The fame won by the tyranni and other leading aristocrats of Sicily in the great national contests of Hellas, in the race with the quadriga, the mule-car and the horse, led to the introduction and supremacy of types commemorating these victories, probably in most cases those achieved at Olympia. It is obvious that no success could be so appropriately figured on the coinage; the charioteer or the horseman, not the city, was the victor, but at the same time the renown of the city was indissolubly connected with the citizen who won it. Hence these types are almost confined to states ruled by tyranni or oligarchies; outside Sicily they are practically only found at Rhegium when it was closely connected with Sicily, at Cyrene, in the money of Philip II. of Macedon and at Olynthus and in Euboea. The horseman is not a frequent type; the mule-car is limited to Messene (and Rhegium); but the quadriga becomes the stereotyped subject for the reverse of the great Sicilian tetradrachms—the bulk of the coinage—and only escapes heraldic sameness by a charming variety in the details. In the age of finest art a divinity of the city takes, in Homeric guise, the place of the charioteer, or Victory herself so wins the contest; commonly she hovers above, about to crown the charioteer or the horses. Yet more interesting are the types connected with nature-worship, especially those portraying river-gods in the form of a man-headed bull, or a youth with the budding horns of a calf, or in the shape of a dog, and also the subjects of the nymphs of fountains. These types occur on either side of the coin. On nearly all, one side (in early times the reverse, later the obverse) is held by the head of a divinity, Persephone and Athene taking the first place.

Syracuse.

The leading position which Syracuse held in the island makes it proper to notice her splendid currency first, the finest for knowledge of the materials, for skill in suitably filling the space, and for delicacy of execution in the whole range of Greek money, though we miss the noble simplicity of Greece, the strong feeling of western Asia Minor, and the simple picturesqueness of Crete. Syracuse was founded in 734 B.C. by Archias of Corinth, an origin which, remembered on both sides, served her well in later history. In the 6th century, perhaps while still under the oligarchy of the Geomori, she issued her most archaic silver money, which, primitive as

it is, gives promise of the care of the later coinage, and begins the agonistic types, thus indicating some early victory at a great Hellenic contest. Gelo, tyrant of Gela, won the chariot race at Olympia in 488 B.C., secured Syracuse in 485 B.C., and, when the Carthaginians, probably by agreement with Xerxes, invaded Sicily, utterly routed them at the great battle of Himera (480 B.C.), the Salamis of the West. These events find their record in the issue and subjects of his Syracusan money, which, however, was struck, as usual in that age, in the name of the people. The chariot type is varied, for Victory appears hovering above the charioteer, about to crown the horses, and the coins issued after the great battle show the lion of Libya beneath the car in the exergue (Pl. I. fig. 6). These last pieces are fixed in date by the famous story how Gelo's wife Demarete, having gained favourable terms for the vanquished Carthaginians, was presented by them with a hundred talents of gold, by means of which were coined the great silver pieces of fifty litrae or ten drachms, which were called after her Demareteia. They bear the head of Victory, crowned with laurel, and the quadriga and lion. The battle of Himera and the death of Gelo (478 B.C.) fix the date of these remarkable coins, which close the archaic series of Syracuse and give us a fixed point in Greek art, at about 479 B.C.

Hiero I. (478–466 B.C.), the brother and successor of Gelo, continues the same types, alluding, as Head well remarks (*loc. cit.*), to his great victory over the Etruscans off Cumae (474 B.C.), by the marine monster in the exergue of the reverse which denotes the vanquished maritime power. It is to be noted that as Gelo introduces the Victory in the chariot type, so in the horseman type we now first see Victory crowning the rider. Gelo had won an Olympic victory in the four-horse contest, Hiero in the horse-race, though he also won with the four horses in the Pythian games. With Hiero's money we say farewell to archaic art. The female heads on the obverse now have the eye in profile and show beauty and variety, and the horses are even exceptionally represented in rapid action. With the short rule of Thrasybulus, the last brother of the house, it came to an end, and the age of the democracy (466–406 B.C.) began. The victories by land and sea of Gelo and Hiero had established the power of the city on a sure basis, and fifty years of prosperity followed. To the earlier part of this age belong the beautiful transitional coins in which the female heads are marked by a youthful simplicity of beauty combined with fanciful and even fantastic treatment of the hair; the reverses remain extremely severe. Towards the close of this age, beginning about 430, there are very fine works, the first signed coins, with the old dignity yet with greater freedom of style, the horses of the quadriga in rapid movement.

The victory of Syracuse in the contest with Athens was the occasion for the reissue of ten-drachm pieces, commonly but erroneously called medallions. On the reverses of these are a victorious chariot and a panoply of arms, representing the prizes offered at the games by which the Syracusans commemorated the defeat of the Athenians on the Assinarus in 413. On the obverses is the head of the local nymph Arethusa. The designs are by the artists Cimon (Pl. I. fig. 8), Euaenetus, and a third who is nameless. These pieces continued to be issued down to about 360 B.C. through the Dionysian period. Contemporary with them are numerous splendid tetradrachms—signed and unsigned—as well as the first gold and bronze issued by Syracuse. The interference of Dion in Syracusan politics (357–353) was marked by the introduction of an electrum coinage, and of a silver didrachm of Corinthian type, corresponding in weight to the tridrachm of Corinth, and with the same types, the head of Athena and the Pegasus. The Dionysian dynasty closed in anarchy, until Syracuse appealed to Corinth, and Timoleon was sent to restore order (344 B.C.). His advent marks an epoch in Sicilian coinage. He restored the gold coinage and issued various silver coins which allude to Corinth and to liberty, and under his influence many small cities in Sicily awoke to political life as members of Timoleon's league and issued a scanty but interesting bronze coinage. The Syracusan democracy was overthrown in 317 B.C. and the city seized by Agathocles (317–289 B.C.), the worst of the tyrants of Syracuse. In the course of his reign he adopted the royal style, and his coins, a reflection of earlier work, give his name first without and then with the title king—a double innovation. The most interesting of his coins are those which bear allusions to his campaign in Africa.

The tyrant Hicetas (288–280 B.C.) and the next ruler, Pyrrhus, king of Epirus (278–275 B.C.), continue the coinage, Pyrrhus issuing money in the name of the Syracusans and also striking his own pieces. The departure of Pyrrhus led to the establishment by Hiero II. (*c.* 270–216 B.C.) of a dynasty which, so long as he ruled, restored the ancient prosperity and preponderance of the rule of his namesake. At first content with inscribing his name alone, he soon not only takes the title of king, conferred on him in the early years of his reign, but also places his portrait on the money. Of his time is the beautiful portrait of his queen Philistis. The money of the short reign of Hieronymus (215–214 B.C.) and of the brief democracy which fell before the Romans (214–212 B.C.) close the independent series of this great city. But her name still appears in bronze money issued after the conquest.

Other Cities of Sicily.

Taking the rest of the money of Sicily in alphabetical order, we first note a very fine bronze coin bearing a beautiful female head, perhaps that of Sicilia, crowned with myrtle, and a lyre, which belongs to the time of Timoleon's league. This coin is conjecturally attributed to Adranum. The first great town is Agrigentum, represented by archaic, transitional, and fine coins, the fine series ending with the overthrow of the city by the Carthaginians in 406 B.C.—a blow from which it never recovered. The usual types are the eagle and the fresh-water crab, but in the age of finest art we see two eagles devouring a hare (cf. Aeschylus, *Agam.* 109 seq.) and a victorious chariot; these occur in the rare decadrachm (Pl. I. fig. 9), on which the river-god Acragas himself drives the car, and the tetradrachms. The eagle is superior to that of Croton, inferior to that of Elis. Many of the bronze coins are of good work. The type most worthy of note is the head of a river-god, with the name Acragas, which was that of the local stream, and on the reverse an eagle standing on an Ionic capital, the Olympic turning-post. The success of Agrigentum at the games is attested by Pindar, while Virgil (*Aen.* iii. 704), Gratius (*Cyneg.* 526) and Silius Italicus (xiv. 210) mention its ancient renown for horses.

The money of Camarina is of especial beauty and interest. Camarina struck but few coins before the year of liberation (461), soon after which was issued a didrachm having on the obverse a helmet upon a round shield and on the reverse a pair of greaves, between which is a dwarf palm. This piece is followed by tetradrachms and didrachms of the best period, most beautiful in style, and varying a little from difference of age. The tetradrachms bear on the obverse the head of Heracles in the lion's skin, and on the reverse Athena as a victor at the Olympic games in a quadriga. It was Athena, protector of the city (πολιάοχε Παλλάς), whose sacred grove was made more illustrious by the success of Psaumis. The didrachms have on the obverse the head of a river-god, portrayed as a young man with small horns and with wet hair. Of the two rivers of Camarina, the Oanus and the Hipparis, the Hipparis is here represented, for in one case the name is given on the coin. Pindar seems to show the same preference, for, while he merely mentions the Oanus (ποταμὸν . . . Ὄανιν), he speaks of the sacred channels by which the Hipparis watered the city (σεμνοὺς ὀχετοὺς, Ἵππαρις οἷσιν ῥόοις στρατόν). On the reverse the nymph Camarina (Ὠκεανοῦ θύγατερ . . . Καμαρίνα) is seen carried across her lake (ἐγχωρίαν . . . λίμναν) by a swan swimming with expanded wings, while she aids it by spreading her veil in the manner of a sail. Some of these didrachms have on either side, around the chief device, fresh-water fishes. The series of Catana comprises fine archaic tetradrachms and others of the time of the best art. The archaic tetradrachms have the types of a river in the form of a man-headed bull and of the figure of Victory, of a type remarkably advanced for the time at which they were struck. From 476 to 461, under the name of Aetna, its coinage is represented especially by a unique tetradrachm (Pl. I. fig. 10), with a wonderful head of Silenus, and Zeus as the god of the volcano holding a thunderbolt and a sceptre made of a vine-branch; before him is an eagle perched on one of the Aetnaean pines. The head of Apollo succeeds, with for reverse the victorious quadriga, in one case passing the turning-post, an Ionic column. Historically interesting is a small silver coin issued by Catana and Leontini in alliance between 405 and 403. Eryx towards the end of the 5th century produced some rare tetradrachms on which Eros is represented at the knees of his mother, asking for the dove which she holds.

Gela is represented by coins of which the archaic tetradrachms must be especially mentioned. They have on the obverse the forepart of the river-god Gelas, whence the city took its name. The Gelas is represented as a bull, having the face of a bearded man. On the reverse is a victorious quadriga, in some examples represented passing

an Ionic column, as on coins of Catana. A beautiful tetradrachm represents the city goddess (Sosipolis) placing a wreath on the head of the monstrous river-god. A little later is a tetradrachm which has types of the head of the Gelas as a young man horned, surrounded by three fishes, and on the reverse Victory in a biga with a wreath above. Small gold coins, and a didrachm representing a Geloan cavalryman spearing an Athenian hoplite, are among the coins issued shortly before the fall of Gela in 405. The money of Himera is of great interest. The oldest didrachms of Himera, which probably began in the 6th century B.C., bear on the obverse a cock and on the reverse an incuse pattern; later, a hen. During the time that Thero of Agrigentum held the city (before 480 to 472), the crab of Agrigentum appears on the didrachms. The transitional tetradrachms bear on the one side a victorious quadriga and on the other a nymph sacrificing, near whom a little Silenus stands under the stream of a fountain issuing from a lion's head in a wall. Leontini is represented by tetradrachms with the head of Apollo and the victorious car, which gives place to a lion's head. The series of Messene begins, when the town was called Zancle, or, as it is written upon the coins, Dancle, with early drachms of smaller pieces of the Aeginetan weight, and of very archaic work. On the obverse is a dolphin, and around it a sickle; on the reverse the earliest pieces repeat the same design incuse (as in the earliest coinage of S. Italy), but later we find a shell in the midst of an incuse pattern. The place is said to have received its name on account of the resemblance of the harbour to a sickle (δάγκλον or δάγκλη). Next to these first coins of Zancle may be placed, as the oldest piece of the Attic weight, a tetradrachm with the Samian types, a lion's scalp on one side and on the other the head of a calf, and bearing the inscription **MEΣΣΕΝΙΟΝ**. This coin was doubtless struck during the rule of the Samians, who took the place about 494 B.C., at the instigation of Anaxilaus, tyrant of Rhegium, by whom they were subsequently expelled (Thucyd. vi. 4). The next pieces are the earliest of those which have on the obverse the mule-car and on the reverse a running hare, like the contemporary coins of Rhegium, with the same devices and equally of the rule of Anaxilaus. These types cease at Rhegium, though they continue at Messene, some of the tetradrachms bearing them being of the age of fine art. About 450 there must have been a temporary restoration of the Zancleans, who struck a tetradrachm with Poseidon and the dolphin as types. A fine piece of rather later date represents Pan caressing a hare. When the town had been seized (287 B.C.) by the Mamertini, money was struck with their name. Naxos is represented by early Aeginetic drachms with an archaic head of Dionysus. Immediately after the year of liberation (461) it produced a tetradrachm with a head of Dionysus and, on the reverse, a squatting Silenus, remarkable for the study of anatomical detail (see Pl. I. fig. 11). These types are repeated in a less severe style some fifty years later, when also an engraver Procles signs some pretty didrachms. Segesta is represented by coins from about 480 B.C. We first notice the head of the nymph Segesta and a hound, probably the river-god Crimisus; then the same type for reverse associated with a young hunter accompanied by two hounds—a charming composition. Another interesting type is a victorious car driven by Persephone, who carries ears of corn.

In the series of the city of Selinus the first coins are didrachms, bearing on the obverse a leaf and on the reverse an incuse square. The city and the river of the same name no doubt derived their name from the plant σέλινον (probably wild celery, *Apium graveolens*), the leaf of which must be here intended. Tetradrachms and didrachms of transitional and of good art have devices of more than usual interest. The obverse exhibits a river-god, sometimes the Selinus, sometimes the Hypsas, sacrificing at an altar to the god of healing, while on the didrachm a wading-bird is sometimes seen behind him, as if departing. The obverse of the didrachms shows Heracles subduing the bull, and the reverse of the tetradrachms generally shows a quadriga in which Apollo stands drawing his bow, while Artemis is charioteer. The reference in all these cases must be to the driving away of the pestilence from the neighbourhood of Selinus by the draining of the marshes.

The Siculo-Punic coins, that is, those actually struck by the Carthaginians in Sicily, will best be dealt with under Carthage, below.

The islands of Melita, Gaulos and Cossura near Sicily issued late coins which belong to the African series, showing a curious mixture of Phoenician and Egyptian elements in some of their types. Of Lipara there is heavy bronze money on the Sicilian system, having on the obverse a head of Hephaestus, or sometimes a figure of the same divinity seated, holding a hammer and a vase, which he seems to have just formed.

In the Tauric Chersonese there are interesting coins, in the three metals, of the city of Panticapaeum, the modern Kertch.

The Tauric Chersonese, &c.

Their obverse usually bears the head of Pan and their reverse a griffin and other subjects; some are of fine Greek style. The gold is of higher weight than usual, owing to the cheapness of the metal at this place. The money of Sarmatia, of Dacia, and of upper and lower Moesia, is chiefly bronze of the Graeco-Roman class. In Sarmatia we may notice the autonomous and imperial pieces of Olbia, which alone amongst Greek cities produced a series of cast bronze coins, and in Dacia the series bearing the name of the province. The Roman colonia Viminacium in upper Moesia is represented by numerous coins of a late time. Of Istrus, in lower Moesia, there are drachms having a strange type on the obverse, representing two beardless heads, side by side, the one upright and the other upside down; on the reverse is an eagle devouring a fish. The style of these coins is in general fair, though it sometimes approaches to barbarism. Apollonia Pontica produced fine silver coins with a head of Apollo and an anchor. There are abundant Greek imperial coins of Marcianopolis and Nicopolis, while Tomi is represented in this class as well as by autonomous money.

The coins of Thrace are of high interest. Here and in Macedonia we observe the early efforts of barbarous tribes to coin the produce of their silver mines, and the splendid issues of the Greek colonies; and we see in the weights the influence of the Asiatic Greeks and the Athenians. The oldest coins are of the early 5th century B.C., and there are others of all subsequent times, both while the country was independent and while it was subject to the Romans, until the cessation of Greek coinage. Some of the best period are of the highest artistic merit. So long as they maintain any general distinctive peculiarities of fabric and design, that is, from their commencement until the age of Philip, the Thracian coins resemble those of Macedonia. The money of Abdera comprises tetradrachms and smaller coins of the periods of archaic and fine art, all but the latest of the Phoenician standard, ultimately superseded by the Persic. The principal type is a seated griffin, copied from its mother-city, Teos. The reverse type, an incuse square, has at first four divisions, but in the age of the finest art contains a variety of beautiful subjects, the signets of the magistrates. Aenus is remarkable for the great beauty of some of its coins. These are tetradrachms of Attic weight, of the late archaic and best ages. The interesting turning-point from growth to maturity is seen in a vigorous head of Hermes in profile, wearing the petasus. A little later is the splendid series of facing heads, the broad, severe, and sculptural treatment of which is truly admirable, and far superior to the more showy handling of the same subject in later drachms. A goat is the reverse type of the larger coins. The money of the city of Byzantium begins with coins on the Persic standard of good style, having on the obverse a bull above a dolphin and on the reverse an incuse square of four divisions, and closes with the series of bronze coins issued under the empire. The star and crescent type first appears in the Roman period. Of Maronea, anciently famous for its wine, there is an interesting series, among which we notice fine tetradrachms of Phoenician weight, having on the obverse a prancing horse and on the reverse a vine within a square. The standard changes to Persic, of which there is a beautiful series of didrachms. Then the series is interrupted by the rule of the Macedonian kings, and resumed is a barbarous coinage of the native Thracians, issued in the second and first centuries before the Christian era, consisting of spread Attic tetradrachms with the types of the head of beardless Dionysus crowned with ivy and on the other side his figure. The Greek imperial coins of Pautalia and Perinthus are worthy of notice. Among those of the latter town we may mention fine pieces of Antoninus Pius and Severus, and large coins, commonly called medallions, of Caracalla and other emperors. The money of the imperial class issued by Philippopolis, Serdica and Trajanopolis should also be noticed. In the Thracian Chersonese the most important series is one of small autonomous silver pieces, probably of the town of Cardia. There is a limited but highly interesting group of coins of Thracian kings and dynasts. The earliest are of kings of the Odrysae, including Sparadocus and Seuthes I., who began to reign in 424 B.C. and whose money bears the two remarkable inscriptions **ΣΕΥΘΑ ΚΟΜΜΑ** and **ΣΕΥΘΑ ΑΡΤΥΡΙΟΝ**. It closes with the issues of Roman vassals, such as Cotys IV. (A.D. 12–19). Lysimachus, commonly classed as king of Thrace, belongs to the group of

Thrace.

Alexander's western successors (see below). Among the islands of Thrace, Imbros with its trace of Pelasgic worship, and, equally with Lemnos, showing evidence of Athenian dominion, and Samothrace with the Asiatic worship of Cybele yield in interest to Thasos. Here a long and remarkable currency begins with very early Persic didrachms, the obverse type a Silenus carrying a nymph, the reverse an incuse square of four divisions. Under the Athenian supremacy we see a decline of weight, and in style the attainment of high excellence. After this we observe coins of Phoenician weight, bearing for their obverse types the head of Dionysus. These are of the best period of art, and some tetradrachms are among the very finest Greek coins. The head of Dionysus is treated in a sculptural style that is remarkably broad and grand. The massive, powerful features, and the formal hair, nearly falling to the neck in regular curls like those of the full beard, are relieved by a broad wreath of ivy-leaves, designed with great delicacy and simplicity. The reverse bears a Heracles kneeling on one knee and discharging his bow—a subject powerfully treated. Of a far later period there are large tetradrachms, much resembling those of Maronea, with the same type of the beardless Dionysus, but on the reverse Heracles.

The money of Macedonia both civic and regal is of great variety and interest. It begins at an early time, probably towards the end of the 6th century B.C. The old pieces are of silver, bronze having come into use a century later, and gold about the middle of the 4th century B.C. The character of the coinage resembles that of Thrace; the earliest pieces are of the Phoenician, Babylonic and Attic standards. The most remarkable denominations are the pieces of eight and twelve Phoenician drachms. The largest coins are of the time of Alexander I. (498–454), and somewhat earlier, and indicate the metallic wealth of the country more than its commercial activity. The chief groups of coins are those of the Pangaean, Bisaltian, Strymonian and Chalcidian districts, of the kings of Macedon and Paeonia, and of Macedon under the Romans. This last series begins with the coins of the "regions" issued by permission of the senate and bearing the name of the Macedonians, from 158 to 150 B.C.; these are followed by coins of the Roman generals against Andriscus and of the pretender himself, and, from 146 onwards, of the Roman province. Under the empire a large series of bronze coins was issued in the name of the Koinon, *i.e.* the provincial diet. As regards the earlier civic coinage: the coinage of Acanthus comprises fine archaic tetradrachms of Attic weight and others of Phoenician weight and very vigorous in style, of the commencement of the period of good art. The type of their obverse is a lion seizing a bull (cf. Herodot. vii. 125 f.). The money of Aeneia is chiefly interesting from its bearing the head of the hero Aeneas; and on one extraordinary coin of archaic fabric, an Attic tetradrachm, the subject is the hero carrying Anchises from Troy, preceded by Creusa carrying Ascanius; this is in date before 500 B.C. The town of Amphipolis is represented by a long series. There are Phoenician tetradrachms of about 400 B.C. having on the obverse a head of Apollo, facing, sometimes in a splendid style, which recalls the art of the immediate successors of Pheidias (Pl. I. fig. 12). The reverse type is a flaming race-torch in an incuse square. The territory of Chalcidice is eminent for the excellence of some of its silver coins. There is a very early Attic tetradrachm of Olynthus, with a quadriga, and an eagle within a double square, which reminds us of the idea of the great Sicilian currencies, the record of Olympic victory. The Phoenician tetradrachms of the best period struck by the Chalcidian League (392–379 B.C., and later), Olynthus being probably the mint, are of great stylistic interest (Pl. I. fig. 13). The obverse bears the head of Apollo in profile crowned with laurel. It is in very high relief and treated with great simplicity, though not with the severity of somewhat earlier pieces. The delicacy of the features is balanced by the simple treatment of the hair and the broad wreath of laurel. On the reverse is a lyre. There is an early series of coins of Lete, none later than about 480. The obverse type is a satyr with a nymph, and on the reverse is an incuse square divided fourfold, first diagonally and then in squares. Mende has money of Attic weight, the types being connected with Silenus, who on a tetradrachm of fine style is portrayed reclining, a wine-vase in his hand, on the back of an ass; the reverse bears a vine. Of Neapolis (Datenon) there are early coins with the Gorgon's head and the incuse square, which in the period of fine art gives way to a charming head of the "Virgin Goddess" crowned with olive. The coins of Philippi in the three metals are mainly of the time of Philip II., who, having found a rich gold mine near Crenides, changed its name to Philippi. The gold coins are Attic staters, the silver pieces of the Phoenician or Macedonian weight, like Philip's own money. The earliest bear the name of the "Thasians of the Mainland," who immediately preceded Philip's colony. All bear the head of young Heracles in a lion's skin, and a tripod. Imperial pieces were struck by the city as a colonia. There is a long but late series of Thessalonica which in the time of the regions was the mint of the second region; the numerous bronze coins of the Roman period show a figure of Cabirus among other types. Uranopolis has a few coins with very curious astronomical types, probably issued by the eccentric Alexarchus, brother of Cassander. The issues of the Thraco-Macedonians are extremely interesting. They are all just anterior to, or it may be contemporary with, Alexander I. of Macedon. The leading coins are octadrachms of the Phoenician standard. They have usually but one type, the reverse bearing a quadripartite incuse square. Their sudden appearance and heavy weight are due to the working of the silver mines on the border of Macedonia and Thrace. The usual types are a warrior leading a horse or a yoke of oxen. The coins bear the names of the Bisaltae, Getas, king of the Edoni, the Orrescii and other tribes. Besides these there are very curious Attic decadrachms of the Derronians of Sithonia, bearing the unusual type of an ox-car, in which is a figure seated, and on the reverse a symbol of three legs.

Macedonia.

The oldest coins of the Macedonian kings are of Alexander I., from 498 to 454 B.C., the contemporary of Xerxes. These are Phoenician octadrachms, having on the obverse a cavalryman by the side of a horse, and coins of a lower denomination with the same or a similar type. The money of Alexander's successors illustrates the movement of art, but it is not until the reign of Philip II. that we have an abundant coinage. He first strikes gold pieces, chiefly Attic didrachms, from the produce of his mine near Philippi (Pl. I. fig. 14). They are of fair style, and bear on the obverse the head of Ares. On the reverse is a victorious Olympic biga. These coins were afterwards known as Φιλίππειοι and the gold money of Alexander as Ἀλεξάνδρειοι—appellations which probably did not include larger or smaller pieces. Horace calls the gold coins of Philip "Philips" ("regale nomisma Philippos," *Epist.* ii. 1, 232). The silver coinage of Philip is mainly composed of tetradrachms of the Phoenician standard (Pl. I. fig. 15). Their type of obverse is a head of Zeus and of reverse either a horseman wearing a causia or a victor in the horse-race with a palm—these last coins being the best of Philip's, although the horse is clumsy.

Kings of Macedonia.

The coinage of Alexander the Great, both in the number of the cities where it was issued and in its abundance, excels all other Greek regal money; but its art is, without being despicable, far below excellence. The system of both gold and silver is Attic. The gold coins are distaters or gold tetradrachms, staters or didrachms (see Pl. I. fig. 17), hemistaters or drachms, with their half or a smaller denomination. The types of the distaters or staters, which last were the most common pieces, are for the obverse the head of Athena and for the reverse Victory bearing a naval standard. The largest silver piece is the decadrachm, which is of extreme rarity. The types of the tetradrachms and most of the lower coins are on the obverse the head of Heracles in the lion's skin and on the reverse Zeus seated, bearing on his hand an eagle (Pl. I. fig. 16). The head has been supposed to be that of Alexander, but this is not the case, although there may be some assimilation to his portrait. The great currency was of tetradrachms. The coinage was struck in different cities, distinguished by proper symbols and monograms. The classification of the series is difficult, but is gradually advancing. (For Alexander's Eastern coinage see § iv. Oriental Coins.)

The coinage of Alexander is followed by that of Philip Arrhidaeus, with the same types in gold and silver. That of Alexander IV. was issued by Ptolemy I. alone. In these coins the types of Alexander were modified, the dead king being represented with the ram's horn of Ammon, and wearing an elephant's skin head-dress and aegis. Meanwhile Seleucus, Lysimachus, Antigonus, king of Asia, struck Alexander's money with their own names, and the tetradrachms of Macedonia were generally of this kind until the time of Philip V. The same coinage, marked by a large flat form, was reissued later by

various cities, especially of western Asia, when the Romans, after the battle of Magnesia in 190 B.C., restored the liberties which Alexander had granted. The series of Alexandrine money is interrupted by various small coinages and the later issues of Lysimachus, king of Thrace, with a fine portrait—head of Alexander with the ram's horn, as the son of Zeus Ammon, a work sometimes worthy of Lysippus and an excellent indication of his style. The reverse has a figure of Athena holding a little Victory (Pl. I. fig. 19). The coins of Demetrius I. (Poliorcetes) comprise fine tetradrachms, some of the types of which have an historic reference. They bear either on the obverse his portrait with a bull's horn and on the reverse a figure of Poseidon, or on the one side a winged female figure (Victory) on the prow of a galley, blowing a trumpet, and on the other Poseidon striking with his trident. The latter types cannot be doubted to relate to the great naval victory which Demetrius gained over Ptolemy in 306; the Victory reproduces the "Victory of Samothrace," dedicated by Demetrius and now in the Louvre. The tetradrachms of Antigonus I. (Gonatas), which are of inferior style and work to those of Demetrius, have types which appear to refer in like manner to the great event of his time. The obverse type is a Macedonian buckler with the head of Pan in the midst, and the reverse type Athene Promachos. The head of Pan is supposed to have been taken as a device in consequence of the panic which led to the discomfiture of the Gauls at Delphi. Another pair of types, the head of Poseidon and Apollo seated on the prow of a warship, probably refers to the victory of Leucolla about 258 B.C. The tetradrachms of Philip V. have on the obverse a head in the helmet of Perseus, representing probably Philip's son, Perseus, in the character of that hero. The reverse bears a club. Other tetradrachms and smaller coins have a simple portrait of Philip. The tetradrachms of Perseus are of fair style, considering the time at which they were struck. They bear on one side the king's head and on the other an eagle on a thunderbolt. Andriscus (Philip VI., 150-149 B.C.) issued tetradrachms some of which represent him as Perseus. The coins of the Paeonian kings (from about 359 to 286 B.C.) show Macedonian influence, but are semi-barbarous.

The coin systems of northern Greece, Thessaly, Epirus, Corcyra, Acarnania and Aetolia present certain difficulties which disappear if we consider them as originally Aeginetan, modified in the west by Corinthian, and later by Roman, influence. The coinage of Thessaly represents very few specimens of a remote period, while pieces of the best time are numerous. These are in general remarkably like the finest coins of Sicily and Italy, although the style is simpler. The prevalence of the horse and horseman is significant. The money of the Thessalian Confederacy, being of late date (196–146 B.C.), is of little interest. The commonest types are the head of Zeus crowned with oak and the Thessalian Athena Itonia in a fighting attitude. The coinage is resumed in imperial times. Numerous small places, such as Gomphi, Homolium, Lamia, Phalanna, produced coins of considerable beauty; more extensive are the issues of Pharsalus, Pherae (with fine coins of the tyrant Alexander), and especially Larissa. The last series begins with archaic pieces and some of the early period of good art, but sometimes of rather coarse execution. The small silver pieces have very interesting reverse types relating to the nymph of the fountain, and to be compared for mutual illustration with the didrachms of Terina and with some of those of Elis. These are followed by coins of fine work. The usual obverse type is the head of Larissa, the nymph of the fountain, facing, and on the reverse is generally a horse, either free or drinking. The head is treated in a very rich manner, like that of the fountain-nymph Arethusa, facing, on tetradrachms of Syracuse; indeed, the debt to the Sicilian type is obvious. The bronze money is also good. The wine-producing island of Peparethus, off the Thessalian coast, is represented by a remarkable series of Attic tetradrachms (about 500–480 B.C.) with a variety of types, partly Dionysiac.

Thessaly.

The coinage of Illyria (strictly Illyris or Illyricum) is usually of inferior or rude art; the pieces are Aeginetic, ultimately changing to Corinthian, and then, in 229 B.C., to the standard of the Roman *Victoriatus*. Of Apollonia there is a large series. The earliest (early 4th century) have the Corcyraean types of the cow and the calf and the floral pattern; the latest, usually the head of Apollo and three nymphs dancing round a fire, the outer ones holding torches. Dyrrhachium, which never bears on its coins the more famous name of Epidamnus, is represented by an important series. First there are reduced Aeginetan didrachms with *Corcyraean* types. These are succeeded by tridrachms with *Corinthian types*, and of Corinthian weight; and then the old types are resumed, but the standard is that of the victoriatus. Dyrrhachium, it must be remembered, was founded partly by Corcyraean and partly by Corinthian colonists. The Illyrio-Epirote mining towns, Damastium, &c., struck barbarous silver coins in the 4th century; on some of the small pieces we see an ingot of metal or a miner's pick.

Illyricum.

The coins of Epirus are of higher interest and beauty than those of Illyria. Of the Epirots there are bronze coins of the regal period (342-272 B.C.), and both silver and bronze of the republic (238-168 B.C.), with the heads of the Dodonaean Zeus and Dione, together or apart. Ambracia is represented by silver pieces, with on the one side a head of Dione, on the other the obelisk of Apollo Agyieus.

Epirus.

The series of Greek imperial money of Nicopolis must also be mentioned. The coinage of the kings begins under Alexander I. His coins have been found in the three metals, but they are rare. It is probable that both gold and silver were struck in Italy while he was in that country. The coins of Pyrrhus in all metals are of high interest, and remarkable for their beauty, though the style is usually florid. There can be little doubt that they were for the most part struck in Italy and Sicily, at Tarentum and Syracuse. The tetradrachm has for the type of the obverse a head of the Dodonaean Zeus crowned with oak and for that of the reverse Dione seated. A fine didrachm bears on the obverse a head of Achilles helmeted, with for the reverse Thetis on a sea-horse carrying the shield of her son. Among the copper coins of Pyrrhus we must remark the beautiful ones with the portrait of his mother Phthia.

The coinage of the island of Corcyra begins with very early reduced Aeginetic didrachms and drachms of the 6th century. The types are the cow suckling the calf and the floral pattern, as at Dyrrhachium. These leading subjects are varied in later times by others illustrating the Corinthian origin of the nation, its maritime power, and the fame of its wine. Not the least curious are the bronze pieces with galleys bearing their names, as Freedom, Glory, Orderly Government, Corcyra, Comus, Cypris, Victory, Youth, Preserver, Fame, Light-bearer. The abundant bronze series goes on under the emperors.

Corcyra.

The coins of Acarnania are not remarkable for beauty or for variety in their types. The money of several cities in the 4th century B.C. is Corinthian in types and weight. That of the Acarnanian League (220–168 B.C.) bears the head of the Acheloüs as a man-headed bull and the seated Apollo Actius. Of Leucas the silver coins show the archaic cultus-figure of Aphrodite Aeneias.

Acarnania.

In Aetolia the gold and silver coins of the Aetolian League have some merit (279–168 B.C.). The gold pieces have on the obverse the head of Athena or that of Heracles in the lion's skin and on the reverse Aetolia personified, seated on Gaulish and Macedonian shields (a figure dedicated after the repulse of the Gauls; Paus. x. 18, 7). These subjects recur, with others indicating the hunter-life of the population, on the silver money: of especial interest are the head of Atalanta and the Calydonian boar, and the spear-head with which he was slain. On some of the copper the spear-head and the jaw-bone of the boar are seen.

Aetolia.

The coinage of Locris, Phocis and Boeotia is entirely on the Aeginetic standard. The coins of the Locri Epicnemidii are mainly didrachms struck at Opus, with the head of Persephone and the figure of the Lesser Ajax in a fighting attitude, sometimes accompanied by his name. These coins were struck between 369 and 338 B.C., and are remarkable for the manner in which a Syracusan head is copied, if indeed the dies were not actually in some cases made in the western city.

Locris.

The money of Phocis begins at a very early age, some time in the 6th century B.C., and extends in silver down to the conquest by Philip (346 B.C.). The prevalent type is a bull's head. The generals Onymarchus and Phalaecus in the Sacred War placed their names on bronze coins. Delphi, geographically included in Phocis, strikes very remarkable money, wholly distinct in types from the Phocian. The principal subjects are heads of rams and goats, the symbols of Apollo as a pastoral divinity, a dolphin (Apollo Delphinius), the omphalos and tripod, and a negro's head, which has not been satisfactorily explained. The Amphictyonic Council struck beautiful didrachms, probably on the occasion of Philip's presidency (346 B.C.), with the head of Demeter, and the Delphian Apollo seated on the omphalos. Under Hadrian and the Antonines there is an imperial coinage of Delphi, some pieces bearing the representation of the temple of Apollo, on one type the letter E appearing between the columns of the face, representing the mystic Delphic EI, on which Plutarch wrote a treatise.

Phocis.

The coinage of Boeotia is chiefly of a period anterior to the reign of Alexander, under whom the political importance of Thebes and the whole country came to an end. The standard until the end of the 4th century is Aeginetic. The main characteristic of the money is the almost exclusive use of the Boeotian shield as the obverse type, marking the federal character of the issues. These were struck by various cities or by Thebes as ruling the League. The earliest pieces are drachms, presumably of Thebes, issued between 600 and 550 B.C.

Boeotia.

These are followed by didrachms of the same and other cities until the time of the Persian War. The result of the unpatriotic policy of Thebes and most of the towns of Boeotia was the degradation of the leading city, and the coins reveal the curious fact that Tanagra for a time became the centre of the League-coinage. We now notice the abandonment of the old incuse reverse and the adoption of regular types, the wheel at Tanagra and the amphora at Thebes. These types increase, and indicate several cities during the short period of Athenian influence (456–446 B.C.). The democratic institutions were next overthrown, and Thebes became again the head of Boeotia, and struck alone and in her own name, not in that of the League. To the earlier part of this period belong splendid didrachms with reverse types chiefly representing Heracles, subsequently varied by heads of Dionysus in a series only less fine. With the peace of Antalcidas (387 B.C.) Thebes lost her power, the League was dissolved, and the other Boeotian cities issued a coinage of some merit. In 379 B.C. Thebes became the chief state in Greece, and the patriotic policy of Pelopidas and Epaminondas is shown in the issue of the Boeotian coins at the great city without any name but that of a magistrate. Among those which occur is ΕΠΑΜ, or ΕΠΑΜΙ, who can scarcely be any other than the illustrious general (Pl. I. fig. 18). After the battle of Chaeronea (338 B.C.), swiftly followed by the destruction of Thebes, the coinage is comparatively unimportant, save only for the appearance of new league-money of Attic weight, with the head of Zeus and the figure of Poseidon, between 288 and 244 B.C.

In Attica the great series of Athens is dominant. Eleusis issued a small bronze coinage of good style in the 4th century. Oropus and the island of Salamis also had an unimportant coinage. The Athenian coinage, apparently introduced by Solon, begins with didrachms on the Euboic standard, which, owing to the fame of the Athenian money, received the name of Attic. The type is an owl, the reverse having only the incuse square. These didrachms were succeeded under Peisistratus by the well-known Attic tetradrachms with head of Athena on the obverse, and owl and olive-spray on the reverse (Pl. I. fig. 20). The change supposed to have been introduced by Hippias (Pseudo-Arist. *Oecon.* ii. 4) was merely one of nomenclature; by calling in the coinage and reissuing it at double its old nominal value he only paid back half of what he had received. To what had previously been called didrachms he gave the name of tetradrachms, by which they have since been known. An obol bearing the name of Hippias himself, and types similar to those of Athens, was probably issued by him during his exile. From the time of the Persian wars the helmet of Athena is adorned with three olive-leaves. A rare decadrachm corresponds at Athens to the Demareteia at Syracuse, and was probably issued for similar reasons in commemoration of victory over the barbarians. Otherwise historical events seem to have left little record in the coinage and the Athenians deliberately affected archaism in the style of their coins, which bear no mark of the splendour of Athens as the centre of the sculptor's art. No doubt commercial reasons dictated this conservative policy, which makes the coinage of Athens a disappointment in numismatics. Her money was precious for its purity not only in the Greek world but among distant barbarians, so that imitations reach us from the Punjab and from southern Arabia, and any change would have injured its wide reception. There are many divisions of silver coinage with the types a little varied, and some different ones; and towards the end of the 5th century (probably in 407 B.C.) gold and bronze were introduced. The gold, of good quality and bad style, was never plentiful. The Macedonian empire put an end to the autonomy of Athens, and when the money is again issued it is of a wholly new style and the types are modified. The great series of spread tetradrachms may be dated from about 229 B.C., and lasted probably until the time of Augustus. The obverse type is a head of Athena with a richly adorned helmet, unquestionably borrowed from the famous statue by Pheidias in ivory and gold, but a poor shadow of that splendid original, and an owl on an amphora within an olive-wreath. The earliest coins have the monograms of two magistrates, the later the names of two who are annual (although the nature of their offices is not certain—possibly they were λειτουργίαι), and, during the period 146–86, a third name, of the treasurer of the prytany in which the coin was issued. Among the names are those of Antiochus (175 B.C.), afterwards Antiochus IV. of Syria, and of Mithradates the Great (Pl. II. fig. 1) and his creature, Aristion (87–86 B.C.); but comparatively few of the coins can be dated exactly. Mithradates issued the only gold staters in this series. The symbols in the field often represent local statues of great interest. The abundance of this money shows the great commercial importance of Athens in these later times. Under the empire Athens issued only quasi-autonomous coins, but these are of great archaeological value as they bear representations of the Acropolis, with the grotto of Pan, the statue of Pallas Promachus, the Parthenon, and the Propylaea, with the steps leading up to the latter; of the theatre of Dionysus, above which are caverns in the rock, and higher still the Parthenon and the Propylaea; and of various statues and groups of sculpture. Megara and other places in Megaris issued a small but interesting coinage.

Athens.

The money of the island of Aegina is of especial interest since with it coinage originated, so far as Greece proper is concerned, probably fairly early in the 7th century B.C. There is no good evidence for connecting the institution of the coinage with Pheidon, king of Argos, who established a system of measures and weights, known as the Pheidonian. The weight of the coins is of course on the Aeginetic standard. The oldest pieces are very primitive didrachms, bearing on the obverse a sea-tortoise and on the reverse a rude incuse stamp (Pl. II. fig. 2). Afterwards the stamp becomes less rude, and later has a peculiar shape. The sea-tortoise is also replaced by a land-tortoise. There are some coins of the early part of the fine period of excellent work. The great currency was of didrachms. The bronze coins are not remarkable, but some appear to be of an earlier time than most Greek pieces in this metal.

Aegina.

The series of Achaea begins under the Achaean League in the time of Epaminondas, with a fine Aeginetic stater and smaller coins in the name of the Achaeans. The later silver coins are either Attic tetrobols or Aeginetic hemidrachms. On all but the earliest, *i.e.* after about 280 B.C., monograms or symbols indicate the cities which were members of the league; on the later bronze coins the names are given in full. The type of the silver is the head of Zeus Homagyrius, the reverse bearing the monogram of the Achaeans in a laurel-wreath. The oldest bronze repeats the silver types; the later bear a standing Zeus and a seated Demeter, with the name of the city at full length. About forty-five cities are represented by this coinage.

Achaea.

Corinth is represented by a very large series of coins, the weight of which is always on the Corinthian standard, equivalent to Attic but differently divided,—the Corinthian tridrachm, the chief coin, corresponding to the Attic didrachm. The oldest pieces, of the 6th century B.C. (some perhaps even earlier), bear on the obverse Pegasus with the letter ϙ, koppa, the initial of the name of Corinth, and on the reverse an incuse pattern. In course of time (about 500 B.C.) the head of Athena in an incuse square occupies the reverse. The incuse square disappears, as generally elsewhere, in the early period of fine art. Of the age of the excellence and decline of art we find beautiful work, though generally wanting in the severity of the highest Greek art (Pl II fig. 3). Pegasus is ordinarily seen galloping, but sometimes standing or drinking, the koppa is usually retained, and the helmet of Athena, always Corinthian, is sometimes bound with an olive-wreath. The smaller coins have the same reverse, but on the obverse a charming series of types, principally female heads, mostly representing Aphrodite. There are some drachms with Bellerophon in a combatant attitude mounted on Pegasus on the one side and the Chimaera on the other. The autonomous bronze money is poor, but often of fair work, and interesting, especially when the type relates to the myth of Bellerophon. In 46 B.C. this city was made a colonia, and we have a large and interesting series of the bronze coins struck by it as such.

Corinth.

including the remarkable type of the tomb of Lais. The coins of the "colonies" of Corinth form a long and important series, struck by Acarnanian towns with Corcyra, and in the west by Locri Epizephyrii in Italy and Syracuse. Some of these cities were not strictly colonies of Corinth, but the Pegasus staters struck by them form a homogeneous group. They range from the time of Dion (357 B.C.) to nearly the end of the 3rd century. The coins are distinguished by the absence of the koppa, and bear the names or monograms of the cities.

Patrae, Sicyon, &c.

There are bronze coins of Patrae as an important Roman colonia, and silver and bronze money of Phlius, both of the period of good art. The coinage of Sicyon, on the Aeginetic standard dominant in the rest of the Peloponnesus, is disappointing for a famous artistic centre. It begins shortly before the period of fine art; in that age the silver is abundant and well executed, but the leading types, the Chimaera and the flying dove within an olive-wreath, are wearying in their repetition, and good work could not make the Chimaera an agreeable subject. Small coins with types of Apollo are the only subjects which suggest the designs of the great school of Sicyon.

Elis.

The money of the Eleans is inferior to none in the Greek world in its art, which reaches the highest level of dignified restraint, and in the variety of its types, which are suggested by a few subjects. The leading types are connected, as we might expect, with the worship of Zeus and Hera and Victory, the divinities of the great Panhellenic contest at Olympia, and the coinage is rather the money of Olympia than of the Eleans as a civic community. The prevalent representations are the eagle and the winged thunderbolt of Zeus, the head of Hera and the figure of Victory. The series begins early in the 5th century B.C. with coins, some of which are didrachms (Aeginetic), having as subjects an eagle carrying a serpent or a hare, and on the reverse a thunderbolt or Victory bearing a wreath—archaic types which in their vigour promise the excellence of later days. From 471 to 421 B.C., while Elis was allied with the Spartans, such types continue; the eagle and Victory (sometimes seated) are both treated with great force and beauty, and the subject of seated Zeus is remarkable for its dignity. The Argive alliance (421–400 B.C.) seems marked by the pre-eminence given to Hera, whose head may suggest the famous statue of Polycleitus at Argos. About the same time was issued a didrachm with a noble head of Zeus (Pl. II. fig. 4), which probably recalls, though it is not a copy of, the Zeus of Pheidias. This alliance broken, the old types recur. Magnificent eagles, some admirably designed on a shield, and eagles' heads (see Pl. II. fig. 5), the seated Victory, and fantastically varied thunderbolts mark this age. Among the artists' signatures at this time is ΔΑ, which may represent the sculptor Daedalus of Sicyon. In 364 B.C. the coinage is interrupted for a year, the Pisatans, who conducted the festival then, issuing small gold coins; these are immediately followed by Elean money with the heads of Zeus and the nymph Olympia. Aristotimus, who was tyrant in 272 B.C., issued coins with his initials. The coinage closes with imperial money, some types of which have a local interest, notably two of Hadrian bearing the head and figure of Zeus, copied from the famous statue by Pheidias.

Cephallenia, &c.

Cephallenia gives us the early silver coins of Cranii, the money of Pale, of charming style, with the figure of Cephalus on the reverse, and that of Same, all cities of this island. Of the island of Zacynthus there are silver pieces, usually of rather coarse work, but sometimes of the style of the best Cephallenian money. Some struck in 357 bear the name of Dion of Syracuse, who collected the forces for his expedition in this island. The coins of Ithaca are of bronze. They are of interest on account of their common obverse type, which is a head of Odysseus.

Messene.

Returning to the mainland, we first notice the money of Messene, or the Messenians. The earliest coin is a splendid Aeginetic didrachm, having on the obverse a head of Persephone, and excels in design the similar subjects on the money of Syracuse, from which it must have been copied, for it is of about the time of Epaminondas. It shows the purer style of Greece, which, copying Syracusan work, raised its character. On the reverse is a figure of Zeus, inspired by the work of Hageladas. The other silver coins are of about the period of the Achaean League. The bronze money is plentiful, but not interesting. Lacedaemon, as we might have expected, has no early coins, the silver money being mostly of the age of the Achaean League, but the King Areus (309–265 B.C.) and the tyrant Nabis (207–192 B.C.) are represented by Attic tetradrachms. On a tetradrachm of the time of the former is a figure of the Apollo of Amyclae. Among the types of the autonomous bronze pieces may be noticed the head of the Spartan lawgiver Lycurgus, with his name. The series of Argos in Argolis begins early in the 5th century. The standard is Aeginetic. The first pieces are the drachm and smaller denominations with a wolf, half-wolf or wolf's head on the obverse, and A on the reverse. A rare iron coin was issued with these types. At the end of the 5th century begin the didrachms, which have for the obverse type the head of the Polycleitan Hera—a design which is not equal to that of the coins of Elis, the style being either careless or not so simple. The reverse type of the drachm represents Diomedes stealthily advancing with the palladium in his left hand and a short sword in his right. A 4th-century drachm of Epidaurus represents the famous seated figure of Asclepius by Thrasymedes of Paros.

Laconia.

Argolis.

Arcadia.

Of the money of Arcadia some pieces are doubtless among the most ancient struck by the Greeks; and the types of these and later coins are often connected with the remarkable myths of this primeval part of Hellas, showing particularly the remains of its old nature-worship. The first series to be noticed is that of the Arcadian League; it begins about 500 B.C. with hemidrachms having the type of Zeus Lycaeus seated, the eagle represented as if flying from his hand, and a female head. Of a later time, from the age of Epaminondas, there are very fine coins (issued from Megalopolis) with the head of Zeus, and Pan seated. The coins of Heraea begin deep in the 6th century B.C. The earliest have for obverse type the veiled head of Hera, and on the reverse the beginning of the name of the town. The silver coins of Mantinea (beginning early in the 5th century) have on the obverse a bear, representing Callisto, the mother of Arcas, who was worshipped here, and on the reverse the letters MA, or three acorns, in an incuse square. Later coins, especially the bronze, have subjects connected with the worship of Poseidon at this inland town. The silver coins of Pheneus must be noticed as being of fine work. The didrachms of the age of Epaminondas have a head of Persephone, and Hermes carrying the child Arcas. The obverse type is interesting as a copy of the Syracusan subject, as in Locris and Messene. As in Locris, the merit is in the greater force and simplicity of the face, here most successful, the hair being treated more after the Syracusan manner than after that of the Messenians, who simplified the whole subject. The finest coin attributed to Stymphalus is a magnificent didrachm of the age of Epaminondas, with a head of the local Artemis laureate, and Heracles striking with his club. The smaller silver coins have on the one side a head of Heracles and on the other the head and neck of a Stymphalian bird. There were representations of these birds in the temple of Artemis. The series of Tegea is not important, but two of the reverse types of its bronze coins are interesting as relating to the myth of Telephus and to the story that Athena gave a jar containing the hair of Medusa to her priestess Sterope, daughter of Cepheus, in order that she might terrify the Argives should they attack Tegea in the absence of Cepheus, when Heracles desired his aid in an expedition against Sparta. Iron coins were issued by Tegea, and also perhaps by Heraea.

Crete.

The peculiar position of Crete and her long isolation from the political, artistic and literary movements of Hellas have been already touched on. It is not until the age of Philip V. that Crete appears in the field of history, and then only as the battle-ground of rival powers. The most remarkable influence of this age was when Athens, by the diplomacy of Cephisodorus, succeeded about 200 B.C. in drawing the Cretans into a great league against Philip V. of Macedon. That this project took actual shape is proved by the issue at all the chief mints of the island of tetradrachms with the well-known types of Athens, to be distinguished from the Atticizing types of other cities at this time.

The oldest coins are probably of about 500 B.C., but few cities seem to have issued many until a hundred years later. Then there is a great outburst of coinage, sometimes beautiful, sometimes barbarously careless, which lasts until the age of Alexander, when the local currency was probably in great part replaced by Alexandrine coins. At the end of the 3rd century the local coinages are revived until the Roman conquest (67 or 66 B.C.). The chief issue is of silver; bronze is less abundant; and gold is all but unknown. The Cretan types have a markedly local character, yet they copy in some instances other coinages. The chief divinities on the pieces are Zeus, Hera, Poseidon, Heracles and Britomartis, and the leading myths are those of Minos, the story of the Minotaur and the labyrinth being prominent, and also that of Europa. There is frequent reference to nature-worship as in Sicily, yet with a distinctive preference for trees, the forms of which, however, lend themselves readily to the free representation of Cretan art, which may in part explain their prominence. The peculiarity of Cretan art lies in its realism. At some places, as Aptera, Polyrrhenium and Cydonia, we find engravers' signatures. The weight is at first Aeginetic of reduced form; and in the resumption of the coinage after Alexander's time it is Attic.

Of the island in general there are Roman silver and bronze coins of the earlier emperors, some of which are of fine work for the period. The most interesting types are Dictynna and

Zeus Cretagenes. The autonomous coins are very varied. The obverse of the didrachms of Aptera bears a head of Artemis and the reverse a warrior (*Ptoioikos*) before a sacred tree. Of Chersonesus, the port of Lyctus, there are didrachms of coarse style, with a head of Artemis Britomartis, who had a temple at the place. The head is copied from Stymphalus, as also is one of the reverse types, Heracles wielding his club. The money of Cnossus is of great interest. The oldest coins may be as early as 480 B.C. They bear the figure of the Minotaur as a bull-headed man, kneeling on one knee, and a maeander-pattern, in one case enclosing a star (the sun), in another a head (Theseus?). Of the period 431–350 there are didrachms with the head of Persephone, and the labyrinthine pattern enclosing the sun or the moon or a bull's head for the Minotaur, and at length becoming a regular maze. To this time belongs the wonderful coin in the Berlin Museum with Minos seated, his name in the field, and the head of Persephone within the maeander-pattern. In the later 4th century a head of Hera (copied without spirit from the coins of Argos) occupies the obverse of didrachms and drachms, and the reverse has a maze through which the way may be clearly traced. This series closes with Alexander's empire, and the native coinage disappears until the league of Cephisodorus revives it with the Athenian tetradrachm of Attic weight, bearing the name of the Cnossians. It is of inferior style, and is followed by base coins with heads of Minos and Apollo, and the Labyrinth, either square as before or in a new circular form, which is interesting as showing it was a mere matter of tradition.

There are interesting coins of Cydonia, some of them of beautiful style and work. One bears an engraver's name, Neuantos. The head is that of a Maenad, and the reverse has a figure of the traditional founder Cydon, stringing his bow, who on other didrachms is seen suckled by a bitch. The style is good, but the execution poor. Gortys, or Gortyna, is represented by most remarkable coins, which generally allude to the myth of Europa. Didrachms of archaic style have on the obverse Europa carried by the bull and on the reverse the lion's scalp. These pieces are followed by a remarkably fine class of spread didrachms; the best are of about 400 B.C. They have on the obverse Europa seated in a pensive attitude on the trunk of a tree, doubtless the sacred plane at Gortyna, mentioned by Pliny, which was said never to shed its leaves, and on the reverse a bull suddenly turning his head as if stung by a fly (Pl. II. fig. 6). Nothing in Greek art exceeds the skill and beauty of these designs. The truth with which the tree is sketched, and the graceful position of the forlorn Europa are as much to be admired as the fidelity with which the bull is drawn, even when foreshortened, sharply turning his head, with his tongue out and his tail raised. These designs, beautiful in themselves, are strikingly deficient in fitness, and afford equally strong illustrations of the excellencies and of the one great fault of the art of Cretan coins. Many pieces of the same class are of rude execution. Of Itanus there are remarkable coins, the earlier, some of which are of good style, with the subject of a Tritonian sea-god (Glaucus?) and two sea-monsters. Lyctus (Lyttus) is represented by strangely rude pieces, with the types of a flying eagle and a boar's head. The coins of Phaestus form a most interesting series. Among the didrachms are some of admirable work, with on the obverse Heracles slaying the Hydra with his club and on the reverse a bull. Others have on the obverse Heracles seated on the ground, resting. Another noticeable obverse type is the beardless Zeus seated in a tree, with his Cretan name, Velchanos. On his knee is a cock crowing, showing that he was a god of the dawn. We also find Talos, the man of brass, said to have been made by Hephaestus or Daedalus, portrayed as a winged youth naked, bearing in each hand a stone, and in a combatant attitude. Apollonius Rhodius (*Argonaut.* iv. 1638 sqq.) relates that Talos prevented the Argonauts from landing in Crete by hurling stones at them, until he was destroyed by the artifice of Medea. The important town of Polyrrhenium is represented by carefully-executed coins with a head of Zeus and a bull's head. A later piece has a *whiskered* head of Apollo, probably Philip V. in that character. Priansus shows the remarkable type of Persephone seated beside a date-palm, placing her right hand on the head of a serpent in reference to the myth of the birth of Zagreus. As usual, the figure is foreshortened. The reverse has a standing figure of Poseidon. Rhaucus has Poseidon beside his horse The rare didrachms of Sybritia, or Sybrita, may fitly close the series; one, among the most exquisite of Greek coins, has heads of Dionysus and Hermes in high relief (see Pl. II. fig. 7), another has on the obverse a charming subject, Dionysus seated on a running panther, and on the reverse Hermes drawing on his right buskin,—a delightful figure. Another beautiful type is a seated Dionysus.

Euboea.

The coinage of Euboea is all on the native standard, of which the Attic was a variety. It includes some of the very earliest Greek money. Carystus begins in the time of the Persian War with the type of the cow and calf, as in Corcyra, and its special badge is the cock. In the period 197–146 it issued gold drachms. Chalcis, the mother of western colonies, has already in the 6th century, or even earlier, a long series with the wheel-type and an incuse diagonally divided, and later, a nymph's head and an eagle devouring a serpent. Eretria probably begins as early as Chalcis, but the obverse type is the Gorgon's head. This is succeeded by the same type and a panther's or bull's head, and fine late archaic coins bear the cow and the cuttle-fish. Eretria was probably the mint of coins with the head of a nymph and a cow or cow's head struck in the name of Euboeans in the fine period. Of Histiaea the usual type is the head of a Maenad and a female figure seated on the stern of a galley.

Cyclades and Sporades.

Among the other islands classed after Euboea, Amorgos must not be passed by, as a bronze coin of Aegiale, one of its towns, presents the curious type of a cupping-glass. To Andros has been attributed a group of early coins bearing an amphora. The silver money of Carthaea, Coressia and Iulis in Ceos is extremely old, beginning in each case in the 6th century. The weight is Aeginetic, and there are didrachms and smaller coins. The usual types of Carthaea are an amphora and then a bunch of grapes; that of Coressia is a cuttle-fish and dolphin. The coinage of Delos is insignificant. Melos coined from the early 5th century to imperial times: its chief type is a canting one, the μῆλον (pomegranate). Naxos is represented by early Aeginetic didrachms and coins of the fine period, the latter being chiefly bronze pieces of remarkably delicate and good work. The types are Dionysiac. A 7th-century coin with the head of a satyr (one of the earliest representations of the human head on a coin) is probably Naxian. Of Paros there are early Aeginetic didrachms with the type of a kneeling goat and beneath a dolphin. Of the 3rd and 2nd centuries B.C. there are Attic didrachms with a head, possibly of Artemis, at first of a charming style, and a goat on the reverse. There are very archaic Aeginetic didrachms of Siphnos, which was famous for its gold and silver mines. A late tetradrachm of Syros is interesting as representing the Cabiri.

Asia Minor.

The coinage of Asia begins with that of Asia Minor. It falls into certain great classes—first, the ancient gold and electrum, Lydian and Greek, in time succeeded by electrum or gold and silver, all struck in the west and mainly on the coast. Then the Persian dominion appears in the silver money of the satraps, circulating with the gold and silver of Persia, and the Greek money is limited to a few cities of the coast, none save the electrum of the great mint of Cyzicus uninterrupted by the barbarian. With the decay of the barbarian empire the renewed life of the Greek cities is witnessed by a beautiful coinage along the coast from the Propontis to Cilicia. On Alexander's conquest autonomy is granted to the much-enduring Hellenic communities, and is again interrupted, but only partially, by the rule of his successors, for there was no time at which Asia Minor was wholly parcelled out among the kings, Greek or native. The Romans, after the battle of Magnesia (190 B.C.), repeated Alexander's policy so far as the cities of the western coast were concerned, and there is a fresh outburst of coinage, which, in remembrance, follows the well-known types of Alexander. When the province of Asia was constituted and the neighbouring states fell one by one under Roman rule, the autonomy of the great cities was generally reduced to a shadow. Still the abundant issues of imperial coinage, if devoid of high merit, are the best in style of late Greek coins, and for mythology the richest in illustration.

The oldest money is the electrum of Lydia, which spread in very early times along the western coast. This coinage, dating from the 7th century B.C., has an equal claim with the Aeginetic silver to be the oldest of all money.

Probably the two currencies arose at the same period, and by interchange became the recognized currency of the primeval marts, otherwise we can scarcely explain the absence of Asiatic silver, though it is easy to explain that of European electrum or gold. The electrum of the coins is gold—the precious metal washed down by the Pactolus—with a native alloy of a varying part of silver. Its durability recommended it to the Lydians, and it had (by convention) the advantage of exchanging decimally with gold, then in the ratio 13·3 to silver. But this commercial advantage allowed the issue of electrum coins on silver standards, while it was natural to coin them on those of gold, hence a variety of weight-systems perplexing to the metrologist. The classification of the earliest coins is exceedingly obscure, it is hardly possible to say which were struck in Lydia itself, which in the Greek coast cities, such as Miletus; but the majority probably belong to Greek mints. The most primitive in appearance are those in which the obverse is merely marked with lines, corresponding to the original rough surface of the die, while the reverse has three depressions, an oblong one flanked by two squares (Pl. II. fig. 8); there are also various coins of small denomination with a plain convex obverse, and a single rough depression on the reverse, known from the excavations at Ephesus. Both the Babylonian and the Phoenician standards were in use in early times. This double currency, as Head suggests, was probably intended, so far as the Lydians were concerned, for circulation in the interior and in the coast towns to the west, the Babylonic weight being that of the land trade, the Phoenician that of the commerce by sea. Croesus (Pl. II. fig. 9) abandoned electrum, and issued pure gold (on the Babylonic and gold-shekel standards), and pure silver (Babylonic), the silver stater exchanging as the tenth of the Euboic gold stater. These results are explained by the metrological data given earlier in this article. Of the Greek marts of the western coast we have a series of early electrum staters, for the most part on the Phoenician weight. An interesting homogeneous group was issued by the various cities which took part in the Ionian revolt (500–494 B.C.). The Euboic weight naturally found its way into the currencies, but was as yet limited to Samos. Phocaea, Teos and Cyzicus, with other towns, followed from a very early period the Phocaic standard, which for practical purposes may be called the double of the Euboic. They alone before Croesus issued gold money, which was superseded at Phocaea and Cyzicus by electrum. This is the main outline of the native coinage of Asia Minor before the Persian conquest. Its later history will appear under the several great towns, the money of Persia (which circulated largely in Asia Minor) being treated in a subsequent place.

Oldest coinage.

The first countries of Asia Minor are Bosporus and Colchis, the coins of the cities of which are few and unimportant. The autonomous coinages of the cities of Pontus are more numerous, but the only place meriting a special notice is Amisus, which almost alone of the cities of Pontus seems to have issued autonomous silver money. The common subjects of the bronze money of this place relate to the myth of Perseus and Medusa, a favourite one in this country.

Bosporus, Colchis, Pontus.

The regal coins are of the old kingdoms of Pontus and of the Cimmerian Bosporus, of the two united as the state of Bosporus and Pontus under Mithradates VI. (the Great), and as reconstituted by the Romans when Polemon I. and II. still held the kingdom of Mithradates, which was afterwards divided into the province of Pontus and the kingdom of Bosporus. The early coinage of the kingdom of Bosporus is of little interest. Of that of Pontus there are tetradrachms, two of which, of Mithradates IV. and Pharnaces I., are remarkable for the unflinching realism with which their barbarian type of features is preserved. Mithradates VI., king of Bosporus and Pontus, is represented by gold staters, and tetradrachms. The portrait on the best of these (see Pl. II. fig. 10) is fine despite its theatrical quality, characteristic of the later schools of Asia Minor. The kings of Bosporus struck a long series of coins for the first three and a half centuries after the Christian era. Their gold money (the only non-imperial gold allowed under the empire) is gradually depreciated and becomes electrum, and ultimately billon and bronze. They bear the heads of the king and the emperor, and are dated by the Pontic era (297 B.C.).

In Paphlagonia we must specially notice the coins of the cities Amastris and Sinope. The silver pieces of the former place bear a youthful head in a laureate Phrygian cap, probably representing Mithras, Amastris, the foundress, being seated on the reverse. The silver pieces of Sinope are plentiful. In the 4th century they bear the names of Persian governors. The types are the head of the nymph Sinope and, as at Istrus, an eagle preying on a dolphin. Bithynia is represented by a more important series. The provincial diet issued Roman silver medallions of the weight of cistophori (to be presently described), with Latin inscriptions, and bronze pieces with Greek inscriptions. The ordinary silver coins of Chalcedon strikingly resemble on both sides those of Byzantium, and a monetary convention evidently at times existed between these sister-cities. Of Cius, also called Prusias ad Mare, there are gold staters and smaller imperial silver pieces. Of Heraclea there are silver coins of good style; the most interesting type is a female head wearing a turreted head-dress, one of the earliest representations of a city-goddess (early 4th century). The tyrants of Heraclea, Clearchus, Satyrus, Timotheus and Dionysius are represented by coins. Of the imperial class there is a large series of Nicaea, and many coins of Nicomedia. The series of the Bithynian kings consists of Attic tetradrachms and bronze pieces, issued by Ziaëlas, Prusias I. and II., and Nicomedes I.–IV.

Paphlagonia.

Bithynia.

The fine Greek coinage of Asia may be considered to begin with Mysia. Cyzicus is in numismatics a most important city. Its coinage begins in the 6th century; and the famous electrum Cyzicene staters were struck here for nearly a century and a half (*c.* 500–350 B.C.). During that whole period they were not only the leading gold coinage in Asia Minor but the chief currency in that metal for the cities on both shores of the Aegean; the value at which they were rated was doubtless a matter of convention, and varied from time to time. The actual weight is of the Phocaic standard, just over 248 grains. The divisions were the hecta or sixth, and the twelfth. The extraordinary variety of "types" at Cyzicus is due to the fact that these types are really symbols differentiating the issues, the true badge of the city, the tunny-fish, being relegated to a subordinate position (Pl. II. fig. 11). The reverse invariably has the quadripartite incuse square in four planes of the so-called mill-sail pattern. The coins are very thick and the edges are rude. The art is frequently of great beauty, though sometimes careless. The silver coinage of Cyzicus comprises beautiful tetradrachms of the Rhodian standard, with a head of Persephone ΣΩΤΕΙΡΑ, veiled and wreathed with ears of corn. Both late autonomous and imperial coins in bronze are well executed and full of interest, the two classes running parallel under the earlier emperors.

Mysia.

Lampsacus is represented by a long series of coins. Its distinctive type is the forepart of a Pegasus, which occurs on its coins from the 6th century onwards. In the first half of the 4th century it issued splendid gold staters with various types (really, as at Cyzicus, symbols distinguishing the issues) on the obverse and the half-Pegasus on the reverse. The most remarkable type is a bearded head (probably of a Cabirus) with streaming hair in a conical cap, bound with a wreath, singularly pictorial in treatment as well as in expression (Pl. II. fig. 12). In contrast to this is a most carefully executed head of a Maenad with goat's ear; and other types of great interest are the Earth-goddess rising from the earth, and Victory nailing a helmet to a trophy, or sacrificing a ram.

The money of the great city of Pergamum is chiefly of a later time. Apart from some rare pieces of gold, the silver coinage is chiefly supplied by the money of the kings of Pergamum and by cistophori. The bronze pieces of the city are numerous both autonomous and imperial, the two classes overlapping, and there are medallions of the emperors. The local worship of

Aesculapius is especially prominent under the Roman rule. The chief coins of the kings are Attic tetradrachms, with on the obverse a laureate head of Philetaerus, the founder of the state, and on the reverse a seated Athene, the common type of Lysimachus, from whom Philetaerus revolted. Variations from these types are rare, the most important being a coin with the name of Eumenes (II.), representing his portrait and the Dioscuri. Otherwise the inscription is always ΦΙΛΕΤΑΙΡΟΥ. The cistophorus probably originated at Ephesus towards the end of the 3rd century, but was soon adopted for the Pergamene dominions, and down to imperial times was the only important silver currency in Asia Minor. It acquired its name from its obverse type, the *cista mystica*, a basket from which a serpent issues, the whole enclosed in an ivy-wreath. The reverse type represents two serpents, and between them usually a bow-case (Pl. II. fig. 13). The half and the quarter of the cistophorus have on one side a bunch of grapes on a leaf or leaves of the vine, and the club with the lion's skin of Heracles within an ivy-wreath. They were tetradrachms equal in weight to about three Attic drachms or three denarii. These coins became abundant when the kingdom of Pergamum was transformed into the province of Asia, and are struck at its chief cities, as Pergamum, Adramyttium, the Lydian Stratoniceia, Thyatira, Sardis, Smyrna, Ephesus, Tralles, Nysa, Laodicea and Apamea. They have at first the names of Greek magistrates, afterwards coupled with those of Roman proconsuls or propraetors. The silver medallions of Asia, the successors of the cistophori, range from Mark Antony to Hadrian and Sabina. They bear no names of cities, but some may be attributed by their references to local forms of worship. The obverse bears an imperial head, the reverse a type either Greek or Roman. The art is the best of this age, more delicate in design and execution than that of any other pieces, the Roman medallions excepted. One of the most remarkable imperial bronze coins of Pergamum represents the Great Altar (Pl. II. fig. 16).

Troas. The coinage of the Troad is interesting from its traditional allusions to the Trojan War. Of Abydos there is a fine gold stater, with the unusual subject of Victory sacrificing a ram, and the eagle, which is the most constant type of the silver money. One of the few imperial coins commemorates the legend of Hero and Leander. The late tetradrachms of Alexandria Troas bear the head of Apollo Smintheus, and on the reverse his figure armed with a bow. There is a long series of the town as a colonia, of extremely poor work. Ilium Novum strikes late Attic tetradrachms with a head of Athene, and on the reverse the same goddess carrying spear and distaff, with the inscription ΑΘΗΝΑΣ ΙΛΙΑΔΟΣ. On the autonomous and imperial bronze we notice incidents of the tale of Troy, as Hector in his car, or slaying Patroclus, or fighting; and again the flight of Aeneas. The island of Tenedos is represented by very early coins, and others of the fine and late periods. The usual obverse type of all the silver pieces is a Janus-like combination of two heads, presumably some primitive god and his consort; this double type is balanced on the reverse by the double-axe, which played an important part in the primitive cults of Asia Minor and the Aegaean.

In Aeolis the most noteworthy coins are the late tetradrachms of Cyme and Myrina, both of the time of decline, yet with a certain strength which relieves them from the general weakness of the work of that age. Cyme has the head of the Amazon Cyme, and a horse within a laurel-wreath; Myrina, a head of the Grynean Apollo and his figure with lustral branch and patera.

Lesbos is remarkable for having coined in base as well as pure silver, its early billon coins being peculiar to the island. This base coinage, which was probably common to Mytilene and Methymna, ceases about 450 B.C., when the Mytilenaean silver begins. Methymna has very interesting archaic silver coins, with the boar and the head of Athene But the most important coinage of Lesbos is the beautiful electrum coinage (a unique tater, Pl. II. fig. 14, and innumerable sixths) which was issued from bout 480 to 350. Phocaea in Ionia issued similar coins, distinguished by a seal (the badge of the city), and a convention egulating the weight and quality of the two coinages, and arranging for the two mints to work in alternate years, is still extant. The types vary accordingly, as at Cyzicus and Lampsacus. There is a long and important series of Mytilene of the imperial time, including very interesting commemorative coins, some of persons of remote history, as Pittacus and Sappho, others of benefactors of the city, as Theophanes the friend of Pompey, from whom he obtained for this his native place the privileges of a free city. The usual style for these persons is hero or heroine, but Theophanes is called a god, and Archedamis, probably his wife, a goddess.

The money of Ionia is abundant and beautiful. For the first century and a half (*c.* 700–545) the chief coinage is of electrum. To the 7th century belongs the remarkable coin in- *Ionia.* scribed ΦΑΕΝΟΣ ΕΜΙ ΣΗΜΑ ("I am the badge of the Bright One" or "of Phanes"), with a stag, which was perhaps issued at Ephesus. From 545 to the Ionic revolt (494) there is considerable diminution in the coinage; silver attains more importance. Thenceforward, the course of the coinage is fairly uniform until the period 301–190, when there is a general cessation of autonomous issues. After the battle of Magnesia there is a great revival, tetradrachms of Alexandrine and also of local types being issued in vast numbers. After the constitution of the Roman province of Asia (133), the cistophori supply the silver coinage. The imperial bronze coinage is numerous, with many interesting local types. Of the coins of the various cities the following demand mention. At Clazomenae in the 4th century there are splendid coins, having for types the head of Apollo, three-quarter face, and a swan. The chief pieces, the gold drachm and a half or octobol, and the silver stater or tetradrachm present two types of the head of Apollo, very grand on the gold and the silver, with the signature of Theodotus, the only known Asiatic engraver, and richly beautiful on the other silver piece. These coins are marked by the intense expression of the school of western Asia Minor. Colophon has fine severe coins of the 5th century with the head of Apollo and the lyre.

The money of Ephesus is historically interesting, but very disappointing in its art, which is limited by the small range of subjects and their lack of beauty. The leading type *Ephesus.* is the bee; later the stag and the head of Artemis appear. Thus the subjects relate to the worship of the famous shrine. The oldest coins are electrum and silver, both on the Phoenician standard. The type is a bee and the reverse is incuse. The silver coinage continues with the same types, unbroken by the Persian dominion, until in 394 B.C. a remarkable new coin appears. When Conon and Pharnabazus defeated the Lacedaemonian fleet and liberated the Greek cities of Asia from Spartan tryanny a federal coinage was issued by Rhodes, Cnidus, Samos, Ephesus, Iasus and Byzantium with their proper types on the reverse, but on the obverse the infant Heracles strangling two serpents; these are Rhodian tridrachms. About this time the Rhodian standard was introduced, and a series of tetradrachms began with the bee, having for reverse the forepart of a stag looking back, and behind him a date-palm. The head of Artemis as a Greek goddess begins to appear in the 3rd century Other series of coins follow with types associated with Artemis, Rhodian and Attic standards alternating; there are also Alexandrine tetradrachms and of course cistophori The connexion of the city with Lysimachus, who called it Arsinoë, after his wife, is commemorated by coins inscribed ΑΡΣΙ The Ephesian form of Artemis, as the cultus figure of a nature-goddess, first appears as a symbol on the cistophori, and then on gold coins struck during the revolt of 87–84, when Ephesus took the side of Mithradates. The imperial money provides many representations of the temples of the city, including that of the famous shrine of Artemis, which shows the bands of sculpture on the columns, as well as many other remarkable subjects, particularly the Zeus of rain seated on Mount Pelion, a shower falling from his left hand, while below are seen the temple of Artemis and the river-god Caÿster; on another coin the strange Asiatic figure of the goddess, frequent in this series, stands between the personified rivers Caÿster and

abundance by that of the Ptolemies, which it excels in its series of portraits, though it is far inferior in its gold money and wants the large and well-executed bronze pieces which make the Egyptian currency complete. The gold of the Seleucids is scarce, and their main coinage is a splendid series of tetradrachms bearing the portraits of the successive sovereigns. The reverse types are varied for the class of regal money. The execution of the portraits is good, and forms the best continuous history of portraiture for the third and second centuries before our era. The reverses are far less careful. The weight is Attic, but the cities of Phoenicia were ultimately allowed to strike on their own standard. Many of the coins of the earlier kings were issued in their Bactrian or Indian dominions. Seleucus I. (312–280 B.C.) began by striking gold staters and tetradrachms with the types of Alexander the Great. The same king, like his contemporaries, then took his own types: for gold staters, his head with a bull's horn, and on the reverse a horse's head with bull's horns; for tetradrachms, his own head in a helmet of hide with bull's horn and lion's skin, and Victory crowning a trophy, or the head of Zeus, and Athene fighting in a car drawn by four or two elephants with bull's horns. Antiochus I. (293–261), like his father, first struck tetradrachms with Alexandrine types, and then with his own head, Apollo on the omphalos occupying the reverse. The portrait of Antiochus has a characteristic realism. Antiochus III. (222–187) is represented by a fine and interesting series with a vigorous portrait. He alone of the Seleucids seems to have struck the great octadrachm in gold in rivalry of the Ptolemies. Coins dated by the Seleucid era (312 B.C.) first appear in his reign. The portrait of Antiochus IV. Epiphanes (175–164) is extremely characteristic, marked by the mad obstinacy which is the key to the tyrant's history. The most remarkable coin is a tetradrachm with the head of Antiochus in the character of Zeus. In his time mints became numerous in the bronze coinage, and there is a remarkable series in that metal with Ptolemaic types, marking his short-lived usurpation in Egypt. From the time of Demetrius I. (162–150) the silver tetradrachms bear both mints and dates. In one type the heads of Demetrius and Queen Laodice occur side by side. With Alexander I. Balas (152–144), Tyre and Sidon begin to strike royal tetradrachms on their own Phoenician weight. Tarsus also first strikes coins for him with the type of the pyre of Sandan. The money of young Antiochus VI. presents the most carefully executed portrait in the whole series, which, despite its weakness, has a certain charm of sweetness that marks it as a new type in art. The same artist's hand seems apparent in the fine portrait of the cruel usurper Tryphon, and also in the picturesque spiked Macedonian helmet with a goat's horn and cheek-piece which occupies the reverse. Antiochus VII. (138–129) continues the series with, amongst other coins, the solitary bronze piece of Jerusalem, bearing the lily and the Seleucid anchor. Alexander II. Zebina (128–123) is represented by a unique gold coin (Pl. II. fig. 18), as well as by silver and bronze. The empire closes with the money of the Armenian Tigranes (83–69), bearing his portrait with the lofty native tiara, and for reverse Antioch seated, the Orontes swimming at her feet (a copy of the famous group by Eutychides).

Syria.

There is a copper coinage of the Syrian *koinon* under Trajan; also of the cities of Commagene, Samosata and Zeugma, and less important mints. The money of the kings of Commagene is in bronze (*c.* 140 B.C. to A.D. 72).

Commagene.

Cyrrhestica has bronze coins of a few cities, nearly all imperial, the chief mints being Cyrrhus and Hieropolis. Hieropolis in the time of Alexander the Great issued some remarkable silver coins in the name of Abd-Hadad and Alexander himself, with figures of the Syrian goddess Atergatis, who also appears on its imperial coins.

Cyrrhestica.

Of Chalcidene there are bronze coins of Chalcis and of the tetrarchs, and Palmyrene shows only the small bronze pieces of Palmyra, the money of Zenobia and the family of Odenathus being found in the series of Alexandria.

Chalcidene, &c.

In Seleucis and Pieria, the four cities of Antioch, Apamea, Laodicea ad Mare and Seleucia Pieria issued a joint coinage inscribed ΑΔΕΛΦΩΝ ΔΗΜΩΝ about the middle of the 2nd century B.C. But the bulk of the money of this territory is of the great city of Antioch on the Orontes. The coinage is both autonomous bronze before and of Roman times, and imperial silver, base metal and bronze. Other mints (as Tyre and Sidon) in this same province issued silver of the same class as Antioch, with different symbols. A large series of coins was issued bearing on the reverse the letters S.C. (*Senatus consulto*), showing that the coinage was under the control of the Roman senate. Both Latin and Greek inscriptions are used until the reign of Trajan. The city is first called a colony on the coins of Elagabalus. The earliest coins are dated by various eras (Seleucid, Caesarian, Actian); later the emperor's consulships are used to date the silver. The leading types are the figure of Antioch seated, the river Orontes swimming at her feet, from the famous statue by Eutychides, and the eagle on a thunderbolt, a palm in front. Under Hadrian the eagle is represented carrying an ox's leg, a reference to the story of the foundation of the city when an eagle carried off part of the sacrifice and deposited it on the site which was consequently chosen. There are few other types. The series (which, strictly speaking, was not the local coinage of Antioch, but an imperial coinage for the province) is very full and includes money of the Syrian emperor Sulpicius Uranius Antoninus (who also struck bronze at Emesa and gold of the Roman imperial class). It ends with Valerian, though it begins anew in the Roman provincial money of the reform of Diocletian, to be noticed later.

Antioch.

Of the other cities of this district, Emisa presents the type of the sacred stone of Elagabal. The imperial money of Gabala shows the veiled cultus-statue of a goddess flanked by sphinxes. Laodicea has an important series. It begins with bronze money of the later Seleucids. The autonomous tetradrachms of the 1st century B.C. have a turreted and veiled female bust of the city, a favourite Syrian and Phoenician type. From 47 B.C. its title is Julia Laodicea; from Caracalla downwards it is a colonia; the inscriptions become Latin; then, very strangely, Greek on the obverse of the coins and Latin on the reverse. Seleucia has a similar regal autonomous and imperial currency, but does not become a colonia. A shrine containing the sacred stone of Zeus Casius, and the thunderbolt of Zeus Keraunius resting on a throne, are among the types.

Apamea, &c.

In Coele-Syria, Damascus issues coins from the 3rd century B.C. (beginning with Alexandrine tetradrachms) onwards; the city becomes a colonia under Philip I. The imperial money of Heliopolis (Baalbek), a colonia, shows a great temple (of the Zeus of Heliopolis) in perspective, another temple containing an ear of corn as the central object of worship, and a view of the Acropolis with the great temple upon it, and steps leading up the rock.

Coele-Syria, &c.

The coinage of Phoenicia is a large and highly interesting series. The autonomous money is here important, and indicates the ancient wealth of the great marts of the coast. The earliest coins were struck about the middle of the 5th century and usually bear Phoenician inscriptions. The coinage falls into three main periods; the first pre-Alexandrine, the second, that of Alexandrine, Ptolemaic and Seleucid rule, the third, that of the empire. In the first period Aradus strikes silver, usually on the Babylonian standard, staters with a head of Melkarth and a galley, and smaller denominations. All the other cities use the Phoenician standard. The regal silver coins of Byblus have a galley as obverse type; on the reverse a vulture standing on a ram, or a lion devouring a bull. Here and at Sidon and Tyre portions of the types are represented incuse. Sidon has a large and important series of silver octadrachms and smaller denominations; on the obverse is a galley (at first with sails set, then without sails, first lying before a fortress, afterwards alone). On the reverse is the king of Persia in a chariot, or slaying a lion. These coins were issued by the kings such as Strato I. and II. and Tennes, and by the satrap Mazaeus. The early silver of Tyre has as reverse type an ox with a crook and flail over its shoulder; on the obverse a dolphin or Melkarth riding on a sea-horse; a common symbol is the purple-shell (Pl. II. fig. 20). In the second period, besides Alexandrine silver and regal coins of the Ptolemies and Seleucids, there are certain large and important issues of autonomous or semi-autonomous silver tetradrachms and smaller denominations as at Aradus (head of the City, and Victory; also drachms with types copied from Ephesus: obv., bee, rev., stag and date palm), Marathus (head of the City, and nude figure at Marathus seated on a pile of shields), Sidon (head of the City, and eagle), Tripolis (busts of the Dioscuri, and figure of the City holding cornucopiae) and Tyre (head of the Tyrian Heracles, Melkarth, and eagle). Tyre also issued a gold decadrachm with the head of the City, and a double cornucopiae. On these and other coins Sidon and Tyre claim the rights of asylum. Berytus as

Phoenicia.

coins in this period, sometimes under the name of Laodicea in Canaan. Ace-Ptolemais (Acre) was an important mint under the Ptolemies; for a time, under the Seleucidae, it was called Antiochia in Ptolemais. Besides the Seleucid era autonomous eras are in use at some of the cities, as at Aradus (259 B.C.), Sidon (111 B.C.) and Tyre (126 B.C.). Under the empire there are some very large coinages of bronze, besides a certain amount of silver resembling that of Antioch. The quasi-autonomous silver of Tyre was also issued as late as A.D. 57. Berytus (a *colonia*) has types relating to the cults of Astarte and Poseidon; Astarte is also prominent at Sidon (a colonia from Elagabalus onwards; a common type represents the wheeled shrine of the goddess) and Tripolis. At Byblus a temple is represented with a conical fetish. Tyre has many interesting types: Dido building Carthage; the Ambrosial Rocks; Cadmus fighting the serpent or founding Thebes, &c. Ptolemais issued coins as a colony from Claudius onwards.

In Trachonitis, the only city of importance is Caesarea Panias, with a famous grotto of Pan, perhaps represented on an imperial coin. Several cities in Decapolis issued imperial coins, among them Gadara and Gerasa. In Galilee the coins struck at Tiberias by its founder, Herod Antipas, may be mentioned. Samaria has money of Caesarea, both autonomous and imperial, the last for the most part colonial, and also imperial of Neapolis, among the types of which occurs the interesting subject of Mount Gerizim surmounted by the Samaritan temple. The coinage of Judaea is an interesting series. The money of Jerusalem is of high interest, and more extensive than appears at first sight. Here was struck the coin of Antiochus VII., with the native lily as a type, the series of the Maccabaean princes, that of the Roman procurators, and the bronze coins countermarked by the tenth legion, quartered by Titus in the ruins of the city. One of these bears the remarkable symbol of a pig. After the reduction of Judaea in the reign of Hadrian, Jerusalem was rebuilt as a colonia with the name Aelia Capitolina. The earliest coin commemorates the foundation. The coinage lasts as late as Valerian. Ascalon strikes autonomous silver and bronze, including remarkable tetradrachms with the portraits of Ptolemy Auletes, of his elder son Ptolemy XIV., and of his daughter Cleopatra (see Pl. II. fig. 21). There is also money of Gaza of some importance; the earliest coins are Attic drachms, &c., of barbarous style, inspired by Greek, especially Athenian models; on its imperial coins the god Marna, and Minos and Io are named.

Palestine.

The independent Jewish coinage begins with the famous shekels. They have been assigned to various periods, but the preponderance of evidence would class them to Simon Maccabaeus, to whom the right of coining was granted by Antiochus VII. The series is of shekels and half-shekels, of the weight of Phoenician tetradrachms and didrachms. The obverse of the shekel bears the inscription "the shekel of Israel," and for type a sacred vessel of the temple, above which (after year 1) is the letter indicating the year of issue and the initial of the word year. The reverse reads "Jerusalem the Holy," and the type is a flowering branch (Pl. II. fig. 19). The half-shekel differs in having the inscription "half-shekel" on the obverse. The types are markedly peculiar; the obverse inscription is equally so, for the regular formula of the neighbouring cities would give nothing but the name of the city; but the reverse inscription is like that of Tyre and Sidon, for instance, "of Tyre sacred and inviolable." This agreement is confirmatory of the assignment to Simon Maccabaeus. This coinage bears the dates of years 1, 2, 3, 4 (rare), and 5 (very rare). There has been much discussion as to the date. It is best reckoned from the decree of Antiochus VII. granting the right of coinage to Simon (139–138 B.C.). The coins of the fifth year were then struck by John Hyrcanus. The certain coins of the successors of Simon are small bronze pieces of John Hyrcanus (135–104), of Judas Aristobulus (104–103), of Alexander Jannaeus (103–76), who strikes bilingual Hebrew and Greek and also Hebrew coins, showing his native name to have been Jonathan, and of Antigonus (40–37), who has the Hebrew name Mattathiah. The types represent only inanimate objects. The Maccabaean coinage is followed by that of the Herodian family, equally of bronze, the two most important issues being those of Herod the Great and Agrippa II. The silver coinage under the early empire was chiefly supplied by the issues of Antioch and Roman denarii; the "penny" with Caesar's image and superscription was such a denarius. The money of the procurators of Judaea, in part parallel with the Herodian, is of small bronze coins, struck between A.D. 6–7 and A.D. 58–59, the latest period of their administration being as yet unrepresented. These are followed by two classes, the money of the first revolt (A.D. 66–70) and that of the second (suppressed A.D. 135). Both risings caused the issue of native coinage, some of which may be assigned with certainty to each. Of the first revolt are bronze pieces of years 2, 3 and 4. Of the second revolt are restruck Antiochene tetradrachms and Roman denarii, usually with the name of Simon, which appears to have been that of the leader surnamed Bar Cochebas. The obverse type of the tetradrachms or shekels is the portico of the temple; on the reverse are a bundle of branches and a citron, symbols of the feast of tabernacles. Besides this native currency there are coins struck in Palestine by Vespasian, Titus and Domitian.

Jewish coinage.

Of Roman Arabia there are bronze imperial coins of Bostra and less important mints; the kings of Nabataea also issued silver and bronze coins from Aretas III. (*c.* 87–62 B.C.) to Rabbel II. (A.D. 75–101). From S. Arabia comes a remarkable silver coinage issued by the Himyarites, beginning in the 4th century B.C., and imitated originally from Attic tetradrachms (both of the old and new style). In Mesopotamia the colonia of Carrhae deserves notice, and the city of Edessa, which issues imperial money as a colonia, and has a series of coins of its kings, striking with Roman emperors in silver and bronze. Curiously, this and the colonial issue are long contemporary. The colonial coinages of Nisibis and of Resaena, which became a colonia, close the group. Babylon was probably a mint of Alexander the Great and of many of the Seleucid kings, certainly of the usurper Molon (222–220) and Timarchus (162 B.C.).

Arabia, Mesopotamia, Babylonia.

Africa.

The coins of Africa are far less numerous then those of the other two continents, as Greek, Phoenician and Roman civilization never penetrated beyond Egypt and the northern coast to the west. The series of Egypt is first in geographical order. As yet no coins have been here assigned of a date anterior to Alexander. The old Egyptians kept their gold, electrum and silver in rings, and weighed them to ascertain the value. During the Persian rule the Persian money must have been current, and the satrap Aryandes is said to have issued a coinage of silver under Darius I. With Alexander a regular Greek coinage must have begun, and some of his coins are of Egyptian mints. A rare bronze coin was struck at Naucratis, probably during his lifetime. With Ptolemy I. the great Ptolemaic currency begins, which lasted for three centuries. The characteristics of this coinage are its splendid series of gold pieces and the size of the bronze money. The execution of the earlier heads is good; afterwards they become coarse and careless. At first the fine pieces were issued by the Phoenician, Cyprian and other foreign mints, the Egyptian work being usually inferior. While the Seleucids were still striking good coins, the Ptolemies allowed their money to fall into barbarism in Egypt and even in Cyprus. The obverse type is a royal head, that of Ptolemy I. being the ordinary silver type (see Pl. II. fig. 22), while that of Arsinoë II. was long but not uninterruptedly continued on the gold. The head of Zeus Ammon is most usual on the bronze coinage. A type once adopted was usually retained. Thus Ptolemy I., Arsinoë II., Ptolemy IV., Cleopatra I., have a kind of commemoration in the coinage on the analogy of the priesthoods established in honour of each royal pair. The almost universal type of reverse of all metals is the Ptolemaic badge, the eagle on the thunderbolt, which, in spite of variety, is always heraldic. For art and iconography this series is far inferior to that of the Seleucids. The weight after the earlier part of the reign of Ptolemy I. (who experimented with the Attic and Rhodian standards) is Phoenician for gold and silver; the metrology of the bronze is obscure. The chief

Egypt.

coins are octadrachms in gold and tetradrachms in silver, besides the abundant bronze money. Ptolemy I. appears to have issued his money while regent for Philip Arrhidaeus (323–318); it only differs in the royal name from that of Alexander. He then struck money for Alexander IV. (317–311) on the Attic standard with the head of Alexander the Great, with the horn of Ammon in the elephant's skin and Alexander's reverse. He soon adopted a new reverse, that of Athene Promachos. This money he continued to strike after the young king's death until he himself (305) took the royal title, when he issued his own money, his portrait on the one side and the eagle and thunderbolt with his name as king on the other. This type in silver, with the inscription "Ptolemy the king," is thenceforward the regular currency. He also issued gold staters (reverse, Alexander the Great in an elephant-car). Ptolemy II. (Philadelphus, 285–247), the richest of the family, continued his father's coinage. Philadelphus also began (after the death and deification of Arsinoë II., about 271 B.C.), the issue of the gold octadrachms with the busts of Ptolemy I. and Berenice I., Ptolemy II. and Arsinoë II., and certainly struck beautiful octadrachms in gold and decadrachms in silver of Arsinoë II., the gold being long afterwards continued. Philadelphus also began the great bronze issues of the system. Ptolemy III. (Euergetes I. *c.* 247–222) struck gold octadrachms with his own portrait, wearing a crown of rays. His queen Berenice II., striking in her own right as heiress of the Cyrenaica and also as consort, issued a showy currency with her portrait, both octadrachms and decadrachms like those of Arsinoë, and a coinage for the Cyrenaica of peculiar divisions. Under Ptolemy IV. (Philopator, 222–205) the gold octadrachms are continued with his portrait and that of Arsinoë III. Ptolemy V. (Epiphanes, 205–181) still strikes octadrachms with his portrait and with that of Arsinoë, and begins the continuous series of the tetradrachms of the three great cities of Cyprus. The coinage henceforward steadily degenerates in style and eventually also in metal. In the latest series, the money of the famous Cleopatra VII., it is interesting to note the Egyptian variety of her head, also occurring on Greek imperial money and on that of Ascalon.

Under the Roman rule the imperial money of Alexandria, the coinage of the imperial province of Egypt, is the most remarkable in its class for its extent and the interest and variety of its types. It begins under Augustus and ends with the usurper or patriot Achilleus, called on his money Domitius Domitianus, overthrown by Diocletian (A.D. 297), thus lasting longer than Greek imperial money elsewhere. In the earlier period there are base silver coins continuing the base tetradrachms struck by Auletes, and bronze money of several sizes. Most of the coins are dated by the regnal years of the emperors, the letter L being used for "year." The types are very various, and may be broadly divided into Greek, Graeco-Roman and Graeco-Egyptian. The Graeco-Roman types have the closest analogy to those of Rome herself; the Graeco-Egyptian are of high interest as a special class illustrative of the latest phase of Egyptian mythology. These native types, at first uncommon, from the time of Domitian are of great frequency. The money of Trajan, Hadrian and Antoninus Pius is abundant and interesting. A coin of Antoninus, dated in his sixth year, records the beginning of a new Sothiac cycle of 1460 years, which happened in the emperor's second year (A.D. 139). The reverse type is a crested crane, the Egyptian bennu or phoenix, with a kind of radiate nimbus round its head, and the inscription ΑΙΩΝ. Under Claudius II. (Gothicus) and thenceforward there is but a single kind of coin of bronze washed with silver. In this series we note the money of Zenobia, and of her son Vabalathus.

Coins bearing the names and local types of the nomes of Egypt were struck by a few emperors at the Alexandrian mint. Their metal is bronze, and they are of different sizes.

Passing by the unimportant coinage of the Libyans, we reach the interesting series of the Cyrenaica, the only truly Greek currency of Africa. It begins under the line of Battus about the middle of the 7th century, and reaches to the Roman rule as far as the reign of Augustus. The coins were issued at Cyrene, Barca, Euesperides and smaller towns. The weight of the gold always, and of the silver until some date not long after 450 B.C., is Euboic; afterwards it is Phoenician. The ruling types are the silphium plant and its fruit, and the head of Zeus Ammon, first bearded (Pl. II. fig. 23) then beardless. The art is vigorous, and in the transitional and fine period has the best Greek qualities. It is clearly an outlying branch of the school of central Greece. The oldest coins are uninscribed, so that it cannot always be said at which mint they were struck. The money with the name of Cyrene comprises a fine series of gold Attic staters and silver tetradrachms. It was an important mint of the Ptolemies. Barca has a smaller coinage then Cyrene. It comprises a wonderful tetradrachm (Phoenician), with the head of Ammon bearded, boldly represented, absolutely full face, and three silphiums joined, between their heads an owl, a chameleon and a jerboa. The money of Euesperides is less important.

Syrtica and Byzacena offer little of interest. Their coins are late bronze, first with Punic inscriptions, then in imperial times with Latin and Punic or Latin. Latin and Greek are used in the same coins at Leptis Minor in Byzacena.

In Zeugitana the great currency of Carthage is the last representative of Greek money, for, despite its Orientalism, its origin is Hellenic, and of this origin it is at first not unworthy. Its range in time is from about 410 B.C., when the Carthaginians invaded Sicily, to the fall of Carthage in 146 B.C. The earliest coins are Attic tetradrachms of the class usually called Siculo-Punic. These, and certain gold coins with similar types, were issued in Sicily down to about 310 B.C. The types owe much to the coinage of Sicilian cities, especially Syracuse; but they show also distinct Punic motives, such as a lion before a palm-tree, or a head of a Punic queen. The Punic inscriptions enable some to be attributed to mints such as Motya, Solus, Eryx; others name "Carthage," "the Camp," "the Paymasters," many, inscribed *Zis*, were issued from Panormus. The coinage from about 340 to 242 B.C., perhaps all issued at Carthage itself, is scanty; the types, head of Persephone and a horse, or horse and palm-tree, now come in, and prevail to the end of the independent coinage. The acquisition of the Spanish mines about 241 caused the issue of a large coinage, but the gold and silver soon degenerate into electrum and potin. The metrology of the various series (excepting the Siculo-Punic) is obscure, but the standard seems to be Phoenician. The late silver 12-drachm pieces and some of the bronzes are among the heaviest struck coins of the ancients. The art of the earlier coins is sometimes purely Greek of Sicilian style. There is even in the best class a curious tendency to exaggeration, which gradually develops itself and finally becomes very barbarous. Roman Carthage has a bronze coinage which is insignificant. There are a few other towns which issued money with Roman legends, such as Utica. The denarii of Clodius Macer, who revolted in A.D. 68, are curiously illustrative of his policy, which was to restore the Roman republic. Carthage.

The cities of Numidia and Mauretania have a late bronze coinage; but an interesting series of silver and bronze coins is attributed with more or less certainty to the Numidian kings from Massinissa (202–148), to Juba I. (60–46 B.C.), and to the Mauretanian kings from Syphax (213–202 B.C.), to Juba II. (who also struck coins with his consort Cleopatra, daughter of Mark Antony and the famous Egyptian queen) and Ptolemy their son, the last of the great family of the kings of Egypt (A.D. 23–40). Numidia, Mauretania.

II. Roman Coins

The Roman coinage is of two great classes,—the republican and the imperial; the first lasted from the origin of money at Rome to the reform of Augustus in 16 B.C., and the second from this date to the fall of the Western empire in A.D. 476. The evidence of the coins themselves as to the origin of the republican coinage is at variance with that of the ancient writers, but the general principles of criticism must be maintained here as in other matters of early Roman story.

The tradition which ascribed the introduction of coins bearing types to Servius Tullius must be unhesitatingly rejected. The style and types of the earliest Roman coins point clearly to a date not earlier than the middle of the 4th century. The native copper which the Italians used from primitive times as a sort of medium of exchange, in amorphous blocks (*aes rude*) was probably not a state-currency, being produced by private enterprise. It was not until Rome unified Latium and Campania under her rule that central Italy acquired a true coinage. This must have been about 338 B.C. The history of the republican

coinage from 338 to 16 B.C. falls into two great periods—the second being marked by the introduction of the denarius system in 269. From 338 to 269 three minor periods may be distinguished, indicating in a striking way the growth of the Roman organization of central Italy. In the period 338–312 Rome consolidated her dominion in Latium and Campania as against her rivals the Samnites. In the second period (312 to *c.* 290) she finally subdued the Samnites. The system of her coinage is from the beginning based on a double mint, one in Rome and one in Capua (perhaps also she struck in some other cities in south Italy). The weight-units with which she starts are, for bronze, the Osco-Latin pound of 273 grammes, for silver the didrachm of 7·58 grammes (the latter being $\frac{1}{36}$ of the former and more or less coincident with the Phocaic-Campanian didrachm current in Campania). The relation between silver and bronze was as 1 : 120 or 1 : 125. The bronze unit was the *as* of 1 pound weight, which was divided into 12 unciae. The reverse type of all bronze denominations was a prow, which alluded to the establishment of Roman sea-power (in 348 she concluded her treaty with Carthage, in 338 she subjugated Antium, her chief rival on the Latin coast, and set up the beaks of the Antiate ships in her forum). The denominations are marked by I (the as), S (semis = $\frac{1}{2}$ as) and for the smaller denominations a number of pellets indicating the value in unciae. On the obverses appear the heads of deities: Janus on the as (see Plate), Jupiter on the semis, Minerva on the triens (4 unciae), Hercules on the quadrans (3 unciae), Mercury on the sextans (2 unciae) and Bellona on the uncia. These heavy coins were all cast at Rome. The Roman mint at Capua, on the other hand, produced a series of silver coins (chiefly didrachms) and small *struck* bronze change with the inscription ROMANO (see Pl. II. fig. 24). In the second period (312 to *c.* 290) the mint at Rome continues to issue cast bronze of the same weights and types. But at Capua the mint becomes much more active, being opened for cast bronze as well as struck silver. The Osco-Latin silver standard is superseded by the Roman scruple-standard (1 scruple of 1·137 grammes = $\frac{1}{324}$ of the pound of 273 grammes). Silver being to bronze as 1 : 120, 2 scruples of silver were equivalent to 1 bronze as of 273 grammes. The first issue of silver in this period consisted of didrachms (six-scruple pieces) with a head of Roma in a Phrygian helmet (alluding to her Trojan foundation), the inscription is ROMANO. Parallel with this is a Capuan issue of libral cast bronze (*aes grave*) for the use of the Latin territory; the 3-asses (tressis), 2-asses (dupondius) and as all have the head of Roma as on the didrachm, and the reverse type of all denominations is a wheel. (This wheel probably alludes to the completion of the internal routes of communication in Roman territory, especially of the via Appia, which was finished in 312). Finally, to this first issue is attributed one of the quadrilateral ingots generally known as *aes signatum*; its types are the Roman eagle on a thunderbolt, and a Pegasus with the inscription ROMANOM. These ingots, according to a plausible but not quite convincing conjecture, were probably not used as money, but only in sacral and legal ceremonies—such as dedication to the gods, *venditio per aes et libram*, &c.—in which the use of *aes rude* was traditional. But from this time onward each issue of silver and aes grave from the Capuan mint was, it is supposed, accompanied by a new ingot of this kind. Three further issues of silver from the Capuan mint took place in this period, each accompanied by its corresponding aes grave series and ingot. These heavy bronze pieces are all uninscribed; on the silver and small struck bronze ROMA replaces ROMANO. The evidence of hoards shows that in this period there must have been some sort of convention between Rome and the autonomous mints of her allies, permitting the circulation, throughout the bronze-using district under Roman control, of all the coins issued from Rome and Capua, on the one hand, and, on the other, all the aes grave issued by the autonomous mints. In the third sub-period (*c.* 290–269) the silver coinage of the Capuan mint becomes thoroughly Romanized; its inscription is, of course, ROMA; its types are the typically Roman ones of the youthful head of Janus and Jupiter in his quadriga (these are the *nummi quadrigati*). There is also a series of struck bronze inscribed ROMA issued from the same mint. The important feature of this period is that bronze is no longer regarded as the most important element in the currency, but is subordinated to silver; the result is that we have what is called the semi-libral reduction, the weight of the as issued from the Roman mint being half the pound. But opinions vary as to whether the pound of which the as represented the half in this period was the old one of 273 grammes or the new Roman pound of 327·45 grammes. As the latter was certainly used for a special series of *aes grave* issued from the Roman mint for the Latins (see below), we may assume that it was also used for the regular Roman coinage. Now since the $\frac{1}{2}$ lb as (163·72 grammes) was equated to 1 scruple of silver (1137 grammes), we get a forced relation of silver to copper of 1 : 144. The as being regarded merely as representing so much silver (1 scruple), so long as the state guaranteed the cover, there was no reason why the as, being merely token money, should not fall in weight; and that it does, sinking by the end of this or beginning of the next period to the weight of $\frac{1}{6}$ of the Oscan or $\frac{1}{4}$ (sextans) of the new Roman pound. We may note the occurrence in this series of the *decussis* or 10-as piece. Of the two series of aes grave issued in this period for the benefit of the Latin district, both are heavier than in the preceding period; the new Roman pound of 327·45 grammes is used for a series issued from the mint of Rome; a still higher weight (perhaps of 341 grammes) for a series issued from Capua. The relation between silver and copper involved in this standard is not quite clear. In this period also we have ingots corresponding according to the theory above mentioned, to the various series of aes grave; one, with a pair of chickens feeding and a pair of rostra, refers to the augury taken by the Roman imperator before battle. Two other ingots commemorate historical events; one, with a Samnite bull on each side, the subjugation of Rome's great rival; the other, with an elephant and a pig, the alleged rout of Pyrrhus's elephants by the grunting of swine at Asculum in 278.

After the introduction in 269 B.C. of the silver denarius (piece of 10 asses, marked X, Pl. II. fig. 25) with its half (the quinarius, V) and its quarter (the sestertius, IIS), no changes of obviously great economic importance take place in the coinage until near the close of the republican period. Although it is not true, as is sometimes stated, that the coinage of silver at all local mints in south Italy, except the Bruttian, came to a close with the introduction of the denarius, yet the new Roman coin entirely dominated the currency from the first. Many mints, however, continued to issue bronze coinage down to 89 B.C., and a Roman coinage in various metals is also attributed to certain local mints, such as Croton and Hatria; not to mention the Roman issues which still continued to be made from Capua, though in a less degree than before. At Rome itself the mint was now localized in the temple of Juno Moneta, who probably received her surname from, rather than gave it to, *money*. The denarius, being equivalent to 10 asses, and weighing 4·55 grammes, would at the rate of 1 : 120 (which was now restored) be equivalent to 546 grammes of bronze. The as of the time must therefore have been the one weighing 54·6 grammes, that is $\frac{1}{6}$ of the Oscan pound of 273 grammes, or $\frac{1}{4}$ (sextans) of the Attic-Roman pound of 327·45 grammes. In other words, the legally recognized as of this period was the as of the sextantal reduction. The bronze coins of this reduction are, like the silver, struck, not cast; the process of striking had already been introduced for the lower denominations of bronze in the previous period. About 241 B.C. the weight of the denarius, having sunk under the stress of the first Punic war, was fixed at 3·90 grammes. Possibly the reduction of the as to the weight of an uncia, which Pliny attributes to the time of the Hannibalian crisis, may really have taken place at the same time. In 228 B.C. (some critics prefer to say nearly forty years earlier) a new silver extra-Roman coin, the *victoriatus*, was introduced. It replaced the old Campanian drachm and, wherever it may have been minted, was meant for circulation outside Rome. The quinarius and sestertius at the same time disappeared from the regular coinage, but

the sesterce remained the unit of account. Marks of value occur on all the coins from 269 B.C. for some time onward, except on the smallest bronze and the victoriatus. After the reduction of the bronze had been carried far, it became possible to issue large denominations of a circular form; thus circular bronze decusses (equal each to 1 denarius) are known of various periods, weighing from over 1100 to 650 grammes.

Gold was not regularly coined by the Romans until the close of the republic; but certain exceptional issues must be noticed. The earliest (some time during the first Punic War) consisted of pieces of 60 (Pl. II. fig. 26), 40 and 20 sestertii; they were issued both from Rome and from some external mint or mints. To the crisis of the second Punic War may be assigned certain electrum coins of 1½ scruple weight (types: janiform female head, and Jupiter in quadriga). It is to this time that Pliny attributes the fixing of the as at the weight of an uncia, and the valuation of the denarius at 16 instead of 10 asses (although in estimating the pay of soldiers the denarius continued to be given for 10 asses). Finally there is some probability in the attribution to the year 209 of the well-known gold coins of 6 and 3 scruples which have on the obverse a head of the young Janus, and on the reverse two soldiers taking an oath of alliance over the carcass of a pig—in allusion to the loyalty to Rome of her Latin colonies (Livy xxvii. 9, 10).

Without following the fortunes of the various denominations, we may note that in 89 B.C. the lex Papiria suppressed all local mints throughout Italy, ordered the reissue of the silver sestertius, and introduced the semuncial (½ ounce) standard for bronze. This was just after the close of the Social War, which had been signalized by the issue, on the part of the revolted allies, of an interesting series of coins (denarii and—most treasonable of all—a gold piece) chiefly from Italia, as they called Corfinium. These coins bear in Oscan letters the names of the Italian military leaders, such as C. Papius Mutilus. In 81 B.C. the regular bronze coinage came to an end, and the denarius remained for a long time the only coin issued by the Roman mint. Roman generals sometimes, however, issued exceptional coins in their own names, such as "bronze sesterces."

We have already dealt with the earliest gold money of the republic. Another exceptional issue was the gold coin bearing the name of T. Quinctius Flamininus, the liberator of Hellas (struck between 198 and 190 B.C.); but it was minted in Greece and conformed to Greek standards. The earliest Roman aurei proper (those of Sulla) were also struck outside Rome. They weigh $\frac{1}{36}$ or $\frac{1}{35}$ of a Roman pound. The aurei of Pompeius were $\frac{1}{36}$, those of Julius Caesar $\frac{1}{41}$, of the pound. After Caesar's time the weight of the aureus fell to $\frac{1}{42}$ lb, under Augustus.

Of the administrative side of the Roman system of coinage little is known but what the coins reveal. The earliest indication of monetary magistrates is found in symbols, which occur on the coins before the close of the first Punic War. Then the names begin to appear, at first abbreviated, then at length. Probably the right of coinage was in the beginning vested in the consuls, but it would seem that about the time of the second Punic War it was transferred to a special board of magistrates, the *tresviri aere argento auro flando feriundo*. Whether they were appointed every year, or only when need arose, we do not know; but it is improbable that there was an annual board until the beginning of the 1st century, if then; and even when annually appointed, they cannot all have exercised their right. On the other hand, there were in some years, as 92 B.C., no less than five moneyers; in *c.* 86 B.C. there were four, two being aediles exercising a specially conferred right. Exceptional issues of this kind were often authorized by the senate, and bear inscriptions indicating the fact, such as P.E.S.C. (*Publice ex Senatus consulto*). An issue for the purpose of the Apollinarian games, defrayed out of a special treasury, bears the inscription S.C.D(e) T(hesauro). Julius Caesar added a fourth moneyer to the board. The first issue of gold by such a board took place in 43 B.C.; all previous issues of gold had been made, so far as we know, in virtue of military imperium (in 44 B.C. by the praetors). Augustus, after the troublous period 41–27 was over, returned to the triumviral system; after his reform of 15 B.C. the bronze coinage which he introduced in that year is signed by the triumvirs, although the gold and silver bears no such names. Shortly afterwards, however, he organized the system which will be dealt with under the empire.

The types of the Roman republican coins are of great interest, although their art never rises above mediocrity. The chief types of the period before 269 have already been mentioned. The earliest denarii, quinarii and sestertii bear a head of the goddess Roma, helmeted, and the Dioscuri charging on horseback, as they appeared at Lake Regillus. The victoriatus has a head of Jupiter and a figure of Victory crowning a trophy. The types of the bronze coins are practically the same as in the earlier period. About 190 B.C. the goddess Diana in her chariot begins to appear on the reverses of some of the denarii. Later, other types gradually encroach on the reverses; first, Victory in a chariot; still later such types as the Juno of Lanuvium in a chariot drawn by goats. This and other types which now begin to relieve the monotony of the series usually have a personal allusion to the moneyer, or to his family history. Thus, on a denarius of Sex. Pompeius Fostlus is seen the shepherd Faustulus discovering Romulus and Remus suckled by the she-wolf. Imaginary or more or less authentic portraits of ancestors, such as Numa, L. Junius Brutus or M. Claudius Marcellus, belong to the same category. An elephant's head on a Macedonian shield, on a coin of M. Caecilius Metellus (*c.* 94 B.C.), alludes to victories won by Caecilii at Panormus (in 251, over Punic elephants) and in Macedonia (in 148). The cult of Venus by the Julian family is illustrated by a denarius of L. Julius Caesar (*c.* 90 B.C.) with a head of Mars and a figure of Venus in a car drawn by two Cupids. The surrender of Jugurtha by Bocchus to Sulla is represented on a denarius of Sulla's son Faustus (62 B.C., Pl. II. fig. 27). The type is probably a copy of the design which we know the dictator used for his signet-ring. M. Aemilius Lepidus (TVTOR REGis) crowning Ptolemy Epiphanes, or Paullus Aemilius erecting a trophy, while King Perseus and his two children stand before him, are other historical types. A contemporary event is commemorated on a special issue inscribed AD FRV(mentum) EMV(ndum) EX S(enatus) C(onsulto), coined by L. Calpurnius Piso and Q. Servilius Caepio in 100 B.C. Caepio, quaestor in that year, defeated the proposal of Saturninus to sell corn publicly at a nominal price; but the senate voted a special issue of money to meet the strain of the market. On the obverse is a head of Saturn, from whose treasury the funds for the issue were drawn; on the reverse are Caepio and Piso on their official seat, and two ears of corn. Perhaps the most graphic allusion to a contemporary event to be found on any coin is furnished by the cap of liberty with two daggers and the inscription EID(ibus) MAR(tiis) on coins of Brutus. Representations of a less obviously historical character, as personifications of countries or places (Hispania, Alexandria) or qualities (Honos and Virtus) or mythological figures (Scylla), are all, it would seem, inspired by some personal interest. Many types will only be explained when more light is thrown on the obscure corners of Roman mythology and ritual; but they will all probably be found to have some personal reference to the moneyer. Roman types of the later republic, therefore, though they may be classified externally as "religious," "historical," "canting," &c., are all inspired by some personal motive. The inevitable outcome of this character was that, when once contemporary portraiture was regarded as legitimate on the coins, it speedily became its most important feature. The portrait of Flamininus on his gold coin struck in Greece long remained without a Roman analogy. In 44 B.C., by order of the senate, the head of Julius Caesar was placed on the silver coins (Pl. III. fig. 1; the gold coin bearing his portrait is of doubtful authenticity). After Caesar's death portraits occur on coins issued by men of all shades of political opinion, showing that portraiture on the coins was not then regarded as the monarchical prerogative, which it became from A.D. 6 onwards, when it was limited to members of the imperial family.

The history of the imperial coinage is full of metrological difficulties. These arise from the conditions fixed by Augustus (16–15 B.C.), by which the emperor alone coined gold and silver, the senate alone bronze. Consequently the senate was wholly at the mercy of the emperor. Augustus struck the aureus at 42 to the pound, equal to 25 denarii at 40 to the pound (Pl. III. fig. 3). He introduced a new coinage in two metals, the sestertius of 4 asses and dupondius of 2, both in fine

Augustus

yellow brass (orichalcum), and the as semis and quadrans in common red copper. This distinction of metals, however, was sometimes ignored, as in the time of Nero, when we have sestertius (Pl. III. fig. 2), dupondius and as, all in brass, and of three different sizes. The as is usually nearly equal in size and weight to the dupondius, but is distinguished by its metal and inferior fabric. All this brass and copper coinage bears the letters S.C., *senatus consulto*. Emperors not acknowledged by the senate are without such money; thus we have no specimens of Otho or Pescennius Niger.

Nero reduced the denarius to $\frac{1}{96}$th of the pound, and alloyed its silver with from 5 to 10% of base metal. Henceforward the quality of the denarius gradually sank, until under Sept. Severus the proportion of alloy was from 50 to 60%. Caracalla also issued lead plated with silver and, among his aurei, copper plated with gold. He also introduced a new coin, called after him the argenteus Antoninianus. It was struck at $\frac{1}{84}$th to $\frac{1}{96}$th of the pound, and seems to have been originally a double denarius struck on a lower standard. The characteristic of this coin is that the head of the emperor is radiate as Sol (Pl. III. fig. 4), that of the empress on a crescent as Luna. Towards the end of Caracalla's reign the weight of the aureus had fallen to $\frac{1}{50}$ lb. Under Elagabalus the taxes were paid in gold alone; this was ruinous, for the treasury paid in debased silver at nominal value, which had to be used to purchase gold by the taxpayer at real value. Under Gordian III. the silver contained 67% of alloy; and eventually under Gallienus the "argenteus" frequently contained no silver whatever. Aurelian (A.D. 270–275) attempted a reform of the coinage by which the previous coin was reduced from its nominal to its intrinsic value. The coins were now of bronze with a wash of silver, and we now find them marked with their value as two denarii. These coins replace at once the base silver and the bronze, which now disappear. The moneying right of the senate had become illusory by the depreciation of silver, which had ceased to have any real value. Aurelian entirely suppressed this right; Tacitus and Florian restored it for a few years, after which the S.C. disappears from the coinage. The reform of Aurelian caused a serious outbreak at Rome, but was maintained by him and by Tacitus. Aurelian also suppressed all local mints but Alexandria. It was the work of Diocletian to restore the issue of relatively pure money in the three metals. He made no less than four unsuccessful attempts to regulate the weight of gold. Not later than 290 he restored a pure silver coinage with a piece of $\frac{1}{96}$ lb. His reformed bronze coins are the *follis*, marked XX, XX·I., K, KA, &c. (all meaning "2 denarii = the unit") and the half-denarius of centenionalis.

Changes under later emperors.

Constantine, probably in A.D. 312 (though some critics attribute the reform to Constantius Chlorus) desiring to rectify the gold coinage, which had long been quite irregular in weight, reduced the chief gold piece to $\frac{1}{72}$ of the pound, and issued the solidus (Pl. III. fig. 5), a piece destined to play a great part in commercial history. It was never lowered in weight, though many centuries later it was debased, long after it had become the parent of the gold coinages of Westerns and Easterns alike throughout the civilized world. The letters OB, which are commonly found in the exergue of gold coins from the 4th century onwards mean *Obryzum* (refined gold), and the letters PS, found on silver coins *Pusulatum* (refined silver). Under Constantius II. (A.D. 360) and Julian the silver coin of $\frac{1}{96}$ lb was suppressed, and the siliqua of $\frac{1}{144}$th of the pound (which had already been issued in small quantities before) took its place. From about 360 there was a system of 4 bronze coins (follis, denarius, centenionalis and $\frac{1}{2}$ centenionalis). The last soon disappeared, and under Honorius (395) only the centenionalis remained. Honorius and his successors issued the silver decargyrus (= 10 denarii). The bronze coinage of this time was small and mean. It will be seen that a fuller system of bronze was originated by Anastasius, the Byzantine emperor.

Under Augustus the Roman monetary system became the official standard of the empire, and no local mint could exist without the imperial licence. Thus the Greek imperial money is strictly Roman money coined in the provinces, with the legends and types of the towns. Many cities were allowed to strike bronze, several silver. The kings of the Cimmerian Bosporus enjoyed the exceptional privilege of striking gold, which, however, became rapidly debased. The silver becomes limited about Nero's time, but lasts under the Antonines, and is also found under Caracalla and Macrinus. It is chiefly supplied by the mints of Caesarea in Cappadocia, Antioch and subsidiary mints in Syria, and Alexandria in Egypt. None of these were strictly city-mints, but served the purposes of the provincial government. The bronze increased in mints and quantity in the 2nd century, but, through the debasement of the Roman silver, one city after another ceased to strike about the middle of the 3rd. The provincial mint of Alexandria, however, continued to strike until the end of the century. From the coins of the ordinary Greek and other cities under the empire must be distinguished the issues of the Roman colonies. In the west these practically ceased in Nero's time; in the east they lasted as long as the other Greek coinage. Purely Roman gold and silver was coined in certain of the provinces, in Spain and Gaul, and at the cities of Antioch and Ephesus. When the base silver had driven the Greek imperial bronze out of circulation, Gallienus established local mints which struck pure Roman types. Diocletian increased the number of these mints, which lasted until the fall of the empire of the West, and in the East longer. These mints were (with others added later), Londinium (or Augusta), Camulodunum, Treviri, Lugdunum, Arelate (or Constantina), Ambianum, Tarraco, Carthago, Roma, Ostia, Ravenna, Aquileia, Mediolanum, Siscia, Serdica, Sirmium, Thessalonica, Constantinopolis, Heraclea, Nicomedia, Cyzicus, Antiochia (ultimately Theupolis) and Alexandria. A few were speedily abandoned.

As regards the internal organization of the mints under the empire, we know that, although the names of the *triumviri monetales* do not occur on the coins after 15 B.C., they continued to exist (with the title *IIIviri aere argento auro flando feriundo*, although their competence was restricted to the first metal) until probably the time of Aurelian, who withdrew the right of coinage from the senate. Officials of the imperial treasury superintended the gold and silver coinage; Trajan placed a *procurator monetae Augusti* of equestrian rank at the head of the whole system, subject to the emperor's *rationalis* (the chief official of the treasury). The system of procurators was extended and regularized by Diocletian. In the Roman colonies (which were only allowed to issue bronze) the formula D.D. or EX D.D. (*ex decurionum decreto*) often occurs, corresponding to the S.C. of the Roman mint. At many colonies, especially in the west, the monetary duumviri sign the coins. At Rome the imperial mint itself was situated behind the Colosseum, near the Caelian hill, the senate retaining its mint on the Capitol probably until the time of Trajan. The three monetae (of the three metals) appear together on medallions for the first time under Hadrian, and probably indicate the organization of the mints for the three metals in one place. From the middle of the 3rd century mint-marks begin to occur on the coins, indicating the various mints, the *officinae* in each mint, &c. Sometimes these marks form "secret combinations"; thus the letters I, O and BI found on three different coins of Diocletian (struck at three different officinae), and the letters HP, KOY and AI on three corresponding coins of Maximian, combine into Greek words representing the genitives of the Latin titles *Iovius* and *Herculius* assumed by these two emperors.

The obverse type of the imperial coins is the portrait of an imperial personage, emperor, empress or Caesar. The type only varies in the treatment of the head or bust—if male, laureate, radiate or bare; if female, sometimes veiled, but usually bare. The reverse types of the pagan period are mythological of divinities, allegorical of personifications, historical of the acts of the emperors. Thus the coins of Hadrian, besides bearing the figures of the chief divinities of Rome, commemorate by allegorical representations of countries or cities the emperor's progresses, and by actual representations his architectural works. Types often occur purely personal to the emperor, such as the sphinx which Augustus used as his signet, or the capricorn, his natal sign. The most remarkable feature of imperial types is the increase of personifications, such as Abundantia, Concordia, Liberalitas, Pudicitia—for the most part drearily conventional. The inscriptions are either simply descriptive, such as the emperor's names and titles in the nominative on the obverse, or partly on the obverse and partly on the reverse, and the name of the subject on the reverse; or else they are dedicatory, the imperial names and titles being given on the obverse in the dative and the name of the type on the reverse. Sometimes the reverse bears a directly dedicatory inscription to the emperor. The inscriptions on the earlier imperial coins from Tiberius to Severus Alexander are generally chronological, usually giving the current or last consulship of the emperor and his tribunitian year. It must be noted that Christian symbols first made their appearance on coins in an unsystematic, almost accidental way. The earliest instance is at the mint of Tarraco in A.D. 314, when a cross occurs as a symbol on the reverse. In A.D. 320 the Christian monogram is found as a detail in the field at several mints. But the types still remain pagan; these symbols are not introduced by order,

Types and inscriptions.

although the officials who introduced them doubtless knew they could do so with impunity. As times goes on the Christian emblems become more popular; on a coin of Constantius II. we find Victory crowning the emperor, who holds the standard of the cross; the inscription is HOC SIGNO VICTOR ERIS. Another type of the same reign is the Christian monogram flanked by *alpha* and *omega*. Under Julian there is a temporary recrudescence of pagan types; with the revival of Christianity monotony of type sets in.

The art of Roman imperial coins, although far inferior to that of Greek, is well worthy of study in its best ages, for its intrinsic merit, for its illustration of contemporary sculpture, and on account of the influence it exercised on medieval and modern art. On the whole the finest work is produced under Augustus, when the portraits still betray a certain refinement of imagination in the artists. Some of it reflects the beauty of Roman monumental sculpture in relief of the time, whether that sculpture be regarded as the work of Greeks or of purely Roman artists. The most vigorous portraiture is perhaps found under the Flavians. Under the Antonines, although still striking and powerful, the portraits lost in subtlety and from the time of Commodus there is a rapid decline. The age of Diocletian and Constantine shows a well-meant but hopeless attempt at revival of art. In spite of its defects, the fact that many of the greatest medallists of the Renaissance drew their inspiration from the art of imperial coins shows that it had many good qualities, of which the chief was an honest directness of effort. The realism in which this resulted is perhaps best seen in the portraits of Nero, the growth of whose bad passions may be seen in the increasing brutality of his features and expression. The medallion series is full of charming subjects, though when they have been treated by Greek artists of earlier ages the contrast is trying; the most satisfactory are the representations of older statues; the purely new compositions are either poor inventions, or have a theatrical air that removes them from the province of good art.

III. Medieval and Later Coins of Europe

The period of the medieval and later coins of Europe must be considered to begin about the time of the fall of the Western empire, so that its length to the present day is about 1400 years. It is impossible to separate the medieval and later coins, either in the entire class, because the time of change varies, or in each group, since there are usually pieces indicative of transition which display characteristics of both periods. The clearest division of the subject is to place the Byzantine coinage first, then to notice the characteristics of its descendants, and lastly to sketch the monetary history of each country. The coinage of the present day, however, having certain definite characteristics, may be dealt with separately.

The Byzantine money is usually held to begin in the reign of Anastasius (A.D. 491–518, Pl. III. fig. 6). The coinage is always in the three metals, but the silver money is rare, and was probably struck in small quantities. At first both the gold and the silver are fine, but towards the close of the empire they are much alloyed. The gold coin is the solidus of Constantine, with its half and its third, the so-called semissis and tremissis. The Byzantine solidus (*besant*) had an enormous vogue throughout the middle ages, being the chief gold coin until the introduction of the Italian gold in the 13th century. The chief silver coin was the miliarision, and a smaller coin, the siliqua or keration. Under Heraclius (610–641) the hexagram or double miliarision was first coined. The silver money of the restored Greek empire is obscure. In 498 Anastasius introduced a new copper coinage, bearing on the reverse, at his time, the following indexes of value as the main type: M, K, I and E, 40 nummi, 20, 10 and 5. These coins bear beneath the indexes the abbreviated name of the place of issue. Justinian I. added the regnal year in A.D. 538, his twelfth year. The money of this class presents extraordinary variations of weight, which indicate the condition of the imperial finances. The Alexandrian coins of this class begin under Anastasius and end with the capture of the city by the Arabs. They have two denominations, IB and S, and Γ or 12, 6 and 3 denarii, and there is an isolated variety of Justinian with A Γ(33). The Alexandrian bronze never lost its weight, while that of the empire generally fell, and thus some of the pieces of Heraclius, while associated with his sons Heraclius Constantinus and Heraclonas, have the double index IB and M. Under Basil I. the bronze money

Byzantine empire.

appears to have been reformed, but the absence of indexes of value makes the whole later history of the coinage in this metal very difficult. There was one curious change in the aspect of the money. Early in the 11th century the solidus begins to assume a cup-shaped form, and this subsequently became the shape of the whole coinage except the smaller bronze pieces. These novel coins are called nummi scyphati. The types, except when they refer simply to the sovereign, are of a religious and consequently of a Christian character. This feeling increases to the last. Thus, on the obverse of the earlier coins the emperors are represented alone, but from about the 10th century they are generally portrayed as aided or supported by some sacred personage or saint. On the reverses of the oldest coins we have such types as a Victory holding a cross (other personifications all but disappear), but on those of later ones a representation of Our Saviour or of the Virgin Mary. Christ first appears on a coin of about A.D. 450, where He is represented marrying Pulcheria to Marcian. He does not appear again until the end of the 7th century, when His bust is introduced by Justinian II. It was perhaps this type, so offensive to Mahommedan feeling, that caused the Caliph Abdalmalik to initiate the Mussulman coinage. From the 9th century Christ appears in various forms on the coins; about 900 we find the Virgin; a few years later saints begin to appear. A remarkable type was introduced by Michael VIII., Palaeologus, who recovered Constantinople from the Latins in 1261, and issued coins with the Virgin standing in the midst of the walls of the city. The principal inscriptions for a long period almost invariably relate to the sovereign, and express his name and titles. The secondary inscriptions of the earlier coins indicate the town at which the piece was struck, and, in the case of the larger bronze pieces, the year of the emperor's reign is also given. From about the 10th century there are generally two principal inscriptions, the one relating to the emperor and the other to the sacred figure of the reverse, in the form of a prayer. The secondary inscriptions at the same time are descriptive, and are merely abbreviations of the names or titles of the sacred personages near the representations of whom they are placed. From the time of Alexius I. (Comnenus) the principal inscriptions are almost disused, and descriptive ones alone given. These are nearly always abbreviations, like the secondary ones of the earlier period. The language of the inscriptions was at first Latin with a partial use of Greek; about the time of Heraclius Greek began to take its place on a rude class of coins, probably local; by the 9th century Greek inscriptions occur in the regular coinage; and at the time of Alexius I. Latin wholly disappears. The Greek inscriptions are remarkable for their orthography, which indicates the changes of the language. In the 11th century we notice a few metrical inscriptions, the forerunners of verse-mottoes on later coins. Of the art of these coins little need be said. It has its importance in illustrating contemporary ecclesiastical art, but is generally inferior to it both in design and in execution. It is noticeable that from the beginning of the Byzantine period the facing representation of the bust begins to be popular, and that from the time of Justinian (6th century) onwards the profile practically disappears from the coinage. The last Byzantine gold coin (a piece of John V. 1341–1391) shows a figure of John the Baptist imitated from the Florentine coinage.

Besides the regular series of the Byzantine empire, in which we include the money assigned to the Latin emperors of Constantinople, there are several cognate groups connected with it, either because of their similarity, or because the sovereigns were of the imperial houses. There are the coinages of the barbarians to be next noticed, and the money of the emperors of Nicaea, of Thessalonica and of Trebizond. The last group consists of small silver pieces, which were prized for their purity; they were called Comnenian white-money (ἄσπρα Κομνήνατα), the princes of Trebizond having sprung from the illustrious family of the Comneni.

Cognate groups.

The coinage of the other states of the West falls into well-defined periods, which have been distinguished as (1) transitional period, from Roman to true medieval coinage, from the fall

of Rome (476) to the accession of Charlemagne (768); (2) true medieval age, during which the Carolingian money was the currency of western Europe, from Charlemagne to the fall of the Swabian house (1268); (3) early Renaissance, from the striking of the florin in Florence (1252) to the classical Renaissance (1450); (4) the classical Renaissance, from 1450 to 1600; (5) the modern period.

Periods of other European coinage.

1. The various coinages of the transitional period will best be considered together (see below).

2. The inconvenience of gold money when it represents a very large value in the necessaries of life must have caused its abandonment and the substitution of silver by the Carlovingians. The denier (denarius) or penny of about 24 grains was at first practically the sole coin. The solidus in gold was struck but very rarely, perhaps as a kind of proof of the right of coining. The Byzantine solidus or bezant was used and probably the equivalent Arab gold. The Arab silver piece, the *dirhem*, was almost exactly the double of the denier, and seems to have been widely current in the north. The new coinage spread from France, where it was first royal and then royal and feudal, to Germany, Italy, where the Byzantine types did not wholly disappear, England, Scandinavia, Castile and Aragon. In Germany and France feudal money was soon issued, and in Italy towns and ecclesiastical foundations largely acquired from the empire the right of coinage, which was elsewhere rare. The consequence of the extended right of coinage was a depreciation in weight, and in the middle of the 12th century the one-sided pennies called bracteates appeared in Germany, which were so thin that they could only be stamped on one side. The types of this whole second coinage are new, except when the bust of the emperor is engraved. The most usual are the cross; and the church as a temple also appears, ultimately taking the form of a Gothic building. There are also sacred figures, and more rarely heads in the later age.

Medieval.

3. The true herald of the Renaissance was the emperor Frederick II. In restoring the gold coinage, however, he followed in the steps of the Norman dukes of Apulia. With a large Arab population, these princes had found it convenient to continue the Oriental gold money of the country, part of the great currency at that time of all the western Moslems, and Roger II. (1130–1154) also struck Latin coins of his own as DVX APVLIAE, the first ducats. Frederick II. (1215–1250), continuing the Arab coinage, also struck his own Roman gold money, solidi and half solidi, with his bust as emperor of the Romans, Caesar Augustus, and on the reverse the imperial eagle (Pl. III. fig. 7). In workmanship these were the finest coins produced in the middle ages. But the calamities which overwhelmed the Swabian house and threw back the Renaissance deprived this effort of any weight, and it was left to the great republics to carry out the idea of a worthy coinage—a necessity of their large commercial schemes. The famous gold florin was first issued in 1252 (Pl. III. fig. 8). The obverse type is the standing figure of St John the Baptist, the reverse bears the lily of Florence. The weight was about 54 grains, but the breadth of the coin and the beauty of the work gave it dignity. The commercial greatness of Florence and the purity of the florin caused the issue of similar coins in almost all parts of Europe. Venice was not long in striking (in 1284) a gold coin of the same weight as the florin, but with the types of a standing figure of Christ and the doge receiving the gonfalon at the hands of St Mark (see Pl. III. fig. 9). It was first called the ducat, the name it always bears in its inscription; later it is known as the zecchino or sequin. Though not so largely imitated as the florin, the extreme purity of the sequin was unquestioned to a time within the memory of living persons. Genoa likewise had a great gold currency, and the other Italian states struck in this metal. It is significant of the power of the Italian republics that the later Mameluke sultans of Egypt found it convenient or necessary for their position between Europe and India to adopt the weight of the florin and sequin for their gold money. Many varieties of gold money appear in course of time in France, England and to a less extent in other countries. The need for a heavier silver coinage caused the issue of the large denier (grossus denarius, gros or groat). This coin appears early in the 14th century. The types from the 14th century onwards are very various and distinctly worthy of the art of the time, which as yet is purely decorative and conventional, so that portraits are not possible. The religious intention also is gradually giving way to the desire to produce a beautiful result, and the symbol of the cross is varied to suit the decorative needs of the coin. Heraldic subjects also appear, and in the shield, which is frequently a reverse type, we see the origin of the usual modern reverse of the most important coins.

Of early Renaissance.

4. 5. With the classical Renaissance we find ourselves in the presence of modern ideas. The elaborate systems of coinage of the various states of Europe are soon to begin, and the prevalence of a general currency to become for the time impossible. Silver money now gains now importance with the issue of the thaler or dollar in Germany, in 1518. This great coin speedily became the chief European piece in its metal, but as it was coined of various weights and varying purity it failed to acquire the general character of the denier. The style of this age is at first excellent. The medals gave the tone to the coinage. Art had wholly thrown off the rules of the age before and attained the faculty of portraiture and the power of simply representing objects of nature and art. Great masters now executed medals and even coins, but speedily this work became a mere matter of commerce, and by the beginning of the modern period it was fast falling into the poverty and barbarism in which it has ever since remained. The details of the numismatics of these two periods belong to the notices of the money of the several countries.

Classical Renaissance, and modern.

A word must be added on money of account. While the denier was the chief and practically the sole coin, the solidus passed from use as a foreign piece into a money of account. The solidus, like the German schilling (shilling), contained usually 12 deniers. As there were 20 shillings to the pound of silver, we obtain the reckoning by £ s. d., librae, solidi and denarii. The pound as a weight contained 12 oz., and its two-thirds was the German mark of 8 oz.

Money of account.

It would be interesting, did space permit, to notice fully the art of this entire class, to examine its growth, and to trace its decline; but, as with that of Greek and Roman coins, we must mainly limit ourselves to the best period. This is a space of about a hundred and fifty years, the age of the classical Renaissance, from the middle of the 15th century to the close of the 16th. The finest works are limited to the first half-century of this period, from a little before 1450 to about 1500, in Italy, and for as long a time, beginning and ending somewhat later, in Germany. The artists were then greater than afterwards, and medal-making had not degenerated into a trade; but with the larger production of the period following the work was more mechanical, and so fell into the hands of inferior men. The medals of this first period may not unworthily be placed by the side of its sculpture and its painting. Not only have some of its medallists taken honourable places in a list where there was no room for ignoble names, but to design medals was not thought an unworthy occupation for the most famous artists. There are, as we should expect, two principal schools, the Italian and the German. The former attained a higher excellence, as possessing not merely a nobler style but one especially adapted to coins or medals. The object which the artists strove to attain was to present a portrait or to commemorate an action in the best manner possible, without losing sight of the fitness of the designs to the form and use of the piece on which they were to be placed. For the successful attainment of this purpose the style of the later pre-Raphaelites was eminently suited. Its general love of truth, symmetrical grouping, simple drapery and severely faithful portraiture were qualities especially fitted to produce a fine portrait and a good medal. It is to be noted that their idea of portraiture did not depend on such a feeling for beauty as influenced the Greeks. Rather did it set before it the moral or intellectual attainments and capabilities, what the Italians called the *virtù*, of the subject. The German art, as seen in the medals, is mostly the work of carvers in wood or honestone, or goldsmiths. It excels in vigorous, realistic portraiture, and in decorative treatment of heraldic subjects, but is lacking in breadth of style and in the imagination shown by the best Italian medallists. Both these schools, but especially the Italian, afford the best foundation for a truly excellent modern medallic art. The finest coins and medals of Italy and Germany have an object similar to that which it is sought to fulfil in the English, and their nearness in time makes many details entirely appropriate. Thus, without blindly imitating them, modern artists may derive from them the greatest aid.

Art.

There are some delicately beautiful Italian medals of the 16th century, too closely imitated from the Roman style. A vigorous realistic school, the only great one of modern times, arose in France before the close of the 16th century and lasted into the next. It was rendered illustrious by Dupré and the inferior but still powerful Warin. From this age until the time of Napoleon there is nothing worthy of note. The style of his medallists is the weak classical manner then in vogue, but yet is superior to what went before and what has followed.

It is not intended here to enter in any detail into the various divisions of the subject already treated in its main outlines. The questions that would require consideration are of too complicated and technical a nature to be illustrated within reasonable limits; the principal matters of inquiry may, however, be indicated.

We begin with a survey of the transitional coinages in the various countries of the West. They cover the period from the 5th to the 8th centuries, and are of immense historical significance. The types throughout are monotonous: the bust of a Roman emperor or local ruler, a cross of some kind, a Victory, &c. The style is quite barbarous. The classification of the earliest servile imitations of Roman and Byzantine money rests solely upon provenance and is uncertain. The following general series are distinguished: (A) The *Vandals* (in Africa, 428–534) issued gold (?), silver and bronze from Hunneric (477–484) to Gelamir (530–534); the gold is anonymous. (B) The *Suevians* (Spain, 409–585) had little but imitations of

Transitional coinages.

Byzantine gold; but Richiar (448–456) issued a denarius in his own name. (C) The *Ostrogoths* (Italy, 489–553) were preceded by the Herulian Odoacer (476–494), who coined silver and bronze; their kings (including Theodoric, 493–526, and Totila or Baduila, 541–552) issued gold, silver and bronze in their own names, from Rome, Ravenna, Milan, &c. (D) The *Lombards* (Italy, 568–774) had no coins in their own names before Grimoald, duke of Beneventum (662–671); later there are gold solidi and thirds and silver from many mints. Gold was issued for the duchy of Beneventum in the 8th century. (E) The *Burgundians* (Gaul, to 534) first issued recognizable coins under Gondebald (473–516). (F) The *Visigoths* (South Gaul and Spain) had imitative gold thirds in the 5th and 6th centuries; the kings' names appear from Leovigild (573–586) to Roderic (710–711). Sixty-one mints were in operation. (G) The *Meroving Franks* first issued under Clovis I. (481–511) coins recognizably Frankish (solidi and thirds). Royal names first appear on silver and copper under Theuderic of Austrasia (511–534) and Childebert I. of Paris (511–558). The chief Frankish inscribed coinage is, however, of gold solidi and thirds, from Theodebert I. (534–548), who broke down the Roman imperial prerogative and issued *gold with his own name in full*, to the beginning of the 8th century. The last Merovings issued no coins in their own names, being mere puppets. And from the middle of the 6th century the coins with kings' names are far less numerous than those bearing the names only of mints and moneyers; some 800 places (not only in what is now France, but in Germany, the Low Countries and Switzerland) are thus named (Pl. III. fig. 12). This coinage seems to have been intimately connected with the fiscal organization, though the generally accepted theory that the taxes collected in each place were there and then converted into money is by no means proved. Certain religious establishments also possessed the right of coining in their own name. The close of the Meroving dynasty saw a revival of silver in the *saiga*, which heralded the introduction of the denier. (H) The Anglo-Saxons began with an imitative coinage similar to the Merovingian, viz. gold, *solidi* and *thirds*, and silver *sceattas* (=treasure, Ger. *Schatz*) of about 20 grains troy, and *stycas* (=pieces, Ger. *Stück*), first of silver, then of copper. The gold is rare and confined to the south; only two *solidi* are known, imitations of Honorius, with runic legends on the reverse. The types of the gold *thirds*, as of the coinage in other metals (which does not begin until the 7th century), are derived more or less directly from Roman. Some of the inscribed sceattas bear the name of London in Roman letters; others, in runes, the names of Epa and Peada (who is perhaps the son of Penda), king of Mercia (d. 655). Sceattas with runic inscriptions were also issued in East Anglia towards the end of the 8th century. But the sceatta was superseded by the penny introduced by Offa (757–796). Offa also struck a gold coin, bearing his name and an inscription copied directly from an almost contemporary Arab coin; but this is quite an exceptional issue, represented now by a unique specimen. The styca, which begins *c.* 670, was characteristic of the Northumbrian coinage, lasting, long after the introduction of the penny farther south, down to the Danish invasions of the second half of the 9th century. A series was issued by the archbishops of York. Wigmund (837–854) struck a gold solidus inscribed MVNVS DIVINVM, copied from the solidi of Louis le Debonnaire, and evidently meant for a religious purpose (Pl. III. fig. 11). For the whole question of Anglo-Saxon coins see BRITAIN: *Anglo-Saxon*. (I) The Frisians had a small coinage of gold thirds (imitated from Byzantine), and one with the name of Audulfus also exists (end of the 6th century?). The chief mint was probably Doccum.

We now proceed to the consideration of the coinages of the various countries from the 8th century to modern times. The money of Portugal begins, after the expulsion of the Moors, with Alphonso I. (1112); it is exclusively regal, and not of great interest except as affording indications of the wealth and commercial activity of the state in the early part of the 18th century. The coinage of Spain, after the reconquest from the Moors, is almost without exception regal. The kingdom of Navarre had a coinage from the time of Sancho III. (1000–1035). The series of Castile and Leon begins with Alphonso VI. (1053) with deniers and obols. Aragon first has coins under Sancho Ramirez I. (1063). Gold (imitated from Moorish money) is introduced in the middle of the 12th century. A plentiful coinage was issued after the union of the crowns in 1479. The Spanish dollar of the 17th and 18th centuries was one of the most widely circulating currencies in the West (see Pl. V. fig. 5). The medals of Spain are not important.

Portugal. *Spain.*

In 755 Pippin abolished the gold coinage of his Merovingian predecessors and introduced the silver denier (see Pl. III. fig. 10); the coinage became a royal prerogative once more, and was confined to a few mints. The denier, which at first weighed *c.* 1·28 gramme (19¾ grains), was for centuries the most important of European silver coins. Under Charlemagne the weight was slightly raised; the Caroline monogram appears, and there are other modifications in the types. Charlemagne also issued money from various Italian, German and Spanish mints. He also introduced the obol, and struck gold (chiefly at Italian mints). Among his types must be noted the temple with the inscription XPISTIANA RELIGIO. Louis le Debonnaire (814–840) was the last Carolingian to strike gold. In the 9th century are perceptible the first traces of the movement which led to the extensive feudal coinage. The advent of the house of Capet made no great change in the system, but the feudal issues now become important. The most widespread denier was that of the abbey of St Martin at Tours (*denier tournois*); the royal coinage was known as the *monnaie parisis*. St Louis (1226–1270) effected a great reform late in his reign, making the sou (hitherto a money of account) into a real coin as the *gros* (see Pl. III. fig. 14), and introducing a gold coinage. Henceforward the coinage increases in complexity; in the 14th century it has great artistic merit (see Pl. III. fig. 17). The French medals are far more interesting than the modern coins. The earliest of artistic importance not by Italian artists show nevertheless strong Italian influence (medals of Charles VIII. and Anne of Brittany, of Philibert of Savoy and Margaret of Austria). A series of large medallions of the Valois is attributed to Germain Pilon. The most characteristically French artists are Guillaume Dupré (working 1595–1643) and Jean and Claude Warin (middle and second half of 17th century). The long historical series of Louis XIV. has no artistic value; but that of the Napoleonic period shows great technical ability on the part of artists like Andrieu, in spite of the false classicalism of their designs.

France.

The silver penny was introduced into England by Offa, king of Mercia (757–796), following the lead of Pippin in France (see Pl. III. fig. 13). It soon rose in weight to about 22 grains troy (1·42 gramme), at which it long remained. The types were usually, *obverse* the king's head, or some form of cross or religious symbol; *reverse* some form of cross, religious symbol or ornament. The inscriptions gave the names of the king and of the moneyer, later also the mint. An important gold coin of Offa was imitated from an Arab *dinar* of 774, with the addition of the words OFFA REX. The Mercian coinage ends about 874. The pennies of the kings of Kent extend from 765 to 825; the archbishops of Canterbury went on striking to the beginning of the 10th century. The East Anglian regal series extends to 890; the memorial coinage of St Edmund circulated largely in East Anglia in the 9th century. The penny appears in Northumbria with the Dane Halfdan (875–877) and continues to the middle of the next century. A coinage of "St Peter" pennies was issued from York *c.* 920–940. The coinage of Wessex begins with Ecgbert, probably *c.* 825, when he got possession of the mint at Canterbury (see Pl. III. fig. 15 with the name of London). The coinage marks the gradual growth of Wessex until England is united under Edgar (957–975). There is henceforward for a long time no change of great importance in the coinage, which continued to consist of pennies, with rare halfpennies (the pennies were usually cut into halves and quarters along the lines of the cross to make small change). During the reign of Stephen the monotony is relieved by a few issues by barons like Robert, earl of Gloucester. The number of mints is much reduced by the time of Henry III., and the moneyers cease

England.

to sign the coins in Edward I.'s reign. Henry III. made an abortive attempt to introduce a gold coinage, which was successfully established by Edward III. in 1343, with the gold florin, and in 1344 with the gold noble (see Pl. III. fig. 20). (The obverse type of the noble, the king in a ship, is generally thought to refer to the victory of Sluys in 1340.) He also introduced the silver groat (4d.) and half-groat. The English coinage, both gold and silver, was now of such high quality and reputation that it (especially the silver sterling) was largely exported and imitated, chiefly in the Low Countries. The gold coinage of Edward III. is perhaps the most successful, from an artistic point of view, in the English series. Subsequent developments of the coinage now become very complicated. Edward IV. distinguished his noble by a rose on the obverse and a sun on the reverse, and introduced a new gold coin, the angel. The Tudor period is distinguished by the splendour, variety and size of the coins; Henry VII. introduced the sovereign of 20s. (240 grains) and the shilling, and on his coins the first serious attempt at portraiture is found (see Pl. III. fig. 21). Under Henry VIII. the quality of the silver money declines, being not effectually restored until the reign of Elizabeth, when an unsuccessful attempt was made to introduce a copper coinage. Private tokens came into use, but the official copper coinage does not begin until the next reign. The use of the mill, as distinct from the hammer, was begun in 1562, but it took just a century to oust the old-fashioned method. In 1613 John, Lord Harrington, obtained a patent for the issue of copper farthings, and private tradesmen's tokens were prohibited. The gold sovereign of James I., from its inscription (FACIAM EOS IN GENTEM VNAM) and the fact that it was meant to circulate on both sides of the Border, was known as the unite. The coinage of Charles I. presents great varieties owing to the civil war. The best workmanship is seen on the milled coins issued by Nicolas Briot. But the majority of the money was still hammered. The scarcity of gold in the royal treasury during the troubles induced the king to coin twenty- and ten-shilling pieces of silver, in addition to the crowns and smaller denominations. Gold three-pound pieces, or triple-unites, however, were issued from the Oxford mint. One of the most remarkable of his pieces is a crown struck at Oxford by Rawlins. It bears on the obverse the king on horseback, with a representation of the town beneath the horse, and on the reverse the heads of the "Oxford Declaration." The so-called "Juxon medal," given by Charles to Bishop Juxon on the scaffold, is really a pattern-piece by Rawlins (see Pl. V. fig. 1). Of equal interest are the siege-pieces of many castles famous in the annals of those days. They are mostly of silver, often mere pieces of plate with a stamp; but Colchester and Pontefract issued gold. The coinage of the Commonwealth is of a plainness proper to the principles of those who sanctioned it. The great Protector, however, caused money to be designed of his own bearing his head. It is not certain that this was ever sent forth, and it is therefore put in the class of patterns. Simon, the chief of English medallists, designed the coins, which are unequalled in the whole series for the vigour of the portrait (a worthy presentment of the head of Cromwell) and the beauty and fitness of every portion of the work. The finest coin produced under Charles II., and technically the best executed piece in the whole English series, is the "Petition Crown" (see Pl. V. fig. 2), a pattern by Simon, to which, however—probably for political reasons—the work of Jan Roettier was preferred. Maundy money was first struck in this reign, and the name guinea was now applied to the 20s. piece. In 1672 a true copper coinage of halfpence and farthings was introduced. Henceforward there is a decline in the coinage, although skill is perceived in the portrait of William III., whose grand features could scarcely have failed to stimulate an artist to more than a common effort. Queen Anne's money is also worthy of note, on account of the attempt, on Dean Swift's suggestion, to commemorate current history on the copper coinage, which led to the issue of the famous farthings (see Pl. V. fig. 4). These have been the cause of an extraordinary delusion, to the effect that a very small number (some say three) of these pieces were struck, and that their value is a thousand pounds each, instead of usually some shillings. Worthless casts of genuine farthings, and counters made in imitation of the sixpence of the time, are constantly mistaken for such farthings. After this there is little to remark, except the baseness of the art of the coins under the first three Georges, until the talent of Pistrucci gave a worthier form to the currency. Between 1760 and 1816 hardly any silver or copper money was issued. The gap was filled by the use of Spanish dollars counterstamped, and silver tokens issued by the Banks of England and Ireland, as well as by vast quantities of tokens issued by private persons. In 1816 the new coinage of gold and silver was issued, since when there have been few changes in the British currency.

English Medals.

The English medals are far more interesting for their bearing on events than as works of art. The best are almost all by foreigners, but the fine pieces of the Simons form notable exceptions. The medals of the Tudors are good in style, and show some excellent portraits, in particular those by Trezzo and Stephen H. (generally known as Stephen of Holland). There is one of Mary queen of Scots by Primavera, representing her in middle life, which is perhaps her most characteristic portrait. Elizabeth's are of historical importance, and some of them, as the Armada medals (see Pl. V. fig. 7), have a certain barbaric grandeur, being probably the work of English artists. The richer series of the Stuart period contains some medals of fine style. These include works by Warin, the Simons and the Roettiers, besides the excellent coin engravers Briot and Rawlins. The numerous badges worn by adherents of various parties during the civil war and Commonwealth have a personal and historical interest. The most curious pieces are those popular issues relating to current events, such as the so-called "Popish plot," and a certain interest attaches to medals of the exiled Stuarts. From this time there are no works deserving notice except military and naval medals, the historical interest of which makes some amends for their poverty of design and execution. The English tokens form a curious class. They are of two periods: the earlier, which are almost always of copper, were issued chiefly at the middle of the 17th century and somewhat later; the later, which are mainly of copper, but also sometimes of silver, were struck during the scarcity of the royal coinage in this metal at the end of the 18th century, and during the earlier years of the 19th century. Both were chiefly coined by tradesmen and bear their names. The colonial money of England was until lately unimportant, but now (except in style) it is not unworthy of the wealth and activity of the dependencies. The "Anglo-Gallic" money struck by the English kings for their French dominions forms a peculiar class. It was begun by Henry II., who struck deniers and half-deniers for Aquitaine. Richard I. (whose name is not found on his English coinage) struck for most of the French domains, but no coins are attributed to John or Henry III. Edward I.'s coins are of billon; of Edward II. there are none. Gold was introduced before 1337, and there are fine series of gold, silver, and billon of Edward III. (see Pl. III. fig. 19) and the Black Prince. Henry, earl of Lancaster, struck silver at Bergerac (1345–1361). The succeeding kings down to Henry VI. (first reign) all issued Anglo-Gallic coins. There was a temporary revival under Henry VIII. at Tournay (1513–1519). The whole series, with the exception of the Calais coinage, is French in character.

Scotland.

The coinage of Scotland is allied to that of England, although generally ruder; but it seems to have been more influenced in the early period from England, and towards its close from France. The oldest pieces are silver pennies or sterlings, resembling the contemporary English money of the reign of David I. (1124–1153). David II. after 1357 introduced a gold coinage. In the 15th and 16th centuries there is an important coinage, both in gold and silver, not the least interesting pieces being the fine bonnet-piece of James V., and the various issues of Queen Mary, many of which bear her portrait. The indifferent execution of the coins of Mary's reign is traceable to the disturbed state of the kingdom. The Scottish coinage came to an end in 1709.

Wales.

Wales has never had a coinage of its own, properly speaking. A unique penny attributed with good reason to Howel the Good, a contemporary of Edmund (died *c.* 950), was perhaps struck at Chester. Various English kings struck coins at Welsh mints such as Rhuddlan, Pembroke.

The money of Ireland is more scanty and of less importance than that of Scotland. The pieces most worthy of notice are the silver pennies of the early Danish kings, the earliest being that of Sihtric III. (989–1029), copied from contemporary English pennies. The Anglo-Irish coinage begins in 1177, when John as lord of Ireland received the right of coinage. A copper coinage was introduced as early as the reign of Henry VI. The quality of the Irish coinage was exceedingly poor in the 16th century, especially under Elizabeth. Between 1642 and 1647 various kinds of money of necessity were issued, including the only gold Irish coin, the Inchiquin pistole. After his expulsion from England James II. issued enormous quantities of coins of necessity made of gunmetal or pewter. The latest Irish coins were the penny and halfpenny of 1822.

Ireland.

The Isle of Man had a regular copper coinage, beginning in 1709 with pence and halfpence under the Derby family, continued by James, duke of Athol (issue of 1758), and by the English sovereigns from 1786 to 1864. The badge of the island is the three-legged symbol, with the motto *Quocunque jeceris stabit.*

Isle of Man.

Belgium occupies the next place in our arrangement. Its coinage, which, except for the few mints operating under the Merovingians and Carolingians, does not begin until the 11th century, comprises many pieces struck by foreign rulers, and has little of an independent character in either the regal or the seignorial class. The most important coinages are those of the house of Burgundy and Charles V. and his son, and of the bishops of Liége. In character the coinage of Belgium approximates to the French on the one side, the German on the other. About 1400 the Burgundian school produced a remarkable series of medals representing Roman emperors, of which two (those of Constantine and Heraclius) have come down to us; these form a link between the late Roman medallion and the Italian medal of the Renaissance. The series of Holland is similar in character until the period of the revolt of the provinces. The Dutch dollars of the 16th to the 18th centuries had an immense circulation (see Pl. V. fig. 3). Among the early Dutch medallists must be mentioned Stephen H., generally without reason known as Stephen of Holland (working 1558–1572), whose portraits show great charm. The Dutch historical medals are of great interest, more especially those which were struck by the Protestants in commemoration of current events. There is also a remarkable series of bronze medallets or jettons, which form a continuous commentary on history during the 16th and early part of the 17th centuries. Both are interesting as largely illustrating not only local events but also those of the chief European states. Such are the pieces recording the raising of the siege of Leiden, likened to the destruction of Sennacherib's army, the assassination of William the Silent, and the discomfiture of the Armada, affording striking indications of the zeal, the piety and the confidence in the right which built up the great political structure of the Dutch republic. After this time the medals lose much of their interest.

Belgium and Holland.

The money of Switzerland illustrates the varying fortunes of this central state, and the gradual growth of the stronghold of European freedom. First we have the gold money of the Frankish kings, among whose mints Basel, Lausanne, St Maurice-en-Valais and Sitten (Sion) already appear. The silver deniers, which Charlemagne made the coinage of the empire, are issued by fewer mints; the dukes of Swabia began to strike at Zurich in the 10th century, and the empire granted during the 10th and to the 13th century the right of coinage to various ecclesiastical foundations, bishoprics and abbeys. Bern was allowed a mint by the emperor Frederick II. in 1218, and other towns and seigneurs subsequently gained the same right. The demi-bracteate appears about the middle of the 11th century, and about 1125 is superseded by the true bracteate, which lasts until about 1300. The 14th century witnessed the rise of the Swiss confederation, and by degrees the cantons struck their own money. These, together with the coins of some few sees and abbacies, form the bulk of Swiss money of the medieval and modern periods. The separate cantonal coinage, interrupted by the French occupation, was finally suppressed in 1848, when a uniform currency was adopted by the whole republic. The monetary systems of the cantonal and ecclesiastical mints were extremely complicated. This was partly due to the variety of coins, partly to the debasement practised by the ecclesiastical mints. Geneva had a peculiar system of her own.

Switzerland.

Italy, with Sicily, has peculiar features. Here the barbaric coinages were mixed with the Byzantine issues which marked the recovery of the Eastern empire, and left a lasting influence in the north at Venice, and in the south at Beneventum. Later the Arab conquest left its mark in the curious Oriental coinages of the Normans of Sicily and the emperor Frederick II., mixed after his fashion with Latin coinage. The earliest money is that of the barbarians, Ostrogoths and Lombards, and local Byzantine issues in Sicily. This is followed by the deniers of Charlemagne and his successors, supplanted by the gold currencies of the Normans and Frederick II. The age of the free cities is marked by the great coinages of Florence, Venice and Genoa, while the Angevin and Aragonese princes coined in the south, and the popes began to issue a regular currency of their own at Rome. The Italian princes of the next period coined in Savoy, and at Florence, Modena, Mantua and other cities, while Rome and the foreign rulers of the south continued their mintages, Venice and Genoa of the republics alone surviving. The Italian monetary systems have already been touched on in the introductory notice. For art the series is invaluable. First in Italy the revival influenced the coins, and in them every step of advance found its record. The Italian medals are without rivals in the works of modern times.

Modern Italy and Sicily.

Following the geographical order which is best suited to the Italian coinage, we first notice the money of Savoy, which is inferior in art to that of the rest of the country. It begins with Umberto II. (1080); in 1720 the dukes became kings of Sardinia and their coinage merged eventually in 1861 in that of the kingdom of Italy. Genoa is the first of the great republics. She obtained the right of coinage from Conrad II. in 1139, and struck gold coins from the time of the general origin of civic coinage in that metal; these are ducats and their divisions, and after a time their multiples also. In the 17th century there are very large silver pieces. In the money of Mantua there are fine coins of Gianfrancesco III. (1484–1519) and Vincenzo II. (1627–1628); these last splendid examples of the late Renaissance, large pieces of gold and silver; the portrait is fine, and the hound on the reverse a powerful design. The vicissitudes of the story of Milan find their record in no less than ten groups of money—Lombard regal coins, Carolingian deniers, money of the republic (1160–1310), next of the Visconti family (1329–1447), succeeded by the republic (1447–1450) and by the Sforza line, next of Louis XII. and Francis I. of France, of the restored Sforza, of Charles V. the Spanish right and his successors of Spain, and lastly of Austria. There are extremely fine coins of the 15th century, showing great beauty in their portraits (see Pl. III. fig. 22). The money of Florence is disappointing in its art. The Athens of the middle ages had the same reason as her prototype to preserve as faithfully as might be the types and aspect of her most famous coin, the gold florin (see Pl. III. fig. 8), and thus those who expect to see in the series the story of Italian art will be much disappointed. The silver florin was first struck in 1189. It is heavier than the denier, weighing about 27 grains, and bears the lily of Florence and the bust of St John the Baptist. These are thenceforward the leading types, the flower never changing, but the representation of the saint being varied. On the gold florin, first issued in 1252, the Baptist is represented standing, while in the contemporary silver florins he is seated. In the 14th century the arms of the moneyer appear in the field, two such officers have had the right of striking yearly, each for six months. The coins of the church from 1532, in spite of their new types, are not a fine series; the best are those of Alessandro, designed by Cellini.

Venice as a mint even surpasses Florence in conservatism, and the early style being distinctly Byzantine, this is the earliest striking in a great artistic city. We find Venice as an important mint issuing Carolingian deniers, but the doges begin to cease placing their own names on their currency, in the 12th century

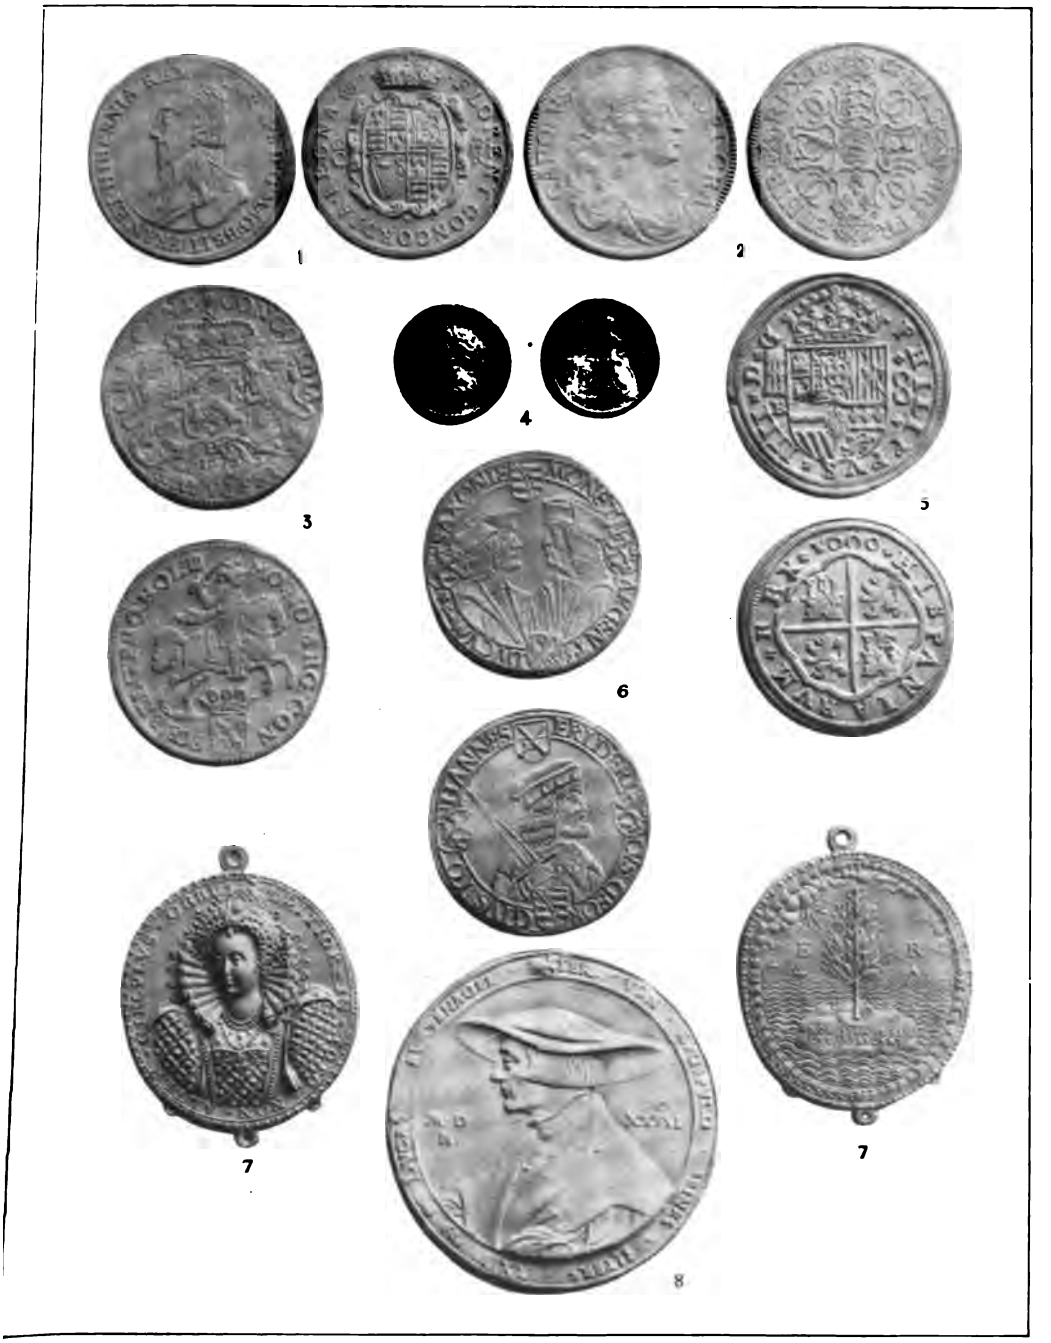
Roman and Medieval Coins.

Oriental Coins.



Modern Coins and Medals.

Italian Medals.

The most famous silver coin, the matapan, was first struck in the brilliant time of Enrico Dandolo (1192–1205). This coin is a grossus weighing about 33 grains, with on the obverse St Mark giving the standard or gonfalon to the doge, both figures standing, and on the reverse the seated figure of the Saviour. The famous Venetian zecchino or sequin (see Pl. III. fig. 9), the rival of the florin of Florence, appears to have been first issued under Giovanni Dandolo (1284). On the obverse St Mark gives the gonfalon to the kneeling doge, and on the reverse is a standing figure of the Saviour within an oval nimbus. Niccolo Trono (1471–1473) introduces his portrait on most of his coins, but this custom is not continued. By the latest part of the 15th century large silver coins appear. The archaic style changes in the beginning of the 16th century, but there is no later movement. The large silver pieces increase in size, and large gold is also struck; the last doge, Ludovico Manin (1788–1797), issued the 100-sequin piece in gold, a monstrous coin, worth over £40. The doges of Venice from 1521 to 1797 issued a peculiar silver token or medallet, the osella, five of which they annually presented to every member of the Great Council. They replaced the wild ducks (*uccelle*) which it had been customary to present at Christmas. Two dogaressas struck similar medallets. Their types are usually allegorical; some are commemorative.

The series of the coins of Rome is rather of historical than of artistic merit. The popes begin to strike money with Adrian I. (A.D. 772–795), whose deniers are in a Byzantino-Lombard style. The coins of his successors, with few exceptions, down to Leo IX. (1049) associate the names of pope and emperor. From Leo IX. to Urban V. (1362) there is no papal coinage at Rome. The Roman senate strikes from 1188 onwards. We then see on the silver the style of the senate and Roman people, and ROMA CAPUT MUNDI. Some coins have the figures of St Paul and St Peter, others Rome seated and a lion. Charles of Anjou, king of Sicily (1263–1285), strikes as a senator, and Cola di Rienzo (1347–1348) as tribune. The gold ducat of about 1300 imitates the types of the Venetian sequin. St Peter here gives the gonfalon to a kneeling senator. The arms of the moneying senator next appear in the field. The papal coinage is resumed at Avignon; and Urban V., on his return to Rome, takes the sole right of the mint. From Martin V. (1417) to Pius IX. there is a continuous papal coinage. The later coins, though they have an interest from their bearing on the history of art, are disappointing in style. There is indeed a silver coin of Julius II. struck at Bologna and attributed to Francia, with a very fine portrait. We have beautiful gold coins of Giovanni Bentivoglio (see Pl. III. fig. 23), lord of Bologna, who employed Francia at his mint, and we know that the artist remained at his post after Julius II. had taken the city. There are also pieces of Clement VII. by Cellini, vigorous in design but careless in execution. There were papal mints at Ancona, Bologna, Piacenza, Parma, Ferrara and other Italian towns; and coins were also struck at Avignon from 1342 to 1700. The papal portraits are highly characteristic and interesting. It is, however, in the fine series of papal medals that we find a worthier artistic record.

Papal Coins.

The coinage of Sicily, afterwards that of the Two Sicilies, or Naples and Sicily, begins with the Normans. Theirs is a curiously mixed series. It begins with Robert Guiscard as duke of Apulia (1075) and Roger I. of Sicily (1072). The gold money is almost wholly Arabic, though Roger II. struck the Latin ducat, the earliest of its class; the silver is Arabic, except the great Latin scyphati of Roger II. with Roger III.; the copper is both Latin and Arabic. The gold series (*Augustales*) of the emperor Frederick II. (1198–1250) shows the first sentiment of reviving classical art, its work being far in advance of the age. These are Latin coins; he also struck small Arabic pieces in gold. Under Conrad and Manfred there is an insignificant coinage, copper only, but with Charles I. of Anjou (1266–1285) the gold money in purely medieval style is very beautiful, quite equal to that of his brother, St Louis of France. After this time there is a great issue of *gigliati*, silver coins with, for reverse, a cross fleurdelisée cantoned with fleurs-de-lis. These coins acquired a great reputation in the Levant, and were even struck by the emirs of Asia Minor. With Alphonso, the founder of the Aragonese line, we note the old style of the coins, which are in singular contrast to his fine medals. Good portraiture begins on the money of Ferdinand I., his successor. The later coinage is interesting only for its illustration of the varying fortunes of the Two Sicilies. The curious early gold coinage of the Lombard dukes of Beneventum, which follows the Byzantine type, has been mentioned under the transitional series; the dukes and princes of Beneventum and the princes of Salerno continued to issue coins (sometimes gold, usually deniers) down to the middle of the 11th century.

Sicily.

Italian medals (Pl. VI.) are next in merit to the works of the Greek die-engravers. Certain small pieces of a medallic character were made in Italy, at Padua, as early as the end of the 14th century, and there existed also large cast and chased pieces representing various Roman emperors (perhaps Burgundian work of the 14th century), which influenced the beginnings of the true medal. This began, and also reached its highest excellence, with Vittore Pisano (Pisanello), the Veronese painter, whose medals date from 1438 (or earlier) to 1449. The finest work of Italian medallists is seen in the cast medals of the 15th and early 16th century; with the increase of classicism in the 16th the style declines rapidly. The earlier medals are independent works, marked by simple vigorous truthfulness. The designs are skilful and the portraits strongly characteristic; the expression of character and *virtù* takes precedence over ideal beauty, especially in the work of the Florentine school. As the art became popular the execution of medals passed into the hands of inferior artists, and by degrees striking became usual for the smaller pieces; at the same time, a slavish imitation of the classical style weakened or destroyed originality and stamped the works with the feebleness of copies. The great medallists of the first age are Pisano, Matteo de' Pasti, Enzola, Boldù, Sperandio, Guazzalotti, Bertoldo, Gambello, Niccolò Fiorentino, Lysippus, Candida, Caradosso. Some of the most beautiful medals, however, are by unknown artists (Pl. VI. fig. 2). In the 16th century must be mentioned Pomedello, Benvenuto Cellini, Leone Leoni, Giovanni Cavino "the Paduan," Pastorino of Siena, Giacomo da Trezzo, Pietro Paolo Galeotto, called Romano, and Antonio Abondio. Incomparably the finest of all Italian medals are the works of Pisano, particularly the medals of Alphonso the Magnanimous, with the reverses of the boar-hunt and the eagle and lesser birds of prey, those of Sigismondo Malatesta, his brother surnamed Novello (see Pl. VI. fig. 1), Leonello d'Este, John VIII. (Palaeologus), Nicolò Piccinino, Inigo d'Avalos (marquis of Pescara), Ludovico and Cecilia Gonzaga of the same family, the great humanists Vittorino da Feltre and Pier Candido Decembrio. Pisano is great in portraiture, great in composition and design, and marvellously skilful in depicting animals. He alone represents the moral qualities of his subject in their highest expression and even capability. That he has high ideal power is seen at once if we compare with his portrait Pasti's inferior though powerful head of Sigismondo Malatesta. Pasti's medal of Isotta, wife of Sigismondo, is also noteworthy, likewise the medal by the otherwise unknown Constantius of Mahomet II., the conqueror of Constantinople—interesting works, but lacking Pisano's technical skill and inspiration. An artist of great power is Sperandio of Mantua; but his productions lack the finish necessary to good medallic work, his drawing and composition are careless, and his realism too often becomes brutal or vulgar. The work of Niccolò Fiorentino and of his pupils is astonishingly vigorous in portraiture, but they lack the power of designing reverses (see Pl. VI. fig. 3). In the later age Cavino executed a remarkable series of imitations of Roman sestertii, which have been frequently mistaken for originals. In art these Italian works frequently surpass the originals in spite of a degree of weakness inseparable from copies. A comparison of the Italian with the Roman pieces is thus most instructive. The works of Pastorino of Siena (who had an extraordinary facility in graceful portraiture) are especially charming (see Pl. VI. fig. 4). Historically the Italian

Italian Medals.

medals supply the defects of the coinages of Florence and Rome, and in a less degree of Venice. The papal series is invaluable as a continuous chronicle, although artistically, after the earliest period, it is monotonous.

Germany.

The money of Germany is, like that of Italy, far too various for it to be possible here to do more than sketch some of its main features. In the Frankish period mints were in operation at cities in the west, such as Mainz, Strassburg, Spires, Treves, Worms, Cologne. Pippin issued denarii from Strassburg and Mainz; under his successors denarii and obols were also coined at other mints, as Bonn, Cologne, Spires, Treves. After the reign of Louis the Child (910–911) the Carolingian system was continued until the advent of the Swabians with Conrad III. (1138–1152). In the succeeding period, which ends with the introduction of the grossus and the gold coinage under Louis of Bavaria (1314–1347), the uniformity of the currency disappears. In the west (in Lotharingia, including the southern Low Countries, the Moselle and Rhine-lands, in Frisia, Bavaria, parts of Franconia and Swabia) the denier continues; but elsewhere we find the bracteate. The right of coinage is acquired in an increasing measure by the feudatories of the empire. These local coinages entirely dominated the system, so that even the imperial coinage is not uniform, but consists of denarii in the west and bracteates in the east. The earliest imperial bracteate is of Frederick I.; the large fine bracteates last but a short time, reaching their acme about the end of the 12th century (see Pl. III. fig. 18). The fine pieces of the bishops of Halberstadt and the abbesses of Quedlinburg are characteristic of this class. With the introduction of the regular gold coinage (chiefly florins) and the grossus in the 14th century, Germany enters on the modern period. From the 16th century the thaler (so called from Joachimsthal in Bohemia, where the counts of Schlick first struck the coin in 1518) dominates the silver currency (see Pl. V. fig. 6). The thalers and other large coins of the 16th and 17th centuries are often good and always vigorous in workmanship. By the convention of 1857 the thaler was recognized as the unit for Berlin and the north, the florin of 100 kreuzers for Austria, the florin of 60 kr. for the south. The present system, based on the gold reichsmark of 100 pfennigs, was established all over the German empire in 1876. Of particular currencies in Germany we must be content with the bare mention of some of the more important. Among the great rulers we note the dukes of Bavaria, who coined from Henry I. (948–955), and issued fine thalers in the 16th century. The Counts Palatine of the Rhine coined from 1294, their mints being at Heidelberg, Frankfort, &c. The Saxon coinage begins with Duke Bernard (973) and includes a large series of bracteates and thalers, the latter being especially famous. The Brunswick coinage begins in the 11th century; besides its bracteates we note the large mining-thalers of the 16th and 17th centuries (up to ten-thaler pieces). There are good bracteates and thalers of the margraves of Brandenburg; from 1701 they coin as kings of Prussia. In Austria there is a ducal coinage from the 12th century; the gold florin of Florentine character appears under Albert II. (1330–1358). The marriage-coin of Maximilian and Maria of Burgundy (a 16th-century reproduction of a medal made by the Italian Candida in 1479) is a striking piece, and in the 16th century there is a large series of fine thalers. The thalers of Maria Theresa had an enormous circulation among savage races, and those of the date 1780 were recoined for the purposes of the Abysinian War of 1867. In Bohemia there is a ducal coinage from the early 10th century to 1192; then came the regal bracteates. Wenceslas II. (1278–1305) struck the first German grossus at Prague (see Pl. III. fig. 16). The gold florin appears under John of Luxemburg (1310–1347). In Hungary the regal coinage begins with St Stephen (1000). Charles I. of Anjou (1310–1342) introduced the florin and grossus. Of historical interest is the money of John Hunyady as regent (1441–1452). The abundance of gold about this time and later shows the metallic wealth of the land. The same is true of the rich gold coinage of the Transylvanian princes in the 16th and 17th centuries. Of ecclesiastical coinages the most important are at Münster, Cologne, Mainz, Treves, Augsburg, Magdeburg, Spires, Würzburg, Salzburg. The Cologne series of coins is almost continuous from the Frankish period; the archbishops first received the right from Otto I., Bruno (953–965) being the first to coin; from Pilgrim (1021–1036) the series, issued at various mints in the Rhineland, is very complete down to 1802. The series of Treves ranges from Theodoric I. (965–975) to Clement Wenceslas (1794). The archiepiscopal coinage of Mainz begins with Willigis (975) and lasts until 1802; its mints included Erfurt, Bingen and many other places. The Salzburg series (beginning 996) is remarkable for its fine thalers (especially of Mathias Lang, 1519–1540). The patriarchs of Aquileia, who may be mentioned here, acquired the right of coinage from Louis II. in the 9th century, but the first who can be identified on the coins is Godfrey (1184); thence onwards there is an interesting series of denarii and smaller coins down to the early 15th century. Of cities with large coinages it is sufficient to mention Aix-la-Chapelle (from the time of Frederick I. to 1795), Frankfort-on-the-Main, Hamburg (with great gold pieces of the 16th and 17th centuries, up to 10 ducats) and Nuremberg. Lastly, we may mention the coins of the grand-masters of the Teutonic Order, issued in Prussia from 1351 to 1512.

German medals perhaps rank next to Italian, although they lack the higher artistic qualities. They are the work of craftsmen —jewellers, wood-carvers, workers in hone-stone— and show great facility of minute workmanship and chasing and decorative design (the last is especially clear in the heraldic reverses); the faults of these qualities are to some extent redeemed by the native German vigour and directness of the portraiture. The original models from which the medals were cast were in many cases made in hone-stone or box-wood, which did not, like the favourite wax of the Italian artists, give much scope for subtlety. The chief centres of the art were Nuremberg and Augsburg. Many medals have been attributed to Albrecht Dürer; whether he did more than design them is uncertain. Among other medallists may be mentioned Hans Schwarz (working 1516–1527), Ludwig Krug, Friedrich Hagenauer (working 1525–1546, see Pl. V. fig. 8), Peter Flötner (*c.* 1538, although it is doubtful whether this artist, whose plaquettes are famous, made any of the portrait-medals ascribed to him), Mattes Gebel, Hans Reinhardt the Elder, &c. Some other good artists are known only by their initials, or quite unidentified. After the middle of the 16th century the art declines, although we still have skilful artists like Valentin Maler (1568–1593). In this later period striking gradually supersedes casting.

Poland.

The earliest Polish coins are of the 10th century; the types are copied from English, German and Byzantine sources. In the 12th and 13th centuries there is a bracteate coinage. The grossus was introduced about 1300. In later times the town of Danzig, while belonging to the kingdom, issued remarkable gold pieces, thalers, &c., down to its restoration to Prussia (1793).

Scandinavia.

The origin of the coinage of the Scandinavian states: Norway, Denmark and Sweden, is clearly English and due to the Danish conquest of England. The runic alphabet is employed, though not by any means exclusively, on many of the early coins of Denmark and Norway. The Norwegian series begins with Hakon Jarl (989–996), who copies the pennies of Æthelred II. In the second half of the 11th century begins a coinage of small, thin pennies, which develop into bracteates. Magnus IV. (1263–1280) restores the coinage, more or less imitating the English sterlings of the time. Norway and Denmark were united under Eric of Pomerania in 1396. The money of Denmark begins with pennies of Sweyn (985–1014) which are copied from the coinage of Æthelred II.; the coins of Canute the Great (1014–1035) and Hardicanute (1036–1042) are mainly English in character. With Magnus (1042–1047) other influences, especially Byzantine, appear and the latter is very strong under Sweyn Æstrithson (1047–1076). Bracteates come in in the second half of the 12th century. The coinage is very difficult of classification until the time of Eric of Pomerania (1396). There are important episcopal coinages at Roskilde and Lund in the 12th and 13th centuries. Sweden has very few early coins, beginning with imitations by Olaf Skötkonung (995–) of English pennies and showing the usual bracteate coinage. The money was restored by Albert of Mecklenburg (1363–1387). The thaler is introduced by Sten Sture the younger (1512–1520). The money of Gustavus Adolphus is historically interesting. Under Charles XII. there is highly curious money of necessity. The daler is struck as a small copper coin, sometimes plated. The types include

the Roman divinities. At the same time and later there was a large issue of enormous plates of copper, stamped with their full value in silver money as a countermark.

Russia.

The earliest Russian coinage begins with the princes of Kiev as early as the end of the 10th century; it shows strong Byzantine influence. The grand princes from the early 15th century struck curious little silver pieces. The coinage was modernized by Peter the Great, who introduced a regular gold coinage. The large silver and copper coins of his successors are very plentiful. Nicholas I. (1825–1855) introduced a platinum coinage of about two-fifths the value of gold.

Balkan States.

The Christian coinages of the northern Balkan States are of great interest. They are chiefly silver grossi, showing a mixture of Byzantine and Venetian influences. The Bulgarians had a regular silver coinage from Asien I. (1186–1196) to John Sismana (1371–1395). The Servian coinage lasts from Vladislas I. (1234–1240) to the middle of the 15th century. There is also a coinage of the Bans of Bosnia (late 13th to 15th century). The modern coinage of the Balkan States is of interest only as a revival. The independent city of Ragusa is remarkable for the bold style of its early copper (13th century, inspired by Roman models of the 4th century) and the richness and variety of its later issues.

Latin East.

There is a most interesting class of coins struck during the middle ages within the limits of the present Turkish empire, the money of the crusaders and other Latin princes of the East. The multitude of states thus designated have been classed by Schlumberger, the authority on the subject, in the following order, the chief divisions of which are here given: First group, principalities of Syria and Palestine, counts of Edessa, princes of Antioch, kings of Jerusalem, counts of Tripoli, fiefs of Jerusalem, crusaders who struck imitations of Arab coins, kings of Cyprus, lords of Rhodes, grand-masters of the order of St John at Rhodes, to which may be added the later grand-masters at Malta; second group, Latin emperors of Constantinople, Frankish princes and lords of Greece and the Archipelago whose power was due to the crusade of 1204, such as the princes of Achaia, the dukes of Athens, Neapolitan kings who struck money for their Eastern possessions, Latin lords of the Archipelago, the Genoese at Chios, the Gattilusi at Mytilene, the Genoese colonies, the Venetian colonies, the Turkoman emirs of western Asia Minor who struck Latin coins. The most important currencies are the billon and copper of the princes of Antioch (Bohemund I., 1098, to Bohemund IV., 1201–1232) and the kings of Jerusalem (Baldwin II., 1118, to Conrad, 1243), the silver and copper of the counts of Tripoli (12th and 13th centuries) and the gold imitations of Arab dīnārs, the currency in that metal of the crusaders of Palestine. These *Bisantii Sarracenati*, or Saracen bezants, are at first imitations of Fatimite dīnārs, known to have been struck by Venetian moneyers at Acre, and probably at Tyre and Tripoli also. After these coins had been current for nearly a century and a half they were forbidden on account of their Mahommedan aspect by Pope Innocent IV. The Venetians then issued gold and silver coins with the same aspect but with Christian inscriptions. The kings of Cyprus issued a really good coinage in the three metals and in billon from Guy de Lusignan (1192) to Catherina Cornaro; from 1489 to 1571 the Venetians issued coins for the island. The coinage of the order of St John begins on the conquest of the island of Rhodes (1309) and the suppression of the Templars; the earliest coins known are of Foulques de Villaret (1305–1319), and the last of the Rhodian series are of Villiers de l'Isle-Adam, the gallant defender of the island who was forced to capitulate to the Turks and sail for a new home in 1522. The coinage is of fine gold, silver, billon and copper. On the establishment of the order at Malta in 1530 it is resumed there till the capture of the island by the French at the close of the 18th century; it has little interest except as showing the wealth of the order. The other currencies of the crusaders, notwithstanding their great historical interest, are far less remarkable numismatically; the influence of the *denier tournois* is, however, noticeable on the coinage of the princes of Achaia (1245–1364), and the dukes of Athens (1225–1308).

Of the money of America little need be said here. Neither the coinages of the Spanish and Portuguese dependencies, and of the states which succeeded them, nor those of the English colonies and of the United States, present much that is worthy of note. In style they all resemble those of the parent countries, but, originating in the decline of art, they are inferior in style and work. They are most remarkable in the south for the abundance of gold and silver. The chief coin is the dollar. Some coins are of historical interest, and there are a few rarities, such as the colonial money of Lord Baltimore struck for Maryland, the pine-tree coins of Massachusetts, and the hog-money of Bermuda.

IV.—Oriental Coins

Oriental coins may be best classed as ancient Persian, Arab, modern Persian and Afghan, Indian and Chinese, and other issues of the far East. The first place is held by the money of the old Persian empire, the Parthians and the Sassanians. The conquests of the Arabs introduce a new currency, carried on by the Moslem inheritors of their empire. The modern Persian and Afghan money, though of Arab origin, is distinguished by the use of the Persian language with Arabic. The Indian currencies, though Greek, Sanskrit, Arab and Persian in their inscriptions, must be grouped together on account of their mutual dependence. They rise with the Bactrian kings, whose Greek types are gradually debased by the Indo-Scythians and Guptas; these are followed by a group of currencies with Sanskrit legends; next follow the money of Arab conquerors and the great series of the Pathans of Delhi and subsidiary dynasties, with Arabic inscriptions; the main series is continued in the currency of the Moguls, who largely use Persian, and the last series is closed by local currencies mainly with Sanskrit or Arabic legends. The Chinese coinages form the source and centre of the group of the far East, which, however, includes certain exceptional issues. The order throughout is historical, each empire or kingdom being followed by the smaller states into which it broke up, and then by the larger ones which were formed by the union of these fragments.

The Persian coinage was probably originated by Darius I. about the time that he organized the empire in satrapies. The regular taxation thus introduced made a uniform coinage necessary. Avoiding the complex gold system of Croesus, which was intended to accommodate the Greek cities in commercial relation with Lydia, Darius chose two weights, the gold shekel of 8·4 grammes and the silver drachm of 5·58 grammes. One gold piece was equal to twenty silver. The gold coin was called the daric, the silver the siglos. The metal was very pure, especially that of the daric. Thus not only were the Lydian gold and silver coins of inferior weight thrown out of circulation, but the Persian gold, from its purity, became dominant, and was the chief gold currency of the ancient world so long as the empire lasted. The issuing of gold was a royal prerogative. Silver money was coined not only by the king but in the provinces by satraps, who used local types, and by tributary states. The following classes must be distinguished: (1) regal, (2) satrapal, (3) of tributary states. The art of Persian coins varies according to the locality, from the beautiful purely Greek work of the west coast of Asia Minor to the more formal style of Cilicia and the thoroughly hieratic stiffness of Phoenicia and Persia.

The regal coinage is of darics (Pl. IV. fig. 2) and subdivisions in gold and of sigli and subdivisions in silver. The obverse type is the king as an archer, the reverse an irregular oblong incuse. The darics show differences of style, and must extend through the whole period of the empire. The sigli no doubt run parallel with them. Both these denominations are uninscribed.

The satrapal coinage is very important and interesting. It belongs mainly to Cilicia. The most remarkable series is that with a bearded head wearing a tiara, with various reverses, struck apparently at Colophon, Cyzicus and Lampsacus, and in one instance bearing the name of the satrap Pharnabazus, but usually the word "king" in Greek. The coin of Colophon shows a splendid portrait, one of the finest instances of Ionian work. It probably represents Pharnabazus (see Pl. IV. fig. 1). Of other satrapal issues those of Datames, of Tiribazus and Cilician issues, struck at Tarsus, are specially noteworthy. Their inscriptions are Aramaic.

The coinages of the tributary states have been in part noticed in their geographical order.

After the fall of the empire, the generals and satraps such as Mazaeus who governed Alexander's newly-acquired dominions issued coins from various mints, especially Babylon. The gold coins were double darics of the same types as their single predecessors. The silver coins were mainly modelled on the coins which Mazaeus had previously issued in Cilicia with the types of Baal-Taro and Lion. Some of them may have been issued as far East as Bactria and North West India. These are followed by the first native coinage, inscribed below under India.

The conquest of Alexander did not wholly destroy the independence of Persia. Within less than a century the warlike Parthians, once subjects of Persia, revolted (249–248 B.C.) against the Seleucids and formed a kingdom which speedily became an empire, ultimately the one successful rival of Rome. Their money is Greek in standard and inscriptions, as well as in the origin of types. The coins are silver, following the Attic weight, the chief piece being the drachm, though the tetradrachm is not infrequent; there are also bronze coins, but none in gold are known. The drachm has the head of the king on the obverse, diademed or with a regal head-dress, and on the reverse the founder Arsaces seated, holding a strung bow, the later tetradrachms varying this uniformity. Every king is styled Arsaces, to which many of the later sovereigns add their proper names. The inscriptions are usually long, reaching a climax in such as ΒΑΣΙΛΕΩΣ ΒΑΣΙΛΕΩΝ ΜΕΓΑΛΟΥ ΑΡΣΑΚΟΥ ΔΙΚΑΙΟΥ ΕΠΙΦΑΝΟΥΣ ΘΕΟΥ ΕΥΠΑΤΟΡΟΣ ΦΙΛΕΛΛΗΝΟΣ of Mithradates III. (57–54 B.C.; see Pl. IV. fig. 4), where we see the double influence of Persian and Seleucid styles and the desire to conciliate the Greek cities. Very noticeable are the coins which bear the portraits of Phraataces (3 B.C.–A.D. 4) and his mother, the Italian slave Musa, with the title queen (ΘΕΑΣ ΟΥΡΑΝΙΑΣ ΜΟΥΣΗΣ ΒΑΣΙΛΙΣΣΗΣ). The last of the Parthian coins are those attributed to Artavasdes (*c.* A.D. 227). *Parthians.*

The coinage of Persis, beginning in the second half of the 3rd century B.C., consists of silver tetradrachms and drachms; the earliest have fine portraits of the kings, but the style rapidly degenerates. The prevailing reverse type is the Persian fire-altar. *Persis.*

The dynasts of Characene, on the lower Tigris, issued coins (silver, bronze and base metal) from the time of the founder, Hyspaosines (*c.* 124 B.C.), down to the 2nd century A.D. The obverses of the tetradrachms have portraits of the kings; the usual reverse type is a seated Heracles. *Characene.*

The Persian line of the Sassanians arose about A.D. 220, and wrested the empire from the Parthians in 226–227, under the leadership of Ardashir or Artaxerxes. This dynasty issued a national and thus Oriental coinage in gold and silver. The denominations follow the Roman system, and there are but two coins, equivalent to the aureus or solidus and the denarius. The obverse has the king's bust, usually wearing a very large and elaborate head-dress, varied with each sovereign, and the reverse the sacred fire-altar (see Pl. IV. fig. 3) ordinarily flanked by the king and a priest. The attachment which Ardashir, the founder, bore to Zoroastrianism established this national reverse type, which endured through the four hundred years of the sovereignty of his line to A.D. 652. The inscriptions are Pahlavi. *Sassanians.*

The Arab coinage forms the most important Oriental group. It has a duration of twelve centuries and a half, and at its widest geographical extension was coined from Morocco to the borders of China. When the Arabs made their great conquests money became a necessity. They first adopted in the East imitations of the current Persian silver pieces of the last Sassanians, but in Syria and Palestine of the Byzantine copper, in Africa of the gold of the same currency. Of these early coins the Sassanian imitations are very curious with Pahlavi inscriptions and shorter ones in Arabic (Cufic). The regular coinage with purely Moslem inscriptions begins with the issue of a silver coin at Basrah, in 40 A.H. (A.D. 660), by the caliph 'Ali; after subsequent efforts thus to replace the Sassanian currency, the orthodox mintage was finally established, in 76 A.H. (A.D. 695), by Abdalmalik. The names of the denominations and the weight of the gold are plainly indicative of Byzantine influence. There were three coins. The dinār of gold (Pl. IV. fig. 6) took its name from the aureus or denarius aureus, of which the solidus must have been held to be the representative, for the weight of the Arab coin (about 4·3 grammes) is clearly derived from the Byzantine gold piece. The dirhem of silver (see Pl. IV. fig. 7) is in name a revival of the Greek drachm; it weighs at most about 3 grammes. The copper piece is the fels, taking its name from the follis of the Greek empire. Commercially the gold easily exchanged, and the silver soon passed as the double of the Carolingian denier. For long these were the only coins issued, except, and this but rarely, half and quarter dinārs. There are properly no types. There was indeed an attempt in the early Byzantino-Arab money to represent the caliph, and in the course of ages we shall observe some deviations from the general practice of Islam, particularly in the coinage of the atābegs and in Mahommedan coinages not of the Arab group, the modern Persian and that of the Moguls of Delhi. The inscriptions are uniformly religious, save in some Tatar coinages and that of the Turks. In general the coins are for the first five centuries of their issue remarkably uniform in fabric and general appearance. They are always flat and generally thin. The whole of both sides of the coins is occupied by inscriptions in the formal Cufic character usually arranged horizontally in the area and in a single or double band around. Towards the fall of the caliphate a new type of coin begins, mainly differing in the greater size of the pieces. There are new multiples of the dinār and ultimately of the dirhem, and the silver pieces frequently have their inscriptions within and around a square, a form also used for gold. The Cufic character becomes highly ornamental, and speedily gives way to the flexuous naskhī of modern writing. The inscriptions are religious, with the addition of the year by the era of the Flight (A.D. 622), the month sometimes being added, and the mint occurs uniformly on silver and copper, but does not appear on the gold until after the fall of the Omayyad dynasty. Subsequently the official name of the caliph occurs. The religious part of the inscriptions is various, the most usual formulae being the profession of the Moslem faith: "There is no deity but God; Mahomet is the apostle of God," to which the Shi'ites or followers of 'Ali in Persia and Africa add "'Ali is the friend of God." The Moorish coins give long formulae and religious citations and ejaculations, and they, like the money of the Pathans of Delhi of the Indian class, have occasionally admonitions urging or suggesting the purer use of wealth. As Arab and other dynasties arose from the dismemberment of the caliphate, the names of kings occur, but for centuries they continued to respect the authority of their religious chief by coining in his name, even in the case of the shadowy Abbāsids of Egypt, adding their own names even when at war with the caliph, as though they were mere provincial governors. After the fall of the caliphate some new denominations came in, chiefly of heavier weight than the dirhem and dinār, but the influence of the commercial states of Italy made the later Egyptian Mamelukes, the Turks and the later Moors adopt the gold sequin. In more modern times the dollar found its way into the Moslem coinage of the states bordering on the Mediterranean. It can be readily seen that Arab coins have no art in the same sense as those of the Greeks. The beautiful inscriptions and the arabesque devices of the pieces of the close of the middle ages have, however, a distinct artistic merit. *Caliphates.*

The Omayyad coins owe their only historical value to the evidence which the silver affords of the extent of the empire at different times. The first separation of that empire dates from the overthrow of this dynasty (which had its capital at Damascus, A.D. 661–750) by the 'Abbāsids (A.D. 750, capital Bagdād) speedily followed by the formation of the rival Omayyad caliphate of the West with its capital at Cordova. The Abbāsid money has the same interest as that which it succeeded, but its information is fuller. Towards the fall of the line (which ended at Bagdād in 1258) it becomes very handsome in the great coins, which are multiples of the dinār (see Pl. IV. fig. 10). The Spanish Omayyads (756–1031) struck silver almost exclusively. Their rise was followed by that of various lesser lines—the Idrisites (788–985, silver) and Aghlabites (800–909, gold chiefly) in western Africa, the Beni Tūlūn (868–905, gold), and, after a short interval, the Ikhshidids (935–969, gold), both of Turkish origin, in Egypt. Meanwhile a new caliphate arose (909) in western Africa which subdued Egypt (969), the Fātimid of the line of 'Ali, and for a while the allegiance of the Moslems was divided between three rival lines, the Omayyads of Spain, the Fātimids of Africa, and the Abbāsids of Bagdād. The Fātimids introduced a new type of dinār, with the inscriptions in concentric circles, and struck little but gold. In the interim the Persians, who had long exercised a growing influence at the court of Bagdād, revived their power in a succession of dynasties which acknowledged the supremacy of the caliphate of Bagdād, but were virtually independent. These were the Tāhirids (820–872), Saffārids (867–903), Sāmānids (874–999), Ziyārids (928–1042), and Buwayhids or Būyids (932–1055), who mostly struck silver, but the last gold also. As the Persians had supplanted the Arabs, so they were in turn forced to give place to the Turks. The Ghaznevids formed a powerful kingdom in Afghanistan (962–1186, gold and silver), and the Seljuks established an empire (gold), which divided into several kingdoms, occupying the best part of the East (1037–1194). Of these dynasties the Seljuks of Rūm or Asia Minor (1077–1300) first struck a modern type of Arab coinage (silver, Pl. IV. fig. 9). *Omayyads. Abbāsids.*

The Seljūk dominions separated into many small states, the central ruled by atābegs or generals (12th–13th cent.), and the similar Turkoman Urtukis (1101–1312). The atābeg money and that of the Turks of the house of Urtuk are mainly large copper pieces bearing on one side a figure borrowed from Greek, Roman, Byzantine and other sources. They form a most remarkable innovation (Pl. IV. fig. 11). In the same age the great but short-lived empire of Khwārizm (Khiva, 1150–1231) arose in the far East. The first caliphate to disappear was that of Spain, which broke up (*c.* 1031) into small dynasties, some claiming the prerogative of the caliphates. They chiefly struck base silver (billon) coins. The Christian kings gradually overthrew most of these lines. In the meantime various Berber families had gained power in western Africa and the Almoravides and the Almohades crossed the straits and restored the Moslem power in Spain. They struck gold money of fine work, and that of the later Muwahhids is remarkable for its size and thinness. At the fall of the Muwahhids the only powerful kingdom remaining was the Arab house of Granada (Nasrids), which, supported by the Berbers of Africa, lingered on until the days of Ferdinand and Isabella (1492). The Fātimite dynasty was supplanted by the Kurdish line of the Ayyubites, the family of Saladin, who from 1169 to 1250 ruled Egypt, Syria and Mesopotamia, with a number of vassal states, were governed by princes of their own family, some by the older lines of the atābeg class which they allowed to survive. In Egypt the Ayyubite coinage is of gold, elsewhere of silver and copper. The caliphate of Bagdād, which latterly was almost limited to that town, though its abundant heavy gold coinage at this very time indicates great wealth, was overthrown by the new power of the Mongols (A.D. 1258), who established a group of empires and kingdoms, comprising the whole

Eastern world eastward of the Euphrates and thence extending northward and reaching into Europe. The most important of these states for their money are that of the Mongols of Persia (1256–1349), founded by Hulagu, the conqueror of Bagdād, and that of the khans of the Golden Horde (1224–1502). Both struck silver, but there is also gold coinage of the Mongols of Persia, who more frequently use the Mongol character for their names and titles than is done under the kindred line. The power of the Mongols was held in check by the Mameluke kings of Egypt and Syria, slave-princes of two dynasties, the Baḥri (1250–1390) and the Burji (1382–1517), who struck money in the three metals. The Mongol power waned, but was revived by Timūr (Tamerlane), who during his rule (1369–1405) recovered all that had been lost. He and his successors (to 1500) struck silver, copper, and brass money (see Pl. IV. fig. 13). The Ottoman Turks, whose power had been gradually growing from 1299 onwards, after a desperate struggle with Timūr (defeat of Bayezid I. at Angora in 1402), gradually absorbed the whole Mahommedan world west of the Tigris, except only Morocco, where they had but a momentary dominion. Constantinople fell to them in 1453, Syria, Egypt and Arabia in 1517. Their money of gold, silver, base metal and bronze is devoid of historical interest. In Tunis and Morocco a group of Berber lines long maintained themselves, but at length only one survived, that of the sharīfs of Morocco, claiming Arab descent, now ruling as the sole independent Moslem dynasty of northern Africa. Its recent coinage is singularly barbarous. It may be remarked that Tunis and Egypt have long coined Turkish money in their own mints, the more western state latterly adding the name of its hereditary prince to that of the sultan.

Persia.

The coins of the shahs of Persia have their origin with Ismā'īl (1502). They are struck in the three metals, and are remarkable for the elegance of their inscriptions, sometimes in flowing Arabic, sometimes in the still more flexuous native character (see Pl. IV. fig. 12). The inscriptions are at first Arabic; after a time the religious formulae are in this language and the royal legend in Persian, usually as a poetical distich. The Persian series is also remarkable for the autonomous issues of its cities in copper, the obverse bearing some type, usually an animal. The coins of the Afghan amirs form a class resembling in inscriptions those of the Persians, and equally using Persian distichs. They commence with Aḥmad Shāh Durrāni (1747).

India.

The first native Indian coinage consists of primitive pieces (the earliest perhaps of the 4th century B.C.) of silver and copper with countermarks (known as "punch-marked" coins). Foreign coins (Persian and Athenian) circulated in the country from the 5th century; the silver coinage of Sophytes, a contemporary of Alexander the Great, shows Athenian influence; and there are not a few coins of Indian provenance showing direct imitation or modification of Athenian types (as the substitution of an eagle for the owl). Alexander himself is represented by a coinage of square bronze pieces. Certain tetradrachms and diobols with the name of Alexander and types: head of Zeus and eagle, probably belong to the end of the 4th century. But the coinage which was to have most effect on that of India was the Bactrian (see also under BACTRIA). This is at first a pure Greek coinage, of fine style, beginning with Diodotus (gold, silver, bronze), who revolted from Antiochus II., *c.* 250 B.C. For about a century the art of these coins, at least as regards portraiture, ranks very high for realism and vigour. The Bactrian rulers seem first to have made incursions into the Kabul valley and north India about 200 B.C., the first Indian conquests being perhaps made by Euthydemus and Demetrius. Of the latter there exists a bronze coin with the regular Greek types, but of the characteristic square Indian form, with a translation on the reverse into Kharoshṭhi characters of the obverse Greek inscription. Some of the coins of succeeding kings are very remarkable, as the tetradrachms of Antimachus (see Pl. IV. fig. 5), with a portrait reminding us of good Italian medals, and the unique 20-stater gold piece of Eucratides (the largest Greek gold coin known to us, although its genuineness has been questioned). The coinage from about 160 B.C. becomes more and more Indian, the Greek power being definitely transferred south of the Paropanisus in the second half of the 2nd century. The Attic standard which had been used for the silver gradually gave way to the Persian. The Greek princes went on reigning in India to about 20 B.C.; their chronology is very obscure. During the last two centuries B.C. several other coinages existed in north India. (1) The Scythic Sacae or Śakas invaded Bactria and then India; the earliest Śaka coinage of north India (that of Maues in the Punjab, *c.* 120 B.C.) shows Parthian influence; so do the slightly later coins of Vonones and others who reigned in Kandahar and Seistan. (2) Another large and varied group of coins consists of the issues of native states, some of which go back to before 200 B.C. Of these we may note the coins of Eran (Sagar district) showing the gradual development of the punch-marked coin into the coin with a type, made up of a collection of such punch-symbols struck from one die; and the coins of Taxila, the earliest of which are struck with a type on one side only. From these were imitated the copper coins of the Greeks, Pantaleon and Agathocles (*c.* 190 B.C.), which again inspired the later coins of Taxila with types on both sides.—In the first century of our era the Indo-Parthian dynasty of Gondophares Gundophorus of the Apocryphal Acts of St Thomas) reigned in Kandahar and Seistan and in India, and is represented by coins. About 25 B.C. the Kushanas (as the Yue-chi were called, after their most important tribe) conquered the remains of the Greek kingdom in the Kabul valley, and in the 1st century of our era they subdued the Punjab and the territory as far as the Jumna. The well-known gold coinage of the Kushanas (due probably to the influx of Roman gold into India) is begun by Hima Kadphises (*c.* A.D. 30–78; see Pl. IV. fig. 14). The best-known kings are Kanishka, Huvishka and Vasudeva. The types are interesting, combining deities of the Greeks, Scythians, the Avesta and the Vedas and Buddha. The Greek inscriptions become meaningless after *c.* A.D. 180. The coinage in gold (of Roman weight) and copper, however, continues probably as late as A.D. 425 in the Kabul valley and the Punjab. Of other dynasties contemporary with the Kushanas, the most important are: (i.) The Andhras, a south Indian power, with territory extending across the peninsula from the Kistna and Godavari deltas to Kolhapur. The coins are chiefly of lead, but copper and silver are also known. (ii.) the satraps of Surāshṭra and Malwa, whose coinage (chiefly of silver) is copied from the half-drachms of the Greek princes of the Punjab; it lasts until the end of the 4th century. (iii.) Early in the 4th century the important imperial Gupta coinage begins with Chandragupta, and continues unbroken to the death of Skandagupta, *c.* A.D. 480. The empire at its greatest extent comprised the whole of north India, except the Punjab. The earliest gold coinage was derived from that of the Kushanas (see Pl. IV. fig. 15); later there was silver derived from the coinage of the satraps; the copper is more original in style. After *c.* A.D. 480 the empire broke up into various dynasties which lasted until A.D. 606. The Great Kushanas had been succeeded in Gandhāra (Kabul valley and Punjab) by the Kidāra Kushanas, and these, *c.* 465–470, were conquered by the Hūṇas (a branch of the Ephthalites or White Huns). The Hūṇa coinage consists almost entirely of imitations of Sassanian, Kushana or Gupta coins. Their power probably broke up *c.* A.D. 544. Of other ancient and medieval non-Mahommedan coinages in India the following may be mentioned: (1) Various series of dynasties reigning in Kanauj and Delhi, from the 7th to the 12th century. (2) Kashmir—coinage beginning probably as early as Kanishka and continuing with the same types (obverse, king standing, reverse, goddess seated) until the Mahommedan coinage in the 13th century. The coins are very rude; but the succession of the kings from *c.* A.D. 850 is fairly certain. (3) Later Shāhi coinage of Gandhara, especially the "bull and horseman" coins (*c.* A.D. 860–950). (4) Pāṇḍya, in the extreme south: this district used first the early punch-marked coins, then coins with a type on one side only, and later double-type coins; these are earlier than *c.* A.D. 300. There is a later gold coinage (type, fish) from the 7th to 10th century. (5) Cola: an earlier coinage, before *c.* A.D. 1022, with the Cola emblem, a tiger; the later coinage (obverse, king standing, reverse, king seated) influenced the coinage over most of south India. (6) Ceylon: a coinage of the rajas imitated from the Cola coins, from A.D. 1153 to 1296. (7) Chalukya coinage, chiefly of gold, in west Deccan and in Pallava country between the Kistna and Godavari; the emblem is a boar. They range from the 7th to the 11th century. (8) Vijayanagar: this power preserved the old character of the coinage south of the Kistna long after the Mahommedan conquest had transformed the coinage north of that boundary. The later coinage of South India is too obscure to be dealt with here.

The Arabs in the first days of conquest had subdued Sind and founded an independent state on the banks of the Indus, which was ruled by them for nearly two centuries from 711; but it is hard to subdue India from this direction, and the strangers decayed and disappeared. The way into India was first really opened by the campaigns of Maḥmud of Ghazni (1001–1024) who annexed the Punjab and gave a raja to Gujarat. The Pathan kings came of the Ghuri stock which rose on the ruins of the empire of Ghazni (1186). Mohammad ibn Sām (d. 1206) made Delhi his capital, and here he and his successors, Pathans or slave-kings, ruled in great splendour as the first exclusively Mahommedan Indian dynasty, latterly rivalled by a line of Pathans of Bengal. Of the Pathans of Delhi (1206–1554) we have an abundant coinage, the principal pieces being the gold mohur of about 168 grains and the silver rupee of about the same weight, besides many pieces of bronze, and at one period of base metal. The coins are large and thick, with the profession of Islam or the style of the caliph on one side, on the other the name and titles of the reigning king. Moḥammad ibn Tughlak (1324–1351, Pl. IV. fig. 8) struck coins with a great variety of inscriptions, some in the name of the shadowy 'Abbāsid caliphs of Egypt, whose successors were for a time similarly honoured by later sovereigns. Towards the close of the rule of the Pathans several dynasties arose (about 1400) in central and southern India and struck similar money, the kings of Gujarat, of Mālwā and the Bahmanids of the Deccan (1347–1526). The Pathan lines closed with Shēr Shāh, an Afghan, the last ruler of Bengal (d. 1539). Bābar, the Turki, of the family of Timur, seeking a kingdom, adventured (1525) on the conquest of Hindustan; and after long wars with Shēr Shāh, carried on by Bābar's son Humāyūn, the famous Shāh Akbar, grandson of the invader, was at length peaceably settled on the throne of Delhi, and he and his successors, the so-called Moguls of Delhi, practically subdued the whole of India. They retained the existing standard, but used the Arabic and Persian languages like the shahs of Persia. Akbar (1556–1605) issued a splendid coinage in gold and silver (Pl. IV. fig. 16),

far more elegant than that of the Pathans, but the money of his son, Jahāngir (1605–1628) is still more remarkable. He issued the famous zodiacal mohurs and rupees, as well as those astonishing Bacchanalian mohurs on which he is represented holding the wine-cup (see Pl. IV. fig. 17). Scarcely less strange is the money of the beautiful queen Nūr-Jahān. Under Shāh Jāhān (1628–1659) there is a visible falling away in the merit of the coins, and an ordinary modern style is reached in the reign of Aurungzib (1659–1707). To the close of the rule of Shāh 'Alam, the last Mogul who actually reigned (1759–1806), gold and silver money is abundant. Much of the money of the East India Company is closely imitated from this late Mogul coinage. Latterly, native states coin with Arabic and also with Sanskrit inscriptions. The most important are the kings of Oudh, the nizams of the Deccan, and the kings of Mysore, besides the maharajas of Indore and the kings of Nepāl. The coinage of Tipu Sultān (Tippu Sāhib) is extremely curious from his innovations in the calendar. Besides these there are a multitude of small states. Most of the Indian princes acknowledged the emperor of Delhi, but some struck independently. At last the English coinage of India has swept away nearly all these moneys, though some native states still issue their own.

We must be content with the briefest summary of the strange coinages of China and the Further East.

China.

The money of China, more certainly than the square punch-marked coinage of India, may claim an origin independent of the Lydian and Greek issues. Although "money" is mentioned in Chinese literary sources as having been in use from a very early period (3rd millennium B.C.) it is probable that before the 7th century B.C. it consisted either of uncoined metal or of other media, such as silk, tortoise-shell, cowries. The shell-currency indeed played a very important part in China even in later times. It was suppressed in 335 B.C., but the usurper Wang Mang, whose reign (A.D. 9–23) separates the two Han dynasties, made an abortive attempt to revive it. The earliest metal currency of which specimens are extant is, like nearly all subsequent Chinese money, of cast bronze. The gold and silver currency, which appeared sporadically, can never have been of much importance; a *kin*, or cubic inch, of gold, representing currency of Han times, is preserved in the Paris collection. The bronze coins fall into two main classes. The earlier (as a rule) have the shape of implements, such as spades, knives, &c.; the later are the well-known round "cash" with a square hole in the centre (see Pl. IV. figs. 18, 19). They are carried strung together, and their value is minute. From the earliest knife-money should be distinguished that of Wang Mang; his coins are short and thick, and the plain ring at the end of the handle is replaced by a piece resembling in shape a cash with ring and square central hole. The older knife-currency practically came to an end with the foundation of the Ts'in dynasty in 221 B.C., though it doubtless lingered on in remote districts. With this dynasty appears the first organized state mintage. Nevertheless the economic history of Chinese coinage continues to be a melancholy record of doubtful financial expedients, debasement and forgery. The value of the coins was supposed to depend on their weight; but the weight inscribed on them was by no means always the true one. The bronze coinage from the reform of Wu-ti in 138 B.C. down to A.D. 622 is fairly uniform; it is chiefly cash of 5 chu (see Pl. IV. fig. 18). Iron money was issued at various periods. The disturbance of the coinage by the usurper Wang Mang has already been noted. The modern coinage may be said in a sense to date from the introduction of the *K'ai yuan* pattern of 7½ chu under the T'ang dynasty in A.D. 622. On the reverse of this coin was a mark (supposed to have been made by the empress Wen-teh in touching with her nail the wax model submitted to her) which has been much copied on coins of other countries in the Far East (see Pl. IV. fig. 19). From this time to the present there has been little change. Paper-money was introduced in the 9th century. The modern cash usually bears on the obverse the name of the reign and the words *t'ung pao* ("current money"), on the reverse the name of the mint. The coinage under the present (Manchu) dynasty has been regular, except during the Taiping rebellion, when some iron coins and copper tokens were issued, owing to the failure of the copper supply. Gold and silver have not been issued by the government until quite recent times (see below), with one or two unimportant exceptions, but circulate by weight. Imitations of Spanish and Mexican dollars, bearing numerous punch-marks placed on them by successive owners, are common. The most interesting Chinese coins are those of small rival dynasties and of rebels, the study of which is important for the elucidation of the obscurities of the history of the country. The Chinese medals are talismans, usually larger than coins, and bear both subjects and inscriptions. They are distributed by Taoist and Buddhist priests of temples. The money of Korea and Annam is similar to that of China, and Chinese coins were long the currency of Java, which more recently has issued the money of its Mahommedan princes.

Japan.

The empire of Japan shows in its coinage that Chinese source modified by the influence of native independence which marks all its institutions. The use of a metallic currency probably began in the 5th century of our era. In character the coins show strong Chinese influence. Amongst the earliest are rude silver pieces, disks of somewhat irregular shape, with a central hole, attributed to the early 5th century; and there are also copper coins of similar character dating from the end of the 7th century. A regular copper coinage, Chinese in pattern, began with the exploitation of the copper mines in A.D. 708. There was a silver coinage in A.D. 760, and a gradually deteriorating copper currency was issued at various dates down to A.D. 958. The twelve varieties issued in these two and a half centuries are known as the twelve antique sen (see Pl. IV. fig. 20). No copper was issued by the government for six hundred years after this date; but coins of the old patterns in lead or tin circulated down to 1302. The lack of copper was supplied by the importation and imitation of Chinese cash. These imitations were due to the great nobles, who made them on their own domains. At the end of the 16th century (*Ten-sho* period) a regular currency of gold, silver and copper, and also iron was instituted, which lasted, with modifications, down to recent times (iron coins with wave-pattern reverse being cast as late as 1860). There is a billon coinage of bean-shaped pieces issued at various dates from 1601–1859. Silver also was frequently issued on the same pattern as the copper coinage; but the greater part of it circulated in ingots or plates. The small oblong pieces known as ichi-bu and ni-bu belong to the 19th century (not issued after 1868). Large plates of silver, like the gold coins to be mentioned immediately, were issued in the 16th century by some provinces. Round coins of gold of the Chinese shape were rarely cast (one in A.D. 760, another in A.D. 1599). But from the 16th century to modern times gold circulated chiefly in large oblong plates, with rounded angles, varying from over 6½ to 3 in. in length. These are called *o-ban* ("large plate" of 10 ryo), *ko-ban* ("small plate" of 1 ryo; see Pl. IV. fig. 21), &c. They bore various countermarks, including the mikado's crest, mint-assayer's test-marks, &c.; some bear the attestations merely written in ink (a device of the imperial officials, who charged fees for the attestations, and were not sorry that they should be easily obliterated). Small gold oblong pieces were cast at various times from 1601–1856 (Pl. IV. fig. 22). A European system of currency, with coins in gold (20 yen and under), silver (1 yen and under), nickel (5 sen) and copper (2 sen and under), was adopted in 1870. Japan has also "picture sen" (E-sen) of a magical and religious character like the temple medals already noticed under China.

Korea.

Korea has had a copper coinage of Chinese style from the beginning of the twelfth century during its intervals of independence; but its coins do not become common until 1790. During the 19th century it issued an extensive copper coinage from various mints.

Annam.

The earliest coins of Annam were imitations of Chinese coins, but since the 10th century its kings have issued a regular coinage bearing their regnal titles as in China. Since 1820 round and oblong silver coins have been struck, the tael and its subdivisions. Peculiar to Annam are the fine series of medals in gold, silver and copper struck since 1841 by its kings for presentation purposes, bearing lucky inscriptions, quotations from the Chinese classics, &c.

Burma, Malay Peninsula, &c.

The peculiar forms of primitive currency characteristic of certain parts of Further India and the Malay Peninsula can only be barely mentioned here. Burma provides silver-money in the shape of snail-shells (a relic of a still more primitive shell-currency). The earlier Siamese ticals are derived from a ring of silver wire doubled up and countermarked. From Pahang come very curious tin "hat coins," shaped like a hollow square pyramid, truncated, with broad, square brim projecting from its base. The peoples of the Indian Ocean and Persian Gulf used in the 16th and 17th centuries pieces of silver wire called larins which in Ceylon took the shape of fish-hooks.

V. Coins of the Present Day

United Kingdom.—The standard of gold and silver has remained unchanged for over two hundred years, and until 1887 the denominations were practically the same as instituted at the great recoinage of 1816. The substitution of a bronze for a copper currency had already taken place in 1860. On the occasion of Queen Victoria's Jubilee in 1887 it was determined to mark the event by a new coinage of gold and silver, and to revise the royal portrait. Two new denominations of five and two pounds were added to the gold series, and the double florin to the silver. For the reverse type of all the gold and of the five-shilling piece, Pistrucci's design of St George and the Dragon was used, and former types of Anne and George IV. were revived for the double florin, florin, half-crown and sixpence; that of the last was, however, soon abandoned. This new coinage did not meet with general approval, especially as regards the portrait of the Queen, and in consequence a third portrait was

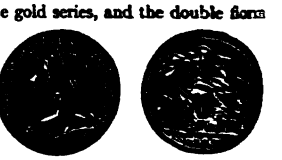


Fig. 1.—Sovereign (gold), England: Queen Victoria (obverse by Brock).

adopted for the gold and silver in 1893, new reverse types were prepared for the half-crown, florin and shilling, and the issue of the double florin was discontinued. The portrait of the queen was the work of the sculptor Thomas Brock, R.A., who was careful to avoid the defects which had been somewhat severely criticized in Sir J. Edgar Boehm's design of 1887. The new type for the half-crown, a spade-shaped shield within the garter, was also executed by Mr Brock; and those for the florin and shilling, three shields placed triangularly, were by Sir Edward Poynter. In 1895 a new issue of bronze money was ordered, when the queen's bust of 1893 was adopted, and a slight alteration made in the reverse type, the representation of a lighthouse and a ship, which had been added to the design in 1860, being eliminated.

FIG. 2.—Sovereign (gold), England: King Edward VII. (obverse by de Saulles).

The coinage of Edward VII. differed but slightly from that of Queen Victoria. The denominations were the same; but on the obverse the head of the king (by G. W. de Saulles, engraver to the Mint) was represented bare, the title "Britanniarum" was changed to "Britanniarum Omnium Rex," the reverse of the florin showed Britannia standing on a ship, and that of the shilling the royal crest, the lion on a crown, as on the so-called "lion-shillings" of 1826. The designing of the new coinage of George V. was entrusted to Mr Bertram Mackennal.

France.—On the establishment of the Third Republic in France in 1870, the coinage was continued on the same lines as before, the types only being altered. The silver franc of 5 grammes (78 grains) as ordered in 1793 and confirmed by the Latin Monetary Union of 1865, which included Belgium, Italy and Switzerland, and subsequently in 1868 Greece, has remained the unit of value. The denominations ordered were, in *gold*, the 100, 50 and 20 francs; in *silver*, the 5, 2 and 1 franc, and 50 and 20 centimes; and in *bronze*, the 10, 5, 2 and 1 centime. The types adopted were those which had been used previously — thus for the gold that of a genius inscribing the tables of the law, as designed by Augustin Dupré for the reverse of the constitutional coinage of Louis XVI.; for the silver and copper the head of the Republic as executed by Oudiné for the money of 1848. Subsequently, in 1871, the type of the 5 francs was changed for that of Hercules leaning on Liberty and Strength, as made by Dupré for the First Republic. In 1889 the 10 francs in gold was added to the list, having the head of the Republic crowned with corn, the work of Merley for the Republic of 1848; but only a small number of these coins was struck in that year and in 1895. No further alteration was made till after 1895, when, in consequence of suggestions that the types should be modified so as to mark the Third Republic, the artists Chaplain, Roty and Dupuis were commissioned to execute new designs—the first for the gold, the second for the silver, and the last for the bronze. The types approved were: for the gold 20 francs, the head of the Republic with a Phrygian cap, and the Gallic cock; for the silver 2 and 1 franc and 50 centimes, the sower sowing, with the rising sun in the background, and a laurel branch; and for the bronze, the bust of the Republic wearing a Phrygian cap, and on the reverse France seated amidst clouds, holding a branch and a flag, and accompanied by a genius. These coins were not issued simultaneously—the 50 centimes appearing in 1897, and 2 and 1 franc and 10, 5, 2 and 1 centime in 1898, and the 20 francs in 1899. In 1903 a nickel piece of 25 centimes was introduced, since 1904 with a polygonal edge to facilitate distinction from the silver. The quartering of the franc is a departure from the strictly decimal system, also adopted in Italy. These later coins are characteristic of modern French medallic art, which has a strong tendency to imitate that of Italy of the 16th century.

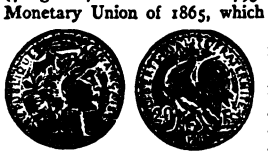

FIG. 3.—Twenty Francs (gold), France (Chaplain).

FIG. 4.—Two Francs (silver), France (Roty).

Belgium.—Of the other states which formed the Latin Monetary Union, Belgium had already in 1832 adopted the French decimal and bimetallic system, with the franc as the unit of value. Her accession to the Union, therefore, only entailed a slight modification of type and denominations, which latter were the same as in France, except that the only gold coin was the 20 francs, the 25 centimes in silver was not issued, and the pieces of 10 and 5 centimes are now in nickel. The gold and silver coins have for types the head of the king and the royal shield, those in nickel the Belgic lion and mark of value, and those in bronze the royal monogram and the lion holding the tables of the constitution. Some of the silver coins have the inscriptions in Flemish. The nickel coinage introduced in 1902 is perforated in the centre to prevent confusion with silver.

Switzerland.—Like Belgium, Switzerland had before her adhesion to the Latin Monetary Union adopted the French system, with the franc of 100 centimes or rappen as the unit of value. The denominations in gold and silver were the same as issued for Belgium, but no gold was struck before 1883. The coins of baser metal were the 20, 10 and 5 centimes in billon, which metal was in 1879 changed for the nickel, and in copper the 2 and 1 centime. Certain changes of type have from time to time occurred. The first issue of the 20 francs in 1883 shows the head of the Republic and the shield of the Confederation; but this was changed in 1897 for the head of Helvetia above a range of mountains, and on the reverse a wreath with mark of value. On the silver coins from 1874 Helvetia is represented standing instead of seated, and on the nickel money of 1879 the shield of the Republic is replaced by the head of Helvetia. The mark of value and a wreath form the general reverse type of all the silver, nickel and copper coins. Since 1888 a 5-franc piece, similar in type to the 20 francs of 1883, has been issued.

FIG. 5.—Twenty Centimes (nickel), Switzerland.

Italy.—When Italy joined the Latin Monetary Union in 1865, she adopted as the unit of her coinage the lira of 100 centesimi, equal to the franc. The coins were of gold, silver and bronze, and of the same denominations as those struck in Belgium and Switzerland. In 1894 a nickel coinage of 20 centesimi was ordered. The general type for all the coinage is the head of the king and the royal arms, but on the reverse of the copper is the mark of value; and the nickel money has on the reverse a crown with a wreath. A new nickel piece of 25 centesimi indicates a departure from the strictly decimal system. The coinages of all the small Italian states, including the Papal, have now passed out of currency.

FIG. 6.—Two Lire (silver), Italy.

Greece.—A special stipulation was made, when Greece was enrolled in the Latin Monetary Union in 1868, that all her money should be struck at a French mint. The unit of the coinage

is the drachm of 100 lepta, which, like the lira, is equivalent to the franc. The denominations are—in *gold*, the 100, 50, 20, 10 and 5 drachms; in *silver*, the 5, 2 and 1 drachm, and 50 and 20 lepta; and in *bronze*, the 10, 5, 2 and 1 lepton. In 1893 nickel was substituted for bronze, and coins of the value of 20, 10 and 5 lepta were issued in this metal. The types of the coins of Greece are similar to those of Italy. Crete has had since 1900 a coinage of its own similar to the Greek (silver of 5, 2 drachmae, 1 and ½ drachma; bronze and nickel of 20, 10, 5, 2 lepta and 1 lepton).

Germany.—Since 1871 the coinage of the German empire has been entirely remodelled. By a convention in 1857 between the states of Germany, north and south, and Austria a general coinage of a silver standard was established on the basis of the new pound of 500 grammes as sanctioned by the *Zollverein*. The contracting countries were divided into three sections, North Germany, South Germany and Austria. From the pound of fine silver of 500 grammes the Northern States struck 30 thalers, Austria 45 florins and the Southern States 52½ florins; their relation being 1 North German thaler = 1½ Austrian florins = 1¾ South German florins. The free towns of Hamburg, Lübeck and Bremen did not join the convention. The first reform in the coinage of the German empire occurred in 1871, when a new gold money was introduced, which had for its unit the silver mark (a money of account) of 100 pfennigs weighing 5·555 grammes. The new gold pieces were of the value of 10 and 20 marks, called crowns and double crowns, and the fineness was $\frac{9}{10}$ pure to $\frac{1}{10}$ alloy. This new issue necessitated a readjustment of the current values of the various silver coinages in circulation. In 1873 a further step was made by the introduction of an entirely new silver coinage throughout the empire, which was also based on the silver mark, and of a new base metal coinage in nickel and bronze. The silver coins were the 5, 2 and 1 mark and 50 and 20 pfennigs; those in nickel the 10 and 5 pfennigs, and in bronze the 2 and 1 pfennig. The silver coins were, like the gold, $\frac{9}{10}$ fine, so that 90 marks were struck to the pound of pure metal. The gold 5 marks was struck in 1877 and 1878, and the 20 pfennigs in silver was replaced by a coin of the same value in nickel in 1886. The reverse type for all the coins is the imperial eagle, but that of the obverse varies; the gold and silver showing the portrait of the reigning king or prince, but the mark, and all lesser denominations, the current value. An exception was made in the case of the coinage of the Free Towns struck at Hamburg, which has the arms of the city instead of a portrait. Each state retained its full rights of coinage, and the various mints throughout the empire with their special marks are: Berlin, A; Hanover, B; Frankfort, C; Munich, D; Dresden (removed since 1877 to Müldner-Hütte), E; Stuttgart, F; Karlsruhe, G; Darmstadt, H; and Hamburg, J. In 1876 a gold standard was proclaimed, and henceforth no person was legally bound to accept in payment more than 20 marks in silver and the value of 1 mark in nickel or bronze. The old thalers (worth 3 marks) still circulate.

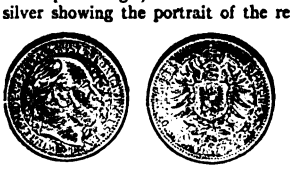

FIG. 7.—Twenty Marks (gold), Germany.

Austria-Hungary.—After the convention of 1857 with Germany (see above), when Austria based her coinage on the silver standard of the florin, two series were issued—(i.) Vereinsmünzen (money of the union), in *gold*, the crown and half-crown; in *silver*, the double thaler (=3 florins) and thaler; (ii.) Landesmünzen (money of the state), in *gold*, the 4 and 1 ducat; in *silver*, the double florin and florin; in *billon*, the 20, 10 and 5 kreuzers; and in *copper*, the 4, 3, 1 and ½ kreuzer. In 1868 Austria abandoned the convention, but made no change in her money; and in the same year the coinage of Hungary was made uniform with that of the empire, both in standard and denominations. In 1870 the Vereinsmünzen crown and half-crown were discontinued, and their place was taken by 8- and 4-florin pieces which were of the current value of 20 and 10 francs. In 1892 the monetary system of Austria-Hungary was entirely reformed on a gold standard, the unit of account being the crown of 100 hellers. This is a decimal coinage, and the denominations are, in *gold*, the 20 crowns (of 164 from the kilogramme of fine gold), 10 crowns and ducat (=9 silver crowns 60 hellers); in *silver*, the crown (=10d.) and half-crown; in *nickel*, the 20 and 10 hellers; and in *bronze*, the 2 and 1 heller. The gold ducat was a trade-money (Handelsmünze) of the current value of 10 francs, and it displaced the 8- and 4-florin pieces of 1870. The types of the Austrian and Hungarian coins somewhat vary. The Austrian gold coins show the head of the emperor and the two-headed eagle, but those of Hungary a full-length figure of the emperor and the national shield surmounted by the crown of St Stephen held by angels. The silver coins of both series have the head of the emperor and the mark of value under the imperial or royal crown. The nickel and bronze money of Austria displays the imperial eagle on the obverse, whilst that of Hungary has the crown of St Stephen. The legends are respectively in Latin and Magyar.

FIG. 8.—Florin (silver), Austria-Hungary.

Spain.—The unit of the Spanish coinage from 1864 to 1868 was the silver escudo of 200 grains divisible into 10 reals. On the dethronement of Isabella in 1868 the provisional government adopted the principles of the Latin Monetary Union and made the peseta the unit of account, this coin being equivalent to the franc. The coins struck during 1869–1870 were, in *gold*, the 100 pesetas; in *silver*, the 5, 2 and 1 peseta, and the 50 and 20 centimos; and in *bronze*, the 10, 5, 2 and 1 centimo. The obverse type of each metal varied; on the gold Spain is standing, on the silver she is reclining; and on the bronze she is seated. During his short reign (1870–1873) Amadeus I. struck only gold coins of 100 and 25 pesetas and silver of 5 pesetas, and there was practically no money issued during the republic which followed his abdication. Don Carlos during the insurrection of 1874–1875 struck 5 pesetas in silver and 10 and 5 centimos in bronze bearing his portrait and title "Carolus VII." After the restoration of Alphonso XII. the coinage consisted of 25 and 10 pesetas in gold; 5, 2 and 1 peseta and 50 centimos in silver; and 10 and 5 centimos in bronze. This coinage was continued under Alphonso XIII., but in 1887 the 20 pesetas in gold was substituted for the 25 pesetas, and in 1897 large coins were struck of 100 pesetas. The types show the head of the king on the obverse and the shield with or without the pillars of Hercules on the reverse.

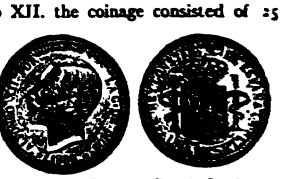

FIG. 9.—Peseta (silver), Spain.

Portugal.—A gold standard was adopted by Portugal in 1854, the unit of value being the milreis of 1000 reis. The coins are, in *gold*, the crown or 10 milreis and the half, fifth and tenth crown or milreis; in *silver*, the 10, 5 and 2 testoon; in *nickel* the 100 and 50 reis; and in *bronze*, the 20, 10 and 5 reis. The general type of the gold and silver is the head or bust of the king and the royal shield; but the bronze varies in having on the obverse a shield and on the reverse the mark of value.

Denmark, Sweden and Norway.—Previous to 1872 in Denmark the unit of value was the silver *rigsbankdaler* of 96 skillings, in Sweden, the *rigsdaler* of 100 öre; and in Norway, the *speciesthaler* of 120 skillings; but in that year a monetary convention was concluded between these countries establishing a decimal coinage, which had for its unit the krone of 100 öre, and of which

the standard was gold. The denominations are, in *gold*, the 20, 10 and 5 kroner; in *silver*, the 2 and 1 krone, and 50, 25 and 10 öre; and in *bronze*, the 5, 2 and 1 ör. The gold and silver money of Sweden and Norway to the 50 öre bears the head of the king and the royal shield; the silver of smaller denominations and the bronze, the monogram of the king and the mark of value. Since the separation of the two kingdoms in 1906, Norway has a coinage of its own in the name of Haakon VII. In Denmark the gold and silver have the head of the king, and, for reverse type, a figure of Denmark, a shield, or the mark of value. The bronze coins are similar to those of Norway and Sweden.

Russia.—The Russian coinage previous to 1885 was based on the silver rouble of 278 grains of pure metal; but during the greater part of the reign of Alexander II. (1855–1881) the currency consisted almost entirely of paper money. In 1885 Alexander III. determined to place the coinage on a proper footing, and introduced the rouble of 100 copeks as the unit of account, with a relative value of gold and silver of 1 to 15½. The coins issued were, in *gold*, the imperial of 10 roubles, and the half-imperial; in *silver*, the rouble, and the 50, 25, 20, 15, 10 and 5 copeks; and in *copper*, the 5, 3, 2, 1, ½ and ¼ copek. In 1897 the relative value of gold and silver was advanced to 1 to 23¼, thus raising the current value of the imperial to 15 roubles; but no change was made in the weights of the coins, and the silver rouble remained the unit of account. In the same year a piece of 5 roubles, called the one-third imperial, was added to the gold coins. The general types of the gold and silver show the head of the emperor and the imperial eagle; and of the copper, the imperial eagle and mark of value.

FIG. 10.—Seven and one-half Roubles (gold), Russia.

Georgia, Poland and Finland.—The separate issues of Georgia and Poland were suppressed in 1833 and 1847 respectively; but Finland in 1878 established a decimal coinage of gold, silver and bronze on the principles of the Latin Monetary Union, having the *markhaa* (= 1 franc) as its unit of value.

Turkey.—There has been practically no change in the money of the Ottoman empire since the reforms of Abdul-Medjid in 1844, when the piastre, or 40-para piece, of the current value of 2¼d., was made the unit of the coinage; 100 piastres go to the gold medjidieh or pound. The denominations are, in *gold*, the 500, 250, 100, 50 and 25 piastres; in *silver*, the 20, 10, 5, 2, 1 and ½ piastre; and in *copper*, the 40, 20, 10, 5 and 1 para. The type in all metals is, on the obverse, the Sultan's *tughra*, or cipher, and on the reverse, a wreath, and the name of the mint, date, &c.

Balkan States.—Since the dismemberment of the Ottoman empire the kingdoms of Rumania and Servia, and the principality of Bulgaria, have each adopted the decimal system of the Latin Monetary Union. In Rumania the unit of account is the *leu* of 100 *bani*; in Servia, the *dinar* or 100 *paras*; and in Bulgaria, the *lev* of 100 *stotinki*—each of these units being the equivalent of the franc. In all these states gold, silver, bronze and nickel is current money.

United States.—In America the most important event connected with the coinage was a change of standard. (See MONEY). Previous to 1873 the standard was silver, having for its unit the dollar of 412½ grains of $\frac{9}{10}$ fine; but in that year a gold standard was adopted, the gold dollar of 25·8 grains and $\frac{9}{10}$ fine being the sole unit of value. This change of standard was accompanied by a slight modification of the denominations, which became, in *gold*, the double-eagle, eagle, half and quarter eagle, three dollars and dollar; in *silver*, the half and quarter dollar, 20 cents and dime; in *nickel*, the 5 and 3 cents; and in *bronze*, the cent. In addition to these a silver piece called the "trade dollar" of 420 grains was struck, not for circulation in the States, but for export to China. The following changes have since occurred: In 1878 the silver dollar of 412½ grains was resumed, and the 20 cents discontinued; in 1887 the issue of the "trade dollar" was suspended; and in 1890 the same fate befell the three dollars and dollar in gold, and the three cents in nickel. The types are—*gold*, head of Liberty and eagle, *silver*, head of Liberty, or Liberty seated, and eagle, except the dime, which has the mark of value; *nickel*, shield (5 cents) and head of Liberty; *bronze*, head of an Indian, and (1910) bust of Lincoln; with reverse types for either metal, the mark of value.

Canada, &c.—The currency for the Dominion of Canada, which includes Nova Scotia, New Brunswick and British Columbia, is of silver and bronze, based on the system of the United States. The denominations are 50, 25, 20, 10 and 5 cents in silver, and the cent in bronze; and they also have a uniform type of the sovereign's head and mark of value. The same system prevails in Newfoundland, which also issues the double dollar in gold: this is the only gold coin issued in a British colony whose standard is not the same as that of the mother country. There is a separate coinage for Jamaica, but of nickel only, and consisting of the penny, halfpenny and farthing.

Mexico, &c.—We need not give any detailed account of the coins of Mexico, and of the various states of Central and South America, in nearly all of which there have been radical changes since 1870. Most of them have adopted the decimal system, with a gold, silver or bi-metallic standard; the unit of value in the gold standard being generally the peso of 3·225 grammes, and in the silver also the peso, but of silver of 20, 25 or 27 grammes.

India.—As to the coins of the East and Far East, we will limit our remarks to the more important countries. In British India the rupee of silver of 150 grains is still the unit of value. In 1893 the mints were closed to the unrestricted coinage of silver for the public. In 1899 they were opened to the free coinage of gold, the sovereign being declared legal tender. At present £1 = 15 rupees of 1s. 4d.; 1 rupee = 16 annas; 1 anna = 4 pice; 1 pice = 3 pie = 1 farthing.

Persia.—In Persia since 1879 a decimal system in conformity with the principles of the Latin Monetary Union has been adopted, having for its unit the *krân* weighing 78 grs., thus being equivalent to the franc, but since reduced to 71 grs. or even less. The denominations are: in *gold*, the 10, 5, 2, 1, ½ and ¼ toman (the toman = 10 krâns); in *silver*, the 5, 2 and 1 krân (= 20 shahis), and the 10 and 5 shahis; and in copper, the 4, 2 and 1 shahi (= 2 pals), and the pal.

Japan.—Since 1870 Japan has formed its coinage on the European decimal system in place of the ancient national coins, the *obangs* and *itsibus*, the unit being the *yen* of 100 *sen*. The standard was bi-metallic, and the relation of gold and silver stood at 1–16·17. In 1898 a gold standard was adopted, the issue of the silver yen was suspended, and the weight of the gold money was reduced by one-half. The coins issued since that date are, in *gold*, the 20, 10 and 5 yen; in *silver*, the 50, 20 and 10 sen; in *nickel*, the 5 sen; and in *bronze*, the sen and half-sen. There is one general type for all the silver, nickel and bronze coins, being the dragon on the obverse and a wreath of flowers with mark of value on the reverse. The gold varies in having flags and flowers on the reverse. On the silver and bronze coins the legends are in English as well as in Japanese.

China.—In 1890 China followed the example of Japan, but only to a limited extent, and instituted a silver coinage having as its unit a dollar of the same value as the United States silver dollar and the Japanese yen. It is calculated in fractions of the *tael*, a money of account of the value of 2s. 11¾d. The coins are the dollar, and the 50, 25, 10 and 5 cents, with the Chinese dragon and inscriptions, mint and mark of value in English on the obverse, and on the reverse the mark of value in Chinese and Manchu. They were first struck at Canton and Wei-Chang, but later other mints have been established. These are not, strictly speaking, imperial money, the sole official coinage and monetary unit being the copper cash. A decree of the 20th of November 1905 proposed to establish an official dollar on the basis of the Kuping tael. An edict of May 1910 provides for a standard currency dollar of 72 candareens, with a subsidiary decimal coinage in silver, nickel and copper, for circulation throughout the empire.

Korea has had since 1905 a new coinage on the Japanese system, but with the Korean date.

Hong Kong.—The only other Asiatic coinage we shall note is that of Hong Kong, where in 1866 was established a coinage, which was also based on the United States standard, having the silver dollar as its unit. The denominations are the dollar and 50, 20 and 5 cents in silver, and the cent and mill in bronze; and, with the exception of the mill, they all have for type the sovereign's head and the mark of value. In connexion with this coinage there was issued in 1895 a "trade dollar" for special currency in the Straits Settlements and Hong Kong in lieu of the Mexican dollar, the scarcity of which was a considerable hindrance of trade. This coin, which was struck at the Bombay mint, shows on the obverse Britannia holding a

trident and shield, and on the reverse within an ornamental design the denomination in Chinese and Malay. Since 1903, however a new

FIG. 11.—" Trade Dollar " (silver), Hong Kong.

special dollar with the king's head has been issued for the Straits Settlements.

Egypt.—Glancing cursorily at the coinage of Africa, we may note that since 1885 Egypt has adopted a gold standard with the gold pound of 100 piastres as the unit of account. The piastre is no longer divisible into 40 paras, but into 10 *ochr-el-guercha* or tenths. The types are similar to the Turkish money, and though bearing the legend " struck at Cairo " the coins are really made at Birmingham. For some years gold has not been issued.

Abyssinia.—In Abyssinia since 1893 there has been a silver coinage, but the Austrian Maria Theresa dollar is still current. The new coins are, in silver, the talari (=dollar, worth about 2s.), ½, ¼ and ⅛ talari, and in copper, the guerche, and ½ and ¼ guerche. They show on one side the head of the king, and on the other a lion holding a banner.

Zanzibar.—Zanzibar has also issued a dollar of the fixed value of 2 rupees and 2 annas, and a copper coin called a *pessa* (=136th of a dollar).

Sudan.—The African coinages which have attracted exceptional attention are those of the Sudan and the South African Republic. The former dates from 1885, when the Mahdi struck the pound of 100 piastres in gold and the 20 piastres in silver, of the same type as the Egyptian coins, but on the silver piece were placed the words " By order of the Mahdi," but no mint name. His successor, Abdullah, struck pieces of 20, 10, 5, 2 and 1 piastre in silver and 10 paras in copper, but no gold. They bear the name of the mint, Omdurman, and the word *makbul, i.e.* accepted. At first the silver coins were of 6 parts silver and 2 copper, but in a few years they were so debased that they degenerated into mere pieces of copper washed with silver. The last issue is dated 1897 (A.H. 1315).

Congo Free State (*Belgian Congo*).—The coinage issued since 1887 consists of silver of 5, 2, 1 fr. and 50 centimes, and copper (with central hole) from 10 centimes to 1 centime.

Transvaal.—The first attempt at a separate coinage in the Transvaal was in 1874, when President Burgers issued sovereigns or pounds showing his portrait on the obverse and the shield of the Republic on the reverse. They were struck by Messrs Heaton of Birmingham, but as each piece of the current value of 20s. cost 26s. to strike, only £680 worth was issued, and but few of these passed into circulation, being preserved as curiosities. No further attempt was made till 1891, when President Kruger induced the Raad to order a coinage in gold, silver and bronze after the English standard. The first issue occurred in 1892, and consisted of the pound and half-pound in gold; the crown, half-crown, florin, shilling, sixpence and threepence in silver; and the penny in bronze. They are all of the same type as the pound of 1874, but with the portrait of President Kruger on the obverse. The first issue of the pound, half-pound and crown was minted at Berlin, and a curious mistake was made in the arms of the state, the wagon being represented with two shafts instead of with one. This blunder was soon noticed, and a recoinage took place in the same year at Pretoria. Since the annexation British coins have been legal tender, but a new copper coinage was approved in 1904.

Gardner, *Coinage of Corea* (Journ. North China Branch of R. Asiatic Soc., vol. xxvii.).

(R. S. P.; H. A. G.; G. F. H.*)

NUMMULITE, NUMMULITES, A. d'Orbigny's name for a genus of Perforate Foraminifera (*q.v.*), distinguished by the flattened, lenticular discoid shell of many turns, finely perforated; chambers subdivided by incomplete septa into squarish chamberlets. This genus is especially abundant in Eocene Limestones, which attain great thickness around the Mediterranean basin; the Pyramids of Egypt are built of it.

NUN (O. Eng. *nunne*, from Lat. *nonnus*, *nonna*, familiar terms for an old man or woman), a member of a community of women, living under vows a life of religious observance (see MONASTICISM). In ecclesiastical Latin *nonnus* was used by the younger members of a religious community for their elders, and so, in the *regula* of St Benedict, cap. 62, *Juniores autem Priores suos nonnos vocant quod intelligitur paterna reverentia* (Du Cange, *Glossarium, s.v. nonnus*). While *nonna* has remained as the generic name of a female religious, *nonnus* has been replaced by *monachus* and its various derivatives (see MONK).

NUNATAK, a name applied in Greenland (and thence extended in use elsewhere) to a hill or mountain peak appearing above the surface of a glacier. Greenland is for the most part covered by an ice-cap of a certain thickness which moves slowly downwards to the sea. It will rise upwards and pass over a barrier if there is no outlet, but it will flow between and around mountain peaks leaving them standing as hills (nunataks) above the general surface of the ice-cap. These prominences are sometimes covered with arctic vegetation, and arctic flowers bloom freely upon them in the summer.

NUNCIO, or NUNTIUS APOSTOLICUS, a representative of the pope sent on diplomatic mission. The nuncios are of lower rank than the *legati a latere*, but have practically superseded them as ambassadors of the papacy. Nuncios were permanently established at various courts and ecclesiastical centres during the 16th century. According to the decision of the congress of Vienna the diplomatic rank of a papal nuncio corresponds to that of an ambassador. The powers of a nuncio are limited by his instructions. If a cardinal, as rarely is the case, he uses the title pro-nuntius. The pro-nuntius at Vienna has practically the position of a *legatus a latere*.

NUNCOMAR or NANDA KUMAR (d. 1775), Indian official, best known for his connexion with Warren Hastings (*q.v.*), was governor of Hugli in 1756, and in 1764 he was appointed collector of Burdwan in place of Hastings, which resulted in a long-standing enmity. In 1775, when Hastings was governor-general, Nuncomar brought accusations of peculation against him, which were entertained by Francis and the other members of council inimical to Hastings. While the matter was still pending Nuncomar was indicted for forgery, condemned and executed. Warren Hastings and Sir Elijah Impey, the chief justice, were both impeached, and were accused by Burke and afterwards by Macaulay of committing a judicial murder; but Sir James Stephen, who examined the trial in detail, states that the indictment for forgery arose in the ordinary course, was not brought forward by Hastings, and that Impey conducted the trial with fairness and impartiality.

See Sir James Stephen, *The Story of Nuncomar* (2 vols., 1885); and, for another treatment of the case, H. Beveridge, *The Trial of Nanda Kumar* (Calcutta, 1886).

NUNEATON, a market town and municipal borough in the Nuneaton parliamentary division of Warwickshire, England, on the river Anker, a tributary of the Tame, and on the Coventry canal. It is an important junction of the London and North

Western railway, by which it is 97 m. N.W. from London, and it is served by the Leicester-Birmingham branch of the Midland railway. Pop. (1901) 24,996, rapidly increasing. The situation is low and almost encircled by rising ground. The church of St Nicholas is a large and handsome structure in various styles of architecture, and consists of nave, chancel and aisles, with a square embattled tower having pinnacles at the angles. It contains several interesting monuments. A free grammar school was founded in the reign of Edward VI., and an English free school for the instruction of forty boys and thirty girls by Richard Smith in 1712. The ribbon industry is of less importance than formerly, but there are ironworks, cotton, hat, elastic and worsted factories, and tanneries; the making of drain-pipes, tiles and blue and red bricks is a considerable industry. In the neighbourhood there are also coal and ironstone mines. The prefix of the name of the town is derived from a priory of nuns founded here in 1150. In the reign of Henry III. a weekly market was granted to the prioress. Nuneaton was incorporated in 1907, and the corporation consists of a mayor, six aldermen and twelve councillors. Area 10,597 acres.

NUNEZ, PEDRO (PETRUS NONIUS) (1492–1577), Portuguese mathematician and geographer, was born at Alcacer do Sal, and died at Coimbra, where he was professor of mathematics. He published several works, including a copiously-annotated translation of portions of Ptolemy (1537), and a treatise in two books, *De arte atque ratione navigandi* (1546). His clear statement of the scientific equipment of the early Portuguese explorers has become famous. A complete edition of all his writings appeared at Basel in 1592.

See F. de B. Garcão-Stockler, *Ensaio historico sobre a origem e progressos das mathematicas em Portugal* (Paris, 1819); R. H. Major, *Prince Henry the Navigator* (London, 1868, p. 55).

NUÑEZ CABEZA DE VACA, ALVARO (*c.* 1490 – *c.* 1564), Spanish explorer, was the lieutenant of Pamfilo de Narvaez in the expedition which sailed from Spain in 1527; when Narvaez was lost in the Gulf of Mexico, Cabeza de Vaca succeeded in reaching the mainland somewhere to the west of the mouths of the Mississippi, and, striking inland with three companions, succeeded, after long wandering and incredible hardship, in reaching the city of Mexico in 1536. Returning to Spain in 1537, he was appointed "adelantado" or administrator of the province of Rio de la Plata in 1540. Sailing from Cadiz in the end of that year, after touching at Cananea (Brazil), he landed at the island of St Catharine in the end of March 1541. Leaving his ships to proceed to Buenos Aires, he set out in November with about 150 men to find his way overland to Ascension (Asunción) for the relief of his countrymen there. The little band reached their destination in the following year. After various successes in war and diplomacy in his dealings with the Indians, Nuñez was sent home under arrest in 1544, and in 1551 was banished to Africa by the council of the Indies for eight years. He was recalled in about a year and appointed to a judgeship in Seville, where he died not later than 1564.

The *Naufragios* ("Shipwrecks") of Cabeza de Vaca, which relate to the Florida expedition and his journey to the city of Mexico, appeared at Zamora in 1542; the work has frequently been reprinted, and an annotated English translation was published by T. Buckingham Smith in 1851. His *Comentarios* (1555) chronicle the events of the South American expedition. See Fanny Bandelier, *Journey of A. Nuñez Cabeza de Vaca* (ed. A. F. Bandelier, New York, 1905).

NUÑEZ DE ARCE, GASPAR (1834–1903), Spanish poet, dramatist and statesman, was born at Valladolid, where he was educated for the priesthood. He had no vocation for the ecclesiastical state, plunged into literature, and produced a play entitled *Amor y Orgullo* which was acted at Toledo in 1849. To the displeasure of his father, an official in the post office, the youth refused to enter the seminary, and escaped to Madrid, where he obtained employment on the staff of *El Observador*, a Liberal newspaper. He afterwards founded *El Bachiller Honduras*, a journal in which he advocated a policy of Liberal concentration, and he attracted sufficient notice to justify his appointment as governor of Logroño, and his nomination as deputy for Valladolid in 1865. He was imprisoned at Cáceres for his violent attacks on the reactionary ministry of Narvaez, acted as secretary to the revolutionary Junta of Catalonia when Isabella was dethroned, and wrote the "Manifesto to the Nation" published by the provisional government on the 26th of October 1868. During the next few years he practically withdrew from political life till the restoration, when he attached himself to Sagasta's party. He served under Sagasta as minister for the colonies, the interior, the exchequer and education; but ill-health compelled him to resign on the 27th of July 1890, and henceforth he refused to take office again. He was elected to the Spanish Academy on the 8th of January 1874 and was appointed a life-senator in 1886. He died at Madrid on the 12th of February 1903.

Nuñez de Arce first came into notice as a dramatist, and he remained faithful to the stage for nearly a quarter of a century. In addition to three plays written in collaboration with Antonio Hurtado, he produced *¿Quién es el autor?* (1859), *La Cuenta del Zapatero* (1859), *¡Como se empeña un marido!* (1860), *Deudas de la honra* (1863), *Ni tanto ni tan poco* (1865), *Quien debe, paga* (1867) and *El haz de leña* (1872). But Nuñez de Arce's talent was more lyrical than dramatic, and his celebrity dates from the appearance of *Gritos del combate* (1875), a collection of poems exhorting Spaniards to lay aside domestic quarrels and to save their country from anarchy, more dangerous than a foreign foe. He maintained his position (in popular esteem) as the only possible rival of Campoamor by a series of philosophic, elegiac and symbolic poems:—*Raimundo Lulio*, *Ultima lamentación de Lord Byron* (1879), *Un Idilio y una Elegía* (1879), *La Selva oscura* (1879) and *La Visión de Fray Martín* (1880). The old brilliance sets off the naturalistic observation of *La Pesca* (1884) and *La Maruja* (1886). The list of his works is completed by *Poemas cortos* (1895) and *¡Sursum corda!* (1900); *Hernán el lobo*, published in *El Liberal* (January 23, 1881) and *Lucbel* remain unfinished. His strength lies in the graciousness of his vision, his sincerity and command of his instrument; his weakness derives from his divided sympathies, his moods of obvious sentiment and his rhetorical facility. But at his best, as in the *Gritos del combate*, he is a master of virile music and patriotic doctrine. (J. F.-K.)

NUORO, a town and episcopal see of Sardinia, Italy, in the province of Sassari, 38½ m. E. of Macomer by rail. Pop. (1901) 6739. It is situated 1905 ft. above sea-level in the east central portion of the island, amid fine scenery. Nuoro was the capital of a province from 1848 to 1860. It is connected by road with Fonni, Bitti and Orosei. An inscription discovered *in situ* about 13 m. W. of Nuoro in 1889, near Orotelli, has the letters FIN NVRR (*fin(es)Nurr. . .*), which are explained as referring to the boundaries of the territory of Nuoro in Roman times, showing (what was not known before) that the name and the place are of Roman origin (F. Vivanet in *Notizie degli scavi*, 1889, 202). (T. As.)

NUPE, formerly an independent state of W. Africa, now a province in the British protectorate of Nigeria. Under Fula rule Nupe occupied both banks of the Niger for a distance of some 150 m. above the Benue confluence. Only the part of Nupe north of the Niger now constitutes the province; area 6400 sq. m.; estimated pop. about 150,000. It is in many portions highly cultivated, and owing to its admirable water supply is likely to prove particularly valuable as a field for the extensive cultivation of cotton. Bida (*q.v.*), the capital, is connected by railway (begun 1907–1908) with Baro, a port on the Niger 70 m. above Lokoja.

Nupe had an ancient and very interesting constitution of which the leading features were adopted by the Fula when their rule was established about the year 1859. Bida was founded in that year. Nupe was conquered by the troops of the Niger Company in 1897, and the legal status of slavery was then nominally abolished. The company was, however, unable to occupy the country, and on the withdrawal of its troops the deposed emir returned. In 1901 it became necessary to subdue Nupe a second time. British troops marched to Bida. The emir fled without fighting and was deposed. Another emir was appointed in his place, took the oath of allegiance to the British crown, and worked cordially with the British residency.

who was stationed at Bida. The province is divided into three administrative districts—Bida, Lapai and Agaie. These are again divided into nine native districts, five to the west and four to the east of the Kaduna river. Provincial courts of justice have been established.

See NIGERIA, BIDA. For an interesting account of the ancient constitution of Nupe see "The Fulani Emirates of Northern Nigeria," by Major J. A. Burdon in the *Geo Journ.*, vol. xxiv (London, 1904).

NUREMBERG (Ger. *Nürnberg*), a city of Germany, the second town in Bavaria in size, and the first in commercial importance. It lies in the district of Middle Franconia in a sandy but well-cultivated plain, 124 m. by rail N.W. from Munich. The city is divided by the small river Pegnitz, a tributary of the Main, into two parts, called respectively the Lorenzer Seite and the Sebalder Seite, after the two principal churches. There are four islands in the Pegnitz, which is crossed here by fourteen bridges. Formerly among the richest and most influential of the free imperial towns, Nuremberg is one of the few cities of Europe that have retained their medieval aspect largely unimpaired. Considerable sections of the ancient walls and moat still remain, though the demolition of portions to meet the exigencies of modern traffic and expansion has somewhat destroyed its quaint medieval character. Of the 365 bastions which formerly strengthened the walls, however, nearly 100 are still *in situ*, and a few of the interesting old gateways have also been preserved. Most of the streets are narrow and crooked, and the majority of the houses have their gables turned towards the street. The general type of architecture is Gothic, but the rich details, which are lavished with especial freedom in the interior courts, are usually borrowed from the Renaissance. Most of the private dwellings date from the 16th century, and there are practically none of earlier date than the 15th century. A praiseworthy desire to maintain the picturesqueness of the town has led most of the builders of new houses to imitate the lofty peaked gables, oriel windows and red-tiled roofs of the older dwellings. Altogether Nuremberg presents a faithful picture of a prosperous town of three hundred years ago.

The old burg, or castle (Kaiserschloss), is picturesquely placed on a rock on the north side of the town. This dates most probably from the early part of the 11th century, but it received its present form mainly during the reign of the emperor Frederick I. about 150 years later. It was restored in careful harmony with its original appearance in 1854–1856, and part of the interior is fitted up as a royal residence, the families of the German emperor and of the king of Bavaria having apartments therein. In the Heidenturm are two late Romanesque chapels, one above the other. Other parts of the castle are the pentagonal tower, the oldest building in the town, wherein are preserved the famous "iron virgin of Nuremberg," and other instruments of torture; the granary (Kornhaus), also called the Kaiserstallung; and the Vestnertor or Vestnerturm. The castle of Nuremberg was a favourite residence of the German sovereigns in the later middle ages, and the imperial regalia were kept here from 1424 to 1796. Near it are the remains of the burg of the Hohenzollerns, the principal existing part of which is the chapel of St Walpurgis, which was destroyed with the rest of the building in 1420, but was restored in 1892. Not far from these ruins stands the Luginsland, a stronghold with four corner turrets, said to have been built by the burghers in 1367 as a watch-tower against the burg of the Hohenzollerns.

Nuremberg contains several interesting churches, the finest of which are those of St Lorenz, of St Sebald and of Our Lady. All three are Gothic edifices and are notable for their elaborately carved doorways, in which free play has been given to the exuberant fancy of the Gothic style, and all three enshrine valuable treasures of art. The Church of St Lawrence, the largest of the three, was built in the 13th and 14th centuries and has recently been restored. In it is the masterpiece of the sculptor, Adam Krafft, consisting of a ciborium, or receptacle for the host, in the form of a florid Gothic spire 65 ft. high; the carving of this work is exquisitely minute and delicate. The west front contains a magnificent rose-window, and some of the stained glass dates from the 15th and 16th centuries. In front of the altar hangs a curious piece of wood-carving by Veit Stoss, representing the Salutation. The shrine of St Sebald, in the church of St Sebald, consisting of a bronze sarcophagus and canopy, in the richest Gothic style, adorned with numerous statues and reliefs, is looked upon as one of the greatest achievements of German art. It was executed by Peter Vischer, the celebrated artist in bronze, who was occupied on the work for thirteen years (1506–1519), and has here shown himself no unworthy rival of Lorenzo Ghiberti. The church of Our Lady possesses some fine old stained-glass windows and some paintings by Michael Wohlgemuth. The Tuchersche altar, with its winged picture, is one of the finest works of the Nuremberg school about the middle of the 15th century. This church was restored in 1878–1881. Other noteworthy churches are those of St Jacob, founded about 1200 and restored in 1824; and of St Aegidius.

The town hall (Rathaus), an edifice in the Italian style, erected in 1616–1619, contains frescoes by Dürer, and a curious stucco relief of a tournament held at Nuremberg in 1446. The building incorporated an older one of the 14th century, of which the great hall, with its timber roof, is part. The most interesting secular buildings are the houses of the old patrician families. Among the most characteristic of these are the old residence of the counts of Nassau, and the houses of the Tucher, Funk and Peller families. A special interest attaches to the dwellings of Albert Dürer, Hans Sachs, the cobbler-poet, and Johann Palm, the patriotic bookseller who was shot by order of Napoleon in 1806. There are statues of Dürer, Sachs, Melanchthon, the reputed founder of the grammar-school, the navigator Martin Behaim, and Peter Henlein, the inventor of the watch; and the streets are further embellished with several fountains, the most noteworthy of which are the Schöne Brunnen, 1385–1396, in the form of a large Gothic pyramid, adorned with statues of the seven electors, the "nine worthies," and Moses and the prophets; and the Gänsemännchen or goose-mannikin, a clever little bronze figure by Pankratz Labenwolf. On the way to the cemetery of St John, which contains the graves of Dürer, Sachs, Behaim and other Nuremberg worthies, are Krafft's stations, seven pillars bearing stone reliefs of the Passion, and ranked among the finest works of the sculptor.

The Germanic national museum, established in an old Carthusian monastery, has developed into one of the largest and most important institutions of its kind in Germany. It includes a picture-gallery, principally of German works of the 15th and 16th centuries, including masterpieces by Holbein, Dürer, Wohlgemuth and others. The municipal library contains about 2000 manuscripts and 80,000 printed books, some of which are of great rarity.

The population of Nuremberg was, in 1905, including a garrison of about 3000 men, 294,344, of whom 145,354 were males and 148,990 females. Of these again 196,907 were Protestants (Evangelical), 86,939 Roman Catholics and 6819 Jews. At the height of its prosperity in the middle ages the population has been estimated at as high a figure as 150,000, but there seems good reason to believe that it did not exceed 40,000 to 50,000 souls. In 1818 it had sunk to 27,000, but since then has steadily increased. On the 1st of January 1899, thirteen outlying communes were incorporated, extending the area of the town from 2805 to 13,700 acres.

Nuremberg occupies a high place among the industrial and commercial centres of Europe. The principal manufactures are toys and fancy articles in metal, carved wood and ivory, which are collectively known as Nuremberg wares. Nuremberg is the chief market in Europe for hops. It is an important junction for railways to all parts of Germany, and is on the main line from Cologne and Frankfort-on-Main to Munich, Vienna and Eger. In addition to its railways, trade is facilitated by the Ludwig canal, connecting the Danube and the Main.

History.—The first authentic mention of Nuremberg, which seems to have been called into existence by the foundation of the castle, occurs in a document of 1050; and about the same period

it received from the emperor Henry III. permission to establish a mint and a market. It is said to have been destroyed by the emperor Henry V. in 1105, but if this was the case the town must have been very speedily rebuilt, as in 1127 we find the emperor Lothair taking it from the duke of Swabia and assigning it to Henry the Proud, duke of Bavaria. An imperial officer, styled the burggrave of Nuremberg, who, however, seems to have been merely the military governor of the castle, and to have exercised no sway over the citizens, became prominent in the 12th century. This office came into the hands of the counts of Hohenzollern at the beginning of the 13th century, and burggrave of Nuremberg is still one of the titles of their descendant, the German emperor. The government of the town was vested in the patrician families, who, contrary to the usual course of events in the free towns, succeeded in permanently excluding the civic gilds from all share of municipal power, although in 1347 there was a sharp rising against this oligarchy. The town was specially favoured by the German monarchs, who frequently resided and held diets here, and in 1219 Frederick II. conferred upon it the rights of a free imperial town. By the terms of this charter the town appears to have been immediately subject to the king, who was represented by his magistrate (or *Schultheiss*). In a short time, however, the latter appears to have been assisted by a council, consisting of 13 *consules* (burgomasters) and 13 *scabini* (assessors), who collectively formed the governing and administrative body under the presidency of the bailiff. The last-named official soon confined himself to the judicial magisterial office, and a further increase in the numbers of the council having taken place by the appointment of 8 nominees of the king, a municipal council of 34, under the direction of the senior consul or burgomaster, dealt with matters exclusively civic. Later this council (the kleine Rat) was increased to 42 members, 8 of whom belonged to the artisan class.

In 1356 Nuremberg witnessed the promulgation of the famous Golden Bull of the emperor Charles IV. At the beginning of the 15th century the burggraves of Nuremberg, who had in the meantime raised themselves to the rank of princes of the Empire, were invested with the margraviate of Brandenburg, and sold their castle to the town. They, however, reserved certain rights, and their insistence on these led to fierce and sanguinary feuds between the burghers and the margraves Albert Achilles and Frederick and Albert Alcibiades of Bayreuth.

The quarrel with the margraves, however, did not interfere with the growth of the town's prosperity, which reached its acme in the 16th century. Like Augsburg, Nuremberg attained great wealth as an intermediary between Italy and the East on the one hand, and northern Europe on the other. Its manufactures were so well known that it passed into a proverb—"Nuremberg's hand goes through every land." Its citizens lived in such luxury that Aeneas Sylvius (Pope Pius II.) has left it on record that a simple burgher of Nuremberg was better lodged than the king of Scotland. The town had gradually extended its sway over a territory nearly 500 sq. m. in extent, and was able to furnish the emperor Maximilian with a contingent of 6000 troops. But perhaps the great glory of Nuremberg lies in its claim to be the principal fount of German art. Its important architectural features have already been described. The love of its citizens for sculpture is abundantly manifest in the statues and carvings on their houses. Adam Krafft, Veit Stoss and Peter Vischer form a trinity of sculptors of which any city might be proud. In painting Nuremberg is not less prominent, as the names of Wohlgemuth and Dürer sufficiently indicate. In the decorative arts the Nuremberg handicraftsman attained great perfection in ministering to the luxurious tastes of the burghers, and a large proportion of the old German furniture, silver-plate, stoves and the like, which are now admired in industrial museums, was made in Nuremberg workshops. Wenzel Jamnitzer (1508–1585), the worker in silver, is perhaps eminent enough to be added to the above list of artists. Its place in literary history—by no means an unimportant one—it owes to Hans Sachs and the other meistersänger. A final proof of its vigorous vitality at this period may be found in the numerous inventions of its inhabitants, which include watches, at first called "Nuremberg eggs," the air-gun, gun-locks, the terrestrial and celestial globes, the composition now called brass, and the art of wire-drawing.

Nuremberg was the first of the imperial towns to throw in its lot with the Reformation, and it embraced Protestantism with its wonted vigour about 1525. Its name is associated with a peace concluded between Charles V. and the Protestants in 1532. The first blow to its prosperity was the discovery of the sea-route to India in 1497; and the second was inflicted by the Thirty Years' War, during which Gustavus Adolphus was besieged here in an entrenched camp by Wallenstein. During the eight or ten weeks that the blockade lasted no fewer than 10,000 of the inhabitants are said to have died of want or disease. The downfall of the town was accelerated by the illiberal policy of its patrician rulers; and the French Revolution reduced it to such a degree that in 1796 it offered itself and its territories to the king of Prussia on condition that he would pay its debts. Prussia, however, refused the offer. In 1803 Nuremberg was allowed to maintain its nominal position as a free city, but in 1806 it was annexed to Bavaria.

NURSE (a shortened form of the earlier "nourice," adapted through the French from Lat. *nutrix*, *nutrire*, to nourish), primarily a woman who suckles and takes care of an infant, and more generally one who has the general charge of children; also a person, male or female, who attends to the sick, and particularly one who has been trained professionally for that purpose (see NURSING).

NURSING. The development of sick-nursing, which has brought into existence a large, highly-skilled, and organised profession, is one of the most notable features of modern social life. The evolution of the sick-nurse is mainly due to three very diverse influences—religion, war and science—to name them in chronological order. It was religion which first induced ladies, in the earlier centuries of Christianity, to take up the care of the sick as a charitable duty. The earliest forerunner of the great sisterhood of nurses of whom we have any record was Fabiola, a patrician Roman lady, who in A.D. 380 founded a hospital in Rome with a convalescent home attached, and devoted herself and her fortune to the care of the sick poor. She had a rival in the empress Flaccilla, the pious consort of Theodosius I. (A.D. 379–395), who also personally visited the hospitals and attended on the sick. Organized nursing does not appear to have formed any part of medical treatment, except in so far as the deacons of the church attended on the poor, until the 4th century of the Christian era. After that date the employment of women for this purpose must have developed rapidly, for in the reign of Honorius (A.D. 395–423) six hundred women were engaged in the hospitals of Alexandria. These institutions were managed by the clergy, and throughout the dark and middle ages the hospital and nursing systems were connected with religious bodies. Nurses were provided by the male and female monastic orders, an arrangement which still continues in most Roman Catholic countries, though it is gradually being abandoned through the increasing demands of medical science, which have led the hospitals to establish training schools of their own. The names of the oldest foundations which still survive, such as the Hôtel Dieu in Paris, St Thomas's and St Bartholomew's in London, the order of St Augustine, and (in the form of a modern revival) that of St John of Jerusalem, sufficiently indicate the original religious connexion. The

History.

order of St Vincent de Paul, founded in 1633 for the express purpose, is still the largest nursing organization in the world. Even in Protestant England, where purely secular training schools have reached their highest development, the generic title of Sister, alike prized by its holders and honoured by the public, remains the popular and professional synonym for head nurse, and perpetuates the old association. Nursing, as a popular or fashionable occupation, is not a modern invention. Sir Henry Burdett quotes an order, dated 30th May 1578, directing the master and the prior of the Hôtel Dieu "not to receive henceforth any novices without speaking of it to the company, because there are an excessive number of nuns and novices, who cause great expense to the said Hôtel Dieu." In Protestant countries a secular nursing system came in with the Reformation. The staff appointed for St Bartholomew's, on its re-establishment by Henry VIII. in 1544, consisted of a matron and twelve nurses, who were engaged in domestic occupations when off duty. Thus nursing became a menial office and an inferior means of livelihood, adopted by women of the lower orders without any training or special skill; and so it continued down to the middle of the 19th century, when a new movement began which was destined to revolutionize the status of the nurse.

Its distinctive feature was the systematic training of nurses for their vocation. Previously a certain amount of regular instruction had no doubt been given here and there by individual physicians and surgeons; lectures to nurses were delivered in the New York Hospital as early as 1790. But these were isolated efforts. Such skill as nurses possessed was picked up in the wards. No qualifications were required, nor indeed would they have been forthcoming, so low had the calling sunk in public estimation. The credit of inaugurating the new order of things belongs to Germany, and here again the religious influence came into play. The beginning of the modern system dates from the foundation of the institute for training deaconesses at Kaiserswerth by Pastor Fliedner in 1836. It is true that state training schools for male nurses had previously existed in Prussia, the oldest having been founded at Magdeburg in 1799; but the employment of men in hospital wards is a feature of the German system which has not been copied by other advanced countries, and seems to be in process of abandonment in Germany. It is a heritage from the middle ages, when the Knights Hospitallers undertook for men the duties discharged in female institutions by the nuns. The male schools, therefore, stand somewhat apart, though they mark a stage in the evolution of nursing as the earliest regular training establishments. The Kaiserswerth Institute, on the contrary, had a far-reaching and lasting influence, and may fairly claim to be the mother of the modern system. England, in particular, owes much to it, for there Florence Nightingale acquired the practical knowledge which enabled her afterwards to turn her remarkable gift of organization to such brilliant account. The example of Kaiserswerth was soon followed, and not in Germany only. In 1838 the Society of Friends founded a nursing organization in Philadelphia, and in 1840 Mrs Fry, a member of the same community, started the Institution of Nursing Sisters in London. In 1857 the nurses attached to it numbered ninety. They received their practical training at Guy's and St Thomas's Hospitals. On the continent institutes for nursing deaconesses were founded at Strassburg, Utrecht, Berlin, Breslau, Königsberg and Carlsruhe between 1842 and 1851. In London a Church of England training institution (St John's House) was opened in 1848. There were three classes —(1) sisters, (2) probationers, (3) nurses. The nursing at King's College Hospital was for many years undertaken by this society, whose members were trained at the hospital.

The training system, thus inaugurated on a semi-religious basis, received a new impetus from the Crimean War, which was further emphasized by the Civil War in America and the subsequent great conflicts on the continent. The despatch of Florence Nightingale with a staff of trained nurses, to superintend the administration of the military hospitals was the direct result of the publicity given to the details of the Crimean War by *The Times*, and it formed a new departure which riveted the eyes of the civilized world. The work undertaken and accomplished by this lady was far more important than the mere nursing of sick and wounded soldiers. She had grasped the principles of hygiene, which were then beginning to be understood, and she applied them to the reform of the hospital administration. In civil life it had a marked effect in stimulating the training movement and raising the status of the nurse; but substantial results were only obtained by degrees. It was not until 1860 that the modern hospital school system was definitely inaugurated by the opening of the Nightingale Fund School at St Thomas's Hospital, founded with the money subscribed by the British public in recognition of Miss Nightingale's national services, and worked on principles laid down by her. In the meantime several nursing societies, in addition to those previously mentioned, had been founded in England, and elsewhere. Among them the Baden Ladies' Society, founded in 1859 by the Grand Duchess Luise, deserves mention. In the same year the first district nurse began work in Liverpool; and in 1865 the reform of the much-neglected workhouse nursing was inaugurated by Miss Agnes Jones and twelve nurses from St Thomas's, who took up the work in Liverpool. At this time England took a decided lead, which she has never lost. Other countries gradually followed. In Germany the Albert Nursing Society was founded by Queen Carola of Saxony, and the Alice Society by the Grand Duchess Alice of Hesse, both in 1867. In France, where the nursing was comparatively well performed by the religious orders, no change was made until 1877, when a training school was opened in Paris by the municipality, and two others by the Assistance Publique, in connexion with the Salpêtrière and Bicêtre Hospitals. In the United States schools were opened in New York, New Haven and Boston in 1873. The British colonies, Austria, and other European countries followed some years later.

It remained for the third influence to complete the work begun and to develop systematic nursing to its present dimensions. Since 1880 the increasing demands of medical knowledge have well-nigh revolutionized the craft in the home, the hospital and the workhouse. A large part of the change may be summed up in the words "scientific cleanliness." The outcome has been to raise the dignity of the calling, to induce persons of a superior class to adopt it in increasing numbers, to enlarge the demand for their services, and to multiply the means of educating them.

Training and organization.

Nursing does not appear to be regulated by law in any country, though attempts in this direction had been made in England.[1] Its organization is voluntary, and even in state or municipal institutions is dependent on the direction of the administration. In Great Britain nearly all the general and special hospitals and many of the poor-law infirmaries offer systematic professional training to nurses. The provisions differ considerably in detail, but in the larger schools the system is uniform in all important respects. Candidates must be between 23 (sometimes 21 or 22) and 35 years of age, and must produce satisfactory evidence of character, education, health and physique; after a personal interview and one, two or three months' trial they are admitted for three years' training. During this period they receive regular instruction in theoretical and practical knowledge, and have to pass periodical examinations. At the end of it they are granted certificates and may serve as staff nurses. They pay no premium, and generally receive a salary of £8 to £12 in the first year, rising annually to £30 or £35 as staff nurse, and subsequently to £40 or £50 as sister or head nurse. They live in a home attached to the institution, under a matron, and in the most modern establishments each nurse has a separate bedroom, with common dining and recreation rooms. Private nursing staffs are attached to several of the hospitals; they are recruited from the staff nurses and probationers on completion of their course, and supply nurses to private patients. In the special

[1] In 1902 an act was passed to establish a Central Midwives Board and regulated the training and employment of midwives.

hospitals the training is shorter, being for one or two years. There seems to be a constant tendency to increase the requirements. At St Bartholomew's, St George's, the London Hospital, St Thomas's and others, probationers must enter for four years, and at St Bartholomew's they have to pass an entrance examination in elementary anatomy, physiology and other subjects. At all the more important schools the number of applications is many times greater than the vacancies.

In Great Britain trained and certificated nurses generally belong to a society or association. The most noteworthy of the associations is Queen Victoria's Jubilee Institute for Nurses. It was founded in 1887 with the object of providing skilled nursing for the sick poor in their own homes. A great many of the provincial nursing associations are affiliated to it. The number of nurses supported by each branch varies. The qualifications for a Queen's nurse are as follows: (1) training at an approved general hospital or infirmary for two years; (2) approved training in district nursing for not less than six months, including the nursing of mothers and infants after child-birth; (3) nurses in country districts must in addition have had at least three months' approved training in midwifery. Candidates possessing the first qualification are received on trial for one month, after which they complete their six months' training for the second qualification, at the same time entering into an agreement to serve as district nurse for one or two years at the end of the six months. The salary during training is £12, 10s., and afterwards £30 to £35 a year, with board, lodging, laundry and uniform. With regard to the earnings of nurses in general, the salaries paid in hospitals have already been mentioned; for private work the scales in force at different institutions vary considerably, according to the other advantages and benefits provided. At some the nurses receive all their own earnings, minus a percentage deducted for the maintenance of the institute; at others they are paid a fixed salary, as a rule from £25 to £30 a year, plus a varying percentage on their earnings or a periodical bonus according to length of service. This is perhaps the commonest system, but some of the best nursing homes give a somewhat higher fixed salary without any percentage. In all these cases the nurses receive in addition board and lodging, laundry and uniform, or an equivalent allowance. For special cases—infectious, massage, mental and maternity—nurses on a fixed salary usually receive extra pay. The fees commonly charged by high-class institutions for the services of a trained and certificated nurse are—for ordinary cases £2, 2s. a week, for special cases £2, 12s. 6d. or £3, 3s. a week; but many provincial associations supply nurses for £1, 1s. a week and upwards. The discrepancy between the fees paid by patients and the salaries received by nurses, especially in London, has occasionally excited unfavourable comment, but it is to be remembered that the nurses are maintained when out of work or ill, and have other advantages; many institutions either provide pensions or assist the members of their staff to join the Royal National Pension Fund.

To complete this account of the organization in Great Britain a few details with regard to special nursing are added.

Fever.—Regular training on the same plan as in general hospitals is provided in London at the fever hospitals of the Metropolitan Asylums Board (12 in number, with from 360 to 760 beds each), and at a considerable number of provincial institutions.

Insanity.—The Medico-Psychological Association of Great Britain and Ireland holds examinations and grants certificates in mental nursing; candidates must undergo three years' regular training, with instruction by lectures, &c., which may be obtained in a large number of public asylums by arrangement with the Association; one county asylum (Northampton) gives its own certificates after a three years' course.

District Nursing.—In addition to the Queen's nurses, of whom details have been given above, many local associations train their own nurses for this work. *Cottage* and *village* nursing are varieties of the same department; the former is organized on the benefit system, and aims at supplying domestic help and sick-nursing combined in rural districts for an annual subscription of from 2s. to 10s., according to the class in life of the family, and a weekly fee of the same amount during attendance.

Monthly Nursing and Midwifery.—Systematic instruction in these subjects is given at some fifty lying-in institutions in different parts of the kingdom. The usual course for nursing is not less than three months, and for midwifery not less than six months; a premium is required of 12 or 13 guineas for three months, and 25 guineas for six months.

Male Nursing.—Two or three associations in London supply male nurses (fees 2 to 4 guineas a week), but there appears to be only one institution, apart from the military and naval services, at which they are systematically trained—namely, the National Hospital for the Paralysed and Epileptic.

Massage is taught regularly at the hospital just named, and at a few other special hospitals. Competent operators are supplied by the Incorporated Society of Trained Masseuses and, to some extent, by other nursing associations; but this branch of the profession is still imperfectly organized (see MASSAGE).

Children.—A large number of children's hospitals throughout the country give regular training in the nursing of children; they take probationers at a somewhat earlier age than the general schools; the course is usually shorter (one or two years), and the salaries slightly lower.

The State offers employment to nurses in the naval and military hospitals. *Queen Alexandra's Imperial Nursing Service* was organized in 1902. Candidates for it must be between 25 and 35 years, single or widows and of good social status. They must have had three years' training in a general hospital. Foreign Service must be taken as required. Nurses are eligible for a pension after 10 years' service, the amount increasing up to the age of 55 when retirement is compulsory. The *Royal Naval Nursing Service* is organized on much the same basis. Other organizations are *The Army Nursing Reserve* and *Queen Alexandra's Imperial Military Nursing Reserve*, and there is also a nursing reserve attached to the territorial forces.

In the more important *British colonies*—Australasia, Canada and South Africa—there are now a considerable number of hospital schools and other institutions formed and conducted on the English model. Salaries and fees are very much the same in Australia; in Canada and South Africa they are higher.

In the *United States* a similar system prevails in New York, Boston, Brooklyn, Chicago, Baltimore, Philadelphia, New Haven and many other large towns. The period of training is either two or three years. At the Johns Hopkins School at Baltimore twelve scholarships of $100 and $120 each are awarded annually; graduate nurses are paid $360 (£72) a year. Salaries are altogether much higher in the United States. At the Boston City Hospital graduate nurses receive $420 (£84) a year, and at the Indianapolis City Hospital those on private duty are paid $72 a month, which is equivalent to £172 a year, with board, lodging, laundry and uniform. This may be taken to indicate the possible earnings of trained nurses working independently, as they usually do in America. The fees charged for trained nurses run from $12 to $25 a week, and even more for special cases. Male nurses are trained at the Bellevue Hospital, New York, the Grace Hospital, Detroit, and elsewhere. In the American schools more attention is paid to the preparation of nurses for private work than in the British (Burdett), and a directory or registry of them is kept in most large towns.

In *Germany*, their original home, both training schools and societies have multiplied and developed. The period of training appears to be considerably shorter than in Great Britain and America. Members of the Albert Society of Saxony, however, spend two years in the wards at Dresden, and a third at Leipzig, attending lectures and demonstrations. They are sent out to nurse rich and poor alike, and their pay is very small. Most of the German institutes have pension funds.

In *France* a great deal of the nursing was formerly in the hands of religious orders, but there too the hospital school system, inaugurated in 1877, has grown. The schools managed by the *Assistance Publique* in Paris give a very thorough course of instruction.

In *Russia* nursing is mainly in the hands of the Red Cross Society, whose members are, however, trained in the hospital schools.

In *Italy*, *Spain*, *Portugal* and *Belgium* scientific nursing is in a backward state. The old religious system still prevails to a large extent, and, though some of the orders do their work with great devotion, the standard of knowledge and skill is not up to modern requirements. At San Remo and Rome institutions have been established for providing English trained nurses to private cases.

Austria is also in a very backward state, in spite of the fame of the Vienna cliniques. The Red Cross Society provides a certain amount of trained nursing, and next to it the best-organized work is done by religious orders; but the nursing in the hospitals appears to be still in a neglected state. The Brothers of Mercy have charge of some of the men's hospitals, and also carry on a remarkable system of district nursing.

In *Holland* and the *Scandinavian countries* the organization is more modern and fairly adequate.

For full details on the large subject of the duties and qualifications of nurses the reader is referred to the numerous text-books and other technical authorities. Only a few general observations can be made here. Many candidates approach the calling with a very imperfect appreciation of its exacting character. The work is not easy or to be taken up lightly. It demands physical strength, sound health, scrupulous cleanliness, good temper, self-control, intelligence and a strong sense of duty. It embraces many duties—some of them menial and disagreeable—besides the purely medical and surgical functions. This is especially the case with district nursing, which is the highest and most exacting branch of the profession, because it imposes the greatest responsibility with the fewest resources and demands the most varied qualifications, while affording none of the attractions incidental to hospital work or private nursing among the rich. It is comparatively easy to fulfil routine duties, when every means is at hand and the standing conditions are the most favourable possible; when ventilation, warmth, light and cleanliness are all provided of the best, and when assistance can be summoned in a moment. To be thrown on your own resources and make the best of adverse conditions is an entirely different matter; it requires a thorough knowledge not of routine, but of principles. It is impossible, therefore, for nurses to be over-educated in the fullest sense of the word; but it is possible for them to be inappropriately educated, and perhaps that is sometimes the case now. Probably nursing has been elaborated to the inevitable point of specialization, and a somewhat different preparation is needed for different branches of the art.

Duties and qualifications.

Allusion has been made above to the subject of male nursing. It hardly finds a place in the British civil system, and was condemned for hospitals in Germany, where it is at its best, by so eminent an authority as Professor Virchow. In the South African War of 1899–1902 it was even suggested that female nurses should replace orderlies at the front. The only valid reason for preferring women to attend men rather than members of their own sex is the difficulty of obtaining a supply of equally well qualified and satisfactory male nurses. But this difficulty need not be permanent, and the assumption is much to be deprecated. It is, indeed, most desirable that men should be nursed by men. The advantages are many and real. For one thing women do not possess the physical strength which is often required. They cannot lift a heavy man, and ought not to be asked to do it. Then it is excessively irksome to a sensitive man to be attended by women for various necessary offices. In order to avoid it he will endeavour to do without assistance, and seriously prejudice his chances of recovery.

NUSHKI, a town and district of Baluchistan. The town lies 70 m. south-west of Quetta, and is situated in a plain at the base of the Quetta plateau, 2900 ft. above the sea. Pop. (1901) 644. From this point the flat Baluchistan desert stretches away northwards and westwards to the Helmund river. The administration of the Nushki district was taken over from the khan of Kalat by the Indian government in 1896, and was leased from him on a perpetual quit rent in 1899. In 1902 a railway of 91 m. was sanctioned from Quetta to Nushki, which was completed in 1905. This railway makes Nushki the starting-point of the caravan route to Seistan. From the strategic point of view a force operating from Nushki would flank any advance from the north on Kandahar, and would also guard the south-west approach to the fortress of Quetta.

NUSKU, the name of the light and fire-god in Babylonia and Assyria, who is hardly to be distinguished, from a certain time on, from a god Girru—formerly read Gibil. Nusku-Girru is the symbol of the heavenly as well as of the terrestrial fire. As the former he is the son of Anu, the god of heaven, but he is likewise associated with Bel of Nippur as the god of the earth and regarded as his first-born son. A centre of his cult in Assyria was in Harran, where, because of the predominating character of the moon-cult, he is viewed as the son of the moon-god Sin (*q.v.*). Nusku-Girru is by the side of Ea, the god of water, the great purifier. It is he, therefore, who is called upon to cleanse the sick and suffering from disease, which, superinduced by the demons, was looked upon as a species of impurity affecting the body

The fire-god is also viewed as the patron of the arts and the god of civilization in general, because of the natural association of all human progress with the discovery and use of fire. As among other nations, the fire-god was in the third instance looked upon as the protector of the family. He becomes the mediator between humanity and the gods, since it is through the fire on the altar that the offering is brought into the presence of the gods.

While temples and sanctuaries to Nusku-Girru are found in Babylonia and Assyria, he is worshipped more in symbolical form than the other gods. For the very reason that his presence is common and universal he is not localized to the same extent as his fellow-deities, and, while always enumerated in a list of the great gods, his place in the systematized pantheon is more or less vague. The conceptions connected with Nusku are of distinctly popular origin, as is shown by his prominence in incantations, which represent the popular element in the cult, and it is significant that in the astro-theological system of the Babylonian priests Nusku-Girru is not assigned to any particular place in the heavens. (M. JA.)

NUSRETABAD, the capital of Persian Seistan, so called after Nusret el Mulk, a former deputy governor of Seistan; when built, *c.* 1870, it was first called Nasirabad in honour of Nasr-ud-din Shah; other names, used locally, are Shahr (town) i Seistan, Shahr i Nassiriyeh, or simply Shahr, the town. It is the residence of British and Russian consuls, and has post and telegraph offices.

NUT (O. Eng. *knutu*, cf. Dutch *noot*, Ger. *Nuss*; allied with Gael. *cno*; it is not of the same form as Lat. *nux*), a term applied to that class of fruit which consists generally of a single kernel enclosed in a hard shell. Botanically speaking, nuts are one-celled fruits with hardened pericarps, sometimes more or less enveloped in a cupule or cup, formed by the aggregation of the bracts as in the hazel and the acorn. In commerce, however, the term has a wider application and embraces many fruits having hard woody indehiscent shells or coverings without reference to their enclosed seeds or kernels, besides leguminous pods, and even tuberous roots. A great number of nuts enter into commerce for various purposes, principally as articles of food or sources of oil, and for several ornamental and useful purposes. For the most part the edible nuts are very rich in oil, with only a small percentage of the other carbohydrates, starch, sugar, &c., and they also contain a large proportion of nitrogenous constituents. Thus possessing rich nutrient principles in a highly concentrated form, nuts are by themselves rather difficult of digestion, and the liability of many of them to become rancid is also a source of danger and a hindrance to their free use. Oleaginous nuts used for food are likewise employed more or less as sources of oil, but on the other hand there are many oil-nuts of commercial importance not embraced in the list of edible nuts.

On the following page is set out an alphabetical enumeration of the more important nuts, and of products passing under that name, used either as articles of food or as sources of oil.

Name.	Source.	Locality.	Remarks
Almond	*Amygdalus communis*, var. *dulcis*	S. Europe	Food, oil.
Almond (bitter)	*Amygdalus communis*, var. *amara*	.....	Oil.
Ar nut or earth nut	Tubers of *Bunium flexuosum* and other species	W. Europe (Britain)	Food.
Bambarra ground nut	*Voandzeia subterranea*	Tropics, especially Africa	Food.
Ben nut	*Moringa pterygosperma* (a winged seed)	India	Oil.
Bitter nut	*Carya amara* (swamp hickory)	N. America	See HICKORY.
Brazil nut	*Bertholletia excelsa*	S. America	Food, oil.
Bread nut	*Brosimum Alicastrum*	W. Indies	Food.
Butter or Souari nut	*Caryocar nuciferum*	Guiana	Food.
Cahoun nut	*Attalea Cohune*	Honduras	Oil.
Candle nut	*Aleurites triloba*	S. Sea Islands	Oil.
Cashew nut	*Anacardium occidentale*	W. Indies and Tropical America	Food, oil.
Chestnut	*Castanea vesca*	S. Europe	Food.
Cob, filbert, or hazel	*Corylus Avellana*	Europe (Britain), &c.	See HAZEL.
Cob nut of Jamaica	*Omphalea diandra*	W. Indies and Tropical America	Food.
Coco-nut	*Cocos nucifera*	Tropics	Food, oil.
Cola nut	*Cola acuminata*	W. Africa	Food.
Dika nut	*Irvingia Barteri*	W. Africa	Food, oil.
Ginkgo nut	*Ginkgo biloba* (seed)	Japan, China	Food, oil.
Ground nut or pea nut	*Arachis hypogaea*	Tropics	See GROUND NUT.
Hickory nut	*Carya alba*	N. America	See HICKORY.
Hog nut	*Carya porcina*	N. America	Eaten by animals.
Jesuit's nut	*Trapa natans*	S. Europe	Food.
Mocker nut	*Carya tomentosa*	N. America	See HICKORY.
Moreton Bay chestnut	*Castanospermum australe*	Australia	Food.
Nutmeg	*Myristica moschata*	E. Indies	Spice. See NUTMEG.
Nutmeg (wild)	*Myristica fatua*, *M. tomentosa*, &c.	Tropics	Spice. See NUTMEG.
Olive nut	*Elaeocarpus Ganitrus*, &c.	E. Indies	Food.
Palm nut	*Elaeis guineensis*	W. Africa	Oil. See PALM.
Pecan nut	*Carya olivaeformis*	N. America	Food, oil. See HICKORY.
Pekea nut	*Caryocar butyrosum*	Guiana	Food.
Physic nut	*Curcas purgans*	Tropical America	Oil.
Pine nut	*Pinus Pinea*, &c.	Italy	Food.
Pistachio nut	*Pistachia vera*	S. Europe, &c.	Food.
Quandang nut	*Fusanus acuminatus*	Australia	Food.
Ravensara nut	*Agathophyllum aromaticum*	Madagascar	Spice.
Rush nut	*Cyperus esculentus* (tubers)	S. Europe, &c.	Food.
Sapucaya nut	*Lecythis Ollaria*	Brazil	Food.
Tahiti chestnut	*Inocarpus edulis*	S. Sea Islands	Food.
Walnut	*Juglans regia*	Asia, Europe	Food, oil.
Water chestnut	Various species of *Trapa*	S. Europe, India, &c.	Food.

There remain to be enumerated a number of nuts of commercial value for turnery and ornamental purposes, for medicinal use, and for several miscellaneous applications in the arts. These include:

Name.	Source.	Locality.	Remarks.
Betel nut	*Areca Catechu*	E. Indies	.....
Bladder nut	*Staphylea pinnata*	S. Europe	Necklaces.
Boomah nut	*Pycnocoma macrophylla*	Africa	Tanning.
Bonduc nut	*Guilandina Bonduc*	India	Medicine, beads.
Clearing nut	*Strychnos potatorum*	India	Clearing water.
Coquilla nut	*Attalea funifera*	Brazil	Turnery.
Corozo nut or vegetable ivory	*Phytelephas macrocarpa*	Tropical S. America	See PALM.
Cumara nut (Tonka bean)	*Dipterix odorata*	Tropical S. America	Perfume.
Grugru nut	*Acrocomia selerocarpa*	S. America	Beads.
Horse chestnut	*Aesculus Hippocastanum*	S. Europe	Starch.
Marking nut	*Semecarpus Anacardium*	E. Indies	Marking ink and varnish.
Nut galls	*Quercus infectoria*	Levant	Dyeing and ink making. See GALLS.
Poison nut	*Strychnos Nux-Vomica*	E. Indies	Medicine. See NUX VOMICA.
Sassafras nut	*Nectandra Puchury*	S. America	Aromatic.
Snake nut	*Ophiocaryon paradoxum*	S America	Curiosity.
Soap nut	*Sapindus Saponaria*	W. Indies	Washing; ornamental

The application of the term nut to many of these products is purely arbitrary, and it is obvious that numerous other bodies not known commercially as nuts might with equal propriety be included in the list. Most of the nuts of real commercial importance are or will be separately noticed, and here further allusion is only made to a few which form current articles of commerce, not otherwise treated of.

The bread nut of Jamaica is the fruit of a lofty tree, *Brosimum Alicastrum*. It is about an inch in diameter, and encloses a single seed, which, roasted or boiled, is a pleasant and nutritious article of food.

The souari or surahwa nut, called also the "Butter nut of Demerara," and by fruiterers the "Suwarrow nut," is the fruit of *Caryocar nuciferum*, a native of the forests of Guiana, growing 80 ft. in height. This is perhaps the finest of all the fruits called nuts. The kernel is large, soft, and even sweeter than the almond, which it somewhat resembles in taste. The few that are imported come from Demerara, and are about the size of an egg, somewhat kidney-shaped, of a rich reddish-brown colour, and covered with large rounded tubercles.

The pekea nut, similar in appearance and properties, is the produce of *Caryocar butyrosum*, growing in the same regions of tropical America.

The Jamaica cob nut is the produce of a euphorbiaceous tree, *Omphalea diandra*, the seeds of which resemble in taste the ordinary cob or hazel nut. The seed, however, contains a deleterious embryo, which must not be eaten.

Cola, kola or goora nuts are the seeds of *Cola acuminata* (Sterculiaceae), a tree, native of tropical Africa, now introduced into the West Indies and South America. The nuts form an important article of commerce throughout Central Africa, being used over a wide area as a kind of stimulant condiment. The nuts, of which there are numerous varieties, are found to contain a notable proportion of theine, as much as 2·13 %, besides theobromine and other important food-constituents, to which circumstances, doubtless, their valuable properties are due.

Coquilla nuts, the hard inner portion ("stone") of the palm, *Attalea funifera*, the piassaba of Brazil, are highly valued for turnery purposes. They have an elongated oval form, 3 to 4 in. in length, and being intensely hard they take a fine polish, displaying a richly streaked brown colour

The marking nut, *Semecarpus Anacardium*, is a fruit closely allied in its source and properties to the cashew nut (*q.v.*). The marking nut is a native of the East Indies, where the extremely acrid juice of the shell of the fruit in its unripe state is mixed with quicklime and used as a marking-ink. The juice also possesses medicinal virtues as an external application, and when dry it is the basis of a valuable caulking material and black varnish. The seeds are edible, and the source of a useful oil.

Physic nuts are the produce of the euphorbiaceous tree, *Curcas purgans*, whence a valuable oil, having similar purgative properties to castor oil, is obtained. The plant is a native of South America, but is now found throughout all tropical countries.

Pine nuts are the seeds of several species of *Pinus*, eaten in the countries of their growth, and also serving to some extent as sources of oil. Of these the most important are the stone pine, *Pinus Pinea*, of Italy and the Mediterranean coasts, and the Russian stone pine, *Pinus Cembra*. The *Pinus Sabiniana* of California and *P. Gerardiana* of the Himalayas similarly yield edible seeds. These seeds possess a pleasant, slightly resinous flavour.

Ravensara nuts, the fruit of *Agathophyllum aromaticum* (Lauraceae), a native of Madagascar, is used as a spice under the name of the Madagascar clove nutmeg.

The Sapucaya nut, a native of Brazil, is seen occasionally in fruit-shops. It is produced by a large tree, *Lecythis Ollaria*, or "cannon-ball tree." Its specific name is taken from the large urn-shaped capsules, called "monkey-pots" by the inhabitants, which contain the nuts. The sapucaya nut has a sweet flavour, resembling the almond, and if better known would be highly appreciated. It is, however, scarce, as the monkeys and other wild animals are said to be particularly fond of it. This nut, which is of a rich amber-brown, is not unlike the Brazil nut, but it has a smooth shell furrowed with deep longitudinal wrinkles.

Soap nuts are the fruits of various species of *Sapindus*, especially *S. Saponaria*, natives of tropical regions. They are so called because their rind or outer covering contains a principle, saponine, which lathers in water, and so is useful in washing. The pods of *Acacia concinna*, a native of India, possess the same properties, and are also known as soap nuts.

NUTATION (from Lat. *nutare*, to nod), a revolution of the celestial pole around its mean position, due to inequalities in the action of the sun and moon, on an earth of ellipsoidal form. When either of these attracting bodies is in the plane of the equator, it produces no change in the direction of the celestial pole. The greater their distance from this plane, the greater the change, for reasons shown in the article ASTRONOMY (*Celestial Mechanics*). The result is a motion which can be divided into two components. One of these is the progressive and nearly uniform motion of a fictitious mean pole, called precession (*q.v.*), and the other a revolution of the true around the mean pole, depending on the varying declinations of the sun and moon, and called nutation. Owing to the revolution of the moon's node and the inclination of its orbit, this body moves through a wider range of declination in some positions of the node than in others. The period of the revolution of the node is 18·6 years. At one time of this period the limits of its declination are more than 28° north and south, while, at the opposite point, they are little more than 18°. The result of these periodic changes is that the nutation takes place nearly in an ellipse, differing little from a circle, at a distance of about 9″, in a period of about 18·6 years. The motion is not exactly an ellipse, having a great number of minute inequalities arising from the ellipticity of the orbits of the sun and moon and their varying declinations. The amount and formulae of nutation from year to year are given in the *Nautical Almanac*.

NUTCRACKER, the name given by G. Edwards in 1758 (*Gleanings*, No. 240) to a bird which had hitherto borne no English appellation, though described in 1544 by Turner, who, meeting with it in the Rhaetic Alps, where it was called "Nousbrecher" (*hodie* "Nussbrecher"), translated that term into Latin as *Nucifraga*. In 1555 C. Gesner figured it and conferred upon it another designation, *Caryocatactes*. It is the *Corvus caryocatactes* of Linnaeus and the *Nucifraga caryocatactes* of modern ornithology. F. Willughby and J. Ray obtained it on the road from Vienna to Venice as they crossed what must have been the Sömmerring Pass, 26th September 1663. The first known to have occurred in Britain was, according to T. Pennant, shot at Mostyn in Flintshire, 5th October 1753, and about fifteen more examples have since been procured, and others seen, in the island. Contrary to what was for many years believed, the nest of the Nutcracker seems to be invariably built on the bough of a tree, some 20 ft. from the ground, and is a comparatively large structure of sticks, lined with grass. The eggs are of a very pale bluish-green, sometimes nearly spotless, but usually more or less freckled with pale olive or ash-colour. The chief food of the Nutcracker appears to be the seeds of various conifers, which it extracts as it holds the cones in its foot, and it has been questioned whether the bird has the faculty of cracking nuts—properly so called—with its bill, though that can be used with much force and, at least in confinement, with no little ingenuity. The old supposition that the Nutcrackers had any affinity to the Woodpeckers (*Picidae*) or were intermediate in position between them and the Crows (*Corvidae*) is now known to be wholly erroneous, for they undoubtedly belong to the latter family (see also CROW). (A. N.)

NUTHATCH, in older English NUTHACK, from its habit of hacking or chipping nuts, which it cleverly fixes, as though in a vice, in a chink or crevice of the bark of a tree, and then hammers them with the point of its bill till the shell is broken. This bird was long thought to be the *Sitta europaea* of Linnaeus; but that is now admitted to be the northern form, with the lower parts white, and its buff-breasted representative in central, southern and western Europe, including England, is known as *Sitta caesia*. It is not found in Ireland, and in Scotland its appearance is merely accidental. Without being very plentiful anywhere, it is generally distributed in suitable localities throughout its range—those localities being such as afford it a sufficient supply of food, consisting during the greater part of the year of insects, which it diligently seeks on the boles and larger limbs of old trees; but in autumn and winter it feeds on nuts, beech-mast, the stones of yew-berries and hard seeds. Being of a bold disposition, and the trees favouring its mode of life often growing near houses, it will become on slight encouragement familiar with men; and its neat attire of ash-grey and warm buff, together with its sprightly gestures, render it an attractive visitor. It generally makes its nest in a hollow branch, plastering up the opening with clay, leaving only a circular hole just large enough to afford entrance and exit; and the interior contains a bed of dry leaves or the filmy flakes of the inner bark of a fir or cedar, on which the eggs are laid. In the Levant occurs another species, *S. syriaca*, with somewhat different habits, as it haunts rocks rather than trees; and four or five representatives of the European arboreal species have their respective ranges from Asia Minor to the Himalayas and Northern China. North America possesses nearly as many; but, curiously enough, the geographical difference of coloration is just the reverse of what it is in Europe—the species with a deep rufous breast, *S. canadensis*, being that which has the most northern range, while the white-bellied *S. carolinensis*, with its western form, *S. aculeata*, inhabits more southern latitudes. The Ethiopian Region has as representative of the group the *Hypositta corallirostris* of Madagascar. *Callisitta* and *Dendrophila* are nearly allied genera, inhabiting the Indian Region, and remarkable for their beautiful blue plumage. *Sittella*, with four or five species, is found in Australia and New Guinea, whilst *Daphnoesitta* occurs in New Guinea. The nuthatches are placed in the *Passerine* family *Sittidae*, intermediate between the *Paridae* and the *Certhiidae*. (A. N.)

NUTMEG (from "nut," and O. Fr. *mugue*, musk, Lat. *muscus*), the commercial name of a spice representing the kernel of the seed of *Myristica fragrans* (fig. 1), a dioecious evergreen tree, about 50 to 60 ft. high, found wild in the Banda Islands and a few of the neighbouring islands, extending to New Guinea.

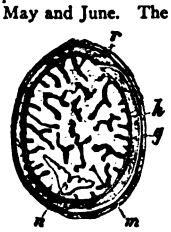
Nutmeg and mace are almost exclusively obtained from the Banda Islands, although the cultivation has been attempted with varying success in Singapore, Penang, Bengal, Réunion, Brazil, French Guiana and the West Indies. The trees yield fruit in eight

From Strasburger's *Lehrbuch der Botanik*, by permission of Gustav Fischer.

FIG. 1.—*Myristica fragrans.* (Official.)

1. Twig with male flowers.
2. Ripe pendulous fruit opening.
3. Fruit after removal of one-half of the pericarp, showing the dark brown seed surrounded by the ruptured arillus.
4. Kernel freed from the seed-coat.

years after sowing the seed, reach their prime in twenty-five years, and bear for sixty years or longer. Almost the whole surface of the Banda Islands is planted with nutmeg trees, which thrive under the shade of the lofty *Canarium commune*. In Bencoolen the tree bears all the year round, but the chief harvest takes place in the later months of the year, and a smaller one in April, May and June. The ripe fruit is about 2 in. in diameter, of a rounded pear-shape, and when mature splits into two, exposing a crimson arillus surrounding a single seed (figs. 1, 2). When the fruit is collected the pericarp is first removed; then the arillus is carefully stripped off and dried, in which state it forms the mace of commerce. The seed consists of a thin, hard testa or shell, enclosing a wrinkled kernel, which, when dried, is the nutmeg. The kernel consists mainly of the abundant endosperm, which is firm, whitish in colour and marbled with numerous reddish-brown vein-like partitions, into which the inner seed-coat penetrates, forming what is known botanically as ruminated endosperm.



After Berg and Schmidt. From Strasburger's *Lehrbuch der Botanik*, by permission of Gustav Fischer.

FIG. 2.—*Myristica fragrans*, seed cut through longitudinally. (Official.)

g, Aril.
h, Outer integument, interrupted at *r* by the raphe.
m, Ruminated endosperm.
n, Embryo (nat. size).

To prepare the nutmegs for use, the seed enclosing the kernel is dried at a gentle heat in a drying-house over a smouldering fire for about two months, the seeds being turned every second or third day. When thoroughly dried the shells are broken with a wooden mallet or flat board and the nutmegs picked out and sorted, the smaller and inferior ones being reserved for the expression of the fixed oil which they contain, and which forms the so-called oil of mace.

The dried nutmegs are then rubbed over with dry sifted lime. The process of liming, which originated at the time when the Dutch held a monopoly of the trade, was with the view of preventing the germination of the seeds, which were formerly immersed for three months in milk of lime for this purpose, and a preference is still manifested in some countries for nutmegs so prepared. It has, however, been shown that this treatment is by no means necessary, since exposure to the sun for a week destroys the vitality of the kernel. Penang nutmegs are never limed. The entire fruit preserved in syrup is used as a sweetmeat in the Dutch East Indies.

FIG. 3.—*Myristica fragrans.*

1. Male flower.
2. Female flower.

"Oil of mace," or nutmeg butter, is a solid fatty substance of a reddish-brown colour, obtained by grinding the refuse nutmegs to a fine powder, enclosing it in bags and steaming it over large cauldrons for five or six hours, and then compressing it while still warm between powerful wedges, the brownish fluid which flows out being afterwards allowed to solidify. Nutmegs yield about one-fourth of their weight of this substance. It is partly dissolved by cold alcohol, the remainder being soluble in ether. The latter portion, about 10% of the weight of the nutmegs, consists chiefly of *myristin*, which is a compound of *myristic acid*, $C_{14}H_{28}O_2$, with glycerin. The fat which is soluble in alcohol appears to consist, according to Schmidt and Roemer (*Arch. Pharm.* [3], xxi. 34-48), of free myristic and stearic acids; the brown colouring matter has not been satisfactorily investigated. Nutmeg butter yields on distillation with water a volatile oil to the extent of about 6%, consisting almost entirely of a hydrocarbon called *myristicene*, $C_{10}H_{16}$, boiling at 165° C. It is accompanied by a small quantity of an oxygenated oil, *myristicol*, isomeric with carvol, but differing from it in not forming a crystalline compound with hydrosulphuric acid. Mace contains a similar volatile oil, *macene*, boiling at 160° C., which is said by Cloëz to differ from that of nutmegs in yielding a solid compound when treated with hydrochloric acid gas.

The name nutmeg is also applied to other fruits or seeds in different countries. The Jamaica or calabash nutmeg is derived from *Monodora Myristica*, the Brazilian from *Cryptocarya moschata*, the Peruvian from *Laurelia sempervirens*, the Madagascar or clove nutmeg from *Agathophyllum aromaticum*, and the Californian or stinking nutmeg from *Torreya Myristica*. The cotyledons of *Nectandra Puchury* were at one time offered in England as nutmegs.

NUTRITION. The physiology of nutrition involves the study of the way in which the tissues of the body, and more especially the great master tissues, muscle and nerve, obtain the material for growth and repair and the energy for mechanical work and heat production, and of the mode in which they get rid of the waste products of their activity. The study is therefore very largely a study of the history of the food of the body, since it is in the food that the necessary matter and energy are supplied. Under DIETETICS the composition and special importance of various foods and the laws which regulate the supply of food under different conditions of the body are separately dealt with. Here the mode of digestion, the utilization and the elimination of the end products of the three great constituents, proteins, carbohydrates and fats, are alone considered. They are treated under the following heads: I. The Chemistry of Digestion; II. The Mode of Formation of the Digestive Secretions; III. The Mechanism by which the Food is passed along the Alimentary Canal; IV. The Absorption of Food; V. Metabolism; VI. Excretion.

I. CHEMISTRY OF DIGESTION

The essential step which prepares the ordinary food for utilization in the body, for the change into living matter, is digestion, a process which the food undergoes under the influence of the ferments or enzymes present in the gastro-intestinal tract. By this process it is broken down into simpler substances, which can be utilized by the body tissues for conversion into protoplasm and as the supply of energy. That part which is unsuited for use in the body is either passed as faeces or absorbed and excreted in the urine.

1. *Enzyme Action generally.*—The substances which bring about this change are known as ferments, enzymes or zymins. Formerly it was believed that there were two distinct classes

of enzymes, those which were living or associated with living cells, and those which were non-living. In 1897, however, E. Buchner and M. Hahn showed that from living cells (yeast) a ferment could be obtained which acted quite as well extracellularly as when it was bound up within the cell. Subsequent work has shown that other organisms act by the enzymes they contain, so that it is now recognized that there is no essential difference between the living or organized ferment and the non-living or unorganized ferment. All ferments probably act as catalysators or catalysts. Catalysis is the process by which reactions are either initiated or accelerated by the mere presence of certain substances which remain unchanged during the process; to these substances the name of catalysators has been given. As an example of such catalytic action the acceleration of the decomposition of hydrogen peroxide (H_2O_2) into water (H_2O) and oxygen (O) by the action of a colloidal solution of platinum may be given. C. Oppenheimer defines an enzyme as a substance produced by living cells, which acts by catalysis. E. Fischer has shown that the action of ferments is specific, that is, the ferment only exerts its action on definite substances or substrates of definite structural arrangement. He has compared the relation of ferment to substrate to that of a key to its lock. Ferments which bring about the breakdown of proteins are without influence on fats and carbohydrates; those which decompose fats leave proteins and carbohydrates untouched, and so on.

The chemical composition of enzymes is unknown. It has been assumed that they are protein in nature, but this is mainly because it has been found that when they are extracted from tissues they are apparently in combination with proteins. In all probability the protein is there as an impurity owing to incomplete separation.

As regards the general properties of enzymes, most of them can be precipitated from their solutions by means of alcohol. They can also be carried down by fine precipitates of certain inorganic salts or by protein precipitation, *e.g.* when a precipitate of casein is produced by acidifying a casein solution with acetic acid. Most of the ferments are soluble in water or saline solutions, and in glycerin and water. The ferments are found to have an optimum temperature of action. This temperature in most cases ranges from 37° to 40° C. All true ferments are thermolabile, being destroyed at about 70° C. Ferments are hindered in their action to some extent by the general protoplasmic poisons, such as salicylic acid, chloroform, &c. The action of many of them is retarded when the products of their action are allowed to accumulate. Just as when a chemical reaction is set up its rate tends to decrease and finally comes to a standstill before the reaction is completed—an equilibrium being established—so the reactions set up by enzymes also tend to come to an equilibrium before the complete conversion of the original substance. In the case of certain enzymes at least this equilibrium may be reached from either side; thus the enzyme maltase may either bring about the breakdown of the sugar maltose to dextrose or cause a synthesis of dextrose to maltose.

A number of the body ferments have now been shown to exist in the tissues in an inactive form. This condition is known as the proferment or zymogen state, and before any action can be exerted it must be activated, usually by some specific substance, as in the case of the activation of trypsinogen by means of enterokinase. The following table gives a list of the principal ferments concerned in the digestion and metabolism of food-stuffs:—

Material acted on.	Enzyme.	Where found.
I. Protein . .	Pepsin	Gastric juice
	Trypsin	Pancreatic juice
	Erepsin	Small intestine
	Various autolytic enzymes	Tissues generally
II. Fats . . .	Lipase	Pancreatic juice and certain tissues
III. Carbohydrates	Ptyalin (salivary diastase)	Saliva
	Pancreatic diastase	Pancreatic juice
	Maltase	Pancreatic juice
		Small intestine
	Invertase	Small intestine
	Lactase	Small intestine
	Various tissue diastases	Liver, muscle, &c.

Certain oxydases, catalases and de-amidizing enzymes are found in the tissues generally and play an important part in the various metabolic processes.

2. *Digestion in the Mouth.*—The first of the digestive secretions which food comes into contact with is the saliva. This is the mixed secretion from the various glands, salivary and other, the ducts of which open in the mouth. The saliva, which is for the most part produced by the three large salivary glands, the parotid, the sub-maxillary and the sub-lingual, is a colourless or a slightly turbid viscous fluid with a faintly alkaline reaction and of low specific gravity. It contains a very small proportion of solids, which vary somewhat in amount and character in the secretions of the different glands. Mucin and traces of other proteins are present. Small amounts of potassium sulphocyanide may nearly always be detected. The functions of the saliva are twofold. First, it has a mechanical action moistening the mouth and the food and thus aiding mastication and swallowing by securing the formation of a proper bolus of food; it also assists by binding the particles together, an action of special importance when the food is dry. Second, in man and in some of the lower animals the enzyme ptyalin exerts an action in digestion on part of the carbohydrates of the diet. The starches or polysaccharides are broken down, first of all to the simple dextrins and then to the still more simple disaccharide, maltose. The further breakdown of the maltose is carried out in the intestine by the action of a ferment maltase which does not exist at all or only in the merest traces in the buccal secretion. The action of ptyalin on starches is thus very similar to that of acids, except that it stops at the formation of maltose. Ptyalin acts best at a temperature of about 40° C. and in a neutral or faintly alkaline medium, its action being inhibited by the presence of even very dilute solutions of the mineral acids. If the acid be in sufficient amount the enzyme is destroyed. For this reason the action ceases in the stomach whenever the bolus is completely permeated by the gastric juice. As it takes time for the gastric juice thoroughly to permeate the food mass, which remains for a considerable periodin the fundus of the stomach unmixed with the secretion, salivary digestion goes on for about half an hour after food is taken.

3. *Gastric Digestion.*—The passage of food from the mouth to the stomach will be dealt with later. The stomach has two digestive functions: (1) It acts as a store chamber permitting a full meal to be taken; (2) It acts as a digestive organ of importance in preparing the food for further attack in the intestinal canal. But the stomach cannot be regarded as an essential organ, since it has been removed in dogs and in man without apparent interference with nutrition and health.

Gastric digestion is brought about by the action of the gastric juice, a clear watery, colourless and strongly acid fluid with a specific gravity of about 1003. The amount of solids present is extremely small, about 0·3 %. They consist of protein, nucleic acid, lecithin and inorganic salts, in addition to the more important constituents, the enzymes and hydrochloric acid.

The amount of hydrochloric acid present in the juice varies with the period of digestion. In man the maximum acid concentration is about 0·2 %. The acid exists in the stomach in two forms as free hydrochloric acid and as combined hydrochloric acid. The amount of each depends on various factors: (1) the secretion itself; (2) the nature of the food; and (3) the rapidity with which the stomach empties itself, &c. For instance, after a protein-free meal the hydrochloric acid is for the most part free, whereas, when protein is present, it combines with it and, unless secreted in very large amount, most of the acid is in a fixed condition.

The hydrochloric acid is formed by the activities of certain gland cells in the middle region of the stomach, and the fact that it does not exist as such in the blood proves that it is formed within these cells. Further, it has been found that the gastric mucous membranes of starving dogs contain 0·74 % of sodium and potassium chloride, much more than is present in any other organ or in the blood plasma. That the chlorine comes from the sodium chloride in the food has been shown by the fact that, when the tissues are deprived of this salt, and sodium bromide is given, hydrobromic acid may appear in the gastric secretion.

The hydrochloric acid is essential for the action of the gastric enzyme, pepsin, in splitting up the protein of the food. In addition to this, the acid has a slight action in splitting polysaccharides and disaccharides. Lastly, it acts as a bactericidal agent, preventing bacterial decomposition from taking place, and it may thus prevent certain noxious bacteria, taken in in the food, from gaining access to the intestinal tract, where there is a chance of their flourishing in the rich alkaline medium. It is owing to the presence of hydrochloric acid that gastric juice can be kept for prolonged periods without undergoing putrefaction.

The quantity of juice secreted varies with the nature of the food consumed. Thus in one experiment, after the use of a test meal consisting of 25 grammes bread and 250 c.c. tea, there was a flow of 106 c.c., whereas in another case with an ordinary meal there was an output of practically 600 c.c. gastric juice.

Pawlow has shown that not only does the amount of juice secreted vary with the nature of the food ingested but that the digestive activity of the secretion also varies in the same way. He gives the following table:—

Quantities and Properties of Gastric Juice with Different Diets: 200 gms. Flesh, 200 gms. Bread, 600 c.c. Milk.

Hour.	Quantities of Juice in c.c.			Digestive Power in mm.		
	Flesh.	Bread.	Milk.	Flesh.	Bread.	Milk.
1st	11·2	10·6	4·0	4·94	6·10	4·21
2nd	11·3	5·4	8·6	3·03	7·97	2·35
3rd	7·6	4·0	9·2	3·01	7·51	2·35
4th	5·1	3·4	7·7	2·87	6·19	2·65
5th	2·8	3·3	4·0	3·20	5·29	4·63
6th	2·2	2·2	0·5	3·58	5·72	6·12
7th	1·2	2·6	..	2·25	5·48	..
8th	0·6	2·6	..	3·87	5·50	..
9th	..	0·9	..	..	5·75	..
10th	..	0·4	..	..	..	..

Thus each separate food gives rise to a definite hourly secretion of the juice and to a characteristic alteration in its properties. The meat diet brings about a very rapid flow, the maximum output taking place within the first two hours; with bread the maximum output is even earlier. With milk somewhat later. When the juice is examined as regards its digestive activity, it is found that with meat the most active juice is secreted within the first hour, with bread in the second and third hours, and with milk in the sixth hour.

According to the nature of the food, the stomach seems to be stimulated to form a secretion which will best serve its purpose and give the minimum of waste. It thus works economically.

The principal ferment found in the gastric juice is pepsin, a ferment which acts only in the presence of a mineral acid. The action proceeds best at a temperature of about 37° C. in an acid medium of 0·2% to 0·3%. Pepsin is elaborated in the so-called chief cells of the gastric glands as an inert precursor—propepsin. It is only when it comes into contact with the acid of the juice that it is activated and rendered capable of attacking the protein of the food.

As already mentioned, the main function of the gastric juice is to deal with the protein moiety of the food and to prepare it for further digestion in the intestine.

The first result of the action of this secretion on protein matter is to render it soluble—a metaprotein or acid albumin (syntonin) being formed. This body may be regarded mainly as the product of the action of the hydrochloric acid independently of the pepsin.

The following steps of decomposition are the result of the action of pepsin. From the metaprotein primary and secondary proteoses, the so-called proto-, hetero- and deutero-albumoses are formed, and from these peptones are finally produced. The result of this process of digestion or hydrolysis induced by the pepsin is that complex protein substances of high molecular weight are converted into simpler bodies of comparatively low molecular weight. Formerly it was believed that the action of the pepsin on protein could not carry the decomposition further than the peptones, but recently it has been shown that still further splitting can be brought about, and that the simple amino acids of which the protein molecule is built up can be produced. This latter process, however, takes a very long time even under favourable circumstances, and it probably never occurs under normal conditions. The contents of the stomach—products of protein digestion—are passed on into the duodenum, chiefly as proteoses and peptones.

In addition to the principal ferment of the gastric juice some workers hold that another enzyme is present. This is the ferment rennet, rennin, or chymosin, the sole action of which, so far as is known at present, is to bring about the curdling of milk, the curd formed being dealt with in the ordinary way by the pepsin. Clotting of milk under the action of rennin occurs at a suitable temperature with great rapidity. This process is said to take place in two stages: (1) the rennin converts the caseinogen of the milk into paracasein, and (2) this paracasein unites with the lime salts present in the milk and forms the curd or precipitate. That lime salts are absolutely essential for this process of clotting has been shown by the fact that, if they are removed by precipitation as by oxalates, no clotting will take place even after the addition of a large amount of active rennin. Immediate clotting takes place, however, when the necessary lime salts are restored. Many observers now hold that this rennet action is not the property of a specific ferment but simply another phase of the action of pepsin. For this view, which has been put forward by well-known workers, there is much to be said and certainly the power of curdling milk is not confined to the stomach, but has been found in various tissue extracts, and, indeed, wherever proteolytic enzymes are found.

The speed with which the stomach is emptied depends to a great extent on the nature of the food. Plain water leaves the stomach almost at once, salt and sugar solutions at a somewhat slower rate. Milk under the action of rennin curdles. The whey rapidly leaves the stomach, whereas the casein and fat are retained for further treatment. On a mixed diet, emptying of the stomach in man proceeds very slowly, requiring about four hours. Cannon, by feeding with food impregnated with bismuth and using X-rays, showed that carbohydrates leave most rapidly, then mixtures of carbohydrates and proteins, then proteins, then fats, and finally mixtures of fats and proteins. The diet which remains longest in the stomach is a mixture of fats and proteins—rich food, as it is popularly called. Here two factors enter to prevent rapid emptying: (1) the presence of much fat, and (2) the acid secretion engendered by the abundant protein.

There is no doubt that fats present in fine emulsion can be decomposed in the stomach. The action proceeds in a medium which is slightly acid or neutral, being entirely prevented by the presence of strong acids and alkalis. Many workers believe this gastrolipase to be of pancreatic or intestinal origin, and suppose that it gains entrance to the stomach by a reflux flow through the pylorus. Evidence is accumulating to show that this view is correct.

By means of pepsin and gastrolipase proteins and fats are dealt with. No specific enzyme for carbohydrates has been found in the stomach in man. Certainly a small amount of polysaccharide decomposition takes place, but this is dependent (1) on the ptyalin which comes from the mouth, and (2) on a certain amount of hydrolysis due to the action of the free hydrochloric acid.

4. *Digestion in the Intestine.*—The passage of food from the stomach to the intestine will be considered later. The food so far digested in the stomach is known as chyme, and it is passed on to undergo intestinal digestion under the influence of (1) the enzymes of the pancreas, and (2) of other enzymes present in the different secretions of the intestine. Digestion in the intestine may accordingly be described under these two heads.

(*a*) *Pancreatic Digestion.*—The pancreatic juice is the secretion from the pancreas and is discharged into the duodenum. The secretion obtained from a fistula of the pancreatic duct varies in character according to whether the opening into the duct has been made recently or some time before the examination. It is a clear, usually thin fluid with a specific gravity of about 1008, and with an alkaline reaction. It contains a certain amount of protein and ash. The most important inorganic constituent is sodium carbonate, which gives the alkaline reaction (alkalinity is, as NaOH = 0·47%). This alkaline salt, along with that contained in the intestinal juice, plays an important part in neutralizing the acid chyme.

In the pancreatic secretion there are at least three important enzymes, each with a definite action: (*a*) trypsin, the proteolytic enzyme which brings about the further breakdown of the food proteins; (*b*) a diastase which deals with the carbohydrates, and (*c*) a lipase which acts on the fats.

(*a*) *Trypsin.*—This ferment, in the form in which it is secreted—trypsinogen—is inert. Before it can exert its hydrolytic action it must be activated. This activation is brought about by another enzyme which is found in the intestinal tract—enterokinase. The conversion is brought about as soon as the trypsinogen comes into contact with the enterokinase, the merest trace of which suffices to activate a large amount of trypsinogen.

Trypsin acts on the protein just as pepsin does, by bringing about hydrolytic changes. It differs from the latter in acting best in an alkaline or neutral medium. Its effect is much more energetic than that of pepsin, so that the protein molecule is more completely decomposed. Whilst it generally finishes the decomposition which the pepsin has begun, it can break down the original protein quite as easily if not more easily than does pepsin, and it carries the splitting as far as the comparatively simple crystalline bodies, the amino acids, or groups of these, the polypeptides, bodies intermediate between the complex peptones and the simple amino acids of which the protein is built up.

The character and properties of the products formed in such digestion depend on the nature of the protein acted upon. As will be seen from the following table these proteins vary fairly widely in the proportion of amino acids which they contain.

100 Grammes Protein yielded

	Caseinogen.	Gelatine.	Globine from Oxy-haemoglobine.	Elastine.

Tryptophane	1·5	..	Present	..

Whether any of the polypeptides found in digestion are further broken down in the course of normal pancreatic digestion is a moot point, but E. Fischer and E. Abderhalden have shown that many of the synthetic polypeptides prepared by them can be broken into their constituents by the action of trypsin. The previous peptic digestion seems to play some part in the extent to which tryptic digestion is carried out, as one of these observers has demonstrated that protein digested first with pepsin and then with trypsin gives a smaller yield of polypeptide and a larger yield of monamino acids than when digestion has been carried out with trypsin alone.

b. Diastase.—This ferment is found in the pancreatic juice apparently secreted in an active form, although some observers hold that it also is secreted in a zymogen form. It is practically identical in its action with the ptyalin of the saliva, converting starch into maltose. It deals with all the starchy food which has escaped conversion into the simple sugars by the ptyalin.

c. Lipase.—Most of this ferment, if not all, is apparently secreted in the form of a zymogen. There is evidence that the bile is the activating agent here, just as the enterokinase acts in the case of trypsin. Lipase can act in any medium acid, neutral, and alkaline, and both on emulsified and non-emulsified fats. It converts the fats by a process of hydrolysis into fatty acids and glycerin. Kastle and Loevenhart found that not only can this enzyme break up fats into their components, but that it also has the power to act in the reverse direction, and in this way bring about the union of fatty acids and glycerin so as to form fats, a process which occurs in the intestinal epithelial cells after absorption.

In addition to these three enzymes the pancreatic juice may contain traces of others, for example, a rennet-like ferment which curdles milk. This again, as in the case of the stomach rennet, is held by some to be only another phase of proteolytic action. Maltase is also said to be present in small amount, as is also lactase under certain conditions. In pancreatic, as in gastric digestion, the nature of the food is said to play a part in controlling the amount and the composition of the secretion with respect to its ferments. The action, if it does exist, is not very well defined.

b. Inlestinal Digestion.—By this is meant the other digestive processes which go on in the intestine under the action of the secretion of Lieberkühn's follicles—the *succus entericus*. This is a yellowish, often opalescent, strongly alkaline fluid. The alkalinity is due to the presence of sodium carbonate. It contains a small amount of protein, shed epithelial cells, &c. The secretion of some 170 c.c. in 24 hours has been observed in a short loop of human intestine by H. S. Hamburger and E. Hekma, but it is almost impossible to get a measure of the actual amount of secretion from the whole gut. Most of the ferments are present in very small amount in the intestinal juice. They seem to be actually within the epithelial lining of the intestine, for extracts made from the intestinal mucous membrane are richer in ferments than the secretion.

Apparently the intestinal secretion contains no trace of a ferment acting on native protein, but a ferment—erepsin—is present in fair amount in the intestinal mucous membrane and in small amount in the secretion, which acts in an alkaline medium on proteoses, peptones, and on casein, converting them into crystalline products of the nature of amino acids.

Another ferment, arginase, has been isolated from the intestinal mucous membrane by A. Kossel and H. D. Dakin, which splits the diamino acid arginin into urea and ornithin. A lipase has also been detected which is very similar to pancreatic lipase; it, however, attacks only emulsified fats.

Several carbohydrate hydrolysing enzymes have been described in the small intestine. Invertin, the ferment which splits cane-sugar, is present in small amount in the secretion, more abundantly in the extract of mucous membrane. In all probability it deals with the saccharose after or in process of absorption. Maltase is also present in large amount, and here again in greater amount in the extract than in the secretion. The presence of lactase has been much discussed, and it seems probable that suckling animals do possess this enzyme. Some workers have stated that an intestinal diastase is to be found, but, if so, it is present in very small amount.

In the large intestine a small amount of erepsin has been discovered at the upper end. Any digestion which does take place is probably either bacterial in origin, or due to ferments which have originated in the lower end of the small intestine, and which have been carried down.

5. *Bile.*—This fluid, in all probability, has little direct action in ordinary digestion, although it contains substances which act indirectly. The bile salts act as solvents for fats and fatty acids, and as activators of pancreatic lipase. The salts also serve to keep cholestrin in solution. Bile is to be looked upon rather as the excretion, the result of the hepatic metabolism, than as a digestive juice. Various workers have shown that when the bile is prevented from entering the intestine owing to a fistula having been made, the animal or patient may continue to enjoy good health, thus proving that this fluid is not essential to any of the digestive processes which normally take place.

Bile as secreted has an orange-brown colour, but the colour varies according to the pigment present. It is more or less viscous (not so viscous as bile taken from the gall bladder) and has a specific gravity of about 1010. It has a slightly alkaline reaction, a bitter taste and a characteristic smell. The daily output is, for a normal individual, over 500 c.c. On analysis it is found to have over 2% of solids, of which more than half are organic. It contains in addition to a nucleo-albumin, derived mainly from the bile passages and gall bladder, bile acids, bile pigments, cholesterin, lecithin, fats, &c. The most abundant solids are the salts of the bile acids, of which in man the most important is sodium glycocholate, sodium taurocholate being present in very small amount. The bile acids are formed in the liver cells, and when the duct is ligatured they tend to accumulate in the blood.

The pigments amount to only about 0·2%. In human bile the chief pigment is bilirubin, whilst in herbivora biliverdin is more abundant. They are derived from the haemoglobin of the blood, but the pigments are iron-free. They may be regarded as purely excretory products arising from the breakdown of the haemoglobin of effete blood corpuscles.

Cholesterin is a monatomic alcohol, and is probably a waste product. It occurs in the bile only in small amount, and there is some evidence that it is not secreted by the liver cells but is added to the bile from the bile passages. Fats and lecithin are both derived from the liver cells. Of the inorganic constituents phosphate of calcium is the most abundant.

The secretion of bile is practically continuous, but it seems to enter the duodenum intermittently. The taking of food increases the flow of bile, the amount of the increase depending to a certain extent on the nature of the food. A protein meal has been found to have the greatest effect and a carbohydrate one the least. The entry of the acid chyme into the duodenum is the stimulus which brings about the ejection of the bile. Pressure on the liver also seems to cause a flow (see section II.).

In connexion with bile secretion attention may be drawn here to a peculiar enterohepatic circulation which is stated to exist. The bile salts are partly absorbed from the intestine, to be carried again by the portal blood to the liver and to be again eliminated. By this circulation the entrance of various alkaloidal and ptomaine poisons into the general circulation may be prevented.

Faeces.—The bulk of the waste matter arising from the foods along with the secretions from the alimentary canal form the faeces. On an absorbable diet the faeces are almost purely intestinal in origin. As a channel of excretion of nitrogenous metabolic waste products they are not very important, although the work of C. Voit indicates that they do play a certain part. The nature of the excreted nitrogenous substances has not been fully examined. Of the inorganic constituents iron is probably for the most part excreted into the large intestine. It is, however, very difficult to come to any definite conclusion as to what is unabsorbed material and what excreted.

II. The Mode of Formation of the Digestive Secretions

1. *Salivary Glands.*—The secretion from the various glands is generally evoked by nervous impulses, through the secretory

nerves. K. Ludwig found that the stimulation of the chorda tympani produced a copious flow of watery saliva from the submaxillary gland, and a general dilatation of the blood-vessels supplying the gland. The same is the case in the sublingual gland. In addition to the chorda tympani fibres also pass to the gland through the cervical sympathetic, and when these are stimulated the saliva excreted is viscous and turbid, and contains much solid matter, while the blood-vessels are contracted. The conclusion formerly drawn was that the flow of saliva was dependent on the increased blood supply. But it has been definitely proved that true secretory fibres exist. If atropine be administered before stimulation of the chorda tympani, the dilatation of the vessels takes place, but no flow of saliva. Further, if the circulation be cut off from the gland the stimulation of the chorda tympani may cause a temporary flow of saliva.

The parotid gland is supplied by the auriculo-temporal nerve which receives its secreting fibres from the glossopharyngeal. Stimulation of these fibres brings about an abundant watery secretion poor in solids. Stimulation of the sympathetic fibres system is not followed by any salivary flow, yet it has an effect on the gland, for, if after the sympathetic has been stimulated a secretion be evoked by stimulation of the glossopharyngeal nerve, the saliva secreted is very rich in organic solids.

2. *Gastric Glands.*—The control of the gastric secretion seems to be under two entirely different mechanisms. Pawlow has clearly shown that the stomach is supplied with secretory nerves which reach that organ through the vagus. The stimuli which bring these nerves into action are the sight, the odour or the taste of food. That the course of the stimulus is through the vagus is shown by the fact that an abundant flow of juice may be caused so long as the vagi are intact, but this flow does not take place when these nerves are cut. Between the stimulation and the secretion there is a lengthy latent time amounting to several minutes. The other stimulus of the secretion is apparently a chemical one. Pawlow states that mechanical stimulation of the mucous membrane fails to bring about a flow of juice, but Beaumont in his classical observation on the stomach of St Martin found that the insertion of a tube did cause a flow. There may be certain substances either present in the food or developed in the course of digestion, which directly stimulate the secretion originally started by a nervous reflex. E. Starling has drawn attention to this chemical mode of stimulating different organs. To the substances known and unknown which evoke the action, he gives the name of hormones, and such "hormone" action he does not limit merely to the secretory organs but extends to all cases where one organ is stimulated by chemical products formed in the same or another organ. Attention has already been drawn to the influence of different food-stuffs on the amount and nature of the gastric secretion.

3. *Pancreatic Secretion.*—The stimuli which evoke this secretion are again two in number. Many have failed to demonstrate that the secretion of the pancreas is under nervous control, but Pawlow and his school have shown that stimulation of the vagus evokes a secretion of pancreatic juice. This flow, as in the case of the stomach, has a latent period of several minutes. Most modern workers hold that the most effective stimulus to the pancreatic flow is the chemical one—a hormone discovered by W. Bayliss and E. Starling, who found that extracts of the duodenal mucous membrane made with dilute hydrochloric acid when injected into the blood caused a flow of pancreatic juice. The active substance present in this extract is known as "secretin," and is supposed to be formed under natural conditions by the action of the acid chyme on a prosecretin. This secretin is not of the ordinary zymin nature, as it is not destroyed by boiling and is soluble in alcohol. The secretin when formed must be absorbed into the blood and then carried round the circulation to the pancreas before it can act.

4. *Intestinal Juice.*—The mode of action of the stimuli which evoke this secretion has not yet been fully investigated. As has been stated, it is quite possible that very little ferment is secreted, and that ferment action mainly takes place within the cells after the various substances have been absorbed. How far the flow is controlled by nervous action, and how far by hormone action, is not known.

III. Motor Mechanism of the Alimentary Canal

Mastication.—This is a purely voluntary act, and consists of a great variety of movements produced by the various muscles in connexion with the lower jaw. By the act of chewing the food is thoroughly broken up and intimately mixed with the saliva.

Deglutition.—The food after thorough mastication is collected on the surface of the tongue, principally by the action (voluntary) of the buccinator muscles, and by the contraction of the tongue muscles it is passed backwards. As soon as the food by the action of the tongue enters the pillars of the fauces the action becomes involuntary and reflex. The soft palate is raised to prevent the food entering the nasal cavity, and the larynx is shut off by closure of the glottis, and approximation of the arytenoid cartilages to one another and to the back of the epiglottis. The food is now passed on into the oesophagus proper by the constrictors of the pharynx. In the oesophagus the downward movement varies with the nature of the food swallowed. If it be fluid it reaches the lower end of the oesophagus in about three seconds and lies at the lower end of the gullet for two or three seconds before entering the stomach. When the consistency is firmer the progress downwards is much slower. Either by the force exerted by the wave of contraction passing down the gullet or by some inhibition of the sphincter, the cardiac orifice opens and permits the food to enter the stomach.

Stomach Movements.—For our knowledge of these we are indebted principally to the work of Cannon, who studied them by feeding an animal with food containing bismuth and then following the movements of the shadow of the food on a screen by means of the X-rays. Soon after food is taken it is found that a contraction begins somewhere about the middle of the stomach and slowly passes towards the pylorus. This is followed by others, in man at regular intervals of about twenty seconds, so that the pyloric part of the organ is soon in active peristalsis. The fundus of the stomach is not actively concerned in these movements; it simply acts as a reservoir. At certain periods, but not with each peristaltic wave, the pyloric sphincter relaxes and allows a portion of the fluid acid chyme to escape into the duodenum. It only opens when stimulated by fluid material; if solid food be forced against it it remains tightly closed. Grützner, by experiments with feeding with different coloured foods, has shown that the food at the fundus may remain undisturbed for quite prolonged periods. In this connexion it must be remembered, of course, that the food is not lying loose in a sack larger than the contents. The cavity of the stomach is only the size of the amount of food present; in other words, the food exactly fills the cavity. The motor nerve fibres to the stomach run in the vagi, which also contain fibres inhibitory to the cardiac sphincter. The splanchnic nerves mainly contain inhibitory fibres. The automatic movements are probably in connexion with the intrinsic plexus of Auerbach, since they continue after section of the extrinsic nerves.

Intestinal Movements.—The intestines owe their peculiar movements to the arrangement of their muscular coats, which are disposed in two layers, an inner circular, and an outer longitudinal. The movements are of two kinds, the so-called swaying myogenic contraction and the peristaltic waves. The former are rapid and have very little to do with the downward movement of the contents. Probably their action is to mix the contents, since Cannon has shown that these contents, in the lower animals at least, get divided into segments. From time to time the separated segments are caught in the course of a peristaltic wave and carried downward a short distance. Then again in their new situation the rhythmic contractions break up the contents anew.

The peristaltic movements are much more powerful. Under normal conditions they begin at the pylorus and passing downwards carry the intestinal contents onwards. The normal movement progresses slowly, although under abnormal conditions

peristaltic waves may become extremely violent and rapid, and may indeed run over the whole length of the intestine within a minute. The muscular coat in front of the contracting zone is relaxed, as is that behind the wave. The waves are probably due mainly to the circular fibres, the longitudinal pulling the gut up over the contents as they are forced onwards. The downward movement seems to be due to some definite arrangement within the intestinal wall, since it has been shown that, when a segment of bowel has been cut out and then the continuity of the canal made good by fixing the section so that the lower end of the excised portion is fixed to the upper divided end of the real gut, upward peristalsis takes place in this segment. An anti-peristalsis has been described in which the movements are all towards the stomach. Under certain conditions the introduction of foreign substances, as hairs, &c., may evoke such anti-peristaltic waves.

The rhythmical movements are held by some to be purely myogenic in origin, as they still continue after section of all the nerves and when the intrinsic ganglia in the intestinal wall have been thrown out of action by the application of nicotine. But recent work by R. Magnus would tend to show that they are controlled by Auerbach's plexus. Peristaltic waves, on the other hand, according to W. Bayliss and E. Starling, although they continue and indeed may become more energetic after section of the extrinsic nerves, are prevented by the application of nicotine and cocaine; in other words, it is presumed that peristalsis is a complicated reflex action through the intrinsic ganglia. The intestines are therefore not dependent for their movement on their connexion with the central nervous system, although of course their activity is more or less regulated by such a connexion.

As regards the movements of the large intestine, they resemble those of the small, although they are much less frequent. The forward movement is slow, thus permitting of the solidification of the contents by the removal of the water. In the first part of the large intestine anti-peristaltic movements are frequent, the regular peristaltic downward movements only becoming prominent when the descending colon is reached to carry contents to the rectum. The anti-peristalsis serves a useful purpose in giving time for the absorption of the fluid in the formation of faeces. The rate at which the contents travel along the intestine varies greatly. Under average conditions the food residue reaches the ileo-caecal valve between the small and large intestine at about four to four and a half hours after a meal, while it takes nine hours to reach the splenic flexure of the colon.

Defaecation.—Food residues, cellular débris and substances derived from the various secretions of the gastro-intestinal tract are forced downwards by peristalsis, and eventually reach the rectum and accumulate there as the faeces. The pressure of the solid and semi-solid mass gives rise to a definite sensation and a desire to empty the rectum. The faeces are retained within the canal partly by the horizontal direction of the rectum before it opens into the anal canal, and partly by the action of two sphincter muscles. At the act of defaecation the strong internal sphincter is first of all relaxed, but unless the rectal stimulus is very strong, the external can be kept contracted, as it is to a certain extent, under the control of the will. The act of defaecation normally is partly voluntary and partly involuntary. The voluntary part consists in the contraction of the abdominal muscles, the closure of the glottis, and the relaxation of the external sphincter and of the levator ani muscle, thus allowing the horizontal part of the rectum to become more vertical; the involuntary in the energetic contractions of the muscular walls of the colon and rectum which sweep the contents of the whole colon downwards. There is a centre in the lumbar enlargement of the spinal cord which presides over the sphincter muscles and probably over the whole involuntary mechanism of defaecation.

Vomiting.—Sometimes the gastric contents are ejected through the cardiac opening of the stomach instead of through the pylorus. The act is a reflex one, probably originally protective in nature, irritation of the gastric mucous membrane being the most frequent cause. The act is generally preceded by a feeling of nausea and a copious salivation, succeeded by a series of powerful expiratory efforts with the glottis closed. The diaphragm is held firmly contracted, then a convulsive contraction of the abdominal muscles with a simultaneous opening of the cardiac orifice of the stomach brings about the sudden ejection of the contents. The wall of the stomach may also contract and press upon the contents. During the act the glottis is firmly closed, and at the same time, if the act be not too violent, the gastric contents are prevented from entering the nasal cavity by the contraction of the soft palate.

IV. Absorption

Mouth.—No absorption of food-stuffs takes place here.

Stomach.—Absorption from the stomach occurs only to a small extent. Water passes rapidly through the stomach and is practically unabsorbed. Salts are apparently absorbed in a limited amount from their watery solution, the extent of absorption depending to some extent on the concentration of the solution. Sugar is also absorbed to a small extent from its solutions, the greater the concentration the greater being the amount of sugar taken up. Alcohol is readily absorbed from the stomach. A small amount of the products of protein digestion may be absorbed. There is no evidence that fats are absorbed under any conditions in the stomach.

Intestine.—The greatest absorption of the foods takes place in the intestine, especially in the small intestine. It has been shown that over 85% of the protein has disappeared before the lower end of the small intestine is reached. How does the absorption take place? There are two channels for the removal of the material from the intestine: (1) the blood capillaries spread in the villi, and (2) the lacteals also present in the villi. The foods may reach the blood direct or through the various lymph channels into the thoracic duct and finally into the blood. The lacteals of the villi are channels for the absorption of the fatty parts of the food. The products of the digestion of the proteins and carbohydrates reach the body directly through the capillaries via the portal system.

Can absorption be explained by the ordinary laws of diffusion and osmosis, or are there certain selective activities of the living epithelial lining? The work of R. Heidenhain, E. Weymouth Reid, and others shows clearly that whatever part the physical laws play in this exchange, there are other activities also at work. For instance, an animal's own serum can be readily absorbed from its intestine, as can also salt and other solutions of higher concentration than that of the blood. Such absorption cannot be explained by ordinary physical laws. In all such cases of absorption the epithelial lining of the gut must be intact and uninjured. O. Cohnheim and others have shown that when the epithelial lining is damaged or destroyed, the intestinal wall behaves like any other animal membrane, and the physical laws governing osmotic pressure come into play. Whether the nervous system plays any part in this absorption is not yet determined.

The form in which the various products resulting from digestion are absorbed must next be considered.

Carbohydrates.—These reach the body, as already mentioned, by way of the blood, and in the form of monosaccharides or simple sugars. F. Rohmann found that the absorption of the disaccharides is dependent on the invert ferment action, and not upon their osmotic characters. E. Weinland too has shown that if lactose be put into a lactase-free intestine, no absorption takes place, the lactose gradually disappearing under bacterial action, whereas when the ferment lactase is present glucose and galactose the products of its splitting are absorbed as readily as cane-sugar and maltose. E. Voit has also demonstrated the fact that the body deals with its carbohydrate supply in the form of mono-saccharides. He injected solutions of various sugars, mono- and di-saccharides, and found that the simple sugars were retained, whereas the double sugars were excreted in the urine. The only di-saccharide which can be dealt with in the body is maltose, as there is a maltase present in the blood which splits it. Carbohydrates which are not absorbed from the intestine are disposed of by bacterial action, giving rise to various fatty acids, carbon dioxide, &c.

Fats. -Fats are absorbed from the intestine in the form of fatty acids and glycerin; *i.e.* in the form in which they exist after the action of the lipase. That a resynthesis takes place in the epithelium is shown by the fact that fatty acids are of equal value with fat as a source of energy, and that as fat absorption goes on fat droplets are seen to grow in the protoplasm away from the free margin of the cells. As already mentioned, the fat is removed by the lacteals from the cells to the thoracic duct, and then to the general circulation. A small amount of the fat may pass into the body via the blood, but this is practically all retained by the liver. The amount of fat absorbed depends a good deal on the nature of the fat, especially with reference to its melting-point, fats of low melting-point being most readily taken up.

Protein.—The older workers held that the protein was absorbed in

the form of proteose and peptone. In support of this it was stated that both proteoses and peptones could be detected in the blood stream. The result of the most recent work tends to show that the material is absorbed in the form of the amino acids either simple or in complex groups, the polypeptides, and that if proteoses or peptones be absorbed they are attacked by the intra-cellular enzyme erepsin, which breaks them down into the simpler products as soon as they are within the intestinal mucous membrane. Certain proteins appear to be absorbed unchanged; for instance, blood serum disappears from the intestine without apparently any change through zymin attack. This fact is made use of in practical medicine, as, when administration of food by the mouth is impossible, patients are frequently kept alive by the giving of nutrient enemata. That the food thus given is absorbed is shown by the increase of nitrogen excretion in the urine.

In the large intestine very little absorption of nutrient matter takes place under normal conditions, mainly of course because most of the absorbable material is removed whilst the food is in the small intestine. That protein matter can be absorbed is shown by the above statement regarding nutrient enemata. The principal substance absorbed here is water; and thus the excreta become firm and formed.

V. Metabolism

In all living matter there is a constant cycle of chemical changes going on, a constant breaking down (catabolism), and a correspondingly constant building up (anabolism). Unless the former is covered by the latter wasting and finally death must supervene. These two changes together make up the metabolism, and the study of this involves a study of the fate of the food absorbed both when it is used immediately and after it has been stored in the tissues of the body. Protein matter is undoubtedly the main constituent of protoplasm, but in what form it exists there is absolutely unknown. One thing is certain, that for the maintenance of life a constant supply of protein matter is necessary. In fact it might be said that this is the essential food and keeps the body alive, fats and carbohydrates being merely subsidiary. In the mammalian organism with which we are specially concerned a supply of these latter substances is also necessary to yield the energy required. The amounts of these various food stuffs which should be present in a suitable diet are dealt with under Dietetics (*q.v.*). Here we are only concerned with the part played by the different materials in the various chemical changes which are the basis of vital activity.

Not many years ago physiologists were very much in the position of unskilled labourers who saw loads of heterogeneous material being "dumped" for building purposes, but who did not know for what particular purpose each individual substance was used. Thanks, however, to the brilliant work of E. Fischer we are no longer in this position. Gradually our knowledge is being broadened by actual facts obtained by direct experiment, or by inference from previous experiments. But it is still far from complete. It is only possible to outline what is at present known about the part played by the different food constituents in metabolism.

Proteins.—Since these alone contain the nitrogen necessary for the building up and repair of the tissues they are essential and will be dealt with first. In considering the digestion of proteins it was shown that in all probability all protein food was reduced in the intestine to comparatively simple crystalline bodies. O. Loewi has shown that an animal can be maintained in health without loss of weight by feeding it on a diet consisting of amino acids obtained by prolonged pancreatic digestion in place of proteins. In addition to these acids abundant carbohydrates and fats were given. It has since been shown that the presence of carbohydrate a certain amount of is absolutely essential before utilization of the amino acids can take place. Further, it has been demonstrated that only a mere fraction of the total amino acids resulting from pancreatic digestion is sufficient as the source of nitrogen supply for the animal organism. Not only so, but, in spite of the attempt to insist on the polypeptides as being the valuable nuclei for the rebuilding up of protein in the body, it has been shown that mixtures of amino acids from which the polypeptides have been removed can serve as the nitrogen supply.

What then does the body gain by breaking down food material to such simple bodies, if it is immediately to be resynthesized ? This complete breakdown appears to be to facilitate rebuilding. The protein in the protoplasm of each animal is characteristic and to build up these different proteins the material must be separated into its nuclei. An experiment carried out by E. Abderhalden shows this very clearly. A protein gliadin absolutely different in constitution from the proteins of blood plasma was fed to an animal from which much of its blood had been removed, so that an active reformation had to take place. The question to be solved was whether by feeding with a protein so absolutely different in constitution the nature of the freshly forming serum protein could be radically changed. But the newly-formed serum was found to be exactly the same in constitution as the old. The tissues had selected simply those nuclei of the gliadin which were required and had rejected the others.

In addition to this breakdown of protein in the intestine, another factor of importance comes into play. After absorption from the lumen of the gut the amino acids are not wholly conveyed as such by the portal blood to the liver. That the portal blood contains a greater amount of ammonia than the systemic blood has long been known, and Jacoby and Lang have shown that many tissues, and among them the intestinal tissues, are able to split off from the amino acids their amino group NH_2. Thus it would seem probable that any excess of the amino acids formed does not reach the liver as such but denitrified as members of the fatty acid series. The ammonia split off is also conveyed to the liver and is excreted for the most part as urea, within the first few hours after a protein meal. Thus, in all probability very early after absorption and before the products of digestion enter into combination or any synthesis occurs, all excess of the absorbed nitrogen is disposed of. The rest of the products circulate in the blood, yielding to the cells the materials of which they are in need. On the other hand some investigators still hold that resynthesis into a neutral protein like serum albumin takes place in the intestinal wall immediately after absorption of the digest products. That the leucocytes play an important part in carrying the products of protein digestion to the tissues is indicated by the enormous increase in their number which occurs during the digestion and absorption of protein foods. How they act, whether simply as carriers of the products of protein digestion combined or uncombined, and how they give the material to the tissues is unknown.

Carbohydrates are generally assumed simply to serve the purpose of yielding energy in their combustion to CO_2 and H_2O, and to act as protein sparers, *i.e.* they save the ingestion of large amounts of costly protein material as a source of energy. There may, however, be other activities in which the ingested sugars play a part, for instance, in the utilization of the nitrogen of proteins. It has already been indicated that the nitrogen in the products of pancreatic digestion can be used only when a sufficient amount of carbohydrates is given at the same time. Only carbohydrates seem to be able to do this, for it has been found that when isodynamic amounts of fat are given the utilization does not take place.

When taken into the body in excess of the immediate requirements the sugar is not utilized all at once, but any excess is stored in the form of glycogen both in the liver and the muscles. This glycogen is an insoluble polysaccharide, and is only utilized according to the requirements of the body, especially during muscular exertion. Carbohydrates, when taken in in excess, are also stored in the tissues in the form of fat. This was demonstrated by the feeding experiments of Lawes and Gilbert at Rothamstead. They took two young pigs of a litter, killed and analysed one, then fed the other for a definite time upon food of known composition, determining the amount of protein absorbed by analysing the urine and the faeces. They then killed the pig and by analysis ascertained the amount of fat put on. They found that this was far in excess of the amount of the protein of the food which had been absorbed and was also in excess of what could have been formed from the small amount of fat in the food. The fat must therefore have been formed from the carbohydrates of the food. The consumption of larger amounts of sugar than can be used or stored as glycogen results in its passing straight through the body and being excreted in the urine. This condition is known as alimentary glycosuria. The power of using and storing sugar varies greatly in different individuals and in the same individual at different times.

Fats.—The fats simply serve as stores of energy. After ingestion, if in small amount, they are, like carbohydrates, oxidized to the same final products CO_2, and H_2O. If in larger amount they are stored as fat, to serve as a reserve in case of need, in the body tissues. Like the carbohydrates they serve as the sources of part of the energy dissipated as heat, but they are not so efficient as sparers of protein material, evidently in part at least because they are less easily digested and absorbed.

Factors which influence Normal Metabolism.

1. *Fasting.*—During fasting the body draws upon its own reserve of stored material for the requirements in the production of energy, and the rate of breakdown varies with the energy requirements. An individual who is kept warm in bed therefore stands fasting longer than one who is compelled to take exercise in a cold place. The breakdown of tissue during the early days of a fast is much greater than later, for as the fast progresses the body becomes more economical in its utilization of tissue. During a fast the tissues do not all waste at an equal rate; those which are not essential are utilized at a much greater rate than those which are essential to the maintenance of the organism. For instance, it has been shown that during a fast the skeletal muscles may lose over 40 % of their weight, whereas an essential organ like the heart loses only some 3 %.

The essential tissues obtain their nourishment from the less essential probably by ferment action, a process which has been

termed autolysis. The autolytic products of the stored material in the tissues are practically identical with those which arise during the ordinary gastro-intestinal digestion.

2. *Muscular Work.*—The muscular tissue plays the most important part in general metabolism. Not only is muscle the most abundant tissue present, but it is constantly active and is the great energy-liberating machine of the body. Formerly it was believed on the authority of Liebig that muscular work was done at the expense of the protein material, but it has been conclusively shown that the real source of energy in moderate work is the non-protein material, carbohydrates and fats; of these the former plays the greater part in a man on ordinary diet. If, however, the supply of non-nitrogenous material be insufficient, then the energy has to be supplied by the protein and the output of nitrogen is thus increased. Variations in the amount of creatinin and uric acid (both products of muscle metabolism) excreted have been described. In hard work it is sometimes found that there may be no immediate rise in the nitrogen output on the day of the work, but that an increase is manifest on the second or third day after. While the excretion of nitrogen shows no increase proportionate to the work done, the output of carbon dioxide produced by the combustion of the carbohydrates and of the fats is increased proportionately to the work done.

3. *Internal Secretions.*—Evidence is accumulating to show that the activities of the various tissues of the body are presided over and controlled not merely by the action of the nervous system but also by chemical substances, the result of the activity of certain organs. To these chemical substances, as already stated, the name of hormones has been given.

The hormone which has been most thoroughly investigated is *adrenalin*, a perfectly definite chemical compound consisting of a secondary alcohol linked to a benzene ring. It is a product of the central or medullary part of the suprarenal bodies. The medullary part of these organs is developed from the sympathetic part of the nervous system, and adrenalin acts as a stimulant to the terminations of the sympathetic nerves which spring from the thoraco-abdominal region. These nerves control the small arteries, and the main action of adrenalin is to cause a powerful contraction of these vessels, and as a result a great rise in the arterial blood pressure. For this purpose it is now largely used in medicine. The constant supply of adrenalin in small quantities seems to play an important part in keeping up the tone of the blood vessels, and when, as a result of disease of the suprarenals, the supply is cut off a serious train of symptoms supervenes.

Allied to adrenalin is a hormone derived from the *pituitary body*. This also causes a constriction of the small arteries except those of the kidney, which it dilates. An increased flow of urine is produced.

In the *thyroid gland* a substance, *iodothyrin*, is constantly being produced, and this appears to exercise a stimulating action on the rate of chemical exchange in the various tissues. Under its administration the waste of both proteins and fats is increased. When the thyroid is removed or destroyed by disease a condition of decreased chemical change and mental sluggishness results, accompanied often by nervous tremors.

A difficulty in explaining these symptoms is caused by the fact that in the thyroid are imbedded four small parathyroids, and it is possible that these produce a special hormone. It has been suggested that this exercises a particular influence upon the nervous system, but further evidence is wanting.

The well-known effects of removal of the *ovaries* or *testes* on the development and character of an animal is due to the absence of the special hormone or hormones of these structures. These hormones appear to be produced, in the case of the testes at least, not in the true genital cells, but in the intermediate cells, since it has been found that ligature of the duct, which leads to destruction of the genital cells, does not abolish the development of the sexual characters of the animal.

There is growing evidence that from the ovaries different hormones may be produced in varying amounts which play an important part in regulating the phenomena of sexual life.

The *thymus gland* is a structure lying in the front of the neck, which is best developed at the time of birth, grows very slowly after birth, and atrophies when the age of puberty is reached. In castrated male animals it continues to grow and persists throughout life. There is some evidence that it may exercise some effect upon the growth of the testes, probably by hormone action.

Pancreas.—Within recent years it has been shown that the internal secretion of this organ plays a very important part in the metabolism of sugar. When the organ is completely extirpated the animal becomes diabetic, *i.e.* sugar appears in the urine and the animal emaciates. How the internal secretion effects the combustion of the sugar is not yet known. Some workers hold that the action of the pancreatic internal secretion is to control the sugar formation in the various sugar-forming organs, of which the liver is the chief, others that it dominates the utilization of sugar as a source of energy by the muscles.

These are some of the best-known examples of the way in which the products of the activity of one organ modify the functions of other organs. In all probability many more examples of hormone action will be discovered, and it will be found that it plays probably even a more important part than the nervous system in the co-ordination of function in the animal.

Other factors, besides those already dealt with, play a part in modifying the various metabolic processes, as age, temperature, climate, &c. Very little, however, is definitely known about these various factors.

Water and inorganic salts are quite as essential for the well-being of the body as the energy-yielding proteins, carbohydrates and fats. They, however, probably undergo little or no change in the body; they are excreted pretty much in the same form in which they are ingested. Although they are not subjected to any very great change yet they are of immense importance. No animal tissue can carry on its work in the absence of the various salts. Many experiments have been carried out in which animals have been fed on food as free from salts as possible, and, although the food was much in excess of the energy requirements, yet all these animals died, whereas other animals to which similar food with salts was given throve well. The most important acids are hydrochloric and phosphoric, and the most important bases sodium of potassium. Calcium and magnesium are also of importance, especially where bone formation is taking place. Another element of really vital importance is iron, which is required for the formation of haemoglobin.

VI. Excretion

While we know comparatively little of the intermediate stages in the breakdown of the food constituents, and more particularly of the protein moiety, our knowledge of the final products of the metabolic changes excreted is fairly full. The urine is the main channel of excretion for the nitrogenous waste products. CO_2, arising for the most part from the metabolism of carbohydrates and fats, is excreted mainly through the lungs. Water is excreted by the lungs, the kidneys and the skin.

So far no entirely satisfactory explanation has been given of how a fluid like urine, having an acid reaction and containing about one hundred times as much urea and generally more than twice as much sodium chloride as the blood, is formed in the kidneys. The urine is a yellowish fluid which varies greatly in its depth of colour, from pale amber to a deep brown. It has a specific gravity of about 1020, varying with the percentage of solids in solution, and it usually has an acid reaction. It is a fluid of complex character, containing, as already mentioned, practically all the waste nitrogen of the body. Among the principal organic substances present are urea, ammonia, purins (uric acid and the so-called purin bases, xanthin, &c.), creatinin, conjugated sulphates, various aromatic bodies and many other substances in small amount, together with the water and inorganic salts.

The following table from Folin gives a good idea of the average composition of the urine as regards the nitrogen-containing constituents, and its variation according to the nature of the diet when this is free of creatin creatinin and the precursors of the purins:—

	Nitrogen-rich Diet.	Nitrogen-poor Diet.
Total nitrogen	14·8-18·2 grms. per day	4·8- 8·0 grms. per day
Urea nitrogen.	86·3-89·4 % of total	62·0-80·4 % of total
Ammonia nitrogen . . .	3·3- 5·1 % ,,	4·2-11·7 % ,,
Creatinin nitrogen . .	3·2- 4·5 % ,,	5·5-11·1 % ,,
Uric acid nitrogen . . .	0·5- 1·0 % ,,	1·2- 2·4 % ,,
Undetermined nitrogen . .	2·7- 5·3 % ,,	4·8-14·6 % ,,

Urea, which forms the chief nitrogenous constituent, amounting on an ordinary diet to about 30 grms. per diem, is for the most part formed in the liver, from ammonia obtained either directly from the blood after absorption from the intestine, or resulting from the denitrification of the amino acids. It may also arise in part from the diamino acids and from uric acid.

Ammonia is present in the form of ammonium salts, and forms about 4 % of the total urinary nitrogen. It may exceed this amount under certain conditions, for the most part pathological. The ammonia is utilized by the body to neutralize acids which arise during the various metabolic processes.

Purins (uric acid, xanthin, hypoxanthin, &c.) are all members of a series which have as their common nucleus a body which E. Fischer called purin. The most important member of this series is uric acid. It forms about 2 % of the total urinary nitrogen. Recent work has shown that it has two quite definite sources of origin: (1) from ingested food containing the precursors, and (2) from the tissue metabolism. The first is known as the exogenous source, and the second as the endogenous. This acid is chemically known as trioxy-purin, and may be regarded as the union of two urea molecules with a three-carbon chain fatty acid. All the uric acid formed in the body is not excreted as such, part being, as already mentioned, converted into urea. The amount which is converted into urea varies

with the species of animal. In man, Burian and Schur state that one half of the total amount is so converted. Some workers, like Wiener, hold that uric acid may be synthesized in the body, but while this is undoubtedly so in the case of the bird, in the mammal it has not been definitely established. The other chief purin bodies present in urine are xanthin and hypoxanthin, purins less oxidized than uric acid; the first is a dioxypurin, and the second is a monoxypurin. The main source of total purin supply would seem to be muscle metabolism. The mother substances from which all are derived in the body are the nucleins. These complex bodies are apparently first broken down by enzyme action to aminopurins. These in their turn have their amino groups split off, and then, according to the degree of oxidation, the different purin bodies are formed.

Creatinin.—The physiological significance of this substance is as yet unknown. The daily excretion varies little with the character of the diet, provided, of course, that the diet be creatin creatinin free. It appears to be proportional to the muscular development and muscular activity of the individual. Hence it would seem to be derived from the creatin of muscle, a substance which is very readily changed into creatinin outside the body. In the body the conversion of creatin into creatinin seems to be strictly limited, and hence when creatin is taken in flesh in the food it tends to appear as such in the urine. It would seem that it is either in great part decomposed in the body into what we do not at present know or that, as suggested by Folin, it may be used as a specialized food. Whatever its source, after urea and ammonia it is one of the most important nitrogenous substances excreted, the daily excretion being about 1·5 grms.

The *sulphur* excreted in the urine comes chiefly from the sulphur of the protein molecule. It is excreted in various forms. (1) As the ordinary preformed sulphates, that is, sulphur in the form of sulphuric acid combined with the ordinary bases. (2) As ethereal sulphates, that is, in combination with various aromatic substances like phenol, indol, &c. (3) In the form of so-called neutral sulphur in such substances as cystin, which are intermediate products in the complete oxidation of sulphur.

Phosphorus appears linked to the alkalis and alkaline earths as phosphoric acid. A very small part of the phosphoric acid may be eliminated in organic combination such as the glycero-phosphates, &c.

Sodium (mostly as sodium chloride), potassium, calcium and magnesium are the common bases present in the urine.

The lungs are *the* important channel of excretion for the waste product of carbon metabolism CO_2 (see RESPIRATORY SYSTEM); and also a very important channel for the excretion of water. As regards the skin, the sweat carries off a large amount of the water, but it is difficult to determine the total amount. It has been estimated that about 500 c.c. is excreted per diem under normal conditions. Sweat contains salts, chiefly sodium chloride, and organic waste products. Of the organic solids excreted from this source urea forms the most important under normal conditions. Under pathological conditions, especially when there is interference with free renal action, the amount of nitrogenous waste excreted may become quite important. There is also a small amount of CO_2 excreted by this channel. (D. N. P.; E. P. C.)

NUTTALL, THOMAS (1786–1859), English botanist and ornithologist, who lived and worked in America from 1808 until 1842, was born at Settle in Yorkshire on the 5th of January 1786, and spent some years as a journeyman printer in England. Soon after going to the United States he was induced by Professor B. S. Barton (1766–1815) to apply himself to the study of the plants of that country. In 1825–1834 he was curator of the botanic gardens of Harvard university. In 1834 he crossed the continent to the Pacific Ocean, and visited the Hawaiian Islands. Some property having been left him in England on condition of his residing on it during part of each year, he left America in 1842, and did not again revisit it except for a short time in 1852. He died at St Helens, Lancashire, on the 10th of September 1859.

Almost the whole of his scientific work was done in the United States, and his published works appeared there. The more important of these are, *The Genera of North American Plants, and a Catalogue of the Species to the year 1817* (2 vols., 1818); *Journal of Travels into the Arkansas Territory during the year 1819* (1821); *The North American Sylva: Trees not described by F. A. Michaux* (3 vols., 1842–1849); *Manual of the Ornithology of the United States and of Canada* (1832 and 1834); and numerous papers in American scientific periodicals.

NUWARA ELIYA, a town and sanatorium of Ceylon. Pop. (1901) 5026, with 1000 additional visitors during the season. It is situated 6240 ft. above sea-level, with the highest mountain in the island, Pedrotallagalla, towering over the plain for 2056 ft. more. Nuwara Eliya is reached from Colombo by railway, eight hours to Namuoya, and thence, by a light 2½-ft.-gauge line, running up to the heart of the sanatorium. The average shade temperature for the year is 58° F.; the rainfall, 95 in. Considerable sums have been spent by the government in improving the place.

NUX VOMICA, a poisonous drug, consisting of the seed of *Strychnos Nux-Vomica*, a tree belonging to the natural order Loganiaceae, indigenous to most parts of India, and found also in Burma, Siam, Cochin China and northern Australia. The tree is of moderate size, with a short, thick, often crooked, stem, and ovate entire leaves, marked with three to five veins radiating from the base of the leaf. The flowers are small, greenish-white and tubular, and are arranged in terminal corymbs. The fruit is of the size of a small orange, and has a thin hard shell, enclosing a bitter, gelatinous white pulp, in which from 1 to 5 seeds are vertically embedded. The seed is disk-shaped, rather less than 1 in. in diameter, and about ¼ in. in thickness, slightly depressed towards the centre, and in some varieties furnished with an acute keel-like ridge at the margin. The external surface of the seed is of a greyish-green colour and satiny appearance, due to a coating of appressed silky hairs. The interior of the seed consists chiefly of horny albumen, which is easily divided along its outer edge into halves by a fissure, in which lies the embryo. The latter is about $\frac{1}{10}$ in. long, and has a pair of heart-shaped membranous cotyledons.

The chief constituents of the seeds are the alkaloids strychnine (*q.v.*) and brucine, the former averaging about 0·4%, and the latter about half this amount. The seeds also contain an acid, strychnic or igasuric acid; a glucoside, loganin; sugar and fat. The dose of the seeds is 1 to 4 grains. The British Pharmacopoeia contains three preparations of nux vomica. The liquid extract is standardized to contain 1·5% of strychnine; the extract is standardized to contain 5%; and the tincture, which is the most widely used, is standardized to contain 0·25%.

The pharmacology of nux vomica is practically that of strychnine. The tincture is chiefly used in cases of atonic dyspepsia, and is superior to all other bitter tonics, in that it is antiseptic and has a more powerful action upon the movements of the gastric wall. The extract is of great value in the treatment of simple constipation.

NYACK, a village of Rockland county, New York, U.S.A., in the town of Orangetown, on the western bank of the Hudson river, about 25 m. north of New York City. Pop. (1890) 4111, (1900) 4275, of whom 583 were foreign-born; (1905) 4441; (1910) 4619. Nyack is served by the Northern Railroad of New Jersey (a branch of the Erie), and is connected by ferry with Tarrytown, nearly opposite, on the eastern bank of the Hudson. The New York, Ontario & Western and the West Shore railways pass through West Nyack, a small village about 2 m. west. For about 2 m. above and 3 m. below Nyack the river expands into Tappan Zee or Bay, which is about 3 m. wide immediately opposite the village. The first grant of land within the present limits of Nyack was made by Governor Philip Carteret, of New Jersey, to one Claus Jansen, in 1671, but the permanent settlement apparently dates from about 1700. The adjacent villages of Upper Nyack, pop. (1905) 648, (1910) 591, and South Nyack, pop. (1910) 2068, form with Nyack practically one community. Nyack was named from a tribe of Algonquian Indians.

See David Cole, *History of Rockland county*, (New York, 1884).

NYANZA (from the ancient Bantu root word *anza*, a river or lake), the Bantu name for any sheet or stream of water of considerable size; especially applied to the great lakes of east Central Africa. The word is variously spelt, and the form "Nyasa" has become the proper name of a particular lake. Nyanza is the spelling used in designating the great lakes which are the main reservoirs of the river Nile.

NYASA, the third in size of the great lakes of Central Africa, occupying the southern end of the great rift-valley system which traverses the eastern half of the equatorial region from north to south. Extending from 9° 29′ to 14° 25′ S., or through nearly 5° of latitude, the lake measures along its major axis, which is slightly inclined to the west of north, exactly 350 m., while the greatest breadth, which occurs near the middle of its length between 11° 30′ and 12° 20′ S., is 45 m. In the northern and southern thirds of the length the breadth varies generally from 20 to 30 m., and the total area may be estimated at 11,000 sq. m.

The lake lies at an altitude of about 1650 ft. above the sea. The sides of the valley in which Nyasa lies, which are somewhat irregular towards its southern end, take a decided character of fault scarps in the northern third, and are continued as such beyond the northern extremity. Apart from the recent alluvium on the immediate shores, the lake lies almost entirely in granite and gneiss formations, broken, however, by a band of horizontally-bedded sandstones, which cuts the axis of the lake in about 10° 30′ S., the flat-topped, terraced form of the latter contrasting strangely with the jagged or rounded outlines of the former. Near the margin, overlying the sandstones, there are beds of limestone with remains of recent molluscs, pointing, like the raised beaches which occur elsewhere, to an upward movement of the coasts. Lacustrine deposits up to 700 ft. above the present lake-level have been discovered. Geologically, the lake is believed to be of no great age, a view supported by topographical evidence. The depth of the lake seems to vary in accordance with the steepness of the shores, increasing from south to north. The greater part of the northern half shows depths of over 200 fathoms, while a maximum of 430 fathoms was obtained by Mr. J. E. S. Moore in 1899, off the high western coast in about 11° 40′ S. A more complete series of soundings, however, since made by Lieut. Rhoades, and published in the *Geographical Journal* in 1902, gives a maximum of 386 fathoms off the same coast in 11° 10′ S. The lake receives its water-supply chiefly from the streams which descend from the mountains to the north, all the rest becoming very small in the dry season. Like other lakes of Central Africa it is subject to fluctuations of level, apparently caused by alternations of dry and wet series of years.

At the north-western end is a plain of great fertility, traversed by the Kivira, Songwe and other streams, rising either among the volcanic masses to the north or on the western plateau. Just north of 10° S. on the delta of the Rukuru, is the British station of Karonga, the northern port of call for the lake steamers, though with but an open roadstead. Southwards the plain narrows, and in about 10½° S. the sandstone scarp of Mount Waller rises sheer above the indentation of Florence Bay, the high western plateaus continuing to fall steeply to the water in wooded cliffs for more than 80 m. In this stretch occur the land-locked bays of Ruarwe (11° 5′ S.) and Nkata (11° 36′ S.), and the mouth of the Rukuru (10° 43′ S)., which drains the plateau from south to north. At Cape Chirombo (11° 40′ S.) the coast bends to the west, and soon the plateau escarpments recede, and are separated from the lake along its southern half by an undulating plain of varying width. In 11° 56′ S. is the British station of Bandawe, and in 12° 55′ that of Kota Kota, on a lake-like inlet, forming a sheltered harbour. A little north of the latter the Bua river, coming from a remote source on the upper plateau, enters by a projecting delta. At Domira Bay, in 13° 35′, the coast turns suddenly east, contracting the lake to a comparatively narrow neck, with the British stations of Fort Rifu on the west, and Fort Maguire, near the headland of Makanjira Point, on the east. Beyond this the lake runs southwards into two bays separated by a granitoid peninsula, off which lie several small rocky islands. On this peninsula was placed the mission station of Livingstonia, the first to be established on the shores of Nyasa. From the extremity of the eastern bay the Shiré makes its exit to the Zambezi. On the eastern side the plateau escarpments keep generally close to the lake, leaving few plains of any extent along its shores. The crest of the eastern watershed runs generally parallel to the shore, which it approaches in places within 20 m. From the north point to 10° 30′ S. the coast is formed by the unbroken wall of the Livingstone or Kinga range, rising where highest (9° 41′ S.) fully 6000 ft. above the water. On this coast, on a projecting spit of land, is the German station of Old Langenburg, some 10 m. from the northern extremity. In 10° 30′ the plateau is broken by the valley of the Ruhuhu, the only important stream which enters the lake from the east. The formation is here sandstone, corresponding to that of Mount Waller on the opposite shore. Just north of the Ruhuhu is the German station of Wiedhafen, on an excellent harbour, formerly Amelia Bay. South of the Ruhuhu the wall of mountains recedes somewhat, and the remainder of the eastern shore shows a variation between rocky cliffs, marshy plains of restricted area and groups of low hills. In 11° 16′ is the deep inlet of Mbampa Bay, offering a sheltered anchorage. South of it the coast forms a wide semicircular bay, generally rock-bound, and ending south in Malo Point (12° 10′ S.), off which are the largest islands the lake possesses, Likoma and Chisamulu, the former measuring about 4 m. by 3. In the southern half the coast is highest in about 13° 10′ S., where the Mapangi hills rise to 3000 ft.

Nyasa, reached in 1859 both by David Livingstone (from the south) and by the German traveller Albrecht Roscher (from the east), was explored by the former to about 11°, and to its northern end by E. D. Young in 1876. From this date onwards it has been the scene of much civilizing work on the part of British (principally Scottish) missionaries, traders and government officials, and, in more recent years, of Germans also. Its shores have been divided between Great Britain, Portugal and Germany, Great Britain holding (within the British Nyasaland Protectorate) all the west coast south of the Songwe, and the southern extremity of the east coast (south of 13½° S.); Portugal the rest of the east coast south of 11½° S.; and Germany the remainder. British steamers, including two or three gunboats, have been launched on Nyasa, which forms an important link in the water-route from the Zambezi mouth to the heart of the continent. Germany also has a gunboat on the lake. The first detailed survey of its shores was executed by Dr James Stewart (1876–1877), but this has been superseded by later work, especially that of Lieuts. Rhoades and Phillips.

Bailey, with note on fossil plants, fish remains, &c., by E. A. N. Arber and others and bibliography in vol. 66 of *Quart. Jnl. Geog. Society* (May 1910). (E. He.)

NYBORG, a seaport of Denmark on the east side of the island of Fünen, in the *amt* (county) of Svendborg, and the point from which the ferry crosses the Great Belt to Korsör in Zealand (15 m.). Pop. (1901) 7790. The fortress, built by Christian IV. and Frederick III., was dismantled in 1869, and the ruins of the castle are used as a prison. In the 12th century the town was founded and a castle erected on Knudshoved (Canute's Head) by Knud, nephew of Waldemar the Great; and from the 13th to the 15th century Nyborg was one of the most important places in Denmark. In 1658 it surrendered to the Swedes; but by the defeat of the latter under the walls of the fortress on the 24th of November 1659, the country was freed from their dominion. In 1808 the Marquis La Romana, who with a body of Spanish troops garrisoned the fortress for France, revolted from his allegiance, and held out till he and a portion of his men escaped with the English fleet.

NYCKELHARPA (Swed. *nyckel*=key, *harpa*=harp; Ger. *Schlüsselfiedel*), a kind of bowed hurdy-gurdy, much used in Scandinavia during the late middle ages, and still in use in some parts of Sweden. It consists of a body some 2 ft. long, shaped like an elongated viol, with sloping shoulders and highly arched sound-board glued over a less arched back, and ribs cut out of a single block of wood. There is no fingerboard, but along the neck, arranged like frets, are a number of keys or wooden tangents, which when pressed inwards bring a little knob or stud into contact with the first string of thin catgut, thus stopping it and raising the pitch as in the hurdy-gurdy. At three points these keys also act upon the third string. There are in the comparatively modern instruments usually four melody strings of catgut and three drones of fine spun wire. The bridge is quite flat, so that when the bow is passed over the strings, they all sound at once. The tailpiece is very long, extending over half the length of the body, and the two oval sound-holes, far removed from the strings, are at the tail end of the instrument.

NYE, EDGAR WILSON (1850–1896), American humorist, was born at Shirley, Maine, on the 25th of August 1850. His parents removed to a farm on the St Croix river in northern Wisconsin in 1852, and young Nye was educated in Wisconsin at the academy at River Falls, where he studied law. In 1876 he was admitted to the bar at Laramie, Wyoming, where he served as justice of the peace, superintendent of schools, member of the city council and postmaster. Here he began to contribute humorous articles under the pseudonym of "Bill Nye" to newspapers, especially the Cheyenne *Sun* and the Denver *Tribune*. In 1881 he founded at Laramie the *Boomerang*, and his reputation as a humorist was soon widespread. Later he became a successful lecturer, and in 1885, with James Whitcomb Riley, the poet, made an extended tour through the country, each reading from his own writings. Nye removed to New York City in 1886, and passed the later years of his life at Arden, a village in Buncombe county, North Carolina (about 10 m. south of Asheville),

where he died on the 22nd of February 1896. His principal books are *Bill Nye and Boomerang* (1881); *Forty Liars and Other Lies* (1882); *Nye and Riley's Railway Guide* (1886), with James Whitcomb Riley; and two comic histories, *Bill Nye's History of the United States* (1894) and *Bill Nye's History of England from the Druids to the Reign of Henry VIII.* (1896).

NYEZHIN or NEZHIN, a town of Russia, in the government of Chernigov, 62 m. by rail S.E. of the town of Chernigov and 79 m. N.E. of Kiev, on the railway between Kursk and Kiev. The old town is built on the left bank of the (canalized) river Oster, and its suburbs, Novoye-Myesto and Magerki, on the right. It has an old cathedral, a technical school and a former high school (lyceum of Bezborodko, at which N. V. Gogol, the novelist, was a student), now transformed into a philological institute. The inhabitants (33,000), are mostly Little-Russians and Jews; there are also some Greeks, descendants of those who immigrated in the 17th century at the invitation of the Cossack chieftain Bogdan Chmielnicki.

Unyezh, which is supposed to have been the former name of Nyezhin, is mentioned as early as 1147. At that time it belonged to the principality of Chernigov; afterwards it fell under the rule of Poland. It was ceded to Russia about 1500, but again became a Polish possession after the treaty of Deulina (1619) between Poland and Russia. In 1649, after the revolt of Little Russia and its liberation from the Polish rule, Nyezhin was the chief town of one of the most important Cossack regiments. It was annexed to Russia in 1664.

NYIREGYHÁZA, the capital of the county of Szabolcs, in Hungary, 169 m. E.N.E. of Budapest by rail. Pop. (1900) 31,875. It is a busy railway junction, and its inhabitants are engaged in agriculture, wine-growing and the manufacture of soda, matches and saltpetre. About 20 m. to the N.W. lies the famous wine-producing district of Tokaj (Tokay).

NYKJÖBING, a seaport of Denmark, in the *amt* (county) of Maribo, on the west shore of the island of Falster, 94 m. S.S.W. of Copenhagen by rail. Pop. (1901) 7345. Its church contains a genealogical tree of the Mecklenburg ducal family, with portraits, dating from 1627 or earlier. Here is the house occupied by Peter the Great of Russia in 1716, restored in 1898. A railway runs south to Gjedser (14 m.), from which the sea-passage (29 m.) to Warnemünde links the fastest route between Copenhagen and Berlin.

Other towns of the name of NYKJÖBING in Denmark are (1) on Limfjord in Thisted amt (pop. 4492); and (2) in Zealand, Holbaek amt (pop. 2000).

NYKÖPING, a seaport of Sweden, chief town of the district (*län*) of Södermanland, 98 m. S.W. of Stockholm by a branch from the Stockholm-Malmö railway. Pop. (1900) 7375. It lies at the head of the Byfjord, an inlet of the Baltic. The ruins of its once famous castle, the town hall (1662), and the district governor's residence, are notable buildings. The port, together with that of Oxelösund (10 m. S.E.) at the mouth of the bay, which is seldom closed in winter, exports iron and zinc ore, timber, wood-pulp and oats.

Nyköping (*i.e.* New-Market, Latinized as *Nicopia*) begins to appear as a town early in the 13th century. Its castle was the seat of the kings of Södermanland, and after those of Stockholm and Kalmar was the strongest in Sweden. The death of Waldemar in 1293, the starving to death of Dukes Waldemar and Eric in 1318, the marriage and the deaths both of Charles IX. and his consort Christina of Holstein, the birth of their daughter Princess Catherine and in 1622 the birth of her son Charles X. are the main incidents of which it was the scene. Burned down in 1665 and again damaged by fire in 1719, it still remained the seat of the provincial authorities till 1760. The town was burned by Albert of Mecklenburg's party in 1389, by an accidental conflagration in 1665, and by the Russians in 1719.

NYLSTROOM, a town of the Transvaal, South Africa, capital of the Waterberg district, and 81 m. N. of Pretoria by rail; altitude 4250 ft. Pop. (1904) 599. It was founded about 1860 and owes its name to the belief of the early Boer trekkers that the river which they had discovered was the head stream of the Nile. The Waterberg gold-fields are 20 m. N.N.E. of the town.

NYMPHAEUM (Gr. *νύμφαιον*, *νυμφαῖον*), in Greek and Roman antiquities, a monument consecrated to the nymphs (*q.v.*), especially those of springs. These monuments were originally natural grottoes, which tradition assigned as habitations to the local nymphs. They were sometimes so arranged as to furnish a supply of water. Subsequently, artificial took the place of natural grottoes. The *nymphaea* of the Roman period were borrowed from the constructions of the Hellenistic east. The majority of them were rotundas, and were adorned with statues and paintings. They served the threefold purpose of sanctuaries, reservoirs and assembly-rooms. A special feature was their use for the celebration of marriages. Such *nymphaea* existed at Corinth, Antioch and Constantinople; the remains of some twenty have been found at Rome and of many in Africa. The so-called *exedra* of Herodes Atticus (which answers in all respects to a *nymphaeum* in the Roman style), the *nymphaeum* in the palace of Domitian and those in the villa of Hadrian at Tibur (five in number) may be specially mentioned. The term *nymphaeum* was also applied to the fountains of water in the atrium of the Christian basilica, which according to Eusebius (x. 4) were symbols of purification.

NYMPHENBURG, formerly a village, but since 1899 an incorporated suburb of Munich, in the kingdom of Bavaria. It has a palace, built about the middle of the 17th century, on the model of that at Versailles, and long a favourite residence of the Bavarian elector, Maximilian Joseph. The famous china manufactory of Nymphenburg, founded in 1754 at Neudeck by a potter named Niedermeyer, was shortly afterwards removed hither and, after being long under royal patronage, is now a private undertaking. The elector Charles Albert of Bavaria was reputed to have made a treaty with Louis XV. of France in May 1741 at the beginning of the War of the Austrian Succession for the division of Austria, and this was called the treaty of Nymphenburg. It has, however, been conclusively proved a forgery. But a treaty was concluded here on the 28th of May 1741, between Bavaria and Spain, and another between Bavaria and the Rhenish Palatinate in 1766.

NYMPHS, in Greek mythology, the generic name of a large number of female divinities of inferior rank, personifications of the creative and fostering activities of nature. The word is possibly connected with the root of *νέφος*, *nubes* ("cloud"), and originally meant "veiled," referring to the custom of a bride being led veiled from her home to that of the husband: hence, a married woman, and, in general, one of marriageable age. Others refer the word (and also Lat. *nubere* and the Ger. *Knospe*) to a root expressing the idea of "swelling" (according to Hesychius, one of the meanings of *νύμφη* is "rose-bud"). The home of the nymphs is on mountains and in groves, by springs and rivers, in valleys and cool grottoes. They are frequently associated with the superior divinities, the huntress Artemis, the prophetic Apollo, the reveller and god of trees Dionysus, and with rustic gods such as Pan and Hermes (as the god of shepherds).

The nymphs were distinguished according to the different spheres of nature with which they were connected. Sea nymphs were *Oceanids* or *Nereids*, daughters of Oceanus or Nereus. *Naiades* (from Gr. *ναεῖν*, flow, cf. *νᾶμα*, "stream") presided over springs, rivers and lakes. *Oreades* (*ὄρος*, mountain) were nymphs of mountains and grottoes, one of the most famous of whom was Echo. *Napaeae* (*νάπη*, dell) and *Alseïdes* (*ἄλσος*, grove) were nymphs of glens and groves. *Dryades* (*q.v.*) or *Hamadryades* were nymphs of forests and trees.

The Greek nymphs, after the introduction of their cult into Latium, gradually absorbed into their ranks the indigenous Italian divinities of springs and streams (Juturna, Egeria, Carmentis, Fons), while the Lymphae (originally Lumpae), Italian water-goddesses, owing to the accidental similarity of name, were identified with the Greek Nymphae. Among the Romans their sphere of influence was restricted, and they appear almost exclusively as divinities of the watery element.

F. G. Ballentine, "Some Phases of the Cult of the Nymphs" in *Harvard Studies in Classical Philology*, xv. (1904).

O The sixteenth letter of the Phoenician and early Greek alphabets, the fifteenth in English and the fourteenth in Latin. Between N and O the Phoenician and the Ionic Greek alphabet have a sibilant—in Greek Ξ=*x*. The Western Greek alphabet had a different symbol, X, for the sound of *x* and placed it at the end, as did its descendant the Latin alphabet. The original form of *o* was a more or less roughly formed circle. The Aramaic ע and Hebrew ע, which seem so different, arise from a circle left open at the top, Ɔ, a form which can be traced in Aramaic from the 5th or 6th century B.C. In the Greek alphabets the circle appears sometimes with a dot in the centre, but in many cases it is doubtful whether this mark is intentional, or is only the result of fixing a sharp point there while describing the circle. Sometimes O is lozenge-shaped ◊ and rarely (in Arcadia and Elis) rectangular □ In many varieties of the Greek alphabet this symbol was used, as it always was in Latin, for the long as well as the short *o*-sound and also for the long vowel (in the Ionic alphabet written *ov*) which arose from contraction of two vowels or the loss of a consonant (δηλοῦτε=δηλόετε, οἶκους=οἴκονς). As early as the 8th century Ionic Greek had invented a separate symbol for the long *o*-sound, viz. Ω. This when borrowed by other dialects showed at first some variety of usage, though practically none in form. As this was placed at the end of the ordinary (not the numeral) Greek alphabet, "alpha and omega" has become a proverbial phrase for first and last. The Greeks themselves, however, did not call Ω omega (great *o*) nor did they call O omicron (little *o*), though these names are given even in modern Greek grammars. The former was called simply *o* and the latter *u* (*ou*, pronounced as *oo* in *moon*). The Hebrew and probably the Phoenician name for O was Ain (Ayin), and in the Semitic alphabet, which does not indicate vowels, the symbol stood for a "voiced glottal stop" and also for a "voiced velar spirant" (Zimmern). The most important feature of this vowel is the rounding of the lips in its production, which, according to its degree, modifies the nature of the vowel considerably, as can be observed in the pronunciation of the increasingly rounded series *saw*, *no*, *who*. In Attic Greek O and Ω were not really a pair, for *o* + *o* became not *ω* but *ou*, *o* being a close and *ω* an open sound. In Latin the converse was more nearly true. Though short *o* changed in the Latin of the last age of the Roman republic to *u* in unaccented syllables always (except after *u* whether vowel or consonant), and sometimes also in accented syllables, this was not equally true of vulgar Latin, as is shown by the Romance languages. In English also the short and the long *o* are of different qualities, the short in words like *not*, *got* being in Sweet's phonetic terminology a low-back-wide-round, the long in words like *no* a mid-back-wide-round. The long vowel becomes more rounded as it is being pronounced, so that it ends in a *u*-sound, though this is not so noticeable in weak syllables like the final syllable of *follow*. The so-called modified *ō* is a rounded *e*-sound found in several varieties. The sound heard in words like the German *Götter* is, according to Sweet, a low-front-wide-round, while Jespersen regards it as not low but middle. A mid-front-narrow-round vowel is found short in French words like *peu*, long in *jeûne* and in endings like that of *honteuse* The Norse sound written *ϕ* is of the same nature (P. Gi.)

OAK (O Eng., *āc*), a word found, variously modified, in all Germanic languages, and applied to plants of the genus *Quercus*, natural order *Fagaceae* (*Cupuliferae* of de Candolle), including some of the most important timber trees of the north temperate zone. All the species are arborescent or shrubby, varying in size from the most stately of forest trees to the dwarfish bush. Monoecious, and bearing their male flowers in catkins, they are readily distinguished from the rest of the catkin-bearing trees by their peculiar fruit, an acorn or nut, enclosed at the base in a woody cup, formed by the consolidation of numerous involucral bracts developed beneath the fertile flower, simultaneously with a cup-like expansion of the thalamus, to which the bracteal scales are more or less adherent. The ovary, three-celled at first, but becoming one-celled and one-seeded by abortion, is surmounted by an inconspicuous perianth with six small teeth. The male flowers are in small clusters on the usually slender and pendent stalk, forming an interrupted catkin; the stamens vary in number, usually six to twelve. The alternate leaves are more or less deeply sinuated or cut in many species, but in some of the deciduous and many of the evergreen kinds are nearly or quite entire on the margin.

The oaks are widely distributed over the temperate parts of Europe, Asia, North Africa and North America. In the western hemisphere they range along the Mexican highlands and the Andes far into the tropics, while in the Old World the genus, well represented in the Himalayas and the hills of China, exists likewise in the peninsula of Malacca, in the Indian Archipelago and Malaya to the Philippine Islands and Borneo. On the

e, Female flowers of *Q. sessiliflora*, after fertilization, enlarged.

mountains of Europe and North America they grow only at moderate elevations, and none approach the arctic circle. The multitude of species and the many intermediate forms render their exact limitation difficult, but those presenting sufficiently marked characters to justify specific rank probably approach 300 in number.

The well-known *Q. Robur*, one of the most valued of the genus, and the most celebrated in history and myth, may be taken as a type of the oaks with sinuated leaves. Though known in England, where it is the only indigenous species, as the British oak, it is a native of most of the milder parts of Europe, extending from the shores of the Atlantic to the Ural; its most northern limit is attained in Norway, where it is found wild up to lat. 63°, and near the Lindesnaes forms woods of some extent, the trees occasionally acquiring a considerable size. In western Russia it flourishes in lat. 60°, but on the slope of the Ural the 56th parallel is about its utmost range. Its northern limit nearly coincides with that of successful wheat cultivation. Southwards it extends to Sardinia, Sicily and the Morea. In Asia it is found on the Caucasus, but does not pass the Ural ridge into Siberia. In Britain and in most of its Continental habitats two varieties exist, regarded by many as distinct species: one, *Q pedunculata*, has the acorns, generally two or more together, on long stalks, and the leaves nearly sessile; while in the other, *Q sessiliflora*, the fruit is without or with a very short peduncle, and the leaves are furnished with well-developed petioles. But,

though the extreme forms of these varieties are very dissimilar, innumerable modifications are found between them; hence it is more convenient to regard them as at most sub-species of *Q. Robur*. The British oak is one of the largest trees of the genus, though old specimens are often more remarkable for the great size of the trunk and main boughs than for very lofty growth. The spreading branches have a tendency to assume a tortuous form, owing to the central shoots becoming abortive, and the growth thus being continued laterally, causing a zigzag development, more exaggerated in old trees and those standing in

From Kotschy, *op. cit.* Plate XXVII.

FIG. 2.—*Q. pedunculata.*

exposed situations; to this peculiarity the picturesque aspect of ancient oaks is largely due. When standing in dense woods the trees are rather straight and formal in early growth, especially the sessile-fruited kinds, and the gnarled character traditionally assigned to the oak applies chiefly to its advanced age. The broad deeply-sinuated leaves with blunt rounded lobes are of a peculiar yellowish colour when the buds unfold in May, but assume a more decided green towards midsummer, and eventually become rather dark in tint; they do not change to their brown autumnal hue until late in October, and on brushwood and saplings the withered foliage is often retained until the spring. The catkins appear soon after the young leaves, usually in England towards the end of May; the acorns, oblong in form, are in shallow cups with short, scarcely projecting scales; the fruit is shed the first autumn, often before the foliage changes.

Vast oak forests still covered the greater part of England and central Europe in the earlier historic period; and, though they have been gradually cleared in the progress of cultivation, oak is yet the prevailing tree in most of the woods of France, Germany and southern Russia, while in England the coppices and the few fragments of natural forest yet left are mainly composed of this species. The pedunculated variety is most abundant in the southern and midland counties, the sessile-fruited kinds in the northern parts and in Wales, especially in upland districts; the straighter growth and abundant acorns of this sub-species have led to its extensive introduction into plantations. The name of "durmast" oak, originally given to a dark-fruited variety of *Q. sessiliflora* in the New Forest, has been adopted by foresters as a general term for this kind of oak; it seems to be the most prevalent form in Germany and in the south of Europe. Many of the ancient oaks that remain in England may date from Saxon times, and some perhaps from an earlier period; the growth of trees after the trunk has become hollow is extremely slow, and the age of such venerable giants only matter of vague surmise. The celebrated Newland oak in Gloucestershire, known for centuries as "the great oak," was by the latest measurement 47½ ft. in girth at 5 ft. from the ground. The Cowthorpe oak, standing (a ruin) near Wetherby in Yorkshire, at the same height measures 38½ ft., and seems to have been of no smaller dimensions when described by Evelyn two centuries ago; like most of the giant oaks of Britain, it is of the pedunculate variety.

The wood of the British oak, when grown in perfection, is the most valuable produced in temperate climates. The heart-wood varies in colour from dark brown to pale yellowish-brown; hard, close-grained, and little liable to split accidentally, it is, for a hard wood, easy to work. Under water it excels most woods in durability, and none stand better alternate exposure to drought and moisture, while under cover it is nearly indestructible as long as dry-rot is prevented by free admission of air. Its weight varies from 48 to about 55 lb the cubic foot, but in very hard slowly-grown trunks sometimes approaches 60 lb. The sap-wood is lighter and much more perishable, but is of value for many purposes of rural economy. The relative qualities of the two varieties have been the frequent subject of debate, the balance of practical testimony seeming to establish the superiority of *Q. pedunculata* as far as durability in water is concerned; but when grown under favourable circumstances the sessile oak is certainly equally lasting if kept dry. The wood of the durmast oak is commonly heavier and of a darker colour, hence the other is sometimes called by woodmen the white oak, and in France is known as the "chêne blanc." The oak of Britain is still in demand for the construction of merchant shipping, though teak has become in some measure its substitute, and foreign oak of various quality and origin largely takes its place. Its great abundance of curved trunks and boughs rendered the oak peculiarly valuable to the shipwright when the process of bending timber artificially was less understood; the curved pieces are still useful for knees. The younger oaks are employed by the carpenter, wheelwright, wagon-builder and for innumerable purposes by the country artisan. The most durable of fences are those formed of small oaks, split lengthwise by the wedge into thin boards. The finely-grained heart-wood is sought by the cabinetmaker for the manufacture

From Kotschy, *op. cit.* Plate XXXII.

FIG. 3.—*Q. sessiliflora.*

of furniture, and high prices are often given for the gnarled and knotted portions of slowly-grown trees, to be sawn into veneers. Oak was formerly largely used by wood-carvers, and is still in some demand for those artists, being harder and more durable than lime and other woods that yield more readily to the sculptor's tool. Oak was thus applied at a very early date; the shrine of Edward the Confessor, still existing in the abbey at Westminster, sound after the lapse of 800 years, is of dark-coloured oak-wood. The wood, of unknown age, found submerged in peat-bogs, and of a black hue, is largely used in decorative art under the name of "bog-oak."

The oak grows most luxuriantly on deep strong clays, on calcareous marl or stiff loam, but will flourish in nearly any deep well-drained soil, excepting peat or loose sand; in marshy or moist places the tree may grow well for a time, but the timber is rarely sound; on hard rocky ground and exposed hillsides the growth is extremely slow and the trees small, but the wood

is generally very hard and durable. The oak will not bear exposure to the full force of the sea gale, though in ravines and on sheltered slopes oak woods sometimes extend nearly to the shore. The cultivation of this tree in Europe forms one of the most important branches of the forester's art. It is frequently raised at once by sowing the acorns on the ground where the trees are required, the fruit being gathered in the autumn as soon as shed, and perfectly ripe seeds selected; but the risk of destruction by mice and other vermin is so great that transplanting from a nursery-bed is in most cases to be preferred.

The acorns should be sown in November on well-prepared ground, and covered to a depth of 1½ or 2 in.; the seeds germinate in the spring, and the seedlings are usually transplanted when one or two years old to nursery-beds, where they are allowed to grow from two to four years, till required for the plantation. Some authorities recommend the tap-roots to be cut in the second year, with the view of increasing the ball of fibre; but, if the trees are removed from the seed-bed sufficiently early, the root is best left to its natural development. The oak requires shelter in the early stages of growth; in England the Scotch pine is thought best for this purpose, though Norway spruce answers as well on suitable ground, and larch and other trees are sometimes substituted. The conifers are allowed to grow to a height of from 3 to 5 ft. before the young oaks are planted, and are gradually thinned out as the latter increase in size. The distance between the oaks depends upon the growth intended before thinning the young wood; usually they are placed from 8 to 12 ft. apart, and the superabundant trees cut out as they begin to interfere with each other. The lower branches often require removal, to ensure the formation of a tall straight trunk, and this operation should be performed before the superfluous shoots get too large, or the timber will be injured; but, as with all trees, unnecessary pruning should be avoided, as every branch removed lessens the vigour of growth. Where artificial copsewood is the object, hazel, hornbeam and other bushes may be planted between the oaks; but, when large timber is required, the trees are best without undergrowth.

The growth of the oak is slow, though it varies greatly in different trees; Loudon states that an oak, raised from the acorn in a garden at Sheffield Place, Sussex, became in seventy years 12 ft. in circumference; but the increase of the trunk is usually very much slower, and when grown for large timber oak can rarely be profitably felled till the first century of its growth is completed. The tree will continue to form wood for 150 or 200 years before showing any symptoms of decay. As firewood oak holds a high position, though in Germany it is considered inferior to beech for that purpose. It makes excellent charcoal, especially for metallurgic processes; the Sussex iron, formerly regarded as the best produced in Britain, was smelted with oak charcoal from the great woods of the adjacent Weald, until they became so thinned that the precious fuel was no longer obtainable.

An important product of oak woods is the bark that from a remote period has been the chief tanning material of Europe. The most valuable kind is that obtained from young trees of twenty to thirty years' growth, but the trunks and boughs of timber trees also furnish a large supply; it is separated from the tree most easily when the sap is rising in the spring. It is then carefully dried by the free action of the air, and when dry built into long narrow stacks until needed for use. The value of oak bark depends upon the amount of tannin contained in it, which varies much, depending not only on the growth of the tree but on the care bestowed on the preparation of the bark itself, as it soon ferments and spoils by exposure to wet, while too much sun-heat is injurious. That obtained from the sessile-fruited oak is richer in tannic acid than that yielded by *Q. pedunculata*, and the bark of trees growing in the open is more valuable than the produce of the dense forest or coppice. The bark of young oak branches has been employed in medicine from the days of Dioscorides, but is not used in modern practice. The astringent principle is a peculiar kind of tannic acid, called by chemists *quercitannic*, which, yielding more stable compounds with gelatine than other forms, gives oak bark its high value to the tanner. According to Neubauer, the bark of young oaks contains from 7 to 10% of this principle; in old trees the proportion is much less.

The acorns of the oak possess a considerable economic importance as food for swine. In the Saxon period the "mast" seems to have been regarded as the most valuable produce of an oak wood; nor was its use always confined to the support of the herds, for in time of dearth acorns were boiled and eaten by the poor as a substitute for bread both in England and France, as the sweeter produce of *Q. Esculus* is still employed in southern Europe. Large herds of swine in all the great oak woods of Germany depend for their autumn maintenance on acorns; and in the remaining royal forests of England the inhabitants of the neighbouring villages yet claim their ancient right of "pannage," turning their hogs into the woods in October and November. Some trees of the sessile-fruited oak bear sweet acorns in Britain, and several varieties were valued by the ancient Italians for their edible fruit. A peculiar kind of sugar called *quercite* exists in all acorns. A bitter principle to which the name of *quercin* has been applied by Gerber, its discoverer, has also been detected in the acorn of the common oak; the nutritive portion seems chiefly a form of starch. A spirit has been distilled from acorns in process of germination, when the saccharine principle is most abundant.

The British oak grows well in the northern and middle states of America; and, from the superiority of the wood to that of *Q. alba* and its more abundant production of acorns, it will probably be much planted as the natural forests are destroyed. The young trees require protection from storms and late frosts even more than in England; the red pine of the north-eastern states, *Pinus resinosa*, answers well as a nurse, but the pitch pine and other species may be employed. In the southern parts of Australia and in New Zealand the tree seems to flourish as well as in its native home.

The oak in Europe is liable to injury from a great variety of insect enemies: the young wood is attacked by the larvae of the small stag-beetle and several other *Coleoptera*, and those of the wood-leopard moth, goat moth and other *Lepidoptera* feed upon it occasionally; the foliage is devoured by innumerable larvae; indeed, it has been stated that half the plant-eating insects of England prey more or less upon the oak, and in some seasons it is difficult to find a leaf perfectly free from their depredations. The young shoots are chosen by many species of *Cynipidae* and their allies as a receptacle for their eggs, giving rise to a variety of gall-like excrescences, from which few oak trees are quite free.

Of the European timber trees of the genus, the next in importance to the British oak is *Q. Cerris*, the Turkey oak of the nurserymen. This is a fine species, having when young straighter branches than *Q. Robur*, but in old age the boughs generally curve downwards, and the tree acquires a wide spreading head; the bark is dark brown, becoming grey and furrowed in large trees; the foliage varies much, but in the prevailing kinds the leaves are very deeply sinuated, with pointed, often irregular lobes, the footstalks short, and furnished at the base with long linear stipules that do not fall with the leaf, but remain attached to the bud till the following spring, giving a marked feature to the young shoots. The large sessile acorns are longer than those of *Q. Robur*, and are dark-brown when ripe; the hemispherical cups are covered with long, narrow, almost bristly scales, giving them a mossy aspect; the fruit ripens the first autumn. The foliage in some of the numerous varieties is almost evergreen, and in Britain is retained long after the autumnal withering.

This oak abounds all over the Turkish peninsula, and forms a large portion of the vast forests that clothe the slopes of the Taurus ranges and the south shores of the Black Sea; it is likewise common in Italy and Sardinia, and occurs in the south of France and also in Hungary. It was introduced into England by Philip Miller about 1735, and is now common in parks and plantations, where it seems to flourish in nearly all soils. The Turkey oak in southern England grows twice as fast as *Q. Robur*; in the mild climate of Devonshire and Cornwall it has reached a height of 100 ft. and a diameter of 4 ft. in eighty years, which is about the limit of its profitable growth for timber. The wood is hard, heavy and of fine grain, quite equal to the best British oak for indoor use, but of very variable durability where exposed to weather. The ships of Greece and Turkey are largely built of it, but it has not always proved satisfactory in English dockyards. The heart-wood is dark in colour, takes a fine polish, and from the prominence of the medullary rays is valuable to the furniture maker; it weighs from 40 to 50 lb the cubic foot. The comparatively rapid growth of the tree is its great recommendation to the planter; it is best raised from acorns sown on the spot, as they are very bitter and little liable to the attacks of vermin; the tree sends down a long tap-root, which should be curtailed by cutting or early transplanting, if the young trees are to be removed. It seems peculiarly adapted for the mild moist climate of Ireland.

In North America, where the species of oak are very numerous, the most important member of the group is *Q. alba*, the white oak, abounding all over the eastern districts to the continent from Lake Winnipeg and the St Lawrence countries of the shores of the Mexican Gulf. In aspect it more nearly resembles *Q. Robur* than any other species, forming a thick trunk with spreading base and, when growing in glades or other open places, huge spreading boughs, less twisted and gnarled than those of

the English oak, and covered with a whitish bark that gives a marked character to the tree. The leaves are large, often irregular in form, usually with a few deep lobes dilated at the end; they are of a bright light green on the upper surface, but whitish beneath; they turn to a violet tint in autumn. The egg-shaped acorns are placed singly or two together on short stalks; they are in most years sparingly produced, but are occasionally borne in some abundance. On rich loams and the alluvial soils of river-valleys, when well drained, the tree attains a large size, often rivalling the giant oaks of Europe; trunks of 3 or 4 ft. in diameter are frequently found, and sometimes these dimensions are greatly exceeded. The wood is variable in quality and, though hard in texture, is less durable than the best oak of British growth; the heart-wood is of a light reddish brown varying to an olive tint; a Canadian specimen weighs 52¼ lb the cubic foot.

From Michaux, *Histoire des chênes de l'Amérique.*

FIG. 4.—*Q. alba.*

Q. obtusiloba, the post oak of the backwoodsman, a smaller tree with rough leaves and notched upper lobes, produces an abundance of acorns and good timber, said to be more durable than that of the white oak.

The pin oak, sometimes called the "burr-oak," *Q. macrocarpa*, is remarkable for its large acorns, the cups bordered on the edge by a fringe of long narrow scales; the leaves are very large, sometimes from 10 in. to 1 ft. in length, with very deep lobes at the lower part, but dilated widely at the apex, and there notched. The tree is described by Prof. C. S. Sargent (*Silva of North America*) as one of the most valuable timber trees of North America, its wood being superior in strength even to that of *Q. alba*, with which it is commercially confounded.

From Michaux, *op. cit.* Plate XXXV.

FIG. 5.—*Q. rubra.*

The over-cup oak, *Q. lyrata*, is a large tree, chiefly found on swampy land in the southern states; the lyrate leaves are dilated at the end; the globose acorns are nearly covered by the tuberculated cups.

In the woods of Oregon, from the Columbia river southwards, an oak is found bearing some resemblance to the British oak in foliage and in its thick trunk and widely-spreading boughs, but the bark is white as in *Q. alba*; it is *Q. Garryana*, the western oak of T. Nuttall. This tree acquires large dimensions, the trunk being often from 4 to 6 ft. in diameter; the wood is strong, hard and close-grained; the acorns are produced in great quantity, and are used by the Indians as food.

The red oak, *Q. rubra*, has thin large leaves on long petioles, the lobes very long and acute, the points almost bristly; they are pink when they first expand in spring, but become of a bright glossy green when full-grown; in autumn they change to the deep purple-red which gives the tree its name. Common throughout the northern and middle states and Canada, the red oak attains a large size only on good soils; the wood is of little value, being coarse and porous, but it is largely used for cask-staves; the bark is a valuable tanning material.

A species nearly allied is the scarlet oak, *Q. coccinea*, often confounded with the red oak, but with larger leaves, with long lobes ending in several acute points; they change to a brilliant scarlet with the first October frosts, giving one of the most striking of the various glowing tints that render the American forests so beautiful in autumn. The trunk, though often of considerable size, yields but an indifferent wood, employed for similar purposes to that of *Q. rubra*; the bark is one of the best tanning materials of the country. Both these oaks grow well in British plantations, where their bright autumn foliage, though seldom so decided in tint as in their native woods, gives them a certain picturesque value.

From Kotschy, *op. cit.* Plate XL.

FIG. 6.—*Q. castaneaefolia.*

Nearly akin to these are several other forms of little but botanical interest; not far removed is the black or dyer's oak, *Q. tinctoria*, a large and handsome species, with a trunk sometimes 4 ft. in diameter, not uncommon in most forests east of the Mississippi, especially in somewhat upland districts. The leaves are frequently irregular in outline, the lobes rather short and blunt, widening towards the end, but with setaceous points; the acorns are nearly globular. The wood is coarsely grained, as in all the red-oak group, but harder and more durable than that of *Q. rubra*, and is often employed for building and for flour-barrels and cask-staves. The bark, very dark externally, is an excellent tanning substance; the inner layers form the *quercitron* of commerce, used by dyers for communicating to fabrics various tints of yellow, and, with iron salts, yielding a series of brown and drab hues; the colouring property depends on a crystalline principle called *quercitrin*, of which it should contain about 8%. The cut-leaved oaks are represented in eastern Asia by several species, of which *Q. mongolica* is widely spread over Dahuria, north China and the adjacent countries; one of the Chinese silkworms is said to feed on the leaves.

From Kotschy, *op. cit.* Plate XXXVIII.

FIG. 7.—*Q. Ilex.*

The chestnut oaks of America represent a section distinguished by the merely serrated leaves, with parallel veins running to the end of the serratures. *Q. Prinus*, a beautiful tree of large growth, and its subspecies *castanea* and *montana*, yield good timber. *Q. Chinquapin* or *prinoides*, a dwarf species, often only 1 ft. in height, forms dense miniature thickets on the barren uplands of Kansas and Missouri and affords abundant sweet acorns; the tree is called by the hunters of the plains the "shin-oak." *Q. castaneaefolia*, represented in fig. 6

is a native of the woods of the Transcaucasian region of western Asia.

Evergreen oaks with entire leaves are represented in North America by *Q. virginiana*, also known as *Q. virens*, the live oak of the southern states; more or less abundant on the Atlantic coasts of the Carolinas and Florida, its true home is the country around the Mexican Gulf, where it rarely grows more than 50 or 60 m. inland. The oval leaves are dark-green above, and whitish with stellate hairs beneath, the margin entire and slightly recurved. The live oak is one of the most valuable timber trees of the genus, the wood being extremely durable, both exposed to air and under water; heavy and close-grained, it is perhaps the best of the American oaks for shipbuilding, and is invaluable for water-wheels and mill-work. The tree in England is scarcely hardy, though it will grow freely in some sheltered places.

The evergreen oak of southern Europe is *Q. Ilex*, usually a smaller tree, frequently of rather shrub-like appearance, with abundant glossy dark-green leaves, generally ovate in shape and more or less prickly at the margin, but sometimes with the edges entire; the under surface is hoary; the acorns are oblong on short stalks. The ilex, also known as the "holm oak" from its resemblance to the holly, abounds in all the Mediterranean countries, showing a partiality for the sea air. The stem sometimes grows 80 or 90 ft. in height, and old specimens are occasionally of large diameter; but it does not often reach a great size. In its native lands it attains a vast age; Pliny attributes to several trees then growing in Rome a greater antiquity than the city itself. The wood is very heavy and hard, weighing 70 lb the cubic foot; the colour is dark brown; it is used in Spain and Italy for furniture, and in the former country for firewood and charcoal. In Britain the evergreen oak is quite hardy in ordinary winters, and is useful to the ornamental planter from its capacity for resisting the sea gales; but it generally remains of small size. *Q. Ballota*, a closely allied species abundant in Morocco, bears large edible acorns, which form an article of trade with Spain; an oil, resembling that of the olive, is obtained from them by expression. *Q. Ilex*, var. *Gramuntia*, also furnishes a fruit which, after acquiring sweetness by keeping, is eaten by the Spaniards.

In America several oaks exist with narrow lanceolate leaves, from which characteristic they are known as "willow oaks." *Q. Phellos*, a rather large tree found on swampy land in the southern states, is the most important of this group; its timber is of indifferent quality.

From Kotschy, *op. cit.* Plate VII.

FIG. 8.—*Q. Vallonea*.

The cork oak, *Q. Suber*, the bark of which yields cork (*q.v.*), is a native of the west Mediterranean area. In Spain the wood is of some value, being hard and close-grained, and the inner bark is used for tanning. From its rugged silvery bark and dark-green foliage, it is a handsome tree, quite hardy in Cornwall and Devonshire, where it has grown to a large size.

The valonia of commerce, one of the richest of tanning materials, is the acorn of *Q. Aegilops*, a fine species indigenous to Greece and the coasts of the Levant, and sometimes called the "Oak of Bashan." The very large acorns are remarkable for their thick cups with long reflexed scales; the leaves are large, oblong, with deep serratures terminating in a bristle-like point. The cups are the most valuable portion of the valonia, abounding in tannic acid; immature acorns are sometimes exported under the name of "camatina." The allied *Q. Vallonea* of Asia Minor likewise yields valonia.

Some oaks are of indirect importance from products formed by their insect enemies. Of these the Aleppo gall (see GALLS) is yielded by *Q. infectoria*, a native of Asia Minor and western Asia. *Q. coccifera*, a small bush growing in Spain and many countries around the Mediterranean, furnishes the kermes dye (KERMES). *Q. persica*, or according to some *Q. mannifera*, attacked by a kind of *Coccus*, yields a sweet exudation which the Kurds collect and use as manna, or as a substitute for honey or sugar in various confections (see MANNA).

OAKHAM, a market town, and the county town of Rutland, England, 94 m. N. by W. of London by the Midland railway. Pop. (1901) 3294. The church of All Saints ranges in style from Early English to Perpendicular, belonging in appearance mainly to the latter style. Of Oakham Castle, founded in the reign of Henry II., the principal remnant is the notable Norman hall, used as the county hall. The manor came in the time of Henry II. into the hands of Walcheline de Ferrers, and subsequently passed, through many owners, to the duchy of Buckingham, whence it descended to the earls of Winchelsea. A peculiar custom attaching to the manor is to claim a horseshoe from every peer who, for the first time, passes through the town. Flore's House in the main street is an interesting building dating from the 13th century. Oakham school was endowed as a grammar school by Robert Johnson, archdeacon of Leicester, in 1584; it now has classical and modern sides. Not far from the town are the kennels of the Cottesmore hunt.

OAKLAND, a city and the county-seat of Alameda county, California, U.S.A., situated opposite and about 6 m. distant from San Francisco, on the eastern shore of San Francisco Bay. Pop. (1890) 48,682; (1900) 66,960, of whom 17,256 were foreign-born, 3197 being Irish, 2742 German, 2026 English, 1544 English-Canadians, 1020 Portuguese and 994 Swedish; (1910 census) 150,174. It is the terminus of the Ogden branch of the Southern (formerly Central) Pacific, of the Coast Line of the Atchison, Topeka & Santa Fé, and of the Western Pacific railways. Passengers and freight from the East to San Francisco are transferred by ferry from Oakland. A branch of the bay (called Oakland Harbour) divides Oakland from Alameda, and the railway piers of Oakland run directly out into the bay for more than 2 m. toward San Francisco, thus shortening the ferry connexions. Lake Merritt, in the heart of the city, a favourite pleasure resort, is the centre of the city's park system. Oakland is the seat of California College (co-educational, Baptist, opened in 1870), and of St Mary's College (Roman Catholic, 1863) for men; and in the suburban village of Mills College, west of the city, is Mills College (non-sectarian, 1871) for women, an institution of high rank. Electric power for the city is derived from Colgate, on the Yuba river, 219 m. distant. Oakland has important manufacturing interests, the total value of its factory products in 1905 being $9,072,539, 69% more than in 1900.

The site of the present city (as well as that of Alameda and Berkeley) lay originally within the limits of a great private Mexican grant which was confirmed by the United States authorities. A settlement was begun—at first by "squatters" in defiance of the private claim—in 1850; in May 1852 this was incorporated as a town (the name being derived from a wood of oaks in the midst of which the first settlement was made), and in March 1854 it was chartered as a city. In 1869 it was selected as the western terminus of the Central Pacific, a choice which greatly promoted Oakland's commercial importance. The water front was recklessly given away in 1852, and the resulting disputes and litigation lasted for more than thirty years; in 1908 the water front reverted to the city. The population increased more than sixfold from 1860 to 1870, and doubled in 1900–1910. It became the county-seat in 1874. In December 1910 a commission form of government was adopted.

OAKUM (O. Eng. *ácumbe* or—*æcumbe*, tow, literally "off-combings"), a preparation of tarred fibre used in shipbuilding, for caulking or packing joints of timbers in wood vessels and the deck planking of iron and steel ships. Oakum is made by preference from old tarry ropes and cordage of vessels, and its picking and preparation has been a common penal occupation in prisons and workhouses. White oakum is made from untarred materials.

OAMARU, a municipal borough on the east coast of South Island, New Zealand, in the county of Waitaki and provincial district of Otago; on the main railway between Christchurch (152 m. N.E.) and Dunedin (78 m. S.S.W.). Pop. (1906) 5071. It is the outlet of the largest agricultural district in New Zealand. A breakwater and mole, constructed of blocks of concrete, enclose a commodious basin, forming one of the safest harbours in the colony. The export of frozen meat is important. The town is built of white Oamaru limestone. Brown coal is obtained at the entrance of Shag valley, 40 m. S. The district is famed for its stock, and the fine quality of its grain; also for the character of the English grasses laid down there, which flourish in a rich black loam on a limestone formation.

OANNES, in Babylonian mythology, the name given by Berossus to a mythical being who taught mankind wisdom. He is identical with the god Ea (*q.v.*), although there may not be any direct connexion between the two names. Berossus describes Oannes as having the body of a fish but underneath the figure of a man. He is described as dwelling in the Persian Gulf, and rising out of the waters in the daytime and furnishing mankind instruction in writing, the arts and the various sciences. The culture-myth on which the account of Berossus rests has not yet been found in Babylonian literature, but there are numerous indications in hymns and incantations that confirm the indentification with Ea, and also prove the substantial correctness of the conceptions regarding Oannes-Ea as given by Berossus. (M. Ja.)

OAR (A.S. *ár*; M. Eng. *ore*; Lat. *rēmus*; Gr. ἐρετμός: Sans. *aritra*; Fr. *rame*; Ital. Span., Port. *rama*), the instrument used for propelling a boat in rowing (*q.v.*). The word "oar" is probably derived from an old root *ar*, meaning to drive, to force away (cf. *ar-ar-e*, *aratrum*, plough). Such an appellation would easily be suggested by the visible difference in the action of the power employed by means of the oar against a thowl, or rowlock, from that of the more primitive paddle, where the power is gained by the action of one hand against the other. In the development of rowing from paddling the task of shaping the instrument of propulsion must have followed gradually the necessities indicated by use. In rowing, as well as in paddling, the leverage is of the second order, in which the weight lies between the power and the fulcrum. The point at which the power pressed the arm of the lever against the weight in rowing would soon attract attention by the frequent breakage of the paddle so employed. Experience would demand a thicker loom, and would soon teach the desirability of increasing the leverage where possible, and upon this would arise naturally the practical questions of the length of the oar, of the breadth of the blade, and of the right proportion of the parts of the oar, inboard and outboard, to each other. Then would also occur the problem of how to keep this proportion, which in practice would be liable to disarrangement by the slipping outward of the oar during the recovery from each stroke. Hence would arise the use of the thong (τροπός, τροπωτήρ), familiar to ancient Greek and modern Levantine, and, in northern and western waters, the invention of the "button," with which in various shapes the rowing world is now provided. Other devices, such as a hole bored in a piece of wood attached to the oar, or even a metal ring, will, in different localities, be found answering the same purpose.

In the early stages of the transition from paddling to rowing, the oar would naturally be used at an acute angle vertically to the boat's side. In paddling the upper hand is used to push from you, the lower hand to pull towards you. But in rowing both hands are used to pull towards you. As long as the oar was used at an acute angle vertically to the boat's side, the position of the upper hand on the oar would have to be reversed, as it would more easily grasp the oar with the wrist turned inward towards the body. In many of the earlier representations of rowing this position of the upper hand seems to be indicated. This distinction should not be lost sight of, as the position of the hands on the oar affects not only the character of the stroke, but also the requirements as to the length of the oar and the breadth of the blade. The form of the oars given in the representations of early Egyptian ships is suggestive of paddles used as oars. Paddle-shaped also are the oars of the Phoenician ships shown on the Assyrian sculptures at Koyunjik (Layard), the date of which is about 700 B.C. The same form is seen on some of the early vases, but in some that are attributed to two centuries later the form is modified, and the oar blade proper begins to take shape.

The types exhibited in the representations of the Roman galleys are generally heavy and clumsy enough in appearance. Still they are veritable oars, not paddles. The material of which the ancient oars were usually made was pine, which then, as now, was most suitable for the purpose, being tough and comparatively light and easily shaped as regards loom and blade.

The oars of the Attic trireme were, if we may judge by those of which only we have the measurement recorded, not much longer for the upper bank than those of a modern racing eight, while those of the middle and lower banks could not have been much longer than those used now in the whalers and dinghies of the Royal Navy. As the oarsmen on either side probably sat in the same vertical plane, the inboard portion of the oars amidships was longer than the inboard of those fore and aft, having to conform to the curvature of the vessel's sides (cf. Aristotle, *Mechanica*, v.). No doubt in vessels of larger size the upper tiers of oars would be longer, and, if we are to believe Callixenus, as cited by Athenaeus, in the great ship of Ptolemy the oars of the upper tier were over 50 ft. in length with handles leaded so as to equalize the weight inboard and outboard.

It is difficult to trace any detail of difference between the oars of the Roman period and those of the Byzantine and medieval galleys. In the medieval galley by the invention of the "apostis," a framework on which the thowls were fixed, sufficient room was given for the play of longer oars, and, as the necessity of combining speed with greater carrying power in the galley became pressing, the arrangement *alla scaloccio* came into vogue, employing four or five or even seven men to each of the long sweeps by which the galleys and galleasses were propelled. For these large oars we hear of ash and beech being used as well as pine.

In the Mediterranean the galley propelled by oars long remained the principal type of war vessel. In the Atlantic, and in the northern seas, it was otherwise.

The employment of artillery on board ship gradually determined a change in the method of propulsion. The use of sails

* Allowed spoon-blade oars.

Notes.—(1) Since 1893 some curved or spoon-bladed oars have been made at Devonport. (2) There is no record of buttons being used, but on fir oars, which were covered with canvas on the loom, it was sometimes customary to work a Turk's head at the end of the canvas for ornament. (3) As regards sweeps, they used to be made of ash and were 30 ft. long. They were used last in training brigs, but there is no record of them for the last twenty years.

became necessary, and remained dominant until the introduction of steam (see SHIP). But as late as the time of the Spanish Armada, and even later, large sea-going vessels were provided with long sweeps which came into use when sailing was not available. In our own time, in the lighters on tidal rivers, may be seen long oars, plied by one or two or more men, which recall the type of oars once in general use in large galleys three centuries ago.

The oars used by the Northmen were, to judge by the remains discovered along with old Viking ships[1] at Gokstad and elsewhere, very similar to those in use at the present time in the fishing boats around our coasts. Those of the large craft were, to judge by the length of one found whole, somewhat over 18 ft. in length with a 5-in. blade and a diameter of 3 in. halfway down the loom. Some smaller oars, evidently used for boats, measured 11 ft. with a 4-in. blade. The oars were of pine, and the looms of some of them showed a groove cut for a clamp at the place where the oar rested on the sill of the rowlock. Comparing these oars with the measurements given below of oars now in use in the Royal Navy, it is apparent that there is no great difference in type between them.

Passing on to oars used on rivers and fresh water generally, we find the type differs considerably from that of the oars used in sea-going craft. The chief difference consists in the shape of the blade, which, instead of continuing the straight line of the loom in its expansion to its proper breadth, is fashioned in a curve calculated to offer a rigid resistance to the water during the stroke.[2] The loom below the button is not rounded but is more of an oval to the front with a flat back. From the oval front a spine runs down into the blade, in some cases to nearly half its length. During the last few years the so-called "girder" oars, with much thicker looms but double grooved along their length, have been used for racing purposes. This invention gives additional strength and stiffness, without increasing the weight of the oar, which varies a little but is usually about 8 lb. The blades vary much in breadth, as indeed do the oars in total length, and in proportion of inboard to outboard. The necessities of the sliding seat in racing boats have given rise to much difference of opinion among rowing men as to the right proportion. In the middle of the 19th century the use of square looms inboard, and of a button to turn inside and against the thowl, was common, and most oars had a small slab of hard wood let in below the button, so as to save the oar from wear and tear at the rowlock. But since round looms came into vogue the round leather ear has taken the place of the old square button, and the *loom* is covered with leather for some inches above and below this so as to protect it from abrasion.

Of late the introduction of swivel rowlocks for racing boats has caused a further modification in the form of buttons. Swivel rowlocks have come into general use for sculling boats, pair oars and coxswainless fours. But as yet they do not appear to have captured the racing eight, except in a few instances. Neither crews nor coaches in English waters seem inclined to part with the time-honoured rhythmic music of the oar in the rowlock, which from the days of antiquity even until now has, to practised ears, told its own tale as to the crew being together or not in the stroke.

In the case of racing eights, when the round loom oars superseded the square loom, the early patterns were commonly (*e.g.* in 1857) 12′ 6″ over all, 3′ 8″ inboard, with a long blade 4½″ to 5″ in breadth. These were succeeded by a pattern 12′ 6″ over all, 3′ 6″ inboard, with a much shorter blade 6″ broad.

Since sliding seats came in the average oar has been 12′ 4″ over all, 3′ 8½″ inboard, with 5½″ to 6¼″ blades. The modern racing oar may be said to date from 1869, the year of the Oxford and Harvard race at Putney. Until very lately no material alteration had taken place in this pattern, except in the matter of width of blade. Some authorities, however, are, as has been said above, far from satisfied with the present average oar, and are using shorter patterns, 11′ 10″ or 12′ 0″ over all, 3′ 7″ inboard, and 7″ blades.

Single grooved oars were first made in America.~ But with the single groove a side weakness is often developed in the loom, and hence the double girder, invented by G. Ayling, has generally superseded the single groove, though many oarsmen prefer the box loom by the same inventor.

It is clear, however, that no finality has been reached in the making of oars. Tubular oars, first introduced at Henley by the Belgian crew in 1906, are now being tried, with circular or quadrangular bores, strengthened by the insertion of an aluminium shell.

For much of the information above given respecting the recent developments in oar-making for racing purposes and river work, the writer is indebted to Messrs Ayling & Sons of Putney, whose patented inventions and improvements are well known to rowing men. (E. WA.)

OASIS (Gr. ὄασις, the name given by Herodotus to the fertile spots in the Libyan desert: it probably represents an Egyptian word, cf. Coptic *ouahe, ouih*, to dwell, from which the Egyptian Arabic *wâ* is derived), a fertile spot surrounded by desert. For example, where the high plateau of the Libyan desert descends into a longitudinal valley between Syrtis and the Nile delta there are a few spots where the water comes to the surface or is found in shallow wells. It may come to the surface in springs, upon the artesian principle, or it may collect and remain in mountain hollows. These areas are of small extent and are closely cultivated, and support thick forests of date-palms. All kinds of tropical vegetables, grains and small fruits grow under cultivation, and land is so precious in these limited areas of great richness and fertility that very narrow pathways divide each owner's plot from his neighbour's. Wherever oases are found they present similar features, and are naturally the halting-places and points of departure of desert caravans.

OAST (O. Eng. *âst*, cf. Dutch *eest*, "kiln"; the Teutonic root is *aidh-* "to burn"; the pre-Teutonic *idh-* is seen in Lat. *aestus*, "heat," *aestas*, "summer," Gr. *αἶθος*, "burning heat"), a kiln, particularly one used for drying hops; the word usually appears in the term "oast-house," a building containing several of such kilns (see HOP). "Oast" is also sometimes used of a kiln for drying tobacco.

OASTLER, RICHARD (1789–1861), English reformer, was born at Leeds on the 20th of December 1789, and in 1820 succeeded his father as steward of the Thornhills' extensive Fixby estates at Huddersfield, Yorkshire. In 1830 John Wood, a Bradford manufacturer, called Oastler's attention to the evils of child employment in the factories of the district. Oastler at once started a campaign against the existing labour conditions by a vigorous letter, under the title "Yorkshire Slavery," to the *Leeds Mercury*. Public opinion was eventually aroused, and, after many years of agitation, in which Oastler played a leading part, the Ten Hours Bill and other Factory Acts were passed, Oastler's energetic advocacy of the factory-workers' cause procuring him the title of "The Factory King." In 1838, however, owing to his opposition to the new poor law and his resistance of the commissioners, he had been dismissed from his stewardship at Fixby; and, in 1840, being unable to repay £2000 which he owed his late employer, Thomas Thornhill, he was sent to the Fleet prison, where he remained for over three years. From prison he published the *Fleet Papers*, a weekly paper devoted to the discussion of factory and poor-law questions. In 1844 his friends raised a fund to pay his debt, and on his release he made a triumphant entry into Huddersfield. Oastler died at Harrogate on the 22nd of August 1861. A statue to his memory was erected at Bradford in 1869.

OAT (O. Eng. *âte*; the word is not found in cognate languages; it may be allied with Fr. *eitel*, knot, nodule, cf. Gr. *οἶδος* swelling), a cereal (*Avena sativa*) belonging to the tribe *Aveneæ* of the order Gramineae or grasses. The genus *Avena* contains about fifty species mostly dispersed through the temperate regions of the Old World. The spikelets form a loose panicle.

[1] See *Viking Ship*, Nicolaysen (Christiania, 1882).

[2] Since 1890 the curved blade seems to have been adopted in some cases in the oars made at Devonport for the Royal Navy.

familiar in the cultivated oat (fig. 1), the flowering glume having its dorsal rib prolonged into an awn (fig. 2), which is in some species twisted and bent near the base.

The origin of the cultivated oat is generally believed to be *A. fatua*, or "wild oat," or some similar species, of which several exist in southern Europe and western Asia. Professor J. Buckman succeeded in raising "the potato-oat type" and "the white Tatarian oat" from grain of this species. *A. strigosa*, Schreb, "the bristle-pointed oat," is the origin of the Scotch oat, according to Buckman. The white and black varieties of this species were cultivated in England and Scotland from remote times, and are still grown as a crop in Orkney and Shetland. *A. strigosa* is probably only a variety of the cultivated oat. The "naked oat," *A. nuda*, was found by Bunge in waste ground about Peking; it was identified by the botanist Lindley with the pilcorn of the old agriculture, and we see from Rogers[1] that it was in cultivation in England in the 13th century. Both this and the "common otes," *A. vesca*, are described by Gerard.[2] Parkinson tells us that in his time (early in the 17th century) the naked oat was sown in sundry places, but "nothing so frequent" as the common sort. The chief differences between *A. fatua* and *A. sativa*, are, that in the former the chaff-scales which adhere to the grain are thick and hairy, and in the latter they are not so coarse and are hairless. The wild oat, moreover, has a long stiff awn, usually twisted near the base. In the cultivated oat it may be wanting, and if present it is not so stiff and is seldom bent. The grain is very small and worthless in the one, but larger and full in the other. There are now many varieties of the cultivated oat included under two principal races—common

FIG. 2.—Spikelet of Oat, *A. sativa*, with two fertile florets, and one terminal, rudimentary.

FIG. 3.—Spikelet of Wild Oat, *A. fatua*, glumes hairy and long-pointed, awn twisted at base. (After Buckman.)

oat or panicled oats with a spreading panicle, *A. sativa* proper, and Tatarian oats or banner oats which has sometimes been regarded as a distinct species, *A. orientalis*, with contracted one-sided panicles. With regard to the antiquity of the oat, A. de Candolle[3] observes that it was not cultivated by the Hebrews, the Egyptians, the ancient Greeks and the Romans. Central Europe appears to be the locality where it was cultivated earliest, at least in Europe, for grains have been found among the remains of the Swiss lake-dwellings perhaps not earlier than the bronze age, while Pliny alludes to bread made of it by the ancient Germans. Pickering also records Galen's observations (*De Alim. Fac.* i. 14), that it was abundant in Asia Minor, especially Mysia, where it was made into bread as well as given to horses.

Besides the use of the straw when cut up and mixed with other food for fodder, the oat grain constitutes an important food for both man and beast. The oat grain (excepting the naked oat), like that of barley, is closely invested by the husk. Oatmeal is made from the kiln-dried grain from which the husks have been removed; and the form of the food is the well-known "porridge." In Ireland, where it is sometimes mixed with Indian-corn meal, it is called "stirabout." Groats or grits are the whole kernel from which the husk is removed. Their use is for gruel, which used to be consumed as an ordinary drink in the 17th century at the coffee-houses in London. The meal can be baked into "cake" or biscuit, as the Passover cake of the Jews; but it cannot be made into loaves in consequence of the great difficulty in rupturing the starch grains, unless the temperature be raised to a considerable height. With regard to the nutritive value of oatmeal, as compared with that of wheat flour, it contains a higher percentage of albuminoids than any other grain, viz. 12·6—that of wheat being 10·8—and less of starch, 58·4 as against 66·3 in wheat. It has rather more sugar, viz. 5·4—wheat having 4·2—and a good deal more fat, viz. 5·6, as against 2·0 in flour. Lastly, salts amount to 3·0% in oat, but are only 1·7 in wheat. Its nutritive value, therefore, is higher than that of ordinary seconds flour.

OATES, TITUS (1649–1705), English conspirator, was the son of Samuel Oates (1610–1683), an Anabaptist preacher, chaplain to Pride, and afterwards rector of All Saints' Church, Hastings. He was admitted on the 11th of June 1665 to Merchant Taylors' school, having, according to one authority, been previously at Oakham. There he remained a year, more or less, and "seems afterwards to have gone to Sedlescombe school in Sussex, from whence he passed to Caius College, Cambridge, on the 29th of June 1667, and was admitted a sizar of St John's, on the 2nd of February 1668–1669, aged 18." Upon very doubtful authority he is stated to have been also at Westminster school before going to the university. On leaving the university he apparently took Anglican orders, and officiated in several parishes, Hastings among them. Having brought malicious charges in which his evidence was rejected, he narrowly escaped prosecution for perjury. He next obtained a chaplaincy in the navy, from which he appears to have been speedily dismissed for bad conduct with the reputation of worse. He now, it is said, applied for help to Dr Israel Tonge, rector of St Michael's in Wood Street, an honest half-crazy man, who even then was exciting people's minds by giving out quarterly "treatises in print to alarm and awake his majesty's subjects." Oates offered his help, and it was arranged that he should pretend to be a Roman Catholic so as the better to unearth the Jesuit plots which possessed Tonge's brain. Accordingly he was received into the church by one Berry, himself an apostate, and entered the Jesuit College of Valladolid as Brother Ambrose. Hence he was soon expelled. In October 1677 he made a second application, and was admitted to St Omer on 10th December. So scandalous, however, was his conduct that he was finally dismissed in 1678. Returning in June 1678 to Tonge, he set himself to forge a plot by piecing together things true and false, or true facts falsely interpreted, and by inventing treasonable letters and accounts of preparations for military action. The whole story was written by Oates in Greek characters, copied into English by Tonge, and finally told to one of Charles II's confidential servants named Kirkby. Kirkby having given the king his information, Oates was sent for (13th August), and in a private interview gave details, in forty-three articles, of the plot and the persons who had engaged to assassinate Charles. The general improbability of the story was so manifest, and the discrepancies were so glaring, that neither then nor at any subsequent time did Charles express anything but amused

incredulity. To bolster up the case a fresh packet of five forged letters was concocted (31st August); but the forgery was transparent, and even Sir William Jones, the attorney-general, though a violent upholder of the plot, dared not produce them as evidence.

Oates now (6th September) made an affidavit before Sir Edmond Berry Godfrey (*q.v.*) to an improved edition of his story, in eighty-one articles. Among the persons named was Coleman, secretary to the duchess of York, whom Godfrey knew, and to whom he sent word of the charges. Coleman in turn informed the duke, and he, since the immediate exposure of the plot was of the utmost consequence to him, induced Charles to compel Oates to appear (28th September) before the privy council. Here Oates delivered himself of a story the falsehood of which was so obvious that the king was able to expose him by a few simple questions. At this moment an accident most fortunate for Oates took place. Amongst the papers seized at his request were Coleman's, and in them were found copies of letters written by the latter to Père la Chaise, suggesting that Louis should furnish him with money, which he would use in the French and Catholic interest among members of parliament. Among them, too, were these passages: "Success will give the greatest blow to the Protestant religion that it has received since its birth"; "we have here a mighty work upon our hands, no less than the conversion of three kingdoms, and by that perhaps the utter subduing of a pestilent heresy, which has so long domineered over great part of the northern world." The credit of Oates was thus, in the eyes of the people, re-established, and Coleman and others named were imprisoned. Charles was anxious for his brother's sake to bring the matter to a conclusion, but he dared not appear to stifle the plot; so, when starting for Newmarket, he left orders with Danby (see LEEDS, DUKE OF,) that he should finish the investigation at once. But Danby purposely delayed; an impeachment was hanging over his head, and anything which took men's minds off that was welcome.

On the 12th of October occurred the murder of Godfrey, and the excitement was at its highest pitch. On the 21st of October parliament met, and, though Charles in his speech had barely alluded to the plot, all other business was put aside and Oates was called before the House. A new witness was wanted to support Oates's story, and in November a man named William Bedloe came forward. At first he remembered little; by degrees he remembered everything that was wanted. Not even so, however, did their witness agree together, so, as a bold stroke, Oates, with great circumstantiality, accused the queen before Charles of high treason. Charles both disbelieved and exposed him, whereupon Oates carried his tale before the House of Commons. The Commons voted for the queen's removal from court, but, the Lords refusing to concur, the matter dropped. It was not, however, until the 18th of July 1679 that the slaughter of Jesuits and other Roman Catholics upon Oates's testimony and that of his accomplices was to some extent checked. Sir George Wakeman, the queen's physician, was accused of purposing to poison the king, and the queen was named as being concerned in the plot. The refusals of Charles to credit or to countenance the attacks on his wife are the most creditable episodes in his life. Scroggs had intimation that he was to be lenient. Sir Philip Lloyd proved Oates to have perjured himself in open court, and Wakeman was acquitted. On the 26th of June 1680, upon Oates's testimony, the duke of York was presented as a recusant at Westminster. But the panic had now worn itself out, and the importance of Oates rapidly declined; so much so that after the dissolution in 1682 he was no more heard of during Charles's reign, but enjoyed his pension of £600 or £900, it is uncertain which, in quiet. Shortly before the death of Charles, James brought, and won, a civil action against Oates, with damages of £100,000; in default of payment Oates was taken to prison; while there he was indicted for perjury, and was tried in May 1685, soon after the accession of James II. He was convicted and received a severe sentence, with repeated floggings, the execution of which was expected to kill him, and which was rigorously carried out; but to the astonishment of all he survived.

Oates was in prison for three and a half years. Upon the flight of James, and during the excitement against the Catholics, he partially gained his liberty, and brought an appeal against his sentence before the Lords, who, while admitting the sentence to be unjust, confirmed it by a majority of thirty-five to twenty-three. The Commons, however, passed a bill annulling the sentence; and a conference was held in which the Lords, while again acknowledging that legally they were wrong, adhered to their former determination. The matter was finally settled by Oates receiving a royal pardon, with a pension of £300 a year. The remainder of his life was spent in retirement, varied by a good deal of sordid intrigue. In 1691 he became acquainted with William Fuller, whom he induced to forge another plot, though not with the success he had himself attained. He married a wealthy widow in 1693, but his extravagance soon brought him into straits. In 1696 he dedicated to William III. a book called *Eikon Basilike*, an elaborate tissue of invection against "the late king James." In 1698 he obtained admission as a member of the Baptist Church, and used to preach at Wapping; but in 1701, as the result of a financial scandal, he was formally expelled from the sect. He died on the 12th of July 1705.

OATH (O. Eng. *âdh*), a term which may be defined as an asseveration or promise made under non-human penalty or sanction. The word is found throughout the Teutonic languages (Goth. *aiths*, Mod. Ger. *Eid*), but without ascertainable etymology. The verb to *swear* is also Old Teutonic (Goth. *svaran*, Mod. Ger. *schwören*); this word, too, is not clear in original meaning, but is in some way connected with the notion of answering—indeed it still forms part of the word *answer*, O. Eng. *and-swarian*; it has been suggested that the swearer answered by word or gesture to a solemn formula or act. Among other terms in this connexion, the Lat. *jurare*, whence English law has such derivatives as *jury*, seems grounded on the metaphorical idea of binding (root *ju*, as in *jungo*); the similar idea of a bond or restraint may perhaps be traced in Gr. ὅρκος. It may be worth notice that Lat. *sacramentum* (whence Mod. Fr. *serment*) does not really imply the sacredness of an oath, but had its origin in the money paid into court in a Roman lawsuit, the loser forfeiting his pledge, which went to pay for the public rites (*sacra*); thence the word passed to signify other solemn pledges, such as military and judicial oaths.

Writers viewing the subject among civilized nations only have sometimes defined the oath as an appeal to a deity. It will be seen, however, by some following examples, that the harm or penalty consequent on perjury may be considered to result directly, without any spirit or deity being mentioned; indeed it is not unlikely that these mere direct curses invoked on himself by the swearer may be more primitive than the invocation of divinities to punish. Examples of the simplest kind of curse-oath may be seen among the Nagas of Assam, where two men will lay hold of a dog or a fowl by head and feet, which is then chopped in two with a single blow of the dao, this being emblematic of the fate expected to befall the perjurer. Or a man will stand within a circle of rope, with the implication that if he breaks his vow he may rot as a rope does, or he will take hold of the barrel of a gun, a spear-head or a tiger's tooth, and solemnly declare, "If I do not faithfully perform this my promise, may I fall by this!" (Butler in *Journ. Asiatic Soc. Bengal*, 1875, p. 316). Another stage in the history of oaths is that in which the swearer calls on some fierce beast to punish him if he lies, believing that it has the intelligence to know what he says and the power to

interfere in his affairs. In Siberia, in lawsuits between Russians and the wild Ostiaks, it is described as customary to bring into court the head of a bear, the Ostiak making the gesture of eating, and calling on the bear to devour him in like manner if he does not tell the truth (G. A. Erman, *Travels in Siberia*, i. 492, London, 1848). Similar oaths are still sworn on the head or skin of a tiger by the Santals and other indigenous tribes of India. To modern views, a bear or a tiger seems at any rate a more rational being to appeal to than a river or the sun, but in the earlier stage of nature-religion these and other great objects of nature are regarded as animate and personal. The prevalence of river-worship is seen in the extent to which in the old and modern world oaths by rivers are most sacred. In earlier ages men swore inviolably by Styx or Tiber, and to this day an oath on water of the Ganges is to the Hindu the most binding of pledges, for the goddess will take awful vengeance on the children of the perjurer. The Tungus brandishes a knife before the sun, saying, "If I lie may the sun plunge sickness into my entrails like this knife." The natural transition from swearing by these great objects of nature to invoking gods conceived in human form is well shown in the treaty-oath between the Macedonians and the Carthaginians recorded by Polybius (vii. 9); here the sun and moon and earth, the rivers and meadows and waters, are invoked side by side with Zeus and Hera and Apollo, and the gods of the Carthaginians. The heaven-god, able to smite the perjurer with his lightning, was invoked by the Romans, when a hog was slain with the sacred flint representing the thunderbolt, with the invocation to Jove so to smite the Roman people if they broke the oath (Liv. i. 24; Polyb. iii. 25). Another form of this Aryan rite was preserved by the old Slavonic nation of Prussia, where a man would lay his right hand on his own neck and his left on the holy oak, saying, "May Perkun (the thunder-god) destroy me!" The oaths of the lower culture show a remarkable difference from those of later stages. In the apparently primitive forms the curse on the perjurer is to take effect in this world. But as nations became more observant, experience must have shown that bears and tigers were as apt to kill truth-tellers as perjurers, and that even the lightning-flash falls without moral discrimination. In the *Clouds* of Aristophanes, indeed, men have come openly to ridicule such beliefs, the Socrates of the play pointing out that notorious perjurers go unharmed, while Zeus hurls his bolts at his own temple, and the tall oaks, as if an oak-tree could perjure itself. The doctrine of miraculous earthly retribution on the perjurer lasted on in legend, as where Eusebius relates how three villains conspired to bring a false accusation against Narcissus, bishop of Jerusalem, which accusation they confirmed by solemn oath before the church, one wishing that if he swore falsely he might perish by fire, one that he might die of the pestilence, one that he might lose his eyes; a spark no man knew from whence burned to ashes the first perjurer's house and all within, the second was consumed by the plague from head to foot, whereupon the third confessed the crime with tears so copious that he lost his sight (Euseb. *Hist. Eccl.* vi. 9). As a general rule, however, the supernatural retribution on perjury has been transferred from the present world to the regions beyond the grave, as is evident from any collection of customary oaths. A single instance will show at once the combination of retributions in and after the present life, and the tendency to heap up remote penalties in the vain hope of securing present honesty. The Siamese Buddhist in his oath, not content to call down on himself various kinds of death if he breaks it, desires that he may afterwards be cast into hell to go through innumerable tortures, among them to carry water over the flames in a wicker basket to assuage the thirst of the infernal judge, then that he may migrate into the body of a slave for as many years as there are grains of sand in four seas, and after this that he may be born a beast through five hundred generations and an hermaphrodite five hundred more.

The forms of oath belonging to all nations and ages, various as they are in detail, come under a few general heads. It may be first observed that gestures such as grasping hands, or putting one hand between the hands of another in token of homage, are sometimes treated as of the nature of oaths, but wrongly so, they being rather of the nature of ceremonies of compact. The Hebrew practice of putting the hand under another's thigh is usually reckoned among oath-rites, but it may have been merely a ceremony of covenant (Gen. xxiv. 2, xlvii. 29; see Joseph. *Ant.* i. 16). Even the covenant among many ancient and modern nations by the parties mixing their blood or drinking one another's is in itself only a solemn rite of union, not an oath proper, unless some such ceremony is introduced as dipping weapons into the blood, as in the form among the ancient Scythians (Herod. iv. 70); this, by bringing in the idea of death befalling the covenant-breaker, converts the proceeding into an oath of the strongest kind. The custom of swearing by weapons, though frequent in the world, is far from consistent in meaning. It may signify, in cases such as those just mentioned, that the swearer if forsworn is to die by such a weapon; or the warrior may appeal to his weapon as a powerful or divine object, as Parthenopaeus swears by his spear that he will level to the ground the walls of Thebes (Aeschyl. *Sept. contra Theb.* 530; see the custom of the Quadi in Ammian. Marcellin. xvii.); or the weapon may be a divine emblem, as when the Scythians swore by the wind and the sword as denoting life and death (Lucian, *Toxaris*, 38). Oaths by weapons lasted into the Christian period; for instance, the Lombards swore lesser oaths by consecrated weapons and greater on the Gospels (see Du Cange, *s.v.* "Juramenta super arma"; Grimm, *Deutsche Rechtsalterth.* p. 896). Stretching forth the hand towards the object or deity sworn by is a natural gesture, well shown in the oath of Agamemnon, who with uplifted hands (Διὶ χεῖρας ἀνασχών) takes Heaven to witness with Sun and Earth and the Erinyes who below the earth wreak vengeance on the perjurer (Homer *Il.* xix. 254; see also Pindar, *Olymp.* vii. 120). The gesture of lifting the hand towards heaven was also an Israelite form of oath: Abraham says, "I have lifted up my hand to Jehovah," while Jehovah Himself is represented as so swearing, "For I lift up My hand to heaven, and say, I live for ever" (Gen. xiv. 22; Deut. xxxii. 40; see Dan. xii. 7; Rev. x. 5). This gesture established itself in Christendom, and has continued to modern times. In England, for example, in the parliament at Shrewsbury in 1398, when the Lords took an oath on the cross of Canterbury never to suffer the transactions of that parliament to be changed, the members of the Commons held up their hands to signify their taking upon themselves the same oath (J. E. Tyler, *Oaths*, p. 99). In France a juror takes oath by raising his hand, saying, "Je jure!" The Scottish judicial oath is taken by the witness holding up his right hand uncovered, and repeating after the usher, "I swear by Almighty God, and as I shall answer to God at the great day of judgment, that I will," &c.

In the ancient world sacrifice often formed part of the ceremony of the oath; typical examples may be found in the Homeric poems, as in Agamemnon's oath already mentioned, or the compact between the Greeks and Trojans (*Il.* iii. 276), where wine is poured out in libation, with prayer to Zeus and the immortal gods that the perjurer's brains shall, like the wine, be poured on the ground; the rite thus passes into a symbolic curse-oath of the ordinary barbaric type. Connected with such sacrificial oaths is the practice of laying the hand on the victim or the altar, or touching the image of the god. A classic instance is in a comedy of Plautus (*Rudens*, v. 2, 45), where Gripus says, "Tange aram hanc Veneris," and Labrax answers "Tango" (Greek instance, Thucyd. v. 47; see Justin xxiv. 2). Thus Livy (xxi. 1) introduces the phrase "touching the sacred objects" (*tactis sacris*) into the picturesque story of Hannibal's oath. Details of the old Scandinavian oath have been preserved in Iceland in the Landnámabók (*Islendinga Sögur*, Copenhagen, 1843): a bracelet (baugr) of two rings or more was to be kept on the altar in every head court, which the godi or priest should wear at all law-things held by him, and should redden in the blood of the bullock sacrificed, the witness pronouncing the remarkable formula: "Name I to witness that I take oath by the ring, law-oath, so help me Frey, and Niörd, and almighty Thor" (hialpi mer svâ Freyr, ok Niörðr, ok hinn almâttki Ass), &c. This was doubtless the great oath on the holy ring or bracelet which the Danes swore to King Alfred to quit his kingdom ("on tham halgan beage," *Anglo-Sax. Chron.*: "in eorum armilla sacra," Ethelwerd, *Chron.* iv.). An oath, though not necessarily expressed in words, is usually so. In the Homeric

instances the prayer which constitutes the oath has a somewhat conventional form, and in the classical ages we find well-marked formulas. These are often references to deities, as "by Zeus!" "I call Zeus to witness" (ναὶ μὰ Δία: ἴστω Ζεύς); "by the immortal gods!" "I call to witness the ashes of my ancestors" (per deos immortales; testor majorum cineres). Sometimes a curse is invoked on himself by the swearer, that he may perish if he fail to keep his oath, as "the gods destroy me," "let me perish if," &c. (dii me perdant; dispeream si). An important class of Roman oaths invokes the deity to favour or preserve the swearer in so far as he shall fulfil his promise —"as the gods may preserve me," "as I wish the gods to be propitious to me" (me ita di servent; ita deos mihi velim propitios). The best Roman collection is to be found in the old work of Brissonius, *De Formulis et Solemnibus Populi Romani Verbis* (Paris, 1583). Biblical examples of these classes of oaths are "as the Lord liveth" (1 Sam. xiv. 39, and elsewhere), "so do God to me, and more also" (2 Sam. iii. 35, and elsewhere).

The history of oaths in the early Christian ages opens a controversy which can hardly be said even yet to have closed. Under Christ's injunction, "Swear not at all" (Matt. v. 34; also James v. 12), many Christians seem at first to have shrunk from taking oaths, and, though after a time the usual customs of judicial and even colloquial oaths came to prevail among them, the writings of the Fathers show efforts to resist the practice. Chrysostom perhaps goes furthest in inveighing against this "snare of Satan": "Do as you choose; I lay it down as a law that there be no swearing at all. If any bid you swear, tell him, Christ has spoken, and I do not swear" (Homil. ix. in *Act. Apostol.*; see a collection of patristic passages in Sixt. Senens. *Bibliothec. Sanct.* vi. adnot. 26). The line mostly taken by influential teachers, however, was that swearing should indeed be avoided as much as possible from its leading to perjury, but that the passages forbidding it only applied to superfluous or trifling oaths, or those sworn by created objects, such as heaven or earth or one's own head. On the other hand, they argued that judicial and other serious swearing could not have been forbidden, seeing that Paul in his epistles repeatedly introduces oaths (2 Cor. i. 23; Phil. i. 8; Gal. i. 20). Thus Athanasius writes: "I stretch out my hand, and as I have learned of the apostle, I call God to witness on my soul" (*Apol. ad Imp. Const.*; see Augustine, *De Mend.* 28; *Epist.* cl. iii. 9; cl. iv. 250; *Enarr. in Psalm.* lxxxviii. (4); *Serm.* 307, 319). This argument is the more forcible from Paul's expressions being actually oaths in accepted forms, and it has also been fairly adduced that Christ, by answering to the adjuration of the high priest, took the judicial oath in solemn form (Matt. xxvi. 63). The passages here referred to will give an idea of the theological grounds on which in more modern times Anabaptists, Mennonites and Quakers have refused to take even judicial oaths, while, on the other hand, the laws of Christendom from early ages have been only directed against such swearing as was considered profane or otherwise improper, and against perjury. Thus from the 3rd or 4th century we find oaths taking much the same place in Christian as in non-Christian society. In the 4th century the Christian military oath by God, Christ, the Holy Spirit, and the majesty of the emperor is recorded by Vegetius (*Rei Milit. Inst.* ii. 5). Constantine's laws required every witness in a cause to take oath; this is confirmed in Justinian's code, which even in some cases requires also the parties and advocates to be sworn (*Cod. Theod.* xi. 39; *Justin. Cod.* iv. 20, 59). Bishops and clergy were called upon to take oath in ordination, monastic vows, and other ecclesiastical matters (see details in Bingham, *Antiq. of Chr. Church*, xvi. 7). By the middle ages oaths had increased and multiplied in Christendom far beyond the practice of any other age or religion. The Reformation made no change in principle, as is seen, for instance, in Art. xxix. of the church of England: "As we confess that vain and rash swearing is forbidden Christian men by our Lord Jesus Christ, and James His apostle, so we judge, that Christian Religion doth not prohibit, but that a man may swear when the Magistrate requireth, in a cause of faith and charity, so it be done according to the Prophet's teaching, in justice, judgement and truth."

The history of swearing in early Christendom would lead us to expect that the forms used would be adopted with more or less modification from Hebrew or Roman sources, as indeed proves to be the case. The oath introduced in the body of one of Constantine's laws—"As the Most High Divinity may ever be propitious to me" (Ita mihi summa Divinitas semper propitia sit)—follows an old Roman form. The Roman oath by the genius of the emperor being objected to by Christians as recognizing a demon, they swore by his safety (Tertull. *Apol.* 32). The gesture of holding up the hand in swearing has been already spoken of. The Christian oath on a copy of the Gospels seems derived from the late Jewish oath taken holding in the hand the scroll of the law (or the phylacteries), a ceremony itself possibly adapted from Roman custom (see treatise "Shebuoth" in *Gemara*). Among the various mentions of the oath on the Gospels in early Christian writers is that characteristic passage of Chrysostom in a sermon to the people of Antioch: "But do thou, if nothing else, at least reverence the very book thou holdest forth to be sworn by, open the Gospel thou takest in thy hands to administer the oath, and, hearing what Christ therein saith of oaths, tremble and desist" (*Serm. ad pop. Antioch.* Homil. xv.). The usual mode was to lay the hand on the Gospel, as is often stated in the records, and was kept up to a modern date in the oath in the university of Oxford, "tactis sacrosanctis Evangeliis"; the practice of kissing the book, which became so well established in England, appears in the middle ages (J. E. Tyler, *Oaths*, pp. 119, 151). The book was often laid on the altar, or (after the manner of ancient Rome) the swearer laid his hand on the altar itself, or looked towards it; above all, it became customary to touch relics of saints on the altar, a ceremony of which the typical instance is seen in the representation of Harold's oath in the Bayeux tapestry. Other objects, as the cross, the bishop's crosier, &c., were sworn by (see Du Cange, *s.v.* "Jurare"). An oath ratified by contact or inspection of a sacred object was called a "corporal" or bodily oath, as distinguished from a merely spoken or written oath; this is well seen in an old English coronation oath, "so helpe me God, and these holy euangelists by me bodily touched vppon this hooly awter." The English word signifying the "sacred object" on which oath is taken is *halidome* (A.S. *hâligdôm*; Ger. *Heiligthum*); the halidome on which oaths are now sworn in England is a copy of the New Testament. Jews are sworn on the Old Testament; the sacred books of other religions are used in like manner, a Mohammedan swearing on the Koran, a Hindu on the Vedas.

Among the oath-formulas used in Christendom, that taken by provincial governors under Justinian is typical of one class: "I swear by God Almighty, and His only begotten Son our Lord Jesus Christ, and the Holy Ghost, and the Most Holy Glorious Mother of God and ever Virgin Mary, and by the Four Gospels which I hold in my hand, and by the Holy Archangels Michael and Gabriel," &c. The famous oath of the kings Louis and Charles at Strassburg in 842 (A.D.) runs: "By God's love and the Christian people and our common salvation, as God shall give me knowledge and power," &c. Earlier than this, as in the oath of fealty in the capitularies of Charlemagne in 802, is found the familiar form "Sic me adjuvet Deus," closely corresponding to above-mentioned formulas of pre-Christian Rome. This became widely spread in Europe, appearing in Old French "Si m'ait Dex," German "So mir Gott helfe," English "So help me God." A remarkable point in its history is its occurrence in the "So help me Frey," &c., of the old Scandinavian ring-oath already described. Among the curiosities of the subject are quaint oaths of kings and other great personages: William Rufus swore "by that and that" (per hoc et per hoc), William the Conqueror "by the splendour of God," Richard I. "by God's legs," John "by God's teeth"; other phrases are given in Du Cange (*l.c.*), as "per omnes gentes," "per coronam," "par la sainte figure de Dieu," "par la mort Dieu," &c.

Profane swearing, the trifling or colloquial use of sacred oaths, is not without historical interest, formulas used being apt to keep up traces of old manners and extinct religions. Thus the early Christians were reproved for continuing to say "*mehercle!*" some of them not knowing that they were swearing by Hercules (Tertull. *De idol.* 20). Oaths by deities of pre-Christian Europe

lasted into the modern world, as when a few generations ago Swedish peasants might be heard to swear, "Odin take me if it is not true!" (Hylten-Cavallius, *Wärend och Wirdarne*, i. 228). The thunder-god holds his place still in vulgar German exclamations, such as "Donner!" (Grimm. *Deutsche Mythologie*, pp. 10, 166). The affected revival of classical deities in Italy in the middle ages still lingers in such forms as "per Bacco!" "cospetto di Bacco!" (by Bacchus! face of Bacchus!). In France the concluding oath of the last paragraph dwindled into "mordieu!" or "morbleu!" much as in England the old oaths by God's body and wounds became converted into "oddsbodikins!" and "zounds!" (E. B. T.)

Law.—Politicians and moralists have placed much reliance on oaths as a practical security. It has been held, as Lycurgus the orator said to the Athenians, that "an oath is the bond that keeps the state together" (Lycurg. *Leocr.* 80; see Montesquieu, *Spirit of Laws*). Thus modern law-books quote from the leading case of *Omichund* v. *Barker*: "No country can subsist a twelvemonth where an oath is thought not binding; for the want of it must necessarily dissolve society." On the other hand, wherever the belief in supernatural interference becomes weakened, and oaths are taken with solemn form but secret contempt or open ridicule, they become a serious moral scandal, as had already begun to happen in classical times. The yet more disastrous effect of the practice of swearing is the public inference that, if a man has to swear in order to be believed, he need not speak the truth when not under oath. The early Christian fathers were alive to this depreciation of ordinary truthfulness by the practice of swearing, and opposed, though unavailingly, the system of oaths which more and more pervaded public business. How in the course of the middle ages oaths were multiplied is best seen by examining a collection of formulas such as the *Book of Oaths* (London, 1649), which range from the coronation oath to the oaths sworn by such as valuers of cloths and the city scavengers.[1] Oaths of allegiance and other official oaths are still taken throughout Europe, but experience shows that in times of revolution they are violated with little scruple, and in the case of the United Kingdom it is doubtful whether they have any more practical value than, if so much as, simple declarations. The question of legal oaths is more difficult. On the one hand, it is admitted that they do induce witnesses, especially the ignorant and superstitious, to give evidence more truthfully than they would do on even solemn declaration. On the other hand, all who practise in courts of justice declare that a large proportion of the evidence given under oath is knowingly false, and that such perjury is perceptibly detrimental to public morals.

The oaths now administered among civilized nations are chiefly intended for maintaining governments and securing the performance of public business. In England the coronation oath is to be administered by one of the archbishops or bishops in the presence of all the people, who, on their parts, reciprocally take the oath of allegiance to the crown. *The archbishop or bishop shall say*: "Will you solemnly promise and swear to govern the people of this United Kingdom of Great Britain and Ireland and the dominions thereto belonging according to the statutes in parliament agreed on, and the respective laws and customs of the same?" *The king shall say*: "I solemnly promise so to do." *Archbishop or bishop*: "Will you to the utmost of your power cause law and justice, in mercy, to be executed in all your judgements?" *King*: "I will." *Archbishop or bishop*: "Will you, to the utmost of your power, maintain the laws of God, the true profession of the Gospel, and the Protestant reformed religion established by law? And will you maintain and preserve inviolably the settlement of the Church of England and the doctrine, worship, discipline and government thereof, as by law established in England. And will you preserve unto the bishops and clergy of England, and to the churches therein all such rights and privileges as by law do or shall appertain to them, or any of them?" *King*: "All this I promise to do."

[1] As to reform of the excessive multiplication of oaths, see Paley, *Moral Philosophy*, bk. iii. pt. i. ch. 16; and J. E. Tyler, *Oaths*.

After this the king, laying his hand upon the holy Gospels, shall say: "The things which I have here before promised I will perform and keep; so help me God," *and then shall kiss the book*.

The chief officers of state take an "official" oath well and truly to serve his majesty. Special oaths are taken by privy councillors, archbishops and bishops, peers, baronets and knights, recruits and others. The old oath of allegiance, as administered (says Blackstone) upwards of 600 years, contained a promise "to be true and faithful to the king and his heirs, and truth and faith to bear of life and limb and terrene honour, and not to know or hear of any ill or damage intended him without defending him therefrom" (Blackstone, *Commentaries*, book i. chap. x.). In the reign of William III. it was replaced by a shorter form; and it now runs: "I . . . do swear that I will be faithful and bear true allegiance to His Majesty . . . , his heirs and successors, according to law." Statutes of Charles II. and George I. enacted that no member should vote or sit in either house of parliament without having taken the several oaths of allegiance, supremacy and abjuration. The oath of supremacy in the reign of William III. was: "I A B doe swear that I doe from my heart abhorr detest and abjure as impious and heretical this damnable doctrine and position that princes excommunicated or deprived by the pope or any authority of the see of Rome may be deposed or murdered by their subjects or any other whatsoever. And I doe declare that no forreigne prince person prelate state or potentate hath or ought to have any jurisdiction power superiority preeminence or authoritie ecclesiasticall or spirituall within this realme. Soe," &c. The oath of abjuration introduced in the time of William III. recognizes the king's rights, engages the juror to support him and disclose all traitorous conspiracies against him, promises to maintain the Hanoverian Protestant succession, and expressly renounces any claim of the descendants of the late Pretender. This oath was not only taken by persons in office, but might be tendered by two justices to any person suspected of disaffection. In modern times a single parliamentary oath was substituted for the three, and this was altered to enable Roman Catholics to take it, and Jews were enabled to sit in parliament by being allowed to omit the words "on the true faith of a Christian." In its present form the parliamentary oath consists of an oath of allegiance and a promise to maintain the succession to the crown as limited and settled in the reign of William III.

The "judicial" oath taken by judges of the court of appeal or of the High Court of Justice, and by justices of the peace, is "to do right to all manner of people after the laws and usages of this realm, without fear or favour, affection or ill-will." Jurors are sworn, whence indeed their name (*juratores*); in felonies the oath administered is: "You shall well and truly try and true deliverance make between our sovereign lord the king and the prisoner at the bar whom you shall have in charge, and a true verdict give according to the evidence." In misdemeanours the form is: "Well and truly try the issue joined between our sovereign lord the king and the defendant and a true verdict," &c. The oath of the jurors in the Scottish criminal courts is: "You [the jury collectively] swear in the name of Almighty God and as you shall answer to God at the great day of judgment that you will truth say and no truth conceal in so far as you are to pass upon this assize." The oldest trace of the form of oath in Scotland is in *Reg. maj.* i. cap. 11, copied from Glanvill, which points to an origin in the Norman inquest or "recognition." In the ancient custom of compurgation, once prevalent in Europe, the accused's oath was supported by the oaths of a number of helpers or compurgators who swore to their belief in its validity.

Witnesses in English law courts must give their evidence under the sanction of an oath, or of what is equivalent to an oath, and the ordinary form of oath adapted to Christians is "The evidence you shall give . . . shall be the truth, the whole truth, and nothing but the truth. So help you God." Many alterations of the English law as to oaths have been made in relief of (1) those Christians who object on conscientious grounds

to the taking of an oath, and (2) of those persons who refuse to admit the binding force of an oath. Special provision was first made for Quakers, Moravians and Separatists; then followed general enactments relating to civil and criminal proceedings respectively, till finally the law was embodied in the Oaths Act 1888, which enacted that "every person upon objecting to being sworn, and stating, as the ground of such objection, either that he has no religious belief, or that the taking of an oath is contrary to his religious belief, shall be permitted to make his solemn affirmation instead of taking an oath in all places and for all purposes where an oath is or shall be required by law, which affirmation shall be of the same force and effect as if he had taken the oath; and if any person making such affirmation shall wilfully, falsely and corruptly affirm any matter or thing which, if deposed on oath, would have amounted to wilful and corrupt perjury, he shall be liable to prosecution, indictment, sentence and punishment in all respects as if he had committed wilful and corrupt perjury." The form of affirmation prescribed by the Oaths Act was as follows: "I, *A. B.*, do solemnly, sincerely, and truly declare and affirm," &c. Under s. 5 of the same act a person might swear in the Scottish form, with uplifted hand (no book of any kind being used) and if he desired to do so "the oath shall be administered to him in such form and manner without question." With the desire of making universal this method of administering the oath the Oaths Act 1909 was passed. It enacted that any oath might be administered and taken in the following form: "The person taking the oath shall hold the New Testament, or in the case of a Jew, the Old Testament, in his uplifted hand, and shall say or repeat after the officer administering the oath the words 'I swear by Almighty God that . . . ,' followed by the words of the oath prescribed by law." The officer also is directed by the act to administer it in this fashion, unless the person about to take it voluntarily objects or is physically incapable of taking it so. To a person who is neither a Christian nor a Jew the oath may be administered in any way in which it was previously lawful.

The form of affirmation given above is that used for Quakers, Moravians and Separatists in the witness-box: "I, *A. B.*, being one of the people called Quakers (one of the United Brethren called Moravians), do, &c." A Christian swears on the Gospels, holding a copy of the New Testament in his right hand (the hand being uncovered), and his head being also uncovered. A witness may elect to be sworn on any version of the Bible which he considers most binding on him, as a Roman Catholic on the Douai Testament or Bible. A Jew is sworn on the Pentateuch, holding a copy thereof in his right hand, the head being covered. A Mahommedan is sworn upon the Koran. He places his right hand flat upon the book and puts the other hand upon his forehead, bringing his head down to the book and in contact with it. He then looks at the book for some moments. Buddhists are sworn on the Buddhist doctrines, Sikhs upon the Granth, Parsees upon the Zend Avesta, Hindus upon the Vedas, or by touching the Brahmin's foot, and, according to caste custom, Indian witnesses sometimes insist upon the oath being administered by a Brahmin; but in India witnesses now generally affirm. Kaffir witnesses swear by their own chief, and a Kaffir chief by the king of England. When a Chinese witness is to be sworn, a saucer is handed to him, which he takes in his hand and kneeling down breaks into fragments. The colonial legislatures generally make provision for receiving unsworn evidence of barbarous and uncivilized people who have no religious belief. The great number of oaths formerly required was much reduced by the Promissory Oaths Act 1868, which prescribed the forms of oath of allegiance, the official oath and the judicial oath. The right to affirm in lieu of taking the parliamentary oath in the case of atheists was first raised in the case of Charles Bradlaugh (*q.v.*).

Profane swearing and cursing is punishable by the Profane Oaths Act 1745. any labourer, sailor or soldier being liable to forfeit 1s., every other person under the degree of a gentleman 2s., and every gentleman or person of superior rank 5s., to the poor of the parish.

OAXACA, OAJACA (from Aztec *Huaxyacac*), or OAXACA DE JUAREZ (official title), capital of the Mexican state of Oaxaca, in the central part of the state 288 m. S.E. of the City of Mexico, and about 153 m. from Puerto Angel on the Pacific; in lat. 17° 3′ N., long. 96° 40′ W. Pop. (1900) 35,049, largely Indians, most of whom are Mixtecas and Zapotecas. Oaxaca is connected with Puebla (211 m.) by the Mexican Southern railway. The city lies in a broad, picturesque valley 5085 ft. above sea-level, and has a mild temperate climate; annual rainfall about 33 in.; mean annual temperature 68° F. It forms the see of a bishopric dating from 1535, and has a fine old cathedral (occupying the north side of the *plaza mayor*), built in the Spanish Renaissance style and dating from 1553; rebuilt in 1702.

According to tradition the Aztec military post and town of Huaxyacac was founded in 1486. The date of the first Spanish settlement is uncertain, but it was probably between 1522 and 1528. The Oaxaca Valley, including several native towns, had been given to Cortés, together with the title marquez del Valle de Oaxaca. To injure him, the *audiencia* then administering the government, founded the *villa* of Antequera in close proximity to Huaxyacac and on lands belonging to Cortés in 1529, though a settlement had been made at the Indian town at an earlier date. Antequera was made a city in 1532 and the see of a bishopric in 1535, though it had but few Spanish inhabitants and no opportunity to expand. This anomalous state of affairs was eventually settled, Antequera was absorbed by Huaxyacac, and the Spanish corrupted the pronunciation to Oaxaca. The city suffered severely in the earthquakes of 1727 and 1787, the cathedral being greatly damaged in the former. It had a chequered career in the War of Independence, being captured by Morelos in 1812, reoccupied by the royalists in 1814, and recaptured by Antonio Leon in 1821. In 1823 it was again captured by Nicolas Bravo in the revolution against Iturbide. In 1865 it was besieged by the French under Bazaine and surrendered by General Diaz (4th Feb.) but was recaptured by him on the 1st of November 1866, after his escape from Puebla. In the revolution promoted by Diaz in 1871–1872 the city was captured by the Juarist general Alatorre on the 4th of January 1872, and in a second revolution of 1876 it was captured by the friends of Diaz on the 27th of January of that year.

OB, or OBI, a river of West Siberia, known to the Ostiaks as the As, Yag, Kolta and Yema; to the Samoyedes as the Kolta or Kuay; and to the Tatars as the Omar or Umar. It is formed, 8 m. S.W. of Biysk in the government of Tomsk, by the confluence of the Biya and the Katun. Both these streams have their origin in the Altai (Sailughem) Mountains, the former issuing from Lake Teletskoye, the latter, 400 m. long, bursting out of a glacier on Mount Byelukha. The Ob zigzags W. and N. until it reaches 55° N.; thence it curves round to the N.W., and again N., wheeling finally eastwards into the Gulf of Ob, a deep (600 m.) bay of the Arctic Ocean. The river splits up into more than one arm, especially after receiving the large river Irtysh (from the left) in 69° E. Other noteworthy tributaries are: on the right, the Tom, the Chulym, the Ket, the Tym and the Vakh; and, on the left, the Vasyugan, the Irtysh (with the Ishim and the Tobol) and the Sosva. The navigable waters within its basin reach a total length of 9300 m. By means of the Tura, an affluent of the Tobol, it secures connexion with the Ekaterinburg-Perm railway at Tyumen, and thus is linked on to the rivers Kama and Volga in the heart of Russia. Its own length is 2260 m., and the area of its basin 1,125,200 sq. m. A system of canals, utilizing the Ket river, 560 m. long in all, connects the Ob with the Yenisei. The Ob is ice-bound at Barnaul from early in November to near the end of April, and at Obdursk, 100 m. above its mouth, from the end of October to the beginning of June. Its middle reaches have been navigated by steamboats since 1845.

OBADIAH, the name prefixed to the fourth of the Old Testament "minor prophets," meaning "servant" or "worshipper" of Yahweh; of a type common in Semitic proper names; cf. the Arabic 'Abdallāh, Taimallāt, 'Abd Manāt, &c., the Hebrew Abdiel and Obed Edom, and many Phoenician forms. "The vision of Obadiah" bears no date, or other historical note, nor can we connect Obadiah the prophet with any other Obadiah of the Old Testament,[1] and our only clue to the date and composition of the book lies in internal evidence.

The prophecy is directed against Edom. Yahweh has sent a messenger forth among the nations to stir them up to battle against the proud inhabitants of Mount Seir, to bring them down from the rocky fastnesses which they deem impregnable. Edom shall be not only plundered but utterly undone and expelled from his borders, and this he shall suffer (through his own folly) at the hand of trusted allies (vers. 1-9). The cause of this judgment is his cruelty to his brother Jacob. In the day of Jerusalem's overthrow the Edomites rejoiced over the calamity, grasped at a share of the spoil, lay in wait to cut off the fugitives (vers. 10-14). But now the day of Yahweh is near upon all nations, Esau and all the heathen shall drink full retribution for their banquet of carnage and plunder on Yahweh's holy mountain. A rescued Israel shall dwell in Mount Zion in restored holiness; the house of Jacob shall regain their old possessions; Edom shall be burned up before them as chaff before the flame; they shall spread over all Canaan, over the mountain of Esau and the south of Judah, as well as over Gilead and the Philistine and Phoenician coast. The victorious Israelites shall come up on Mount Zion to rule the mountain of Esau, and the kingdom shall be Yahweh's (vers. 15-21).

The most obvious evidence of date lies in the cause assigned for the judgment on Edom (vers. 10-14). The calamity of Jerusalem can only be the sack of the city by Nebuchadrezzar (586 B.C.); the malevolence and cruelty of Edom on this occasion are characterized in similar terms by several writers of the exile or subsequent periods, but by none with the same circumstance and vividness of detail as here (Ezek. xxv. 8, 12 f., xxxv.; Lam. iv. 21; Psalm cxxxvii. 7). The prominence given to Edom, and the fact that Chaldea is not mentioned at all, make it probable that the passage was not written in Babylonia. On this evidence, taken alone, we should be justified in saying that the prophecy was written at some time after 586 B.C., at a period when misfortunes incurred by Edom were interpreted as a Divine judgment on its unforgotten treachery in that year of tragedy.

The critical problem is, however, complicated by certain phenomena of literary relationship.[2] Obad. 1-6, 8 agree so closely and in part verbally with Jer. xlix. 14-16, 9, 10, 7 that the two passages cannot be independent; nor does it seem possible that Obadiah quotes from Jeremiah, for Obad. 1-8 is a well-connected whole, while the parallel verses in Jeremiah appear in a different order, interspersed with other matter, and in a much less lucid connexion. In Jeremiah the picture is vague, and Edom's unwisdom (ver. 7) stands without proof. In Obadiah the conception is quite definite. Edom is attacked by his own allies, and his folly appears in that he exposes himself to such treachery. Again, the probability that the passage in Jeremiah incorporates disjointed fragments of an older oracle is greatly increased by the fact that the prophecy against Moab in the preceding chapter uses, in the same way, Isa. xv., xvi., and the prophecy of Balaam. Scholars who assign the passage in Jeremiah to 604 B.C. (*e.g.* Driver, *L.O.T.* chap. vi. § 4), explain this relationship by assuming with Ewald (*Prophets*, i. 430 f.) Graf (*Jeremia*, p. 558 f.), Robertson Smith and others, that Jeremiah and our book of Obadiah alike quote from an older oracle. Others, however, who do not regard Jer. xlix. as Jeremianic, explain the relationship as one of dependence on Obadiah. This explanation, simpler in itself, is not discredited by the fact that in some details (cf. Obad. 2 and Jer. xlix. 15) the text

[1] An early Hebrew tradition recorded by Jerome (*Comm. in Ob.*) identified the prophet with the best-known Obadiah of the historical books, the protector of the prophets in the reign of Ahab (1 Kings xviii.).

[2] Between Joel and Obadiah there are points of material and verbal agreement so close as to imply that Joel used the earlier book (Joel iii. 19—Ob. 10, 14; Joel iii. 3—Ob. 11; Joel ii. 32, iii. 7—Ob. 17).

of the dependent passage may be preferable to that of the original. On this latter, and more probable, view (taken by Wellhausen, Nowack and Marti) there is no need to separate Obad. 1-7 from 10-14. The immediate occasion of the prophecy[1] was doubtless the pressure of nomadic Arabs ("the men of thy covenant," "the men of thy peace," v. 7) upon Edom, which had resulted, by 312 B.C. at latest, in the occupation by Arabs of Petra, the chief city of the Edomites (Wellhausen, p. 214). But the desolation of Edom has already been accomplished in the time of Malachi i. 1-5, a passage belonging to the earlier half of the 5th century. We may, therefore, with Wellhausen, Nowack and Marti, assign Obadiah 1-14 to the same period.

The remainder of the book, vers. (15) 16-21, must belong to a later date. That the book of Obadiah, short as it is, is a complex document might have been suspected from an apparent change of view between vers. 1-7 and vers. 15 f. In the former verses Esau is destroyed by his allies, and they occupy his territory, but in the latter he perishes with the other heathen in the day of universal retribution, he disappears before the victorious advance of Israel, and the southern Judaeans occupy his land.[2] The ideas of this passage belong to the eschatological outlook of later centuries, but afford no data for chronology. The conceptions of the "rescued ones" (R.V. "those that escape," v. 17), of the sanctity of Zion, of the kingship of Yahweh, are the common property of the post-exilic writers. The restoration of the old borders of Israel and the conquest of Edom and the Philistines are ideas as old as Amos ix., Isa. xi. 14; but such passages represent this conquest as a suzerainty of Israel over its neighbours, as in the days of David, while in Obadiah, as in other later books, the intensified antithesis—religious as well as political—between Judah and the surrounding heathen finds its expression in the idea of a consuming judgment on the latter—the great "day of Yahweh." The chief interest of the book of Obadiah lies in its references to the historical relations between Israel and Edom. From the point of view of religion, we may notice the emphasis on the doctrine of strict retribution (vers. 10 f., 15 *b*) which remains applicable to other peoples, even when its inadequacy as a complete theory of providence has been slowly and painfully discovered in the case of Israel itself.

LITERATURE.—Wellhausen, *Die kleinen Propheten*[3] (1898); Nowack, *id.* (1897, 2nd ed., 1904); G. A. Smith, *The Book of the Twelve*, vol. ii. (1898); J. A. Selbie, art. "Obadiah," in Hastings's *Dict. of the Bible*, iii. 577-580 (1900); Cheyne, *id.* in *Ency. Biblica*, iii. c. 3455-3462 (incorporating the article of W. Robertson Smith in the 9th edition of the *Ency. Brit.*) (1902); Marti, *Dodekapropheton* (1903). For a sketch of the history of the Edomites, see Nöldeke's article "Edom" in the *Ency. Biblica*. (W. R. S.; H. W. R.*)

OBAN, a municipal and police burgh and seaport of Argyllshire, Scotland. Pop. (1901) 5374. It is situated 113 m. N.W. of Glasgow by the Caledonian railway via Stirling and Callander, and about the same distance by water via the Crinan Canal. The fine bay on which it lies is screened from the Atlantic gales by the island of Kerrera (4½ m. long by 2 m. broad), which practically converts it into a land-locked harbour. Being also sheltered from the north and east by the hills at the foot of which it nestles, the town enjoys an exceptionally mild climate for its latitude. The public buildings include the Roman Catholic pro-cathedral, erected by the 3rd marquis of Bute, the county buildings and two hospitals. It is the centre of tourist traffic for western Argyllshire and the islands. Oban was a small village at the date of Johnson's visit during his Hebridean tour; in 1786 it became a government fishing station; it was made a burgh of barony in 1811 and a parliamentary burgh in 1832. With Ayr, Campbeltown, Inveraray and Irvine (the Ayr burghs) it unites to send one member to parliament.

At the north end of the bay stands the ruin of Dunolly Castle, the old stronghold of the Macdougalls of Lorne, whose modern mansion adjoins it. In the grounds is a huge conglomerate rock called the Dog Stone (*Clach-a-choin*), from the legend that Fingal used to fasten his favourite dog Bran to it. About 3 m. N.E. are the ruins of Dunstaffnage Castle. It was here that the "Stone of Destiny," now contained in the base of the coronation chair at Westminster Abbey, was kept before its removal to Scone. At the south end of the island of Kerrera stand the ruins of Gylen Castle, an old fortalice of the Macdougalls.

[1] Wellhausen and Nowack regard *vv.* 8, 9 as a later addition, intended to apply *vv.* 1-7 to the future; so Marti, who groups with these verses 15*a*, because of the common reference to "the day of Yahweh."

[2] The Judaeans are addressed in *v.* 16 ("as ye have drunk"), not the Edomites. Verse 20 anticipates that the exiles from northern Israel will occupy Phoenician territory, whilst those from Jerusalem "which are in Sepharad" will occupy the southern districts in the Messianic restoration. "Sepharad" has been connected with various places, *e.g.* Saparda in south-west Media (G. A. Smith), and Çparda of Darius in the Behistun inscription (Robertson Smith); whilst, according to Winckler (*K.A.T.*[3] p. 301), it is the name, from the Persian period onwards, for Asia Minor. Many of the Jews were doubtless sold as slaves by Nebuchadrezzar. Lydia was a great slave-market, and Asia Minor was a chief seat of the Diaspora at an early date (comp. Gutschmidt, *Neue Beiträge*, p. 77), so that "Sepharad" in itself does not supply ground for Hitzig's argument that Obadiah was written in the Greek period, when we read of many Jews being transplanted to Asia Minor (Jos. *Ant.* xii. 3).

OBBLIGATO, or OBLIGATO, in the modern sense, a musical term (adopted from the Italian, and strictly meaning obligatory or binding) for an instrumental accompaniment to a musical composition which, while in one way independent, is included by the composer on purpose and in a prescribed form, instead of being left to the discretion (*ad libitum*) of a performer.

OBELISK (Gr. ὀβελίσκος, diminutive of ὀβελός, a spit), a form of monumental pillar; and also the term for a bibliographical reference-mark in the form of a dagger. The typical Egyptian obelisk is an upright monolith of nearly square section, generally 10 diameters in height, the sides slightly convex, tapering upwards very gradually and evenly, and terminated by a pyramidion whose faces are inclined at an angle of 60°. Obelisks were usually raised on pedestals of cubical form resting on one or two steps, and were set up in pairs in front of the entrance of temples. Small obelisks have been found in tombs of the age of the Old Kingdom. The earliest temple obelisk still in position is that of Senwosri I. of the XIIth Dynasty at Heliopolis (68 ft. high). A pair of Rameses II. (77 and 75 ft. high respectively) stood at Luxor until one of them was taken to Paris in 1831. Single ones of Tethmosis I. and Hatshepsut (109 ft. high) still stand at Karnak and remains of others exist there and elsewhere in Egypt. Colossal granite obelisks were erected by only a few kings, Senwosri I. in the Middle Kingdom and Tethmosis I., Hatshepsut, Tethmosis III. and Rameses II. of the Empire. Smaller obelisks were made in the Saïte period. The Romans admired them, and the emperors carried off some from their original sites and caused others to be made in imitation (*e.g.* that for Antinous at Benevento): twelve are at Rome, one in Constantinople; two, originally set up by Tethmosis III. at Heliopolis, were taken by Augustus to adorn the Caesareum at Alexandria: one of these, "Cleopatra's Needle," was removed in 1877 to London, the other in 1879 to New York. Such obelisks were probably more than mere embellishments of the temples. The pyramidions were sheathed in bright metal, catching and reflecting the sun's rays as if they were thrones of the sunlight. They were dedicated to solar deities, and were especially numerous at Heliopolis, where there was probably a single one sacred to the sun of immemorial antiquity. The principal part of the sun-temple at Abusir built by Neuserrē of the Vth Dynasty appears to have been in the shape of a stumpy obelisk on a vast scale, only the base now remains, but hieroglyphic pictures indicate this form. The hieroglyph of some other early sun-temples shows a disk on the pyramidion  . The material employed for the great obelisks was a pink granite from the quarries of Syene, and in these quarries there still remains, partially detached, an example 70 to 80 ft. long. The largest obelisk known is that in the piazza of St John Lateran at Rome; this had been set up by Tethmosis III. at Heliopolis in the 15th century B.C., was brought over from Egypt by Constantine the Great and erected in the Circus Maximus, being ultimately re-erected in 1552 by Pope Sixtus V. It was 105 ft. 9 in. high, including the pyramidion, and its sides measured 9 ft. 10 in. and 9 ft. 8 in. respectively. On the base of the magnificent

obelisk of Hatshepsut at Karnak, 97 ft. 6 in. high, there is an inscription stating that it and its fellow were made within the short space of seven months. In consequence of the breaking away of the lower part of "Cleopatra's Needles" when removed to Alexandria and re-erected, the Roman engineers supported the angles on bronze crabs, one of which with three reproductions now supports the angles of the obelisk on the Thames Embankment.

There was another form of obelisk, also tapering, but more squat than the usual type, with two of the sides narrow and terminating in a rounded top. One such of Senwosri I., covered with sculpture and inscriptions, lies at Ebgig in the Fayum. Stelae, inscribed with the names of the kings, occurred in pairs in the royal tombs of the Ist Dynasty at Abydos, and pairs of small obelisks are said to have been found in private tombs of the IVth Dynasty. The origin of the obelisk may be sought in sacred upright stones set up in honour of gods and dead, like the menhirs, and the Semitic Massebahs and bethels.

In Abyssinia, at Axum and elsewhere, there is a marvellous series of obelisk-like monuments, probably sepulchral. They range from rude menhirs a few feet high to elaborately sculptured monoliths of 100 ft. The loftiest of those still standing at Axum is about 60 ft. high, 8 ft. 7 in. wide, and about 18 in. thick, and is terminated by a rounded apex united by a necking to the shaft. The back of the obelisk is plain, but the front and sides are subdivided into storeys by a series of bands and plates, each storey having panels sunk into it which seem to represent windows with mullions and transom. These architectural decorations are derived from a style of building found by the recent German expedition extant in an ancient church; courses of stone here alternate in the walls (both inside and out) with beams of wood held by circular clamps. In front of the best-preserved obelisk is a raised altar with holes sunk in it apparently to receive the blood of the sacrifice to the ancestors. Most of these must date before the adoption of Christianity as the state religion in the 6th century.

See G. Maspero, *L'Archéologie égyptienne* (new ed., Paris, 1907), p. 105; H. H. Gorringe, *Egyptian Obelisks* (New York, 1882; London, 1885, &c.); F. W. von Bissing and L. Borchardt, *Das Re-Heiligtum des Königs Ne-woser-Re* (Berlin, 1905); on the ancient method of raising obelisks, L. Borchardt, "Zur Baugeschichte des Amonstempel von Karnak," in Sethe's *Untersuchungen zur Geschichte und Altertumskunde Aegyptens*, v. 15. For the Abyssinian obelisks see especially E. Littmann and D. Krencker, *Vorbericht der deutschen Aksum Expedition* (Berlin, 1906). (F. Ll. G.)

OBERAMMERGAU, a village of Bavaria, Germany, district of Upper Bavaria, situated amongst the foot-hills of the Alps in the valley of the Ammer, 64 m. S.S.W. of Munich. Pop. about 1400. The village folk are mainly engaged in making toys, and carving crucifixes, rosaries and images of saints.

The place is famous for their performance of a Passion Play every tenth year (*e.g.* in 1910), to which thousands of visitors flock. This dramatic representation of the sufferings of Christ is not a survival of a medieval mystery or miracle-play, but took its rise from a vow made by the inhabitants in 1633, with the hope of staying a plague then raging. The original text and arrangements were probably made by the monks of Ettal, a monastery a little higher up the valley; but they were carefully remodelled by the parish priest at the beginning of the present century, when the Oberammergau play obtained exemption from the general suppression of such performances by the Bavarian government. The music was composed by Rochus Dedler, schoolmaster of the parish in 1814. The performances take place on the Sundays of summer, in a large open-air theatre holding 6000 persons, and each lasts about nine hours, with a short intermission at noon. Each scene from the history of Christ is prefaced by a tableau of typical import from the Old Testament. About 700 actors are required, all belonging to the village. The proceeds of the performances are devoted to the good of the community, after defrayal of the costs and payment of a small remuneration to the actors. The villagers regard the Passion Play as a solemn act of religious worship, and the performances are characterized by the greatest reverence. The principal parts are usually hereditary in certain families and are assigned with regard to moral character as well as dramatic ability. It is considered a disgrace not to be allowed to take part in the play, and the part of Christ is looked upon as one of the greatest of earthly honours.

Edward Devrient (in 1850) was among the first to direct general attention to Oberammergau; and numerous accounts have since appeared. An English version of the text of the Passion Play has been published by E. Childe (1880).

OBERHAUSEN, a town of Germany, in the Prussian Rhine province. It is situated 5 m. from the east bank of the Rhine, 20 m. N.E. of Düsseldorf, on the main line of railway to Hanover and Berlin, and at the centre of an important network of lines radiating hence into the extensive Westphalian coal and iron fields. Pop. (1905) 52,096. The town possesses large iron-works, coal-mines, rolling-mills, zinc smelting-works, railway workshops and manufactures of wire-rope, glass, chemicals, porcelain and soap. The first houses of Oberhausen were built in 1845, and it received its municipal character in 1874.

OBERLAHNSTEIN, a town of Germany, in the Prussian province of Hesse-Nassau, on the right bank of the Rhine, at the confluence of the Lahn 4 m. above Coblenz, on the railway from Cologne to Frankfort-on-Main. Pop. (1905) 8472. It still retains parts of its ancient walls and towers, and possesses a castle, the Schloss Martinsburg, formerly the residence of the electors of Mainz, and the chapel, Marien Kapelle, in which the German king Wenceslaus was deposed by the electors in 1400. Near the town is the castle of Lahneck, built about 1290, destroyed by the French in 1689, and restored in 1854. In the neighbourhood are lead and silver mines.

See J. Wegeler, *Lahneck und Oberlahnstein* (Trier, 1881).

OBERLÄNDER, ADAM ADOLF (1845–), German caricaturist, was born at Ratisbon, but after 1847 lived in Munich. He studied painting at the Munich Academy under Piloty, and soon discovered that the true expression of his genius was in the field of caricature and comic drawings. He joined the staff of the *Fliegende Blätter*, to which he became a constant contributor. Unlike Busch, whose aim was the utmost simplicity of line and whose drawings form a running commentary to the legend, Oberländer's work is essentially pictorial, and expressive in itself, without the extraneous aid of the written line. Among his best drawings are his parodies on the style of well-known painters, such as the "Variations on the Kissing Theme." His works have been collected in the *Oberländer-Album*, published by Braun and Schneider in Munich.

OBERLIN, JEAN FRÉDÉRIC (1740–1826), German Protestant pastor and philanthropist, the son of a teacher, was born on the 31st of August 1740 at Strassburg, where he studied theology. In 1766 he became Protestant pastor of Waldbach, a remote and barren region in the Steinthal (Ban-de-la-Roche), a valley in the Vosges on the borders of Alsace and Lorraine. He set himself to better the material equally with the spiritual condition of the inhabitants. He began by constructing roads through the valley and erecting bridges, inciting the peasantry to the enterprise by his personal example. He introduced an improved system of agriculture. Substantial cottages were erected, and various industrial arts were introduced. He founded an itinerant library, originated infant schools, and established an ordinary school at each of the five villages in the parish. In the work of education he received great assistance from his housekeeper, Louisa Scheppler (1763–1837). He died on the 1st of June 1826, and was interred with great manifestations of honour and affection at the village of Urbach.

Among the many accounts of the labours of Oberlin, mention may be made of Thomas Sims, *Brief Memorials of Oberlin* (London, 1830); *Memoirs of Oberlin, with a short notice of Louisa Scheppler* (London, 1838, 2nd ed. 1852); H. Ware, *Biography of Oberlin* (Boston, 1845); L. Spach, *Oberlin le pasteur* (Strassburg, 1865, 2nd ed. 1868); F. W. Bodemann, *J. F. Oberlin* (3rd ed., 1879); K. F. Riff, *Drei Bilder aus dem Leben von Papa Oberlin* (Strassburg, 1880); Josephine Butler, *Life of J. F. Oberlin* (1882); G. H. von Schubert, *Züge aus dem Leben Oberlins* (11th ed., 1890); Armin Stein, *Johann Friedrich Oberlin, ein Lebensbild* (1899). See also the article in Herzog-Hauck, *Realencyklopädie*. The collected writings of Oberlin were published by Burkhardt at Stuttgart in 1843 in 4 vols.

OBERLIN, JÉRÉMIE JACQUES (1735–1806), Alsatian philologist and archaeologist, brother of Jean Frédéric Oberlin, was born at Strassburg on the 8th of August 1735. While studying theology at the university he devoted special attention to Biblical archaeology. In 1755 he was chosen professor at the gymnasium of his native town, in 1763 librarian to the university, in 1770 professor of rhetoric, and in 1782 of logic and metaphysics. Oberlin published several manuals on archaeology and ancient geography, and made frequent excursions into different provinces of France to investigate antiquarian remains and study provincial dialects, the result appearing in *Essai sur le patois Lorrain* (1775); *Dissertations sur les Minnesingers* (1782–1789); and *Observations concernant le patois et les mœurs des gens de la campagne* (1791). He also published several editions of Latin authors. He died on the 10th of October 1806.

OBERLIN, a village of Lorain county, Ohio, U.S.A., 34 m. W.S.W. of Cleveland. Pop. (1890) 4376; (1900) 4082 (641 negroes); (1910) 4365. It is served by the Lake Shore & Michigan Southern railway, and by the Cleveland & South-Western (electric) railway, which furnishes connexions directly with Cleveland and Elyria, and at the village of Wellington (about 10 m. S.) connects with the Cleveland, Cincinnati, Chicago & St Louis, and the Wheeling & Lake Erie railways. Oberlin is primarily an educational centre, the seat of Oberlin College, named in honour of Jean Frédéric Oberlin, and open to both sexes; it embraces a college of arts and sciences, an academy, a Theological Seminary (Congregational), which has a Slavic department for the training of clergy for Slavic immigrants, and a conservatory of music. In 1909 it had twenty buildings, and a Memorial Arch of Indiana buff limestone, dedicated in 1903, in honour of Congregational missionaries, many of them Oberlin graduates, killed in China in 1900. Its libraries contained in 1909 98,000 bound volumes and an equal number of pamphlets, and the college had a faculty numbering 113 and a student enrolment of 1944. The resources of the college in 1909 were about $3,500,000. Under the editorship of a professor emeritus is published the *Bibliotheca Sacra*, a quarterly founded in 1843, and for many years the organ of the Andover Theological Seminary.

The village was founded as Oberlin Colony in 1833 (in 1846 it was incorporated as the village of Oberlin), by the Rev. John J. Shipherd (1802–1844), pastor of a church in Elyria, and the Rev. Philo Penfield Stewart (1798–1868), a missionary to the Choctaws of Mississippi, as a home for Oberlin Collegiate Institute, which was chartered in 1834; the name Oberlin College was adopted in 1850. To the Theological Seminary, opened in 1835, there came in the same year forty students from Lane Theological Seminary in Cincinnati, after the discussion of slavery there had been forbidden by its board of trustees. A former member of the board, Asa Mahan (1800–1889), who had strongly disapproved of the action of the trustees, came to Oberlin, and became the first president of the college. Oberlin was the first American college to adopt coeducation of sexes, and was a pioneer in America (1835) in the coeducation of the white and black races.[1] The village became a station on the Underground Railway, and an important centre of anti-slavery sentiment. Manual labour was adopted at first as a means for students to defray their college expenses. As late as 1906 it was estimated that nearly two-thirds of the men were to a greater or less degree self-supporting, as were many of the young women. What is known as the "Oberlin Theology" (no longer identified with the college) centred in the teaching of Charles Grandison Finney (1792–1875), who became professor of theology in 1835 and was Mahan's successor in the presidency (1851–1866). He was a powerful preacher and teacher, who broke from Calvinism in denying imputation and teaching perfect freedom of the will, by which perfect holiness might be attained. Finney carried

[1] A runaway slave, Littlejohn, was taken at Oberlin in September 1858 by a United States marshal, but was rescued at Wellington. Several of the rescuers, notably Professor Henry Everard Peck of Oberlin College, were arrested and were imprisoned in Cleveland for several months. This was a famous fugitive slave case.

of a person's death (now "obituary"). An "obit" was also a service performed at a funeral or in commemoration of a dead person, particularly the founder or benefactor of a church, college or other institution, hence "obit-days," "obit Sunday," &c. A "post-obit" is a bond given as a security for the repayment of money lent upon the death of a person from whom the borrower has expectations (see BOND).

OBITER DICTUM, that which is said by the way or in passing (Lat. *ob*, by, and *iter*, road); specifically, in law, an opinion expressed by a judge incidentally in the course of a case, on a point of law not necessarily connected with the issue or not forming part of the grounds of the decision; such *obiter dicta* have no binding authority.

OBJECT and **SUBJECT**, in philosophy, the terms used to denote respectively the external world and consciousness. The term "object" (from Lat. *ob*, over against, and *jacere*, to throw) is used generally in philosophy for that in which an activity of the mind ends, or towards which it is directed. With these may be compared the ordinary uses of the term for "thing" simply, or for that after which one strives, or at which one aims. "Subject," literally that which is "thrown under" (*sub*), is originally the material or content of a discussion or thought, but in philosophy is used for the thought or the thinking person. The relation between the thinking subject and the object thought is analogous to the grammatical antithesis of the same terms: the "subject" of a verb is the person or thing from which the action proceeds, while the "object," direct or indirect, is the person or thing affected. The true relation between mind or thought (subject) and matter or extension (object) is the chief problem of philosophy, and may be investigated from various standpoints (see PSYCHOLOGY and METAPHYSICS). It should be observed that the philosophical use of "subject" is precisely the opposite of the common use. In ordinary language the "subject" of discussion, of a poem, of a work of art, is that which the speaker, author or artist treats.

OBJECTIVE, or OBJECT GLASS, the lens of any optical system which first receives the light from the object viewed; in a compound system the rays subsequently traverse the eye-piece. The theoretical investigations upon which the construction of an optical system having specified properties is based, are treated in the article ABERRATION, and, from another standpoint, in the article DIFFRACTION. Here we deal with the methods by which the theoretical deductions are employed by the practical optician. It should be noted that the mathematical calculations provide data which are really only approximations, and consequently it is often found that a system constructed on such data requires modification before it fulfils the practical requirements. For example, take the case of a photographic objective. Calculations of the paths of two extreme rays in the meridional section of an oblique pencil of large aperture may prove that the rays intersect on a plane containing the axial focus, but similar calculations of many other rays would be necessary before the mean point of intersection could be settled with sufficient exactness. Suppose, however, that the optician has accurately realized the results of the mathematician, he can then determine the divergence of the practical from the theoretical properties by measuring the positions and conformation of the most distinct or mean foci, and, if sufficiently acquainted with the theory of the construction, he can modify one or more curvatures or thicknesses and so attain to a closer agreement with the ideal. Theory and practice co-operate in the realization of an original system. The order is not always the same, but generally the mathematician, by notoriously laborious calculations, supplies data which are at first closely followed by the constructor and afterwards modified in accordance with experimental observations.

In addition to the problem of constructing an original system, the optician has to deal with the reproduction of a realized system in different sizes. Two questions then arise: (1) To what degree of accuracy the radii of curvature can, or should, be repeated, and (2) to what degree of uniformity the surfaces can, or should be figured. With regard to the first point there is no great difficulty in working the requisite iron or brass tools of any curvature to within an error of $\frac{1}{1000}$th% of the radius; male and female templets being used for very deep curves, and the spherometer for tools of longer radii (by appropriate grinding together, the radii are alterable at will within narrow, but sufficient, limits). The accuracy attained in the grinding, however, is open to very perceptible modification by the subsequent polishing and figuring processes. This is particularly undesirable in the case of deep curves and large apertures. A variation in a radius of curvature may occasion a little spherical aberration at the axial focus, but if the amount be small it may be neutralized by imparting to the lens a parabolic form or its opposite. Such an artifice is frequently adopted in correcting large telescope objectives.

With optical systems which transmit large pencils with considerable obliquity (such as wide angle photographic objectives) the curves are very deep, and a departure from the true radius which would be tolerated in a telescope cannot be permitted here. Such lenses are usually tested by means of a master curve worked in glass. The master curve is fitted to the experimental lens, and an inspection of the interference fringes shows the quality of the fit—whether it be perfect, or too shallow or too deep. The workman then modifies his polisher or stroke in order to correct the divergence. Flat surfaces are tested similarly. This test by contact has been strongly advocated and has been regarded as sufficient to detect all irregularities of any moment. This claim, however, is not justified, for the test is not sensitive to errors sufficient in amount to render a telescope objective almost valueless; but such errors are easily discernible by other optical devices. In general, accuracy in the radii of curvature is of primary importance and trueness of figuring is of secondary importance in photographic objectives, while the reverse holds with telescopic objectives; in wide angle microscopic objectives these two conditions are of equal moment. Eye pieces do not require the same degree of accuracy either in the curvature or the figuring.

A rough idea of the exactitude to which the figuring of the finest telescope objectives must be carried out is readily deduced. If two slips of paper, bearing printed letters $\frac{1}{10}$ of an in. high be placed in almost exact alignment, one 31·2 in. from the eye and the other 39 in., and viewed in moderate daylight with the eye having a pupillary aperture of $\frac{1}{8}$ of an in., one set of the letters will be legible while the other is not. In this case the difference of convergence or refracting power exercised by the eye in transferring its focus from one slip to the other is $\frac{1}{4}\frac{1}{3}$ or one quarter diopter. If an image on the retina is $\frac{1}{n}$ diopter out of focus, then each point of the object is represented by a circle of confusion 0·0004 in. or 2′ 45″ in angular measure in diameter, the focal length of the eye being assumed to be 0·5 in. and the pupillary aperture $\frac{1}{8}$ of an in. If the effective aperture of the pupil or the aperture of a pencil traversing the pupil be $1/n$th of this standard, the size of the disk of confusion will be the same (viz. 0·0004 in.) if the retinal image be n quarter diopters out of focus. In general, for a constant size of the circle of confusion or, in other words, the same amount of visual blurring, the apertures of the pencils traversing the pupil and the focussing errors (expressed in quarter diopters) vary inversely.

If a portion of a figured surface of a telescope objective differs in curvature from the major portion of the lens so as to form a circle of confusion on the retina of a diameter not less than 2′ 45″, it is clear that the lens is faulty, the image formed by the perfect portion being sharp and well defined, and that formed by the imperfect portion blurred to the extent above determined, and to a greater extent if we allow for the effect of diffraction in the formation of the image. For example, a protuberance 1 in. in diameter at the centre of an object glass of 12 in. aperture refracting to a separate focus would theoretically form a spurious disk of about 5 seconds diameter, which would subtend a diameter of 50 minutes at the retina under a power of 600.

Regarding 2′ 45″ as the maximum diameter of a geometric circle of confusion permissible in a telescopic object glass, we proceed to determine the heights of the protuberance or depression which causes it. If f be the equivalent focal length of the eye-piece and F that of the objective (the back focal length in the case of the microscope), then the linear error at the focus of the eye-piece is $\frac{1}{1\,2\,8}f^2$, or, expressed as a variation of $1/F$, $\frac{1}{1\,2\,8}(f/F)^2$, $\left(=\Delta\frac{1}{F}\right)$. If a lens has one side plane and is worked to a mathematically sharp edge, its thickness t at the centre is (approximately) $A^2/8r$, where A is the whole aperture and r the radius; and if g be the equivalent focal length and μ the refractive index, we may write $r=g(\mu-1)$ and obtain

$$t=A^2/8g(\mu-1) \quad . \quad . \quad . \quad . \quad (1).$$

It is clear that for lenses in which the focal length is large compared with the aperture, the thickness t is independent of the shape of the lens so long as the focal length and aperture remain constant. Consequently a protuberance may be regarded as a thin meniscus lens with mathematically sharp edges accurately fitted to a perfectly regular spherical surface. Substituting for $1/g$ the $\frac{1}{156}(f/F)^2$ obtained above it follows that

$$t = \frac{A^2}{8(\mu-1)}\frac{1}{156}\left(\frac{f}{F}\right)^2 \quad . \quad . \quad . \quad (2).$$

The effective aperture of the eye has been supposed to be $\frac{1}{4}$ in.; calling this P, it is then obvious that (since F/f is the magnifying power) $P(F/f)$ is the theoretical aperture of objective requisite to supply the $\frac{1}{4}$ in. eye-pencil. Substituting $P(F/f)$ for A in equation (2) we obtain

$$t = P^2/8(\mu-1)\times 156 \quad , \quad . \quad . \quad (3).$$

This relation gives the thickness of a meniscus protuberance fitted to an objective (assumed to have an unlimited aperture) which fills the $\frac{1}{4}$ in. pupil and occasions the maximum blurring permissible. If μ be 1·5, t is equal to 1/39,936 in.

If the thickness t correspond to the aperture A, then for another aperture a to produce the same blurring we must have $\Delta'(1/F) = \Delta(1/F)A/a$, *i.e.* the focal length of the protuberance, and therefore the thickness t must vary as A. Consider a telescope of 12 in. aperture, focal length of objective (F) = 180 in., focal length of eye-piece (f) 0·3 in. and magnifying power (F/f) = 600. The aperture theoretically requisite to transmit the pupillary pencil of $\frac{1}{4}$ in. aperture is $\frac{1}{4}\cdot 600 = 75$ in. If the permissible protuberance cover the entire aperture of 75 in. its thickness would be 1/39,936 in. as above, but if restricted to a diameter of 1 in., then the maximum allowable thickness would be $1/75\times 1/39{,}936$ in. = say 1/3,000,000 in. Since the latter protuberance is assumed to fill only $\frac{1}{75}$ of the aperture of the pupil of the eye, it produces an error in focussing equivalent to 75 quarter diopters or $\frac{75}{156}$. If we take the power of the eye-piece to be 1/·3 in. and subtract from it 75/156, we obtain 1/·35, so that ΔF is −·05 in.

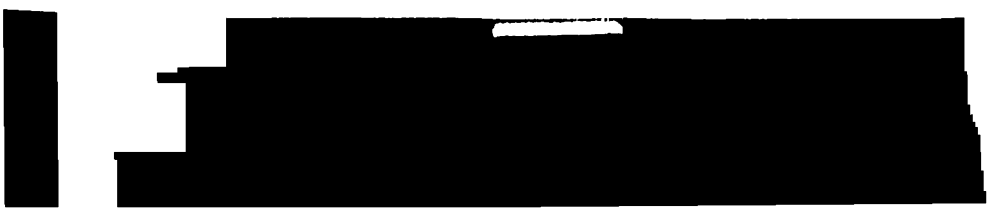
Either the knife-edge test, or the more usual method of testing figuring by examining the out-of-focus disks formed on the retina when the eye-piece is inside and outside its correct focus, would certainly show the effect of this protuberance as a bright central spot when inside focus, and a dark central patch when outside; a practised eye can detect one-half the above error, and a quarter when the power is 1200 instead of 600. It may be noticed that, under the same circumstances, the error permissible in a reflecting telescope is only one quarter of that admitted in the refractor. In the case of a microscope objective of 10 in. back-focal-length used with a 1 in. eye-piece, the aperture required to transmit the pupillary pencil of $\frac{1}{4}$ in. aperture is $1\frac{1}{4}$ in. Regarding the supposititious protuberance or depression as $\frac{1}{75}$ in. in diameter, its thickness or depth must not exceed $1/39{,}936\times 0\text{·}05/1\text{·}25$, or say 1/1,000,000 in. Therefore the accuracy of figuring required in the best microscopes does not fall far short of that required in telescopes.

The best optical workmanship, as applied to large reflecting surfaces, aims at reducing local protuberances or depressions to within the limiting height or depth of one twelve-millionth part of their diameter (A) and the optical methods which detect these errors are exceedingly delicate. The finest spherometer detects errors down to about three-millionths of an inch, below which it is valueless. The same applies to the study of the interference fringes formed when a master curve is fitted. It will not show up such fine errors. The figuring of spherical surfaces 12 in. or more in diameter by abrasion with a polisher so that no part of the surface is elevated or depressed above the average level by more than the above defined amounts is commonly practised, but much technical knowledge is necessary for success. It is a *sine qua non* that the material of the polisher should be as plastic and inelastic as is consistent with a moderate degree of hardness. The best material for large work is Stockholm pitch from which the greater part of the turpentine has been removed by evaporation, and the abrasive used is the finest rouge and water. For small work certain waxes, more or less mixed with rouge or putty powder, are used. Water is used as the lubricant. During delicate figuring temperature changes must be carefully avoided, otherwise buckling and consequent bad figuring of the lens or a variation in the hardness of the polisher may supervene. The motion of the polisher must therefore be leisurely. Moreover, any surface must be allowed to attain a uniform temperature before testing. When, as often happens, an elevation or depression on a large lens apparently refuses to be dislodged by straightforward polishing, recourse is had to local retouching. The faulty parts are localized by optical tests and then rubbed down by small polishers of an inch or more in diameter. In this way a central protuberance 1 in. in diameter and 1/2,000,000 of an in. high standing on the centre of a large objective may be removed by a polisher less than an inch in diameter worked at 200 half inch strokes per minute and at a pressure of 6 ozs. in about a minute. Great care is required, for if the process be carried too far, the whole surface must be re-figured. Local retouching serves to remove those conspicuous zones of aberration to which certain photographic lenses of large relative aperture are necessarily liable. An annular channel is polished out at a mean distance equal to $\frac{1}{75}$ of the semi-aperture from the centre of the lens, and this is carefully shaded off towards the centre and also towards the edge, this corrects the zone of rays which focus at a point short of the focus of the centre and edge rays. This correction is particularly necessary in the case of certain lenses designed for stellar photography. (H. D. T.)

OBJECTIVISM, in philosophy, a term used, in contradistinction to SUBJECTIVISM, for any theory of knowledge which to a greater or less extent attributes reality (as the source and necessary pre-requisite of knowledge) to the external world. The distinction is based upon the philosophical antithesis of the terms Object and Subject, and their respective adjectival forms "objective" and "subjective." In common use these terms are opposed as synonymous respectively with "real" and "imaginary," "practical" and "theoretical," "physical" and "psychic." A man "sees" an apparition; was there any physical manifestation, or was it merely a creation of his mind? If the latter the phenomenon is described as purely subjective. Subjectivism in its extreme form denies that mind can know more than its own states. Objects, *i.e.* things-in-themselves, may or may not exist: the mind knows only its own sensations, perceptions, ideal constructions and so forth. In a modified form "subjectivism" is that theory which attaches special importance to the part played by the mind in the accumulation of experience. See PSYCHOLOGY; RELATIVITY OF KNOWLEDGE.

OBLATION, an offering (Late Lat. *oblatio*, from *offerre*, *oblatum*, to offer), a term, particularly in ecclesiastical usage, for a solemn offering or presentation to God. It is thus applied to certain parts of the Eucharistic service in the Roman Church. There are "two oblations," the "lesser oblation," generally known as the "offertory," in which the bread and wine yet unconsecrated are presented, and the "greater oblation," the "oblation" proper, forming the latter part of the prayer of consecration, when the "Body and Blood" are ceremonially presented. The word "oblate" is an ecclesiastical term for persons who have devoted themselves or have been devoted as children by their parents to a monastic life. "Oblate" is more familiar in the Roman Church as the name of a religious congregation of secular priests, the Oblate Fathers of St Charles. They are placed under the absolute authority of the bishop of the diocese in which they are established and can be employed by him on any duties he may think fit. This congregation was founded in 1578 under the name of Oblates of the Blessed Virgin and St Ambrose by St Charles Borromeo, archbishop of Milan (see BORROMEO, CARLO). There is a similar congregation of secular priests, the Oblates of Mary the Immaculate, founded at Marseilles in 1815.

OBLIGATION, in law, a term derived from the Roman law, in which *obligatio* signified a tie of law (*vinculum juris*) whereby one person is bound to perform or forbear some act for another. The *obligatio* of Roman law arose either from voluntary acts or from circumstances to which legal consequences were annexed. In the former case it was said to arise *ex contractu*, from contract, in the latter *quasi ex contractu*, *ex delicto*, or *quasi ex delicto*—that is to say, from tort, or from acts or omissions to which the law practically attached the same results as it did to contract or tort. *Obligatio* was used to denote either end of the legal chain that bound the parties, the right of the party who could compel fulfilment of the *obligatio*, the *creditor*, or the duty of the party who could be compelled to fulfilment, the *debitor*. In English law obligation has only the latter sense. Creditor and debtor have also lost their Roman law signification; they have been narrowed to mean the parties where the obligation is the payment of a sum of money. In English law obligation is used in at least four senses—(1) any duty imposed by law; (2) the special duty created by a *vinculum juris*; (3) not the duty, but the evidence of the duty—that is to say, an instrument under seal, otherwise called a bond; (4) the operative part of a bond. The third use of the word is chiefly confined to the older writers. *Simplex* and *duplex obligatio* were the old names for what are now more commonly called a single and a double or conditional bond. The party bound is still called the obligor, the party in whose favour the bond is made the obligee. The



fourth, like the third, is a use scarcely found except in the older writers. The word "bond" is of course a mere translation of *obligatio*. Obligations may be either perfect or imperfect. A perfect obligation is one which is directly enforceable by legal proceedings; an imperfect or moral obligation (the *naturalis obligatio* of Roman law) is one in which the *vinculum juris* is in some respects incomplete, so that it cannot be directly enforced, though it is not entirely destitute of legal effect. A perfect obligation may become imperfect by lapse of time or other means, and, conversely, an imperfect obligation may under certain circumstances become perfect. Thus a debt may be barred by the Statute of Limitations and so cease to be enforceable. The obligation, however, remains, though imperfect, for if there be a subsequent acknowledgment by the debtor, the debt revives, and the imperfect obligation becomes again perfect. At one period there was some doubt among English lawyers whether a moral obligation could be regarded as sufficient consideration for a contract; it has now, however, been long decided that it cannot be so regarded.

American law is in general agreement with English, except in the case of Louisiana, where the terms obligor and obligee are used in as wide a sense as the *debitor* and *creditor* of Roman law. By art. 3522 of the Louisiana civil code obligor or debtor means the person who has engaged to perform some obligation, obligee or creditor the person in favour of whom some obligation is contracted, whether such obligation be to pay money or to do or not to do something. The term obligation is important in America from its use in art. i. s. 10 of the constitution of the United States, "No state ... shall pass any ... law ... impairing the obligation of contracts." This does not affect the power of Congress to pass such a law. Contracts between private individuals are of course within the provision. So are private conveyances, charters of private corporations and statutory and other grants by a state. On the other hand, marriage and divorce, and arrangements which are political in their nature, such as charters of municipal corporations, licences to carry on particular trades or regulations of police are not within the provision. In order to fall within it, the law must act upon the terms of the agreement, and not merely upon the mode of procedure. If it act not upon the terms but upon the remedy, it impairs the obligation if it purport to be retrospective, but it is valid so far as it applies to subsequent contracts.

OBNOXIOUS (Lat. *obnoxiosus*, from *ob*, over, against, and *noxa*, harm), a word originally meaning "exposed to harm or injury," but now "exciting aversion or dislike." The current use dates from the later 17th century.

OBOE, or HAUTBOY (Fr. *hautbois*, Ger. *Hoboe*, Ital. *oboe*), the treble member of the class of wood-wind instruments, having a conical bore and a double reed mouthpiece. The oboe consists of a conical wooden tube, composed of three joints, upper, middle and bell, and of a short metal tube to which are bound by many turns of waxed silk the two thin pieces of cane that form the mouthpiece. These pieces of cane are so bevelled and thinned at the end which is taken into the mouth that the gentlest stream of compressed air suffices to set them vibrating. Practice has demonstrated that the reed stalk of which the double reed mouthpiece is made, should not be of narrower internal diameter than the pipe containing the column of air upon which it is destined to act. The player breathes gently into the aperture, which has the form of a very narrow ellipse, managing his breath as for singing. The vibrations of the double reed produce in the stream of compressed air issuing from the player's lips the rhythmical series of pulses necessary to generate sound waves in the stationary column of air within the main tube of the instrument.

In the upper and middle joints are the rings and keys covering lateral holes bored through the tube, by means of which the column of air, and consequently the wave length, may be shortened at will; the bell joint contains one or two keys normally open, which when closed extend the lowest register by lengthening the air column. These holes and keys produce the fundamental scale of the oboe, which possesses notes sufficient for an octave with all chromatic intervals. The next octaves are obtained by means of cross fingering (Fr. *doigté fourché*, Ger. *Gabelgriff*), and of the octave keys, which do not give out an independent note of their own, but determine a node in the column of air, whereby the latter divides and vibrates in two half sections producing the second harmonic overtone or octave. In order to obtain this result the player increases the pressure of his breath and also the tension of his lips against the reed.

The compass of the oboe is from  with all chromatic semitones. The G clef is used in notation and all notes are sounded as written.

The quality of tone or timbre depends primarily on the configuration of the sound waves (see HORN), which is influenced by the special characteristics of the mouthpiece: the musical tone of an instrument may be said to be due more directly to the prevalence and relative strength of the many harmonics which go to make up a composite tone or clang. The quality of the oboe tone resembles that of the E string of the violin, but is more nasal, more penetrating and shriller. The lower register is thin and somewhat sweeter, approximating to the upper register of the *cor anglais*. But the timbre does not vary appreciably in the different registers, and to this want of variety in tone colour is due the unpopularity of the oboe as a solo instrument, although it is invaluable as a melody-leading instrument in the orchestra, balanced by clarinets and flutes. The oboe lends itself admirably to pastoral music. The technical capabilities of the instrument are very varied. It is possible to play on it diatonic and chromatic scale and arpeggio passages, legato and staccato, leaps; cantabile passages; sustained notes, crescendo and diminuendo, grace notes and shakes (with reservations). The keys having many sharps and flats are the most difficult for the oboist.

Rudall, Carte & Co.

FIG. 1.—The Oboe.

The double reed is the most simple, as it is probably the oldest, of all reed contrivances. It is sufficient to flatten the end of a wheat straw to constitute an apparatus capable of setting in vibration by the breath the column of air contained in the rudimentary tube; the invention of this reed is certainly due to chance. An apparatus for sonorous disturbance thus found, it was easy to improve it: for the wheat stalk a reed stalk was substituted, and in the extremity of its pipe another reed stalk much shorter in length was inserted, pared and flattened at the end; and then came the lateral holes, probably another discovery of the great inventor chance. For the reed tube a wooden one was substituted, still preserving the reed tongue, and it is in this form, after having played an important part amongst the sonorous contrivances of antiquity, that we find the ancestor of the oboe playing a part no less important in the 16th century, in which it formed the interesting families of the cromornes, the corthols and the cervelas. All these families have disappeared from the instrumental combinations of Europe, but they are still to be found in Eastern wind instruments, such as the Caucasian *salamouri*, the Chinese *hsuntze*, and the *hitchiriki* of Japan.

It is impossible to say when it was that man first employed the phenomena of double reeds and conical pipes, but the knowledge of them must at least have been later than that of the cylindrical pipe, which we may regard as directly furnished by nature. That antiquity made use of them, however, has been proved by Gevaert in his admirable *Histoire de la musique dans l'antiquité*; but the learned author states that the double-reed pipes held but an insignificant place in the instrumental music of ancient Greece and Rome, a statement which is open to challenge (see AULOS).

The first appearance of the instrument we call oboe in a musical work occurs in Sebastian Virdung's *Musica getutscht und aussgezogen* (1511). It there bears the name of *Schalmey*, and is already associated with an instrument of similar construction called *Bombardt*.

There exists, however, much earlier evidence, in the illuminated MSS. and in the romances of the middle ages, of the great popularity of the instrument in all parts of Europe. The origin of wind instruments with conical tubes must be sought in the East, in Asia. An early medieval Schalmey with three holes may be seen on the silver cup of the goddess Nana-Anat.[1]

There are two or three Schalmeys in the fine 13th-century Spanish MS. *Cantigas de Santa Maria* executed for Alphonso the Wise, preserved in the Library of the Escorial[2] (J. b 2).

The oboe was known during the early middle ages as *Calamus*, *Chalumeau* (France), *Schalmei* (Germany), *Shawm* (England). It is mentioned in the *Roman de Brut* (12th century) (line 10,822 seq.) "Lyres, tympres, et chalemiax." An interesting MS. at the British Museum, Sloane 3983, contains among other musical instruments on fol. 13 a large shawm with 6 finger-holes described at the side as *Calamus aureus*.

A miniature in the Paris Manesse MS.[3] of the 14th century depicts Heinrich von Meissen, better known as Frauenlob, conducting, from a raised platform, a band of musicians, one of whom is holding a Schalmey with 6 or 7 holes.

The chaunter of the bagpipe was a shawm, having the double reed concealed within an air-chamber, while the drones had single beating reeds concealed in the same manner. Mersenne calls both *chalumeaux*.[4] The cornemuse or chalemie of shepherds and peasants was of this kind, but a special cornemuse, used in the 17th century in concert with the hautbois de Poitou, had double reeds throughout in chaunter and drone. The hautbois de Poitou was a primitive oboe with the reed placed in a bulb, forming an air-chamber, having a raised slit at the top through which the performer breathed in compressed air; as the reed could not be controlled by the lips, it was impossible to play with expression on the hautbois de Poitou or to obtain the harmonic octaves; the compass was therefore limited. The kind of bagpipe (*q.v.*) known as *Musette*,[5] inflated by bellows, also had double reeds throughout in spite of having a cylindrical chaunter.

The manufacture of musical instruments could not remain unaffected by the great artistic movement known as the Renaissance; accordingly, we find them not only improved and purified in form in the 16th century, but also ranged in complete families from the soprano to the bass. Praetorius, in his *Syntagma Musicum* (1615–1620), gives us the full nomenclature of the family with which we are concerned, composed of the following individuals: (1) The little Schalmey, rarely employed, measured about 17 in. in length, and had six lateral holes. Its deepest note was  . (2) The discant Schalmey (fig. 2), the primitive type of the modern oboe; its length was about 26 in., and its deepest note  . (3) The alto Pommer (fig. 3), 30½ in. long, with its deepest note  (4) The tenor Pommer (fig. 4), measuring about 4 ft. 4 in.; besides the six lateral holes of the preceding numbers there were four keys which produced the notes  . (5) The bass Pommer, having a length of nearly 6 ft.; it had six lateral holes and four keys which produced  . (6) The great double quint Pommer, measuring about 9 ft. 8 in. in length; its four keys permitted the production of the notes  . These instruments, and especially numbers (2), (3), (4) and (5), occupied an important place on the continent of Europe in the instrumental combinations of the 16th-18th centuries. the 18th century much-appreciated improvements in the boring of the instrument. The *Méthode* of Sellner, published at Vienna in 1825, shows nine keys  , and one, the octave key, which, when opened, establishes a loop or ventral segment of vibration in the column of air, facilitating the production of sounds in the octave higher. Triebert of Paris owes his great reputation to the numerous improvements he introduced in the construction of the oboe.

The alto Pommer was but slowly transformed: it was called in French "hautbois de chasse," in Italian "oboe di caccia." In the 18th century we find it more elegant in form, but with all the defects of the primitive instrument. The idea of bending the instrument into a half circular form to facilitate the handling is usually attributed to an oboist of Bergamo, one Jean Ferlendis, who was established at Salzburg at about 1760. This is obviously incorrect, since Ferlendis would then have been five years old.[1] It has been suggested that the fact of the instrument's resembling a kind of hunting

FIG. 5.

horn used at that time in England probably gained for it the name of "corno inglese," which it still retains ("cor anglais" in French).[2] The first employment of it in the orchestra is referred to Gluck, who had two "cors anglais" in his *Alceste*, as played at Vienna in 1767. But it was not until 1808 that the cor anglais was first heard in the Paris opera; it was played by the oboist Vogt in *Alexandre chez Apelle* by Catel. The improvements in manufacture of this instrument closely followed those introduced in the oboe. The 18th century produced an intermediate oboe between (2) and (3), which was called hautbois d'amour, and was frequently employed by J. S. Bach. It was a third lower than the ordinary oboe, and was characterized by the pear-shaped bell with narrow aperture common to all wind instruments known as *d'amour* to which is due their veiled sweet quality. In the Spanish *Cantigas*, there are two Schalmeys with pear-shaped bells. This is in all probability the *douçaine* mentioned in the 13th and 14th-century romances. The oboe d'amore fell into disuse after the death of the great German composer. It has been resuscitated by the firm of C. Mahillon of Brussels, and reconstructed with the improvements of modern manufacture. A similar timbre was artificially produced in the oboe by means of mutes or *sordini* composed of hollow cones of wood, balls of paper,[3] pieces of sponge,[4] &c.

After the 16th century we find the instruments which were designated by the name of "gros bois," the (5) and (6) of Praetorius, transformed into shorter instruments, the Fagott and Contrafagott, having a column of air of the same length and form as the Pommers, but the instrument itself consisted of two conical tubes communicating at the lower part of the instrument; they were pierced in a single piece of wood. It is probably owing to the aspect of this double pipe that the satirical name of fagot was given, preserved in Italian as fagotto, and in German as Fagott. A canon of Ferrara named Afranio has been named as the author of the transformation, about 1539, of the bass Pommer, but Count Valdrighi, the curator of the Estense library,[5] and Wasielewski,[6] who has reproduced the drawing of Afranio's invention, deprive him of the merit of the innovation. The fagottino was transformed in the same fashion.

Sigismund Schnitzer of Nuremberg[7] acquired a great reputation in the 16th century for making the "basson," a French word substituted for the old fagot, and adopted in England as bassoon. His instrument had only two keys  . We cannot tell when the bassoon gained its present form, but it was probably at the end of the 17th century. It was used in the orchestra in Germany by H. Schütz in 1619 (*cir.*),[8] and in 1625, 5 fagotti were in use.[9]

Cesti, in his grand opera *il Pomo d'oro*,[10] which was performed with the utmost brilliancy at the nuptials of the emperor Leopold in Vienna, where printed editions of 1667 and 1668 are preserved, used fagotti combined with two cornets, three trombones and a regal to suggest the terrors of Hades.

Michael Praetorius (1618) expressly mentions the fagotto as an orchestral instrument.

In France it was used with the oboe in 1671 in Cambert's *Pomona* in the newly founded French Opera, for which Cambert & Perrin had received in 1669 a Royal *Privilège* expiring in 1672, and thereafter granted to Lully.

It had three keys then  . The B flat key rendering a lengthening of the instrument necessary, we may suppose it took its modern form at that epoch. The fourth key  is found in a bassoon stamped Stanesby Junior, London, 1747.[11] and also in one without maker's name, obviously earlier, to judge by the very early pattern of the keys.[12] The bassoon appears with four keys in the *Encyclopédie* of Diderot and d'Alembert (Paris, 1751–1765). The number of keys increased by the beginning of the present century to eight, viz.:  , and two keys to facilitate the production of acute harmonics. It was improved by Almenräder in Germany, Savari, and more recently Triebert and Goumas, Paris, and C. Mahillon, Brussels. (See also BASSOON.)

The reform in the construction of the flute due to Theobald Boehm of Munich about 1840, a reform which principally consisted in the rational division of the tube by the position of the lateral holes, prompted Triebert to try to adapt the innovation to the oboes and bassoons; but he failed, because the application of the system denaturalized the timbre of the instruments, which it was necessary, before all things, to preserve, but further improvements made upon the same lines by Barret and later by Rudall Carte, have transformed the oboe into the most delicate and perfect of reed instruments. In 1856 a French bandmaster, M. Sarrus, thought out the construction of a family of brass instruments with conical tubes pierced at regular distances, which, by diminishing the length of the air column, has rendered a series of fundamental sounds easy—more equal and free in timbre than that of the oboe family. Gautrot of Paris realized the inventor's idea, and, under the name of "sarrusophones," has created a complete family, from the sopranino in E flat to the contrabass in B flat, of which his firm preserves the monopoly.

In order to replace the old double-bassoon of wood, the firm of C. Mahillon, Brussels, produced in 1868, a reed contrabass of metal, since much used in orchestras and military bands. The first idea of this instrument goes back to 1839, and is attributed to Schöllnast & Son of Pressburg. It is a conical brass tube of very large proportions, with lateral holes placed as theory demands, in geometrical relation, with a diameter almost equal to the section of the tube at the point where the hole is cut. From this it results that for each sound one key only is required, and the seventeen keys give the player almost the facility of a keyboard. The compass written for the contrabass is comprised between  and but sounds an octave lower. *See* CONTRAFAGOTTO. (V. M.; K. S.)

OBOK, a seaport on the north shore of the Gulf of Tajura, N.E. Africa, acquired by France in 1862. It gave its name to the colony of Obok, now merged in the French Somali coast protectorate (see SOMALILAND: *French*). The port is separated from the open sea by coral reefs, but is only partially sheltered from the winds. This led to the practical abandonment of the town by the French, who in 1896 transferred to Jibuti, on the opposite shore of the Gulf of Tajura, the seat of government of the colony. Obok is connected with Aden and Jibuti by submarine cables. Population about 500.

OBRA, a river of Germany, in the Prussian province of Posen, a left-bank tributary of the Warthe. It rises near Obra, N.W. from Koschmin, and forms in its course marshes, lakes and the so-called Great Obrabruch (fen). The latter, 50 m. long and about 5 m. broad, is a deep depression in the undulating country of south-west Posen. The river is here dammed in and canalized and affords excellent water transit for the agricultural produce of the district.

O'BRIEN, WILLIAM SMITH (1803–1864), Irish revolutionary politician, son of Sir Edward O'Brien, a descendant of Brian Boroimhe (d. 1014), king of Ireland (see CLARE), was born in Co. Clare on the 17th of October 1803, and received his education at Harrow and at Cambridge. He took the additional name of Smith on inheriting his maternal grandfather's estates in Limerick. He entered parliament in 1828 as member for Ennis, and from 1835 to 1848 represented the county of Limerick. Although he spoke in 1828 in favour of Catholic emancipation, he for many years continued to differ on other points from the general policy of O'Connell. But he opposed the Irish Arms Act of 1843, and became an active member of the Repeal Association. Though he was destitute of oratorical gifts, his arraignment of the English government of Ireland secured him enthusiastic attachment as a popular leader. In July 1846 the "Young Ireland" party, with Smith O'Brien and Gavan Duffy at their head, left the Repeal Association, and in the beginning of 1847 established the Irish Confederation. In May 1848 he was tried at Dublin for sedition, but the jury disagreed. In the following July he established a war directory, and attempted to make a rising among the peasantry of Ballingarry, but although he was at first joined by a large following the movement wanted cohesion, and the vacillating crowd dispersed as soon as news reached them of the approach of the dragoons. O'Brien was arrested at Thurles, tried and sentenced to death. The sentence was, however, commuted to transportation to Tasmania for life. In February 1854 he received his liberty on condition of never revisiting the United Kingdom; and in May 1856 he obtained a full pardon, and returned to Ireland. In 1856 he published *Principles of Government, or Meditations in Exile*. He died at Bangor, north Wales, on the 18th of June, 1864. He had five sons and two daughters. His eldest brother, Lucius, became 13th Baron Inchiquin in 1855, as heir male to the 3rd marquis of Thomond, at whose death in 1855 the marquisate of Thomond and the earldom of Inchiquin became extinct. (See INCHIQUIN, 1ST EARL OF.)

OBSCENITY (from the adjective "obscene," Lat. *obscenus*, evil-looking, filthy). By English law it is an indictable misdemeanour to show an obscene exhibition or to publish any obscene matter, whether it be in writing or by pictures, effigy or otherwise. The precise meaning of "obscene" is, however, decidedly ambiguous. It has been defined as "something offensive to modesty or decency, or expressing or suggesting unchaste or lustful ideas or being impure, indecent or lewd." But the test of criminality as accepted in England and Canada is whether the exhibition or matter complained of tends to deprave and corrupt those whose minds are open to immoral influences and who are likely to visit the exhibition, or to see the matter published. If the exhibition or publication is calculated to have this effect, the motive of the publisher or exhibitor is immaterial. Even in the case of judicial proceedings, newspapers are not privileged to publish evidence which falls within the definition. In dealing with writings alleged to be obscene, the court and jury have to consider the effect of the whole work and not merely the particular extract challenged as improper; and in practice it is difficult to induce juries to convict the publishers of well-known and old-established works of real literary quality on the ground that they contain passages offensive to modern notions of propriety. In the case of exhibitions of sculpture and pictures some difficulty is found in drawing the line between representations of the nude and works which fall within the definition above stated—a difficulty raised in a somewhat acute form before the London County Council in 1907 by theatrical representations of "living statuary."

Besides the remedy by indictment there are statutory provisions for punishing as vagabonds persons who expose to public view in public streets or adjacent premises obscene prints, pictures or other indecent exhibitions. These are supplemented by similar provisions, applicable to the metropolis and to county towns, and (by a statute of 1889) for suppressing certain kinds of indecent advertisements. By an act of 1857 powers are given for searching premises on which obscene books, &c., are kept for sale, distribution, &c., and for ordering their destruction, and the post office authorities have power to seize postal packets containing such matter and to prosecute the sender. In 1906 the London publisher of a weekly comic paper was punished for inserting advertisements inviting readers to acquire by post from abroad matter of this kind.

The use of obscene or indecent language in public places is punishable as a misdemeanour at common law, but it is usually dealt with summarily, under the Metropolitan Police Act 1839, or the Town Police Clauses Act 1847, or under local by-laws.

British Possessions.—In British India obscene publications, exhibitions, &c., are punished under articles 292, 293 and 294 of the Penal Code. Special exception is made for representations in temples or on cars used for conveyance of idols or kept or used for religious purposes. In those British possessions whose law is based on the common law the offences above dealt with are offences at common law or under colonial statutes embodying the common law, *e.g.* Queensland Code, 1899, ss. 172, 227, 228; 374 (3); Western Australian Code, 1901, ss. 203, 204, 352 (3); Canadian Criminal Code, s. 179. In New South Wales and Western Australia, by acts of 1901 and 1902, provisions have been made for dealing summarily with indecent and obscene publications based to some extent on the English legislation of 1889 against indecent advertisements. In the Colonial acts no penalty is incurred if the defence can prove that the incriminated publication is a work of recognized literary merit, *e.g.* Aristophanes or Boccaccio's *Decameron*, or is a bonâ-fide medical work circulated in the manner permitted by the statutes.

United States.—Under the Federal Law (Revised Statutes, s. 3893) penalties are imposed for transmitting obscene matter by the U.S. mails; see *U.S.* v. *Wales* (1892), 51 Fed. Rep. 41. (W. F. C.)

OBSEQUENS, JULIUS, a Latin writer of uncertain date, generally placed about the middle of the 4th century A.D. He is the author of a small extant work *De prodigiis*, taken from an epitome of Livy, and giving an account of the prodigies and portents that occurred in Rome between 249–12 B.C.

The editio princeps was published by Aldus (1508); later editions by F. Oudendorp (1720) and O. Jahn (1853, with the *periochae* of Livy).

OBSEQUIES (Med. Lat. *obsequiae*, formed after class. Lat. *exsequiae*), a term for funeral rites and ceremonies, especially such as are carried out with great ceremony. The Lat. *obsequium* (from *obsequi*, to follow close after) produced the obsolete English "obsequy," in the sense of ready complaisant service, especially of an inferior to a superior, still found in the adjective "obsequious."

OBSERVATORY. Up to a comparatively recent date an "observatory" was a place exclusively devoted to the taking of astronomical observations, although frequently a rough account of the weather was kept. When the progress of terrestrial magnetism and meteorology began to make regular observations necessary, the duty of taking these was often thrown on astronomical observatories, although in some cases separate institutions were created for the purpose. In this article the astronomical observatories will be chiefly considered.

Up to about 300 B.C. it can scarcely be said that an observatory existed anywhere, as the crude observations of the heavens then taken were only made by individuals and at intervals, employing the simplest possible apparatus. Thus, according to Strabo.

Eudoxus had an observatory at Cnidus. But, when philosophical speculation had exhausted its resources, and an accumulation of facts was found to be necessary before the knowledge of the construction of the universe could advance farther, the first observatory was founded at Alexandria, and continued in activity for about four hundred years, or until the middle or end of the 2nd century of the Christian era. Hipparchus of Rhodes, the founder of modern astronomy, by repeating observations made at Alexandria, discovered the precession of the equinoxes, and investigated with considerable success the motions of the sun, moon and planets. His work was continued by more or less distinguished astronomers, until Ptolemy (in the 2nd century A.D.) gave the astronomy of Alexandria its final development. When science again began to be cultivated after the dark ages which followed, we find several observatories founded by Arabian princes; first one at Damascus, next one at Bagdad built by the caliph Al-Mamun early in the 9th century, then one on the Mokattam near Cairo, built for Ibn Yunis by the caliph Ḥakim (about 1000 A.D.), where the Ḥakimite tables of the sun, moon and planets were constructed. The Mongol khans followed the example; thus arose the splendid observatory at Maragha in the north-west of Persia, founded about A.D. 1260 by Hulagu Khan, where Nasir Uddin constructed the Ilohkhanic tables; and in the 15th century the observatory at Samarkand was founded by Ulugh Beg, and served not only in the construction of new planetary tables but also in the formation of a new catalogue of stars.

With the commencement of scientific studies in Europe in the 15th century the necessity of astronomical observations became at once felt, as they afforded the only hope of improving the theory of the motions of the celestial bodies. Although astronomy was taught in all universities, the taking of observations was for two hundred years left to private individuals. The first observatory in Europe was erected at Nuremberg in 1472 by a wealthy citizen, Bernhard Walther, who for some years enjoyed the co-operation of the celebrated astronomer Regiomontanus. At this observatory, where the work was continued till the founder's death in 1504, many new methods of observing were invented, so that the revival of practical astronomy may be dated from its foundation. The two celebrated observatories of the 16th century, Tycho Brahe's on the Danish island of Hven (in activity from 1576 to 1597) and that of Landgrave William IV. at Cassel (1561–1597), made a complete revolution in the art of observing. Tycho Brahe may claim the honour of having been the first to see the necessity of carrying on for a number of years an extensive and carefully-planned series of observations with various instruments, worked by himself and a staff of assistants. In this respect his observatory (Uraniburgum) resembles our modern larger institutions more closely than do many observatories of much more recent date. The mighty impulse which Tycho Brahe gave to practical astronomy at last installed this science at the universities, among which those of Leiden and Copenhagen were the first to found observatories. We still find a large private observatory in the middle of the 17th century, that of Johannes Hevelius at Danzig, but the foundation of the royal observatories at Paris and Greenwich and of numerous university observatories shows how rapidly the importance of observations had become recognized by governments and public bodies, and it is not until within the last hundred and thirty years that the development of various new branches of astronomy has enabled private observers to compete with public institutions.

The instruments employed in observatories have of course changed considerably during the last two hundred years. When the first royal observatories were founded, the principal instruments were the mural quadrant for measuring meridian zenith distances of stars, and the sextant for measuring distances of stars *inter se*, with a view of determining their difference of right ascension by a simple calculation. These instruments were introduced by Tycho Brahe, but were subsequently much improved by the addition of telescopes and micrometers. When the law of gravitation was discovered it became necessary to test the correctness of the theoretical conclusions drawn from it as to the motions within the solar system, and this necessarily added to the importance of observations. By degrees, as theory progressed, it made greater demands for the accuracy of observations, and accordingly the instruments had to be improved. The transit instrument superseded the sextant and offered the advantage of furnishing the difference of right ascension directly; the clocks and chronometers were greatly improved; and lastly astronomers began early in the 19th century to treat their instruments, not as faultless apparatuses but as imperfect ones, whose errors of construction had to be detected, studied and taken into account before the results of observations could be used to test the theory. That century also witnessed the combination of the transit instrument and the mural quadrant or circle in one instrument—the transit or meridian circle.

While the necessity of following the sun, moon and planets as regularly as possible increased the daily work of observatories, other branches of astronomy were opened and demanded other observations. Hitherto observations of the "fixed stars" had been supposed to be of little importance beyond fixing points of comparison for observations of the movable bodies. But when many of the fixed stars were found to be endowed with "proper motion," it became necessary to include them among the objects of constant attention, and in their turn the hitherto totally neglected telescopic stars had to be observed with precision, when they were required as comparison stars for comets or minor planets. Thus the field of work for meridian instruments became very considerably enlarged.

In addition to this, the increase of optical power of telescopes revealed hitherto unknown objects—double stars and nebulae—and brought the study of the physical constitution of the heavenly bodies within the range of observatory work. Researches connected with these matters were, however, for a number of years chiefly left to amateur observers, and it is only since about 1830 that many public observatories have taken up this kind of work. The application of spectrum analysis, photometry, &c., in astronomy has still more increased the number and variety of observations to be made, while the use of photography in work of precision has completely revolutionized many branches of practical astronomy. It has now become necessary for most observatories to devote themselves to one or two special fields of work.

It would be difficult to arrange the existing observatories into classes either according to the work pursued in them or their organization, as the work in many cases at different times has been directed to different objects, while the organization depends mostly on national and local circumstances. As already alluded to above, one of the principal characteristics of the larger observatories of the present day is the distribution of the work among a number of assistants under the general superintendence of a director. This applies principally to the great observatories, where the sun, moon, planets and a limited number of fixed stars are without interruption being observed, but even among these institutions hardly two are conducted on the same principles. Thus in Greenwich the instruments and observations are all treated according to strict rules laid down by the astronomer-royal, while in Washington or Pulkowa each astronomer has to a certain extent his choice as to the treatment of the instrument and arrangement of the observations. The same is the case with the smaller institutions, in most of which these arrangements vary very much with change of personnel.

The way in which the results of observations are published depends principally on the size of the institutions. The larger observatories issue their "annals" or "observations" as separate periodically-published volumes, while the smaller ones chiefly depend on scientific journals to lay their results before the public, naturally less fully as to details.

Subjoined is a catalogue of public and private observatories still in activity in 1910 or in existence within the past hundred years. ($1^m = 1°$ of long.)

(*Abbreviations*: ap., aperture; equat., equatorial; obs., observatory or observations; o.g., object-glass; phot., photographic; refl.,

reflector; refr., refractor; s.g., silvered glass; vis., visual; univ., university. Where the names of two makers are given, the first is responsible for the optical, the second for the mechanical part of the instrument.)

Great Britain and Ireland

A. Public Observatories.

Greenwich, royal obs., lat. +51° 28′ 38·4″. Founded in 1675 for the promotion of astronomy and navigation. The obs. have therefore from the first been principally intended to determine the positions of standard stars, the sun and planets, and above all to follow the motion of the moon with as little interruption as possible, both on and outside the meridian. Since 1873 spectroscopic obs. and a daily phot. record of sun-spots have been taken. The eighth satellite of Jupiter was discovered photographically in 1908. The obs. is under the direction of the astronomer-royal; and from the time of its first astronomer, Flamsteed, the institution has always maintained its place in the foremost rank of obs. Thus the obs. of Bradley (*ob.* 1762) form the foundation of modern stellar astronomy; but it was especially during the directorship of Airy (1835–1881) that the obs. rose to its present high state of efficiency. There are now two chief assistants, six assistants, and a staff of computers employed. The principal instruments now in use are: a meridian circle by Simms (and Ransomes and May as engineers), erected in 1850, having a circle of 6-ft. diameter and a telescope of 8-in. ap., Lassell's 2-ft. refl., erected 1884; 13-in. phot. refr. with 10-in. vis. o.g. by Grubb; 28-in. refr. by Grubb; 26-in. phot. refr. by Grubb, with the old 12·8-in. refr. as guiding telescope; 9-in. phot. refr. by Grubb, and 30-in. s.g. refl. by Common, the last four being on one stand; 8-in. altazimuth by Simms, erected 1896. The 26-in. and the 9-in. were presented by Sir H. Thompson. The standard "motor clock" is the centre of a system of electrically-controlled clocks scattered over the United Kingdom. The magnetic and meteorological department was founded in 1838; it contains a complete set of instruments giving continuous phot. records. The *Observations* are published with all details from 1750, beginning with 1836 in annual bulky quarto volumes; special results—*e.g.*, *Star Catalogues*, *Reductions of Lunar and Planetary Observations*—are published in separate volumes.

South Kensington, Solar physics obs., lat. +51° 29′ 48·0″, long. 0 h. 0 m. 41·5 s. W. Founded 1879, under Sir N. Lockyer; 3-ft. refl. and 30-in. refl. by Common; 10-in. refr. by Cooke, and several siderostats with attachments for spectroscopic and phot. work.

Oxford Radcliffe obs., lat. +51° 45′ 35·4″, long. 0 h. 5 m. 2·6 s. W. Founded in 1771 by the Radcliffe trustees. Obs. were regularly made, but none were published until 1839, when systematic obs. were begun with an 8-ft. transit instrument by Bird (1773) and a 6-ft. mural circle by Jones (1836). Heliometer (7½ in.) by Repsold (1849); meridian circle by Troughton and Simms, mounted in 1861, formerly belonging to Mr Carrington; 10-in. refr. by Cooke (1887), Grubb refr. with 24-in. phot. and 18-in. vis. o.g. (1902); self-recording meteorological instruments. Besides the annual 8vo vols. of *Observations* (from 1840), four catalogues of stars have been published.

Oxford, univ. obs., lat. +51° 45′ 34·2″, long. 0 h. 5 m. 0·4 s. W. Finished in 1875; is under the Savilian professor of astronomy; 12½-in. refr. by Grubb, and a 13-in. refl. made and presented by De La Rue. The former has been used for photometric obs.; the latter for taking lunar photographs, by means of which the late Professor Pritchard investigated the libration of the moon; 13-in. phot. refr. by Grubb attached to the 12½-in., used for phot. zone work.

Cambridge, lat. +52° 12′ 51·6″, long. 0 h. 0 m. 22·8 s. E. Founded by the univ. senate in 1820. Chiefly devoted to meridian work—up to 1870 with a 5-in. transit by Dollond and a mural circle by Jones; a new meridian circle by Simms, of 8-in. ap. and 3-ft. circles, was then erected. The "Northumberland equatorial" was mounted in the "English" fashion in 1838; the o.g. by Cauchoix is of 11½-in. ap. R. S. Newall's 25-in. refr. by Cooke, erected 1891, used for spectrographic work; siderostatic refr. with 12-in. o.g. by Cooke, 1898. In 1908 the instruments of Sir W. Huggins' obs. were presented by the Royal Society.

Durham, univ. obs., lat. +54° 46′ 6·2″, long. 0 h. 6 m. 19·8 s. W. Founded in 1841; small meridian circle by Simms, refr. by Fraunhofer of 6½-in. ap., Almucantar of 6-in. ap. by Cooke (1900).

Liverpool (Bidston, Birkenhead), lat. +53° 24′ 4·8″, long. 0 h. 12 m. 17·3 s. W. Founded in 1838 by the municipal council; transferred in 1856 to the Docks and Harbour Board; moved to Birkenhead in 1867. Specially intended for testing the rates of chronometers under different temperatures. Transit instrument by Troughton and Simms, and an 8-in. refr. by Merz.

Kew (Richmond), lat. +51° 28′ 6″, long. 0 h. 1 m. 15·1 s. W. The central meteorological obs. of the United Kingdom, with self-registering meteorological and magnetical instruments. Established in 1842 under the auspices of the British Association, afterwards transferred to the Royal Society. Since 1900 a department of the National Laboratory. A photoheliograph was employed at De La Rue's expense to take daily sun-pictures from 1863 to 1872.

Edinburgh, royal obs., Blackford Hill, lat. +55° 57′ 28·0″, long. 0 h. 12 m. 44·2 s. W. Founded in 1811 by subscription; the building on Calton Hill erected in 1818. In 1834 the founders handed over the administration to the government, and in 1846 the ownership was similarly transferred. Since 1034 the obs. has been under the direction of the astronomer-royal for Scotland, who is also professor of practical astronomy in the univ. Professor T. Henderson (1833–1845) began extensive meridian obs. of fixed stars with a mural circle of 6-ft. diameter and an 8-ft. transit. A 2-ft. s.g. refl. by Grubb was erected in 1872. New obs. erected on Blackford Hill 1893–1895 for the instruments presented by Lord Crawford; 15-in. refr. by Grubb, transit circle by Simms of 8-in. ap., 12-in. s.g. refl. by Browning, two 6-in. refrs. and a very fine library; also the 2-ft. refl. The old obs. on Calton Hill now belongs to the city and is used for instruction; a 21-in. refr. by Wragge has been erected.

Glasgow, univ. obs., lat. +55° 52′ 42·8″, long. c h. 17 m. 10·6 s. W. Organized in 1840 by subscription, aided by subsidies from the univ. and the state. Meridian circle by Ertel of 6-in. ap.; 9-in. refr. by Cooke, 20-in. s.g. refl. by Grubb with spectrograph. Two catalogues of stars were published by the late director, R. Grant.

Dublin, situated about 4 m. N.W. of Dublin at Dunsink, lat. +53° 23′ 13·1″, long. 0 h. 25 m. 21·1 s. W. Belongs to the univ.; erected in 1785; is under the direction of the "Andrews professor of astronomy and royal astronomer of Ireland." In 1808 a reversible meridian circle by Ramsden and Berge of 8-ft. diameter was put up, with which Brinkley observed assiduously till 1827. In 1868 was erected a refr. of 11¾-in. ap. by Cauchoix (o.g. formerly belonging to and given by Sir J. South), which has been used for researches on stellar parallax. A meridian circle by Pistor and Martins of 6·4-in. ap. was mounted in 1873, and a 15-in. s.g. refl. for phot. work in 1889. *Astronomical Observations and Researches made at Dunsink* in 4to parts.

Armagh, lat. +54° 21′ 12·7″, long. 0 h. 26 m. 35·4 s. W. Founded and endowed by Archbishop R. Robinson in 1790. Possessed very few instruments until the obs. was enlarged by Archbishop Lord John George Beresford in 1827, when a mural circle and a transit by Jones were provided, with which meridian obs. were made till 1883, published in two star catalogues; 10-in. refr. by Grubb (1885) used for micrometer work.

B. Principal Private Observatories in 1908.

Mr W. Coleman's obs., Buckland, Dover, lat. +51° 8′ 12″, long. 0 h. 5 m. 11 s. E. Cooke 8-in. refr. used for obs. of double stars.

Mr J. Franklin-Adams's obs., Mervel Hill, Hambledon, Surrey, lat. +51° 8′ 11·6″, long. 0 h. 2 m. 30·2 s. W. Erected 1903; twin equatorial by Cooke with 12-in. and 6-in. lenses, another with 8-in. and 6-in. lenses, used for phot. survey of the heavens with special reference to the Milky Way. The former instrument was used at the Cape in 1903–1904.

Rev. T. E. Espin's obs., Tow Law, Darlington, lat. +54° 43′ 30″, long. 0 h. 7 m. 14 s. W. 17½-in. refl. by Calver, used since 1888 for spectroscopy and obs. of double stars.

Mr W. H. Maw's obs., Kensington, lat. +51° 30′ 2·8″, long. 0 h. 0 m. 49·4 s. W., 6-in. refr. by Cooke (1886). Also at Outwood, Surrey, lat. +51° 11′ 38″, long. 0 h. 0 m. 23·7 s. W., 8-in. refr. by Cooke (1896), both used on double stars.

Sir Wilfrid Peek's obs., Rousdon, Lyme Regis, lat. +50° 42′ 38″, long. 0 h. 11 m. 59·0 s. W. Erected by the late Sir Cuthbert Peek in 1885; 6·4-in. refr. by Merz used for obs. variable stars.

Earl of Rosse's obs., Birr Castle, King's county, Ireland, lat. +53° 5′ 47″, long. 0 h. 31 m. 40·9 s. W. In 1839 the earl made and mounted a refl. of 3-ft. ap. (remounted as equat. in 1876), and in 1845 he completed the celebrated refl. of 6-ft. ap. and 54-ft. focal length. These instruments, particularly the latter, were used from 1848 to 1878 for obs. of nebulae, and revealed many new features in these bodies; results published in the *Phil. Trans.* and collected systematically in the *Trans. Roy. Dubl. Soc.* (1879–1880). Experiments were made by the present earl to determine the amount of heat radiated from the moon.

Rugby School (Temple Obs.), lat. +52° 22′ 7″, long. 0 h. 5 m. 2 s. W. Founded in 1872; 8¼-in. refr. by Clark, used for obs. of double stars and of stellar spectra.

Stonyhurst College obs., Lancashire, lat. +53° 50′ 40″, long. 0 h. 9 m. 52·7 s. W. An 8-in. refr. by Troughton and Simms, mounted in 1867, used for spectroscopic and micrometric obs.; 15-in. Perry memorial refr. by Grubb mounted in 1893, used chiefly for solar work.

C. Private Observatories now discontinued.

Mr J. G. Barclay's obs., Leyton, Essex, lat. +51° 34′ 34″, long. 0 h. 0 m. 0·9 s. W. In activity from 1862 till 1886, 10-in. refr. by Cooke; chiefly devoted to double stars.

Mr G. Bishop's obs., South Villa, Regent's Park, London, lat. +51° 31′ 29·9″, long. 0 h. 0 m. 37·1 s. W. In activity from 1836 to 1861, then removed to Twickenham, and discontinued in 1874; had a 7-in. refr. by Dollond, with which Mr J. R. Hind discovered ten minor planets and several comets, and constructed maps of stars near the ecliptic.

Mr R. C. Carrington's obs., Redhill, lat. +51° 14′ 25·3″, long. 0 h. 0 m. 41·3 s. W. Established in 1854; had a 4½-in. refr. and transit circle of 5-in. ap. (now at Radcliffe Obs.). With the latter a catalogue of the positions of 3735 stars within 9° of the pole, with the former regular obs. of sun-spots, were made from 1853 to 1861.

Mr A. A. Common's obs., Ealing, London, W. (1876–1903). 18-in. s.g. refl. erected in 1876, s.g. refl. of 36-in. ap. (mirror by Calver, mounting by the owner), erected in 1879; chiefly used for celestial photography, replaced by a refl. of 5-ft. ap. in 1889.

Colonel Cooper's obs., Markree Castle, Co. Sligo, Ireland, lat. +54° 10′ 31·8″, long. 0 h. 33 m. 48·4 s. W. Founded by the late E. J. Cooper, who in 1834 erected a refr. of 13·3-in. ap. (o.g. by Cauchoix). This instrument was from 1848 to 1856 used for determining the approximate places of 60,000 stars near the ecliptic. The obs. was restored in 1874, and the refr. was used for double-star obs. till 1883.

Earl of Crawford's obs., Dunecht, Aberdeenshire, lat. +57° 9′ 36″, long. 0 h. 9 m. 40 s. W. Founded in 1872; 15-in. refr. by Grubb, 12-in. s.g. refl. by Browning, two 6-in. and several smaller refrs. meridian circle by Simms similar to the one at Cambridge, numerous spectroscopes and minor instruments, also a large library and a collection of physical instruments. Chiefly devoted to spectroscopic and cometary obs. Whole equipment presented to Edinburgh obs. in 1888.

Mr E. Crossley's obs., Bermerside, Halifax, Yorkshire. Equatorial refr. by Cooke of 9·3 in. ap., erected in 1871, chiefly used for obs. of double stars till 1902.

Rev W. R. Dawes's obs., first at Ormakirk (1830–1839), lat. +53° 43′ 18″, long. 0 h. 11 m. 36 s. W.; afterwards at Cranbrook, Kent (1844–1850), lat. +51° 6′ 31″, long. 0 h. 2 m. 10·8 s. E.; then at Wateringbury, near Maidstone, lat. +51° 15′ 12″, long. 0 h. 1 m. 39·8 s. E., till 1857; and finally at Hopefield, Haddenham, lat. +51° 45′ 54″, long. 0 h. 3 m. 43·4 s. W., till Mr Dawes's death in 1868. Possessed at first only small instruments, then successively a 6-in. refr. by Merz, a 7½-in. and an 8½-in. refr. by Clark, and an 8-in. refr. by Cooke, with all of which a great many measures of double stars were made.

Mr W. De La Rue's obs., Cranford, Middlesex, lat. +51° 28′ 57·8″, long. 0 h. 1 m. 37·5 s. W. Established in 1857; with 13-in. refl., devoted to solar and lunar photography. The Kew photoheliograph was employed here from 1858 to 1863 to take daily photographs of the sun. The refl. was presented to the Oxford univ. obs. in 1874.

Mr S. Groombridge's obs., Blackheath, lat. +51° 28′ 2·7″, long. 0 h. 0 m. 0·6 s. E. In 1806 Mr Groombridge obtained a new transit circle of 4-ft. diameter by Troughton, with which he up to 1816 observed stars within 50° of the pole forming a catalogue of 4243 stars.

Sir William and Sir John Herschel's obs. at Slough near Windsor, lat. +51° 30′ 20″, long. 0 h. 2 m. 24 s. W. William Herschel settled at Datchet in 1782, and at Slough in 1786, and erected several 20-ft. refl. (of 18-in. ap.), and in 1789 his 40-ft. refl. of 4-ft. ap. The latter was comparatively little used (two satellites of Saturn were discovered with it), while the former served to discover about 2500 nebulae and clusters, 800 double stars, and two satellites of Uranus, as also to make the innumerable other obs. which have made the name of Herschel so celebrated. Sir J. Herschel used a 20-ft. refl. at Slough from 1825 to 1833, and from 1834 to 1838 at the Cape of Good Hope, to examine the nebulae and double stars of the whole of the visible heavens, discovering 2100 new nebulae and 5500 new double stars.

Sir William Huggins's obs., Upper Tulse Hill, London, lat. +51° 26′ 47″, long. 0 h. 0 m. 27·7 s. W. Founded in 1856; furnished with an 8-in. refr. (by Clark and Cooke). In 1870 was erected an equat. mounting with a 15-in. refr. and a Cassegrain refl. of 18-in. ap., both made by Grubb for the Royal Society. With these Sir W. Huggins has made his well-known spectroscopic observations and photographs of stellar spectra. The instruments were transferred to the Cambridge obs. in 1908.

Rev T. J. Hussey's obs., Hayes, Kent, lat. +51° 22′ 38″, long. 0 h. 0 m. 3·6 s. E. In activity from about 1825 for about twelve years; 6½-in. refr. by Fraunhofer, used for making one of the star maps published by the Berlin Academy.

Mr G. Knott's obs., Cuckfield, Sussex (from 1860 to 1873 at Woodcroft, lat. +51° 0′ 41″, long. 0 h. 0 m. 34 s. W., afterwards at Knowles Lodge, Cuckfield); 7·3-in. refr. by Clark, used for observing double stars and variable stars till 1894.

Mr W. Lassell's obs., from 1840 to 1861 at Starfield near Liverpool, lat. +53° 25′ 28″, long. 0 h. 11 m. 38·7 s. W.; contained refl. of 9- and 24-in. ap.; employed for obs. of the satellites of Saturn, Uranus and Neptune, and of nebulae. The 2-ft. refl. was used at Malta in 1852–1853, and a 4-ft. refl. was mounted in 1861, also at Malta, and used till 1864 for obs. of satellites and nebulae. The eighth satellite of Saturn, the two inner satellites of Uranus and the satellite of Neptune were discovered at Starfield by Mr Lassell.

Dr J. Lee's obs., Hartwell, Bucks, lat. +51° 48′ 36″, long. 0 h. 3 m. 24·3 s. W. In 1836 Dr Lee came into possession of Captain Smyth's 6-in. refr., and mounted it at Hartwell House where it continued to be occasionally employed for double-star obs. and other work up to about 1864.

Mr F. McClean's obs., Rusthall House, Tunbridge Wells. Phot. 12-in. refr. and o.g. prism by Grubb used for photos. of star spectra, 1895–1904.

Mr R. S. Newall's obs., Gateshead, Newcastle-on-Tyne. A 25-in. refr. by Cooke was mounted in 1870 but never used; presented to Cambridge obs. in 1891.

Dr Isaac Roberts's obs., Crowborough, Sussex, lat. +51° 3′ 7″, long. 0 h. 0 m. 37 s. E. 20-in. s.g. refl. by Grubb (with 7-in. refr.) used for phot. of nebulae and clusters 1890–1904.

Captain W. H. Smyth's obs., Bedford, lat. +52° 8′ 27·6″, long. 0 h. 1 m. 52·0 s. W. In 1830 Captain (afterwards Admiral) Smyth erected a 6-in. refr. by Tulley, and observed the double stars and nebulae contained in his "Bedford Catalogue" (1844).

Sir James South's obs., from 1816 to 1824 at Blackman Street, Southwark, long. 0 h. 0 m. 21·8 s. W. Here South took transit obs. of the sun, and he and J. Herschel measured double stars, in 1821–1823. In 1826 South erected an obs. at Campden Hill, Kensington, lat. +51° 30′ 12″, long. 0 h. 0 m. 46·8 s. W., and procured a 12-in. o.g. from Cauchoix. As Troughton, however, failed to make a satisfactory mounting, the glass was never used till after it had been presented to Dublin obs. in 1862.

Colonel Tomline's obs. at Orwell Park, Ipswich, lat. +52° 0′ 33″, long. 0 h. 4 m. 55·8 s. E. 10-in. refr. by Merz, used for obs. of comets from 1874 to 1889.

Mr W. E. Wilson's (d. 1908), obs., Daramona, Streete, Co. Westmeath, Ireland, lat. +53° 41′ 12″, long. 0 h. 29 m. 59 s. W. 2-ft. refl. by Grubb, and other instruments for phot. and solar work.

Lord Wrottesley's obs., from 1829 to 1841 at Blackheath, lat. +51° 28′ 2″, long. 0 h. 0 m. 2·7 s. E., where a catalogue of the right ascensions of 1318 stars was formed from obs. with a transit instrument by Jones. In 1842 a new obs. was built at Wrottesley Hall, lat. +52° 37′ 2·3″, long. 0 h. 8 m. 53·6 s. W., where the transit and a 7½ in.-refr. by Dollond were mounted. Obs. were here made of double stars.

FRANCE

Paris, national obs., lat. +48° 50′ 11·2″, long. 0 h. 9 m. 20·9 s. E. Founded in 1667, when the construction of a large and monumental building was commenced by the architect Claude Perrault. J. D. Cassini's obs. made the institution for some time the most celebrated obs. existing, but later the activity declined, although several eminent men, as Bouvard and Arago, have held the post of director. Since 1854, when Leverrier assumed the directorship, the obs. have been conducted with regularity, and, together with a number of most important theoretical works, published in the *Annals* (*Observations* and *Memoirs*). The principal instruments now in use are: a meridian circle by Secretan and Eichens, with an o.g. of 9·5-in. ap., another by Eichens (given by M. Bischoffsheim) of 7·5-in. ap., a 15-in. refr. by Lerebours and Brünner, a 12-in. refr. by Secretan and Eichens, a refr. of 9·5-in. ap., an equat. coudée by Henry and Gautier of 10½-in. ap. (1883), another by the same of 23½-in. ap., vis. and phot. (1891), phot. refr. of 13 in. by the same. A s.g. refl. of 4-ft. ap. was mounted in 1875, but has never been used.

In addition to this national obs. there were during the latter half of the 18th century several minor obs. in Paris, which only lasted for some years. Among these were the obs. at *Collège Mazarin*, lat. +48° 51′ 29″, where Lacaille observed from 1746 to 1750, and from 1754 to 1762, and the obs. at the *École Militaire*, lat. +48° 51′ 5″, built in 1768 and furnished with an 8-ft. mural quadrant by Bird, with which J. L. d'Agelet observed telescopic stars (1782–1785), and which was afterwards (1789–1801), under Lalande's direction, employed for observing more than 50,000 stars, published in the *Histoire Céleste* (1801).

Meudon, close to Paris, lat. +48° 48′ 18″, long. 0 h. 8 m. 55·6 s. E. Founded in 1875; devoted to physical astronomy, and especially to celestial photography, under the direction of J. Janssen; 32-in. vis. and 24½-in. phot. refr. by Henry and Gautier, refl. by the same of 39-in. ap. There is a branch obs. on Mont Blanc, where a polar siderostat with 12-in. o.g. and 20-in. mirror is occasionally used for solar and spectroscopic work (15,780 ft. above sea-level).

Montsouris, situated in the Montsouris Park, south of Paris, lat. +48° 49′ 18″, long. 0 h. 9 m. 20·7 s. E. Founded in 1875 for the training of naval officers.

Juvisy (Seine-et-Oise), private obs. of N. C. Flammarion, lat. +48° 41′ 37″, long. 0 h. 9 m. 29·0 s. E. 9½-in. refr. used for obs. of planets.

Chevreuse (Seine-et-Oise), private obs. of M. Farman (1903), lat. +48° 42′ 33″, long. 0 h. 8 m. 4·5 s. E.; 8-in. refr. by Mailhat used on double stars.

Besançon, chronometric and meteorol. obs., lat. +47° 14′ 59·0″, long. 0 h. 23 m. 57·1 s. E. Opened 1884; 8-in. refr., 12-in. equat. coudée, 7½-in. transit circle, all by Gautier.

Lyons, old obs. in lat. 45° 45′ 46″, long. 0 h. 19 m. 18 s. E., at the Jesuit college. A new obs. was erected in 1877 at St Génis-Laval, at some distance from the city, lat. +45° 41′ 41·0″, long. 0 h. 19 m. 8·5 s. E. Transit circle by Eichens (6-in. o.g.), 12-in. equat. coudée by Gautier, 12-in. siderostat.

Bordeaux, univ. obs. at Floirac, 4 km. N.W. of the city, lat. +44° 50′ 7·3″, long. 0 h. 2 m. 5·5 s. W. Founded 1882; 7-in. transit circle by Eichens, 14-in. refr. by Merz and Gautier, 13-in. phot. refr by Henry and Gautier.

Marseilles, lat. 43° 18′ 17·5″, long. 0 h. 21 m. 34·6 s. E. Originally belonging to the Jesuits, taken over by the ministry of the navy in 1749. It was here that J. L. Pons made his numerous discoveries of comets. New buildings erected in 1869; 9½-in. Merz refr., refl. of 32-in. ap. s.g. by Foucault, 7½-in. transit circle.

Toulouse, lat. 43° 36′ 45·0″, long. 0 h. 5 m. 49·9 s. E. Erected in 1841 (Darquier had observed at the Lyceum towards the end of the 18th century); reorganized 1873; 9-in. refr. and 13-in. phot. refr. by Gautier, 13-in. and 32-in. refl.

Nice, lat. + 43° 43′ 16·9″, long. 0 h. 29 m. 12·2 s. E., founded and endowed by R. L. Bischoffsheim for the Bureau de Longitude (1880), situated at Mont Gros, north-east of Nice; a refr. of 30-in. ap. by Henry and Gautier, a meridian circle by Brünner of 8-in. ap., 15-in. refr. and 15½-in. equat. coudée by Henry and Gautier.

Abbadia (Basses Pyrénées), lat. + 43° 22′ 52·2″, long. 0 h. 7 m. 0·1 s. W. Founded by A. d'Abbadie, 1858, belongs now to the Paris Acad. of Science. 6-in. transit circle.

Germany

Altona, lat. + 53° 32′ 45·3″, long. 0 h. 39 m. 46·1 s. E. Founded in 1823 by the Danish government to assist in the geodetic operations in Holstein. A meridian circle by Reichenbach (of 4-in. ap.) was procured, to which in 1858 was added a 4½-in. equat. by Repsold. The obs. is best known by the fact that the *Astronomische Nachrichten*, the principal astronomical journal, was published here from 1821 (by H. C. Schumacher up to 1850, by C. F. W. Peters from 1854). The obs. was moved to Kiel in 1874.

Bamberg, lat. + 49° 53′ 6·0″, long. 0 h. 43 m. 33·6 s. E. Founded and endowed by the late Dr K. Remeis, completed 1889; 7½-in. heliometer by Merz and Repsold, 10½-in. refr. by Schröder.

Berlin, royal obs., lat. + 52° 30′ 16·7″, long. 0 h. 53 m. 34·9 s. E. Was erected in 1705 as part of the building of the Academy of Sciences (lat. + 52° 31′ 12·5″, long. 0 h. 53 m. 35 s. E.), a very unsuitable locality. A new obs. was built in the southern part of the city, finished in 1835. Refr. by Utzschneider and Fraunhofer of 9-in. ap. (used chiefly for obs. of minor planets), a meridian circle by Pistor and Martins of 4-in. ap., another by the same makers of 7-in. ap.

Berlin, obs. of Urania Society for diffusing natural knowledge, lat. + 52° 31′ 30·7″, long. 0 h. 53 m. 27·4 s. E. Opened 1889; 12-in. refr. by Schott. In the Treptow Chaussee is a popular obs. with a 27-in. refr. by Schott and Steinheil.

Bonn, univ. obs., lat. + 50° 43′ 45·0″, long. 0 h. 28 m. 23·2 s. E. Finished in 1845; meridian circle by Pistor of 4½-in. ap., heliometer by Merz of 6-in. ap. The former was used by F. W. A. Argelander for observing the stars contained in his three great catalogues. The obs. is chiefly known by the zone obs., made from 1852 to 1859, with a small comet-seeker, on which Argelander's great atlas of 324,198 stars between the north pole and −2° decl. is founded, continued with a 6-in. refr. from −2° to −31° decl. by Schönfeld. A meridian circle of 6-in. ap. by Repsold was mounted in 1882.

Bothkamp, F. G. von Bülow's obs., lat. + 54° 12′ 9·6″, long. 0 h. 40 m. 31·2 s. E. Situated a few miles from Kiel, founded in 1870. With a refr. of 11-in. ap. by Schröder, Dr K. H. Vogel obtained valuable results in 1871–1874; since then it has only been used occasionally.

Bremen. In the third storey of his house in Sandstrasse, H. W. M. Olbers (d. 1840) had his obs., lat. + 53° 4′ 38″, long. 0 h. 35 m. 10 s. E.; though the principal instrument was only a 3¾-in. refr. by Dollond, many comets and the planets Pallas and Vesta were discovered and observed here.

Breslau, univ. obs., lat. + 51° 6′ 55·8″, long. 1 h. 8 m. 8·7 s. E. Founded 1790. In a small and unsuitable locality; 8-in. refr. by Clark and Repsold erected 1898.

Dresden, Baron von Engelhardt's obs., lat. + 51° 2′ 16·8″, long. 0 h. 54 m. 54·8 s. E. A 12-in. refr. by Grubb (mounted 1880), used for obs. of comets and double stars, presented to Kasan obs. in 1897.

Düsseldorf (Bilk, originally a suburb, now part of the city), lat. + 51° 12′ 25·0″, long. 0 h. 27 m. 5·5 s. E. Founded and endowed by Professor J. F. Benzenberg (d. 1846); best known by the discovery of twenty-one minor planets by K. T. R. Luther; 4½-in. refr. by Merz, 7½-in. refr. by Merz and Bamberg.

Gotha.—In 1791 an obs. was founded by Duke Ernest II. at Seeberg, lat. + 50° 56′ 5·2″, long. 0 h. 42 m. 55·8 s. E., on a hill a few miles from Gotha, the chief instrument being a large transit instrument by Ramsden. Through the labours, principally theoretical, of F. X. Zach, B. A. von Lindenau, J. F. Encke and P. A. Hansen, the institution ranked with the first obs. A new obs. was built at Gotha in 1857, lat. + 50° 56′ 37·5″, long. 0 h. 42 m. 50·4 s. E., which received the instruments from Seeberg, including a small transit circle by Ertel (made in 1824), also a new equat. by Repsold of 4½-in. ap.

Göttingen, univ. obs., lat. + 51° 31′ 48·2″, long. 0 h. 39 m. 46·2 s. E. An obs. had existed here from 1751, where Tobias Mayer worked. In 1811 a new building was constructed. Besides his mathematical works, K. F. Gauss found time to engage in important geodetic and magnetic obs.; meridian circle by Repsold (4½-in. ap.), another by Reichenbach (4½-in.), 6-in. heliometer by Repsold (1888).

Hamburg, lat. + 53° 33′ 7·0″, long. 0 h. 39 m. 53·6 s. E. Built in the year 1825. With a meridian circle of 4-in. ap. by Repsold, K. L. C. Rümker observed the places of 12,000 stars. A refr. of 10-in. ap. by Merz and Repsold was mounted in 1868. A new obs. is now being built 20 km. south-east of the city, lat. + 53° 28′ 46″, long. 0 h. 40 m. 58·5 s. E., with a 23½-in. refr by Steinheil and Repsold, 7½-in. transit circle by Repsold, and a 39-in. refl.

Heidelberg, grand ducal obs., lat. + 49° 23′ 54·9″, long. 0 h. 34 m. 53·1 s. E. On the Königstuhl hill, 500 ft. above the Neckar; opened 1898. Consists of an astrometric and an astrophysical department. The former has a 13-in. refr. by Steinheil and Repsold, an 8-in. refr. by Merz and a 6½-in. transit circle by Repsold. The astrophysical department is chiefly devoted to phot. work with a triple equat. with two 16-in. lenses and 10-in. guiding telescope, as well as with a 28-in. s.g. refl. by Zeiss.

Jena, univ. obs., lat. + 50° 55′ 34·9″, long. 0 h. 46 m. 20·3 s. 7-in. refr. mounted 1891.

Kiel, univ. obs., lat. + 54° 20′ 27·6″, long. 0 h. 40 m. 35·6 s. E. Contains the instruments removed from Altona in 1874, also an 8-in refr. by Steinheil and a 9-in. transit circle by Repsold.

Königsberg, univ. obs., lat. + 54° 42′ 50·4″, long. 1 h. 21 m. 59·0 s. E. Built 1813; F. W. Bessel was the director till his death in 1846, and nearly all his celebrated investigations were carried out here, e.g. obs. of fundamental stars, zone obs. of stars, researches on refraction, heliometric obs., by which the annual parallax of the star 61 Cygni was first determined, &c. The instruments are a 4-in. transit circle by Repsold (1841), a 6-in. heliometer by Utzschneider (1829), and a 13-in. refr. by Reinfelder and Repsold (1898).

Landstuhl (Palatinate), private obs. of J. P. H. Fauth, lat. + 49° 24′ 42·9″, long. 0 h. 30 m. 16·3 s. E.; 7½-in. refr.

Leipzig, univ. obs. Erected 1787–1790 on the "Pleissenburg"; lat. + 51° 20′ 20·5″, long. 0 h. 49 m. 30·2 s. E.; possessed only small instruments, the largest being a 4½-in. refr. by Fraunhofer (1830). In 1861 a new obs. was erected, lat. + 51° 20′ 5·9″, long. 0 h. 49 m. 33·9 s. E., with a refr. of 8½-in. ap. by Steinheil, replaced in 1891 by a 12-in. refr. by Reinfelder and Repsold, a meridian circle by Pistor and Martins of 6·3-in. ap. and a 6-in. heliometer by Repsold.

Lilienthal, near Bremen, lat. + 53° 8′ 25″, long. 0 h. 36 m. 1 s. E. J. H. Schröter's private obs.; from 1779 to 1813. Contained a number of refl. by Herschel and Schrader, the largest being of 27-ft. focal length and 20-in. ap. (movable round the eye-piece), used for physical obs., chiefly of planets. Destroyed during the war in 1813; the instruments (which had been bought by the government in 1800) were, for the greater part, sent to the Göttingen obs.

Mannheim, lat. + 49° 29′ 10·9″, long. 0 h. 33 m. 50·5 s. E. Built in 1772; very few obs. were published until the obs. was restored in 1860, when a 6-in. refr. by Steinheil was procured. In 1879 the obs. was moved to Karlsruhe and later to Heidelberg.

Munich, at Bogenhausen, royal obs., lat. + 48° 8′ 45·5″, long. 0 h. 46 m. 26·1 s. E. Founded in 1809; a transit circle by Reichenbach was mounted in 1824, an 11-in. equat. refr. by Fraunhofer in 1835. The former was used from 1840 for zone obs. (about 80,000) of telescopic stars. 6-in. transit circle by Repsold mounted 1891.

Potsdam, lat. + 52° 22′ 56·0″, long. 0 h. 52 m. 15·9 s. E. "Astrophysical obs.," founded in 1874, devoted to spectroscopic and photographic obs. A refr. by Schröder of 11½-in. ap., another by Grubb of 8-in. ap., a refr. by Steinheil and Merz with 9-in. vis. and 13-in. phot. o.g. and a refr. by Steinheil and Repsold with 31-in. phot. and 19½-in. vis. o.g., spectroscopes, photometers, &c. Results are published in 4to vols.

Strassburg, univ. obs., lat. + 48° 35′ 0·3″, long. 0 h. 31 m. 4.5 s. E. Finished in 1881; an 18-in. refr. by Merz; altazimuth of 5½-in. ap., meridian circle of 6½-in. ap., and a 6½ in. orbit sweeper, all by Repsold.

Wilhelmshaven (Prussia), naval obs., lat. + 53° 31′ 52·2″, long. 0 h. 32 m. 35·1 s. E.; situated on the Jahde to the north of Oldenburg. Founded in 1874; meridian circle by Repsold of 4½-in. ap., and meteorological, magnetical, and tide-registering instrumer.

Austria-Hungary

Vienna, imperial and royal obs. On the univ. building an obs. was founded in 1756, lat. + 48° 12′ 35·5″, long. 1 h. 5 m. 31·7 s. E. Owing to the unsuitable locality and the want of instruments, very few obs. of value were taken until the obs. was rebuilt in 1826, when some better instruments were procured, especially a meridian circle of 4-in. ap., and a 6-in. refr. by Fraunhofer (mounted in 1832), used for obs. of planets and comets. From 1874 to 1879 a large and magnificent building (with four domes) was erected at Währing, north-west of the city, lat. + 48° 13′ 55·4″, long. 1 h. 5 m. 21·5 s. E. In addition to the old instruments, two refrs. were erected, one by Clark of 11½-in. ap., another by Grubb of 27-in. ap. (mounted 1882); later a 15-in. equat. coudée by Gautier and a 13-in. phot. refr. by Repsold have been mounted.

Vienna (Josephstadt), private obs. of T. von Oppolzer (d. 1886), lat. + 48° 12′ 53·8″, long. 1 h. 5 m. 25·3 s. E. Established in 1865; 5-in. refr. by Merz, 4-in. meridian circle.

Vienna (Ottakring), private obs. of M. von Kuffner, lat. + 48° 12′ 46·7″, long. 1 h. 5 m. 11·0 s. E. Completed 1886; 10½-in. vis. and 6·3-in. phot. refr. by Steinheil and Repsold, 8-in. heliometer and 4½-in. transit circle by Repsold.

Prague, univ. obs., lat. + 50° 5′ 15·8″, long. 0 h. 57 m. 40·3 s. E. Founded in 1751 at the Collegium Clementinum, on a high tower. 6-in. refr. by Steinheil and a 4-in. meridian circle.

Senftenberg (in the east of Bohemia), lat. + 50° 5′ 55″, long. 1 h. 5 m. 51 s. E. Baron von Senftenberg's obs.; established in 1844. Obs. of comets and planets made with small instruments till the owner's death (1858).

Olmütz, lat. +49° 35′ 40″, long. 1 h. 9 m. 0 s. E. E. von Unkrechtsberg's obs.; 5-in. refr. by Merz. J. F. Julius Schmidt observed planets and comets from 1852 to 1858.

Kremsmünster (Upper Austria), lat. +48° 3′ 23·1″, long. 0 h. 56 m. 31·6 s. E. Founded in 1748 at the gymnasium of the Benedictines. 3-in. meridian circle (mounted in 1827); 5½-in. refr. (mounted in 1856), used for comets and minor planets. Transit circle by Repsold (1907).

Pola (sea-coast, Austria), naval obs., lat. +44° 51′ 48·7″, long. 0 h. 55 m. 23·1 s. E. Founded in 1871; meridian circle of 6-in. ap. by Simms, 6-in. refr. by Steinheil, magnetic and meteorological instruments. Twenty-eight minor planets were discovered here from 1874 to 1880 by J. Palisa.

Cracow, univ. obs., lat. +50° 3′ 50·0″, long. 1 h. 19 m. 51·1 s. E. Possesses only small instruments.

Lussinpiccolo (island of Lussin, Adriatic), private obs. of Madame Manora, lat. +44° 32′ 11·0″, long. 0 h. 57 m. 52·4 s. E. Erected 1894; 7-in. refr. by Reinfelder, used for obs. of planets.

Kis Kartal (north-east of Budapest), private obs. of Baron Podmaniczky, lat. +47° 41′ 54·8″, long. 1 h. 18 m. 11·7 s. E. 7½-in. refr. by Merz and Cooke.

O'Gyalla (near Komorn, Hungary), lat. +47° 52′ 27·3″, long. 1 h. 12 m. 45·6 s. E. Nicolas de Konkoly's obs., since 1899 a royal obs. Established in 1871, rebuilt and enlarged in 1876, devoted to astrophysics. A 10-in. s.g. refl. by Browning was in use up to 1881, when it was disposed of and a 10-in. refr. (o.g. by Merz) mounted in its place; also a 6-in. refr. by Merz, and a 6·3 in. phot. refr.

Kalocza (south of Budapest), lat. +46° 31′ 41″, long. 1 h. 15 m. 54 s. E. Obs. of the Jesuit college, founded in 1878 by Cardinal Haynald; 7-in. refr. by Merz, used for solar obs.

Herény (Vas, Hungary), lat. +47° 15′ 47·4″, long. 1 h. 6 m. 24·7 s. E. E. and A. von Gothard's obs. Founded in 1881; 10-in. refl. by Browning.

Switzerland

Zürich, lat. +47° 22′ 40·0″, long. 0 h. 34 m. 12·3 s. E. An obs. existed since 1759; handed over to the Polytechnic School in 1855; new building erected in 1863. A 6-in. refr. by Merz and Kern with two phot. telescopes, two transit instruments, &c. Sun-spots are regularly observed, but the institution is chiefly devoted to educational purposes.

Neuchâtel, lat. +46° 59′ 51·0″, long. 0 h. 27 m. 49·9 s. E. Erected in 1858; meridian circle of 4½-in. ap. by Ertel, 6½-in. refr. by Merz.

Geneva, lat. +46° 11′ 59·3″, long. 0 h. 24 m. 36·6 s. E. Founded in 1773; a new building erected in 1830. The obs. has been the centre of the important geodetic operations carried on in Switzerland since 1861. An 11-in. refr. (o.g. by Merz) was presented by the director E. Plantamour in 1880; 4-in. transit circle.

Spain and Portugal

Madrid, royal obs., lat. +40° 24′ 29·7″, long. 0 h. 14 m. 45·1 s. W. 10½-in. refr. by Merz, 8½-in. refr. by Grubb, 6-in. transit circle by Repsold.

Barcelona, obs. of Acad. of Science, lat. +41° 25′ 18″, long. 0 h. 8 m. 28 s. E. Opened 1904; 15-in. refr., phot. and vis. by Mailhat, 7½-in. transit circle by the same.

Cadiz, naval obs., at San Fernando, lat. +36° 27′ 42·0″, long. 0 h. 24 m. 49·3 s. W. Founded in 1797; 11-in. refr. by Brünner, 13-in. phot. refr. by Henry and Gautier, 8-in. transit circle by Simms.

Lisbon, royal obs., lat. +38° 42′ 31·3″, long. 0 h. 36 m. 44·7 s. W. Founded 1861; 15½-in. refr. by Merz and Repsold, transit circle by Repsold.

Coimbra, univ. obs., lat. +40° 12′ 25·5″, long. 0 h. 33 m. 43·1 s. W. Founded 1792; 6½-in. transit circle by Repsold, 16-in. refl. by Secretan.

Italy

Turin, univ. obs., lat. +45° 4′ 7·9″, long. 0 h. 30 m. 47·2 s. E. Founded in 1790 by the Academy of Science; rebuilt in 1820 on a tower of the Palazzo Madama, 4½-in. transit circle by Reichenbach, 12-in. refr. by Merz; handed over to the univ. in 1865. A new obs. is being erected 6 km. from the city.

Milan, originally obs. of Brera College, now royal obs. of Brera, lat. +45° 27′ 59·2″, long. 0 h. 36 m. 45·9 s. E. Founded in 1763. The publication of an annual ephemeris from 1775 to 1875 and important theoretical works absorbed most of the time of the directors B. Oriani and F. Carlini, and the instruments were rather insufficient. In 1875 an 8-in. refr. by Merz was mounted, with which G. V. Schiaparelli has made valuable obs. of Mars; 18-in. refr. by Merz.

Padua, univ. obs., lat. +45° 24′ 1·0″, long. 0 h. 47 m. 29·2 s. E. Founded in 1767. In 1837 a meridian circle by Starke of 4-in. ap. was mounted, with which stars from Bessel's zones were reobserved; the results were published in five catalogues; 4½-in. refr. by Merz and Starke (1858); Dembowski's 7-in. refr. mounted in 1881.

Gallarate, near Lago Maggiore, from 1860 to 1879, Baron E. Dembowski's obs. From 1852 to 1859 Baron Dembowski had observed double stars at Naples with a 5-in. dialyte by Plössl and a small transit circle by Starke. From 1860 he used a 7-in. refr. by Merz.

Bologna, univ. obs., lat. +44° 29′ 47·6″, long. 0 h. 45 m. 24·5 s. E. Founded in 1724 on a tower of the univ. building. Obs. have only been made occasionally. A 3½-in. meridian circle was mounted in 1846.

Florence.—In 1774 a museum of science and natural history was established, part of which was used as an obs., but very few obs. were made; a new obs., built 1872 at Arcetri, lat. +43° 45′ 14·4″, long 0 h. 45 m. 1·3 s. E. 11-in. and 9½-in. refrs. by Amici.

Teramo (Abruzzo), private obs. of V. Cerulli, lat. +42° 39′ 27″, long 0 h. 54 m. 56 s. E. 15½-in. refr. by Cooke.

Rome, obs. of the Roman College, lat. +41° 53′ 53·6″, long. 0 h. 49 m. 55·4 s. E. Established in 1787, taken over by the government 1879. In 1853 a new obs. was erected on the unfinished piles of the church of St Ignatius, and furnished with a 9-in. refr. by Merz, a meridian circle by Ertel of 3½-in. ap. (in use from 1842). With these instruments, to which were later added powerful spectroscopes, A. Secchi made a great many obs., chiefly relating to spectrum analysis and physical astronomy; 15-in. refr. by Steinheil.

Rome, obs. of the Capitol, lat. +41° 53′ 33·6″, long. 0 h. 49 m. 56·3 s. E. Established in 1848; belongs to the univ.; small transit circle and a 4½-in. refr. by Merz. The latter was used by L. Respighi for obs. of solar prominences.

Rome (Vatican), papal obs., lat. +41° 54′ 4·8″, long. 0 h. 49 m. 49·3 s. E. Founded 1890; 10½-in. refr. by Merz, 13-in. phot. and 8-in. vis. refr. and 5½-in. photoheliograph by Henry.

Naples, royal obs., situated at Capo di Monte, lat. +40° 51′ 46·3″, long. 0 h. 57 m. 1·7 s. E. Erected in 1812–1819; a 4-in. meridian circle by Reichenbach, a 6½-in. refr. by Reichenbach and Fraunhofer, 6-in. Merz. refr.

Palermo, royal obs., lat. +38° 6′ 44·5″, long. 0 h. 53 m. 25·9 s. E. Erected in 1790 on a tower of the royal palace. The principal instruments were a reversible vertical circle by Ramsden of 5-ft. diameter with a 3-in. telescope, and a transit instrument of 3-in. ap. With these G. Piazzi observed the stars contained in his celebrated Catalogue of 7641 Stars (1814); this work led him to the discovery of the first minor planet, Ceres, on the 1st of January 1801. The activity was revived in 1857, when a meridian circle by Pistor and Martins of 5-in. ap. was mounted; a 9½-in. refr. by Merz has been used for spectroscopic work.

Catania, lat. +37° 30′ 13·3″, long. 1 h. 0 m. 20·6 s. E. Founded 1885; 13-in. phot. refr. by Henry and Gautier, and a 13-in. refr. by Merz. The latter is used in summer on a duplicate mounting on Mount Etna, where in 1879–1880 an obs. was built at the "Casa degl' Inglesi," 9650 ft. above the sea, for solar obs.

Greece

Athens, lat. +37° 58′ 20″, long. 1 h. 34 m. 55·7 s. E. Erected in 1846; founded by Baron Sina. With a refr. of 6½-in. ap. Julius Schmidt (d. 1884) made obs. of the physical appearance of the moon, planets and comets. Reorganized 1895; 15½-in. refr. by Gautier, 6½-in. transit circle.

Russia

St Petersburg, obs. of the Academy of Sciences, lat. +59° 56′ 29·7″, long. 2 h. 1 m. 13·5 s. E. Founded in 1725, restored in 1803; meridian circle by Ertel. Abolished in 1884. A univ. obs. was founded in 1880, lat. +59° 56′ 32·0″, long. 2 h. 1 m. 11·4 s. E.; 9½-in. refr. by Reinfelder and Repsold, used on double stars, during the summer at Domkino, lat. +58° 35·6′, long. 1 h. 59 m. 25 s. E.

Pulkovo (Pulkowa), Nicholas Central Obs., lat. +59° 46′ 18·7″, long. 2 h. 1 m. 18·6 s. E. Finished in 1839. Was under the direction of F. G. W. Struve till 1861, then of his son O. Struve till 1889. The staff consists now of the director, five astronomers, six assistants and computers. The principal instruments are: a transit instrument by Ertel of 6-in. ap., a vertical circle by Ertel of 6-in. ap. (the circle of 3½-ft. diameter has been redivided by Repsold),—these two instruments are for determining standard places of stars; a meridian circle by Repsold (6-in. ap., 4-ft. circles), used since 1843 to observe all stars north of −15° decl. down to the 6th mag., and all others observed by Bradley; a prime vertical transit by Repsold with 6½-in. ap., used for determining the constant of aberration; a 7½-in. heliometer by Merz; a refr. by Merz of 14·9-in. ap. (remounted by Repsold in 1880), which was used by O. Struve to observe double stars; 30-in. refr. by Clark and Repsold, erected 1886, chiefly used for spectrographic work; 13-in. phot. refr. See also Odessa.

Abo (Finland), univ. obs., lat. +60° 26′ 56·8″, long. 1 h. 29 m. 8·3 s. E. Founded in 1819. With the meridian circle by Reichenbach of 4-in. ap. F. W. A. Argelander observed the 560 stars contained in the Abo catalogue. In consequence of a great fire in 1827 the univ. and obs. were moved to Helsingfors.

Helsingfors (Finland), univ. obs., lat. +60° 9′ 42·6″, long. 1 h. 39 m. 49·1 s. E. Erected in 1832–1835; furnished with a 7-in. refr. and the instruments from Abo, including a transit instrument by Fraunhofer of 5½-in. ap.; 13-in. phot. refr. erected 1890.

Dorpat (Yuriev), univ. obs., lat. +58° 22′ 46·8″, long. 1 h. 36 m. 53·2 s. E. Founded in 1808; 1814–1839 under the direction of F. G. W. Struve. With a meridian circle by Reichenbach obs. were made from 1822 to 1843, chiefly of double stars, while the 9½-in. refr. by Fraunhofer was used from 1824 to 1837 for measuring double stars.

Warsaw, univ. obs., lat. +52° 13′ 5·7″, long. 1 h. 24 m. 7·3 s. E. Erected in 1820–1824; meridian circle by Reichenbach; 6-in. refr. by Merz.

Moscow, univ. obs., lat. +55° 45′ 19·8″, long. 2 h. 30 m. 17·0 s. E. An obs. was built in 1825–1832; the present building was erected about 1850; 10·7-in. refr by Merz; a meridian circle by Repsold of 5·3-in. ap.; 15½-in. vis.; and phot. refr. by Henry and Repsold.

Kazan, univ. obs., lat. +55° 47′ 24·2″, long. 3 h. 16 m. 28·9 s. E. Founded in 1814, restored in 1842; 6½-in. refr. by Merz; meridian circle by Repsold. New obs. built 1899, lat. +55° 50′ 20·0″, long. 3 h. 15 m. 16·5 s. E., for Engelhardt's instruments (see Dresden).

Kharkov, univ. obs., lat. +50° 0′ 9·6″, long. 2 h. 24 m. 55·8 s. E.; 6½-in. transit circle by Repsold.

Kiev, univ. obs., lat. +50° 27′ 11·8″, long. 2 h. 2 m. 0·6 s E. Erected in the years 1840–1845; 9-in. refr. by Merz and Repsold; and a meridian circle.

Odessa, univ. obs., lat. +46° 28′ 36·7″, long. 2 h. 3 m. 2·0 s. E.; 6½ vis. and 6-in. phot. refr.

Odessa, branch of Pulkowa obs., lat. +46° 28′ 37·9″, long. 2 h. 3 m. 2·2 s. E. Established 1898 for obs. of more southerly standard stars, with a 4-in. transit by Freiberg and a 4-in. vertical circle by Repsold.

Nikolayev, naval obs., lat. +46° 58′ 21·8″, long. 2 h. 7 m. 53·8 s. E. Erected in 1824; meridian circle by Ertel of 4-in. ap.; 9½-in. refr. by Repsold.

Sweden, Norway and Denmark

Stockholm, lat. +59° 20′ 33·0″, long. 1 h. 12 m. 14·0 s. E., is under the Academy of Sciences. Founded in 1750. Meridian circle by Ertel of 4½-in. ap.; 7½-in. vis. and 6½-in. phot. refr. by Repsold.

Upsala, univ. obs., lat. +59° 51′ 29·4″, long. 1 h. 10 m. 30·1 s. E. Founded in 1730, but very little was done until the obs. acquired a 9-in. refr. by Steinheil, which was used by Schultz for micrometric obs. of nebulae. 13-in. phot. and 14-in. vis refr. by Steinheil.

Lund, univ. obs., lat. +55° 41′ 52·0″, long. 0 h. 52 m. 45·0 s. E. Built in 1866; 9½-in. refr., o.g. by Merz; meridian circle by Repsold of 6½-in ap.

Christiania, univ. obs., lat. +59° 54′ 44·0″, long. 0 h. 42 m. 53·6 s. E. Erected in 1831; meridian circle by Ertel of 4-in. ap.; 7-in. refr. by Merz.

Copenhagen, univ. obs. Founded in 1641 on the top of a high tower, lat. +55° 40′ 53·0″, long. 0 h. 50 m. 19·8 s. E. The locality was so very unsuitable that O. Römer (the inventor of the transit instrument and modern equat., d. 1710) established his own obs. at Vridlösemagle, at some distance from the city. A new obs. was erected in 1861, lat. +55° 41′ 12·9″, long. 0 h. 50 m. 18·7 s. E., furnished with a refr. by Merz of 11-in. ap., with which H. L. d'Arrest made obs. of nebulae, and a meridian circle by Pistor and Martins of 4½-in. ap. Later the refr. was replaced by a 14-in. vis. and 8-in. phot. refr. by Steinheil.

Copenhagen, Urania obs. (private), lat. +55° 41′ 19·2″, long. 0 h. 50 m. 9·1 s. E. Established 1898; 9½-in. refr. by Cooke.

Holland and Belgium

Leiden, univ. obs., lat. +52° 9′ 20·0″, long. 0 h. 17 m. 56·2 s. E. Founded already in 1632, but the instruments were always very small, and hardly any obs. were taken until F. Kaiser became director in 1837. In 1858–1860 a new obs. was erected and furnished with a 7-in. refr. by Merz, and a meridian circle by Pistor and Martins of 6·3-in. ap. Later a 10½-in. refr. by Clarke and Repsold has been erected.

Groningen, astron. laboratory of the univ., lat. +53° 13′ 19·1″, long. 0 h. 26 m. 15·2 s. E. Established 1896; instruments for measuring celestial photographs.

Utrecht, univ. obs., lat. +52° 5′ 9·5″, long. 0 h. 20 m. 31·0 s. E. Erected in 1855; 10-in. refr. by Steinheil.

Brussels, royal obs., lat. +50° 51′ 10·7″ long. 0 h. 17 m. 28·6 s. E. Erected in 1829–1834. Had a transit instrument by Gambey and a mural circle by Troughton, but the institution was, while under the direction of L. A. J. Quetelet, chiefly devoted to physics and meteorology. In 1877 a 6-in. refr. by Merz was mounted, and a meridian circle by Repsold and a 15-in. refr. by Cooke provided. A new obs. was erected in 1891 at Uccle, lat. +50° 47′ 55·5″, long. 0 h. 17 m. 26·9 s. E., with the instruments from Brussels, a 9-in. phot. refr. by Grubb, and a 13-in. phot. refr. by Gautier.

Liége, univ. obs., lat. +50° 37′ 6″, long. 0 h. 22 m. 15·4 s. E.; 10-in. refr. and 7-in. transit circle by Cooke.

United States

Albany (New York), Dudley obs. Erected in 1851–1856 by subscription, lat. +42° 39′ 49·5″, long. 4 h. 54 m. 59·2 s. W. Refr. by Fitz of 13-in. ap., meridian circle by Pistor and Martins of 8-in. ap. New obs. erected 1893, lat. +42° 39′ 12·7″, long. 4 h. 55 m. 6·8 s. W.; 12-in. refr. by Brashear.

Allegheny (Pa.), lat. +40° 27′ 41·6″, long. 5 h. 20 m. 2·9 s. W. Founded in 1859, transferred to the Western Univ. of Penn. (now Univ. of Pittsburgh) in 1867; 13-in. refr. by Fitz (improved by Clark), mounted in 1867; instruments for researches on solar energy.

Amherst (Mass.), lat. +42° 21′ 56·5″, long. 4 h. 50 m. 5·9 s. W. Founded in 1857 as an annex to Amherst College; 7½-in. refr. by Clark. New building 1903; 18-in. refr. by Clark; 6½-in. transit circle by Pistor and Martins.

Ann Arbor (Michigan), lat. +42° 16′ 48·8″, long 5 h. 34 m. 55·2 s. W. Detroit obs. of the Univ. of Michigan; erected in 1854; meridian circle by Pistor and Martins of 6½ in. ap.; 12½-in. refr. by Fitz.

Berkeley (Cal.), Students' obs. of Univ. of California, lat. +37° 52′ 23·6″, long. 8 h. 9 m. 2·7 s. W.; 8-in. refr.

Cambridge (Mass.), Harvard College obs., lat. +42° 22′ 47·6″, long. 4 h. 44 m. 31·0 s. W. Erected in 1839. Refr. of 15-in. ap. by Merz, with which W. C. Bond discovered a satellite of Saturn (Hyperion) in 1848, employed by E. C. Pickering for extensive photometric obs. of fixed stars and satellites; a meridian circle by Troughton and Simms of 8½-in. ap., mounted in 1870; 12-in. horizontal telescope for photometric obs. of faint stars, 11-in. and 8-in. Draper refrs. for phot. work; 15-in. Draper refl.; 24-in. phot. doublet (Bruce telescope) with which the ninth and tenth satellites of Saturn have been discovered by W. H. Pickering. Branch obs. at Arequipa, Peru.

Charlottesville (Va.), obs. of Univ. of Virginia, lat. +38° 2′ 1·2″, long. 5 h. 14 m. 5·2 s. W. Founded 1882; 26-in. refr. by Clark.

Chicago (Illinois), Dearborn obs., lat. +41° 51′ 1·0″, long. 5 h. 50 m. 26·8 s. W. Attached to North-western Univ., founded in 1862; 18½-in. refr. by Clark; 6-in. meridian circle by Repsold. Obs. removed to Evanston (Ill.) in 1889, lat. +42° 3′ 33·4″, long. 5h. 50 m. 42·3 s. W.

Cincinnati (Ohio). In 1842 an obs. was founded by subscription, lat. +39° 6′ 26·5″, long. 5 h. 37 m. 58·9 s. W., and furnished with a refr. of 11¾-in. ap. by Merz. In 1873 the obs. was removed to a distance from the city, to Mount Lookout, lat. +39° 8′ 19·5″, long. 5 h. 37 m. 41·3 s. W.; 5-in. transit circle by Fauth.

Clinton (New York), Litchfield obs. of Hamilton College, lat. +43° 3′ 16·5″, long. 5 h. 1 m. 37·4 s. W. Erected by subscription 1852–1855; refr. of 13½ in. by Spencer, employed by C. H. F. Peters for construction of celestial charts, in the course of which work he discovered forty-one minor planets.

Columbia (Mo.), Laws obs. of Univ. of Missouri, lat. +38° 56′ 51·7″, long. 6 h. 9 m. 18·3 s. W. Founded 1853; 7½-in. refr. by Merz.

Columbus (Ohio), State Univ. obs., lat. +40° 0′ 1″, long. 5h. 32 m. 10 s. W.; 12-in. refr. by Brashear and Warner & Swasey.

Denver (Col.), Univ. of Denver obs., lat. +39° 40′ 36″, long. 6 h. 59m. 47·6 s. W.; 5400 ft. above sea-level. Founded 1891; 20-in. refr. by Clark; 6-in. refr. by Grubb; 4-in. transit circle by Saegmüller.

Flagstaff (Arizona), private obs. of Percival Lowell, lat. +35° 12′ 30·5″, long. 7 h. 26 m. 44·6 s. W. 7300 ft. above sea-level. Erected 1894; 24-in. refr. by Clark; 6-in. vis. by Clark; and 5-in. phot. refr. by Brashear, all used chiefly on planets.

Georgetown (District of Columbia), Georgetown Univ. obs., lat. +38° 54′ 26·7″, long. 5 h. 8 m. 18·3 s. W. Erected in 1844; 12-in. refr. by Clacey and Saegmüller; 9-in. phot. transit instr. (1890) by Saegmüller; 6-in. phot. zenith telescope by Brashear.

Glasgow (Missouri), Morrison obs., lat. +39° 16′ 16·8″, long. 6 h. 11 m. 18·1 s. W. Founded in 1876; attached to Pritchett College; 12½-in. refr. by Clark; meridian circle by Simms of 6-in. ap.

Hanover (New Hampshire), Shattuck obs. of Dartmouth College, lat. +43° 42′ 15·3″, long. 4 h. 49 m. 7·9 s. W. Founded in 1853; 9½-in. refr. by Clark; meridian circle by Simms of 4-in. ap.

Hastings (New York), Professor Henry Draper's obs., lat. +40° 59′ 25″, long. 4 h. 55 m. 29·7 s. W. Built in 1860; 28-in. refl. by the owner, 11-in. refr. (with photo. lens) by Clark, both used up to the owner's death (1882) for celestial and spectrum photography.

Haverford (Pa.), Haverford College obs., lat. +40° 0′ 40·1″, long. 5 h. 1 m. 12·7 s. W.; 10-in. refr. by Clark.

Madison (Wisconsin), Washburn obs., lat. +43° 4′ 36·8″, long. 5 h. 57 m. 38·1 s. W. Erected at the expense of Governor Washburn in 1878; belongs to the Univ. of Wisconsin; meridian circle by Repsold of 4·8-in. ap.; 15½-in. refr. by Clark.

Mount Hamilton (Cal.), Lick obs. of the Univ. of California, lat. +37° 20′ 25·6″, long. 8 h. 6 m. 34·9 s. W., about 4250 ft. above sea-level. Erected in pursuance of the will of James Lick (1796–1876), opened in 1888; 36-in. refr. by Clark with 33-in. phot. lens, 12-in. refr by Clark, 6½-in. transit circle by Repsold, 3-ft. s.g. refl. by Common, several phot. telescopes, a second 3-ft. s.g. refl. by Brashear with spectrograph. The 5th satellite of Jupiter was discovered by E. E. Barnard in 1892 with the 36 in., and the 6th and 7th by C. D. Perrine on photos with the refl. in 1904–1905.

Mount Wilson (Cal.). Solar obs. of the Carnegie Institution, lat. +34° 12′ 59·5″, long. 7h. 52 m. 14·3 s. W. Erected 1904; 60-in. refl.; "Snow telescope" with 30-in. coelostat and 24-in. concave mirror with large spectroheliograph. A 100-in. refl. has been ordered.

New Haven (Connecticut), Winchester obs. of Yale College, lat. +41° 19′ 22·3″, long. 4 h. 51 m. 40·6 s. W. An obs. had existed since 1830, possessing a 9-in. refr. by Clark and a meridian circle by Ertel. In 1881 the obs. was rebuilt, and furnished with a 6-in. heliometer by Repsold, and an 8-in. refr. by Grubb.

New York, L. M. Rutherfurd's obs., lat. +40° 43′ 48·5″, long. 4 h. 55 m. 56·6 s. W.; 13-in. refr. by Rutherfurd and Fitz, used for celestial photography. Presented to Columbia College in 1884. New obs. (Wilde), lat. +40° 45′ 23·1″, long. 4 h. 55 m. 53·6 s.

Northfield (Minnesota), Goodsell obs. of Carleton College, lat. +44° 27′ 41·6″, long. 6 h. 12 m. 35·8 s. W. Erected in 1878, enlarged 1887; 8½-in. refr. by Clark with phot. o.g.; 16-in. refr. by Brashear; 4½-in. transit circle by Repsold.

Philadelphia, Flower obs. of Univ. of Pennsylvania, lat. +39° 58′ 2·1″, long. 5 h. 1 m. 6·6 s. W. Founded 1895; 18-in. refr., 4-in. transit circle and 4-in. zenith telescope, all by Brashear and Warner & Swasey.

Poughkeepsie (N.Y.), Vassar College obs., lat. +41° 41′ 18″, long. 4 h. 55 m. 33·7 s. W. Founded 1865; 12-in. refr. by Fitz and Clark; small transit circle.

Princeton (New Jersey). Attached to Princeton Univ. are two obs.—the "Observatory of Instruction," lat. +40° 20′ 57·8″, long. 4 h. 58 m. 37·6 s. W., erected in 1877, and furnished with a 9½-in. refr. by Clark; and the Halsted obs., lat. +40° 20′ 55·8″, long. 4 h. 58 m. 39·4 s. W., in which a 23-in. refr. by Clark was mounted in 1883.

Rochester (New York), Warner obs., lat. +43° 9′ 16·8″, long. 5 h. 10 m. 21·8 s. W. Erected by H. H. Warner in 1879–1880; 16-in. refr. by Clark. Discontinued 1895.

Washington (D.C.), U.S. naval obs., lat. +38° 53′ 38·8″, long. 5 h. 8 m. 12·1 s. W. Organized in 1842; obs. begun in 1845 with a mural circle by Troughton & Simms of 4 in., a transit instrument by Ertel of 5·3-in. ap., and a 9·6-in. refr. by Merz. A meridian circle by Pistor & Martins of 8·5-in. ap., mounted in 1865, and used for observing standard stars and planets; a 26-in. refr. by Clark, mounted in 1873—with this instrument A. Hall discovered the satellites of Mars in 1877. A new obs. on Georgetown Heights was opened in 1893, lat. +38° 55′ 14·0″, long. 5 h. 8 m. 15·8 s. W.; in addition to the old instruments there is a 40-ft. photoheliograph of 5-in. ap., 6-in. transit circle built of steel by Warner & Swasey, 5-in. steel altazimuth by same, 12-in. refr. by Clark.

Washington (D.C.), astrophysical obs. of the Smithsonian Institution, lat. +38° 53′ 17·3″, long. 5 h. 8 m. 6·2 s. W. Founded 1890 for the study of solar radiation; 20-in. siderostat, spectrobolometer, &c.

Williams Bay (Wis.).—Yerkes obs. of Univ. of Chicago, lat. +42° 34′ 12·6″, long. 5 h. 54 m. 13·2 s. W. Opened 1897; 40-in. refr. by Clark and Warner & Swasey; also a 12-in. refr., 24-in. refl., 10-in. phot. refr.

Williamstown (Mass.), lat. +42° 42′ 49″, long. 4 h. 52 m. 33·5 s. W. Founded in 1836; 7½-in. refr. by Clark; meridian circle of 4½-in. ap. by Repsold, mounted in 1882 in the Field Memorial obs., lat. +42° 40′ 30″, long. 4 h. 52 m. 50 s. W.

CANADA

Ottawa, Dominion obs., lat. +45° 23′, long. 5 h. 3 m. W. Founded 1902; 15-in. refr. by Brashear; 8-in. transit circle by Simms; 16-in. coelostat.

MEXICO

Tacubaya.—National obs. erected 1882, lat. +19° 24′ 17·5″, long. 6 h. 36 m. 46·7 s. W., 7600 ft. above sea-level; 15-in. refr. by Grubb, 13-in. phot. refr. by Henry & Gautier, 8-in. transit circle by Simms.

SOUTH AMERICA

Santiago (Chile), national obs., lat. −33° 26′ 42·0″, long. 4 h. 42 m. 46·2 s. W. In 1849 the U.S. government sent an astronomical expedition to Chile. When the expedition returned in 1852, the government of Chile bought the instruments—a 6-in. meridian circle by Pistor and Martins, a 6½-in. refr. by Fitz, &c. New building erected 1860; 9½-in. refr. by Merz and Repsold, 13-in. phot. refr. by Gautier.

Arequipa (Peru).—Branch of Harvard College obs., lat. −16° 24′, long. 4 h. 45 m. 30 s. W., 8060 ft. above sea-level; 24-in. Bruce refr. by Clark; and 13-in. Boyden telescope for phot. charts and spectra of faint stars; 4-in. transit photometer extends the Harvard photometry to the south pole.

Rio de Janeiro (Brazil), national obs., lat. −22° 54′ 23·7″, long. 2 h. 52 m. 41·4 s. W. Founded in 1845; no work done until 1871. The principal instruments are a meridian circle by Gautier of 7¼-in. ap., an altazimuth, a 9½-in. refr. by Henry, &c.

Cordoba (Argentina), national obs., lat. −31° 25′ 15·4″, long. 4 h. 16 m. 45·1 s. W. Erected in 1871 under the direction of B. A. Gould till 1883. With a meridian circle by Repsold of 5-in. ap. 105,000 zone obs. of stars between −23° and −80° decl. have been made; 11¼-in. phot. refr. by Clarke; 5-in. phot. refr. by Henry & Gautier.

La Plata (Argentina), univ. obs., lat. −34° 54′ 30·3″, long. 3 h. 51 m. 37·0 s. W. Founded 1883; 18-in. equat. coudée, 13-in. phot. refr. and transit circle, all by Henry & Gautier.

AFRICA

Cape of Good Hope, royal obs., lat. −33° 56′ 3·5″, long. 1 h. 13 m. 54·8 s. E. Founded in 1820; erected in 1825–1829, about 3½ m. from Cape Town. Obs. were begun in 1829 with a transit instrument by Dollond of 5-in. ap. and a mural circle by Jones. Thomas Maclear undertook to verify and extend the arc of meridian measured by N. L. de Lacaille in 1751–1753, which work occupied the obs. staff for a number of years. In 1849 a 7-in. refr. by Merz was mounted, and in 1855 a new meridian circle, a facsimile of the one at Greenwich, superseded the older instruments. Maclear was succeeded by E. J. Stone (1870 to 1879), who devoted himself and the staff to obs. of stars, embodied in a catalogue of 12,441 stars for the epoch 1880. Under Sir David Gill (1879–1906) a 7-in. heliometer by Repsold has been used since 1887 for researches on solar parallax and annual parallax of stars, while a complete review of the heavens has been made south of −23° decl. with a 6-in. phot. Dallmeyer lens. A 24-in. phot. and 18-in. vis. refr. by Grubb, with 24-in. o.g. prism, and a 6-in. transit circle by Simms have also been mounted.

Besides the obs. of Lacaille in Cape Town (lat. −33° 55′ 16·1″, long. 1 h. 13 m. 41 s. E.), another temporary obs. at Feldhausen, lat. −33° 58′ 56·6″, long. 1 h. 13 m. 51 s. E., 6 m. from Cape Town, deserves to be mentioned. It was here that Sir John Herschel observed nebulae and double stars from 1834 to 1838 with a refl. of 18½-in. ap.

Durban (Natal).—Government obs., lat. −29° 50′ 46·6″, long. 2 h. 4 m. 1·2 s. E. Erected in 1882; 8-in. refr. by Grubb.

Mauritius.—Royal Alfred obs., lat. −20° 5′ 39″, long. 3 h. 50 m. 12·5 s. E. Chiefly meteorological, but solar photos regularly taken.

Helwân (near Cairo, Egypt), khedivial obs., lat. +29° 51′ 34″, long. 2 h. 5 m. 22 s. E. Erected in 1904; 30-in. refl. used for photos of southern nebulae.

Algiers (Algeria), national obs., lat. +36° 47′ 50″, long. 0 h. 12 m. 8·4 s. E. Founded 1881; 12·5-in. equat. coudée and 13-in. phot. refr. by Gautier; transit circle.

St Helena, lat. −15° 55′ 26·0″, long. 0 h. 22 m. 54·6 s. W. With a transit instrument and mural circle. M. Johnson observed the places of 606 southern stars from 1829 to 1833.

INDIA

Madras, government obs., lat. +13° 4′ 8·0″, long. 5 h. 20 m. 59·6 s. E. In 1831 a transit instrument and a mural circle, both of 3½-in. ap., by Dollond, were mounted, and with these T. G. Taylor observed 11,000 stars. A meridian circle by Simms was mounted in 1858, and in 1865 an 8-in. refr., also by Simms, was put up; with the former 5303 stars were observed in 1862–1887. New obs. built in 1899 at Kodaikanal (Palni Hills), lat. +10° 13′ 50″, long. 5 h. 9 m. 52 s. E., 7700 ft. above sea-level; 12-in. siderostat and phot. vis. o.g. by Cooke, spectroheliograph, &c. To be devoted chiefly to solar physics.

Poona.—Obs. of College of Science. Founded 1888. 12-in. siderostat by Cooke with 9-in. lens by Grubb; 16½-in. a.g. refl. by Grubb, with 6-in. refr. by Cooke; spectroscopes, &c., chiefly for solar work.

Dehra Dûn.—Obs. of Indian Survey, lat. +30° 18′ 51·8″, long. 5 h. 12 m. 13·5 s. E. Regular solar phot. work.

Trivandrum, lat. + 8° 30′ 32″, long. 5 h. 7 m. 59 s. E. Founded by the raja of Travancore in 1836. No astronomical work done, but valuable magnetical and meteorological obs. were made by J. A. Broun from 1852 to 1863.

JAPAN

Tokyo, univ. obs., lat. +35° 39′ 17·5″, long. 9 h. 18 m. 58·0 s. E.; 5½-in. transit circle by Repsold; 6½-in. refr.

CHINA

Zo-Se (near Shanghai), Jesuit obs., lat. +31° 5′ 47·1″, long. 8 h. 4 m. 44·7 s. E. Erected 1899–1901; 16-in. vis., and phot. refr. for solar and stellar phot. and spectroscopic work.

Hong Kong, lat. +22° 18 13·2″, long. 7 h. 36 m. 41·9 s. E. In 1883 the colonial government established an obs., furnished with a 6-in. refr., a small transit instrument and full equipment of magnetical and meteorological instruments.

TURKESTAN

Tashkent, lat. +41° 19′ 31·4″, long. 4 h. 37 m. 10·8 s. E. Founded in 1874; 6-in. refr. and meridian circle by Repsold; 13-in. phot. refr. by Henry & Repsold.

AUSTRALIA

Paramatta (New South Wales), lat. −33° 48′ 50″, long. 10 h. 4 m. 6·3 s. E. Erected by Sir Thomas Macdougall Brisbane in 1821; handed over to the New South Wales government in 1826; furnished with a transit instrument and a mural circle by Troughton. From about 1835 no obs. seem to have been made; the obs. was abolished in 1855.

Sydney (New South Wales), lat. −33° 51′ 41·1″, long. 10 h. 4 m. 49·5 s. E. Founded in 1855; furnished with the instruments from Paramatta. In 1861 a 7½-in. refr. by Merz, and in 1874 an 11¼-in. refr. by Schröder, were mounted; in 1879 a meridian circle by Simms of 6-in. ap. was acquired, and later a 13-in. phot. refr. by Grubb.

Windsor (New South Wales), lat. −33° 36′ 28·9″, long. 10 h. 3 m. 21·7 s. E. Private obs. of Mr J. Tebbutt, who has devoted himself since 1861 to discoveries and obs. of comets, using a 4½-in. refr. by Cooke and an 8-in. refr. by Grubb.

Melbourne (Victoria).—Founded in 1853 at Williamstown, lat. −37° 52′ 7·2″, long. 9 h. 39 m. 38·8 s. E. In 1861 a meridian circle by Simms of 5-in. ap. was mounted, but in 1863 the obs. was removed to Melbourne, lat. −37° 49′ 53·2″, long. 9 h. 39 m. 54·0 s. E. "The great Melbourne telescope," a Cassegrain refl., equatorially mounted, of 4-ft. ap., made by T. Grubb, was erected in 1869, but very little used; there is also an 8-in. refr. by Cooke and a 13-in. phot. refr. by Grubb.

Adelaide (South Australia), lat. −34° 55′ 33·8″, long. 9 h. 14 m. 21·3 s. E. In operation since 1861; has been gradually improved and contains now an 8-in. refr. by Cooke and a 6-in. transit circle by Simms.

Perth (West Australia), lat. −31° 57′ 7·4″, long. 7 h. 43 m. 21·7 s. E. Founded 1897; 13-in. phot. and 10-in. vis. refr. by Grubb; 6-in. transit circle by Simms.

AUTHORITIES.—In addition to their *Annals* or *Observations*, the leading national obs. (Greenwich, Paris, Washington, &c.) publish annual reports stating the nature of the work and changes in *personnel* and instruments. Short reports from nearly all British obs. are annually published in the February number of the *Monthly Notices R. Astr. Soc.*, and from most German and some other continental obs. in the *Vierteljahrsschrift d. astr. Gesellschaft*. Since 1889 much information about American obs. is given in the *Publications of the Astr. Soc. of the Pacific*. Stroobant's *Les Observatoires astronomiques et les astronomes* (Brussels, 1907) gives a convenient summary of the *personnel* and equipment of all existing obs. (J. L. E. D.)

OBSIDIAN, a glassy volcanic rock of acid composition. A similar rock was named *obsianus* by medieval writers, from its resemblance to a rock discovered in Ethiopia by one Obsius. The early printed editions of Pliny erroneously named the discoverer Obsidius, and the rock *obsidianus*. Rhyolitic lavas frequently are more or less vitreous, and when the glassy matter greatly predominates and the crystals are few and inconspicuous the rock becomes an obsidian; the chemical composition is essentially the same as that of granite; the difference in the physical condition of the two rocks is due to the fact that one consolidated at the surface, rapidly and under low pressures, while the other cooled slowly at great depths and under such pressures that the escape of the steam and other gases it contained was greatly impeded. Few obsidians are entirely vitreous; usually they have small crystals of felspar, quartz, biotite or iron oxides, and when these are numerous the rock is called a porphyritic obsidian (or hyalo-liparite). These crystals have, as a rule, very good crystalline form, but the quartz and felspar are often filled with enclosures of glass.

All obsidians have a low specific gravity (about 2·4) both because they are acid rocks and because they are non-crystalline. Their lustre is vitreous except when they contain many minute crystals; they are then velvety or even resinous in appearance. Thin splinters and the sharp edges of fragments are transparent. Black, grey, yellow and brown are the prevalent colours of these rocks. In hand specimens they often show a well-marked banding which is sometimes flat and parallel, but may be sinuous and occasionally is very irregular, resembling the pattern of damascened steel. In such cases the molten rock cannot have been homogeneous, and as it flowed along the ground the different portions of it were drawn out into long parallel streaks. As the rock was highly viscous and the surface over which it moved was often irregular the motion was disturbed and fluctuating; hence the sinuous and contorted appearance frequently assumed by the banding. When crystals are present they generally have their long axes parallel to the fluxion.

Even when conspicuous and well formed crystals are not visible in the rock there is nearly always an abundance of minute imperfect crystallizations (microlites, &c.). They are often so small that high magnifications may be necessary to ascertain their presence. Some are globular and others are rod-shaped; they may be grouped in clusters, stars, rosettes, rows, chains or swarms of indefinite shape. In banded obsidians these microlites may be numerous in some parts but few or absent in others. The larger ones polarize light, have angular outlines like those of crystals, and may even show twinning and definite optical properties by which they can be identified as belonging to felspar, augite or some other rock-forming mineral. The variety of their shapes is endless. Some are black, very thin and curved like threads or hairs (trichites); often a group of these is seated on a small crystal of augite or magnetite and spreads outwards on all sides. Others have hollow or funnel-shaped ends and are constricted at the middle like a dice cup. In some rocks small rod-like microlites are grouped together in a regular way to form growths which resemble fir branches, fern leaves, brushes or networks, in the same manner as minute needles of ice produce star-like snow crystals or the frost growths on a window pane.

These crystallites (*q.v.*) show that the glassy rock has a tendency to crystallize which is inhibited only by the very viscous state of the glass and the rapidity with which it was cooled. Another type of incipient crystallization which is excessively common in obsidian is spherulites (*q.v.*), or small rounded bodies which have a radiating fibrous structure. They are of globular shape, less frequently irregular or branching, and may be elongated and cylindrical (axiolites). In some obsidians from Teneriffe and Lipari the whole rock consists of them, so closely packed together that they assume polygonal shapes like the cells of a honeycomb. In polarized light they show a weak grey colour with a black cross, the arms of which are parallel to the cobwebs in the eyepiece of the microscope and remain stationary when the section is rotated. Often bands of spherulites alternate with bands of pure glass, a fact which seems to indicate that the growth of these bodies took place before the rock ceased to flow.

As cooling progresses the glassy rock contracts and strain phenomena appear in consequence. Porphyritic crystals often contract less than the surrounding glass, which accordingly becomes strained, and in polarized light may show a weak double refraction in a limited area surrounding the crystal. Minute cracks are sometimes produced by the contraction; they are often more or less straight, but in other cases a very perfect system of rounded fissures arises. These surround little spherules of glass which are detached when the rock is struck with a hammer. There may be concentric series of cracks one within another. The minute globular bodies have occasionally a sub-pearly lustre, and glassy rocks which possess this structure have been called perlites (*q.v.*). If we take a thin layer of natural Canada balsam and heat it strongly for a little time most of the volatile oils are driven out of it. When it cools it becomes hard, but if before it is quite cold we plunge it into cold water a very perfect perlitic structure will arise in it. Occasionally the rounded cracks extend from the matrix into some of the crystals especially those of quartz which have naturally a conchoidal fracture. If the matrix, however, is originally crystalline it does not seem probable that perlitic structure can develop in it. Hence it may be regarded as diagnostic of rocks which were vitreous when they consolidated.

In mineralogical collections rounded nodules of brown glass, varying from the size of a pea to that of an orange, may often be seen labelled *marekanite*. They have long been known to geologists and are found at Okhotsk, Siberia, in association with a large mass of perlitic obsidian. These globular bodies are, in fact, merely the more coherent portions of a perlite; the rest of the rock falls down in a fine powder setting free the glassy spheres. They are subject to considerable internal strain, as is shown by the fact that when struck with a hammer or sliced with a lapidary's saw they often burst into fragments. Their behaviour in this respect closely resembles the balls of rapidly cooled, unannealed glass which are called Prince Rupert's drops. In their natural condition the marekanite spheres are doubly refracting, but when they have been heated and very slowly cooled they lose this property and no longer exhibit any tendency to sudden disintegration.

Although rocks wholly or in large part vitreous are known from very ancient geological systems, such as the Devonian, they are certainly most frequent in recent volcanic countries. Yet among the older rocks there are many which, though finely crystalline, have the chemical composition of modern obsidians and possess structures, such as the perlitic and spherulitic, which are very characteristic of vitreous rocks. By many lines of evidence we are led to believe that obsidians in course of time suffer devitrification, in other words they pass from the vitreous into a crystalline state, but as the changes take place in a solid mass they require a very long time for their achievement, and the crystals produced are only of extremely small size. A dull stony-looking rock results, the vitreous lustre having entirely disappeared, and in microscopic section this exhibits a cryptocrystalline structure, being made up of exceedingly minute grains principally of quartz and felspar. Often this felsitic devitrified glass is so fine-grained that its constituents cannot be directly determined even with the aid of the microscope, but chemical analysis leaves little doubt as to the real nature of the minerals which have been formed. Many vitreous rocks show alteration of this type in certain parts where either the glass has been of unstable nature or where agencies of change such as percolating water have had easiest access (as along joints, perlitic cracks and the margins of dikes and sills). Obsidians from Lipari often

have felsitic bands alternating with others which are purely glassy. In Arran there are pitchstone dikes, some of which are very completely vitreous, while others are changed to spherulitic felsites more or less silicified. The pitchstone of the Scuir of Eigg is at its margins characterized by a dull semi-opaque matrix which seems to be the result of secondary devitrification. In the same way artificial glass can be devitrified if it be kept at a temperature slightly below the fusing point for some days. Window glass exposed to alkaline vapours often shows a thin iridescent surface film which is supposed to be due to crystallization; the same change is found in pieces of Roman glass which have been dug out of the ruins of Pompeii.

Obsidians occur in many parts of the world along with rhyolites and pumice. In Europe the best-known localities for them are the Lipari Islands, Pantellaria, Iceland and Hungary. Very fine obsidians are also obtained in Mexico, at the Yellowstone Park, in New Zealand, Ascension and in the Caucasus. Included in this group are some rocks which are more properly to be regarded as vitreous forms of trachyte than as glassy rhyolites (Iceland), but except by chemical analyses they cannot be separated. It is certain, however, that most obsidians are very acid or rhyolitic. The dark, semi-opaque glassy forms of the basic igneous rocks are known as tachylytes. The typical obsidians exhibit the chemical peculiarities of the acid igneous rocks (viz. high percentage of silica, low iron, lime and magnesia, and a considerable amount of potash and soda).

The chemical composition of typical obsidians is shown by the following analyses:—

	SiO_2.	Al_2O_3.	FeO.	Fe_2O_3.	CaO.	MgO.	K_2O.	Na_2O.	H_2O.
I. Yellowstone Park .	74·70	13·72	0·62	1·01	0·78	0·14	4·02	3·90	0·62
II. Iceland . . .	75·28	10·22		4·24	1·81	0·25	2·44	5·53	0·23
III. Mexico . . .	73·63	14·25	1·80	..	tr.	1·42	4·39	4·61	..

Obsidian, when broken, shows a conchoidal fracture, like that of glass, and yields sharp-edged fragments, which have been used in many localities as arrow-points, spear-heads, knives and razors. For such purposes, as also for use as mirrors, masks and labrets, it was extensively employed, under the name of *itztli*, by the ancient Mexicans, who quarried it at the Cerro de las Navajas, or "Hill of Knives," near Timapan. The natives of the Admiralty Islands have used it for the heads of spears. By the ancient Greeks and Romans obsidian was worked as a gem-stone; and in consequence of its having been often imitated in glass there arose among collectors of gems in the 18th century the practice of calling all antique pastes "obsidians." At the present time obsidian is sometimes cut and polished as an ornamental stone, but its softness (H = 5 to 5·5) detracts from its value. Certain varieties, notably some from Russia, possess a beautiful metallic sheen, referable to the presence of either microscopic fissures or enclosures. The substance known as moldavite, often regarded as an obsidian, and the so-called obsidian bombs, or obsidianites, are described under MOLDAVITE. (J. S. F.)

OBSTETRICS, the science and art of midwifery (Lat. *obstetrix*, a midwife, from *obstare*, to stand before). Along with Medicine and Surgery, Obstetrics goes to form what has been called the Tripos of the medical profession, because every person desiring to be registered under the Medical Acts must pass a qualifying examination alike in medicine, surgery and midwifery. The term Gynaecology (*q.v.*), which has come to be applied to the study of the diseases of the female generative system, in its primary sense includes all that pertains to women both in health and disease. Obstetrics, or midwifery, is more specially that part of the science of gynaecology which deals with the care of a pregnant woman and the ushering of her child into the world.

Tokology—the doctrine of parturition—is the most distinctive sphere of interest for obstetricians, and here their activities bring them into a closer approximation to the work of surgeons. As a science it demands a study of the phenomena of labour, which in their ordered succession are seen to present three distinct stages: one of preparation, during which the uterus dilates sufficiently to allow of the escape of the infant; a second, of progress, during which the infant is expelled; and a third, of the extrusion of the after-birth or placenta. In each of the stages analysis of the phenomena reveals the presence of three elements which are known as the factors of labour, viz. the powers or forces which are engaged in the emptying of the uterus; the passages or canals through which the ovum is driven; and the passenger or body that is being extruded. The mechanism of labour depends on the balance of these factors as they become adjusted to each other in the varying phenomena of the several stages. The diversities that are met with in different labours even of the same woman have led to their being classified into different groups. A natural labour is commonly defined as one where the child presents by the head and the labour is terminated within twenty-four hours. From this it is obvious that no case of labour can be defined at its onset. The relation of the factors may warrant a favourable expectation; but until the labour is completed, and completed within a reasonably safe period, it cannot be classed as natural. The element of time has this importance, that it is found that, apart from all accidents and interferences, the mortality both to mother and child becomes greater the longer the duration of the labour. Hence lingering or tedious labours, in which the child still presents with the head, but is not expelled within twenty-four hours after the onset of labour-pains, are properly grouped in a separate class, although they are terminated without operative interference. In the class of preternatural labours, where the head comes last instead of first, there are two subdivisions, according as the child presents by the breech and feet, or lies transversely as a cross-birth, and has usually to be delivered artificially. Operative or instrumental labours vary according as the procedures adopted are safe in principle to mother and child, such as turning and the application of the midwifery forceps; or as they involve damage to the infant in the various forms of embryotomy; or are more dangerous to the mother, as in the Caesarean section and symphysiotomy. A final class of labours includes the cases where some complication or anomaly arises and becomes a source of danger, independently of disturbances of the mechanism or of any operative interference. These complex labours are due to complications that may be maternal, such as haemorrhage and convulsions; or foetal, such as twins or prolapse of the umbilical cord. To cope with these anomalies an obstetrician requires all the resource of a physician and all the dexterity of a surgeon.

The interest of obstetricians in their patients does not end with the birth of the children, even after natural labours. The puerpera is still a subject of care. The uterus, that during its nine months' evolution had been increasing enormously in all its elements, has in six weeks to undergo an involution that will restore it to its pregravid condition. The allied organs share in their measure in the change, all the systems of the body feel the influence, and especially the mammary glands take on their function of providing milk for the nutriment of the new-born infant. A patient with some latent flaw in her constitution may pass the test of pregnancy and labour with success, only to succumb during the puerperium. Of patients who become insane in connexion with child-bearing, a half manifest their mental disorder first during the days or weeks immediately succeeding their confinement, and numbers more whilst they are suckling their infants. A woman may have had an easy labour, and may have been thankful at the time for help from a hand that she did not know to be unclean; three days later germs left by that hand may have so multiplied within her that she is in mortal danger from septicaemia. The management of the puerperal patient requires not only the warding off of deleterious influences, but the watching of the normal processes, because slight deviations in these, undetected and uncorrected now, may become later a source of lifelong invalidism. It remains further to be noted that to obstetricians belong the earliest stages of pediatrics in their care of the new-born child. In some old works practitioners of this branch of the profession are described as *ὀμφαλοτόμοι*, because their first business was to cut the umbilical cord. The causes of the high death-rate among infants, whether due to ante-natal, intra-natal or neo-natal conditions, come under their observation. They have charge of the whole wide field of the hygiene, pathology and therapeutics of infancy.

Historical Sketch.—The origin of midwifery is lost in the mists of human origins. The learned Jean Astruc, who gave a lead to higher critics in their analysis of the Pentateuch by pointing out the presence of Elohistic and Jehovistic elements, exercised his imagination in fancying how the earliest pair comported themselves at the birth of their first child, and especially how the husband would have to learn what to do with the placenta and umbilical cord. His speculations are not in the least illuminative. The Mosaic writings let us see women of some experience and authority by the side of a Rachel dying in labour, or a Tamar giving birth to twins, and superintending the easy labours of Hebrew slaves in Egypt. The Ebers Papyrus (1550 B.C.), which Moses may have studied when he grew learned in all the wisdom of the Egyptians, is the oldest known medical production. It contains prescriptions for causing abortion, for promoting labour, for curing displacements of the uterus, &c. But there is no indication as to how labours are to be managed, and with regard to the child there are only auguries given as to whether it will live or die, according, *e.g.* as its first cry after it is born sounds like *ni* or *bâ*.

The story of the rise and progress of midwifery is intimately bound up with the history of medicine in general. The obstetrician, looking for the dawn of his science, turns like his fellow-workers in other medical disciplines to the Hippocratic writings (400 B.C.). Now the father of medicine was not an obstetrician. As with Egyptians and Hebrews, the skilled attendants on women in labour among the Greeks were also women. But since nothing that concerned the ailments of humanity was foreign to Hippocrates, there are indications in the writings that are accounted genuine of his interest in the disorders of females—in their menstrual troubles, in their sterility, in their gestation symptoms, and in their puerperal diseases; his oath forswears the use of abortifacients, and he recommends the use of sternutatories to hasten the expulsion of the after-birth. In the Hippocratic writings that are supposed to be products of his followers, some of these subjects are more fully dealt with; but whilst the physician is sometimes called in to give advice in difficult labours, so that he can describe different kinds of presentation and can speak of the possibility of changing an unfavourable into a favourable lie of the infant, it is usually only with cases where the child is already dead that he has to deal, and then he tells how he has to mutilate and extract it. So these writings furnish us with the earliest account of the accoucheur's armamentarium, and let us see him possessed of a *μαχαίριον*—a knife or perforator for opening the head; a *πίεστρον*—a comminutor for breaking up the bones; and a *ἑλκυστήρ*—an extractor for hooking out the infant. The classical writers of Greece give the same impression as to the primitive stage of obstetrics. Women, like the mother of Socrates, have the charge of parturient women. Where divine aid is sought, goddesses are invoked to facilitate the labour. Gods or men are only called in where graver interference is required, as when Apollo rescued the infant Aesculapius by a Caesarean section performed on the dying Semele. Some midwives are known to history, and extracts from the writings of one Aspasia are embedded in the works of later authors. In the great medical school of Alexandria, when the science of human anatomy began to take shape, Herophilus rendered a service to obstetrics in giving a truer idea of the anatomy of the female than had previously prevailed; other physicians give evidence of their interest in midwifery and the diseases of women, and some experience was gradually being acquired and transmitted through the profession until we find from Celsus (in the reign of Augustus) that when surgeons were called in to help the attendant woman they could sometimes bring about the delivery, without destroying the infant, by the operation of turning. In the 2nd century Soranus wrote a work on midwifery for the guidance of midwives, in which for the first time the uterus is differentiated from the vagina and instruction is given for the use of a speculum. A contemporary, Moschion, wrote a guide for midwives which, with that of Soranus, may be said to touch the high-water mark of archaic midwifery. It is written in the form of question and answer, was much prized at the time of the Renaissance, and was used as the basis of the first obstetric work that issued from a printing-press. Philumenos wrote a treatise of some value at the same epoch, but it is only known from the free use made of it by subsequent writers, such as Aëtius in the beginning of the 6th century. Like Oribasius, who preserved in his compilation the work of Soranus, Aëtius draws largely on preceding writers. His treatises on female diseases constitute an advance on previous knowledge, but there is no progress in midwifery, though he still makes mention of turning. This operation has disappeared from the pages of Paulus Aegineta, an 8th-century author, the last to treat at length of obstetrics and gynaecology ere the night of the dark ages settled down on the Roman world, and it is not heard of again till a millennium had passed. During the centuries when the progress of medicine was dependent on the work of the Arabian physicians, the science of obstetrics stood still. We are curious to know what Rhazes and Avicenna in the 9th and 10th centuries have to say on this subject. But they know little but what they have learned from the Greek writers, and they show a great tendency to relapse to the rudest procedures and to have recourse to operative interferences destructive to the child. Interest attaches to the work of Albucasis in the 12th century, in that he is the first to illustrate his pages with figures of the knives, crushers and extractors that were employed in their gruesome practices, and that he gives the first history of a case of extra-uterine pregnancy.

We come down to the 16th century before we begin to see any indication of the development of obstetrics towards a place among the sciences. Medicine and surgery profited earlier by the intellectual awakenings of the Renaissance and the Reformation. In anatomical theatres and hospital wards associated with universities great anatomists and clinicians began to discard the dogmas of Galen, and to teach their pupils to study the body and its diseases with unprejudiced minds. But the practice of midwifery was still among all people in the hands of women, and when in 1513 Eucharius Roesslin of Frankfort published a work on midwifery, it bore the title *Der schwangeren Frawen und hebammen Rosengarten*. Translated into English by Thomas Raynald with the altered title, *The Birth of Mankynd*, it is mainly compiled from Moschion, and the Soranus and Philumenos fragments of Oribasius and Aëtius, and is intended as a guide to pregnant women and their attendant nurses. It was illustrated with fanciful figures of the foetus *in utero* that were reproduced in other works of later date—as in the *Rosengarten* of Walter Reiff of Strassburg in 1546 and the *Hebammenbuch* of Jacob Rueff of Zurich in 1554, the latter of which appears in English dress as *The Expert Midwife*. The greatest impulse to the progress of midwifery was given in the middle of the 16th century by the famous French surgeon Ambroise Paré, who revived the operation of podalic version, and showed how by means of it surgeons could often rescue the infant even in cases of head presentation, instead of breaking it up and extracting it piecemeal. He was ably seconded by his pupil Guillemeau, who translated his work into Latin, and at a later period himself wrote a treatise on midwifery, an English translation of which was published in 1612 with the title *Child-Birth; or, The Happy Deliverie of Women*. The close of the 16th century is rendered further memorable in the annals of midwifery by the publication of a series of works specially devoted to it. Three sets of compilations, containing extracts from the various writers on obstetrics and gynaecology from the time of Hippocrates onwards, were published under the designation of *Gynaecia* or *Gynaeciorum*—the first edited by Caspar Wolff of Zurich in 1566, the second by Caspar Bauhin of Basel in 1586, and the third by Israel Spach of Strassburg in 1597. Spach includes in his collection not only Paré's obstetrical chapters, but the Latin translation of the important *Traitte nouveaux de l'hysterotomotokie*, published by the French surgeon Francis Rousset in 1581, which is the first distinct treatise on an obstetric operation, and advocates the performance of Caesarean section on living women with difficult labours. From this time onwards evidence accumulates of the growing interest

of members of the medical profession, and more especially of surgeons, in the practice of midwifery, and after the middle of the 17th century they began to publish the records of their experiences in special treatises. The most important of these writers were French—as Mauriceau, Viardel, Paul Portal, Peu and Dionis. The work of Mauriceau, which first appeared in 1668, is specially interesting from its having been translated into English in 1672 by Hugh Chamberlen, who in his preface made the then incredible statement that his father, his brothers, and himself had long attained to and practised a way to deliver women in difficult labours without hooks, where other artists used them, and without prejudice to mother or child. Many years had still to elapse before the secret of the Chamberlens leaked out. In the course of this century some women who had large experience in midwifery appeared as authors. Thus in England Jane Sharp in 1671 wrote *The Midwives' Book, or the whole art of Midwifery discovered*; in Germany, Justine Siegemund, in 1690, *Die Chur-Brandenburgische Hoff-Wehemutter*; and earlier and better than either, in France, Louise Bourgeois in 1626 published *Observations sur la stérilité et maladies des femmes*. Perhaps they were beginning to feel that there was some need to assert their power, for it was during this century that parturient ladies began to call in men to attend them in natural labours. According to Astruc, Madame de la Vallière wished her confinement to be kept secret, and Louis XIV., in June 1663, sent for Jules Clement, the court surgeon, to superintend the delivery. This was accomplished successfully. The king gave him the title of accoucheur. Clement afterwards attended the dauphiness and other court ladies, and went thrice to Madrid to assist at the confinement of the queen of Philip IV. Up till this epoch physicians and surgeons had only been summoned to the lying-in room by midwives who found themselves at the end of their resources, to give help in difficult cases where the child was usually dead and the mother often moribund. Now that it began to be a fashion for women in their ordinary confinements to be under the surveillance of a physician, it became possible for men with their scientific training to study the normal phenomena of natural labour, and through the medium of the printing-press to communicate the results of their observation and experience to their professional brethren. Hence the books of the men already referred to, and of others that appeared later, such as the *Traité complet des accouchemens* of De la Motte, 1721, which is a storehouse of acute observations and wise discussion of obstetric measures. In other countries than France physicians and surgeons began to take up midwifery as a speciality and not as a subsidiary part of their practice, of which they were somewhat ashamed (le Bon, one of the writers whose work is found in Bauhin's *Gynaecia*, says: "Haec ars viros dedecet"), and it was in Holland that a work was produced that has earned for its author the designation of the Father of Modern Midwifery. Heinrich van Deventer, who practised as an obstetrician at the Hague along with his wife (a Vroedvrow, as he was a Vroedmeester), published in 1696 a preliminary treatise called *Dageraat* (*Aurora*) *der Vroedvrouwen*, and in 1701 he followed it up by a more complete second volume, of which the Latin edition that came out simultaneously with the Dutch has a title beginning *Operationes Chirurgicae Novum Lumen Exhibentes Obstetricantibus*. It has the supreme value of being the first work to give a scientific description of the pelvis, and to take some steps towards the development of the mechanism of labour. The "obstetricantes" for whom Deventer wrote are both men and women. In the early part of the 18th century women had still the main and often the sole charge of their parturient sisters; but the practice of having a doctor to superintend or to supersede the midwives kept spreading among the classes who could afford to pay the doctor's fee; and by the time Deventer's treatise was doing its educational work in an English translation, as *The Art of Midwifery Improved*, in 1716, the doctors were getting into their hands the "harmless forceps" with which a living child could be extracted without detriment to the mother, in conditions where formerly her child's life was sacrificed and her own endangered. This life-saving instrument was invented in London, but by a man not of English birth. The Huguenot, William Chamberlen, fled from Paris to escape the St Bartholomew massacres, carrying with him to Southampton his wife, his two sons, and a daughter. William Chamberlen seems to have been a surgeon, and his descendants through four generations had large and lucrative practices in London. The eldest son Peter, who was old enough when he came to England to be able to attest the birth and baptism of a younger brother, is, on good grounds, credited with being the inventor of the forceps, which for a century was kept a secret among brothers, sons and grandsons. Hugh, indeed, a great-grandson of William, and the translator of Mauriceau, had offered to sell the family secret for 10,000 crowns; but his failure to effect delivery in a test case that Mauriceau put to him led the profession to believe that he was a boastful quack. Palfyn of Ghent, when in Paris in 1723, putting a work on anatomy through the press, laid before the Academy of Science a pair of forceps, which was figured in Heister's surgery in 1724. He has thus the honour of first laying before the profession a midwifery forceps. But his implement was ill-constructed, and never came into general use. Meanwhile the knowledge that the Chamberlens were really possessed of a serviceable instrument must have stimulated other practitioners. Perhaps a colleague with a keen eye may have got sight of it on some occasion, or an intelligent midwife had been able to describe the "tongs" which she had seen one of the family apply. In 1734 Dr Edward Hody published a record of *Cases in Midwifery* that had been written by Mr William Giffard, "surgeon and man-midwife." The dates range from January 1724 to 1731. Amongst the cases are several where he effected the delivery by means of the forceps—"extractor," he calls it—of which a figure is given; and when Edmund Chapman, who practised first at Halstead and afterwards in London, published his *Treatise on the Improvement of Midwifery* in 1733, he speaks of the use of the forceps as "now well known to all the principal men of the profession both in town and country."

In the course of the 18th century the development of midwifery in the hands of medical men made greater strides than in all the preceding ages. The progress was accelerated by the establishment of chairs of midwifery in the universities of various countries, Edinburgh taking the lead in the appointment of a professor in 1726, and Strassburg coming closely after in 1728. In Strassburg the chair had the advantage of being at once associated with a clinical service. Lecturing was carried out, moreover, by men who were devoting themselves as specialists in midwifery and the diseases of women and infants, and were succeeding in developing lying-in institutions for the benefit of poor women in labour that became schools of instruction both for midwifery nurses and for medical students. Two new operations came during this epoch to enhance the powers of the obstetrician, viz. symphysiotomy, first introduced by Sigault in Paris; and the induction of premature labour, first carried out by Macauley in London in circumstances described by Denman in the preface to his *Midwifery*. William Hunter in London, Sir Fielding Ould in Dublin, Röderer in Göttingen, Camper in Amsterdam, Baudelocque in Paris, Saxtorph in Copenhagen, and many other authors contributed to progress by their atlases and their books. But there are three whose names stand out pre-eminently because of the influence they exerted on the whole obstetric world—Levret, Smellie and Boër. Kilian, in his vidimus of the history of midwifery, calls Levret "one of the greatest masters in the department that ever lived." Of Smellie he says: "Inferior to Levret in nothing, he excels him in much." Boër he characterizes as "the most meritorious and important of German obstetricians." Levret improved the construction of the forceps, and widened the sphere of their applicability; Smellie worked in the same direction, and furnished, moreover, descriptions and illustrations of natural and morbid labours that are of classical value; and Boër first clearly placed pregnancy (which Mauriceau, *e.g.* had spoken of as "a nine months' disease") and parturition in the category of physiological processes that might be hindered rather than

elped by the pragmatical interferences of meddlesome mid-ives.

Throughout the 19th century midwifery continued to advance, ynaecology grew into a special department with an extensive terature, the mechanism of labour developed under the clinical bservations of men like Nägele and the study of such frozen ections of cadavera as were made by Braune, the indications r interference became more clear and the methods of inter-rence more simple and safe, and a whole realm of antenatal athology and teratology was added to the domain of science, hile practitioners learned the art of saving premature and elicate infants by the use of the incubator and proper alimenta-on. Every advance in all the cognate sciences was appreciated nd applied for the advancement of obstetrics. But there are wo achievements which will make the 19th century for ever emorable in the annals of midwifery—the abolition of the ains of labour and the arrest laid on mortality from the so-alled puerperal fever. In February 1847 Sir J. Y. Simpson, hoosing a case where he had to deliver by turning, put the atient asleep with ether. Seeing that the uterine contractions ontinued, though the attendant pain was abolished, he pro-eeded to administer ether in cases of natural labour, and in lovember of the same year demonstrated the virtues of chloro-orm, and so furnished the most serviceable anaesthetic, not only o the obstetrician in the lying-in room, but to the surgeon on he battlefield, and to the general practitioner in his everyday ork. Ignaz Philipp Semmelweiss, assistant in the maternity ospital of Vienna, was struck and saddened with the appalling ortality that attended the delivery of the women under his are, as many as one (in some months three) out of every ten f the puerperae being carried out dead. He observed that the ortality was much higher in the wards allotted to the tuition f students than in those set apart for the training of nurses. n the spring of 1847 he saw at the post-mortem examination f a young colleague who had died of a poisoned wound, that he appearances were the same as he had too often had occasion o see at the post-mortem examinations of his puerperae. He rdered that every student who assisted a woman in her labour ust first wash his hands in a disinfectant solution of chloride f lime, and in 1848 already the mortality was less in the students' han it was in the nurses' wards. Thus the first light was shed n the nature of the mischief of which multitudes of puerperal atients perished, and the first intelligent step was taken to ssen the mortality. When, some twenty years later, Lister ad applied the bacteriological principles of Pasteur, with eneficent results to surgery, obstetricians gladly followed his ead, and the 19th century beheld added to the comfort of naesthetic midwifery the confidence of midwifery antiseptic nd even aseptic

The most exhaustive treatise on the earlier history of midwifery s von Siebold, *Versuch einer Geschichte der Geburtshülfe* (Berlin, 1839). (A. R. S.)

OCALA (a Seminole word for green or fertile land), a city nd the county-seat of Marion county, Florida, U.S.A., in the N. central part of the state, about 100 m. S.W. of Jacksonville. Pop. (1900) 3380, (1905) 4493, of whom 2467 were negroes, (1910) 5370. It is served by the Seabord Air Line and the Atlantic Coast Line railways. About 6 m. E. is Silver Spring, the largest nd best known of the springs of Florida. Its basin is circular, bout 600 ft. in diameter; it is about 65 ft. in depth, and its aters are remarkable for their transparency and refractive owers. According to the estimate of Dr D. G. Brinton, the pring discharges more than 300,000,000 gallons of water daily, s outflow forming what is known as Silver Spring Run, 9 m. ong, emptying into the Oklawaha river and navigable by small iver steamers. For the drainage and sewerage of the city a ubterranean river whose source and mouth are unknown is tilized. The city is the seat of the Emerson Memorial and Industrial Home (Methodist Episcopal) for negro girls. Ocala was settled in 1845, but its development dates from 1880, when it was first chartered as a city. In December 1890 it was the meeting-place of the National Convention of the Farmers' Alliance, which promulgated a statement of political principles generally known as the "Ocala Platform." (See FARMERS' MOVEMENT.)

OCAÑA, a town of central Spain, in the province of Toledo, on the extreme north of the tableland known as the Mesa de Ocaña, with a station on the railway from Aranjuez to Cuenca. Pop. (1900) 6616. The town is surrounded by ruined walls, and in it are the remains of an old castle. In one of its parish churches is the chapel of Nuestra Señora de los Remedios, in which Ferdinand and Isabella were married in 1469. Ocaña is the Vicus Cuminarius of the Romans, and was the dowry that El Motamid of Seville gave his daughter Zaida on her marriage with Alphonso VI. of Castile (1072–1109). Near Ocaña, on the 19th of November 1809, the Spanish under their Irish general Lacy were routed by the French under Joseph Bonaparte and Marshal Soult.

OCARINA, a wind instrument invented in Italy, which must be classed with musical toys or freaks, although concerted music has been written for it. The ocarina consists of an earthenware vessel in the shape of an egg with a pointed base and a tube like a spout in the side, which contains the mouthpiece. There are usually 10 holes in the front surface of the instrument, nine for fingers and thumb and a vent hole, the newer models have 8 holes and two keys. By half covering the holes the semitones are obtained.

O'CAROLAN (or CAROLAN), **TURLOGH** (1670–1738), Irish bard, son of John O'Carolan, a farmer, was born at Newtown, near Nobber, in the county of Meath. The family is said to have belonged to the sept of MacBradaigh, and the bard's great-grandfather was a chieftain. The O'Carolans forfeited their estates during the civil wars, and Turlogh's father settled at Alderford, Co. Roscommon, on the invitation of the family of M'Dermott Roe. In his eighteenth year he became blind from smallpox. He received special instruction in music, and used to wander with his harp round the houses of the surrounding gentry, mainly in Connaught. The famous song *Receipt for Drinking* may be responsible for the allegation that he was addicted to intemperate drinking, but Charles O'Conor (1710–1791), the antiquary, who had personal knowledge of him, gives him a good character in private life. The number of Carolan's musical pieces, to nearly all of which he composed verses, is said to exceed two hundred. He died on the 25th March 1738, and was buried at Kilronan.

His poetical *Remains* in the original Irish, with English metrical translations by Thomas Furlong, were printed in Hardiman's *Irish Minstrelsy* (1831). Many of his songs were preserved among the Irish MSS. in the British Museum.

OCCAM, WILLIAM OF (d. *c.* 1349), English schoolman, known as *Doctor invincibilis* and *Venerabilis inceptor*, was born in the village of Ockham, Surrey, towards the end of the 13th century. Unattested tradition says that the Franciscans persuaded him while yet a boy to enter their order, sent him to Merton College, Oxford (see G. C. Brodrick, *Memorials of Merton College*, p. 194), and to Paris, where he was first the pupil afterwards the successful rival, of Duns Scotus. He probably left France about 1314, and there are obscure traces of his presence in Germany, in Italy, and in England during the following seven years. It has generally been held that in 1322 he appeared as the provincial of England at the celebrated assembly of the Franciscan order at Perugia, and that there he headed the revolt of the Franciscans against Pope John XXII.; but, according to Little (*English Historical Review*, vi. 747), the provincial minister on this occasion was William of Nottingham. Probably, however, Occam was present at the assembly. His share in this revolt resulted in his imprisonment, on the charge of heresy, for seventeen weeks in the dungeons of the papal palace at Avignon. He and his companions —Michael of Cesena, general of the order, and Bonagratia— managed to escape, and found their way to Munich, where they aided Louis IV. or V. (q.v.) of Bavaria in his long contest with the papal curia. It was for Occam's share in this controversy that he was best known in his lifetime. Michael of Cese

died in 1342, and Occam, who had received from him the official seal of the order, was recognized as general by his party. The date of his death and the place of his burial are both uncertain. He probably died at Munich in 1349.

William of Occam was the most prominent intellectual leader in an age which witnessed the disintegration of the old scholastic realism, the rise of the theological scepticism of the later middle ages, the great contest between pope and emperor which laid the foundations of modern theories of government, and the quarrel between the Roman curia and the Franciscans which showed the long-concealed antagonism between the theories of Hildebrand and Francis of Assisi; and he shared in all these movements.

The common account of his philosophical position, that he reintroduced nominalism, which had been in decadence since the days of Roscellinus and Abelard, by teaching that universals were only *flatus vocis*, is scarcely correct. The expression is nowhere found in his writings. He revived nominalism by collecting and uniting isolated opinions upon the meaning of universals into a compact system, and popularized his views by associating them with the logical principles which were in his day commonly taught in the universities. He linked the doctrines of nominalism on to the principles of the logic of Psellus, which had been introduced into the West in the *Summulae* of Peter of Spain, and made them intelligible to common understandings. The fundamental principles of his system (see SCHOLASTICISM) are that "Essentia non sunt multiplicanda praeter necessitatem" ("Occam's Razor"), that nouns, like algebraical symbols, are merely denotative terms whose meaning is conventionally agreed upon (*supposito*), and that the destructive effect of these principles in theological matters does not in any way destroy faith (see the *Centilogium Theologicum*, Lyons, 1495, and *Tractatus de Sacramento Altaris*).

In the *Opus nonaginta dierum* (1330) (written in reply to John XXII.'s libellus against Michael of Cesena), and in its successors, the *Tractatus de dogmatibus Johannis XXII. papae* (1333–1334), the *Compendium errorum Johannis XXII. papae* (1335–1338) and in the *Defensorium contra errores Johannis XXII. papae* (1335–1339), Occam only incidentally expounds his views as a publicist; the books are mainly, some of them entirely, theological, but they served the purpose of the emperor and of his party, because they cut at the root of the spiritual as well as of the temporal supremacy of the pope. In his writing *Super potestate summi pontificis octo quaestionum decissiones* (1339–1342) Occam attacks the temporal supremacy of the pope, insists on the independence of kingly authority, which he maintains is as much an ordinance of God as is spiritual rule, and discusses what is meant by the state. His views on the independence of civil rule were even more decidedly expressed in the *Tractatus de jurisdictione imperatoris in causis matrimonialibus*, in which, in spite of the medieval idea that matrimony is a sacrament, he demands that it belongs to the civil power to decide cases of affinity and to state the prohibited degrees. By 1343 there was in circulation his great work the *Dialogus* (see Goldast ii. 398-957), in which he attempted to present his views in a complete summary. It consists of three parts. The first is the *De fautoribus hereticorum*, and deals with the pope as arbiter in the matter of heresy. The second part is the refutation of the doctrines of John XXII. (see above treatises). The third was to be in nine sections, of which the first and second sections alone remain to us. It is probable that the *Opus nonaginta dierum* and the *Compendium errorum* were intended to form part of the work. His last work, *De Electione Caroli IV.*, restates his opinions upon temporal authority and adds little that is new.

In all his writings against Pope John XXII. (*q.v.*), Occam inveighs against the pope's opinions and decisions on the value of the life of poverty. The *Compendium errorum* selects four papal constitutions which involved a declaration against evangelical poverty, and insists that they are full of heresy. Occam was a sincere Franciscan, and believed with his master that salvation was won through rigid imitation of Jesus in His poverty and obedience, and up to his days it had always been possible for Franciscans to follow the rules of their founder within his order. John XXII., however, condemned the doctrine and excommunicated its supporters, some of whom were so convinced of the necessity of evangelical poverty for a truly Christian life that they denounced the pope when he refused them leave to practise it as Antichrist. After Occam's days the opinions of Francis prevailed in many quarters, but the genuine Franciscans had no place within the church. They were Fraticelli, Beghards, Lollards or other confraternities unrecognized by the church and in steady opposition to her government.

Beside the theological and political works above quoted, Occam wrote *Summa Logices* (Paris, 1488, Oxford, 1675) commentaries on Porphyry's *Isagoge*, on the *Categoriae*, *De Interpretatione* and *Elenchi* of Aristotle. These latter were printed in 1496 at Bologna, and entitled *Expositio Aurea super totam artem veterem*; *Quaestiones in quattuor libros sententiarum* (Lyons, 1495).

There is no good monograph on Occam. For an account of his logic, see Prantl, *Geschichte der Logik* (1855–1870); for his philosophy, see Stöckl, *Geschichte der Philosophie des Mittelalters* (1864–1866), vol. ii., for his publicist writings, see Riezler, *Die literarischen Widersacher der Päpste zur Zeit Ludwig des Baiers* (1874). See also T. M Lindsay's article on "Occam and his connexion with the Reformation," in the *Brit. Quart. Review* (July, 1872). Among ancient documents consult Denifle and Chatelain's *Chartularium Universitatis Parisiensis*, vol. ii. pt. i. (Paris, 1887); Wadding's *Annales Minorum* (ed. Fonseca, vols. 7 and 8, Rome, 1733). For a list of Occam's works, see Little's *Grey Friars*, pp. 225-234.

(T. M. L.)

OCCASIONALISM (Lat. *occasio*, an event), in philosophy, a term applied to that theory of the relation between matter and mind which postulates the intervention of God to bring about in the one a change which corresponds to a similar change in the other. The theory thus denies any direct interaction between matter and mind. It was expounded by Geulincx and Malebranche to avoid the difficulty of Descartes's dualism of thought and extension, and to explain causation. Thus mind and matter are to Geulincx only the "occasional" causes of each other's changes, while Malebranche, facing further the epistemological problem, maintains that mind cannot even know matter, which is merely the "occasion" of knowledge.

OCCLEVE (or HOCCLEVE), **THOMAS** (1368–1450?), English poet, was born probably in 1368/9, for, writing in 1421/2 he says he was fifty-three years old (*Dialog*, i. 246). He ranks, like his more voluminous and better known contemporary Lydgate, among those poets who have a historical rather than intrinsic importance in English literature. Their work rarely if ever rises above mediocrity; in neither is there even any clear evidence of a poetic temperament. Yet they represented for the 15th century the literature of their time, and kept alive, however faintly, the torch handed on to them by their "maister" Chaucer, to whom Occleve pays an affectionate tribute in three passages in the *De Regimine Principum*. What is known of Occleve's life has to be gathered mainly from his works. At eighteen or nineteen he obtained a clerkship in the Privy Seal Office, which he retained on and off, in spite of much grumbling, for about thirty-five years. He had hoped for a benefice, but none came; and in 1399 he received instead a small annuity, which was not always paid as regularly as he would have wished. "The Letter to Cupid," his first poem to which we can affix a date, was translated from *L'Epistre au Dieu d'Amours* of Christine de Pisan in 1402, evidently as a sort of antidote to the moral of *Troilus and Cressida*, to some MSS. of which we find it attached. "La Male Regle," one of his most readable poems, written about 1406, gives some interesting glimpses of his "misruly" youth. But about 1410 he settled down to married life, and the composition of moral and religious poems. His longest work, *The Regement of Princes* or *De Regimine Principum*, written for Prince Hal shortly before his accession, is a tedious homily on the virtues and vices, imitated from Aegidius de Colonna's work of the same name, from the supposititious epistle of Aristotle, known as the *Secreta secretorum*, and the work of Jacques de Cessoles (fl. 1300) englished later by Caxton as *The Game and Playe of Chesse*. It is relieved by a proem, about a third of the whole, containing some further reminiscences of London tavern and club life, in the form of dialogue between the poet and a beggar. On the accession of Henry V. Occleve turned his muse to the service of orthodoxy and the Church, and one of his poems is a remonstrance addressed to Oldcastle, calling upon him to "rise up, a manly knight, out of the slough of heresy." Then a long illness was followed for a time, as he tells us, by insanity. His "Dialog with a Friend," written after his recovery, gives a naïve and pathetic picture of the poor poet, now fifty-three, with sight and mind impaired, but with hopes still left of writing a tale he owes his good patron, Humphrey of Gloucester, and of translating a small Latin treatise, *Scite Mori*, before he dies. His hopes were fulfilled in

his moralized tales of "Jereslaus' Wife" and of "Jonathas," both from the *Gesta Romanorum*, which, with his "Learn to die," belong to his old age. After finally retiring from his privy seal clerkship, he was granted in 1424 sustenance for life in the priory of Southwick, Hants, on which, with his former annuity, he appears to have lived till about the middle of the century. A "Balade to my gracious Lord of Yorke" probably dates from 1448 or later.

The main interest for us in Occleve's poems is that they are characteristic of his time. His hymns to the Virgin, balades to patrons, complaints to the king and the king's treasurer, versified homilies and moral tales, with warnings to heretics like Oldcastle, are illustrative of the blight that had fallen upon poetry on the death of Chaucer. The nearest approach to the realistic touch of his master is to be found in Occleve's "Male Regle." But these pictures of 15th-century London are without even the occasional flash of humour that lightens up Lydgate's *London Lackpenny*. Yet Occleve has at least the negative virtue of knowing the limits of his powers. He says simply what he means, and does not affect what he does not feel. A Londoner, to whom the country was evidently a bore, he has not afflicted us with artificial May mornings; and it is doubtful whether a single reference to nature can be found among his poems. He has yet another distinction among his contemporaries: he wrote no allegory. Whether we ascribe it to his lack of "engine," or to the influence of Chaucer when in his later years he had discovered the limitations of this poetic form, we cannot but be grateful to the poet who has spared us. As a metrist Occleve is also modest of his powers. He confesses that

> Fader Chaucer fayn wolde han me taught,
> But I was dul and learned lite or naught;

and it is true that the scansion of his verses seems occasionally to require, in French fashion, an accent on an unstressed syllable. Yet his seven-line (or *rime royale*) and eight-line stanzas, to which he limited himself, are perhaps more frequently reminiscent of Chaucer's rhythm than are those of Lydgate.

A poem, "Ad beatam Virginem," generally known as the "Mother of God," and once attributed to Chaucer, is copied among Occleve's works in MS. Phillipps 8151 (Cheltenham), and may thus be regarded as his work. Occleve found an admirer in the 17th century in William Browne, who included his "Jonathas" in the *Shepheards Pipe* (1614). Browne added a eulogy of the old poet, whose works he intended to publish in their entirety (*Works*, ed. W. C. Hazlitt, 1869, ii. 196-198). In 1796 George Mason printed six *Poems by Thomas Hoccleve never before printed . . .*; "De Regimine Principum" was printed for the Roxburghe Club in 1860, and by the Early English Text Society in 1897. See Dr F. J. Furnivall's introduction to *Hoccleve's Works; I. The Minor Poems, in the Phillipps MS. 8151, and the Durham MS. III. 9* (Early English Text Society, 1892). (W. S. M.)

OCCULTATION (from Lat. *occultare*, the frequentative of *occulere*, to hide), in astronomy, the hiding of one celestial body by another passing in front of it; commonly the passage of the moon or of a planet between the observer and a star or another planet.

OCEAN AND OCEANOGRAPHY. "Ocean" is the name applied to the great connected sheet of water which covers the greater part of the surface of the Earth. It is convenient to divide the subject-matter of physical geography into the atmosphere, hydrosphere and lithosphere, and in this sense the ocean is less than the hydrosphere in so far as the latter term includes also the water lying on or flowing over the surface of the land. The conception of an encompassing ocean bounding the habitable world is found in the creation myths of the most ancient civilizations. The Babylonians looked on the world as a vast round mountain rising from the midst of a universal sheet of water. In the Hebrew scriptures the waters were gathered together in one place at the word of God, and the dry land appeared. The Ionian geographers looked on the circular disk of the habitable world as surrounded by a mighty stream named Oceanus, the name of the primeval god, father of gods and men, and thus the bond of union between heaven and earth. The Greek word *ὠκεανός* is related to the Sanskrit *açâyanas*, "the encompassing." Philologists do not know of any related word in Semitic languages. Pictet, however, recognizes allied forms in Celtic languages, *e.g.* the Irish *aigean* and Cymric *eigiawn*.

Since the Pythagorean school of philosophy upheld the spherical as against the disk-shaped world, some of the ancient geographers, including Eratosthenes and Strabo, looked upon the hydrosphere as forming two belts at right angles to each other, one belt of ocean following the equator, the other surrounding the earth from pole to pole as in the *terra quadrifida* of Macrobius; while others, including Aristotle and Ptolemy, looked upon the inhabited land, or *oikumene*, as occupying the greater part of the earth's surface, so that the Indian Ocean was an enclosed sea and India (*i.e.* eastern Asia) was only separated from Europe by the Atlantic Ocean. The latter view prevailed and was as a rule held by the Arab geographers of the middle ages, so that until the discovery of America and of the Pacific Ocean the belief was general that the land surface was greater than the water surface, or that at least the two were equal, as Mercator and Varenius held. Thus it was that a great South Land appeared on the maps, the belief in the prodigious extension of which certainly received a severe shock by Abel Tasman's voyage of circumnavigation, but was only overthrown after Cook's great voyages had proved that any southern land which existed could not extend appreciably beyond the polar circle. Only in our own day has the existence of the southern continent been demonstrated within the modest limits of Antarctica.

Oceanography is the science which deals with the ocean, and since the ocean forms a large part of the earth's surface oceanography is a large department of geography. The science is termed *talassografia* by the Italians, and attempts have been made without success to introduce the name "thalassography." Of recent years the use of "hydrography" as the equivalent of physical oceanography has acquired a certain currency, but as the word is also used with more than one other meaning (see SURVEYING) it ought not to be used for oceanography.

Like geography, oceanography may be viewed in two different ways, and is conveniently divided into *general oceanography*, which deals with phenomena common to the whole ocean, and *special oceanography*, which has to do with the individual characteristics of the various divisions of the ocean. This article is restricted to general oceanography in its physical aspects, the closely-related meteorological, biological and economic aspects being dealt with elsewhere.

Methods of Research.—When research in oceanography began, the conditions of the sea were of necessity observed only from the coast and from islands, the information derived from mariners as to the condition of parts of the sea far from land being for the most part mere anecdotes bearing on the marvellous or the frightful. In recent times, especially since the rapid increase in the study of the exact sciences during the 19th century, observations at sea with accurate instruments have become common, and the ships' logs of to-day are provided with headings for entering daily observations of the phenomena of the sea-surface. The contents of the sailors' scientific logs were brought together by the American enthusiast in the study of the sea, Matthew Fontaine Maury (1806–1873), whose methods and plans were discussed and adopted at international congresses held in Brussels in 1853 and in London in 1873. By 1904 more than 6800 of these meteorological logs with 7,000,000 observations had been accumulated by the Meteorological Office in London; 20,000 with 10,600,000 observations by the German Marine Observatory at Hamburg; 4700 with 3,300,000 observations by the Central Institute of the Netherlands at de Bilt near Utrecht. The Hydrographic Office of the United States had collected 3800 meteorological logs with 3,200,000 entries before 1888; but since that time the logs have contained only one observation daily (at Greenwich noon) and of these 2,380,000 entries had been received by 1904. In the archives of the French Marine in Paris there were 3300 complete logs with 830,000 entries and 11,000 abstract logs from men-of-war. The contents of these logs, it is true, refer more to maritime meteorology than to oceanography properly so-called, as their main purpose is to

promote a rational system of navigation especially for sailing ships, and they are supplied by the voluntary co-operation of the sailors themselves.

While the sailors' logs supply the greater part of the scientific evidence available for the study of the surface phenomena of the ocean, they have been supplemented by the records of numerous scientific expeditions and latterly by publications embodying systematic observations on a permanent basis. Valuable observations were made in oceanography during the expeditions of Captain James Cook and the polar explorers, especially those of Sir John Ross in the north and Sir James Ross in the south, but the voyage of H.M.S. "Challenger" in 1872–1876 formed an epoch marking the end of the older order of things and the beginning of modern oceanography as a science of precision. The telegraph cable companies were quick to apply and to extend the oceanographical methods useful in cable-laying, and to their practical acuteness many of the most important improvements in apparatus are due. A second epoch comparable to that of the "Challenger" and resulting like it in a leap forward in the precision of the methods previously employed was marked by the institution in 1901 of the International Council for the Study of the Sea. This council was nominated by the governments of Norway, Sweden, Denmark, Finland, Russia, Germany, Great Britain, Holland and Belgium, with headquarters in Copenhagen and a central laboratory at Christiania, and its aim was to furnish data for the improvement of the fisheries of the North Sea and surrounding waters. In the course of investigating this special problem great improvements were made in the methods of observing in the deep sea, and also in the representation and discussion of the data obtained, and a powerful stimulus was given to the study of oceanography in all the countries of Europe. The efforts of individual scientific workers cannot as a rule produce such results in oceanography as in other sciences, but exceptions are found in the very special services rendered by the prince of Monaco, who founded the Oceanographical Institute in Paris and the Oceanographical Museum in Monaco; and by Professor Alexander Agassiz in the investigation of the Pacific.

Extent of the Ocean.—The hydrosphere covers nearly three-quarters of the earth's surface as a single and continuous expanse of water surrounding four great insular land-masses known as the continents of the Old World (Europe, Asia, Africa), America, Australia and Antarctica. As we are still ignorant of the proportions of land and water in the polar regions, it is only possible to give approximate figures for the extent of the ocean, for the position of the coast-lines is not known exactly enough to exclude possible errors of perhaps several hundred thousand square miles in estimates of the total area. Speaking generally, we may say with confidence that water predominates in the unexplored north polar area, and that it is very unlikely that new land of any great extent exists there. On the other hand, recent Antarctic exploration makes it practically certain that a great continent surrounds the south pole with a total area considerably more than Sir John Murray's estimate in 1894, when he assigned to it an area of 9,000,000 sq. km. (3,500,000 sq. statute miles). It is probable that the Antarctic continent measures about 13,000,000 sq. km. (5,000,000 sq. statute miles); and thus if we accept Bessel's figure of 509,950,000 sq. km. (196,900,000 sq. m.) for the whole surface of the sphere, there is a total land area of 148,820,000 sq. km. (57,460,000 sq. m.), and a total water area of 361,130,000 sq. km. (139,435,000 sq. m.), 29% of land and 71% of water, or a ratio of 1: 2·43.

Divisions of the Ocean.—The arrangement of the water surface on the globe is far from uniform, the ocean forming 61% of the total area of the northern and 81% of that of the southern hemisphere. Of the whole ocean only 43% (154·9 million sq. km.) lies in the northern hemisphere and 57% (206·2 million sq. km.) in the southern. If the globe is divided into hemispheres by the meridians of 20° W. and 160° E., as is usual in atlases, the eastern hemisphere, to which the Old World belongs, has 62% of its surface made up of water, while the western hemisphere, including America, has 81%. A great circle can be drawn upon a terrestrial globe in such a way as to divide it into two hemispheres, one of which contains the greatest amount of land and the other the greatest amount of sea of any possible hemispheres. The centre of the so-called land-hemisphere lies near the mouth of the Loire (47½° N. and 2½° W.), while the centre of the so-called water-hemisphere lies to the S.E. of New Zealand and eastward of Antipodes Island. Even in the land hemisphere the water area (134·5 million sq. km.) is in excess of the land area (121 million sq. km.), while in the water-hemisphere the amount of land is quite insignificant, being only 24·5 million sq. km. compared with 230·5 million sq. km. of water.

The outline of the water surface depends on the outline of the basins in which it is contained. The four great continental masses therefore give the ocean a distinctly tripartite form, the three great divisions being known as the Atlantic, the Indian and the Pacific Oceans, all three running together into one around Antarctica. Thus the connecting belt of water is narrow as compared with the extent of the oceans from north to south—Drake Strait south of South America is barely 400 m. wide, from Cape Agulhas to Enderby Land, 2200 m., and from Tasmania to Wilkes Land, 1550 m., while the meridianal extension of the Indian Ocean is 6200 m., of the Pacific, 9300 m., and of the Atlantic, 12,500 m., measuring across the North Pole to Bering Strait. These proportions are not readily grasped from a map of the world on Mercator's projection, and must be studied on a globe. A simple, practical boundary between the three oceans can be obtained by prolonging the meridian of the southern extremity of each of the three southern continents to the Antarctic circle. A committee of the Royal Geographical Society—the deliberations of which were interrupted by the departure on his last voyage of Sir John Franklin, one of the members—suggested these meridians as boundaries; the north and south boundaries of the Atlantic and Pacific Oceans being the polar circles, leaving an Arctic and an Antarctic Ocean to complete the hydrosphere. We now know, however, that the Antarctic circle runs so close to the coast of Antarctica that the Antarctic Ocean may be left out of account. It has been found more convenient to take as northern boundaries the narrowest part of the straits near the Arctic circle, Bering Strait on the Pacific side, and on the Atlantic side the narrowest part of Davis Strait, and of Denmark Strait, then the shortest line from Iceland to the Faeroes, thence to the most northerly island of the Shetlands and thence to Cape Statland in Norway. It has also been found convenient to take the boundary between the Atlantic and Pacific, as the shortest line across Drake Strait, from Cape Horn through Snow Island to Cape Gunnar, instead of the meridian of Cape Horn. Possibly ridges of the sea-bed running southward from the southern continents may yet be discovered which would form more natural boundaries than the meridians. The committee of the Royal Geographical Society settled the existing nomenclature of the three great oceans. Some authors include the Arctic Sea in the Atlantic Ocean, and some prefer to consider the southern part of the Atlantic, Indian and Pacific Oceans as a Great Southern Ocean. Sir John Herschel took as the northern boundary of the southern ocean the greatest circle which could touch the southernmost extremities of the three southern continents. Such a circle, however, runs so near the coast of Antarctica as to make the southern ocean very small. Others like Malte Brun (1803) and Supan (1903), take the loxodromes between the three capes and call the ocean to the south the Antarctic Ocean. G. v. Boguslawski suggested the parallel of 55° S. and Ratzel that of 40° S. as limits; but in none of these schemes has the coast of Antarctica been adequately considered and they have all been too much influenced by the Mercator map. Each of the three oceans, Atlantic, Indian and Pacific possesses an Antarctic facies in the southern part and a tropical facies between the tropics, and the Atlantic and Pacific an Arctic facies in their northern parts.

Where the ocean touches the continents the margin is in places deeply indented by peninsulas and islands marking off portions of the water surface which from all antiquity have been known as "seas." These seas are entirely dependent on the ocean for their regime, being filled with ocean water, though subject to

influence by the land, and the tides and currents of the ocean affect them to a greater or less extent. They owe their origin to depressions of the earth's crust of no very wide extent and not running very far into the continental mass, and geologically they are of recent age and still subject to change. In these respects they contrast with the great oceans which owe their origin to the most extensive and the profoundest depressions of the crust, date back at least to Mesozoic times, and have perhaps remained permanently in their present position from still remoter ages.

Seas may be classified according to their form either as "enclosed" or as "partially enclosed" (or "fringing"). Enclosed seas extend deeply into the land and originate either by the breaking through of the ocean or by the overflowing of a subsiding area. They are connected with the ocean by narrow straits, the salinity of the water contained in them differs in a marked degree from that of the ocean, and the tidal waves are of small amplitude. Four great intercontinental enclosed seas are included between adjacent continents—the Arctic Sea, the Central American or West Indian Sea, the Australo-Asiatic or Malay Sea and the Mediterranean Sea. There are also four smaller continental enclosed seas each with a single channel of communication with the ocean, viz. the Baltic Sea and Hudson Bay with very low salinity, the Red Sea and Persian Gulf with very high salinity.

The fringing or partially enclosed seas adjoin the great land masses and are only separated from the oceans by islands or peninsulas. Hence their tidal conditions are quite oceanic, though their salinity is usually rather lower than that of ocean water. The four fringing seas of eastern Asia, those of Bering, Okhotsk, Japan and East China, are arranged parallel to the main lines of dislocation in the neighbouring land-masses, and so are the Andaman Sea and the Gulf of California. On the contrary, the North Sea, the British fringing seas (English Channel, Irish Sea and Minch), and the Gulf of St Lawrence cross the main lines of dislocation.

In addition to these seas notice must be taken of the subordinate marginal features, such as gulfs and straits. Gulfs may be classified according to their origin as due to fractures of the crust or overflowing of depressed lands. The former are either the extensions of oceanic depressions, *e.g.* the Arabian Sea, Bay of Bengal and Gulf of Arica, or such caldron-depressions as the Gulfs of Genoa and Taranto, or rift depressions like the Gulfs of Aden and Akaba. Compound gulfs are formed seawards by fracture and landwards by the overflowing of depressed land, *e.g.* the Bay of Biscay, Gulf of Alaska and Gulf of the Lion. Gulfs formed by the overflowing of depressed lands lie upon the continental shelf, *e.g.* the Gulf of Maine, Bay of Fundy, Bay of Odessa, Gulf of Martaban.

Straits have been formed (1) by fracture across isthmuses, and such may be by longitudinal fracture as in the Strait of Bab-el-Mandeb, or transverse fracture as in the Strait of Gibraltar or Cook Strait; (2) by erosion, *e.g.* the Strait of Dover, the Dardanelles and Bosporus; (3) by overflowing through the subsidence of the land, as in the straits of Bering, Torres and Formosa.

Surface of the Ocean.—If the whole globe were covered with a uniformly deep ocean, and if there were no difference of density between one part and another, the surface would form a perfect ellipsoid of revolution, that is to say, all the meridians would be exactly equal ellipses and all parallels perfect circles. At any point a sounding line would hang in the line of the radius of curvature of the water surface. But as things are the water-surface is broken by land, and the mean density of the substance of the land is 2·6 times as great as that of sea-water, so that the gravitational attraction of the land must necessarily cause a heaping up of the sea around the coasts, forming what has been called the continental wave, and leaving the sea-level lower in mid-ocean. Hence the geoid or figure of the sea-surface is not part of an ellipsoid of rotation but is irregular. The differences of level between different parts of the geoid have been greatly overestimated in the past; F. G. Helmert has shown that they cannot exceed 650 ft. and are probably much less. Recent pendulum observations have shown that it is incorrect to assume a uniform density of 2·6 in the elevated part of the earth's crust, that on the contrary there are great local differences in density, the most important being a confirmation of Airy's discovery that there is a marked deficiency of mass under high mountains and a marked excess under the bed of the ocean. The intensity of gravity at the surface of the sea far from land has been measured on several occasions. During Nansen's expedition on the "Fram" in 1894–1895, Scott Hansen made observations with a Sterneck's half-seconds pendulum on the ice where the sea was more than 1600 fathoms deep and found only an insignificant deviation from the number of swings corresponding to a normal ellipsoid. In 1901 O. Hecker took the opportunity of a voyage from Hamburg to La Plata, and in 1904 and 1905 of voyages in the Indian and Pacific Oceans to determine the local attraction over the ocean by comparing the atmospheric pressure measured by means of a mercurial barometer and a boiling-point thermometer, and obtained results similar to Scott Hansen's. The inequalities of the geoid in no case exceed 300 ft. Distortion of the ocean surface may also arise from meteorological causes, and be periodic or unperiodic in its occurrence, but it does not amount to more than a few feet at the utmost. Solar radiation warms the tropical more than the polar waters, but, assuming equal salinity, this cause would not account for a difference of level of more than 20 ft. between tropical and polar seas. The annual range of temperature between summer and winter of a surface layer of water about 25 fathoms thick in the Baltic is as much as 20° F., but this only corresponds to a difference of level of 1¼ in. due to expansion or contraction.

Atmospheric precipitation poured into the sea by the great rivers must necessarily create a permanent rise of the sea-level at their mouths, and from this cause the level round the coasts of rainy lands must be greater than in mid-ocean. H. Mohn has shown how the inequalities of what he terms the density-surface can be found from the salinity and temperature; and he calculates that the level of the Skagerrak should be about 2 ft. higher than that of the open Norwegian Sea between Jan Mayen and the Lofoten Islands. The level of the Gulf of Finland at Kronstadt and of the Gulf of Bothnia at Haparanda should similarly be 15 in. higher than that of the Skagerrak. Recent levellings along the Swedish and Danish coasts have confirmed the higher level of the Baltic; and the level of the Mediterranean has also been determined by exact measurements to be from 15 to 24 in. lower than that of the Atlantic on account of evaporation. Apart from the effects of varying precipitation and evaporation the atmosphere affects sea-level also by its varying pressure, the difference in level of the sea-surface from this cause between two given points being thirteen times as great as the difference between the corresponding readings of the mercurial barometer. In the north tropical belt of high pressure south of the Azores the atmospheric pressure in January is 0·87 in. higher than in the Irminger Sea; hence the sea-level near the Azores is almost 1 ft. lower than in the northern sea. In the monsoon region, where the barometer rises 0·38 in. between July and January, the level of the sea falls in consequence by 5 in. Wind also gives rise to differences of level by driving the water before it, and the prevailing westerly wind of the southern Baltic is the chief cause of the sea-level at Kiel being 5½ in. lower than at Arkona on Rügen. Periodic variations of level due to meteorological causes account for the Baltic being fuller in the time of the summer rains than in winter, when the rivers and lakes are frozen and most of the precipitation on the land is in the form of snow. The range on the Arkona gauge is from 3·5 in. below mean level in April to 2·75 in. above the mean level in August. A similar range occurs on the Dutch coast in the North Sea, where the maximum level is reached in October, the month of highest rainfall, and there is a range of 8 in. to the minimum level at the time of least rainfall in early spring. In the monsoon regions the half-yearly change from on-shore to off-shore winds produces noticeable differences in

level; thus fifteen years' observations at Aden show a maximum in May at the end of the north-east monsoon, and a rapid falling off after the beginning of the south-west monsoon to a minimum in August, the total range being 9½ in. The influence of wind on water-level is most remarkable in heavy storms on the flat coasts of the North Sea and Baltic, when the rise may amount to very many feet. In the region of tropical hurricanes the converging wind system of a circular storm causes a heaping up of water capable of devastating the low coral islands of the Pacific. On the 1st of November 1876 a cyclone acting in this way submerged a great area of the level plain of the Ganges delta to a depth of 46 ft.; here the influence of the difference of pressure within and without the cyclone acted in the same direction as the wind. The old speculations as to a great difference of level between the Mediterranean and the Red Sea, and on the two sides of the Isthmus of Panama, which hindered the projects for canals connecting those waters, have been proved by modern levelling of high precision to be totally erroneous.

Deep-sea Soundings.—The hand-lead attached to a line divided into fathoms was a well-known aid to navigation even in high antiquity, and its use is mentioned in Herodotus (ii. 5) and in the Acts of the Apostles (xxvii. 29). Greater depths than those usually sounded by a hand-line may possibly not have been beyond the reach of the earlier navigators, for Strabo says "of measured seas the Sardonian is the deepest with full one thousand fathoms" (i. 3, p. 53 Cas.). Yet we find that the great discoverers of the modern period were only familiar with the hand-lead, and the lines in use did not exceed 200 fathoms in length. Ingenious devices had indeed been tried in the 17th century and earlier, by which a lead thrown into the sea without a line detached a float on striking the bottom, and it was proposed to calculate the depth by the time required for the float to reappear. The earliest deep-sea sounding on record is that of Captain Phipps on the 4th of September 1773 in the Norwegian Sea, in 65° N. 3° E., on his return from his expedition to Spitsbergen. He spliced together all the sounding-lines on board, and with a weight of 150 lb attached he found bottom in 683 fathoms and secured a sample of fine soft blue mud. He detected the moment of the lead touching the bottom by the sudden slackening in the rate at which the line ran out. Polar explorers frequently repeated those experiments in deep-sea soundings, both William Scoresby and Sir John Ross obtaining notable results, though not reaching depths of more than 1200 fathoms. The honour of first sounding really oceanic depths belongs to Sir James Clark Ross, who made some excellent measurements in very deep water, though in a few instances he overestimated the depth by failing to detect the moment at which the lead touched bottom. The pursuit of these isolated investigations received a great impetus from the enthusiasm of the great American oceanographer Captain Matthew Fontaine Maury, U.S.N., who directed the whole impetuous strength of his character to the task of compelling the silent depths of the ocean to tell their tale. Instead of the expensive mile-long stout hemp lines used by Ross, Maury introduced a ball of strong twine attached to a cannon shot, which ran it out rapidly; when the bottom was reached the twine was cut and the depth deduced from the length of string left in the ball on board. The time of touching bottom was judged by timing each 100-fathom mark and noting the sudden increase in the time interval when the shot reached the bottom. Maury, however, recognized that in great depths the surest guarantee of bottom having been reached was to bring up a sample of the deposit. To do this with a heavy lead attached required a very strong hemp line, and the twine used in the American method was useless for this purpose. In 1854 J. M. Brooke, a midshipman of the U.S.N., invented the principle already foreshadowed by Nicolaus Cusanus in the 15th century and by Robert Hooke in the 17th, of using a heavy weight so hung on the sounding-tube that it was automatically released on striking the bottom and left behind, while the light brass tube containing a sample of the deposit was easily hauled up. This principle has been adopted universally for deep soundings, and is now applied in many forms. In 1855 Maury published the first chart of the depths of the Atlantic between 52° N. and 10° S. At this period an exact knowledge of the depths of the ocean assumed an unlooked-for practical importance from the daring project for laying a telegraph cable between Ireland and Newfoundland. Deep soundings were made in the Atlantic for this purpose by vessels both of the British and of the American navies, while in the Mediterranean and in the Indian Ocean many soundings were made in connexion with submarine cables to the East. Another stimulus came from the biologists, who began to realize the importance of a more detailed investigation of the life conditions of organisms at great depths in the sea. The lead in this direction was taken by British biologists, beginning with Edward Forbes in 1839, and in 1868 a party on board H.M.S. "Lightning" pursued researches in the waters to the north of Scotland. In 1869 and 1870 this work was extended to the Irish Sea and Bay of Biscay in H.M.S. "Porcupine," and to the Mediterranean in H.M.S. "Shearwater." The last-named vessel secured 157 trustworthy deep soundings, with samples of the deposits, and also observations of temperature and salinity in different depths, as well as dredgings for the collection of the organisms of the deep sea.

These preliminary trips of scientific marine investigation were followed by the greatest purely scientific expedition ever undertaken, the voyage of H.M.S. "Challenger" round the world under the scientific direction of Sir Wyville Thomson and the naval command of Sir George Nares. This epoch-making expedition lasted from Christmas 1872 to the end of May 1876, and gave the first wide and general view of the physical and biological conditions of the ocean as a whole. Almost simultaneously with the "Challenger," a German expedition in S.M.S. "Gazelle" conducted observations in the South Atlantic, Indian and South Pacific Oceans; and the U.S.S. "Tuscarora" made a cruise in the North Pacific, sounding out lines for a projected Pacific cable. The successor of Sir Wyville Thomson in the editorship of the "*Challenger*" *Reports*, Sir John Murray, has rightly said that since the days of Columbus and Magellan no such revelation regarding the surface of our planet had been made as in that eighth decade of the 19th century. Since that time the British cable-ships have been busy in all the oceans making sections across the great expanses of water with ever-increasing accuracy, and in that work the government surveying ships have also been engaged, vast stretches of the Indian and Pacific Oceans having been opened up to knowledge by H.M.S.S. "Egeria," "Waterwitch," "Dart," "Penguin," "Stork," and "Investigator." American scientific enterprise, mainly under the guidance of Professor Alexander Agassiz, has been active in the North Atlantic and especially in the Pacific Ocean, where very important investigations have been made. The eastern part of the North Atlantic has been the scene of many expeditions, often purely biological in their purpose, amongst which there may be mentioned the cruises of the "Travailleur" and "Talisman" under Professor Milne-Edwards in 1880–1883, and since 1887 those of the prince of Monaco in his yachts, as well as numerous Danish vessels in the sea between Iceland and Greenland, conspicuous amongst which were the expeditions in 1896–1898 on board the "Ingolf." The Norwegian Sea was studied by the Norwegian expedition on board the "Vöringen" in 1876–1878, and the north polar basin by Nansen and Sverdrup in the "Fram" in 1893–1896, the Mediterranean by the Italians on the "Washington" and by the Austrians on the "Pola" in 1890–1893, the latter carrying the investigations to the Red Sea in 1895–1898, while the Russians investigated the Black Sea in 1890–1893. For high southern latitudes special value attaches to the soundings of the German deep-sea expedition on the "Valdivia" in 1898–1899, and to those of the "Belgica" in 1897–1898, the "Gauss" in 1902–1903, and the "Scotia" in 1903–1904. The soundings of the Dutch expedition on the "Siboga" during 1899–1900 in the eastern part of the Malay seas and those of the German surveying ship "Planet" in 1906 in the South Atlantic, Indian and North Pacific Oceans were notable, and Sir John Murray's expedition on the "Michael Sars" in the Atlantic in 1910 obtained important results.

Modern surveying ships no longer make use of hempen lines with enormously heavy sinkers, such as were employed on the "Challenger," but they sound instead with steel piano wire not more than $\frac{1}{16}$ to $\frac{1}{18}$ of an inch in diameter and a detachable lead seldom weighing more than 70 lb. The soundings are made by means of a special machine fitted with a brake so adjusted that the revolution of the drum is stopped automatically the instant the lead touches the bottom, and the depth can then be read directly from an indicator. The line is hauled in by a steam or electric winch, and the sounding-tube containing a sample of the bottom deposit is rapidly brought on board. The sounding machines most frequently employed are those of Admiral C. D. Sigsbee, U.S.N., of Lucas, which was perfected in the Telegraph Construction and Maintenance Company's ships, and of the Prince of Monaco, constructed by Leblanc of Paris. All attempts to dispense with a lead and line and to measure the depth by determining the pressure at the bottom have hitherto failed when applied to depths greater than 200 fathoms; a new hydraulic manometer has been tried on board the German surveying ship "Planet." A. Siemens has pointed out that a profile of the sea-bed can be delineated by taking account of the varying strain on a submarine cable while it is being laid, and the average depth of a section can thus be ascertained with some accuracy. All deep-sea measurements are subject to uncertainty because the sounding machine merely measures the length of wire which runs out before the lead touches bottom, and this agrees with the depth only when the wire is perpendicular throughout its run. It is improbable, however, that the smooth and slender wire is much influenced by currents, and the best deep-sea soundings may be taken as accurate to within 5 fathoms.

Relief of the Ocean Floor.—Recent soundings have shown that the floor of the ocean on the whole lies some 2 or 3 m. beneath the surface, and O. Krümmel has calculated the mean depth to be 2010 fathoms (12,060 ft.), while the mean elevation of the surface of the continents above sea-level is only 2300 ft. Viewed from the floor of the ocean the continental block would thus appear as a great plateau rising to a height of 14,360 ft. Nevertheless, the greatest depths of the ocean below sea-level and the greatest heights of the land above it are of the same order of magnitude, the summit of Mount Everest rising to 29,000 ft. above the sea-level, while the Nero Deep near Guam sinks to 31,600 ft. (5268 fathoms) below sea-level. Of course the area at great heights is very much less than the area at corresponding depths. Above the height of 15,000 ft. there are 800,000 sq. km. (310,000 sq. m.), and below the depth of 15,000 ft. there are 120,000,000 sq. km. (46,300,000 sq. m.); above the height of 20,000 ft. there are on the whole surface of the earth only 33,000 sq. km. (12,800 sq. m.), while below the depth of 20,000 ft. there are no less than 5,400,000 sq. km. (2,100,000 sq. m.). According to Krümmel's calculation the areas of the ocean beyond various depths are as follows:—

Fathoms.	sq. km.	sq. st. m.
More than		
100	350,500,000	135,300,000
500	319,500,000	123,400,000
1000	304,000,000	117,400,000
1500	276,500,000	106,800,000
2000	215,000,000	83,000,000
2500	120,000,000	46,300,000
3000	22,500,000	8,700,000
3500	3,000,000	1,200,000
4000	1,200,000	460,000

On the whole the floor of the ocean is very smooth in its contours, and great stretches can almost be called level. Modern orometry has introduced the calculation of the mean angle of the slope of a given uneven surface provided that maps can be prepared showing equidistant contour lines. If the distance between the contour lines is h and the length of the individual contour lines l, the sum of their lengths $\Sigma(l)$, and A the area of the surface under investigation, then the mean angle of slope is obtained from the equation

$$\tan \alpha = \frac{h\Sigma(l)}{A}.$$

Calculating from sheet A I of the Prince of Monaco's *Atlas of Ocean Depths*,[1] Krümmel obtained a mean angle of slope of 0° 27′ 44″ or an average fall of 1 in 124 for the North Atlantic between 0° and 47° N., the enclosed seas being left out of account. In the same way a mean angle of slope of approximately half a degree was found for the Adriatic and the Black Sea. Large angles of slope may, however, occur on the flanks of oceanic islands and the continental borders. On the submarine slopes leading up to isolated volcanic islands angles of 15° to 20° are not uncommon, at St Helena the slopes run up to 38½° and even 40°, at Tristan d'Acunha to 33⅓°. E. Hull found a mean angle of slope of 13° to 14° for the edge of the continental shelf off the west coast of Europe, and off Cape Toriñana (43° 4′ N.) as much as 34°. Where the French telegraph cable between Brest and New York passes from the continental shelf of the Bay of Biscay to the depths of the Atlantic the angle of slope is from 30° to 41°. Such gradients are of a truly mountainous character, the angle of slope from the Eibsee to the Zugspitze is 30°, and that from Alpiglen station to the summit of the Eiger is 42°. Particularly steep slopes are found in the case of submarine domes, usually incomplete volcanic cones, and there have been cases in which after such a dome has been discovered by the soundings of a surveying ship it could not be found again as its whole area was so small and the deep floor of the ocean from which it rose so flat that an error of 2 or 3 m. in the position of the ship would prevent any irregularity of the bottom from appearing. While such steep mountain walls are found in the bed of the ocean it must be remembered that they are very exceptional, and except where there are great dislocations of the submarine crust or volcanic outbursts the forms of the ocean floor are incomparably gentler in their outlines than those of the continents. Being protected by the water from the rapid subaerial erosion which sharpens the features of the land, and subjected to the regular accumulation of deposits, the whole ocean floor has assumed some approach to uniformity. Still there are everywhere gentle inequalities on the smoothest ocean floor which give to its greater features a distinct relief.

In spite of the increase of deep-sea soundings in the last few decades, they are still very irregularly distributed in the open ocean, and the attempt to draw isobaths (lines of equal depth) on a chart of the world is burdened with many difficulties which can only be evaded by the widest generalizations. Bearing this caution in mind the existing bathymetrical charts, amongst which that of the prince of Monaco stands first, give a very fair idea of the great features of the bed of the oceans. A definite terminology for the larger forms of sub-oceanic relief was put forward by the International Geographical Congress at Berlin in 1899 and adopted by that at Washington in 1904. Equivalent terms, which are not necessarily identical or literal translations, were adopted for the English, French and German languages, the equivalence being closest and most systematic between the English and German terms.

The larger forms designated by special generic terms include the following. The *continental shelf* is the gentle slope which extends from the edge of the land to a depth usually about 100, though in some cases as much as 300 fathoms, and is there demarcated by an abrupt increase in the steepness of the slope to ocean depths. In the deep sea two types of feature are recognized under the general names of *depression* and *elevation*. The depression is distinguished according to form and slope as (1) a *basin* when of a roughly round outline, (2) a *trough* when wide and elongated, or (3) a *trench* when narrow and elongated lying along the edge of a continent. The extension of a basin or trough stretching towards the continent is termed an *embayment* when relatively wide and a gully when narrow The elevation includes (1) the gently swelling rise which separates

[1] *Carte générale bathymétrique des océans* dressée par ordre de S.A.S. *le Prince Albert de Monaco*, 24 sheets (Paris, 1904).

troughs and basins in the middle of the ocean, (2) the steeply sloping *ridge* which interposes a narrower barrier between two depressions, and (3) the *plateau* or wide elevation rising steeply on all sides from a depression. The deepest part of a depression is termed a *deep*, and the highest part of an elevation when not reaching the surface a *height*. In addition to these larger forms a few minor forms must be recognized. Amongst these are the *dome*, an isolated elevation rising steeply but not coming within 100 fathoms of the surface; the *bank*, an elevation coming nearer the surface than 100 fathoms, but not so near as 6 fathoms; and finally the *shoal* or *reef*, which comes within 6 fathoms of the surface, and so may constitute a danger to shipping. Similarly we may note the *caldron* or small steep depression of a round outline, and the *furrow* or long narrow groove in the continental shelf.

According to the resolutions of the International Geographical Congress the larger individual forms which have been described by generic terms shall have specific names of a purely geographical character; but in the case of the minor forms the names of ships and persons are considered applicable. In 1899 A. Supan published a chart of the oceans with a suggested nomenclature based on these principles; and the larger forms in the Prince of Monaco's great chart also are named in accordance with the rule. Although put forward by the highest international authority recognized by geographers the system of nomenclature has not been adopted universally. In particular Sir John Murray considers that only deeps exceeding 3000 fathoms in depth should be named, and in his charts he has named these deeps after persons whether the individuals thus honoured had themselves discovered or explored the deeps in question or not. Some of the "deeps" to which names have been given disappear or are divided into two or three smaller deeps when the contour lines representing hundreds of fathoms are translated into contour lines representing hundreds of metres. A similar change in the contour lines may result from the substitution of lines in fathoms for those originally drawn in metres, and hence it is extremely desirable that specific names should only be given to such features as are pronounced enough to appear on maps drawn with either unit. For the sake of uniformity it is to be hoped that the system of nomenclature recommended by the International Geographical Congress will ultimately be adopted.

The continental shelves are parts of the great continental blocks which have been covered by the sea in comparatively recent times, and their surface consequently presents many similarities to that of the land, modified of course by the destructive and constructive work of the waters. Waves and tidal currents produce their full effects in that region, and in high latitudes the effect of transport of materials by ice is very important; while in the warm water of the tropics the reef-building animals and plants (corals and calcareous algae) carry on their work most effectively there. The continental shelves include not only the oceanic border of the continents but also great areas of the enclosed seas and particularly of the fringing seas, the origin of which through secular subsidence is often very clearly apparent, as for instance in the North Sea and the tract lying off the mouth of the English Channel. A closer investigation of the numerous long, narrow banks which lie off the Flemish coast and the Thames estuary shows that they are composed of fragments of rock abraded and transported by tidal currents and storms in the same way that the chalk and limestone worn off from the eastern continuation of the island of Heligoland during the last two centuries has been reduced to the coarse gravel of the off-lying Düne. Numerous old river valleys and furrows entrenched in the continental shelf bear witness to its land origin. Such valleys are very clearly indicated in the belts of the western Baltic by furrows a thousand yards wide and twenty to thirty fathoms deeper than the neighbouring sea-bed. Amongst the best known of the furrows of the continental shelf are the Cape Breton Deep, in the Bay of Biscay, the Hudson Furrow, southward of New York, the so-called Congo Cañon, the Swatch of No Ground off the Ganges delta, the Bottomless Pit off the Niger delta, and numerous similar furrows on the west coast of North America and outside the fjords of Norway, Iceland and the west of Scotland, as well as in the Firth of Forth and Moray Firth.

The seaward edge of the continental shelf often falls steeply to the greatest depths of the ocean, and not infrequently forms the slope of a *trench*, a form of depression which has usually a steep slope towards a continent or an island-bearing rise on one side and a gentler slope towards the general level of the ocean on the other. All the greatest depths of ocean, *i.e.* all soundings exceeding 4000 fathoms, occur in trenches, and there are only a few small trenches known (on the west coast of Central America) in which the maximum depth is less than 3000 fathoms. Most trenches are narrow, but of considerable length, and their steeper side is believed to be due in every case to a great fracture of the earth's crust. Strong evidence of this is afforded by the association of some of the depressions, notably the Japan Trench and the Atacama Trench, with the origin of frequent submarine earthquakes. Troughs and rises are features of more frequent occurrence and are best described as they occur in the particular oceans.

In the Atlantic the prevailing meridianal direction of the shore lines extends to the submarine features also. Captain Sherard Osborn in 1870 was the first to recognize that the North Atlantic Basin was divided by a central rise running generally from north to south into two parallel depressions. In 1876 the "Challenger" expedition found that a similar configuration exists in the South Atlantic also. As the result of all the deep-sea surveys now available we know that the central rise of the Atlantic starts from Iceland as the Reykjanes Ridge with less than 1000 fathoms of water over it in most parts and runs south-westward until in 51° N. it widens into what was called by Maury the Telegraph Plateau. Continuing southwards the rise joins the Azores Plateau, which has in parts a very marked relief, and runs thence southward almost exactly in the middle of the ocean, becoming gradually lower as it goes. As far as 20° N. the depth over it is less than 1500 fathoms, thence to 12° N. the depths are between 1500 and 2000 fathoms, and then it rises again to about 1500 fathoms and runs eastward under the name of the Equatorial Ridge. Crossing the equator in 13° W. the rise resumes a southerly direction and from Ascension to Tristan d'Acunha, the depth is in many places less than 1500 fathoms. The soundings of Bruce's Antarctic expedition in the "Scotia" showed that the rise cannot be traced beyond 55° S. where the depths increase rapidly to over 2000 fathoms. The whole length of the rise which divides the Atlantic into an eastern and a western basin may be taken as 7500 nautical miles. Between 30° and 40° S. two lateral ridges diverge from the great Atlantic rise, the Rio Grande ridge towards the north-west and the Walfisch ridge towards the north-east. The existence of the latter, which extends to the African continent, was announced by Sir Wyville Thomson in 1876 as a result of his discussion of the deep-sea temperature observations of the "Challenger" expedition, though the fact was not confirmed by soundings until many years later.

The West Atlantic Trough lying on the western side of the Central Rise widens in the north into the North American Basin, and its greatest depths appears to be in the Porto Rico Trench, where in 1882 Capt. W. H. Brownson, U.S.N., obtained a sounding of 4561 fathoms in 19° 36′ N., 66° 26′ W. The Brazilian Basin has also a large area lying at a depth greater than 2500 fathoms and culminates in the Romanche Deep close to the Equatorial Ridge in 0° 11′ S., 18° 15′ W. with a depth of 4030 fathoms. The Eastern Atlantic Trough cannot boast of such great depths though the Peake Deep with 3284 fathoms sinks abruptly from the Azores Plateau in 43° 9′ N., 19° 45′ W., and several soundings exceeding 2700 fathoms have been obtained in the Bay of Biscay east of the meridian of 5° E. The North African Basin has several deeps with more than 3300 fathoms to the north-west and the south-west of the Cape Verde Islands, but the South African Basin is less deep. In the South Atlantic there is no connexion between the Central Rise and the Antarctic Shelf,

for the Indo-Atlantic Antarctic Basin stretches from near the South Sandwich Islands towards Kerguelen with depths exceeding 2500 fathoms and reaching in places 3100. The Cape Trough runs northward from this basin. It was long believed on the strength of a sounding of "4000 fathoms, no bottom" reported by Sir James Ross in 68° 22′ S., 12° 49′ W., that the Indo-Atlantic Basin was of enormous depth, but W. S. Bruce, in the "Scotia," showed in 1904 that the real depth at that point is only 2660 fathoms.

In the Indian Ocean the Kerguelen Rise stretches broadly southward, east of the island which gives it a name, to the Antarctic Shelf with the greatest depths upon it usually less than 2000 fathoms, and it stretches northward beyond New Amsterdam to 30° S. This rise is separated from the Crozet Rise by a depression extending to 2675 fathoms, through which the Kerguelen Trough (which lies north of Kerguelen) is brought into free communication with the Indo-Atlantic Antarctic Basin. The greater part of the Indian Ocean is occupied by the great Indian Basin, which covers 35,000,000 sq. km. (13,500,000 sq. m.) and extends from the Chagos Islands eastward to Australia and south-eastward to Tasmania. The Australian Shelf rises steeply as a rule from depths of 2500 to 3000 fathoms. A broad depression with depths of from 3300 to 3500 fathoms lies to the east of the Cocos Islands and extends into the angle between the Malay Archipelago and Australia. On the north this depression sinks into the long and narrow Sunda Trench south of Java, and here in 10° 15′ S., 108° 5′ E., the German surveying-ship "Planet" obtained a sounding of 3828 fathoms in 1906. The Sunda Trench is distinguished by the wave-like configuration of its floor, and this wave-like character is continued to the westward of Sumatra with islands rising from the higher portions. The western part of the Indian Ocean has been shown by the surveys of H.M.S. "Sealark" and the German surveying-ship "Planet" to have a somewhat complicated configuration, the island groups and banks of atolls which occur there rising abruptly as a rule from depths of about 2000 fathoms or more. Between the Seychelles and Sokotra (0°–9° N.) there are great stretches of the ocean floor forming an almost level expanse at a depth of 2800 fathoms. The Arabian Gulf and Gulf of Aden are also very uniform with depths of about 1900 fathoms, while the floor of the Bay of Bengal rises very gradually northwards and is 1000 fathoms deep close up to the Ganges Shelf.

The Pacific Ocean consists mainly of one enormous basin bounded on the west by New Zealand and the Tonga, Marshall and Marianne ridges, on the north by the festoons of islands marking off the North Pacific fringing seas, on the east by the coast of North America and the great Easter Island Rise and on the south by the Antarctic Shelf. The total area of this basin is about 80,000,000 sq. km. (30,000,000 sq. m.), its surface being almost twice that of Asia. Half of this basin lies deeper than 2750 fathoms, and the greater part of it belongs to the northern hemisphere. From the floor of this vast and profound depression numerous isolated volcanic cones rise with abrupt slopes, and even between the islands of the Hawaiian group there are depths of more than 2000 fathoms. The Society Islands and Tahiti crown a rise coming within 1500 fathoms of the surface, two similar rises form the foundation of the Paumotu group where Agassiz found soundings of 2187 fathoms between Marokau and Hao. This greatest of ocean basins contains also the largest and deepest trenches. The Tuscarora Deep of the Japan Trench (4655 fathoms in 44° 55′ N., 152° 26′ E.) was famed for many years as the deepest depression of the earth's crust. This great trench is continued along the Luchu Islands where the cable-steamer "Stephan" sounded in 4080 fathoms, and through the Bonin Trench (with a maximum of 3595 fathoms) to the famous Marianne Trench in which the U.S.S. "Nero" in 1899 found 5269 fathoms in 12° 43′ N., 145° 49′ E., the greatest depth yet measured. The northern part of the Marianne Trench leads to a wave-like configuration of the ocean floor, the depth to the east of Saipan being over 4300 fathoms, followed by a rise to 1089 fathoms and then a descent to 3167 fathoms. The trenches of Yap (4122 fathoms) and Palau (Pelew) (4450 fathoms) are not immediately connected with that of Marianne. To the east of the Philippines a sounding of 3490 fathoms is found close to the Strait of St Bernardino and north-east of Talaut there is a trench with 4648 fathoms. To the north-east the Japan Trench adjoins the Aleutian Trench, where a depth of 4038 fathoms has been found south-west of Attu. Trenches of great size also occur south of the equator. The Tonga and Kermadec trenches, both deeper than 4000 fathoms, stretch from the Samoa Islands southwards toward New Zealand for a distance of 1600 nautical miles. The deepest sounding obtained in the Tonga Trench is 5022 fathoms in 23° 39·4′ S., 175° 4′ W., and in the Kermadec Trench, 5155 fathoms, 30° 27·7′ S., 176° 39′ W. The steep western sides of these trenches often show an angle of slope of 7°.

The south-western part of the Pacific Ocean has a very rich and diversified submarine relief, abounding in small basins separated by ridges and rises. There are no depths, however, much exceeding 2500 fathoms amongst these depressions. The south-eastern part of the Pacific is mainly occupied by the Easter Island Rise with depths rarely so great as 2000 fathoms; but close to the continent of South America the Atacama Trench is a typical example of the deepest form of depression culminating with 4175 fathoms in 25° 42′ S., 71° 31·5′ W. The Pacific Antarctic Basin occupies the vast region south of 50° S. right up to the Antarctic Shelf, with depths ranging down to 2500–3000 fathoms, and communicating with the main Pacific Basin to the east of New Zealand.

The greatest of the intercontinental seas, the Arctic, comes nearest to oceanic conditions in the extent and depth of its depressions. The soundings of Nansen and Sverdrup on the "Fram" expedition indicate that northward from the Siberian Shelf the great North Polar Basin has an area of about 4,000,000 sq. km. (1,500,000 sq. m.) with depths down to 2200 fathoms. A rise between Spitsbergen and Greenland separates the Norwegian Trough (greatest depth 2005 fathoms in 68° 21′ N., 2° 5′ W.) which in turn is divided from the Atlantic by the Wyville Thomson Ridge which runs between the Faeroe and Shetland islands and is covered by only 314 fathoms of water at the deepest point. The ridge across Denmark Strait west of Iceland nowhere exceeds 300 fathoms in depth, so that the deeper water of the North Polar Basin is effectively separated from that of the Atlantic. A third small basin occupies Baffin Bay and contains a maximum depth of 1050 fathoms. Depths of from 100 to 300 fathoms are not uncommon amongst the channels of the Arctic Archipelago north of North America, and Bering Strait, through which the surface water of the Arctic Sea meets that of the Pacific, is only 28 fathoms deep.

The Central American Sea communicates with the Atlantic through the channels between the Antilles, none of which is quite 1000 fathoms deep, and it sinks to a depth of 2843 fathoms in the Caribbean Basin, 3428 fathoms in the Cayman Trench and 2080 fathoms in the Gulf of Mexico.

The Austral-Asiatic or Malay Sea is occupied by a great shelf in the region west of Borneo and north of Java, while in the east there are eight abruptly sunk basins of widely different size. The China Sea on the north has a maximum depth of 2715 fathoms off the Philippines, the Sulu Basin reaches 2550 fathoms, and the Celebes Basin 2795 fathoms. Some of the channels between the islands are of very great depth, Macassar Strait exceeding 1000 fathoms, the Molucca Passage exceeding 2000 fathoms, and the Halmahera Trough sinking as deep as 2575 fathoms. The deepest of all is the Banda Basin, a large area of which lies below 2500 fathoms and reaches 3557 fathoms in the Kei Trench. A depth of 2789 fathoms also occurs north of Flores. The borders of the Malay Sea are everywhere shallower on the side of the Indian Ocean than on that of the Pacific, and consequently water from the Pacific preponderates in the depths.

The Mediterranean Sea, the best-known member of the intercontinental class, is separated from the Atlantic Ocean by a ridge running from Cape Spartel to Cape Trafalgar on which

the greatest depth is only 175 fathoms. The depth increases so rapidly towards the east that soundings exceeding 500 fathoms occur off Gibraltar. The Balearic Basin, between Spain and the rise bearing Corsica and Sardinia, has a maximum depth of 1742 fathoms, and the Tyrrhenian Basin between that rise, Italy and Sicily deepens to 2040 fathoms. The larger Eastern Mediterranean Basin stretches eastward from Sicily with large tracts more than 2000 fathoms below the surface, and the greatest depth ascertained during the detailed researches of the Austrian expedition on board the "Pola" was 2046 fathoms in 35° 44·8′ N., 21° 46·8′ E. The Adriatic Sea though very shallow in the north deepens southward to about 900 fathoms, and the Aegean Sea has a maximum depth of 1230 fathoms north of Crete. The Black Sea, connected with the Mediterranean by long and narrow channels, is occupied in the north by an extensive shelf on which lies the extremely shallow Gulf of Azov; but the greater part of the sea consists of a deep basin, the central part of which is an almost flat expanse at a uniform depth of 1220 fathoms.

Mean Depths of Oceans and Seas.

Name.	Depth. Fathoms.	Area.		Volume.	
		sq. km.	sq. st. m.	cb. km.	cb. st. m.
Atlantic Ocean	2110	81,657,800	31,529,390	314,821,680	75,533,900

Hydrosphere	2013	361,279,160	139,495,660	1,329,945,870	319,087,500

The smaller enclosed seas are for the most part very shallow. The Persian Gulf nowhere exceeds 50 fathoms, the southern part of Hudson Bay does not exceed 100 fathoms except at one spot, though in the less-known fjords of the northern part depths up to 200 fathoms have been reported. The Baltic Sea exceeds 50 fathoms in few places except the broad central portion, though small caldron-like depressions here and there may sink below 200 fathoms. The Red Sea on the other hand, though shut off from the Indian Ocean by shallows of the Strait of Bab-el-Mandeb with little more than 100 fathoms, sinks to a very considerable depth in its central trough, which reaches 1209 fathoms in 20° N.

The fringing seas as a rule show little variety of submarine relief. The Bass Sea (Bass Strait), Irish Sea and North Sea lie on the continental shelf. In the North Sea the depth of 100 fathoms is only exceeded to any extent in the Norwegian gully, which has a maximum depth of 383 fathoms in the Skagerrack. Most of the other seas of this class are formed on a common plan. Towards the continent there is a broad shelf, and just before the chain of islands separating them from the ocean runs a narrow and deep trough. In the Bering Sea the trough north of Buldir in the Aleutian Islands sinks to 2237 fathoms, and in the Sea of Okhotsk, north-west of the Kuriles, to 1859 fathoms. Similar conditions prevail in the East China Sea and the Andaman Sea. The Sea of Japan has a wide shelf only in the north, the central part forms a broad basin with depths of 1650 fathoms. The Laurentian Sea (Gulf of St Lawrence) has a narrow branching gully running between wide shelves, in which a depth of 312 fathoms is found south of Anticosti.

The area, general depth and total volume of the oceans and principal seas have been recalculated by Krümmel, and the accompanying table presents these figures.

Oceanic Deposits.—It has long been known that the deposits which carpet the floor of the ocean differ in different places, and coasting sailors have been accustomed from time immemorial to use the lead not only to ascertain the depth of the water but also to obtain samples of the bottom, the appearance of which is often characteristic of the locality. In depths down to 100 fathoms the old-fashioned hand-lead, hollow below and "armed" with tallow, suffices to bring up a sample large enough to be recognizable. Captain Phipps in 1773 secured samples of soft blue clay in this manner from a depth of 683 fathoms, but as a rule when sounding in great depths the sample is washed off the tallow before it can be brought on board. Various devices have consequently been attached to leads intended to catch and hold the material when soft enough to be penetrated. One of the most effective early forms was the snapper or "deep-sea clamm" of Sir John Ross, a pair of powerful spring jaws held apart by an arrangement which when released on striking the bottom allowed the jaws to close, biting out and holding securely a substantial portion of the ground. A simpler form of collector, now almost universally used, is a plain brass tube which is driven into the bottom of the sea by the weight of the sounding lead, and in which the deposit may be retained by a valve or other contrivance, though in many cases friction alone suffices to hold the punched-out core. Larger quantities of deposit may be conveniently collected by means of the dredge, which can be worked in any depth and brings up large stones, concretionary nodules or fossils, of the existence of which a sounding-tube could give no indication.

The voyage of the "Challenger" supplied for the first time the nucleus of a collection of deep-sea deposits sufficient to serve as the basis for comprehensive classification and mapping. The "Challenger" collections supplemented by those of other expeditions and of many telegraph and surveying-ships were studied in detail by Sir John Murray and Professor A. Renard, whose monograph,[1] published in 1891, laid the foundations and

[1] "*Challenger*" *Reports*, "Deep Sea Deposits."

reared the greater part of the structure of our present knowledge on the subject. The classification adopted was a double one, taking account both of the origin and of the distribution in depth of the various deposits, thus:—

I. Deep Sea Deposits (beyond 100 fathoms)	1. Red Clay.	A. Pelagic Deposits (formed in deep water remote from land)
	2. Radiolarian Ooze	
	3. Diatom Ooze	
	4. Globigerina Ooze	
	5. Pteropod Ooze	
	6. Blue Mud	
	7. Red Mud	
	8. Green Mud	
	9. Volcanic Mud	
	10. Coral Mud	
II. Shallow Water Deposits (in less than 100 fathoms)	Sands, gravels, muds, &c.	B. Terrigenous Deposits (formed in deep or shallow water close to land)
III. Littoral Deposits (between high and low-water marks)	Sands, gravels, muds, &c.	

Krümmel prefers to simplify this by grouping the deposits in a single category arranged according to their position into:

(α) *Littoral* (including Murray and Renard's littoral and shallow water deposits [II. and III.]).
(β) *Hemipelagic* (including Nos. 6-10 of Deep Sea Deposits).
(γ) *Eupelagic* (including Nos. 1-5 of Deep Sea Deposits).

As so defined the hemipelagic deposits are those which occur in general on the slope from the continental shelves to the ocean depths and also in the deep basins of enclosed and fringing seas. The eupelagic deposits are subdivided by Krümmel into two main groups; (*a*) *epilophic*,[1] including the pteropod, globigerina and diatom oozes occurring on the rises and ridges and in the less deep troughs. (*b*) *Abyssal*, including the radiolarian ooze and red clay of the deepest abysses.

The littoral deposits include those of the actual shore on the wash of the waves and of the surface of the continental shelf.

Shore Deposits are the product of the waste of the land arranged and bedded by the action of currents or tidal streams. On the rocky coast of high latitudes blocks of stone detached by frost fall on the beach and becoming embedded in ice during winter are often drifted out to sea and so carry the shore deposits to some distance from the land. Similar effects are produced along the boulder-clay cliffs of the Baltic. Where the force of the waves on the beach produces its full effect the coarser material gets worn down to gravel, sand and silt, the finest particles remaining long suspended in the water to be finally deposited as mud in quiet bays. A particularly fine-grained mud is formed on the low coasts of the eastern border of the North Sea by a mixture of the finest sediment carried down by the slow-running rivers with the calcareous or siliceous remains of plankton. Pure calcareous sand and calcareous mud are formed by wave action on the shores of coral islands where the only material available is coral and the accompanying calcareous algae, crustacea, molluscs and other organisms secreting carbonate of lime. Recent limestones are being produced in this way and also in some places by the precipitation of calcium carbonate by sodium or ammonium carbonate which has been carried into the sea or formed by organisms. The precipitated carbonate may agglomerate on mineral or organic grains which serve as nuclei, or it may form a sheet of hard deposit on the bottom as occurs in the Red Sea, off Florida, and round many coral islands in the Pacific. Only the sand and the finest-grained sediments of the shore zone are carried outwards over the continental shelf by the tides or by the reaction-currents along the bottom set up by on-shore winds. The very finest sediment is kept in a state of movement until it drops into the gulleys or furrows of the shelf, where it can come to rest together with the finer fragments of the remains of littoral or bank vegetation. Thus are formed the "mud-holes" of the Hudson Furrow so welcome as guides telling their position to ship captains making New York harbour in a fog. Sand may be taken as the predominating deposit on the continental shelves, often with a large admixture of remains of calcareous organisms, for instance the deposits of *maërl* made up of nullipores off the coasts of Brittany and near Belle Isle. Amongst the most widely distributed of the deposits actually formed on the continental shelf are phosphatic nodules; these are especially abundant on the east coast of the United States and on the Agulhas Bank, where the amount of calcium phosphate in the nodules is as much as 50%. Sir John Murray finds the source of the phosphoric acid to be the decomposition of large quantities of animal matter, and he illustrates this by the well-known circumstance of the death of vast shoals of fish when warm Gulf-Stream water displaces the cold current which usually extends to the American coast. Glacial detritus naturally plays a great part in the deposits on the polar continental shelves.

[1] ἐπὶ λόφος—on the threshold.

Hemipelagic deposits are a mixture of deposits of terrigenous and pelagic origin. The most abundant of the terrigenous materials are the finest particles of clay and calcium carbonate as well as fragments derived from land vegetation, of which twigs, leaves, &c., may form a perceptible proportion as far as 200 m. from land. Blue mud, according to Murray and Renard, is usually of a blue or slaty or grey-green colour when fresh, the upper surface having, however, a reddish tint. The blue colouring substance is ferrous sulphide, the upper reddish layer contains more ferric oxide, which the predominance of decomposing organic matter in the substance of the mud reduces to ferrous oxide and subsequently by further action to sulphide. The proportion of calcium carbonate varies greatly according to the amount of foraminifera and other calcareous organisms which it contains. Blue mud prevails in large areas of the Pacific Ocean from the Galapagos Islands to Acapulco. In the Indian Ocean it covers the Bay of Bengal, the Arabian Gulf, the Mozambique Channel and the region to the south-west of Madagascar. In the Atlantic it is the characteristic deposit of the slopes of continental shelves of western Europe and of New England, being largely mixed with ice-borne material to the south of Newfoundland. It is particularly in evidence round the whole of the Antarctic Shelf, where it occurs down to depths of 2500 fathoms. It is the chief deposit, according to Nansen, of the North Polar Basin and, according to Schmelck and Böggild, of the Norwegian Sea also, where it is largely mixed with the shells of the bottom-living foraminifer Biloculina. Max Weber states that blue mud occurs in the deep basins of the eastern part of the Malay Sea. In the form of volcanic mud it is common round the high volcanic islands of the South-Western Pacific.

Red mud may be classed as a variety of blue mud, from which it differs on account of the larger proportion of ochreous substance and the absence of sufficient organic matter to reduce the whole of the ferric oxide. This variety surrounds the tropical parts of the continental shelves of South America, South Africa and eastern China.

Green mud differs to a greater extent from the blue mud, and owes its characteristic nature and colour to the presence of glauconite, which is formed inside the cases of foraminifera, the spines of echini and the spicules of sponges in a manner not yet understood. It occurs in such abundance in certain geological formations as to give rise to the name of green-sand. Green mud abounds off the east coast of North America seawards of Cape Hatteras, also to the north of Cuba, and on the west off the coast of California. The "Challenger" expedition found it on the Agulhas Bank, on the eastern coasts of Australia, Japan, South America and on the west coast of Portugal. When the proportion of calcium carbonate in the blue mud is considerable there results a calcareous ooze, which when found on the continental slope and in enclosed seas is largely composed of remains of deep-sea corals and bottom-living foraminifera, pelagic organisms including pteropods being less frequently represented. The floors of the Caribbean, Cayman and Mexican Basins in the Central American Sea are covered with a white calcareous ooze, which is clearly distinguished from the eupelagic pteropod and globigerina oozes by the presence of abundant large mineral particles and the remains of land plants. In this deposit the occurrence of calcareous concretions is very characteristic, as L. F. de Pourtalès pointed out in 1870; they consist of remains of deep-sea corals, serpulae, echinoderms and mollusca united

by a calcareous cement. Similar formations are found in the Mediterranean, where a dark mud predominates in the western part, passing into a grey, marly slime in the Tyrrhenian Basin and replaced by a typical calcareous ooze in the Eastern Basin. The bottom of the Black Sea is covered by a stiff blue mud in which Sir John Murray found much sulphide of iron,[1] grains or needles of pyrites making up nearly 50% of the deposit, and there are also grains of amorphous calcium carbonate evidently precipitated from the water. The formation of the blue mud is largely aided by the putrefaction of organic matter, and as a result the water deeper than 120 fathoms is extraordinarily deficient in dissolved oxygen and abounds in sulphuretted hydrogen, the formation of which is brought about by a special bacterium, the only form of life found at depths greater than 120 fathoms in the Black Sea.

In the Red Sea the "Pola" expedition discovered a calcareous ooze similar to that of the Mediterranean, and the formation of a stony crust by precipitation of calcium and magnesium carbonates may be recognized as giving origin to a recent dolomite.

The terrigenous ingredients in the deposits become less and less abundant as one goes farther into the deep ocean and away from the continental margins. Still, according to Murray and Irvine, finely divided colloidal clay is to be found in all parts of the ocean however remote from land, though in very small amount, and there is less in tropical than in cooler waters. A minute fraction is always separating out of the water, and as a prodigious length of time may be accepted for the accomplishment of all the chemical and physical processes in the deep sea, we must take account of the gradual accumulation of even this infinitesimal precipitation. As well as the finest of terrigenous clay there is present in sea-water far from land a different clay derived from the decomposition of volcanic material. Volcanic dust thrown into the air settles out slowly, and some of the products of submarine and littoral volcanoes, like pumice-stone, possess a remarkable power of floating and may drift into any part of the ocean before they become waterlogged and sink. To this inconceivably slowly-growing deposit of inorganic material over the ocean floor there is added an overwhelmingly more rapid contribution of the remains of calcareous and siliceous planktonic and benthonic organisms, which tend to bury the slower accumulating material under a blanket of globigerina, pteropod, diatom or radiolarian ooze. When those deposits of organic origin are wanting or have been removed, the red clay composed of the mineral constituents is found alone. It is a remarkable geographical fact that on the rises and in the basins of moderate depth of the open ocean the organic oozes preponderate, but in the abysmal depressions below 2500 or 3000 fathoms, whether these lie in the middle or near the edges of the great ocean spaces, there is found only the red clay, with a minimum of calcium carbonate, though sometimes with a considerable admixture of the siliceous remains of radiolarians. Thus red clay and radiolarian ooze are distinguished as abyssal deposits in contradistinction to the epilophic calcareous oozes.

Globigerina ooze was recognized as an important deposit as soon as the first successful deep-sea soundings had been made in the Atlantic. It was described simultaneously in 1853 by Bailey of West Point and Ehrenberg in Berlin. Murray and Renard define globigerina ooze as containing at least 30% of calcium carbonate, in which the remains of pelagic (not benthonic) foraminifera predominate and in which remains of pelagic mollusca such as pteropods and heteropods, ostracodes and also coccoliths (minute calcareous algae) may also occur. Not more than 25% of the deposit may consist of bottom-dwelling foraminifera, echini or worm-tubes, and as a rule these make up only from 9 to 10%. These peculiarities, combined with the striking absence of mineral constituents, distinguish the eupelagic globigerina ooze from the hemipelagic calcareous mud. Out of 118 samples of globigerina ooze obtained by the "Challenger" expedition 84 came from depths of 1500 to 2500 fathoms, 13 from depths of 1000 to 1500 and only 16 from depths greater than 2500 fathoms. Viewed as a whole this deposit may be taken as a partial precipitation of the plankton living in the upper waters of the open sea. A small proportion of organic matter including the fat globules of the plankton is mixed with the calcium carbonate, the amount according to Gümbel's analysis being about 1 part in 1000. Secondary products, such as glauconite, phosphatic concretions and manganese nodules, occur though less frequently than in the hemipelagic sediments. Globigerina ooze is the characteristic deposit of the Atlantic Ocean, where it covers not less than 44,000,000 sq. km. (17,000,000 sq. statute m.). In the Indian Ocean the area covered is 31,000,000 sq. km. (12,000,000 sq. m.) and in the huge Pacific Ocean only 30,000,000 sq. km. (11,500,000 sq. m.).

Pteropod ooze is merely a local variety of globigerina ooze in which the comparatively large but very delicate spindle-shaped shells of pteropods happen to abound. These shells do not retain their individuality at depths greater than 1400 or 1500 fathoms, and in fact pteropod ooze is only found in small patches on the ridges near the Azores, Antilles, Canaries, Sokotra, Nicobar, Fiji and the Paumotu islands, and on the central rise of the South Atlantic between Ascension and Tristan d'Acunha.

Diatom ooze was recognized by Sir John Murray as the characteristic deposit in high latitudes in the Indian Ocean, and later it was found to be characteristic also of the corresponding parts of the Indian and Pacific covering a total area of about 22,000,000 sq. km. (8,500,000 sq. m.). It has been found sporadically near the Aleutian Islands, between the Philippines and Marianne Islands and to the south of the Galapagos group. It is made up to a large extent of the siliceous frustules of diatoms. It is usually yellowish-grey and often straw-coloured when wet, though when dried it becomes white and mealy.

Red clay was discovered and named by Sir Wyville Thomson on the "Challenger" in 1873 when sounding in depths of 2700 fathoms on the way from the Canary Islands to St Thomas. The reddish colour comes from the presence of oxides of iron, and particles of manganese also occur in it, especially in the Pacific region, where the colour is more that of chocolate; but when it is mixed with globigerina ooze it is grey. Red clay is the deposit peculiar to the abyssal area; 70 carefully investigated samples collected by the "Challenger" came from an average depth of 2730 fathoms, 97 specimens collected by the "Tuscarora" came from an average depth of 2860 fathoms, and 26 samples obtained by the "Albatross" in the Central Pacific came from an average depth of 2620 fathoms. Red clay has not yet been found in depths less than 2200 fathoms. The main ingredient of the deposit is a stiff clay which is plastic when fresh, but dries to a stony hardness. Isolated gritty fragments of minerals may be felt in the generally fine-grained homogeneous mass. The dredge often brings up large numbers of nodules formed upon sharks' teeth, the ear-bones of whales or turtles or small fragments of pumice or other volcanic ejecta, and all more or less incrusted with manganese oxide until the nodules vary in size from that of a potato to that of a man's head. A very interesting feature is the small proportion of calcium carbonate, the amount present being usually less as the depth is greater; red clay from depths exceeding 3000 fathoms does not contain so much as 1% of calcareous matter.

Murray and Renard recognize the progressive diminution of carbonate of lime with increase of depth as a characteristic of all eupelagic deposits. The whole collection of 231 specimens of deep-sea deposits brought back by the "Challenger" shows the following general relationship:—

Proportion of Calcium Carbonate in Deep-Sea Deposits.

68	samples	from less than 2000 fathoms	=	60-80 %
68	"	" 2000-2500	"	46-7 %
65	"	" 2500-3000	"	17·4 %
8	"	" more than 3000	"	0·9 %

In deep water there is a regular process of solution of the calcareous shells falling from the surface. Murray and Renard ascribe this to the greater abundance of carbonic acid in the

[1] *Scot. Geog. Mag.*, vol. 16 (1900), p. 695.

deeper water, which aided by the increased pressure adds to the solvent power of the water for carbonate of lime. It is, however, a curious question how, considering the increase of carbonic acid by the decomposition of organic bodies and possible submarine exhalations of volcanic origin, the water has not in some places become saturated and a precipitate of amorphous calcium carbonate formed in the deepest water. The whole subject still requires investigation.

Amongst the foreign material found embedded in the red clay are globules of meteoric iron, which are sometimes very abundant. Derived products in the form of crystals of phillipsite are not uncommon, but the most abundant of all are the incrustations of manganese oxide, as to the origin of which Murray and Renard are not fully clear. The manganese nodules afford the most ample proof of the prodigious period of time which has elapsed since the formation of the red clay began; the sharks' teeth and whales' ear-bones which serve as nuclei belong in some cases to extinct species or even to forms derived from those familiar in the fossils from the seas of the Tertiary period. This fact, together with the extraordinarily rare occurrence of such remains and meteoric particles in globigerina ooze, although there is no reason to suppose that at any one time they are unequally distributed over the ocean floor, can only be explained on the assumption that the rate of formation of the epilophic deposits through the accumulation of pelagic shells falling from the surface is rapid enough to bury the slow-gathering material which remains uncovered on the spaces where the red clay is forming at an almost infinitely slower rate. Sir John Murray believes that no more than a few feet of red clay have accumulated in the deepest depressions since the close of the Tertiary period. The red clay is the characteristic deposit of the Pacific Ocean, where about 101,000,000 sq. km. (39,000,000 sq. m.) are covered with it, while only 15,000,000 sq. km. (5,800,000 sq. m.) of the Indian Ocean and 14,000,000 sq. km. (5,400,000 sq. m.) of the Atlantic are occupied by this deposit; it is indeed the dominant submarine deposit of the water-hemisphere just as globigerina ooze is the dominant submarine deposit of the land-hemisphere.

Radiolarian ooze was recognized as a distinct deposit and named by Sir John Murray on the "Challenger" expedition, but it may be viewed as red clay with an exceptionally large proportion of siliceous organic remains, especially those of the radiolarians which form part of the pelagic plankton. It does not occur in the Atlantic Ocean at all, and in the Indian Ocean it is only known round Cocos and Christmas Islands; but it is abundant in the Pacific, where it covers a large area between 5° and 15° N., westward from the coast of Central America to 165° W., and it is also found in patches north of the Samoa Islands, in the Marianne Trench and west of the Galapagos Islands.

The total areas occupied by the various deposits according to the latest measurements of Krümmel are as follows:—

Area of Submarine Deposits.

Deposit.	Sq. km.	Sq. st. m.	%.
I. Littoral deposits . .	33,000,000	12,700,000	9·1
II. Hemipelagic „ . . .	55,700,000	21,500,000	15·4
III. Eupelagic „ . . .	272,700,000	105,300,000	75·5
1. Globigerina ooze .	105,600,000	40,800,000	(29·2)
2. Pteropod ooze . .	1,400,000	500,000	(0·4)
3. Diatom ooze . .	23,200,000	8,900,000	(6·4)
4. Red clay . . .	130,300,000	50,300,000	(36·1)
5. Radiolarian ooze .	12,200,000	4,700,000	(3·4)

Geologists are agreed that littoral and hemipelagic deposits similar to those now forming are to be found in all geological systems, but the existence in the rocks of eupelagic deposits and especially of the abysmal red clay, though viewed by some as probable, is totally denied by others. There is even some hesitation in accepting the continuity of the chalk with the globigerina ooze of the modern ocean. From the obvious rarity of true abysmal rocks in the continental area Sir John Murray deduces the permanence of the oceans, which he holds have always remained upon those portions of the earth's crust which they occupy now, and both J. Dana and Louis Agassiz had already arrived at the same conclusion. This theory accords well with the enormous lapse of time required in the accumulation of the red clay.

Salts of Sea-water.—Sea-water differs from fresh water by its salt and bitter taste and by its unsuitability for the purposes of washing and cooking. The process of natural evaporation in the *salines* or salt gardens of the margin of warm seas made the composition of sea-salt familiar at a very early time, and common salt, Epsom salts, gypsum and magnesium chloride were recognized amongst its constituents. The analyses of modern chemists have now revealed the existence of 32 out of the 80 known elements as existing dissolved in sea-water, and it is scarcely too much to say that the remaining elements also exist in minute traces which the available methods of analysis as yet fail to disclose. Many of the elements such as copper, lead, zinc, nickel, cobalt and manganese have only been found in the substance of sea-weeds and corals. Silver and gold also exist in solution in sea-water. Malaguti and Durocher[1] estimate the silver in sea-water as 1 part in 100,000,000 or 1 grain in 1430 gallons. If this estimate is correct there exists dissolved in the ocean a quantity of silver equal to 13,300 million metric tons, that is to say 46,700 times as much silver as has been produced from all the mines in the world from the discovery of America down to 1902. No quantitative determination of the amount of gold in solution is available. E. Sonnstadt[2] detected gold by means of a colour test and roughly estimated the amount as 1 grain per ton of sea-water, and on this estimate all the projects for extracting gold from sea-water have been based.

The elements in addition to oxygen which exist in largest amount in sea salt are chlorine, bromine, sulphur, potassium, sodium, calcium and magnesium. Since the earliest quantitative analyses of sea-water were made by Lavoisier in 1772, Bergman in 1774, Vogel in 1813 and Marcet in 1819 the view has been held that the salts are present in sea-water in the form in which they are deposited when the water is evaporated. The most numerous analyses have been carried out by Forchhammer, who dealt with 150 samples, and Dittmar, who made complete analyses of 77 samples obtained on the "Challenger" expedition. Dittmar showed that the average proportion of the salts in ocean water of 35 parts salts per thousand was as follows (calculated as parts per thousand of the sea-water, as percentage of the total salts and per hundred molecules of magnesium bromide):—

The Salts in Ocean Water.

	Per 1000 Parts Water.	Per cent. Total Salts.	Per 100 Molecules $MgBr_2$.
Common salt, sodium chloride (NaCl) . .	27·213	77·758	112,793
Magnesium chloride ($MgCl_2$)	3·807	10·878	9,690
Magnesium sulphate ($MgSO_4$)	1·658	4·737	3,338
Gypsum, calcium sulphate ($CaSO_4$) . .	1·260	3·600	2,239
Potassium sulphate (K_2SO_4)	0·863	2·465	1,200
Calcium carbonate ($CaCO_3$) and residue	0·123	0·345	298
Magnesium bromide ($MgBr_2$)	0·076	0·217	100
	35·000	100·000	

As Marcet had foreshadowed from the analysis of 14 samples in 1819, the larger series of exact analyses proved that the variations in the proportion of individual salts to the total salts are very small, and all analyses since Dittmar's have confirmed this result. Although the salts have been grouped in the above

[2] *Chemical News* (1870), vol. 22, pp. 25, 44; (1872) vol. 26, p. 159.

table it is not to be supposed that a dilute solution like sea-water contains all the ingredients thus arbitrarily combined. There must be considerable dissociation of molecules, and as a first approximation it may be taken that of 10 molecules of most of the components about 9 (or in the case of magnesium sulphate 5) have been separated into their ions, and that it is only during slow concentration as in a natural *saline* that the ions combine to produce the various salts in the proportions set out in the above table. One can look on sea-water as a mixture of very dilute solutions of particular salts, each one of which after the lapse of sufficient time fills the whole space as if the other constituents did not exist, and this interdiffusion accounts easily for the uniformity of composition in the sea-water throughout the whole ocean, the only appreciable difference from point to point being the salinity or degree of concentration of the mixed solutions.

The origin of the salt of the sea is attributed by some modern authorities entirely to the washing out of salts from the land by rain and rivers and the gradual concentration by evaporation in the oceans, and some (*e.g.* J. Joly) go so far as to base a calculation of the age of the earth on the assumption that the ocean was originally filled with fresh water. This hypothesis, however, does not accord with the theory of the development of the earth from the state of a sphere of molten rock surrounded by an atmosphere of gaseous metals by which the first-formed clouds of aqueous vapour must have been absorbed. The great similarity between the salts of the ocean and the gaseous products of volcanic eruptions at the present time, rich in chlorides and sulphates of all kinds, is a strong argument for the ocean having been salt from the beginning. Two other facts are totally opposed to the origin of all the salinity of the oceans from the concentration of the washings of the land. The proportions of the salts of river and sea-water are quite different, as Julius Roth shows thus:—

	Carbonates.	Sulphates.	Chlorides.
River water . . .	80	13	7
Sea water	0·2	10	89

The salts of salt lakes which have been formed in the areas of internal drainage in the hearts of the continents by the evaporation of river water are entirely different in composition from those of the sea, as the existence of the numerous natron and bitter lakes shows. Magnesium sulphate amounts to 4·7% of the total salts of sea-water according to Dittmar, but to 23·6% of the salts of the Caspian according to Lebedinzeff; in the ocean magnesium chloride amounts to 10·9% of the total salts, in the Caspian only to 4·5%; on the other hand calcium sulphate in the ocean amounts to 3·6%, in the Caspian to 6·9%. This disparity makes it extremely difficult to view ocean water as merely a watery extract of the salts existing in the rocks of the land.

The determination of salinity was formerly carried out by evaporating a weighed quantity of sea-water to dryness and weighing the residue. Forchhammer, however, pointed out that this method gave inexact and variable results, as in the act of evaporating to dryness hydrochloric acid is given off as the temperature is raised to expel the last of the water, and Tornöe found that carbonic acid was also liberated and that the loss of both acids was very variable. Tornöe vainly attempted to apply a correction for this loss by calculation; and subsequently S. P. L. Sörensen and Martin Knudsen after a careful investigation decided to abandon the old definition of salinity as the sum of all the dissolved solids in sea-water and to substitute for it the weight of the dissolved solids in 1000 parts by weight of sea-water on the assumption that all the bromine is replaced by its equivalent of chlorine, all the carbonate converted into oxide and the organic matter burnt. The advantage of the new definition lies in the fact that the estimation of the chlorine (or rather of the total halogen expressed as chlorine) is sufficient to determine the salinity by a very simple operation. According to Knudsen the salinity is given in weight per thousand parts by the expression $S = 0{\cdot}030 + 1{\cdot}8050\ Cl$ where S is the salinity and Cl the amount of total halogen in a sample. Such a simple formula is only possible because the salts of sea-water are of such uniform composition throughout the whole ocean that the chlorine bears a constant ratio to the total salinity as newly defined whatever the degree of concentration. This definition was adopted by the International Council for the Study of the Sea in 1902, and it has since been very widely accepted.

Besides the determination of salinity by titration of the chlorides, the method of determination by the specific gravity of the sea-water is still often used. In the laboratory the specific gravity is determined in a pyknometer by actual weighing, and on board ship by the use of an areometer or hydrometer. Three types of areometer are in use: (1) the ordinary hydrometer of invariable weight with a direct reading scale, a set of from five to ten being necessary to cover the range of specific gravity from 1·000 to 1·031 so as to take account of sea-water of all possible salinities; (2) the "Challenger" type of areometer designed by J. Y. Buchanan, which has an arbitrary scale and can be varied in weight by placing small metal rings on the stem so as to depress the scale to any desired depth in sea-water of any salinity, the specific gravity being calculated for each reading by dividing the total weight by the immersed volume; (3) the total immersion areometer, which has no scale and the weight of which can be adjusted so that the instrument can be brought so exactly to the specific gravity of the water sample that it remains immersed, neither floating nor sinking; this has the advantage of eliminating the effects of surface tension and in Fridtjof Nansen's pattern is capable of great precision.

In all areometer work it is necessary to ascertain the temperature of the water sample under examination with great exactness, as the volume of the areometer as well as the specific gravity of the water varies with temperature. All determinations must accordingly be reduced to a standard temperature for comparison. Following the practice of J. Y. Buchanan on the "Challenger" it has been usual for British investigators to calculate specific gravities for sea-water at 60° F. compared with pure water at the maximum density point (39·2°) as unity. On the continent of Europe it has been more usual to take both at 17·5° C. (63·5° F.), which is expressed as "$S\ \frac{17{\cdot}5°}{17{\cdot}5°}$", but for pyknometer work in all countries where the sample is cooled to 32° F. before weighing and pure water at 39·2° taken as unity the expression is (0°/4°). On the authority of the first meeting of the International Conference for the Study of the Northern European Seas at Stockholm in 1899 Martin Knudsen, assisted by Karl Forch and S. P. L. Sörensen, carried out a careful investigation of the relation between the amount of chlorine, the total salinity and the specific gravity of sea-water of different strengths including an entirely new determination of the thermal expansion of sea-water. The results are published in his *Hydrographical Tables* in a convenient form for use.

The relations between the various conditions are set forth in the following equations where σ_0 signifies the specific gravity of the sea-water in question at 0° C., the standard at 4° being taken as 1000, S the salinity and Cl the chlorine, both expressed in parts by weight per mille.

(1) $\sigma_0 = -0{\cdot}093 + 0{\cdot}8149\ S - 0{\cdot}000482\ S^2 + 0{\cdot}0000068\ S^3$
(2) $\sigma_0 = -0{\cdot}069 + 1{\cdot}4708\ Cl - 0{\cdot}00157\ Cl^2 + 0{\cdot}0000398\ Cl^3$
(3) $S = 0{\cdot}030 + 1{\cdot}8050\ Cl.$

The temperature of maximum density of sea-water of any specific gravity was found by Knudsen to be given with sufficient accuracy for all practical purposes by the formula $\theta = 3{\cdot}95 - 0{\cdot}266\sigma_\theta$, where θ is the temperature of maximum density in degrees centigrade. The temperature of maximum density is lower as the concentration of the sea-water is greater, as is shown in the following table:—

Maximum Density Point of Sea-Water of Different Salinities.

Salinity per mille . .	0	10	20	30	35	40
Temperature θ° C .	3·95°	1·80°	−0·31°	−2·47°	−3·52°	−4·54°
Density σ_θ . . .	0·00°	8·18°	16·07°	24·15°	28·22°	32·32°

Further Physical Properties of Sea-water.—The laws of physical chemistry relating to complex dilute solutions apply to sea-water, and hence there is a definite relation between the osmotic pressure, freezing-point, vapour tension and boiling-point by which when one of these constants is given the others can be calculated.

The most easily observed is the freezing-point, and according to the very careful determinations of H. T. Hansen the freezing-point τ° C. varies with the degree of concentration according to the formula

$$\tau = -0{\cdot}0086 - 0{\cdot}0064633\sigma_0 - 0{\cdot}0001055\sigma_0^2.$$

According to the investigations of Svante Arrhenius the osmotic pressure in atmospheres may be obtained by simply multiplying the temp rature of freezing (τ) by the factor −12·08, and it varies with temperature (t) according to the law which holds good for gaseous pressure.

$$P_t = P_0(1 + 0{\cdot}00367t)$$

and can thus be reduced to its value at 0° C. Sigurd Stenius has calculated tables of osmotic pressure for sea-water of different degrees of concentration. The relation of the elevation of the boiling-point (ε°) to the osmotic pressure (P) is very simply derived from the formula $\varepsilon = 0{\cdot}02407P_0$, while the reduction of vapour pressure proportional to the concentration can be very easily obtained from the elevation of the boiling-point, or it may be obtained directly from tables of vapour tension.

Physical Properties of Sea-Water.

Salinity per mille . .	10	20	30	35	40
Freezing-point (C.) .	−0·53	−1·07	−1·63	−1·91	−2·20
Osmotic pressure P_0 atmospheres . . .	6·4	13·0	19·7	23·1	26·6
Elevation of boiling-point (C.) . . .	0·16	0·31	0·47	0·56	0·64
Reduction of vapour pressure (mm.) . .	4·2	8·5	13·0	15·2	17·6

The importance of the osmotic pressure of sea-water in biology will be easily understood from the fact that a frog placed in sea-water loses water by exosmosis and soon becomes 20% lighter than its original weight, while a true salt-water fish suddenly transferred to fresh water gains water by endosmosis, swells up and quickly succumbs. The elevation of the boiling-point is of little practical importance, but the reduction of vapour pressure means that sea-water evaporates more slowly than fresh water, and the more slowly the higher the salinity. Unfortunately no observations of evaporation from the surface of the open sea have been made and very few comparisons of the evaporation of salt and fresh water are on record. The fact that sea-water does evaporate more slowly than fresh water has been proved by the observations of Mazelle at Triest and of Okado in Azino (Japan). Their experiments show that in similar conditions the evaporation of sea-water amounts to from 70 to 91% of the evaporation of fresh water, a fact of some importance in geophysics on account of the vast expanses of ocean the evaporation from which determines the rainfall and to a large extent the heat-transference in the atmosphere.

The optical properties of sea-water are of immediate importance in biology, as they affect the penetration of sunlight into the depths. The refraction of light passing through sea-water is dependent on the salinity to the extent that the index of refraction is greater as the salinity increases. From isolated observations of J. Soret and E. Sarasin and longer series of experiments by Tornöe and Krümmel this relation is shown to be so close that the salinity of a sample can be ascertained by determining the index of refraction. According to Krümmel the following relations hold good at 18° C. for the monochromatic light of the D line of the sodium spectrum in units of the fifth decimal place.

Relation of Refractive Index and Salinity.

For water of salinity (per mille)	0	10	20	30	35	40
Refractive index 1·33000+ units of 5th decimal place	308	502	694	885	981	1077

The refractometer constructed by C. Pulfrich (of the firm of Zeiss, in Jena) has been successfully used by G. Schott and E. von Drygalski for the measurement of salinity at sea, and was found to have the same degree of accuracy as an areometer with the great advantage of being quite unaffected by the motion of the ship in a sea-way.

The transparency of sea-water has frequently been measured at sea by the simple expedient of sinking white-painted disks and noting the depth at which they become invisible as the measure of the transparency of the water. For the north European seas disks of about 18 or 20 in. in diameter are sufficient for this purpose, but in the tropics, where the transparency is much greater, disks 3 ft. in diameter at least must be used or the angle of vision for the reflected light is too small. In shallow seas the transparency is always reduced in rough weather. In the North Sea north of the Dogger Bank, for instance, the disk is visible in calm weather to a depth of from 10 to 16 fathoms, but in rough weather only to 6½ fathoms. Knipovitch occasionally observed great transparency in the cold waters of the Murman Sea, where he could see the disk in as much as 25 fathoms, and a similar phenomenon has often been reported from Icelandic waters. The greatest transparency hitherto reported is in the eastern basin of the Mediterranean, where J. Luksch found the disk visible as a rule to from 22 to 27 fathoms, and off the Syrian coast even to 33 fathoms. In the open Atlantic there are great differences in transparency; Krümmel observed a 6 ft. disk to depths of 31 and 36 fathoms in the Sargasso Sea, but in the cold currents of the north and also in the equatorial current the depth of visibility was only from 11 to 16½ fathoms. In the tropical parts of the Indian and the Pacific Oceans the depth of visibility increases again to from 20 to 27 fathoms. Some allowance should be made for the elevation of the sun at the time of observation. Mill has shown that in the North Sea off the Firth of Forth the average depth of visibility of a disk in the winter half-year was 4½ fathoms and in the summer half-year 6½ fathoms, and, although the greater frequency of rough weather in winter might tend to obscure the effect, individual observations made it plain that the angle of the sun was the main factor in increasing the depth to which the disk remained visible.

There are some observations on the transparency of sea-water of an entirely different character. Such, for instance, were those of Spindler and Wrangell in the Black Sea by sinking an electric lamp, those of Paul Regnard by measuring the change of electric resistance in a selenium cell or the chemical action of the light on a mixture of chlorine and hydrogen, by which he found a very rapid diminution in the intensity of light even in the surface layers of water. Many experiments have also been made by the use of photographic plates in order to find the greatest depth to which light penetrates. Fol and Sarasin detected the last traces of sunlight in the western Mediterranean at a depth of 254 to 260 fathoms, and Luksch in the eastern Mediterranean at 328 fathoms and in the Red Sea at 273 fathoms. The chief cause of the different depths to which light penetrates in sea-water is the varying turbidity due to the presence of mineral particles in suspension or to plankton. Schott gives the following as the result of measurements of transparency by means of a white disk at 23 stations in the open ocean, where quantitative observations of the plankton under 1 square metre of surface were made at the same time.

	Volume of Plankton.	Depth of Visibility.
Mean of 11 stations poor in plankton .	85 cc.	14½ fathoms
Mean of 12 stations rich in plankton .	530 „	8¾ „

Any influence on transparency which may be exercised by the temperature or salinity of the water is quite insignificant.

The colour of ocean water far from land is an almost pure

of local disturbances, the usual cause being turbidity of some kind, and this in the high seas is almost always due to swarms of plankton. The colour of sea-water as it is seen on board ship is most readily determined by comparison with the tints of Forel's xanthometer or colour scale, which consists of a series of glass tubes fixed like the rungs of a ladder in a frame and filled with a mixture of blue and yellow liquids in varying proportions. For this purpose the zero or pure blue is represented by a solution of 1 part of copper sulphate and 9 parts of ammonia in 190 parts of water. The yellow solution is made up of 1 part of neutral potassium chromate in 199 parts of water, and to give the various degrees of the scale, 1, 2, 3, 4, &c., % of the yellow solution is mixed with 99, 98, 97, 96, &c., % of the blue in successive tubes. Observations with the xanthometer have not hitherto been numerous, but it appears that the purest blue (0–1 on Forel's scale) is found in the Sargasso Sea, in the North Atlantic and in similarly situated tropical or subtropical regions in the Indian and Pacific Oceans. The northern seas have an increasing tendency towards green, the Irminger Sea showing 5–9 Forel, while in the North Sea the water is usually a pure green (10–14 Forel), the western Mediterranean shows 5–9 Forel, but the eastern is as blue as the open ocean (0–2 Forel). A pure blue colour has been observed in the cold southern region, where the "Valdivia" found 0–2 Forel in 55° S. between 10° and 31° E., and even the water of the North Sea has been observed at times to be intensely blue. The blue of the sea-water as observed by the Forel scale has of course nothing to do with the blue appearance of any distant water surface due to the reflection of a cloudless sky. Over shallows even the water of the tropical oceans is always green. There is a distinct relationship between colour and transparency in the ocean; the most transparent water which is the most free from plankton is always the purest blue, while an increasing turbidity is usually associated with an increasing tint of green. The natural colour of pure sea-water is blue, and this is emphasized in deep and very clear water, which appears almost black to the eye. When a quantity of a fine white powder is thrown in, the light reflected by the white particles as they sink assumes an intense blue colour, and the experiments of J. Aitken with clear sea-water in long tubes leave no doubt on the subject.

Discoloration of the water is often observed at sea, but that is always due to foreign substances. Brown or even blood-red stripes have been observed in the North Atlantic when swarms of the copepod *Calanus finmarchicus* were present; the brown alga *Trichodesmium erythraeum*, as its name suggests, can change the blue of the tropical seas to red; swarms of diatoms may produce olive-green patches in the ocean, while some other forms of minute life have at times been observed to give the colour of milk to large stretches of the ocean surface.

On account of its salinity, sea-water has a smaller capacity for heat than pure water. According to Thoulet and Chevallier the specific heat diminishes as salinity increases, so that for 10 per mille salinity it is 0·968, for 35 per mille it is only 0·932, that of pure water being taken as unity. The thermal conductivity also diminishes as salinity increases, the conductivity for heat of sea-water of 35 per mille salinity being 4·2% less than that of pure water. This means that sea-water heats and cools somewhat more readily than pure water. The surface tension, on the other hand, is greater than that of pure water and increases with the salinity, according to Krümmel, in the manner shown by the equation $\alpha = 77{\cdot}09 + 0{\cdot}0221\ S$ at 0° C., where α is the coefficient of surface tension and S the salinity in parts per thousand. The internal friction or viscosity of sea-water has also been shown by E. Ruppin to increase with the salinity. Thus at 0° C. the viscosity of sea-water of 35 per mille salinity is 5·2% greater and at 25° C. 4% greater than that of pure water at the same temperatures; in absolute units the viscosity of sea-water at 25° C. is only half as great as it is at 0° C.

The compressibility of sea-water is not yet fully investigated. with the degree of pressure. Thus J. Y. Buchanan found a mean of 20 experiments made by piezometers sunk in great depths on board the "Challenger" give a coefficient of compressibility $\kappa = 491 \times 10^{-7}$; but six of these experiments made at depths of from 2740 to 3125 fathoms gave $\kappa = 480 \times 10^{-7}$. The value usually adopted is $\kappa = 450 \times 10^{-7}$. The compressibility is in itself very small, but so great in its effect on the density of deep water *in situ* that the specific gravity (0°/4°) at 2000 fathoms increases by 0·017 and at 3000 fathoms by 0·026. In other words, water which has a specific gravity of 1·0280 at the surface would at the same temperature have a specific gravity of 1·0450 at 2000 and 1·0540 at 3000 fathoms. If the whole mass of water in the ocean were relieved from pressure its volume would expand from 319 million cub. m. to 321·7 million cub. m., which for a surface of 139·5 million sq. m. means an increased depth of 100 ft. The rate of propagation of sound depends on the compressibility, and in ocean water at the tropical temperature of 77° F. the speed is 1482·6 metres (4860 ft.) per second, in Baltic water of 8 per mille salinity and a temperature of 50° F. it is 1448·5 metres (4750 ft.) per second, that is to say, 4½ times greater than the velocity of sound in air. This accounts for the great range of submarine sound signals, which can thus be very serviceable to navigation in foggy weather.

The electrical conductivity of sea-water increases with the salinity; at 59° F. it is given according to E. Ruppin's formula as $L = 0{\cdot}001465\ S - 0{\cdot}00000978\ S^2 + 0{\cdot}0000000876\ S^3$ in reciprocal ohms.

The radio-activity of sea-water is extraordinarily small; indeed in samples taken from 50 fathoms in the Bay of Danzig it was imperceptible, and R. T. Strutt found that salt from evaporated sea-water did not contain one-third of the quantity of radium present in the water of the town supply in Cambridge.

Dissolved Gases of Sea-water.—The water of the ocean, like any other liquid, absorbs a certain amount of the gases with which it is in contact, and thus sea-water contains dissolved oxygen, nitrogen and carbonic acid absorbed from the atmosphere. As Gay-Lussac and Humboldt showed in 1805, gases are absorbed in less amount by a saline solution than by pure water. The first useful determinations of the dissolved gases of sea-water were made by Oskar Jacobsen in 1872. Since that time much work has been done, and the methods have been greatly improved. In the method now most generally practised, which was put forward by O. Pettersson in 1894, two portions of sea-water are collected in glass tubes which have been exhausted of air, coated internally with mercuric chloride to prevent the putrefaction of any organisms, and sealed up beforehand. The exhausted tube, when inserted in the water sample and the tip broken off, immediately fills, and is then sealed up so that the contents cannot change after collection. One portion is used for determining the oxygen and nitrogen, the other for the carbonic acid. The former determination is made by driving out the dissolved gases from solution and collecting them in a Torricellian vacuum, where the volume is measured after the carbonic acid has been removed. The oxygen is then absorbed by some appropriate means, and the volume of the nitrogen measured directly, that of the oxygen being given by difference. In the second portion the carbonic acid is driven out by means of a current of hydrogen, collected over mercury and absorbed by caustic potash.

C. T. T. Fox, of the Central Laboratory of the International Council at Christiania, has investigated the relation of the atmospheric gases to sea-water by very exact experimental methods and arrived at the following expressions for the absorption of oxygen and nitrogen by sea-water of different degrees of concentration. The formulae show the number of cubic centimetres of gas absorbed by 1 litre of sea-water; t indicates the temperature in degrees centigrade and Cl the salinity as shown by the amount of chlorine per mille:—

$$O_2 = 10{\cdot}291 - 0{\cdot}2809\ t + 0{\cdot}006009\ t^2 - 0{\cdot}0000632\ t^3 - \mathrm{Cl}(0{\cdot}1161 - 0{\cdot}003922\ t^2 + 0{\cdot}000063\ t^3)$$

$$N_2 = 18{\cdot}561 - 0{\cdot}4282\ t + 0{\cdot}0074527\ t^2 - 0{\cdot}00005494\ t^3 - \mathrm{Cl}(0{\cdot}2149 - 0{\cdot}007117\ t^2 + 0{\cdot}0000931\ t^3)$$

In the case of ocean water with a salinity of 35 per mille, this gives for saturation with atmospheric gases in cc. per litre:—

	at 0° C.	15° C.	25° C.
Oxygen . . .	8·03	5·84	4·93
Nitrogen . .	14·40	11·12	9·78

The reduction of the absorption of gas by rise of temperature is thus seen to be considerable. As a rule the amount of both gases dissolved in sea-water is found to be that which is indicated by the temperature of the water *in situ*. Jacobsen on some occasions found water in the surface layers of the Baltic supersaturated with oxygen, which he ascribed to the action of the chlorophyll in vegetable plankton; in other cases when examining the nearly stagnant water from deep basins he found a deficiency of oxygen due no doubt to the withdrawal of oxygen from solution, by the respiration of the animals and by the oxidation of the deposits on the bottom. When these processes continue for a long time in deep water shut off from free circulation so that it does not become aerated by contact with the atmosphere the water becomes unfit to support the life of fishes, and when the accumulation of putrefying organic matter gives rise to sulphuretted hydrogen as in the Black Sea below 125 fathoms, life, other than bacterial, is impossible. The water from the greatest depths of the Black Sea, 1160 fathoms, contains 6 cc. of sulphuretted hydrogen per litre.

The distribution of dissolved oxygen in the depths of the open ocean is still very imperfectly known. Dittmar's analysis of the "Challenger" samples indicated an excess of oxygen in the surface water of high southern latitudes and a deficiency at depths below 50 fathoms.

The facts regarding carbonic acid in sea-water are even less understood, for here we have to do not only with the solution of the gas but also with a chemical combination. On this account it is very difficult to know when all the gas is driven out of a sample of sea-water, and a much larger proportion is present than the partial pressure of the gas in the atmosphere and its coefficient of absorption would indicate. These constants would lead one to expect to find 0·5 cc. per litre at 0° C. while as a matter of fact the amount absorbed approaches 50 cc. The form of combination is unstable and apparently variable, so that the quantities of free carbonic acid, bicarbonate and normal carbonate are liable to alter. Since 1851 it has been known that all sea-water has an alkaline reaction, and Tornöe defined the *alkalinity* of sea-water as the amount of carbonic acid which is necessary to convert the excess of bases into normal carbonate. The alkalinity of North Atlantic water of 35 per mille salinity is 26·86 cc. per litre, corresponding to a total amount of carbonic acid of 49·07 cc. According to the researches of August Krogh,[1] the alkalinity is greatly increased by the admixture of land water. This is proved by E. Ruppin's analysis of Baltic water, which has an alkalinity of 16 to 18 instead of the 5 or 6 which would be the amount proportional to the salinity, while the water of the Vistula and the Elbe with a salinity of 0·1 per mille has an alkalinity of 28 or more. Thus the alkalinity serves as an index of the admixture of river water with sea-water. Carbonic acid passes from the atmosphere into the ocean as soon as its tension in the latter is the smaller; hence in this respect the ocean acts as a regulator. The amount of carbonic acid in solution may also be increased by submarine exhalations in regions of volcanic disturbance, but it must be remembered that the critical pressure for this gas is 73 atmospheres, which is reached at a depth of 400 fathoms, so that carbonic acid produced at the bottom of the ocean must be in liquid form. The respiration of marine animals in the depths of deep basins in which there is no circulation adds to the carbonic acid at the expense of the dissolved oxygen. This is frequently the case in fjord basins; for instance, in the Gullmar Fjord at a depth of 50 fathoms with water of 34·14 per mille salinity and a temperature of 40·1° F., the carbonic acid amounts to 51·55 cc. per litre, and the oxygen only to 2·19 cc. Vegetable plankton in sunlight can reverse this process, assimilating the carbon of the carbonic acid and restoring the oxygen to solution, as was proved by Martin Knudsen and Ostenfeld in the case of diatoms. Little is known as yet of the distribution of carbonic acid in the oceans, but the amount present seems to increase with the salinity as shown by the four observations quoted:—

Water from				
Gulf of Finland of	3·2 per mille salinity	= 17·2 cc. CO_2		at 4·1° C.
Western Baltic of	14·2 „ „	= 37·0 „		at 1·6° C.
North Atlantic of	35·0 „ „	= 49·0 „		at about 10° C.
Eastern Mediterranean of	39·0 „ „	= 53·0 „		at 26·7° C.

Unfortunately the very numerous determinations of carbonic acid made by J. Y. Buchanan on the "Challenger" were vitiated by the incompleteness of the method employed, but they are none the less of value in showing clearly that the waters of the far south of the Indian Ocean are relatively rich in carbonic acid and the tropical areas deficient.

Distribution of Salinity.—A great deal of material exists on which to base a study of the surface salinity of the oceans, and Schott's chart published in *Petermanns Mitteilungen* for 1902 incorporates the earlier work and substantially confirms the first trustworthy chart of the kind compiled by J. Y. Buchanan from the "Challenger" observations. In each of the three oceans there are two maxima of salinity—one in the north, the other in the south tropical belt, separated by a zone of minimum salinity in the equatorial region, and giving place poleward to regions of still lower salinity. The three oceans differ somewhat between themselves. The North Atlantic maximum is the highest with water of 37·9 per mille salinity; the maximum in the South Atlantic is 37·6; in the North Indian Ocean, 36·7; the South Indian Ocean, 36·4; the South Pacific, 36·9; and the North Pacific has the lowest maximum of all, only 35·9. The comparatively fresh equatorial belt of water, has a salinity of 35·0 to 34·5 in the Atlantic, 35·0 to 34·0 in the Indian Ocean, 34·5 in the Western and 33·5 in the Eastern Pacific. Taking each of the oceans as a whole the Atlantic has the highest general surface salinity with 35·37.

The salinity of enclosed seas naturally varies much more than that of the open ocean. The saltest include the eastern Mediterranean with 39·5 per mille, the Red Sea with 41 to 43 per mille in the Gulf of Suez, and the Persian Gulf with 38. The fresher enclosed seas include the Malay and the East Asiatic fringing seas with 30 to 34·5 per mille, the Gulf of St Lawrence with 30 to 31, the North Sea with 35 north of the Dogger Bank diminishing to 32 further south, and the Baltic, which freshens rapidly from between 25 to 31 in the Skagerrak to 7 or 8 eastward of Bornholm and to practically fresh water at the heads of the Gulfs of Bothnia and Finland. The Arctic Sea presents a great contrast between the salinity of the surface of the ice-free Norwegian Sea with 35 to 35·4 and that of the Central Polar Basin, which is dominated by river water and melted ice, and has a salinity less than 25 per mille in most parts. The average salinity of the whole surface of the oceans may be taken as 34·5 per mille.

The vertical distribution of salinity has only recently been investigated systematically, as the earlier expeditions were not equipped with altogether trustworthy apparatus for collecting water samples at great depths. Two main types of water-bottle for collecting samples have been long in use. The older, devised by Hooke in 1667, is provided with valves above and below, both opening upward, through which the water passes freely during descent, but which are closed by some device on hauling up. The newer or slip water-bottle type consists of a cylinder allowed to drop on to a base-plate when a sample is to be collected. The first form of slip water-bottle due to Meyer retained the water merely by the weight of the cylinder pressing on the base-plate. J. Y. Buchanan introduced an improved form on the "Challenger," also remaining closed by weight, the cylinder being very heavy and ground to fit the bevelled base-plate very accurately.

[1] *Meddelelser om Grönland* (Copenhagen, 1904), p. 331.

H. R. Mill in 1885 devised a self-locking arrangement by which the bottle once closed was automatically locked and rendered watertight; H. L. Ekman made further improvements; and, finally, O. Pettersson and F. Nansen perfected the instrument, adapting it not only for enclosing a portion of water at any desired depth, but by a series of concentric divisions insulating in the central compartment water at the temperature it had at the moment of collection. By means of a weight dropped along the line the water-bottle can be shut and a sample enclosed at any desired depth. The use of a sliding weight is not recommended in depths much exceeding 200 fathoms on account of the time required and the risk of the line sagging at a low angle and so stopping the weight. In deep water the closing mechanism is usually actuated by a screw propeller which begins to work when the line is being hauled in and can be set so as to close the water-bottle in a very few fathoms. A small but heavy water-bottle has been devised by Martin Knudsen, provided with a pressure gauge or bathometer, by which samples may be collected from any moderate depth down to about 100 fathoms, on board a vessel going at full speed. This has made it possible to obtain many samples from moderate depths along a long line in a very short space of time. Sigsbee's small water-bottle on the double valve principle actuated by a propeller requires extremely skilful handling to enable it to give good results.

As yet it is only possible to speak with confidence of the vertical distribution of salinity in the seas surrounding Europe, where there is a general increase of salinity with depth. For the open ocean the only quite trustworthy results are those obtained by the prince of Monaco in the North Atlantic, and by the recent Antarctic expeditions in the South Atlantic and South Indian Oceans. The observations made on the "Challenger" and "Gazelle," though enabling some perfectly sound general conclusions to be drawn, require to be supplemented. It appears, as J. Y. Buchanan pointed out in 1876, that the great contrasts in surface salinity between the tropical maxima and the equatorial minima give place at the moderate depth of 200 fathoms to a practically uniform salinity in all parts of the ocean.

In the North Atlantic a strong submarine current flowing outward from the Mediterranean leaves the Strait of Gibraltar with a salinity of 38 per mille, and can be traced as far as Madeira and the Bay of Biscay in depths of from 600 to 2800 fathoms, still with a salinity of 35·6 per mille, whereas off the Azores at equal depths the salinity is from 0·5 to 0·7 per mille less. In the tropical and subtropical belts of the Atlantic and Indian Oceans south of the equator the salinity diminishes rapidly from the surface downwards, and at 500 fathoms reaches a minimum of 34·3 or 34·4 per mille; after that it increases again to 800 fathoms, where it is almost 34·7 or 34·8, and this salinity holds good to the bottom, even to the greatest depths, as was first shown by the "Gauss" and afterwards by the "Planet" between Durban and Ceylon.

Our knowledge of the Pacific in this respect is still very imperfect, but it appears to be less salt than the other oceans at depths below 800 fathoms, as on the surface, the salinity at considerable depths being 34·6 to 34·7 in the western part of the ocean, and about 34·4 to 34·5 in the eastern, so that, although the data are by no means satisfactory, it is impossible to assign a mass-salinity of more than 34·7 per mille for the whole body of Pacific water.

The causes of difference of salinity are mainly meteorological. The belt of equatorial minimum salinity corresponds with the excessively rainy belt of calms and of the equatorial counter-current, the salinity diminishing towards the east. The tropical maxima of salinity on the poleward side of the trade-winds coincide with the regions of minimum rainfall, high temperature, strong winds and consequently of maximum evaporation. Evaporation is naturally greatest in the enclosed seas of the nearly rainless subtropical zone such as the Mediterranean and Red Sea. Where the evaporation is at a minimum, the inflow of rivers from a large continental area and the precipitation from the atmosphere at a maximum, there is necessarily the greatest dilution of the sea-water, the Baltic and the Arctic Sea being conspicuous examples.

Temperature of the Oceans.—There is no difficulty in observing the temperature of the surface of the sea on board ship, the only precautions required being to draw the water in a bucket which has not been heated in the sun in summer or exposed to frost in winter, to draw it well forward of any discharge pipes of the steamer, to place it in the shade on deck, insert the thermometer immediately and make the reading without delay. The measurement of temperature in the depths, unless a high-speed water-bottle be used, involves stopping the ship and employing thermometers of special construction. Many forms have been tried, but only three types are in general use. The first is the slow-action thermometer which was originally used with good effect by de Saussure in the Mediterranean in 1780. He covered the bulb of the thermometer with layers of non-conducting material and left it immersed at the desired depth for a very long time to enable it to take the temperature of its surroundings. When brought up again the thermometer retained its temperature so long that there was ample time to take a correct reading. Since 1870 thermometers on this principle have been in use for regular observations at German coast and light-ship stations. Following the suggestion of Cavendish, Irving made observations of deep temperature on Phipps's Spitsbergen voyage of 1773 with a valved water-bottle, insulated by non-conducting material. A similar instrument gave excellent results in the hands of E. von Lenz on Kotzebue's second voyage of circumnavigation in 1823–1826. The last elaboration of the insulated slip water-bottle by Ekman, Nansen and Pettersson has produced an instrument of great perfection, in which the insulation is effected by layers of water between a series of concentric ebonite cylinders, all of which are closed both above and below when the apparatus encloses a sample, and each of which in turn must be warmed considerably before there is any rise of temperature in the chamber within. This can be used with certainty to ·02° C. for water down to 250 fathoms, after taking account of the slight disturbance produced by the expansion of the greatly compressed deep water.

The second form of deep-sea thermometer is the self-registering maximum and minimum on James Six's principle. These instruments must be constructed with the greatest care, but when well made in accordance with J. Y. Buchanan's large model they can be trusted to give a good account of the vertical distribution of temperature, provided the water grows cooler as the depth increases. They would act equally well if the water grew continually warmer as the depth increases, but they cannot give an exact account of a temperature inversion such as is produced when layers of warmer and colder water alternate.

The third form is the outflow or reversing thermometer, first introduced by Aimé, who used a very inconvenient form in the Mediterranean in 1841–1845, but greatly improved and simplified by Negretti and Zambra in 1875. The principle is to have a constriction in the tube above the bulb so proportioned that when the instrument is upright it acts in every way as an ordinary mercurial thermometer, but when it is inverted the thread of mercury breaks at the constriction, and the portion above the point runs down the now reversed tube and remains there as a measure of the temperature at the moment of turning over. For convenience in reading, the tube is graduated inverted, and when it is restored to its original position the mercury thread joins again and it acts as before. Various modifications of this form of thermometer have been made by Chabaud of Paris and others. It has the advantage over the thermometer on Six's principle that, being filled with mercury, it does not require such long immersion to take the temperature of the water. A correction has, of course, to be made for the expansion or contraction of the mercury thread if the temperature of reading differs much from that of reversing. Magnaghi introduced a convenient method of inverting the thermometer by means of a propeller actuated on beginning to heave in the line, and this form is used for all work at great depths. For shallow water greater precision and certainty are obtained by using a lever

actuated by a weight slipped down the line to cause the reversal, as in the patterns of Rung, Mill and others.

All thermometers sunk into deep water must be protected against the enormous pressure to which they are exposed. This may be done by the method suggested by Arago in 1828, introduced by Aimé in 1841 and again suggested by Glaisher in 1858, of sealing up the whole instrument in a glass tube exhausted of air; or, less effectively, by surrounding the bulb alone with a strong outer sheath of glass. In both forms it is usual to have the space between the bulb and the protecting sheath partly filled with mercury or alcohol to act as a conductor and reduce the time necessary for the thermometer to acquire the temperature of its surroundings.

The warming of the ocean is due practically to solar radiation alone; such heat as may be received from the interior of the earth can only produce a small effect and is fairly uniformly distributed. On account of the high specific heat of sea-water the diurnal range of temperature at the surface is very small. According to A. Buchan's discussion of the two-hourly observations on the "Challenger" the total range between the daily maximum and minimum in the warmer seas is between 0·7° and 0·8° F., and for the colder seas still less (0·2° F.), compared with 3·2° F. in the overlying air. The maximum usually occurs between 1 and 2·30 P.M., the minimum shortly before sunrise. The temperature of the surface water is generally a little higher than that of the overlying air, the daily average difference being about 0·6° F., varying from 0 9° lower at 1 P.M. to 1·6° higher at 1 A.M. There are few observations available for ascertaining the depth to which warmth from the sun penetrates in the ocean. The investigations of Aimé in 1845 and Hensen in 1889 indicate that the amount of cloud has a great effect. Aimé showed that on a calm bright day in the Mediterranean the temperature rose 0·1° C. between the early morning and noon at a depth of about 12 fathoms. Luksch deduced a much greater penetration of solar warmth from the comparison of observations at different hours at neighbouring stations in the eastern Mediterranean, but his methods were not exact enough to give confidence in the result. The penetration of warmth from the surface is effected by direct radiation, and by convection by particles rendered dense by evaporation increasing salinity. Conduction has practically no effect, for the coefficient of thermal conductivity in sea-water is so small that if a mass of sea-water were cooled to 0° C. and the surface kept at a temperature of 30° C., 6 months would elapse before a temperature of 15° C. was reached at the depth of 1·3 metres, 1 year at 1·85 metres, and 10 years at 5·8 metres. Great irregular variations in radiation and convection sometimes produce a remarkably abrupt change of temperature at a certain depth in calm water; the layer in which this sudden change occurs has been termed the *Sprungschicht*. How closely two bodies of water at different temperatures may come together is shown by the fact that in the Baltic in August between 10 and 11 fathoms there is sometimes a fall of temperature from 57° to 46·5° F. Such a condition of things is only possible in very calm weather, the action of waves having the effect of mixing the water to a considerable depth. After a storm the whole of the water in the North Sea assumes a homothermic condition, *i.e.* the temperature is the same from surface to bottom, and this occurs not only south of the Dogger Bank, where the condition is normal, but also, though less frequently, in the deeper water farther north. Similar effects are produced in narrow waters by the action of tidal currents, and the influence of a steady wind blowing on- or off-shore has a powerful effect in mixing the water.

The warmest parts of the Indian Ocean and Western Pacific have a mean annual temperature of 82° to 84° F., but such high temperatures are not found in the tropical Atlantic. In the Indian Ocean between 15° N. and 5° S. the surface temperature in May averages 84° to 86° F., and in the Bay of Bengal the temperature is 86°, and no part of the Atlantic has so high a monthly mean temperature at any season. G. Schott's investigations show that the annual range of surface temperature in the open ocean is greatest in 40° N., with 18·4° F., and in 30° S., with 9·2° F.; on the contrary, near the equator it is less, only 4° F. in 10° N., and in high latitudes it is also small, 5·2° F. in 50° S. The figures quoted above are differences between the average surface temperatures of the warmest and of the coldest month. As to the absolute extremes of surface temperature, Sir John Murray points out that 90° F. frequently occurs in the western part of the tropical Pacific, while among seas the Persian Gulf reaches 96° F., only 2° under blood-heat, and the Red Sea follows closely with a maximum of 94°. The greatest change of temperature at any place has been recorded to the east of Nova Scotia, a minimum of 28° F. and a maximum of 80°, and to the north-east of Japan with a minimum of 27° F. and a maximum of 83°. In those localities, however, it is not the same water which varies in temperature with the season, but the water of different warm and cold currents which periodically occupy the same locality as they advance and retreat. The zones of surface temperature are arranged roughly parallel to the equator, especially in the southern hemisphere. Between 40° N. and 40° S. the currents produce a considerable rearrangement of this simple order, the belts of warm water being wider on the western sides of the oceans and narrower on the eastern.

The arrangement of the isotherms thus affords a basis for valuable deductions as to the direction of ocean currents. The surface temperature of the Atlantic is relatively lower than that of the other oceans when the whole area is considered. According to Krümmel's calculation the proportional areas at a high temperature are as follows:—

Percentage of Ocean Surface with Temperature.

	Atlantic.	Indian.	Pacific.
Over 77° F. (25° C) . . .	22·4	38·0	40·1
Over 68° F. (20° C) . . .	50·1	51·7	58·4

This disparity results in some degree at least from the comparative narrowness of the inter-tropical Atlantic, and the absence of a cool northern area in the Indian Ocean. Krümmel calculates that the mean temperature of the whole ocean surface is 63·3° F., while the mean sea-level temperature of the whole layer of air at the surface of the earth is given by Hann as 57·8° F.

We are still ignorant of the depth to which the annual temperature wave penetrates in the open ocean, but observations in the Mediterranean enable us to form some opinion on the matter. The observations of Aimé in 1845 and of Semmola in the Gulf of Naples in 1881 show that the surface water in winter cools until the whole mass of water from the surface to the bottom, in 1600 fathoms or more, assumes the same temperature. Towards the end of summer the upper layers have been warmed to a depth which indicates how far the influence of solar radiation and convection have reached. Aimé estimated this depth at 150–200 fathoms, while the observations of the Austrian expedition in the eastern Mediterranean found it to be from 200 to nearly 400 fathoms. In the Red Sea, where a similar seasonal change occurs, the depth to which the surface layer warms up is about 275 fathoms. The great difference in salinity between the surface and the deep water excludes the possibility of effective convection in the seas of northern Europe, and in the open ocean the currents which are felt everywhere, and especially those with a vertical component, must exercise a very disturbing influence on convection.

The vertical distribution of temperature in the open ocean is much better known than that of salinity. The regional differences of temperature at like depths become less as the depth increases. Thus at 300 fathoms greater differences than 9° F. hardly ever occur between 50° N. and 50° S., in 800 fathoms the differences are less than 5·5° and in 1500 fathoms less than 2°. Even in the tropics the high temperature of the surface is confined to a very shallow layer; thus in the Central Pacific where the surface temperature is 82° F. the temperature at 100

fathoms is only 52° F. The whole ocean must thus form but a cold dwelling-place for the organisms of the deep sea. Sir John Murray calculates that at least 80% of the water in the ocean has a temperature always less than 40° F., and a recent calculation by Krümmel gave in fact a mean temperature of 39° F. for the whole ocean.

The normal vertical distribution of temperature is illustrated in curve A of fig. 1, which represents a sounding in the South Atlantic; and this arrangement of a rapid fall of temperature giving place gradually to an extremely slow but steady diminution as depth increases is termed *anathermic* (ἀνά, back, and θερμός, warm). Curve B shows the typical distribution of temperature in an enclosed sea, in this case the Sulu Basin of the Malay Sea, where from the level of the barrier to the bottom the temperature remains uniform or *homothermic*. Curve C shows a typical summer condition in the polar seas, where layers of sea-water at different temperatures are superimposed, the arrangement from the surface to 200 fathoms is termed

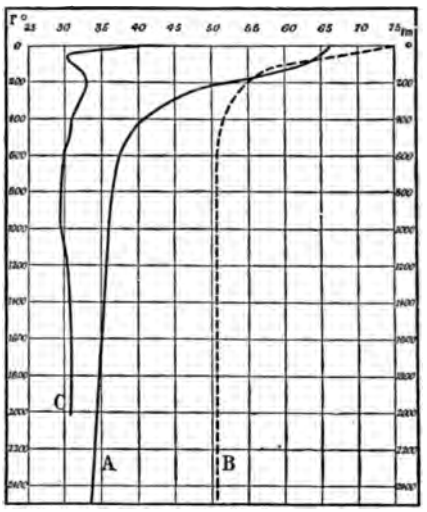

FIG. 1.—Diagram illustrating Distribution of Sea Temperature.

dichathermic (δίχα, apart), from 1000 to 2000 fathoms it is termed *katathermic* (κατά, down). In autumn the enclosed seas of high latitudes frequently present a thermal stratification in which a warm middle layer is sandwiched between a cold upper layer and a cold mass below, the arrangement being termed *mesothermic* (μέσος, middle). The nature of the change of temperature with depth below 2500 fathoms is entirely dependent on the position of the sub-oceanic elevations, for the rises and ridges act as true submarine watersheds. As the Arctic Basin is shut off from the North Atlantic by ridges rising to within 300 fathoms of the surface and from the Pacific by the shallow shelf of the Bering Sea, and as the ice-laden East Greenland and Labrador currents consist of fresh surface water which cannot appreciably influence the underlying mass, the Arctic region has no practical effect upon the bottom temperature of the three great oceans, which is entirely dominated by the influence of the Antarctic. The existence of deep-lying and extensive rises or ridges in high southern latitudes has been indicated by the deep-sea temperature observations of Antarctic expeditions. Temperatures so low as 31·5° to 31·3° F. do not occur much beyond 50° S. The "Belgica" even found a temperature of 33·1° F. in 61° S., 63° W., at a depth of 2018 fathoms. The conditions of temperature in the South Atlantic are characteristic. South of 55° S. in approximately 3000 fathoms the bottom temperature is 31·1° F.; in the Cape Trough it is 32·7° in 45° S., and 33·8° to 34·3° in 35° S., while north of the Walfisch Ridge and east of the South Atlantic Rise bottom temperatures of 36° to 36·7° F. prevail right northwards across the equator into the Bay of Biscay, showing a steady rise of bottom temperature as successive submarine elevations restrict communication with the Antarctic. On the other hand, in the more open Argentine Basin, which carries deep water far to the south, the bottom temperature in 40° S. is only from 32·2° to 32·7° F., and the same low temperature continues throughout the Brazil Basin to the equator; but in the North American Basin from the West Indies to the Telegraph Plateau no satisfactory bottom temperature lower than 35·6° F. has been reported. On the floor of the Indian Ocean temperatures of 33·3° to 33·6° occur south of 35° S. in depths of 2700 fathoms or more, but north of 35° S. the prevailing bottom temperatures are from 34·0° to 34·3°. In similar depths in the Pacific south of the equator temperatures of 33·8° to 34·5° are found, and north of the equator bottom temperatures at the same depth increase to 35·1° in the neighbourhood of the Aleutian Islands, again completely justifying the conclusion as to the Antarctic control of deep water temperature throughout the ocean.

The marginal rises and continental shelves prevent this cold bottom water from penetrating into the depths of the enclosed and fringing seas. Thus in the Central American Sea below 930 fathoms, the depth on the bar, no water is found at a temperature lower than that prevailing in the open ocean at that depth, viz. 39·6° F., not even at the bottom of the great Bartlett Deep in 3439 fathoms. Such homothermic masses of water are characteristic of all deep enclosed seas. Thus in the Malay Sea the various minor seas or basins are homothermic below the depth of the rim, at the temperature prevailing at that depth in the open ocean: in the China Sea below 875 fathoms with 36·5° F.; in the Sulu Sea (depth 2550 fathoms) below 400 fathoms with 50·5° F.; in the Celebes Sea below 820 fathoms with 38·6° F.; in the Banda Sea below 902 fathoms with 37·9° F. In other enclosed seas which are shut off from the ocean by a very shallow sill the rule holds good that the homothermic water below the level of the sill is at the lowest temperature reached by the surface water in the coldest season of the year, provided always that the stratification of salinity is such as to permit of convection being set up. To this group belongs the Arctic Sea; the Norwegian Sea is homothermic below 550 fathoms at 29·8° F., but this cold water does not penetrate into the Arctic Basin on account of the ridge between Spitsbergen and Greenland, and there the water below 1400 fathoms has a temperature of 30·6° to 30·7° F. because the surface layers of water are too light, on account of the low salinity due to ice-melting, to enable even the cold of a polar winter to set up a downward convection current. The Mediterranean Sea also belongs to this group; its various deep basins are homothermic (at the winter surface temperature) below the level of their respective sills—the Balearic Basin below 190 fathoms at 55° F.; the Eastern Basin below 270 fathoms at 55·9° F; the Ionian Sea at 56·3° F.; and at 56·7° south of Cyprus. Similarly in the Red Sea the water below 380 fathoms is homothermic at 70·7° F.

An under-current flows out from the Red Sea through the Strait of Bab-el-Mandeb, and from the Mediterranean through the Strait of Gibraltar, raising the salinity as well as the temperature of the part of the ocean outside the gates of the respective seas. The action of the Red Sea water affects the whole of the Gulf of Aden and Arabian Sea, raising the temperature at the depth of 550 fathoms to 52° or 53° F. or 9 Fahrenheit degrees higher than the water of the Bay of Bengal at the same depth. The effect of the Mediterranean water in the North Atlantic does not require such large figures to express it, but is none the less extraordinarily far-reaching, as first indicated by the work of the "Challenger" and subsequently defined by H. N. Dickson's discussion of the observations of Wolfenden in the little sailing yacht "Silver Belle." The temperature at 550 fathoms is raised to 49° or 50° F. between Madeira and the Biscay Shelf, *i.e.* 5·4° F. above the temperature at the same depth off the Azores.

In shallow seas such as the North Sea and the British fringing

seas, where tidal currents run strong, there is a general mixing together of the surface and deeper water, thus making the arrangement of vertical temperature anathermic in summer and katathermic in winter, while at the transitional periods in spring and autumn it is practically homothermic. Thus at Station E_2 of the international series at the mouth of the English Channel in 49° 27′ N., 4° 42′ W., the following distribution of temperature F. has been observed by Matthews:—

	August 1904.	November 1904.	February 1905.	May 1905.
Surface . . .	63·7°	56·2°	50·7°	51·3°
16½ fathoms . .	55·5	56·5	50·8	50·5
52 fathoms . .	55·4	56·5	50·8	50·5

It is noticeable that there is a marked vertical temperature gradient only at the end of summer when a warm surface layer is formed, though in August 1904 that was only 8 fathoms thick. In small nearly land-locked basins shut off from one another by bars rising to within a short distance of the surface and affected both by strong tidal currents and by a considerable admixture of land water, the contrasts of vertical distribution of temperature with the seasons are strongly marked, and there are also great unperiodic changes effected mainly by wind, as is shown by the investigations of H. R. Mill in the Clyde Sea Area, and of O. Pettersson, J. Hjort and Helland-Hansen in the Scandinavian fjords.

Sea Ice.—The freezing-point of sea-water is lower as the salinity increases and normal sea-water of 35 per mille salinity freezes at 28·6° F. Experience shows that sea-water can be cooled considerably below the freezing-point without freezing if there is no ice or snow in contact with it. Freezing takes place by the formation of pure ice in flat crystalline plates of the hexagonal system, which form in perpendicular planes and unite in bundles to form grains so that a thick covering of ice exhibits a fibrous structure. It is only the water that freezes; the dissolved salts are excluded in the process in a regular order according to temperature. At temperatures about 17° F. sodium sulphate is the first ingredient of the salts to separate out, potassium chloride follows at 12° F., sodium chloride at −7·4° F., magnesium chloride at −28·5° F., and, as G. Pettersson was the first to point out, calcium chloride not until −67° F. During the rapid formation of ice the still unfrozen brine is often imprisoned between the little plates of frozen water; hence without some special treatment sea-ice is not suitable as a source of drinking water. After long continued frost the last of the included brine may be frozen and the salts driven out in crystals on the surface; these crystals are known to polar explorers by the Siberian name of *rassol*. Ice is a very poor conductor of heat and accordingly protects the surface of the water beneath from rapid cooling; hence new-formed pancake ice does not increase excessively in thickness in one winter, and even in the centre of the Arctic Basin the ice-covering only amounts to 6 or at most 9 ft. in the course of a year, while in the Antarctic regions the season's growth is only half as great; in the latter also the accumulated snow is an important factor in the thickness of the ice, and snow is an even worse conductor of heat. The influence of wind and tide breaks up the frozen surface of the sea, and sheets yielding to the pressures slide over or under one another and are worked together into a hummocky ice-pack, the irregularities on the surface of which, caused by repeated fractures and collisions, may be from 10 to 20 ft. high. Such formations, termed *toross* by the Russians, may extend under water, according to Makaroff's investigations, to at least an equal depth. Such old sea-ice when prevented from escaping forms the palaeocrystic sea of Nares; but, as a rule, it is carried southward in the East Greenland and Labrador currents, and melted in the warmer seas of lower latitudes. In the southern hemisphere the ice-pack forms a nearly continuous fence around the Antarctic continent. Pack-ice forms regularly in the inner part of the Baltic every winter, but not in the Norwegian fjords. Even in the Mediterranean sea-ice is formed annually in the northern part of the Black Sea, and more rarely in the Gulf of Salonica and at the head of the Adriatic off Triest. Hudson Bay is blocked by ice for a great part of the year, and the Gulf of St Lawrence is blocked every winter. Ice also clothes the continental shores of the northern fringing seas of eastern Asia. In addition to sea-ice, icebergs which are of land origin occur at sea. In the north, icebergs break off, as a rule, from the ends of the great glaciers of Greenland, and in the far south from the edge of the great Antarctic ice-barrier. The latter often gives birth to prodigious icebergs and ice islands, which are carried northward by ocean currents, nearly as far as the tropical zone before they melt. Thus in December 1906, an iceberg was seen off the mouth of the La Plata in 38° S., and in 1840 one was seen near Cape Agulhas in 35° S. The Antarctic icebergs are of tabular form and much larger than those of Greenland, but in either case an iceberg rising to 200 ft. above sea-level is uncommon, and one exceeding 300 ft. is very rare. The Greenland icebergs are carried by the Labrador current across the great banks of Newfoundland, where they are often very numerous in the months from February to August, when they constitute a danger to shipping as far south as 40° N. No icebergs occur in the North Pacific, and none has ever been reported nearer the coasts of Europe than off the Orkney Islands, and there only once, in 1836.

Oceanic Circulation.—Although observations on marine currents were made near land or between islands even in antiquity, accurate observations on the high seas have only been possible since chronometers furnished a practicable method of determining longitude, *i.e.* from the time of Cook, the circumnavigator. The difference between the position as determined astronomically and by dead-reckoning gives an excellent idea of the general direction and velocity of the surface currents. The first comprehensive study of the currents of the Atlantic was that carried out by James Rennell (1790–1830), and since that time Findlay in his *Directories*, Heinrich Berghaus, Maury and the officials of the various Hydrographic Departments have produced increasingly accurate descriptions of the currents of the whole ocean, largely from material supplied by merchant captains. Direct observations of currents in the open sea are difficult, and even when the ship is anchored the veering and rolling of the vessel produce disturbances that greatly affect the result. Such current-meters as those used by Aimé in 1841 and by Irminger since 1858 only gave the direction of the deeper current by comparison with the surface current at the time of observation. Later apparatus, such as Pettersson's bifilar current-meter or his more recent electric-photographic apparatus, and Nansen and Ekman's propeller current-meter, measure both the direction and the velocity at any moderate depth from an anchored vessel. One of the indirect methods of investigating currents is by taking account of the initial temperature of the current and following it by the thermometer throughout its course; hence the familiar contrast between warm and cold currents, of which the Gulf Stream and the Labrador current are types. Benjamin Franklin in 1775 and Charles Blagden in 1781, by means of numerous observations of temperature made on board the packets plying on the Atlantic passage, determined the boundaries of these two currents and their seasonal variations with considerable precision. The differences of salinity support this method, and, especially in the northern European seas, often prove a sharper criterion of the boundaries than temperature itself; this is especially the case at the entrance to the Baltic. Evidence drawn from drift-wood, wrecks or special drift bottles is less distinct but still interesting and often useful; this method of investigation includes the use of icebergs as indicators of the trend of currents and also of plankton, the minute swimming or drifting organisms so abundant at the surface of the sea.

The general lines of the currents of the oceans are fairly well understood, and along the most frequented ocean routes the larger seasonal variations have also been ascertained. The general scheme of ocean currents depends on the prevailing

winds taken in conjunction with the configuration of the coast and its submarine approaches. The trade-wind regions correspond pretty closely with westward-flowing currents, while in the equatorial calm belts there are eastward-running counter-currents, these lying north of the equator in the Atlantic and Pacific, but south of the equator in the Indian Ocean. In the region of the westerly winds on the poleward side of 40° N. and S. the currents again flow generally eastward. A cyclonic circulation of the atmosphere is associated with a cyclonic circulation of the water of the ocean, as is well shown in the Norwegian Sea and North Atlantic between the Azores and Greenland. Where the trade-winds heap up the surface water against the east coasts of the continents the currents turn poleward. The north equatorial current divides into the current entering the Caribbean Sea and issuing thence by the Strait of Florida as the Gulf Stream, and the Antilles current passing to the north of the Antilles. Both currents unite off the coast of the United States and run northward, turning towards the east when they come within the influence of the prevailing westerly winds. In a similar manner the Brazil current, the Agulhas current and the East Australian current originate from the drift of the south-east trades, and in the North Pacific the Japan current arises from the north-east trade drift. The west-wind drifts on the poleward side carry back part of the water southward to reunite with the equatorial current, and thus there is set up an anticyclonic circulation of water between 10° and 40° in each hemisphere, the movement of the water corresponding very closely with that of the wind. The coincidence of wind and current direction is most marked in the region of alternating monsoons in the north of the Indian Ocean and in the Malay Sea.

The accordance of wind and currents is so obvious that it was fully recognized by seafaring men in the time of the first circumnavigators. Modern investigations have shown, however, that the relationship is by no means so simple as appears at first. We must remember that the ocean is a continuous sheet of water of a certain depth, and the conditions of continuity which hold good for all fluids require that there should be no vacant space within it; hence if a single water particle is set in motion, the whole ocean must respond, as Varenius pointed out in 1650. Thus all the water carried forward by any current must have the place it left immediately occupied by water from another place, so that only a complete system of circulation can exist in the ocean. Further, all water particles when moving undergo a deviation from a straight path due to the forces set up by the rotation of the earth deflecting them towards the right as they move in the northern hemisphere and towards the left in the southern. This deflecting force is directly proportional to the velocity and the mass of the particle and also to the sine of the latitude; hence it is zero at the equator and comes to a maximum at the poles. When the wind acts on the surface of the sea it drives before it the particles of the surface layer of water, and, as these cannot be parted from those immediately beneath, the internal friction of the fluid causes the propelling impulse to act through a considerable depth, and if the wind continued long enough it would ultimately set the whole mass of the ocean in motion right down to the bottom. The current set up by the grip of the wind sweeping over the surface is deflected by the earth's rotation about 45° to the right of the direction of the wind in the northern hemisphere and to the left in the southern. The deeper layers lag behind the upper in deflection and the velocity of the current rapidly diminishes in consequence. The older theory of the origin of drift currents enunciated by Zöppritz in 1878 was modified as indicated above by Nansen in 1901, and Walfrid Ekman subsequently went further. He showed that at a certain depth the direction of the current becomes exactly the opposite of that which has been imposed by deflection on the surface current, and the strength is reduced thereby to only one-twentieth of that at the surface. He called the depth at which the opposed direction is attained the drift-current depth, and he found it to be dependent on the velocity of the surface current and on the latitude. According to Ekman's calculation with a trade-wind blowing at 16 m. per hour, the drift-current depth in latitude 5° would be approximately 104 fathoms, in latitude 15°, 55 fathoms, and in latitude 45° only from 33 to 38 fathoms. A strong wind of 38 m. an hour would produce a drift-current depth of 82 fathoms in latitude 45°, and a light breeze of 3 m. an hour only 22 fathoms. It follows that a pure trade-wind drift cannot reach to any great depth, and this seems to be confirmed by observation, as when tow-nets are sunk to depths of 50 fathoms and more in the region of the equatorial current they always show a strong drift away from the side of the ship, the ship itself following the surface current. Ekman shows further that in a pure drift current the mean direction of the whole mass of the current is perpendicular to the direction of the wind which sets it in motion. This produces a heaping-up of warm water towards the middle of the anti-cyclonic current circulation between 10° and 40°, and on the other hand an updraught of deep water along the outer side of the cyclonic currents. The latter phenomenon is most clearly shown by the stripes of cold water along the west coasts of Africa and America, the current running along the coast tending to draw its water away seawards on the surface and the principle of continuity requiring the updraught of the cool deep layers to take its place. For this reason the up-welling coastal water is coldest close to the shore, and hence it only appears on the Somali coast during the south-west monsoon. On the flat coasts of Europe the influence of on-shore wind in driving in warm water, and of off-shore wind in producing an updraught of cold water, has long been familiar to bathers. In a similar way updraughts of cold water to the surface occur in the neighbourhood of the equator, especially in the Central Atlantic and Pacific.

When a drift-current impinges directly upon a coast there is a heaping up of surface water, giving rise to a counter-current in the depths, which maintains the level, and this counter-current, although subject to deflection on account of the rotation of the earth, is deflected much less than a pure drift-current would be. Such currents, due to the banking up of water, have a large share in setting the depths of the sea in motion, and so securing the vertical circulation and ventilation of the ocean.

The difference in density which occurs between one part of the ocean and another, shares with the wind in the production of currents. Vertical movements are also produced by difference of temperature in the water, but these can only be feeble, as below 1000 fathoms the temperature differences between tropical and polar waters are very small. If we assign to a column of water at the equator the density $S_t^4 = 1{\cdot}022$ at the surface and 1·028 at 1000 fathoms, or an average of 1·025, and to a column of water at the polar circle a mean density of 1·028, there would result a difference of level equal to $(1{\cdot}028 - 1{\cdot}025) \times 1000 =$ 3 fathoms in a distance from the equator to the polar circle of some 4600 m. A gradient like this, only 1 in 1,350,000, could give rise only to an extremely feeble surface current polewards and an extremely feeble deep current towards the equator. If there were strong currents at the bottom of the ocean the uniform accumulation of the deposit of minute shells of globigerina and radiolarian ooze would be impossible, the rises and ridges would necessarily be swept clear of them, and the fact that this is not the case shows that from whatever cause the waters of the depths are set in motion, that motion must be of the most deliberate and gentlest kind. In exceptional cases, when a strong deep current does flow over a rise, as in the case of the Wyville Thomson Ridge, the bottom is swept clear of fine sediment.

Strongly marked differences in density are produced by the melting of sea-ice, and this is of particular importance in the case of the great ice barrier round the Antarctic continent. O. Pettersson has made a careful study of ice melting as a motive power in oceanic circulation, and points out that it acts in two ways: on the surface it produces dilution of the water, forming a fresh layer and causing an outflow seaward of surface water with very low salinity; towards the deep water it produces a strong cooling effect, leading to increase of density and sinking of the chilled layers. Both actions result in the drawing in of

an intermediate layer of water from a distance which takes part in the double system of vertical circulation as is indicated in fig. 2. The actual direction of this circulation is strongly modified by the influence of the earth's rotation. The existence of a layer of water of low salinity at a depth of 500 fathoms in the tropical oceans of the southern hemisphere is to be referred to this action of the melting ice of the Antarctic regions. Pettersson's view that ice-melting dominates the whole circulation of the oceans and regulates in particular the currents of the seas round northern Europe must, however, be looked on as carrying the explanation too far.

Differences of density between the waters of enclosed seas and of the ocean are brought about in some instances by concentration of the water of the sea on account of active evaporation, and in other instances by dilution on account of the great influx of land water. A very powerful vertical circulation is thus set up between enclosed seas and the outer ocean. The very dense water of the Red Sea and the Mediterranean makes the column of water salter and heavier and the level lower than in the ocean beyond the straits. Hence a strong surface current sets inwards through the Straits of Bab-el-Mandeb and Gibraltar, while an undercurrent flows outwards, raising the temperature and salinity of the ocean for a long distance beyond the straits.

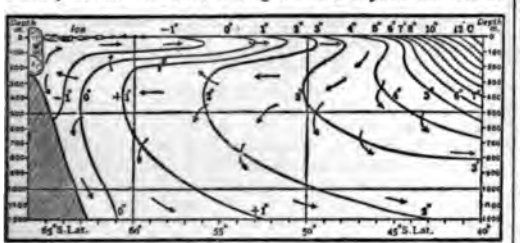

FIG. 2.—Diagram of the stratification of temperature and the vertical components of currents in high southern latitudes.

Through the Bosporus and Dardanelles at the entrance of the Black Sea, and through the sound and belts at the entrance of the Baltic, streams of fresh surface-water flow outwards to the salter Mediterranean and North Sea, while salter water enters in each case as an undercurrent. Wind and tide greatly alter the strength of these currents due to difference of density, and the surface outflow may either be stopped or, in the case of the belts, actually reversed by a strong and steady wind. Both outflowing and inflowing currents are subject to the deflection towards the right imposed by the earth's rotation.

Modern oceanography has found means to calculate quantitatively the circulatory movements produced by wind and the distribution of temperature and salinity not only at the surface but in deep water. The methods first suggested by H. Mohn and subsequently elaborated by V. Bjerknes have been usefully applied in many cases, but they cannot take the place of direct observations of currents and of the fundamental processes and conditions underlying them. The determination of the exact relationship of cause and effect in the origin of ocean currents is a matter of great practical importance. The researches of Pettersson, Meinardus, H. N. Dickson and others leave no doubt, for example, that the variations in the intensity of the Gulf Stream, whether these be measured by the change in the strength of the current or in the heat stored in the water, produce great variations in the character of the weather of northern Europe. The connexion between variations of current strength and the conditions of existence and distribution of plankton are no less important, especially as they act directly or indirectly on the life-conditions of food fishes.

(O. K.; H. R. M.)

OCEAN CITY, a city and seaside resort of Cape May county, New Jersey, U.S.A., in the S.E. part of the state, about 10 m. S.W. of Atlantic City. Pop. (1890), 452; (1900), 1307; (1905), 1835; (1910), 1950. It is served by the Atlantic City and the West Jersey & Seashore Railways. The city is laid out to face both the ocean and Great Egg Harbor Bay, and is a popular resort during the summer months. Ocean City was incorporated as a borough in 1884, and was chartered as a city in 1897.

OCEAN GROVE, a summer resort of Monmouth county, New Jersey, U.S.A., in the eastern part of the state, on the Atlantic coast, and 55 m. by rail S. of New York City. Pop. (1909), about 2500. It is served by the Pennsylvania and the Central of New Jersey railways. It is noted as a religious and musical seaside resort, and in July and August, and especially in the last ten days of August, during its annual camp-meeting, is visited by thousands of people. Ocean Grove was founded in 1869 by the Ocean Grove Camp-Meeting Association of the Methodist Episcopal Church, as a place for religious worship, rest and recreation, free from all forms of questionable amusement, and is governed under a corporation charter, the corporation having power to place restrictions in all leases.

OCEANIA, or OCEANICA, a name used to cover all the islands of the Pacific Ocean (*q.v.*) which are included in the divisions of Polynesia, Micronesia, Melanesia, Australasia, &c.

OCEANUS (Gr. Ὠκεανός), in Greek mythology, the greatest of rivers and at the same time a divine personification. Never mingling with the sea which it encloses, according to Homer it has neither source nor mouth. On its southern banks, from east to west, dwell the "blameless Aethiopians" in perfect happiness, and beyond it on the west, in the realms of eternal night, the "Cimmerians," wrapped in fogs and darkness. Here are the grove of Persephone and the entrance of the underworld. Personified, Oceanus is in Hesiod (*Theog.* 133, 337-370) the son of Uranus and Gaea, the husband of Tethys, father of 3000 streams and 4000 ocean nymphs. In Homer he is the origin of all things, even the father of the gods, and the equal in rank of all of them save Zeus. This conception recurs in the theory of Thales, who made water the first principle of all things. The idea of Oceanus as a river flowing unceasingly round the earth, which was regarded as a flat circle, was of long continuance. Euripides was the first among the tragic poets to speak of it as a sea, but Herodotus before him ridiculed the notion of Oceanus as a river as an invention of the poets and described it as the great world sea. As the geographical knowledge of the Greeks extended, the name was applied to the outer sea (especially the Atlantic).

In art, Oceanus was represented as an old man of noble presence and benevolent expression, with the horns of an ox and sometimes crab's claws on his head. His attributes are a pitcher, cornucopiae ("horn of plenty"), rushes, marine animals and a sceptre. On the altar of Pergamum he is depicted taking part in the battle of the giants.

Homer, *Iliad*, i. 423, xiv. 201, 245, xxi. 196; *Odyssey*, x. 508, xi. 14; Herodotus ii. 23, iv. 8; Euripides, *Orestes*, 1376; Caesar, *Bell. Gall.* iii. 7, iv. 10.

OCELLUS LUCANUS, a Pythagorean philosopher, born in Lucania in the 5th century B.C., perhaps a pupil of Pythagoras himself. Stobaeus (*Ecl. Phys.* i. 13) has preserved a fragment of his Περὶ νόμου (if he was really the author) in the Doric dialect, but the only one of his alleged works which is extant is a short treatise in four chapters in the Ionic dialect generally known as *On the Nature of the Universe*. Excerpts from this are given in Stobaeus (i. 20), but in Doric. It is certainly not authentic, and cannot be dated earlier than the 1st century B.C. It maintains the doctrine that the universe is uncreated and eternal; that to its three great divisions correspond the three kinds of beings—gods, men and daemons; and, finally, that the human race with all its institutions (the family, marriage and the like) must be eternal. It advocates an ascetic mode of life, with a view to the perfect reproduction of the race and its training in all that is noble and beautiful.

Editions of the Περὶ τῆς τοῦ παντὸς φύσεως, by A. F. Rudolph (1801, with commentary), and by F. W. Mullach in *Fragmenta philosophorum graecorum*, i. (1860); see also E. Zeller, *History of Greek Philosophy*, i. (Eng. trans.), and J. de Heyden-Zielewicz in *Breslauer philologische Abhandlungen*, viii. 3 (1901). There is an English translation (1831) by Thomas Taylor, the Platonist.

OCELOT (Mexican *Flalocelotl*, literally field-jaguar, from *Flalli*, field, and *ocelotl*, tiger, jaguar), an American member (*Felis pardalis*) of the family *Felidae*, ranging from Arkansas in the north to Paraguay. The species is subject to great racial variation. The fur has, however, a tawny yellow or reddish-grey ground colour, marked with black spots, aggregated in streaks and blotches, or in elongated rings enclosing areas rather darker than the general ground-colour. In the typical form the total length may reach 4 ft.; the average measurement of the

Ocelot (*Felis pardalis*).

head and body lies between 26 in. and 33 in., and of the tail between 11 in. and 15 in. The ocelot is essentially a forest cat, and a ready climber; its disposition is said to be fierce and bloodthirsty but in confinement it becomes tame and playful. In Asia the group is represented by the Tibetan *Felis tristis*.

OCHAKOV, a fortified town and port of Russia, in the government of Kherson, 41 m. E. of Odessa, on a cape of the Black Sea, at the entrance to the estuary of the Dnieper, and opposite to Kinburn. Pop. (1897), 10,784. Strong fortifications have been built at Ochakov and on the Kinburn promontory, to protect the entrance to the Dnieper. Ochakov stands close to the site of the old Miletan (Greek) colony of *Olbia* and the Greek colony of *Alektor*. The fortress of Kara-kerman or Ozu-kaleh was built on this spot by the khan of the Crimea, Mengli Girai, in 1492. At a later date it became the centre of a Turkish province which included Khaji-dereh (Ovidiopol), Khaji-bey (Odessa), and Dubossary, as well as some 150 villages. Russia, regarding it as the main obstacle to the possession of the Black Sea littoral, besieged it in 1737, when it was captured by Marshal Münnich, but in the following year it was abandoned, and in 1739 restored to Turkey. The second siege by Russia was begun in 1788, and lasted six months, until the fortress was stormed and taken, after a terrible loss of life. By the peace of 1791 it became Russian. In 1855 it was bombarded by the Anglo-French fleet, and after that the Russians demolished the fortifications.

OCHILTREE, a barony in the county of Ayr, Scotland, from which a title in the Scottish peerage was held in the 16th and 17th centuries by a branch of the house of Stewart. Sir Andrew Stewart (d. 1488), chancellor of Scotland, a great-grandson of the regent Albany (d. 1420), was created Baron Avandale or Avondale about 1457. This peerage became extinct at his death, but was revived about 1490 in favour of his nephew and heir Andrew Stewart, who, being killed at the battle of Flodden in 1513, was succeeded by his son Andrew, 2nd Baron Avandale of this creation; and the latter obtained an act of parliament in 1543 empowering him to exchange the title of Lord Avandale for that of Lord Ochiltree, or Lord Stewart of Ochiltree. His son, Andrew, 2nd Lord Ochiltree (d. *c.* 1600), was a zealous supporter of the lords of the congregation, and especially of John Knox, in the struggle against Mary queen of Scots, and was wounded at the battle of Langside while fighting against the queen. Of his five sons, William was slain by the earl of

Bothwell in 1588, and James, created earl of Arran in 1581, was the father of Sir James Stewart of Killeith who became 4th Lord Ochiltree in 1615; his daughter Margaret was the second wife of John Knox. His brother Henry Stewart married Margaret Tudor, widow of James IV. of Scotland, and was created Baron Methven by James V. in 1528; and another brother, Sir James Stewart of Beath, was ancestor of the Stewart earls of Moray, through his son James who was created Lord Doune in 1581.

The second Lord Ochiltree was succeeded in the peerage by his grandson Andrew, who resigned the title in 1615, and having been summoned by writ to the Irish House of Lords was created Baron Castle Stewart in the Irish peerage in 1619. The barony of Ochiltree which he thus resigned was conferred in 1615 on his cousin Sir James Stewart of Killeith (see above), son of the earl of Arran; and on the death without issue of his son William, 5th Lord Ochiltree, in 1675, the title became extinct. In 1774 Andrew Thomas Stewart successfully claimed the barony of Castle Stewart in the peerage of Ireland as heir male under the creation of 1619; but although he was permitted in 1790 to vote as Lord Ochiltree in an election of Scottish representative peers, his claim to this barony as collateral heir of the grantee of 1615 was disallowed by the House of Lords in 1793.

OCHINO, BERNARDINO (1487–1564), Italian Reformer, was born at Siena in 1487. At an early age he entered the order of Observantine Friars, the strictest sect of the Franciscans, and rose to be its general, but, craving a yet stricter rule, transferred himself in 1534 to the newly founded order of Capuchins, of which in 1538 he was elected vicar-general. In 1539, urged by Bembo, he visited Venice and delivered a remarkable course of sermons, showing a decided tendency to the doctrine of justification by faith, which appears still more evidently in his *Dialogi VII.* published soon after. He was suspected and denounced, but nothing ensued until, at the instigation of the austere zealot Caraffa, the Inquisition was established at Rome, June 1542. Ochino was at once cited, but was deterred from presenting himself at Rome by the warnings of Peter Martyr and of Cardinal Contarini, whom he found at Bologna, dying of poison administered by the reactionary party. After some hesitation he escaped across the Alps to Geneva. He was cordially received by Calvin, and within two years published six volumes of *Prediche*, tracts rather than sermons, explaining and vindicating his change of religion. Twenty-five of these were published in English at Ipswich in 1548. In 1545 he became minister of the Italian Protestant congregation at Augsburg, which he was compelled to forsake when, in January 1547, the city was occupied by the imperial forces in the Schmalkaldic War. Escaping by way of Strassburg he found an asylum in England, where he was made a prebendary of Canterbury, received a pension from Edward VI.'s privy purse, and composed his chief work, *A Trajedy or Dialogue of the unjust usurped Primacy of the Bishop of Rome* (1549). This remarkable performance, originally written in Latin, is extant only in the translation of John Ponet, bishop of Winchester, a splendid specimen of nervous English. The conception is highly dramatic; the form is that of a series of dialogues. Lucifer, enraged at the spread of Christ's kingdom, convokes the fiends in council, and resolves to set up the pope as Antichrist. The state, represented by the emperor Phocas, is persuaded to connive at the pope's assumption of spiritual authority; the other churches are intimidated into acquiescence; Lucifer's projects seem fully accomplished, when Heaven raises up Henry VIII. and his son for their overthrow. The conception bears a remarkable resemblance to that of *Paradise Lost*; and it is almost certain that Milton, whose sympathies with the Italian Reformation were so strong, must have been acquainted with it, and with some of his later works. In the *Labyrinth* (dedicated to Queen Elizabeth of England), a discussion of the freedom of the will, he covertly assailed the Calvinistic doctrine of predestination, and showed that his views were tinged with Socinianism.

The accession of Mary in 1553 drove him from England, and he became pastor of the Italian congregation at Zürich. In 1563 the long-gathering storm of obloquy burst upon the occasion of the publication of his *Thirty Dialogues*, in one of which his adversaries maintained that he had justified polygamy under colour of a pretended refutation. His dialogues on divorce and the Trinity were also obnoxious. Ochino was banished from Zürich, and, after being refused a shelter by other Protestant cities, directed his steps towards Poland, at that time the most tolerant state in Europe. He had not resided there long when the edict of the 6th of August 1564 banished all foreign dissidents. Flying from the country, he encountered the plague at Pinczoff; three of his four children were carried off; and he himself, worn out by age and misfortune, died in solitude and obscurity at Schlakau in Moravia, about the end of 1564. His reputation among Protestants was at the time so bad that he was charged with the authorship of the treatise *De tribus impostoribus*, as well as with having carried his alleged approval of polygamy into practice. It was reserved for Dr Benrath to justify him, and to represent him as a fervent evangelist and at the same time as a speculative thinker with a passion for free inquiry. The general tendency of his mind ran counter to tradition, and he is remarkable as resuming in his individual history all the phases of Protestant theology from Luther to Socinus.

See *Life* by B. O. Benrath (2nd ed., Brunswick, 1892), translated into English by Helen Zimmern (London, 1876). In addition to the books already named, he wrote Italian expositions of *Romans* (Geneva, 1545) and *Galatians* (Augsburg, 1546).

OCHRES, a class of pigments varying in colour from yellow to red, and consisting mainly of hydrated iron oxide. The *Yellow Ochres* are native earths coloured with hydrated ferric oxide, the brownish yellow substance that colours, and is deposited from, highly ferruginous water. These ochres are of two kinds—one having an argillaceous basis, while the other is a calcareous earth, the argillaceous variety being in general the richer and more pure in colour of the two. Both kinds are widely distributed, fine qualities being found in Oxfordshire, the Isle of Wight, near Jena and Nuremberg in Germany, and in France in the departments of Yonne, Cher and Nièvre. The original colour of these ochres can be modified and varied into browns and reds of more or less intensity by calcination. The nature of the associated earth also influences the colour assumed by an ochre under calcination, aluminous ochres developing red and violet tints, while the calcareous varieties take brownish-red and dark-brown hues. The well-known ochre *Terra da Sienna* which in its raw state is a dull-coloured ochre, becomes when burnt a fine warm mahogany brown hue highly valued for artistic purposes. Yellow ochres are also artificially prepared—*Mars Yellow* being either pure hydrated ferric oxide or an intimate mixture of that substance with an argillaceous or calcareous earth, and such compounds by careful calcination can be transformed into *Mars Orange*, *Violet* or *Red*, all highly important, stable and reliable pigments.

OCHRIDA (also written OHRIDA and ACHRIDA; Turkish *Ochri*), a city of Albania, European Turkey, in the vilayet of Monastir; on the north-eastern shore of Lake Ochrida, and at the eastern end of the Roman Via Egnatia. Pop. (1905) about 11,000, including Albanians, Turks, Greeks and Slavs. Ochrida occupies the site of the ancient Lychnidos, which was added to the Macedonian empire by Philip II. (382–336 B.C.), and destroyed by the Bulgarians in A.D. 861. It is the seat of Bulgarian and Greek bishops. From the creation of the Bulgarian patriarchate of Ochrida in 893 to its abolition in 1767 the city was the ecclesiastical headquarters of the Bulgarians in the west of the Balkan Peninsula. Lake Ochrida is 2260 ft. above sea-level, in a mountainous limestone region of Karst formation. It measures 107 sq. m., and has a maximum depth of 938 ft. Its waters are supplied by subterranean streams. Its chief outlet is the river Black Drin, on the north.

See Gelzer, *Der Patriarchat von Achrida* (Leipzig, 1902); and "Dr Jovan Cvijić's Researches in Macedonia, &c.," in *The Geographical Journal*, vol. xvi. (London, 1900).

OCHSENFURT, a town of Germany, in the kingdom of Bavaria, situated on the left bank of the Main, here crossed by a stone bridge, 13 m. S. from Würzburg by the railway to Munich, and at the junction of a line to Röttingen. Pop. (1905) 3333. It contains an Evangelical and five Roman Catholic churches, among them that of St Michael, a fine Gothic edifice. There is a considerable trade in wine and agricultural produce, other industries being brewing and malting.

OCHTERLONY, SIR DAVID, Bart. (1758–1825), British general, was born at Boston, Mass., U.S.A., on the 12th of February 1758, and went to India as a cadet in 1777. He served under Lord Lake in the battles of Koil, Aligarh and Delhi, and was appointed resident at Delhi in 1803. In 1804, having been promoted to the rank of major-general, he defended the city with a very inadequate force against an attack by Holkar. On the outbreak of the Nepal War (1814–15) he was given the command of one of four converging columns, and his services were rewarded with a baronetcy in 1815. Subsequently he was promoted to the command of the main force in its advance on Katmandu, and outmanœuvring the Gurkhas by a flank march at the Kourea Ghat Pass, brought the war to a successful conclusion and obtained the signature of the treaty of Segauli (1816), which dictated the subsequent relations of the British with Nepal. For this success Ochterlony was created G.C.B., the first time that honour had been conferred on an officer of the Indian army. In the Pindari War (1817–18) he was in command of the Rajputana column, made a separate agreement with Amir Khan, detaching him from the Pindaris, and then, interposing his own force between the two main divisions of the enemy, brought the war to an end without an engagement. He was appointed resident in Rajputana in 1818, with which the residency at Delhi was subsequently combined. When Durjan Sal revolted in 1825 against Balwant Singh, the infant Raja of Bharatpur, Ochterlony acting on his own responsibility supported the raja by proclamation and ordered out a force to support him. Lord Amherst, however, repudiated these proceedings. Ochterlony, who was bitterly chagrined by this rebuff, resigned his office, and retired to Delhi. The feeling that the confidence which his length of service merited had not been given him by the governor-general is said to have accelerated his death, which occurred at Meerut on the 15th of July 1825. The Ochterlony column at Calcutta commemorates his name.

See Major Ross of Bladensburg, *The Marquess of Hastings* ("Rulers of India" series) (1893).

OCHTMAN, LEONARD (1854–), American painter, was born in Zonnemaire, Zeeland, Holland, on the 21st of October 1854. His family removed to Albany, New York, in 1866. In 1882 he began to exhibit landscapes at the National Academy, and he became a National Academician in 1904. His most characteristic pictures, which recall the work of Inness, are scenes on Long Island Sound and on the Mianus river.

OCKLEY, SIMON (1678–1720), English orientalist, was born at Exeter in 1678. He was educated at Queen's College, Cambridge, became fellow of Jesus College and vicar of Swavesey, and in 1711 was made professor of Arabic at Cambridge. He had a large family, and the pecuniary embarrassments of his later days form the subject of a chapter in D'Israeli's *Calamities of Authors*. The preface to the second volume of his *History of the Saracens* is dated from Cambridge Castle, where he was imprisoned for debt. Ockley maintained that a knowledge of Oriental literature was essential to the proper study of theology, and in the preface to his first book, the *Introductio ad linguas orientales* (1706), he urges the importance of the study. In 1707 he published a translation of Leon Modena's *History of the Present Jews throughout the World*; and in 1708 *The Improvement of Human Reason, exhibited in the Life of Hai Ebn Yokdhan*. His chief work is *The History of the Saracens* (1708–1718), of which a third volume was published posthumously in 1757. Unfortunately Ockley took as his main authority a MS. in the Bodleian of the pseudo-Wakidi's *Futuh al-Sham*, which is rather historical romance than history. He also translated from the Arabic the *Second Book of Esdras* and the *Sentences of Ali*. Ockley died at Swavesey on the 9th of August 1720.

O'CLERY, MICHAEL (1575–1643), Irish chronicler, grandson of a chief of the sept of O'Clery in Donegal, was born at Kilbarrow on Donegal Bay, and was baptized Tadhg (or "Poet"), but took the name of Michael when he became a Franciscan friar. He was a cousin of Lughaidh O'Clery (fl. 1595–1630), who, with his son Cacrigcriche O'Clery (d. 1664)—one of Michael's co-workers—is also famous as an Irish historian. He had already gained a reputation as an antiquary and student of Irish history and literature, when he entered the Irish College of St Anthony at Louvain. In 1620, through the initiative of Hugh Boy Macanward (1580–1635), warden of the college, and himself a famous Irish historian and poet, and one of an old family of hereditary bards in Tyrconnell, he began to collect Irish manuscripts and to transcribe everything he could find of historical importance; he was assisted by other Irish scholars, and the results were his *Reim Rioghroidhe* (Royal List) in 1630, *Leabhar Gabhala* (Book of Invasions) in 1631, and his most famous work, called by John Colgan (d. 1659), the Irish biographer, the "Annals of the Four Masters" (1636). Subsequently he produced his *Martyrologium* of Irish saints, based on various ancient manuscripts, an Irish glossary and other works. He lived in poverty, and died at Louvain.

O'CONNELL, DANIEL (1775–1847), Irish statesman, known as "the Liberator," was born on the 6th of August 1775 near Cahirciveen, a small town in Kerry. He was sprung from a race the heads of which had been Celtic chiefs, had lost their lands in the wars of Ireland, and had felt the full weight of the harsh penal code which long held the Catholic Irish down. His ancestors in the 18th century had sent recruits to the famous brigade of Irish exiles in the service of France,[1] and those who remained at home either lived as tenants on the possessions of which they had once been lords, or gradually made money by smuggling, a very general calling in that wild region. Thus he inherited from his earliest years, with certain traditions of birth and high station, a strong dislike of British rule in Ireland and of the dominant owners of the soil, a firm attachment to his proscribed faith, and habitual skill in evading the law; and these influences may be traced in his subsequent career. While a boy he was adopted by his uncle, Maurice O'Connell of Derrynane, and sent to a school at Queenstown, one of the first which the state in those days allowed to be opened for Catholic teaching; and a few years afterwards he became a student, as was customary with Irish youths of his class, in the English colleges of St Omer and Douai in France. These years in France had a decided effect in forming his judgment on political questions of high moment. He was an eye-witness on more than one occasion of the folly and excesses of the French Revolution; and these scenes not only increased his love for his church, but strongly impressed him with that dread of anarchy, of popular movements ending in bloodshed, and of communistic and socialistic views which characterized him in after life. To these experiences, too, we may partly ascribe the reverence for law, for the rights of property, and for the monarchical form of government which he appears to have sincerely felt; and, demagogue as he became in a certain sense, they gave his mind a deep Conservative tinge. In 1798 he was called to the bar of Ireland, and rose before long to the very highest eminence among contemporary lawyers and advocates. This position was in the main due to a dexterity in conducting causes, and especially in examining witnesses, in which he had no rival at the Irish bar. He was, however, a thorough lawyer besides, inferior in scientific learning to two or three of his most conspicuous rivals, but well read in every department of law, and especially a master in all that relates to criminal and constitutional jurisprudence. As an advocate, too, he stood in the very highest rank; in mere oratory he was surpassed by Plunket, and in rhetorical gifts by Bushe, the only

[1] See the account of O'Connell's uncle, Count Daniel O'Connell (1745–1833), to whose property he fell heir, in Mrs O'Connell's *Last Colonel of the Irish Brigade* (1892), and O'Callaghan's *Irish Brigade in the Service of France* (1870).

speakers to be named with him in his best days at the Irish bar; but his style, if not of the most perfect kind, and often disfigured by decided faults, was marked by a peculiar subtlety and manly power, and produced great and striking effects. On the whole, in the art of winning over juries he had scarcely an equal in the law courts.

To understand, however, O'Connell's greatness we must look to the field of Irish politics. From early manhood he had turned his mind to the condition of Ireland and the mass of her people. The worst severities of the penal code had been, in a certain measure, relaxed, but the Catholics were still in a state of vassalage, and they were still pariahs compared with the Protestants. The rebellion of 1798 and the union had dashed the hopes of the Catholic leaders, and their prospects of success seemed very remote when, in the first years of the 19th century, the still unknown lawyer took up their cause. Up to this juncture the question had been in the hands of Grattan and other Protestants, and of a small knot of Catholic nobles and prelates; but their efforts had not accomplished much, and they aimed only at a kind of compromise, which, while conceding their principal claims, would have placed their church in subjection to the state. O'Connell inaugurated a different policy, and had soon given the Catholic movement an energy it had not before possessed. Himself a Roman Catholic of birth and genius, unfairly kept back in the race of life, he devoted his heart and soul to the cause, and his character and antecedents made him the champion who ultimately assured its triumph. He formed the bold design of combining the Irish Catholic millions, under the superintendence of the native priesthood, into a vast league against the existing order of things, and of wresting the concession of the Catholic claims from every opposing party in the state by an agitation, continually kept up, and embracing almost the whole of the people, but maintained within constitutional limits, though menacing and shaking the frame of society. He gradually succeeded in carrying out his purpose: the Catholic Association, at first small, but slowly assuming larger proportions, was formed; attempts of the government and of the local authorities to put its branches down were skilfully baffled by legal devices of many kinds; and at last, after a conflict of years, all Catholic Ireland was arrayed to a man in an organization of enormous power, that demanded its rights with no uncertain voice. O'Connell, having long before attained an undisputed and easy ascendancy, stood at the head of this great national movement; but it will be observed that, having been controlled from first to last by himself and the priesthood, it had little in common with the mob rule and violence which he had never ceased to regard with aversion. His election for Clare in 1828 proved the forerunner of the inevitable change, and the Catholic claims were granted the next year, to the intense regret of the Protestant Irish, by a government avowedly hostile to the last, but unable to withstand the overwhelming pressure of a people united to insist on justice. The result, unquestionably, was almost wholly due to the energy and genius of a single man, though the Catholic question would have been settled, in all probability, in the course of time; and it must be added that O'Connell's triumph, which showed what agitation could effect in Ireland, was far from doing his country unmixed good.

O'Connell joined the Whigs on entering parliament, and gave effective aid to the cause of reform. The agitation, however, on the Catholic question had quickened the sense of the wrongs of Ireland, and the Irish Catholics were engaged ere long in a crusade against tithes and the established church, the most offensive symbols of their inferiority in the state. It may be questioned whether O'Connell was not rather led than a leader in this, the movement, at least, passed beyond his control, and the country for many months was terrorized by scenes of appalling crime and bloodshed. Lord Grey, very properly, proposed measures of repression to put this anarchy down, and O'Connell opposed them with extreme vehemence, a seeming departure from his avowed principles, but natural in the case of a popular tribune. This caused a breach between him and the Whigs; but he gradually returned to his allegiance to them when they practically abolished Irish tithes, cut down the revenues of the established church and endeavoured to secularize the surplus. By this time O'Connell had attained a position of great eminence in the House of Commons: as a debater he stood in the very first rank, though he had entered St Stephen's after fifty; and his oratory, massive and strong in argument, although too often scurrilous and coarse, and marred by a bearing in which cringing flattery and rude bullying were strangely blended, made a powerful, if not a pleasing, impression. O'Connell steadily supported Lord Melbourne's government, gave it valuable aid in its general measures, and repeatedly expressed his cordial approval of its policy in advancing Irish Catholics to places of trust and power in the state, though personally he refused a high judicial office. Though a strict adherent of the creed of Rome, he was a Liberal, nay a Radical, as regards measures for the vindication of human liberty, and he sincerely advocated the rights of conscience, the emancipation of the slave and freedom of trade. But his rooted aversion to the democratic theories imported from France, which were gradually winning their way into England, only grew stronger with advancing age. His conservatism was most apparent in his antipathy to socialistic doctrines and his tenacious regard for the claims of property. He actually opposed the Irish Poor Law, as encouraging a communistic spirit; he declared a movement against rent a crime; and, though he had a strong sympathy with the Irish peasant, and advocated a reform of his precarious tenure, it is difficult to imagine that he could have approved the cardinal principle of the Irish Land Act of 1881, the judicial adjustment of rent by the state.

O'Connell changed his policy as regards Ireland when Peel became minister in 1841. He declared that a Tory régime in his country was incompatible with good government, and he began an agitation for the repeal of the union. One of his motives in taking this course no doubt was a strong personal dislike of Peel, with whom he had often been in collision, and who had singled him out in 1829 for what must be called a marked affront. O'Connell, nevertheless, was sincere and even consistent in his conduct: he had denounced the union in early manhood as an obstacle to the Catholic cause; he had spoken against the measure in parliament; he believed that the claims of Ireland were set aside or slighted in what he deemed an alien assembly; and, though he had ceased for some years to demand repeal, and regarded it as rather a means than an end, he was throughout life an avowed repealer. It should be observed, however, that in his judgment the repeal of the union would not weaken the real bond between Great Britain and Ireland; and he had nothing in common with the revolutionists who, at a later period, openly declared for the separation of the two countries by physical force. The organization which had effected such marvellous results in 1828–1829 was recreated for the new project. Enormous meetings, convened by the priesthood, and directed or controlled by O'Connell, assembled in 1842–1843, and probably nine-tenths of the Irish Catholics were unanimous in the cry for repeal. O'Connell seems to have thought success certain; but he had not perceived the essential difference between his earlier agitation and this. The enlightened opinion of the three kingdoms for the most part approved the Catholic claims, and as certainly it condemned repeal. After some hesitation Peel resolved to put down the repeal movement. A vast intended meeting was proclaimed unlawful, and in October 1843 O'Connell was arrested and held to bail, with ten or twelve of his principal followers. He was convicted (February 1844) after the trials that followed, but they were not good specimens of equal justice, and the sentence of imprisonment for a year and a fine of £2000 was reversed on a writ of error by the House of Lords (September 1844), and he and his colleagues were again free. The spell, however, of O'Connell's power had vanished; his health had suffered much from a short confinement; he was verging upon his seventieth year; and he was alarmed and pained by the growth of a party in the repeal ranks who scoffed at his views, and advocated the revolutionary doctrines which he had always feared and abhorred. Before long famine had fallen on the

land, and under this visitation the repeal movement, already paralysed, wholly collapsed. O'Connell died on the 15th of May 1847, at Genoa, whilst on his way to Rome. His body was brought back to Dublin and buried in Glasnevin cemetery.

O'Connell was a remarkable man in every sense of the word, of splendid physique, and with all the attractions of a popular leader. Catholic Ireland calls him her "Liberator" still; and history will say of him that, with some failings, he had many and great gifts, that he was an orator of a high order, and that, agitator as he was, he possessed the wisdom, the caution and the tact of a real statesman. Nevertheless he not only failed to accomplish the chief aim of his life, but Lecky trenchantly observes that "by a singular fatality the great advocate of repeal did more than any one else to make the Union a necessity. . . . He destroyed the sympathy between the people and their natural leaders; and he threw the former into the hands of men who have subordinated all national to ecclesiastical considerations, or into the hands of reckless, ignorant, and dishonest adventurers." O'Connell married in 1802 his cousin Mary O'Connell, by whom he had three daughters and four sons, Maurice, Morgan, John (1810–1858), known as the "Young Liberator," and Daniel, who all sat in parliament.

His son John published a *Life* in 1846 and *Recollections and Experiences* in 1849. There are also biographies by W. Fagan (1847), M. F. Cusack (1872), J. O'Rourke and O'Keeffe (1875), and J. A. Hamilton (1888). See especially W. E. H. Lecky's essay in the revised edition of his *Leaders of Public Opinion in Ireland* vol. ii. (1903). (W. O. M.)

O'CONNOR, FEARGUS EDWARD (1794–1855), Chartist leader, was a son of the Irish Nationalist politician Roger O'Connor (1762–1834), and nephew of Arthur O'Connor (1763–1852), who was the agent in France for Emmet's rebellion; both belonged to the "United Irishmen." He entered parliament as member for the county of Cork in 1832. Though a zealous supporter of repeal, he endeavoured to supplant O'Connell as the leader of the party, an attempt which aroused against him the popular antipathy of the Irish. In 1835 he was unseated on petition, and after standing unsuccessfully for Oldham he took to stumping England in favour of the new Radical doctrines of the day, and the use of physical force for their adoption. In 1837 he established the *Northern Star* newspaper at Leeds, and became a vehement advocate of the Chartist movement. He was imprisoned for seditious libel in 1840, and after his release became prominent for his attack on John Bright, and the anti-corn-law league. In 1847 he was returned for Nottingham, and in 1848 he presided at a Chartist demonstration on Kennington Common, which caused great alarm (see CHARTISM). But the projected march on Westminster fizzled out when the preparations made to receive it became known. The eccentricity which had characterized his opinions from the beginning of his career gradually became more marked until they developed into insanity. He began to conduct himself in a disorderly manner in the House of Commons, and in 1852 he was found to be of unsound mind by a commission of lunacy. He died at London on the 30th of August 1855, and was buried in Kensal Green cemetery.

OCONOMOWOC, a city of Waukesha county, Wisconsin, U.S.A., about 33 m. W. of Milwaukee. Pop. (1890) 2729; (1900) 2880; (1905) 3013; (1910) 3054. It is served by the Chicago, Milwaukee & St Paul railway and by an electric railway connecting with Milwaukee. Oconomowoc is one of the most popular summer resorts in the Middle West. Along the shore of Lakes Fowler and La Belle are some beautiful country estates, several large hotels and fine club houses, and two sanatoria. At Delafield and at Dousman (8 m. S. of Oconomowoc) there are state fish hatcheries, the former for black bass. Oconomowoc was settled about 1837 and incorporated in 1875; its name is an Indian word, said to mean "home of the beaver."

O'CONOR, CHARLES (1804–1884), American lawyer, was born in the city of New York on the 22nd of January 1804, and was the son of Thomas O'Conor (1770–1855), who in 1801 emigrated from Roscommon county, Ireland, to New York, where he devoted himself chiefly to journalism. The son studied law, was admitted to the bar in 1824, and soon won high reputation in his profession. He was United States district attorney for New York in 1853–1854. In politics an extreme States'-Rights Democrat, he opposed the coercion of the South, and after the Civil War became senior counsel for Jefferson Davis on his indictment for treason, and was one of his bondsmen; these facts and O'Conor's connexion with the Roman Catholic Church affected unfavourably his political fortunes. In 1872 he was nominated for the presidency by the "Bourbon" Democrats, who refused to support Horace Greeley, and by the "Labour Reformers"; he declined the nomination but received 21,559 votes. He took a prominent part in the prosecution of William M. Tweed and members of the "Tweed Ring," and published *Peculation Triumphant, Being the Record of a Five Years' Campaign against Official Malversation, A.D. 1871–1875* (1875). He removed to Nantucket, Massachusetts, in 1881, and died there on the 12th of May 1884.

OCONTO, a city and the county-seat of Oconto county, Wisconsin, U.S.A., about 130 m. N. of Milwaukee, on the W. shore of Green Bay, at the mouth of the Oconto river. Pop. (1890) 5219; (1900) 5646, of whom 1544 were foreign-born; (1905) 5722; (1910) 5629. It is served by the Chicago & North-Western and the Chicago, Milwaukee & St Paul railways. The city lies in a good farming country, and has a considerable lake commerce in lumber and fish. The first settlement was made here in 1846, and Oconto was chartered as a city in 1882.

OCRICULUM (mod. *Otricoli*), an ancient town of Umbria, Italy, on the Via Flaminia, near the E. bank of the Tiber, 44 m. N. of Rome and 12 m. S. of Narnia. It concluded an alliance with Rome in 308 B.C. The modern village lies higher than the ancient town, and excavations on the site of the latter in 1775 and following years led to the discovery of the baths, a theatre, a basilica and other buildings. In the baths were found a number of works of art, now in the Vatican, notably the mosaic pavement of the Sala della Rotonda, and the celebrated head of Zeus and the head of Claudius in the same room. An amphitheatre is still visible, but the other buildings have in the main been covered up again.

OCTAHEDRON (Gr. ὀκτώ, eight, ἕδρα, base), a solid bounded by eight triangular faces; it has 6 vertices and 12 edges. The regular octahedron has for its faces equilateral triangles; it is the reciprocal of the cube. Octahedra having triangular faces other than equilateral occur as crystal forms. See POLYHEDRON and CRYSTALLOGRAPHY.

OCTAVE (from Lat. *octavus*, eighth, *octo*, eight), a period or series of eight members. In ecclesiastical usage the octave is the eighth day after a particular church festival, the feast day itself and the "octave" being counted. The octave thus always falls on the same day of the week as the festival, and any event occurring during the period is said to be "in the octave." In music, an octave is the eighth full tone above or below any given note. It is produced by double or half the number of vibrations corresponding to the given note. In the interval between a note and its octave is contained the full scale, the octave of a note forming the starting-point of another scale of similar intervals to the first. The interval between a note and its octave is also called an octave. The name is also applied to an open metal stop in an organ, and to a flute (more usually known as the piccolo) one octave higher in pitch than the regular flute. It is also a term for a "parade" in fencing. The "law of octaves" was a term applied in 1865 to a relationship among the chemical elements enunciated by J. A. R. Newlands.

In literature an octave is a form of verse consisting of eight iambic lines, and complete in itself. From its use by the poets of Sicily, the recognized type of this form is usually called the Sicilian Octave. It is distinguished from a single stanza of *ottava rima*, in which the rhyme-arrangement is *abababcc*, by having only two rhymes, arranged *abababab*. In German literature the octave has been used not infrequently since 1820, when Ruckert published "Sicilianen," as they are called in German, for the first time. The word octave is also often used to describe

the eight opening lines of a sonnet, in which the rhyme-arrangement is *abbaabba*, or some modification of this, but properly always on two rhymes only.

OCTAVIA, the name of two princesses of the Augustan house. (1) Octavia, daughter of Gaius Octavius and sister of the emperor Augustus, was the wife of Gaius Marcellus, one of the bitterest enemies of Julius Caesar. In 41 B.C. her husband died, and she was married to Marcus Antonius, with the idea of bringing about a reconciliation between him and her brother. Her efforts were at first successful, but in 36 Antony left for the Parthian War and renewed his intrigue with Cleopatra. Though Octavia took out troops and money to him (35), he refused to see her and formally divorced her in 32, but she always protected his children, even those by Fulvia and Cleopatra. Her beauty and virtues are praised by all ancient authorities. By her first husband she was the mother of Marcus Marcellus (*q.v.*), who died in 23 B.C. (2) OCTAVIA, daughter of the emperor Claudius, was the wife of Nero, by whom she was put to death. A Latin tragedy on her fate is attributed, though wrongly, to Seneca.

OCTAVO, a shortened form of Lat. *in octavo*, "in an eighth, *i.e.* of a sheet of paper, a term applied to a size of paper and to a size of a printed volume. Paper is *in octavo* when a whole single sheet is folded three times to form eight leaves; a book is technically termed of "octavo" size when made up of sheets folded three times (see BIBLIOGRAPHY and PAPER).

OCTOBER, the eighth month of the old Roman year, which began in March. In the Julian calendar, while retaining its old name, it became the tenth month, and had thirty-one days assigned to it. The meditrinalia, when a libation of new wine was made in honour of Meditrina, were celebrated on the 11th, the faunalia on the 13th, and the equiria, when the *equus October* was sacrificed to Mars in the Campus Martius, on the 15th. Several attempts were made to rename the month in honour of the emperors. Thus it was in succession temporarily known as Germanicus, Antoninus, Tacitus and Herculeus, the latter a surname of Commodus. The senate's attempt to christen it Faustinus in honour of Faustina, wife of Antoninus, was equally unsuccessful. The principal ecclesiastical feasts in October are those of St Luke on the 18th and of St Simon and St Jude on the 28th. By the Slavs it is called "yellow month," from the fading of the leaf; to the Anglo-Saxons it was known as Winterfylleth, because at this full moon (*fylleth*) winter was supposed to begin.

OCTODON, the generic name for a small South American rodent mammal (*Octodon degus*) locally known as the degu. It is the type of the family *Octodontidae*, the members of which —collectively termed octodonts—are exclusively Central and South American. Several of them, such as *Echinomys* and *Loncheres*, are rat-like creatures with spiny or bristly fur (see RODENTIA).

OCTOPUS (Gr. ὀκτώ, eight and πούς, foot), the name in scientific zoology belonging to a single genus of eight armed Cephalopoda (*q.v.*), one of whose distinguishing characters is that it has two rows of suckers on each arm. This true octopus occurs occasionally on the British coasts, at least the south coast, but is usually rare. It is more common on the southern coasts of Europe, including those of the Mediterranean. The usual species of Octopoda on the British south coast is *Eledone cirrosa*, which has only one row of suckers on each arm, and is a smaller animal. The celebrated account of the octopus given by Victor Hugo in his *Travailleurs de la mer* is not so fictitious as some critics with a knowledge of natural history have maintained. It is true that the great French author has made the mistake of using the name Cephaloptera, which belongs to a large tropical fish similar to a skate, instead of Cephalopoda, and that he applies the term devil-fish, which belongs to Cephaloptera, to the octopus. His description is exaggerated, imaginative and sensational; but it is correct in its most important particulars, and bears evidence that the author was to some extent personally acquainted with the animal and its habits, although he was not a scientific observer. The octopus feeds on crabs, and crabs feed on carrion, and, therefore, there is nothing impossible in Hugo's account of the skeleton of a drowned man surrounded by the shells of numbers of crabs which the octopus had devoured. Whether an octopus would attack and kill a man is another question, but it certainly might seize him with its arms and suckers while holding to the rocks by other arms, and a man seized in this way when in the water might be in danger of being drowned.

The octopus and many of the Octopoda move about by means of their arms on the sea bottom, and are not free-swimming, though like other Cephalopods they can propel themselves on occasion backwards through the water by means of the funnel. Other Octopoda, however, are pelagic and free-swimming, and such habits are not confined to those forms which are provided with lateral fins. The Argonaut (see NAUTILUS) is one of the Octopoda. The separation of one of the arms of the male for purposes of reproduction is one of the most remarkable peculiarities of the Octopoda. It does not occur, however, in octopus nor in many other members of the group. One arm is always considerably modified in structure and employed in copulation, but it is only in three genera, one of which is Argonauta, that the arm spontaneously separates. The detached arm is found still alive and moving in the mantle cavity of the female, and when first discovered in these circumstances was naturally regarded by the older naturalists as a parasite. Cuvier, on account of the numerous suckers of the detached arm, gave it the name Hectocotylus (hundred suckers). When the arm is not detached but only altered in structure it is said to be hectocotylized. In Octopus and Eledone it is the third right arm which is hectocotylized. The extremity of this arm is expanded and assumes the shape of a spoon. Whether detached or not the modified arm possesses a cavity into which the spermatophores are passed and the arm serves to convey them to the mantle cavity of the female.

It has been mentioned above that the true octopus (*Octopus vulgaris*) is usually rare on the English coast. In 1899 and 1900, however, they became so abundant on the south coast as to attract general notice, and to constitute a veritable plague which threatened complete ruin to the shell-fish fisheries. This visitation and its effects were described by W. Garstang in the *Journal of the Marine Biological Association*. The abnormal abundance occurred all along the west coast of France, whence it extended to the Channel, and was probably due to a succession of unusually warm summers and mild winters, beginning with the warm spring and hot summer of 1893. The octopus in the years mentioned entered the lobster pots of the fishermen and devoured or killed the crabs and lobsters captured. The pots when hauled contained usually only living octopus and the mutilated remains of their victims. One fisherman took in a single week 64 specimens of octopus and only 15 living uninjured lobsters. The octopus also almost exterminated the swimming crabs (*Portunus*) in Plymouth Sound, and in the tanks of the Plymouth aquarium attacked and devoured all the specimens of its smaller relative *Eledone cirrosa*.

With regard to the size which the octopus may attain, the dimensions of the body are not usually given in records, but it is stated that the arms in the largest specimens measured 3½ ft., and in numerous cases were 3 ft. in length. This would enable the eight arms to extend over a circle 6 ft. in diameter, but the globular body is not more than about a third of the length of an arm in diameter. When not in pursuit of prey the octopus hides itself in a hole between rocks and covers itself with stones and shells. Like its victims it seems to be active chiefly at night and to remain in its nest during the day.

For a technical account of the Octopoda see CEPHALOPODA; also W. Garstang, "The Plague of Octopus on the South Coast, and its Effect on the Crab and Lobster Fisheries," *Journ. Mar. Biol. Assoc.* vol. vi. (1900) p. 260. (J. T. C.)

OCTOROON, or OCTAROON (from Lat. *octo*, eight, formed on the example of quadroon), the offspring of a quadroon and a white; a person having one-eighth negro blood. In rare instances such persons are called tercerons, as being *third* in descent from a negro ancestor. Occasionally persons are called octoroons

when the non-white element is not negro but some other coloured blood.

OCTOSTYLE (Gr. ὀκτώ eight, and στῦλος, a column), in architecture, a portico of eight columns in front (see TEMPLE).

OCTROI (O. Fr. *octroyer*, to grant, authorize; Lat. *auctor*), a local tax collected on various articles brought into a district for consumption. Octroi taxes have a respectable antiquity, being known in Roman times as *vectigalia*. These vectigalia were either the *portorium*, a tax on the entry from or departure to the provinces (those cities which were allowed to levy the portorium shared the profits with the public treasury); the *ansarium* or *foricarium*, a duty levied at the entrance to towns; or the *edulia*, sale imports levied in markets. Vectigalia were levied on wine and certain articles of food, but it was seldom that the cities were allowed to use the whole of the profits of the taxes. Vectigalia were introduced into Gaul by the Romans, and remained after the invasion by the Franks, under the name of *tonlieux* and *coutumes*. They were usually levied by the owners of seigniories. But during the 12th and 13th centuries, when the towns succeeded in asserting their independence, they at the same time obtained the recognition of their right to establish local taxation, and to have control of it. The royal power, however, gradually asserted itself, and it became the rule that permission to levy local taxes should be obtained from the king. From the 14th century onwards, we find numerous charters granting (*octroyer*) to French towns the right to tax themselves. The taxes did not remain strictly municipal, for an ordinance of Cardinal Mazarin (in 1647) ordered the proceeds of the octroi to be paid into the public treasury, and at other times the government claimed a certain percentage of the product, but this practice was finally abandoned in 1852. From an early time the octroi was farmed out to associations or private individuals, and so great were the abuses which arose from the system that the octroi was abolished during the Revolution. But such a drastic measure meant the stoppage of all municipal activities, and in 1798 Paris was allowed to re-establish its octroi. Other cities were allowed gradually to follow suit, and in 1809 a law was passed laying down the basis on which octrois might be established. Other laws have been passed from time to time in France dealing with the octroi, especially those of 1816, 1842, 1867, 1871, 1884 and 1897. By the law of 1809 octroi duties were allowed on (1) beverages and liquids; (2) eatables; (3) fuel; (4) forage; (5) building materials. A scale of rates was fixed, graduated according to the population, and farming out was strictly regulated. A law of 1816 enacted that an octroi could only be established at the wish of a municipal council, and that only articles destined for local consumption could be taxed. The law of 1852 abolished the 10% of the gross receipts paid to the treasury. Certain indispensable commodities are allowed to enter free, such as grain, flour, fruit, vegetables and fish.

French octroi duties are collected either by the (1) *régie simple*, *i.e.* by special officers under the direction of the maire; (2) by the *bail à ferme*, *i.e.* farming, the contractor paying yearly a certain agreed upon sum calculated on the estimated amount; (3) the *régie interessé*, a variation of the preceding method, the contractor sharing the profits with the municipality when they reach a given sum; and (4) the *abonnement avec la régie des contributions indirectes*, under which a department of the treasury undertakes to collect the duties. More than half the octrois are collected under (1), and the numbers tend to increase; (2) is steadily decreasing, while (3) has been practically abandoned; (4) tends to increase. The gross receipts in 1901 amounted to £11,132,870. A law of 1897 created new sources of taxation, giving communes the option of (1) new duties on alcohol; (2) a municipal licence duty on retailers of beverages; (3) a special tax on wine in bottle; (4) direct taxes on horses and carriages, clubs, billiard tables and dogs; (5) additional centimes to direct taxes.

From time to time there has been agitation in France for the abolition of octroi duties, but it has never been pushed very earnestly. In 1869 a commission was appointed to consider the matter, and reported in favour of their retention. In Belgium, on the other hand, they were abolished in 1870, being replaced by an increase in customs and excise duties; and in 1903 those in Egypt were also abolished. Octroi duties exist in Italy, Spain, Portugal and in some of the towns of Austria.

Ripert, *Traité des octrois municipaux* (Paris, 1904); L. Hourcade, *Manuel encyclopédique des contributions indirectes et des octrois* (Paris, 1905); much useful matter from some of the foregoing will be found in *Report on the French Octroi System*, by Consul-general Hearn (British Diplomatic and Consular Reports, 1906); the abolition of the Belgian octrois produced a voluminous official report: *Abolition des octrois communaux en Belgique documents et discussions parlementaires*. (T. A. I.)

O'CURRY, EUGENE (1796–1862), Irish scholar, was born at Dunaha, county Clare, in 1796, the son of a farmer who was a man of unusual intelligence. After being employed for some time in the topographical and historical section of the Irish ordnance survey, O'Curry earned his living by translating and copying Irish manuscripts. The catalogue of Irish manuscripts in the British Museum was compiled by him. On the founding of the Roman Catholic University of Ireland (1854) he was appointed professor of Irish history and archaeology. His lectures were published by the university in 1860, and give a better knowledge of Irish medieval literature than can be obtained from any other one source. Three other volumes of lectures were published posthumously, under the title *On the Manners and Customs of the Ancient Irish* (1873). His voluminous transcripts, notably eight huge volumes of ancient Irish law, testify to his unremitting industry. The Celtic Society, of the council of which he was a member, published two of his translations of medieval tales. He died in Dublin in 1862.

OCYDROME, a word formed from *Ocydromus*, meaning "swift-runner," and suggested by J Wagler in 1830 as a generic term for the New Zealand bird called in the then unpublished manuscripts of J. R. Forster *Rallus troglodytes*, and so designated in 1788 by S. G. Gmelin, who knew of it through J Latham's English description. Wagler's suggestion has since been generally adopted, and the genus *Ocydromus* is accepted by most ornithologists as a valid group of *Rallidae*; but the number of species it contains is admittedly doubtful, owing to the variability in size and plumage which they exhibit, and their correct nomenclature must for the present be considered uncertain. Sir W Buller in his *Birds of New Zealand* identifies the "Wood-hen," observed in great abundance on the shores of Dusky Bay in 1773 by Cook and his companions on his second voyage, with the *Gallirallus fuscus* described and figured by Du Bus in 1847, and accordingly calls it *O. fuscus*; but it cannot be questioned that the species from this locality—which appears to have a somewhat limited range in the Middle Island,[1] and never to be met with far from the sea-coast, where it lives wholly on crustaceans and other marine animals—is identical with that of the older authors just mentioned. In 1786 Sparrman, who had also been of Cook's company, figured and described as *Rallus australis* a bird which, though said by him to be that of the southern coast of New Zealand, differs so much from the *R. troglodytes* as to compel a belief in its specific distinctness; and indeed his species has generally been identified with the common "Weka" of the Maories of the Middle Island, which can scarcely be the case if his statement is absolutely true, since the latter does not appear to reach so far to the southward, or to affect the seashore. It may therefore be fairly inferred that his subject was obtained from some other locality. The North Island of New Zealand has what is allowed to be a third species, to which the name of *Ocydromus earli* is attached, and this was formerly very plentiful; but its numbers have rapidly decreased, and there is every chance of its soon being as extinct as is the species which tenanted Norfolk Island on its discovery by Cook in 1774.

[1] It also occurs in Stewart Island, and singularly enough on the more distant group known as the Snares. The *Gallirallus brachypterus* of Lafresnaye, of which the typical (and unique?) specimen from an unknown locality is in the Caen Museum, has also been referred to this species, but the propriety of the act may be doubted.

and which was doubtless distinct from all the rest, though no specimen of it is known to exist in any museum.[1] Another species, *O. sylvestris*, smaller and lighter in colour than any of the rest, was found in 1869 to linger yet in Lord Howe's Island (*Proc. Zool. Society*, 1869, p. 473, pl. XXXV.). Somewhat differing from *Ocydromus*, but apparently very nearly allied to it, is a little bird peculiar, it is believed, to the Chatham Islands (*Ibis*, 1872, p. 247), and regarded by Captain Hutton as the type of a genus *Cabalus* under the name of *C. modestus*, while other naturalists consider it to be the young of the rare *Rallus dieffenbachi*. So far the distribution of the Ocydromine form is wholly in accordance with that of most others characteristic of the New Zealand sub-region; but a curious exception is asserted to have been found in the *Gallirallus lafresnayanus* of New Caledonia, which, though presenting some structural differences, has been referred to the genus *Ocydromus*.

The chief interest attaching to the Ocydromes is their inability to use in flight the wings with which they are furnished, and hence an extreme probability of the form becoming wholly extinct in a short time. Of this inability there are other instances among the *Rallidae* (see MOOR-HEN); but here we have coupled with it the curious fact that in the skeleton the angle which the scapula makes with the coracoid is greater than a right angle, a peculiarity shared only, so far as is known, among the *Carinatae* by the dodo. The Ocydromes are birds of dull plumage, and mostly of retiring habits, though the common species is said to show great boldness towards man, and, from the accounts of Cook and the younger Forster, the birds seen by them displayed little fear. They are extremely destructive to eggs and to any other birds they can master. (A. N.)

ODAENATHUS, or ODENATUS (Gr. *'Οδαίναθος*, Palm, עדנא = "little ear"), the Latinized form of ODAINATH, the name of a famous prince of Palmyra, in the second half of the 3rd century A.D., who succeeded in recovering the Roman East from the Persians and restoring it to the Empire. He belonged to the leading family of Palmyra, which bore, in token of Roman citizenship, the *gentilicium* of Septimius; hence his full name was Septimius Odainath (Vogüé, *Syrie centrale*, Nos. 23, 28 = Cooke, *North-Semitic Inscrr.* Nos. 126, 130). It is practically certain that he was the son of Septimius Ḥairān the "senator and chief of Tadmor," the son of Septimius Odainath "the senator" (*N.S.I.* p. 285). The year when he became chief of Palmyra is not known, but already in an inscription dated A.D. 258 he is styled "the illustrious consul our lord" (*N.S.I.* No. 126). He possessed the characteristic vigour and astuteness of the old Arab stock from which he sprang; and in his wife, the renowned Zenobia (*q.v.*), he found an able supporter of his policy. The defeat and captivity of the emperor Valerian (A.D. 260) left the eastern provinces largely at the mercy of the Persians; the prospect of Persian supremacy was not one which Palmyra or its prince had any reason to desire. At first, it seems, Odainath attempted to propitiate the Parthian monarch Shāpūr (Sapor) I.; but when his gifts were contemptuously rejected (Petr. Patricius, § 10) he decided to throw in his lot with the cause of Rome. The neutrality which had made Palmyra's fortune was abandoned for an active military policy which, while it added to Odainath's fame, in a short time brought his native city to its ruin. He fell upon the victorious Persians returning home after the sack of Antioch, and before they could cross the Euphrates inflicted upon them a considerable defeat. Then, when two usurping emperors were proclaimed in the East (A.D. 261), Odainath took the side of Gallienus the son and successor of Valerian, attacked and put to death the usurper Quietus at Emesa (Ḥōmṣ), and was rewarded for his loyalty by the grant of an exceptional position (A.D. 262). He may have assumed the title of king before; but he now became "totius Orientis imperator," not indeed joint-ruler, nor Augustus, but "independent lieutenant of the emperor for the East" (Mommsen, *Provinces*, ii. p. 103).[2] In a series of rapid and successful campaigns, during which he left Palmyra under the charge of Septimius Worod his deputy (*N.S.I.* Nos. 127-129), he crossed the Euphrates and relieved Edessa, recovered Nisibis and Carrhae, and even took the offensive against the power of Persia, and twice invested Ctesiphon itself, the capital; probably also he brought back Armenia into the Empire. These brilliant successes restored the Roman rule in the East; and Gallienus did not disdain to hold a triumph with the captives and trophies which Odainath had won (A.D. 264). While observing all due formalities towards his overlord, there can be little doubt that Odainath aimed at independent empire; but during his lifetime no breach with Rome occurred. He was about to start for Cappadocia against the Goths when he was assassinated, together with Herōdes his eldest son, by his nephew Maconius; there is no reason to suppose that this deed of violence was instigated from Rome. After his death (A.D. 266–267) Zenobia succeeded to his position, and practically governed Palmyra on behalf of her young son Wahab-allath or Athenodorus (see PALMYRA). (G. A. C.*)

ODALISQUE, a slave-woman who is a member of an oriental harem, especially one in the harem or seraglio of the sultan of Turkey. The word is the French adaptation of the Turkish *ōdaliq*, formed from *ōdah*, chamber or room in a harem.

ODD (in middle English *odde*, from old Norwegian *oddi*, an angle of a triangle; the old Norwegian *oddamann* is used of the third man who gives a casting vote in a dispute), that which remains over after an equal division, the unit in excess of an even number; thus in numeration the word is used of a number either above or below a round number, an indefinite cardinal number, as "eighty and odd," or "eighty odd." As applied to individuals, the sense of "one left after a division" leads to that of "solitary," and thus of "uncommon" or "strange." In the plural, "odds" was originally used to denote inequalities especially in the phrase "to make odds even." The sense of a difference in benefit leads to such colloquialisms as "makes no odds," while that of variance appears in the expression "to be at odds." In betting "the odds" is the advantage given by one person to another in proportion to the supposed chances of success.

ODDE, or ODDA, a village of Norway, in South Bergenhus *amt* (county), on the Sör Fjord, a head-branch of the great Hardanger Fjord. It is 48 m. directly S.E. of Bergen, but 123 by water (to Eide), road (to Vossevangen), and rail thenceforward, or about the same distance by water alone. It is one of the principal tourist-centres in southern Norway, being at the end of the road from Breifond (27 m.) near which the routes join from Stavanger by Sand, Lake Suldal, and the Bratlandsdal, and from the south-eastern coast towns by the Telemark. This road, descending from the Horrebrackke, passes through the gorge of Seljestadjuvet, passes the Espelandsfos and Lotefos falls, and skirts the Sandven lake. Odde is also a centre for several favourite excursions, as to the Buarbrae, one of the glaciers descending from the great Folgefond snowfield, situated in a precipitous valley (*Jordal*) to the west of Sandven lake; to the Skjaeggedalsfos, a magnificent fall (525 ft.); or across the Folgefond to Suldal, a station on the Mauranger branch of the Hardanger fjord. Touring steamers and frequent local steamers from Bergen call at Odde, and there are several large hotels.

[1] The younger Forster remarked that the birds of Norfolk Island, though believed by the other naturalists of Cook's ship to be generally the same as those of New Zealand, were distinguished by their brighter colouring (see also NESTOR). There can be no doubt that all the land-birds were specifically distinct. It is possible that Sparrman's *R. australis*, which cannot very confidently be referred to any known species of *Ocydromus*, may have been from Norfolk Island.

[2] The late Roman chronicler Trebellius Pollio goes further and asserts "Odenatus rex Palmyrenorum optinuit totius Orientis imperium. . . . Gallienus Odenatum participato imperio Augustum vocavit," *Hist. Aug.* xxiii. 10 and 12. This is not borne out by the evidence. The highest rank claimed for him by his own people is recorded in an inscription dated 271 (*N.S.I.* No. 130) set up by the two generals of the Palmyrene army; Odainath is styled "king of kings and restorer of the whole city"; but this does not mean that he ever held the title of Augustus, and the inscription was set up after his death and during the revolt of Palmyra.

ODDFELLOWS, ORDER OF, a secret benevolent and social society, having mystic signs of recognition, initiatory rites and ceremonies, and various grades of dignity and honour. Great antiquity has been claimed for the order of Oddfellows—the most popular tradition ascribing it to the Jewish legion under Titus, who, it is asserted, received from the emperor its first charter written on a golden tablet. Oddfellows themselves, however, now generally admit that the institution cannot be traced back beyond the first half of the 18th century, and explain the name as adopted at a time when the severance into sects and classes was so wide that persons aiming at social union and mutual help were a marked exception to the general rule. Mention is made by Defoe of the society of Oddfellows, but the oldest lodge of which the name has been handed down is the Loyal Aristarcus, No. 9, which met in 1745 "at the Oakley Arms, Borough of Southwark; Globe Tavern, Hatton Garden; or the Boar's Head in Smithfield, as the noble master may direct." The earliest lodges were supported by each member and visitor paying a penny to the secretary on entering the lodge, and special sums were voted to any brother in need. If out of work he was supplied with a card and funds to reach the next lodge, and he went from lodge to lodge until he found employment. The lodges gradually adopted a definite common ritual and became confederated under the name of the Patriotic Order. Towards the end of the century many of the lodges were broken up by State prosecutions on the suspicion that their purposes were "seditious," but the society continued to exist as the Union Order of Oddfellows until 1809. In 1813, at a convention in Manchester, was formed the Independent Order of Oddfellows, Manchester Unity, which now overshadows all the minor societies in England. Oddfellowship was introduced into the United States from the Manchester Unity in 1819, and the grand lodge of Maryland and the United States was constituted on the 22nd of February 1821. It now rivals in membership and influence the Manchester Unity, from which it severed its connexion in 1842. In 1843 it issued a dispensation for opening the Prince of Wales Lodge No. 1 at Montreal, Canada. The American society, including Canada and the United States, has its headquarters at Baltimore. Organizations, connected either with the United States or England, have been founded in France, Germany, Switzerland, Gibraltar and Malta, Australia, New Zealand, the Fiji Islands, the Hawaiian Islands, South Africa, South America, the West Indies and Barbados, and elsewhere.

The rules of the different societies, various song-books, and a number of minor books on Oddfellowship have been published, but the most complete and trustworthy account of the institution is that in *The Complete Manual of Oddfellowship, its History, Principles, Ceremonies and Symbolism*, privately printed (1879). See also FRIENDLY SOCIETIES.

END OF NINETEENTH VOLUME.
