SCF-MO calculations of the vibration frequencies and IR absorption intensities of 3radialene are reported. Complete normal coordinate analysis for the molecule was done. The C=C str. frequencies of 3radialene are found to be intermediate between the values for ethylene and acetylene. The results are explained in terms of a modified Förster-Walsh model for the 3ring in which the central carbon atoms show sp hybridization.

**Key words:** 3Radialene; Vibration Frequencies; MINDO/3-FORCES.

## Introduction

The chemistry of 3radialene started to become known through its synthesis, Köbrich et al. [1]. Its peculiar structure was interesting from both the theoretical and synthetic point of view due to its threefold conjugated cyclopropyl structure (Scheme 1):

In its special type of bonding it formed the first member of a new class of organic compounds. Due to this fact both UV spectroscopic [2] and X-Ray diffraction studies [1] were done for its alkyl substituted derivatives. Hexamethyl-3radialene was found to be coplanar with all six methyl groups falling in the plane of the molecule:

Due to this result the H atoms of the non-substituted 3radialene are expected to fall in the molecular plane too, since less repulsive interaction is expected for them than in the case of the poly-methyl derivatives. The IR-

spectrum of the methyl 3radialene showed an absorption band at  $1610\text{ cm}^{-1}$ , which was attributed to the C=C bond vibration [1]. Subsequent IR study allowed a detailed discussion of the vibration spectrum for the non-substituted 3radialene [3]. We have decided to study this interesting problem.

Our study is based on applying the MINDO/3-FORCES SCF-MO method, which was described and applied formerly for the IR spectral studies of various molecules [4]. The method allowed good estimations of the forces constants of organic molecules applying the Pulay's Forces method [5]. The solution of Wilson's secular equation [6]

$$\sum_j L_j (F_{ij} - M_{ij} \lambda_j) = 0$$

provides us with both vibration frequencies ( $\lambda = 4 \pi^2 \nu^2$ ) and vibration mode's eigenvector coefficients ( $L$ ). These allow a graphical description of the vibration mode of each atom in the molecule when applied to the DRAW.MOL routine developed by Shanshal et al. [7], Figure 1. The same coefficients are used to evaluate the partial contribution of each atom to the molecular vibration in terms of the so-called atomic partial participation (APP) values [8].

## Results and Discussion

The evaluation of the vibration frequencies of 3radialene was done for its equilibrium geometry as calculated by minimizing its total energy as function of all its 3N Cartesian coordinates. The resulting geometry corresponds to the following values  $1.437\text{ Å}$  (C–C),  $1.322\text{ Å}$

(C=C),  $111^\circ$  (HCH),  $124.5^\circ$  (C–C–H), and  $1.100 \text{ \AA}$  (C–H) (the calculated geometric values are similar to those calculated by Dewar et al. [8]). Interesting is the C=C distance which falls between  $1.337 \text{ \AA}$  for ethylene and  $1.21 \text{ \AA}$  for acetylene. The small HCH bond angles are also remarkable. The ring C–C bond distances are similar to those of the cyclopropyl ring. These results might be explained if one accepts the Förster-Walsh description of bonding in cyclopropane with some modification. Accordingly, the ring C atoms should possess  $sp$  hybridization in order to form both cyclopropyl C–C bonds and the external C=C double bond, as the following scheme shows:

This type of bonding explains the short distance, being formed between a  $C_{sp}$  atom with small atomic radius and  $C_{sp2}$  of an expectedly normal atomic radius. The higher electronegativity of the ring  $C_{sp}$  atoms causes an electron shift from the external  $C_{sp2}$  atom to the ring atoms. This fact could be partly responsible for the unusual by small HCH bond angles of the external bonds. An impact of this description should be noticed in the frequency values of the molecule.

3radialene is a planar molecule with  $D_{3h}$  symmetry. Its total number of vibrations ( $3N-6$ ) is 30. These are classified into the following irreducible representations:

In plane  $4 A'_1 + 3 A'_2 + 7 E'$ ,  
out of plane  $A''_1 + 2 A''_2 + 3 E''$ ,

where  $A'_1$ ,  $A'_2$  and  $E''$  are Raman active,  $E'$  and  $A'_2$  are IR active,  $A''_1$  is Raman and IR inactive.

Our treatment, based on the MINDO/3-FORCES, yielded all these vibration modes correctly. The corresponding scaled frequency values are listed in Table 1 together with the calculated IR absorption intensities. The applied scaling factors were determined for ethylene considering the experimental frequencies of Duncan et al. [9] and are; 0.87 ( $CH_2$  str.); 0.90 (C=C str.); 1.06 ( $CH_2$  sciss.); 1.00 ( $CH_2$  rock.); 1.15 ( $CH_2$  twist.); 1.00 ( $CH_2$  wag.); 1.00 ( $\gamma CH_2$  and  $\gamma CC$ ); 1.00 ( $\gamma CCC + \gamma CH_2$ ).

Figure 2 shows graphical pictures for some vibration modes of 3radialene as drawn through DRAW-MOL

routine. Such pictures were used for the assignment of the vibration frequencies.

Inspection of the frequency values in Table 1 reveals the following interesting results;

$\nu\text{CH}_2$  asym.str. >  $\nu\text{CH}_2$  sym.str.,  
 $\nu\text{C}=\text{C}$  sym.str. >  $\nu\text{C}=\text{C}$  asym.str.,  
 $\nu\text{CH}_2$  (rock.) >  $\nu\text{CH}_2$  (sciss.),  
 $\nu\text{CH}_2$  (wag.) >  $\nu\text{CH}_2$  (twist.).

The most apparent difference is that  $\nu\text{C}=\text{C}$  str. in ethylene ( $1656\text{ cm}^{-1}$ ) [10] is lower than both  $\nu\text{C}=\text{C}$  sym.str. and  $\nu\text{C}=\text{C}$  asym.str. in 3radialene. The obvious reason is the different hybridization of the C atom of the ring

in 3radialene,  $\text{C}_{\text{sp}}$ , as explained in a former paragraph causing a shift of the frequency towards that of the  $\text{C}\equiv\text{C}$  bond ( $\Delta\nu = 17\text{ cm}^{-1}$ ). Also, the calculated  $\nu\text{CH}$  sym.str. in ethylene ( $3116\text{ cm}^{-1}$ ) is higher than  $\nu\text{CH}$  sym.str. in 3radialene ( $3068\text{ cm}^{-1}$ ). The reason seems to be the diminishing of electron density at the external C atoms of 3radialene caused by the higher electronegativity of the ( $\text{C}_{\text{sp}}$ ) ring atom. The smaller number of electrons does cause a decrease in the C–H force constant and the vibration frequencies. The electron transfer from  $\text{C}_{\text{sp}2} \rightarrow \text{C}_{\text{sp}}$  carbon atom seems to be responsible for the following comparative relations too;

scaled ethylene	scaled 3radialene
$\nu\text{CH}_2$ sym. (sciss.)	> $\nu\text{CH}_2$ sym. (sciss.)
( $1371\text{ cm}^{-1}$ )	( $1455\text{ cm}^{-1}$ ),
$\nu\text{CH}_2$ asym. (rock.)	> $\nu\text{CH}_2$ sym. (rock.)
( $1029\text{ cm}^{-1}$ )	( $917\text{ cm}^{-1}$ ),
$\nu\text{CH}_2$ (twist.) ( $1021\text{ cm}^{-1}$ )	> $\nu\text{CH}_2$ (twist.) ( $744\text{ cm}^{-1}$ ),
$\nu\text{CH}_2$ (wag.) ( $973\text{ cm}^{-1}$ )	> $\nu\text{CH}_2$ (wag.) ( $851\text{ cm}^{-1}$ ).

Other interesting results are viewed on comparing the 3radialene frequencies with the frequencies of similar nature of ethylene, Table 2.

## Conclusion

The calculated vibration frequencies of 3radialene as well as its geometric values show some peculiar properties when compared with those of ethylene. A thorough discussion of the results suggests their explanation through the  $\text{C}_{\text{sp}}$  hybridization form of the ring C atom. The type of C–C bonding conforms to a description which might be viewed as an extension of the Förster-Walsh bond description of cyclopropane.

## Acknowledgement
