Rotational transitions in the millimeter wave region are reported for a number of excited vibrational states of KOH and KOD. From an analysis of the  $J$ -dependence of the  $l$ -type resonance interactions the separation of the  $l$  sublevels of several  $v_1 v_2^l 0$  states has been obtained. The cubic anharmonic contributions to  $\alpha_1$  and  $\alpha_2$  were determined and the sign and isotopic variation of  $\alpha_2$  are shown to be consistent with a nearly harmonic bending potential function. An  $r_e$  structure has been determined from the data using a calculated value for  $\alpha_3$ . On the basis of the present data, a severely anharmonic bending potential function for KOH can be excluded. Our results are compared with those for the heavier alkali hydroxides.

## Introduction

In spite of the experimental difficulty of obtaining spectra of alkali hydroxide monomers, a considerable body of data is now available for these molecules. Matrix isolation spectra giving the two low-frequency fundamental vibrations of CsOH, RbOH, KOH, and NaOH have been reported<sup>1–3</sup>. More extensive information has been obtained from microwave and millimeter wave pure rotational transitions of CsOH, RbOH, KOH and NaOH<sup>4–9</sup>, which have established structural parameters for these three molecules, and the unusual spacing of the many vibrational satellites observed in the rotational spectrum has yielded information concerning the anharmonicity of the force fields of CsOH and RbOH. Lide and Matsumura<sup>6</sup> have shown that for these two molecules the spectra can be explained in terms of rather small stretch-bend ( $f_{122}$ ) anharmonic force constants. The anomalies in the spectra arise from an amplification of these anharmonic effects through the large amplitude bending motion. However, none of the data so far reported could be used to determine the form of the bending potential function itself, as represented by the quartic anharmonic constant  $f_{2222}$ . We report here vibrational satellites

for KOH and KOD over a wide enough range in  $J+1 \leftarrow J$  transitions so that we can obtain an estimate of  $f_{2222}$  as well as constants corresponding to those previously reported for CsOH and RbOH.

Pearson and Trueblood have reported the ground state spectroscopic constants of KOH and KOD and have given an  $r_0$  structure<sup>7</sup>. Recently Kuijpers et al. reported an analysis of a very large number of vibrational satellites of the  $J=6 \leftarrow 5$  transition, including various combination state lines<sup>9</sup>. This work demonstrated that it is difficult to obtain a satisfactory fit of the bending-mode satellites, even for restricted series such as  $0 v_2^l 0$  or  $1 v_2^l 0$ , to the usual frequency expression for a well-behaved linear molecule. Polynomials that do fit the observed frequencies to within approximate experimental errors include many higher order terms and do not converge rapidly.

The present work is based upon measurements of vibrational satellites of various  $J+1 \leftarrow J$  transitions in the millimeter wave region which were measured at the same time as the ground state lines reported by Pearson and Trueblood<sup>7</sup>. In analysing the data we have not attempted to obtain an overall fit to the spectrum but rather to do a state-by-state analysis making use of accurate determinations of the effective centrifugal distortion coefficients. These constants, which vary by as much as 15 per cent among the various vibrational states observed, contain information about the sign and magnitude of the energy intervals determining the strength of intrin-

sic  $l$ -type resonance interactions. We have thus been able to determine the spacing of the different  $l$  sub-levels in several of the bending and combination states. Using this information, together with matrix isolation values of the two lowest fundamentals, we have constructed an approximate energy level diagram which shows possible resonances.

While this work was in progress the measurements of the  $J=6 \leftarrow 5$  transition were published by Kuijpers *et al.* To extend the range of our analysis we have included their data in our calculations. Experimental details concerning the measurements can be found in Ref. <sup>7</sup> and <sup>9</sup>.

### Theory

The unperturbed rovibrational energy term values of a linear triatomic molecule are given by

$$E = E_v + E_r,$$

$$E_v = \sum_i \omega_i \left( v_i + \frac{d_i}{2} \right) + \sum_{i,j} x_{ij} \left( v_i + \frac{d_i}{2} \right) \left( v_j + \frac{d_j}{2} \right) + x_{ll} l^2, \quad (1)$$

$$E_r = [B_v + \gamma_{ll} l^2][J(J+1) - l^2] - D_v[J(J+1) - l^2]^2, \quad (2)$$

where the vibrational expansion of the rotational and centrifugal distortion constants is

$$B_v = B_e - \sum_i \alpha_i \left( v_i + \frac{d_i}{2} \right) + \sum_{i,j} \gamma_{ij} \left( v_i + \frac{d_i}{2} \right) \left( v_j + \frac{d_j}{2} \right), \quad (3)$$

$$D_v = D_e + \sum_i \beta_i \left( v_i + \frac{d_i}{2} \right), \quad (4)$$

and where

- $\omega_i$  = harmonic frequency of the  $i^{\text{th}}$  vibrational mode,
- $x_{ij}, x_{ll}$  = vibrational anharmonicity constants,
- $d_i$  = degeneracy of the  $i^{\text{th}}$  mode,
- $\alpha_i, \gamma_{ij}, \gamma_{ll}, \beta_i$  = vibration-rotation interaction constants,
- $l$  = vibrational angular momentum quantum number.

The perturbations among rovibrational energy levels can be evaluated by setting up the energy matrices for states with different  $l$  values but with given  $v_2$  and  $J$  values. For the data available in this work it is sufficient to consider only the diagonal terms given by Eqs. (1) and (2) and off-diagonal

terms of the form

$$\begin{aligned} & \langle v_t, l, | H_2' | v_t, l \pm 2 \rangle \\ &= \frac{q}{4} \{ (v_t \mp l) (v_t \pm l + 2) [J(J+1) \\ & \quad - l(l \pm 1)] [J(J+1) - (l \pm 1)(l \pm 2)] \}^{1/2} \end{aligned} \quad (5)$$

where

$$q = q^{(0)} - q^{(1)} J(J+1),$$

and  $H_2'$  is the second-order transformed Hamiltonian of Amat and Nielsen <sup>10-12</sup>.

The most pronounced perturbation effect upon the spectrum is the familiar  $l$ -type doubling of states with  $|l|=1$ , for which the splitting between the two rotational lines is given by

$$\Delta\nu = \frac{1}{2}(v+1)[2q^{(0)}(J+1) - 4q^{(1)}(J+1)^3] \quad (6)$$

over the range of  $J+1 \leftarrow J$  transitions observed here. For  $v_2 > 1$  states a shift of the energy levels due to  $l$ -type resonance interaction occurs, which leads to anomalous values for the effective centrifugal distortion constants,  $D_v$ , and gives rise to a splitting of  $l=2$  rotational lines.

For the pure rotational transitions, it would appear that none of the terms in  $E_v$  should contribute to the frequencies. However,  $x_{ll}$  determines the separation of the interacting levels and thus the strength of the resonance interaction, so that both the sign and magnitude of  $x_{ll}$  can be obtained from the anomalous  $J$  dependence of the rotational energy. This quantity reflects the anharmonicity in the bending potential function.

### Spectrum Analysis

Our measurements for the  $J=9 \leftarrow 8$ ,  $11 \leftarrow 10$  and  $13 \leftarrow 12$  transitions of KOH and the  $J=9 \leftarrow 8$ ,  $12 \leftarrow 11$ , and  $16 \leftarrow 15$  transitions of KOD are given in Tables I and II respectively. In obtaining the molecular constants for KOH we have included the measurements of the  $J=6 \leftarrow 5$  transition reported by Kuijpers *et al.*<sup>9</sup> In our data, the low intensity of the observed lines plus broadening from the background pressure of non-condensable decomposition products determined the experimental uncertainty of about  $(6 \times 10^{-7}) \times \nu$ .

As a first step in analyzing the data we obtained effective values of  $B$  and  $D$  for each component of each vibrational state. These results are also compiled in Tables I and II. Assignment of the lines of KOH to various vibrational states and  $l$  components

<sup>a</sup> Extrapolated unperturbed  $D_V$ .

<sup>b</sup> Determined from extrapolated unperturbed  $D_V$  and splitting of  $l=2$  transitions.

<sup>c</sup> Determined from one frequency and predicted  $D_V$ .

was made independently from the work of Kuijpers *et al.* and is completely consistent with that work. The general pattern of the vibrational satellite structure is similar to that found in CsOH and RbOH. Simple trends in  $D$  with  $v_i$  were used to confirm assignments. Particular help was found in the shifts in  $D$  due to  $l$ -type resonance. For example, the three components of a  $v_2=2$  state can be identified by noting that interaction between the  $l=0^+$  and  $l=2^+$  states shifts the two corresponding effective  $D$  values such that their average value is equal to the value for the  $l=2^-$  state. Thus the symmetry assignment of the components of all  $l=2$  doublets could be found.

The second part of the analysis consisted of reducing the observed frequencies to effective spectroscopic constants for each value of  $v_2$  following the procedure outlined in Ref. <sup>13</sup> for another molecule with large amplitude motion, HCNO. The re-

sults are presented in Tables III and IV. Sum rules derived from the traces of the factored energy submatrices permit the determination of the unperturbed rotational constants  $B_v$  and  $D_v$ , and for  $v_2 > 1$ , also  $\gamma_u$ . For  $v_2=1$ ,  $\gamma_u$  values obtained by extrapolation from  $v_2=l$  states were used to compute the listed  $B_v$ . The difference between the two values of  $\gamma_u$  obtained for the 040 state of KOH is not understood at this time. From Table III it is seen that there is a smooth trend in the values of  $\gamma_u$  obtained for  $v_2=l$ , but the  $l$  dependence of  $\gamma_u$  is not a simple function of  $l^2$ .

The constants  $q^{(0)}$  and  $q^{(1)}$  for  $v_2=1, 3$  and  $5$  could be obtained directly from Equation (6). This equation is valid so long as the resonance interaction between the  $l=1$  and  $l=3$  states is not strong enough to split the lines for  $l=3$  observably, and thus shift the  $l=1$  lines by unequal amounts. For the data reported here, this condition is fulfilled.

<sup>a</sup> The constants in brackets are extrapolated values. The errors in parentheses are three times the standard deviation for the 0 1 0 and 0 2 0 states, while those for the remaining states are determined by propagation of errors from the estimated experimental error.

<sup>b</sup> The  $B_v$  value for the  $v_2=1$  states has been corrected for  $\gamma_u$  as in Equation (2).

<sup>c</sup> Determined for the  $l=2$  state only.

In the case of  $v_2 = 2$  or 3 the closed frequency expressions found in Ref. <sup>13</sup>, Eqs. (14), (15), (23), and (24), were used to iteratively fit the observed frequencies and determine  $x_{ll}$ . In the expressions for  $v_2 = 2$  or 4,  $x_{ll}$  is so strongly correlated with  $q$  that it was necessary to employ interpolated values of  $q$  in the analysis.

No lines were observed for the 05<sup>5</sup>0 or 14<sup>4</sup>0 levels of KOH. For the 04<sup>4</sup>0 level, although lines were observed and assigned, the attempt to include them in a determination of  $x_{ll}$  was unsuccessful; the error in the measurements seems to be as large as the resonance effect on these lines. Since only the  $l < 4$  components of these three states were fitted, it was possible to fit their frequencies using a modified version of the same closed expressions used for the  $v_2 = 2$  and 3 states. These frequency expressions were obtained by using Eq. (5) to derive the appropriate matrix elements, truncating the energy matrices for  $l < 4$ , and diagonalizing them. The results were compared with those obtained using the full matrix for  $v_2 = 4$ , and the effect on the determination of  $x_{ll}$  is well within the error limits.

In view of the large number of parameters employed to analyze the data and the fact that we have not attempted to achieve an overall fit to one set of constants we have not tabulated observed minus calculated frequency differences. In general, the agreement between most observed and calculated line positions, including resonance effects, was better than 100 kHz. The errors given for  $x_{ll}$  were derived from the experimental errors and the uncertainty in extrapolated values of  $q$ , where necessary.

The agreement among the values of  $x_{ll}$  obtained for the various vibrational states supports the correctness of the procedure applied to this data. Except in the case of near accidental resonance, these values represent accurately the energy intervals between the various  $l$  components of the vibrational states analyzed.

The values of  $D_v$  given in Tables III and IV were fitted to a modified version of Eq. (4),

$$D_v = D' + \beta_i(v_i + \frac{1}{2}d_i), \quad i = 1 \text{ or } 2. \quad (7)$$

The prime indicates that we are not determining  $D_e$ , since only one vibrational mode at a time is considered. The results of this procedure are shown in Table V. From this analysis we again conclude that no strong perturbing interactions, in particular Coriolis interactions, are present. Anomalous varia-

of calculating an equilibrium structure. This table and the structure are discussed in the next section.

Experimental values for <sup>41</sup>KOH constants were derived from the data of Kuijpers *et al.* <sup>9</sup> plus our measurement of the  $J = 11 \leftarrow 10$  ground state transition (see Table I). The isotopic shift of  $D_0$  for both <sup>41</sup>K and for  $D$  substitution agrees very well with the shift predicted from the harmonic force field. This further confirms the assignment of the <sup>41</sup>KOH lines.

## Discussion

### Vibration Rotation Interaction Constants and Structure

By considering an effective  $\gamma_{ll}$  for each vibrational state, we have obtained a reduced  $B_v$  for each

$v_2$  vibrational state. These were then fitted to a second order polynomial in  $v_1$  or  $v_2$ , corresponding to Eq. (3) with a fixed value of  $v_1$  or  $v_2$  and  $v_3 = 0$ , to obtain the values of the vibration-rotation constants  $\alpha_i$  and  $\gamma_{ij}$  given in Table VI.  $\alpha_1$  and  $\gamma_{11}$  were obtained from the  $v_100$  series. The values of  $\alpha_2$  for the series of  $B$  values for  $0v_20$  and  $1v_20$  were compared to determine  $\gamma_{12}$  in KOH. Both  $\alpha_1$  and  $\alpha_2$  were then corrected for  $\gamma_{12}$ . The value of  $\gamma_{12}$  in KOD could not be determined because the values of  $\alpha_2$  and  $\gamma_{22}$  for the series  $0v_20$  and  $1v_20$  differed too strongly to allow the simple model defining  $\gamma_{12}$  to be applied.

Kuijpers *et al.* have noted anomalies in  $\alpha_1$  and  $\gamma_{11}$  in KOH (see Ref. <sup>9</sup>, Table II). Some improvement in the determination of  $\alpha_1$  can be obtained by using our reduced  $B_v$  values and by the inclusion of  $\gamma_{12}$  but irregularities remain; the effective  $\alpha_1$  and  $\gamma_{11}$  for successive fixed  $v_2$  are not a smooth, monotonic series. Error limits given reflect only the limits of the fit and not confidence in the accuracy of the constants as unperturbed constants.

The magnitudes and the isotopic shifts of all the constants obtained are consistent with those obtained for the heavier alkali hydroxides. To complete the comparison of these results with those for CsOH and RbOH, we have examined the harmonic and anharmonic contributions to  $\alpha_2$  and determined the anharmonic potential constant  $f_{122}$  from the isotopic shift of  $\alpha_2$  following the procedure outlined by Lide and Matsumura <sup>6</sup>. As a basis for these calculations we used the matrix isolation measurements of the fundamentals  $\nu_1$  and  $\nu_2$  as harmonic frequencies <sup>3</sup>, and the force field that best reproduces them, as given in Table VII. The notation and scaling for the anharmonic force constants in

<sup>a</sup> Assumed value. <sup>b</sup> From Ref. <sup>3</sup>.

the following discussion is that used in Ref. <sup>6</sup>, although in programming the transformation from f's to k's the formalism of Hoy, Strey, and Mills <sup>15</sup> was found most useful. Since the gas phase fundamentals could differ from the matrix isolation frequencies by as much as 10% the errors of the anharmonic force constants and the quantities derived from them reflect this uncertainty.

As shown in Ref. <sup>6</sup>,  $\alpha_2$  can be separated into three terms,

$$\alpha_2 = (\alpha_2)_{h1} + (\alpha_2)_{h2} + (\alpha_2)_{anh} \quad (8)$$

which represent respectively the harmonic, pseudo-anharmonic and anharmonic contributions. In Table VIII these terms are compared for the three alkali hydroxides whose spectra have so far been analyzed. The values of  $f_{122}$  obtained are also compared. It is seen that the smaller mass of potassium relative to cesium or rubidium does not reduce the effect on the spectroscopic constants produced by the combination of a small bending force constant, small K-O stretching force constant and the small mass of the hydrogen. Table VIII includes the coefficients of the valence force constants  $f_{122}$  and  $f_{322}$  which

<sup>a</sup> From Ref. 6.

contribute to  $(\alpha_2)_{anh}$ . Compared to HCN, the coefficients of  $f_{122}$  in all three of the alkali hydroxides are very large, and the coefficients of  $f_{322}$  very small. The comparison with HCN shows why  $\alpha_2$  for the hydroxides appears to be so anomalous, even though the cubic anharmonic force constants are only slightly larger relative to the quadratic force constants than in the case of HCN. From  $\alpha_1$  the constant  $f_{111}$  could also be determined, and is compared for the three alkali hydroxides in Table IX. In order to obtain equilibrium rotational constants,  $\alpha_3$  was calculated as in Ref. 6 from an estimate of  $f_{333}$  obtained following Reference 17.

The internuclear distances of the alkali hydroxides are compiled in Table X. The errors given for

while the M-O distances show a consistent trend. The decrease of M-O distance with mass corresponds to, but is not as fast as, the drop in ionic radius (1.69, 1.48, 1.33 Å for Cs, Rb, K, respectively), just as has been observed in the alkali fluorides<sup>18</sup>. Table X includes ground state parameters ( $r_0$ ), parameters calculated from  $B_0 - \alpha_2$  ( $r_e'$ ) and equilibrium parameters ( $r_e$ ). A comparison of the three sets of values shows the importance of correcting for anharmonicity, and for  $\alpha_2$  in particular, in these molecules.

### Vibrational Intervals $x_{ll}$

The analysis of the  $l$ -type resonance interactions in each bending vibrational state yielded effective values of the vibrational anharmonicity constant  $x_{ll}$ . Although the successive  $\Delta v = 1$  vibrational intervals are not known, we have found it useful to construct approximate energy level diagrams for KOH and KOD as shown in Figure 1. The measurements upon which they are based are our determinations of  $x_{ll}$ , matrix isolation absorption fre-

KOH are the same as those given for the heavier hydroxides and are dominated not by experimental uncertainty but by model errors. The latter take into consideration the uncertainty in the calculated value of  $\alpha_3$ , the neglect of the undetermined  $\gamma_{ij}$ , and estimated errors in  $\alpha_i$  and  $\gamma_{ij}$  due to possible perturbations. Within the quoted error, the O-H distance is unchanged in the three hydroxides,

Fig. 1. Approximate vibrational energy level diagram for KOH and KOD. Fundamentals are taken from Ref. 3, relative intensity measurements determining  $02^00$  from Ref. 4 and 9, and the separation of the  $l$  sublevels from the present work.

quencies<sup>3</sup>, relative intensity measurements of Kuijpers *et al.*<sup>9</sup>, and assuming an analogy with CsOH, the relative intensity measurements of Lide and Kuzkowski<sup>4</sup>. Considering both sets of relative intensity measurements, we concluded that the successive vibrational intervals must be nearly harmonic. Given the large uncertainties, the most important aspect of Fig. 1 is that the Fermi resonance between 100 and 02<sup>0</sup>0 must be small in KOH, since the levels are over 100 cm<sup>-1</sup> apart, whereas in KOD the separation between these two levels is such that this resonance and analogous resonances for higher levels may be significant. The value of  $k_{122}$  for KOD is approximately -1300 cm<sup>-1</sup>, so that with an energy level separation which is probably less than 40 cm<sup>-1</sup> the resonance effect could be appreciable. The evidence in the spectrum for such a resonance is: (1) the values of  $x_{ll}$  for KOD, which are smaller than expected (Calculations undertaken to reproduce the isotopic shift of  $x_{ll}$  by fitting the values for both isotopic species to a single value of  $f_{2222}$  failed, as is discussed in more detail below); (2) the decrease in  $x_{ll}$  upon excitation of  $\nu_1$  in both isotopic species, which is just the effect expected in the case of Fermi resonances; (3) the fact that the interval  $B_{(120)} - B_{(110)}$  is larger than the adjacent interval  $B_{(110)} - B_{(100)}$  for KOD, which is the only occurrence of such an increase in any of the series  $B_{(v_2+1)} - B_{(v_2)}$  in either species. This shift in  $B$ , and the corresponding value of  $x_{ll}$ , are consistent with a resonance involving the vibrational states 200, 120, and 040. Unfortunately, the extent to which Fermi resonances contribute to the observed spectrum cannot be determined more quantitatively from the pure rotational spectrum alone.

From the positive sign of  $x_{ll}$  for all levels studied in both KOH and KOD, we can confirm that the molecule is not quasilinear; that is, there is no flattening or hump at the bottom of the bending potential well. Our first impression upon obtaining

the rather large positive  $x_{ll}$  values was that KOH might be a "superlinear" molecule, with a steeper potential function at the bottom of the well than higher up, or with a negative hump as defined by Yamada and Winniewisser<sup>19</sup>.

We tried to obtain an estimate of the quartic potential constant  $f_{2222}$  using the expression for  $x_{ll}$

$$x_{ll} = -k_{2222}/2 - \frac{1}{4}k_{122}^2\omega_1/(4\omega_2^2 - \omega_1^2) - \frac{1}{4}k_{322}^2\omega_3/(4\omega_2^2 - \omega_3^2), \quad (9)$$

$$= T_1 + T_2 + T_3,$$

and expressing the  $k$ 's in terms of  $f$ 's<sup>15</sup>. The quadratic and cubic force constants were those given in Tables VII–IX. It was not possible to fit the experimental values of  $x_{ll}$  for both KOH and KOD with a single value of  $f_{2222}$ . These results are given in Table XI, together with a calculation of  $x_{ll}$  for KOH omitting all valence anharmonicity contributions. The contribution of  $f_{2222}$  alone is (-18.61)  $f_{2222}$ , which for  $f_{2222} = 0.24$  mdyn, is -4.47 cm<sup>-1</sup>. Since the observed value is 8.1 cm<sup>-1</sup>, we must conclude that the large positive  $x_{ll}$  is primarily a pseudo-anharmonic effect. Our values of  $f_{2222}$  are subject to large errors due to the uncertainty in the harmonic force field and frequencies, though these errors should not be as large as the discrepancy between the two  $f_{2222}$  values. As noted above, the strong isotope shift of  $x_{ll}$  may well be due to the 100–020 Fermi resonance in KOD.

In conclusion, we find that the surprisingly large value of  $x_{ll}$  in KOH and KOD can be explained in terms of large amplitude motion, with only a modest contribution from quartic anharmonicity of the potential function. This result is consistent with the analysis of  $\alpha_2$  for the alkali hydroxides. The close agreement of  $x_{ll}$  from various levels for each isotopic species indicate that higher order terms in the expansion of the energy in  $l^2$  and  $v_2$  are not very significant, further indicating that the potential function is not strongly anharmonic.
