocytomas LOH at 10q was detected only in one patients. Ki-67 LI was greater than 10% for all anaplastic astrocytomas. In 13 GBMs only one patient showed LOH of 1p and 10q . In this case Ki-67 LI was lower than 10% conversly from others whose LI were greater than 10%. Conclusion: Although LOH 10q is the most frequent genetic alteration in primary GBMs, LOH of chromosome 19q is common in secondary GBMs and loss of both the whole p arm of chromosome 1 and q arm of 19 is closely correlated with the oligodendroglial phenotype; not all oligodendrogliomas and GBMs have these chromosomal deficiency and the unpredictable cases do. These data demonstrate that despite rapid progress with these molecular features, histologic features still the most important characteristics of glial tumors. Ki-67 LI is objective grading marker for glial tumors.

PP1-158
VEGF AND VEGF RECEPTORS IN HUMAN MEDULLOBLASTOMA

Marina Gardiman[1], Giorgio Perilongo[2], Maurizio Onisto[3], Angelo Rosolen[4]
[1] Dept. of Pathology- University Hospital of Padua, Italy
[2] Dept. of Paediatrics-Div. of Haemathology-Oncology University Hospital of Padua, Italy
[3] Dept. of Exp. Biomed. Sciences University of Padua, Italy
[4] Dept. of Paediatrics- Div of Haematology. Oncology University Hospital of Padua, Italy

BACKGROUND: Medulloblastoma (MB) is the most common childhood malignant brain tumour. Despite recent progress in prognosis, a third of these children succumb to their disease whereas the remaining ones suffer significant long-term side effects. Neoangiogenesis seems to be a critical factor for tumour growth and progression and a pre-requisite for metastases. VEGF is one of the most powerful mitogen for endothelial cells in central nervous system tumours. The different isoforms bind to two tyrosine kinase receptors(Flt-1 or VEGFR-1 and KDR or VEGFR-2) and, upon binding, the receptor is phosphorylated thus triggering the intracellular transduction signal pathway. Although VEGF receptors were initially found on endothelial cells, recent studies have shown that tumour cells of different origins express VEGF receptors too. This suggest that VEGF may act as an autocrine signal. Starting from these considerations, we investigated the role of VEGF/VEGFR signalling on MB growth. METHOD: 13 paraffin embedded cases of classic MB were analyzed to determine expression of VEGF, VEGFR-1 and VEGFR-2. Transcript and protein expression of the same targets were also analyzed by RT-PCR and western-blot techniques on 3 MB cell lines, along with their functional status. RESULTS: Cells of our MB cases showed an intense and diffuse cytoplasmic expression of VEGF. VEGFR-1 expression was lower and more heterogeneous than VEGF but with several cells reacting intensively. VEGFR-2 expression was

lower than VEGF and VEGFR-1. All targets showed a stronger staining in the interfollicular than in the follicular areas. Positive reaction for VEGF and its receptors was also seen around the endothelia of tumour-supplying vessels. Semiquantitative analysis of VEGF and VEGFR expression was also performed and generally showed moderate to high expression levels. VEGF and its receptors were expressed in all the MB cell lines and were functional. CONCLUSION: Immunohistochemical analysis of MB specimens and the in vitro studies of MB cell lines support an autocrine role of VEGF in vivo given the concomitant expression of VEGF and its cognate receptors in MB cells.

PP1-159
ANALYSIS OF PURKINJE CELLS AND CEREBELLUM VOLUME IN FEMALE OBESE RATS: A STEREOLOGICAL AND HISTOPATHOLOGICAL STUDY

M. Eyup Altunkaynak[1], B. Zuhal Altunkaynak[1], Deniz Unal[1], Mukadder Sunar[2], Bunyami Unal[1]
[1] Department of Histology and Embryology, School of Medicine, Ataturk University, Erzurum, Turkey
[2] Department of Anatomy, School of Veterinary Medicine, Ataturk University, Erzurum, Turkey

Background: It was previously demonstrated that obese people have reduced grey matter (GM) in several brain areas, including regions implicated in the regulation of taste (i.e., inferior frontal operculum and postcentral gyrus), reward (i.e., putamen), and behavioural processing (i.e., middle frontal gyrus), compared with their lean counterparts. It is well established that the brain may serve as a direct target for adiposity signals, one of the most important being leptin, adiponectin, resistin i.e… We investigated the relationships between high fat diet intake and cerebellum morphology. Methods: In this study, twenty adult female Sprague Dawley rats (150-200 g each) from the Experimental Research and Application Center (Ataturk University, Erzurum, Turkey) were randomly allocated into two equal-sized groups. In the control group, rats were fed a commercial rat diet (7-10 % fat, 68-70% carbohydrate, 18-20% protein, 1-2% vitamins and minerals; 210 kcal/100 g/day) for 3 months, and rats in the high-fat diet group were fed a high-fat diet (30% calories as fat) for the same period of time. Cerebellum of control and high fat diet fed rats were analyzed stereologically and histopathologically. Results: Both numerical density and total number of Purkinje cells was significantly reduced ($p < 0.01$). Also volume of the cerebella was increased when compared with those of the controls due to edema. Conclusion: As a result of the study, it was thought that high fat intake may cause some of the abnormalities in brain morphology and morphometry associated with excess body fatness.

PP1-160
CELL SIGNALLING FACTORS IN GLIOMAS: HIGH P4EBP1 AND TGFB-PSMAD2 ACTIVITY ASSOCIATE WITH MALIGNANT ASTROCYTOMAS AND GLIOBLASTOMAS

Arantxa Ortega-Aznar[1], Elena A. Martinez-Saez[1], Teresa Osteso[1], Vicente Peg[1], Josep Castellví[1], Silvia Planas[1], Joan Seoane[2], Santiago Ramon Y Cajal[1]
[1] Pathology Department, Vall d´Hebrón University Hospital, Barcelona, Spain
[2] Institució Catalana de Recerca i Estudis Avancats, Barcelona. Medical Oncology Program, Vall d´Hebrón University Hospital Research Institute. Barcelona, Spain

BACKGROUND: Gliomas are the most frequent primary CNS tumors. Four grade of malignancy are actually admitted by the WHO classification and Glioblastoma multiforme (GBM), the most frequent grade IV glioma, is considered one of the most aggressive neoplasms. It can derive from low grade (AGII) and anaplastic astrocytomas (AGIII),or arise de novo. Secondary glioblastoma usually harbour overexpression of PDGFR, a mutated p53 (over 60%) and PTEN alteration (around 10% of cases). GBM de novo show EGFR amplification (30%), p53 mutations in less than 30% and loss of heterozygosity 10q or PTEN mutations in over 70% of cases. Moreover, it has been recently described that high TGFβ-pSMAD2 activity confers poor prognosis in glioma affected patients. In previous studies we identified that the factor p4EBP1, a protein that plays a control role in selective protein synthesis, acts as a funnel factor in breast and ovarian carcinomas, reflecting the oncogenic role of this signalling pathway. The aim of this study is to analyse the role of these pathways in astrocytic tumors evaluating involved factors expression. DESIGN: tissue microarrays of 67 astrocytic tumours were performed, including 40 GBM (59.7%), 9 AGIII (13.4%), 7 AGII (10.5%) and 11 (16.4%) pilocytic astrocytomas (PA). Immunohistochemistry for p53, p4EBP1, MAPK, pSMAD2 and AKT was done. Levels of expression were semiquantitatively evaluated as percentage and intensity of stained tumoral cells (histo-score [H score]). RESULTS: high expression of p4EBP1 was found in 100% of GBM and more than 60% of AGIII, while all the AGII and PA showed the lowest scores. Almost 100% of GBM, >90% of AGIII and AGII showed high expression of pSMAD2, nevertheless 85% of PA showed lower levels. Conversely no differences ERK1-2 expression were seen among the four groups of gliomas. CONCLUSIONS: These results show that overexpression of p4EBP1 is strongly related to anaplastic astrocytomas and glioblastomas (more than 60% and 100%) and may also discriminate tumoral progression between grade II and III astrocytomas. Furthermore, we could observe that high TGFβ-pSMAD2 expression correlates with diffuse astrocytomas and GBM, while this molecular pathway shows lower activity in better prognosis tumours as PA, therefore TGFβ-pSMAD2 may be a prognostic molecular marker. Ongoing studies are analyzing the association between p4EBP1 and its upstream markers and TGFβ-SMAD2 activity as well as with survival.

OLFACTORY NEUROBLASTOMA: A STUDY OF 7 CASES

Ben Abdelkader Atef[1], Yacoubi Mohamed Tahar[1], Trabelsi Amel[1], Abid Lilia[1], Abdelkefi Mohamed[2], Mokni Moncef[3], Korbi Sadok[3]
[1] Depatment of Pathology, Tunisia
[2] ENT Department, Tunisia
[3] Department of Pathology, Tunisia

Background : Olfactory neuroblastoma is a rare malignant neuroectodermal tumor, accounting for nearly 1,2 % of all naso-sinusal malignancy. It can occur in all age groups, without sex or racial predilection. The aim of our study is to specify the clinico-pathological, the differential diagnosis, the treatment and the behaviour of this tumor. Material and Methods : We studied seven cases of olfactory neuroblastoma diagnosed in the department of pathology during 20 years. Clinical and radiological informations were collected from patient files. Morphologic characteristics provided from histopathological reports. The grade of the tumors was established according to the grading scheme proposed by Hyams, based on tumor differentiation and varying from I to IV in surgical samples. We evaluated the tumor extension according to the Kadish staging system. Results : Our population is composed by fives women and two men with a mean age of 36 years. The presenting symptoms were mainly nasal obstruction and epistaxis in all cases associated to ophthalmic or neurological symptoms due to loco-regional involvement in two cases. Two cases were classed grade I, Three grade II, one grade III and one case grade IV according to the Hyams grading. On Immunohistochemistry, NSE (Neuron Specific Enolase) was expressed in all cases. The other markers were expressed differently in cases. Four cases were classified stage B, two stage C and one stage A according to the Kadish staging system. All patients were treated by surgery

followed by radiotherapy in four cases. Recurrence was seen in three cases (respectively after 2 months, 3 months and one year). Two patients (grade II, Stage B and grade II, stage C) were alive respectively after a period of one and three years, one patient (grade I, stage A) was alive after a period of 9 years. No information was available on the outcome of four cases. Conclusion: Olfactory neuroblastoma is a locally aggressive tumor. Craniofacial resection is presently the preferred surgical therapy. Multiples local recurrences are frequent. Postoperative adjuvant radiation therapy is useful for cases with close margins or for recurrent disease. Chemotherapy is indicated for advanced stages. Our study confirm us the useful of the grade and the stage as a prognostic factors. Since, we noted a correlation between theses parameters and the behaviour of patients.

AMOEBIC CEREBRAL ABSCESS MIMICKING BACTERIAL MENINGITIS: CASE REPORT

Sehnaz Sayhan[1], Deniz Altinel[1], Umit Bayol[1], Olcay Ozcolpan[1], Ayca Tan[1], Ozan Ganiusmen[2]
[1] Izmir Tepecik Teaching Hospital, Department of Pathology, Turkey
[2] Tepecik Teaching Hospital, Department of Neurosurgery,Turkey

Background: Entamoeba Histolytica is a well-known cause of infectious colitis, typically producing diarrhea and occasionally frank dysantery. This organism may also spread to involve extraintestinal sites such as the liver, lung, central nervous system, usually in the form of amoebic abscess Cerebral Amoebiasis is a rare and dreadful complication of E. Histolytica infection. Case Presentation: We report a case of an amoebic brain abscess (due to Entamoeba Histolytica) in a 2-year-old-girl, with symptoms mimicking meningitis with no evidence of disease elsewhere. Aspiration of the abscess revealed the organism, and the abscess regressed in response to specific medical treatment. This article reviews the rarity of cerebral amoebic abscesses and the difficulty of the diagnosis. Conclusion: As it is demonstrated by this case, the alert surgical pathologist has the potential to be the first to suspect and establish the diagnosis. This case report is to note that the patients with cerebral amoebic abscess may show any clinical evidence of extracerebral amoebic lesions which is important for early diagnosis and management to achieve cure.

PP1-163
SELECTIVE ATROPHY OF TYPE II MUSCLE FIBERS IN MYASTHENIA GRAVIS

Josef Zamecnik[1], Dan Vesely[1], Branislav Jakubicka[1], Libuse Simkova[2], Jiri Pitha[3], Jan Schutzner[4]
[1] Department of Pathology and Molecular Medicine, Charles University, 2nd Medical Faculty and Faculty Hospital Motol, Prague, Czech Republic

[3] Department of Neurology, Charles University, 3rd Medical Faculty, Prague, Czech Republic
[4] 3rd Department of Surgery, Charles University, 1st Medical Faculty and Faculty Hospital Motol Prague, Czech Republic

Background: Selective atrophy of type II muscle fibers has been reported in the literature as a common change in muscle biopsy in limited series of myasthenia gravis (MG) patients and it was considered as a possible prognostic marker. We performed histomorphometric study to confirm the previous findings in a larger cohort of patients and we searched for correlations between the fiber atrophy and the clinical features of the disease to evaluate possible prognostic implications. Methods: Muscle biopsies (sternothyroid muscle) from 179 patients with pure MG were obtained during thymectomy. Histochemical staining (myofibrillary ATPase) and immunohistochemistry (myosin heavy chain) was performed for muscle fiber typing in tissue cryosections. Histomorphometrical study with statistical evaluation of histograms was preformed using computer assisted image analysis. Clinical data of the patients were analyzed and correlated with the morphometrical results. Results: The statistically significant type II fiber atrophy was observed in only 23 (12,8%) cases of MG. No significant association was disclosed between the duration and severity of the disease or outcome of the patients. The only significant relationship was demonstrated between the type II fiber atrophy and long-term use of corticosteroids (methylprednisolone in particular). Conclusion: Type II fiber atrophy in MG muscle represents rather a steroid-induced change (i.e. chronic steroid myopathy, either clinically apparent or subclinical) than a morphological feature of the MG proper. Prognostic value of type II fiber atrophy in muscle biopsy in MG could not be demonstrated in our series. Supported by the Grant of Ministry of Health of the Czech Republic No. IGA MZCR NR/8924-3 and by the Research Project VZ FNM 00064203.

MENINGIOMA; A CLINICOPATHOLOGICAL PROFILE OF 300 ARCHIVE CASES

Evrim Ozturk[1], Ataturker Arikok[1], Hakan Seckin[2], Cetin Akyol[2], Ozlem Ergul[1], Fulya Koybasioglu[1]
[1] SB Ankara Diskapi YB Research and Training Hospital, Department of 1st Pathology, Turkey
[2] SB Ankara Diskapi YB Research and Training Hospital, Department of 2nd Neurosurgery, Turkey

Background: Meningiomas are the most common benign tumors of the CNS. Meningiomas usually have good long-term prognosis after surgical excision but some manifests aggressive clinical behavior leading to increased patient morbidity and mortality. Method: In this study we retrospectively review meningiomas operated on in SB Ankara Diskapi Y.B. Research and Training Hospital, 2nd Neurosurgery Clinic between years of 1995-2005. There were 300 cases which were pathologically examined in Pathology Clinic of the same hospital. Patient age, sex, tumor localization and tumor subtype are documented and reviewed. Results: The data about age could be obtained for 286 patients. Mean age was 50.72 ±13,394. Mean ages were 51.05±12,91 and 50.56±13,66 for males and females respectively.Over 300 patients, 200 was female and 100 were male with a female/male ratio of 2:1. Among 287 cases with known tumor localization, 49(17,1%) were convexity meningioma, 66(23%) falx-parasagital meningioma, 51(17,8%) tentorium-posterior fossa meningioma, 88(30,7%) skull base meningioma, 28(9,8%) spinal meningioma, 5(1,7%) intraventricular meningioma. Mean ages for these locations were 51.27, 52.08, 49.9, 48.44, 55.46, 47.4 respectively. There was no statistically meaningful association between age and localization (p=0,084). Among 300 pathological examinations, meningiomas were subtyped in 203 cases. The most common meningioma subtype was meningothelial meningioma with 86(43.3%) cases. The others were as follows: transitional 37(18.3%), fibroblastic 29(14.3%), psammomatous 22(10.8%), malignant 10(4.9%), angiomatous 8(3.9%), atipical 7(3.4%), metaplastic 2(1)%, microcystic 1(0.5%) and secretory 1(0.5%). Frequencies for locations of different subtypes demonstrated great variation. The skull base was most frequent site of location for meningothelial, fibroblastic, atipical and malignant. The rate of involvement of skull base in meningothelial, fibroblastic, atipical and malignant meningiomas were 36.1%, 27.6%, 50%, 33.3% respectively. Spinal cord was the most frequent site for psammomatous meningioma with the percentage of 55%. The difference for localizations of different histological subtypes were statistically non significant. Conclusion: Our results are in concordance with the literature data. In conclusion meningiomas are benign tumors seen predominantly in females who were in their 5th and 6th decades of life, commonly located in the skull base. They are mostly grade 1 tumors with the most common subtypes being meningothelial, transitional, and fibroblastic meningiomas

PP1-165
CELL DEATH AND SURVIVAL MECHANISMS IN THE HIPPOCAMPAL TISSUE OF PATIENTS WITH MESIAL TEMPORAL SCLEROSIS

Nese Dericioglu[1], Figen Soylemezoglu[2], Turgay Dalkara[1], Nejat Akalan[3], Abdurrahman Ciger[1], Serap Saygi[1]
[1] Hacettepe University, Faculty of Medicine, Department of Neurology, Ankara, Turkey
[2] Hacettepe University, Faculty of Medicine, Department of Pathology, Ankara, Turkey
[3] Hacettepe University, Faculty of Medicine, Department of Neurosurgery, Ankara, Turkey

Background- Mesial temporal lobe epilepsy syndrome due to hippocampal sclerosis is the most common type of focal epilepsy. Surgical resection of the mesial temporal structures renders 60-80% of these patients seizure free. This finding supports the idea that the severe neuronal loss observed in the hippocampus may somehow lead to synaptic reorganization and thus contribute to the progressive nature of the disease. Therefore prevention of cell loss may slow down or prevent epileptogenesis and seizure occurence. Method- In this study we aimed to investigate the pro-apoptotic and anti-apoptotic mechanisms, in cell death and survival respectively, in epileptic human hippocampi. Twenty five patients were selected randomly among those who underwent anterior temporal lobectomy with amygdalohippocampectomy due to mesial temporal lobe epilepsy in our center between 2001-2003. We applied immunohistochemical techniques in the formalin-fixed paraffin embedded hippocampal tissues and for cell death, we investigated the presence of pro-apoptotik molecules Bax (intrinsic apoptotic pathway) and tBid (extrinsic apoptotic pathway) in the tissue. Besides, we looked for the nuclear translocation of AIF, which is presumed to be a caspase independent pathway factor. Regarding the mechansims of cell survival, we searched for the expression profile of the following proteins: c-IAP1, c-IAP2. Results- Cells, that were stained, were counted in different regions of the hippocampus, namely CA1, CA2, CA3, dentate gyrus, hilus and subiculum. The results were compared with non-epileptic autopsy controls. We observed that Bax and tBid immunoreactivity were significantly increased in patient hippocampi. There was no nuclear translocation of AIF. c-IAP1 and c-IAP2 were absent in control hippocampi whereas the expression was dramatic in the patients in all hippocampal subfields. Finally, Hsp70 immunreactivity was significantly increased in all surviving neurons in patient hippocampi and degenerating neurons failed to express Hsp70 at all. Conclusion- Our findings indicate that both pro-apoptotic and anti-apoptotic mechanisms are activated in the hippocampus of patients with mesial temporal lobe epilepsy. Future investigations may provide novel therapeutic strategies that will inhibit pro-apoptotic cell death or encourage anti-apoptotic cell survival mechanisms. Supported by HUBAB (0201101005).

[2] Department of Pathology, Shcool of Medicine, University of Pamukkale, Denizli, Turkey
[3] Department of Neurosurgery, Shcool of Medicine, University of Pamukkale, Denizli, Turkey

Backround: Gliosarcoma is a rare primary central nervous system neoplasm characterized by biphasic histological pattern with both glial and sarcomatous components. It was classified by the World Health Organization as grade IV tumor. Our aim is to describe the clinical, morphological and immunohistochemical features of five cases of gliosarcomas and to discuss its pathogenetic mechanisms. Materials and Methods: We studied five cases of gliosarcomas to describe its clinical and pathological features. Immunohistochemical and histochemical analyses were performed to confirm diagnosis, assess histogenetic origin, and evaluate the proliferation index in all cases. Results: The male:female ratio was 4:1. The mean age was 50,2 years, ranging from 35 to 64. Headache was the commonest clinical symptom. All patients underwent craniotomy with microsurgery and total resection of the tumor. Immunohistochemical analysis was positive for p53 both glial and sarcomatous cells in four cases, however one case was negative for p53 both glial and sarcomatous cells. Conclusions: Our findings support monoclonal origin of gliosarcomas involving the TP53 tumor-supressor gene. However, alternative pathways can not be ruled out.

PP1-167
ATYPICAL TERATOID RHABDOID TUMOR

Ipek Coban[1], Demet Yilmazer[1], Hasan Basri Sener, Murat Alper[1], Esra Erden[2]
[1] Ankara Diskapi Y. B. Training and Research Hospital, 2. Pathology Department, Ankara, Turkey
[2] Ankara University Faculty of Medicine, Pathology Department, Ankara, Turkey

INTRODUCTION: Atypical teratoid rhabdoid tumor is a malignant embryonal central nervous system tumor manifesting in children (generally younger than 2 years old). There is a male predominance. This tumor is composed of rhabdoid cells, sometimes with PNET, epitelial tissues or neoplastic mesenchymal tissues in it. It usually occures in the posterior fossa (cerebellum, cerebellopontine angle, brainstem) Its clinical presentation differs depending upon its site, size and localization. Here we present a case of atypical teratoid rhabdoid tumor in the deep parietal lobe of cerebrum. CASE: A 1 year old male infant was admitted to our hospital with right sided convulsion which soon became generalized. MR imaging showed a mass measured 5x4x4 cm in diameter which is localized at the deep parietal lobe, adjacent to the lateral ventricule wall. The initial working diagnosis was dysembryoplastic neuroepithelial tumor. The tumor was totally removed. Macroscopically the tumor was gray-tan coloured and had soft consistency. Two months after the initial operation the tumor recured locally with a bigger mass which is 6x6x5 cm in diameter. The recurrent tumor is totally removed but the patient died during the operation. Histologically the tissues were composed of neoplastic cells that are diffusely arranged in a highly vascularized stroma. These cells were forming short fascicules in focal areas. They were pleomorphic, polygonal, rhabdoid shaped neoplastic cells with large eosinophilic cytoplasm, hiperchromatic nuclei and prominent nucleoli. There were eosinophilic inclusion like bodies in the cytoplasms of these cells and sometimes in extracytoplasmic localizations. There also were large areas of necrosis and common mitotic figures. Tumor cells were diffuse positive for vimentin, S–100, GFAP; focally positive for EMA, SMA, synaptophysin, chromogranin, CD 99 and negative for desmin. Ki–67 proliferation index was %50. CONCLUSION: This case is diagnosed as atypical teratoid rhabdoid tumor and is discussed as it is a rare diagnosis.

PP1-168
HER-2/NEU, ESTROGEN AND PROGESTERONE RECEPTOR EXPRESSION IN WHO GRADE I MENINGIOMAS: A PILOT STUDY

Nilufer Onak Kandemir[1], Aylin Ege Gul[2], Banu Dogan Gun[1], Nimet Karadayi[2], Gamze Yurdakan[1], Sukru Oguz Ozdamar[1]
[1] Zonguldak Karaelmas University, Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Dr. Lutfi Kirdar Kartal Research and Training Hospital, Department of Pathology Istanbul, Turkey

BACKGROUND: Meningiomas are generally benign central nervous system neoplasms, which frequently express progesterone receptor (PR) and rarely express the estrogen receptor(ER). Her-2/ neu is represented a well- known prognostic factor in various tumors such as breast carcinomas. However, the significance of Her-2/ neu expression in meningiomas is unclear. We evaluated the correlation with Her-2/ neu, PR, ER expressions and clinicopathologic parameters in WHO Grade I meningiomas. MATERIALS AND METHODS: In total, 34 cases of meningiomas (WHO grade I) were included in this study. Formaline-fixed, paraffin- embedded tissue sections were immunostained for Her-2/ neu, PR and ER. The level of Her-2/ neu expression in each sample was semiquantatively evaluated as follows: 0=no staining; 1+ = faint, incomplete membranous pattern; 2+ = moderate, complete membranous pattern and 3+ = strong membranous pattern. An immunohistochemistry score of 2+ or greater was considered as Her-2/ neu overexpression. Over 5% nuclear staining of tumor cells was considered positive for hormone receptors. RESULTS: There were 25 females and 10 males in study group. The age of the patients ranged from 38 to 78 (mean 56.9±11.5) years. According to the histological type, 16 (45.7%), 10 (28.6%), 5 (14.3%) and 4 (11.4%) cases had a meningotheliomatous, transitional, psammomatous and fibroblastic type, respectively. Whereas 18 (51.4%) of meningiomas were positive for PR, no staining was determined for ER. Her-2/ neu immunostaining was detected in 27 of the 34 meningiomas. Her-2/ neu overexpression were observed in 20 (58.8%) cases. There were positive correlation between Her-2/ neu and PR expressions (p=0.015). Her-2/neu overexpression was frequently seen in meningotheliomatous type (p=0.03). There were no correlations with Her-2/ neu, ER, PR and other clinicopathologic parameters. CONCLUSION: We observed that Her-2/ neu protein is overexpressed in about 58.8% of the WHO grade I meningiomas that essentially have a meningothelial patterns and PR positivity. The effect of Her-2/neu overexpression on pathogenesis and progressions of meningiomas could be better understanding the further studies which have large group and different histological grade. Thus, different pharmacologic treatment methods could be revealed in meningiomas.

A RARE TUMOR IN AN UNUSUAL SITE: INTRAVENTRICULAR ASTROBLASTOMA. CASE REPORT

Marina Gardiman[1], Milena Calderona[2], Domenico D'Avella[3], Luca Denaro[3], Marta Rossetto[3], Felice Giangaspero[4]
[1] Department of Surgical and Oncological Sciences, Pathology Section, University of Padua, Via A. Gabelli 61,Padova, Italy
[2] Neurosurgical Department, Neuroradiology Service, University of Padua, Padova, Italy
[3] Unit of Pediatric Neurosurgery University of Padua, Padova, Italy
[4] Department of Neuropathology, Policlinico Umberto I, Roma Italy

BACKGROUND: Astroblastoma (AB) is a rare central nervous system glioma which mostly occurres in young adults. AB is usually a circumscribed, well-demarcated tumor of the cerebral hemispheres, located close to the surface, with a distinctive perivascular orientation of neoplastic cells. On MRI images, AB typically appears as a solid or cystic, lobulated mass with inhomogeneous contrast enhancement and no oedema or mass effect. The biological behaviour of this tumor is unpredictable. CLINICAL HISTORY: Our patient is a 6 year old girl presented with a 5 week history of progressive headache and vomiting. Brain MRI showed a large demarcated solid-cystic mass in the left temporal-occipital ventricular horn. The patient underwent a left temporal-occipital craniotomy and intraoperatively the tumor appeared as a soft, reddish intraventricular mass. The tumor was totally removed and the postoperative course was uneventful. DISCUSSION: In our case the age of the patient and the intraventricular location of the mass strongly suggested the diagnosis of ependymoma. Histological examination revealed a tumor with solid compact pattern of growth with some papillary areas in which the tumor cells were clustered about the vessels, giving the appearance of pseudorosettes. The cellular processes were however broad and short and the nuclei of tumor cells were located at some distance away from the vessels, without a tapering of glial processes toward the vascular lumen. The vessel walls showed a conspicuous hyaline thickening. We found a brisk mitotic activity (MIB 1: 14%), small discrete foci of necrosis, no vascular endothelial proliferation. Immunohistochemical examination showed a positive staining with GFAP, S-100 and EMA. Our final diagnosi was astroblastoma. CONCLUSION: The very young age of the patient, the intraventricular location of the tumor and the presence of pseudorosettes might have been able to suggest a diagnosis of ependimoma, but the distinctive soap-bubble appearance on MRI and the anchoring of tumor cells by short cytoplasmic processes to vessels with hyaline thickening walls led us to the diagnosis of astroblastoma.

"LEUKOENCEPHALOPATHY OR LYMPHOMA – THAT IS THE QUESTION"

Alexandra H. Gene[1], Jeronimo Forteza Vila[2], Marta Brell[1], Antonio Mas[1], Paula Carrillo[1], Ana V Forteza[1], Rafael Ramos[1], Ramon Canet[1], Jose Rodriguez[1], Marta E. Couce[1]
[1] University Hospital Son Dureta, Spain
[2] Complejo Hospitalario Universitario Santiago, Spain

BACKGROUND: Primary CNS lymphoma (PCNSL) is an uncommon form of non-Hodgkin lymphoma comprising 1-2% of all primary brain tumors.It affects the brain parenchyma, leptomeninges, spinal cord and eyes and typically remains confined to the CNS. It is usually associated with acquired immunodeficiency syndrome(AIDS) or with other causes of long term immunosuppression. However,elderly patients are also affected.These lymphomas are usually of B cell type and the expression of BCL6 appears to be associated with a better prognosis. Although treatment-related leukoencephalopathy is well recognized in PCNSL and other CNS neoplasms,the mechanisms involved in its development are poorly understood.Additionally,there are few reports of focal and diffuse leukoencephalopathy preceding the diagnosis of PCNSL or seen at the time of PCNSL presentation. Radiologic evidence of leukoencephalopathy may lead to a broad differential diagnosis, including inflammatory, infectious, genetic, or neoplastic diseases. Additionally, the histologic finding of demyelinization, without any other diagnostic feature could compromise the pathologic differential diagnosis in some cases. METHODS: We reviewed clinical histories and preoperative MRI of 15 PCNSL that presented at the University Hospital Son Dureta, between the years 2003-2006. Hematoxylin&Eosin slides were examined. Luxol Fast Blue stains for myelin were done in all cases. In addition, we performed a battery of stains to better characterize these neoplasms, as follows: CD20, CD3, BCL2, BCL6, CD8, CD4, CD10, MIB1, ALK, MUM1, and in situ hybridization for EBV. RESULTS: All lymphomas were diagnosed as Diffuse large B-cell lymphoma (DLBCL) and all showed an accompanying T-cell infiltrate in varying degrees, with a larger percentage of CD8+ lymphocytes.The presence of T cell infiltrate did not correlate with the diagnosis of demyelinization. Positive EBV in situ was observed in 5 immunosuppressed patients. Six lymphomas expressed BCL2 and BCL6.Radiologic findings of leukoencephalopathy was seen in 7 cases and correlated with histologic evidence of demyelinization in 4 cases;this was characterized by rarefaction of the white matter,myelin loss,gliosis and partial axonal loss. CONCLUSIONS: 1.The finding of leukoencephalopathy on MRI with histological demonstration of demyelinization seems to be more common than originally thought in PCNSL. 2. Radiologic

leukoencephalopathy and histologic evidence of demyelinization are more common in those lymphomas expressing BCL2 and BCL6 FUTURE DIRECTIONS: We are in the process of investigating the presence of JCV DNA in these tissue samples.

PP1-171
LIPOMATOUS EPENDYMOMA : A CASE REPORT

Nihal Ozkalay Ozdemir[1], Nagihan Yalcin[1], Tuncer Suzer[2]
[1] Department of Pathology, Pamukkale University School of Medicine, Denizli, Turkey
[2] Department of Neurosurgery, Pamukkale University School of Medicine, Denizli, Turkey

BACKGROUND: Ependymomas consitute 3-9 %of all glial tumors. It may develope in all age groups but manifest predominantly in children and young adults. The variants of ependymoma according to the WHO classification are cellular, papillary, clear cell and tanycytic types. And other rare variants are; ependymoma of the filum terminale, ependymoma with extensive tumour cell vocuolation, melanotic ependymoma, signet ring cell ependymoma and ovarian ependymoma. CASE: This 47 year-old man presented with complaint of headache and difficulty in walking for 3 months. CT scan of the head revealed a large hyperdense mass lesion in the posterior fossa. Through a suboccipital craniotomy total excision of tumor was done. In the pathological examination with H&E stained sections, showed a celluler neoplasm with sheets of monotonous cells possesing dark round nuclei. Perivascular pseudo-rosettes, necrotic areas and occasional mitoses were found. In addition, there were large areas where the tumor cells had a signed ring apparance with large vacuoles in the cytoplasm. CONCLUSION: Lipomatous Ependymoma is a rare variant of ependymomas reported in literature.The outcomes for this lipomatous form may be similar to those of ependymomas of similar grade.

PP1-172
CENTRAL NERVOUS SYSTEM METASTASES: AN ANALYSIS OF 169 BIOPSY CASES

Dubravka Cvetkovic Dozic[1], Milica Skender Gazibara[1], Emilija Manojlovic[1], Danica Grujicic[2], Sanja Milenkovic[3], Slobodan Dozic[1]
[1] Institute of Pathology, School of Medicine, University of Belgrade, Serbia
[2] Institute of Neurosurgery, KCS, Serbia
[3] Clinical Hospital Center Zemun-Belgrade, Serbia

Background: Central nervous system (CNS) metastases are common complications of systemic cancers. They may develop from any primary neoplasm but some tumors have a predilection for the CNS. These are lung and breast carcinoma, melanoma, renal cell carcinoma and adenocarcinoma of colorectal origin. However, at the time of neurosurgery approximately one half of metastases may be of unknown primary. Aim of the study was to evaluate an algorithm of immunohistochemical markers which could be useful in diagnostic routine for identification the origin of the most frequent CNS metastases with unknown primary. Methods: Among the 997 biopsies of CNS tumors operated on during the 2006 at the Institute of Neurosurgery KCS there were 169 (16.9%) cases of CNS metastases. Males were more frequently affected (M: F ratio, 2.5:1). All cases were in adults. The locations were cerebral hemispheres (71.92%), cerebellum (16.95%), meninges (5.26%), spinal cord region (3.51%), brain stem (1.75%) and bones (0.58%). In 75 cases (44.37%) the primary tumor was known and in the majority of cases it was lung carcinoma (24.85%), followed by melanoma (7.10%), breast carcinoma (4.73%), colorectal carcinoma (4.14%), renal cell carcinoma (0.59%) and tumors of uncommon origin such as testis and urinary bladder (2.95%). In 92 cases (54.43%) the primary tumor was unknown. Microscopically, the first step in our investigation was to point out whether the CNS tumor was primary or metastatic and if metastatic to determine its phenotype. The panel of monoclonal antibodies for poorly differentiated CNS metastases derived from the most common primaries was performed. Results: Using the algorithm of monoclonal antibodies we were able to identify the primary tumor in more than 80% of cases. Immunohistochemically, the CNS metastases derived from lung adenocarcinomas were positive to CK7, TTF-1 and CD56; from squamocellular lung carcinomas, positive to CK5/6, negative to CK7 and TTF-1; from colorectal adenocarcinomas, positive to CK20 and CDX2, negative to CK7; from melanomas, positive to melan-A, HMB-45 and S-100; from breast carcinomas, positive to CK7, ER and negative to TTF-1; from renal cell carcinomas, positive to vimentin, CD10 and keratin AE1/AE3. Conclusion: The performed algorithm of immunohistochemical markers may represent an important role in surgical neuropathology taking into consideration that the evaluation of CNS metastases with unknown primary represents a very important process that helps in the strategies to maximize the patient's survival.

PP1-173
AN IMMUNOHISTOCHEMICAL STUDY OF EGFR, p53, Ki67 IN GLIOBLASTOMAS AND THEIR RELEVANCE TO SURVIVAL

Vassilis Samaras[1], Efstathios Samaras[2], Magdalini Tsamouri[1], Maria Tsopanomichalou[1], Konstantinos Bakopoulos[2], Olga Pantzartzi[1], Vassilis Varsos[2], Calypso Barbatis[1]
[1] Department of Pathology, Red Cross Hospital, Athens, Greece
[2] Department of Neurosurgery, Red Cross Hospital, Athens, Greece

BACKGROUND It is well-documented that the epidermal growth factor receptor (EGFR) gene is involved in the control of cell proliferation and is amplified and overexpressed in more than one third of glioblastoma cases. On the other hand, TP53 mutations as well as overexpression of the corresponding gene are frequent in secondary glioblastomas. In addition, according to some studies, the Ki67 labelling index can be used in order to subdivide glioblastomas on the basis of their proliferative activity. However, there is a great deal of debate about the prognostic significance of these factors in the malignant course of glioblastomas. In our study we analysed immunohistochemically the expression of EGFR, p53 protein and Ki67 in 31 glioblastomas and their relationship to patients' survival. METHOD 31 adult patients with glioblastoma were enrolled in the present study. Formalin-fixed paraffin-embedded tissue sections were immunohistochemically studied. The topography and cellular distribution of the three markers was analysed as well as semi-quantitative assessement of EGFR intensity of staining was made (negative, mild, moderate, high). P53 and Ki-67 were measured using digital morphometry and for the statistical analysis of the results the SPSS 13.0 programme for Windows was used. RESULTS The percentage of p53 and Ki67 nuclear positivity was ranged between 2-90% and 3-35%, respectively. The EGFR immunostaining was evaluated as negative (4 cases), mild (1 case), moderate (14 cases) and high (12 cases) with membranous and cytoplasmic localization. A predominantly heterogeneous pattern of staining was detected, within the specimens. We observed that the patients with Ki67≥15% demonstrated shorter survival periods than the patients with Ki67<15%, at a statistically significant level (p=0,036, log-rank test). There was no correlation among the three markers while EGFR and p53 expression levels were unrelated to survival. CONCLUSION In our study we observed a rather heterogeneous pattern of EGFR staining reaction, in contrast to previous experiments. On the other hand, our findings agree with several published data regarding the absence of prognostic significance of EGFR and p53 expression in glioblastomas. Furthermore, we reconfirm our previous studies that Ki67≥15% is a cut-off point for predicting worse survival. The extensive EGFR expression needs further evaluation as it may be used for targeted treatment.

PP1-174
PRIMARY CENTRAL PRIMITIVE NEUROECTODERMAL TUMOUR OF THE CENTRAL NERVOUS SYSTEM. REPORT OF A CASE AND REVIEW OF THE LITERATURE

Vassilis Samaras[1], Efstathios Samaras[2], Spyros Kalantzakis[1], Konstantinos Bakopoulos[2], Vassilis Varsos[2], Efstratios Patsouris[3], Calypso Barbatis[1]
[1] Department of Pathology, Red Cross Hospital, Athens, Greece
[2] Department of Neurosurgery, Red Cross Hospital,Athens,Greece
[3] Department of Pathology, University of Athens Medical School, Athens, Greece

BACKGROUND: Primitive neuroectodermal tumours (PNETs) are a rare group of highly malignant neoplasms which arise from pluripotent neural crest cells. These tumours occur predominantly in childhood and young adults. According to new proposals, based on immunohistochemical, ultrastructural and cytogenetical characteristics they are subdivided in two categories: central PNETs and peripheral PNETs. In this context, we present a rare case of a primary central PNET which was multifocal in the spinal cord and in the posterior fossa of a woman with a review of the literature. METHOD: A 42-year old woman presented with reduced mobility and sensory disturbances of one week duration of her right leg. Neurological examination revealed a paresis of the right leg and increased bilateral tendinous reflexes. MRI of the brain and spinal cord demonstrated a tumour in the roof of the posterior fossa consistent rather with a meningioma and multiple intramedullary and extramedullary obstructive masses along the entire spinal cord. Decompressive surgery took place and formalin-fixed paraffin-embedded tissue was examined with hematoxylin/eosin and immunohistochemically for: GFAP, S-100, Vimentin, Desmin, CD56, NSE, NF, Chromogranin A, Synaptophysin, CD99, MCK, EMA, CD45, C-Kit, Myo-1, Ki67. RESULTS: Hypercellular, small round-cell malignant tumour with ill-defined rosettes (Homer–Wright rosettes), numerous mitoses, Ki67 index >50% and areas of geographic necrosis. The malignant cells were diffusely positive for CD56 and Vimentin, focally for Synaptophysin, NSE, C-Kit and negative for CD99 and for all the other markers. The immunohistochemical profile was compatible with that of central PNET. The patient received adjuvant radiotherapy but she survived a few months after the initial diagnosis. CONCLUSION: Central PNETs are highly aggressive neoplasms without a sex predilection. Bibliographical data regarding the exact incidence of intraspinal localization in central PNETs are confusing. It seems that 10–30% of cases of central PNETs (medulloblastomas) are already disseminated through the CSF at the time of diagnosis, as in our case, and they rarely metastasise outside the CNS (<5%). The distinction between central PNET and peripheral PNET is of great importance as they require different treatment protocols. The main immunophenotypic difference between central and peripheral PNET is the CD99 expression in the latter.

PP1-175
INTRACRANIAL INTRAPARENCHYMAL PSEUDOTUMORS WITH EXTENSIVE CALCIFICATION AND FIBROSIS; CLINICOPATHOLOGICAL SPECTRUM OF THE SO-CALLED CALCIFYING PSEUDONEOPLASM OF NEUROAXIS

Hulya Akgun[1], Ashley Aiken[2], Nicholas Barbaro[3], Tarik Tihan[4]

[2] Department of Radiology,UCSF School of Medicine, San Francisco CA, USA
[3] Department of Neurosurgery,UCSF School of Medicine, San Francisco CA, USA
[4] Department of Pathology,UCSF School of Medicine, San Francisco CA, USA

Background: Extensively calcified masses without an associated neoplasm or an underlying systemic process are extremely rare in the central nervous system, and are often defined as “calcifying pseudoneoplasms of the neuraxis”. While this term appears to represent a unique and interesting clinicopathological entity, the lesions within this category appear to be diverse. Patients: We present four patients with extensively calcified intraparenchymal masses not associated with a neoplastic, inflammatory or a systemic process. Results: These lesions occurred in three males and one female, ages 16, 35, 49 and 59. Three patients presented with seizures, while the fourth case was discovered incidentally. Two lesions were located in the temporal lobe, one within the lateral ventricle, and one in the parietal lobe. Radiologically, all masses were dense solid calcifications that were hypointense on T1 and T2-weighted magnetic resonance imaging. The variations in the type and extent of histological features portended a superficial similarity of tumors to one another. The spectrum of histological changes included focal ossification with peripheral striations, proliferation of fibroblast-like cells, extensive psammomatous calcifications (in three cases), and limited reactive changes in the surrounding tissue. We present a brief comparison of our findings with the lesions reported in the literature as “calcifying fibrosseous pseudoneoplasms of neuraxis”. Conclusion: Intracranial non-neoplastic masses with extensive calcifications and fibrosis appear to outline a spectrum of pathological processes rather than a specific entity. It is still possible that the histological diversity reflects minor phenotypic variations in the same etiological process.

PP1-176
CYCLIN D1 IMMUNOREACTIVITY IN MENINGIOMAS

Sanja Milenkovic[1], Dubravka Cvetkovic-Dozic[2], Iva Berisavac[1], Milica Skender-Gazibara[2], Milica Stefanovic[1]
[1] Clinical Hospital Center Zemun–Belgrade, Serbia
[2] Institute of Pathology, School of Medicine, University of Belgrade, Serbia

BACKGROUND: Cyclin D1 is an important nuclear protein required for progression of cells through the G1 phase of the cell cycle. Routine pathologic examination could not predict the clinical course of meningiomas because even histological benign tumors may recur after total surgical resection. Quantifying of their proliferative potential may help in prediction of biological behavior of tumors with comparable histology. Degree and type of the Cyclin D1 expression has been poorly investigated in the meningiomas AIM: The aim of our study was to explore the usefulness of Cyclin D1 expression as a proliferative marker in meningiomas and its relationships to Ki-67/PCNA, WHO grade and mitotic activity. METHODS: We evaluated immunoreactivity for proliferative markers (Cyclin D1, Ki-67 and PCNA) in a consecutive series of 64 meningiomas samples graded according to the WHO classification. Immunohistochemical staining with Ki-67, PCNA and Cyclin D1 was performed using the microwave processing procedure and LSAB+ methodology. The number of positive cells for proliferative markers has been counted in ratio to 1000 cells. The results have been statistically correlated for each other, with tumor grade and in ratio to number of mitosis in 10 and 20 HPF. RESULTS: There was significant correlation in expression of proliferative markers (Ki-67, PCNA, Cyclin D1): for each other ($p< o, o1$), tumor grade ($p< o, o1$), number of mitosis on 20 /HPF ($p<o, o1$) and on 10 /HPF ($p< o, o5$). All meningiomas samples showed Cyclin D1 (nuclear, cytoplasmic and 'ring' shape) immunostaining. CONCLUSION: Cyclin D1 immunostaining was found to be very sensitive and it may be used as a proliferative marker for meningiomas.

PP1-177

PRIMARY DURAL LYMPHOMAS. A CASE REPORT

Chryssoula Glava[1], Xanthippi Grammatoglou[1], Ioannis Nikolaidis[2], Evangelia Skafida[1], Maria-Eleni Nikolaidou[1], Adamandia Zizi-Sermpetzoglou[1]
[1] Department of Pathology, Tzaneion General Hospital of Piraeus, Piraeus, Greece
[2] Neurosurgical department, Tzaneion General Hospital of Piraeus, Piraeus, Greece

Objectives: Primary dural lymphoma (PDL) is exccedingly rare. It arises from dura mater and differs biologically from other primary central nervous system lymphomas (PCNSL). It is usually a low-grade B-cell marginal zone lymphoma, whereas other types of PCNSL are usually high-grade, diffuse, large B-cell lymphomas. The pathogenesis of PDL is not well understood because the dura is devoid of any lymphoid tissue. One hypothesis is that a benign inflammatory condition of the dura could attract polyclonal lymphocytes from which a monoclonal lymphoma could arise. The most common clinical presentations are headache, seizures, focal sensory or motor deficits and visual disturbances. Case Report: We report a case of a 54-year-old woman who admitted to the emergency because of seizures. She had a past medical history of hypothyroidism. A CT and MRI scan before and after contrast medium revealed an enhanced mass arising from the dura localized in the right parietoccipital region and the tentorium as well. The radiological features were considered as a meningioma en plaque. The patient underwent a right parietoccipital craniotomy and a subtotal excision of the tumor was performed. The surgical specimen was histologically Low-grade marginal zone B-cell lymphoma. Immunohistochemically the tumor cells were positive for CD45, CD19, CD20, CD79a, but negative for CD5, CD10, CD23, CD30, EMA, cytokeratins, vimentin, GFAP and S-100p. After additional clinical and laboratory screening there was no other evidence of lymphatic disease. Postoperatively the patient experienced infection of Listeria monocytogenese and after 8 days in intensive care unit she died. Conclusions: PDL is more indolent and has a better prognosis than parenchymal PCNSL or systemic lymphoma with CNS metastasis. However, further studies with longer clinical follow up are necessary to assess the final outcome in these patients.

PP1-178

VIMENTIN AND SURVIVIN EXPRESSION RATES AS PROGNOSTIC FACTORS IN MEDULLOBLASTOMA

Jae Yeon Seok, Se Hoon Kim, Yoon Hee Lee, Jieun Kwon, Tai Seung Kim
Department of Pathology, College of Medicine, Yonsei University, Seoul, Korea, Brain Korea 21 Project for Medical Science, Korea

Background: A medulloblastoma is a primitive neuroepithelial tumor of the cerebellum that occurs in children and metastasizes through the cerebrospinal fluid. It is highly malignant and invasive, and the 5-year survival rate is only 60%. Surgical resection techniques, radiation, and chemotherapy have improved the overall survival but the patients suffer life-long cognitive dysfunctions or endocrine abnormalities as the side effects of treatment. Therefore it is essential to identify prognostic markers to determine the appropriate treatment strategy in order to minimize the side effects. Methods: This study evaluated the immunohistochemical differentiation and survival rate with synaptophysin, glial fibrillary acidic protein, epithelial membrane antigen, vimentin and primitive neuroepithelial marker nestin of 55 paraffin-embedded medulloblastomas, using a tissue microarray. The expression of survivin, the apoptotic inhibitor, and the survival rate with regard to the proliferation index of Ki-67 were also investigated. Results: The group testing positive to vimentin, a mesenchymal differentiation marker, had a worse prognosis and there was a strong correlation between vimentin expression and nestin expression. Patients with a survivin expression rate >35% had a significantly poorer clinical course and there was a correlation between the survivin expression rate and Ki-67 expression rate. Conclusion: In conclusion, vimentin and survivin are negative prognostic markers in medulloblastomas.

PP1-179

SPECIFIC EXPRESSION OF COX-2 IN TYPE 1 MUSCLE FIBERS

Chang Lim Hyun, Se Young Moon, Yoon Kyoung Lee, Haeryung Kim, Hye Seung Lee, So Yeon Park, Jin Haeng Chung, Gheeyoung Choe
Department of Pathology, Seoul National University College of Medicine, Korea

[Background] A skeletal muscle biopsy is important for the diagnosis of diseases of the motor unit. Basic pathologic reactions of muscle can be recognized in paraffin sections of formalin fixed biopsy specimens; however, frozen sections for histochemistry to determine patterns of muscle fiber types are essential for a proper pathological evaluation of skeletal muscle. Many Pathology Laboratories cannot perform histochemistry routinely by limitations in having a specially trained technician and low volume of the muscle biopsy. Recently, Troponin C and Troponin T have been developed for muscular fiber typing in formalin fixed, paraffin embedded tissue; however, the antibodies are useful only for skeletal muscle typing, and therefore, low cost-benefit effect still does not allow most general hospitals to run muscle biopsy section in Pathology laboratories. We incidentally discovered expression of cyclooxygenase -2 (COX-2) in skeletal muscle tissue around breast cancer, and the "checkerboard" pattern of COX-2 expression was suggestive of fiber typing of the skeletal muscle. [Objective] We performed this study to verify whether COX-2 is expressed in a specific muscle fiber type and to validate applicability of COX-2 immunohistochemistry in the formalin-fixed, paraffin-embedded muscle biopsy specimens. [Method] We used 58 cases of muscle biopsy specimens in Seoul National University Bundang Hospital, which consisted of 27 cases of neurogenic atrophy, 9 cases of muscular dystrophy, 8 cases of inflammatory myopathy, 7 cases of other muscular diseases, and 7 cases of nonspecific changes. Immunohistochemistry was performed with COX-2, Troponin C and Troponin T monoclonal antibodies. Expression of COX-2 was comparatively analyzed with expression of Troponin C and Troponin T in individual muscle fibers. Expression of COX-2 was also compared with the results of histochemistry in the cases which frozen samples were available. [Results] Compared with immunohistochemical expression of Troponin-C and Troponin-T, and compared with histochemical studies of NADH-TR and ATPase pH9.4, COX-2 was specifically expressed in type 1 muscle fibers in various muscle diseases and normal skeletal muscle. [Conclusion] Specific expression of COX-2 in type 1 myofibers is a brand new finding hitherto undescribed in the literatures. *This work was supported by the Korea Research Foundation Grant funded by the Korean Government (MOEHRD) (KRF-2006-E00221).

UNUSUAL PRIMARY OCULAR NEOPLASM IN A CHILD: LEIOMYOSARCOMA OF THE CILIARY BODY

Mariana Cajaiba[1], Martha Chojniak[2], Isabela Cunha[1]
[1] Department of Pathology - Hospital do Câncer AC Camargo - Sao Paulo, Brazil
[2] Department of Ophthalmology - Hospital do Câncer AC Camargo - Sao Paulo, Brazil

BACKGROUND: Primary uveal tract neoplasms are extremely rare in childhood; the most common lesions found are melanocytic. Leiomyomas have been reported, occurring mainly at the ciliary body. These tumors are believed to arise from primitive mesectodermal tissue giving rise to the ciliary body muscle, although they may also arise from vascular smooth muscle. METHOD: We study the case of a 7 year-old girl who underwent enucleation of the right eye with clinical suspicion of choroid melanoma due to a ciliary body mass, and describe its histological and immunohistochemical findings. RESULTS: Histologically, the neoplasm featured spindle cell morphology, atypia and mitoses, in addition to invasion of choroid and retina. The tumor expressed smooth muscle alpha actin, pan-actin HHF-35 and desmin, whereas immunohistochemistry for melanocytic markers, such as S-100, Melan-A and HMB-45 was negative. The proliferation index, measured by Ki-67 reactivity, was 9% in tumor cells. Based on these features, the diagnosis of leiomyosarcoma of the ciliary body was established. CONCLUSION: Smooth muscle neoplasms arising from the uveal tract are extremely rare, with few cases having a diagnosis confirmed by immunohistochemical or ultrastructural methods. Many cases formerly diagnosed as leiomyomas were in fact well-differentiated amelanotic melanomas with a fusiform pattern. Immunohistochemistry is an indispensable tool in the diagnosis of uveal tract neoplasms, and expression of myogenic differentiation markers allow distinction from the most common melanocytic tumors arising in this location. Although several leiomyomas have been reported in the literature, there are only two previously reported cases of primary leiomyosarcoma of the uveal tract. Therefore, the case presented here represents an extremely rare ocular neoplasm.

PP1-181
HYALINE MEMBRANE DISEASE: A REPORT OF 62 AUTOPSY CASES

Alexander Zubritsky
Municipal Institution "Taldom Central Regional Hospital, Russia

The present work aimed to reveal the incidence rate at hyaline membrane disease (HMD) based on the pathoanatomical material of the Municipal Institution "Taldom Central Regional Hospital" over 1983-2006. The obtained findings revealed that of a total of 1,967 post-mortem examinations and 245 perinatal cases there were 62 cases of HMD (41 neonatal boys and 21 neonatal girls) which turned out to be the primary cause of death. The immediate cause of death was determined to be the progressing pulmonary insufficiency related to the presence of resorptive atelectasis, and in 13 newborn infants it was accompanied by microfocal pneumonia. Death in HMD more often occured during the first 48 hours (57 cases). HMD was registered in 50 neonates on the background of immaturity, with stage I immaturity being determined in 12 cases, stage II - in 19, and stage III immaturity - in 19 cases. Hence, in the present study, HMD turned out to amount to 3% of the 1,967 post-mortem examinations and to 25% of the 245 perinatal sections performed at the general hospital over 24 years. The incidence rate of HMD was almost 2 times higher in neonatal boys than in neonatal girls, with the majority of cases accounting for premature neonates (81%). Neonatal mortality caused by hyaline membrane pathology more often occurs within the first 48 hours (92%), and the incidence rate thereof increases with the deepening of the immaturity degree.

PP1-182
PULMONARY, LIVER AND SPLEEN HEMOSIDERIN DEPOSITION OBSERVED IN INFANT AND CHILDREN AUTOPSIES

Nursel Turkmen[1], Bulent Eren[1], Recep Fedakar[1], Semra Akgoz[2], Nil Comunoglu[3], Filiz Eren[4]
[1] Uludag University Medical Faculty, Forensic Medicine Department, Council of Forensic Medicine of Turkey, Turkey
[2] Uludag University Medical Faculty, Department of Biostatistics, Turkey
[3] Yeditepe University Medical Faculty, Pathology Department, Turkey
[4] Bursa Sevket Yilmaz Public Hospital, Pathology Department, Turkey

Background: Hemosiderin deposition is not often recognized on routine examination with hematoxylin and eosin staining; however, iron stains may be helpful in the evaluation of hemosiderin deposition in infant deaths. Methods: This report describes the data obtained from autopsy of 86 infants and children whose deaths were investigated in Forensic Medicine Council Bursa Morgue Department from January 2000 to January 2003. A histochemical technique was used to identify haemosiderin in lung, liver and spleen specimens and correlated the observations with other descriptive variables such as the reported cause of death, postmortem interval, trauma history, gender, age. Results: There was weak positive, significant correlation between lung and liver hemosiderin scores (spaermann correlation coefficient rho= 0,348, p=0,001); with the increased lung hemosiderin scores, an increase in liver hemosiderin scores was observed. Similarly, a positive marked correlation between spleen and liver hemosiderin scores (spaermann correlation coefficient rho= 0,335, p=0,002) was present; with the raised liver hemosiderin scores an increase in spleen hemosiderin scores was seen. When statistical analysis was performed, there was no significant statistical differences between age groups, gender, lung hemosiderin deposition scores ($p > 0.05$). Out of 56 liver hemosiderin positive cases, 35(62,5%) and of 30 liver hemosiderin negative cases, 6(20%) were in the under 6 month age group with significant statistical correlation (person ki-squre test $p<0.001$). Probability of liver hemosiderin positive cases to be in the under 6 month age group was detected to be 6,7 times more than those who were hemosiderin negative (CI %95=2,3-18,9). Likewise, of 25 spleen hemosiderin positive cases, 18(72%) and of 61 spleen hemosiderin negative cases, 23(37,7%) were in the under 6 month age group with remarkable statistical correlation(person ki-squre test $p = 0.004$). Probability of spleen hemosiderin positive cases to be in the under 6 month age group was detected to be 4,3 times more than those who were hemosiderin negative(CI%95=1,6-11,8). Conclusion: This study was undertaken to provide data for further studies of hemosiderin deposition in infant's lung, liver and spleen. After the major differential diagnoses were ruled out, this study demonstrated, depending on statistically assessed morphometric grounds, that the presence of haemosiderin deposits in the liver and spleen were significantly higher in a under 6 month age group.

PP1-183
AMELOBLASTIC FIBROSARCOMA OF THE MAXILLARY SINUS IN AN INFANT: A CASE REPORT WITH LONG-TERM FOLLOW UP

Nona Zabolinejad[1], Mehran Hirdfar[2], Kazem Anvari[3], Alale Shoja Razavi[4]
[1] Department of Pathology, Dr Sheikh Pediatrics Hospital, Mashhad, Iran
[2] Department of Pediatric Surgery, Dr Sheikh Pediatrics Hospital, Mashhad, Iran
[3] Department of Radiotherapy and Oncology, Omid Hospital, Mashhad, Iran
[4] Research Development Unit, Dr Sheikh Pediatrics Hospital, Mashhad, Iran

Ameloblastic fibrosarcoma (AFS) or ameloblastic sarcoma is an extremely rare odontogenic neoplasm. The authors report ameloblastic fibrosarcoma (AFS) in the maxillary sinus of a 4-month-old boy. The tumor composed of odontogenic epithelium, resembling that of ameloblastoma and a mesenchymal part exhibiting features of fibrosarcoma. We also found some areas with deposition of dentinoid material closely adjacent to ameloblastic epithelium. Although AFS has been occurred in a wide age range, this is the first report of this tumor in infancy with long term follow up.

PP1-184
IMMUNOHISTOCHEMICAL EXPRESSION OF P53 PROTEIN IN HISTOLOGICALLY FAVORABLE WILMS TUMOR AND ITS RELATIONSHIP TO TUMOR STAGE AT PRESENTATION

Nona Zabolinejad[1], Nourieh Sharifi[2], Abbas Tabatabaee[2], Saadat Mirsadraee[3]
[1] Department of Pathology, Dr Sheikh pediatrics hospital, Mashhad, Iran
[2] Department of Pathology, Ghaem Hospital, Mashhad University of Medical Sciences, Iran
[3] Department of Pathology, Imam Reza Hospital, Mashhad University of Medical Sciences, Iran

Background: Wilms tumor as the most common renal tumor of children has been associated with chromosomal abnormalities. Although a correlation between anaplasia and mutations of P53 tumor suppresser gene has been found in Wilms tumor, significance of these mutations in different clinical stages of favorable-histology Wilms tumor remains largely unresolved. Objective: The goal of this study was to determine the frequency of P53 expression in histologicaly favorable Wilms tumors and its correlation to tumor-stage at presentation. Material & Methods: In this retrospective study 48 cases of confirmed Wilms tumor with favorable-histology were retrieved from the files of departments of pathology in 3 hospitals in Mashhad between 1990 and 2004. Histological characteristics and clinicopathological staging were in accordance with NWTS guidelines. P53 expression was determined by immunohistochemical method. For each section, the proportion of neoplastic cells exhibiting nuclear positivity was broady quantified and intensity of staining was charted based on visual impression by two pathologists. Result: A total of 48 cases of histologically favorable Wilms tumor were assessed. 11 cases (23%) showed positivity for P53 which were 3 (27.3%) with stage II, 3 (27.3%) with stage IV, 2 (18.2%) with stage I, 2 (18.2%) with stage III and 1 case (9.1%) with stage V. The P53 immunopositivity was seen in 1-25% of tumor cells in 9 cases (18.8%), in 26 to 50% of tumor cells in 1 case (2.1%) and in >75% of tumor cells in the other one case (2.1%). The intensity of staining was moderate in 6 cases (12.5%), weak in 4 (6.3%) and strong only in one case (4.2%). The most common component with P53 immunoreactivity was blastemal in 11 cases (100%). Conclusion: We found no correlation of P53 immunoreactivity and its intensity to tumor stage at presentation in individuals with histologically favorable Wilms tumors (P-Value=0.66, P-Value=0.52 respectively).

PP1-185
POSTMORTEM STUDY: DENNYS-DRASH SYNDROME

Mar Pascual, Ester Gimeno, Isabel Marquina, Francesc Felipo, Ana Fuertes, Guillermo Muñoz
Pathology Department, Miguel Servet University Hospital, Zaragoza, Spain

BACKGROUND: Dennys-Drash syndrome is characterized by male pseudohermaphroditism, Wilms' tumour and glomerulopathy with fast progression to end-stage renal disease. It is caused by a mutation in supressor gene WT1, located in 11p13. MATERIAL: Two year-old male newborn that presented acute respiratory insufficiency and acute renal failure. As previous history he had bilateral chriptorchidism partially treated with surgery; the right testicle was brought near the entrance of scrotum, waiting for a second operation. He also presented a hormonal dysfunction that was being studied. Unfortunately, he dies and a necropsy is performed. RESULTS: External exam shows the absence of testicles inside the scrotum, penile curvature and hypospadias penile-scrotal. The rest of external exam is normal. After opening cavities, bilateral pleural effusion stands out, with congestive lungs. Testicles are seen in abdominal cavity, one of them adherent to abdominal wall and the other attached to a rudimentary uterine structure, which shows continuity with a short and ill-developed vaginal channel. The remaining organs are normal in appearance and situation. Microscopic study reveals dysgenetic testicles, structures derived from müllerian conducts (uterus and vagina), and a nephropathy consisting in diffuse glomerular and mesangial sclerosis with increased sclerosed glomeruli. Bilateral pneumonia, oedema and pulmonary congestion are also found. CONCLUSION: According to the original description, Dennys-Drash syndrome (DDS) is constituted by male pseudohermaphroditism, Wilms' tumour and progressive glomerulopathy. After this original description, patients with incomplete forms were found, so this syndrome was divided into three categories: 1) male genotype with all three abnormalities, 2) male genotype, nephropathy and ambiguous external genitals, and 3) female genotype, nephropathy and Wilms' tumour. Clinically, it is characterized by massive proteinuria with nephrotic syndrome at short age and fast evolution to renal insufficiency; the histological lesion is diffuse mesangial sclerosis (DMS). From a clinical (ambiguous genitals, nephrotic syndrome with early appearing symptoms and fast progression to renal failure) and histological (DMS) point of view, our patient has the features of DDS. Cases like ours have a high risk of developing Wilms' tumour subsequently.

PP1-186
MECKEL'S DIVERTICULUM IN PEDIATRIC PATHOLOGY OWN EXPERIENCE

Niculescu Liviu[1], Citu Rafira[2], Berdan Gabriela[3], Hulea Ionela[3], Gaitanidis Raluca[3], Petrescu Amelia[4]
[1] University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania
[2] Emergency Children Hospital "Grigore Alexandrescu", Bucharest, Romania
[3] "Prof. Dr. Th. Burghele" Hospital, Bucharest, Romania

Introduction: Meckel Diverticulum is the most common anomaly of the gastro-intestinal tract, with an incidence between 0, 5-2% and is more frequent in males. It is the result of the persistence of the proximal portion of the yolk sac. Macroscopically it consists in a figer-like structure, 2 to 8 cm in length, located on the antero-mesenteric border of the ileum, usually 30 cm proximal to the ileo-cecal valve in children and 90 cm in adults. From 1986 to 2006 in "Grigore Alexandrescu"Hospital 156 children have been diagnosed and treated , 104 of them boys and 52 girls, aged 1 month - 16 years . Fifty two cases were asymptomatic, usually an incidence finding in laparatomy, 104 cases presented colonic obstruction (volvulus or intussusception), bleedings, diverticulitis, perforation. Colonoscopy and gastroscopy excluded other causes of bleeding. Surgical excision was performed. Material and methods: Fragments of the diverticulum were fixed in formaldehyde 10%, included in paraffin and the sections were stained with HE and VG. Results: Histologically, colonic diverticulum had a wall lined by intestinal mucosa, in 18 cases had an ectopical gastric mucosa features , in 5 cases pancreatic tissue, in 4 cases intermingled aspects: 2 cases intestinal and gastric mucosa and 2 cases gastric mucosa and pancreatic tissue. Conclusions: Because of malignancy risk (adenocarcinoma, carcinoid, leiomyosarcoma, etc) and the complications that may occur, resection is indicated and also the carefully analysis for the discovery of nodular or papillary zones with this potential .

PP1-187
VALUE OF ELECTRON MICROSCOPY EPON BLOCK BANKING IN PAEDIATRIC PATHOLOGY
Safiye Aktas[1], Gulden Diniz[1], Huseyin Aktug[2]
[1] Dr Behcet Uz Children Research Hospital Izmir, Turkey
[2] Ege University Faculty of Medicine, Department of Histology and Embriology, Izmir, Turkey

Background: The use of electron microscopy (EM) in human medicine has been decreasing in recent years. But in pediatric pathology, EM is still required in the diagnosis of some skeletal muscle diseases, renal biopsies, metabolic and storage diseases, some undifferentiated tumors and research. EM laboratories are very seldom planned. The reasons of this are expensive prices of electron microscope and the other equipments, housing problems of the EM, educated technician and pathologist supply. In pediatric pathology laboratories where EM is not available, it is a problem to send specimen of the cases that requires EM. EM tissue processing and blocking is not very difficult and expensive. In this prospective study, we aimed to evaluate the value of tissue blocking for EM in which EM required disorders have been suspected before the biopsy was fixed in formalin. Method: In this study 48 biopsies were EM blocked between 2004-2006. The fresh tissues in 1mm diameter were fixed in Karnovsky fixative at 4C°, dehydrated in increasing concentrations of alcohol, infiltrated with liquid embedding medium, polymerized and produced solid blocks from each case. After histochemically and immunohistochemically light microscopic evaluation of the cases; the EM blocks of the patients which required to evaluate with EM was sent to different centers where EM is possible. The final decision of diagnosis was reevaluated by pathologic, clinical and EM findings. Results: Between these 48 biopsies EM blocked nine blocks from skeletal biopsies were studied for EM. One of them brought the diagnosis. One was not satisfactory. In the other seven cases EM helped in differential diagnosis together with the findings of light microscopy and other techniques. Two cases were sent for evaluation for EM from renal biopsies. One of them did not contain glomeruli and considered as unsatisfactory. The other was diagnosed brought the diagnosis. One biopsy from subcutaneous nodule helped in the diagnosis of storage disease. The cases sent for EM from EM epon block banking collection consisted of 25% of the cases. Among them 16% were unsatisfactory, 16% brought the diagnosis and 68% helped the diagnosis. Conclusion: Our results indicate that separating fresh tissue for EM epon block banking might be useful in pediatric pathology.

PP1-188
TENASCIN EXPRESSION IN PAPULOSQUAMOUS DISORDERS OTHER THAN PSORIASIS IN PEDIATRIC PATIENTS: A PATHOGENIC FEATURE?
F. Sule Afsar, Safiye Aktas, Gulden Diniz
Dr Behcet Uz Children Research Hospital, Izmir, Turkey

BACKGROUND: Tenascin is a large extracellular matrix protein that is expressed in the basal membrane zone during embryonic development, tissue repair, and oncogenesis. In vitro studies suggest that proliferating epithelium induces the production of tenascin by mesenchymal cells. In this study, our goal was to compare the expression of tenascin in psoriasis with other papulosquamous disorders of skin in pediatric patients. METHOD: The study was conducted on skin biopsy samples of 37 pediatric patients [twenty male (54.1%) seventeen female (45.9%), mean age 8.35 (range from 3 to 14 years)] suffering from psoriasis or other papulosquamous disorders. Of the 37 skin biopsy samples, 17 (45.9%) were diagnosed as psoriasis and 20 (54.1%) were diagnosed as other papulosquamous disorders [6 (16.2%) pityriais rosea, 5 (13.5%) pityriasis lichenoides, 3 (8.1%) lichen planus, 2 (5.4%) lichen nitidus, 2 (5.4%) lichen striatus, and 2 (5.4%) pityriasis rubra pilaris] histopathologically. The expression of tenascin was evaluated in all biopsy samples immunhistochemically. Data analysis was carried out by Spearman correlation analysis. RESULTS: Among the total of 37 skin biopsy samples, tenascin expression was positive in 16 (43.2%) and negative in 21 (56.7%) at perilesional superficial dermis. Of the 17 biopsy samples diagnosed as psoriasis histopathologically, 16 (94.1%) were negative and 1 (5.8%) was positive for tenascin; and of the 20 biopsy samples diagnosed as other papulosquamous disorders, 15 (75.0%) were positive and 5 (25.0%) were negative for tenascin (p=0,001). CONCLUSION: Our results suggest that immunohistochemically tenascin expression might be a pathogenic feature and an indicator for the papulosquamous disorders other than psoriasis in pediatric patients.

PP1-189
MONOZYGOTIC TWINS AND METASTASIS OF NEUROBLASTOMA TWIN-TO-TWIN THROUGH FOETOPLACENTAL CIRCULATION
Antonia Jakovčević[1], Marijana Ćorić[2], Mislav Novak[3], Kamelija Žarković[4]
[1] Department of Pathology, University Hospital Zagreb, Croatia
[2] Department of Pathology,University Hospital Zagreb, Croatia
[3] Department of Pediatrics, University Hospital Zagreb, Croatia
[4] Department of Pathology, University Hospital and Medical School Zagreb, Croatia

Introduction: Neuroblastoma is the common childhood solid tumor of neural crest cells. It may arise at any site in the sympathetic nervous system, most commonly in the adrenal medulla. We report a case of congenital neuroblastoma in a pair of monozygotic twins which is rare and only few cases have been described. Clinical History:The patients were two baby girls born at 37 week' gestation following a riskfull pregnancy. There was no significant family history and parents had one older healthy child. The twins were born asymptomatic. The first twin was admitted to our hospital at the age of 10 days with marked abdominal distension and firmness, weight loss and hiperbilirubinemia. Abdominal ultrasound showed large liver with numerous hyperchoic nodules. A needle core biopsy of the liver revealed a histological and immunohistochemical diagnosis of neuroblastoma. The tumor is composed of small blue cells partially arranged in Homer-Wright pseudorosettes. Immunohistochemicaly tumor cells were positive for NSE and synaptophysin, but negative for LCA. Treatment commenced with standard chemotherapy protocol but soon the therapeutic course was complicated with respiratory symptoms and liver failure. After 20 days of therapy she died at age of 1 month. Autopsy showed icteric skin, general edema, well defined nodular mass in left adrenal gland measuring 2.5x2.5x2 cm and large liver with multiple nodules. A few days after her death, twin sister was admitted to hospital with similar symptoms. An extensive physical, laboratory and radiological examination and liver biopsy confirmed diagnosis of metastasis neuroblastoma in the liver. Treatment commenced with chemotherapy and after two cycles, the therapeutic course was complicated with liver failure. The biopsy specimen showed extensive toxic damage of liver with fibrosis and hemosiderosis. At 6 months of age she died. Autopsy showed postnecrotic cirrhotic changes in liver without metastasis, hypersplenism, diffuse alveolar damage of lungs and ascites. Conclusion: This is a rare case of metastasis neuroblastoma from twin-to-twin through foetoplacental circulation in utero that is confirmed at autopsy. First twin had primary tumor in adrenal gland with liver metastasis while second twin had liver metastasis without a primary tumor site.

PP1-190
ARTHROGRYPOSIS, RENAL TUBULAR DYSFUNCTION AND CHOLESTASIS AS A RARE ARC SYNDROME – REPORT OF ONE CASE ON AUTOPSY

Blagica Dukova, Snezana Duganovska, Vanja Filipovski
Institute of Pathology, Faculty of Medicine, Skopje, R. Macedonia

AIM: To present a rare case of ARC syndrome (only one on autopsy in 2006). We present arthrogryposis, renal tubular dysfunction and cholestasis as ARC syndrome with additional features of dysmorphio, hypoplastic lungs and variation of blood vessels on arch of aorta. METHODS: Standard protocol of autopsy was preformed with additional Rtg examination. Specimens of all organ tissues were taken and proceeded in standard H&E staining. RESULTS: It was a female newborn that lived 45 minutes, weight 2350gr, length 43cm with abnormal position of left leg (end flexion). Left foot lies on the left shoulder and has equinovarus position. Rtg was preformed and showed bilateral fractures of both humeral and femoral bones. There is universal hypotonia with neurogenic muscle atrophy. Renal histology reveals dysplasia changes with cystic dilatation of many tubules and concentric layers of immature mesenchyme. Bowman's space is enlarged and some glomerules show segmental or complete sclerosis. There are focuses of cartilage bars and many proliferated blood vessels. Microscopic analysis of liver sections showed both cholestasis and giant cell transformation of hepatocytes. CONCLUSION: It is considered that arthrogryposis, renal tubular dysfunction and cholestasis give picture of ARC syndrome with many additional features. As a rare syndrome, it should be put in differential diagnoses of all cases with muscular or/and skeletal deformities.

PP1-191
IMMUNOHISTOCHEMICAL EXPRESSION OF CELL CYCLE, APOPTOSIS REGULATORS AND EPIDERMAL GROWTH FACTOR RECEPTOR [EGFR] IN PEDIATRIC INTRACRANIAL EPENDYMOMAS

Kalliopi Stefanaki[1], Amalia Patereli[1], Catherine Van Vliet –Constantinidou[1], Maria Moschovi[2], Kalliopi Karamolegou[2], Clio Fragouli[1], Christiana Hatzigiorgi[3], George Sfakianos[4], Fivos Prodromou[4], Ourania Karentzou[1]

[2] Hematology -Oncology Unit 1st Department of Pediatrics of Athens University, Greece
[3] Department of Computerized Tomography, Aghia Sophia Children's Hospital, Greece
[4] Department of Neurosurgery, Aghia Sophia Children's Hospital, Greece

Background: Intracranial ependymomas are the third most common primary brain tumor in children. Since conflicting data have been reported regarding the prognostic significance of grading in ependymomas,especially in children ,the expression of proliferation and apoptosis regulators may contribute in the assessment of grading and prognosis The aim of this study was to investigate the expression of: p-53 tumor-suppressor oncoprotein, p-27/kip-1 cyclin/CDK inhibitor,bcl-2 anti-apoptotic protein and EGFR in pediatric ependymomas in correlation with Ki-67/MIB-1 proliferative index and prognosis Method:Our material comprised 17 ependymomas[14 cerebellar,3 supratentorial] from 13 children. One child suffered from two tumor recurrences and 2 children from one recurrence each.The ependymal tumors were classified into 3 classical ependymomas [grade II,WHO],4 anaplastic ependymomas[grade III,WHO] and 10 anaplastic with areas of classical ependymoma. The Streptavidin-Biotin method was performed on paraffin sections for the detection of Ki-67/MIB-1,p-53[DO-7],bcl-2[100/D5],p-27[1B4,EGFR [cl.EGFR25] Results: Ki-67 was detected in all cases,[range 5-50% of the nuclei]showing a high[>20%]expression in 14 anaplastic ependymomas[10 of them with a classical ependymal component]p-53 was detected in 15/17 ependymomas,showing a parallel high[>10%]expression with Ki-67 in 10 anaplastic ependymomas[7 with a classical ependymal component] EGFR was detected in a considerable number of ependymomas [88%15/17], showing a heterogenous high[>20%] expression in 11 anaplastic tumors[8 with a classical ependymal component]p-27 and bcl-2 proteins were detected in all ependymomas,showing a parallel high expression[>50% and >30% respectively]in 12 tumors[2 classical,10 anaplastic],while a parallel high Ki-67/p-27/EGFR expression was observed in 64,7%of the cases[11/17,3 anaplastic, 8 anaplastic with a classical ependymal component] The 2 cases of anaplastic ependymomas with a classical component showing recurrences showed high Ki-67/p-27/EGFR expression at initial presentation. In conclusion,high Ki-67/p-27/EGFR expression was correlated with the anaplastic phenotype of ependymal tumors suggesting that cell cycle deregulation may play an important role in their pathogenesis. EGFR detection in a considerable number of ependymomas probably reflects its involvement in the neoplastic transformation and may serve as a therapeutic target

PP1-192
MULTICYSTIC RENAL DYSPLASIA: A MISSING SPECIMEN FOR PATHOLOGIST

Safiye Aktas, Gulden Diniz, Erkin Serdaroglu, Ragip Ortac, Basak Ucan, Irfan Karaca, Mustafa Bak, Malik Ergin
Dr. Behcet Uz Children's Research Hospital Izmir, Turkey

Background: Multicystic renal dysplasia (MCRD) is the most common form of cystic renal disease in children and it is a clinically important consequence of abnormal nephrogenesis. Surgery was used as the treatment of choice for MCRD because of the potential complications of hypertension, infection and malignant change. After the results of prolonged follow-up of children with conservatively managed MCRD suggested that clinical approach was safe, the incidence of complications was small, and that there was a clear tendency for MCRD to decrease in size, surgery is not the preferred therapy. As a result the pediatric pathologists nowadays seldom find opportunity to examine a specimen of nephrectomy with MCRD. The aim of this study is to report a retrospective study of MCRD in children assessing the clinicopathologic properties. Method: The cases of MCRD diagnosed, treated and followed up in Dr.Behcet Uz Children Hospital Izmir Turkey between 1990 and 2007 were retrospectively reevaluated for clinicopathologic parameters and statistically analyzed. Results: Among 422 pediatric uropathologic specimens, 77 consisted of nontumoral nephrectomy specimens of which 17 (22.1%) were MCRD. The mean age is 2.58±3.59 (2 months-14 ages). The cases were left-sided in 8 and right-sided in 9 of the cases. The cases were male in 9 and female in 8 of the cases. The weight of the kidneys with MCRD was above normal in five cases, lower than normal in six cases and in normal limits in six cases according to the age. Associated renal pathology (ureteropelvic obstruction etc.) existed in eight cases (47%). Sixteen of the cases were operated before 2002 and only one case after 2002 till 2007. There are 41 cases diagnosed as MCRD in follow-up without operation in recent five years. Following surgical removal of the affected kidney, these cases progressed normally. Conclusion: Nowadays all children diagnosed as MCRD are submitted to conservative management with follow-up visits every six months following clinical parameters, blood pressure, urinary tract infection, renal function, involution of MCRD kidney, contra lateral renal growth. That is why MCRD is becoming a missing or "ancient" specimen for pathologist.

PP1-193
PEUTZ-JEGHERS SYNDROME IN CHILDREN, HISTOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL STUDY, A CASE REPORT

Niculescu Liviu[1], Citu Rafira[2], Berdan Gabriela[3], Hulea Ionela[3], Gaitanidis Raluca[3], Becheanu Gabriel[3], Terzea Dana[3], Ardeleanu Carmen[1], Petrescu Amelia[3]
[1] University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania
[2] "Grigore Alexandrescu" Emergency Children Hospital, Bucharest, Romania
[3] "Prof. Dr. Th. Burghele" Hospital, Bucharest, Romania

Introduction: Most polyps in children are sporadic, usually they are isolated or like colorectal juvenile polyposis, they don't require any supervision after surgical treatment. It has been noticed the increase frequency of some syndromes like: familial adenomatous polyposis, juvenile polyposis coli, hereditary mixed polyposis, Peutz-Jeghers syndrome, etc. We present the case of a 12 years old girl hospitalized to "Grigore Alexandrescu" Hospital for black pigmentation of the oral mucose, vomiting, signs of obstruction. The X-ray and computer tomografic exams have shown the presence of two polypoid masses located at the antrum level. Resection of the masses was performed. Material and methods: Fragments of the polyps were fixed in formaldehyde 10%, included in paraffin, the sections were stained with HE and VG and processed for immunohistochemical marker (ACT). Results: The microscopical exam revealed mucose glands separated and intermingled by thick smooth muscular fibers, this aspect being characteristic for hamartomatous polyps in Peutz-Jeghers syndrome. Conclusions: According to the latest literature data, the patients with this syndrome are supervised for long time because the malignancy risk. We agree for the necessity of screening protocols as well as the supervision of the risk organs.

PP1-194
NEONATAL GIANT CELL HEPATITIS AN UNUSUAL CAUSE OF NEW-BORN CHILD DEATH. REPORT OF TWO CASES

Milanka Mrčela, Branko Dmitrović
Department of Pathology and Forensic Medicine, Clinical Hospital, Osijek, Croatia

Intorduction Neonatal giant cell hepatitis is a very rare condition in a clinical praxis. It is characterised by syncytial giant cell hepatocytes. Case report Both children with neonatal giant cell hepatitis were born in the same family in a two year interval and both died in the first 24 hour period. In the first case the female child's authopsy finding showed haemorrhagic diathesis: intraalveolar, kidney and ventricular mucosae bleeding. In the second case the male new-born child's authopsy finding showed petechial cutaneous bleeding of the head, trunck and extremities, fetal hidrops and ascites. Both cases share the same histological findings in the liver. Severe disorder of the liver parenchima with syncicial giant cell transformation of the hepatocytes. Transformed giant cell hepatocytes contained yellow pigment wich react with Berlin blue. Conclusion As hemosiderin deposites were found in the multinucleated transformed hepatocytes both of our cases we concluded that metabolic disorder in transportation and storage of iron is in the background of both cases so that hepatocellurar damage caused fatal haemorrhagic disorder.

PP1-195
ASSESSMENT OF DUCTAL PLATE MALFORMATION IN BILIARY ATRESIA. A HISTOLOGICAL STUDY OF 50 CASES

Simona Saccani[1], Paola Francalanci[2], Francesca Minnei[2], Riccardo Mariani[2], Matilde Marcellini[3], Piero Bagolan[4], Francesco Callea[2]
[1] Department of Pathology, University of Cagliari, Cagliari, Italy
[2] Departments of Pathology,Children's Hospital Bambino Gesù, Rome, Italy
[3] Hepatology, Children's Hospital Bambino Gesù, Rome, Italy
[4] Neonatal Surgery, Children's Hospital Bambino Gesù,Rome,Italy

Background. Biliary Atresia (BA), one of the commonest cause of neonatal cholestasis, is characterized by a necroinflammatory process affecting the entire biliary tree (sclerosing pan-colangitis). The process leads to the obstruction of the extrahepatic bile ducts and to the disappearance of intrahepatic ducts. The porto-enterostomy (Kasai operation), aimed to re-establish the biliary flow, can be curative on the sole condition that the basic disease process is subsiding after the corrective operation. If not the disease evolves unavoidably into biliary cirrhosis even after initially successful operation. Two distinct histological forms of BA have been described: the embryonic type or antenatal-fetal (early-severe BA) and the neonatal-perinatal form (classic BA). The early-severe (ES) form is characterized by arrest of remodelling of the embryonic ductal plate or ductal plate malformation. Incidence, clinical implications and outcome of the two forms are still controversial. Methods. We have reviewed the histology of 50 BA cases undergoing Kasai operation over a ten years period (1996-2006). According to the age at the time of Kasai operation the patients were divided in two groups: group A: <60 days, 20 patients (range: 22-58 days; median: 44); Group B: >60 days, 30 patients (range: 60-173 days; madian: 82). The main histological evaluation parameters were: persistence of ductal plate (lack of resorption and remodelling of the excess epithelial structures), degree of fibrosis, giant cell transformation and extramedullary haematopoiesis. Results. The distribution of histological forms was found to be: ES form 40 cases (80%), classic form 10 cases (20%). Severe biliary fibrosis was found in all ES forms; whereas fibrosis was mild in classic forms. Extramedullary haematopoiesis and giant cell transformation was equally distributed among the two forms. With regard to the age, the cases were distributed as follows: group A, 17 ES (85%) and 3 classic forms (15%); group B: 23 ES (77%) and 7 classic forms (23%). Conclusions: This study has yield three main results: 1) the ES form has turned to represent the vast majority of BA (up to 80%); 2) the patients age at Kasai operation does not differ between the two histological forms; 3) accompanying histological features such as extramedullary haematopoiesis and giant cell transformation are not useful histological criteria in differentiating the two forms.

PP1-196
EOSINOPHILIC ESOPHAGITIS IN CHILDREN: HISTOLOGY AND THERAPY COMPARISON.

Francesca Minnei[1], Paola Francelanci[1], Paola Deangelis[2], Simona Saccani[3], Francesca Diomedi Camassei[1], Filippo Torroni[2], Luigi Dall' Oglio[2], Gavino Faa[3], Francesco Callea[1]
[1] Department of Pathology, "Bambino Gesù" Children's Hospital, Rome, Italy
[2] Department of Gatroenterology, "Bambino Gesù" Children's Hospital, Rome, Italy
[3] Department of Pathology, University of Cagliari, Cagliari, Italy

Introduction: Eosinophilic esophagitis (EE) is a chronic inflammatory immuno-allergic disease presenting with solid food dysphagia, food impaction, vomiting and abdominal pain. On endoscopy EE may appear as a patchy panesophagitis with white

spikes, vertical linear strictures, concentric rings up to esophageal stenosis. The histological hallmark is more than 20 eosinophils per high power field (HPF) and/or eosinophilic micro-abscesses in the superficial epithelium. EE is unresponsive to acid suppression. Therapy is aimed to eliminate the antigenic stimuli. Methods: To evaluate the histological response to current treatments, we reviewed 110 mid and distal esophageal biopsies from 32 pediatric patients (20M/12F, range 2-19 years, median 7) with gastro-esophageal symptoms unresponsive to Proton Pomp Inhibitor (PPI) undergoing upper gastrointestinal endoscopy between 2002-2007. Seven patients had esophageal motor disorder: 3 with esophageal atresia repaired, 3 with neurologically impairment and one with dismobility. Biopsies were stained with hematoxylin-eosin and alcian blue. Results: Twenty-nine patients were diagnosed as having EE on the basis of the eosinophil count (median eosinophil count 42 per HPF, range 21-100) and/or presence of eosinophilic micro-abscesses. Twenty-four patients underwent follow-up biopsies after treatment (prednisone, fluticasone oral swallowed, elemental or restricted diet). Five patients had just diagnostic biopsy. According to the diagnostic criteria, histological remission was obtained in 12 out 24 patients. In nine children the persistence of high number of eosinophils was concomitant with reintroduction of food in the restricted or elemental diet, whereas 3 patients did not gain either histological remission or symptom improvement. Finally in three patients although endoscopic features were suggestive for EE, the diagnosis was not confirmed histologically. As four patients had associated reflux esophagitis, PPI treatment was given. Two patients received surgical therapy. Two of these patients received a diagnosis of Barrett's esophagus. Conclusions: EE is a recent entity, almost rare in children. Our experience suggest that: 1) current treatment (restricted diet and/or corticosteroid drugs) seems to be effective in most patients with EE; 2) persistence of high level of eosinophils may be due to food reintroduction in elemental or restricted diet; 3) the unresponsiveness could be due to an incomplete or not compliance therapy and 4) occasionally reflux esophagitis can coexist; in this case PPI therapy or surgery is suggested.

PP1-197

DESMOPLASTIC SMALL ROUND CELL TUMOR [DSRT] IN CHILDREN CORRELATION OF IMMUNOHISTOCHEMICAL WITH GENETIC FEATURES

Kalliopi Stefanaki[1], Efthimios Dimitriadis[2], Catherine Van Vliet /Constantinidou[1], Anna Maria Athanassiadou[1], Maria Moschovi[3], Vassilios Papadakis[4], Nikolaos Pandis[2], Ourania Karentzou[1]
[1] Department of Pathology Aghia Sophia Children's Hospital Athens, Greece
[2] Department of Genetics Saint Savvas Anticancer Hospital Athens, Greece
[3] Hematology -Oncology Unit,1st Department of Pediatrics,University of Athens, Greece
[4] Department of Hematology Oncology Aghia Sophia Children's Hospital Athens, Greece

Background: Desmoplastic small round cell tumor[DSRT] is a rare aggressive,usually intra-abdominal neoplasm with divergent differentiation affecting children and young adults,which may present with unusual clinical and histological features.The aim of this study was to investigate the immunophenotypic features of 8 pediatric DSRT in correlation with the expression of Ki-67,proliferative index,p-53,p-27/kip-1,bcl-2 proteins and genetic findings. Method:Our material comprised 7 intra-abdominal and 1 pleural DRST from 7 boys and 1 girl,aged 8-16 years. The Streptavidin-Biotin method was performed on paraffin sections for the detection of epithelial,mesenchymal and neural markers, CA-125,MyoD1, WT-1[cl.6FH2], Fli-1[SC-C19], CD99/MIC-2[12E7], c-kit/CD117, Ki-67/MIB-1, p-53[DO7], bcl-2[100/D5], p-27[cl.1B4] RT-PCR was performed on frozen and paraffin-embedded tissues of 7 cases for the detection of the EWS/WT-1 fusion gene.Results:The immunophenotype of DSRT was :8+/8 Desmin and Vimentin,6+/8 Cytokeratin AE1/AE3,Cytokeratin 8.18 and Cytokeratin 19, 8+/8 EMA, 8+/8 NSE,7+/8 CD/NCAM and/or CD57,0/8 Synaptophysin and S-100,5+/8 Neurofilaments 2F11,1+/8 Chromogranin A,2+/8 CA-125,1+/8 Smooth muscle actin,0/3 Calretinin and Cytokeratin 5/6,1+/8 bcl-2. CD99/MIC-2 was detected in 4/8 DSRT showing mainly a cytoplasmic expression and a membranous one in the pleural case with a parallel nuclear Fli-1 expression. There was no nuclear expression of WT-1 by the use of the 6FH2 clone.CD117/c-kit was detected in 2 DSRT showing a heterogenous membranous expression. Ki-67/MIB-1 was detected in >60% of the nuclei in 7 cases showing an inverse correlation with p-27 expression and a parallel one with p-53 protein. RT-PCR revealed the EWS/WT-1 fusion gene in 5/7 cAses regardless of the tissue used [frozen or paraffin-embedded] Cases with an unusual phenotype [2 cases Cytokeratin -, 1 Smooth muscle actin +, 1 pleural case Fli-1+] showed no particular variant of the EWS/WT-1 fusion gene. Six children died, 1 child is alive with disease and the boy with the pleural DSRT is alive without disease. Although there was no correlation of the immunophenotype with prognosis, the pleural DSRT showed a lower proliferative index [Ki-67:10-20%] In conclusion, the combination of clinical, immunohistochemical and genetic features is necessary for the diagnosis of DSRT. The detection of the specific EWS/WT-1 fusion gene on fresh and archival tissue contributes significantly in the diagnosis of unusual cases.

PP1-198

A THORACIC LIPOBLASTOMA IN 11-MONTH-OLD GIRL WITH REARRANGEMENT OF CHROMOSOMAL REGION 8Q11-13

Sabah Boudjemaa[1], Christine Perot[2], Michele Larroquet[3], Hubert Ducou Lepointe[4], Liliane Boccon Gibod[1]
[1] Department of Pathology, Hopital Armand Trousseau, Paris, France
[2] Cytogenetics Department, Hopital Saint Antoine, Paris, France
[3] Department of Surgery, Hopital Armand Trousseau,Paris,France
[4] Department of Radiology, Hopital Armand Trousseau, Paris, France

Background : Lipoblastoma is a rare benign mesenchymal tumor of embryonic fat with a good prognosis despite its potential for rapid growth and local invasion. It occurs in children under the age of 3 years (M/F, 3:1) and has predilection for the (lower) extremities. Although the first published lipoblastomatosis originated from the thorax, lipoblastoma arising from the chest wall is rare, often associated with extrathoracic component. The circumscribed form is named lipoblastoma and the diffuse form lipoblastomatosis. The main differential diagnosis is myxoid liposarcoma, which may have the same clinical and radiological presentation, but in liposarcoma, exceedingly rare in this age group, lipoblasts present nuclear atypia and pleomorphism. Karyotypic analysis showing the characteristic alterations in 8q11-13.may be of use when diagnosis is difficult Design: An 11-month-old girl presented with bronchiolitis. At chest X-ray a mass with a large intrathoracic component was present, associated with pulmonary and tracheal displacement and costal involvement. The tumour extended outside the thorax in the axillary region. CT scan displayed areas of low attenuation suggesting a fatty component. Fine needle biopsy displayed a benign lesion with admixture of fat and fibro-connective tissue. A surgical resection was performed, incorporating the segment of the third rib included in the mass. Results: The tumour weighed 514 gr and measured 13 x 9 x 5 cm. It was firm, fatty, partially encapsulated, with a central buldging zone corresponding to extrathoracic extension. Histologic examination showed typical lipoblastoma with a focal myxoid component. Conventional cytogenetics analysis showed in all tumoral cells the following

caryotype: 46,XX,ins(11;8)(q22-23;q12q24). The insertion had been confirmed by molecular cytogenetics. The breakpoints on the chromosome 8 were those involved in lipoblastoma. In situ hybridization is ongoing to confirm the rearrangment of the interest genes. Conclusions : Although most lipogenic tumours are relatively easily dignosed histologically, pathological diagnosis based on purely morphological parameters may be difficult. Cytogenetic studies have shown that the various dignostic entities among lipogenic and even lipomatous tumours are characterized by different, more or less specific chromosomal abnormalities. This information is used to establish a more biologically meaningful pathogenetic classification of these tumours.

PP1-199
MORPHOMETRICAL CRITERIA OF PATHOLOGY AND ADAPTATION IN HELICOBACTER PYLORI (HP) - ASSOCIATED GASTRITIS IN CHILDREN, TEENAGERS AND YOUTH

Yulia Kakabadze, Sergei Kakabadze
Republical Pathologoanatomic Bureau, Russia

Background.Peculiarities of Hp-associated gastritis during the first and second decades of life are brought about by the continuing development of immune system, formation of antiinfectional resistance and morfo-functional maturation in prepubertal and pubertal periods. Morphometrical criteria of ontogenetic evolution, pathological changes and adaptive reformation of GM at Hp-assosiated gastritis in children, teenagers and youth have been studied. Methods.Antral biopsies of 9 children under 7 years, 14 children 8-13 years, 30 teenagers and 9 youth were studied according to the Sydney systen. The following morphometrical findings analysed: the quantities of pits and glands per 1 mm of GM length, GM thickness, dimensions of GM components (the depth of pits, length of neck and glands). Metrical indicators are given in mm. Results. Morphometrical indicators of GM with aging tend to decrease (in the number of pits and glands) or increase (thickness of GM), and they do not change (depth of pits, length of neck) or statistically reliable ($p<0,05$) increase (number of glands) in GM. In groups 1 and 4 pit-glandular index amounted to 2,74 and 2,70. Percentage of pit-glandular complex components (pits, necks, glands) in groups 1 and 4 amounted to 43,7%, 23,0%, 33,3% and 40,0%, 20,0%, 40,0%. In groups with minimal and maximal manifestations of inflammation pits number ($p<0,05$) and glands number ($p<0,001$)decrease, thickness of GM ($p<0,001$) and glands length ($p<0,001$) increase. Pit-glandular index in both groups amounted to 2,92 and 2,60 and pit-glandular complex components percentage amounted to 41,7%, 20,8%, 37,5% and 37,9%, 19,0%, 43,1%. Conclusions. Received groups data reflect of ontogenetical evolution of GM: the decreasing of pits and glands number testifyes to growth of stomach. The increase of GM glandular part satisfies a requirements of growing organism.The reduction of pits number per GM is because of increase of inflammatory infiltrate in GM. In this case some of the glands undergo destruction and the remaining structures provide for adaptive reformation: increase of GM glandular part. Morthometrical indicators of GM at minimal manifestation of inflammation could be considered at close to normal. In this cases Hp-gastritis manifested itself for the first time and had short duration and changes in GM were completely reversible. Maximal manifestation of inflammation are typical for long term (recurring) course of Hp-gastritis but changes in GM are only partially reversible and go with the adaptive reformations.

PP1-200
PRIMARY ANAPLASTIC LARGE CELL LYMPHOMA OF SKELETAL MUSCLE SIMULATING ALVEOLAR RHABDOMYOSARCOMA

Maha Driss, Karima Mrad, Lamia Charfi, Samia Sassi,
Imen Abbess, Ryme Dhouib, Dhekra Kacem,
Khaled Ben Romdhane
Department of Pathology, Institut Sala Azaiez, Tunisia

Background: Primary skeletal muscle involvement by anaplastic large cell lymphoma (ALCL) is quite uncommon and few cases studies were reported in the international literature. We report a new case of CD30/ALK positive anaplastic large cell lymphoma simulating clinically and pathologically an alveolar rhabdomyosarcoma. Case: An 8–year-old boy presented with an enlarging painful mass of the right buttock without associated lymphadenopathy. A diagnosis of rhabdomyosarcoma was initially suspected. Results: Tumor biopsy revealed large anaplastic cells appearing as ill-defined cellular aggregates that show central loss of cellular cohesion reminiscing of alveolar areas. A panel of immunohistochemistry markers showed these large cells to be CD30 and ALK positive. Conclusion: Anaplastic large cell lymphoma should be included in the differential diagnoses of tumors in the soft tissue and pertinent immunohistochemestry is recommended.

PP1-201
RETROPERITONEAL MALIGNANT TERATOMA IN INFANCY

Raoudha Doghri[1], Samia Sassi[1], Faical Oubiche[2], Karima Mrad[1], Maha Driss[1], Imen Abbes[1], Rym Dhouib[1], Sihem Barsaoui[2], Khaled Ben Romdhane[1]
[1] Department of Pathology, Salah Azaeiz Institute, Bab Saadoun, Tunis, Tunisia
[2] Unit of Pediatric Oncology, Department of Pediatric A, Pediatric Hospital, Bab Saadoun, Tunis, Tunisia

Retroperitoneal teratomas are uncommon germ cell tumors in children. They account for less than 10% of all primary retroperitoneal tumors and 3% of the tumours in childhood. They occur mainly below 2 years of age. Majority of tumors are benign, situated on the left side and pararenal in location. Malignant teratoma was higher in adults than in children, with incidence of 26% and 10% respectively. We report an unusual case of a 4 months-old infant presented with abdominal pain and a left-sided abdominal mass. His alpha-fetoprotein was 79,49 mg/ml, β HCG was 0,54 mUl/ml. Abdominal ultrasound and CT scan showed a well circumscribed retroperitoneal mass of 84x80 mm in size with a variety of tissues and calcifications and located on the left side. During surgery, he was found to have a very large left retroperitoneal tumor adherent to the kidney. The entire tumor and the left kidney were excised. Pathological examination revealed a malignant cystic teratoma. Postoperative course was uneventful and the patient was well and asymptomatic at the 7months follow-up.

PP1-202
SOLID PSEUDOPAPILARY TUMOR: A CASE REPORTS

Milena Djukic[1], Gordana Samardzija[1], Slavisa Djuricic[1],
Srdjan Bosnic[2], Dejan Kafka[2]
[1] Department of Pathology, Mother and Child Health Institut "dr Vukan Cupic", Belgrade, Serbia
[2] Department of Surgery, Mother and Child Health Institut "dr Vukan Cupic", Belgrade, Serbia

BACKGROUND: We report SPT of pancreas, which was diagnosed in the period of last 10 years in Department of Pathology of our Institute. SPT is benign neoplasm of low malignant potential, with clear morphological charecteristics, unclear origin and recurrency. Most frequently appearing at young women and adolescnts. METHOD: We analysed clinical

symptoms and performed diagnostic methods: radiography and ultrasound imaging, MRI, as well as patohistology of tissue samples, stained by HE and using immunohistochemistry. RESULTS: During the period of 1997 to 2007 there was diagnosed two SPT-s on girls at the age of thirteen. First girl was operated with diagnosis of insulinoma, two years before admittion to our hospital. We suspect on cystic change on pancreas. Second girl was admitted at our hospital after abdominal trauma because of shoulder ache, pallor, perspiration and tachicardia. Lungs radiographic shows us no significant changes for the both of girls. Ultrasound for the first girl had shown that pancreas was not accessible, and MRI has shown the presence of tumor mass, for second girl hipoechogenic, oval mass of 6 cm diameter was noticed at the epigastric area. By laparatomic interventions, significant amount of blood and haemorrhagic-necrotic tumor tissue were evacuated from the head and pancreas body. Multiple fragments of dark-red, soft, structureless tissue, and pale-grey, homogeneous, partly compound solid mass, were sent at the pathology department. Microscopic findings: tumor tissue was imbibed by blood, partly necrotic, consisted of nests of tumor cells, medium-sized, oval, pale-eosinophylic cytoplasms with uniformly grooved nuclei within the stroma capillary rich. Around the stromal capillaries, tumor cells are cohesive and further away partly destructed, discohesive, pseudopapillary arranged. Tumor cells have shown excessive immunopositivity towards α-1-antitripsin and α-1-antihimotripsin, weaker immunopositivity towards NSE and vimentin, while negative towards citokeratin. Both patients are free of disease till now. CONCLUSION: With thorough microscopic and immunohistochemic analyses and correlation with clinical symptoms, the differential diagnosis was made easier in contrast with other, more frequent pancreas tumors. Complete surgical resection of SPT is treatment which insures long survival period after operation and good prognosis. It is necessity to monitor patients for long period of time in order to avoid rare metastatic deposits and frequent recurrency.

PP1-203
CLEAR CELL ADENOCARCINOMA IN DUPLICATION OF THE URINARY BLADDER - CASE REPORT

Jerusia Oliveira Ibiapina[1], Lina Gomes Dos Santos[2], Teresinha Castelo Branco Carvalho[1], Elisa Rosa De Carvalho Nunes Galvao[1], Graziela Morena De Moura Viana[3], Jose Klerton Luz[2], Mauricio Marinho[2], Prisco Medeiro De Melo Neto[2], Benedito Borges Da Silva[2], Joao Bosco Parentes Vieira[2], Jucelia Saraiva E Silva[4], Ana Maria Lima Furtado Veloso[4], Kelson James De Almeida[2], Bruno Pinheiro[3], Edinaldo Goncalves Da Silva[4]
[1] Sao Marcos Hospital, Brazil
[2] Federal University of Piaui, Brazil
[3] NOVAFAPI, Brazil
[4] Estadual University of Piaui , Brazil

BACKGROUND: Clear cell adenocarcinomas of the urinary bladder are rare tumors with an unknown histogenesis. Since these tumors appear histologically similar to clear cell tumors of the female genital tract, a mullerian histogenesis has been proposed. The isolated incident of vesical complete duplication is a very rare event that is characterized for the formation of two bladders with mucous membrane and muscular wall, each unity receiving ureter and presenting urethral duplication. The authors report an important case with atypical presentation of adenocarcinoma of clear cells when there is appearing in patient bearer of the rare one evil-formation of the urinary appliance. CASE REPORT: Patient of the masculine sex, 10 years, asymptomatic up to that time, presented suddenly a picture of urinary obstruction. He carried out computerized tomography of abdomen, when what revealed bulky cystic formation intraperitoneal and retroperitoneal, besides accented hydronephrosis to the straight one and absence of left kidney, confirmed by secretory urography. He was subjected to a surgery, taking two vesical bags as a find, one of them completely occupied by neoplasic vegetating injury. The duplicated and bearer of the neoplasic process bladder was excised. Macroscopically, the surgical specimen was consisting of cystic cavity with 9.0 x 7.0 x 5.0cm, occupied by neoplastic injury brownish violet and friable, not infiltrative and measuring 6.5 x 4.5 x 2.5cm. Microscopically, it was a papillary standard neoplasia with tubular and cystic areas, presenting columnar and cubic flattened cells with spacious and clearly cytoplasm and vesicular nucleolus. This morphological context associated to expression of CK7 and absence of calretinin and WT-1, confirm the diagnosis of adenocarcinoma of clear cells. The patient evolved well in the postoperative one, without urinary complaints. CONCLUSION: The primary adenocarcinoma of clear cells of bladder (mesonefric carcinoma) is a very rare tumor in this topography and it has like differential diagnosis since kind injuries, like the nephrogenic adenoma, but also malignant tumors as the urotelial carcinoma with clear cells or the metastatic carcinoma of renal cells. There is still not a long time of continuation in a great deal of these tumors, but the experience accumulated in the literature indicates that the adenocarcinoma of clear cells cannot be so aggressive like initially it was believed. The majority has a model of exophytic growth and they can be diagnosed in precocious traineeships with a better relative prediction.

PP1-204
ALLOGRAFT REJECTION AFTER LIVER TRANSPLANTATION IN CHILDREN

Kyung Mo Kim[1], Eunsil Yu[2], Young Joo Lee[3], Sung Gyu Lee Lee[3]
[1] Departments of Pediatrics, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea
[2] Departments of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea
[3] Departments of Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea

Purpose: We performed this study to assess the clinical course of acute rejection and chronic rejection after liver transplantation in children. Methods: Seventy-six liver transplantations were performed in 75 children between December 1994 and March 2002. Twenty-five boys and 50 girls were included in this study, and the mean age was 20 months old. We analyzed the incidence, clinical course and outcome of acute and chronic rejection after liver transplantation retrospectively. Results: Forty out of 75 children (53%) experienced 45 episodes of acute rejection, and 32 episodes (71%) of them occurred within 1 month after transplantation. The degree of acute rejection was mild in 16 (36%), moderate in 14 (31%) and severe in 2 (4%) cases. Younger (＜2 years old) recipient experienced higher incidence of acute rejection. But there was no association with recipient´s sex, ABO matching, type of donor, and the kind of immunosuppressant. All 40 children with acute rejection improved with conventional treatment. There was no significant statistical relation between acute rejection and recipient´s survival. Chronic rejection occurred in 7 (9%) children, and 3 of them died of chronic rejection itself but another 3 children improved during the follow-up periods. Conclusion: Acute rejection occurred in more than half of the pediatric liver transplantation recipients. Most rejection episodes were mild and occurred within 1 month after transplantation. Acute rejection did not affect the recipient´s survival and graft function.

PP1-205
CHILDHOOD DEATHS IN MEDICO – LEGAL AUTOPSY CASES, IN ADANA – TURKEY
Mete Korkut Gulmen, Demet Meral, Ramazan Akcan
Cukurova University School of Medicine, Dept. of Forensic Medicine, Turkey

Adana city is one of the major cities in Turkey. Forensic Sciences mostly practiced by the University although autopsies mostly held at the City Morgue by The Forensic Medicine Council Branch of the Ministry of Justice within consultation and laboratory supports of the University. The Department of Forensic Medicine at the University carries the autopsy histopathology of the 12 cities at the Eastern Mediterranean region of Turkey. In this study we analyzed the childhood age group of cases (0 –6 ages) during the 2005 – 2006 period. A total of 1197 cases are yielded to our laboratory for histopathological examination of the tissues and organ samples which had been taken during the autopsies at this region of the country. 216 (18%) of those cases were in the 0 – 6 age groups. 95 (44%) of them were natural deaths. 81 (37.5%) of them were unnatural deaths. 25 (11.6%) of them were stillborn cases whilst 15 (6.9%), remained unexplained. Of those childhood cases, 129 (59.7%) were female whilst 87 (40.3%) of it were male. Infectious diseases were the main cause of death in all cases with 57 (26.4%). Drowning had taken the second stage of all cases.

PP1-206
ACUTE PLASTIC BRONCHITIS: A CASE REPORT
Svetlana Kocmanovska-Petreska[1], Boro Ilievski[1], Saso Banev[1], Milco Ristovski[1], Ilija Kirovski[2]
[1] Institute of Pathology, Faculty of Medicine, Skopje, Macedonia
[2] Department of Pulmology and Allergology, University Children's Hospital, Skopje, Macedonia

Introduction: Plastic bronchitis is a rare disorder characterized by the formation of branching mucoid bronchial casts. It is usually associated with underlying pulmonary diseases like bronchial asthma, allergic bronchopulmonary aspergillosis, cystic fibrosis, bronchiectasis and at times other system diseases like congenital heart defects and sickle cell disease. It is presented as acute respiratory distress with wheezing, breathlessness and cough mimicking foreign body aspiration. Plastic bronchitis has been reported from newborn period up to seventh decade but its exact pathophysiology is unknown. The bronchial casts may be divided into two types. Type 1, inflammatory cast with fibrin with cellular infiltrates associated with inflammatory diseases of the lung and Type 2, cellular cast made up of mucin with few cells usually associated with congenital cyanotic heart disease. Case report: A two-year-old boy was admitted to the hospital with complaints of cough, fever for two days and progressively increasing breathlessness. One month prior to the admission he had upper respiratory tract infection which was treated with antibiotics. There was no history of asthma; the chest X-ray showed atelectasis of the right upper lobe. Sweat chloride and tuberculin tests were negative. Serum immunoglobulins IgA, IgG and IgM were normal. Bronchial cast of the right main bronchus was extracted by forceps during bronchoscopy. It resembled a wax model of bronchial tree; was stained with H.E., PAS, Alcian Blue, Masson Goldner, Alcian PAS and Weighert for fibrin. The pathologic examination of this cast showed mucin, epithelial cells, fibrin and inflammatory cells neutrophils. Conclusion: Any child with acute respiratory distress refractory to conventional medical therapy with unusual radiographic picture needs intraluminal evaluation with bronchoscopy and pathologic examination.

UNUSUAL ELECTRON MICROSCOPIC FINDINGS IN MICROVILLUS INCLUSION DISEASE
Hatice Germen Unverdi[1], Ayse Ozgun[2], Duygu Kankaya[1], Berna Savas[1], Odul Egritas[2], Sinan Sira[2], Belgin Can[3], Buket Dalgic[2], Arzu Ensari[1]
[1] Ankara University, Medical Faculty, Department of Pathology, Turkey
[2] Gazi University, Medical Faculty, Department of Pediatrics, Turkey
[3] Ankara University, Medical Faculty, Department of Histology, Turkey

Background: The underlying causes of protracted diarrhea of infancy can be divided into those entities having a normal villus-crypt ratio and those associated with villus flattening. Microvillus inclusion disease (MID) is one of the causes of intractable diarrhoea in infants. Although ultrastructural detection of pathognomonic microvillous inclusions in the enterocyte cytoplasm is essential for the diagnosis of MID, unusual electron microscopic (EM) features such as intermediate structures between microvillous inclusions and lysosomes, inclusions containing few microvilli, dense apical granules in the apical cytoplasm can be observed in some cases. Therefore, two cases of MID with interesting EM findings are discussed further in order to draw attention to the variation in the ultrastructure of MID cases. Method: A 45-day-old boy and a 56-day-old boy were admitted to hospital with complaints of onset of diarrhea since the first and second weeks of their birth. Physical examination revealed abdominal distention and malnutrition in both babies. Laboratory findings showed anemia and hypoalbuminemia. They both underwent endoscopic duodenal biopsies. Formalin fixed biopsy specimens were stained with H&E, PAS and CD10 using streptavidin-Biotin peroxidase technique whereas gluteraldehyde fixed specimens were routinely processed for EM. Results: Duodenal biopsies showed partial to total villus flattening with brush border loss as demonstrated by PAS stain and CD10 antibody. PAS and CD10 also showed intracytoplasmic positivity in the form of apical vacuoles in both cases. EM showed marked brush border loss, and scattered typical apical intracytoplasmic vesicles containing microvillus inclusions in the enterocytes. Some vesicles had microvillus-like structures also located in the apical cytoplasm. There were also numerous dens apical granules. Conclusion: Though the diagnosis of MID depends upon the typical microvillus inclusions observed in EM, some cases may show less specific findings such as dens apical granules and intermediate structures resembling microvillus inclusions and also some atypical inclusions. Further studies seem to be necessary to evaluate the clinical significance of these unusual EM findings.

PP1-208
CONGENITAL RHABDOMYOMA OF HEART
Blagica Stojmanovska[1], Liljana Spasevska[2], Blagica Dukova[2]
[1] Laboratory for Pathologic Anatomy and Forensic Medicine, Medical Center Kumanovo, Macedonia
[2] Institute of Pathology, Faculty of Medicine, Skopje Macedonia

Background: Rhabdomyoma is reported to be the most common tumor of the heart in the pediatric age group. Tuberous sclerosis of the brain is the most frequently associated lesion, noted in approximately 50% of the reported cases. Case report: A male baby was born in the 29th week of gestation with birth weight 1200 g, birth length 36 cm and Apgar 1/1.The family and gestational histories were not remarcable. Physical examination showed bradycardy, ascites and anasarca. There were no neurologic signs and the skin was normal. The newborn died 9 min. after the delivery. The post-mortem examination revealed rhabdomyoma in the heart`s left ventricle (2,5x2x1,5 cm), multiple glial tubera with foci of calcification in the cerebellum and internal hydrocephalus. The cause of death was heart failure.

Tissue specimens from myocardium were fixed in 10% neutral formaline and processed by usual methods; paraffin sections were cut at 5 μm and stained with: H.E., PTAH, PAS, Alcian blue, Trichrom and lipid stain. Histological examination showed nodules of large, vacuolated spider cells, with PTAH positive cross-striation in myofibrills. The PAS stain revealed scanty amounts of cytoplasmic material with granular appearance. Lipid and alcian blue stainings were negative. Rhabdomyoma of the heart, responsible for death, accompanied with brain lesions known as tuberous sclerosis is rarely diagnosed in the newborn period.

[4] Dpt. of Pathomorphology, National Research Institute of Mother and Child, Poland

Neuroblastoma, one of the most common extracranial solid tumor in children, has a highly heterogeneous clinical presentation and course. Current risk-based therapy is effective in patients who have low or intermediate risk features, however, intensive treatment of advanced neuroblastoma in children over one year of age is far from satisfactory. Expression of epidermal growth factor (EGF) receptors (EGFRs) has been associated with aggressive behavior in some tumors. The study was based on 40 tumors, including 32 neuroblastomas,4 ganglioneuroblastomas and 4 ganglioneuromas. The clinicopathological data comprised: patients' age, gender, tumour site and stage, tumour histology and MYCN status. The immunohistochemical analysis of expression of EGFR and c-erbB2 was performed with monoclonal antibodies on tumor sections from paraffin blocks. The staining was considered as positive if more than 10% of neoplastic cells were immunoreactive. The proliferation index was established on Ki-67 staining. 30 of examined tumors showed EGFR expression and statistical analysis showed tendency for significant relations between this and lower tumor differentiation and proliferation index (p=0,08), older age (p=0,11) and higher stage (p=0,14). In 24 tumors immunoreactivity for c-erbB2 was found and statistical analysis showed its siginificant correlations with proliferation index (p=0,04) and lower tumor differentiation (p=0,05). The tendency for significant c-erbB2 expression relations with tumor stage (p=0,09) was also found. Our results reveal frequent expression of EGFRs in neuroblastoma and show its relations to some clinicopathological features. These facts suggest that specific inhibitors of EGFRs can create the new promising therapeutic agents in neuroblastoma therapy. [3] Dept. of Pathology, Childrens' Memorial Health Institute, Warsaw, Poland
[4] Dept. of Oncology, Childrens' Memorial Health Institute, Warsaw, Poland

The study was performed on tissue samples from 62 neuroblastoma (NB) Schwannian stroma-poor tumours including 39 untreated and 23 chemotherapy pretreated tumours. The aim of the study was to determine microscopic angiogenic parameters and looking for the associations between vascular parameters and clinicopathological features of tumours and basic prognostic factors. The clinicopathological data comprised: patients' age, gender, survival, tumour site and stage, tumour histology and MYCN status. The morphological analysis of the angiogenic potential concentrated on examination of vascular patterns - classical type or pathological angiogenesis with mural microvascular proliferation (MVP). The quantitative study included semi-automatic assessment of vascular density (VD) in CD34 stained tumour sections. Pathologic angiogenesis with MVP, including simple and/or glomeruloid type, was encountered in 25 cases and was more frequent in differentiating histology subtype and extraadrenal tumours. VD value ranged from 56 to 385 vessels/mm2 (median 149). Higher VD was connected with younger patient's age. In untreated tumours VD was significantly higher in infants than in children over one year of age. Pathologic type angiogenesis and lower VD were found to be associated with shorter patients survival. Our study confirmed high vascularization of NB and revealed common occurrence of pathological vascular pattern with MVP. Angiogenic potential in the analysed group showed diversity related to some clinicopathological tumour features. These facts show heterogeneity of NB tumours in vascular aspects, which possibly influence on tumours' response to antiangiogenic therapy.

PP1-211
P53 EXPRESSION IN DEVELOPING AND MATURE HUMAN KIDNEY

Nagihan Yalcin[1], Murat Colakoglu[2], Ferda Bir[1], Ender Duzcan[1]
[1] Department of Pathology, Pamukkale University School of Medicine, Denizli, Turkey
[2] Department of Nephrology, Pamukkale University School of Medicine, Denizli, Turkey

Background: p53 is a negative regulator of the G1-S phase transition in the cell cycle. In the case of DNA damage it induces growth arrest or apoptosis in the damaged cells. In human embryos aged 4 to 8 weeks, p53 is expressed in the mesonephric secretory canal epithelium and focally in the cells of the mesonephric glomeruli. The aim of this study was to examine p53 expression in developing and mature human kidney tissues. Material and Methods: We examined human fetal kidneys obtained from therapeutic abortions (N=5;9-12) and kidneys from autopsied cases (N=13;12-36 week) and mature kidneys (N=7) from nephrectomia for neoplasia. P53 expression was examined by immunocytochemical tecniques. Results In the early stages of the fetal kidney, no staining was seen in metanephric blastemal cells, S-shaped bodies and ureteric buds. In the maturation stage of the fetal and adult kidneys no staining was seen all tubule segments and visceral, parietal epithelial cells in the glomeruli. Conclusion: No, p53 expressions were seen in fetal and mature kidneys.

PP1-212
ATYPICAL TERATOID/RHABDOID TUMOUR OF THE CENTRAL NERVOUS SYSTEM: HISTOPATHOLOGIC AND IMMUNOHISTOCHEMICAL FEATURES OF 4 CASES

Yesim Ertan[1], Murat Sezak[1], Yusuf Ersahin[2], Saffet Mutluer[2], Taner Akalin[1]
[1] Ege University School of Medicine, Department of Pathology, Izmir, Turkey
[2] Ege University School of Medicine, Department of Pediatric Neurosurgery, Izmir, Turkey

Atypical teratoid/rhabdoid tumour (AT/RT) of the central nervous system is a rare aggressive infantile neoplasm of

uncertain origin. Here we are describing the clinicopathologic and immunohistochemical features of four cases diagnosed as atypical teratoid/rhabdoid tumour. Of the four cases, three were male, one was female whose ages were ranged from 1 to 8 years (mean age, 3.2). Tumours were located in posterior fossa (two cases), frontal lobe (one case) and third ventricule (one case). Histopathologically, rhabdoid cells were prominent at least focally in three of them, but one of them was characterized with mesencymal appearence through the tumor. Undifferantiated small cells mixed with epitheloid components were evident in two of them. Immunohistochemically, epithelial membran antigen (4/4), cytokeratin (3/4), smooth muscle actin (3/3), GFAP (4/4), S-100 (2/2) and synaptophysin (1/3) were positive in a varying proportion but desmin(0/2) was negative. One of the patients died of disease within five months after surgery, another one was alive 26 months after surgery. One of them has recently diagnosed and the other was alive with disease 6 months after the surgery. The unique immunohistochemical profile of AT/RT helps to distinguish it from a PNET/medulloblastoma. This is of clinical importance because the prognosis of a patient with AT/RT is worse than that of a PNET/medulloblastoma despite aggressive therapy.

PP1-213
CARDIAC MALFORMATION IN THORACOPHAGUS TWINS

Sofija Glumac[1], Ida Jovanovic[2], Sanja Radojevic-Skodric[1], Zorica Stojsic[1], Radmila Stevanovic[1], Milica Stefanovic[1], Jovan D. Vasiljevic[1]
[1] Institute of Pathology, Medical School, University of Belgrade, Belgrade, Serbia
[2] University Children Hospital, Belgrade, Serbia

Background: Conjoined thoracophagus twins (CTT) have a very high incidence of congenital heart malformations, including joined and individual congenital heart diseases (CHD). The aim of our study was to investigate types of CHD in 5 autopsied, unoperated cases of CTT. Method: All twins were female, 2 of them were stillborns, 2 were 2 months old, and 1 was only 4 days old. All autopsies were performed using standard or modified Rokitansky technique, and wide accepted segmental diagnostic approach for CHD. Results: In case #1, hearts were completely separated, and in other 4 cases the twins had common pericardium and fusion at the atrial and/or ventricular level. In case #2, the only communication was at the ventricular level, in apical region. But each heart individually showed complex cardiovascular anomalies (complete AVSD in one, and TGA with single inlet and single outlet in the other heart. In cases #3 and #4, conjoined hearts had 4 chambers with connection at atrial and ventricular level, i.e. common atrium and common ventricle. In case #5, one of the twins had the heart with 4 chambers, and the other one with only 2. Connections were at the atrial and ventricular level too. In 4/5 cases TGA was present, and the right aortic arch was found in 3 cases. Conclusion: These findings indicates that in CTT are present major congenital heart malformations, and some individual CHD. Besides the case #1 (with 2 separated hearts), eventual surgical separation of CTT was possible only in case #2 (connection in apical region), but presence of associated complex anomalies in both hearts would make this separation aimless. In the remaining cases any surgical attempt would be impossible.

PP1-214
OSTEOPONTIN (OPN) IS EXPRESSED IN HUMAN ADRENAL TISSUES AND ENHANCES WITH ITS RECEPTOR INTEGRIN ß3 THE INVASION OF HUMAN ADRENOCORTICAL CARCINOMA CELL LINE NCI259R

Juliane Nowak[1], Joscha Niemann[2], Ana-Maria Bamberger[2], Liu Wei[3], Sylvia L Asa[3], Shereen Ezzat[3], Christoph M Bamberger[2]
[1] Department of Laboratory Medicine and Pathobiology, University of Toronto and Department of Pathology, University Health Network and Toronto Medical Laboratories, Canada
[2] Section on Endocrinology and Metabolism of Ageing, University Clinic Hamburg-Eppendorf, Hamburg, Germany
[3] Department of Laboratory Medicine and Pathobiology, University of Toronto and Department of Pathology, University Health Network and Toronto Medical Laboratories, Canada

Background: Osteopontin (OPN) is a glycoprotein of the extracellular matrix and interacts with its receptor integrin ß3, which we previously found to be expressed in benign and malignant endocrine tissues of the utero-placental system, and which were shown to mediate cellular migration and invasion and to contribute to tumorigenesis in several types of cancers. Recently, expression profiling of adrenal neoplasms revealed OPN mRNA to be expressed in these tumors. The present study was designed to analyze the expression of OPN protein in normal and tumorous adrenal tissues. Method: Immunohistochemistry with specific anti-OPN and anti-integrin ß3 antibodies were performed in normal adrenal tissue as well as in benign and malignant adrenocortical tumors. In addition, we studied OPN and integrin ß3 protein expression using Western blot analysis. Invasion assays were used to study the functional role of OPN in regulating tumor cell invasion. Result: In the normal human adrenal gland, OPN and its receptor integrin ß3 were found to be expressed strictly in the cortex, with the staining intensity increasing in a centripetal fashion. Expression of OPN and integrin ß3 was more heterogenous in the analyzed adrenocortical adenomas and carcinomas with staining intensity being more accentuated in single tumor cells or nests. These results were confirmed by Western blot analysis. OPN protein expression could also be found in the human adrenocortical cell line NCI259R. Treatment of these cells with human OPN increased invasiveness dramatically; this increase was partially reversed by transfection of the cells with with integrin ß3, supporting the idea that OPN acts to facilitate tumor development and metastases. Conclusion: In this study we show for the first time, that OPN protein is expressed in the human adrenal gland. Furthermore, we demonstrate that OPN expression is strictly confined to the cortex, making it, thus, a potential diagnostic marker to distinguish between adrenal cortex and medulla. Our ongoing studies aim to clarify the role of OPN in adrenal tumorigenesis.

INTERRELATIONSHIP BETWEEN DIABETES MELLITUS AND ARTERIAL HYPERTENSION: MOLECULAR ENDOCRINOPATHOLOGIC ASPECTS

Vasile V Anestiadi[1], Vasileos Anestiadis[1], Vasile Fedas[1], Zinaida Anestiadi[2], Ilie Tsiple[1], Lilian Birzoi[1]
[1] Centre for Pathobiology and Pathology, Academy of Sciences, Chisinau, Moldova
[2] Chair of Endocrinology, Medical University, Chisinau, Moldova

Background. The aim of the study was clarification of interrelationships between hormonal, metabolic, electrolyte, renal factors and the activity of the renin-angiotensin-aldosterone system (RAAS) in the aspect of predisposition of patients (pts) to arterial hypertension (AH) and possibilities of its prevention. Methods. There were studied 176 patients with newly-diagnosed diabetes mellitus (DM) and 45 healthy controls. 82 pts had DM I,

94 pts had DM II, 53.40% of DM pts had borderline hypertension, 48.30% had microproteinuria. 57.92% had hyperlipoproteinemia (HLP). The main parameters of carbohydrate, lipid, lipoprotein and electrolyte metabolism, the condition of insulin-producing function of the pancreas, plasma renin activity (PRA) and contrainsulin hormones were studied. Insulin, C-peptide, STH, ACTH, cortisol, aldosterone, PRA were determined by radioimmunoassay. Total cholesterol, alpha-cholesterol, triglycerides, total lipids, beta-lipoproteins were analyzed by biochemical methods; including HLP phenotyping according to Fredrickson (1978). Results. The results were analyzed in pts, grouped according to presence of borderline AH, microproteinuria, HLP presence and type, with consideration of DM type I or II. The study has demonstrated that changes of the hormonal, lipoprotein, electrolyte, filtration-reabsorbtion renal function, RAAS activity regulation occur at the early stages of the evident DM, leading to dyslipoproteinaemias and HLPs with atherogenic character, endogenous and exogenous hyperinsulinism, RAAS elevation, to enhancement of the filtration of the kidneys, to electrolyte disbalance, creating a high risk of AH. A differentiated approach to determining the predisposition towards AH was used, including such parameters as HLP, HLP type, presence of microproteinuria, DM type. The study has revealed their high diagnostic value for determining the early stages of the disease. Conclusion. It has been found that the DM compensation leads to a lowering, up to normalization, of many hormonal, humoral, electrolyte and renal factors, to lowering of RAAS activity, becomes an early measure of preventing the risk of AH establishing in DM, and of the prophylactics of the progression of diabetic angiopathies.

PP1-216
CD10 AS A MARKER OF TUMORS FORMING MORULES WITH BIOTIN-RICH, OPTICALLY CLEAR NUCLEI THAT CAN APPEAR IN DIFFERENT ORGANS

José Cameselle-Teijeiro[1], Lara Alberte-Lista[2], Silvia Chiarelli[3], Catalina Buriticá[4], Lucy Gonçalves[4], Ricardo González-Cámpora[5], Francisco Nogales[4]

[4] Department of Anatomic Pathology, Hospital Universitario San Cecilio, Granada, Spain
[5] Department of Anatomic Pathology, Hospital Universitario Virgen Macarena, Seville, Spain

Background: It has been demonstrated that CD10 immunostaining represents a useful marker of morules in endometrioid lesions of the female genital tract, allowing us to identify various low grade lesions which are associated with these nodular structures. Morules with a characteristic nuclear clearing have been reported in endometria, ovarian endometrioid tumors, colorectal adenomas and carcinomas, gastric polyps, gallbladder adenomas, pulmonary blastomas, low-grade adenocarcinomas of fetal lung type, some papillary lung carcinomas, pancreatoblastomas, and finally, in the cribriform-morular variant (C-MV) of papillary thyroid carcinomas. Here we investigate the usefulness of CD10 in the diagnosis of morular metaplasia in neoplasms of extragenital locations. Method: We studied the immunoexpression of CD10 and beta-catenin in seven cases of tumors containing morules with cells displaying biotin-rich optically clear nuclei (BROCN) (BROCN-family tumors), corresponding to four instances of CM-V of papillary thyroid carcinoma (one of them in the setting of a familial adenomatous polyposis), one case of low-grade adenocarcinoma of fetal lung type, one case of pulmonary blastoma and one pancreatoblastoma in a child with Beckwith-Wiedemann syndrome. Immunohistochemical studies were performed on paraffin sections with a universal second antibody kit that used a peroxidase-conjugated labeled-dextran polymer (Dako EnVision Peroxidase/DAB; DAKO, Glostrup, Denmark). Results: For CD10 (clone 56C6, dilution 1:10, microwave oven, Tris-EDTA, Novocastra, Newcastle Upon Tyne, UK), all cases revealed strong membranous positive staining in morules, with some cytoplasmic staining probably due to diffusion. As a consequence, CD10 positivity allowed easy identification of morules at low power in the different samples. CD10 immunostaining also outlined the luminal borders of the neoplastic cells in the glandular formations of all tumors. Aberrant nuclear expression of beta-catenin (beta-catenin-1, 1:300, microwave oven, DAKO) was detected only in neoplastic cells of all samples examined. Conclusions: Confirming previous reports on the expression of CD10 in morules, our findings support the notion that CD10 can represent a useful tool in identifying morules in the BROCN-family tumors of various organs. Our results also support the concept of BROCN-family tumors as entities sharing morphological features and alterations in the APC/beta-catenin pathway. Supported by grant PI060209 from Instituto de Salud Carlos III, Spain.

THYROID CARCINOMA ASSOCIATED WITH FAMILIAL ADENOMATOUS POLYPOSIS - A CASE REPORT

Kalliopi Patsiaoura, Anastasios Chatzitolios, Eleftherios Anagnostou, Maria Leontsini
Department of Pathology, Hippokration General Hospital, Thessaloniki, Greece

Thyroid carcinoma is an extracolonic manifestation that is present in 1% to 2% of patients with familial adenomatous polyposis (FAP). We report a case of a 26 year old female with familial adenomatous polyposis (6 years ago), who was admitted to hospital because of an incidental finding of two thyroid nodules. The fine-needle aspiration biopsy revealed thyroid papillary carcinoma. The patient treated by total thyroidectomy without lymph node dissection. Gross examination of the thyroid identified four whitish circumscribed solid nodules ranging from 0,5 cm to 2,8 cm. Histological examination of the nodules revealed the presence of tumours which showed a variety of architectural pattern of growth . The pathological findings identified nuclear clearing, trabecular, follicular, papillary pattern and morular formations. There were solid areas with spindle cells in short fascicles or whorls and cribriform areas composed of varying sized follicles. The neoplastic cells sometimes formed tubular structures lined by ampophilic to oxyphilic tall cells. Immunohistochemistry showed strong positivity for cytokeratin 19 and focal positivity for HBME-1 and galectin-3. The tumour was negative for thyroglobulin, calsitonin, NSE, CEA, synaptophysin and chromogranin. The morphological and the immunohistochemical profile of the tumour suggested the diagnosis of multicentral papillary thyroid carcinoma associated with familial adenomatous polyposis. The patient is well with no evidence of disease 6 months following resection of the tumour. It has been suggested that FAP associated thyroid carcinoma is significantly different morphologically from both papillary and follicular types and can be considered as a separate entity. In general these carcinomas show good prognosis. We present this case because of its rarity and we review the findings in the literature.

PP1-218

ASSESSMENT OF FIXATIVES, FIXATION AND TISSUE PROCESSING ON MORPHOLOGY, ANTIGENICITY, AND ACID NUCLEIC INTEGRITY FROM TUMORAL AND NON TUMORAL THYROID TISSUES

Virginie Gavric-Tanga[1], Sandra Lassalle[2], Véronique Hofman[2], Katia Havet[3], Céline Loubatier[1], Olivier Bordone[1], Catherine Butori[3], Nicolas Guevara[4], José Santini[4], Paul Hofman[2]

[3] Laboratory of Clinical and Experimental Pathology,University of Nice, Nice, France
[4] Department of Oto-Rhino-Laryngology, University of Nice, Nice, France

Histotechnology arguably can be viewed as a discipline devoted to optimizing the microscopic morphology of formalin-fixed tissues. Unfortunately, for molecular biology techniques, formalin fixation may be too successful in its ability to prevent autolysis (the degradation of proteins into amino acids). So, formalin preserves tissues by cross-linking proteins; however RNA (and sometimes DNA) is fragmented, chemically altered and difficult to isolate in quantity from formalin-fixed, paraffin-embedded samples. In this regard, frozen tissues specimens are the gold standard for molecular analysis. However, snap freezing presents several challenges regarding collection and storage, and preservation of histological detail. The aim of this study was to evaluate different alternative preservation methods (RCL2, Excell plus, Glyofix, Finefix solutions) by analyzing morphology (after different stainings such as hematoxylin eosin safran, PAS, Gordon-Sweet), antigenicity (immunostaining with HBME1, CK19, Galectin 3, TTF1 antibodies) and RNA/DNA integrities (quantity and quality) on different thyroid tissues (normal tissue, adenoma, nodular hyperplasia, papillary thyroid carcinoma). These different analyses were performed after 6h, 12h and 24h of fixation and compared to 6h, 12h and 24h of fixation in formalin. Results showed that all alternative preservation methods used in this study preserved morphology, staining and antigenicity of the different used thyroid specimens. In each case, the fixed and embedded tissues produced results similar to that obtained from formalin-fixed specimens. Recovery of mRNA was reduced in both quantity and quality in the different alternative preservation methods comparatively to that obtained from snap-frozen tissues, but was strongly superior to that obtained from formalin-fixed samples and largely sufficient to perform reverse transcription polymerase chain reactions. Recovery of DNA from all the different alternative preservation methods was superior to formalin-fixed samples as determined by one-dimensional gel electrophoresis and polymerase chain reaction. In conclusion, thyroid specimens fixed in the different alternative preservation methods used in this study, and embedded in paraffin, produce good histology, and immunohistochemistry and permit recovery of DNA, and mRNA sufficient for several downstream molecular analyses.

PP1-219

RE-CLASSIFICATION OF NEUROENDOCRINE TUMOURS OF THE RECTUM - A STUDY OF 97 CASES

Juha Jernman, Caj Haglund, Matti Välimäki, Johanna Arola
Helsinki University Central Hospital, Finland

Background: The WHO classification for neuroendocrine tumours (NETs) of the gastrointestinal tract was introduced in 2000. Before that, tumours, which showed neuroendocrine differentiation were classified as carcinoids or atypical carcinoid tumours or as neuroendocrine carcinomas. The WHO classification divides these tumours into three distinct groups: Group 1 includes well-differentiated neuroendocrine tumours, Group 2 well-differentiated neuroendocrine carcinomas and Group 3 poorly-differentiated neuroendocrine carcinomas. This classification is based on tumor size, invasive growth and proliferation index. Rectal tumours represent approximately 10% of all GI-NETs. According to Kang et al. the incidence rate in the U.S. was 6.8/million in 1992 and 10.6/million in 2000, suggesting an increase in incidence. The aim of this study was to re-classify all rectal NETs from the pathology database of Helsinki University Central Hospital and its affiliate hospitals in the Hospital District of Helsinki and Uusimaa in southern Finland from time periods 1980-2000 and 2001 - 2005. . Method: The total number of rectal NET cases found was 97. All tumours were re-analysed independently by two pathologists. In addition to HE stain, immunohistochemical chromogranin A stain was done to confirm the neuroendocrine diagnosis. MIB-1 stain was used to evaluate the proliferation index and CD31 to confirm or exclude angioinvasion. Re-classification of the tumours was then made according to the WHO criteria. Results: The first 20 years time period from 1980 to 2000 gave a total number of 46 cases. The following 5 year time period (2001-2005) consisted of an additional 51 cases. Out of the first 46 cases 38 (83%) were classified as WHO group 1, 8 (17 %) as WHO group 2, and none as group 3 tumour. Tumours from years 2000 to 2005 are still under investigation. Conclusions: 83 % of rectal NETs from 1980 - 2000 belong to WHO group 1 and 17% to group 2. Poorly differentiated neuroendocrine carcinomas were not found. The number of rectal NETS found from the database during the past five year (n=51) compared to previous 20 years (n=46) supports the studies reporting an increase in the incidence of rectal NETs. Increasing awareness of this tumour entity may also partly explain the increase in incidence. In further analyses we shall relate the WHO classification to tumour behaviour and patient survival.

PP1-220

ABSENCE OF BRAF MUTATIONS IN THE CRIBRIFORM-MORULAR VARIANT OF PAPILLARY THYROID CARCINOMA

José Cameselle-Teijeiro[1], Lara Alberte-Lista[2], Ihab Abdulkader[1], Clara Ruíz-Ponte[3], Nuria Caramés[1], Lidia Puñal[1], Manuel Sobrinho-Simões[4]
[1] Department of Anatomic Pathology, Clinical University Hospital, University of Santiago de Compostela, Santiago de Compostela, Spain

[4] Institute of Molecular Pathology and Immunology, University of Porto, Porto, Portugal

Background: The cribriform-morular variant (C-MV) of papillary thyroid carcinoma (PTC) is the term coined for a sporadic type of PTC morphologically indistinguishable from most of the thyroid carcinomas that arise in the setting of the familial adenomatous polyposis (FAP). Somatic or germline mutations in the APC-beta-catenin pathway are associated with this particular subtype of PTC that may also harbour RET/PTC gene rearrangements. The majority of studies on record have found that RET/PTC rearrangements and BRAF mutations are mutually exclusive PTC; there is, however, one study that advanced that BRAF mutations may cooperate with RET/PTC rearrangements in the development of PTC. Objective: To find whether or not BRAF mutation play a role in the setting of C-MV of PTC. Method: We examined two familial and three sporadic cases of C-MV of PTC, for BRAF mutations. DNA was isolated from paraffin-embedded tumor tissues and the exon 15 of the BRAF gene was sequenced directly. We also estudied the immunoexpression of beta-catenin (beta-catenin-1, 1:300, microwave oven, Dako) on paraffin sections with a universal second antibody kit that used a peroxidase-conjugated labeled-dextran polymer (Dako EnVision Peroxidase/DAB; Dako, Glostrup, Denmark). Results: Aberrant nuclear expression of beta-catenin was detected in all tumors. No

mutations were found in any tumor samples analyzed. Conclusions: BRAF mutations do not seem to play, at variance with RET/PTC and APC/beta-catenin mutations, a role in the etiopathogenesis of C-MV of PTC (neither the typical V600E mutation nor the mutation associated to the follicular variant of PTC-K600E, were detected in any case of the C-MV of PTC). Supported by grant PI060209 from Instituto de Salud Carlos III, Spain.

PP1-221
CD 56 IN INVASIVE OVARIAN CANCER AND BORDERLINE TUMORS

Wolfgang Pokieser[1], Steffen Hauptmann[2], Walter Ulrich[1], Christian Peters-Engl[3]
[1] Institute for Pathology, Krankenhaus Lainz, Vienna, Austria
[2] Institute for Pathology, Martin-Luther-Universität Halle-Wittenberg, Germany
[3] Department of Obstetrics and Gynecology, Krankenhaus Lainz, Vienna, Austria

Introduction: CD56 is a glycoprotein that plays a critical role as neuroadhesion molecule in cell binding, migration and differentiation. It is expressed on NK cells and neuroendocrine neoplasm. We investigated CD56 in ovarian carcinomas in a retrospective study of consecutive cases. Methods: 115 female patients with a history of ovarian cancer were analyzed in a retrospective study. Immunohistochemical study of CD56 Expression was undertaken for 107 invasive carcinomas and 8 borderline tumors. The two groups were compared in respect of the immunohistochemical expression of CD56. Results: 71cases (66,4%) out of 107 invasive carcinomas showed positive staining for CD56 whereas one out of eight (12,5%) borderline tumors was focally stained with CD56. The CD56 positive borderline tumor turned out to be a micropapillary type. Invasiveness of ovarian cancer was highly significant associated with CD56 expression in comparison with borderline ovarian neoplasm (p£0.05; chi-square tests). The expression of CD56 was not associated with overall survival. Conclusion: Our results of different staining of invasive carcinomas and borderline tumors of the ovary suggest that CD56 may play a role in ovarian epithelial tumor cells becoming invasive. Further studies will have to determine whether CD56 is a useful additional marker in borderline tumors of the ovary to select for adjuvant treatment.

PP1-222
C-KIT EXPRESSION IN NORMAL AND NEOPLASTIC, INFLAMMATORY, REACTIVE LESIONS OF THYROID

Oguz Aydin, Levent Yildiz, Mehmet Kefeli, Bedri Kandemir
Ondokuz Mayis University, Faculty of Medicine, Department Of Pathology, Samsun, Turkey

Background: The c-kit proto-oncogene encodes a transmembrane receptor tyrosine kinase (KIT). The oncogenic mutations of c-kit gene or activation of KIT lead to signal transduction ascades activation which regulates cell proliferation, apoptosis, chemotaxis, and adhesion. The aim of this study is to investigate the expression of c-KIT in normal, inflammatory, neoplastic, and reactive lesions of thyroid. Methods: Immunohistochemical staining using a polyclonal anti-c-kit antibody was performed on tissue blocks from 92 papillary carcinomas, 19 follicular carcinomas, 31 follicular adenomas, 25 nodular goiters, 13 Hashimoto's thyroiditis, 5 Graves diseases, 1 De Quervain thyroiditis, 19 lymphocytic thyroiditis, and 25 normal adult thyroid tissues. Extend of staining was evaluated in a semi-quantitative method; staining ≤10% was accepted as negative regardless of the staining intensity. Staining between 11 to 50% was accepted as (1+) and staining more than 50% was accepted as (2+). Intensity of the staining was evaluated qualitatively. Weak staining (1+), obvious staining (2+), and heavy staining (3+). Results: Positive staining was determined in 65 of 92 papillary carcinoma cases. Staining intensity of papillary carcinoma cases were found as (3+), (2+), (1+) in 26, 22, and 17 cases, respectively. Positive staining was determined in 9 of 19 follicular carcinoma cases. Staining intensity of follicular carcinoma cases were found as (3+), and (2+) in 3, and 6 cases, respectively. Positive staining was determined in 13 of 31 follicular adenoma cases. Staining intensity of follicular adenoma cases were found as (3+), (2+), (1+) in 2, 4, and 7 cases, respectively. We found positive staining in only two out of 25 cases of normal thyroid tissue, and their staining intensity were evaluated as (+2). Positive staining was found in only two out of 25 cases of nodular colloidal goiters, and their staining intensity were evaluated as (+1). Positive staining was determined in two out of five Graves' disease cases. Their staining intensity were (3+), (1+) each. Positive staining was determined in two cases of 13 Hashimoto's thyroiditis cases. Their staining intensity were found as (3+), and (2+) each. Conclusion: Immunohistochemical c-KIT positivity was detected in a wide range of neoplastic and inflammatory thyroid diseases. Especially notable is the high rate positivity in papillary carcinomas which can lead to new diagnostic and therapeutic approaches. Our results need to be confirmed by other molecular and genetic studies.

PP1-223
ANALYSIS OF THE CYTOLOGICAL FEATURES OF 9054 FNA OF THYROID AND CORRELATION TO THE CYTOLOGICAL AND HISTOLOGICAL DIAGNOSES

Emmanouil Zoulias[1], Hariklia Gakiopoulou[2], Efstratios Patsouris[2], George Matsopoulos[1], Nikolaos Uzunoglu[1], Sofia Tseleni-Balafouta[2]
[1] Microwave and fiber optics laboratory, National Technical University of Athens, Greece
[2] A' Department of Pathology Medical School, University of Athens, Greece

Background FNA has been widely accepted as the best tool in selecting thyroid nodules for surgery. We analyze the various cytologic features of 9054 FNA and correlate them to histologic diagnoses aiming to estimate the diagnostic accuracy of FNA and to identify possible sources of erroneous diagnosis as well. Method A total of 9054 patients were examined by FNA of the thyroid during the period 2000-2004. The cytologic reports were retrieved from our files and a data list comprising all reported cytologic features, final cytologic diagnosis, histologic verifications from 262 patients and the comparison between cytologic and histologic diagnoses was entered in a data base (MS SQL server,2005). Statistical analysis was performed using SPSS1/13. Results The diagnostic results of FNA were classified as benign (82.63%), malignant (2.77%), neoplastic (of unknown behavior) (1.38%), suspicious for malignancy (3.31%), and as indeterminate (borderline lesions between a benign follicular/oncocytic lesion and a follicular/oncocytic neoplasm), (1.19%). According to the cytologic diagnoses, 10% of our patients were expected to underwent subsequent surgery. A definite classification was achieved in 98.5% of malignancy, papillary carcinoma being the commonest diagnosis. Correlation of cytology and histology showed that 84.7% of FNA results correlated with the histologic diagosis (138 true negative and 89 true positive results) while there were 16 false-negative (5.97%), 1 false positive (0.3%) and 25 false-suspicious results (9.3%).Accordingly, the sensitivity of our method was 85% and the specificity 84.12% when both false-positive and false-suspicious were grouped together and 99.28% when false suspicious were not included in the false-positive group. The cytologic profile of false positive/suspicious FNAs was characterized by high cellularity (62.5%), scanty colloid (58.3%), presence of oxyphillic cells (41.6%) and many lymphocytes (50%). False-negative smears contained few epithelial cells (75%), scanty colloid (81.2%) and lymphocytes in various proportions (75%). True positive smears exhibited frequently high cellularity (74.1%), oxyphilic cells (20.2%), intranuclear inclusions (19.1%), multinucleated giant cells

(32.5%) and lymphocytes (16.8%). Conclusion: FNA consists a method of high diagnostic value in the management of thyroid nodules. Confusing features in the direction of false suspicious diagnosis are the high degree of cellularity and the presence of oxyphilic cells while lymphocytes proved to be confusing feature leading to either a false suspicious or false negative result.

PP1-224
ONCOMARKERS OF MITOGENETIC PATHWAYS IN DIFFERENT HISTOLOGICAL TYPES OF PAPILLAR THYROID CARCINOMA

Ekaterina Rozhkova[1], Evguenija Kogan[1], Paola Soares[2], Manuel Sobrinho-Simoes[2], Michail Paltsev[1]
[1] Moscow Setchenov Medical Academy, Russia
[2] Ipatimup, Porto, Portugal

The aim of the study was to investigate oncomarkers of mitogenetic pathways in different histological types of papillar thyroid carcinoma (PTC). Surgical material was used of completely removed thyroids or their fragments from 65 patients operated in faculty surgical clinic of I.M.Setchenov's MMA (40 cases in 1998-1999), the Moscow munitipal hospital ¹ 61 (25 cases in 1998-2000) on account of central formations in thyroid. In 11 cases there has been executed a thyreoidectomy, in 27 - a subtotal resection of a thyroid and in 27 cases - hemithyroidectomy. The patients were observed till February 2006 during the period from 6 till 8 years after the surgical treatment. Ultrasonic thyroid investigation was performed 2 times per year in every patient. Key factors of the basic mitogenetic pathways in PTC (c-kit, c-erb B2, c-Met, caveolin-1), as well as the markers of proliferation (Ki-67), invasive growth (CD10) and malignancy (HBME-1) were studied by the method of tissue micro array (TMA) and immunohystochemistry. Results. In proliferation of the PTC tumour cells are activated the mitogenetic pathways with participation c-kit, c-erb B2, c Met, caveolin-1. In papillary variant of PTC the mitogenetic pathways with c-kit, c-Met, c-erb B2 is the most active, and in oxifillic variant of PTC - caveolin 1, c-erb B2 and c-Met; in follicular variant of PTC all mitogenetic pathways take part, but at lower activity level. CD10 increases in the sites of tumour invasion more than two fold and can be also used as a prognostic marker. Proliferation of tumoral cells at different histologic types of PTC is carried out due to work of various mitogenic pathways, which activity depends on a phenotype of a tumour. During tumoral progression of PTC, at development of the remote metastasises and relapsing of the tumours, the general level of the cancer cells does not change. The contribution in proliferation of tumoral cells of such mitogenetic stimuli as c-kit, c-erb B2 decreases, that is possibly compensated by other growth factors. Conclusion. Obtained results show that different types on PTC are characterized by particularities in mitogenetic pathways of growth stimulation that can be useful in target therapy.

PP1-225
THE VALUE OF TTF-1 EXPRESSION IN DIFFERENT THYROID NEOPLASMS

Ellen Caroline Toledo Nascimento,
Celia Sebastiana De Jesus Fazzio, Juliana Micelli,
Elaine Aparecida Gouveia,
Elaine Keid Leso Martins, Patricia Maluf Cury
Faculdade de Medicina de São José do Rio Preto, Brazil

Background: Currently studies show that TTF-1 immunohistochemical expression is usually present in many thyroid and lung neoplasm. Due to its restrict expression, TTF-1 is a very useful marker in the diagnosis of these lesions. However, there is a diversity of TTF-1expression when we analyze the different thyroid neoplasm subtypes. The aim of this study is to evaluate the TTF-1 patterns of expression in variable subtypes of thyroid cancer. Casuistics and Methods: Slides from 40 patients with thyroid neoplasm were selected for the immunohistochemical study with TTF-1 antibody (Novocastra, 1:100). Twenty-four cases of papillary carcinoma, nine of follicular carcinoma, four of Hurthe cell carcinoma, two medullar carcinoma and one poor differentiated carcinoma. Results : From the 40 cases, we observed the following pattern of positivity for TTF-1: 21/24 in papillary carcinoma (87.5%), 9/9 in follicular carcinoma (100%), 4/4 in Hurthe cell carcinoma (100%), 2/2 in medullar carcinoma (100%) and one poor differentiated carcinoma (100%). Conclusion: Although the small number of cases, all the Hurthe cell and medullar carcinomas were positive for TTF-1 and three cases of papillary carcinoma were negative. These values are different from the literature and demonstrate the need of further studies in this area.

[7] Department of Pathology, TU Munich, Germany

Background: Microadenomatosis of the endocrine pancreas is thought to be a hallmark of the multiple endocrine neoplasia type 1 syndrome (MEN1). Here we describe a new type of pancreatic microadenomatosis that was not associated with a hereditary syndrome. Methods: Pancreatic tissue specimens from five patients with multiple glucagon-producing microadenomas were examined by immunohistochemistry, double fluorescence microscopy and morphometric methods. The MEN1 and Von Hippel-Lindau (VHL) status was assessed on the basis of clinical criteria, PCR based mutational analysis and loss of heterozygosity (LOH) analysis using specific FISH probes. The clinical features were recorded. Results: All patients showed exclusively glucagon-expressing neoplasms, with a total number of 10 macrotumors (all well differentiated neuroendocrine tumors) and more than 700 microadenomas. None of the patients displayed evidence of MEN1 or VHL germline mutations. Allelic deletions of the MEN1 and VHL gene were not detected. Only one of the patients showed a glucagonoma syndrome. Conclusions: We observed a novel previously not described benign non-MEN1 and non-VHL-associated type of pancreatic endocrine microadenomatosis, which may be functionally silent or produce a glucagonoma syndrome. This disease entity is characterized by glucagon cell microadenomatosis on which occasionally macrotumors develop. The tumors show no signs of malignancy.

PP1-227
EXPRESSION OF CK-19, cErb B2, GALECTIN- 3 AND p53 IN PAPILLARY THYROID CARCINOMAS

Selda Seckin, Ulker Karagece
Ankara Numune Training And Research Hospital, Department of Pathology, Ankara, Turkey

The purpose of our study is to determine the expression of CK-19, cErb B2 and Galectin-3 in papillary thyroid carcinomas. Besides, we tried to assess the potential staining of those tumors by p53. Immunohistochemistry was performed on 43 formalin fixed paraffin-embedded thyroid tumors (23 papillary carcinoma (PC) and 20 papillary microcarcinoma (PMC)). The extent of staining was scored semiquantitatively as 0 (no staining), 1+ (< 25 %), 2+ (25 %-75 %) and 3+ (>75 %) and the staining intensity was evaluated as faint or strong. Statistical analysis was

performed using Chi-square test. Of the PC cases 56,5 % and of the PMC cases 15,0 % were stained strongly by cErbB2. Although by means of staining intensity of cErbB2, the difference in PC and PMC cases was significant statistically (p= 0,019), the results in extent of staining were not (p= 0,195). Of the PC cases 47,8 % was scored as 2+ while only 10,0 % was scored as 2+ in PMC by Galectin-3 (p= 0,003). Strong immunoreaction for Galectin-3 was obtained in 52,2 % of PC and 15,0 % of PMC (p= 0,006). All PMC cases were stained by CK-19 (35,0 % 1+, 25,0 % 2+, 40,0 % 3+) and 21 cases of PC (17,4 % 1+, 21,7 % 2+, 52,2 % 3+) expressed positivity. CK-19 expression was strong in 73,9 % of PC and 65,0 % of PMC (p= 0,140). No nuclear immunostaining was detected by p53 in PC and PMC. However, 65,2 % of PC and 55,0 % of PMC cases showed cytoplasmic reactivity. Both PC and PMC cases showed similar staining extention and intensity by CK-19. This may conclusively help in identifying the papillary carcinoma cases. The majority of PCs stained diffusely and strong by Galectin-3 and expressed strong reaction by cErb B2 might suggest a relation with the size of the tumor as PMCs stained less diffusely and strong. As no nuclear staining was detected by p53 in totally 43 papillary carcinomas we support the idea that p53 expression is a late event in thyroid carcinogenesis.

PP1-228
TWO YEARS EXPERIENCES OF THE NATIONAL PROJECT OF A STANDARDIZED BIOPSY DIAGNOSIS OF NEUROENDOCRINE TUMORS OF THE GASTROINTESTINAL TRACT IN SLOVAKIA

Katarina Machalekova, Karol Kajo, Michal Terek, Peter Szepe, Zuzana Kviatkovska, Lukas Plank
Department of Pathology, Comenius University, Jessenius Medical Faculty, Martin, Slovakia

BACKGROUND: The neuroendocrine tumors (NETs) of the gastrointestinal tract (GIT) show unique biological behaviour and require a specialized diagnostic and therapeutic management. Because of limited experiences of clinicians and pathologists with these tumours, a national program (NP) of a standardized biopsy examination and interpretation of all the clinical and laboratory results for the patients with NETs in Slovakia was established in January 2005 and introduced at ESP congress in Paris in 2005. METHODS: The NP is based on a cooperation of pathologists and involved clinicians within the accepted regional centralisation system. It includes a second look opinion of the cases at 3 accepted biopsy centres in Slovakia, in relation to clinical data evaluation. In addition to the unified panel of morphologic and IHC methods of the NETs biopsy diagnosis, all hormonal and prognostic markers may be examined in situ at our department being in a position of a coordination centrum of the NP. Tumors were classified according to the WHO classification (2000). All the data are summarized by using standardized protocols. RESULTS: The benefit of the NP is increasing number of diagnosed NETs cases. From the January 2005 until the March 2007, 66 cases of primary NETs in GIT were diagnosed and registered in the centrum. Another 28 cases were excluded, because 18 cases represented metastatic NETs and in 10 cases the diagnosis of NET was not proved. Age of patients was in range from 9 to 84 years (median 55 y.), male (n=43) to female (n=23) ratio was almost 2:1. Functional status was known only in 12 patients. The most common localizations were appendix (n=16) and ileum (n=12) which represents 23% and 18%, respectively. Morphologically, well differentiated endocrine tumors predominated (n=30), followed by well differentiated endocrine carcinomas (n=26). Poorly differentiated endocrine carcinomas comprised only 10 cases. CONCLUSIONS: The NP starts to offer standardized results of NETs diagnosis for the clinical practice, representing a good basis for their management, including their targeted therapy. Moreover, centralisation of these rare tumors increases the diagnostic assurance as well as quality of the histopathological diagnosis.

PP1-229
UNEXPECTEDLY HIGH INCIDENCE OF PAPILLARY THYROID CARCINOMA IN CASES RESECTED FOR HYPERTHYROIDISM

Suna Erkilic
Department of Pathology, Faculty of Medicine, University of Gaziantep, Gaziantep, Turkey

Objective: The coexistence of hyperthyroidism and thyroid malignancy is considered a rare occasion. However this association has been reported more frequently in recent literature. Papillary carcinoma is the most frequently seen, yet any type of thyroid cancer may co-exist with hyperthyroidism. The aim of the study was to evaluate the association of hyperthyroidism and papillary thyroid cancer and its features such as size, variants and multifocality. Method: One hundred nineteen patients who underwent a thyroidectomy for hypertiroidism between 06, 2005 and 03, 2007 were reviewed. Seventy-five (63 %) of the 119 patients had toxic nodular goiter, 36 (30 %) had toxic diffuse goiter and 8 (7%) had toxic adenoma. Results: Histological examination revealed the presence of papillary thyroid carcinoma in 35 (29%) of 119 patients with hyperthyroidism. Concurrent carcinoma was detected in 23(31%) patients with toxic nodular goiter, in 11(31%) patients with toxic diffuse goitre and in 1(13%) patient with toxic adenoma. The patients of papillary carcinoma consisted of 25 females and 10 males, ranging in age from 22 to 76 years (mean age 45). Twenty nine (83%) papillary carcinomas were microcarcinoma with a diameter less than 1cm. The papillary carcinoma in thirteen cases (37%) were seen multifocally and eight (23%) of them were bilobar, five (14%) were unilobar. Twenty-two (63%) of 35 papillary carcinoma were follicular variant, the remaining 13 cases were classical variant. Conclusion: The coincidence of hyperthyroidism and thyroid carcinoma is not a rare phenomenon. Furthermore, the rate of papillary thyroid carcinoma in resected cases of hyperthyroidism is unusually high in our series, which we believe is the result of thorough gross and histological examination of the specimen. Besides, regional factors may have influenced the rate of incidence. Microcarcinomas may be overlooked because nuclear features of hyperfonctioning follicles and papillary carcinoma are alike, especially in follicular variant of papillary microcarcinoma. Histopathologic examination of the hyperfunctioning thyroid should be done carefully because of its impact on the clinical management of the cases.

PP1-230
MIXED MEDULLARY-PAPILLARY CARCINOMA OF THE THYROID: A CASE REPORT WITH AN UNUSUAL PRESENTATION

Charlette Nungue[1], Luc Bron[2], Luc Portman[3], Marco Volante[4], Hans-Heat Ris[5], Philippe Monnier[2], Snezana Andrejevic-Blant[1]

[3] Department of Endocrinology, CHUV Hospital CH-1011 Lausanne, Switzerland
[4] Department of Clinical and Biological Sciences, University of Turin and San Luigi Hospital, Regione Gonzole10, 10043 Orbassano-Torino, Italy
[5] Department of Thoracic Surgery, CHUV Hospital CH-1011 Lausanne, Switzerland

The term mixed medullary-follicular (or papillary, presenting follicular component) thyroid carcinoma denotes a tumor showing the morphological features of both medullary carcinoma with immunoreactive calcitonin, and follicular areas with immunoreactive thyreoglobulin. We report the case of 41-year-old female, presented with a 6 months history of right swelling in the neck, increasing in size for last several weeks. Local examination revealed a well-defined, non-tender nodule in right thyroid lobe, which was mobile upon deep tissues and with

deglutition. Fine needle-aspiration cytology suggested a diagnosis of medullary thyroid carcinoma. The preoperative value of serum calcitonin was 1140 ng/ml, while the level of thyreoglobulin was normal (7,1 □g/l). A total thyroidectomy, presenting a 3,1x2x1 cm whitish nodule in the right lobe, as well as bilateral radical cervical lymph nodes dissection and bilateral medistinal lymph nodes dissection, were performed. Microscopic examination, confirmed the presence of medullary carcinoma. In addition, a focus of papillary carcinoma intimely intermingled within the medullary component was observed, representing nearly 10% of the whole tumor. The mediastinal lymph nodes were free of tumor cells. Among numerous cervical lymph nodes, only one at the homo-lateral level III, present two micro-foci of medullary carcinoma tumor cells. No C-cell hyperplasia was found, nor nodular goiter or significant inflammation in the adjacent thyroid parenchyma. Serum calcitonin levels decreased to normal after operation and are currently stable. No clinical history suspected for familial medullary carcinoma was recorded for this patient, and RET proto-oncogene point mutations was absent by DNA analysis on peripheral leucocytes. The presence of microscopic metastasis in a single homo-lateral cervical lymph node, underlines the great importance of large cervico-mediastinal lymph nodes dissection in medullary thyroid carcinoma. Moreover, as for the majority of the reported cases of mixed medullary and follicular thyroid carcinomas, in the present case the medullary carcinoma component seemed to possess the more aggressive biological behaviour, although the therapeutic strategy in this particular type of thyroid cancer is still controversial.

PP1-231

UTILITY OF ECO-COLOUR DOPPLER SONOGRAPHY IN THE SELECTION OF THYROID NODULES FOR FINE-NEEDLE ASPIRATION CYTOLOGY

Moira Ragazzi[1], Silvia Bianchini[2], Stefania Lega[1], Luciano Castaldini[3], Paolo Vezzadini[2], Maria Pia Foschini[1]
[1] Section of Anatomo Pathology, University of Bologna Bellaria Hospital, Italy
[2] Department of Medicine and Gastroenterology, University of Bologna Bellaria Hospital, Italy
[3] Department of Radiology, Bellaria Hospital Bologna, Italy

BACKGROUND: Ultrasonography guidance has increased the sensitivity of fine-needle aspiration biopsy (FNAB). Nevertheless, in multinodular goiters the choice of nodule to submit to FNAB is still a problem. In a previous work, we have shown that thyroid nodules have a characteristic vessel distribution, that can be visualized on eco-colour doppler sonography (ECD). Purpose of the present study is to evaluate if the vascular pattern can be useful to select thyroid nodules for FNAB. METHOD: 263 thyroid nodules were analysed by ECD before FNAB and classified as follow: no vessels evident (type 1), only peripheral vessels evident (type 2), intranodular vessels (type 3). RESULTS: Type 1 nodules were 45 and were diagnosed on FNAB as negative for malignancy in 36 (80%) cases, follicular lesions (FL) in 5 (11,1%), papillary carcinomas (PC) in 2 (4,4%) and inadequate in 2 (4,4%) cases. Type 2 nodules were 57: 45 negative for malignancy (78,9%), 11 FL (19,3%) and 1 inadequate (1,7%). Type 3 nodules were 161: 93 negative for malignancy (57,8%), 56 FL (34,8%), 8 PC (5%), 1 medullary carcinoma (0,6%) and 3 inadequate (1,9%). CONCLUSION: Type III nodules show a highe rate of neoplastic lesions (40,4%). This suggests that vascular pattern may be useful in the selection of thyroid nodules for FNAB.

PP1-232

THE USEFULNESS OF CYTOKERATIN-19 IMMUNOHISTOCHEMISTRY IN THE DIFFERENTIAL DIAGNOSIS OF PAPILLARY THYROID CARCINOMAS

Figen Barut[1], Sibel Bektas[1], Burak Bahadir[1], Nilufer Onak Kandemir[1], Arzu Sonmez[1], Sevinc Keser[2], Nimet Karadayi[2], Sukru Oguz Ozdamar[1]
[1] Zonguldak Karaelmas University Faculty of Medicine, Department of Pathology, Zonguldak, Turkey
[2] Lutfi Kirdar Kartal Training and Research Hospital, Department of Pathology, Istanbul, Turkey

Background: The gold standard for diagnosis of papillary thyroid carcinoma is conventional histology, the essential element of which is its characteristic nuclear features, regardless of whether papillary architectures are present or not. This study has been carried on to evaluate cytokeratin-19 immunohistochemical marker in the diagnosis and differential diagnosis of papillary thyroid carcinoma. Methods: Cytokeratin-19 has been tested on formalin-fixed, paraffin-embedded tissue from 380 surgically resected thyroid lesions including hyperplastic nodules (n: 243), granulomatous thyroiditis (n:3), lymphocytic (n:53) and Hashimoto's thyroiditis (n:11), follicular adenomas (n: 17), Hürthle cell adenomas (n:3) and neoplasia (n:1), well-differentiated thyroid tumor with follicular architecture of uncertain malignant potential (n:1), papillary carcinomas (n:45), follicular carcinoma (n:1), insular carcinoma (n:1) and medullary carcinoma (n:1). Using a monoclonal antibody to cytokeratin-19 and a standard avidin-biotin complex technique, immunostaining has been performed. The immunoreactivity has been scored as negative (less than 10% cells positive), 1+ (poor-focal cells positive), 2+ (strong-focal cells positive), 3+ (poor-diffuse cells positive), 4+ (strong-diffuse cells positive) based on the extent of the reaction regardless of previous diagnosis. Results: No cytokeratin-19 has been found in 100% of hyperplastic nodules, 1.9% of lymphocytic thyroiditis, 33.3% of granulomatous thyroiditis, 52.9% of follicular adenomas, 66.7% of Hürthle cell adenomas, 100% of Hürthle cell neoplasia and 100% of follicular carcinoma. All of the 45 cases of papillary carcinomas have positively reacted to cytokeratin-19, respectively; 57.8% 4+, 33.3% 3+ and 8.9% 2+. Here, to prevent confusion on, it can be said that the group with 2+ reaction is the micropapillary variant of papillary carcinomas. 100% of well-differentiated thyroid tumors with follicular architecture of uncertain malignant potential, 5.9% of follicular adenoma and 3.8% of lymphocytic thyroiditis have shown reaction 4+. 11.8% of follicular adenoma, 18.2% of Hashimoto's thyoiditis and 1.9% of lymphocytic thyroiditis have reacted 3+. Other cases have shown focal reactions. Conclusion: Papillary thyroid carcinomas have presented strong diffuse cytoplasmic reactivity with cytokeratin-19. Along with careful histologic evaluation, cytokeratin-19 provides a useful and objective means for the diagnosis of papillary thyroid carcinomas.

PP1-233

HASHIMOTO'S THYROIDITIS DOES NOT INCREASE THE RISK OF PAPILLARY THYROID CARCINOMA: A LARGE CLINICAL-PATHOLOGIC RETROSPECTIVE STUDY

Maria Letizia Lai[1], Giuseppe Floris[1], Cristina Manieli[1], Giovanni Pinna[2], Sara Pillai[1], Francesco Boi[2], Stefano Mariotti[2], Gavino Faa[1]
[1] Department of Cytomorphology, Section of Pathology, University of Cagliari, Italy
[2] Department of Endocrinology, University of Cagliari, Italy

Background Several studies report a higher rate of papillary thyroid carcinoma (PTC) in patients with Hashimoto's thyroiditis (HT), suggesting (and vice-versa) a correlation between the two diseases. The occurrence in HT of foci of follicular cell proliferation showing striking nuclear clearing has been interpreted by some authors as a precancerous state leading to

subsequent increased incidence of PTC. This hypothesis is also supported by the detection of RET/PTC rearrangements in HT thyroid glands, although the relevance of this finding is still controversial. The aim of the present retrospective study is to re-evaluate the association of HT with PTC and other malignant or benign thyroid neoplasias in a large series of pathological specimens. Methods We retrieved 1350 consecutive cases of patients submitted to total thyroidectomy whose gland were analysed in the Pathology Department of the University of Cagliari in the period January 2001 - December 2005. Common histological criteria were employed for the diagnosis of thyroid neoplasm. The histological diagnosis of HT was made on the basis of histological parameters (diffuse lymphocytic infiltration with prominent germinal centers, oxyphilic metaplasia; cases with focal lymphocitic infiltration were not considered). Results Pathological evaluation showed: 491 cases of PTCs (36,4%), 202 cases of follicular adenomas (15%), 87 cases of follicular carcinomas (6,4%). HT has been found in 452/1350 cases (33,5%) and in association with PTC in 177/491 cases (36%) The proportion of PTC not associated with relevant lymphocitic infiltration was similar (314/898 = 35%, p= ns vs HT). In contrast , the proportion of malignant and benign follicular tumors associated with HT was significant lower than that found in the absence of HT. However we found a statistically significative negative correlation between the incidence of follicular carcinomas (12/452 in HT vs 75/898 without HT, p=<0.0001) and follicular adenomas (47 /452 vs 155 /898, p=0.0009) Conclusions Our results, suggest that, although the proportion of PTC associated with HT is higher than that found in follicular carcinomas and adenomas, an increased incidence of PTC in HT is unlikely. On the other hand, our data suggest that HT could be a protective factor against the development of these entities, but further studies are warranted to confirm this hypothesis.

PP1-234
IMMUNOHISTOCHEMICAL EXPRESSION OF THE APOPTOTIC AND ANTIAPOPTOTIC MARKERS FAS/FASL, Bcl-2, BAX AND P53 IN NEOPLASTIC AND NON NEOPLASTIC THYROID DISEASES

Maria Karagiannis[1], Antigoni Karakosta[1], Eleni Sotiriou[1], Rosaria Mennonna[1], Panagiota Pantoula[1], Sofia Xyristaki[1], Iokasti Kiafa[1], Eleni Carga[2], Aikaterini Parasi[1]

[2] Endocrinology Department, General Hospital of Athens "Alexandra", Greece

Backround: The role of the apoptosis is considered crucial in the pathogenesis and development of the thyroid diseases. The most important proteins, involved in the mechanism of the apoptosis in thyroid tissues are the Fas/FasL system, p53, bax and Bcl-2. The Fas- protein functions as a cell-surface receptor against the factor FasL, which is mainly produced from the lymphocytes. The Fas/FasL system, which induces apoptosis, is regulated by p53 and bax proteins, which in turn also induce apoptosis and by bcl-2 protein which inhibits apoptosis. The purpose of this study is the examination of the apoptotic mechanisms, via immunohistochemical expression of the Fas, FasL, Bax, bcl-2 and p53 proteins in thyroid carcinoma. Methods: Our material consisted of 21 papillary, 6 follicular, 3 insular and 1 anaplastic carcinomas, 6 colloid nodules, 3 autoimmune thyroiditis and 5 normal thyroids. Immunohistochemical stains were performed on paraffin sections. The results were analysed statistically with the method x2. Results: Fas receptor was expressed in almost every carcinoma (94%), but also in a high percentage (78%) in non-neoplastic diseases (p=0.08). FasL factor was expressed in a lower percentage in carcinomas (35%), as well as in non-neoplastic diseases (50%), without important statistic significance. Bax protein expression was detected in 71% of the carcinoma-cases, but only in one non-neoplastic case (p=0.0004). Bcl-2 protein expression was also statistically significant (p=0.007) between carcinomas (35%) and non-neoplastic diseases (86%). Additionally, the correlation of bcl-2:Bax protein expression in carcinomas showed a significant statistic difference p<5. P53 protein was expressed only in the anaplastic carcinoma. Conclusion: Non-neoplastic thyroid, in this small sample, seems to resist to apoptosis. In the apoptotic mechanism of thyroid carcinoma, bax proteins seems to be mainly involved. The role of the Fas-FasL apoptotic pathway is not proved in our sample. However, the frequent expression of Fas- receptor in the neoplastic population might indicate its increased sensitivity in Fas-mediated apoptosis. This pathway needs more investigation for the possible involvement of other apoptotic or antiapoptotic signals.

PP1-235
MEDULLARY THYROID CARCINOMA PRESENTING AS A CYSTIC LESION

Francesca Poli[1], Stefania Lega[1], Maddalena Sansovini[2], Paolo Zagni[2], Bartolomeo Bellanova[2], Maria Pia Foschini[1], Giuseppe Nicola Martinelli[3]
[1]Anatomic Pathology University of Bologna,Bellaria Hospital,Italy
[2]Nuclear Medicine University of Bologna,S. Orsola Hospital,Italy
[3]Anatomic Pathology University of Bologna, S.Orsola Hospital,Italy

Background: Ultrasonography has gained a more important role in the thyroid nodule evaluation. Medullary thyroid carcinoma (MTC) usually presents as a solid nodule, only three cases showing a cystic component have been reported in the literature. Purpose of the present study is to report on two further cases of MTC presenting as cystic lesions. Method and Result: Case 1: a 52 yr-old female presented with ultrasonographic 2 cm solid nodule with a cystic component. There was no family history of thyroid diseases. The patient had normal levels of TSH; T3; T4, and high levels of calcitonin (57,1 pg/ml). A fine needle aspiration (FNA) of the lesion was performed for cytologic examination. The intranodular level of calcitonin obtained by syringe's washing was 2000 pg/ml. Case 2: a 63 yr-old female, with no family history of thyroid diseases, showed at ultrasonography a 4 cm partially cystic nodule located in the left thyroid lobe. FNA led to the diagnosis of malignancy. The plasma level of calcitonin was high (6000 pg/ml). Both patients underwent total thyroidectomy with neck dissection. No lymph-node metastases were present. On histology both cases were composed of a central cystic area lined by neoplastic cells positive with anti-calcitonin antibody which confirmed the cytological and clinical diagnoses of MTC. No clinical evidence of recurrence has been noted in both patients. Conclusion: The risk of malignancy in thyroid cystic nodules is low, nevertheless the possibility of a cystic MTC should be taken in consideration. In this respect, very useful appears to be the evaluation of CT level in the syringe's washing, which is able to demonstrate the presence of intranodular CT-producing tissue.

PP1-236
CAVERNOUS HAEMANGIOMA OF THE THYROID GLAND

Ioannis Moisidis[1], B. Christoforidou[1], P. Xirou[1], D. Anestakis[1], G. Zafeiriou[2], F. Patakiouta[1], M. Kalaitzi[3]
[1] Theageneion Cancer Hospital, Pathology Department, Thessalonica, Greece
[2] Theageneion Cancer Hospital, Surgical Oncology Department, Thessalonica, Greece
[3] Theageneion Cancer Hospital, Technician, Thessalonica,Greece

Background: Haemangioma is a type of the commonly observed soft tissue tumours, composed of dilated, generally thin-walled blood vessels. At all sites, it is often difficult to determine whether benign vascular lesions are malformations or true neoplasms. The thyroid gland is an uncommon site for this type of neoplasm. Case description: We present a female patient 59 years old, who complaint of a thyroid mass. The x-ray showed a solid, heterogeneous structure at the right lobe of the thyroid

gland, and scintigraphy revealed a “cold” nodule at the right lobe of the thyroid gland. The results of biochemical examination, including thyroid hormone levels, were normal. The patient underwent thyroidectomy. Pathologic findings: Grossly a reddish nodule, 3 cm in size, spongy and of soft consistency, was found. Microscopically the lesion consisted of numerous proliferated vessels that enlarged to an irregular shape, and the lumen was full of red blood cells. Occasionally organized thrombi, were observed. The inner wall of vessels was covered with monolayered endothelial cells and the outer wall was fibrous. Stromal hyalinization, myxomatous degeneration and inflammatory infiltrates, were quite common. The findings mentioned above indicate the diagnosis of cavernous haemangioma, which as far as we know, is extremely rare in the thyroid gland. The patient is doing well, seven months after the surgical excision.

PP1-237
TWO UNUSUAL CASES OF ADRENAL HEMANGIOMAS

Anna Tanoglidi, Ageliki Drougou, Maria Kefala,
Magdalini Tsamouri, Calypso Barbatis
Department of Pathology, Hellenic Red Cross Hospital, Greece

BACKGROUND: Hemangiomas of the adrenal gland are very rare, benign, capillary or cavernous tumors with a tendency to thrombosis. Until 2006 only 50 cases have been published and none was associated with adrenal cortical hyperfunction. Papillary endothelial hyperplasia (PEH), an exuberant proliferation of vascular endothelial cells, very rarely develops in the adrenals. We present two cases of adrenal vascular lesions one with multifocal cavernous hemangioma and the other with a PEH arising at the periphery of a thrombosed, hyalinized, calcified cavernous hemangioma. METHOD: Case1: A 71 years old female with mild cortical hyperfunction underwent right adrenalectomy and the entire gland was removed weighing 16 gr and measuring 5,5X4,5X2,5cm. In between the solid yellow areas cystic hemorrhagic or myxoid foci up to 1 cm. Case 2: A 73 years old male with a suspected metastatic asymptomatic mass in the right adrenal gland during a follow-up for a resected colon adenocarcinoma two years previously. The tumor was 3 cm in diameter, well-circumscribed, white-yellowish, granular and chalcky and the entire specimen weighed 13 gr. Both cases were examined with H+E and immunohistochemically for CD34, CD31, Factor VIII, VEGF, Desmin, a-SMA. RESULTS: Case1: Multifocal cavernous hemangioma intermingled with hyperplastic adrenal cortex. Several vessels were thrombosed in different stages of organization. Case2: A non-encapsulated, well-circumscribed hemangioma thrombosed and hyalinized in most part with focal nodular calcifications. At the periphery there was a dilated sinus containing hyalinized papillary projections lined by a thin layer of endothelial cells without cytological atypia or mitotic activity. The mass was surrounded by residual islands of adrenal cortex. CONCLUSION: Multifocal adrenal hemangiomas are unusual and this is the first case associated with cortical hyperplasia. Despite their benign nature they should be removed for exclusion of malignancy. The etiology of PEH is not completely understood, is often associated with trauma and may require differential diagnosis from angiosarcoma. It usually occurs within the lumina of veins, hemangiomas, pyogenic granulomas and cystic lymphangiomas. In our case there was no history of post-colectomy vein thrombosis or septicaemia

PP1-238
ISLET 1 (Isl1) IS AN EXCELLENT MARKER FOR PANCREATIC ENDOCRINE TUMORS (PET) AND THEIR METASTASES

Anja Schmitt[1], Florian Riniker[2], Sonja Schmid[2], Holger Moch[2], Philipp U. Heitz[2], Paul Komminoth[3], Aurel Perren[4]

[4] Institute of Pathology, Klinikum rechts der Isar, Technical University Munich, Munich, Germany

Background: Metastases of pulmonary and gastrointestinal endocrine tumors can be diagnosed using the markers TTF1 and Cdx2, respectively. The identification of a pancreatic origin, however, is still an unsolved issue. Islet1 (Isl1) is a LIM homeodomain protein expressed in endocrine cells of normal pancreatic islets. The purpose of this study was to examine the diagnostic value of Isl1 as a marker for pancreatic endocrine tumors and their metastases. Study design: A tissue micro array (TMA), comprising 215 gastroenteropancreatic endocrine tumors and their metastases was constructed. Sections of the TMA were incubated with the antibodies directed against Isl1, Cdx2 and Ttf1. The stainings were scored semiquantatively. Results: Isl1 proved to be a highly specific marker for islet cells and PET. In primary PET its specificity was 92.1% (sensitivity 63.4%) and in metastases of PET the specificity reached 100% (sensitivity 72.4%). Depending on whether only a strong immunostaining or both a strong and a moderate immunoreaction were scored as positive, Cdx2 showed a specificity for gastrointestinal origin in primary tumors of 89.7% and 66% (sensitivity 75.7% and 79.3%) and in metastases of 100% and 93.3% (sensitivity 40% and 68%). Ttf-1 was not expressed by pancreatic or intestinal endocrine tumors. Conclusions: Isl1 is an excellent marker for identifying PET and their metastases. Moreover, our findings confirm that Cdx2 is a valuable marker for endocrine tumors of gastrointestinal origin.

PP1-239
AMYLOID IN PITUITARY ADENOMAS: INCIDENCE AND MORPHOLOGICAL ASPECTS

Inês Liguori Padrão, Patrícia Sabino De Matos
UNICAMP School of Medicine, Campinas, S. P. Brazil

Introduction:Amyloid deposits in tumoral hypophysis is found in 40% of pituitary adenomas and the amyloid protein precursor in these cases is a hormonal polipeptyde.Lactotroph and somatotroph adenoma series mention the presence of amyloid deposits in 50% and 65%, respectively. Amyloid may be interstitial with a fibrillary, starry sky pattern or rarely as spherules.The blood vessel walls are also compromised. Aim:1)Evaluate the incidence of amyloid deposits in pituitary adenomas through Congo-red stain and polarized light.2)Observe the morphology and distribution of amyloid material in positive cases.3)Correlate the occurrence of amyloid with hormonal production. Material and Methods: Forty eight pituitary adenomas operated by the Neurosurgery Service of UNICAMP Clinical Hospital and submitted to immunohistochmistry were distributed as such: 10 somatotroph adenomas, 5 lactotroph adenomas, 5 corticotroph adenomas and 28 non-functioning adenomas. The cases were stained by Congo-red and observed through polarized light. Results:The incidence of amyloid material in the total sample was 62,5%. The interstitial amyloid deposits showed a fibrillary and band like patterns specially in blood vessel wall. All the hormonal type adenomas showed amyloid deposits: somatotroph adenomas 30%, lactotroph adenomas 80%, corticotroph adenomas 60%, non-functioning adenomas 71,4%. Conclusion: Pituitary adenomas show a high incidence of amyloid deposits, no matter if it is a non-functioning or functioning adenoma. Among functioning adenomas, amyloid incidence was higher in lactotroph adenomas, followed by corticotroph and somatotroph adenomas.

WHAT HAS CHANGED IN RUSSIAN PATHOLOGY SINCE THE FIFTIES?
Kitty Felinescu[1], Sergei V. Jargin[2]
[1] Moscow Medical Academy, Russia
[2] Independent, Moscow, Russian Federation, Russia

The question can be answered by the example of the Department of Pathological Anatomy of Moscow Medical Academy. This Department has been leading in our country. All main textbooks have been created here. Professor A. I. Strukov was Head of the Department in 1953-72. In spite of his support of Lysenko-affaire, Strukov was known as a highly educated pathologist and good practical specialist. Under his guidance much attention was given to the autopsy technique; trainees were taught to perform autopsy correctly and in detail. Histological laboratory was staffed with qualified technicians, numerous histological stains were performed routinely. Professor V.V. Serov, perfect lecturer and specialist in autopsy, was Head of the Department from 1973 to 1990. During this period, autopsy partly lost its academic profoundness. Post mortem diagnoses were sometimes adapted to a preconceived idea and formulated without sufficient evidence. Biopsy diagnostics was performed by experienced specialists individually. Discussions of biopsy cases at the departmental conferences were seldom; much more time was given to research and autopsy. Trainee pathologists were taught biopsy diagnostics only sporadically. Technique of gross examination remained primitive. For example, in case of mastectomy or gastrectomy, only 2-3 lymph nodes were usually embedded. Immunohistochemistry and other modern methods were available only for research and were not used on biopsy material. For making successful career, candidate's and doctoral theses and regular publications have been needed. Limited technical possibilities and access to foreign literature made global newness of research hardly possible. Nonetheless, global newness and practical significance were officially required from theses. This alone forced researchers towards strained interpretations and biased presentation of facts. Researchers often planned their results in advance and tried to formulate conclusions accordingly. Along with studies having value of review or compilation, numerous useless reports were published. Many scientists compiled their reference lists by means of Current Contents or reference lists from other articles. False quotation and incorrect statistical assessment could be encountered. Plagiarism from foreign sources was not infrequent. By the end of the eighties a new phenomenon became apparent: young functionaries, predestined for high positions, published and defended as theses largely fabricated papers, containing provable manipulations of statistics etc.

PP1-241
THE USE OF ARCHIVAL PATHOLOGY SAMPLES IN FORENSIC SCIENCES
Aysim Tug, Yesim Dogan Alakoc
Ankara University, Medical Faculty Forensic Department, Ankara, Turkey

DNA identity testing has gained widespread in the field of forensic sciences since the first forensic use in 1985. The main fields of forensic DNA analysis are, linking biological evidence to suspects-victims-crime scene, paternity and maternity identification, missing persons and disaster victim identification. After disasters some special criterias are determined by police and multidisciplinary scientists. Evidences for identification provided by personal effects such as clothing, jewellery and pocket contents, external examination, internal examination, dental examination and genetic analysis. Human biological samples such as blood, saliva, semen,hair, bone, teeth are the main sources for DNA anaysis. Some other samples, which can be used in research for forensic cases although they were not created for that purpose. During more than a century of diagnostic practice, a large number of archival paraffin-embedded tissue banks have been established worldwide. When no other reference material is available, archival pathology specimens can be used as a source in forensic identification.

PP1-242
IMMUNOHISTOCHEMICAL DETECTION OF MAGE-3 PROTEIN IN COLORECTAL CARCINOMA & POLYPS
Božena Šarčević[1], Tajana Stančerić[2], Antonio Juretić[3], Giulio Spagnoli[4]
[1] Departement of Pathology, University Hospital for Tumours, Zagreb, Croatia
[2] Department of Internal Oncology, University Hospital for Tumours,Zagreb, Croatia
[3] Department of Oncology, Clinical Hospital Center, Zagreb, Croatia
[4] Department of Surgery and Research, University of Basel, Basel, Switzerland

BACKGROUND:The MAGE(melanoma antigen)gene family consists of 12 members and is expressed almost exclusively in cancer tissues and also encode tumor-specific antigens that are recognized by autologous cytotoxic T lymphocytes.The MAGE genes are activated in spermatozoa but silent in normal somatic cells.In cancers, these genes are re-activated and their encoding proteins are frequently expressed in various histological types of cancers.Because of this distribution characteristic,the MAGE proteins are termed as cancer-testes(CTAs)antigens.The human MAGE-gene family has been located to the X chromosome.The MAGE-3 is one of 12 closely related MAGE genes.It belongs to a growing clas of T-cell defined CTAs that are normally expressed only in the testes and ovary,yet are aberrantly expressed in a wide variety of primary tumors and cancer lines. This characteristic feature of CTAs makes them promising antigens for cancer-specific immunotherapy. METHODS:We examined the frequency of MAGE-3 immunopositivity within a group of 126 patients with primary colorectal adenocarcinoma and a group of 40patients with polyps.Paraffin blocks of all patients were examined immunohistochemically with monoclonal antibody 57mAb.MAGE-3 expression was compared with tumor differentiation degree, Dukes classification,age and gender. RESULTS:50 out of 126 colorectal adenocarcinoma were positive for MAGE-3 (39,68%)and 76 out of 126 colorectal adenocarcinoma werw negative (60,32%)($p<0.025$).According to the tumor grade,80.26% of patients with MAGE-3 negative tumor had tumors grade I and II. On the other hand, positive reaction on MAGE-3 protein was more often observed in poorly differentiated tumors ($p<0.05$).Also, more patients with Dukes A tumor had MAGE-3 negative tumor than the patients with Dukes B or C tumor ($p<0.05$).At the same time, patients with MAGE-3 positive tumors were slightly oldes comparing with the group of MAGE-3 negative tumors.There was no statistically significant difference in MAGE-3 expression between adenomatous polyps and villous adenomas. CONCLUSIONS: The results showed that MAGE-3 gene products could be identified by the 57mAb in colorectal adenocarcinoma and polyps. Also, the patients with advanced stage of the colorectal adenocarcinoma (Dukes B and C)could take advantage of active specific immunotherapy procedures targeting this antigen.

PP1-243
SIGNIFICANCE OF P21 AND C-myc EXPRESSION IN BLADDER UROTHELIAL LESIONS

Omran Zeinab[1], Badawy Afkar[1], Elhindawy Ali[2], Khattab Hany[2], Abo-Shousha Tarek[1], Elshahat Noha[1]
[1] Theodor Bilharz Research Institute, Egypt
[2] Faculty of Medicine, Cairo University, Egypt

Abstract: Immunohistochemical tissue expression of the anti-proliferative marker P21 and the oncogenic marker C-myc were estimated in 40 cases with non-neoplastic and neoplastic urinary bladder lesions with or without schistosomal infection to assess the significance of their urothelial expression as a diagnostic tool in patients with higher risk of developing cancer bladder and as a prognostic indicator in malignant lesions. P21 expression was detected randomly in normal urothelial nuclei, while 50% of simple cystitis cases and all cases with premalignant changes were positive for P21 immuno-reactivity expressed into about 16% of urothelial cells. Eighty five percent of malignant cases expressed P21 in 48-55% of urothelial cells without significant variance between different histologic tumor types. Extent of P21 expression inversely correlated with bilharzial association, upgrading of malignancy and tumor invasiveness. C-myc was detected in 50% of normal urothelium (as cytoplasmic staining), in 80% of simple chronic cystitis cases (75% cytoplasmic, 25% cytoplasmic and nuclear expression), and in all cystitis cases with premalignant changes (as cytoplasmic and nuclear expression). Eighty nine percent of cancer cases were C-myc positive with predominance of nuclear expression to be seen in 16.7% and mixed with cytoplasmic expression in another 58.3% of positive cases. Malignancy upgrading and invasiveness raised C-myc positivity. In conclusion: P21 expression increases in an attempt to check cellular proliferation, but when the matter is out of hand, P21 is down- regulated, while the increase in the oncogen C-myc goes ahead. Loss of P21 and increased C-myc expression in a malignant lesion is a predictor of malignancy progress to higher grade or stage.

PP1-244
HEDGEHOG SIGNALING IN NEUROBLASTOMA

Mayrhauser Ursula, Alinger Beate, Lechner Berta, Dietze Otto, Hauser-Kronberger Cornelia
Department of Pathology, General Hospital and Paracelsus Medical University Salzburg, Muellner Hauptstrasse 48, Salzburg, Austria

The Hedgehog (Hh) signaling pathway is essential for embryonic patterning, cell proliferation and differentiation. Activation of the pathway has been shown in several human tumours and in neuroblastoma. Sonic (Shh), Indian (Ihh) and Desert Hedgehog (Dhh) are the three mammalian Hedgehog ligands. Hh binds to the receptor Patched (Ptch), leading to activation of the Gli transcription factors Gli1, Gli2 and Gli3. In the absence of the ligand, Ptch inhibits Smoothened (Smo), a downstream protein in the pathway. Nestin is expressed in many cells during the embryonic development and overexpression is linked to increased aggressiveness in several nervous system tumors. Routinely FFPE tissue from undifferentiated human neuroblastoma (n=6), well differentiated ganglioneuroblastoma (n=3), paraganglioma (n=2) were used. Immunohistochemistry was performed on cell blocks of the neuroblastoma cell lines SK-N-SH, CHP-212 and SH-SY5Y using a standard streptavidin-biotin-peroxidase technique (Dako). For in vitro differentiation of SH-SY5Y cells retinoic acid (RA) was applied. Immunohistochemistry was performed using antibodies against Gli1, Gli2, Gli3, Shh, Ihh, Dhh, Ptch, Smo, Hip, Ptch2. To investigate correlation of Hh signaling with other stem cell developing pathways b-Catenin, Notch and Nestin were determined. Transcriptional activity was analyzed in undifferentiated SH-SY5Y and differentiated SH-SY5Y-RA performing real time PCR on a Corbett Rotor-Gene 6000 platform. Immunohistochemical staining of the NB tissue showed expression of Hh signaling components in the well differentiated gangliocytes, whereas undifferentiated neuroblastoma cells did not show Hh activity. Nestin was overexpressed in well differentiated gangliocytes and in Schwann cells, but was not detected in ganglion cells. Double-immunofluorescence results showed Shh and Nestin co-expression, in contrast Ptch and Nestin were not expressed within the same gangliocytes. Immunohistochemical staining of SK-N-SH and CHP-212 show an expression of all Hedgehog components (Gli1, Gli2, Gli3, Shh, Ihh, Dhh, Ptch, Smo), whereas SH-SY5Y express only a few. Real time PCR of SH-SY5Y displays a overexpression of Ptch and Smo and a normal expression of Gli1 und Gli2. Real time PCR of SH-SY5Y-RA has been performed. Hedgehog pathway is active in human neuroblastoma and may be involved in neuronal cancer cell differentiation. As Nestin is present in Shh expressing cells and not in the recipient cells, this may indicate that Nestin and Hedgehog may crosstalk in the signaling of differentiation of neurogenic cells in NB.

PP1-245
MATCH PROJECT: IMPROVEMENT OF THERAPY SELECTION BY MATCHING MOLECULAR DATA FROM COLON CANCER PATIENTS

Lorenzo Memeo[1], Stefano Forte[2], Konrad Matysiak[3], Mariusz Duplaga[4], Salvatore Scarpulla[5], Massimo Gulisano[2]
[1] Mediterranean Institute of Oncology, Catania, Italy
[2] Fondazione IOM, Catania, Italy
[3] Poznan University of Medical Sciences, Poznan, Poland
[4] Jagiellonian University Medical College, Krakow, Poland
[5] IOM Ricerca, Catania, Italy

The main focus of the MATCH project is the development of an automatic computer-based system supporting decision process in patients with colorectal cancer. The strategic foundation of the MATCH project addresses the challenge of the integration of clinical practice and molecular approach through establishment of a framework enabling efficient handling of diversified data sources. The framework is expected to improve adequacy of treatment options offered to colon cancer patients. Since the response to therapy is affected by genetic variability, one can assume that genetic fingerprinting could be one of the most relevant ways to assess the sensitivity of a patient with specific molecular profile to a particular therapeutic mode. Since Single Nucleotide Polymorphisms (SNPs) represent the molecular substrate of this variability, SNPs fingerprinting provides molecular snapshot of a patient profile with information highly relevant for anticipating the susceptibility to therapeutic agents or modes. The process of the MATCH system functionality development was planned to take place in three stages. In the first one, the system will be filled with quantitative and qualitative clinical and genetic (mainly SNPs information for tumour suppressor genes) data. Next, computational process will be carried out and finally, the results that concern more effectively colon cancer treatment will be obtained. The first stage crucial for the initiation of the process is provision of clinical and genetic data from medical facilities. Genetic data are represented mainly by SNPs information of TSGs from: patient normal tissues, patient primary tumour, lymph nodes and distant metastasis (when available). Additional genetic and molecular data may be also used. Clinical and genetic data of all patients are used to generate homogeneous clusters of patients with the longest subset of features (both clinical and genetic). It is expected that all members of a cluster will respond to specific therapeutic modes in similar way since their molecular profiles reveals high level of concordance. The automated decision support system is then used to match the clinical and genetic profile of a new patient with the clusters representing homogeneous groups of patients in MATCH data set. The new profile is assigned to the cluster that shows the smallest distance in its centroid profile. Statistical analysis of cluster population provides information on the best available therapy for the new patient based on the outcomes of all cluster members.

PP1-246
EXPRESSION OF COLLAGEN TYPE I AND III, MMP-1 AND TIMP-1 GENES IN MYOCARDIUM FROM PATIENTS WITH HYPERTROPHIC OBSTRUCTIVE CARDIOMYOPATHY AND PATIENTS WITH ESSENTIAL HYPERTENSION

Leo Bokeria[1], Alexandra Gudkova[2], Evgeny Semernin[2], Alexey Chukhlovin[2], Areg Totolian[2], Konstantin Borisov[1], Evgeny Shlyakhto[2]
[1] Bakulev Research Center of Cardiosurgery, Moscow, Russia
[2] Pavlov State Medical University, Department of Faculty Therapy, Saint-Petersburg, Russia

AIM: Studying gene expression for collagen type I and III, matrix metalloproteinase-1 (MMP-1) and tissue inhibitor of matrix metalloproteinase-1 (TIMP-1) in myocardium of the right half of interventricular septum (IVS) from the children and adults with hypertrophic obstructive cardiomyopathy (HOCM). MATERIAL AND METHODS: Twenty-three patients with HOCM have been examined (9 children and 14 adults). Myocardial samples were taken from the right half of IVS (areas of maximal hypertrophy) upon surgery correction of HOCM (myotomy/myectomy), and used for RNA isolation with subsequent RT-PCR. We used autopsy myocardial samples from 8 patients with essential hypertension (EH) as controls. RESULTS: In children with HOCM, gene expression of type I collagen, as related to constitutive gene activities, was widely ranged from 0.37 to 1.07; (0.67±0.07), and in adults, from 0.53 to 1.31; (0.88±0.07; $p<0.09$). In children, the expression of type III collagen gene varied from 0.09 to 0.39; (0.26±0.04); in adults, from 0 to 0.39; (0.19±0.03; NS). MMP-1 gene expression was lower in children i.e., from 0 to 0.22; (0.11±0.04), as compared with adult group, from 0 to 0.45 (0.26±0.04; $p<0.008$). TIMP-1 gene expression in IVS was higher in children with HOCM, ranging from 0.21 to 2.18; (1.10±0.21), as compared to adults, i.e., 0 to 1.21; (0.70±0.11; $p=0.05$). In adult with HOCM gene expression of type I collagen varied from 0.53 до 1.31, (0.88±0.07) and was higher compared to patients with EH. Gene expression of type I collagen in patients with EH varied from 0.36 to 0.89; (0.60±0.057; $p<0.013$). In adult with HOCM gene expression of type III collagen varied from 0.00 до 0.39, (0.189±0.03) and was higher compared to patients with EH. Gene expression of type I collagen in patients with EH varied from 0.00 to 0.14; (0.08±0.014; $p<0.01$). In adult with HOCM TIMP-1 gene expression varied from 0.00 to 1.21, (0.70±0.11) and was higher compared to patients with EH. In patients with EH TIMP-1 gene expression varied from 0.00 to 0.42; (0.28±0.055; $p<0.01$). In adult with HOCM MMP-1 gene expression varied from от 0.00 to 0.45; (0,26±0,036), in patients with EH from 0.00 to 0.67; (0,22±0,067; NS). CONCLUSION: In myocardium of IVS children with HOCM, an imbalanced expression of genes encoding collagenolysis factors was demonstrated, due to decreased MMP-1 and increased TIMP-1. Increased expression of genes encoding production of TIMP-1, collagen of I and III types was detected in primary myocardial hypertrophy, compared to myocardial hypertrophy in patients with EH.

PP1-247
THE ROLE OF ANGIOGENESIS OF THROMBOXANE A2 SYNTHESIS PROTEIN

Pao-Hsien Chu
Chang Gung Memorial Hospital, Taiwan

The role of blood vessel formation within diseased blood vessels has become one of the outstanding puzzles in the biology of cardiovascular disease. The role of angiogenesis in atherosclerosis and other cardiovascular diseases has emerged as a major unresolved issue. Angiogenesis, by which new capillaries for from preexisting blood vessels, is essential embryonic development, normal physiological growth, tumor expansion, and wound healing. Wound healing is a complex processes involving cell proliferation and angiogenesis. Little is known about the role of coagulopathy in angiogenesis. Angiogenic cytokine therapy has been widely regarded as an attractive approach both for treating ischemic heart disease and for enhancing arterioprotective functions of the endothelium; conversely, a variety of studies suggest that neovascularization contributes to the growth of atherosclerotic lesions and is a key factor in plaque destabilization leading to rupture. The knockout mice model is a novel tool to assess the detailed pathophysiology of angiogenesis. Previous studies have shown that thromboxane A2 synthase (TXAS) is involved in lymphocyte differentiation, hemostasis, thrombosis, and thrombopoiesis. This study investigates in detail angiogenesis in TXAS knockout mice with corneal injury models. We find that TXAS is crucial to angiogenesis, and will help to understand the relationship between angiogenesis and coagulopathy.

[2] Institute of Pathology and Molecular Medicine, Charles University, 2nd Medical Faculty, Prague, Czech Republic
[3] Department of Oncology, Charles University, 1st Medical Faculty, Prague, Czech Republic
[4] Institute of Biophysics, Charles University, 1st Medical Faculty, Prague, Czech Republic

OBJECTIVE: Proteinase-activated receptor – 2 (PAR-2) is a ubiquitous surface molecule participating in many biological processes. It belongs to the family of G protein-coupled receptors activated by the site-specific proteolysis of trypsin and similar proteases. Altered function of PAR-2 has been described in different malignant tumours. In the present study, we investigated the expression of PAR-2 in breast cancer surgical specimens and the role of trypsin in breast cancer cell line MDA MB-231 proliferation and metabolism. MATERIALS AND METHODS: A total of 40 surgical samples of infiltrative ductal breast cancer and breast cancer cell line were included in this study. We analysed PAR-2 expression by immunohistochemistry, RT-PCR and western blot. Activation of PAR-2 on cell line MDA MB – 231 was measured using calcium mobilisation assay determined by flow cytometry. MTT cell metabolism assay and cell count analysis were used to assess the trypsin influence on breast cancer cell line MDA MB – 231 proliferation. RESULTS: Immunohistochemical examination showed the expression of PAR-2 in all samples of breast cancer surgical specimens and cell lines in high level, this was confirmed by RT-PCR and western blot. Calcium mobilization assay corroborated the activation of PAR-2 on cell line MDA MB – 231 either by trypsin or by agonistic peptide. Cell metabolism assay and cell count analysis showed significant differences of proliferative activity of breast cancer cells dependent on presence or absence of trypsin and serum in culture medium. CONCLUSIONS: PAR-2 is expressed in a high level in infiltrative ductal breast cancer tissue specimens. PAR-2 is expressed in studied breast cancer cell lines in a high level. PAR-2 is activated by trypsin and by agonistic peptide as well in the model of breast cancer cell line MDA MB-231. Activation of PAR-2 in vitro influences proliferative and metabolic activity of breast cancer cell line MDA MB-231. The action of trypsin is modified by the presence of serum which is a potential source of protease inhibitors.

MUTATIONAL ANALYSIS OF THE BRAF GENE IN VARIOUS CONDITIONS OF THE PARATHYROID GLANDS

Chryssa Louverdi[1], Gerassimos Voutsinas[2], Eleni Litsiou[1], Efstratios Patsouris[1], Sophia Tseleni-Balafouta[1]
[1] First Department of Pathology, Medical School, University of Athens, Greece
[2] Laboratory of Environmental Mutagenesis and Carcinogenesis, Institute of Biology, NCSR "Demokritos", Greece

BACKGROUND: The product of the BRAF gene is a cytoplasmic protein that plays a critical role in the mediation of signals from the cytoplasmic membrane to the nucleus via the RAS/RAF/MEK/ERK/MAPK pathway and it has been suggested to be implicated in many endocrine neoplastic disorders. The result is the activation of transcription factors which regulate gene expression, cell proliferation, apoptosis, and differentiation. In the present study we examined in total 34 specimens of enlarged parathyroid glands, including eleven cases of primary hyperplasia, twelve cases of secondary hyperplasia, ten of adenoma, and one case of carcinoma. The purpose of our study was the detection of BRAF mutations related to various conditions of the parathyroid glands since the pathogenesis of hyperplastic and neoplastic disorders is not well understood and the differential diagnosis between them is not always possible. METHODS: Our material constituted 34 paraffin-embedded parathyroid specimens from which genomic DNA was extracted by the method of phenol/chloroform. BRAF exons 11 and 15 were amplified by PCR using specific primers. The amplified products were purified by the QIAquick PCR Purification Kit (QIAGEN). Sequencing-PCR reactions were performed for both exons, using the BigDye Terminator Cycle Sequencing Kit (QIAGEN). Furthermore, a last purification of the Sequencing-PCR products was performed using the DyeExTM 2.0 Spin Kit (QIAGEN). Finally, the amplified products were sequenced on an ABI PRISM 310 automated capillary DNA Sequencer. RESULTS: Sequence analysis confirmed no mutations of the BRAF gene in all 34 cases used in this study. Even the common genetic alteration, the valine to glutamate substitution at residue 600 (V600E) was absent. CONCLUSIONS: These findings suggest that the BRAF gene -and particularly exons 11 and 15- do not appear to represent a frequent molecular event in the pathogenesis of various conditions of the parathyroid glands. Consequently, it is not possible to use the V600E substitution as a molecular marker for the diagnosis of hyperplasia, adenoma or carcinoma. Furthermore, these results enhance the suggestion that different biological pathways are activated in endocrine tumors of various localisations.

PP1-250
RET/PTC REARRANGEMENTS IN GREEK PATIENTS WITH PAPILLARY THYROID CARCINOMA

Eleni Litsiou[1], Galinos Fanourakis[1], Spiridon Vernadakis[1], Artemis Vintila[1], Gerassimos Voutsinas[2], Efstratios Patsouris[1], Sophia Tseleni-Balafouta[1]
[1] First Department of Pathology, Medical School, University of Athens, Greece
[2] Laboratory of Environmental Mutagenesis and Carcinogenesis, Institute of Biology, NCSR "Demokritos", Greece

Background Papillary thyroid carcinoma (PTC) is the most prevalent endocrine malignancy in humans. Chromosomal alterations that affect the RET tyrosine kinase receptor are associated with PTC. Three most common rearrangements, RET/PTC1, RET/PTC2 and RET/PTC3 account for the vast majority of all rearrangements found in the general population. Some geographical differences regarding frequencies of these alterations have been reported. Our aim was to evaluate the presence of RET/PTC rearrangements in Greek patients with papillary thyroid carcinoma. Method In this study, total RNA was isolated from 24 fresh papillary thyroid carcinomas. One μg RNA was reverse transcribed to cDNA, followed by polymerase chain reaction (PCR) using specific primers for RET/PTC 1, 2, 3. The efficiency of reverse transcription was verified by the amplification of the GAPDH gene. All PCR products were resolved on a 2% agarose gel containing ethidium bromide and visualized under ultraviolet light. Products indicating a RET/PTC rearrangement were direct sequenced to verify the result. Results Two rearrangements in two papillary thyroid carcinomas were detected by RT-PCR (8%). RET/PTC3 rearrangement was found in one carcinoma and RET/PTC2 in the second one. All rearrangements were confirmed by sequencing. Conclusion This study is the first regarding RET/PTC rearrangements in Greek patients with papillary thyroid carcinoma. The reported frequency of RET activation varies widely among different series from 0% to approximately 80% in post-Chernobyl papillary carcinomas. This variation reflects geographical distribution as well as influence of environmental factors such as ionizing radiation exposure. In our study, two RET/PTC rearrangements were detected among 24 samples (8%) by RT-PCR. One patient with papillary thyroid carcinoma exhibited RET/PTC3 rearrangement, while another patient exhibited RET/PTC2 rearrangement. These findings indicate that RET/PTC may not be of significant role in the pathogenesis of papillary thyroid carcinoma in the Greek population. Moreover, the relatively lower prevalence of chromosomal RET alterations in Greek patients compared to similar studies in neighboring countries (such as Italy, 33%) point toward to a minor effect due to exposure in I131 from the Chernobyl accident. Supported by the Community Support Framework 2000-2006, Operational Programme "COMPETITIVENESS", co-funded from the EU by 75% and from the Hellenic State by 25%.

HISTOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL STUDY OF E-CADHERIN IN BREAST NEOPLASIA

Marwa Elshaer
The National Research Centre, Cairo, Egypt

Background :.Although EC is emerging as an excellent marker to type breast carcinomas. The conflicting reports of EC loss as predictor of increased invasiveness. Metastatic potential ,and poor survival raise questions about its reliability for typing.Methods: Immunohistochemical staining was undertaken for E-cadherin (EC), estrogen and progesterone receptors; on tissue sections of normal,proliferative and malignant breast lesions. The EC positive expression manifested itself as sharp membranous staining and was assessed semi-quantitative into four categories:0;1+ were considered negative immunoreactivity, while 2+ and 3+ were scored as positive immunoreactivity. Results: Although 95% of non malignant proliferative breast lesions showed positive EC immunoreactivity , and reduced or lost EC expression in all Pre-invasive cases .None of invasive lobular cases express EC, in contrast to 30 % of invasive duct carcinoma cases, showed reduced or lost EC expression in high histological grades. Tubular Carcinoma showed a highly statistically significant difference between the groups ($P < 0.001$). Overall, negative staining of EC was specific for the diagnosis of invasive lobular cases However, positive staining did not exclude its diagnosis Conclusion: There was a significant relationship between E-Cadherin expression and different breast neoplastic histological types .The molecular "signature" of breast lobular carcinomas is the loss of E-cadherin protein expression as evidenced by immunohistochemistry, whereas ductal carcinomas are typically E-cadherin positive. Our study suggests that E-cadherin may be involved in the pathogenesis of this form of breast cancer.

PP1-252
HER 2/neu PROTEIN IMMUNOHISTOCHEMICAL EXPRESSION CORRELATED WITH ESTROGEN AND PROGESTERONE RECEPTORS IN HUMAN PAPILLOMA VIRUS-RELATED CERVICAL NEOPLASIA
Marwa Elshaer
The National Research Centre, Cairo, Egypt

Background: The natural history of cervical neoplasias appears unpredictable with 1/3 to 1/2 of CIN lesions regressing without intervention; therapeutic targeting aids in screening and selecting patients at risk and elucidating treatment response. This study aimed at determining if a pattern of tumor suppressor, oncogene, and growth factor expression (specifically HER-2/neu), progesterone and estrogen receptors (ER/PR), exists in the progression of cervical cancer utilizing the widely applicable process of immunohistochemistry. Methods:17 Paraffin sections from were obtained from the surgical pathology department ,the national cancer institute Cairo University ,between the period of 2001 and 2002. Levels of expression in normal, low and high grade dysplasias, and invasive squamous carcinomas were measured via immunohistochemical analysis. Results: HER-2/neu staining occurred at greater levels in high grade lesions and invasive carcinomas being of prognostic significance. ER and PR expression generally remained low with a penchant for parabasal cells .Conclusions: While HPV infection immortalizes cervical cells the equivocal expression of pre-invasive and more aggressive lesions suggests the involvement of other. PR and ER play only a minor role in the development of carcinomas, indicating a lack of hormonal control in cervical tumor growth and proliferation. Her-2/neu, however, participates in the late events of cervical malignancy. Although HER-2/neu perhaps holds limited prognostic value in cervical carcinogenesis, similar molecular pathways independent of HPV need to be investigated.

PP1-253
CHROMOSOMAL ALTERATIONS IN LUNG METASTASES OF COLORECTAL CARCINOMAS: ASSOCIATIONS WITH TISSUE SPECIFIC TUMOR DISSEMINATION
Thomas Knosel, Karsten Schluns, Manfred Dietel, Iver Petersen
Institute of Pathology, Charité, Campus Mitte, Germany

Comparative genomic hybridization was used to screen colorectal carcinomas for chromosomal aberrations that are associated with the metastatic phenotype of the lung. Thirteen lung metastases, six primary tumors, one lymph node metastasis, one liver metastasis, and one ovarian metastasis were investigated and added to our CGH colon cancer tumor collective, comprising 85 tumor specimens from 56 patients (see CGH online tumor database at http://amba.charite.de/cgh). Lung metastases showed more alterations than liver metastases, particularly more deletions at 1p, 3p, 9q, 12q, 17q, 19p and 22q and gains at 2q, 5p, and chromosome 6. Comparing lung metastases with their corresponding primary tumors, particularly more deletions at 3p, 8p, 12q, 17q, and 21q21 and gains at 5p were observed. Based on our results, we wish to suggest a metastatic progression model. Specific subpopulations of metastatic cells have a distinct metastatic potential which is reflected by a non-random accumulation of chromosomal alterations. Distinct alterations already exist within the primary tumor and this “ready to go package” gives the cells the metastatic potential to achieve the complex series of events needed for metastasis.

PP1-254
EXPRESSION ANALYSIS OF NDRG2 PROTEIN IN ADULT HUMAN TISSUES
Song Mei Huang[1], Shengjin Li[1], Jin-Man Kim[2]
[1] Department of Pathology, Chungnam National University College of Medicine, Korea
[2] Cancer Research Institute and Department of Pathology, Chungnam National University College of Medicine , Korea

Background: NDRG2 (N-myc downstream regulated gene 2), a member of a new family of differentiation related gene, belongs to the NDRG family, which includes NDRG1-4. Although several functions of NDRG2 were studied, the exact molecular and cellular function remains to be illustrated. Design: To realize the more function of NDRG2 protein, we generated a mouse monoclonal antibody against NDRG2 to analyze the expression pattern of NDRG2 protein with immunohistochemistry in a large set of normal human tissues. Result: In human tissues, NDRG2 expression was seen in various epithelia of small intestine, large intestine, breast, bronchus, kidney, prostate, liver, salivary glands, endometrium, and pancreas. Dendritic cells of lymphoid tissue, skeletal muscles, cardiac muscle, peripheral nerve plexuses, Cajal cells of intestine, thymic Hassalls corpuscles, adrenal cortical cells, ovarian stromal cells, Leydig cells and astrocytes of brain were strongly expressed for NDRG2. The cellular localization of this protein was mostly in cytoplasm. Conclusion: In the present study, we demonstrate the expression pattern and cellular location of NDRG2 protein in a large set of human adult tissues. This is the first systemic demonstration of NDRG2 protein expression in adult human tissues. The multiple localization of this protein in normal human tissues indicates that NDRG2 protein might play multiple functions.

MUTATION FREQUENCY OF C-KIT AND PLATELET DERIVED GROWTH FACTOR RECEPTOR ALPHA (PDGFRA) TYROSINE KINASE GENE IN SAUDI GASTROINTESTINAL STROMAL TUMORS (GISTS)
Fouad Al Dayel[1], Muhammad Faiyaz Ul-Haque[1], Asma Tulbah[1], Hala Abalkhail[1], Muhammad Memon[1], Tarek Amin[1], Mohamed Satti[2]
[1] King Faisal Specialist Hospital & Research Centre, Saudi Arabia
[2] King Abdulaziz Medical City, Saudi Arabia

Background: Although gastrointestinal stromal tumors (GISTs) are rare, comprising about 1% of gastrointestinal cancer, they are the most common mesenchymal tumors of the gastrointestinal tract. The overwhelming majority of these tumors express mutations in the c-KIT gene that may produce gain-of-function effect on the tyrosine kinase binding pathway resulting in ligand-independent activation of the KIT receptor tyrosine kinase. Most frequent KIT mutations target exon 11 (66%), followed by exon 9 (10%), then exon 13 (1.2%) and exon 17 (0.6%). About 7% of GIST exhibit mutations of platelet derived growth factor receptor alpha (PDGFRA). GISTs is a good example of a neoplasm with an effective molecularly targeted therapy. Method: DNA extraction, polymerase chain reaction (PCR) and sequencing were performed on paraffin embedded tissue from 11 histologically confirmed GISTs that involve stomach and small bowel and show KIT (CD117) immunoreactivity. We analyzed the tumor samples for mutations in the exon 11, 9, 13 and 17 of the c-KIT gene and exon 12 and 18 of the PDGFRA. Results: A direct sequence analysis revealed c-KIT mutations in seven of the available tumor samples. Among the GISTs with c-KIT mutations, three had previously reported exon 11 mutations Valine to Aspartic Acid at codon 560, one had a novel mutation in which Valine changes into Alanine on the same codon 560 and three tumor samples had novel inframe deletion in the exon 11. DNA quality was not optimal for analysis in the other four samples. Conclusion: All mutations in the present study fall on the exon 11 of the c-KIT gene. Recent publications show the importance of mutational status of GISTs to predict response to target therapy. KIT tyrosine kinase inhibitor, imatinib mesylate, offers an effective treatment for most patients with advance GIST. The likelihood of clinical response appears to be significantly better for patients with exon 11 mutations than for patients with other mutations. Although the number of cases is small, this study provides the initial data for mutational status of c-KIT/PDGFRA oncoproteins in Saudi population that will be useful to predict the clinical response to therapy.

PP1-256
4EBP1, A KEY MOLECULAR "FUNNEL FACTOR" IN HUMAN CANCER WITH CLINICAL IMPLICATIONS
Vicente Peg, Berta Pons, Federico Rojo, Josep Castellvi, Carmela Iglesias, Gemma Armengol, Santiago Ramon Y Cajal
Pathology Department, Vall d´Hebrón University Hospital, Barcelona, Spain

BACKGROUND: in an attempt to identify molecules that clearly reflect the oncogenic role of cell signaling pathways in human tumors, we propose a concept we term "funnel" factor, a factor where several oncogenic signals converge and drive the proliferative signal downstream. MATERIAL AND METHODS: we studied the expression of several factors involved in cell signaling in 110 ovarian tumors, 105 breast carcinomas, 90 prostate tumors and 120 colon carcinomas by immunohistochemistry and Western blotting. The factors studied were: Her1 and Her2 growth factor receptors, the RAS-RAF-MAPK and the PI3K-AKT-mTOR pathways and the downstream factors p70S6K, S6, 4EBP1, and eIF4E. DISCUSSION: we found that phosphorylated 4EBP1 (eukaryotic translation initiation factor 4E binding protein 1) expression in breast, ovary, and prostate tumors was associated with malignant progression and an adverse prognosis, regardless of the upstream oncogenic alterations. Moreover, various cell lines were studied, including normal human fibroblasts (IMR90), kidney cells (293T) and breast cancer cell lines (MDA-MB-231 and MDA-MB-435). These cell lines were treated with rapamycin in order to investigate 4EBP1 hyperphosphorylation and its correlation with mTOR, and levels of p4EBP1 were evaluated by Western blot, as well as cell survival. Finally, a wild-type and a mutant 4EBP1 were both transfected into various cell lines. Rapamycin blocked phosphorylation of 4EBP1 in MDA-MB-231 and in 293T, but not in MDA-MB-435. However, all these cell lines were resistant to rapamycin, since cell numbers did not decrease. In addition, transfection in those cell lines of 4EBP1 with phosphorylation site mutations suppressed cell proliferation. CONCLUSION: p-4EBP1 seems to act as a funnel factor for an essential oncogenic capability of tumor cells, self-sufficiency in growth signals, and could be a highly relevant molecular marker of malignant potential.

[2] Institute of Medical Biochemistry, Gothenburg University, Sweden
[3] Department of Surgery, University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland
[4] Department of Pathology, University of Turku and Turku University Hospital, Finland

Human cells are covered by a layer of sugar moieties (glycans) that change in cancer and contribute to cancer progression and metastasis. Due to the lack of suitable analysis technology the cancer glycome – the whole spectrum of glycans in malignant tumors – has remained unknown. We combined MALDI-TOF mass spectrometry with specific enzymatic and chemical glycan modifications to identify tumor-associated changes in the protein-linked glycome. Material was collected from over 100 archival paraffin-embedded tumors (small cell lung adenocarcinoma, lobular and ductal breast carcinomas, pancreatic adenocarcinoma, colorectal adenocarcinoma, ovarian serous carcinoma, renal cell carcinoma) and related normal tissues. The analysis identified significant differences in each of the tumor/control tissue pairs. A number of distinct glycan signal groups were identified as the dominating tumor-associated protein-linked glycans in various carcinomas. These glycans were shown to be consistently upregulated in tumors, indicating that tumor progression is reflected in the expressed glycan structures. In lung carcinomas, the analysis led to identification of a tumor-associated glycan group characterized by abnormal terminal β-N-acetyl-D-glucosamine (GlcNAc) residues. Similar glycan antigens were also expressed in glycolipids extracted from the same tumors, suggesting a common biosynthetic background. The results suggest that global analysis of the cancer glycome is an effective tool for discovery of new molecular targets in cancer. The discovered glycan antigens have potential as diagnostic markers and as targets for novel therapeutic anti-neoplastic agents.

PP1-258
INVOLVEMENT OF VIP RECEPTORS IN SIGNALLING NETWORKS REGULATING CYCLOOXYGENASE-2 IN HUMAN PROSTATE CANCER TISSUE
Ana B. Fernández-Martínez[1], Ana M. Bajo[1], Sandra Sotomayor[1], M. Isabel Arenas[2], Manuel Sánchez-Chapado[3], Antonio Ruíz-Villaespesa[4], Juan C. Prieto[1], M. José Carmena[1]

[3] Urology Department, Príncipe de Asturias Hospital, Spain
[4] Pathology Department, Príncipe de Asturias, Spain

BACKGROUND: The vasoactive intestinal peptide (VIP)-$VPAC_1$ and $VPAC_2$ G protein-coupled receptors (GPCR) are related to prostate cancer progression to androgen-independent stage. Recently, we have demonstrated that VIP enhances the expression of the proinflammatory enzyme cyclooxygenase (COX)-2 in both human prostate non neoplastic and tumoral cell lines, acting through the nuclear factor-kappaB. The aim of this study was to detect the coexistence of $VPAC_1$ receptors and COX-2 enzyme in human prostate tissue as well as to compare the observations in healthy and malignant tissue from the same specimen. METHOD: Samples were obtained from patients undergoing radical prostatectomy (n=15, age range 51-73 years). Thereafter, tissue fragments were embedded in paraffin and the postoperative pathologic situation was staged pT1-pT4 (pN0M0, n=15) according to TNM classification. In order to quantify the expression of mRNAs for COX-2 and $VPAC_1$ receptor, RNA was isolated from paraffin sections and real time RT-PCR was performed. RESULTS: The results showed increases of COX-2 and $VPAC_1$ mRNAs in 14/15 and 10/15 samples, respectively, as compared to the corresponding normal tissue. The enhancement of expression for both molecules was coincident in 67% of cases. Immunohistochemical studies showed a similar coexistence of $VPAC_1$ receptor and COX-2 proteins in the same samples. CONCLUSION: Taken together, these results support VIP involvement in inflammatory signals. Such signals may initiate and promote prostatic oncogenesis, which gives a potential usefulness to $VPAC_1$ receptors and COX-2 as therapeutical targets in this disease.

PP1-259
EXPRESSION PROFILE OF NANOG USING TISSUE MICROARRAY
Ana Díez, Socorro María Rodríguez, Raquel Pajares, Lorena Alonso, Lydia Sánchez-Verde
CNIO, Spain

Introduction: Nanog is a key regulator of embryonic stem cell (ESC) self-renewal and pluripotency. Aims: To analyse expression profile of Nanog in a multitumoral Tissue Micrroarray Material and methods: We analyse the exprresion of Nanog in at least 500 cases using tissue-microarrays containing melanomas,seminomas, embryonal carcinomas, colon, breast and lung cancers, as well as their corresponding normal tissues. Results: We observe two different patterns of expression. Nuclear

in normal testis and seminoma, and cytoplasmic in the other tumors analyzed in a percentage of 10%, 40%, 50% and 10%for breast, colon, lung and melanomas, respectively. Conclusions:1- TMA are a useful tool to identify expression profile.2-Nanog is highly expressed in the nucleus in normal testis, seminomas and embryonal carcinomas which could be used to differential diagnosis among testicular tumors. 3- Cytoplasmic expression must be analyzed in order to know its biologic significance and relation to prognosis.

PP1-260

MOLECULAR SCREENING IN PATIENTS WITH CLINICAL CRITERIA OF LYNCH SYNDROME BY COMBINATION OF IMMUNOHISTOCHEMISTRY AND MOLECULAR BIOLOGY

Javier Hernandez-Losa[1], Stefania Landolfi[1], Miriam Cuatrecasas[2], Judith BalmañA[3], Ana Solsona[1], Teresa Osteso[1], Teresa Moline[1], Santiago Ramon Y Cajal[1]
[1] Department of Pathology, Vall d'Hebron University Hospital, Spain
[2] Department of Pathology, Sant Pau University Hospital, Spain
[3] Department of Oncology, Vall d'Hebron University Hospital , Spain

Background. The Lynch Syndrome (LS) is the most prevalent genetic disease in hereditary non-poliposys colorectal cancer (HNPCC). It is characterized by germinal mutations in the Mismatch Repair (MMR) genes (hMLH1, hMSH2, hMSH6 and PMS2) and presence of microsatellite instability (MSI), although 15% of sporadic tumors present MSI without expression of hMLH1 because of promoter hypermethylation. MSI consists in DNA insertions and deletions in microsatellites sequences. In order to select patients for further genetic mutation studies, the techniques used in the daily practice are immunohistochemistry (IHC) of MMR proteins and MSI analysis by PCR using a panel recommended by NCI (Bethesda Panel). We decided value MSI by using a new pentaplex system in combination with IHC study. Methods. We collected 91 patients with colorectal cancer (CCR) selected by Bethesda clinical Criteria of LS. Haematoxylin-eosin stained slides obtained from formalin-fixed, paraffin-embedded tissues were reviewed and the areas with tumor and normal tissue were identified. We evaluated by IHC the nuclear expression of MLH1, MSH2 and MSH6 proteins in the neoplastic areas. Furthermore we extracted DNA from a paired normal-tumor samples for each patient and we evaluated the presence of MSI using a pentaplex method with BAT25, BAT26, MONO27, NR21 and NR24 microsatellites enclosed in the "MSI Analysis System" kit (Promega Corporation). Results. We detected loss of nuclear expression of MMR proteins in 19% (17/89) of the samples (MLH1: 12/17, MSH6: 3/17 and MSH2-MSH6: 2/17). 2 cases were not valuables because of formalin fixation problems. About MSI analysis by PCR we analysed 91 paired normal-tumor samples and we detected positivity for MSI in 14% (13/91) patients: 12/13 with High-MSI (instability in two or more microsatellites) and 1/13 with Low-MSI (instability only in BAT26 microsatellite). We found a complete concordance between the presence of MSI by PCR and loss of expression of any MMR protein by IHC (13 cases). 4 cases did not show expression of MLH1 protein by IHC without presenting MSI. Conclusion. We have demonstrated that the combination of MSI (pentaplex system) and IHC analysis allows us a better selection of the patients who will benefit of further germinal mutations studies. Both techniques are complementary in this screening, but others factors must be considerated in the future in order to improve the knowledge of the difference between hereditary and sporadic CCR.

Radiotherapy is successfully used to treat human cancers. However, patients locally recurring after treatment are at increased risk of developing metastases. The clinical management of this condition is a challenge, and its underlying mechanisms remain largely unknown. Since radiotherapy modifies the tumour microenvironment, we hypothesized that radiation-induced modifications of the tumour microenvironment might favour the spreading of metastatic tumour cells. Here, we report that the irradiation of naïve stroma promotes tumour metastasis through the suppression of angiogenesis, increased of tumour hypoxia and selection of aggressive tumour cell populations that retain an invasive and metastatic phenotype even when they leave their hypoxic microenvironment. Through gene expression profiling and gain and loss of function experiments, we identified the matricellular protein CYR61 as a critical mediator of tumour cell survival during hypoxia, invasion and metastasis. Inhibition of aV integrin prevented tumour cell invasion and metastasis induced by stroma irradiation and CYR61 over-expression. We found high CYR61 metagene expression to correlate with tumour hypoxia and shorter relapse-free survival in human breast cancer. These results identify CYR61 and aV-integrins as proteins that co-operate to mediate metastasis of tumours growing in irradiated stroma and as potential therapeutic targets in patients at risk for post-radiation recurrences. They also illustrate the potential impact of therapy-induced microenvironmental hypoxia in determining tumour evolution.

THE PRACTICE OF PATHOLOGY IN RUSSIA

Max Omutov[1], Sergei V. Jargin[2]
[1] Ostroumovski Hospital, Moscow, Russia
[2] Independent, Moscow, Russia

Pathologists at Ostroumovski Hospital, one of the leading clinical centers in Moscow, encounter problems, which are typical of those seen across Russia. Although the department has above-average equipment and is staffed by experienced specialists, problems with supplies and personnel management create impediments to quality care. Of about five available stains only hematoxylin-eosin is of acceptable quality; and only the Romanovsky-Giemsa stain is used for cytological smears. In the case of patients who had been previously hospitalized in other hospitals, histological slides of the biopsies performed in the past are requested and reviewed. While reviewing, diagnostic errors are sometimes found, but the original pathologist never receives any feedback, and opportunity for quality improvement is lost. Since cytologists and pathologists in Russia belong to different medical specialties, they are frequently located in different departments. Correlation of cytological and histological slides and diagnoses is not performed (regularly), and again this mechanism of quality control does not function. However, some cytologists do compare histological and cytological diagnoses on their own initiative. The gross examination of material in many departments is done without rinsing with water. The detritus and dirt are wiped with cloths or paper. For that reason and also because of inadequate washing of containers, there is increased risk of contamination by floaters. Previous slides are rarely pulled for comparison, and archives of blocks and slides are in bad condition even in the leading institutions such as the Cancer Research Center in Moscow. Biopsy reports are delivered to the clinic on the third to fifth day (or later) after submission of the specimen. It is one of the reasons why frozen sections are used very extensively. The mortician's offices are situated together with the departments of pathology on the hospital premises. Autopsy helpers are employed part-time in mortuary service. The request of a pathologist to an autopsy helper (for example to bring formalin) can be met with the reply that he has no time because he has to dress or shave a corpse. Difficulties are sometimes caused by poor discipline of ancillary personnel. All said, Russian pathology has many positive aspects. Pathologists work in close contact with clinicians, know their needs and requirements. There are medical technicians who consistently produce thin slides using old equipment. Despite remaining shortages, there are grounds for optimism.

HPV-DNA TESTING AND Ki-67 IMMUNOCYTOCHEMISTRY IN LIQUID BASED CERVICAL CYTOLOGY: IN PROSTITUTE WOMEN

Esin Atik[1], Baris Otlu[2], Meryem Cetin[3], Devrim Tok[4], Riza Durmaz[2]
[1] Department of Pathology, Mustafa Kemal University, Faculty of Medicine, Antakya-Hatay / Turkey
[2] Department of Microbiology, Inonu University, Faculty of Medicine, Malatya/ Turkey
[3] Department of Microbiology, Mustafa Kemal University, Faculty of Medicine, Antakya-Hatay / Turkey
[4] Department of Obstedric and Gynecology, Mersin University, Faculty of Medicine, Mersin/ Turkey

Aim HPV causes several changes in the function of host genes, and these interactions cause deregulation of the cell cycle manifested by abnormal expression of cell cycle associated proteins, such as Ki-67. The detection of Ki-67 can play a role in screening and diagnosis of HPV infection with risk of progression towards dysplasia and carcinoma. We aimed to show this relation in prostitute women. Materials and methods Cervical cells were collected in the PapSpin Collection Fluid (Thermo Shandon, Pittsburg, USA). A starting volume of 1000 µl for each sample, a 200 µl cell suspension was used to prepare each thin layer liquid based cytology (LBC) and stained by Papanicolaou. The cytological results were classified according to the Bethesda 2001 system. From the remaining cell suspension of 800 µl, 400µl was used for HPV DNA detection by PCR. From the remaining 400 µl cell suspension 50 µl was used to make thin layer preparations for immunocytochemistry. Single antigen staining was performed with Ki 67 protein, (Neomarkers-Biogen, Lab Vision Corp. USA). Cells were considered immunopositive if the nuclei were stained. All cells in one high power field (X400), which was considered to be representative of the whole cell area, were counted, and the fraction of positive cells on the slide was calculated. This fraction was expressed as the number of positive cell /1000 cells to compare results of samples. Results HPV types 6 and 32 in study group, HPV types 6 and 51 in control group were detected. The mean Ki-67 values were 2.7 ± 1.2 and 3.6 ± 4.1 in HPV positive and negative cases respectively. There was a positive correlation only with nuclear changes and HPV positivity (X^2=28.8 $p<0.001$). Our other results were not statistically meaningful. There was not a significant relation with HPV or Ki-67 and leucocytosis. There was not also a relation with HPV and contraseption, smoking, concurrent genital infection. Conclusions The prevelance of HPV types in different geographical locations and racial factors may indicate different etiologies of cervical cancer. Our results suggest that Ki-67 immunocytochemistry is not useful as a surrogate marker for 6, 32 and 51 types of HPV.

PP1-264
CYTOLOGIC FINDINGS IN PAP SMEARS WITH ACTINOMYCES-LIKE ORGANISMS: A RETROSPECTIVE STUDY

Dilek Kaya[1], Mehmet Sinan Beksac[2], Gamze Mocan Kuzey[3], Sayeste Demirezen[1]
[1] Hacettepe University, Faculty of Science, Department of Biology, Turkey
[2] Hacettepe University, Faculty of Medicine, Department of Gynecology and Obstetrics, Turkey
[3] Hacettepe University, Faculty of Medicine, Department of Pathology , Turkey

Background: To detect whether there is a relationship between the presence of Actinomyces-like organisms (ALOs) and cytologic findings. Method:Cervico-vaginal smears obtained from 2490 women were stained with the Papanicolaou technique and were examined cytologically. Twenty-five (1.00 %) of the 2490 were diagnosed with ALOs and became the study group. Patients without infectious agents (n=1926) were the control group. Statistical analyses were conducted with the Chi-square test using the SPSS programme. The limit for statistical significance was $p=0.05$. Results: The study and control groups were compared statistically. There was a significant correlation between the presence of ALOs and other cytologic findings,such as Trichomonas vaginalis,cocci, endocervical cells, superficial cells, lactobacilli and polymorphonuclear leucocytes ($p<0.05$), but there was no statistically significant difference between the presence of ALOs and metaplastic cells or parabasal cells ($p>0.05$). Conclusions: ALOs in cervico-vaginal smears might provide a milieu for growing some infectious agents such as Trichomonas vaginalis and cocci. Lactobacilli were less plentiful in these cases. The exfoliation of superficial cells, more than of other type of cells such as parabasal cells, might be a clue to the presence of ALOs. Endocervical cells, might have been exfoliated because of the involvement of ALO cells with cervical tissue.

PP1-265
EVALUATION OF TZANCK SMEARS IN HERPES SIMPLEX VIRUS INFECTIONS EVALUATION OF TZANCK SMEARS IN HERPES
Fakhrozaman Pezeshkpoor, Mahnaz Banihashemi
Ghaem Hospital, Department of Dermatology, Mashhad University of Medical Sciences, Mashhad, Iran

Back ground: The diagnosis of herpes simplex virus may require virological confirmation. Tzanck smear is a old and inexpensive method but it is not specific. Objective: This study was conducted to compare for diagnosis of herpes simplex virus by Tzanck smears and viral culture .In patients who clinically suspected herpes simplex virus infection. Method: Cutaneous swab from vesicles fluid and base of vesicles on patients with herpes simplex infections were taken and then viral culture and Tzanck smears were preformed. Results: Of 56 samples 71.4% was culture positive and Tzanck smear was positive in 64.3% of cases. In all of cases in which Tzanck smear was positive ,viral culture was positive too. In 90% patients who culture was positive,Tzanck smear was also positive. Conclusions: These results demonstrate that Tzanck smear suitable for diagnosis of herpes simplex virus infections when culture or other virological method is not available.

PP1-266
MALIGNANT MESOTHELIOMA. OUR CLINICAL, CYTOLOGIC AND IMMUNOCYTOCHEMICAL FINDINGS
Charalampos Charalampidis, L. Kampas, D. Gerasimidou, R. M Valeri, J. Angel, C. Destouni
Department of Cytopathology, Anticancer Hospital of Thessaloniki “Theagenio”, Greece

Objective: Mesothelioma has an increased rate and contributed significantly to cancer-related morbidity and mortality in the last decades. The differdiagnosis mesothelioma from adenocarcinoma remains a major challenge for most cytopathologists. The early detection of mesothelioma in combination with appropriate therapy are of great significance for patients’ long term survival. Immunocytochemistry seems to be the key of diagnosis. The aim of the present study was the investigation of mesotheliomas with a panel of immunocytochemical markers and the response of new therapeutical schedule in these patients. Material and Methods: In this study included pleural and ascitic fluids collected by 15 cancer patients. The specimens were prepared with the use of Thin monolayer Cytology (ThinPrep technique) and stained by Papanicolaou method. Moreover, we used a panel of immunocytochemical markers (Calretinin, HBME-1, Cytokeratin 5 and Mesothelin) in order to distinguish mesotheliomas, especially epithelioid type, from adenocarcinomas. Immunocytochemistry was performed with the use of Ventana Nex Es Automated slide stainer and related Ventana reagents. Results: Diagnosis was based on clinical, cytologic and immunocytochemical findings. Calretinin had the best sensitivity and specificity for the mesothelioma followed by HBME-1, Mesothelin and CK 5. Furthermore, 10 out of 15 patients who were treated with chemotherapeutical agents (carboplatin and pemetrexed) had better survival rate (16-24 months). Conclusions: 1. The tumour markers Calretinin, HBME-1, Mesothelin and CK 5 seem to have the best sensitivity and specificity for the diagnosis of mesotheliomas. 2. The early detection of malignant mesothelial cells with appropriate immunocytochemistry contributes in prompt treatment procedure. 3. Consequently, this point is of high interest because the application of this new therapeutical schedule (carboplatin and pemetrexed) seems to improve the survival of these patients.

PP1-267
IS HPV TESTING NECESSARY FOR THE ADEQUATE EVALUATION OF THE ABNORMAL PAP SMEAR WITH A NEGATIVE BIOPSY? A CORRELATION STUDY WITH SURGICAL BIOPSIES
Rosalina Reyes[1], Janice Matthews-Greer[2], Runhua Shi[3], Dorothy Rivette[4], Elba A. Turbat-Herrera[5]
[1] Pathology, LSUHSC, Shreveport,LA, United States
[2] Pathology and PediatricsLSUHSC, Shreveport,LA,United States
[3] Medicine,LSUHSC, Shreveport, LA, United States
[4] LSUHSC, Shreveport, LA, United States
[5] Otolaryngology and Pathology, Saint Louis University School of Medicine, St Louis, MO, United States

Background: Several tests have been used as adjunct to the Pap smear for objective assessment of women at risk and guidelines developed for management and follow up of these women. The ALTS Study recommends colposcopy, cytologic follow up and triage by HPV DNA testing using Hybrid Capture II (HCII). Reported low HCII specificity poses a problem in the diagnosis of women with little/no immediate risk of disease. This retrospective study was conducted to estimate HCII s effectiveness to predict HSIL by correlation of Pap smears and available biopsy samples. Also addresses the question of the abnormal Pap with HPV results and negative biopsies. Design: 1,579 Pap smears in women with corresponding HR HCII were retrieved from LSUHSC files from January 2004 to October 2005. A total of 1413 (90.6%) had an ASCUS (ASC-US and ASC-H) on cytology and 981 (69.4%) were positive for HR HPV HCII. Available biopsies (n=438) were correlated with cytology and HPV HCII results, discordant results were reviewed by 2 authors. Results: When ASC-US was subcategorized into ASC-US, ASC-US suggestive of HPV and ASC-H, HPV HCII positivity was 65.56%, 81.69% and 81.51% respectively, $p<0.0001$. Total of 438 biopsies retrieved, majority cervical (n=373). Of the HR HCII positive cases: 82.3% LSIL and 92.5% HSIL. LSIL biopsy breakdown: 91%ASCUS (ASC-US and ASC-H), 0.9% LSIL,and 5.6% HSIL. HSIL biopsy breakdown: 56.98% ASC-US,16.0% HSIL, 0% LSIL . Of the 92 negative biopsies reviewed (3 cases unavailable), 15 % were ASC-US (combined ASC-US and ASC-H), 20.7% LSIL, 3 % HSIL. 59/92 (64 %) tested positive for HR HPV, one case had insufficient material. Conclusion: 1)The high number of abnormal Pap smears with positive HPV in women with abnormal biopsies confirms the usefulness of HCII. 2)A positive HPV test combined with atypical Pap should prompt review of negative biopsies. 3)The absence of squamo-columnar junction represents an important cause for false negative biopsies (30.0% in our study). 4)Endocervical curettage is not adequate to verify abnormal Pap results, justified by 18/22 (81.8%) negative cases after review. 5)ASCUS, suggestive of HPV with negative HPV DNA correlates with post-menopausal pseudokoilocytosis. 6)ASC-US, cannot rule out HSIL, with HPV negativity, could represent metaplastic epithelium with atypia.

PP1-268
ASSESSMENT OF PAP SMEAR QUALITY
Dussadee Sakonlaya[1], Luckakul Yodharma[2]
[1] Division of Pathology, Faculty of Medicine, Thammasat University, Pathumthani, Thailand
[2] Pathology Unit, Thammasat University Hospital, Pathumthani, Thailand

Background: Papanicolaou (Pap) smear is widely accepted as the important screening test for detection and prevention of cervical cancer which is one of the most common cancer worldwide. As smear quality may limit the interpretation, the Bethesda System recommends that evaluation of specimen adequacy should be included in Pap smear reports. Such feedback to clinicians is useful for improving the quality of sampling and smear preparation techniques, resulting in better specimen quality and

interpretation. This study aimed to evaluate quality of Pap smears in terms of specimen adequacy and contribution of factors affecting smear quality. Methods: A retrospective analysis of 377 Pap smears acquired from the OB-GYN out-patient department at Thammasat University Hospital was performed. Cervical smears were obtained by gynecologists and interns using Ayre spatula as sampling devices. Slides were processed according to standard Papanicolaou staining protocol. Adequacy of each smear was interpreted by a pathologist (D.S.) using the 2001 Bethesda System criteria. Results: Of 377 smears, 374 (99%) were classified as 'satisfactory for evaluation', and 3 (1%) as 'unsatisfactory for evaluation'. All of unsatisfactory samples were due to inadequate epithelial cell yield. In the group of satisfactory smears, 302 (81%) showed limited adequacy mainly caused by absence of endocervical cells (EC)/transformation zone (TZ) component (69%); thick areas (23%); obscuring inflammation or blood (22%); and airdry artifact (15%). Number of factors affecting adequacy of each smear varied from 1 to 4. 64% of smears with limited adequacy related to single factor, including absence of EC/TZ (62%); obscuring elements (13%); airdry (11%); and thick areas (8%). 32% of smears with limited adequacy were affected by 2 factors. Conclusion: In the present study, most Pap smears are satisfactory for evaluation. However, adequacy limitations of the smears are common, predominantly due to absence of EC/TZ component. All of unsatisfactory samples in this study relate to inadequate epithelial cell yield.

PP1-269
TRICHOMONAS VAGINALIS AND BACTERIAL VAGINOSIS

Emine Korkmaz, Sinan Beksac, Gamze Mocan Kuzey, Sayeste Demirezen
Hacettepe University, Ankara, Turkey

Background: To determine whether there is a relationship between the presence of Trichomonas vaginalis (Tv) and bacterial vaginosis (BV) in cervicovaginal smears. Methods: Cervicovaginal smears taken from 800 women were stained with Papanicolaou technique and examined cytologically to determine bacterial vaginosis and Trichomonas vaginalis. Statistical analysis was performed with the chi-square test using the SPSS programme. The limit for statistical significance was p=0.05. Results: According to cytological examination, 51 of (6.37%) 800 women were diagnosed as having Trichomonas vaginalis [Tv(+)].Clue cells and free cocci without Döderlein bacilli were observed in 18 of (44.4%) 51 Tv (+) cases. These 18 Tv (+) BV(+) cases were evaluated as Group 1. Fourty of 749 Tv(-) smears (5.3%) were also positive for bacterial vaginosis and these 40 Tv (-) BV(+) cases were evaluated as Group 2. There was a statistically significant correlation between the two groups ($p<0.05$). Conclusion: It could be possible that Tv might create an anaerobic environment, thereby changing the vaginal flora and this flora becomes a more suitable milieu for growing of anaerobic microorganisms. It can be postulated that Tv might be the most important protozoan that contribute the overgrowth of BV-related microorganisms.

PP1-270
CYTO-HISTOLOGIC CORRELATION OF CERVICAL INTRAEPITHELILAL NEOPLASIA; OUR EXPERIENCE

Alenka Repše Fokter
Dept for Pathology and Cytology, Celje General Hospital, Celje, Slovenia

Background: Cytology screening interpretations define which women require focused clinical attention and histologic examination. Cyto-histologic correlation is an important determinant of quality control in cervical cancer screening. Methods: We compared cytologic interpretations in Pap smears with all representative cervical biopsy specimens (542 cases) which were processed at our department in the year 2006. We calculated the degree of agreement for negative cytologic interpretations, for low grade squamous intraepithelial lesions and for high grade squamous intraepithelial lesions. Results: We achieved 79% agreement for normal cytologic interpretations and 55% agreement for reactive changes. The cyto-histologic correlation of low grade squamous intraepithelial lesions was 60% and of high grade lesions 82%. The correlation between atypia/severe atyipa of glandular cells in Pap smears (15 cases) and pathologic findings on biopsy specimens was 73% if both, glandular (40%) and squamous (33) changes were considered. The average accuracy was 60% and accuracy within one degree was 93,5%. Conclusion: Our results showed that the cyto-histologic correlation was better for high grade squamous lesions than for low grade squamous lesions, which is in concordance with some previous studies.

PP1-271
CYTOLOGY IN FUNGAL KERATITIS

Canan Ersoz[1], H. Aysun Uguz[1], T. Reha Ersoz[2], Meltem Yagmur[2]
[1] Cukurova University, School of Medicine, Dept. of Pathology & Cytology, Turkey
[2] Cukurova University, School of Medicine, Dept. of Ophthalmology , Turkey

BACKGROUND & OBJECTIVES: Fungal keratitis is a supurative and ulcerative infection of the cornea. The disease has a high ocular morbidity and is an important cause of monocular blindness. Rapid detection of the fungi plays a critical role to prevent important complications. The objectives of this study are to evaluate the cytomorphological findings and their contribution to the diagnosis in fungal keratitis. METHODS: A total of 25 corneal scraping and cytobrush smears of 19 (5 female and 14 male) patients were diagnosed as fungal keratitis between 2004 – 2006 at our institute and private clinics. Retrospective analyses of corneal cytology smears was carried out to investigate the cytomorphological findings in smears taken by corneal scraping or cytobrush. All the smears were alcholol fixed and stained with Papanicolaou and PAS stains. RESULTS: The hyphae and / or spores were seen in all 25 smears of 19 patients. However, in most cases hyphae could be seen within the inflamatory exudate or at the edges of the thick corneal epithelial sheets resulting difficulty to discriminate. Three smears revealed low numbers of corneal epithelium while 11 smears had scattered and groups of epithelial cells and 11 smears had sheets of epithelium. Sixteen (64 %) smears revealed inflamatory exudate, 7 smears had a small amount of neutrophils and 2 smears did not have any neutrophils. Amourphous groups of necrotic squamous cells (squame) were seen in 20 (80 %) smears. CONCLUSION: Although positive culture is accepted as the gold standart for diagnosing fungal keratitis, the method has its own limitations such as being expensive and time consuming. Antifungal therapy can be administered when fungal filaments are seen in the corneal smears stained with Papanicolaou and / or PAS. Hyphae intermingled with inflamatory exudate or thick sheets of corneal epithelium seems to be the major difficulty in microscopic examination. Corneal smears revealing squames are highly suggestive for fungal keratitis. However, further investigations to test this finding in other microbial keratitis are needed.

PP1-272
THE USEFULNESS OF CEREBROSPINAL FLUID ANALYSIS IN THE DIAGNOSIS OF PRIMARY PINEAL SEMINOMA PRODUCING BETA HCG

Hannachi Sassi Samia[1], Mezlini Amel[2], Mrad Karima[1], Allani Bassem[2], Rifi Hela[2], Driss Maha[1], Dhouib Rym[1], Abbes Imen[1], Makadem Abdejabbar[1], Ben Romdhane Khaled[1]
[1] Department of Pathology Salah Azaeiz Institute, Tunusia
[2] Department of Oncology Salah Azaeiz Institute, Tunusia

The cytologic features of germ cell tumors such as seminoma are sufficiently characteristic to make specific cytologic diagnosis possible in technically high quality smears even when the biopsy is difficult to practice. We report a case of a primary intracranial seminoma producing beta HCG diagnosed by cytology cerebrospinal fluid in a 19 year-old-boy. The tumor was located in the pineal and the suprasellar ventricles. It was associated with a slight elevation of the beta-human chorionic gonadotropin (HCG) serum level (5, 2 mUI/ml) and a high cerebrospinal fluid level of beta-HCG (480 mUI/ml) indicating that trophoblasts cells were present in the tumor. Smears preparations were stained with May Grünwald Giemss (MGG) and hematoxylin and eosin stains. The tumor cells had large round nuclei with dispersed chromatin and one or multiple prominent nucleoli. The cytoplasm was usually scanty, often vacuolated and strongly positive to PAS-stain. Immunohistochemistry on cytologic smears was negative for placental alkaline phosphatase (PLAP). These cytologic features favourite the diagnosis of seminoma with syncytiotrophoblastic giant cells even though none were seen in cytologic preparation. Cytologic features of pineal seminoma are characteristic. So, we can conclude that cytology is performs and plays a great role in the therapeutic management of pineal seminoma particularly when histological verification can not be done.

PP1-273
KARYOCYTOMETRIC CHANGES OF ENDOTHELIUM AORTA AND LUNG ARTERY IN ATHEROSCLEROSIS

Nadejda Solovjeva, Lubov Lysenko, Anatoly Lysenko
Moscow Medical Academy, Moscow, Russia

Objective: We analyzed karyometric parameters 5 heterogeneous types of endothelial cells (EC) of lung artery (LA) and aorta (AO) in view of severity of atherosclerosis. Methods: It was received the imprints fatty streaks, plaques and unaffected surfaces of LA and AO from 5 died patients (age of 35-85 yrs). The samples were stained on Romanovsky-Gimsa. It were measured the area and volume of 2434 EC nuclei of LA and 2627 EC nuclei of AO. Results: Histograms of parameters showed skewing of values aside large and giant nuclei. Over fatty streaks of LA area and volume of nuclei of giant mononuc1ear EC averaged 332 mkm^2 and 4847 mkm^3, binuclear-331 mkm^2 and 5147 mkm^3, trinuclear-426 mkm^2 and 8037 mkm^3, giant multinuclear- 766 mkm^2 and 20347 mkm^3. The area and volume of usual nuclei EC over unaffected LA surface was equaled 101 mkm^2 and 762 mkm^3, respectively. Over LA plaques the average area and volume of nuclei of giant mononuclear EC amounted 283 mkm^2 and 3730 mkm^3, binuclear - 285 mkm^2 and 4286 mkm^3, trinuclear- 351 mkm^2 and 6149 mkm^3, giant multinuclear - 686 mkm^2 and 18133 mkm^3, horseshoe-shape nuclei - 319 mkm^2 and 4391 mkm^3. Over fatty streaks AO the average area and volume of nuclei giant mononuclear EC amounted 304 mkm^2 and 4229 mkm^3, binuclear - 288 mkm^2 and 4509 mkm^3, trinuclear- 403 mkm^2 and 8091 mkm^3, giant multinuclear - 709 mkm^2 and 19359 mkm^3, horseshoe-shape nuclei - 248 mkm^2 and 3042 mkm^3. The EC area and volume over unaffected surface of AO was equaled 103 mkm^2 and 793 mkm^3. Over AO plaques area and volume of nuclei giant mononuclear EC averaged 312 mkm^2 and 4248 mkm^3, binuclear - 332 mkm^2 and 5781 mkm^3, trinuclear - 387 mkm^2 and 7515 mkm^3, giant multinuclear- 676 mkm^2 and 18543 mkm^3, horseshoe-shape nuclei - 239 mkm^2 and 3172 mkm^3. Parameter values of heterogeneous and usual EC nuclei were statistically different. Conclusion: the average area and volume of heterogeneous types of EC nuclei over fatty streaks and plaques is higher than usual EC nuclei over unaffected arterial surfaces. The area excess reached 3-7 times and the volume excess - 5-27 times. The karyometric analysis showed increasing dimensional attributes of EC nuclei as the atherosclerosis progresses. [GTEQ]

PP1-274
TREATMENT ASPECTS OF PLEURAL MESOTHELIOMA IN RELATION TO PATIENT SURVIVAL

Charalampos Charalampidis, J. Angel, D. Gerasimidou, L. Kampas, R. M. Valeri, C. Destouni
Anticancer Hospital of Thessaloniki, Greece

The median survival of patients diagnosed with pleural malignant mesothelioma does not exceed 24 months. This is a retrospective study of all the cases presented and treated in our hospital during the last 10 years. Materials and methods: We examined the follow-up of 32 patients diagnosed with pleural malignant mesothelioma. A fraction of these patients were treated conservatively and the rest were subjected to various surgical procedures. Results: a) Surgical biopsy was performed on 18 patients, which ultimately were treated with chemotherapy after diagnosis was established. The median survival of these patients was 28 months. b) 10 patients were treated with local excision of tumor involved pleura, removal of the adjacent pneumonic parenchyma and adjuvant chemotherapy and radiotherapy. The mean survival in this group of patients was prolonged to 30 months. c) 4 patients under-went external pleural excision of the lung with accompanying excision of the diaphragm and adjuvant chemotherapy. The median survival was 20 months. Results: Even though the biological behaviour varies among histological subtypes of malignant mesothelioma, it is evident that limited surgical excisions accompanied with chemo/radiotherapy cause lower morbidity, such as visceral pain and excessive dyspnoea. More importantly, the survival rate of these patients is raised by 33.3% compared to the survival rate of patients treated with more radical surgical procedures.

FINE NEEDLE ASPIRATION CYTOLOGY OF THE PANCREATIC LESIONS – REVIEW OF THREE YEAR EXPERIENCE

Daniela Kodetova[1], Radan Keil[2], Ludek Hrdlicka[2]
[1] Dept. of Pathology and Molecular Medicine, Charles University Prague, 2nd Medical Faculty and Faculty Hospital Motol, Czech Republic
[2] Gastroenterology, Department of Internal Medicine, Charles University, 2nd Medical Faculty and Faculty Hospital Motol, Prague, Czech Republic

Background: Fine needle aspiration (FNA) cytology represent an increasingly used diagnostic tool in diagnosing the pancreatic lesions, mainly of the pancreatic tumors. In our study, we introduce our experiences with that method in correlation with subsequent histopathological findings. Further, we discuss an unusual case of a cytological diagnosis of a solid pseudopapillary tumor. Methods: Specimen for cytological analysis was obtained from 43 patients using Linear Endoscopic Ultrasound, Hitachi Pentax. Cytologic smears stained by standard Giemsa stain were analyzed in each case. Results: From the total 43 specimens, in 23 cases (53.5%) the tumor, suspected from MRI examination, was not present in the smear. From them, however, pancreatic cancer was disclosed in three cases in the surgical specimen by histopathological analysis. In the 19 cases (44.2%) the pancreatic cancer was suspected by FNA and it was verified by the subsequent histopathological examination in 8 cases. In one case, the suspected pancreatic tumor was not confirmed by histopathology and the final diagnosis was chronic pancreatitis. One case was cytologically suspected as a solid pseudopapillary tumor of pancreas, diagnosis of which was verified also by histology and immunohistochemical analysis. Conclusion: Fine needle aspiration (FNA) cytology represents a powerful tool helpful in differential diagnosis of pancreatic lesions, even in case of uncommon disorders. Supported by the Grant of Ministry of Health of the Czech Republic IGA 1A/8611-3 and VZ FNM 00064203.

PP1-277
SPINDLE CELL LIPOMA OF THE PAROTID GLAND
Fotios Chatzinikolaou[1], Barbara Christophoridou[1], Persefoni Xirou[1], Melanie Koumpanaki[1], George Koloutsos[2], Frideriki Patakiouta[1], Georgia Zoupoudi[1]
[1] Department of Pathology1, "Theagenion" Cancer Hospital, Thessaloniki, Greece
[2] Department of Oral Maxilofascial2 ,"Theagenion" Cancer Hospital,Thessaloniki,Greece

Back ground: Spindle cell / Pleomorphic lipoma is a circumscribed subcutaneous lesion, occurring typically on the neck and back,usually of males. The parotid gland is an uncommon site for this distinct histological variant of lipoma. Report of the case: A 74 years old man presented in December 2006, with a long history of an asymptomatic swelling of his left chick. The computed tomographic scan revealed a tumor with fatty density located in the parotid gland. Superficial parotidectomy was performed. The specimen received for pathologic analysis, was a 7X6X3 cm resection of the parotid gland. A well circumscribed, encapsulated soft, fatty tumor, 2.5 cm in diameter, was found in the gland. Microscopic examination revealed lobules of mature adipocytes and bland, mitotically inactive spindle cells arranged in parallel registers between them. Among them "floret like" multinucleated giant cells were also found as well as large numbers of mast cells. There was also prominent myxoid change of the stroma. Immunohistochemically spindle cells were positive for CD34 antigen and S-100 protein. Based on the above mentioned pathologic and immunohistochemical findings, the diagnosis was spindle cell / pleomorphic lipoma. The patient is doing well, four months after the surgical excision.

CARBOWAX THIRTEEN YEARS OF EXPERIENCE
Ericka Sagrario Peña Mirabal, Euridice Robles Pérez
Instituto Nacional de Enfermedades Respiratorias, Mexico

CARBOWAX Thirteen years of experience in our profession we have to count on with an excellent preservation sample material. In our cytological archives we collected random samples, dated between 1993 - 2005. The selected material were sputum 16, bronchial lavage 27, pleural fluid 7, saliva gland secretion 1. We made the cytology diagnosis and compare it with the previous diagnosis and cellular material. We found identical cellular material and a 100% match in diagnosis in all samples. Since 1980 we have used Saccomano's fixative as a preservation media solution for all our cytological samples. Carbowax is capable to conserve cellular elements and microorganism thought many years. It is easy to manufacture, inexpensive and it does not require refrigeration.

PP1-279
ALCOHOLIC FIXATIVE AND QUALITY OF NUCLEIC ACIDS
Alessia Gazziero, Marta Zoletto, Roberta Salmaso, Vincenza Guzzardo, Roberto Salmaso, Ambrogio Fassina
Dept. of Pathology, University of Padova, Italy

Background: In surgical pathology, the large majority of tissues are formalin fixed and paraffin embedded (PET) as a routine procedure. This traditional method of tissue preservation retains tissues integrity for future analyses, such as immunocytochemistry (ICC), but it compromises the quality and integrity of nucleic acids essential for biomolecular analyses. In routine practice with the advent of new diagnostic tools and therapeutical strategies, the clinicians, the pathologists and the researchers feel the urgent need of a practical fixative in order to simultaneously maintain good morphological qualities of tissues for light microscopy and ICC, along with satisfactory length of nucleic acids. We present the comparison of an alcoholic-based fixative (FineFix, FF, Milestone, Italy) to formalin for cytological material obtained by fine-needle aspiration (FNA) and biopsies. Methods: 50 samples from true-cut biopsies or FNA were divided into two parts: a part was fixed in FF (group A) and the other in formalin (group B) and both of them, subsequently, were paraffin embedded. ICC with a panel of 10 commonly employed antibodies was conducted under the same conditions for the group A and B. DNA and RNA were obtained from A and B tissues by phenol/chloroform extraction, resuspended in deionised water and loaded on agarose gel to check the quality of nucleic acids and RT-PCR and PCR analyses were performed to assay their integrity , using beta-actin as house-keeping gene. Results: DNA extraction resulted more efficient in group A samples compared to group B tissues. In particular, beta-actin fragment amplification of 815 bp was obtained from group A DNA, while no amplification resulted from group B DNA. DNA and RNA yield and purity improved at least 10-folds in group A compared to group B. ICC results did not demonstrate significant differences, as well as for routine stains. Conclusions: This formalin-free fixative FF demonstrated to be suitable not only for tissue preservation, but also for DNA and RNA extraction for molecular purposes. DNA, RNA and proteins are well preserved, with a quality comparable to fresh tissues and the use of this fixative allows extensive molecular analysis of biological samples, than from formalin. Moreover, laboratory safety is better achieved with formalin free procedures.

PP1-280
HYBRID CAPTURE (CH-2) VS. PCR (KIT CLINICAL ARRAYS PVH)
Sofia Loureiro Santos[1], Ema Dias[1], Ângela Pista[2], Ana Moriés[1], Maria José Brito[1]
[1] Hospital Garcia de Orta, Portugal
[2] Instituto Ricardo Jorge, Portugal

Background: HPV infection is common in general female population. Though only some types of HPV seem to correlate with cervical cancerigenesis. Different methods are available to typify HPV. Aim: To compare Hybrid Capture (CH2, Digene) with CLINICAL ARRAYS Papillomavirus Human kit (kCA da ALFAGENE) in thin prep cervical cytology HPV tipification. Material and methods: HPV was typified, both by CH2 and kCA, in 181/744 cervical cytology specimens, selected according to our hospital protocol. We analysed a) High risk (hr), probably high risk (phr), undetermined risk (ur) and low risk (lr) HPV types; b) co infection viral types; c) cytological diagnosis (CD) and HPV types. When there was a discrepancy DNA was sequenced. Results: 1. Out of 181 cases 37% where positive by CH-2 and 60.7% by kCA: 41,4% - one type of HPV (27 HPVhr, 6 HPVphr; 8 HPVlr e 5 HPVur; 57,6% - co infections of 2 to 7 types, 79.6% had one or more HPVhr types. The more frequent types were: HPVhr [16 (31), 51 (21), 33 (20) e 58 (11)], HPVphr 53 (25); HPVlr [70 (21), 61 (17) e 81 (11)]. 2. In 92 cases that had no cytological lesion, 9 had one HPVhr type, 2 one HPVphr and 21 co infections (HPVhr, HPVphr, HPVur e HPVlr) by kCA. In 74 cases that had CH-2 negative and no cytological lesion 26 had HPV infection by kCA (10 HPVhr, 6 HPVphr with one or more types). 3. All CD with ASC-H and HSIL had HPVhr and /or co infections. 4. In 24 cases DNA was sequenced: only one was discordant (kCA(-)/seq. HPV16). Conclusions: kCA is a more sensitive method than CH-2 in the detection of HPVhr, HPVphr infections and co infections in cytological specimens.

PP1-281
IS THE CYTOLOGICAL DIAGNOSIS OF CHROMOPHOBE RENAL CELL CARCINOMA POSSIBLE? A REPORT OF EIGHT CASES

Jose Jimenez-Heffernan[1], Eva Tejerina[1], Pilar Gonzalez-Peramato[2], Blanca Vicandi[2], Alvaro Serrano[3], Clara Salas[1], Ana Perez-Campos[3]
[1] University Hospital Puerta de Hierro, Spain
[2] University Hospital Puerta de Hierro, Spain
[3] University Hospital Guadalajara, Spain

BACKGROUND: There is an increasing tendency to perform conservative surgical procedures and preoperative chemotherapy for selected cases of renal neoplasms. Such therapeutic approaches demand a precise preoperative diagnosis. Both, fine needle aspiration and intraoperative cytology are increasingly used to evaluate renal tumors, preoperatively or during surgery. Due to their different therapeutic management, the cytologic recognition of chromophobe renal cell carcinoma (CRCC) and its distinction from conventional clear cell carcinoma and oncocytoma is particularly important. The purpose of this study is to review our experience with eight cases of CRCC. The cytologic descriptions of this entity are still few, and information concerning the diagnostic capacity of cytology is needed. METHOD: Eight cases of CRCC evaluated preoperatively using FNA cytology (five cases) or scrapping cytology during intraoperative studies (three cases) were selected. The cytologic samples were air-dried or alcohol fixed and stained with Diff-Quik and Papanicolaou, respectively. The expression of vimentin was evaluated in four cases using immunocytochemistry that was performed in alcohol-fixed material. In all cases a complete histopathologic and immunohistochemical study was available. RESULTS: Neoplastic cells were arranged mainly in small, discohesive monolayered groups and single cells. These cells were heterogeneous creating a pleomorphic image. A transition from small to large cells was seen. All of them exhibited large amounts of ill-defined cytoplasm. Its quality was granular with clear spaces that in many cases resembled perinuclear halos. Microvacuolizated or dense, homogeneous cytoplasms were uncommon. Nuclei was pleomorphic but no intense atypia was seen. Binucleation and marginal nuclear location was a common event. Some cells showed a very large amount of cytoplasm and relatively small nuclei, determining a balloon-like image. Necrosis, basal membrane or other stromal material were not present. Vimentin was not expressed in the four cases analysed. A precise cytologic recognition was possible in our last five cases. CONCLUSION: There is increasing evidence that a cytologic diagnosis of CRCC is possible. In our experience, histopathologic features of CRCC were well reflected in cytologic samples allowing in most cases a specific recognition. In our cases the only differential diagnosis considered was clear cell carcinoma, since differentiation from oncocytoma was always possible. Cytology can be specially helpful in the evaluation of intraoperative samples.

PP1-282
ENDOBRONCHIAL ULTRASOUND-GUIDED TRANSBRONCHIAL NEEDLE ASPIRATION FOR MEDIASTINAL STAGING OF LUNG CANCER.

Lara Pijuan[1], Núria Juanpere[1], Albert Sanchez[2], Sara Albert[1], Emilia Romero[1], Josep Lloreta[1], Sergi Serrano[1]
[1] Department of Pathology[1] and Respiratory Medicine[2], Hospital del Mar-IMAS., Spain
[2] Autonomous University of Barcelona and Pompeu Fabra University. Barcelona, Spain

Background: Staging of the mediastinum in lung cancer is essential for patient management. Mediastinoscopy is an invasive method with a certain level of morbidity. Endobronchial ultrasound (EBUS) is a new minimally invasive method in which a flexible ultrasound miniprobe is inserted through the working channel of the flexible bronchoscope, which helps to localize mediastinal lymph nodes and allows a transbronchial needle aspiration (TBNA). Methods: The aim of the current study was to evaluate the usefulness of EBUS-guided TBNA in the staging of lung cancer in the 50 first cases done at our institution from March 2006 to February 2007. EBUS-guided TBNA was performed using the 20 MHz ultrasound miniprobe (UM-BS 20-26 R) connected to an ultrasound unit (EU-M60 Olympus). The method, needle features, and cytopathologist were the same throughout the study. The aspirated material from 3-4 passes was smeared onto glass slides, fixed in alcohol and stained with the Papanicolaou method. Specimens were categorized as positive (presence of tumor cells), negative (lymphocytes but no tumor cells), or inconclusive (poor cellularity or only bronchial cells). Final diagnosis was based on mediastinal biopsy results, surgery and/or clinical follow-up. Results: EBUS-guided TBNA was used to sample 50 lymph nodes from 41 patients with mediastinal lymph nodes that were suspicious by CT scan or PET. A positive cytological diagnosis was achieved in 7 cases (14%). Of these, 5 showed non-small cell carcinoma, 1 case contained atypical cells and 1 metastatic adenocarcinoma. Specimens from 18 patients (36%) were recorded as negative (one of them was an unsuspected granulomatous lesion) and 25 (50%) as inconclusive. Conclusions: EBUS-guided TBNA is a safe and useful method for lymph node staging in patients with lung cancer. A positive diagnosis avoids more invasive staging procedures. To improve the inconclusive cases (in our study 50%) immediate interpretation by an on site cytopathologist would be necessary to confirm adequate material.

PP1-283
DIAGNOSIS OF CYSTIC LESIONS OF THE JAW BY FINE NEEDLE ASPIRATION CITOLOGY

Vasile Liliana Eleonora.
University of Medicine-Pharmacy, Romania

Background: The phenotypic diversity of primary intraosseous jaw cystic lesions poses some clinic, radiological and histopathologic diagnostic difficulties. Cytodiagnosis by fine needle aspiration (FNA) technique can be an evaluation method of the tumours vs tumor-like conditions of intraosseous jaw lesions. Method: Our study included 27 FNA of intraosseous jaw cystic lesions performed at the oral and maxillo-facial clinic from Timisoara, between 2005-2006. Cytodiagnosis was correlated with histodiagnosis. Results. Aspirated samples were adequate for evaluation and allowed citodiagnosis in 24 of 27 cases. In 10 of 24 cases malignant cells were found. Cytodiagnosis was confirmed by histodiagnosis in all these 10 cases (100% accuracy). Cytodiagnosis of benign lesions was confirmed in 9 of 14 cases (65%). Difficulties in distinguishing between benign vs malign were met in odontogenic tumors. Conclusion. Differentiation is a prerequisite to treatment becouse the management differs in each lesion.

PP1-284
IS IT POSSIBLE TO START THE TREATMENT BASED ON IMMEDIATE CYTOLOGIC EVALUATION (IMPRINT AND/OR SMEAR) OF CORE NEEDLE BIOPSY OF THE SPINAL LESIONS?

Turkan Rezanko[1], Hasan Kamil Sucu[2], Mine Tunakan[1], Betul Bolat[1], Mustafa Minoglu[2]
[1] Izmir Ataturk Training and Research Hospital, Department of Pathology, Turkey
[2] Izmir Ataturk Training and Research Hospital, Department of Neurosurgery, Izmir, Turkey

BACKGROUND: Core needle biopsy are widely used to diagnose spinal lesions. Final histopathological report of the specimen usually could be given after several days. In some patients these several days delay hamper the acute treatment. The aim of this study was to determine the value of immediate

cytological evaluation of the core needle biopsy regarding to provide a reliable immediate diagnosis which guide the correct treatment strategies in spinal lesions. METHOD: The cytological materials (imprint and/or smear) of the 213 core needle spinal biopsies which were prepared immediately after biopsy, in the Izmir Ataturk Training and Research Hospital during the period January 2003 - November 2006 were analyzed retrospectively. Cytological assessments were compared with both histopathological analysis and final clinical diagnoses obtained by open surgery or clinical follow up. RESULTS: Of 213 cases, a final diagnosis could be reached in 176 patients. 101 of these had both histological and cytological material that formed the backbone of current study. According to final diagnoses 40 patients had infections, 59 patients had neoplasms and 2 patients had no pathology. The positive predictive values of diagnoses of malignancy and infection on cytology were 1 and 0.93 respectively while the values for histology were as follows 1 and 0.97 respectively. The sensitivity of diagnoses of malignancy and infection on cytology were 0.8 and 0.68 respectively while the values for histology were as follows 0.78 and 0.75 respectively. In the spinal metastases positive predictive value was 0.97 for cytological and 1 for histological assessments. In the subgroup of tuberculosis infection, lymphoma and plasmositoma positive predictive values of both cytological and histological assessments were 1. CONCLUSIONS: Immediate cytological evaluation of core needle biopsy is a useful and reliable tool to assess the spinal lesions that necessitates urgent treatment. In case cytological specimen disclose the diagnose of spinal metastasis, lymphoma, plasmositoma or tuberculosis, the treatment of the patient may be started without waiting the result of the histological examination.

PP1-285
DIAGNOSTIC VALUE OF FNA APPLICATION IN THE CYTOLOGICAL EXAMINATION OF THE THYROID GOITER

Jelena Sopta[1], Svetislav Tatic[1], Marija Havelka[1], Vesna Mijucic[2], Dejan Minic[3]
[1] Institute of Pathology, Schoool of Medicine, Belgrade, Serbia
[2] Institute of Oncology, Belgrade, Serbia
[3] Institute of Pathology, School of Medicine, Belgrade, Serbia

Introduction: FNA is very useful method in cytological diagnosing of different lesion in the thyroid gland, among them is benign goiter. In consideration of the goiter; it is the most frequent lesion in the thyroid tissue, significance of FNA as a diagnostic method become greater. Material and methods: In the period of 2 years citologically was analyzed 600 aspirates from the thyroid lesions. Aspirates was stained with: hematoxylin-eosin (HE), May-Grunwald-Giemsa (MGG) and Prussian blue. In patients with cytological diagnosis goiter we analyzed: 1) sex distribution, 2) age distribution, 3) correlation between clinical and cytological diagnoses and 4) goiter classification in accordance with cytological characteristics. Results: From 600 analyzed aspirates 414 cases (69%) were diagnosed as goiter. This lesion was five times frequent in females then males (348 women, 66 men). Statistically by X^2 test was confirmed high significance for arising goiter (X^2=192,08; p<0,005) in females. In our examination the most patients were old between 41 and 50 years. In the opposite, the least patients (only 6) were younger then 20. The youngest patient was 13, and the oldest was 78 years old (the average years were 46,5). Statistically by X^2 test was confirmed high significance for arising goiter (X^2=494,30; p<0,005) according to the ages of life. From 414 cytological confirmed goiters 222 had clinical diagnosis “nodular goiter”, 127 “diffuse goiter”, Our conclusions are: 84% of cytological diagnosed goiters had the some clinical diagnosis, in only 1,5% of all patients clinically tumor was suspected. We confirmed high correlation between clinical and cytological diagnosis. According to the cytological characteristics all goiters was classified in 2 categories: goiters with and without degenerative changes. From all cases in 174 (42%) we found degenerative changes-hemorrhage. Without hemorrhage were 240 goiters (58%). X^2 test confirmed statistical significance in appearing such goiter, but it is not high statistical significance (X^2=10,4;p<0.01). Conclusion: FNA permits a substantial reduction or even elimination of other diagnostic procedure, such as imaging, with consequent saving in time and money. Furthermore, benign cystic lesion may be cured by FNA (a diagnostic and unexpected therapeutic value of FNA).

PP1-286
THE RELATION BETWEEN QUALITY OF THE CYTOLOGICAL SMEARS AND STATUS OF THE MEDICAL CARE UNIT TAKING A CERVICAL SPECIMEN FOR CYTOLOGY. THE STUDY OF 33842 SMEARS EVALUATED IN 2006 DURING PROPHYLACTIC SCREENING PROGRAM “CERVICAL CARCINOMA”

Dariusz Lange, Dorota Ponikiewska, Ewa Stobiecka, Bogna Szczesniak-Klusek, Agata Stanek, Barbara Lange, Andrzej Czuba
Institute of Oncology, Poland

Background. The quality of the cytological smears is critical for proper evaluation according to Bethesda system. It seems that worse smears quality has a direct influence on quantity of ambiguous diagnosis (ASCUS). The objective of this study was the assessment of the correlation between the quality of the smears and medical unit experience in screening program examinations (the quantity of smears taken) or the type of the management (public v. private). Verification of the thesis about correlation of the quality of the smears and the percentage of ASC-US diagnosis was an addition aim. Methods and results: 33842 cytological smears were evaluated in prophylactic program “ Cervical Cancer” in PTD OC between January and December 2006. The optimal quality (AI) was noted in 15091 (44,59%) cases. 790 (2,33%) smears were evaluated as insufficient for diagnosis, the percentage ranged from 0% to 19% depending on medical unit. 447 (1,32%) ASC-US and 115 precancerous lesions and cancers were diagnosed. The lowest medium percentage of insufficient smears for diagnosis (1,6%) was observed in medical units taking between 100 and 400 smears. Over twice more frequently (3,31%) insufficient smears for diagnosis were evaluated in material from medical units preparing more than 400 smears. Higher percentage of insufficient for diagnosis smears was connected with a decrease of the percentage of ASC-US diagnosis. Good quality of the smears correlated with positive diagnosis (HSIL, carcinoma). Over twice lower percentage of insufficient for diagnosis smears and slight higher percentage of positive diagnoses (HSIL, carcinoma) was observed in material from public medical units comparing the private one. Conclusions: The quality of the smears is higher in medical units with low and medium quantity of the smears contracted and in public medical units. Worse smears’ quality is connected with lower percentage of neoplastic lesions and paradoxically with lower percentage of ASCUS.

PP1-287
FINE-NEEDLE ASPIRATION BIOPSY FINDINGS IN SCLEROSING POLYCYSTIC ADENOSIS OF THE PAROTID GLAND

Demet Etit[1], Ben Z. Pilch[1], Rebecca Osgood[2],William C. Faquin[1]
[1] Department of Pathology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA
[2] Cambridge Health Alliance, Harvard Medical School, Cambridge, MA, USA

Introduction: Sclerosing polycystic adenosis (SPA) is a recently described, rare lesion of the salivary gland analogous to fibrocystic disease of the breast. Recognition of this benign entity is important since the differential diagnosis includes other more common benign and malignant salivary gland neoplasms, particularly mucoepidermoid carcinoma and tumors with cystic

and oncocytic features. While the histomorphology of SPA is well documented, there is only one other cytologic description of SPA in the English literature. Case: We describe the fine-needle aspiration biopsy (FNAB) findings in a case of SPA of the parotid gland in an 84 year-old woman. The aspirate was characterized by flat cohesive sheets of epithelial cells with moderate amounts of finely granular oncocytic cytoplasm and enlarged round nuclei with indistinct nucleoli. Some epithelial groups formed glandular structures with lumens, and the background contained small amounts of delicate mucoproteinaceous material. Occasional markedly vacuolated cells were present as well as many cells with apocrine change manifested by well-defined apical snouting. Familiarity with the cytomorphologic features of SPA, including its characteristic apocrine changes, is important for distinguishing it from other more clinically significant salivary gland lesions.

[2] Internal Medicine Department Hospital de Tortosa Verge de la Cinta, Spain
[3] Digestive Unit Hospital de Tortosa Verge de la Cinta, Spain
[4] Microbiology Department Hospital de Tortosa Verge de la Cinta, Spain
[5] Intensive Care Unit Hospital de Tortosa Verge de la Cinta, Spain

INTRODUCTION: Strongyloides stercoralis (Ss) is an endemic nematode of the Mediterranean countries. The main risk factors for infection in humans are being a farmer of advanced age (79%) and having worked barefoot in contact with soil of irrigated areas. 13% of patients develop severe forms of disease and 4% die. In the Spanish Mediterranean coast, the delta of Ebro River is a wet zone with similar environmental conditions to the area of Gandia in the Valencian community, where Ss has been found to be endemic. AIM: To identify the number, type of diagnostic samples and clinical context of cases of Ss diagnosed at the Pathology Service of the Hospital de Tortosa Verge de la Cinta which is the referral hospital of Ebro Delta. METHODS: We identified all cases diagnosed of Ss at surgical pathology department from 1990 up to now using the SNOMED code (E 45770, E45780). After identifying the cases, we revised the slides and the clinical records. RESULTS: 10 patients, 9 men and 1 woman with a mean age of 70 years (range: 63-80 y.) were identified. In 4 patients, the Ss identification was made by cytology (2 patients in a sputum, 1 patient in a bronchial washing (BW) and a sputum, and 1 patient in a pleural fluid and a BW), in 5 patients by biopsy (2 from stomach, 2 from duodenum and 1 from colon) and in one case of hyperinfection, the Ss was discovered in the necropsy. Subjacent diseases were pulmonary carcinoma (n=3), lymphoma (n=1), advanced chronic obstructive pulmonary disease (COPD) (n=2), Helicobacter pylori gastritis (n=3) and hypertension and mental retardation (n=1). No patient was affected by human immunodeficiency virus infection. CONCLUSIONS: In our hospital, the pathological diagnosis of Ss has been mainly made in men of advanced age who were affected by a neoplasm or an advanced COPD. In 40% of the cases, the parasites were identified in a cytological study, mostly from respiratory secretions and in, one case, in a pleural fluid. In 50% of the cases, it was identified in a biopsy of duodenum, stomach or colon. Death directly related with a Ss hyperinfection was only observed in a case (10%). (PI 04/1440, 04/1467, 05/1527)

PP1-289
WHICH HEMATOXYLIN FORMULA IS THE BEST FOR LIQUID-BASED CYTOLOGY?

Fatma Akgul, Funda Eren, Rengin Ahiskali
Marmara University School of Medicine, Department of Pathology, Istanbul, Turkey

BACKGROUND: The most important element of a perfect Papanicolaou stain is hematoxylin. Especially for malignant serous effusions, diagnosis depends heavily on the malignant nuclear features. Many studies in the literature evaluated the best nuclear stains for conventional smear techniques. In the last decade, liquid-based cytology (LBC) emerged as an alternative to conventional cytopreparatory methods. However, in contrast to conventional techniques, studies on the applicability of hematoxylin formulas suitable for LBC are absent. We aimed to examine and compare the performance of various hematoxylin formulas for LBC of body cavity fluids. METHOD: Total of 168 LBC slides were prepared from two different malignant effusions. The slides were coded and stained with 7 different alum hematoxylin formulas(Harris hematoxylin, Mayer hematoxylin, Carazzi hematoxylin ,Lillie hematoxylin,Gill I hematoxylin, Gill II hematoxylin and Gill III hematoxylin) followed by standard classical Papanicolaou stain. All slides from were evaluated semiquantitatively for the visibility of nuclear membrane, chromatin structure, nucleoli, cytoplasmic staining, and background staining. The slides were reviewed independently by two pathologists and one student of cytotechnology. General Linear Model Univariate Analysis of Variance is used to analyze data among hematoxylin types and between graders. RESULTS: For mono-layered smears, hematoxylin Carazzi and Mayer were found to be significantly better than the other formulas ($p<0,001$). In the presence of 3-dimensional configurations seen in metastatic adenocarcinomas, there was no statistically significant difference among hematoxylin types. There was a statistically significant difference among graders in the presence of such clusters. Studies have suggested that Gill hematoxylins are the best for conventional cytology while in our study, they fared among the worst for LBC. Slides stained with Carazzi hematoxylin had the highest quality nuclear membrane and chromatin patern staining, with visible nucleoli, transparent cytoplasm and clean background. An additional advantage is that, it requires a shorter staining time compared to the other hematoxylins. CONCLUSION: Our findings indicate that for the LBC of serous effusions, application of Carazzi hematoxylin gives the best results.

PP1-290
A COMPARATIVE STUDY WITH CONVENTIONAL SMEARS AND LIQUID-BASED CYTOLOGY FOR DIAGNOSTIC PERFORMANCE

Aysun Uguz[1], Canan Ersoz[1], Emine Bagir[1], Cuneyt Evruke[2], Mehmet Ali Vardar[2]
[1] Cukurova University, Medical School Dept. of Pathology, Adana Turkey
[2] Cukurova University, Medical School Dept. of Gynecology and Obstetrics, Adana Turkey

Objectives: For over 30 years, screening for cervical cancer has used the conventional Papanicolaou smear. Despite limited accuracy of the test the incidence of cervical cancer has fallen substantially. Liquid-based cytology (LBC) has since been developed as an alternative to conventional cytology. The objective of this study is to compare the diagnostic performance of cervical smears prepared by conventional methods and liquid based cytology procedure. Methods: Cervical smear samples from 540 randomly selected cases from women which admitted to the Gynecology outpatient clinics of the Cukurova University Hospital were examined at the Pathology Department of the same hospital. Conventional Papanicolaou smear (CP) and liquid-based cytology (Papspin-PS) were taken from same woman

simultaneously. Before gynecologists prepared the LBC procedure they spreaded the CP with one side of the cervical brush tool of the PS equipment. Then the remainder of the cells on the brush were put in to the container of the PS. Two pathologists evaluated the smears. The results were evaluated in terms of the Bethesda III classification. Statistical analysis was done according to the CP results as a golden standart. Results: From the standpoint of epithelial cell abnormalities, sensitivity and specificity rates of the PS were 42.8% and 99.8% respectively. Positive predictive value (PPV) was 75.0% and negative predictive value was 99.2%. According to the adequacy, the PS sensitivity rate was 33.3% and specificity was 95.9%. The PPV and NPV of the endocervical and/or metaplastic cells were calculated as 99.2% and 9.3% respectively in PS. Conclusion: Liquid-based cytology is reported to increase the sensitivity of cervical cytology and the proportion of slides that are satisfactory for assessment, in comparison with conventional cytology. Although some countries have changed to liquid-based cytology for cervical screening, controversy remains. Some meta analysis on this subject is claimed that new technology will not be the answer to the remaining incidence and mortality rates of cervical cancer. At this point, despite the confident results of larger studies and the preparing techniques that may have affected the PS; the results of our study do not show an improvement concerning increased rate of specimen adequacy and higher sensitivity to detect epithelial cell abnormalities in LBC.

PP1-291
ENDOSCOPIC BILIARY TRACT BRUSH CYTOLOGY

Isin Soyuer[1], Fatma Tokat[1], Arzu Tasdemir[1], Sebnem Gursoy[2], Nevzat Ozcan[3]
[1] Erciyes University Medical Faculty Pathology Department, Turkey
[2] Erciyes University Medical Faculty Gastroenterology Department, Turkey
[3] Erciyes University Medical Faculty Radiology Department, Kayseri, Turkey

Objective: Endoscopic bile duct brushing (EBDB) is performed in patients who have pancreaticobiliary disease to differentiate benign from malignant biliary strictures. Study Design:The study included 40 patients with bile duct obstruction or pancreatic mass who underwent EBDB and follow-up surgery or biopsy between 2006 to 2007 years. Results: Seventeen (42.5%) of these cases were positive for malignancy in both EBDB and follow-up surgical biopsy; nine cases (22.5%) were negative in both EBDB and follow-up surgical biopsy specimens. Seven cases 17.5%)were negative in EBDB cytology but were positive in the surgical or biopsy specimens (false-negative). Our sensitivity rate was 70.83% and specificity rate 100%. Conclusion: Endoscopic brushing is a safe diagnostic procedure for the evaluation of biliary tree lesions. Small, three-dimensional epithelial clusters with marked atypia signify malignancy and warrant the diagnosis of a malignant neoplasm even when only one or two such clusters are seen in the smears. Single cells, cytoplasmic vacuoles and prominent nucleoli are not essential for a diagnosis of malignancy.

PP1-292
HOW MANY WOMEN WITH CARCINOMA OF THE CERVIX UTERI HAVE NOT BEEN PROTECTED BY THE PROGRAMMED SCREENING IN THE NETHERLANDS? AN AUDIT OVER 2005

F. Van Kemenade
Dep of Pathology VUmc Amsterdam, The Netherlands

Aim An audit of cervical carcinoma is important for quality control in screening programmes to gain insight into the relation between having been screened and incident carcinomas. Previously, others showed that in women aged 30-65 797 (55%) women had never been screened at all prior to the diagnosis of cancer. The other 661 (45%) did have a smear (either opportunistic of programmed) any time prior to the diagnosis of cancer. From these 661 women, only 285 (19% of all the 1458 cases) had been screened in a programme within one round prior to their diagnosis. We addressed the nationwide databases to measure whether this small fraction of 19% was still applicable over the year 2005. Method Query nr 506 into the national database PALGA counted 629 squamous- or adenocarcinoma cases of the cervix uterus in women 28-67. Prior history of all these cases going back to 6 years (coinciding with screening interval in the Netherlands) was obtained based on matching records. Screen smears could be identified and further divided into invitational versus non-invitational smears and further subdivided on the basis of their conclusion/ advice. Smears obtained with 2 weeks of the cancer diagnoses were excluded, being very probably part of the diagnostic work for carcinoma, i.e. not a lead-smear. Results. Of the 629 women with carcinoma of the cervix, 220 (35%) had never been screened at all prior to the diagnosis of cancer in 2005. 409 women had had a cervical smear among whom 289 (46%) an invitational screening smear and 120 (19%) an opportunistic smear. The ‘advice profile’ of the 289 women with proper screening history was as follows: 113 (40% of 289) had a regular advices (within normal limits), while 45 (16%) had had a repeat smear advice based on ASCUS/mild dyskaryosis and the residual 127 (44%) had a colposcopy advice. Conclusion. The percentage of women that had not been protected by the program has been lowered from 55% to 34%, suggesting an improved coverage in the programmed cervical screening in the Netherlands in 2005 as compared to the situation in 1994-1998. Further queries are needed to confirm whether this constitutes a trend or not.

PP1-293
IS THE REST OF THE BLOOD IN THE NEEDLE FOR THE LIVER CORE BIOPSY USEFUL FOR DIAGNOSIS LIVER TUMOR?

Isin Soyuer[1], Fatma Tokat[1], Arzu Tasdemir[1], Sebnem Gursoy[2], Alper Yurci[2], O. Ibrahim Karahan[3]
[1] Erciyes University Medical Faculty Pathology Department, Kayseri, Turkey
[2] Erciyes University Medical Faculty Gastroenterology Department, Kayseri, Turkey
[3] Erciyes University Medical Faculty Radiology Department, Kayseri, Turkey

BACKGROUND/AIMS: Although fine needle aspiration biopsy is a useful tools in the diagnosis of primary malignancies and metastatic lesions of the liver the core biopsy more common use for diagnostic procedure. Histologic and cytologic preparations from the rest of the material in the needle of the liver core biopsy were examined. The aim of this study was to determine efficiency of disease and tumors diagnosed by this method. METHODS: The liver core biopsy and cytologic material were obtained from 45 patients with a variety of liver diseases. The results were compared each other. RESULTS: There were 10 cases (22%) including malign lesion and 30 cases (66%) non-malign diseases. The inadequate materials rate was 11%. Malignant neoplasms were detected by cytology alone in whole of the patients (metastatic carcinoma 9/1 patients and 1/10 hepatocellular carcinoma). CONCLUSIONS: The cytologic examination of the rest of the material in the needle of the liver core biopsy could use for a diagnostic tool for liver tumors.

PP1-294
BILATERAL SEROUS PSAMMOCARCINOMA OF THE OVARIES IN A 28 YEARS OLD FEMALE. REPORT OF A CASE

Evangelia Athanasiou[1], Stella Makri[1], Matheus Bobos[2], Alexandros Papanikolaou[3], Dimitrios Hatzibougias[2], Ioannis Hatzibougias[1]
[1] School of Health and Medical Care, Alexandrian Technological Educational Institution of Thessaloniki, Greece
[2] Department of Pathology, Aristotle University of Thessaloniki, Greece
[3] Department of Gynecology Aristotle University Thessaloniki, Greece

Introduction: Psammocarcinoma is a very rare variant of serous neoplasm that appears to arise as often in the peritoneum as in the ovaries. The mean age of patients with ovarian psammocarcinoma is 59 years. The most common presentation is with abdominal or pelvic pain and pelvic mass. Description of the case: We present the case of a 28 years old female with a cyst in left ovary (9cm in diameter) and a papillary tumor in the surface of the left ovary. The tumours consisted of papillae or nests with 2 or 3 neoplastic cells in diameter with no areas of solid epithelial proliferation. There was mild cytological atypia and foci of hobnail differentiation. Mitotic figures were rare. Psammoma bodies were numerous and replaced over 75% of the papillae. There was destructive invasion of ovarian stroma and extraovarian tumor implants were invasive consisted of psammoma bodies surrounded by neoplastic cells in omentum and fallopian tubes. Sample of peritoneal washing revealed by cytological analysis a large number of psammoma bodies and small to medium size tumor cells with fine cytoplasmic vacuolisation, nuclear abnormalities and increased nuclear to cytoplasmic ratio. Conclusion: Serous psammocarcinoma is a rare form of ovarian carcinoma with only 14 cases reported in literature and only one case of them concerned an adolescent. The clinical behaviour of psammocarcinoma more closely resembles that of borderline serous tumors than of serous carcinomas of the usual type, following a protracted course and being associated with a relatively favourable prognosis.

PP1-295
HPV-DNA TYPING AND CERVICAL CYTOLOGY AND PERSISTENCE MUCOPURULENT ENDOCERVICAL DISCHARGE

Guler Ateser[1], Feray Gunver[2], Serdar Celik[1], Pelin Koca[1], Derya Yavuzdoggan[1], Zeynep Urgan[3], Vedat Koksal[3], Birtan Boran[1]

[2] SB Istanbul Research and Training Hospital Pathology Department, Turkey
[3] Burc Molecular Diagnosis and Research Laboratory, Istanbul, Turkey

Background:N Gonorrhoeae and C Trachomatis are responsible for mucopurulent endocervisitis (MPC). Treatment of MPC consists of treatment patient and all sexual partners with some antibiotic regimen for Gonococcal and Chlamydial infections. Treatment of bacterial vaginosis aids this regimen. HPV infection is a sexually transmitted disease and coexist other infections. We detected HPV –DNA and cervical cytologic abnormalities in patients who had persistent mucopurulent endocervistis. Methods: We screen 66 women aged 20-58years. On this screening, we has taken two sample using cone –shaped cervical sampler brush, the first for conventional cytology and the second for HPV DNA testing. We have used a PCR-based assay to detect Human Papillomaviruses (HPV) in samples and determine genotype. For the detection of HPV, nested-PCR was applied to amplify consensus MY09/11 region of HPV with MY09/11 and GP5+/6+ primers. For the HPV genotyping, after amplification of E6/E7 oncogene region of HPV using consensus E6/E7 primers, nested multiplex PCR with type specific primers were used to genotype each 13 high risk HPV (HPV-16,-18,-31,-33,-35,-39,-45,-51,-52,-56,-58,-59,-66, and -68). The amplification products were visualized in EtBr stained agarose gel electrophoresis. We assesed individuals who had HPV –DNA positive result and abnormal cytological findings. Findings: We found high rate HPV-DNA positive results (56 % n= 37) in this study. Abnormal cytology was 30,158 % of all patients (n=18). HPV positive test with abnormal cytology was 73,68 % (n= 14 of 19). The mean age, duration of sexual intercouse, mean number of birth and abortion, oral contraceptive usage were unrelated HPV-DNA positive test. Smoking, educational level, usage IUD and condom were found with high ratio in HPV-DNA positive people. Also, in this group abnormal cervical biopsy results were high. High oncogenic HPV types that we detected in our study group were HPV 16, 18,35, 45,56, 58 . Conclusion:We found high HPV-DNA prevalence in patients with MPC. The risk factors determined in this study were smoking, educatonal level, usage IUD and condom. Finally, HPV-DNA detection is very effective sceening method. But it is expensive for our population; so, cytology is kept value as common screening test.

PP1-296
THE ROLE OF NUCLEAR MORPHOMETRY IN EQUIVOCAL BREAST FINE NEEDLE ASPIRATION CYTOLOGY

Turkan Rezanko, Fatma Pehlivan, Gozde Evcim, Gulsen Sirkeci
Izmir Ataturk Training and Research Hospital, Department of Pathology, Izmir, Turkey

INTRODUCTION: The most common breast lesions that result in equivocal diagnosis, hence form the gray zone in fine needle aspiration cytology (FNAC), are fibrocyctic changes, fibroadenomas and low grade ductal carcinomas. In case of equivocal FNAC, a multidisciplinary approach is required and usually the case necessitates histopathological confirmation. Current study aims to determine value of nuclear morphometric analysis (NMA) in cases with equivocal FNAC results for further categorization. MATERIAL AND METHOD: 45 equivocal breast FNAC cases that were accessed between 2001-2006 in our department (Izmir Ataturk Training and Research Hospital) and evaluated by same cytopathologist, have been analyzed retrospectively. All cases had histopathological confirmation. NMA has been performed on alcohol fixed H&E stained archival FNAC slides. We utilized computerized image analysis software to obtain mean nuclear diameter (MND), mean nuclear perimeter (MNP) and mean nuclear area (MNA) from measuring 30-50 nuclei in a microscope with 40X objectives. These values were compared with histopathological diagnosis. RESULTS: Of 45 cases, 12 were benign (7 fibroadenomas, 3 fibrocystic changes, 1 tubuler adenoma, 1 sclerozing adenosis). In benign group, MNP was 9,9 µ (7.2-11.34); MNA was 29,26µ (21.57-35.15) and MNA was 68,19µ2 (37.18-96.02). Malignant group were composed of 21 infiltrative ductal carcinomas, 5 intraductal carcinomas, 3 lobuler carcinomas, 2 mixed invasive ductal and lobular carcinomas, 1 invasive papillary carcinoma and 1 tubuler carcinoma. MND was 10µ (6.86-13,72); MNP was 30,28µ (20,94-55,67) and MNA was 70,03µ2 (34,35-121,98) in malignant group. In infiltrative ductal carcinoma subgroup MNP was 10,41µ, MNP was 27,42µ and MNA was 72,79µ2. No statistical differences of MNA, MNP and MND were found between malignant and benign groups with nonparametric tests. CONCLUSION: Limiting the number of equivocal FNAC diagnosis would decrease the number of unnecessary biopsies in patients with benign breast lesions. Our results showed that lesions leading to equivocal FNAC diagnosis (such as fibradenomas and low grade invasive ductal carcinomas) display similar nuclear morphometric values. NMA based on image analysis did not help to distinguish the borderline lesion for further categorization of FNAC groups.

PP1-297

THE VALUE OF THYROID TRANSCRIPTION FACTOR-1 (TTF-1) IN DIFFERENTIAL DIAGNOSIS OF METASTATIC PULMONARY AND EXTRAPULMONARY CARCINOMAS IN PLEURAL EFFUSIONS

Deniz Nart, Irem Paker, Banu Yaman, Yesim Ertan, Ali Veral
University of Ege, Faculty of Medicine, Department of Pathology, Izmir, Turkey

Metastasis of unknown primary site in serous pleural effusion is common and cytopathological analysis may have important therapeutic implications. Primary lung and metastatic tumors may share similar cytopathological features with difficulties in differential diagnosis especially in routine cytology practice. TTF-1 is highly specific and sensitive in the diagnosis of certain types of primary lung carcinomas, especially adenocarcinoma and small cell carcinoma in histological sections. In this study, we determined the usefulness of TTF-1 in pleural fluids for the differential diagnosis of carcinomas of pulmonary and extrapulmonary origin. Cytological material from 36 patients with malign pleural effusion were evaluated. The diagnosis of primary site was identified for all cases by clinical, radiological, cytological and/or histological correlation. Twenty-five out of 36 cases were primary lung carcinomas and 11 were metastatic. Immunohistochemical study was performed on the cell block sections or unstained effusion cytology specimens. Among 25 metastatic pulmonary carcinomas, 19 cases showed strong nuclear positivity with TTF-1 (15 adenocarcinoma, 3 nonsmall cell carcinoma and 1 small cell carcinoma) (sensitivity %76) and 6 cases were negative (2 nonsmall cell carcinoma, 1 adenocarcinoma, 1 squamous cell carcinoma, 1 large cell carcinoma, 1 small cell carcinoma). None of the 11 metastatic extrapulmonary carcinomas stained for TTF-1 (6 breast, 2 gastric, 1 kidney, 1 ovary, 1 oesophagus) (specifity %100). Our results show that, TTF-1 is sensitive and also highly specific marker in discriminating between metastatic pulmonary and extrapulmonary carcinomas in effusion cytology specimens.

PP1-298

CLINICAL SIGNIFICANCE OF STAGE-DEPENDENT QUALITATIVE DIFFERENCES OF AMYLOID A DEPOSITS IN RHEUMATOID ARTHRITIS

Miklós Bély[1], Ágnes Apáthy[2]
[1] Policlinic of the Hospitaller Brothers of St. John of God in Budapest, Hungary
[2] National Institute of Rheumatology and Physiotherapy, Budapest, Hungary

The histochemical characteristics of amyloid deposits are different and depend on (a) the type of amyloidosis, and (b) the stage of amyloidosis (i.e. on the extent and quantity of amyloid eposition) (1). Aim of the study was to determine the qualitative differences between fresh and old amyloid A deposits in RA. Patients and Methods A randomized autopsy population of 161 in-patients with rheumatoid arthritis was studied. Amyloidosis was diagnosed histologically, according to Romhányi (1971), and the type of amyloid deposits were determined histochemically according to Romhányi (1979), and Wright (1977). The quantitative differences of amyloid A deposits were evaluated by semi-quantitative, visual estimation of amyloid deposits on a 0 to 3 plus scale. The solubility and resistance of amyloid deposits were analyzed according to Bély (2006). In selected cases the structural arrangement of amyloid A deposits was investigated by electron microscopic methods. Results The early stage of amyloidosis is characterized by minimal loose amyloid A deposits, involving only a few tissue structures in some organs. Advanced stages of amyloidosis are characterized by extensive, dense amyloid A deposits, involving most of the tissue structures of investigated organs. Relatively fresh amyloid A deposits are more sensitive to KMnO4 oxidation-induced proteolysis: they are resistant for 30 sec- 1 min, and soluble within 2-3 min. Old amyloid deposits are more resistant to KMnO4 oxidation-induced degradation: they are resistant for 30 sec - 4 min, and soluble in 5 min, or longer. All amyloid A deposits are sensitive to performate pre-treatment in early as well as late stages of the disease. By electron microscope early amyloid A deposits are smaller in amount and looser in structure; in advanced stages the amyloid A filaments are present in larger amounts and more compactly arranged within the vessel walls or around the capillaries. Conclusions In early stages, amyloid A deposits are fewer in number and smaller in size, as well as structurally looser and more soluble. Therapy is more likely to be successful in early stages of amyloidosis (when deposits are structurally loose), than in advanced stages (when massive and dense amyloid A deposits are present). For this reason early diagnosis of AAa is important. Biopsy is suggested in all hospitalised RA patients, with or without clinical signs of amyloidosis.

PP1-299

THE ULTRASTRUCTURAL INVESTIGATION OF MITOCHONDRIA IN B – CLL CELLS DURING PROCESS APOPTOSIS

Goran Brajuskovic[1], Snezana Cerovic[1], Milica Strnad[1], Slobodan Marjanovic[2]
[1] Institute of Patholgy, Military Medical Academy,Belgrade,Serbia
[2] Clinic of Hematology, Military Medical Academy,Belgrade,Serbia

B - Chronic lymphocytic leukemia (B-CLL) is an example of human malignancy caused by alternations in the pathways of apoptosis. Mitochondria play a critical role in the regulation of this process. The B-CLL cells dying in apoptosis showed typical morphological characteristics: the reduction of the nuclear volume is accompanied with the reduction of the cytoplasmatic volume, while many of organelles remain intact. The aim of our study is ultrastructural investigation of mitochondrial morphology in apoptotic B- CLL cells. Our study included peripheral blood samples from 40 B-CLL patients. The samples were fixed in 4% glutar-aldehyde buffered in 0.1 cacodylate

buffer and post fixed in 1% osmium-tetroxide in the same buffer. The specimens were dehydrated in a graded series of alcohol and embedded in EPON 812. The ultra-thin sections stained with uranyl acetate and lead citrate. Ultrastructural analysis of sections was performed on Philips electron microscope 208S at 80kV. The most frequent mitochondrial abnormalities in apoptotic B-CLL cells were a reduction of size with a hyperdensity of their matrix (mitochondrial pyknosis), and markedly swollen with peripherally placed, disorientated and disintegrate cristae. In some apoptotic cells, we also detected close association of mitochondria with loops of rough endoplasmatic reticulum. The results of our study showed the numerous of mitochondria damages in B – CLL cells during apoptotic process. The correlation between ultrastructural damage and functional activity of mitochondria in apoptotic B-CLL cells is still not clear and requires further investigation.

MORPHOLOGICAL EVALUATION OF RESPIRATORY TRACT MUCOSA IN PATIENTS WITH CLINICALLY SUSPECTED CILIARY DYSKINESIA SYNDROME

Monika Seget[1], Andrzej Marszalek[2], Wieslawa Biczysko[1]
[1] Department of Clinical Pathomorphology Poznan University of Medical Sciences, Poland
[2] Department of Clinical Pathomorphology Poznan University of Medical Sciences and Department of Pathomorphology, Poland Collegium Medicum Nicolaus Copernicus University, Bydgoszcz, Poland

Background. Primary ciliary dyskinesia is a rare syndrome with a genetic background. The structural ciliary abnormalities lead to dysfunction of ciliary motility and in turn caused impairment of muco-ciliary escalator. The aim of the presented work was to define ultrastructural abnormalities of cilia as well as lesions in the respiratory mucosa in the patients with a clinical suspicion of primary ciliary dyskinesia. The indications for the biopsy of respiratory mucosa, were recurrent untreatable chronic bronchitis (with short or very short remission). Method. The material consisted of 114 biopsies of the bronchial and nasal mucosa. The age of the patients ranged from 2 months to 62 years. All samples were processed for epoxy resin blocks. Tissue sections were studied using light and transmission electron microscopy. Results. In all examined material abnormalities in the ciliary structure were found. The most common was lack of inner dynein arms (68% cases). There were also cases with lack of both dynein arms (12%) or mixed forms (20%). Additionally, there were other ultrastructural abnormalities such as: aberrant arrangement of microtubules (peripheral and central) and presence of mega cilia. Furthermore, between cilia there were present microvillus cytoplasmic outpouching (single, in groups or branching). On the free surface of ciliated cells decreased number or complete absence of cilia was observed. In such cells rete ridges was mis-shaped. In respiratory epithelium changes in proportion between goblet cells and ciliated cells was reported. Goblet cells appeared in higher numbers and focally formed clusters. In the lamina propria of the bronchial mucosa features of fibrosis were present (numerous fibrocytes and fibroblasts, and collagen fibbers which focally formed bundles). Moreover there were changes in number, placement and structure of vessels. In patients with clinically diagnosed exacerbation of bronchitis numerous inflammatory cells between epithelial cells were found. In some patients squamous metaplasia and/or dysplasia were diagnosed. Conclusion. The results of the present work reflect cause-effect relationship between primary ciliary dyskinesia and following alterations. The observed broad fibrosis of the lamina propria of the mucosa can be treated as an effect of recurrent inflammatory events resulting from inappropriate in ciliary transport and mucus retention. Moreover, long term inflammatory processes causing frequent regeneration of epithelium can lead to irregularities in the structure epithelium.

SILVER IN SITU HYBRIDISATION (SISH) – A NOVEL TECHNIQUE FOR THE ROUTINE ASSESSMENT OF HER2 STATUS IN BREAST CANCER

Silvana Di Palma[1], Nadine Collins[1], Cate Faulkes[1], Bruno Ping[1], Mark Kissin[1], Anna Sapino[2]
[1] Royal Surrey County Hospital, United Kingdom
[2] University of Turin, Italy

Background: The accurate assessment of HER2 status is essential for the correct management of breast cancer patients. Until very recently immunohistochemistry (IHC) and reflex fluorescent in situ hybridisation (FISH) analysis has been the accepted standard procedure for this assessment despite the sometimes inaccurate data obtained by IHC and the time –consuming nature of the two test strategy. The aim of this study was to evaluate a novel technique for use as a single frontline test for HER2 status. Design: We assessed the accuracy, reproducibility and practicality of a new-to-the-market, FDA-approved, fully automated brightfield ISH technique. Silver in situ hybridisation (SISH) uses the process of reducing the hybridised silver ions to metallic silver atoms in order to visualise the bound HER2 probe. We tested 49 breast cancer cases on tissue microarrays (TMA) using SISH and compared the results to those obtained when tested with dual colour FISH. Results: 35 cases were not amplified, 13 cases were amplified and one case was classed as borderline by both techniques. The results were identical in every core taken from the same tumour sample. There was 100% concordance between the results for the two ISH techniques. Conclusion: Brightfield ISH allows for clear-cut correlation between tumour morphology (e.g. invasive tumour versus DCIS) and gene copy number. With SISH there was excellent preservation of nuclear detail and the hybridised signals were distinct and easily enumerated within the nuclei. In addition the use of TMA for HER2 analysis will make routine assessment significantly more affordable.

PP2-2
THE EXPRESSION OF CD44 IN THE DIFFERENTIATION OF BENIGN AND MALIGNANT PAPILLARY LESIONS OF THE BREAST

Doxakis Anestakis[1], Chrisoula Tsobanidou[1], Melanie Koumpanaki[1], Ioannis Dimitriadis[1], Persefoni Xirou[1], Aristidis Bousoulegas[2], Frideriki Patakiouta[1]
[1] Pathology Department “Theagenio” Cancer Hospital, Greece
[2] Surgery Department “Theagenio” Cancer Hospital, Thessaloniki, Greece

Background: CD44 is a family of transmembrane glycoproteins that play an important role in the malignant transformation of breast epithelium. Recently, it has been reported that CD44 expression was significantly higher in normal breast epithelium and breast papilloma than in papillary carcinoma. The diagnosis of carcinoma within papillary lesions of the breast and the differentiation from papilloma is often difficult. In these cases immunohistochemistry plays an important role in assisting such differentiation, considering the fact that CD44 expression is different between benign and malignant papillary lesions of breast. The purpose of this study was to evaluate the diagnostic value of CD44 in distinguishing between benign and malignant papillary lesions of the breast which may be difficult morphologically. Material-Methods: In this preliminary announcement, 27 patients with papillary tumors of the breast treated surgically were examined retrospectively. All patients were female with an age range of 34 to 80 years (mean age 57 years). The tumors were 8 papillomas and 19 invasive papillary carcinomas. The surgical tumor specimens were formalin fixed, paraffin embedded and immunostained to CD44 (clone DF1485 Dako dilution 1:50). The positivity of CD44 was based on percentage of stained epithelial cells and was scored and categorized as ≤10%, 10-70%, >70%. The normal breast tissues surrounding the lesions served as control. Results: The staining was membranous and generally restricted to the basal and basolateral epithelial cells. Myoepithelial cells were also positive. Normal breast epithelial cells and 4 of papillomas expressed CD44 in a high proportion of cells (10-70%). In contrast the majority of papillary carcinoma cases (14 of 19) expressed this marker in <10% of the cells. Immunostaining for CD44 was positive (10-70%) in 4 of 8 (50%) papillomas and in 5 of the 19 papillary carcinomas (26.3%). The difference in CD44 staining between these two groups in our study is lower than that which reported previously. Conclusions: We conclude that CD44 detection by immunohistochemistry is useful in assisting the differentiation between benign and malignant papillary lesion of the breast.

PP2-3
THROMBOSPONDIN 1 EXPRESSION AND ANGIOGENESIS IN PATIENTS WITH BREAST CARCINOMA AND THEIR RELATION WITH PLATELET ACTIVITY

Cigdem Tokyol[1], Gulriz Ersoz[2], Fatma Husniye Dilek[1], Ercan Gencer[2], Mehmet Nuri Kosar[3], Osman Nuri Dilek[3]
[1] Afyon Kocatepe University School of Medicine Department of Pathology, Turkey
[2] Ankara University School of Medicine Department of Physiology, Turkey
[3] Afyon Kocatepe University School of Medicine Department of General Surgery, Turkey

Background: This study investigates angiogenesis and the expression of TSP-1 in invasive ductal carcinoma of the breast and their possible relation to platelet counts and platelet activity in breast carcinoma patients. Method: The study included 20 cases of invasive ductal carcinoma. Platelet count was measured in Coulter counter T890. Platelet activity was evaluated by determining thromboxane B2 and cGMP levels by EIA. The expression of TSP-1 was studied in formalin fixed, paraffin embedded tumour tissues. Endothelial cells were labeled immunohistochemically using CD34. Microvessel counts were determined by using the method of Weidner et al. Results: Platelet counts were within normal ranges in both groups, but mean platelet count of the patient group was significantly greater than the mean platelet count of the control group ($p=0.05$). The platelet counts were positively-correlated with tumour size ($r=0.61$; $p=0.004$) and MVD grade ($r=0.46$; $p=0.05$). The mean basal platelet cGMP level in the patient group was significantly lower than it is in the control group ($p=0.02$). There was no significant difference between TxB2 levels of the controls and the patients. Focal TSP immunoreactivity was detectable in 5 (20%) of the tumours in the tumour cells, and in 9 (45%) of the tumours in the stroma. TSP-positive cell zone composed of macrophages was observed in 7 (%35) of the tumours. We did not observe TSP staining in adjacent normal breast tissue. Microvessels were noted to be most numerous at the periphery of the infiltrating tumour cells. We did not find any correlation between TSP-1 staining and angiogenesis, platelet counts, platelet activity, and the histological prognostic parameters. Conclusion: The platelet counts were positively-correlated with tumour size and MVD grade. This confirms the essential role of platelets in angiogenesis and tumour growth. We found increased platelet counts and decreased cGMP levels in the patient group. Decreased levels of cGMP may cause platelet hyperreactivity, but there was no correlation between cGMP levels and angiogenesis. Since cGMP level is accepted as an index of NO production, we thought that further studies are needed to explain the role NO-cGMP pathway in carcinogenesis and tumour-induced platelet aggregation. Although TSP-1 may be up-regulated in malignant breast tissue, this is not sufficient for tumour growth and dissemination according to our results.

PP2-4

THE CORRELATION AMONG EGFR AND MMP-9 LEVELS AND PROGNOSTIC FACTORS IN THE EARLY AND LOCALLY ADVANCED BREAST CANCER

Yucel Aritas[1], Alper Akcan[1], Turgut Kose[1], Hizir Akyildiz[1], Can Kucuk[1], Hulya Akgun[2], Turhan Okten[2]
[1] Erciyes University School of Medicine Department of General Surgery, Turkey
[2] Erciyes University School of Medicine Department of Pathology, Turkey

Background: We aimed to investigate the correlation among EGFR and MMP-9 and classical prognostic factors in patients with breast cancer and the effects of neoadjuvant chemotherapy to these prognostic factors our patients with stage III breast cancer. Method: In the study, 20 patients with the diagnosis of fibroadenoma were assigned as the control group (Group 1). Twenty patients who were diagnosed as stage I, II breast cancer (Group 2). 20 patients found as stage III breast cancer according to evaluation of the pathological specimens (Group 3), neoadjuvant chemotherapy receiving 16 patients whom diseases were accepted as stage III after physical examination and imaging studies (Group 4), 10 of the group 4 patients who underwent surgical treatment after neoadjuvant chemotherapy (Group 5). Modified radical mastectomy was performed in the study groups and excisional biopsy for the control group. Results: Statistical significance was found for EGFR positivity ($p<0.05$) but not MMP-9 ($p>0.05$) among the groups. Estrogen and progesteron receptor levels and axillary lymph node involvement were not found different ($p>0.05$) in EGFR positive patients. Weak and opposing correlation was found between MMP-9 level and axillary involvement and hystologic grade ($p>0.05$). Between the group 4 and 5 which treated with neoadjuvant chemotherapy statistical significancy was found in terms tumor diameter and MMP-9 levels ($p<0.05$) but not EGFR status ($p>0.05$). Conclusion: Besides the classical prognostic factors, EGFR and MMP-9 levels may predict the prognosis and response to the treatment. Tumor diameter can be reduced with neoadjuvant chemotherapy in patients with stage III breast cancer and this allows better surgical outcome.

[8]Department of Pathology, Faculty Hospital Bratislava-Kramáre, Bratislava, Slovakia
[9]Department of Pathology of Safarik University Medical Faculty & Faculty Hospital, Košice, Slovakia

Background: A standardized testing of HER2 status represents an essential component of the invasive breast carcinoma diagnosis. The aim was to develope a national system of a standardized HER2 protein and gene testing of all diagnosed breast carcinomas and its quality control based on the principles of a cooperation of pathology departments in the Slovak Republic. Methods: A national network system of a breast carcinoma biopsy diagnosis provided by regional centralization of biopsies in 11 departments of pathology in Slovakia using a standardized biopsy diagnostic approach, incl. immunohistochemical HER2 protein testing was introduced in 01/2003. For cases showing 2+ protein positivity, HER2 gene testing is since 01/2006 provided centrally in the coordination center of the project first by CISH technique and for cases showing low amplification also by FISH. The quality of HER2 protein testing was controlled in 2003 and 2006 by using blind testing cases being examined in the participating departments and subsequently evaluated centrally by a panel of experts. Results: On the basis of quality controls and numbers of the examined cases (2003: 973, 2004: 1287, 2005: 1655 and 2006: 1831 cases), the examinations of the biopsies were centralized to 9 regional centers. Technical and interpretational problems related to HER2 testing and all the experiences are regularly evaluated and discussed by the educational conferences and joint meetings of the involved participants. Altogether biopsy examinations of 5746 cases diagnosed in 01/2003-12/2006 proved HER2 protein positivity in 1481 cases (25.8 %): 3+ positivity in 768 (13.4 %) and 2+ in 713 (12.4 %) cases. From 213 cases tested in 2006 centrally by in situ hybridization techniques, 31 were found to show amplification of HER2 gene: 25 of 167 cases with HER2 protein positivity 2+ and 6 cases with HER2 protein posivity 3+. Correlation of HER2 status with other parameters seems to be significant. Conclusions: The described program offers standardized results representing a good basis for the therapeutical considerations and for further optimization of HER2 testing and studies of all the parameters of the disease. The number of the tested cases in the last evaluated year seems to correspond to the expected incidence of the cases in Slovakia.

THE PROGNOSTIC VALUE OF THE DUCTAL AND LOBULAR IN SITU CARCINOMA OF THE BREAST

Pricop Mihai[1], Musca Simona[2], Stolnicu Simona[3], Slatineanu Sebastian[1]
[1] University of Medicine and Pharmacy “Gr. T. Popa” Iasi,Romania
[2] Laboratory of Histopathology, Clinical Hospital of Obstetrics-Ginecology “Cuza Voda” Iasi, Romania
[3] Department of Pathology, University of Medicine Targu Mures Romania

Introduction. The carcinoma in situ is considered a heterogeneous neoplasia with clinic, pathologic and biologic variability. It is the most important risk factor for developing invasive carcinoma. Material and Methods. We reviewed 69 cases that have been operated between 1995 and 2005. Among these, 54 were ductal carcinoma in situ (DCIS), 5 were lobular carcinoma in situ (LIN) and 2 were mixt carcinoma in situ (ductal and lobular). The diagnosis of carcinoma in situ was established on frozen section examination (the clear margins were also assessed in order to perform conservative surgery) or during histopathologic examination for another condition. Special atention also was payed to the evaluation of multifocal lesions and of the integrity of the basal membrane (microinvasion assessment). The Van Nuys prognostic index was evaluated in DCIS cases according to the usual parameters: tumor size, cytonuclear grade, comedonecrosis and histological margin status. Most of the cases (69%) had a moderate prognostic index and 21% had an unfavorable score. All recurrences (6 cases) occurred in high grade DCIS. Conclusions. The results of this study confirmed the value of the conventional histologic parameters. The evaluation of the Van Nuys prognostic index has an important role in the local recurrences control for conservatively treated cases. Margins status remains the most important factor for the success of conservative treatment for carcinoma in situ.

PP2-7

BENIGN MAMMARY LESIONS IN MENOPAUSE

Pricop Mihai[1], Musca Simona[2], Stolnicu Simona[3], Maxim Razvan[1]

[3] Department of Pathology, University of Medicine Targu Mures Romania

Breast benign pathology is characteristic for young age women but can also be identified in postmenopausal patients. In this group diagnostic errors may occur. Clinical examination is of low value, imagistic investigation may be confuse, pathological diagnosis is essential. We analyse 891 patients operated in our clinic for benign mammary lesions between January 1993-December 2007. 82 women (9,8 %) were postmenopausal. Risk factors for breast cancer after the diagnosis of benign breast disease include the histologic classification of a benign breast lesion and a family history of breast cancer. Histopathology certified the diagnosis and excluded in situ lesions or invasive carcinoma. Surgical treatment consisted in wide local excisions considering the possibility of unexpected malignancy.

PP2-8

CHANGES IN THE EXPRESSION OF STROMAL PROTEINS FOLLOWING PREOPERATIVE SYSTEMIC THERAPY IN BREAST CANCER

Anna-Mária Tőkés[1], Adrienn Ildikó Tóth[1], A. Marcell Szász[1], Andrea Farkas[1], Lilla Vanda Lukács[1], Magdolna Dank[2], István Arthur Molnár[3], László Harsányi[3], András Kiss[1], Janina Kulka[1]

[3] 1st Department of Surgery Semmelweis University Budapest, Hungary

Introduction. Tumors of similar histological appearance may have different response to preoperative systemic therapy (PST). Stromal component of the cancer tissue has a proven effect on the regulation of cancer cells. Significant stromal alterations are being observed following PST in breast cancer. Aims. To analyze the qualitative and quantitative changes in the tumor stroma in the context of the response rate of breast cancer patients undergoing PST. Patients and Methods. Breast cancer samples of 50 patients receiving PST were evaluated for clinical and pathological parameters. To evaluate the pathological response to PST, samples were classified according to Chevallier's (classes I-IV) and Sataloff's classification (classes A-D). Using immunohistochemistry we analyzed the expression of representative extracellular matrix (ECM) proteins: adhesion molecule (tenascin-C), proteoglycan (syndecan-1) and structural proteins (collagen-IV, smooth muscle actin /SMA/). The expression levels of the above mentioned proteins were compared to 10 breast cancer samples of patients previously not treated with PST. The results of the immunohistochemical reactions were evaluated by the Leica QWin V3.1.0 software. Statistical analysis with Mann-Whitney method was performed. Real-time PCR procedure was also accomplished to evaluate the mRNA expression level of the syndecan-1 and tenascin-C proteins. The PCR data were analysed with REST software. Results. The median age was 51 years (range, 27 to 69). Among the structural proteins the expression of the collagen-IV was significantly up-regulated in all four groups both in Chevallier's and Sataloff's classification ($p = 0,025$, $p = 001$; respectively) compared to the not treated group. Syndecan-1 levels were down-regulated in all four groups ($p = 0,015$, $p = 0,015$; respectively). Tenascin-C was significantly up-regulated in the Chevallier IV class of patients ($p = 0,008$) and the according Sataloff D class of patients ($p=0,003$). The results of immunohistochemistry were in concordance with the real-time PCR data. Conclusion. The role of cell-ECM interactions to modulate the cellular phenotype and gene expression of tumor cells is well known. According to our observations the stromal component of breast carcinomas developed significant changes following PST. Up-regulation of structural protein levels is presumed. Possible role of tenascin-C and syndecan-1 is implicated in stromal changes, which suggests their indirect effect on tumor cells during PST. Supported by the Hungarian Society of Clinical Oncology in 2006.

HISTOCHEMICAL CHARACTERISTICS OF THE STROMA IN INVASIVE AND IN SITU LESIONS OF THE BREAST: AN HYPOTHESIS OF DESMOPLASTIC-LIKE CHANGES IN THE STROMA SURROUNDING IN SITU CARCINOMAS

Gabriella Canavese, Gianluigi Candelaresi, Elena Margaria, Roberto Giani, Riccardo Bussone, Ester Berardengo
Ospedale S. Giovanni Antica Sede, Torino, Italy

BACKGROUND - The importance of the interactions between epithelial structures, basal membrane and stroma in breast carcinonogenesis has been widely demonstrated in literature. We observed a strong Alcian Blue stain of desmoplastic stain in a single case of invasive breast carcinoma. We couldn't find previous reports about these findings in literature. The aim of the study was to investigate the occurrence of the same staining features in other invasive carcinomas and in in situ carcinomas, in order to evaluate the histochemical properties of the stroma in neoplastic breast lesion. MATERIALS - We stained with Alcian Blue dye 20 ductal invasive carcinomas, 5 lobular invasive carcinomas , 5 non high grade in situ ductal carcinomas, 5 high grade in situ ductal carcinomas, 5 mixed in situ and invasive carcinomas 2 lobular in situ carcinomas, and 2 cases of adenosis. The nuclei was counterstained with Feulgen stain. RESULTS – The desmoplastic stroma was strongly stained with alcian in all invasive carcinomas and in all invasive foci in mixed invasive – in situ lesions, and the stain was specific, since the stroma of normal parenchyma and benign lesions was negative, and we observed the same staining properties exclusively in easily distinguishable lesion, as in mucous accumulations and in a peritumoral fibradenoma with hyaline change. We observed the same staining in defined areas of the stroma surrounding high grade in situ carcinomas and around the foci of microinvasion. A series of double staining with actin, S-100 and laminin proved that the alcian-stained spots were present around glandular structures where no invasion or microinvasion could be demonstrated. In lobular in situ carcinomas we obsesved some foci around in situ lesions were stained with alcian, and in one of these areas we could demonstrate a corresponding small focus of invasive lobular carcinoma. CONCLUSION Alcian Blue stains performed in a series of in situ and invasive breast lesions show that the desmoplastic tissue and the stroma surrounding in situ breast carcinomas with high risk of invasion, (as high grade intraductal lesions and lobular lesions) share the same histochemical properties. Notwithstanding the relatively small number of cases and the restrictions of histochemistry, these evidences suggest that the stroma around in situ foci could get the biochemical structure of the desmoplastic tissue when the basal membrane damage in not still evident. Further studies are mandatory to strengthen these preliminary observations with immunohistochemical evidences.

PP2-10

MOLECULAR ANALYSIS OF C-erb-B2/HER2/neu GENE AMPLIFICATION IN INVASIVE PRIMARY BREAST ADENOCARCINOMAS WITH BORDERLINE (2+) C-erb-B2/HER2/neu PROTEIN IMMUNOREACTIVITY

Christos Valavanis, Theofani Gavresea, Chrysa Lekanidou, Olympia Tzaida, Helen Trihia, Maria Lekarakou, Prokopis Vogiatzis, Joanna Iakovidou, Joanna Lekka, Petroula Arapantoni-Dadioti
Molecular Pathology Unit, Dept. of Pathology, METAXA Cancer Hospital, Piraeus, Greece

BACKGROUND-OBJECTIVE: c-erb-B2/HER2/neu oncogene encodes a 185 kDa membrane glycoprotein with tyrosine kinase activity involved in signal transduction pathways. Dysregulation of HER2 expression through gene amplification and protein overexpression has been observed in various neoplasms including 15-30% of breast carcinomas and leads to chemoresistance and poor prognosis, independently of lymph nodes status and/or hormonal receptors (ERα/PgR) expression levels. Patients with increased HER2 protein expression respond well to targeted therapy with monoclonal antibodies.Targeted therapy is effective only in patients whose breast tumors exhibit HER2 gene amplification and/or protein overexpression (3+ in immunohistochemical evaluation). Breast carcinomas with borderline (2+) HER2 immunoreactivity should be assessed by in situ hybridization in order to detect the HER2 gene copy number and evaluate the efficacy of targeted therapy.The objective of this study was the assessement of HER2 gene status by in situ chromogenic hybridization (CISH) in sporadic primary breast carcinomas with borderline (2+) HER2 protein immunoreactivity and to correlate gene copy number with tumor type and histological grade.MATERIALS AND METHODS:Retrospective study of 239 cases of sporadic primary invasive breast carcinomas (201 ductal, 20 lobular, 10 mixed, 8 other types) with borderline (2+) HER2 protein immunoreactivity evaluated by immunohistochemistry using monoclonal antibodies (Hercept test) and according to the accepted guidelines. Semiquantitative assessement of HER gene copy number by chromogenic in situ hybridization (CISH). RESULTS AND CONCLUSIONS:A. CISH revealed: 185 (77.4%) of the carcinomas, independently of tumor type, showed no gene amplification (2 copies/nucleus) or putative polysomy of chromosome 17 (3-5 copies/nucleus, not evaluated by Chr 17 centromeric probe), 24 (10%) with low gene amplification (LGA, 6-10 copies/nucleus) and 30 (12.6%) with high gene amplification (HGA, >10 copies/nucleus and gene clusters).B. Correlation with tumor type revealed: Among HGA tumors (N=30) 27 were ductal (90%), 1 lobular(3.3%),others 1 (3.3%).LGA tumors (N=24): 21 ductal (87.5%) and 3 lobular (12.5%), no gene amplification carcinomas (N=185) :153 ductal (82.1%), 16 lobular (8.6%), 9 mixed (4.8%) and others 7 (3.8%). C. Correlation with histological grade demonstrated: Grade I:LGA 8 (3.8%), HGA 0, no gene amplification 0, Grade II: LGA 5 (2.4%), HGA 11 (5.3%), no gene amplification 74 (35.9%), Grade III: LGA 13 (6.3%), HGA 21 (10.2%), no gene amplification 74 (35.9%).

PP2-11

IMMUNOHISTOCHEMICAL STUDY OF TUMOR SUPPRESSOR GENE PTEN EXPRESSION IN SPORADIC PRIMARY BREAST ADENOCARCINOMAS. CORRELATION WITH C-erb-B2/HER2/neu EXPRESSION STATUS

Christos Valavanis, Theofani Gavresea, Olympia Tzaida, Helen Trihia, Rebeca Kaltsa, Joanna Iakovidou, Petroula Arapantoni-Dadioti
Molecular Pathology Unit, Dept. of Pathology, METAXA Cancer Hospital, Piraeus, Greece

BACKGROUND-OBJECTIVE: The tumor suppressor gene PTEN encodes a dual-specificity phosphatase antagonizing PIK3 kinase activity through dephosphorylation of cell membrane lipid PIP3 to its inactive form PIP2. PIK3 mediates growth factors induced activation of receptor tyrosine kinases (HER2, IGF-R1) via phosphorylation of PDK and Akt kinases. Activated PTEN prevents the mitogenic signal transduction. Genetic and/or epigenetic alterations of PTEN gene results in inactive protein or loss/reduction of PTEN expression and eventualy in carcinogenesis. PTEN mutations have been implicated in syndromes with high risk of cancer development (Cowden, Bannayan-Riley-Ruvalcaba) and in sporadic cancer (melanoma, glioblastoma, prostate Ca, endometrial carcinoma). Loss of heterozygosity (LOH) or gene deletion of PTEN has been observed in breast and prostate cancer. Recently, it has been demonstrated that decrease or loss of PTEN expression with parallel high expression or amplification of HER2 gene is associated with resistance to HER2 targeted therapy.Thus, information on the expression status of PTEN could be a valuable predictive factor for HER2 targeted therapy of breast cancer.In this context we investigated PTEN expression in invasive breast carcinomas and correlated its expression loss with tumor type, histological grade, lymph nodes status and HER2 expression levels. MATERIALS AND METHODS:Retrospective study of 345 cases of sporadic primary breast adenocarcinomas. IHC detection of PTEN and HER2 expression using monoclonal antibodies. Semiquantitative protein expression assessement according to the accepted guidelines. RESULTS AND CONCLUSIONS:A. Overall and independently of tumor type 54.8% of adenocarcinomas demonstrated high expression, 27.8% weakly positive and 17.4% negative. B. In 60 tumors with loss of PTEN expression, 70% were ductal, 20% lobular and 10% mixed type. C. Correlation of PTEN loss of expression with tumor type and histological grade revealed: Ductal (N=40, ND:2): Grade I 5%, II 37.5%, III 57.5%, Lobular (N=10, ND:2): Grade I 10%, II 50%, III 40%, Mixed (N=5, ND:1): Grade I 40%, II 40%, III 20%. D. In 40 PTEN (-) breast carcinomas with resected axillary lymph nodes, 39% were positive for metastasis while 61% were negative. E. Correlation of PTEN loss of expression with HER2 expression: In 75 HER2 (3+) breast cancers, 21.3% were weakly positive for PTEN and 14.6% were negative.

PP2-12

SYNOVIAL METAPLASIA OF BREAST IMPLANTS CAPSULES

Theofani Gavresea[1], Christos Valavanis[2], Joanna Lekka[1], Gino Vecchini[1], Petroula Arapantoni-Dadioti[1]
[1] Dept. of Pathology, METAXA Cancer Hospital,Piraeus,Greece
[2] Molecular Pathology Unit, Dept. of Pathology, METAXA Cancer Hospital, Piraeus, Greece

BACKGROUND: Synovial metaplasia is developing in tissues surrounding joint prosthesis, in skin and soft tissues in healing or in surgical wounds. The latest years synovial metaplasia has been described in periprosthetic breast capsules, after silicone leakage. We recorded an increased incidence of cases with synovial metaplasia due to the expansion of breast augmentation for cosmetic reasons and therapeutics treatments after breast cancer. MATERIALS AND METHODS: We examined 12 cases with silicone implants after breast augmentation . The patients were female, from 46 to 65 years old and have been operated for breast cancer and breast restoration. Sections have been obtained from the adjacent the silicone capsule tissue and microscopic, histochemical and immunohistochemical examination followed. RESULTS AND CONCLUSIONS: In 6 cases, from totally 12 cases of periprosthetic capsular removal, the microscopic examination revealed the presence of synovial metaplasia in the inner surface of the capsules (50%). The capsule consisted of dense fibrocollagenous connective tissue. The adjacent tissue was infiltrated by lymphocytes,plasma cells, histiocytes and foreign body giant cells. In addition to this foreing body reaction, a significant feature was the presence of synovial type cells. Histochemically, these cells were positive for glycogen and

mucin with PAS and Alcian Blue. Immunohistochemically, they were vimentin positive and focally positive for a1-antitrypsin, a1-anti-chymotrypsin, lysozyme and CD68. No immunoreactivity was observed for cytokeratin AE1-AE3 and S100. In conclusion, synovial metaplasia in breast implants capsules is developing in 50% of periprosthetic capsules cases and although is a benign histological feature the unknown -so far- clinical significance and the increased occurence during the last years demands for the attention of surgical pathologist in order to recognise this entity.

PP2-13
INVESTIGATION OF MICROORGANISMS IN CASES OF MAMMARY DUCT ECTASIA BY HISTOCHEMICAL METHODS

Iclal Gurses[1], Tuba Karabacak[1], Bulent Mizrak[2]
[1] Mersin University Faculty of Medicine Department of Pathology, Mersin, Turkey
[2] Inonu University Faculty of Medicine Department of Pathology, Malatya, Turkey

Background: We investigated the presence of microorganisms in cases of mammary duct ectasia by histochemical stainings in histological sections. Methods: Seventeen cases diagnosed as ductal ectasia at Departments of Pathology of Inonu and Mersin Universities Faculties of Medicine were included in this study. Histochemically, Periodic Acid Schiff, Grocott's methanamine silver, gram and Erlich-Ziehl-Nelsen stainings were performed. The intensity of periductal and interstitial inflammation, presence of granulomatous inflammation and rupture of ducts were also evaluated. Results: Rupture of ducts was seen in ten cases. Granulomatous inflammation was observed in five cases. While mild inflammation was present in seven cases, six cases showed moderate inflammation. Severe inflammation was seen in four cases. In ten cases, a few gram positive microorganisms were detected in the lumen, especially in the cytoplasm of macrophages. No organisms were seen by the other stainings. Conclusion: In the literature, the culture media studies made of nipple discharge of patients with duct ectasia exist. Some authors reported a low frequency of bacteria in duct ectasia, others were not showed. There are controversies about the microorganisms present in duct ectasia. In our study, while a few gram positive microorganisms in the lumen were observed in tissue sections, no organisms were detected by Periodic Acid Schiff, Grocott's methanamine silver, Erlich-Ziehl-Nelsen stainings. Sensitivity of histochemical stainings might be correlated with the number of bacteria. To our knowledge, this is the first study to investigate the presence of microorganisms in duct ectasia by histochemical stainings in tissue sections.

PP2-14
PSEUDOANGIOMATOUS STROMAL HYPERPLASIA WITH JUVENILE FIBROADENOMA FOCI (CASE REPORT)

Sevinc Hallac Keser, Nagehan Ozdemir Barişik, Aylin Ege Gul, Melin Ozgun Gecer, Nimet Karadayi, Ramazan Geyyas
Dr. Lutfi Kirdar Kartal Educational and Research Hospital, Pathology Department, Istanbul, Turkey

BACKGROUND: Pseudoangiomatous stromal hyperplasia (PASH) of the breast is a rare, benign proliferative mesenchymal lesion which may present with rapid growth. Capillary-like clefts that are formed due to separation of collagen fibers and myofibroblasts as a result of stromal hyperplasia and endotelium-like spindle cells surrounding these clefts are charasterics of the lesion. Differentiation of this entity from especially low grade angiosarcoma is crucial. CASE: The case was a 16 years old female patient complaining of left breast enlargement. At physical examination, a tumoral mass involving almost all of the left breast and thinning the nipple and breast skin was found. At mammography, a 145x 100 mm tumoral mass localized at left breast was observed. Ultrasonography (USG) revealed edema at left breast epidermal and subepidermal regions. At tru-cut biopsy, at intralobular and interlobular regions, anastomosing capillary-like spaces and spindle myofibroblast-like cells lining those spaces were seen in increased collagenous dense stroma. Occasionally, branching ducts were found which were increased in number and frequency and lined by hyperplastic epitel without atypia. The case was determined to be pseudoangiomatous stromal hyperplasia with juvenil fibroadenoma foci. Subcutaneous mastectomy was performed. At the specimen, a 22x12x9 cm white nodular lesion involving almost all of the breast was seen. At histopathological examination, morphological findings similar to tru-cut biopsy was observed. Low grade angiosarcoma was taken into account at differential diagnosis. Immunohistochemical examination (IHC) revealed cells layering capillary clefts that showed positive staining with CD34 and actin and negative staining wih CD31, F8 and cytokeratin. By the contibution of IHC and histopathology, the diagnosis was established as PASH with juvenile fibroadenoma foci. CONCLUSION: Although PSAH is a rare entity, it should be included in the differential diagnosis of benign and malign mass forming breast lesions. Results should be supported by IHC.

PP2-15
THE EVALUATION OF CONCORDANCE BETWEEN THE INTRAOPERATIVE PATHOLOGY CONSULTATION (FROZEN SECTION AND IMPRINT CYTOLOGY) AND THE FINAL PATHOLOGY OF SENTINEL LYMPH NODES IN PATIENTS WITH BREAST CANCER

Fatma Gursoy, Fugen Vardar Aker
Haydarpasa Numune Egitim ve Arastirma Hastanesi, Turkey

The techniques for intraoperative evaluation of sentinel lymph nodes (SLNs) vary. We used the most common techniques in the world which include the frozen section, imprint cytology / touch preparation cytology, and scrape cytology (SC). The purpose of this study was to evaluate whether there is concordance between the result of intraoperative pathology consultation and the final pathology of SLNs in patients with breast cancers. From June 2003 to April 2007 sentinel lymph node biopsies were attempted in 67 patients with breast cancer using a blue dye. From the sample of 67 sentinel lymph node materials, intraoperative and postoperative lymph nodes were not obtained in 5 cases (93% success rate). Of 62 sentinel lymph nodes, 18 sentinel lymph nodes have metastatic tumor infiltration. Two of these 18 sentinel lymph nodes have micrometastas(<2 mm). 42 patients had negative for metastatic tumor. Two false negative cases occurred, one of them with micrometastasis (90% sensitivity rate). There was no false positive case in our study (100% spesivity rate). As a result, intraoperative pathology consultation is safe choice with high diagnostic accuracy rate for evaluation of SLNs.

PP2-16
EVALUATION OF HER-2/neu AND EGFR IN PURE MUCINOUS BREAST CARCINOMA

Karima Mrad, Maha Driss, Neziha Ben Hamida, Lamia Charfi, Imene Abbess, Samia Sassi, Rim Dhouib, Houda Arbi, Khaled Ben Romdhane
Salah Azaiez Institute, Tunisia

Background: HER-2/neu and EGFR are two important growth factor receptors for oncogenesis. They are now potential therapeutical target in case of overexpression. They are poorly investigated in breast mucinous carcinoma. Aims: to assess the expression of both HER-2/Neu and EGFR in mucinous breast carcinoma. Material and methods: 24 formalin-fixed paraffin-embedded pure breast mucinous carcinoma were tested for both HER-2/Neu and EGFR using Dako® Kits. The intensity of reactivity was scored by using a 4-tier system (negative, 1+, 2+, and 3+) and the site of immunolabelling was noticed (membranous and/or cytoplasmic. The Prognostic factors (age,

tumor grade, node status) and cytological type (with or without intracytoplasmic mucine) were also studied. Results: All cases showed no overexpression for both proteins. Immunohistochemical study of HER-2/Neu showed either absence of labelling (18 cases) or incomplete weak staining (1+) in 6 cases. Immunohistochemical study of EGFR showed either absence of labelling (21 cases) or weak cytoplasmic staining (1+) in 3 cases. Conclusion: The low expression of HER-2/Neu and EGFR in pure mucinous breast carcinoma could be related to their good prognosis. Testing these markers fails in identifying a sub-group with less good prognosis in our study but merits analyse of a larger number of cases.

PP2-17
COMPARATIVE STUDY OF THE MORPHOLOGICAL PECULIARITIES OF HORMONE-DEPENDENT BREAST CANCER

Peter Ghenev[1], Stanko Dandanov[2], Deyan Dzhenkov[1], Penka Kolova[1]
[1] Department of Pathology, Medical University of Varna, Varna, Bulgaria
[2] Department of Pathology, Oncological Dispansery, Burgas, Bulgaria

In defining the prognosis and the treatment strategies of breast cancers a constantly increasing number of morphological criteria are applied, such as more accurate gross characteristics, histological features, hormonal status of cancers cells, and the involvement of axillary lymph nodes. The aim of the present study is to assess the morphological peculiarities and the immunohistochemical profile of estrogen, progesterone and HER2 receptor positive tumors. These findings were correlated with patient and tumor characteristics at the time of surgery. In total, 120 cases of breast cancer derived from two diagnostic centers along the Bulgarian Black sea coast were examined. In all of them hematoxylin-eosin-stained paraffin sections of the primary tumor and from all the axillary lymph nodes removed during surgery were studied. Besides grading and staging, several other microscopic parameters, including lymphoid stroma, pushing margin, comedo-type necrosis, vascular cellular emboli were evaluated. The hormonal status (estrogen, progesterone and HER2 receptors) was determined with primary antibodies and LSAB Kit (DAKO). Estrogen and progesterone-receptor negative cancers constituted the major part of tumors showing more aggressive criteria – low grade, invasive edge, positive HER2 status, and most of them presented with axillary lymph node metastases at time of surgery. On the other pole, estrogen and progesterone-receptor positive cancers showed greater variability in regard to the distribution of the other microscopic criteria. The interrelationships of these pathologic correlates and their relative value as prognostic indicators were studied.

PP2-18
CYTOKERATIN 5/14 EXPRESSION IN INVASIVE DUCTAL CARCINOMAS OF THE BREAST: AN IMMUNOHISTOCHEMICAL STUDY

Sibel Yenidunya, Reyhan Bayrak
Fatih University School of Medicine, Ankara, Turkey

Breast ducts contain two types of epithelial cells, inner luminal cells and outer basal/myoepithelial cells. These cells can be distinguished by their immunophenotypes. Cytokeratins (CKs) 8 and 18 are expressed in the luminal layer, whereas CK5 and CK14 characterize the basal epithelial layer. For this reason, tumors expressing these CKs have been named 'basal-like subtype' breast cancers. Retrospectively expression of CK5 and CK14 was studied in 92 invasive ductal carcinoma using immunohistochemistry. The CK5 and CK14 expression were compared with histologic grade, existence of lymph node metastasis, tumor size, immunohistochemical findings for estrogen receptor (ER), progesterone receptor (PR), and c-erb B-2. The two basal cell CKs (CK5 and CK14) were not identified exactly in the same tumor when used alone. Among the 92 tumors, there were twenty one positive for CK5 (22,8%) and ten positive for CK14(10.9%). Our results showed that CK5 and CK14 are coexpressed in most tumors, but the tumors expressing CK5 only also exist. In basal-like tumor ER was negative in 19 cases (91%)(p [LTEQ]0.001), and PR was negative in 18 cases (86%)(p [LTEQ]0.001), and c-erb B-2 was negative in 16 cases (76%). All CK14 positive basal-like tumor were negative for c-ErbB2 (0/10, 100%); while in CK5 positive basal-like tumor, c-erb B-2 negativity were seen sixteen cases of 21(76%) The rate of grade 3 histology seen in the basal-like tumors was %86. (p [LTEQ] 0.001). CK5 positive breast cancers represent about 22% and CK14 positive breast cancers %11 of sporadic invasive ductal breast cancers. These tumors were mostly aggressive grade III, steroid hormone receptor-negative breast cancers and they were inversely associated. Our results showed that there was no statistically significant association between CK5/14 positivity and stage of the tumor.

PP2-19
IMMUNOHISTOCHEMICAL STUDY OF ANDROGEN RECEPTOR IN BREAST CARCINOMAS

Reyhan Bayrak, Sibel Yenidunya
Fatih University School of Medicine , Turkey

Androgen and androgen receptor (AR) are involved in the pathogenesis of breast cancer. Epidemiologic studies have shown a significant association between the risk of breast cancer and androgens. The present study was set up to investigate the prevalence of a AR in a series of consecutive invasive breast carcinomas. Among the 110 consecutive invasive breast carcinomas (consisting of 92 ductal, 14 lobular, 1 medullar, and 3 musinous neoplasms), AR immunoreactivity was observed in 77/110 (70 %) cases, being expressed in 61/92 (66 %) ductal, 13/14 (93 %) lobular, 1/1 (100%) medullar, and 2/3 (67 %) musinous carcinomas. AR expression was frequently associated with estrogen receptor (ER) (78%), PR positivity (82 %) (p[LTEQ] 0.001), and c-erb B-2 negativity (86 %) (p[LTEQ] 0.05). Most AR positive cases showed a low or intermediate histological grade (G1-G2) (88 %). No association between AR expression and tumor size, and lymph node metastasis was found. The potential role and the impact of ARs in breast carcinoma needs further study; however, ARs are a potential new target for hormonal therapies and they may be clinically useful predictors.

PP2-20
THE VALUE OF CORES WITH MICROCALCIFICATIONS EXCISED BY VACUUM-ASSISTED BREAST BIOPSY

Flora Zagouri[1], Afroditi Nonni[2], Theodoros Sergentanis[1], Vassiliki Oikonomou[1], Maria Fotou[1], Philip Domeyer[1], George Filippakis[1], Nikolaos Pararas[1], Effrosyni Panopoulou[1], Effstratios Patsouris[2], George Zografos[1]
[1] Breast Unit, 1st Department of Propaedeutic Surgery, Hippokratio Hospital, University of Athens, Athens, Greece
[2] Department of Pathology University of Athens, Greece

BACKGROUND: To assess cores with microcalcifications and cores without microcalcifications obtained from Vacuum-assisted breast biopsy (VABB). METHOD: The study included: 12 atypical ductal hyperplasias (ADH), 37 ductal carcinomas in situ (DCIS), and 7 invasive ductal carcinomas (IDC), diagnosed by VABB (11G) on the stereotactic Fischer's table. More than 24 cores were excised. For cores with and without microcalcifications, a separate pathology report was given. Open surgery followed, and underestimation was calculated. The discrepancy of cores with and without microcalcifications was evaluated (superiority, identity, inferiority). RESULTS: Cores without microcalcifications failed to make the diagnosis in 8.3% and 35.1% of ADH and DCIS, respectively. In 28.6% of IDC,

diagnosis was made through cores without microcalcifications. The volume of cores with microcalcifications was 1.2±0.3 cc for the two IDCs missed by cores with microcalcifications, 1.0±0.4 cc for the 40 cases of identical diagnoses and 1.4±0.5 cc for the 14 cases of superiority of cores with microcalcifications (p=0.048, Kruskal-Wallis test). The volume of cores without microcalcifications was 6.3±1.8 cc the two IDCs missed by cores with microcalcifications, 2.6±1.8 cc for cases with identical diagnoses and 3.4±1.6 cc for cases of CM superiority (p=0.018, Kruskal-Wallis test). The underestimation rate was 8.3% in ADH, and 10.8% in DCIS. CONCLUSION: Cores with microcalcifications are superior for DCIS/ADH diagnosis. However, cores without microcalcifications may be valuable for the diagnosis of the invasive component.

PP2-21

IMMUNOHISTOCHEMICAL ASSESSMENT OF C-erbB2 AND p-53 PROTEINS IN VACUUM-ASSISTED BREAST BIOPSY SPECIMENS OF BREAST CARCINOMA

Afroditi Nonni[1], Flora Zagouri[2], Theodoros Sergentanis[2], Vassiliki Oikonomou[2], Maria Fotou[2], Dimitra Koulocheri[2], Philip Domeyer[2], Dimitris Dardamanis[2], Georgia Giannakopoulou[2], Effstratios Patsouris[1], George Zografos[2]
[1] Department of Pathology University of Athens, Greece
[2] Breast Unit, 1st Department of Propaedeutic Surgery, Hippokratio Hospital, University of Athens, Athens, Greece

BACKGROUND: Vacuum-assisted breast biopsy (VABB) is a minimally invasive technique for the evaluation of mammographically detected, non-palpable breast lesions. This study examines whether VABB specimens provide an accurate immunohistochemical assessment of c-erbB-2 and p53 proteins. METHOD: Fifty-one consecutive cases with a VABB diagnosis of ductal carcinoma in situ (DCIS, n=34) or invasive ductal carcinoma (IDC, n=17) were included in the study. VABB (11G) was performed on the Fischer's table, and 24 or more cores were obtained in all cases. A preoperative and a postoperative diagnosis were established. Only when the two pathological diagnoses were concordant, their immunohistochemical profiles were comparatively evaluated. RESULTS: Among the 34 DCIS cases, three (8.8%) were postoperatively revealed to be IDC, i.e. were underestimated. In 12/34 DCIS cases (35.3%) and 5/17 (29.4%) IDC cases, no malignant tissue was found in the postoperative pathologic examination. Concerning c-erbB-2, there was 100% concordance for both DCIS (one-sided CI: 82.4%-100%), and IDC (one-sided CI: 71.5%-100%). As far as p53 is concerned, the observed concordance rate was 11/12 for IDC (91.7%, 95% CI: 61.5-99.8%) and 100% for DCIS. CONCLUSION: Specimens derived by VABB provide an accurate immunohistochemical evaluation of p53 and c-erbB-2 proteins. This is of great importance since no malignant tissue is found frequently in the postoperative pathologic examination, and thus VABB specimens are the only material available.

PP2-22

ESTROGEN AND PROGESTERONE RECEPTORS IN VACUUM-ASSISTED BREAST BIOPSY SPECIMENS OF BREAST CARCINOMA: IMMUNOHISTOCHEMICAL ASSESSMENT

Flora Zagouri[1], Afroditi Nonni[2], Theodoros Sergentanis[1], Vassiliki Oikonomou[1], Maria Fotou[1], Dimitra Koulocheri[1], Andromachi Tsakiri[1], Theodora Drouveli[1], Effstratios Patsouris[2], George Zografos[1]
[1] Breast Unit, 1st Department of Propaedeutic Surgery, Hippokratio Hospital, University of Athens, Athens, Greece
[2] Department of Pathology University of Athens, Greece

BACKGROUND: Vacuum-assisted breast biopsy (VABB) is a minimally invasive technique for the evaluation of mammographically detected, non-palpable breast lesions. This study examines whether VABB specimens provide an accurate immunohistochemical assessment of estrogen receptors (ER) and progesterone receptors (PR). METHOD: Fifty-one consecutive cases with a VABB diagnosis of ductal carcinoma in situ (DCIS, n=34) or invasive ductal carcinoma (IDC, n=17) were included in the study. VABB (11G) was performed on the Fischer's table, and 24 or more cores were obtained in all cases. A preoperative and a postoperative diagnosis were established. Only when the two pathological diagnoses were concordant, their immunohistochemical profiles were comparatively evaluated. RESULTS: Among the 34 DCIS cases, three (8.8%) were postoperatively revealed to be IDC, i.e. were underestimated. In 12/34 DCIS cases (35.3%) and 5/17 (29.4%) IDC cases, no malignant tissue was found in the postoperative pathologic examination. Regarding ER, the concordance rate was 100% in DCIS (one-sided CI: 82.4%-100%), and 11/12 in IDC (91.7%, 95% CI: 61.5-99.8%). For PR, the concordance rate was 18/19 (94.7%, 95% CI: 74.0%-99.9%) for DCIS and 11/12 in IDC (91.7%, 95% CI: 61.5-99.8%). CONCLUSION: Specimens derived by VABB provide an accurate immunohistochemical evaluation of ER and PR receptors. This is of great importance since no malignant tissue is found frequently in the postoperative pathologic examination, and thus VABB specimens are the only material available.

PP2-23

THE IMMUNOHISTOCHEMICAL EXPRESSION OF ESTROGEN RECEPTOR BETA IN BREAST CANCER, ITS CORRELATION WITH SURVIVAL AND RESPONSE TO TAMOXIFEN

Maria Litwiniuk, Violetta Filas, Jan Breborowicz
Chair Oncology, Medical University, Poznan, Poland

Background: The role of estrogen (ER) and progesterone receptors (PgR) in breast cancer is well established. Less is known about the recently discovered another type of estrogen receptor, termed ERβ, and its potential role as a prognostic or predictive factor is still disputed. Recent clinical evidence suggests that high levels of estrogen receptor beta predict a better overall, and better disease-free survival of patients treated with adjuvant tamoxifen. The purpose of this work was to determine the extent of ERβ and ERa, PgR expression in breast cancer and to determine if the ERβ expression is associated with clinical outcome. Methods: Formalin-fixed, paraffin embedded breast cancer tissues used in our study came from 120 women who had undergone surgery at our department between 1998-1999. None of the patients had been treated pre-operatively with endocrine therapy. Immunostaining for ERα, ERβ and PgR was performed using monoclonal antibodies against ERα, PgR (DakoCytomation), and against ERβ (CHEMICON). The EnVision detection system was applied. The data were analyzed using a nonparametric Fisher-Freeman-Halton test and log-rang test for disease-free survival (DFS) and overall survival (OS). The statistical significance was considered when p<0,05. Results: 55% of tumors were ERβ positive, 57.5% were ERα positive and 64% were PgR positive. As many as 14% of ERβ positive tumours had no expression of ERα. The expression of ERβ protein correlated significantly with ERα and PgR, and ERβ positive tumours were of a lower histological grade. There was no correlation between ERβ expression and tumour size axillary node involvement and age. Patients with tumours expressing ERβ had better DFS (8 years follow-up) and better OS. Seventy three patients were treated with adjuvant tamoxifen.. In that group DFS and OS were also better in patients with ERβ positive tumours. Conclusions: Expression of ERb was found in a significant proportion of breast cancers. It was also present in a noticeable proportion of ERα negative tumors which in the past would have been considered hormonal receptor negative. Further, the improved survival of ERβ positive patients treated with tamoxifen suggests that ERβ may be an independent predictor of response to hormonal therapy.

PP2-24

CD10, Ki67/MIB1, p53 EXPRESSION IN DIFFERENTIAL DIAGNOSIS OF BREAST CANCERS WITH TUBULAR COMPONENT

Robert Koktysz, Piotr Wisniewski, Cezary Jochymski, Wojciech Kozlowski
Pathology Dept. Military Institute of Health Services Warsaw, Poland

CD10-positive cells have been reported in the stroma of various carcinomas such as prostate, breast, colorectal, and lung ones. CD10 positivity has also been reported in stromal myoepithelial cells from normal tissue and benign myoepithelial tumors of breast. Some reports indicated that stromal CD10 expression is associated with biological aggressiveness in various epithelial malignancies. Several reports denoted that the tubular cancer is a part of mixed types of breast neoplasms. AIM: The aim of presented study is evaluation of usefullness of CD10, p53 and Ki67/MIB1 expression in differential diagnosis of breasts cancers with tubular component and morphological evaluation of mixed tumors with that histological pattern. METHODS: In the years 1996 to 2006 in the 656 total mastectomy specimens, 41 (6,25%) cases with different forms of tubular component have been diagnosed. It should be stressed that in this group there were 1,1% „pure" tubular cancers. All these selected cases have been reevaluated. An immunohistochemistry evaluations with CD10, p53 and MIB1 have been also performed. RESULTS: These evaluated cases of cancers with tubular component include 22,8% „pure" tubular, 25,7% tubular mixed with cribriform intraductal cancer, 31,4% ductal infiltrative cancer with tubular component and 19,9% of other forms of mixed patterns . Only about 30% cases in this group were positive for Estrogen and Progesteron receptors. Stromal expression of CD10 has been observed in 80% of mixed type of cancer in contrast to „pure" form (about 50% positive for that antibody) and it was correlated with low expression of p53 (70% cases has less than 1% of p53 positive cells) and a low MIB1 positive cells rate. Positivity for CD10 of stromal cells correlates with tumor size, but there were no correlation with nodal status. CONCLUSIONS: Tubular cancer of the breast presents mixed pattern in majority of cases. Stromal expression of CD10 is rare in "pure" tubular cancer of the breast and does not correlate with p53 status. In 30% cases of tubular cancer expressions of Estrogen and Progesteron receptors have been noted.

PP2-25

CYCLIN D1 AND Ki-67 EXPRESSION IN COLUMNAR CELL LESIONS OF THE BREAST

Semir Vranic[1], Adela Cimic[1], Asja Pasanovic[1], Delila Hodzic[2], Nurija Bilalovic[1]
[1] Department of Pathology, Clinical Center of the University of Sarajevo, Bosnia and Herzegovina
[2] Faculty of Health Sciences, University of Copenhagen, Denmark

Introduction: Columnar cell lesions (CCLs) encompass a heterogeneous disorder that might progress to some forms of low grade invasive breast carcinomas. The aim of this study was to explore the biological potential of CCLs measuring its proliferative activity (via Ki-67) and cell cycle regulation (via cyclin D1). Material and methods: Forty four breast samples, diagnosed in period 2005-2007 at the Department of Pathology, Clinical Center of the University of Sarajevo, were randomly selected and retrospectively analyzed. All CCLs were categorized into: Columnar change disease (CCD), columnar cell hyperplasia (CCH) and flat epithelial atypia (FEA) as earlier proposed. For immunohistochemical purposes, monoclonal antibodies for cyclin D1 and Ki-67 were applied. All immunohistochemical staining were captured by Olympus Digital Camera and semiquantitatively measured as a percentage of positive cells. All samples were measured independently by three researchers and mean value was taken as a final result. Statistical Package for Social Sciences (SPSS, version 11.5, Chicago, IL, USA) was used for statistical analysis. Results: The lesions were distributed as follow: Columnar cell change (21 cases, 47.7%), columnar cell hyperplasia (20 cases, 45.5%) and flat epithelial atypia (3 cases or 6.8%) as earlier proposed. We found significant association between CCH and FEA and low grade breast carcinomas (p=0.008, Chi-Square test). Significant positive correlation was found between CCH and FEA and carcinomas (p=0.001, Spearman's rank Correlation coefficient, rs=0.474). Cyclin D1 expression was generally low in CCLs of the breast with mean value of 9.86% positive cells. Significantly higher expression of cyclin D1 was detected in CCH and FEA compared with CCD (p=0.013, Chi-Square test). Ki-67 expression was also very low with an average of 3.48% positive cells. Ki-67 had a higher positivity in CCH and CEA in comparison with CCD (p=0.012, Chi-Square test). There was also a trend toward positive correlation between cyclin D1 and Ki-67 expression (p=0.066, Spearman's Correlation Test). Conclusion: Significant positive correlation was detected between CCH and FEA and low grade invasive breast carcinomas. Cyclin D1 and Ki-67 expressions were generally low in CCLs of the breast. Both markers showed significantly higher expressions in CCH and FEA in relation to CCD. Therefore, attention has to be paid on CCH and FEA as potential precursors of low grade breast carcinomas.

PP2-26

GHRELIN EXPRESSION IN INVASIVE DUCTAL CARCINOMA OF THE BREAST

Hulya Akgun[1], Figen Ozturk[1], Alper Akcan[2], Metin Ozkan[3], Munevver Baran[1], Turhan Okten[1]
[1] Erciyes University School of Medicine, Department of Pathology, Kayseri, Turkey
[2] Erciyes University School of Medicine, Department of General Surgery, Kayseri, Turkey
[3] Erciyes University School of Medicine, Department Medical Oncology, Kayseri, Turkey

BACKGROUND: Ghrelin, the endogenous ligand for the GH secretagogue receptor (GHS-R), has been primarily linked to the central neuroendocrine regulation of GH secretion and food intake, although additional peripheral actions of ghrelin have also been reported. Ghrelin is expressed in some malignant tumors, but little is known about the contributions of Ghrelin in breast carcinogenesis. The aims of this study were to investigate the expression of the Ghrelin in breast carcinomas and to compare the results with several established prognostic markers of breast cancer. METHODS: Formalin-fixed, paraffin-embedded tissue sections from 48 invasive ductal carcinomas were immunostained for Ghrelin, ER, PR and HER2/neu. Immunohistochemical staining was performed using the avidin-biotin complex with microwave antigen retrieval. The cytoplasmic immunostains for Ghrelin were scored using a four-scale (0 to 3+) system based on the percentage of cells stained and the intensity of staining. Ghrelin staining was compared to ER, PR, HER2 status, tumor size, histologic grade, and nodal status. The relationship between the clinical and histopathological markers was analyzed by chi-square test. RESULTS: All the patients were female, with a median age of 53 (24-77). The histological type in all cases was invasive ductal carcinoma, not otherwise specified. The majority of cases were graded as G2 (54%), 18% were G1 and 27% were G3. 14.6 % of the tumors were [LTEQ]2 cm in size, 60.4% were between 2 and 5 cm and 25% were more than 5 cm in size. Ghrelin was expressed in 37 (77%) of 48 breast carcinomas and demonstrated a diffuse cytoplasmic pattern of staining. Concerning the size of the tumor, Ghrelin positive were 81.8% of the tumors [LTEQ]2 cm, 45.5% of the tumors between 2 and 5 cm and 72.7% of the tumors more than 5 cm in size. Ghrelin positive were 63.6% of G1 carcinomas, 72.7% of G2 and 63.6% of the G3 breast carcinomas. 75% of the lymph node positive tumors were Ghrelin positive. Regarding the ER and PR

immunohistochemical expression, 72.9% (35/48) were concomitant Ghrelin and ER positive, 81.3% (39/48) were Ghrelin and PR positive and 54.2% (26/48) were Ghrelin and HER2/neu positive cases. CONCLUSION: The present data suggest that Ghrelin was expressed in invasive ductal carcinomas. The majority of our Ghrelin positive carcinomas were well and moderately differentiate, 72.9% of ER positive, 81.3% of PR positive carcinomas. Our results suggest that increased expression of Ghrelin may be involved in the carcinogenesis of the breast and may be a potential therapeutic target.

PP2-27
THE PREVALENCE OF BREAST CANCER IN UNIVERSITY HOSPITALS IN AHVAZ FROM 2001-2002
Mahin Taherimoghadam, Iran Rashidi
Gondishapoor University, Iran

Breast cancer is the most common organic malignancy in women and is the second cause of death after lung cancer. Early diagnosis for breast cancer is important because if the stage is lower when cancer was diagnosed, prognosis will better. The propose of this study is demonstrating of breast cancer stage and determine it's relation with age and histological type of tumor. Method: This study was performed cross-sectional on pathology Result of Mastectomy in pathology laboratory in teaching centers of Ahvaz University of medical science at 2001 and 2002. We used Fisher's test and chi-square test and spss software for statistical analysis. Results: According to this study, the most common type of carcinoma is undifferentiated carcinoma (84/4% of cases). The most common stages are III a (%30 of cases), III b (%27/3 of cases) and the rarest stage is stage I (%3 of cases). In undifferentiated carcinoma, the most common stages are III a,II a and III b respectively. In papillary carcinoma, stage II a and III a each include 50% of cases. There is one case of medullary carcinoma with stage II a, on case of Mucinous carcinoma with stage III b and one case of Puget's disease and undifferentiated carcinoma with stage III b and one case of Puget's disease and undifferentiated carcinoma with stage I. In age group of 50 and younger than 50 years, late stage (%68/8) is more than early stage (%33/3) and also in older them 50 years: the late stage (%58/8) is more common than early stage (%41/2) and there is no significant correlation between these age group with two stage groups (p.v>0/05). There is significant correlation between the early stage and late stage with skin metastasis (p.v=0/02) but there is no significant relation with vascular metastasis (p.v>0/05). Conclusion According to this study, In breast cancer high grade stages are common is young ages, There fore, screening programs must be consider and instruct women about the important of breast examine and related symptoms must be instructed and should be perform mammography from 40 years old.

PP2-28
HISTOLOGICAL PROFILE, IMMUNOHISTOCHEMICAL EXPRESSION AND NOTTINGHAM PROGNOSTICATION INDEX (NPI) OF BREAST CARCINOMAS
Stephanos Milias[1], Epaminondas Molyvas[1],
Charisios Karanikiotis[2]
[1] Department of Pathology 424 General Military Hospital, Thessaloniki, Greece
[2] Department of Medical Oncology, 424 General Military Hospital, Thessaloniki, Greece

Background: To evaluate the histological profile, the immunohistochemical expression, the Nottingam Prognostication Index and their usefulness for the prognosis of female breast carcinomas. Method: 62 archival cases of breast carcinomas from our hospital, from the period 1997-2007 were reviewed. Clinical information were available for 37 cases. All cases were stained for ER, PR, c-erbB2, p53, ki-67, PS2, bax, bcl2, MDR and EGFR. The Nottimgham Prognostication Index of each case was evaluated from the grade, stage and the tumor diameter. Results: 15 carcinomas were located at the right and 22 at the left breast. The age of the patients ranged 23-86 years (median 56.7). 33/37 cases underwent mastectomy and lymph node dissectomy. 18 cases had lymph node metastases. The tumor diameter ranged 0.6- 7.5 cm. 34 cases were ductal carcinomas, 1 case was lobular carcinoma and 2 cases were mixed type. The ductular carcinomas were graded as grade I (15 cases), grade II (11 cases) and grade III (8 cases). The majority of cases were positive for ER or /and PR, bcl2 and MDR and negative for c-erbB2. Few cases showed overexpression of p53 and very high proliferating index and rare cases were positive for EGFR. PS2 and bax were variably positive. NPI ranged 2,2-7,5. According to NPI 13 cases were classified as having good prognosis, 14 cases as moderate and 6 cases as poor prognosis. The rest 4 cases did not get a NPI because there was no lymphadenectomy. All patients received adjuvant chemotherapy including anthracycline containing regimens. Node negative patients also received FEC while node positive ones received dose dense sequential chemotherapy with Epirubicin, Cyclophosfamide and Taxanes. One patient with a high NPI died of the disease 4 years after initial appearance. Two patients, one with a low and one with a medium NPI relapsed. Another patient with low NPI showed in situ carcinoma at the other breast. One patient with low NPI had bone metastasis and another one with a high NPI had liver metastasis. Conclusion: According to our results it seems that NPI is not an independent prognostic factor but it must be taken in consideration with the histological and immunohistochemical profile of a breast carcinoma to predict its possible biological behavior.

PP2-29
ANDROGEN RECEPTOR (AR) IS FREQUENTLY EXPRESSED IN BREAST CARCINOMA AND CO-EXPRESSED WITH ER AND PGR. A NEW MOLECULAR MARKER?
Vela-Chávez Teresa Andrea[1], Arrecillas-Zamora Myrna Doris[1], Pérez Sánchez Victor Manuel[1], Castañeda Noel[1], Bornstein-Quevedo Leticia[2], Hernández-Rodríguez Norma[1]
[1] Instituto Nacional de Cancerología, Mexico City
[2] Instituto Nacional de Pediatría, Mexico City

Background: ER and PgR are important prognostic and predictive factors involved in development, growth and differentiation in breast carcinoma; related with low-grade tumors and inversely correlated with Her2/neu. AR has been studied recently as a new molecular marker in breast carcinoma, expressed approximately in 35-70%. We analyzed the expression of AR correlated with another prognostic molecular factors in breast cancer patients. Methods: We studied a group of 35 patients with diagnostic of ductal carcinoma, all the cases had histopathological confirmation. We assessed the expression pattern of AR and ER by immunoblotting and IHQ in primary tumor samples; also we analyzed the expression of PgR and Her2/neu by IHQ. Chi-square and log rank tests were used to determine differences between proportions of each AR and ER isoforms and mortality and survival distributions respectively. Results: The median follow-up was 56 months (1-77mo); the median age of the patients was 48 years (30-81yr). In 46% of the cases (16/35) AR was expressed. ERα and ERβ were expressed in 34% (12/35) and 54% (19/35), respectively. Seven of 35 (20%) patients over-expressed Her2/neu. Eleven of 35 (31%) cases over-expressed AR/ERα (P=0.0068) and 17/35 were AR/PgR (49%) (P=0.0437). Four of 35 (11%) patients developed metastases, all of them were positive for AR. Twenty of 35 (57%) patients are still alive and 10 of them (50%) were AR positive. Conclusion: In this study we demonstrated the frequent expression of AR in breast carcinoma (46%) and the co-expression with ER and PgR. AR may be a predictive factor for adjuvant treatment in patients with metastases. Further studies are needed to demonstrated clinical significance in these patients.

PP2-30

SECRETORY BREAST CARCINOMA PRESENTED WITH METASTATIC AXILLARY LYMPH NODE

Ahu Senem Demiroz[1], Ovgu Aydin[1], Sennur Ilvan[1], Zerrin Calay[1], Metin Ertem[2]
[1] Department of Pathology, University of Istanbul, Cerrahpasa Faculty of Medicine, Istanbul, Turkey
[2] Department of Surgery, University of Istanbul, Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Secretory mammary carcinoma is a rare breast neoplasia originally described in children but sometimes also found in adults, presenting at the average age of nine with range of 3 to 87. It presents a more favourable outcome than the more common histological types of breast carcinoma; published literature in fact reports only a few cases with axillary lymph node metastases and only four cases with distant metastases. We report a rare case of secretory breast carcinoma with axillary lymph node metastases. Case : 62 year old woman presented with palpable axillary lymph node. The histopathological examination of the incisional biopsy revealed a carcinoma with CK7, GCDFP, ER positivity and CK20, TTF-1, thyroglobulin negativity. After that, a mass smaller than 1 cm was recognized radiologically on the lateral quadrant of right breast. The mass was excised, frozen section was performed; sclerosing adenosis and ductular proliferation areas were seen in microscopic examination at frozen section. Modified radical mastectomy was performed. Grossly, tumor was 0.9 cm in greatest diameter with irregular outline, had a hard and gritty cut face and white to yellow color and was submitted completely. Microscopically the lesion showed solid nests consisting of small, uniform, well differentiated cells, with granular cytoplasm. Mitoses was absent and atypia was mild. Immunohistochemically the neoplastic cells showed a strong positive staining for alpha-lactalbumin and milk fat protein. They were positive for ER and S-100. So the histological and immunohistochemical findings of the permanent sections of the mass were consistent with secretory carcinoma. There was one metastatic lymph node in the axilla. Conclusion: Secretory breast carcinoma is known as a juvenile carcinoma but has been found in patients ranging from 3 to 87 years of age both in men and women. It is not a aggressive tumor and presents an excellent prognosis. It may be difficult on hematoxylin –eosin slides and even more difficult at frozen section to decide how much of the tumor is invasive and how much is in situ. Treatment should be as conservative as possible.

PP2-31

MUTATION ANALYSIS OF EXONS 1 AND 2 OF CTNNB1 (BETA CATENIN) IN INVASIVE BREAST CARCINOMAS

Eleni Papanikolaou[1], Foukas Periklis[2], Irene Theohari[3], Ioanna Giannopoulou[3], Panayiotis Bakarakos[3], Christina Magkou[3], Sonia Markaki[4], Lydia Nakopoulou[3]
[1] Cell and Gene Therapy Lab, Foundation for Biomedical Research of the Academy of Athens, Athens, Greece
[2] 2nd Department of Pathology, Attikon University Hospital, National and Kapodistrian University of Athens, Athens, Greece
[3] 1st Department of Pathology, School of Medicine, National and Kapodistrian University of Athens, Goudi, Athens, Greece
[4] Department of Pathology, Alexandra Hospital, Athens, Greece

Introduction: beta-Catenin has a crucial role in cell–cell adhesion as well as a signaling role as a member of the Wnt pathway. Mutations in the beta-catenin gene have been found in numerous cancers; however, in breast and prostate cancer, mutations of beta-catenin have been found to be infrequent. The aim of this study was to identify new mutations in exons 1 and 2 of the beta catenin gene and correlate these with the clinicopathological parameters and overall survival of the patients in breast cancer. Materials and Methods: A total of 36 paraffin-embedded breast tissue specimens were available from patients with clearly invasive breast carcinomas, aged 25–84 years (mean age 56.43 years). DNA extraction from paraffin embedded tissues was performed using the Qiamp DNA Mini Kit (Qiagen) according to manufacturer's instructions. 10ul of the purified DNA were used as template for the PCR reaction using Platinum Pfx read-proof DNA polymerase (Invitrogen) and the following primers for exon 1:forward 5'ATTTTAAGCCTCTCGGTCT3',reverse 5'AAGCACCTCAGGGGAACA3', and for exon 2: forward 5'CAGGTATCCCAGTGACTTAGGAG3',reverse 5'GCAGAGCCCCAATTCAGTAAC3'. The amplified bands were gel extracted and sequenced using the same primers in an ABI PRISM 3100 Avant DNA sequencer (Applied Biosystems). Results: For exon 1 mutations were detected in 13 out of 36 samples (36%) and for exon 2 mutations were detected in 21 out of 36 samples (58,3%). The mutations comprise of point substitutions, missing bases, and a probable increase in the beta catenin gene copy number/cell. Specifically for exon 2 a certain point substitution at position 405 that corresponds to the 2nd intron of the gene (GenBank Accession Number X89579) was detected in 19 out of 21 mutated genes (90,47%) and seemed to correlate with lower cytosolic localization of beta-catenin in cancer cells ($p=0.009$, $\chi 2$ test). No correlation was observed with clinicopathological parameters and patients' survival. Discussion: This is the first report of mutations of beta-catenin gene in breast cancer. Previous work concerning mutations of beta-catenin and breast cancer was limited to the mutation detection in the 3rd exon of the gene. We have mapped the 405 point mutation in the second intron of beta-catenin gene but in order to make any correlation with clinicopathological parameters or any biological markers we need a larger line of patients.

PP2-32

PREVALENCE OF HUMAN PAPILLOMA VIRUS IN BREAST LESIONS IN MEXICAN PATIENTS

David Cantu De Leon[1], Delia Perez Montiel[1], Iva Mikyskova[2], Ondrej Hes[2], Jose Luis Aguilar Ponce[3]
[1] Instituto Nacional de Cancerologia, Mexico
[2] University Hospital Plzen, Czech Republic
[3] Instituto Nacional de Cancerologia Mexio

Background: Breast cancer is the second most common female cancer in Mexico. Some classical risk factors are well recognized; nevertheless up to 80% of patients with this tumor do not have any recognizable risk factor. In the world, there is some evidence of an association between breast cancer and viruses, such as human papilloma virus and mouse mammary tumor virus (MMTV). At present time there is no report of detection of HPV sequences in mexican patients with breast cancer. Materials and Methods: From January 1999 to December 2003, 65 cases of breast cancer were selected from the pathology files. One representative paraffin block was selected, HPV DNA was analyzed by polymerase chain reaction (PCR) and sequenced for different types of HPV. Of all selected cases 51 specimens showed DNA integrity by b-globin amplification. These cases were matched by age and size with 51 cases of benign conditions (fibroadenoma, fibrocystic disease and phyllodes tumor) and HPV DNA was analyzed by polymerase chain reaction (PCR). Descriptive analysis of clinical and pathological variables was performed and comparisons between positive and negative cases were done. Results: Of all selected cases with breast cancer 51 specimens were evaluated, mean age was 53.3, cervicovaginal cytology was evaluated and only 1 patient (1.5%) had HPV no cases were diagnosed with cervical dysplasia. 92.3% of tumors were ductal carcinomas, mean tumor was 9.4cms, SBR 8 and 9 were 11(16.9%) and 10 (15.4%), respectively. 36 (70.5%) were negative to HVP and 15 (29.4%) were positive, when typing was performed, 10(66.6%) were positive for HPV 16, 3(20%) for HPV 18, and two cases (13.3%) were positive for HPV 16 and 18. When comparisons between HPV positive and negative were done in relation to all clinical and pathological variables the only one which was significant was tumor size, since only one tumor larger than 4cms was positive for HPV (p=0.008). In the group

of benign conditions all were negative to HPV-DNA Conclusions: A high prevalence of HPV in breast tumors in Mexican woman was found, similar to other reports in the literature, the most common type was HPV 16. Tumors larger than 4 cms rarely have HPV DNA, this feature is similar to large carcinomas of uterine cervix. Study of a larger series of cases need to be analyzed in order to establish the exact role of HPV virus in the pathogenesis of breast cancer.

PP2-33
IMMUNOHISTOCHEMICAL DEFINITION AND PROGNOSTIC SIGNIFICANCE OF SPORADIC BASAL-LIKE BREAST CARCINOMAS. A GRADE 3 COHORT OF PATIENTS.

Socorro Maria RodríGuez-Pinilla[1], Marta Hergueta[2], David Hardisson[3], Pepe Palacios[4], Gema Moreno-Bueno[2]
[1] CNIO, Spain
[2] UAM, Spain
[3] HLP, Spain
[4] HVR , Spain

Introduction: Breast basal-like tumors are high grade carcinomas with a charactheristic morphologic appearence and agressive clinical behaviour. Although there are still not universal accepted immuohistochemical definition for these subgroup of tumors, Nielsen et al using a panel of four antibodies (ER, HER1, HER2 and cytokeratin 5/6) could identify them with a specificity of 100% and a sensitivity of 76%. Nevertheless, it is still unclear whether these tumors maintain their properties when compared to a similar grade matched subgroup of tumors. Aims: 80 grade 3 breast carcinomas were subclassify using expression profiles studies into different subgroups. First of all, we tested the tumors included into the basal-like subgroup for Nielsen et al immunohistochemical profile. Secondly, we tried to identify an immunohistochemical panel which higher sensitivity testing 30 immnuohistochemical markers using TMA. Moreover, we evaluated the prognostic significance of our findings. Results: Data still being evaluated.

PP2-34
ACINIC CELL CARCINOMA OF THE BREAST

Maria Papaevangelou[1], Nikiforos Kapranos[2], Efthymios Koniaris[1]
[1] Pathology Dept Anticancer Oncological Hospital of Athens, 'Ag. Savvas', Athens Greece
[2] Molecular Pathology Dept, 'Mitera' Maternity and Surgical Center, Athens, Greece

Background: Acinic Cell Carcinoma of the breast (ACC) is the rare counterpart of a similar tumor that occur in the salivary glands. It was described quite recently by Roncaroli et al. in 1996 and has a unique immunohistochemical profile. Eleven cases have been reported in the international bibliography so far. We present a very interesting new case. Methods: A 65-year old patient was presenting an asymmetric density during the repeating mammographic screening the past 5 years. The last mammography of the right breast showed an area of distorted architecture and a stellate radio-opaque change in its center. The FNA examination was positive for adenocarcinoma and the patient was treated by a modified radical mastectomy. Grossly, the tumor measured 7cm, with infiltrative margins, whitish to greyish-pink pallor and a consistency that varied from outer soft to inner hard. Results: Histologically, the core of the stellate lesion consisted of pleomorphic tumor cells embedded into an exuberant desmoplastic stroma (md: 1.5cm), while the surrounding projections consisted of a ductal type adenocarcinoma with nodular, solid, microglandular tumor nests or combination of these patterns. These nests of neoplastic cells were delimited by a network of thin connective tissue. The tumor cells were strikingly clear in most areas or had an abundant granular eosinophilic cytoplasm. Clear cells were also noted in numerous foci of lobular cancerization.The glandular structures were filled with eosinophilic PAS positive material. The nuclei were round and irregular with a single eosinophilic nucleolus. The 26 excised lymph nodes had no metastases. The immunohistochemical profile of the tumor showed intense staining with S-100, EGFR, CK7, EMA and PAS. Ki67 and p53 were positive (>10-49%, 80% respectively). ER, PR receptors, SMA and HER-2 neu were negative as well as the GCDFP-15 protein. Conclusion: In our case was a pure ACC coexisted with a small NOS and had all the morphological and immunohistochemical characteristcs which were identical to that of the acinic cell carcinoma of the salivary glands. Differential diagnosis involved microglandular adenosis, adenomyoepithelial carcinomas, secretory and glycogen-rich adenocarcinomas. On conclusion, the rarity of ACC, its excellent prognosis, the low rate of lymph node metastases and the good response to neoadjuvant chemotherapy, make its diagnosis important.

PP2-35
ANALYSIS OF ESTROGEN RECEPTOR POSITIVE (ER+), PROGESTERON RECEPTOR NEGATIVE (PR-) PHENOTYPE AND HER2 STATUS IN BREAST CANCER (BC) PATIENTS

Slobodanka Mitrović, Vesna Stanković, Goran Azanjac, Srđan Ninković
Clinical Center Kragujevac, Serbia

BACKGROUND: The most important morphological prognostic factors in BC are tumor size, axillary lymph node involvement and histological grade. The main non morphological prognostic factor is hormone receptors and HER2 status.HER2 overexpression usually correlates to a poorer prognosis and higher metastatic risk. ER and PR expression are the only predictive factors with proven usefulness in selecting patients who are likely to respond to adjuvant endocrine therapy. Various clinical studies indicate that patients with ER+/PR- BC have a different HER2 phenotype possibly resistant to tamoxifen therapy.
MATERIALS AND METHODS: From December 2005 to April 2007, two hundred and fifty nine BC evaluated using immunohistochemistry (IHC)for ER, PR and HER2 receptor. HER2 expression was interpreted as negative(0,1+) or positive(2+,3+). In addition, six HER2 2+ BC were also evaluated using chromogenic in situ hybridization (CISH). Independent variables such as age, tumor size, nodal status, grading and histological type were also included in the analysis.
RESULTS: Of the 259 cases, 137 (52,9%) BC were ER+/PR+/HER2- , 44 (17%) were ER-/PR-/HER2-, 28 (11%) were ER-/PR-/HER2+, 11 (4,2%) were ER+/PR+/HER2+, 3 (1,1%) were ER-/PR+/HER2- and 36 (13,9%) were ER+/PR-. Seven (19,4%) of the 36 ER+/PR- BC showed HER2 3+ membrane staining, 23 (63,9%)HER2 0 and 1+, and 6 (16,7%) showed HER2 2+ membrane staining. For HER2-2+ by IHC, two (2/6) were positive by CISH and both patients had poorly differentiated ductal BC. In the group ER+/PR-/HER2 3+, all tumors were ductal histological type, 4 (57,1%) were grade 2 and 3 (42,9%) were grade 3. Median age was 56 (range 44-67), median tumor size 36mm (range 23-54) and 5 (71,4%) patients had positive lymph nodes. In group ER+/PR-/HER2– BC, the majority of tumors were grade 1 (30,4%) and 2 (60,1%),and the commonest histological types were ductal (47,8%) and lobular (34,8%). Median age was 64 (range 49-76), median tumor size 34 mm (range 14-68) and 11 (47,8%) patients had positive lymph nodes. CONCLUSION: ER+/PR- status does not preclude a positive HER2 status. 19,4% of the ER+/PR- BC showed overexpression HER2. BC with ER+/PR-/HER2+ phenotype had higher histological grade and bigger stage of the disease than ER+/PR-/HER2- BC.

PP2-36
CHONDROLIPOMA OF THE MALE BREAST
Işin Gokcol Erdogan, Umit Bayol, Bengu Gunay Yardim, Olcay Ozcolpan, Muhammed Ahmet Guldur
SB Izmir Tepecik Teaching Hospital, Department Of Pathology, Turkey

Background :Cartilage is the most often found component in malignant mesenchymal and epithelial tumors of the breast. The benign cartilage containing tumors of the breast are very rare. Chondrolipomas are benign lesions consisting of fat, cartilage and fibrous tissue. They are well circumsribed, firm nodules that clinically resemble fibroadenomas. The question of whether these lesions are neoplasms, hamartomas or choristomas is unsettled. Case presentation : We present a case of well circumscribed, painless breast mass in a 60 year old man. A few cases of chondrolipomas in female patients have been reported so far. To our knowledge, this is the first case in a man to be reported in English literature.

PP2-37
AN IMMUNOHISTOCHEMICAL EVALUATION OF CD44+/CD24-/LOW CELLS IN INVASIVE BREAST CANCER: CORRELATION WITH ANGIOGENETIC PHENOTYPE
Christina Magkou[1], Emmanouil Fasomytakis[1], Alexandros Nomikos[1], Panagiotis Bakarakos[1], Eumorphia Boltetsou[2], Kleio Papaparaskeva[2], Sophia Markaki[3], Lydia Nakopoulou[1]
[1] 1st Department of Pathology, Medical School, University of Athens, Greece
[2] 2nd Department of Pathology, Attikon University Hospital, Athens, Greece
[3] Department of Pathology, Alexandra Hospital, Athens, Greece

BACKGROUND: CD44+/CD24-/low breast cancer cells (cells with strong expression of CD44 adhesion molecule and no/very low expression of CD24 adhesion molecule) resemble normal stem cells with respect to their ability to self-renew, to proliferate and to differentiate into various cell types. Previous studies showed the ability of CD44+/CD24-/low cells to form new tumors in mouse models. In human breast cancer, the identification of these tumorigenic cells is crucial for the development of effective targeted therapies. The aim of our study was to identify CD44+/CD24-/low cells in invasive breast cancer and to correlate them along with classical clinicopathological parameters and angiogenetic factors. METHOD: Double-staining immunohistochemical technique was performed on paraffin-embedded tissue specimens from 138 invasive breast carcinomas to detect the CD44+/CD24-/low cells. CD44+/CD24-/low expression was assessed in combination with classical clinicopathological parameters (menopausal status, histological type, tumor size, stage, nuclear and histological grade, lymph node metastases), ER and PR receptor status, p53, Ki67, c-erbB-2, VEGF-A, VEGF-C, Flt-1 and Flt-4. The results were estimated by automated image analysis and statistically processed using chi-square test. Overall and disease-free survival distribution curves were assessed by Kaplan-Meier test and log-rank statistics. RESULTS: The phenotype CD44+/CD24-/low ranged from 0% to 70% in breast cancer specimens. The prevalence of CD44+/CD24-/low cells was ≤10% in the majority of cases (85.2%) and >10% in 14.8% of cases. There was no significant correlation between CD44+/CD24-/low prevalence and clinicopathological parameters, biological markers (ER, PR, p53, Ki67, c-erbB-2) as well as overall and disease-free patients' survival. CD44+/CD24-/low phenotype was associated with VEGF-C and Flt-1 ($p=0.028$ and $p=0.023$ respectively), while no relationship was found between CD44+/CD24-/low phenotype and VEGF-A or Flt-4 expression. CONCLUSION: CD44+/CD24-/low tumor cells are associated with Flt-1 and VEGF-C. Both of them are well known angiogenetic and lymphangiogenetic factors contributing to tumor metastasis. In a recent study (Abraham et al., 2005) breast cancer stem cells were found to be associated with distant metastases. However, this observation needs further investigation in order to clarify the role of these cells in the metastatic process.

PP2-38
HISTOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL PROFILES OF BREAST CANCER IN POSTMENOPAUSAL WOMEN
Raluca Balan[1], Cornelia Amalinei[1], Vlad Gheorghita[2], Emil Gheorghita[2]
[1] Pathology Department, University of Medicine and Pharmacy, Iasi, Romania
[2] The IIIrd Clinical Hospital of Obstetrics and Gynecology, Iasi, Romania

Background: Breast cancer in the postmenopausal women is a common disease that is ussualy undertreated compare to younger pacients. The proportion of estrogen receptor-positive tumors is increased in postmenopausal women. Although the observations support the perception that breast carcinoma tends to have less aggressive biologic features and a more favorable clinical course in the elderly, there are no significant differences in prognosis for patients younger than 35 years and older than 75 years, on the basis of tumor stage. Material and method: We retrospectively analyzed 120 cases of breast cancer in women between 50 and 85 years. All H&E sections from the cases were reviewed and specific changes were classified. Selected blocks were immunohistochemically evaluated with the following markers: estrogen receptor (ER), progesterone receptor (PR), HER2/neu, E-cadherin, and pan-cytokeratin. Results: There were 46.66% invasive ductal carcinomas, 18,33% invasive lobular carcinomas, 2.5% (3 cases) in situ ductal carcinomas, 1.66% (2 cases) lobular intraepithelial neoplasia (LIN), and 30.83% other types. From the last cathegory, the entities were represented, with decreasing frequency, by medullary carcinoma, mucinous carcinoma, Paget disease, inflammatory carcinoma. 15.45% presented pre-operative core biopsies and frozen sections were performed in 18.66% of cases. Intra-operative diagnoses corresponded to subsequently histopathological diagnoses. 26.66% of cases presented axillary lymph node metastases and 2.5% of cases presented ovarian metastases. Conclusions: Our data show that the incidence of breast carcinoma in postmenopausal women is increased compare to younger patients. Although invasive lobular carcinoma is relatively more common in elderly women, in our study the predominant histological type was invasive ductal carcinoma. The patients were generally diagnosed as T3 and T4. Because most of them had estrogen-receptor positive tumors, they could benefit to an adjuvant tamoxifen therapy. The proportion of estrogen and progesterone receptor-positive tumors did not increase significantly in postmenopausal women older than 65 years, fact which is in concordance with the existing data from the literature.

PP2-39
PERIPHERAL MULTIPLE RECURRENT PAPILLOMAS OF THE BREAST. A CASE REPORT
Salima Bellefqih[1], Marianne Lorenzato[1], Olivier Graesslin[2], Philippe Birembaud[1]
[1] Laboratoire Pol Bouin, CHU Hopital Maison Blanche Reims, France
[2] Service de Gynecologie-Obstetrique, CHU Maison Hopital Maison Blanche Reims, France

Introduction: Peripheral multiple breast papillomas are benign lesions which are often clinically occult. They are defined as papillary projections within dilated lumina of terminal ductules lined by epithelial and myoepithelial (ME) cells. They are frequently associated with atypical ductal hyperplasia (ADH), and have a significant risk of carcinoma. Case history: A 52-year-

old female underwent a left-sided mastectomy for recurrent (four) multiple intraductal papillomas in spite of free surgical resection margin (with 20 years of follow up). All histologic sections were assessed for the presence of coexisting fibrocystic lesions, including florid ductal hyperplasia and ADH. The retrospective study of Mib1 prolifrative index and DNA ploidy on several samples revealed evolutive lesions, which could be predictive of a malignant degeneration. The immunohistochemical study shown the following results in ME cells: CK5/6+++, Actin++, P63+++, and CD10++, and epithelial cells CK7+++, CD10++, ER++, PR++, Bcl-2++, cyclin D1+++, c-erB-2-. The foci of ADH were faintly positive with ME markers cyclin D1 and p53. Conclusion: This observation illustrate that the immunophenotype of the papillary lesions of the breast is a useful tool in anticipating the invasive carcinoma and in differentiating between papillomas and invasive carcinomas.

PP2-40
GASTROINTESTINAL METASTASES OF BREAST CANCER
Merih Guray, Lavinia Middleton, Michael Cohn, Aysegul Sahin
University of Texas M.D. Anderson Cancer Center, USA

Background: Gastrointestinal (GI) metastases of primary invasive breast cancer are rare, and they often mimic primary carcinomas of the GI tract. Breast cancer can metastasize to any part of the GI tract. Distinguishing metastatic disease from a second primary tumor can become a challenging issue from time to time, however, it has great significance for management of patients. Design: We identified 55 patients with metastatic breast cancer to the GI tract, treated at M.D. Anderson Cancer Center between 1986 and 2007, and reviewed the clinicopathologic features of these patients. In selected cases, immunohistochemistry for estrogen receptor was performed. Results: The median patient age at the time of GI metastasis was 57 years (range 31–81). Primary diagnoses included invasive ductal (46%), invasive lobular (40%), and mixed invasive ductal and lobular (7%) carcinomas. In 7%, the histologic type of primary breast cancer was unknown. In 64% of patients, GI tract was the first distant metastatic site, as part of systemic metastatic disease. The metastatic sites included stomach (44%), small intestine (31%), colon/rectum (38%), liver (11%) and the appendix (2%). Histologically, 56% of the metastatic sites had poorly differentiated carcinoma, and 31% had lobular carcinoma with focal signet ring cell morphology. Transmural involvement of the GI tract was identified in 16% of the cases. 78% of metastatic tumors were positive for estrogen receptor. Conclusion: Stomach is the most common site for GI metastases of primary invasive breast cancer, and lobular histology is the most common histologic type. Metastatic tumors commonly have features of poorly differentiated carcinoma, and most of the tumors are estrogen receptor positive. In patients with the diagnosis of breast cancer, estrogen receptor staining may be helpful to determine primary versus metastatic nature on GI biopsies.

PP2-41
ASSOCIATION BETWEEN HER2 STATUS AND HORMONE RECEPTORS IN INVASIVE BREAST CARCINOMA
Matej Bracko, P. Drev, S. Frkovic Grazio
Institute of Oncology Ljubljana, Slovenia

Background: Clinical experience indicates that efficacy of endocrine treatment invasive breast carcinoma (IBC) is impeded in tumors that express estrogen receptors (ER) at low levels, those that lack progesterone receptors (PR), and in HER2 positive disease. Data on quantitative associations between ER, PR and HER2 in IBC is scarce and our aim was to analyze these relationships. Methods: A total of 1457 consecutive primary IBC were analyzed. HER2 was assessed by IHC (HercepTest™) and FISH (PathVysion™). Strong protein expression (3+) and/or gene amplification indicated positive HER2 status (HER2+). HR were evaluated by IHC and tumors were categorized in three ways based on: 1. cut-off ≥10% as ER+/- and PR+/-, 2. semi-quantitatively evaluated HR expression, in 6 groups (1: 0%, 2: 1–9%, 3: 10–40%, 4: 41–60%, 5: 61–80% and 6: 81–100% positive cells) and 3. joint HR expression, in 4 groups: ER+/PR+, ER+/PR-, ER-/PR+ and ER-/PR-. Results: 14.6% of tumors were HER2+. Among ER- tumors there was no significant difference in proportion of HER2+ cases between groups 1 (39.1%) and 2 (37.0%); on the other hand, among ER+ cases there was a significant continuous decrease of HER2+ cases from group 3 (22.4%) to group 6 (8.0%; $rs = -0.137$, $p < 0.001$). In addition, in ER+/HER2+ tumors, the average level of HER2 gene amplification showed a steady decrease from group 3 to group 6 ($rs = -0.279$, $p = 0.03$). Among PR- tumors, the proportion of HER2+ cases was significantly higher in group 1 (31.9%) than in group 2 (14.8%); among PR+ tumors the decrease of HER2+ cases from group 3 (14.7%) to group 6 (6.4%) was also significant ($rs = -0.130$, $p < 0.001$). In PR+/HER2+ tumors, a decrease in the average level of HER2 gene amplification from group 3 to group 6 was also observed ($rs = -0.186$, $p = 0.05$). 9.2% of ER+/PR+ tumors were HER2+. This proportion was significantly higher in ER+/PR- tumors (16.2%) and was highest in ER-/PR- (38.5%) and ER-/PR+ tumors (41.2%); the difference between the last two groups was not significant. Conclusion: This report presents, for the first time, results on association between HR status of IBC evaluated semiquantitatively by IHC, and HER2 status evaluated both by FISH and IHC. In IBC, HER2 positivity is closely associated with absence and lower levels of ER and PR expression, which might explain the relative resistance of HER2+ tumors to hormonal therapy. In addition, level of gene amplification is inversely related to level of ER and PR expression.

PP2-42
MORPHOLOGIC CHARACTERIZATION OF THE ESTROGEN RECEPTOR-NEGATIVE AND THE ESTROGEN-RECEPTOR POSITIVE INVASIVE DUCTAL BREAST CARCINOMAS
Tatjana Ivkovic-Kapicl, Slavica Knezevic-usaj, Olga Mihajlovic, Zoran Nikin, Bratislav Stojiljkovic
Department of Pathology, Institute of Oncology Sremska Kamenica, Novi Sad, Serbia

Background: Estrogen receptor (ER) status is a prognostic factor for patients with breast cancer, as well as a therapeutic one. ER-negative ductal breast carcinomas are usually poorly differentiated and carry a poor prognosis. The aim of this study was to assess the morphological characteristics and immunohistochemical profile of ER-negative and ER-positive tumors, in an attempt to understand the different nature of these lesions. Methods: In total, 120 cases of invasive ductal breast carcinomas, 31 (25.8%) ER-negative, and 89 (74.2%) ER-positive, as assessed immunohistochemically, were included in this study. The clinicopathologic characteristics analyzed were the size of the tumor, axillary lymph node status, tumor grade, lymphoid stroma, comedo-type necrosis, central tumor necrosis/fibrosis, p53, Ki-67, Her-2/neu, angiogenesis, and patient age. Results: ER-negative status was seen in 31 (25,8%) cases. ER-negativity was present in 12 of 63 T1 lesions (19%), in 11 of 44 T2 lesions (25%), in 3 of 7 T3 lesions (43%), and in 5 of 6 T4 lesions (83%), ($p<0.01$). ER- negative status was seen in 12 of 21 grade III tumors (57%), in 18 of 72 grade II tumors (25%), and in 1 of 27 grade I tumors (4%), ($p<0.01$). ER-negative tumors showed Her-2/neu protein overexpression in 14 (45%) cases, whereas ER-positive tumors showed Her-2/neu protein overexpression in 9 (10%) cases ($p<0.01$). ER-negative status was seen in 29 of 93 high Ki-67 tumors (31%), whereas ER-negativity was detected in 2 low Ki-67 cases (7%). ER-negative tumors showed p53 protein expression in 14 (52%) cases, whereas ER-positive tumors showed p53 protein expression in 13

(14%) cases. The presence of comedo-type tumor necrosis and lymphoid infiltration were associated with ER-negativity with statistical significance ($p<0.05$ and $p<0.01$, respectively). Conclusion: ER-negative status was significant associated with some poor prognostic tumor characteristics such as large tumor size, high histologic grade, Her-2/neu protein overexpression, high Ki-67 proliferative index, p53 protein expression, comedo-type tumor necrosis, and lymphoid infiltration. There was no association with patient age, lymphonodal status, central tumor necrosis/fibrosis or angiogenesis.

PP2-43

SECRETORY BREAST CARCINOMA IN A 48 YEAR OLD FEMALE

Vasilios Stoukas[1], Charalambos Patralexis[2], Kalliopi Petraki[2]
[1] Medical School, University of Patras, Patras, Greece
[2] Department of Pathology, Metropolitan Hospital, Athens, Greece

Introduction Secretory breast carcinoma (SBC) is considered to be a subtype of infiltrating ductal carcinoma of the breast. It is a quite rare (<1% of infiltrating carcinomas) low grade breast carcinoma, composed of cells with abundant granular or clear vacuolated cytoplasm. Historically, this carcinoma has been named as "juvenile breast carcinoma" or "juvenile secretory carcinoma", because it usually develops in females under the age of 30. Only a few cases of secretory breast carcinoma have been reported in the medical literature. Case Report At the pathology department four segments of mammary parenchyma, measuring 2.3x2x1.5cm, 2x1.5x1.3cm, 1.8x1.2x0.7cm and 2x1.4x0.8cm respectively, were sent from a 48 year old Greek female. Dissecting the mammary parenchyma segments, four solid tumors were detected measuring 1.5cm, 0.4cm, 0.6cm and 0.6cm in diameter respectively. The diagnosis was secretory breast carcinoma. As far as immunohistology is concerned, a full set of tests was performed. Estrogen Receptor (ER) and Progesterone Receptor (PR) markers were highly (in a few, scattered cells) and moderately (in 20-25% of cells) expressed, respectively. Special staining for protein p53 (D07) showed moderate to high expression (10-15% of the cell population). Oncoprotein c-erbB-2 (CB11) staining was negative. MIB-1 index revealed that 5-10% of the cell population was actively dividing. Staining for protein B-Cell Lymphoma 2 (BCL-2) and Epidermal Growth Factor Receptor (EGFR) oncogene (31g7-Zymed) were negative and positive respectively. Conclusions Secretory breast carcinoma (SBC) is associated with a better prognosis compared to the other types of invasive ductal carcinomas (even when axillary metastases are present). Treatment involves simple mastectomy and axillary dissection. The prognosis seems to correlate with age. The younger population has a 100% survival rate at 5-years, whereas the adult population with SBC has a much poorer prognosis on par with infiltrating ductal carcinoma. Unfortunately, due to the fact that our case is recent, we cannot comment on its survival and its course. Size and extent of infiltration may be the most important determinants of metastatic potential in adults.

PP2-44

CARCINOSARCOMA OF THE BREAST - CASE REPORT

Marijana Dasovic-Knezevic
Department of Pathology and Forensic Medicine,
General Hospital Zadar, Croatia

Breast carcinosarcoma (BCS)is very rare mixed epithelial/mesenchymal metaplastic tumor. It appears in <0,1% of all invasive mammary carcinomas. Most of the patients with BCS are postmenopausal (70%) with average age at presentation of 55 years. In the present case is described a 56 years old woman with two well circumscribed palpable masses in upper outer quadrant of the right breast. They measured 1-2cm in diametar.On cut surface they were firm and white. Microscopic examination revealed an invasive well to moderate differentiated ductal carcinoma with malignant proliferation of spindle cells. Mitotic activity was 8-10mt/10hpf.On IHC analysis the carcinomatous component of the tumor showed intense reactivity for EMA and Polycytokeratin(MNF116). The sarcomatous component showed Vimetin, SMA and MNF116 strong positivity. Immunoreactivity for NSE and S100 protein was strong too.The immunoreactivity of the p53 gene product was positive in more then 60% of the tumor.The same IHC results were present in metastatic tumor tissue in axillary lymph nodes.IHC analysis of HER2/neu, ER+ and PR+ receptors was negative. The patient received adjuvant chemotherapy and radioactive therapy too. She developed diseminated metastatic disease after four years time period and died. In conclusion, BCS is very aggressive tumor especially because of infiltrative high proportion of metaplastic mesenchymal stromal element, probably of myoepithelial origine showing typical S100 and NSE immunoreactivity.

PP2-45

PRIMARY BILATERAL ANGIOSARCOMA OF THE BREAST: CASE REPORT

Mustac Elvira, Dordevic Gordana, Mokrovic Hrvoje, Sonnenschein Ivan
Department of Pathology, School of Medicine Rijeka, Croatia

Angiosarcoma of the breast is a rare and aggressively malignant tumor with high mortality rate and a very poor prognosis.This tumor tends to grow very quickly and is generally difficult to treat successfully. This is a case report of a 37-year old woman who had primary bilateral angiosarcoma of the breast. The patient presented with a lump in her left breast, which she had noticed three months earlier. The tumor was located at the outer upper quadrant. An incisional biopsy showed moderately differentiated angiosarcoma, which had already infiltrated the surrounding breast and fibrofatty tissue. Mastectomy was performed without axilary dissection. No further therapeutic procedure was undertaken. Two years later the patient noticed a lump in the upper inner quadrant of her right breast. The lump was sonographically and mammographically detectable. Tumorectomy was performed. Histopathologic analysis showed a well differentiated angiosarcoma. Immediate mastectomy was suggested to the patient, but she didn't accept it. A year later the patient noticed a lump under the postoperative scar in her right breast. Biopsy revealed a local recurrence of the tumor with a well differentiated angiosarcoma pattern. Radical mastectomy with large excision of the great pectoral muscle and dissection of the axillary lymph nodes was done. The pectoral muscle was partially infiltrated. Two years after the operation, the patient got pregnant and unfortunately there was a relapse of the illness. She decided to bring the pregnancy to term. Multiple bone and right ovary metastases were detected. Four months after the metastasis was found on the right ovary an ipsilateral adnexectomy was done. After the operation she got six lines of chemotherapy. Five months later craniotomy and cranioplasty followed due to local recurrence. The patient died two months later. Early diagnosis, surgical treatment and low histological grade play an important role in survival, whereas the benefit of adjuvant therapy remains to be demonstrated. The decision to treat should be preceded by a preoperative multidisciplinary assessment.

PP2-46

COMPARISON OF HER-2, EGFR AND CYCLIN D1 IN PRIMARY BREAST CANCER AND PAIRED METASTATIC LYMPH NODES: AN IMMUNOHISTOCHEMICAL AND CHROMOGENIC IN SITU HYBRIDIZATION STUDY

Yoon-La Choi, Jae Joon Han, Young Lyun Oh
Department of Pathology, Samsung Medical Center,
Sungkyunkwan University School of Medicine, Korea

The significant advance in the development of molecular-targeting drugs has made an evaluation of Her-2, EGFR and cyclin D1 an important clinical issue in breast cancer patients. This study compared the Her-2, EGFR and cyclin D1 statuses of primary tumors as well as their matching lymph node metastases using immunohistochemistry (IHC) and chromogenic in situ hybridization (CISH) in 73 breast cancer patients. Her-2, EGFR and cyclin D1 protein showed concordance between the primary lesion and the metastatic regional lymph nodes in 82%, 90% and 60%, respectively. CISH also revealed 92%, 93% and 85% concordance in the gene amplification status of the Her-2, EGFR and cyclin D1. There was a reasonable correlation between amplification of the Her-2, EGFR and cyclin D1 genes in axillary metastatic lymph nodes and the amplification of these genes in primary tumors. On the other hand, in terms of the expression of their protein, there was statistically significant agreement in only Her-2. We conclude that Her-2 status can be reliably assessed on primary tumor but a possible difference in EGFR and cyclin D1 status between the primary and the metastatic sites would be concerned for breast cancer patients considering molecular targeting therapy.

PP2-47

DNA PROMOTER HYPERMETHYLATION OF BLU GENE IN INVASIVE BREAST DUCTAL CARCINOMA IN TUNISIA

Mohamed Hachana, Mounir Trimeche, Khaled Amara, Sonia Ziadi, Ines Bellamine, Moncef Mokni, Badreddine Sriha, Sadok Korbi
Department of Pathology, CHU Farhat Hached, Sousse, Tunisia

Background: Many distinct regions of chromosome 3p shows frequent allelic losses in a wide range of tumor types comprising breast cancer, suggesting the presence of several tumor suppressor genes in these regions. The BLU candidate tumor suppressor gene located in a gene-rich critical deleted region in 3p21.3 was found to be inactivated by promoter CpG islands hypermethylation in several human tumors. Data about the frequency of hypermethylation of the promoter of BLU gene in breast cancer are largely lacking. The present study was undertaken to evaluate the prevalence and the clinicopathological significance of hypermethylation of BLU promoter in breast cancer. Methods: DNA extraction, bisulfite treatment, and methylation specific polymerase chain reaction (MS-PCR) was performed on 70 frozen tissues obtained from patients with invasive ductal carcinomas of the breast collected in the laboratory of pathology, Farhat-Hached Hospital, Sousse, Tunisia. Both specific methylated and unmethylated primers were used for PCR and the products were visualized with agarose gel electrophoresis. Results: Promoter hypermethylation of BLU was found in 28 (40%) out of 70 breast cancer samples. No correlation was found between hypermethylation of BLU promoter status and clinicopathological parameters including age, tumor size, lymph node metastasis, histological grade, and immunohistochemical status of estrogen and progesterone receptors. Conclusion: This study shows that hypermethylation of BLU promoter is frequent in breast cancer. Further analysis of a much larger number cases with clinical follow-up are needed to clarify the prognostic value of promoter methylation of this gene and to clarify its role in breast cancer.

PP2-48

IMMUNOHISTOCHEMICAL AND MORPHOLOGIC FINDINGS IN COLUMNAR CELL LESIONS COEXISTING WITH INVASIVE BREAST CARCINOMAS

Ebru Demiralay, Beyhan Demirhan, Alper Kocbiyik, Aylin Sar
Pathology Department, Faculty of Medicine, Baskent University, Ankara, Turkey

AIM: Columnar cell lesions (CCL) of the breast are classified as with atypia and without atypia. CCL with atypia (flat epithelial atypia) is considered as DIN (ductal intraepithelial neoplasia) 1a. CCL with or without atypia frequently coexist with invasive or in-situ carcinomas. In this study, CCL coexisting with invasive breast carcinomas are investigated. Expression of estrogen receptor (ER), progesterone receptor (PR) and p53 antibodies in CCL and coexisting invasive tumors, type of invasive tumor, histopathological grade and presence of atypia in CCL have been studied. MATERIALS AND METHODS: Thirty-nine mastectomy specimens containing CCL's coexisting with invasive carcinomas were retrospectively analysed for cellular characteristics and structural pattern of CCL neighboring the tumor. Histopathological type-grade of invasive tumor and existence of atypia in neighboring CCL have been identified. RESULTS: Histopathological types of carcinomas and coexisting CCL atypia existence are given as follows: 21 were with invasive ductal carcinoma, 7 of which were CCL with atypia and 14 without atypia, 7 were with invasive lobular carcinoma, 3 of which were CCL with atypia and 4 without atypia, 4 were with mixt carcinoma, 2 of which were CCL with atypia and 2 without atypia, 5 were with tubular carcinoma, 3 of which were CCL with atypia and 2 without atypia. Eight of the invasive carcinomas were ER (-). However, in 6 of them coexisting CCLs were ER(+) and without atypia. Coexisting CCLs in the other two invasive carcinomas were with atypia and one was ER (+) and the other was (-). PR was (-) in 4 invasive carcinomas. All of the coexisting CCLs were PR (+) and 3 were without atypia and 1 was with atypia. Two of the CCLs neighboring PR(+) invasive carcinomas were PR (-), one of them with atypia and one without atypia. p53 positivity rate in invasive carcinomas was 33% (13 cases). Among those, 6 had coexisting CCL with atypia (46%) and 7 had coexisting CCL without atypia (54%). P53 expression was present only in 2 (9%) of all 23 CCLs without atypia and 1 (6%) of all 16 CCLs with atypia. CONCLUSION: CCL with atypia was determined frequently in tubular carcinoma 60%, mixt carcinoma %50, invasive lobular carcinoma %43 and invasive ductal carcinoma %33. Correlation of histopathological grade and existence of atypia in CCL has not been observed. ER and PR expressions in CCL was not correlated with ER and PR expressions in coexisting carcinoma. Existance or non-existance of atypia in neighboring tumors was not correlated with the expression of p53 in invasive tumor.

[3] Department of Gynaecology and Obstetrics, Faculty of Medicine and Biochemical Sciences, University of Yaounde I, Cameroon

Background: the histopathological study of tumor stages on surgical specimens is important for diagnosis purpose but can also be used as an element of evaluation of the effectiveness of breast cancer screening in the population.With this in mind, we carried out a retrospective study with the objective to analyse the histopathologic characteristics of cancers found in breast surgical specimen. Material and methods: Pathology reports on surgical specimen (nodulectomy, quadrantectomy, mastectomy, with or without axillary currage) issued between 1st April 2002 and 31st March 2007 were consulted: the tumor size, the grade (differentiation) using Scaff Bloom and Richardson Scale for carcinoma, the presence or absence of metastasis were analysed. We used the TNM system. Results: 1-The average age of our patients was 38 years with a range between 20 and 67 years. 2-

Tumor: 63 cases of breast cancer were diagnosed, with 60 cases of carcinoma, 2 cases of liposarcoma, 1 case of kaposi sarcoma and 1 case of lymphoma. 2a) Size: 8 out of 60 (13, 4 %) had carcinoma in situ; 13 out of 60 (21,6%) had a tumor of PT1 of whom 7 patients had PT1c. 27 out of 60 (45,0%) cases had PT2 carcinoma. Tumors of PT2 and above were found in 12 (20%) of the 60 cases. The two cases of liposarcoma were PT3. The Kaposi sarcoma came from a HIV positive Patient. 2b) Grade: 47 out o 52 invasive carcinoma (90, 3%) were ductal carcinoma, 4 (7,6 %) lobular carcinoma, and 1 (2,1%) medullary carcinoma. 10 (19,2%) cases were grade 1, 39 (75,0%) were grade 2 and 3 (5,8%) were grade 3. 3- Metastasis: 33 specimens were accompanied by axillary dissection: At least 3 lymph nodes invasions were present in each case. All of these cases were PT2 and above. Conclusion: Most of the patients received in our service for breast carcinoma were diagnosed in the late stage. The prognosis was thus poor. A lot still has to be done in the domain of screening in our milieu.

PP2-50

ESTROGEN RECEPTOR EXPRESSION AND Ki67 PROLIFERATIVE ACTIVITY IN NORMAL BREAST, COLUMNAR CELL LESOINS AND DCIS GRADE I: A PILOT STUDY

Nilgun Kapucuoglu, Sema Bircan, Metin Ciris, Gulsun Inan
Suleyman Demirel University, Faculty of Medicine, Department of Pathology, Isparta, Turkey

Background: Columnar cell lesions (CCLs) of the breast present a spectrum of histologic alterations that have in common the presence of columnar epithelial cells lining variably enlarged terminal duct lobular units, ranging from those that show little or no cytologic or architectural atypia to those that show sufficient cytologic and architectural features to warrant a diagnosis of atypical ductal hyperplasia or DCIS.Estrogen has proliferative effects on breast epithelium and disregulation of proliferative activity is importat in carcinogenesis.In this study we evalaute the expression of ER and prolifertative activity in normal breast, CCLs and DCIS grade I. Material and Methods: Breast biopsies were re-evaluated for CCLs using the criteria proposed by Schnitt and Vincent-Salomon. For grading DCIS Van Nuys classification was used. ER expression and Ki67 proliferative activity were assessed immunohistochemically in 9 normal breast tissues from benign breast biopsises, 13 CCLs and 9 DCIS grade I. ER and Ki67 immunoreactivities were examined under x20 objective and positively stained nuclei were counted in 4 consequative fields. Results: Of 306 breast biopsies 13 (4.4%) were CCLs. Of 13 cases 7 (53.8%), and 6 (46.2%) were nonatypical and atypical CCLs, respectively. The median values and standart deviations for ER in normal breast, nonatypical CCLs, atypical CCLs and DCIS grade I were, 309±97.20, 1316.0±309.89, 1192.0±280.37 and, 1917.0±1561.45, respectively. The median values and standart deviations for Ki67 immunoreactivity in normal breast, nonatypical CCLs, atypical CCLs and DCIS grade I were, 60.0±44.02, 39.0±10.73, 140.50±127.35 and 205.0±163.75, respectively. There were statistically significant differences between normal breast tissue and all other groups and atypical CCLs- DCIS I for ER expression. There were significant differences between normal breast-atypical CCLs, normal breast-DCIS I, nonatypical-atypical CCLs for Ki67 reactivity. Conclusions: Increase in ER expression started from CCLs which were phenotypically normal. The proliferative activity of nonatypical CCLs was less than atypical CCLs and there was no difference between proliferative activities of atypical CCLs and DCIS I. Therefore nonatypical and atypical CCLs were different lesions and, atypical CCLs can be early stage of low grade DCIS.

PP2-51

EXPRESSION OF E-CADHERIN, HMWKER34βE12 AND CK 5/6 IN INVASIVE BREAST CARCINOMAS. CORRELATION WITH OTHER CLASSICAL PROGNOSTIC MARKERS

Stiliani Papaemmanouil, Natalia Vladika, Anthoula Assimaki, Barbara Christoforidou, John Efstratiou, Athanasios Kamas, Despina Kessaridou, Anastassia Kiziridou, John Kostopoulos, Soultana Meditskou, Eleni Nenopoulou, Athanasios Papanikolaou, Chrisoula Tsobanidou, Persefoni Xirou, Frideriki Patakiouta
Breast Cancer Study Group of Hellenic Society of Pathology,Greece

Background: The invasive ductal and lobular carcinomas of the breast have usually distinct histological pattern. However, some cases are indistinguishable on the basis of morphology. Specific antibodies in immunohistochemical level, as shown in literature, can help in such cases. The aim of this study is to investigate the expression of E-Cadherin, HMWKer34βE12 and CK5/6 in invasive breast carcinomas. E-Cad demonstrates strong membrane staining of luminal cells in normal breast tissue and ductal carcinoma, but it is absent in lobular breast cancer. The HMWKer34βE12 constitutes a useful marker for lobular differentiation. The CK5/6 expresses in basal/myoepithelial cells of breast ducts and in a small number of high grade ductal carcinomas. Furthermore, we tried to correlate the invasive breast carcinomas with classical prognostic and predictive markers. Method: We investigated 100 cases of invasive breast carcinomas, of which 71 were ductal (IDC), 25 lobular (ILC) and 4 mixed types (IMC). Paraffin-embedded archival tissue was used with monoclonal antibodies against E-Cadherin, HMWKer34βE12, CK5/6, p53, HER-2, ER/PR. Results: Group IDC (n=71). 66 cases (93%) were E-Cadherin positive, of which six were moreover focal positive for HMWKer34βE12. The remaining 5 cases were E-Cadherin(-). 4 cases of them were HMWKer34βE12 and CK5/6 negative and the fifth case was CK5/6 positive. 6/71 cases (8,4%) were E-Cadherin, HMWKer34βE12 and CK5/6 positive, of which five were ER/PR/HER-2 negative. Group ILC (n=25). 24/25 were E-Cadherin and keratins negative. The remaining case was E-Cadherin(+) and focal HMWKer34βE12(+). Group IMC (n=4). 4/4 were E-Cadherin (+) only in the ductal component. All cases were negative for keratins. Conclusion: Evaluating of E-Cadherin expression alone in breast cancers is useful for distinguishing lobular from ductal carcinomas. E-Cadherin expression inversely correlates to tumour size and histological grade. Loss of E-Cadherin correlates with ER negativity. There was no association between E-Cadherin positivity, ER/PR status and p53 expression in our study. The majority of poorly differentiated invasive ductal carcinomas (84%) looses expression of HMWKer34βE12. The five CK 5/6 positive ductal carcinomas were ER/PR/HER-2 negative and probably represent basal-type carcinomas.-

PP2-52

SINGLE PROBE BRIGHTFIELD ISH IS A ROBUST AND REPRODUCIBLE TECHNIQUE FOR THE ASSESSMENT OF HER2 STATUS IN BREAST CANCER.

S. Di Palma[1], N. Collins[1], M. Mottolese[2], F. Schmitt[3], A. Sapino[4], N. Kapranos[5], W. Boecker[6], M. Bilous[7], J. Isola[8]

[6] Gerhard-Domagk- Institute for Pathology, Germany
[7] Institute of Clinical Pathology and Medical Research, United Kingdom
[8] Institute of Medical Technology, Finland

Background: Brightfield ISH has recently begun receiving wider recognition as a useful tool in the assessment of HER2 status in

breast tumours. Whilst there have been numerous reports indicating the high level of concordance of these techniques with the widely accepted dual colour FISH assay, the lack of a single test incorporating the HER2 probe and a chromosome 17 probe has hampered the acceptance of brightfield ISH techniques. The aim of this study was to highlight the robustness and reproducibility of these assays in the assessment of breast cancer cases for eligibility for treatment with Herceptin. Design: Eight laboratories with expertise in brightfield ISH techniques were identified and invited to assess 30 breast cancer cases previously tested by dual colour FISH and IHC. Many of the cases were chosen because they had borderline scores and were difficult to interpret. The lab standard protocols and interpretation methods were used. Results were collated and assessed for concordance and a review of any discordant cases at a multi-headed microscope is planned. Results: Preliminary data available from two laboratories indicate that CISH was technically successful in all but one case where repeat analysis was needed. The agreement between two labs was total in all but 2 cases. One, with a FISH ratio of 2.69, was interpreted as low amplification by one centre and negative by the other. The second discordant case had a FISH ratio of 2.9 but was interpreted as negative by one centre and positive by the other. Conclusions: The success rate of CISH was high in this study indicating that it works well on routine formalin-fixed paraffin-embedded tissue. The laboratory agreement of CISH interpretation was excellent but revealed potential problems with low amplification and different cut-off values between CISH and FISH. This large inter-laboratory study will enable us to assess the problem of evaluating cases with very low level amplification and the effect of variability in threshold values.

PP2-53
COMPARISON OF FISH AND IMMUNOHISTOCHEMISTRY IN BREAST CANCER

Gulcin Kamali, Deniz Ozcan
Okmeydani Training Hospital, Pathology Department, Istanbul, Turkey

The role of HER-2 (HER -2/ neu or c-erB-2) has increased as a prognostic and predictive factor. The human epidermal growth factor receptor 2 oncoprotein is overexpressed in one third of invasive breast carcinomas. It is an independent prognostic marker of clinical outcome as predictor of benefit from chemotherapy regime and for metastatic disease for benefit from anti-HER -2 antibody therapy. Various laboratory methods have been used for this purpose. Results obtained in the routine practice by immunohistochemistry (IHC) and fluorescence In Situ hybridization (FISH) in determination of HER-2 status. We analyzed the concordance between immunohistochemical analysis and Fluorescence In Situ hybridization (FISH) for HER 2 status. We studied paraffin blocks of 632 mammary tumors between 21.12.2004 and 15.02.2007, in Okmeydani Training Hospital, Pathology Department. Before 2001 we applied alcalen phosphatase method, after 2001 we applied immunoperoxidase technique. We studied Dako, Biogenex, and NeoMarkers antibodies. Immunohistochemical results were interpreted as negative (0), or positive (1+, 2+,3+) as membraneous staining intensity. All this cases were interpreted by independent pathologists. None of 421 cases (% 66.61) revealed immune staining. 63 cases (% 9.96) were scored immunohistochemically (1+) , 70 cases (% 11.7)(2+), and 78 cases (%12.34) (3+). FISH test were performed by using Vysis PathVysion method. In 16 cases which were 2+ tumors, all of the patients were females, 35-83 years old, median 52,7, SD:11,4 . Only 1 case was invasive lobuler carcinoma and the others were invasive ductal carcinoma (Grade II-III) and one of these cases had suspect metastatic lung disease and one patient had multipl bone metastases, in one case there was local recurrens.In 7 cases both ER and PR receptors both were negative. In 4 cases were ER negative, PR weakly positive. In 5 cases both were ER and PR positive, and other cases were variable. Six of these test results were avaliable (positive), in 10 cases there was discrepancy between the FISH test and IHC. Our study revealed no correlation with ER and FISH method (p:0,36); PR and FISH method (p:0,89), IHC and FISH method (p:0,45) Best results will be obtained by immunohistochemistry of indeterminate results with complementary FISH testing .

PP2-54
PRECANCEROUS LESIONS IN BENIGN BREAST MASSES: A HISTOPATHOLOGICAL STUDY IN YAOUNDE-CAMEROON

Zacharie Sando[1], Jean-Claude Pache[2], Jean-Louis Essame[1], Emile Mboudou[3], Maryse Fiche[4]
[1] Department of Morphological Sciences and Pathology, Faculty of Medicine and Biochemical Sciences, University of Yaounde I, Cameroon
[2] Department of Pathology, Faculty of Medicine, University of Geneva, Switzerland
[3] Department of Gynaecology and Obstetrics, Faculty of Medecine and Biochemical Sciences, University of Yaounde I, Cameroon
[4] University Institute of Pathology, Lausanne Switzerland

Background: Benign breast diseases raise a problem of their relationship with cancers of this gland. In Cameroon, breast cancers constitute one of the most common malignancies in women and are often diagnosed at a late stage. Risk factors are numerous, some of which are histopathological and are often described as precancerous, necessitating specific follow up of the patients. Material and methods: The purpose of this study was to highlight the relationship between some benign histopathological lesions of the breast that could be considered as risk factors for malignant evolution and the occurrence of the breast cancer in Yaounde-Cameroon. Slides bearing a record of benign lesion, associated or not to a malignant non invasive tumor, observed from 1st October 2002 and 28 February 2006 were re-examined. Results: of the 212 cases recruited in our study, we observed: -110 (51,9%) fibroadenoma amongst which 2 cases had atypical lobular hyperplasia, from two patients aged 45 and 55. -60 (28,3%) fibrocystic mastopathy among which 30 (50%) had no or slight ductular/lobular epithelial hyperplasia, 16 (26,7%) moderate or atypical hyperplasia and 14 (23,3%) carcinoma in situ. All cases of carcinoma in situ were associated with atypical or moderate epithelial hyperplasia. -38 (17,9%) fibrous mastopathy. -Other benign lesions were less frequent and included 4 (1,8%) lipoma, 1 (0,1%) benign phylloide tumor. -12 papillomas, 8 associated with fibrocystic mastopathy, 3 with fibrous mastopathy and 1 not associated with a significant lesion. 5 of the papillomas were multiple. Conclusion: breast masses considered as benign are present in our milieu. Some are known to have the risk of cancerous evolution, but this risk seems variable with the histopathological type of lesion, the predominant forms in our series being fibrocystic mastopathy with moderate or atypical (ductular/lobular) hyperplasia.

[2] Immunology Department, Portuguese Institute of Oncology, Porto, Portugal
[3] Pathology Department, Portuguese Institute of Oncology, Porto, Portugal

Background: Carcinomas account for 80-90% of the feline mammary gland tumours, and are known for their unfavourable prognosis due to a strong tendency for local recurrence and metastasis. The World Health Organization (WHO) classification of feline mammary lesions is a descriptive histological classification difficult to reproduce, because mammary carcinomas of queens present several histological patterns, a mixture of which is found in the same tumour. Histologic assessment of these tumours is not sufficiently discriminator in predicting prognosis, as it was demonstrated in various studies. However, there are some cases in which the histology justifies its individualisation by indicating a more or less aggressive behaviour. Micropapillary invasive pattern is a distinct histological type associated with poor prognosis. The World Health Organization (WHO) of feline mammary lesions does not recognize the micropapillary pattern, which is included in the spectrum of papillary tumours. Material and methods: In this study we report 16 carcinomas of the feline mammary gland displaying histological features that correspond to the invasive micropapillary carcinoma (IMC) of the women breast. The clinicopathological findings, overall survival, disease-free survival and nuclear DNA content of these cases were compared with 65 more common invasive mammary carcinoma of non-specified type (other FMCs). Results: IMC cases were associated with higher histological grade ($p<0.0001$), deeper muscle invasion ($p=0.004$), more frequent lymphovascular invasion and nodal metastases ($p=0.009$ and $p=0.001$, respectively) than other FMCs. The aneuploid pattern was more frequent in IMC lesions. IMCs were also associated with lower survival rates. Conclusion: All cases of feline IMCs were associated to pathological features of high biologic aggressiveness. In addition to histology, they also presented DNA content pattern, and survival rates that justify its individualization as an independent histotype of the mammary gland of queens.

PP2-56

NUCLEAR PLANIMETRY ON THE SAMPLES FROM CYTOLOGICALLY SIMILAR BREAST LESIONS

Bulent Kurt, Yildirim Karslioglu, Ertugrul Celik, Ayhan Ozcan, Onder Onguru, Salih Deveci
GATA Patoloji Anabilim Dalı, Turkey

BACKGROUND: Discrimination of low-grade invasive ductal carcinomas and tubular carcinomas from cellular fibroadenomas on the fine-needle aspiration materials may sometimes be problematic. In some cytological samples from such benign or low-grade malignant breast tumors, both the cells' nuclei and patterns of cell clusters show substantial overlapping morphologic characteristics. Therefore, most of the time, histopathological confirmation from small tissue samples is needed prior to any major surgical intervention. Nuclear morphometry on cytological materials is suggested as an ancillary method for the differential diagnosis in many lesions including breast tumors. METHODS: Twenty-five cytological samples obtained from patients with lesions, which were histopathologically confirmed as grade I invasive ductal carcinomas (n=10), tubular carcinomas (n=5) and fibroadenomas with focal proliferative features (n=10) were utilized in this study. Eight geometric features of about 2000 nuclei in total from these tumors, such as perimeter, nuclear area and circular form factor, were measured with the aid of a computer assisted image analysis system. Discriminant analysis was performed on this data set in order to test the correct classification based on the eight measured variables. Statistical analyses were carried out with two fundamentally different approaches: In the first one, the entire data from all measured nuclei were used for classification. In the second one, a subset of data representing the ten percent most deviated values of variables, was extracted from the entire dataset to simulate the selective examination performed during classical morphologic evaluation. RESULTS: When the entire data was used in discriminant analysis, the overall performance in correct classification rate was found approximately 50%, which was considered as an unacceptable value in routine diagnostic practice. In the data set constructed with our systematic and reproducible selection bias, the overall performance of correct classification rate of same discriminant model was improved dramatically up to the 97%. CONCLUSIONS: A pathologist always exploits the most abnormal findings encountered during screening to reach a final decision. Therefore, morphologic examination is actually based on selection. Using data obtained from all of the cells in morphometry, as always used in nearly all of the statistical methods, may cause a masking effect in diagnostically important features. Morphometric studies may seem to be useless when this effect is not taken into account. But with a systematic and reproducible selection of the values with a proper bias, morphometry may provide some discriminatory information in overlapping lesions.

PP2-57

PLANIMETRIC FEATURES OF CELL CLUSTERS IN FIBROADENOMAS: A PRELIMINARY STUDY

Yildirim Karslioglu, Bulent Kurt, Onder Onguru, Ayhan Ozcan
Department of Pathology, Gulhane Military Medical Academy and School of Medicine, Turkey

BACKGROUND: In addition to the nuclear and cytoplasmic features, morphologic appearance of cell clusters usually provide considerable diagnostic clues in cytological diagnosis for many lesions. Most of the fibroadenomas are easily recognized from cytological specimens. However, aspirates from cellular fibroadenomas, sometimes cause diagnostic difficulties because of their resemblance to the low-grade malignant lesions. Morphometric assessment of cell cluster morphology may contribute to routine cytological examination by emphasizing its value. In this preliminary study, we investigated whether the cell cluster segmentation on cytological specimens is possible. METHOD: This study was carried out on 45 fine-needle aspirates reported as consistent with fibroadenoma and confirmed histopathologically. A blank-field image for shading correction and three digital photographs from the most representative areas on slides belonging to each case were taken under x25 magnification and saved as tiff images in 768x576 pixel resolution. Morphometric measurements were realized using a series of small macro programs prepared by one of the authors (YK) in ImageJ, an open source image processing and analysis software supported and maintained by NIH. Every recognizable cell clusters which are not touching to the boundaries of images measured automatically for eight different variables, such as area, perimeter and circularity. Resulting data set was composed of 1448 records. Two-step cluster analysis was performed on these data to assess the heterogeneity of cell clusters. RESULTS: Statistics showed that the cell clusters in fibroadenomas may be classified into two different groups. Major group (83%) contained predominantly the small cell clusters. The second – inconsiderable- (17%) group contained large cell aggregates. Our test results do not indicate any importance attributable to this categorization. CONCLUSION: This preliminary study showed that the morphometric cell cluster segmentation and analysis are possible in the fine needle aspirates. In an ongoing study, we planned to include benign and malignant lesions that have overlapping features with fibroadenomas. We hypothesized that the cell cluster shape may contribute to the cytological assessment in breast lesions as a stand alone variable. However, this hypothesis needs to be tested in similar studies.

PP2-58
PEUTZ-JEGHERS SYNDROME WITH BILATERAL BREAST AND OVARIAN CANCER (A CASE REPORT)

Diana Taheri[1], Noushin Afshar-Moghadam[1], Parvin Mahzoni[1], Amin Eftekhari[1], S. Mozafar Hashemi[2], Mohammad Hasan Emami[2], Mehdi Fesharakizadeh[4], Hamid Reza Ghasemi-Basir[1]
[1] Department of Pathology, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran
[2] Department of Surgery, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran
[3] Department of Gastroenterology, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran
[4] Department of Surgery, School of Medicine, Azad University of Medical Sciences, Isfahan, Iran

Abstract Peutz-Jeghers syndrome is a rare autosomal dominantly inherited condition, characterized by the presence of hamartomatous gastrointestinal polyps and mucocutaneous pigmentation. Patients with this syndrome can be associated with other neoplasms such as ovarian neoplasms known as sex-cord tumor with annular tubules that is associated in one third of the cases with this syndrome and other type of malignancies. We report a 42 year-old woman with a history of Peutz-Jeghers Syndrome (PJS) and bilateral breast cancer that presented with abnormal uterine bleeding. Total abdominal hysterectomy with bilateral salpino-oophorectomy (TAH & BSO) was done and an ovarian sex cord tumor with annular tubules was incidentally diagnosed. By reviewing of literatures and in agreement with pervious studies we suggest routine screening for malignancies in patients with peutz-jeghers syndrome.

PP2-312
EVALUATION OF BIOMARKERS IN LOBULAR CARCINOMA IN SITU

Deepa Patil, Carol Schiller, Marina Ivanovic, Barbara Susnik
Northwestern University Feinberg School of Medicine, USA

Background: Classic lobular carcinoma in situ lesions (LCIS) are associated with low grade morphology, low proliferation rate, positive ER, PR and negative HER-2 expression. Variants of LCIS have been described which exhibit high grade nuclei, pleomorphism and/or necrosis. The biomarker profile of spectrum of LCIS lesions has not been well defined. In the present study, a panel of biomarkers was analyzed and correlated with histomorphological features. Design: We reviewed consecutive cases of LCIS in surgical specimens from 2004 to present and selected LCIS cases based on negative E-cadherin, positive high molecular weight cytokeratin staining, and involvement of at least 3 lobules in at least 1 slide. Morphological features including nuclear grade, presence of apocrine features or signet ring cells, discohesion, and degree of distention of lobular units were recorded. Nuclear grading was similar to that used for DCIS (per CAP recommendations). We grouped lesions with nuclear grade 1 in low grade category and grades 2 and 3 in high grade category. Immunostaining for ER, androgen receptor (AR), HER-2, Ki-67, and p53 was evaluated in the corresponding LCIS foci. Result: The median age of 53 patients was 57 years (range 35-82 years). LCIS was associated with invasive carcinoma in the same specimen in 72% (38/53) cases. Low nuclear grade was assigned to 23 cases and high nuclear grade to 30 cases. Nuclear grade was associated with presence of necrosis (p=0.045) and showed borderline significant association with apocrine features (p=0.06). It was not related to presence of invasion, signet ring cells, or degree of distension of lobular units. LCIS cells showed strong ER expression in 95% of cases. AR expression (74% cases) was significantly associated with high nuclear grade (p=0.026). Increased expression of p53 (>10% nuclei) and Ki-67 (more than 10% nuclei) was limited to high grade cases (4%). HER-2 was positive (3+) in a single case of high grade LCIS (2%). Conclusion: Although rare cases of high grade LCIS show an aggressive biomarker profile (decreased ER, increased Ki-67, p53, or overexpressed HER-2), unlike DCIS, the majority of LCIS lesions appear to show a benign biomarker profile unrelated to morphological features. The only exception is AR expression which is associated with high grade LCIS with apocrine morphology. Further molecular studies may be required to classify and predict the biological behavior of these lesions.

PP2-59
THE HISTOLOGY OF CARDIOESOPHAGEAL JUNCTIONAL MUCOSA IN PEDIATRIC PATIENT POPULATION

Zorica Stojsic[1], Radmila Stevanovic[1], Nedeljko Radlovic[2], Zoran Lekovic[2], Sofija Glumac[1], Jovan Vasiljevic[1]
[1] Institute of Pathology, School of Medicine University of Belgrade, Serbia
[2] Department of Pediatric Gastroenterology, University Children's Hospital, Belgrade, Serbia

Background. The origin and histology of cardiac mucosa remains controversial. The classical concept that the cardiac mucosa is of gastric origin has been challenged by those who consider that the cardiac mucosa is metaplastic esophageal mucosa. By the latter theory, cardiac region does not exist early in life and direct continuity between the esophageal squamous and oxyntic mucosa is normalcy. The morphology of the gastric cardia in children and the significance of inflammation in this region have been studied only in a few series. The aim of this study was to evaluate the morphologic features of the cardia in an unselected pediatric population and to determine the significance of inflammation in this region. Method. Fourty five consecutive patients (age range 1 – 17 years) in whom cardiac mucosa was present in biopsy samples from the gastroesophageal squamocolumnar junction were selected. Biopsies that straddled the squamocolumnar junction represented the distal esophagus and proximal stomach, i.e. cardia. In addition, each patient had biopsies of the duodenum and gastric antrum and body. Inflammation of the cardia, irrespective of its exact anatomic location, was defined as carditis and classified as active or chronic, based on the type of inflammatory cells present. Inflammation of the esophageal mucosa in biopsy specimens was also recorded. Patients with Barrett's esophagus were excluded. Results. None of the patients had pure oxyntic mucosa (OM) at the squamocolumnar junction, adjacent to squamous epithelium. All patients had cardiac mucinous mucosa (CM) (17/45), or oxyntocardiac mucosa (OCM) (28/45). CM was highly associated with inflammation (14/17; $p<0.05$), contrary to OCM (17/28; $p>0.05$). Overall, carditis was seen in 31/45 patients (69%) ($p<0.05$). Of these 31 patients, 9 (29%) had Helicobacter pylori (H. pylori) carditis, which was always associated with H. pylori gastritis, and 3 (10%) had non-H. pylori carditis and gastritis (in corrosive injury, ulcerative colitis and lymphocytic gastritis). The remaining 19/31 patients (61%) had non-H. pylori isolated carditis, without any concomitant gastritis. Esophagitis was highly associated with non-H. pylori isolated carditis (17/19; 89%) ($p<0.01$). There was no significant association between esophagitis and H. pylori carditis ($p<0.01$). Conclusion. The finding of uninflammed gastric cardiac mucosa supports the concept that the gastric cardia is a normal structure. Normal cardia consists of CM and OCM mucosa. The etiologies of carditis are H. pylori infection and gastroesophageal reflux disease.

PP2-60
FLOW CYTOMETRIC VARIABLES AS PROGNOSTIC FACTORS IN SURGICALLY RESECTED GASTRIC CARCINOMA: A 7-YEAR PROSPECTIVE STUDY

Gabriella Nesi[1], Lorenzo Bruno[1], Calogero Saieva[2], Lucia Roberta Girardi[1], Ines Zanna[2], Paolo Bechi[1], Camillo Cortesini[1], Domenico Palli[2]
[1] University of Florence, Italy
[2] Centre for Cancer Research and Prevention, Florence, Italy

Background. DNA ploidy and S-phase fraction (SPF) measured by DNA flow cytometry (FC) were shown to correlate with several clinicopathological variables in several types of tumours. Materials and Methods. DNA FC was performed on multiple frozen tumour samples obtained from 115 patients undergoing curative surgery for gastric cancer (GC), and the findings were prospectively correlated with traditional clinicopathological indicators of prognosis. Vital status at 7 years was assessed in all patients. The crude survival probability was estimated by the Kaplan-Meier method and differences between patient groups were compared by the log rank test. Cox regression models were used to evaluate the risk of dying. Results. Overall, 20 tumours (17.4%) were diploid, 46 (40.0%) monoclonal and 49 (42.6%) multiclonal. Excluding 4 patients who died within 1 month of surgery, high SPF (>9.6%) was detected in 55 patients (49.6%), and was found to be significantly associated with vascular invasion and multiclonality ($p=0.02$). An association of borderline statistical significance emerged with macroscopic type ($p=0.06$) and pN and pM status ($p=0.07$). Multivariate regression analysis did not show a significant effect of SPF ($p=0.11$) or DNA ploidy ($p=0.28$) on 7-year survival. Conclusions. Investigations carried out on fresh tissue, with multiple sampling of single lesions, allow cytometric data to be correctly acquired. Aneuploidy appears to be a prognostic factor of low penetrance, whereas SPF is a more promising parameter of tumour aggressiveness in patients with GC.

PP2-61
MESOTHELIN EXPRESSION IN PANCREATIC CANCER

Ali Abdul-Mhsin, Jasim Radhi
Department of Pathology, McMaster University, Hamilton, ON Canada

Background: Mesothelin is an emerging marker for cancer diagnosis and target based therapy. In addition to malignancies of mesothelial origin, mesothelin has been shown to have positive staining by immunohistochemistry in malignancies from the ovary, and more recently from the pancreas. The purpose of this study is to evaluate the expression of this monoclonal antibody in pancreatic carcinoma versus chronic pancreatitis at our institution. Methods: The authors reviewed 74 cases of pancreatic ductal carcinomas (both biopsies and resections) from the files of McMaster University Medical Centre. Representative blocks of tumour and adjacent non-neoplastic pancreas were selected for immunohistochemistry. Staining was performed using a well-characterized mesothelin monoclonal antibody (5B2, Nova Castra). Staining of greater than 25% of tumour cells was considered to be a strong positive, less than 1% was considered negative and the remaining cases were called focally positive. Intensity of staining was semi quantitatively graded on a scale of 1-3 (weak, moderate and strong). Result: Mesothelin staining was seen in 90% of pancreatic ductal carcinomas, of which 78% of cases showed staining in 25% or more of the tumour cells. The staining intensity was graded as 2 in the majority of the positive cases. 36 cases of chronic pancreatitis and 5 cases of normal pancreatic tissue were included. Cases of chronic pancreatitis showed only occasional focal positive staining and the normal pancreatic tissue was negative in all cases. Conclusion: We conclude that mesothelin is a useful marker for the diagnosis of pancreatic ductal carcinoma and may be helpful in discriminating cases from chronic pancreatitis.

PP2-62
CANCER PROGRESSION OF HYPERPLASTIC POLYPS AND SERRATED ADENOMAS OF THE COLORECTUM

Seiji Haraoka[1], Akinori Iwashita[1], Ikuko Iwashita[2]
[1] Department of Pathology, Chikushi Hospital, Fukuoka University, Japan
[2] Nishifukuoka Hospital, Japan

The serrated polyps of large intestine, including hyperplastic/metaplastic polyps (HPs) and serrated adenomas (SAs), are characterized by sawtooth-like infoldings of the crypt and surface epithelium. The current molecular studies proposed the serrated neoplasia pathway as a model of colorectal carcinogensis through the HPs and SAs. The aim of this study

was to clarify the clinicopathological and immunohistochemical characteristics of SA with carcinoma (CA) and HP with CA, and to provide morphological evidence that HP and SA are the precursor lesions of colorectal carcinomas arising along the serrated neoplasia pathway. A clinicopathological study of 14 SAs with CA and 11 HPs with CA of the large intestine was carried out. 64% of SA with CA and 80% of HP with CA were located in the caecum, ascending colon, and transverse colon and they were frequently observed in the right-sided colon rather than in the left-sided colon. The average largest diameter of SA with CA and HP with CA was approximately 16mm. As for the macroscopic features of SA with CA, there were many pedunculated and subpedunculated elevated lesions, and there were many sessile elevated lesions in HP with CA. Most of the CA components were intramucosal, well differentiated adenocarcinoma, and the proportion of CA component was mostly less than that of HP and SA in their respective lesions. Immunohistochemically, the cytokeratin 7 (CK7)-positive rate was as follows; 35.7% of SAs and 50% of CAs in the SA with CA group, and 27.3% of HPs and 36.4% of CAs in the HP with CA group. The CK7 expression was more frequent in the CA than in SA and HP. 50% of CAs in SA with CA group presented a CK7+/CK20+ pattern. Concerning the expression of the human apomucins, in the SA with CA group, the mixed mucinous phenotype combining both gastric foveolar and intestinal mucin (MUC5AC+, HGM+/MUC2+) was 78.6% of SA and 42.9% of CA, and all of the HP and 90.9% of CA were mixed phenotype in the HP with CA group. The expression of gastric mucin was increased in the SA with CA group, and most of the lesions in the HP with CA group expressed the gastric mucin. In conclusion, the CAs accompanied by SA and HP have immunohistochemical characteristics which are similar to those of SA and HP, and are different from those of common colorectal carcinomas. These findings indicate that SA and HP are the precursor lesions of some colorectal carcinomas.

PP2-63
CPP32, CD34 AND VEGF EXPRESSION IN COLORECTAL CRYPTAL HYPERPLASIA, ADENOMA AND MALIGNANT ADENOMA

Stanislav Tretyakov, Eugene Kurenkov
Medical Academy, Chelyabinsk, Russia

Background. We investigated immunohistochemically the expression of cpp32, CD34 and VEGF on tissue samples of 104 endoscopically removed colorectal polyps. 21 tumors were classified as carcinoma-in-adenoma, 19 as colorectal adenoma with high grade atypia, 39 as adenoma with low grade atypia and 25 as cryptal hyperplasia, respectively. The aims of our study were to describe cpp32, CD34 and VEGF expression in colorectal adenomas and in malignant adenomas and to investigate the correlation between these markers and dysplasia in adenomas. Method. For immunohistochemical detection of cpp32, CD34 and VEGF on formalin-fixed paraffin-embedded tissue sections mouse monoclonal antibodies were used. The percentage of positive tumor cells was estimated and scored semiquantitatively. Tumors showing more than 10% positive cells were considered positive. Results. 8% of carcinomas-in-adenomas compared to 21% high grade adenomas, 43% low grade adenomas and 87% cryptal hyperplasia, respectively, were cpp32 positive (p<0,000l). In contrast 63% of carcinomas and 74% high grade adenomas were VEGF positive, compared to 57% low grade adenomas and 21% cryptal hyperplasia (p<0,0001). CD34 expression could be demonstrated in 64% carcinomas-in-adenomas, 68% high grade adenomas, 70% low grade adenomas and 61% cryptal hyperplasia, respectively (p>0,05). Conclusion. The expression of cpp32 and VEGF clearly shows differences between cryptal hyperplasia, adenoma and malignant adenoma. Based on these markers subgroups of patients could be identified who might be high risk patients and possibly need a closer follow-up after polypectomy.

PP2-64
MATRIX METALLOPROTEIN EXPRESSION IN GASTROINTESTINAL STROMAL TUMORS

Hale Kirimlioglu[1], Burak Isik[2], Vedat Kirimlioglu[2]
[1] Inonu University Medical School, Pathology Department, Malatya, Turkey
[2] Inonu University Medical School, General Surgery Department, Malatya, Turkey

AIM: The growth of a cancer is accompained by progressive infiltration, invasion, penetration and destruction of the surrounding tissues. Next to development of the metastasis, invasiveness is the most reliable feature that differentiates malignant from benign tumours. Many criteria are considered to determine the malignant potential of the gastrointestinal stromal tumors (GIST) but the unique criterium of malignancy is metastasis. A group of enzymes which are involved in the degradation of different components of extracellular matrix, matrix metalloproteinases (MMP), have important roles in tumor invasion and metastasis. We aim to determine the expression profiles of MMPs and investigate whether MMPs correlate with the metastasis and prognosis of GIST. METHODS: Using immunohistochemistry, we examined the expression of MMP-2, MMP-9, and MMP-14 in 18 gastrointestinal tumors. For each tumor, the immunohistochemical panel of CD-117, CD-34, alpha sm-actin, S-100, antibody were performed, Ki-67 proliferation indices were determined. RESULTS: The expression of MMP-2 was not detected in GIST. MMP-9 and MMP-14 expression were detected both in the metastatic or nonmetastatic GIST lesions. In all of the GISTs moderate and strong MMP-9 and MMP-14 expression were detected. When we compared according to the staining intensity, the strong expression of MMP-9 and MMP-14 were significantly correlated to mitotic and Ki-67 indices ($p<0.05$). And also in all of the metastatic cases , strong expression was detected, but there was not any relation with respect to the size, localization, cellularity, cell type, degree of atypia, presence of necrosis, lymphoid infiltration, with the margins of the tumor, mucosal infiltration, and the immunstaining properties of the antibodies at the panel. CONCLUSION: The prominent overexpressions of MMP-9 and MMP-14 were detected in GIST lesions that were having mitotic indices higher than 5/50BBA, this correlation showed that those played a key role in the tumor progression. Mitosis as a criterium to determine the risk of malignancy, had a main role. So we considered that the strong expression of MMP-9 and MMP-14 could be a feature of high risk of malignancy. The number of metastatic cases were not enough to determine the role of those MMPs on the prognosis of the tumors.

PP2-65
EVALUATION OF EGFR GENE COPY NUMBER IN SELECTED IMMUNOHISTOCHEMICALLY EGFR – POSITIVE PATIENTS WITH COLORECTAL CANCER

Monika Durzynska, Anna Mrozkowiak, Wlodzimierz Olszewski, Katarzyna Suszylo
Department of Pathology Memorial Maria Sklodowska Curie Oncology Hospital Warsaw, Poland

Treatment of patients with recurrent or metastatic colorectal cancer with anti-epidermal growth factor receptor (anti-EGFR) monoclonal antibodies demonstrate a clinical response in about 10% cases. At present the main clinical problem is the selection of patients for therapy with anti-EGFR monoclonal antibodies who will have benefit from this treatment. EGFR analysis by immunohistochemistry does not seem to be a useful tool, because no correlation between EGFR expression and clinical answer was found. The goal of our study was to investigate EGFR gene copy number in patients with colorectal cancer with EGFR positive status examined by immunohistochemistry as a possible method useful in selecting patients for anti-EGFR monoclonal antibodies treatment in the future. Patients and methods Our material

consisted of 104 patients with colorectal cancer. EGFR expression was determined on paraffin - embedded and formalin fixed histological specimens by immunohistochemistry, using system kit EGFR pharmDx (DakoCytomation). EGFR status was evaluated as positive if the percentage of membrane stained tumor cells was ≥ 1%. Sixty-five (63%) patients were evaluated as EGFR - positive and 39 (37%) as negative. In selected group of 30 patients with positive EGFR status we evaluated EGFR gene copy number using fluorescence in situ hybridization (FISH). Results Based on EGFR gene status patients were classified into two groups: EGFR FISH – positive cases, when a ratio of EGFR gene to chromosome 7 was ≥ 2, or high amplification (presence of tight EGFR gene clusters) was found and EGFR FISH – negative group when a ratio was < 2. To EGFR FISH – positive group 5 patients (16%) were qualified: in one case gene amplification was found and in 4 cases a ratio was ≥ 2 (range from 2 to 3,69). Twenty-five (84%) patients were found to be EGFR FISH-negative (ratio < 2). Conclusion In our material 16% patients with immunohistochemically EGFR – positive status have high EGFR gene copy number. It needs further investigation, whether the correlation between increased EGFR gene copy number in colorectal cancer and the clinical response for therapy with anti-EGFR monoclonal antibodies exists. These group of patients is clinically closely follow - up.

COLONIC ADENOCARCINOMA REVEALING SMALL INTESTINAL MULTIPLE CARCINOID TUMORS

Ben Yacoub-Abid Lilia, Trabelsi Amel, Achach Thouraya, Yacoubi Tahar, Kalamoun Ines, Kebir Fatima-Zahra, Mestiri Sarra, Korbi Sadok
Department of Pathology, Farhat Hached Hospital Sousse,Tunisia

Background: Neuroendocrine tumors of the small intestine are also called carcinoids. Most are non-functionning and they are often discovered accidentually. This tumor can be multiple and can be associated with others tumors, particularly gastro-intestinal malignancies. Method: Among a case of a 68-year-old man in which we discovered a multiple neuroendocrine tumors in the small intestine associated with colonic adenocarcinoma, we discuss the epidemiology, the clinicopathologic features, the pathological diagnosis problems and the surgical approach of this association with review of the literature. Results: A 68-year-old male patient was admitted for exploration of an abdominal pain with subocclusive syndrome. Colonoscopy showed a budding tumor 60 cm far from the anal margin. Biopsy concluded to an adenocarcinoma. Per-operative exploration revealed an expended small intestine with multiple polyps. Total colectomy with resection of the last portion of the ileum was achieved. After histopathological study, the diagnosis of a colonic adenocarcinoma associated with multiple neuroendocrine tumors was established. Conclusion: Through this observation, we emphasize the concept of multiple neuroendocrine tumors and the possibility of synchronous malignancies.

PP2-67
PRIMARY MELANOMA OF THE SMALL BOWEL: A CASE REPORT AND REVIEW OF THE LITERATURE

Ayca Tan[1], Isin Erdogan Gokcol[1], Umit Bayol[1], Mehtap Canikoglu[1], Eyup Kebapci[2], Sedat Tan[2]
[1] Izmir Tepecik Teaching Hospital, Department of Pathology, Izmir, Turkey
[2] Izmir Tepecik Teaching Hospital, Department of General Surgery, Izmir, Turkey

Background: Malignant melanoma is the most common tumor metastating to the gastrointestinal (GI) tract, especially to small intestine. Although small bowel involvement by malignant melanoma is most frequently metastatic, a primary origin at this site has been reported in rare cases. Case presentation: From January 1997 to March 2007 we diagnosed 14 patients as primary malignant melanoma originating from GI tract. Localizations of tumors are anorectal region (12 patients) and small bowel (2 patient). Endoscopic biopsies of 2 and wide excisions of 12 were available in the archieve of our department. Amongst them we report a case (76-year-old woman) of primary melanoma of the jejenum. The patient was admitted to the emergency department with abdominal pain for 15 days. She had complains of abdominal distention and melena for 3 months. Laboratory investigation revealed mild anemia. Abdominal ultrasound was interpreted as acute appendicitis by radiologists. Mild anemia, melena, abdominal distention and critical age were the clues for probability of malignancy. Exploratory laparotomy revealed multiple masses and partial obstruction of the jejenum. Histopathological examination of the resected small bowel specimen was confirming the diagnosis of melanoma. A thorough postoperative investigation did not reveal a primary lesion of the skin, anus, oculus, or any other location. Thus, we diagnosed the tumor as a primary intestinal melanoma. Conclusion: Malignant melanoma is the most common metastatic tumor of the gastrointestinal tract and can present with fairly common constitutional symptoms. Though the possibility of primary malignant melanoma in the small intestine do exist, the incidence is extremely low.

PP2-68
IMPORTANCE OF ANGIOGENESIS IN COLORECTAL ADENOCARCINOMAS AS A PROGNOSTIC PARAMETER

Rabia B. Arpaci[1], Ayse Polat[1], Tuba Karabacak[1], Ilhan Tuncer[2]
[1] Mersin University Medical School Pathology Department, Mersin, Turkey
[2] Cukurova University Medical School Pathology Department, Adana, Turkey

Background: Angiogenesis is an important step in tumor biology and prognosis. Research in angiogenesis and relation to pathogenesis is rewieved in a large group of tumor such as malignant melanoma, lung, ovary, prostate and brain carcinoma. Several growth factors have been identified that regulate angiogenesis in colorectal cancer; the most important of these are vascular endothelial growth factor (VEGF), basic fibroblastic growth factor (bFGF) and of several angiogenic factors. The aim of this study is to evaluate the angiogenic factors in colorectal adenocarcinoma as a prognostic parameter and to search correlation with the basic prognostic findings. Method: In this study, H-E slides of 39 cases of colorectal adenocarcinoma were (5 of stage 2, 17 of stage 3, 17 of stage 4) reexamined and vascular endothelial growth factor (VEGF), basic fibroblastic growth factor (bFGF) were evaluated with immuno-histochemical technique. Staining intensity of both parameters was correlated with microvessel density (MVD showed by using CD31 antibody) and with the tumor stage, histological grade, lymph node metastasis and vascular invasion. Results: Significant correlations were found; between the pathological tumor stage and MVD ($p<0.05$), histological grade and MVD ($p<0.05$) and also VEGF staining and MVD ($p<0.05$). Conclusion: Our results support that VEGF and MVD may be used as an important prognostic parameters in the colorectal adenocarcinoma. But in a larger series with different tumor stages and the follow up studies are needed to define the role of the tumor associated angiogenesis in the biologic behaviour of colorectal adenocarcinomas.

PP2-69
THE IMPORTANCE OF THE MARKERS IMMUNOHISTOCHEMICAL: APOPTOTIC GENES, PROLIFERATION FACTORS AND ENDOTHELIAL ANTIGENS IN BARRETT ESOPHAGUS AND ITS COMPLICATIONS

Sajin Maria[1], Chefani Alina Elena[1], Lazaroiu Anca Mihaela[1], Simion George[1], Fierbinteanu Braticevici Carmen[2], Balan Costica[2], Stanescu Alina[3], Hurduc Victoria[4]
[1] Department of Pathology of Universitary Emergency Hospital Bucharest, Romania
[2] Department of Gastroenterology of Universitary Emergency Hospital Bucharest, Romania
[3] Department of Gastroenterology of "Alfred Rusescu" Hospital Bucharest, Romania
[4] Department of Gastroenterology of "Victor Gomoiu" Hospital Bucharest , Romania

Introduction. The most serious complication of the chronic reflux esophagitis, or Barrett esophagus (BE), with glandular metaplasia is secondary esophagial adenocarcinoma. Purpose: Checking the link between the progress of Barrett's metaplasia to adenocarcinoma and the application of tumor markers involved in increased proliferation aspects with presence of apoptotic genes (p-53, bcl-2) proliferation factors (PCNA, Ki-67) and endothelial antigenes (CD 34) Material and methods. The study included 52 cases, mainly males, aged between 23 and 65, who were subjected to endoscopic and histopathologic investigation. Biopsies were fixed in 10% formol and parafin included.. Than ue used HE and histochemical staining for neutral and acid mucopolysaccharides and IHC staining: (indirect tristadial Avidine-Biotine-Peroxidase method). Results: The 52 cases, diagnosed by endoscopic and histologic methods, classified as follows: 20 cases of Barrett esophagus with specialised epithelium, 6 cases of non-determined metaplasia, 8 cases of initial intraepithelium neoplasic lesions, 5 cases of advanced intraepithelium neoplasic lesions and 13 cases of moderate and undifferentiated carcinoma (one of them abounding in Russell bodies). Immunohistochemical, Mutated tumor marker p-53 evidentiation was expressed in 61% cases (high grade of displasia of Barrett's esophagus and adenocarcionoma). The second antiapoptotic marker bcl-2 was inconstantly positive, especially in the lymphocytes of lamina propria. Monoclonal PCNA and 85% of Ki-67 antibodies were positive especially in the undifferentiated carcinoma. Endothelial antigenes (CD 34) were positive especially in the areas with the highest vascularization of well differentiated carcinoma. Follow-up studies are necessary to evaluate the prognostic value of BE complications. Conclusion: To diagnose the distal esophagus precancerous and cancerous conditions, assess the prognosis and risk of progression and to determine effective treatment, a wider panel of tissue tumour markers could help.

PP2-70
MYCOPHENOLATE MOFETIL RELATED COLITIS

Ioanna Delladetsima[1], George Liapis[1], Maria Darema[2], Christos Mavrogiannis[3], Alkiviadis Kostakis[2], John Boletis[2]
[1] Pathology Department Laiko General Hospital University Of Athens, Greece
[2] Transplantation Center Laiko General Hospital Athens, Greece
[3] Gastroenterology Department H. Venizelou Hospital, Athens, Greece

Background: Enterocolitis causing afebrile diarrhea is the most common adverse effect in mycophenolate mofetil (MMF) treated renal transplant patients. However, the histological lesions are still obscure and the pathogenesis has not yet been clarified. The aim of this study is to describe the histological features of the MMF-colitis and to define diagnostic criteria. Histological findings of possible pathogenetic significance are also discussed. Materials and Methods: The examined material consists of colonic biopsies which were obtained from seventeen renal transplant recipients having persistent afebrile diarrhea during treatment with an MMF-containing immunosuppressive regimen. Cases with colonic lesions attributed to other causative agents (CMV, cryptosporidium, bacteria) were excluded. Results: Three cases showed no significant changes. The rest fourteen cases displayed drug induced colitis which was mainly localized in the cecum and ascending colon and exhibited the following histological features: oedema (10), moderate cellular infiltrate (12), increased number of eosinophils (14), small number of neutrophils (9), crypt distortion (10), mucosal atrophy (5), crypts with flattened epithelium and cell apoptosis (5), crypt abscesses (7), erosions and ulcerations (4) and lymphoid aggregates (2). Crypt abscesses were usually few and often contained neutrophils, eosinophils and apoptotic bodies admixed with mucinous material. Conclusions: MMF-related colitis is often associated with a distinct histological pattern resembling chronic IBD. Crypt cell apoptosis in the absence of cryptitis speaks in favor of direct drug toxicity while mucosal architectural disarray and atrophy provide some indications of impaired epithelial regeneration.

PP2-71
MMP-7 EXPRESSION IN COLORECTAL CANCER AND RELATION TO E-CADHERIN AND BETA-CATENIN EXPRESSION

Fatma Husniye Dilek, Nevin Topak, Fatma Aktepe, Onder Sahin, Kadir Serkan Turel, Dursun Ali Sahin
Medical School of Kocatepe University, Turkey

BACKGROUND:It is widely known that colorectal cancer formation is a complex, multistep process involving the accumulation of genetic lesions in genes that regulate the pathways of cell proliferation, adhesion, differentiation, and death required for normal development. E-cadherin/β-catenin complex has a critical role in cell–cell adhesion. β -catenin is a critical component of the highly conserved Wnt signaling pathway that regulates cell proliferation and differentiation When the Wnt pathway is activated, β -catenin ubiquitination and degradation are inhibited and β -catenin enters the nucleus where it complexes with transcription regulator proteins activating target genes and the proteolytic enzymes, such as matrix metalloproteinase-7 (MMP-7, matrilysin). MMP-7 is thought to be directly involved in the processes of growth, invasion, and metastasis of colorectal cancer. METHOD: We were analyzed the expression pattern of E-cadherin, β -catenin and MMP7 in a group of 42 patients with colorectal cancer, 25 of them with lymph node metastases or distant metastases, on immunohistochemical staining using the labeled streptavidin-biotin method. RESULT:MMP-7 staining was significantly higher for colorectal cancer (61.9 %) than for colonic mucosa (19 %) ($p < 0.001$). Cytoplasmic or membranous expression of β -catenin and E-cadherin were observed in 76.2 % and 75.7 % of tumor, respectively. Nuclear expression of β -catenin was detected only in 26.2% of tumors. β -catenin expression scores were closely associated with E-cadherin expression scores. CONCLUSION: There was no association expression of matrilysin or b-catenin and lymph node metastases or distant metastases. The results of this study indicate that expression of MMP-7 may play a role in carcinogenesis of colorectal cancers and correlated with β-catenin and E-cadherin expression.

PP2-72
ASSESSMENT OF Ki-67 IMMUNOHISTOCHEMISTRY IN GASTROINTESTINAL STROMAL TUMOURS (GIST)

Vesna Zivkovic, Vuka Katic, Jasmina Gligorijevic, Biljana Djordjevic, Aleksandar Petrovic, Miljan Krstic
Institute of Pathology, Medical School, University of Nis, Serbia

Background The prognostic significance of Ki-67 proliferation marker in GIST is debatable. Only a few reports have shown that

Ki-67 index should be used as predictor for the malignant potential of GIST. Therefore, we examined 33 cases of GIST immunohistochemically and focused on the differences between benign and malignant groups. Methods The paraffin embedded tissues were immunostained for c-kit, CD34, and Ki-67 antigen by employing labeled streptavidin-biotin (LSAB) method. For Ki-67 index, the results were classified into two groups: stained cells < 10% and > 10% in 50 randomly selected high power fields. Statistical evaluation was carried out with the software SigmaStat for Windows v 3.0 (SPSS Inc., Chicago, IL, USA). Results Of the 33 cases, 17 classified as benign and 16 as malignant. Immunoreaction for c-kit was demonstrated and strongly expressed in all GIST. The almost half the tumours were stained positively for CD34. The total cases stained for Ki-67 >10% were 19/33 (57.58%). The Ki-67 index gretaer than 10% in benign GIST were significantly lower than in malignant GIST (7/17, 41.18 % vs 12/15, 80 %, P<0.05). Conclusion The expression of Ki-67 proliferation marker clearly show differences between benign and malignant GIST and it is useful as a most important prognostic parametar.

PP2-73

EXPRESSION OF AMACR AND THYMIDYLATE SYNTHASE IN RECTAL CANCERS AND CLINICAL OUTCOME

Chmielik Ewa, Chmielarz Andrzej, Liszka Joanna, Kolosza Zofia, Lange Dariusz, Zeman Marcin, Stobiecka Ewa, Kryj Mariusz
M. Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Gliwice, Poland

Background: AMACR or P504S (α-methylacyl coenzyme A racemase) is a mitochondrial and perioxisomal enzyme involved in β-oxidation of dietary branched-chain fatty acids. It is overexpressed in various malignant neoplasms, such as prostate and colon cancer. Thymidylate synthase (TS), in turn, is involved in 5-fluorouracil (5-FU) metabolism and has been used as an important biomarker in predicting tumor response to 5-FU-based therapies. The aim of this study was to analyse AMACR and thymidylate synthase expression in rectal cancers and to find correlations with histopathological features as well as clinical outcome. Method: Study cases included surgically resected primary rectal carcinomas from 36 neoadjuvantly treated patients (25 males and 11 females; median age 61) and 20 patients without preoperative treatment (10 males and 10 females; median age 64.5). Immunohistochemical studies were carried out using anti-AMACR (Polyclonal, 1:100, Dako) and anti-TS (Monoclonal 1: 25, Dako) antibodies. The staining was evaluated using three different scoring systems: intensity, pattern and intensity + pattern. Results were compared with histopathological features such as grade, morphological pattern, pT, pN, tumor response after treatment as well as clinical features such as preoperative CEA level and disease-free survival. Results: 91 % of cases showed positive expression of AMACR. Diffuse pattern and strong staining intensity in case of AMACR expression was correlated with decreased disease-free survival (p=0.027). Positive expression of TS was observed in 71 % of cases. There was a significant correlation between preoperative CEA level and staining intensity as well as stainig pattern of TS expression in patients without lymph node metastases (p=0.020). However, there was no significant correlation of grade, morphological pattern, pT, pN and tumor response after treatment or type of treatment with AMACR expression or TS expression. Conclusions: Additional studies are required to confirm the prognostic significance of AMACR expression in rectal cancers.

PP2-74

MORPHOGENESIS AND PECULIARITIES OF ACUTE MUCOSAL PEPTIC LESION REPARATION IN GERD

Irina Derizhanova, Victor F. Golovitsky, Irina Tumasova
Rostov State Medical University, Russia

The topicality of GERD problem is due to its high incidence. Purpose: to investigate morphogenesis and peculiarities of peptic erosive-ulcerous lesion reparation in GERD. 600 samples taken from esophageal mucosa (EM) of 206 patients were studied. 58 patients underwent reexaminations in the course of treatment. In addition to standard histological methods, staining with combined method of alcian blue+PAS-reaction was used. Peptic erosions and ulcers occurred in 52,9% of examined cases, in 68,5% and 31,5% respectively. The most severe lesions were localized in gastro-esophageal junction or in the area of stratified squamous epithelium (SSE). Acute peptic lesions characterized by necrosis of collagen and muscular fibers and vascular walls. There are 2 possible variants of peptic lesion healing. In typical cases 4 stages can be noted: of leukocyte infiltration and necrotic mass rejection, of granulating, of epithelization (either by SSE or by columnar epithelium (CE) and of tissue remodeling after scarring. The second way of healing is that of encapsulation and organization of necrotic masses and their transformation into hyalinotic sites. In these cases leukocyte and macrophage infiltration and angiogenesis are poorly marked, typical granular tissue being not formed. Re-epithelization becomes impaired; active SSE and CE cellular proliferation and hyperplasia of mucous glands are noted at defect margins. This background promotes precancerous epithelial changes. If columnar cell metaplasia (CM) of EM was having been formed, peptic lesions localize superficially. Mucosal lesions result in active formation of different mucous glands; its secrete becomes amphophilic. In the course of GERD treatment 3 variants of its dynamics are possible – partial SSE restoration; keeping CE of a gastric type invariable; transformation of a mixed type CE into gastric epithelium. When not treated, cell containing intestinal mucus, including goblet cells predominate in mucosa. Conclusion: acute peptic erosive and ulcerous lesions of EM in GERD have definite stages of development and present an obligatory stage in “esophagus Barrett” forming. There are 2 types of their healing; CM development of EM, either of a gastric or of an intestinal type, being possible at any of its stage. CM should be regarded as a body compensatory adaptive reaction under the effect of gastro-duodenal content.

PP2-75

RELATIONSHIP BETWEEN INVOLVED LYMPH NODE, METASTATIC NEST DIAMETERS AND PROGNOSIS OF COLORECTAL CANCER

Fariborzeh Mokarian, Mohammad Hossein Sanei, Ali Chehrei, Victoria Nourozi, Akbar Nourozi
Isfahan University of Medical Sciences, Iran

Introduction: Nowadays colorectal cancer is the third cause of mortality from cancer. For this reason, there have been expanded studies about the effect of various factors, such as depth of tumoral invasion, size of involved lymph nodes, number of these nodes, their place and the extent of metastatic nest, on prognosis of patients with colorectal cancer. We decided to study on relationship between metastatic nest diameter to involved lymph node diameter ratio and prognosis of patients with colorectal cancer. Materials and methods: This historical cohort study was done on Alzahra hospital patients with colorectal cancer who have had metastasis to lymph nodes, it has been at least 1 year since diagnosis of their disease and they have been treated with the same chemotherapy protocol in less than 2 month from surgery. In order to collect data, pathologic samples of 63 patients were prepared and size of lymph nodes with metastasis were registered, by teacher-student microscope, then borders of metastatic nest was marked by a marker and microscope magnification (40). Also, size of metastatic nest was registered with the ruler, and finally, metastatic nest to involved lymph node ratio was calculated. Then, data were entered to SPSS soft were, and Kaplan Meier and Acturial methods in results' analysis and cox regression, Log rank test in comparing the survival appurtenances were used. Results: Based on the results of this

study, about the effect of metastatic nest on prognosis of patients, no meaning full relationship was observed between size of metastatic nest and prognosis (p=0.07). In the case of involved lymph node's size, no meaningful relation with prognosis was seen (p=0.1). Also, no meaningful relationship was seen between metastatic nest to lymph node ratio and prognosis of patients (p=0.2). Conclusion: Despite the fact that our study did not show a clear relation between size of involved lymph node and metastatic nest to involved lymph node ratio and prognosis of patients with colorectal cancer, concerning discrepancies in results of studies by different researchers, more studies are likely necessary. Metaanalytic researches that will possibly be based on all the existed studies, will lead us to a definite conclusion. Key words: Colorectal cancer, Metastatic nest, Prognosis, lymph node.

PP2-76
CLINICOPATHOLOGIC AND IMMUNOPHENOTYPIC FINDINGS IN 4 CASES OF ENTEROPATHY-TYPE T-CELL LYMPHOMA

Angel Panizo, Carlos Panizo, Jesus Javier Sola, Javier Pardo
Clinica Universitaria de Navarra. Universidad de Navarrra, Spain

Background: Enteropathy-type T-cell lymphoma (ETCL) is a rare tumour often occurring in a background of coeliac disease (CD). ETCL is often disseminated at diagnosis, and extraintestinal presentations are not uncommon in the liver/spleen, skin, nasal sinus, and brain. We evaluated ETCL from 4 patients presenting with a history of adult CD. Design: Patients were identified from our hospital lymphoma database. All four cases were studied with respect to clinical (staging, treatment, and outcome), histopathological, and immunophenotypic features. We performed immunohistochemistry using a broad panel of antibodies for CD20, CD3, CD4, CD8, CD30, CD45Ro, CD5, CD23, CD7, CD43, CD15, CD56, perforin, granzyme B, ALK, cytokeratins, and EMA, in formalin-fixed, paraffin embeded tumors and adjacent intestinal mucosa. Results: There were 3 men and 1 women with a mean age of 51.5 yrs (range: 49-54). All patients had a documented clinical history of adult-onset CD. The presenting symptoms were weight loss, small-bowel perforation or B symptoms. One patient had extraintestinal presentation of the lymphoma, in the maxillary sinus. In all four cases, there were clinical and histopathologic evidence of CD and failed to respond to gluten-free diet. Histologic examination of the tumor revealed aggregates of neoplastic pleomorphic large cells, with vesicular nuclei, prominent nucleoli, and abundant cytoplasm. Intramucosal spread of an epitheliotropic T-cell population was observed in the vicinity or even at distant segments of the small bowel. All cases were CD30+, and all showed evidence of T-cell lineage with cytotoxic potential by expression of cytoplasmic CD3, CD43, or CD45RO, or perforin; and all tumors were CD8 negative. Granzyme B was found in two of four cases, mostly in a smaller number of tumour cells. All cases were ALK negative, corroborated by the absence of the t(2:5). Two cases showed cavitation of mesenteric lymph nodes. After diagnosis of ETCL, the patients were treated with chemotherapy. Of the total 4 patients, 3 have died, from progressive disease (dissemination into the CNS, spleen, and colon) or from complications of the disease and/or its treatment. Conclusions: The enteropathy-associated T-cell lymphoma is an aggressive and fatal complication of CD. Loss of response to a gluten-free diet is a complication of CD that may progress to ETCL. The phenotype (cytoplasmic CD3+, CD8-, CD30+), and the intraepithelial accumulation of lymphoma cells observed in the adjacent surviving mucosa are clues to the diagnosis.

PP2-77
PRECANCEROUS ESOPHAGEAL PROCESSES IN GASTROESOPHAGEAL REFLUX DISEASE (GERD)

Irina Derizhanova, Victor F. Golovitsky, Irina Tumasova
Rostov State Medical University, Russia

Two types of malignant tumors – squamous cell carcinoma (SCC) and adenocarcinoma (AC) occur in esophagus. Obligate precancerous processes include high-grade dysplasia of stratified squamous epithelium (SSE) and cylindrical epithelium (CE). Facultative precancerous process is GERD, which is traditionally associated with adenocarcinoma; real epithelial dysplasia incidence and its character in GERD have remained unknown. Purpose: to investigate metaplastic and dysplastic SSE and CE changes in GERD by biopsies from esophageal mucosa. 600 samples taken from 204 patients were studied. In addition to standard methods, the preparations were stained with alcian blue in combination with PAS-reaction, methylene blue and selectively, with monoclonal antibodies to mutant P53, HPV, VEB viruses. Chronic esophagitis of one or another grade was revealed in all the patients. Superficial catarrhal esophagitis and severe erosive – ulcerous lesions were observed in 25,9% and 52,9%, respectively. SSE columnar cell metaplasia (CM) was revealed in 38,7% of cases, 42,7% of them being of a gastric type, 40% - of a mixed type and 17,3% - of an intestinal type. In CM of a gastric type PAS+ mucus was revealed in the cytoplasm of surface and glandular epithelial cells. In incomplete intestinal metaplasia (second type), both gastric and intestinal mucus was revealed in the cells. The least common forms were those in which intestinal goblet cells predominated. Mainly mild dysplastic epithelium changes in esophageal mucosa were revealed in 14 patients (6,8%), changes in SSE and CE making up 64,3% and 35,7%, respectively. Discorrelation of the layers due to basal cells proliferation and nuclear hyperchromasia were noted in SSE. Signs of HPV, HSV and VEB infection were demonstrated in 50%. In CE dysplasia there was increase of glands in number, piling of cells on each other, cellular atypia and nuclear hyperchromasia. 4,9% of the patients had cancer: SC (70%), low-differentiated (10%), glandular (10%), glandular-squamous (10%). Low- and high-grade changes up to Ca in situ typical for SSE dysplasia were noted in areas adjacent to the tumor in all cases of SCC. Besides, in 3 cases of SCC these changes were noted against the background of CM with numerous goblet cells containing intestinal mucus. Conclusion: in esophageal mucosa SSE cellular dysplasia occurred almost twice as often as cylindrical one in case of GERD. In 30% of cases SCC developed against the background of intestinal metaplasia of surface epithelium. Thus, GERD is significant for developing not only AC, but SCC, as well.

PP2-78
A CLINICOPATHOLOGICAL ANALYSIS OF GASTRIC LYMPHOMAS

Deniz Altinel, Olcay Ozcolpan, Umit Bayol, Ayca Tan, Sehnaz Sayhan
S. B Izmir Tepecik Teaching Hospital, Department of Pathology, Turkey

Background: The stomach is the most common site of primary extranodal Non-Hodgkin's Lymphomas (NHL). The aim of this study was to evaluate retrospectively 29 gastric lymphoma cases in accordance to the criteria of the new WHO classification for neoplastic diseases of the hematopoietic and lymphoid tissues. Material-Method:To obtain information, we examined charts of all 29 cases of primary gastric NHL between January 2000 and December 2006. Our cases affected all age groups in both genders and for each group, the rate was higher among men than women, with an overall gender ratio of 1,23. The age of patients ranged from 30 to 69, with a median of 54,07 for males and 61,8 for females. The mean tumor size was 9.4 cm. In 10 of the 21 patients, lymph node involvement has been observed (%49). 13 cases were extranodal marginal zone lymphomas of mucosa-associated lymphoid tissue (MALT)-type(MALT lymphomas) (%44), 10 were diffuse large B-cell lymphomas(%30) and 1 was follicular lymphoma(%6), the rest were diagnosed as NHL NOS(Not otherwise specified)(%20). Conclusion:. Clinical and histopathological characteristics of our cases were characterized

by a higher incidence of stomach location(50%), MALT type (mucosa associated lymphoid tissue)(40%) and B-cell type(90%) The subtype range of our cases was almost similar to those of the cases in Western countries with a few differences.

PP2-79
THE ROLE OF THE DIFFERENTIAL EXPRESSION OF FASCIN IN CHRONIC PANCREATITIS AND PANCREATIC ADENOCARCINOMA

Domniki Gerasimidou[1], Georgia Karayannopoulou[1], Theodora Kehagia[2], Efthemios Hatzitheoklitos[3], Georgios Karkavelas[1]

[3] Department of Surgery, "Agios Dimitrios" Hospital, Thessaloniki, Greece

Chronic pancreatitis is a condition that in some cases may simulate adenocarcinoma. The purpose of this study was to evaluate the usefulness of fascin, a monomeric actin filament bundling protein, which is known to be expressed in ductal pancreatic carcinoma, as a potential differentiating marker between the former and chronic pancreatitis when routine immunohistochemistry is inconclusive. Materials and methods: 48 specimens obtained from patients diagnosed with chronic pancreatitis and 44 specimens from patients with ductal pancreatic adenocarcinoma were studied. Whole tissue sections were immunohistochemically stained and expression of fascin was evaluated. Results: Fascin was positive in 33 out of 44 specimens with pancreatic adenocarcinoma studied. On the contrary, no positivity was observed in all of the 48 chronic pancreatitis specimens studied. In addition, fascin expression in cases of ductal pancreatic adenocarcinoma was of variable intensity related to the differentiation of the tumors with intense expression observed especially in less differentiated tumors. Discussion and Conclusions: The up-regulation of fascin in pancreatic adenocarcinoma related to the progression of the neoplasm, as well as its expression in tumors of the large bowel, the lung and skin have been well documented in previous studies. The fact that none of the chronic pancreatitis cases expressed fascin, leads to the suggestion that it could possibly be used in every day practice, along other tumor markers, especially in cases with limited available tissue samples. Therefore, the differential expression of fascin could be of diagnostic utility in cases when these two entities are hardly distinguished.

PP2-80
THE SIGNIFICANCE OF FASCIN IN THE DIFFERENTIAL DIAGNOSIS OF AMPULLARY VS PANCREATIC ADENOCARCINOMA

Domniki Gerasimidou[1], Georgia Karayannopoulou[1], Theodora Kehagia[2], Efthemios Hatzitheoklitos[3], Georgios Karkavelas[1]
[1] Department of Pathology, Aristotle University medical School, Thessaloniki, Greece
[2] Department of Pathology, "Agios Dimitrios" Hospital, Thessaloniki, Greece
[3] Department of Surgery, "Agios Dimitrios" Hospital, Thessaloniki, Greece

Purpose: Adenocarcinomas of the ampulla of Vater are rare neoplasms, the distinction of which from pancreatic adenocarcinoma is not an easy task in every day practice. The purpose of this study is to clarify the mode of expression of human homolog of the sea urchin fascin, an actin-binding cytoskeletal protein implicated in cell motility, in neoplasms encountered in the ampullary area in comparison to its expression in ductal pancreatic neoplasms. Materials and methods: We examined 6 specimens from patients diagnosed with adenocarcinoma of the ampulla of Vater, one of which showed features of a villous adenocarcinoma and 45 specimens from patients diagnosed with pancreatic adenocarcinoma. Immunohistochemical staining for fascin was performed using the ABC method in formalin fixed, paraffin-embedded sections. Results and Conclusions: Only one specimen of ampullary adenocarcinoma expressed intense positivity of fascin, whereas two specimens showed weak focal positivity of tumor cells. The remaining three specimens, including the one with villous adenocarcinoma features, were negative. 34/45 pancreatic neoplasms expressed fascin with variable staining intensities of tumor cells. These findings suggest a possible synergic utility of fascin in diagnosing neoplasms originating from the ampulla of Vater, especially those with features of pancreatobilliary-type tumors.

PP2-81
SYNCHRONOUS OCCURENCE OF GASTROINTESTINAL STROMAL TUMORS AND OTHER PRIMARY GASTROINTESTINAL CARCINOMAS

Kemal Behzatoglu[1], Tugce Guzelcay[1], Meltem Oznur[1], Sule Canberk[1], Pelin Yildiz[1], Gulben Erdem Huq[1], Erol Rustu Bozkurt[2]
[1] Istanbul Educational and Research Hospital, Turkey
[2] Goztepe Educational and Research Hospital,Turkey

Gastrointestinal (GI) stromal tumor (GIST) is the most common mesenchymal neoplasm of the GI tract wall. This tumor aries in the muscularis mucosa and muscularis propria layers anywhere from the esophagus to the rectum, and its most common anatomic sites of origin are the stomach (60-70%), small intestine (20-30%), colon and rectum (5%), and esophagus (<5%). Syncronous accurence of epithelial and GIST in the GI tract is uncommon. We present a series of eight patients, from two institutions, with GIST and a second primary neoplasm occuring synchronously. The syncronous GISTs were located in the stomach (5 cases), small intestine (3 cases) and were incidentally found during the operation. The coexistent tumors were pancreatic duct adenocarcinoma, gastric adenocarcinoma (5 cases), and small intestinal adenocarcinoma (2 cases). The syncronous occurence of GISTs and other gastrointestinal malignancies is more common than it has been considered. Various hypotheses have been proposed regarding this simultaneous development, and it is not known whether or not such an association is a simple incidental coexistence or whether the two lesions are connected by causal relationship.

PP2-82
THE EFFECTS OF ERDOSTEINE, N-ACETYLCYSTEINE ON INTESTINAL TISSUE PATHOLOGICAL DAMAGE AND APOPTOSIS INDUCED BY SEPSIS

Nesrin Gursan[1], Rezzan Demiralay[2]
[1] Department of Pathology, School of Medicine, Ataturk University, Erzurum, Turkey
[2] Department of Pulmonary Medicine, School of Medicine, Suleyman Demirel University, Isparta, Turkey

This study investigated the frequency of apoptosis in rat small intestinale enterocyt after intraperitoneal endotoxin (LPS) injection, the effects of LPS on inflammatory markers [myeloperoxidase (MPO), tumor necrosis factor alpha (TNF-α), and vascular endothelial growth factor (VEGF)] in small intestinale damage and the protective effects of two known antioxidant agents, erdosteine and N-acetylcysteine (NAC). Male Wistar rats were divided into six groups, each composed of nine rats: two control groups, two LPS-treated groups, one erdosteine-treated group (150 mg/kg), and one NAC-treated group. LPS was intraperitoneally injected at a dosage of 20 mg/kg. Following LPS injection, the antioxidants were administered orally. The rats were killed 24 h after LPS administration. Intestinale tissue samples were stained with hematoxylin–eosin (H&E) for histopathological assessments. Apoptosis level in enterocyt was

determined by using TUNEL (terminal deoxynucleotidyl transferase-mediated dUTP nick endlabelling) method. Staining of cytoplasmic TNF-α and VEGF in enterocyt, and epithelial MPO activity were evaluated by immunohistochemistry. Posttreatment with erdosteine and NAC significantly reduced the increases in the local production of TNF-α and VEGF, and epithelial MPO activity. The effects of NAC on apoptosis, the increases in the local production of TNF-α and VEGF, were weaker than the effects of erdosteine. This finding suggests that the effects of erdosteine at the administered dose on apoptosis regulation are stronger than that of NAC.

PP2-83
GASTROINTESTINAL STROMAL TUMORS – EPIDEMIOLOGY, MORPHOLOGIC AND IMMUNOHISTOCHEMICAL CHARACTERISTICS OF 53 CASES FROM TWO CENTERS IN BULGARIA

Bogomila Manevska[1], Margarita Kamenova[2], Aneliya Kulova[1]
[1] Department of General and Clinical Pathology, Medical University of Varna, Varna, Bulgaria
[2] Department of Pathology, The Pirogov Institute for Emergency Medicine, Sofia, Bulgaria

For a period of five years (2002-2006) 53 cases of stromal gastrointestinal tumors (GIST) were diagnosed in pinch biopsies and surgical materials. The analysis of cases including immunohistochemical typization by CD 117, S100 protein, CD 34, smooth-muscle actin and vimentin. Only CD 117 positive tumors were recognized as GISTs. The tumors were distributed according to the patient age and gender, tumor location (esophagus, stomach, small and large intestine, or extragastric). GIST tumors were more common in women, from the middle age-group intervals (60-74 and 45-49 years of age). For all tumors the grade of malignancy was evaluated, according to the size, invasive growth, and the presence of necroses and mitotic activity. Immunohistochemical typization allows differentiation of the typical (true type) GISTs, from the other types, which show definite differentiation (leiomyomatous, myoblastic or neurogenic).

PP2-84
THE EFFECTS OF ERDOSTEINE, N-ACETYLCYSTEINE ON LIVER TISSUE PATHOLOGICAL DAMAGE AND APOPTOSIS INDUCED BY SEPSIS

Nesrin Gursan[1], Rezzan Demiralay[2], Ilknur Calik[1], Havva Erdem[1], Mevlut Albayrak[1]
[1] Department of Pathology, School of Medicine, Ataturk University, Erzurum, Turkey
[2] Department of Pulmonary Medicine, School of Medicine, Suleyman Demirel University, Isparta, Turkey

This study investigated the frequency of apoptosis and expression of VEGF in rat hepatocyt after intraperitoneal endotoxin (LPS) injection, the effects of LPS and vascular endothelial growth factor (VEGF)] in liver damage and the protective effects of three known antioxidant agents [N-acetylcysteine (NAC), erdosteine] on liver tissue. Male Wistar rats were divided into six groups, each composed of nine rats: two control groups, two LPS-treated groups, one erdosteine-treated group (150 mg/kg), and one NAC-treated group. LPS was intraperitoneally injected at a dosage of 20 mg/kg. Following LPS injection, the antioxidants were administered orally. The rats were killed 24 h after LPS administration. Liver tissue samples were stained with hematoxylin–eosin (H&E) for histopathological assessments. Staining of cytoplasmic VEGF in epithelial cells and in Apoptosis level in epithelial cells was determined by using TUNEL (terminal deoxynucleotidyl transferase-mediated dUTP nick endlabelling) method. Posttreatment with erdosteine and NAC significantly reduced the rate of LPS-induced epithelial cell apoptosis and in the local production of VEGF. The effects of NAC on apoptosis, the increases in the local production of VEGF, were weaker than the effects of erdosteine. This finding suggests that the effects of erdosteine at the administered dose on apoptosis regulation are stronger than that of NAC.

PP2-85
PROGNOSTIC IMPLICATIONS OF IMMUNOEXPRESSION OF CELL CYCLE REGULATORY PROTEINS IN GASTROINTESTINAL STROMAL TUMOURS

Marjan Micev[1], Vera Todorovic[2], Neda Drndarevic[2], Milena Cosic Micev[1], Olivera Mitrovic[2], Mila Krsmanovic[1], Predrag Pesko[1], Michael Heinrich[3]
[1] Institute of Digestive Diseases, Clinical Centre of Serbia, Belgrade, Serbia
[2] Institute for Medical Research, University of Belgrade, Serbia
[3] Department of Medicine, Oregon Health & Science University Cancer Institute and Portland VA Medical Center, Portland, USA

Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors of the gastrointestinal tract with wide spectrum of biological behaviour. The evaluation of malignancy of GISTs is still difficult and risk grading for possible adverse outcome based on tumour size and mitotic counts proposed by Fletcher in 2002 have been widely accepted. The aim of this study was to elucidate the prognostic values of alterations of cell-cycle related proteins and correlate them to risk grades and mutation status of GIST. We reexamined clinically, histologically and immunohistochemically 124 cases of paraffin-embedded GISTs noted in the Tumor Registry of Clinical Centre of Serbia from the total of 418 patients operated for abdominal mesenchymal mostly visceral tumours between 1992 and 2004. There were 25 cases of low-risk grade, 24 cases of intermediate-risk grade and 69 cases of high-risk grade. In addition, mutation status in 91 cases were examined showing 4 subgroups, according to Kit mutations on exon 9 in 7 cases (7,69%) exon 11 in 59 cases (64,84%), PDGFrA mutations on exon 12 in 3 cases (3,30%), exon 18 in 7 cases (7,69%) and wildtype mutations in 15 cases (16,48%). Immunohistochemistry was performed for several cell cycle related proteins including Ki-67, p16ink4a, p21WAF1/CIP1, p27KIP1, p53 and bcl-2. The positive immunophenotypes were as follows: p53 40.68%, p21 32.2%, bcl-2 57.63%, Ki-67 47.46% (cut off values were 5% for p53 and Ki-67, and 10% for others). However, loss of expression of p16 and p27 was found in 85,6% and 83,05% of cases respectively (cut off values 50%). Altered expression of cell cycle related proteins in our series were statistically significant only for positive p53 and Ki-67 as well as negative p16 expression. PDGFrA exon 18 point mutations and exon 12 size mutations are more likely to be associated with high risk GIST. Therefore, they might be potentially useful for predicting aggresive behaviour of GIST.

PP2-86
REGULATION OF NICOTINE-INDUCED APOPTOSIS OF LIVER AND SMALL INTESTINAL CELLS BY POSTTREATMENT OF ERDOSTEINE AND N-ACEYLCYSTEINE

Nesrin Gursan[1], Rezzan Demiralay[2]
[1] Department of Pathology, School of Medicine, Ataturk University, Erzurum, Turkey
[2] Department of Pulmonary Medicine, School of Medicine, Suleyman Demirel University, Isparta, Turkey

Nicotine is a major toxic component of cigarette smoke that induces a wide range of biological effects in human cells. The aim of this study was to determine the effect of nicotine in small intestinal and liver tissue and to determine the protective effects of three known antioxidant agents (N-acetylcysteine (NAC) and erdosteine). Sixty three Wistar rats were divided into seven groups, each composed of nine rats: two negative control groups, two positive control groups, one erdosteine-treated group (500 mg/kg), one NAC-treated group (500 mg/kg), and one vitamin E-

treated group (500 mg/kg). Nicotine was injected intraperitoneally at a dosage of 0.6 mg/kg for 21 days. Following nicotine injection, the antioxidants were administered orally, treatment was continued until the rats were killed. In small intestinal and liver tissue samples were stained with hematoxylin–eosin (H&E) for histopathological assessments. The apoptosis level in the hepatocyte and cyrpt epithelium was determined by using the terminal deoxynucleotidyl transferase-mediated dUTP nick end labelling (TUNEL) method. Cytoplasmic TNF-α in the hepatocyte and crypt epithelial cells and MPO activity were evaluated immunohistochemically. Posttreatment with erdosteine and NAC significantly reduced the rate of nicotine-induced epithelial cell apoptosis. Posttreatment with erdosteine and NAC significantly reduced the increases in the local production of TNF-α and VEGF, and epithelial MPO activity. The effects of NAC on apoptosis, the increases in the local production of TNF-α and VEGF, were weaker than the effects of erdosteine. This finding suggests that the effects of erdosteine at the administered dose on apoptosis regulation are stronger than that of NAC.

PP2-87

CAR EXPRESSION IN GASTROINTESTINAL AND PANCREATIC ADENOCARCINOMA

Stamatios Theocharis[1], Maria Papaefthymiou[2], Constantinos Giaginis[1], Elisavet Gatzidou[1], Stefania Vgenopoulou[1], Ioannis Sfiniadakis[2], Gregorios Kouraklis[3]
[1] Department of Forensic Medicine and Toxicology, Medical School, National and Kapodistrian University of Athens, Athens, Greece
[2] Department of Pathology, Naval Hospital, Athens, Greece
[3] Second Department of Propedeutic Surgery, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background: Coxsackievirus adenovirus receptor (CAR) functions as the primary receptor for both coxsackie B viruses and adenoviruses, playing a crucial role for their entry into host cells. CAR expression on target tumor cells is correlated with their sensitivity to adenoviral infection. Tumor cells lacking or expressing low CAR levels are resistant to adenovirus infection and to efficient oncolysis by recombinant adenoviruses. The aim of our study was to examine CAR expression on clinical material of gastric, colon and pancreatic adenocarcinoma. Methods: CAR expression was detected immunohistochemically on paraffin-embedded tissue sections of 44 gastric, 64 colon, and 53 pancreatic adenocarcinoma cases. CAR positivity and overexpression (expression in more than the mean percentage value) were correlated with patients' gender, age, TNM stage; tumors histopathological grade of differentiation and proliferative capacity (Ki-67 immunohistochemical expression); and with patients' survival. Results: CAR positivity was noted in 26 out of 44 (59%) gastric, 53 out of 64 (82.8%) colon and 44 out of 55 (80%) pancreatic adenocarcinoma cases, examined. CAR overexpression was noted in 14 out of 26 (53,8%) gastric, in 23 out of 53 (43,4%) colon and 22 out of 44 (50%) pancreatic adenocarcinoma CAR positive cases. CAR positivity and overexpression were not statistically significantly correlated with patients' gender, age, TNM stage, tumors histopathological grade, proliferative capacity and patients' survival. Additionally, in gastric carcinoma CAR positivity and overexpression were not statistically significantly correlated with histopathological type (diffuse vs intestinal). Conclusion: Our data reveal, immunohistochemical expression of CAR protein in clinical material obtained from patients with gastric, colon and pancreatic adenocarcinoma. CAR expression was not correlated with clinicopathological variables of prognostic significance and the patients' final outcome. However, CAR expression is considered of possible clinical importance in future cancer gene therapy, as this receptor appears to modulate the proliferation and characteristics of tumor cells.

PP2-88

THE COMPARISON OF NUCLEAR MORPHOMETRIC ANALYSIS WITH CLASSICAL PROGNOSTIC FACTORS IN COLORECTAL CARCINOMAS

Nesrin Gursan[1], Muhammed Calik[2], Ilknur Calik[1], M. Sevki Gursan[2], Sare Altas[1], Cemal Gundogdu[1]
[1] Department of Pathology, School of Medicine, Ataturk University, Erzurum, Turkey
[2] Numune Hospital Erzurum, Turkey

Colorectal carcinomas are one of the most commonly seen malign tumor in the world. Despite innovations in diagnosis and treatment, it has been continuing to become serious problem as regards mortality and morbidity. In order to recognize the prognosis in colorectal carcinomas, a lot of clinic and pathologic parameters. As most of these parameters are subjective, there need more objective and useful prognostic factors in determination of suitable treatment options by assessing the whole biologic behavior before. In this study, operation materials belonging to 83 colorectal carcinoma cases were examined retrospectively. In the study, by mean of morphometric method, nuclear area, nuclear surrounding, minimum and maximum diameter in tumor cells were carried out. We couldn't find relationship between morphometric data and age, sex and tumor localization. Nevertheless, there was statistical relationship between the result of morphometric measurements and histological type, grade, invasion depth of the tumor, lymph node metastasis, vascular invasion, inflammatory reaction, stage and life durations. It was found out that nuclear area became related to stage, life duration and histological type. The maximum nuclear diameter was related to histological grade. In conclusion; colorectal cancers, the values of nuclear morphometric measurement obtained by means of image analysis method are worth of being investigated as the indicator of prognosis.

PP2-89

GASTROINTESTINAL LYMPHOMAS: CLINICOPATHOLOGIC AND IMMUNOPHENOTYPIC FEATURES

Ahu Senem Demiroz, Gulen Bulbul Dogusoy, Hilal Aki, Sibel Erdamar Cetin, Suha Goksel, Nukhet Tuzuner
Department of Pathology, University of Istanbul, Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Gastrointestinal lymphomas (GIL) comprise a group of distinctive clinicopathological entities of B- or T-cell type. Most low-grade B-cell gastrointestinal lymphomas are of mucosa-associated lymphoid tissue (MALT) type and most MALT lymphomas arise in the stomach to arise as a reaction to infection of Helicobacter pylori. Low-grade MALT lymphomas, which usually have a very favorable clinical course, may undergo high-grade transformation but high-grade diffuse large B-cell lymphomas may also arise de novo. In this study, clinicopathologic and immunophenotypical features of GIL which were diagnosed in last 5 years, at our department were reviewed. Method: During the period from 2001 to 2006, 36 gastrointestinal resection specimens were diagnosed as GIL in our department. Their hematoxylin-eosin stained slides were reexamined by standard light microscope and an immunhistochemical panel was used including Ki67, CD20, CD3 or CD5 for all and bcl-2, bcl-6 and others for some cases. The features were statistically analyzed by multiple comparison tests and the results were discussed. Results: Of the 36 patients age range was from 17 to 81 with a median age of 54.5 years. 20 cases were female, while 16 were male. The most common location of tumors was stomach (22 cases), 5 cases located in the small bowel, 4 were in the colon, 2 of them were both in the small bowel and colon together. 3 cases took place in salivary gland. All of the cases were B-cell type lymphomas, as all expressed B-cell phenotype immunohistochemically. 22 cases were diffuse large B-cell type (DLBCL) where 8 cases were MALT lymphomas. 4 DLBCL cases had MALT components. 12

cases which all were DLBCL had high proliferation rate with Ki67 score over than 50%. However, there were no statistical differences between the clinicopathologic features of MALT type and DLBCL and proliferation rates of DLBCL cases with or without MALT components. Conclusion: Primary GIL represents the most common location of extranodal lymphomas and gastric lymphomas are the majority of them. Gastric MALT lymphoma occurs predominantly in individuals over 50 years. Some DLBCL cases of the stomach in which a MALT lymphoma component cannot be detected are transformed MALT lymphomas that have been completely overgrown by DLBCL, but others are true primary DLBCL. However, there is no difference in the clinical behavior between transformed MALT lymphoma and primary DLBCL.

PP2-90

C-FLIP EXPRESSION IN COLORECTAL CARCINOMAS: ASSOCIATION WITH FAS/ FASL EXPRESSION AND PROGNOSTIC IMPLICATIONS.

Georgia Levidou, Penelope Korkolopoulou, Angelica A Saetta, Fanie Gigelou, Andreas Lazaris, Irene Thymara, Melina Scliri, Katerina Bourboukea, Nicolaos V Michalopoulos, Nikiforos Apostolicas, Anastasia Konstantinidou, Michalis Tzivras, Efstratios Patsouris
National and Kapodistrian University of Athens, Department of Pathology, 11527, Athens, Greece

Backround: Disruption of apoptotic cell death has been implicated in tumour aggressiveness in colon carcinogenesis. The Fas-Fas ligand (FasL) system is involved in the execution of apoptosis induced by the immune system. c-FLIP protein constitutes an inhibitor of Fas and other (TRAIL) death receptor-mediated apoptosis. Published information regarding the significance of c-FLIP overexpression in human tumours has only recently begun to accumulate. However, there is as yet no study addressing the issue of concurrent Fas/FasL expression and c-FLIP overexpression in colorectal carcinoma. Therefore, in this study, we investigated the simultaneous expression of Fas, FasL and c-FLIP in relation to standard clinicopathological parameters and patients' outcome in this tumour. Methods: Fas, FasL and c-FLIP protein expression levels were quantified immunohistochemically in paraffin-embedded tissues from 90 patients with colorectal carcinomas, by using the following rabbit polyclonal antibodies, diluted 1:200: 1) Fas 2) FasL, and 3) c-FLIPS/L. The labelling index (LI) was defined as the percentage of neoplastic cells with clear cytoplasmic and/or cell surface immunoreactivity out of the total number of neoplastic cells counted. Basic statistical analysis was performed in order to determine the associations of LIs with several clinicopathological parameters as well as their prognostic significance. Results: Positive immunostaining was detected for Fas, FasL and c-FLIP in 71%, 35.5% and 68.8% of cases respectively. Concurrent expression of Fas/FasL was seen in 28 samples (31%) of which 24 (85.7%) also displayed c-FLIP positivity (p=0.04). Univariate logistic regression analysis showed that Fas, FasL and c-FLIP LIs were unrelated to grade, stage or tumour location (P>0.10). When analysis was performed on a categorical basis, c-FLIP over-expression (>10%) seemed to marginally prevail in higher stage tumours (III/IV vs I/II p=0.09). A positive correlation also emerged between c- FLIP and FasL expression (R=0.3115, P=0.0028). Additionally, FasL and c-FLIP labelling indexes adversely affected survival in both univariate (p=0.001 and p=0.0024 respectively) and multivariate analysis (HR=3.491, p=0.005 and HR=2.960, p=0.036 respectively). Conclusions: The frequent expression and co-expression of Fas, FasL and c-FLIP in colorectal carcinomas implicates c-FLIP as an inhibitor of the Fas-FasL-induced death pathway in these tumours. Moreover, c-FLIP conveys independent prognostic information in the presence of classical prognosticators.

PP2-91

HISTOPATHOLOGIC CHANGES OF GUT MUCOSA DURING ANESTHESIA AND ABDOMINAL SURGICAL PROCEDURES

Branko Dmitrovic[1], Danijela Gulam[2], Damir Kovacic[3], Borna Kovacic[3], Lada Zibar[4]
[1] Department of Pathology and Forensic Medicine, Osijek Clinical Hospital, Osijek, Croatia
[2] Department of Anesthesiology and Intensive Care, Osijek Clinical Hospital, Osijek, Croatia
[3] Department of Abdominal Surgery, Osijek Clinical Hospital, Osijek, Croatia
[4] Department of Internal Medicine, Osijek Clinical Hospital, Osijek, Croatia

A perfusion and integrity of small bowel mucosa were examined during anesthesia and surgery on open abdomen in 60 patients in various length treatments. Patients (44 man, 16 woman) age range was 21 to 80 years (mean age 58 years). During the surgery, two samples of the intestinal mucosa were removed: T0 at the beginning of the procedure, and TN at the end (N = treatment duration in hours – 2 to 7 hours). All the biopsies were examined and classified according to the observed mucosal injury into 4 grades (Knichwitz: Crit Care Med 1998;26(9):1550-7): grade 0 – no injury, grade 1 – isolated hemorrhage in lamina propria, grade 2 – lifting of the villus epithelium and isolated hemorrhage, grade 3 – damaged villi and hemorrhage, grade 4 - damaged villi and ulcerations with necrosis. The changes of intestinal mucosa were found in 31 patients: in 19 patients grade 1 changes were recorded, in 10 patients grade 2, and in 2 patients grade 3. Grade 4 lesions were not recorded. During the anesthesia and surgery on open abdomen, the length of the procedure influences the grade of the intestinal mucosa injury. Aggravation of the patohistological changes in intestinal mucosa correlates with high lactate blood level, proving that the cause of these changes is connected with tissue hypoxia.

PP2-92

PSAMMOMATOUS AND DIFFUSE CALCIFICATION IN GASTRIC CARCINOMA: REPORT OF TWO CASES WITH LITERATURE REVIEW

Nilsen Yildirim Erdogan[1], Osman Nuri Huten[2], Fadime Bahadir[2]
[1] Department of Pathology, Zonguldak Gynecology and Obstetrics, and Pediatrics Hospital, Zonguldak, Turkey
[2] Department of Pathology, Istanbul Educational Hospital, Istanbul, Turkey

Background: Psammoma bodies are round, concentrically laminated calcospherits ranging from 5 m in diameter. They may indicate certain types of tumors includingμto 100 papillary carcinoma of thyroid, meningioma and papillary serous tumors of the ovary, and to a lesser extent contribute leiomyomas and angiomas of gastrointestinal tract. Distrophic calcification is uncommon in gastric cancer and displays either diffuse or psammomatous pattern. Diffuse type calcification is generically seen within the pools of mucin in advanced mucinous adenocarcinoma. Conversely, psammomatous calcification is associated with non-mucin producing carcinomas and detected not only within the carcinomatous glandular lumina but also in the stroma. Case: Total gastrectomy specimens of a 54 year-old female and 74 year-old male with ordinary moderately differentiated intestinal type adenocarcinomas revealed psammomatous and diffuse calcification, respectively. Conclusion: Although diffuse type calcification is well-documentated, psammomatous type is exceptionally rare and only 6 such cases have been reported in the literature; the current case represents the seventh one.

PP2-93
CK7 AND CK20 IMMUNOREACTIVITY IN PRIMARY CARCINOMAS OF THE COLON
Reyhan Bayrak, Sibel Yenidunya
Fatih University School of Medicine, Ankara, Turkey

The expressions of cytokeratin (CK) 7 and 20 have been studied in various primary and and metastatic carcinomas, and their determination may help distinguish the site of origin of origin of metastatic carcinomas. Colorectal carcinomas consistently express CK20, whereas CK7 is found in many ductal and glandular epithelia, including the lung, breast, ovary, and endometium and their carcinoma cells. CK7 expression in colorectal carcinoma has been reported to be rare, and when present, a metastatic origin needs to be excluded. We investigated the expression of CK7 and CK20 in 107 cases of colon carcinomas. Parafin sections of 78 left side colorectal carcinomas, and 29 rigtht side colon carcinomas were immunostained for CK7 and CK20 with standart avidin-biotin complex method. Cytoplasmic CK20 immunoreactivity was detected in 65 of 107 (61%) while cytoplasmic CK7 immunoreactivity was detected 17 of 107(16%) colorectal carcinomas. In term of the combined expression patterns, CK20+/CK7- was the most common pattern, accounting for 51% of colon carcinomas. The CK20-/CK7+ pattern was seen in 7 cases (7%). The CK20+/CK7+ pattern was seen in 10 cases (9%). No association between CK7 expression and anatomic location of carcinomas, tumor size, and grade was found. There was a correlation between CK 7 expression and lymph node metastasis (p[LTEQ]0.02). No association was established among CK20 expression, and grade, and stage. CK20 positivity was more common in left side colon carcinoma (55/65, 85%). There was an association between CK20 expression and anatomical location of tumors which was statistically highly significant (p=0.001). Because of the CK7 expression in colon adenocarcinomas, when CK7 is applied to distinguish primary colorectal versus metastatic origin, its reactivity should be interpreted with caution and should not be used as the sole evidence for excluding a rectal primary, particularly in tumor involving the rectal or pelvic region.

PP2-94
A CASE OF GASTRIC LARGE CELL NEUROENDOCRINE CARCINOMA WITH PANETH CELL DIFFERENTIATION
Reyhan Bayrak, Sibel Yenidunya
Fatih University School of Medicine, Ankara, Turkey

A distinct morphological variant of a high-grade gastric neuroendocrine carcinoma of nonsmall cell type (large cell neuroendocrine carcinoma) of the stomach with Paneth cell differentiation was reported. The tumor was a Borrmann's Type III carcinoma measuring 9.0 x 5.5 cm at the body along the lesser curvature. Histologically it was composed of Paneth cells in addition to poorly differentiated adenocarcinoma cells.. The Paneth cell differentiation was characterized histologically by cytoplasmic distinct coarse eosinophilic granules stained red with periodic acid-Schiff and Masson trichrome reagents and reddish brown with phosphotungstic acid hematoxylin, and immunohistochemically by lysozyme and alpha-1 antitripsyn positivity. Immunohistochemically the tumor with poorly differentiated adenocarcinoma morphology were strong and diffusely positive for synaptophysin and chromogranin A. This case is unusual, since Paneth cells occur only rarely in adenocarcinomas of the stomach. The incidence and significance of the Paneth cell and endocrine differentiation in gastric carcinomas were discussed with the review of the literature.

PP2-95
THE PROGNOSTIC IMPORTANCE OF EGFR EXPRESSION AND GENE AMPLIFICATION IN COLORECTAL ADENOCARCINOMAS
Medine Murtazaoglu[1], Dilek Yavuzer[1], Nimet Karadayi[1], Taflan Salepci[2], Sibel Sensu[1], Sibel Kayahan[1]
[1] Dr. Lutfi Kirdar Kartal Educational and Research Hospital, Department of Pathology, Istanbul, Turkey
[2] Dr. Lutfi Kirdar Kartal Educational and Research Hospital, Department of Oncology, Istanbul, Turkey

BACKGROUND: Epidermal Growth Factor Receptor (EGFR) is a transmembrane protein located at 7th chromosome and which includes tyrosine kinase activity. EGFR and its ligand types provide the growth and regeneration of intestinal mucosa. Accordingly, it can be considered to be related with generation and improvement of gastrointestinal system tumours. In Gastric and Colorectal Carcinomas, by the combination of immunohistochemistry and Fluorescent in Situ Hybridization (FISH) methods, overexpression of EGFR has been shown. The main aim of this research is to show the relationship of EGFR protein expression and gene amplification with each other and with other morphological prognostic parameters at colorectal carcinomas. METHOD: Sixty colorectal adenocarcinoma cases diagnosed at Dr. Lutfi Kirdar Kartal Educational and Research Hospital were investigated. Gene amplification with EGFR overexpression was assessed by using immunohistochemistry and FISH methods. Morphological parameters were age of the patient, gender of the patient, histological grade, local invasion, vein invasion, perineural invasion, lymphoid metastases, stage and the lymphocytic response to the tumour. RESULTS: At immunohistochemical examination, no staining was observed with EGFR at 19 cases (31.6%). There was (+) staining at 13 cases (21.6%), (++) staining at 24 cases (40%) and (+++) staining at 4 cases (6.6%). Nine (75%) of the poor differentiated cases showed staining with EGFR while 3 (25%) of them had no staining. Five (40.2%) of the well differentiated cases did not stain with EGFR while 7 of them (50.8%) showed staining. With FISH method, 8 (13.3%) cases had gene amplification and 52 (86.7%) had none. At the cases showing gene amplification, EGFR expression was seen immunohistochemically. CONCLUSION: As the tumour differentiation becomes poorer and its stage becomes higher, EGFR expression will increase. However, a statistically significant relation between EGFR expression and prognostic parameters is not observed. Besides, at the 8 cases showing gene expression, although EGFR expression was seen immunohistochemically, no statistical significance was found between the parameters. Therefore, mechanisms other than gene amplification may be responsible for EGFR expression. These results may suggest that at colorectal adenocarcinomas, for the evaluation of the response to anti-EGFR monoclonal antibody therapy, molecular diagnostic values as FISH may not be appropriate.

PP2-96
THE DIFFERENCE IN CYCLIN D1, HSP 105, EGFR, RB, AND MSH2 GENE EXPRESSIONS IN CHRONIC GASTRITIS WITH AND WITHOUT HELICOBACTER PYLORI INFECTION
Cetin Boran[1], Yasemin Balaban[2], Fahri Yilmaz[1]
[1] Abant Izzet Baysal University, Izzet Baysal Medical Faculty, Department of Pathology, Bolu, Turkey
[2] Abant Izzet Baysal University, Izzet Baysal Medical Faculty, Department of Gastroenterology, Bolu, Turkey

Background: The main goal of the present study is to show differences in the expression of various genes in patients with chronic gastritis with and without Helicobacter pylori infection. Method: Sixty three samples between 2005 and 2006 were available for the study, including 20 samples with normal gastric fundic mucosa, 22 with moderate to severe chronic gastritis in

fundic mucosa with Helicobacter pylori infection, and 21 with moderate to severe chronic gastritis in fundic mucosa without Helicobacter pylori infection. No samples with chronic gastritis had intestinal metaplasia or dysplasia. Expression of cyclin D1, HSP 105, EGFR, RB, and MSH2 were detected by means of immunohistochemical method. Results and Conclusion: Expression of HSP 105, cyclin D1, and EGFR in gastric mucosal crypts were higher in patients with chronic gastritis without Helicobacter pylori infection than in those with Helicobacter pylori infection. In contrast, RB was higher in patients with chronic gastritis with helicobacter pylori infection. No reaction was detected for MSH2 in any of the samples. Similar results were observed in lymphoid infiltrate of gastric mucosa, excluding cyclin D1. The gene expressions in both crypt cells and lymphoid infiltrate of gastric mucosa with Helicobacter pylori infection were different from chronic gastritis without Helicobacter pylori infection. This result may have been due to the products of Helicobacter pylori. In addition to the bacterial products, some chemical mediators of inflammation in chronic gastritis with Helicobacter pylori infection may have an effect on immunohistochemical reactivity of some genes. Consequently, the immunohistochemical reactivity may be decreased or increased for different genes. These variations are possibly because of alteration in antigenic structure of gene products or changing of gene expressions. In conclusion, these different expression profiles for some genes may explain the difference in behavior of chronic gastritis with Helicobacter pylori infection from chronic gastritis without Helicobacter pylori infection.

PP2-97
MACROSCOPIC AND HISTOPATHOLOGIC EVALUATIONS OF SMALL INTESTINE AND COLON RESECTION SPECIMENS DIAGNOSED AS CROHN DISEASE

Aylin Gonultas, Guray Kilic
Department of Pathology, Haydarpasa Numune, Education and Research Hospital, Istanbul, Turkey

PURPOSE: The aim of this study is to evaluate the macroscopic and histopathologic findings on the resection specimens of colon and small intestine on people who are operated with different reasons and diagnosed with Crohn Disease, to determine the frequency of findings resulted in Crohn Disease diagnosis, to establish the accuracy of histopathologic diagnosis on these cases which has pre-operative endoscopic biopsies and compare them with mucosal lesions in specimens.MATERIALS AND METHODS: The colon and small intestine resection specimens of 28 cases diagnosed as Crohn Disease which are hospitalized in Haydarpaşa Numune Education and Research Hospital Pathology Laboratory between July 2003-February 2007 are used as study groups. Among these cases, 11 had pre-operative endoscopic biopsies. Macroscopic findings evaluated from their pathologic reports and frequencies were determined. Cases' preparations prepared with Hematoxylen-Eosine were reevaluated and frequency of histopathologic properties stated after comparing them to microscopic findings on pathology reports. The accuracy of pre-operative endoscopic biopsy diagnosis was determined. Mucosal lesions of endoscopic biopsies and resection pieces were compared.RESULTS: Cases include 19 male and 9 female patients. Ages are between 17-81. 14 patients' pre-operative diagnosis was Crohn Disease. The other 14 patients were operated because of 2 acute appendicitis, 6 masses, 2 intestinal obstructions, 1 relapse Crohn Disease or mass, 1 terminal ileitis, 1 enterocutanous fistulae, 1 mesentery ischemia. From pathological reports 15 cases were directly diagnosed as Crohn Disease and 13 were said to be related with Crohn Disease after the histopathologic descriptions were done. In the macroscopic evaluations of resection specimens; % 39.2 gato formations, % 23 membrane appearances on serosal surface, %7.14 antimesenteric lipid appearance, %17.8 thickening on intestine wall and firm consistency and %17.8 construction of lumen were found. On mucosa in addition to normal appearance pili disorder as focal centers, hyperemia and edema was %17.8, %67.8 ulcers, % 35.7 disappearances of pilis and %10.7 cobble stone appearances were established. Microscopic findings include; %92.8 focality (structural anomaly of crypt and villus and lymphoplasmasiter cell infiltration in lamina propria), %57.1 focal mucosal ulcer, %7.1 common mucosal ulcer, %46.4 fissure, %17.8 basal plasmasitosis, %35.7 antral metaplasia. Transmural lesions were determined as; %46.4 submucosal edema and fibrosis, %35.7 lymphoid aggregate, %39.2 neuronal hypertrophy, %57.1 serosal fibrosis and %17.8 granuloma. During our work, membrane appearance on serosa (peritonitis), gato formation, thickening of intestine wall and construction of lumen were the most frequently seen properties of macroscopic findings. Commonest histopathologic findings were focality, ulcer, fissure, submucosal edema and fibrosis, neuronal hypertrophy, transmural lymphoid aggregate and serosal fibrosis. 11 cases were evaluated with pre-operative endoscopic biopsy. 2 of these diagnoses were related with Crohn Disease mucosal lesions and 9 were nonspecific for Crohn Disease. These 9 cases were diagnosed as following; 2 focal active chronic colitis, 1 inflammatory pseudopolip, 1 acute and chronic nonspecific inflammation, 1 suspect lymphoma, 2 normal colon mucosa and inadequate small intestine mucosa.

MALIGNANT HISTIOCYTOFIBROMA OF THE PANCREAS / A CASE REPORT WITH REVIEW OF THE LITERATURE

Assia Boufennara[1], Sabrina Mellouk[1], Nadjiba Debabeche[1], Oussama Hocine[2], Nadjia Terki[1]
[1] Department of Pathology, Algeria
[2] Department of Surgery, Algeria

INTRODUCTION: The cancer of the pancreas remains bad forecast for the common forms of adenocarcinoma; it is not less in the unusual and rarer types like the sarcoma; since, in the large majority of the cases, the assessment of extension made at the moment of the diagnosis shows that the tumour was impossible to remove, either because of a vascular invasion, or because of the presence of nodes and/or hepatic metastasis. The clinical signs are not specific and are late, generally translating the invasion of the bodies of vicinity; the two most frequent symptoms are the abdominal icterus and pains. Material and Method: It is about the patient A.Z 57 years old who presented abdominal pain for 3 months and an important and generalized icterus . The scanner reveals a process of 3,5 cm in the head of the pancreas with proximal nodes. A cephalic duodenopancreatectomy was performed. The morphological study, showed an intracystic heterogeneous lesion of 4 cm in largest axis and altered by necrosis and haemorrhage corresponded to malignant histicytofibroma with infiltrated nodes. EVOLUTION: The patient had presented a syndrome of cytolysis and died after 6 days. CONCLUSION: This sarcoma is rare and of unusual localization whose fatal exit will always remain of dark forecast . No chemotherapy currently clearly was the proof of its effectiveness and the treatment remains palliatives for the most invalidating symptoms like the icterus and the pains.

PP2-99
MGMT EXPRESSION IN COLORECTAL CANCER: RELATION TO CLINICOPATHOLOGIC AND MOLECULAR FEATURES

Roberta Gafà, Iva Maestri, Maurizio Matteuzzi, Alba Gaban, Elena Miotto, Silvia Sabbioni, Massimo Negrini, Giovanni Lanza
Department of Experimental and Diagnostic Medicine, University of Ferrara, Italy

Background: The O6-methylguanine-DNA-methyltransferase (MGMT) is a DNA repair protein that removes mutagenic and cytotoxic adducts from O6-guanine in DNA. MGMT inactivation by promoter methylation is thought to play a major role in the development of a subgroup of colorectal tumors. Aim of this

study was to evaluate whether colorectal adenocarcinomas (CRCs) with MGMT inactivation display distinctive clinical, pathologic and molecular features. Methods: MGMT protein expression was evaluated by immunohistochemistry in a series of 196 surgically resected CRCs using the anti-MGMT monoclonal antibody MT3.1. Tumor DNA mismatch repair (MMR) status was determined by immunohistochemical evaluation of MLH1, MSH2 and MSH6 expression and microsatellite genotyping. In addition, MGMT and MLH1 promoter methylation were assessed in 57 tumors using methylation-specific PCR. Results: Loss of MGMT expression was detected in 44 (22.4%) of the 196 tumors examined. In most cases (40/44) a complete loss of MGMT immunoreactivity was observed. MGMT expression was closely related to MGMT methylation status. MGMT promoter methylation was observed in 11 of the 13 MGMT-negative (84.6%) and in 6 of the 44 MGMT-positive (13.6%) carcinomas examined (P< 0.001). MGMT-negative carcinomas occurred more frequently in the proximal colon (P= 0.02) and among patients older than 70 years (P= 0.01). No significant relationship was found with other clinical and pathologic features. MGMT expression was found to be related to the MMR status of the tumors. Infact, loss of MGMT reactivity was observed in 13 of 40 (32.5%) MMR-defective tumors and in 31 of 156 (19.9%) MMR-proficient carcinomas. Specifically, loss of MGMT expression occurred in 33 of 168 (19.6%) MLH1-positive carcinomas and in 11/28 (39.3%) MLH1-negative carcinomas (P= 0.02). To more properly define the relationship between MMR status and MGMT expression, we examined further 63 MSI-H colorectal adenocarcinomas and evaluated MLH1 promoter methylation in a subset of cases. Lack of MGMT expression was detected in 34/82 (41.5%) MSI-H MLH1-negative and in 1/21(4.7%) MSI-H MSH2 or MSH6-negative carcinomas (P= 0.01). A significant relationship between MGMT and MLH1 promoter methylation was observed in the 57 cases examined by methylation-specific PCR (P< 0.01). Conclusion: Our results indicate that MGMT-negative CRCs are characterized by certain clinical and molecular features. The role of MGMT expression in cancer recurrence and in disease-free and overall survival after curative surgery and chemotherapy needs to be carefully evaluated.

PP2-100

DIFFUSE NODULAR LYMPHOID HYPERPLASIA: CASE REPORT

Cigdem Vural[1], Nalan Akyurek[1], Ayse Dursun[1], Sukru Dumlu[2]
[1] Gazi University Faculty of Medicine, Department of Pathology, Ankara, Turkey
[2] Gazi University Faculty of Medicine, Department of Gastroenterology, Ankara, Turkey

Introduction: Diffuse nodular lymphoid hyperplasia is a very rare lesion of the gastrointestinal tract which is especially encountered in patients with primary immune deficiency and is defined as the presence of multiple lymhoid nodules in the small and large bowels. The pathognesis of diffuse nodular lymphoid hyperplasia is unclear. It is two times more common in women. Diffuse nodular lymphoid hyperplasia is a risk factor for all gastrointestinal tumors but for gastrointestinal lymphoma in the first line. Case presentation: The endoscopic examination of a 42 years-old male patient with diarrhea revealed grape-bunch like nodular appearance in the stomach and duodenum and biopsies from the related regions were sent to our department. The histologic sections of the upper gastrointestinal endoscopic biopsies displayed superficial erosion, intestinal metaplasia and active-chronic gastritic changes of the epithelium. Additionally, the mucosa and the submucosa contained localized lymphoid follicles with prominent germinal centers. The following lower gastrointestinal endoscopy of the patient showed similar findings in the terminal ileum and colon. All biopsy samples were immunhistochemically stained with CD-3, CD-20, CD-43, CD-5, CD-10, Cyclin-D1 and bcl-2 for the differential diagnosis of lymphoma and no findings suggestive of lymphoma were observed. We found our case worth presentation because diffuse nodular lymhoid hyperplasia is a rare lesion which may mimic lymhoma both in endoscopic and histopathologic examination and it should be considered in the differential diagnosis.

PP2-101

NEOADJUVANT THERAPY IN RECTAL CARCINOMA: STUDY OF 28 CASES

Lina Gomes Dos Santos[1], Teresinha Castelo Branco Carvalho[2], Jerusia Oliveira Ibiapina[2], Gil Carlos Modesto Alves[2], Celio Marcos De Oliveira[3], Jose Klerton Luz Araujo[1], Mauricio Miranda Nunes[1], Ismar Do Vale Martins[1], Arnaldo Escorcio[1], Sabrina Cabral Bezerra[1], Anaide Rosa Nascimento[1], Hermano Rodrigues Pinheiro[1], Kelson James De Almeida[1], Sabas Carlos Vieira[1], Edilson Carvalho De Sousa Junior[1]
[1] Federal University of Piaui, Brazil
[2] São Marcos Hospital, Brazil
[3] Biocelula Lab, Brazil

INTRODUCTION: Local advanced the rectal carcinoma has a private prognostic. However, since the introduction of the neoadjuvant radiochemotherapy, the evolution of these neoplasias has suffered deep modifications. However, until the moment, no histopathologic features has been told as predictive factor to the reply to the therapeutical neoadjuvant, even so some molecular alterations have been considered as potential markers. An increase in the supervened one of the patients with retal cancer is one of the biggest challenges of the oncologic surgery, a time that only half of the patients one has supervened average one of 5 years. Thus, different therapeutical protocols have been considered, such with association of the neoadjuvant radiotherapy and chemotherapy. This therapeutical boarding induces a tumoral regression of the 60% order, causing an important reduction the recurrence frequency local and an improvement in the taxes of overlife. The objective of the present study is to evaluate the impact of the radiochemotherapy preoperative in the patients with local advanced rectal carcinoma, through the study of clinical and anátomo-pathological characteristics. MATERIAL AND METHODS: To estimate the effects of the radio and chemotherapy preoperative in the rectal carcinoma, the authors had studied 28 surgical specimens of patients with advanced rectal carcinoma (Stage T3 and T4) diagnosed through biopsy. All the patients had been submitted the neoadjuvant radiochemotherapy. All the surgical specimens had been examined by an only pathologist and all the area of the injury is submitted the histopathologic examination. Using a standardized boarding, the following morphologic parameters had been evaluated: Index of tumoral regression; degree of cytological atipia; intensity of the inflammatory reaction and tumoral necrosis. The tumoral regression was graduated in agreement criteria praised for Mandard et al, that it used a scale of 1-5 established one in the absence of residual tumoral cells and in the extension of fibrosis. Other conventional parameters had been also analyzed, among these the age, the sex, the histologic type (WHO), the surgical depth of tumoral invasion, linfonodal status and still the clinical and pathological stage. RESULTS/CONCLUSION: Between the 28 patients who had been studied, it had complete tumoral regression in 10 (35.7%) and minim or no tumoral regression in 18 (64.3%).

INCREASED EXPRESSION OF NUCLEAR FACTOR-KAPPA B/P50 CORRELATES WITH DISEASE PROGRESSION AND PROGNOSIS IN COLORECTAL ADENOCARCINOMA

Nalan Akyurek[1], Ipek Isik Gonul[1], Ayse Dursun[1], Mustafa Benekli[2], Aytug Uner[2], Deniz Yamac[2]
[1] Gazi University Medical School, Department of Pathology, Ankara, Turkey
[2] Gazi University Medical School, Department of Medical Oncology, Ankara, Turkey

Background: The nuclear transcription factor nuclear factor-kappa B (NF-kB) has been found to play a role in cancer development and progression through its influence on apoptosis. The aim of this study was to determine whether NF-kB is constitutively activated in colorectal cancer tissues and to determine the role of NF-kB in colorectal cancer development and tumor progression. Method: Immunohistochemical staining was performed using the p65 and p50 subunits of NF-kB in normal and neoplastic colorectal tissues. To identify the correlations between clinicopathological parameters and the survival, expression of both the NF-kB/p65 and NF-kB/p50 was assessed in 210 consecutive patients with colorectal carcinomas who had undergone colectomy or polypectomy due to intramucosal carcinoma arising from pre-existing adenomas. Results: The immunoreactivity of both the NF-kB/p65 and NF-kB/p50 was significantly increased in the transition from normal mucosa and adenoma with low dysplasia to adenocarcinoma ($p<0.05$). Among the 210 cases of adenocarcinoma, NF-kB/p50 immunoreactivity was significantly correlated with the angiolymphatic invasion ($p< 0.01$), lymph node metastasis ($p<0.05$), liver metastasis ($p<0.05$), distant metastasis ($p<0.05$), and increasing stages of the Dukes classification ($p<0.05$). On the other hand, well-differentiated adenocarcinoma is showed significantly higher expression of NF-kB/p65 than moderate and poorly differentiated adenocarcinomas ($p<0.05$). Importantly, the patients with expression of NF-kB/p50 (but not of NF-kB/p65) had significantly worse prognosis (Log-rank test, $p=0.001$). On multivariate analysis, Dukes stage ($p=0.001$) and NF-kB/p50 expression ($p=0.003$) were independent prognostic indicators. Conclusion: These results suggest that, both the NF-kB/p50 and NF-kB/p65 play an important role in colorectal tumorigenesis. Overexpression of NF-kB/50 is showed aggressive clinical biology and poor outcome; thereby suppression of NF-kB may be a useful therapeutic strategy for a subset of patients with colorectal carcinoma.

MICROVESSEL DENSITY AND IMMUNOHISTOCHEMICAL EXPRESSION OF ANGIOGENIC PROTEINS VEGF, VEGFR1 AND VEGFR2 IN GASTRIC ADENOCARCINOMA

Evangeli Lampri[1], Ann Goussia[1], Evdoxia Sintou-Mantela[1], Eufemia Balasi[1], Antonia Charchanti[2], Sevasti Kamina[1], Antonio Capizzelo[3], Pericles Tsekeris[3], Evangelos Briasoulis[4], Vasiliki Malamou-Mitsi[1], Niki J.Agnantis[1], Maria Bai[1]
[1] Department of Pathology, Medical School, University of Ioannina, Greece
[2] Department of Anatomy-Histology-Embryology, Medical School, University of Ioannina, Greece
[3] Department of Radiation Therapy, Medical School, University of Ioannina, Greece
[4] Department of Oncology, Medical School, University of Ioannina, Greece

Background. Recently, many studies have demonstrated that angiogenesis is related to tumor growth and progression. Vascular endothelial growth factor (VEGF) is one of the most important angiogenic factors and acts through its specific receptors VEGFR1 and VEGFR2. In the present study, we analyzed the immunohistochemical expression of VEGF, VEGFR1 and VEGFR2 proteins as well as the microvessel density (MVD) in relation to the proliferation profile (expression of Ki67 and cyclin A proteins), p53 protein expression and clinicopathological parameters in a series of gastric adenocarcinomas. Materials and Method. Tissue specimens from 69 cases of surgically resected gastric adenocarcinomas were studied immunohistochemically for the expression of VEGF, VEGFR1 and VEGFR2 proteins. MVD was estimated after immunostaining for CD34 (MVD-CD34) and CD105 (MVD-CD105) and evaluated as the mean (±SD) vessel count/high-power microscopic field (HPF). Spearman's correlation coefficient test was used for the statistical analysis. Results. Expression of VEGF, VEGFR1 and VEGFR2 proteins was found in 49/69 (71.4%), 56/68 (82.4%) and 46/68 (67.6%) cases, respectively. The MVD-CD34 and the MVD-CD105 were 59.96 (±23.5) and 20.94 (±16.82), respectively. VEGF expression was positively correlated with VEGFR1 and VEGFR2 protein expression ($p=0.027$ and $p=0.011$, respectively). Moreover, a similar correlation between the expression of VEGF and Ki67, cyclin A and p53 proteins was found ($p=0.038$, $p=0.01$ and $p=0.001$, respectively). Conclusions. The results of this study suggest that in gastric adenocarcinomas a) the expression of the angiogenic proteins VEGF, VEGFR1and VEGFR2 is a common event, b) VEGF may act as an autocrine growth factor and c) VEGF protein expression may be regulated by p53.

PP2-104
CALBINDIN – D28K AND PARVALBUMIN IMMUNOREACTIVITY IN HUMAN GASTROINTESTINAL CARCINOMAS

Maria Tzaneva[1], Diyana Prangova[1], Bogomila Manevska[2]
[1] Department of Pathology, Medical Faculty, Trakia University, Stara Zagora, Bulgaria
[2] Department of Pathology, Medical University, Varna, Bulgaria

Calbindin D28k (Ca-D28k) and parvalbumin (PV) are calcium-binding proteins which maintain cellular calcium homeostasis. They express mainly in central and peripheral nervous system. Ca-D28k is thought to play a role in inhibiting apoptosis. The aim of this study was to investigate the expression of CA-D28k and PV in tumour tissue of gastrointestinal adenocarcinomas and neuroendocrine carcinomas using light and electron microscope immunohistochemical techniques. Material and methods. 17 adenocarcinomas and 15 neuroendocrine carcinomas with different differentiation were immunostained with the both antibodies using peroxidase - antiperoxidase technique and immunogold technique. Results. Light microscopically intracellular localization of Ca-D28k and PV was found in 11.7% /2 cases/ and 17.6 7% /3 cases/, respectively in adenocarcinomas and 66.6% /10 cases/ and 86.6% /13 cases/, respectively in neuroendocrine carcinomas. Immunoreactivity varied from weak to moderate. The both proteins were found in a few cells in gastric and intestinal mucosa next to the carcinomas. In well-differentiated neuroendocrine carcinomas Ca-D28k and PV were found mainly in the nuclei of tumor cells and perinuclear zones while in poorly differentiated neuroendocrine carcinomas the both peptides were localized mainly in tumor cell cytoplasm. In adenocarcinomas the expression was mainly in tumor cytoplasm. Ultrastructurally Ca-D28k and PV were found in the nucleus and next to nucleus in tumour cells in well-differentiated neuroendocrine carcinomas. In poorly differentiated neuroendocrine carcinomas and in the adenocarcinomas the both proteins were localized mainly in the cell tumour cytoplasm. Conclusion. Our results reveal that Ca-D28k and parvalbumin can be used in the diagnostic tumour immunohistochemistry. The presence of the both proteins in the nuclei and the perinuclear zone in well-differenciated neuroendocrine carcinomas suggest a participation in the regulation of tumour cell apoptosis.

A CASE OF COLLISION TUMOR OF THE RECTUM; COMPOSED OF A CONVENTIONAL ADENOCARCINOMA AND LARGE CELL NEUROENDOCRINE CARCINOMA

Dinc Suren, Banu Bilezikci, Beyhan Demirhan
University of Başkent, Faculty of Medicine, Department of Pathology, Ankara, Turkey

Collision glandular-neuroendocrine tumors of the gastrointestinal tract are extremely rare. The term "collision" applies when glandular and neuroendocrine components are closely juxtaposed but the individual cell types are not mixed. The aim of our article

was to describe a collision tumor involving the rectum. Our patient was a 75-year-old man who presented with rectal bleeding. Two necrotic hypervascular masses were detected in the liver and the wall of the rectum by computerized tomography. Histological examination showed of a tumor composed of an adenocarcinoma of conventional type and a component consisting of large round to polygonal cells exhibiting clear-cut neuroendocrine differantiation morphologically and immunohistochemically. These two components were closely juxtaposed but the individual cell types were not mixed. Adenocarcinoma was located superficially and continued with dysplastic surface epithelium. The neuroendocrine component was deeply infiltrating. Metastatic tumor was found in 6 of regional lymph nodes. Although the metastatic lymph nodes contained both the conventional adenocarcinoma and a large cell neuroendocrine carcinoma, a needle biopsy from the liver masses were consisted only of the metastatic conventional colonic adenocarcinoma. To our knowledge, this is the first report of collision tumor occuring in the rectum.

PP2-106
MALIGNANT PERITONEAL DECIDUOID MESOTHELIOMA: A CASE REPORT

Aysenur Akyildiz Igdem[1], Elife Sahan[1], Erkan Celik[1], Hakan Ozgur[1], Nusret Erdogan[1], Omer Aycan[2], Ferda Nihat Koksoy[2]
[1] Taksim Hospital, Department of Pathology, Istanbul, Turkey
[2] Taksim Hospital, Department of Surgery, Istanbul, Turkey

Malignant Deciduoid Mesothelioma is a rare morphological variant of epithelioid mesothelioma. Frequently it arises from the peritoneum of young women. We present a case of malignant deciduoid mesothelioma in a 17 years old man. He presented with peritoneal mass and abdominal pain and his clinic was very aggressive. His physical examination revealed ascites. He underwent laparoscopic exploration and granuloma-like masses of the peritoneum, omentum and mesothelial surface were seen. Microscopically, there was diffuse deciduoid cellular proliferation. The immunohistochemical staining showed positivity for calretinin and the case was evaluated as malign peritoneal deciduoid mesothelioma. He progressed so quickly that he died four months after initial diagnosis. This observation confirms the poor prognosis of this rare entity.

PP2-107
UNUSUAL TUMOUR OF THE STOMACH

Ayadi Lobna, Kallel Rim, Abbes Karima, Chaabouni Salma, Sellami Ahmed, Gouiaa Naourez, Makni Saloua, Boudawara Tahya
EPS Habib Bourguiba SFAX, Tunusia

Introduction: Gastro-intestinal stromal tumors (GIST) are rare accounting for 2.2% of malignant gastric tumors. Histologically, they vary from cellular spindle cell tumors to epithelioïd ones. Pleomorphic variant is rare. We report an unusual case of malignant GIST particular by marked and diffuse cellular pleomorphism. Observation: A 65-year-old woman had a 6 week-history of vague abdominal discomfort. The endoscopy and the computed tomography demonstrated a hudge epigastric mass that was 15 cm in diameter. The patient underwent a gastrectomy. On macroscopic exam, the tumor was intra-mural, protruding into the gastric lumen; on sectoning, the tumor was well circonscribed with massive necrosis. On histopathologic exam, the tumor was composed of slightly cohesive epithelioid cells with clear cytoplasm and pleomorphic nuclei mixed with numerous giant cells; the mitotic activity was high. The tumor showed a strong positivity for c-kit, CD34, vimentine and a slight positivity for protein S100. It was negative for smooth muscle actin (SMA). The diagnosis of pleomorphic variety malignant stromal tumor of the stomach was made. The patient have not received any adjuvant therapy and she was alive without evidence of disease 3 months later. Conclusion: The pleomorphic variety of GIST is very rare, the marked and diffuse pleomorphism is unusual and should alert to the possibility of other differential diagnosis. Among GIST, the pleomorphic variety suggests a worse biologic behavior.
